Message from the General Chair

Welcome to the 2022 meeting of the North American Association for Computational Linguistics! Due to the COVID-19 pandemic, NAACL-2021 was held virtually, and NAACL-2022 is the first major NLP conference that is run as an hybrid conference in North America. It is my pleasure to welcome many of you who are joining us in Seattle, as well as those who chose to participate in the conference virtually.

COVID safety is important to us and we will do whatever we can to help you enjoy the in-person conference despite the difficulties we all experience coming back to normality. At the same time, thanks to the virtual conference platform put together by Underline, we hope that our virtual attendees will experience the conference almost as if they are in Seattle and enjoy the conference.

NAACL-2022 decided, along with ACL-2022, to experiment with a new reviewing process, based on "rolling review" (ARR). While we believe that, eventually, this process will converge to an efficient review process that would benefit our community, pioneering such a process is not without difficulties. This would not have been possible without the incredible effort, devotion, thoughtfulness, patience, and many work hours put by our program chairs, Marine Carpuat, Marie-Catherine de Marneffe, and Ivan Vladimir Meza Ruiz, and the help from the ACL-2022 program chairs, Smaranda Muresan, Preslav Nakov, Aline Villavicencio. This process necessitated developing a new software package to support our publication, an effort that was done in collaboration with ACL-2022, and I am thankful to Ryan Cotterell who led this effort.

Among other innovations we installed in NAACL-2022 is a reproducibility track, where we attempted to incentivize authors to release models, code, and other information necessary to reproduce the main results and findings of their papers. We hope that this effort, led by Niranjan Balasubramanian, Jesse Dodge, Annie Louis, Daniel Deutsch and Yash Kumar Lal, will be followed in future conferences. Other initiatives include incorporating a "Responsible NLP Research" checklist into the submission process, a new special theme on "Human-Centered Natural Language Processing", and many innovative activities led by our very active and thoughtful Diversity and Inclusion Committee, led by Diana Galván, Snigdha Chaturvedi and Yonatan Bisk, with Pranav A and Luciana Benotti as advisors.

Organizing a conference as large as NAACL, especially under the constraints of the times we live in, requires the support of a large number of volunteers who care deeply about our community and are willing to spend a lot of time and effort in this long process. It is an honor to coordinate such a team. I would like to thank the members of the organizing committee for their dedication, creativity, and hard work.

First, it is hard to imagine the amount of thought, care, and time, our program chairs Marine Carpuat, Marie-Catherine de Marneffe, and Ivan Vladimir Meza Ruiz put into all aspects of organizing this conference – resulting in an exciting and high quality scientific program.

Many other volunteers have worked hard to make this conference a success and it would not be possible to name all of them here. I will only list the chairs of the main committees whose dedication, creativity, hard work and lively communication contributed to making NAACL-2022 a successful event:

- The diversity & inclusion committee chaired by Diana Galván, Snigdha Chaturvedi and Yonatan Bisk, with advisors Pranav A and Luciana Benotti.
- The industry track chairs, Rashmi Gangadharaiah, Anastassia Loukina and Bonan Min, and advisors Owen Rambow and Yunyao Li.
- The tutorial chairs, Cecilia Alm, Miguel Ballesteros and Yulia Tsvetkov.
- The demonstration chairs, Hannaneh Hajishirzi, Qiang Ning and Avi Sil.

- The workshop chairs, Dan Goldwasser, Yunyao Li and Ashish Sabharwal.
- The student research workshop chairs, Daphne Ippolito, Liunian Harold Li, Maria Leonor Pacheco and advisors, Danqi Chen and Nianwen Xue.
- The publication chairs, Ryan Cotterell, Danilo Croce and Jordan Zhang.
- The reproducibility chairs, Niranjan Balasubramanian, Jesse Dodge, Annie Louis, Daniel Deutsch and Yash Kumar Lal.
- The sponsorship chair, Byron Wallace.
- The volunteer chair, Daniel Khashabi.
- The publicity chairs, Nanyun (Violet) Peng, Emily Sheng, Sameer Singh.
- The virtual infrastructure chairs, Deepak Ramachandran, Martín Villalba, and Rishita Anubhai.
- The website chairs, Ice Pasupat and Vered Shwartz.

Many thanks to Chris Callison-Burch, the ACL Sponsorship Director, for helping the NAACL-2022 Sponsorship chair, Byron Wallace, managing the relations between the sponsors and NAACL-2022.

I am also very grateful to the chairs of previous years' conferences, who were always ready to help and share their experience, and to the members of the ACL and NAACL Executive Committees for their support, feedback and advice.

As usual, special thanks go to Priscilla Rasmussen and to Jennifer Rachford who has stepped into the role of the ACL business manager just in time to help us with NAACL-22. They have been our local organizers and have dealt with all aspects of organizing and managing the conference, from room assignment, to food, to COVID tests.

Finally, I would like to thank all authors, invited speakers and panelists, area chairs and reviewers, the volunteers organizing and chairing sessions, and all attendees, in-person and virtual, for making this a scientifically exciting and socially engaging conference.

Welcome and hope you all enjoy the conference!

Dan Roth
University of Pennsylvania and AWS AI Labs
NAACL-2022 General Chair
June 2022

Message from the Program Chairs

Welcome to the 2022 Annual Conference of the North American Association for Computational Linguistics! For the first time, NAACL-HLT 2022 is a hybrid conference. After two years of exclusively virtual conferences due to the COVID-19 pandemic, we are pleased that attendees and presenters will be able to join us in person in Seattle and from all over the world online for this year's edition.

Review Process NAACL 2022 invited the submission of long and short papers featuring substantial, original, and unpublished research in all aspects of Computational Linguistics and Natural Language Processing (NLP). Our paper review process was organized in a hierarchical structure similar to recent years. We recruited 62 senior area chairs (SACs) for 26 areas, following the areas defined for NAACL 2022. There were two paths for submitting papers: special theme papers were directly submitted to the NAACL OpenReview site, and other main conference papers were reviewed through a new ACL-wide centralized reviewing process. In coordination with the ACL 2022 organizers, we experimented with the ACL Rolling Review (ARR) introduced as part of an initiative to improve efficiency and turnaround of reviewing for ACL conferences. Within this system, reviewing and acceptance of papers to publication venues was done in a two-step process: (1) centralized rolling review via ARR, where submissions receive reviews and meta-reviews from ARR reviewers and action editors; (2) commitment to a publication venue (e.g., NAACL 2022), so that Senior Area Chairs and Program Chairs make acceptance decisions for a submission using the ARR reviews and meta-reviews. During the first phase of the review process, we served as guest Editors in Chief for the ACL Rolling Review and worked to ensure that all papers submitted received at least three review and one meta-review, while balancing the reviewing load for reviewers and action editors. NAACL SACs acted as guest senior area chairs in the ARR system, by helping monitor review progress and supporting the 408 action editors and 3379 reviewers in their work. While the new reviewing mechanism was not as smooth as one could have hoped for, all papers submitted to ARR received at least three reviews and a meta-review, so that authors could decide to commit it to NAACL 2022 if they wanted to. The ACL Executive Committee, based on feedback from the community, will decide whether the advantages of a centralized rolling review system outweigh the disadvantages, taking into account the fast growth of our research field. Once papers were committed to the NAACL OpenReview site, SACs were in charge of making acceptance recommendation per area, taking into account the submission itself, (meta-)reviews, as well as comments to SACs provided by the authors and ethics reviews when applicable.

In coordination with Jesse Dodge, Anna Rogers, Margot Mieskes, Amanda Stent, and the ACL Ethics Committee, we incorporated a "Responsible NLP Research" checklist into the submission process, designed to encourage best research practices in our field, from an ethics and reproducibility perspective. The ARR Responsible NLP Research checklist is largely based on the NeurIPS 2021 paper checklist, the reproducible data checklist from Rogers, Baldwin, Leins's paper "Just What do You Think You're Doing, Dave? A Checklist for Responsible Data Use in NLP", and the NLP Reproducibility checklist introduced by Dodge, Gururangan, Card, Schwartz and Smith in "Show Your Work: Improved Reporting of Experimental Results". Authors were asked to follow the ACL code of ethics and to fill the checklist to ensure that best practices are put in place. Reviewers were asked to consult the checklist when deciding whether the paper requires ethics review. Based on input from reviewers and action editors, SACs flagged papers that required an in-depth ethics review, which was handled by a committee of 11 ethics reviewers. The ethics chairs provided guidance and office hours to help SACs decide when ethics review was required. The ethics reviews were integrated in the final acceptance recommendation by SACs and decisions by PCs.

Special Theme We highlighted "Human-Centered Natural Language Processing" as the special theme for the conference. As NLP applications increasingly mediate people's lives, it is crucial to understand how the design decisions made throughout the NLP research and development lifecycle impact people, whether there are users, developers, data providers or other stakeholders. For NAACL 2022, we invited submissions that address research questions that meaningfully incorporate stakeholders in the design, development, and evaluation of NLP resources, models and systems. We particularly encouraged submissions that bring together perspectives and methods from NLP and Human-Computer Interaction. Given their interdisciplinary nature, theme papers were reviewed through a dedicated process by reviewers with expertise in NLP and in Human-Computer Interaction. We received 52 submissions to the special theme, of which 14 have been accepted to appear at the conference.

Submission Statistics The ACL Rolling Review received 196 submissions in December and 1897 in January, which were the two submission deadlines between the ACL and NAACL commitment deadlines. Of these 2103 submissions, 56% (1073) were committed to NAACL 2022 for the senior program committee to make an acceptance decision. We accepted a total of 442 papers (358 long papers and 84 short papers), representing 21.96% of papers submitted to ARR in December and January and to the NAACL special theme, and 41.19% of papers committed to NAACL (including the special theme papers). As a reference point, NAACL-HLT 2021 received 1797 submissions and accepted 477 papers, including 350 long and 127 short, for an overall acceptance rate of 26%. From the accepted papers, and based on the nominations from SACs, the best paper committee selected best papers, as well as a small number of outstanding papers with the goal of recognizing diverse types of contributions (including contributions to the special theme on human-centered NLP; innovation in model design, training or evaluation; resource or dataset contribution).

Additionally, 209 submissions (183 long and 26 short) were accepted for publications in the "Findings of ACL: NAACL 2022" (or Findings for short), an online companion publication for papers that are not accepted for publication in the main conference, but nonetheless have been assessed by the program committee as solid work with sufficient substance. A total of 5 accepted Findings papers were withdrawn. Findings paper were given the option to be presented as posters during the main conference: 183 took this opportunity and will be presented either in person or virtually.

NAACL 2022 will also feature 15 papers that were published at Transactions of the Association for Computational Linguistics (TACL) and 3 papers from the journal of Computational Linguistics (CL).

Program Format The conference program was designed to allow for presentation and attendance in person in Seattle and virtually from all over the world. Oral sessions will consist of presentations done either in person or virtually. The Q&A session for each paper will alternate between in-person and online questions, with a volunteer helping monitor the online questions. All oral sessions will be live-streamed and recorded. All main conference posters will be presented with a 5-minute video pitch available online and with a virtual Q&A session, where papers will be grouped by topic to foster discussion. In addition, authors who attend the conference in Seattle will present their poster in person during traditional poster sessions. Finally, asynchronous interaction between authors and attendees will be made possible before, during and after the conference on the Underline platform. We also chose to start the conference early in the morning to overlap with normal waking hours in distant time zones.

The program includes several plenary sessions, which we hope will provide thought-provoking perspectives that will enrich discussions during the conference and beyond. In addition to a session for best paper awards, we are delighted to have keynote talks by Batya Friedman (University of Washington) and Manuel Montes-y-Gómez (National Institute of Astrophysics, Optics and Electronics of Mexico). Dan Roth (University of Pennsylvania and Amazon) will moderate a discussion on the role of linguistics and symbolic representations in NLP, with panelists Chitta Baral (Arizona State University), Emily Bender (University of Washington), Dilek Hakkani-tur (Amazon), and Christopher D. Manning (Stanford University). The industry track, demonstrations track and the student research workshop will have dedicated sessions during the main conference to round up the program, including a plenary panel on careers in NLP organized by the industry track chairs.

Gratitude NAACL would not have been possible without the hard work of many volunteers. We are very grateful to all who contributed to make the conference possible, especially given the ongoing challenges raised by the COVID-19 pandemic.

We would like to start by thanking all the authors who submitted their work to the ACL Rolling Review and NAACL 2022. We could only accept a small fraction of submissions but hope that most papers received valuable feedback.

Next, we would like to thank all members of the Program Committee – who are too numerous to be all named here, but are listed elsewhere in the proceedings:

- The senior area chairs, who were incredibly responsive throughout the reviewing process and patiently helped improve the new reviewing infrastructure.
- ARR action editors and reviewers. Special thanks to those who stepped in at the last minute to serve as emergency reviewers. This was tremendously appreciated!
- The special theme area chair, Jeff Bigham, and all reviewers, with a special note of appreciation for those who contributed their time and expertise even though they do not usually publish in NLP conferences.
- The ethics Chairs, Kai-Wei Chang, Dirk Hovy and Diyi Yang, for designing a process to encourage consistent evaluation of ethical considerations during the review process, and their timely input to ensure the integration of ethics review in acceptance recommendations and decisions.
- The ethics reviewers: Yonatan Bisk, Kevin Bretonnel Cohen, Francien Dechesne, Jack Hessel, Jin-Dong Kim, Anne Lauscher, Dave Lewis, Margot Mieskes, Xanda Schofield, Lyle Ungar, Jingbo Xia.
- The outstanding reviewers and action editors who were nominated by the senior area chairs for writing reviews that were particularly helpful in the decision making process. They are recognized by name later in this volume.

Experimenting with a new reviewing system on the large scale required by NAACL would not have been possible without the following people:

- Amanda Stent and Goran Glavaš, as ARR Editors-in-Chiefs, for their tireless work in support of the ARR December and January cycles.
- Graham Neubig, Dhruv Naik and Nils Dycke, as ARR Tech Team for these two cycles.
- Celeste Martinez Gomez, Melisa Bok, and Nadia L'Bahy, as OpenReview Tech Team.
- Elijah Rippeth for his help coordinating the special theme submissions.

The following committees helped shape the conference in countless ways:

- The best paper committee: Thamar Solorio (Chair), Isabelle Augenstein, Gemma Bel Enguix, Alona Fyshe, Shafiq Joty and Emily Prud'hommeaux who enthusiastically read and recommended papers for awards in a short time frame.
- The diversity & inclusion committee chaired by Diana Galván, Snigdha Chaturvedi and Yonatan Bisk, with advisors Pranav A and Luciana Benotti.
- The industry track chairs, Rashmi Gangadharaiah, Anastassia Loukina and Bonan Min, and advisors Owen Rambow and Yunyao Li.
- The tutorial chairs, Cecilia Alm, Miguel Ballesteros and Yulia Tsvetkov.
- The demonstration chairs, Hannaneh Hajishirzi, Qiang Ning and Avi Sil.

- The workshop chairs, Dan Goldwasser, Yunyao Li and Ashish Sabharwal.
- The student research workshop chairs, Daphne Ippolito, Liunian Harold Li, Maria Leonor Pacheco and advisors, Danqi Chen and Nianwen Xue.
- The publication chairs, Ryan Cotterell, Danilo Croce and Jordan Zhang.
- The reproducibility chairs, Niranjan Balasubramanian, Jesse Dodge, Annie Louis, Daniel Deutsch and Yash Kumar Lal.
- The sponsorship chair, Byron Wallace.
- The volunteer chair, Daniel Khashabi.
- The publicity chairs, Nanyun (Violet) Peng, Emily Sheng, Sameer Singh.
- The virtual infrastructure chairs, Deepak Ramachandran, Martín Villalba, and Rishita Anubhai.
- The website chairs, Ice Pasupat and Vered Shwartz for their exceptional reactivity and thorough checks of the conference schedule.

Finally, we would not have been able to organize this conference without the guidance, advice and cooperation of the following people:

- Damira Mrsic, Jernej Masnec, and Sol Rosenberg from Underline, who have been very prompt at answering all our questions and very helpful in setting up the virtual platform.
- Priscilla Rasmussen and Jenn Rachford who make all the logistics of the conference possible.
- Smaranda Muresan, Preslav Nakov, Aline Villavicencio, the Program co-Chairs of ACL 2022 who shared with us their materials and recent experience, and provided moral support.
- Anna Rumshisky, Thamar Solorio and Luke Zettlemoyer, as previous Program co-Chairs of NAACL, who answered many questions and provided invaluable guidance.
- TACL Editorial Assistant Cindy Robinson, and CL Editor-in-Chief Hwee Tou Ng for coordinating TACL and CL presentations with us.
- And last but not least, our General Chair, Dan Roth, whose guidance and support throughout the process were truly invaluable: his quiet strength, big picture thinking, and respect for all the parties involved were a soothing balm and an inspiration.

We hope you will enjoy the NAACL 2022 conference!

Marie-Catherine de Marneffe, Marine Carpuat and Ivan Vladimir Meza Ruiz
NAACL 2022 Program Committee Co-Chairs
June 2022

Organizing Committee

General Chair

Dan Roth, University of Pennsylvania and AWS AI Labs

Program Chairs

Marine Carpuat, University of Maryland
Marie-Catherine de Marneffe, The Ohio State University
Ivan Vladimir Meza Ruiz, National Autonomous University of Mexico

Local Arrangements

Priscilla Rasmussen, ACL
Jennifer Rachford, ACL

Industry Track Chairs

Rashmi Gangadharaiah, Amazon
Anastassia Loukina, Grammarly
Bonan Min, Raytheon BBN Technologies

Advisors for the Industry Track

Owen Rambow, Stony Brook University
Yunyao Li, IBM Research

Keynote Talk: Shaping Technology with Moral Imagination: Leveraging the Machinery of Value Sensitive Design

Batya Friedman
Information School, University of Washington

Abstract:

Monday, July 11, 2022 - Room: **Columbia A/C/D & 302 Beckler** - Time: **9:15-10:15**

Abstract: Tools and technologies are fundamental to the human condition. They do no less than create and structure the conditions in which we live, express ourselves, enact society, and experience what it means to be human. They are also the result of our moral and technical imaginations. Yet, with our limited view, it is not at all obvious how to design and engineer tools and technology so that they are more likely to support the actions, relationships, institutions, and experiences that human beings care deeply about – a life and society of human flourishing.

Value Sensitive Design (VSD) was developed as an approach to address this challenge from within technical design processes. Drawing on over three decades of work, in this plenary talk I will provide an introduction to value sensitive design foregrounding human values in the technical design process. My remarks will present some of value sensitive design's core theoretical constructs. Along the way, I'll provide some examples of applying value sensitive design to robots for healthcare and to bias in computing systems as well as demonstrate one toolkit—The Envisioning Cards—in the context of a design activity.

As time permits, I will turn to a discussion of structure, scale and time: we act within existing structure in the now, from which futures unfold across time and scale. I will unpack these observations and their implications for artificial intelligence and machine learning technologies. Thinking longer-term and systemically, I will bring forward a range of potential challenges and offer some constructive ways forward. My comments will engage individual lives, society writ large, what it means to be human, the planet and beyond.

Please have scratch paper and a pencil handy for the design activity.

Bio: Batya Friedman is a Professor in the Information School and holds adjunct appointments in the Paul G. Allen School of Computer Science & Engineering, the School of Law, and the Department of Human Centered Design and Engineering at the University of Washington where she co-founded the Value Sensitive Design Lab and the UW Tech Policy Lab. Dr. Friedman pioneered value sensitive design (VSD), an established approach to account for human values in the design of technical systems. Her work in value sensitive design has resulted in robust theoretical constructs, dozens of innovative methods, and practical toolkits such as the Envisioning Cards. Value sensitive design has been widely adopted nationally and internationally where it has been used in architecture, biomedical health informatics, civil engineering, computer security, energy, global health, human-computer interaction, human-robotic interaction, information management, legal theory, moral philosophy, tech policy, transportation, and urban planning, among others. Additionally, value sensitive design is emerging in higher education, government, and industry as a key approach to address computing ethics and responsible innovation. Today, Dr. Friedman is working on open questions in value sensitive design including multi-lifespan design, and designing for and with non-human stakeholders – questions critical for the wellbeing of human societies and the planet.

Dr. Friedman's 2019 MIT Press book co-authored with David Hendry, Value Sensitive Design: Shaping Technology with Moral Imagination, provides a comprehensive account of value sensitive design. In 2012 Dr. Friedman received the ACM-SIGCHI Social Impact Award and the University Faculty Lecturer award at the University of Washington, in 2019 she was inducted into the CHI Academy, in 2020 she received an honorary doctorate from Delft University of Technology, and in 2021 she was recognized as an ACM Fellow. She is also a stone sculptor and mixed media artist. Dr. Friedman received both her B.A. and Ph.D. from the University of California at Berkeley.

Keynote Talk: NLP in Mexican Spanish: One of many stories

Manuel Montes-y-Gómez
National Institute of Astrophysics, Optics and Electronics (INAOE)

Abstract:

Wednesday, July 13, 2022 - Room: **Columbia A/C/D & 302 Beckler** - Time: **16:15-17:15**

Abstract: Spanish is one of the most widely spoken languages in the world, however, the development of language technologies for it has not been in the same proportion. This is particularly true for some of its Latin American variants, such as the Mexican Spanish. This talk will focus on presenting the development of NLP for Mexican Spanish, emphasizing one of its many research stories related to the analysis of social media content.

This talk will present some data on the languages spoken in Mexico and on the development of the area of Natural Language Processing in our country, and will describe a research project that combined the efforts of several groups: the identification of abusive language in Mexican tweets. The talk will conclude by exposing some calls for collaboration, with the intention of increasing and improving the research in Mexican Spanish as well as in the many indigenous languages spoken in Mexico.

Bio: Manuel Montes-y-Gómez is Full Professor at the National Institute of Astrophysics, Optics and Electronics (INAOE) of Mexico. His research is on automatic text processing. He is author of more than 250 journal and conference papers in the fields of information retrieval, text mining and authorship analysis.

He has been visiting professor at the Polytechnic University of Valencia (Spain), and the University of Alabama (USA). He is also a member of the Mexican Academy of Sciences (AMC), and founding member of the Mexican Academy of Computer Science (AMEXCOMP), the Mexican Association of Natural Language Processing (AMNLP), and of the Language Technology Network of CONACYT. In the context of them, he has been the organizer of the National Workshop on Lanuage Technologies (from 2004 to 2016), the Mexican Workshop on Plagiarism Detection and Authorship Analysis (2016-2020), the Mexican Autumn School on Language Technologies (2015 and 2016), and a shared task on author profiling, aggressiveness analysis and fake news detection in Mexican Spanish at IberLEF (2018-2021).

Panel: "The Place of Linguistics and Symbolic Structures"

Tuesday, July 12, 2022 - Room: **Columbia A/C/D & 302 Beckler** - Time: **9:15-10:15**

The widespread adoption of neural models in NLP research and the fact that NLP applications increasingly mediate people's lives have prompted many discussions about what productive research directions might look like for our community. Since NAACL is a meeting of a chapter of the Association for Computational Linguistics, we would like to highlight specifically the role that linguistics and symbolic structures can play (or not) in shaping these research directions.

Moderator: Dan Roth, University of Pennsylvania & AWS AI Labs
Bio: Dan Roth is the Eduardo D. Glandt Distinguished Professor at the Department of CIS, UPenn, the NLP Lead at AWS AI, and a Fellow of the AAAS, ACM, AAAI, and ACL. In 2017 Roth received the John McCarthy Award. Roth has published broadly in ML, NLP, KRR, and learning theory, and has given keynote talks and tutorials in all ACL and AAAI major conferences. Roth was the Editor-in-Chief of JAIR until 2017, and the program chair of AAAI'11, ACL'03 and CoNLL'02.

Emily M. Bender, University of Washington
Bio: Emily M. Bender is a Professor of Linguistics at the University of Washington and the Faculty Director of UW's Professional Master's in Computational Linguistics. Her research interests include computational semantics, multilingual grammar engineering, the interplay between linguistics and NLP, and societal impacts of language technology. She is the author of two books which present linguistic concepts in a manner accessible to NLP practitioners: Linguistic Fundamentals for Natural Language Processing: 100 Essentials from Morphology and Syntax (2013) and Linguistic Fundamentals for Natural Language Processing II: 100 Essentials from Semantics and Pragmatics (2019; with Alex Lascarides), as well as the co-author of recent influential papers such as Climbing towards NLU: On Meaning, Form, and Understanding in the Age of Data (ACL 2020) and On the Dangers of Stochastic Parrots: Can Language Models Be Too Big? (FAcct 2021).

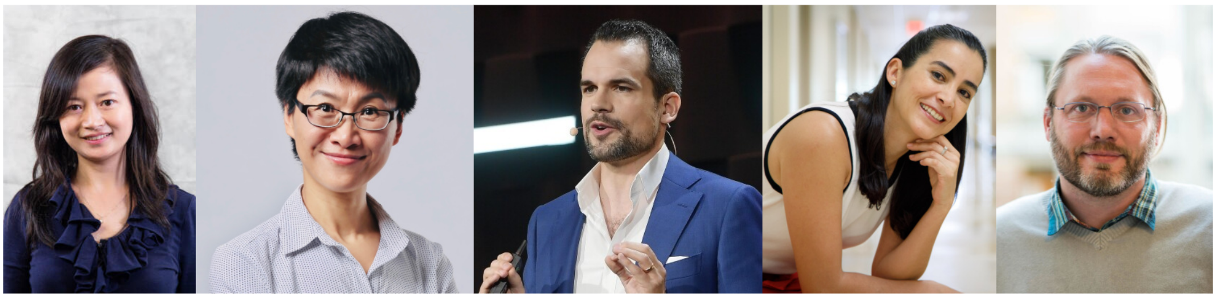
Dilek Hakkani-Tür, Amazon Alexa AI
Bio: Dilek Hakkani-Tür is a senior principal scientist at Amazon Alexa AI, focusing on enabling natural dialogues with machines. Prior to joining Amazon, she was a researcher at Google, Microsoft Research, International Computer Science Institute at UC Berkeley and AT&T Labs-Research. Her research interests include conversational AI, natural language and speech processing, spoken dialogue systems, and machine learning for language processing. She received best paper awards for publications she co-authored on conversational systems from IEEE Signal Processing Society, ISCA and EURASIP. Recently, she served as a program chair for NAACL 2020, the editor-in-chief of IEEE Transactions on Audio, Speech, and Language Processing and an IEEE Distinguished Industry Speaker. She is a fellow of ISCA and IEEE.

Chitta Baral, Arizona State University

Bio: Chitta Baral is a Professor in the School of Computing and AI at Arizona State University. His research interests include Knowledge Representation and Reasoning (KR & R), Natural Language Understanding (NLU), Image/Video Understanding; and their applications to Molecular Biology, Health Informatics and Robotics. Chitta is the author of the book "Knowledge Representation, Reasoning and Declarative Problem Solving" and a past President of KR Inc. His current research focus is on leveraging decades of research in KR & R for better understanding of natural language and images/videos. Towards that end he has worked on a framework for translating natural language to formal representations (NL2KR); abducing missing knowledge and knowledge hunting; exploring NLU challenges where reasoning with knowledge, reasoning about actions, and commonsense reasoning are crucial; exploring the use of natural language as a knowledge representation and instructional formalism; and exploring the role of reasoning and knowledge in enhancing generalizability, robustness, and few-shot learning.

Christopher D. Manning, Stanford University
Bio: Christopher Manning is a professor of linguistics and computer science at Stanford University, Director of the Stanford Artificial Intelligence Lab (SAIL), and an Associate Director of the Stanford Institute for Human-Centered AI (HAI). He is a leader in applying deep neural networks to natural language processing (NLP), including work on neural machine translation, tree-recursive models, natural language inference, summarization, parsing, question answering, and the GloVe word vectors. Manning founded the Stanford NLP group (@stanfordnlp), teaches and has co-written textbooks for NLP (CS 224N) and information retrieval (CS 276), co-developed Stanford Dependencies and Universal Dependencies, manages development of the Stanford CoreNLP and Stanza software, is the most-cited researcher in NLP, and is an ACM, AAAI, and ACL Fellow and a Past President of ACL.

Panel: “Careers in NLP”



Monday, July 11, 2022 - Room: **Columbia A/C/D & 302 Beckler** - Time: **13:15-14:15**

The Careers in NLP Panel is a standing feature of NAACL Industry Track. The panel is addressed to graduate students and junior researchers as well as their supervisors and mentors, although all NAACL participants are welcomed. The panellists will discuss the diversity of career paths in NLP: from more research-oriented NLP scientist roles to careers in product.

Moderator: Yunyao Li, Apple Knowledge Platform
Bio: Yunyao Li is the Head of Machine Learning, Apple Knowledge Platform, where her team builds the next-generation machine learning solutions to help power features such as Siri and Spotlight. Previously she was a Distinguished Research Staff Member and Senior Research Manager at IBM Research - Almaden. She is particularly known for her work in scalable NLP, enterprise search, and database usability. She has built systems, developed solutions, and delivered core technologies to over 20 IBM products under brands such as Watson, InfoSphere, and Cognos. She has published over 80 articles with multiple awards and a book. She was an IBM Master Inventor, with over 50 patents filed/granted. She is an ACM Distinguished Member. She was a member of the inaugural New Voices program of the US National Academies (1 out of 18 selected nationwide) and represented US young scientists at World Laureates Forum Young Scientists Forum in 2019 (1 of 4 selected nationwide).

Yang Liu, Amazon, Alexa AI
Bio: Yang Liu is currently a principal scientist at Amazon, Alexa AI. Her research interest is in speech and language processing. She received her BS and MS from Tsinghua University, and Ph.D. from Purdue University. Before joining Amazon, she was the head of LAIX Silicon Valley AI lab, a research scientist at Facebook, visiting scientist at Google, a faculty member at the University of Texas at Dallas, and researcher at ICSI in Berkeley. She received NSF CAREER award and Air Force Young Investigator Program award. She is currently a member of the IEEE SLTC committee, a senior area editor for IEEE/ACM Transactions on Audio, Speech and Language Processing, an action editor for TACL. She was one of the program chairs for EMNLP 2020, and has served regularly as an area chair and reviewer in the past NLP conferences. She is a fellow of IEEE and ISCA.

Timo Mertens, Grammarly
Bio: Timo Mertens is the Head of Machine Learning & NLP Products at Grammarly. In his role, he oversees the teams that design and build products that use machine learning and natural language processing. These technologies empower Grammarly to offer a digital writing assistant that helps millions of users write more clearly and effectively every day. Timo has focused on the intersection between machine learning and delivering impactful products throughout his career, spanning academia—with a Ph.D. in Speech Recognition—and industry, where he’s held product leadership positions across Microsoft, Google, and Dropbox.

Thamar Solorio, University of Houston and Bloomberg LP
Bio: Thamar Solorio is a Professor of Computer Science at the University of Houston (UH) and she is also a visiting scientist at Bloomberg LP. She holds graduate degrees in Computer Science from the Instituto Nacional de Astrofísica, Óptica y Electrónica, in Puebla, Mexico. Her research interests include information extraction from social media data, enabling technology for code-switched data, stylistic modelling of text, and more recently multimodal approaches for online content understanding. She is the director and founder of the Research in Text Understanding and Language Analysis Lab at UH. She is the recipient of an NSF CAREER award for her work on authorship attribution, and recipient of the 2014 Emerging Leader ABIE Award in Honor of Denice Denton. She is currently serving a second term as an elected board member of the North American Chapter of the Association of Computational Linguistics.

Luke Zettlemoyer, University of Washington and Meta
Bio: Luke Zettlemoyer is a Professor in the Paul G. Allen School of Computer Science & Engineering at the University of Washington, and a Research Scientist at Meta. His research focuses on empirical methods for natural language semantics, and involves designing machine learning algorithms, introducing new tasks and datasets, and, most recently, studying how to best develop self-supervision signals for pre-training. His honors include being named an ACL Fellow as well as winning a PECASE award, an Allen Distinguished Investigator award, and multiple best paper awards.

Social Norms Guide Reference Resolution

Mitchell Abrams and **Matthias Scheutz**

Abstract

Humans use natural language, vision, and context to resolve referents in their environment. While some situated reference resolution is trivial, ambiguous cases arise when the language is underspecified or there are multiple candidate referents. This study investigates how pragmatic modulators external to the linguistic content are critical for the correct interpretation of referents in these scenarios. In particular, we demonstrate in a human subjects experiment how the social norms applicable in the given context influence the interpretation of referring expressions. Additionally, we highlight how current coreference tools in natural language processing fail to handle these ambiguous cases. We also briefly discuss the implications of this work for assistive robots which will routinely need to resolve referents in their environment.

1 Introduction

Humans interacting in natural language need to resolve referential expressions often referring to referents in their environment; utterances like *pick up the green box* or *pick it up*, for instance, highlight some referring expressions that point to a referent. These expressions appear in various forms, from clear and specific—*the green box*—to underspecified and ambiguous—*it*. But reference resolution, especially situated reference resolution, also requires vision and pragmatic context to disambiguate references. In the linguistically underspecifed example of *pick it up*, a listener may have to look for the candidate objects in the environment to figure out what *it* refers to. Additionally, the social setting can modulate what referent is intended, given the same referring expression and objects in the environment; in a dining room, for instance, a spoon on the ground may be the more likely candidate than a pencil. In this paper we investigate the role of pragmatic modulators like this in reference resolution.

The psycholinguistics literature has leveraged eye tracking to infer what referents humans resolve in various contexts (Tanenhaus et al., 1995; Spivey et al., 2001). Pragmatic modulators outside of the linguistic content can further constrain the referential domain and affect referent interpretation, such as task-relevant constraints (Hanna and Tanenhaus, 2004). There is a gap, however, in understanding how other pragmatic modulators, such as social norms and conventions affect the interpretation of referents. For example, while there has been work on modeling what social norms are activated in various contexts and settings (Malle et al., 2020), it is unclear how norms guide humans to interpret referring expressions. Similarly, conventions such as standing on the right side of an escalator while walking on the left, or sitting in the back of cab, can have modulatory influence on reference resolution and object selection.

The aim of this paper is to demonstrate the role of pragmatic modulators, especially social norms, in guiding situated reference resolution. First we provide background on reference resolution and context, with a focus on situated reference resolution in particular. Then, we show how referents are guided by social norms in certain contexts through a human-subjects experiment. We proceed to compare results from this experiment—the referents selected given the situational context and referring expressions—against several coreference tools that attempt to resolve these referents. Lastly, with an eye towards assistive robots, we conclude by outlining an approach for teaching robots to leverage social norms and context for object selection.

2 Background

2.1 Reference Resolution in NLP

Reference resolution is a key task in natural language processing. State-of-the-art approaches in NLP—through significant strides in deep learning—

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 1 - 11
July 10-15, 2022

perform well on text-based reference resolution by learning important syntactic and semantic features. Indeed, coreference phenomenon are naturally guided by several linguistic phenomena as discussed in (Jurafsky and Martin, 2009). Among them are gender agreement, number agreement, person agreement, recency, binding constraints, verb semantics, and selectional restrictions—features often useful for coreference models in NLP such as CoreNLP (Finkel et al., 2005). A more recent end-to-end neural model, part of AllenNLP (Lee et al., 2017), moves away from traditional engineered features and syntactic information and instead relies on word embeddings within and around potential coreferent mention spans as well as the distance between spans, among other approaches.

However, while powerful models encode important linguistic cues for reference interpretation, and use word embeddings to capture word similarity, they fail to take into account contextual knowledge (Emami et al., 2018). This renders current NLP tools insufficient for situated reference resolution.

Recently, coreference tasks such as the Winograd Schema Challenge (WSC), proposed by Levesque et al. (2012), challenge coreference models to handle world knowledge and common sense reasoning. The KnowRef dataset (Emami et al., 2018), a coreference corpus of natural texts, provides a new benchmark for coreference resolution that requires systems to reason about context. The coreference task created sentences stripped of linguistic cues from syntax, gender agreement, and number agreement, forcing systems to rely on context and world knowledge. Emami et al. (2018) fine-tuned a BERT model on the KnowRef dataset to improve its accuracy over other state-of-the-art models. This shows that reference resolution systems can encode world knowledge and common sense reasoning to an extent when trained on these Winograd Schema type datastets. Yet these powerful models remain opaque and do not explicitly model the pragmatic constraints of social norms and conventions.

3 Pragmatic Constraints and Social Norms

Work on multi-modal reference resolution gets closer to modeling pragmatic constraints, mainly by moving beyond text and considering gesture and context to help disambiguate referring expressions (Matuszek et al., 2014; Whitney et al., 2016; Chai et al., 2004). Whitney et al. (2016), in addition to speech and gesture, incorporates contextual knowledge to improve the accuracy of their model on a dataset where people refer to objects on a table. The model exploits information from the kitchen domain and uses recipes as a knowledge base to understand tools and ingredients that typically belong together. Chai et al. (2004) also uses domain knowledge in a graph-matching algorithm for multi-modal referring expressions with a map showing houses and prices. The guiding context, here, is conversational history and domain knowledge about house pricing.

Within the psycholinguistics literature, Hanna and Tanenhaus (2004) use eye-tracking in a cooking simulation to show that pragmatic constraints have modulatory influence on the interpretation of referring expressions. In this experiment, participants followed a confederate cook's instructions for a recipe, where the cook used the the definite noun phrase *the cake mix* to signal potential referents in the cooking space. The addressee's domain of interpretation changed with the task-based constraints—cued perceptually with the cook's hands being empty or full. As the addressees monitor the speaker, they tend to interpret the referent in the cook's area when the cook's hands were full and the referent in their own area when the cook's hands were empty. The results support constraint-based models, where speaker constraints are taken into account for interpretation alongside linguistic ones; indeed, this study highlights how a definite referring expression can point to a few possible candidate objects in a restricted domain, just based on its linguistic form, yet people can disambiguate which referent is being referred to from the pragmatic context. While this study focuses on speaker-based constraints, there is still a lack of knowledge about the modualtory influence of social norms and conventions in interpreting referring expressions.

A promising step in this direction are attempts to computationally model social norms with the ultimate aim of creating norm competent artificial agents (Malle et al., 2020). Malle et al. (2020) experimentally collected responses from humans to generate social norms for eight contexts, including a library, boardroom, bathroom, and restaurant, among others. While social norms can be elusive and challenging to define, since they vary by culture and appear on various levels of demand, Malle et al. (2020) follows Janoff-Bulman et al. (2009) in viewing social norms as *prescriptions* and *prohibitions* and giving attention the gradability of these norms by mapping the deontic force—how strong or weak these norms are to be followed—to the collected *prescriptions* and *prohibitions*. Malle et al. (2020) define norms more formally as such:

> *A norm is an instruction, in a given community, to (not) perform an action in a given context, provided that a sufficient number of individuals in the community (i) demand, to a certain degree, of each other to follow the instruction and (ii) do in fact follow it.*

We will adopt this definition for *social norms* in this study, which formalizes the idea of *prescriptions* and *prohibitions* being followed by many people. We also broaden the definition of *social norms* to include descriptive norms and conventions, although Bicchieri (2005) makes a more fine-grained distinction between *social norms*, *conventions*, and *descriptive norms*. We do not consider moral norms or legal obligations in the present paper.

Equally important, this study offers an approach for teaching norms to robots for guiding actions and balancing norms with goals. They outline an enriched Markvov Decision Process (MDP) approach that uses a starting norm base, which are predefined norms collected in the experiment, and refines it through human interaction and feedback. We look at this proposal optimistically for, in a similar vein, teaching embodied agents the specific behavior of performing situated reference resolution.

A referring expression can appear in a variety of linguistic forms, but pragmatics, regardless of the linguistic form, has the potential to modulate the meaning of the sentence and referent entirely. This will be true for humans that use natural language with robots as well. Imagine a situation where someone commands an assistive robot in a home: *take it away*. The robot can use the natural language and vision input to scan the area for potential referents of *it*. If a shoe and a spoon are salient objects on a dining room table, the convention of a shoe not belonging on a table would make the shoe the more likely candidate. Alternatively if a shoe and a spoon are salient objects on the floor of a bedroom, the spoon would likely be the referent.

Marrying the work on pragmatic constraints on reference resolution and social norms, we conduct an experiment where humans are tasked with identifying the referent of an ambiguous referring expression across various contexts and, thus, various social norms and conventions.

This experiment relates to previous work that leverages crowd sourcing for collecting anaphora annotations and judgments (Poesio et al., 2019, 2013; Chamberlain et al., 2008; Kicikoglu et al., 2019). Although this body of work focuses on a game-with-a-purpose (GWAP) approach to crowd sourcing (Von Ahn, 2006), our study does not gamify our annotation task but it does avoid using linguistic and annotation terminology for participants. Poesio et al. (2019), specifically, collects several judgements and disagreements over ambiguous cases of anaphora. Similarly, our study captures the reasons and explanations people make when resolving a referent, although there is no adjudication process. Through overall decisions and explanations, we are then able to study the agreement and interpretations over our ambiguous scenarios.

4 Experiment and Results

Here, we report the details of an online vignette-based human-subjects experiment designed to explicate the potential role of social norms in resolving references in context. We recruited 50 participants on Prolific (see `https://prolific.co`), an online participant recruitment site which is known to provide better results on tasks like ours. Participants were free to leave the study at any point, their data was anonymized, and they received adequate payment for the study. A consent form was presented at the beginning of each study with information on how their data would be used. We restricted our recruitment to people living in the United States and at the time of the study and native speakers of English.

Each participant was presented with eight text vignettes where each vignette described a scene within a daily-life context. Each scene contains four pieces of information: an explicit mention of the setting (*The scene takes place in a library*), a description of the background—that is, the objects and people in the scene—an underspecified referring expression (e.g., *remove it*), and an actor in the scene acting on an object. There are always two salient referents that are potential candidates for the referring expression. Participants must determine whether the referent chosen by the actor in

Contexts	Items	Hypothesized Norms
Library	head seat, side seat	*do not interrupt someone at the library; give space to others*
Boardroom	head seat, side seat	*do not sit at the head of the table*
Taxicab	front seat, back seat	*you should sit in the front seat*
Friend's Car	front seat, back seat	*you should sit in the back seat*
Dining Room	shoe, spoon	*a shoe should not be on a dining table*
Leather Shop	shoe, spoon	*a spoon should not be on a non dining table*
Bookstore	magazine, toothbrush	*a toothbrush should not be on the floor of a bathroom*
Bathroom	magazine, toothbrush	*a magazine for display should not be on the ground*

Table 1: Overview of contexts in the experiment, the items mentioned in the reference task, and some hypothesized norms activated in each context.

the scene was the *correct* one.

With the information still in view, participants are asked to select the best explanation for their answer and are provided a multiple choice listing of five potential explanations and one open text response option labeled *other*. These reasons include: *typical for the setting*, *object is mentioned first*, *object is mentioned more recently*, *time sensitive option*, *more convenient option*, and *other*. We included reasons that could explain that the correct referent was the one that was intended, rather than subjective options that potentially frame the question as a personal preference. We also offered a text response if none of the options fit.[1] We summarize the contexts, candidate objects, and a hypothesized norm associated with each context in Table 1.

Each context, some of which are inspired by Malle et al. (2020), are assumed to activate their own inventory of norms to help disambiguate the referring expression. Our hypothesized norms are partly based on intuition but also inspired by previous work on norms and behavior. Aarts and Dijksterhuis (2003), for instance, conducted a survey with undergraduates to confirm the normative behavior of acting silently in a library setting. This norm is applied to our study in a library scene: there is an open seat at a table right next to someone and a seat further away from someone. Although there is no mention to noise, seating right next to someone else—a stranger—is potentially noisy and interruptive. Additionally, similar to the norm of not littering (Cialdini et al., 1991), we focused on *prohibitions* of objects not belonging in certain contexts; a shoe is not supposed to be on a clean dining room table and a toothbrush should not be on the bathroom floor. We posit other norms that tend to influence frequent behavior such as sitting with your friend in their car, as opposed to the backseat, and sitting in the back of a taxicab.

Similar to Winograd schema datasets, each referring expression is stripped of linguistic surface cues such as gender, number, and person that would give away the referent. Instead, these scenes are set up so that subjects in the experiment have to rely on information outside of the text to help them make a decision. The only linguistic cue we maintain in the study, however, is *recency*, where we change the ordering of the referents. These scenes include: library, boardroom, taxicab, friend's car, dining room, leather shop, bookstore, home bathroom.

Each scene has a complementary scene that shares the same referents; the library and boardroom share two seats, the taxicab and friend's car share two seats, the dining room and leather shop share a shoe and a spoon, and the bookstore and home bathroom share a toothbrush and a magazine. The purpose of creating complementary scenes with the same referent was to demonstrate how, when the referring expression is constant, the context, and thus the social norms and conventions associated with it, modulate the interpretation of the referent. We posit, for instance, that people will select the seat in the back of the cab as opposed to the front of the cab. This would be guided by the norm of sitting in the back of a cab. Alternatively, people would most likely choose to sit in the front seat in a friend's car and not the back seat, also for conventional reasons.

The following excerpts show examples of the scenes participants read during the experiment. The

---

[1] The experimental design of a posthoc explanation of whether the referent was "correct" was chosen after initial pilot experiments showed that asking subjects for the correct referent rather than providing them with the choice of the actor in the scene led to a confound: subjects often choose the referent they would have chosen instead of hypothesizing the referent the actor in the given context would have selected.

one below is for the dining room context:

> *The scene takes place in a dining room. There is a shoe and a spoon sitting on a dining room table. Dinner is about to be served.*
>
> *Someone says, "remove it."*
>
> *Someone else removes the shoe from the table.*

This next example, describing a leather shop, shows a complementary scene using the same candidate objects of the shoe and spoon and the same definite referring expression, *remove it*.

> *The scene takes place in a leather shop. There is a spoon and a shoe sitting on a worktable. Nothing else is on the table. A customer is coming into the store.*
>
> *Pointing to the worktable, someone in the room says, "remove it."*
>
> *The employee removes the spoon.*

While each participant sees all eight scenes, there are two conditions where the ordering of the referents mentioned in the text are flipped. Condition A lists the intended (correct) referent last and condition B lists the intended referent first. In the dining room scene, for instance, condition A lists the spoon first and then the shoe and condition B lists the shoe first and then the spoon. We create these conditions to test whether people are biased by the recency of referents and to also evaluate these texts on coreference tools which may be biased by recency in performing reference resolution.

The results in Table 2 show how many people agreed that the selected referent was correct or incorrect in a "yes-no" question. Overall, the majority of people agreed that the referent selected was the *correct* one across all scenes, and the frequency distributions seem consistent across both conditions. Stronger agreement trends towards scenes with seats as referents—that is, the library, boardroom, taxicab, and friend's car. The scenes with the most disagreement were the bookstore and home bathroom scenes, which used a toothbrush and magazine as candidate objects. For these scenes, we hypothesized contexts with a *prohibition* type norm where it is unacceptable for a toothbrush and a magazine to be on the ground. But these were, perhaps, less airtight scenarios. In a home bathroom, magazines can be stowed in the corner for casual reading, but a toothbrush has a its place in a cabinet or cup holder. In a bookstore, a magazine should belong on the shelf along with other books and magazines, but a stray toothbrush in a public space can be left alone, unless a norm of not littering is competing. The explanations people chose offer some more clarity to this picture.

	A		**B**		
Contexts	**yes**	**no**	**yes**	**no**	**Total**
Library	21	3	22	4	43-7
Boardroom	23	1	26	0	49-1
Taxicab	24	0	26	0	50-0
Friend's Car	23	1	25	1	48-2
Dining Room	23	1	25	1	48-2
Leather Shop	20	4	21	5	41-9
Bookstore	16	8	20	6	36-14
Bathroom	23	1	23	3	46-4

Table 2: Counts for *yes* or *no* in response asking whether the referent identified is *correct*. Results reported for conditions A and B where each condition is a different ordering of the referents mentioned in the text (e.g. ... *shoe and spoon ...* v.s. ... *spoon and shoe ...*)

Table 3 provides an overview of the reasons people gave for their agreement or disagreement with the selected referent. One obvious trend that stands out is that **Convention** (displayed as *typical for the setting* in the study) outnumbers the other reasons across all scenes and conditions. Where there was high consensus on the correct referent for the seat related scenes, there was a commensurate high rate of selecting the conventional explanation. For the library scene, however, we see a tension between conventional explanation and a convenient choice for choosing a seat at the head of the table rather than a seat next to someone else. For some, it seems, the convention of keeping distance from a stranger at a library, as not to cause a disruption, is either not activated or is overruled by convenience.

Then there are the bookstore and home bathroom scene that have a lower consensus and, thus, a higher count of alternative explanations. Interestingly, when people disagree that the selected object was correct, their explanations suggest a normative reason is stronger in the other direction. For example, if a magazine is more conventional in a bookstore (*prescription*) a toothbrush is unconventional and suggests a prohibition norm. We present a sample of explanations for these scenes:

		Convention	**Last**	**First**	**Time Sensitive**	**Convenient**	**Other**
Library	A	10	2	0	0	9	3
Library	B	10	0	0	0	9	7
Boardroom	A	20	0	0	0	2	2
Boardroom	B	23	0	1	0	1	1
Taxicab	A	23	0	0	0	0	1
Taxicab	B	25	0	1	0	0	0
Friend's Car	A	19	0	0	0	5	0
Friend's Car	B	17	0	1	0	8	0
Dining Room	A	16	0	1	0	1	6
Dining Room	B	22	0	0	0	1	3
Leather Shop	A	12	1	0	1	1	9
Leather Shop	B	17	0	1	1	4	3
Bookstore	A	13	1	2	0	1	7
Bookstore	B	16	1	3	1	0	5
Bathroom	A	16	0	1	3	1	3
Bathroom	B	11	1	5	3	0	6

Table 3: Counts for best explanation for correct or incorrect referent selected. The shortened label **Convention** corresponds to the *typical for the setting* option in the experiment; **Last** to *object is mentioned more recently*; **First** to *object is mentioned first*; **Other** to *other* with free text response; **Time Sensitive** to *time sensitive option*; **Convenient** to *more convenient option*

Bookstore:
toothbrush doesn't belong...
the toothbrush is the more out-of-place object, and therefore, it is implied to have that removed rather than the magazine
the toothbrush does not match the setting/misplaced

Home Bathroom:
object is irrelevant to the setting and should be removed

We also note that for these scenes and others in the study, some of the explanations people articulate can be classified as norms even though they did not select the normative option in the multiple choice:

Home Bathroom:
The toothbrush should not be on the floor toothbrush does not belong on the floor

Boardroom:
The boss usually sits at the head of the table.

Library:
The head of the table doesn't have anyone sitting next to it.

Although it was unclear for some that *typical for the setting* subsumed the normative or conventional explanations, the fact that people gave normative explanations support that reasoning even more.

To summarize this experiment, given the same two referents, people interpreted one referent as correct in one context and the other as correct in another context, each according to specific norms that are activated in that context. This suggests that social norms activated by the context had enough modulatory influence to determine the interpretation of an ambiguous referring expression favored by the norm. As a consequence, not knowing the norms that apply in these context will likely lead to incorrect interpretations of referential expressions as other factors not necessarily congruent with the norm-based interpretation will be used for reference resolution, as the next section on current NLP tools will demonstrate.

4.1 Evaluating NLP Tools

To complement our empirical study, we evaluated several coreference and natural language processing tools on our experimental scenes to determine if they achieve human performance for norm-guided reference resultion tasks. These include Neural-

Coref, an extension of SpaCy (Honnibal and Johnson, 2015) and based on (Clark and Manning, 2016), Stanford CoreNLP (Finkel et al., 2005), AllenNLP (Lee et al., 2017). We also evaluated the GPT-3 base models, Davinci and Curie, by OpenAI, (Brown et al., 2020) designed for text generation and question-answering tasks. For this experiment, we specifically focus on the scenes that use a definite referring expression such as *pick it up*, in the bookstore and home bathroom scenes, and *remove it*, in the dining room and leather shop scenes. For the GPT-3 models, we prompt the Davinci model with the phrase *which one* but do not prompt the Curie model with a question. We made this decision to probe the different capabilities of these models; for the Curie model, we chose not to prompt it to see if would coherently generate the rest of the text and the resolve the correct referent likely to follow from the referring expression in the command (e.g. *pick it up*, *remove it*); for the Davinci model, we tested the question-answering capabilities by providing a question. This evaluation did not use a similar question as the main study—*Was this the correct object?*— as understanding a yes-no response is more opaque and we wanted to see if it could return the referents. We also note that all of these models were used off the shelf without fine tuning.

Table 4: Evaluation of coreference tools on contexts that use a definite reference. The dining room scene and leather shop scene both use the referring expression *remove it*; the bookstore scene and home bathroom scene, similarly, use the referring expression *pick it up*. We report whether these tools can detect if *it* is referential and refers to the correct object.

Results are summarized in Table 4 where we list the referents that the tools selected to match the referring expression. We represent an entity in brackets and also note when the referent is the coordination of the two referents (e.g. *a shoe and a spoon*) or the referring expression was interpreted as non-referential. A check mark ✓denotes the correct referent and an ✗denotes the incorrect referent.

The experimental conditions have a role, here, since the recency or distance of the referent serves as a traditional feature for coreference models in NLP. Swapping the ordering of the referents ensures that if a model resolves the correct referent, it is consistent and is more likely taking into account the context then the surface structure. This swapping method is similar to (Emami et al., 2018)'s evaluation of BERT on the KnowRef test set for consistency.

In the results, there are only three cases where the coreference models choose the right referent. CoreNLP and AllenNLP both correctly link [a shoe] and *it* in the dining room scene. For this condition (condition B), shoe is mentioned first in the text. Although, once the objects are switched, the models choose the wrong object—CoreNLP selects [dinner] (none of the candidate referents) and AllenNLP selects both the shoe and the spoon in a coordination. CoreNLP seems to do the best by selecting another correct referent: [a magazine] in the bookstore scene. But it fails yet again once the objects are swapped.

The GPT-3 models perform poorly overall but the Davinci model, prompted by *which one*, gets closer to the right answer by picking out individual referents more often than the Curie model. Davinci is consistently incorrect in the bookstore scene but consistently correct in the bathroom scene, yielding the only correct result when the referents are switched. The correct referent selected in the bathroom, the toothbrush, was also selected in the bookstore for both conditions. This suggests that the model is biased towards picking the toothbrush over the magazine more generally.

For most of the tools doing reference resolution on these scenarios, we see a theme of referring back to the coordination of the two referents, when only one referent should be selected. Therefore, it is clear these results do not match human intuition for this specific reference resolution task and, more importantly, fail to understanding social norms in order to consistently infer the correct referent.

5 Discussion & Future Implementations

The coreference task performed by humans and the NLP tools show a striking difference in outcomes. Given the same context and text, people tended to agree on the correct referent. Since the examples were stripped of linguistic cues that would give away the referent, people relied on context and social norms based on the reasons they selected and the written explanations they provided. Notably, however, the inconsistent agreement across all scenes can be reconciled with the fact that social norms and conventions are not equally shared across all people. This is supported, in part, by the written responses too. Additionally, these results also suggest that not every norm is weighed the same; the deontic force—how strongly the norm is to be followed—potentially influences how the norm guides a behavior or interpretation and competes with other norms. Admittedly, a limitation of our study is that we do not explicitly categorize our hypothesized social norms and conventions in a gradable fashion, but future work will consider deontic force for a more fine-grain understanding of social norms.

NLP tools, on the other end, tell a different story. Many of the tools specifically designed for coreference resolution failed to consistently select the correct referent. The more powerful NLP engines, such as GPT-3 model, also performed poorly. This shows that relying on such a system to resolve references in these contexts would be problematic. The Davinci model when prompted by the question *which one?* justifies its response with an explanation of grammatical appropriateness: *If we use the noun that appears in the context, it is clear that the speaker is referring to the toothbrush. There is no other "it" in the sentence... We would never say, "Pick up the magazine." This is why it's important to know whether the noun is the subject or object of a sentence*. This explanation echoes something meaningful about grammar, yet is faulty and unclear. Rather, this argument is produced from statistical correlations the system extracted from large corpora. Furthermore, the system has no understanding of norms or how to apply them. The potential danger, here, is that simply employing deep learning systems without giving them a sense of norms will lead such systems to also violate norms. While the consequences of breaking norms can range in severity, at the most extreme end, they can include harm to other people.

A norm aware reference resolution system, therefore, will not only help to disambiguate referents but help a system know what *not* to do. This is especially important with embodied agents whose actions in the real world will be influenced by its reference resolution capabilities and natural language understanding.

5.1 Implementation in Embodied Agents

Inspired by our experimental results, we outline a potential methodology for robots to use social norms and conventions in performing situated reference resolution. In order to make the inferences necessary for selecting the correct referent in our scenarios, a novel pragmatic component must be tightly integrated with vision and natural language processing in a robotic cognitive architecture. All three inputs will simultaneously contribute to the interpretation of a referring expression.

A pragmatic component will serve as a knowledge base specifically for social norms and it would require a baseline representation of norms, which can be collected experimentally for a particular domain (Malle et al., 2020). Upon hearing natural language input from a co-located speaker, a robot will begin incrementally processing the natural language and look for a referring expression. At the same time, the visual system will scan the environment for two purposes: to search for perceptually salient objects that potentially match the referring expression and to trigger the setting to activate a set of norms. For example, spotting a fork, plate, or table, the robot can infer with greater probability that it is located in a dining room and cue an inventory of social norms operationalized as prescriptions and prohibitions. Some of these prescriptions, informally, might be: *food or drinks are allowed on the table* or *you are allowed to sit at the dinner table*. Alternatively, some prohibitions might be *X items should not be on the dining table* or *food and drink should be contained on the dinner table*.

Incremental processing will allow the robot to gradually look for potential referents in the scene and, if it finds potential candidates to match the referring expression, it will also consider the joint probability of each referent given the social norms. The social norms activated from the setting should contribute to the interpretation from the start, not only when an ambiguous situation arises, since they can modulate the interpretation at any point; as seen from our experimental results, regardless of the linguistic form of the referring expression, the social norms can flip the interpretation of the referent when everything else is constant. An advantage to using an inventory of social norms in this way is that they can eliminate potential referents right away. The strength of the norm, roughly corresponding to their deontic force, must be considered for a fine-grained application of norms as some norms will compete with each other. Additionally, it will be critical to understand what norms may or may not be overruled as not to cause harm to human users. While norm activation begins early on, it can continually update through visual and natural language input. If the robot is uncertain about the setting, for instance, it can ask clarifying questions to gain more information. This approach seems applicable in preventing harm where it might be better in many instances to ask questions in uncertain contexts than to overstep boundaries.

To walk through a situated reference resolution scenario, and use a scenario from our experiment, imagine someone commanding the robot: *remove it*. Even if the speaker pauses after the verb *remove*, incremental processing begins to parse the utterance and the robot visually scans the environment for the setting and salient objects. The robots activates the norms stored in the social norm knowledge base and continues processing the input. Once the utterance is completely processed, the expression, *it*, is linked to either a shoe or a spoon. With no other cue from the linguistic input, the prohibition of shoes on dining room tables pushes the interpretation towards removing the shoe. The norm is determined to be strong enough for the robot to act and so it proceeds to remove the shoe. Thus, the robot successfully uses its norm knowledge base in tandem with its vision and natural language processing abilities, to handle what appears on the surface to be an underspecified referring expression.

6 Conclusions

We conducted a human subjects study to demonstrate how social norms can guide reference resolution. Given a text vignette and a referring expression stripped of linguistic cues, the majority of subjects confirmed the intended referent in each context and relied on knowledge of conventions to make their decision. In contrast, several NLP tools evaluated on the same examples consistently failed to select the correct referent. We argue that these NLP tools critically lack an understanding of conventions and social norms and should not be completely relied on for reference resolution as they can also violate norms.

Finally, we integrate our findings into designing a methodology for teaching robots to use social norms and conventions to perform situated reference resolution. In future work, we experiment with using visual scenes for activating norms and evaluate larger NLP models with fine-tuning to our task. Lastly, we will implement our methodology into a cognitive architecture and look more closely at how the gradability of social norms influences reference resolution.

Abstract

This paper introduces TRUncated ReinForcement Learning for Language (TrufLL), an original approach to train conditional language models without a supervised learning phase, by only using reinforcement learning (RL). As RL methods unsuccessfully scale to large action spaces, we dynamically truncate the vocabulary space using a generic language model. TrufLL thus enables to train a language agent by solely interacting with its environment without any task-specific prior knowledge; it is only guided with a task-agnostic language model. Interestingly, this approach avoids the dependency to labelled datasets and inherently reduces pretrained policy flaws such as language or exposure biases. We evaluate TrufLL on two visual question generation tasks, for which we report positive results over performance and language metrics, which we then corroborate with a human evaluation. To our knowledge, it is the first approach that successfully learns a language generation policy without pre-training, using only reinforcement learning. [1]

1 Introduction

Since the development of generic language models trained on massive unlabelled text corpora (Radford et al., 2019; Brown et al., 2020), state-of-the art language processing systems rely on *sequential transfer learning* (Ruder, 2019). The pretrained Language Model (LM) is fine-tuned on the downstream task using a standard supervised learning (SL) objective (Wu et al., 2019; Peters et al., 2019). Yet, such an approach suffers from several issues (Chen et al., 2020): (i) catastrophic forgetting when a model forgets previously learned knowledge and overfits to target domains, (ii) computational inefficiency from fine-tuning billion-parameters networks, and (iii) the need of supervised datasets. Moreover, task-specific language models learned with SL suffer from well-studied text degeneration issues (Holtzman et al., 2019), such as the exposure bias (Bengio et al., 2015), language biases (Saleh et al., 2020; Jaques et al., 2020), or a lack of diversity (Li et al., 2015).

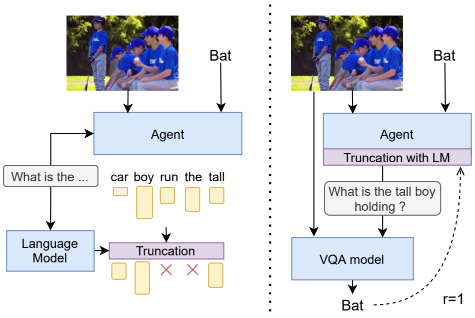

Figure 1: (left) In a conditional language generation task as VQG, TrufLL truncates the vocabulary space by using a language model. Here, 'run,' and 'the' are syntactically incorrect and thus truncated. Yet, 'car' is not trimmed as the LM is not visually grounded. (right) In a VQG training loop, the agent generates a question given an image-answer pair, which is then fed to a VQA model predicting an expected answer. If both answers match, the agent is rewarded.

On the other hand, text generation can be naturally framed as a sequential decision making problem, with the sequence of words seen as successive actions over a vocabulary. Thus, some researchers have recently focused on learning language models using instead

Reinforcement Learning (RL) (Strub et al., 2017; Das et al., 2017; Narasimhan et al., 2015). RL methods allow acquiring language through interactions within rich and diverse environments (Luketina et al., 2019), help understanding language acquisition and language pragmatics (Lazaridou et al., 2016; Bisk et al., 2020). "Reward is enough" (Silver et al., 2021) highlights the necessity of using RL for AI systems to acquire language in its full richness. Indeed, (i) language may be intertwined with other modalities of action and observation, (ii) the utility of language varies according to situations and behaviours, (iii) it is consequential and purposeful, and (iv) some linguistic problems are better solved dynamically, through experience (such as using a diplomatic tone in a speech.) In addition, RL allows optimizing a non-differentiable learning signal, hence handles more diverse objective functions, and also avoids some of the text degeneration issues previously mentioned. So far, RL-based text-generation tasks have relied on a pre-training phase to ease learning: the policy language model is trained with SL on the task dataset, before being fine-tuned with policy gradient methods (Sutton et al., 1999) on the task at hand. Those approaches often require human-labelled datasets. Besides, combining pre-training and fine-tuning phases either barely change the policy distribution, or induces *language drift* (Lazaridou et al., 2020; Lu et al., 2020b), i.e the generated language drifts semantically or syntactically from natural language.

In this paper, we aim at learning a conditional language model using *RL without a pre-training phase*, so that (i) we get free from datasets with human annotations, and (ii) we avoid the text generation flaws induced by the common methods. While appealing, such an approach requires overcoming the hurdle of the combinatorial language action space, a vocabulary usually containing more than 10,000 words. Yet, while large and discrete, a language action space contains a specific structure, made of all the syntactical and semantics rules of a given language. TrufLL leverages such structure to drive the exploration of the RL-based language agent during training. At each time step of the text generation process, TrufLL truncates its effective action space to a small subset of words provided by a pretrained task-agnostic language model. Such an approach injects a generic prior linguistic knowledge into the RL algorithm, is usable on tasks lacking in-domain labeled data, and can be easily transferred to new RL-based text generation tasks. Thus, TrufLL can be applied to any language generation task given a generic LM and a reward. We here evaluate it on two Visual Question Generation (VQG) tasks, the synthetic CLEVR dataset (Johnson et al., 2017), and the natural language VQAv2 dataset (Goyal et al., 2017). Unlike alternative RL without pre-training approaches, TrufLL manages to ask meaningful and valid questions on large vocabularies, exhibiting success rate and language metrics close to pretrain models with labeled data, while producing more original language.

2 Background

Language Generation as an RL Problem. We cast the word-based text generation task as a Markov Decision Process to apply RL methods (Sutton et al., 1998). In this setting, a language model agent generates a sequence of words $w_{<t} = (w_0, w_1, ..., w_{t-1})$ drawn from a vocabulary $\mathcal{V}$, given an initial context c associated with a reward r_t. Translation, text summarization or image captioning are examples of such tasks respectively using a source sentence, a text article, or an image as a context (c). During this process, the agent may be rewarded with language scores (Ranzato et al., 2016), human preferences (Stiennon et al., 2020) or task completion scores (Strub et al., 2017).

Formally, a language generation agent is defined by a policy π_θ (a distribution over $\mathcal{V}$) parametrized by θ, first initialized with the context c. At each time step t, the agent samples a new word w_t from its policy $\pi_\theta(w_t|w_{<t}, c)$. It moves to a new state $(w_{<t+1}, c)$ and receives a reward $r_t = r(w_{<t}, c, w_t)$, where r is a reward function relative to the language task. The RL language agent aims to learn a policy that maximizes $\mathbb{E}_{\pi_\theta}[\sum_{t=0}^{T} r_t]$,[2] while generating the sequence of words $w_{<T}$, where $\mathbb{E}_{\pi_\theta}$ is the expectation under π_θ, and T the maximal length of the words sequence.

Policy Gradient This optimization process may be performed through Policy Gradient (PG) algorithms (Sutton et al., 1999). In the language literature, REINFORCE (Williams, 1992) has been used as a simple Monte Carlo approximation of this gradient (Strub et al., 2017; Li et al., 2016).Yet, in this paper, we use a Proximal Policy Optimization approach (PPO) (Schulman et al., 2017) to have a lower variance and better convergence rate; PPO clips the gradient estimate to have smooth policy updates. For all $0 \leq t \leq T$, let $s_t = (w_{<t}, c)$ and $a_t = w_t$ be the state and action at time t. Policy gradient methods

---

[2] We cast the language modelling as an episodic problem with $\gamma = 1$ and omit the discount factor in the paper for clarity.

minimize the objective:

$$L_{\text{pg}}(\theta) = \mathbb{E}_{\pi_\theta}\left[\sum_{t=0}^{T} \log\pi_\theta(a_t|s_t)\hat{A}_t\right],$$

where $\hat{A}_t$ is an estimator of the advantage function, here defined as $\hat{A}_t = \sum_{u=t}^{T} r_u - V_\phi(s_t)$ with $V_\phi(s)$ an estimator of the value function $V_{\pi_\theta}(s) = \mathbb{E}_{\pi_\theta}[\sum_{u=t}^{T} r(s_u, a_u)|s_t = s]$. PPO then keeps track of the previous policy $\pi_{\theta_{old}}$ before the PG update to compute the training objective:

$$L_{\text{ppo}}(\theta) = \mathbb{E}_{\pi_{\theta_{old}}}\left[\sum_{t=0}^{T} \rho_t^\theta \hat{A}_t \wedge \text{clip}(1-\epsilon, \rho_t^\theta, 1+\epsilon)\hat{A}_t\right],$$

where for all real numbers a, b, $a \wedge b = \min(a,b)$, $\rho_t^\theta = \pi_\theta(a_t|s_t)/\pi_{\theta_{old}}(a_t|s_t)$, ϵ is a hyper-parameter controlling the magnitude of the policy updates, and $\text{clip}(a,x,b)$ is the function that clips x in interval $[a,b]$. The expectation is estimated in practice using a Monte Carlo approach, with an empirical average over a finite batch of episodes, i.e a succession of transitions $(s_t, a_t \sim \pi_{\theta_{old}}(.|s_t), r_t)$ from an initial state s_0 to a terminal state s_T. Finally, the training loss is completed first with a value-based loss to learn the baseline V_ϕ that reduces the gradient variance; it computes for each timestep t of an episode the mean squared error $|\sum_{u=t}^{T} r_u - V_\phi(s_t)|^2$.[3] Secondly, the loss is completed with an entropy term to soften the policy distribution, which computes for each timestep t of an episode $H(\pi_\theta(a_t|s_t))$, where H is the entropy function.

3 TrufLL

We here aim at making RL methods feasible in the language setting by dynamically reducing the action space, i.e., by restricting the language agent to select a word within a subset of the vocabulary at each time step. We detail below the action space's truncation model and the associated RL algorithm to learn the language agent.

3.1 Dynamic Vocabulary Truncation

TrufLL combines two distinct language models, which share the same vocabulary $\mathcal{V}$: a RL language agent π_θ and a pretrained language model f_{LM}. At each timestep t, TrufLL restricts the vocabulary space of the RL language agent with:

$$\mathcal{V}_t^- = \{w | w \in \mathcal{V}, g_{trunc}(w|w_{<t}) = 1\},$$

where g_{trunc} is a truncation function based on f_{LM} which either associates 0 or 1 with each word in the vocabulary given the past words $w_{<t}$. From a language modelling perspective, the vocabulary space of the language agent is reduced from $\mathcal{V}$ to $\mathcal{V}^-$ where $|\mathcal{V}^-| \ll |\mathcal{V}|$, with $|\cdot|$ the cardinal of a finite set. From a RL perspective, the RL agent follows a truncated policy π_θ^- which only samples actions over the subset $\mathcal{V}^-$. In practice, such a policy is computed using a masked softmax function over the truncated vocabulary $\mathcal{V}_t^-$: $\pi_\theta^-(.|w_{<t}, c) = \text{softmax}(m * logits_{\pi_\theta}(w_{<t}, c))$ where $m = 1$ when $g_{trunc}(w|w_{<t}) = 1$ otherwise $m = -\infty$.

3.2 Truncation Functions

We here list the different truncation functions g_{trunc} explored through the paper.

Top-k words: This function selects the k words with the highest probability given by $f_{LM}(.|w_{<t})$:

$$g_{\text{top(k)}}(w_t|w_{<t}; k) = \mathbb{1}_{w_t \in \text{top(k)}(f_{LM}(.|w_{<t}))}.$$

Probability threshold (α): This function only keeps words having a probability $f_{LM}(.|w_{<t})$ greater than α:

$$g_{\text{Pth}(\alpha)}(w_t|w_{<t}; \alpha) = \mathbb{1}_{f_{LM}(w_t|w_{<t}) > \alpha}.$$

Top-p: This function is based on nucleus sampling (Holtzman et al., 2019), and it keeps the most likely words contained in a probability mass p of $f_{LM}(.|w_{<t})$. Formally, we define $\mathcal{V}_t^p$ as:

$$\mathcal{V}_t^p = \underset{|V_t|, V_t \subset \mathcal{V}}{\text{argmin}} \{w | w \in V_t, \sum_{w \in V_t} f_{LM}(w|w_{<t}) > p\},$$

and readily, $g_{\text{top(p)}}(w_t|w_{<t}; p) = \mathbb{1}_{w_t \in \mathcal{V}_t^p}$.

Sample (k): This function randomly samples k words from the language model with replacement to directly build the truncated vocabulary:

$$g_{\text{sample(k)}}(w_t|w_{<t}; k) = \mathbb{1}_{w_t \in \{w_i \sim f_{LM}(.|w_{<t})\, i \in [\![1,\ldots,k]\!]\}}.$$

Only top(k) provides a fixed number of words at each time step. $\text{p}_{\text{th}}(\alpha)$, top(p), and sample(k) have a dynamic truncation, whose size at t depends on the language model entropy.

3.3 Task-Specific vs. Generic LM

We benchmark two types of language models for truncation. On the one hand, we use an *external language model* pretrained on a large task-agnostic language corpora. Such a model provides a generic linguistic prior to the RL agent exploration process, solely encoding syntactic and semantic information. On the other hand,

---

[3] Note that other TD-based losses are applicable (Sutton et al., 1998; Schulman et al., 2016; Espeholt et al., 2018).

we use a *task-related language model* pretrained on the supervised dataset associated with the task. Such a model provides a task-specific linguistic prior to the RL language agent, and captures language pragmatics. We emphasize that this paper aims at leveraging task-agnostic language models as they discard the need for task-specific data. For the sake of completeness, we also study the truncation with the task-related LM as an additional benchmark to assess our approach.

4 Experimental Setting

We here list the experimental setting and detail the network and hyperparameters in Appendix A.4.

4.1 Visual Question Generation

We showcase TrufLL on the task of Visual Question Generation (VQG) (Mostafazadeh et al., 2016), which is a form of Visual Jeopardy! ™ (Ferrucci, 2012). There, the language agent observes an image-answer pair and has to generate a question that results in a similar answer, as illustrated in Figure 1. Such a task presents multiple advantages. First, by combining vision, scene understanding and language generation, it requires high-level reasoning and exhibits a large spectrum of language difficulties. Secondly, the success criterion is naturally non-differentiable, hence a natural fit for RL methods. Such a criterion, unlike metrics based on ground-truth sentences, allows generating diverse grounded questions given an image-answer pair.

Formally, the initial context c is composed of the image-answer pair $(\mathcal{I},\mathcal{A})$. The RL agent then generates a sequence of words $w_{<t}$ of maximum length T. We then provide the generated question to a pretrained VQA model. This model takes as inputs the image $\mathcal{I}$, the generated question $w_{<t}$ and outputs a predicted answer $\hat{\mathcal{A}}$. Finally, the agent receives a reward $r(w_t,w_{<t},c)$ based on $\mathcal{A}$ and $\hat{\mathcal{A}}$.

4.2 Datasets

We evaluate TrufLL on the CLEVR and VQAv2 datasets to simulate large-scale VQG datasets. The two datasets have been originally created for the task of Visual Question Answering (VQA), i.e. for multi-modal classification algorithms predicting an answer given an image-question pair.

CLEVR The CLEVR VQA dataset (Johnson et al., 2017) is made of template questions on synthetic images, which contain simple objects with four distinct properties (shape, material, color, size). The vocabulary contains 86 words and 28 potential answers, making it a valuable proof of concept for assessing TrufLL. Both language models are single-layer LSTMs (Hochreiter and Schmidhuber, 1997) with 512 units, and 512 word embedding dimension. The task-specific LM is trained over the full train dataset of CLEVR questions. The external language model is trained on the mixture of CLOSURE (Bahdanau et al., 2019) and CLEVR-Dialog (Kottur et al., 2019) datasets. Although those two datasets share the CLEVR vocabulary, their language distribution differs from vanilla CLEVR. Finally, we use a pretrained GT-Vector-NMN (Bahdanau et al., 2019) to compute the reward $r(w_t,w_{<t},c)=\mathbb{1}_{\mathcal{A}=\hat{\mathcal{A}},t=T-1}$, where $\mathbb{1}$ is the indicator function.

VQAv2 The VQAv2 dataset (Goyal et al., 2017) is made of natural language and open-formed questions on images from the MS-Coco Dataset (Lin et al., 2014). It has a vocabulary of 14,810 words and 3,149 answers. The task-specific language model is a one-layer LSTM with 512 units and a 512 word embedding dimension, pretrained over the full training dataset of VQAv2 questions. The External Language Model is Open-AI's GPT-2 (Radford et al., 2019). The original language model outputs a probability distribution over $50{,}257$ tokens, but we use a masked softmax function to restrict the probability distribution to the $14{,}810$ tokens of the VQAv2 dataset. Unlike most NLP tasks relying on pretrained generic language models, we do not fine-tune it on the task dataset. Instead, we leverage the few-shot generalization capabilities of GPT-2, by feeding the language model with the prompt "Here are a few examples:" followed by 100 random questions $q_{<100}$ from the dataset. The truncation is then based on the probability distribution $f_{LM}^{gpt2}(.|q_{<100},w_{<t})$. Finally, we used a pretrained VilBERT to compute the reward (Lu et al., 2020a). Given the large number of answers, we use as reward a decreasing function of the rank of the reference answer $\mathrm{rk}(\mathcal{A})$: $r(w_t,w_{<t},c)=\mathbb{1}_{\mathrm{rk}(\mathcal{A})\leq 10,t=T-1}e^{-\mathrm{rk}(\mathcal{A})/2}$, as further explained in Appendix A.5.

In these two settings, we acknowledge that the task dataset is still used to train the VQA models. Please note that the VQA modules are only used to model the environment, i.e. to provide a positive/negative feedback to the agent. In other settings, TrufLL would still work if we replace the VQA model by any language interface: text-game (e.g. Zork), expert-systems, or humans. Here, we only use the VQG framework as a proof of concept that natural language can be learned *through pure interaction* given any task reward. Other language generation applications are discussed in Section 5.3.

4.3 Baselines

In this paper, we aim to show that a RL language agent can be trained from scratch, i.e. without the usual pre-training phase by solely interacting with another language system, the VQA model, when supported by truncation methods. The truncation with the task-related LM is referred to as TrufLL (Task-LM), while the one with the External LM is referred as TrufLL (Ext-LM). We first emphasize the difficulty of training an RL language agent without a supervised pre-training phase through two baselines. We trained a simple on-policy PPO algorithm without any action space pruning, and refer to it as *scratch*. Then, we added a Kullback-Leibler (KL) regularization term to the loss, $\lambda_{\text{KL}}\text{KL}(\pi_\theta || f_{LM})$, with $\lambda_{\text{KL}} > 0$, to incorporate language prior to the agent as in (Jaques et al., 2017, 2019). We refer to it as *scratch + KL-task* when distilling the task-specific language model, and *scratch + KL-ext* with the external language model. Finally, we include two baselines with a pre-training phase. We trained a language agent on the task-dataset with a log-likelihood objective, and refer to it as *pretrain*. Then, we fine-tune the pretrained language agent with PPO without truncation, and refer to it as *pretrain + RL fine-tune*. These two baselines should be viewed as gold standards as they rely on task-related data; additionally, *pretrain + RL fine-tune* is today the state-of-the-art method for learning RL-based LM.

4.4 Metrics and Evaluation Methods

Evaluating text generation is an open-research problem in language literature. We decompose automatic language evaluation into three categories to assess different facets of language, and perform as well a human evaluation study.

Performance metrics. We measure the task-completion score or recall @ 1 which states whether the target answer $\mathcal{A}$ is the top answer of the VQA models, and the recall @ 5 (R@5), which assesses whether $\mathcal{A}$ is in the 5 top answers. These scores measure the task-solving abilities of the agent, but they are also conditioned by the VQA model abilities.

Language Metrics. First, we used n-grams metrics, BLEU (Papineni et al., 2002), METEOR (Banerjee and Lavie, 2005) and CIDEr (Vedantam et al., 2015), to measure the similarity between the generated question and the reference questions in the evaluation set. While those scores can capture syntactic and semantic properties of language, they also fall short when dealing with open-form language, e.g. an identical answer may arise from two non-overlapping but syntactically correct questions. Thus, we also compute two metrics assessing the quality of the language independently of reference questions, the perplexity of the question given an external LM (ppl-e), and its perplexity given the task-related LM (ppl-t).

Diversity Metrics. We here estimate a self-BLEU (sBLEU) score (Zhang et al., 2017) over 10 questions generated on the same image-answer pair. Although such score detects potential mode collapse, i.e., when the language utters identical sequences of words, it also values babbling, i.e., outputting random words. We thus also measure the probability mass of the ten most frequent words (Choshen et al., 2020), and refer to it as peakiness (peak).

Human Evaluation. On the VQAv2 task, we also performed human evaluation by surveying 53 participants on the first 50 questions produced by some of the models at test time. The study (further detailed in Appendix C) is based on pairwise comparison of question samples produced by the concurrent algorithms according to four criteria. First, we evaluated the language quality of the question samples, by asking the participants to select the most syntactically and semantically correct question among the two samples of the questions pair. Secondly, we evaluated language grounding, i.e adequacy of the sample to the image-answer pair, by asking the participants to select the question most suitable given the two elements. Thirdly, we evaluated the language originality and diversity, by asking participants to select the question the most different from the dataset reference question. Finally, we evaluated the number of syntax errors by asking participants to tick the question if it is grammatically incorrect. Examples of questions asked during the study are included in the Appendix C.

4.5 Sampling methods for text generation

When generating text from a trained language model, the quality and diversity of samples depend on the decoding algorithm (Zhang et al., 2020). We consider three text generation methods. *greedy* uses the argmax of the policy, while *sampling* uses the multinomial distribution. Finally, we sampled ten text sequences from the policy, and selected the one with the lowest perplexity according to the external language model, and refer to it as *lm-ranking*. This process has been used recently in Text-to-Image Generation tasks (Ramesh et al., 2021).

Method	Score	R@5	BLEU	Meteor	CIDEr	ppl-t (↓)	ppl-e (↓)	sBLEU (↓)	peak.(↓)
Pretrain	0.30	0.71	0.19	0.38	0.83	3.1	31	0.44	0.96
Pretrain + RL fine-tune	0.44	0.86	0.17	0.34	0.70	4.0	35	0.46	0.95
Scratch	0.17	0.47	0.05	0.08	0.10	10^9	10^6	**0.14**	**0.26**
Scratch + KL-task	0.14	0.38	0.15	0.30	0.53	92	10^2	0.34	0.94

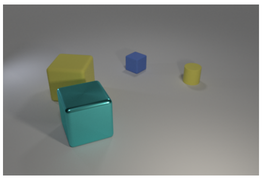
TrufLL (Ext-LM)	0.48	**0.93**	0.08	0.18	0.34(±0.10)	10^3	**3.0**	0.95	1.00

Table 1: **CLEVR metrics** on 5k test episodes with 50k train episodes on 20k Images. Scores are averaged over the three decoding procedures mentioned in Section 4.5 and over 5 seeds; standard deviations are displayed when greater than 0.01 for accuracy metrics. We here report the models with the highest task-success:, i.e. the *scratch+KL* baselines with $\lambda_{KL} = 0.1$, and the truncation model with a probability threshold, $\mathrm{p_{th}}(\alpha = 0.05)$. Best values are underlined, best values without task-data (from scratch) are in bold.



Human	There is a blue thing that is the same shape as the big cyan metallic object ; what is its size? **A:Small**
pretrain	There is a red metallic object that is the same size as the yellow rubber block ; what is its size?
pretrain + RL	What size is the thing that is the same color as the matte cube ? ☑
scratch	size sphere small blue or a yellow green large else in cylinders cubes color and how matte objects cube
scratch+KL-task	How big is the shiny cylinder ?
scratch+KL-ext	How many other objects in the are of same color as that shiny object ?
TrufLL (Task-LM)	How big is the thing that is to the right of the big matte thing ? ☑
TrufLL (Ext-LM)	What is the size of the thing that is right of the big cyan thing and is the same shape? ☑

Human	What color is the cat **A:Black**
pretrain	What color is the cat's collar? ☑
pretrain + RL	What color is the cat? ☑
scratch	AmazingAmazingAmazingAmazingAmazingAmazingAmazing
scratch+KL-task	What color is their hat of the fingers of this?
scratch+KL-ext	The the first time is a bit of the way
TrufLL (Task-LM)	What color is her outfit? ☑
TrufLL (Ext-LM)	What color can these cats look like in real life? ☑

5 Results

5.1 CLEVR results

Quantitative performance: In Table 1, vanilla RL from scratch fails to have a decent performance even with synthetic language. Besides, adding a KL regularisation term does kick-start the learning process. Yet, as soon as we apply the dynamic truncation, TrufLL matches the pretrained baselines performance when using the external LM, and even outperforms them with the task-specific LM. In this synthetic VQG setting, TrufLL seems to be a viable and promising procedure to learn a RL language agent without a supervised training phase. Pretrained baselines have high language scores when assessed with dataset-based metrics, e.g BLEU or task-perplexity. Yet, they also remain close to the original dataset distribution with a medium external perplexity. Noticeably, TrufLL with the task-specific LM follows the same pattern. On the other hand, TrufLL with the external LM reports poor dataset-based language scores, while maintaining a low external perplexity. Therefore, TrufLL seems to correctly capture the language distribution of the initial LM. As the performance score is high when using an external LM, it suggests that our approach can learn a policy on a language task without the need of a task-related dataset. Less positively, TrufLL diversity metrics suggest potential mode collapse, with a high peakiness and self-BLEU score.

Qualitative performance: We display qualitative samples in Figure 2 and Appendix D. On the one hand, the pretrained baselines generate either a question inconsistent with the visual context, or which fails to answer the expected answer. They inaccurately capture the pragmatics of the task. On the other hand, TrufLL generate adequate questions, resulting in the expected answer. Interestingly, they are often grounded with different objects of the image. It is remarkable that TrufLL with a generic LM still manages to capture the necessary subtleties of VQG, without any prior task knowledge. Despite a peaky distribution, TrufLL has moderate repetitions across images, and is mostly overconfident. As for the scratch+KL samples, they are either not grounded, or showcase degenerated language.

Truncation function in CLEVR: In Table 2, we evaluate the different truncation functions defined in Section 3. While all truncation methods report similar task performance, the dynamic truncation functions, i.e. $\mathrm{p_{th}}(\alpha)$, $\mathrm{top(p)}$ and $\mathrm{sample(k)}$, outperform the $\mathrm{top(k)}$ regarding language metrics. Interestingly, the $\mathrm{sample(k)}$ one, which generates a stochastic truncated

Trunc.	Score	BLEU	CIDEr	ppl-e(↓)	sBLEU(↓)

action space, while having a lower performance, yields to the most correct and diverse language, with higher language scores and a lower self-BLEU. A stochastic action space might be harder to explore efficiently for reaching good task-solving abilities, but might strengthen the agent language generation properties.

5.2 VQAv2 task

In CLEVR, we observe that TrufLL seems a promising approach to learn a language policy without a supervised training phase, by solely interacting with another language system. We scale our approach to natural language with large vocabulary (15k tokens) through the VQAv2 dataset.

Quantitative performance: Table 3 reports the VQAv2 results, for which TrufLL and the baselines present a similar trend than on CLEVR. First, the scratch baselines keep failing to learn a valuable policy, with performance scores and n-grams metrics close to zero. Although TrufLL does not outperform the performance of the pretrained baselines anymore, it still leads to similar performances, and satisfactory language scores. The similarity between TrufLL (Task-LM) and TrufLL (Ext-LM) results suggests that the truncation approach is viable when using a generic LM whose original vocabulary distribution differs from the task. Interestingly, TrufLL displays a self-BLEU score similar to the pretrained baselines. This suggests that the poor diversity behavior observed on CLEVR is likely attributable to the small vocabulary and synthetic language distribution.

Qualitative performance: In Figure 2 and Appendix D, we display question samples for all models. TrufLL and the pretrained baselines successfully generate a question giving the expected answer ("Black"), while the RL from scratch baselines fail, and even showcase degenerated language. Pretrained baselines tend to output a question closer to the reference question whereas TrufLL outputs original questions which differs from the VQA distribution, yet consistent with the context.

Human Evaluation: Figure 3 details the Human Evaluation results. Among the RL from scratch baselines, we selected scratch+KL-task as the only model producing sometimes meaningful questions. Yet, it fails to generate correct and grounded language; it is thus not a viable approach despite its diverse output. In line with the automatic metrics, the supervised baselines produce the best language, while being accurately grounded. Yet, they exhibit significantly less diversity with the reference language; this suggests in particular that pretrain+RL fails to go beyond the initial task-data distribution. Finally, unlike TrufLL (Task-LM) which suffers from syntactic errors, TrufLL (Ext-LM) produces language that qualitatively competes with pretrain models (53%), with a similar ratio of syntactic uncorrect samples. Although its questions are less grounded, they are diverse, which suggests that they follow a different distribution from the initial VQA dataset. It confirms that TrufLL (Ext-LM) could be an alternative approach as it has an excellent trade-off between language quality, diversity, and grounding.

Decoding procedure: In Table 4, we evaluate the text sampling procedures described in Section 4.5. While greedy decoding produces the best outcome for pretrained models, lm-ranking provides an excellent trade-off between task performance and language quality with RL-based methods. As PG solely optimizes the task success ratio, this may reduce overall language quality, the re-ranking thus retrieves the best syntactically sentences a posteriori.

5.3 Discussion

Removing the truncation at evaluation with off-policy RL. So far, TrufLL directly learns the truncated policy over the truncated vocabulary $\mathcal{V}_t^-$ in an on-policy scheme. Hence, the algorithm requires the truncation, and a fortiori the language model, at test time. In this section, we investigate if we can directly learn a policy over the full vocabulary, and thus removing the truncation at test time. In such a setting, we adopt an off-policy training scheme, where the trajectories used to learn the behavior π_θ at training time are sampled under a different policy, the truncated policy π_θ^-. Thus, we need to unbiased the PG by using an importance sampling term between the exploratory policy π_θ^- and the behavior policy π_θ (Degris et al.,

2012). Formally, the off-policy PPO loss is defined by:

$$L_{\text{ppo}}^{off}(\theta)=\mathbb{E}_{\pi_{\theta}^{-}}\left[\min(\bar{\rho}_t^{\theta}A_t,\text{clip}(1-\epsilon,\bar{\rho}_t^{\theta},1+\epsilon)A_t)\right],$$

where $\bar{\rho}_t^{\theta}=\frac{\pi_{\theta}(a_t|s_t)}{\pi_{\theta_{old}}(a_t|s_t)}\frac{\pi_{\theta_{old}}(a_t|s_t)}{\pi_{\theta_{old}}^{-}(a_t|s_t)}$ is the new ratio.[4]

Table 5 displays the on-policy and off-policy results on both VQG tasks for TrufLL (task-LM), and is further detailed in Appendix B.3. We also monitor the probability mass of the policy attributed to the truncated action space (sumVA). The policy only samples words within the truncated action space when $\text{sumVA} = 1$, without needing the truncation. On CLEVR, the $\text{TrufLL}_{\text{off}}$ has lower - yet close - performance on language and task scores than TrufLL. As its sumVA ratios are very close to 1, the agent has learned to generalize over the full vocabulary. However, the approach does not manage to sufficiently scale to VQAv2. It could be improved with regularisation techniques and the use of TruFLL within state-of-the-art off-policy RL algorithms. We leave such possibilities to future works.

Algo	Score	BLEU	CIDEr	ppl-e	sBLEU	sumVA

Table 5: On-policy vs. off-policy scores: when training with an off-policy loss, we remove the truncation at test time.

---

[4] Note that we did not simplify the expression to highlight the importance sampling ratio.

Additional experiments. We sweep over truncation hyper-parameters in Table 6 of Appendix B. In Table 8, we observe that rewarding an agent with a BLEU score is sub-optimal in both language and task scores on CLEVR. In VQA, we apply temperature scheduling on the LM to perform fine-grained truncations in Table 9 of B.2. Finally, we explore TrufLL with a pre-training phase in Table 10.

Generalization of the approach. TrufLL learns conditional language models able to solve specific Natural Language Generation tasks given a context *c*. For solving such tasks, it only requires the context, a reward function that scores the language generated by the RL agent with respect to the task, and eventually a few natural language demonstrations fed as input prompt to the generic language model used in the truncation algorithm. Hence, the method is transferable to a wide variety of NLG tasks, without requiring upfront large-scale labelled datasets. Additionally, the RL framework allows to optimize non-differentiable objectives, making TrufLL a natural choice to learn end-to-end task-oriented dialogs, such as (De Vries et al., 2017; Das et al., 2017). Other interesting tasks for TrufLL include the ones typically found in Vision and Language Representation Learning (Lu et al., 2020a), such as Image Captioning, Grounding Referring Expressions (generation of a referring expression over a specific bounding box of an image), Caption-based Image Retrieval (generation of a caption that discriminates an image between a set of images). Reward functions for such tasks can be based on similarity scores between the generated language and the associated image or image region, which can be computed using pretrained language representations such as BERT (Devlin et al., 2019) or multi-modal pretrained systems such as ViLBERT (Lu et al., 2019). The context can be any kind of data structure (natural language, database, video, etc): if it is a linguistic input, TrufLL can be applied for instance to text summarization, paraphrase generation (with reward functions based on similarity scores between the context and the generated language) or text-based games (Ammanabrolu and Riedl, 2018).

6 Related work

RL and NLP Tasks. Following (Singh et al., 2002; Lemon and Pietquin, 2007), recent RL-based task-oriented dialogues (De Vries et al., 2017; Das et al., 2017; Lewis et al., 2017; Narasimhan et al., 2015) have been developed, where the policy language model is generally pretrained with SL followed RL fine-tuning. Yang et al. (2018); Fan et al. (2018) focused on tackling VQG tasks with RL, respectively on CLEVR and on the VQG dataset. Yet, the former uses slot filling with template questions, while the later computes a mixed objective with a MLE loss using ground-truth sentences. Bahdanau et al. (2016); Rennie et al. (2017) use RL to train language models as an alternative to SL to prevent typical text degeneration issues, but within training algorithms relying on ground-truth examples from labelled datasets.

RL methods for Language Action Spaces. Several RL algorithms have been developed to tackle large discrete action spaces. Hence, Dulac-Arnold et al. (2015); Tennenholtz and Mannor (2019); Chandak et al. (2019) embed the actions into a continuous action space, and then use classic RL algorithms to learn a policy over this continuous space. Zahavy et al. (2018); Seurin et al. (2020) proposes Q-learning algorithms with an elimination signal to eliminate forbidden actions. Closer to our work, a few algorithms (Ammanabrolu and Riedl, 2018) use the structure of language to prune the action space of text-based games, but within value-based algorithms, which are less scalable to large vocabularies. Similarly to TrufLL, CALM (Yao et al., 2020) combines a pretrained language model to prune the action space with a Deep-Q network, aka DRNN (He et al., 2016). Yet, its truncation language model remains fine-tuned on the RL dataset. Besides, CALM is only evaluated on a vocabulary of 697 tokens, and on 4-words action sequences.

Learning Language Models from scratch. (Ziegler et al., 2019; Garg et al., 2021) finetune pretrained GPT-2 models with RL for language generation tasks without task-related data, only using reward signals. Yet, they still face optimization and computational challenges (Parisotto et al., 2020).

7 Conclusion

We proposed TrufLL, an original approach to learn a natural language generation (NLG) task using RL, without the usual pre-training phase requiring supervised datasets. To our knowledge, this is the first RL-based algorithm dedicated to learning a word-based text-generation task, which does not rely on a pre-training phase while scaling to large vocabularies. Although it comes with its limitations, the truncated RL algorithm provided by TrufLL gets free from labelled data in task-oriented language models, presents interesting language generation properties, and provides a generic and transferable method to learn any NLG problem.

A Dataset and training details

A.1 Evaluation Metrics

For the BLEU and METEOR scores, we used the NLTK[5] implementations with the smoothing function number 2 for the BLEU score. For the CIDEr score, we used the nlg-eval implementation[6].

A.2 Answer filtering

For each dataset, we remove yes and no question-answer pairs which frequency largely exceeds other answers, to avoid any bias in the question generation process, as usually done in the VQG litterature (Mostafazadeh et al., 2016).

A.3 Dataset split

For CLEVR (resp. VQAv2), the RL language agent is trained for 50k (resp. 100k) episodes over the first 20k images (resp. all the images) of the training dataset, and is then evaluated on the first 5k (resp. 20k) images of the validation set. Besides, we uniformly sample the answer in the set of reference answers for each image to reduce the bias in the distribution of answers. Finally, questions are limited to 20 (resp. 10) words.

A.4 Language Agent Networks and Training

For CLEVR (resp. VQAv2), we used a single-layer LSTM with 64 (resp. 256) units for the policy network. At every time step, the LSTM input is then the concatenation of the word embedding of dimension 32 (resp. 128), the answer embedding of dimension 32 (resp. 128), and the image representation. For CLEVR, the image representation is extracted from a pretrained ResNet50 and projected into a tensor of size (32,7,7) before being flattened. For VQAv2, the image representation is the average of 200 bounding box features of dimension 1048, extracted from a faster R-CNN (Ren et al., 2015).

We optimize the full loss $L = L_{PPO} + \alpha L_{VF} + \beta L_E$ with $\alpha = 0.5$, $\beta = 0.01$ and a PPO clipping ratio $\epsilon = 0.02$ (resp. 0.01) for CLEVR (resp. VQAv2). We use Adam optimizer (Kingma and Ba, 2014) with a learning rate (lr) of 10^{-3} for TrufLL and the scratch baseline, 10^{-5} (resp. 10^{-6}) for RL algorithms with a pre-training phase on CLEVR (resp. VQAv2), and $5*10^{-4}$ for models including a KL regularization term. We use a batch size (bs) of 128 for all models except the ones with KL regularization, for which we use a batch size of 64. Finally, for the RL from scratch baselines, we perform gradient clipping (gladclip) of 1 (resp. 5) for CLEVR and VQAv2.

Such hyper-parameters were selected, after conducting an extensive hyper-parameter search. The following values were tested: $\beta \in \{0.01, 0.02, 0.05, 0.1\}$, $\epsilon \in \{0.01, 0.02, 0.05, 0.1, 0.5, 0.9\}$, lr $\in \{10^{-6}, 10^{-5}, 10^{-4}, 5*10^{-4}, 10^{-3}, 5*10^{-3}, 10^{-2}, 5*10^{-2}\}$, gradclip $\in \{\text{None}, 1, 5, 10, 100\}$, bs $\in \{32, 64, 128\}$.

Additionally, we also tested for VQAv2 policy networks with 64, 256 and 1024 units, with respectively 32, 128 and 512 word embedding dimensions. We kept the network size giving the best performances, i.e. policy network of 256 units and 128 word embedding dimension.

A.5 Reward formula for VQAv2

In this section, we detail the reward function used for the VQAv2 task. $r(w_t, w_{<t}, c) = \mathbb{1}_{\text{rk}(\mathcal{A}) \leq 10, t=T-1} e^{-\text{rk}(\mathcal{A})/2}$, with $\text{rk}(\mathcal{A})$ the rank of the ground-truth answer given by the VQA model, when predicting the actual answer from the terminal state $(c, w_{<T})$. Formally, it is defined as:

$$\text{rk}(\mathcal{A}) = \text{rank}(\text{VQA}(c, w_{<T})[\mathcal{A}]),$$

with $\text{VQA}(c, w_{<T})$ the probability distribution given by the VQA model over the set of answers, and rank the function which ranks the probability of answer $\mathcal{A}$ within $\text{VQA}(c, w_{<T})$ probability distribution.

B Additional experiments

B.1 CLEVR

Table 6 displays the complete ablation on the truncation functions with parameters sweep. The 'sizeVA' variable indicates the average size of the truncated action space for each truncation function. Table 7 displays the

---

[5] https://www.nltk.org/

[6] `https://github.com/Maluuba/nlg-eval`

ablation over the three decoding procedures defined in Section 4.5. Such an ablation presents a similar pattern than VQAv2 results described in section 5.2.

Finally, Table 8 reports CLEVR metrics when using the BLEU score as the reward. While on such a task TrufLL still exhibits promising language scores, the n-grams metrics remain lower than the pretrained baselines. This illustrates that using a language similarity score as a reward signal is much less interesting than a reward based on a task completion score.

Table 6: **CLEVR task:** Ablation on the truncation functions with parameters sweep. Best values are in bold.

trunc.	Score	BLEU	CIDEr	ppl-e(↓)	sBLEU(↓)	Size VA

B.2 VQAv2

Temperature scheduling: On the CLEVR task, we observed that dynamic truncations outperform static ones such as top(k): indeed, they better take into account the inherent variability of the language structure at the sentence-level. When scaling up to the 15k words of the VQAv2 task, we also dynamically decrease the truncation size through training, by applying a decreasing temperature schedule on the language model. While temperature scaling (Bahdanau et al., 2015) is usually used at test time to control the smoothness of the language model distribution, temperature schedules during training of language models have been used in several settings (Jang et al., 2016; Zhang et al., 2018; Wang et al., 2020). Formally, $f_{LM}(w_i|w_{<t})$ distribution is computed as $\text{softmax}(x_i) = e^{-x_i/\tau}/\sum_j e^{-x_j/\tau}$, with x_j the LM logits and τ the temperature, which decreases from τ_{max} to τ_{min} by a factor T_F every T_u training step. In Table 9, both TrufLL (Task-LM) and TrufLL

Table 8: **CLEVR, BLEU reward**. Scores are averaged over the three decoding procedures detailed in Section 4.5 and over 5 seeds, standard deviation are displayed whenever greater than 0.01 for accuracy metrics. We here report the models with the highest task-success, i.e. the *scratch with KL regularization* baseline with $\lambda_{KL}=0.1$, and the truncation model with a probability threshold, $\mathrm{p_{th}}(\alpha=0.05)$. Baseline and Metrics are respectively detailed in Section 4.4 and 4.3. Best overall values are underlined, while best values for models without task-data (i.e RL from scratch algorithms) are in bold.

Method	Score	R@5	BLEU	Meteor	CIDEr	ppl-t (↓)	ppl-e (↓)	sBLEU (↓)	peak.(↓)
pretrain	0.30	0.71	0.19	0.38	0.83	3.1	31	0.44	0.96
pretrain + RL fine-tune	0.34	0.80	0.20	0.38	0.83	3.8	12	0.56	0.96
scratch	0.03	0.19	0.06	0.09	0.09	10^8	10^6	**0.13**	**0.14**
scratch + KL-task	0.09	0.33(±0.15)	0.15	0.31	0.58(±0.23)	3.8	63	0.34	0.95
scratch + KL-ext	0.06	0.30(±0.23)	0.13	0.25	0.42	10^3	3.6	0.37	0.96
scratch + Truncation-task	**0.17**	**0.51**	**0.18**	**0.37**	**0.80**	**2.6**	17	0.63	1.0
scratch + Truncation-ext	0.07	0.36	0.16	0.29	0.49	10^2	**2.3**	0.60	1.0

(Ext-LM) benefit slightly from truncation with a temperature schedule compared to a vanilla truncation. The former displays the best performance/language scores trade-off for the schedule "τ: 3 > 1. & T_u=5,000", while the latter has the best metrics trade-off for "τ: 1.5 > 1. & T_u=5,000".

Finally, Figure 4 displays the evolution of the training return for TrufLL and the baselines. As expected, the pretrain+RL fine-tune baseline return does not evolve much, confirming that the policy distribution almost does not shift through the fine-tuning phase. The training curves of TrufLL present a steady increase in the return until reaching convergence, confirming that our approach, by guiding the exploration of the action space, provides a sufficient learning signal. On the other hand, the scratch+KL baselines stay stuck to a low training return. This suggests that the KL regularization term, while encouraging the policy distribution to resemble the language model distribution, fails to capture the task pragmatics, which requires generating a language that is visually grounded.

Table 9: **VQA task:** Ablation on the temperature schedules. "no temp. sch" is a classic truncation without temperature scheduling. We then report different schedules $\tau: \tau_{max} > \tau_{min}$, T_u, with τ_{max}, τ_{min}, T_u, and $T_f=0.75$ as defined in section B.2. Best values are in bold.

Scheduling		Score	BLEU	CIDEr	ppl-e(↓)	sBLEU(↓)

B.3 Additional discussion

TrufLL with a pre-training phase. Although TrufLL aims at providing a robust method to learn a language model (almost) from scratch, we investigate whether such algorithm can be complementary to RL algorithms with a pre-training phase. Therefore, when using the task-related dataset, we evaluate TrufLL from a pretrained policy, and we refer to it as $\mathrm{TrufLL_{pretrain}}$.

In table 10, while on CLEVR, $\mathrm{TrufLL_{pretrain}}$ marginally improves the results of the pretrain+RL fine-tune baseline, the combination of TrufLL with a pre-training phase leads to performance degradation on VQAv2. This suggests that on a large vocabulary task, the language distribution learned by the SL pretrained policy is significantly different from the one learned with TrufLL.

On-policy TrufLL versus off-policy TrufLL. To ease off-policy learning, we propose to add a KL-regularization term in the RL loss (Jaques et al., 2017, 2019; Wu et al., 2019), and refer to it as $\mathrm{TrufLL_{off,KL}}$. Intuitively, it encourages the policy to stay close to the language model's distribution, with a distribution support attributing negligible probabilities to words outside the truncated action space.

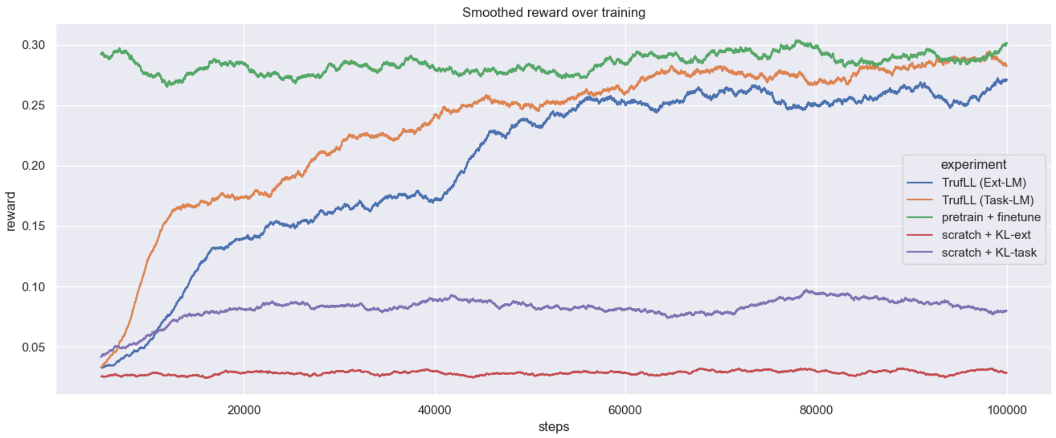

Figure 4: **VQAv2:** Training curves. Reward is a rolling average over 5000 timesteps.

Table 10: $\text{TrufLL}_{\text{pretrain}}$ results on the 2 tasks. Additionally, we report the results for the pretrain+RL fine-tune baseline as a comparison. Best values are in bold.

Algo	Score	BLEU	CIDEr	ppl-e	sBLEU
CLEVR					
pretrain+RL	0.44	0.17	0.70	35	**0.46**
$\text{TrufLL}_{\text{pretrain}}$	**0.61**	**0.18**	**0.77**	**22**	0.84
VQAv2					
pretrain+RL	**0.41**	**0.31**	**0.98**	50	**0.78**
$\text{TrufLL}_{\text{pretrain}}$	0.33	0.27	0.42	**35**	1.0

Table 11 displays the full results of on-policy versus off-policy scores for TrufLL (Task-LM) and TrufLL (Ext-LM) on the two tasks. The full results emphasize the challenges of the approach for the large vocabulary of VQAv2. Indeed, on the off-policy setting for such a task, the exploding values for e-ppl suggest that the optimized language agent samples incoherent words taken outside the truncated action space, as corroborated by the low values of the sumVA ratio.

Interestingly, while on CLEVR, $\text{TrufLL}_{\text{off,KL}}$ trades off task performance for language quality when compared to $\text{TrufLL}_{\text{off}}$, on VQAv2, it mainly provides a better learning signal for the complete (large) vocabulary. In such a setting, it hence improves the global scores of the off-policy version of TrufLL, and enables a much better generalization at test time of the global policy over the full vocabulary. Yet, keeping truncation at test time remains crucial with large vocabulary. Note that for VQAv2, the poor performances of $\text{TrufLL}_{\text{off,KL}}$ on the external LM is mainly due to numerical instability challenges when using GPT-2 as the target policy of the KL regularization term.

Additionally, on-policy versus off-policy scores split per sampling procedure are displayed in table 12: unsurprisingly, greedy decoding for $\text{TrufLL}_{\text{off}}$ outperforms the two sampling-based methods, that are more penalized by the imperfect generalization of the optimized policy over the full vocabulary.

Table 11: On-policy vs. off-policy scores for different variants of TrufLL: when training with an off-policy loss, we remove the truncation at test time. $\text{TrufLL}_{\text{off,KL}}$ is evaluated with $\lambda_{KL} = 0.05$. Best values are in bold.

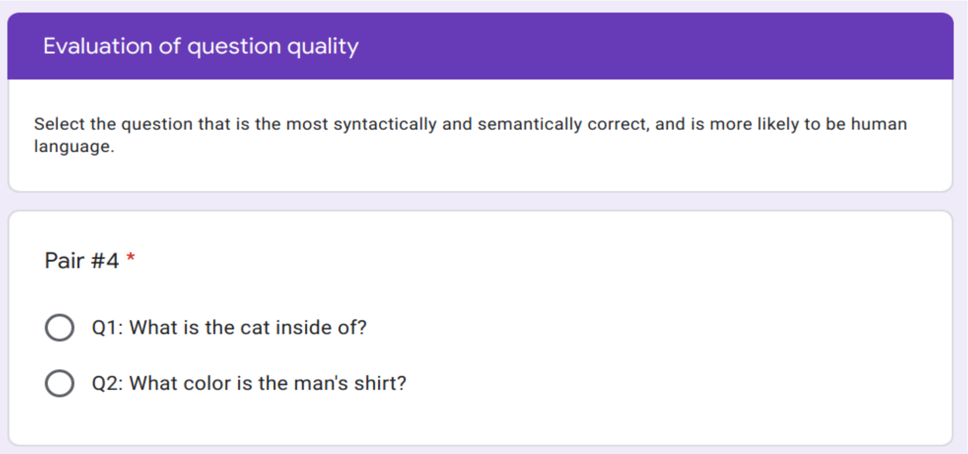
C Human Evaluation details

For the Human Evaluation study, we designed one form per participant, with three sections evaluating respectively the language quality, language grounding and diversity criteria. Given the five evaluated models, there are ten different model pairs: each section of the form contains 10 pairwise comparison covering all the possible model pairs for the criteria. Each pairwise comparison is sampled uniformly over the 50 first question samples generated by the algorithms at test time. The evaluation of syntax errors was made within the diversity section: for each questions pair, we asked participants to tick the questions if they are grammatically incorrect. Figure 5 displays one pairwise comparison example for the three sections, and a full form example is available at the following url: `https://forms.gle/kkL38x31wF7A9YKx5`.



Evaluation of question quality

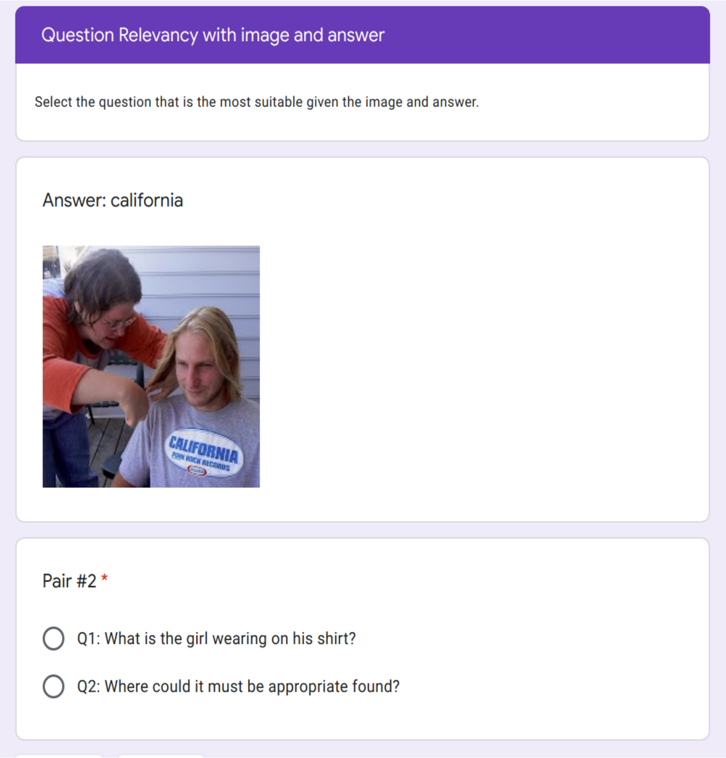
Select the question that is the most syntactically and semantically correct, and is more likely to be human language.

Pair #4 *

○ Q1: What is the cat inside of?

○ Q2: What color is the man's shirt?

(a) Language Quality pairwise comparison



Question Relevancy with image and answer

Select the question that is the most suitable given the image and answer.

Answer: california

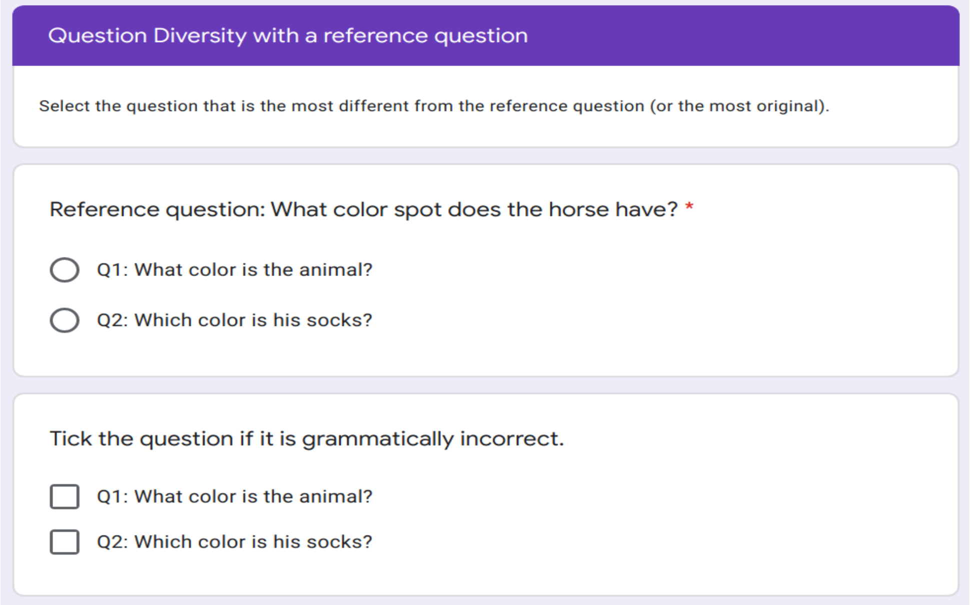
Pair #2 *

○ Q1: What is the girl wearing on his shirt?

○ Q2: Where could it must be appropriate found?

(b) Language Grounding pairwise comparison

Figure 5: Examples of pairwise comparison for each evaluated criteria.



Question Diversity with a reference question

Select the question that is the most different from the reference question (or the most original).

Reference question: What color spot does the horse have? *

○ Q1: What color is the animal?

○ Q2: Which color is his socks?

Tick the question if it is grammatically incorrect.

☐ Q1: What color is the animal?

☐ Q2: Which color is his socks?

(c) Diversity/Originality with reference question. Pairwise comparison and evaluation of syntax errors.

Figure 5: Examples of pairwise comparison for each evaluated criteria. (cont.)

D Additional VQG Samples

Figure 6 and Figure 7 display the 10 first dialog samples produced at test time on CLEVR, while figures 8, 9, and 10 display the 15 first dialog samples produced at test time on VQAv2.

Abstract

The state-of-the-art adaptive policies for simultaneous neural machine translation (SNMT) use monotonic attention to perform *read/write* decisions based on the partial source and target sequences. The lack of sufficient information might cause the monotonic attention to take poor *read/write* decisions, which in turn negatively affects the performance of the SNMT model. On the other hand, human translators make better *read/write* decisions since they can anticipate the immediate future words using linguistic information and domain knowledge. In this work, we propose a framework to aid monotonic attention with an external language model to improve its decisions. Experiments on MuST-C English-German and English-French speech-to-text translation tasks show the future information from language model improves the state-of-the-art monotonic multi-head attention model further.

1 Introduction

A typical application of simultaneous neural machine translation (SNMT) is conversational speech or live video caption translation. In order to achieve live translation, an SNMT model alternates between performing *read* from source sequence and *write* to target sequence. For a model to decide whether to *read* or *write* at certain moment, either a fixed or an adaptive *read/write* policy can be used.

Earlier approaches in simultaneous translation such as Ma et al. (2019a) and Dalvi et al. (2018) employ a fixed policy that alternate between *read* and *write* after the waiting period of k tokens. To alleviate possible long delay of fixed polices, recent works such as monotonic infinite lookback attention (MILk) (Arivazhagan et al., 2019), and monotonic multihead attention (MMA) (Ma et al., 2019c) developed flexible policies using monotonic attention (Raffel et al., 2017).

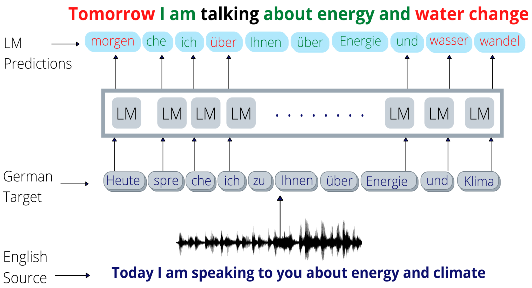

Figure 1: The finetuned XLM-RoBERTa language model predicts German words using the prefix as input.(Green: Correct, Red: Incorrect, Black: Neutral).

While these monotonic attention anticipates target words using only available prefix source and target sequence, human translators anticipate the target words using their language expertise (linguistic anticipation) as well as contextual information (extra-linguistic anticipation) (Vandepitte, 2001). Inspired by human translation experts, we aim to augment monotonic attention with future information using language models (LM) (Devlin et al., 2019; Conneau et al., 2019).

Integrating the external information effectively into text-to-text machine translation (MT) systems has been explored by several works (Khandelwal et al., 2020; Gulcehre et al., 2015, 2017; Stahlberg et al., 2018). Also, integrating future information implicitly into SNMT system during training is explored in Wu et al. (2020) by simultaneously training different wait-k SNMT systems. However, no previous works make use of explicit future information both during training and inference. To utilize explicit future information, we explored to integrate future information from LM directly into the output layer of the MMA model. However, it did not provide any improvements (refer to Appendix A), thus motivating us to explore a tighter integration of the LM information into SNMT model.

In this work, we explicitly use plausible future

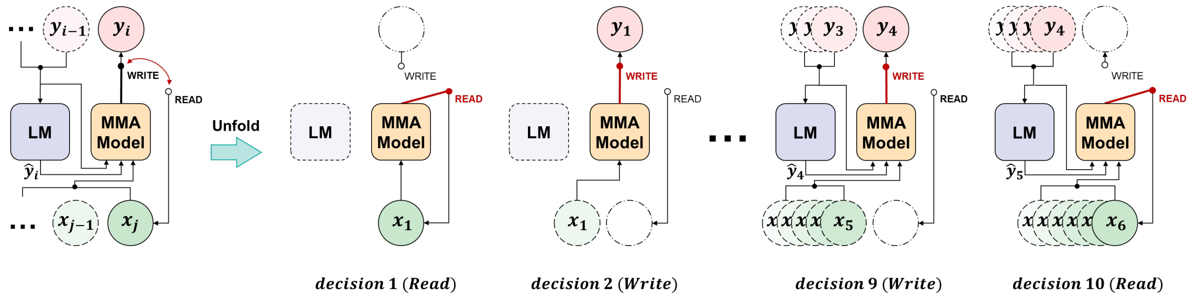

Figure 2: Overview of the proposed language model augmented monotonic attention for SNMT.

information from LM during training by transforming the monotonic attention mechanism. As shown in Figure 1, at each step, the LM takes the prefix target (and source, for cross-lingual LM) sequence and predicts the probable future information. We hypothesize that aiding the monotonic attention with this future information can improve MMA model's *read/write* policy, eventually leading to better translation with less delay. Several experiments on MuST-C (Di Gangi et al., 2019) English-German and English-French speech-to-text translation tasks with our proposed approach show clear improvements of latency-quality trade-offs over the state-of-the-art MMA models.

2 Monotonic Attention with Future Information Model

2.1 Monotonic Attention

In simultaneous machine translation (SNMT) models, the probability of predicting the target token $y_i \in \mathbf{y}$ depends on the partial source and target sequences ($x_{\leq j} \in \mathbf{x}, y_{<i} \in \mathbf{y}$). In sequence-to-sequence based SNMT model, each target token y_i is generated as follows:

$$h_j = \mathcal{E}(x_{\leq j}) \tag{1}$$

$$s_i = \mathcal{D}(y_{<i}, c_i = \mathcal{A}(s_{i-1}, h_{\leq j})) \tag{2}$$

$$y_i = Output(s_i) \tag{3}$$

where $\mathcal{E}(.)$ and $\mathcal{D}(.)$ are the encoder and decoder layers, and c_i is a context vector. In monotonic attention based SNMT, the context vector is computed as follows:

$$e_{i,j} = MonotonicEnergy(s_{i-1}, h_j) \tag{4}$$

$$p_{i,j} = Sigmoid(e_{i,j}) \tag{5}$$

$$z_{i,j} \sim Bernoulli(p_{i,j}) \tag{6}$$

When generating a target token y_i, the decoder chooses whether to *read/write* based on Bernoulli selection probability $p_{i,j}$. When $z_{i,j} = 1$ (*write*), model sets $t_i = j$, $c_i = h_j$ and generates the target token y_i. For $z_{i,j} = 0$ (*read*), it sets $t_i = j + 1$ and repeats Eq. 4 to 6. Here t_i refers to the index of the encoder when decoder needs to produce the i^{th} target token. Instead of hard alignment of $c_i = h_j$, Raffel et al. (2017) compute an expected alignment in a recurrent manner and propose a closed-form parallel solution. Arivazhagan et al. (2019) adopt monotonic attention into SNMT and later, Ma et al. (2019c) extend it to MMA to integrate it into the Transformer model (Vaswani et al., 2017).

2.2 Monotonic Attention with Future Information

The monotonic attention described in Section 2.1 performs anticipation based only on the currently available source and target information. To augment this anticipation process using future information extracted using LMs, we propose the following modifications to the monotonic attention.

Future Representation Layer: At every decoding step i, the previous target token y_{i-1} is equipped with a plausible future token $\hat{y}_i$ as shown in the Figure 2. Since the token $\hat{y}_i$ comes from an LM possibly with a different tokenizer and vocabulary set, applying the model's tokenizer and vocabulary might split the token $\hat{y}_i$ further into multiple sub-tokens $\{\hat{y}_i^1, \hat{y}_i^2, \cdots, \hat{y}_i^m\}$. To get a single future token representation $\tilde{\mathbf{s}}_i \in \mathcal{R}^d$ from all the sub-tokens, we apply a sub-token summary layer:

$$\tilde{\mathbf{s}}_i = \Gamma(\{\hat{y}_i^1, \hat{y}_i^2, \cdots, \hat{y}_i^m\}) \tag{7}$$

The Γ represents a general sequence representation layer such as a Transformer encoder layer or a simple normalized sum of sub-token representations.

We enrich $\tilde{\mathbf{s}}_i$ at every layer l of the decoder block by applying a residual feed-forward network.

$$\tilde{\mathbf{s}}_i^l = FFN(\tilde{\mathbf{y}}_i^{l-1}) \tag{8}$$

Monotonic Energy Layer with Future Information: Despite the fact that we can add the plausible future information to the output layer (Appendix A) or append it to the target token representation y_{i-1}, the MMA *read/write* decisions happen in Eq. 4. Therefore, we integrate $\tilde{\mathbf{s}}_i$ into the Eq. 4 instead.

The integration is carried out by modifying Eq. 4 - Eq. 5. We compute the monotonic energy for future information using the enriched future token representation $\tilde{\mathbf{s}}_i$ available at each layer:

$$\tilde{e}_{i,j} = MonotonicEnergy(\tilde{\mathbf{s}}_i, h_j) \tag{9}$$

We integrate the future monotonic energy function into Eq. 5 as follows:

$$\tilde{p}_{i,j} = Sigmoid(e_{i,j} + \tilde{e}_{i,j}) \tag{10}$$

After computing $\tilde{p}_{i,j}$, we compute c_i similar to MMA model.

This way of integration of future information allows the model to condition the LM output usage on the input sequence. The model can control the relative weightage given to the LM output by varying the $\tilde{e}_{i,j}$. In case of insufficient source information in the low latency regime, we expect the model's decision policy to rely more on $\tilde{e}_{i,j}$.

Inference: During inference, the *start* token does not contain any plausible information. After predicting the first target token, for every subsequent prediction of target token y_i, we invoke the LM to predict the next plausible future token and integrate this new information into Eq. 10.

3 Experiments and Results

3.1 Experimental Settings

Datasets and Metrics: We conduct our experiments on the MuST-C English(En)-German(De) and English(En)-French(Fr) speech-to-text (ST) translation task. The speech sequence is represented using 80-dimensional log-mel filter bank features. The target sequence is represented as subwords using a SentencePiece (Kudo and Richardson, 2018) model with a unigram vocabulary of size 10,000. We evaluate the performance of the models on both the latency and quality aspects. We use Average Lagging(AL) as our latency metric and case-sensitive detokenized SacreBLEU (Post, 2018) to measure the translation quality, similar to (Ma et al., 2020). The best models are chosen based on the dev set results and reported results are from the MuST-C test (tst-COMMON) sets.

Language Models We use two language models to train our proposed modified MMA model. Firstly, we use the pretrained XLM-RoBERTa (Conneau et al., 2019) model from Huggingface Transformers[1] model repository. Since the LM output can be very open-ended and might not directly suit/cater to our task and dataset, we finetune the head of the model using the MuST-C target text data for each task.

We also train a smaller language model (SLM), which contains 6 Transformer decoder layers, 512 hidden-states and 24M parameters. We use the MuST-C data along with additional data augmentation to reduce overfitting. The SLM helps to remove the issues related to vocabulary mismatch as discussed in the Section 2.2.

Implementation Details: Our base model is adopted from Ma et al. (2020). We use a pre-decision ratio of 7 , which means that the simultaneous *read/write* decisions are made after every seven encoder states. We use λ or $\lambda_{latency}$ to refer to the hyperparameter corresponding to the weighted average(λ_{avg}) in MMA. The values of this hyperparameter λ are chosen from the set $\{0.01, 0.05, 0.1\}$. The Γ layer in Eq. 7 computes the normalized sum of the sub-token representations. For SLM, it simply finds the embedding since it shares the same vocabulary set. All the models are trained on a NVIDIA v100 GPU with $update\_freq$ set to 8.

Simultaneous Translation Models: Even though future information can be integrated explicitly into the fixed policy approaches such as Wait-K (Ma et al., 2019b), we choose monotonic attention as our baseline due to its superior performance (Arivazhagan et al., 2019; Ma et al., 2019c). We train a baseline based on Ma et al. (2020) work, called as MMA model. The MMA model encoder and decoder embedding dimensions are set to 392, whereas our proposed model's encoder and decoder embeddings are set to 256 to have similar parameters ($\approx 39M$) for a fair comparison. We train two models using the

---

[1] https://huggingface.co/transformers/

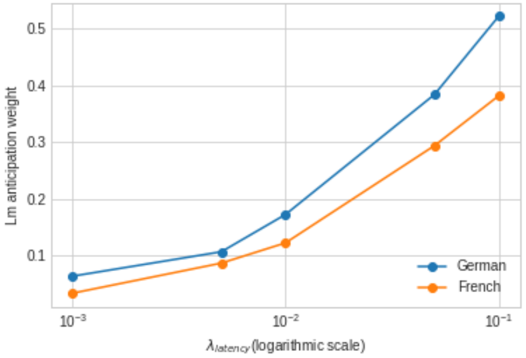

Figure 3: LM prediction weight vs λ

modified MMA based on two LMs (XLM, SLM), referred as MMA-XLM and MMA-SLM.

3.2 Results

We first analyze how the LM predictions are being utilized by the our model. In order to measure the relative weight given to model's internal states versus the predictions from the LM, we compare the norm of the monotonic energies corresponding to the LM predictions e_{pred} (Eq. 9) and the previous output tokens e_{output} (Eq. 4). Let us define LM prediction weight as follows:

$$LM_{pw} = \left(\frac{\|e_{pred}\|}{\|e_{output}\|} \right) \tag{11}$$

In Figure 3, we plot the variation of LM_{pw} (averaged) vs. λ. We use two additional values of $\lambda \in \{0.005, 0.001\}$ to obtain this plot. We can observe that as the latency requirements become more and more strict, the model starts to give more weightage to the predictions coming from the LM. This shows that the model learns to utilize the information coming from LM predictions based on latency requirements.

Next, we discuss the performance improvements obtained from our proposed approach. By varying the λ, we train separate models for different latency regimes. Moreover, the quality and latency for a particular model can also be varied by controlling the speech segment size during the inference. Speech segment size or step size refers to the duration of speech (in ms) processed corresponding to each *read* decision. We vary these hyperparameters for all the three models, namely MMA, MMA-XLM and MMA-SLM.

The BLEU-AL curves for all the models have been provided in Figure 4 and BLEU-AL numbers for all models are included in Appendix F for reference. We vary the step sizes in intervals of 80ms from 120 ms to 520 ms in order to get performances corresponding to different latency regimes. We can observe that the LM-based models using both XLM and SLM provide a significant performance improvement over the baseline MMA model. We observe improvements in the range of 1-2 BLEU scores consistently across all the latency regimes ($\lambda = 0.1, 0.05, 0.01$). The MMA using SLM language model performs slightly better than MMA using XLM language model. This is due to SLM's higher accuracy on the next token prediction task as compared to XLM, 30.15% vs. 21.5% for German & 31.65% vs. 18.45% for French. The high accuracy of SLM is attributed to its training on in-domain data.

4 Conclusion

In this work, we provide a generic framework to integrate the linguistic and extra-linguistic information into simultaneous models. We rely on language models to extract this plausible future information and propose a new monotonic attention mechanism to infuse this information. Several experiments on speech-to-text translation tasks show the effectiveness of proposed approach on obtaining superior quality-latency trade-offs, compared to the state-of-the-art monotonic multihead attention.

A LM at MMA Output Layer

We explored a naive approach of integrating LM information into the MMA. In this approach, we integrate the future information obtained from the LM directly into the output layer of the MMA model. We refer to this experiment as 'LM Rescoring(LMR)', and the corresponding model is called MMA-LMR.

As observed in Figure 5, MMA-LMR has inferior performance compared to the MMA model. Since the LM information integration is only done at the output layer of the model, the MMA model cannot easily discard the incorrect information from LM. This motivates us to tightly integrate the LM information into the simultaneous model.

B Language Models

As mentioned earlier, we train two different language models (LMs) and use them to improve the anticipation in monotonic attention based Simultaneous models.

B.1 XLM-Roberta(XLM-R)

XLM-R Large model [2] was trained on the 100 languages CommonCrawl corpora total size of 2.5TB with 550M parameters from 24 layers, 1024 hidden states, 4096 feed-forward hidden-states, and 16 heads. Total number of parameters is 558M. We finetune the head of the XLM-R LM model using the Masked Language Modeling objective which accounts for 0.23% of the total model parameters, i.e., 1.3M parameters.

B.2 Smaller Language Model

Since the LM predictions are computed serially during inference, the time taken to compute the LM token serves as a bottleneck to the latency requirements. To reduce the LM computation time, we train a smaller Language Model (SLM) from scratch using the Causal Language Modeling objective. SLM is composed of 6 Transformer decoder blocks, 512 hidden-states, 2048 feed-forward hidden-states & 8 attention heads. It alleviates the need for the sub-token summary layer since it shares the vocabulary and tokenization with the MMA models. The train examples are at the sentence level, rather than forming a block out of multiple sentences(which is the usual case for Language Models).

Since the target texts contain lesser than 250k examples, we use additional data augmentation techniques to upsample the target data. We also use additional data to avoid overfitting on the MuST-C target text. Details have been provided in B.2.1.

B.2.1 Data Augmentation

Up-Sampling: To boost the LM performance and mitigate overfitting, we use contextual data augmentation (Kobayashi, 2018) to upsample the MuST-C target text data by substituting and inserting words based on LM predictions. We use the NLPAUG [3] package to get similar words based on contextual embeddings. From the Hugging Face Repository, we use two different pretrained BERT (Devlin et al., 2019) models for German *bert-base-german-dbmdz-cased* & *bert-base-german-dbmdz-uncased* and *bert-base-fr-cased* for French. We upsample German to 1.13M examples and French to 1.38M examples.

Additional Data: We also use additional data to avoid overfitting. For German we use the Newscrawl(WMT 19) data which includes 58M examples. For French, we use Common Crawl and Europarl to augment 4M extra training examples.

We observe that both upsampling and data augmentation help us to reduce the overfitting on the MuST-C dev set.

B.3 Token Prediction

For each output token, the LM prediction is obtained by feeding the prefix upto that token to the LM model. These predictions are pre-computed for training and validation sets. This ensures parallelization and avoids the overhead to run the LM simultaneously during the training process. During

inference, the LM model is called every time a new output token is written.

C Dataset

The MuST-C dataset comprises of English TED talks, the translations and transcriptions have been aligned with the speech at sentence level. Dataset statistics have been provided in the Table 1.

D Effect of LM Size on Latency-Quality

We train several SLM models with varying sizes in our experiments and choose the best model based on the top-1 accuracy. As we increase the number of layers in the LM model from 2 to 4 to 6 layers, the SLM and the proposed MMA with future information models have shown performance improvements. However, increasing the number of layers greater than 6 does not yield any performance improvements. We also notice this degradation of performance with the XLM model while varying the number of hidden layers in the LM head.

E Training Details

We follow the training process similar to Ma et al. (2020) training process. We train an English ASR model using the source speech data. Next, we train a simultaneous model without the latency loss (setting $\lambda_{latency} = 0$) after initializing the encoder from the English ASR model. After this step, we finetune the simultaneous model for different λs. This training process is repeated for all the reported models and for each task. The details regarding the hyperparameters for the model have been provided in Table 2.

F BLEU-AL Numbers

As mentioned in the results section of the main paper, we vary the latency weight hyperparameter (λ) to train different models to obtain different latency regimes. We also vary the step-size/speech segment size during inference. In total, we obtain 18 different data points corresponding to each model. In Table 3, we compare the results obtained using MMA, MMA-XLM and MMA-SLM under similar hyperparameter settings. It will help the reader to quantify the benefits obtained from our proposed approach.

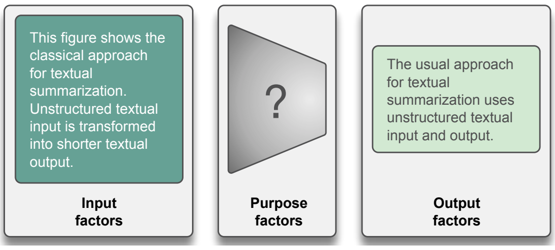
Abstract

Automatic text summarization has enjoyed great progress over the years and is used in numerous applications, impacting the lives of many. Despite this development, there is little research that meaningfully investigates how the current research focus in automatic summarization aligns with users' needs. To bridge this gap, we propose a survey methodology that can be used to investigate the needs of users of automatically generated summaries. Importantly, these needs are dependent on the target group. Hence, we design our survey in such a way that it can be easily adjusted to investigate different user groups. In this work we focus on university students, who make extensive use of summaries during their studies. We find that the current research directions of the automatic summarization community do not fully align with students' needs. Motivated by our findings, we present ways to mitigate this mismatch in future research on automatic summarization: we propose research directions that impact the design, the development and the evaluation of automatically generated summaries.

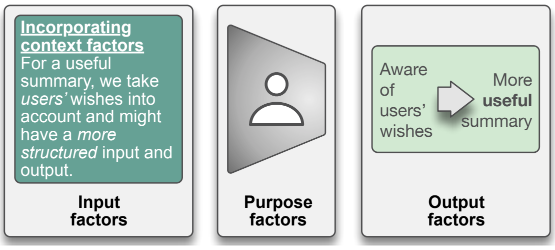
1 Introduction

The field of automatic text summarization has experienced great progress over the last years, especially since the rise of neural sequence to sequence models (e.g., Cheng and Lapata, 2016; See et al., 2017; Vaswani et al., 2017). The introduction of self-supervised transformer language models like BERT (Devlin et al., 2019) has given the field an additional boost (e.g., Liu et al., 2018; Liu and Lapata, 2019; Lewis et al., 2020; Xu et al., 2020).

The—often *implicit*—goal of automatic text summarization is to generate a condensed textual version of the input document(s), whilst preserving the main message. This is reflected in today's most common evaluation metrics for the task; they focus on aspects such as informativeness, fluency, succinctness and factuality (e.g., Lin, 2004; Nenkova and Passonneau, 2004; Paulus et al., 2018; Narayan et al., 2018b; Goodrich et al., 2019; Wang et al., 2020; Xie et al., 2021). The *needs* of the users of the summaries are often not explicitly addressed, despite their importance in *explicit* definitions of the goal of automatic summarization (Spärck Jones, 1998; Mani, 2001a). Mani defines this goal as: "*to take an information source, extract content from it, and present the most important content to the user in a condensed form and in a manner sensitive to the user's or application's needs.*"



(a) Most current automatic text summarization techniques. Left: input document. Right: summary.



(b) Example of summarizing while taking users' wishes and desires into account. Left: input document. Right: summary.

Figure 1: Example of most current summarization techniques vs. summarization while incorporating the users in the process.

Different user groups have different needs. Investigating these needs explicitly is critical, given the impact of adequate information transfer (Bennett et al., 2012). We propose a survey methodology to investigate these needs. In designing the survey, we take stock of past work by Spärck Jones (1998) who argues that in order to generate useful summaries, one should take the context of a summary

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 46 - 75
July 10-15, 2022 ©2022 Association for Computational Linguistics

into account—a statement that has been echoed by others (e.g., Mani, 2001a; Aries et al., 2019). To do this in a structured manner, Spärck Jones introduces three *context factor* classes: *input factors*, *purpose factors* and *output factors*, which respectively describe the input material, the purpose of the summary, and what the summary should look like. We structure our survey and its implications around these factors. In Figure 1 we give an example of incorporating the context factors in the design of automatic summarization methods.

Our proposed survey can be flexibly adjusted to different user groups. Here we turn our focus to university students as a first stakeholder group. University students are a particularly relevant group to focus on first, as they benefit from using pre-made summaries in a range of study activities (Reder and Anderson, 1980), but the desired characteristics of these pre-made summaries have not been extensively investigated. We use the word *pre-made* to differentiate such summaries from the ones that users write themselves. Automatically generated summaries fall in the pre-made category, and should thus have the characteristics that users wish for pre-made summaries.

Motivated by our findings, we propose important future research directions that directly impact the design, development, and evaluation of automatically generated summaries. We contribute the following:

C1 We design a survey that can be easily adapted and reused to investigate and understand the needs of the wide variety of users of automatically generated summaries;

C2 We develop a thorough understanding of how automatic summarization can optimally benefit users in the educational domain, which leads us to unravel important and currently underexposed research directions for automatic summarization;

C3 We propose a new, feasible and comprehensive evaluation methodology to explicitly evaluate the usefulness of a generated summary for its intended purpose.

2 Related work

In Section 1 we introduced the context factors as proposed by Spärck Jones (1998). Each context factor class can be divided into more fine-grained subclasses. To ensure the flow of the paper, we list an overview in Appendix A. Below, we explain and use the context factors and their fine-grained subclasses to structure the related work. As our findings have implications for the evaluation of automatic summarization, we also discuss evaluation methods. Lastly, we discuss the use-cases of automatic summaries in the educational domain.

2.1 Automatic text summarization

Input factors. We start with the fine-grained input factor *unit*, which describes how many sources are to be summarized at once, and the factor *scale*, which describes the length of the input data. These factors are related to the difference between single and multi-document summarization (e.g., Chopra et al., 2016; Cheng and Lapata, 2016; Wang et al., 2016; Yasunaga et al., 2017; Nallapati et al., 2017; Narayan et al., 2018b; Liu and Lapata, 2019). *Scale* plays an important role when material shorter than a single document is summarized, such as sentence summarization (e.g., Rush et al., 2015). Regarding the *genre* of the input material, most current work focuses on the news domain or Wikipedia (e.g., Sandhaus, 2008; Hermann et al., 2015; Koupaee and Wang, 2018; Liu et al., 2018; Narayan et al., 2018a). A smaller body of work addresses different input genres, such as scientific articles (e.g., Cohan et al., 2018), forum data (e.g., Völske et al., 2017), opinions (e.g., Amplayo and Lapata, 2020) or dialogues (e.g., Liu et al., 2021). These differences are also closely related to the input factor *subject type*, which describes the difficulty level of the input material. The factor *medium* refers to the input language. Most automatic summarization work is concerned with English as language input, although there are exceptions, such as Chinese (e.g., Hu et al., 2015) or multilingual input (Ladhak et al., 2020). The last input factor is *structure*. Especially in recent neural approaches, explicit structure of the input text is often ignored. Exceptions include graph-based approaches, where implicit document structure is used to summarize a document (e.g., Tan et al., 2017; Yasunaga et al., 2017), and summarization of tabular data (e.g., Zhang et al., 2020a) or screenplays (e.g., Papalampidi et al., 2020).

Purpose factors. Although identified as the most important context factor class by Spärck Jones (1998)—and followed by, for example, Mani (2001a)—purpose factors do not receive a substantial amount of attention. There are some exceptions, e.g., query-based summarization (e.g., Nema et al., 2017; Litvak and Vanetik, 2017), question-driven summarization (e.g., Deng et al., 2020), personalized summarization (e.g., Móro and Bieliková, 2012) and interactive summarization (e.g., Hirsch et al., 2021). They take the *situation* and the *audience* into account. The *use*-cases of the generated summaries are also clearer in these approaches.

Output factors. We start with the output factors *style* and *material*. The latter is concerned with the degree of coverage of the summary. Most generated summaries have an *informative* style and cover most of the input material. There are exceptions, e.g., the XSum dataset (Narayan et al., 2018a) which constructs summaries of a single sentence and is therefore more *indicative* in terms of style and inevitably less of the input material is covered. Not many summaries have a *critical* or *aggregative* style. Aggregative summaries put different source texts in relation to each other, to give a topic overview. Most popular summarization techniques focus on a *running format*. Work on template-based (e.g., Cao et al., 2018) and faceted (e.g., Meng et al., 2021) summarization follows a more *headed* (structured) *format*. Falke and Gurevych (2017) build concept maps and Wu et al. (2020) make knowledge graphs. The difference between abstractive and extractive summarization is likely the best known distinction in output type (e.g., Nallapati et al., 2017; See et al., 2017; Narayan et al., 2018b; Gehrmann et al., 2018; Liu and Lapata, 2019), although it is not entirely clear which output factor best describes the difference.

In Section 5 we use the context factors to identify future research directions, based on the difference between our findings and the related work.

2.2 Evaluation

Evaluation methods for automatic summarization can be grouped in *intrinsic* vs. *extrinsic* methods (Mani, 2001b). Intrinsic methods evaluate the model itself, e.g., on informativeness or fluency (Paulus et al., 2018; Liu and Lapata, 2019). Extrinsic methods target how a summary performs when used for a task (Dorr et al., 2005; Wang et al., 2020). Extrinsic methods are resource intensive, explaining the popularity of intrinsic methods.

Evaluation methods can also be grouped in *automatic* vs. *human* evaluation methods. Different automatic metrics have been proposed, such as Rouge (Lin, 2004) and BERTScore (Zhang et al., 2020b) which respectively evaluate lexical and semantic similarity. Other methods use an automatic question-answering evaluation methodology (Wang et al., 2020; Durmus et al., 2020). Most human evaluation approaches evaluate intrinsic factors such as informativeness, readability and conciseness (DUC, 2003; Nallapati et al., 2017; Paulus et al., 2018; Liu and Lapata, 2019)—factors that are difficult to evaluate automatically. There are also some extrinsic human evaluation methods, where judges are asked to perform a certain task based on the summary (e.g., Narayan et al., 2018b). So far, *usefulness*[1] has not been evaluated in a feasible and comprehensive manner, whereas it is an important metric to evaluate whether summaries fulfil users' needs. Therefore, we bridge the gap by introducing a feasible and comprehensive evaluation methodology to evaluate usefulness.

2.3 Automatic summarization for education

Summaries play a prominent role in education. Reder and Anderson (1980) find that students who use a pre-made summary score better on a range of study activities than students who do not use such a summary. As the quality of automatically generated summaries increases (e.g., Lewis et al., 2020; Xu et al., 2020), so does the potential to use them in the educational domain, especially given the increasing importance of digital tools and devices for education (Luckin et al., 2012; Hashim, 2018). With these developments in mind, it is critical that educators are aware of the pedagogical implications; they need to understand how to best make use of all new possibilities (Hashim, 2018; Amhag et al., 2019). The outcomes of our survey result in concrete suggestions for developing methods for automatic summarization in the educational domain, whilst taking students' needs into account.

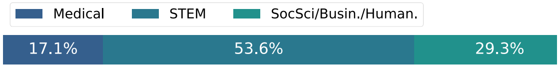
3 Survey Procedure and Participants

Here we detail our survey procedure. For concreteness, we present the details with our intended target group in mind. The context factors form the backbone of our survey and the setup can be easily adjusted to investigate the needs of different target groups. For example, we ask participants about a pre-made summary for a recent study activity, but it is straightforward to adapt this to a different use-case that is more suitable for other user groups.

---

[1] We follow the definition of the English Oxford Learner's Dictionary (`www.oxfordlearnersdictionaries.com/definition/english/`) for usefulness: *"the fact of being useful or possible to use"*, where *useful* is defined as *"that can help you to do or achieve what you want"*.

(a) Study levels.



(b) Study backgrounds.

Figure 2: Participant details.

3.1 Participants

We recruited participants among students at universities across the Netherlands by contacting ongoing courses and student associations, and by advertisements on internal student websites. As incentive, we offered a ten euro shopping voucher to ten randomly selected participants.

A total of 118 participants started the survey and 82 completed the full survey, resulting in a 69.5% completion rate. We only include participants who completed the study in our analysis. Participants spent 10 minutes on average on the survey. In the final part of our survey we ask participants to indicate their current level of education and main field of study. The details are given in Figure 2.

3.2 Survey procedure

Figure 3 shows a brief overview of our survey procedure. A detailed account is given in Appendix B. We arrived at the final survey version after a number of pilot runs where we ensured participants understood their task and all questions. We ran the survey with SurveyMonkey (`surveymonkey.com`). A verbatim copy is included in Appendix C and released under CC BY license.[2]

Introduction. The survey starts with an introduction where we explain what to expect, how we process the data and that participation is voluntary. After participants agree with this, an explanation of the term *pre-made summary* follows. As we do not want to bias participants by stating that the summary was automatically generated, we explain that the summary can be made by anyone, e.g., a teacher, a good performing fellow student, the authors of the original material, or a computer. Recall that an automatically generated summary is a pre-made summary. Hence, our survey identifies the characteristics an automatically generated summary should have. We also give examples of types of pre-made summaries; based on the pilot experiments we noticed that people missed this information. We explicitly state that these are just examples and that participants can come up with any example of a helpful pre-made summary.

Context factors. In the main part of our survey we focus on the context factors. First, we ask participants whether they have made use of a pre-made summary in one of their recent study activities. If so, we ask them to choose the study activity where a summary was most useful. We call this group the *Remembered group*, as they describe an existing summary from memory. If people indicate that they have not used a pre-made summary in one of their recent study activities, we ask them whether they can imagine a situation where a pre-made summary would have been helpful. If not, we ask them why not and lead them to the final background questions and closing page. If yes, we ask them to keep this imaginary situation in mind for the rest of the survey. We call this group the *Imagined group*.

Now we ask the Remembered and Imagined groups about the input, purpose and output factors of the summary they have in mind. We ask questions for each of the context factor subclasses that we discussed in Section 2. At this point, the two groups are in different branches of the survey. The difference is mainly linguistically motivated: in the Imagined group we use verbs of probability instead of asking to describe an existing situation. Some questions can only be asked in the Remembered group, e.g., how helpful the summary was.

In the first context factor question we ask what the study material consisted of. We give a number of options, as well as an 'other' checkbox. To avoid position bias, all answer options for multiple choice and multiple response questions in the survey are randomized, with the 'other' checkbox always as the last option. If participants do not choose the 'mainly text' option, we tell them that we focus on textual input in the current study[3] and ask whether they can think of a situation where the input did consist of text. If not, we lead them to the background questions and closing page. If yes, they proceed to the questions that give us a full overview of the input, purpose and output factors of the situation participants have in mind. Finally, we ask the Remembered group to suggest how their described summary could be turned into their ideal

---

[2] `https://github.com/maartjeth/survey_useful_summarization`

[3] Different modalities are also important to investigate, but we leave this for future work to ensure clarity of our results.

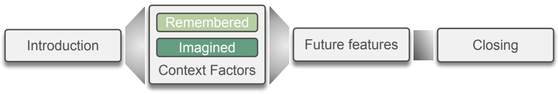


Figure 3: Overview of the survey procedure.

summary. We then ask both groups for any final remarks about the summary or input material.

Trustworthiness and future features questions. So far we have included the possibility that the summary was machine-generated, but also explicitly included other options so as not to bias participants. At this point we acknowledge that machine-generated summaries could give rise to additional challenges and opportunities. Hence, we include some exploratory questions to get an understanding of the trust users would have in machine-generated summaries and to get ideas for the interpretation of the context factors in exploratory settings.

For the first questions we tell participants to imagine that the summary was made by a computer, but contained all needs identified in the first part of the survey. We then ask them about trust in computer- and human-generated summaries. Next, we ask them to imagine that they could interact with the computer program that made the summary in the form of a digital assistant. We tell them not to feel restricted by the capabilities of today's digital assistants. The verbatim text is given in Appendix C. We ask participants to select the three most and the three least useful features for the digital assistant, similar to ter Hoeve et al. (2020).

4 Results

For each question we examine the outcomes of all respondents together and of different subgroups (Table 1). For space and clarity reasons, we present the results of all respondents together, unless interesting differences between groups are found. We use the question formulations as used for the Remembered group and abbreviate answer options. Answers to multiple choice and multiple response questions are presented in an aggregated manner and we ensure that none of the open answers can be used to identify individual participants.

4.1 Identifying branches

Of our participants, 78.0% were led to the Remembered branch and of the remaining 22.0%, 78.2% were led to the Imagined branch. We asked the few remaining participants why they could not think of a case where a pre-made summary could be useful for them. People answered that they would not trust such a summary and that making a summary themselves helped with their study activities.

1 All respondents together
2 Remembered branch vs Imagined branch
3 Different study fields
4 Different study levels
5 Different levels of how helpful the summary was according to participants, rated on a 5-point Likert scale (note that only the *remembered* group answered this question)

Table 1: Levels of investigation. We did not find significant differences for each, but add all for completeness.

4.2 Input factors

Figure 4 shows the input factor results. We highlight some here. Textual input is significantly more popular than other input types (Figure 4a),[4] stressing the relevance of automatic text summarization. People described a diverse input for *scale* and *unit* (Figure 4b), much more than the classical focus of automatic summarization suggests. Most input had a considerable amount of structure (Figure 4e). Structure is often discarded in automatic summarization, although it can be very informative.

4.3 Purpose factors

Figure 5 shows the purpose factor results. Participants indicated that the summary was *helpful* or *very helpful* (Figure 5f), which allows us to draw valid conclusions from the survey.[5] We now highlight some results from the other questions in this category. For the intended *audience* of the summaries, students selected level (4) and (5) (*"a lot (4) or full (5) domain knowledge is expected from the users of the summary"*) significantly more often than the other options (Figure 5d). Although perhaps unsurprising given our target group, it is an important outcome as this requires a different level of detail than, for example, a brief overview of a news article. People used the summaries for many different use-cases (Figure 5e), whereas current research on automatic summarization mainly focuses on giving an overview of the input. We show the results for the Remembered vs. Imagined splits,

---

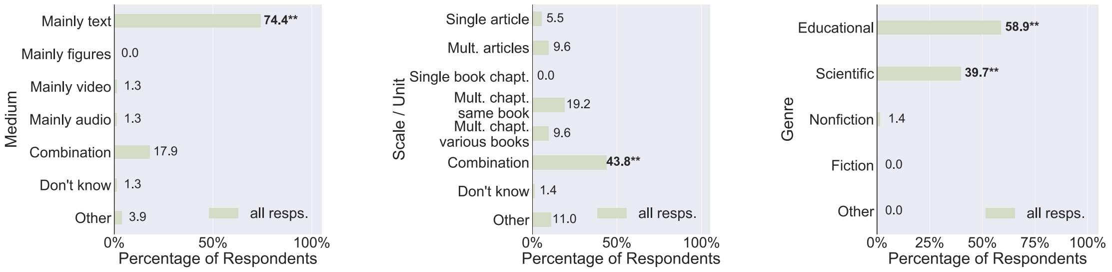
[4] This is based on people's initial responses and not on the follow up question if they selected another option than 'text'.

[5] Because we do not find significant differences in the overall results when we exclude the few participants who did not find their summary helpful and we do not find many correlations w.r.t. how helpful a summary was and a particular context factor, we include all participants in the analysis, regardless of how helpful they found their summary, for completeness.

(a) *Medium:* The study material consisted of (MC)

(b) *Scale / Unit:* What was the length of the study material? (MC)

(c) *Genre:* What was the genre of the study material? (MC)



(d) *Subject Type:* How would you classify the difficulty level of the study material? (MC)

(e) *Structure:* How was the study material structured? (MR)

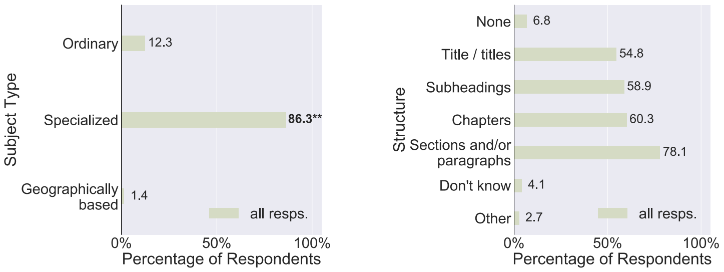


Figure 4: Results for the ***input factor*** questions. Specific input factor in italics. Answer type in brackets: MC = Multiple Choice, MR = Multiple Response. ** indicates significance (χ^2), after Bonferroni correction, with $p \ll 0.001$. If two options are flagged with **, these options are not significantly different from each other, yet both have been chosen significantly more often than the other options.

as the Imagined group chose *refresh memory* and *overview* more often than the Remembered group (Fisher's exact test, $p < 0.05$). Although not significant after a Bonferroni correction, this can still be insightful for future research directions. Lastly, participants in the Imagined group ticked more boxes than participants in the Remembered group: 3.33 vs. 2.57 per participant on average, stressing the importance of considering many different use-cases for automatically generated summaries.

4.4 Output factors

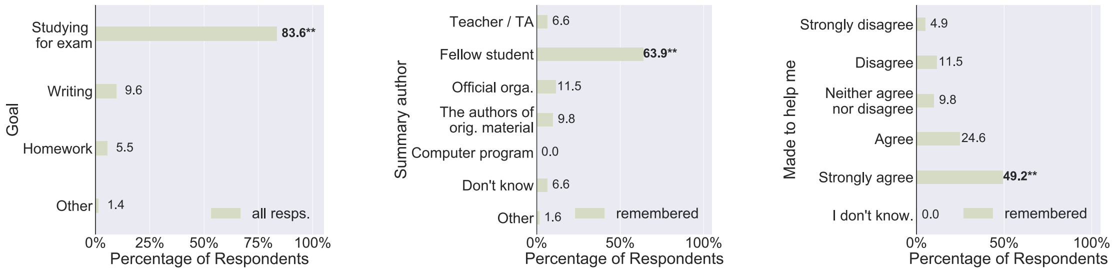
Figure 6 shows the results for the output factor questions. Textual summaries were significantly more popular than other summary types (Figure 6a), which again stresses the importance of automatic text summarization. Most participants indicated that the summary covered (or should cover) most of the input *material* (Figure 6c). For the output factor *style* we find an interesting difference between the Remembered and Imagined group (Figure 6d). Whereas the Remembered group described significantly more often an *informative* summary, the Imagined group opted significantly more often for a *critical* or *aggregative* summary. Most research on automatic summarization focusses on informative summaries only. For the output factor *structure* (Figure 6b), people described a substantially richer format of the pre-made summaries than adopted in most research on automatic summarization. Instead of simply a running text, the vast majority of people indicated that the summary contained (or should contain) structural elements such as special formatting, diagrams, headings, etc. Moreover, the Imagined group ticked more answer boxes on average than the Remembered group: 4.17 vs. 3.56 per participant, indicating a desire for structure in the generated summaries, which is supported by the open answer questions.

Open answer questions. We asked participants in the Remembered group how the summary could be transformed into their ideal summary and 86.9% of these participants made suggestions. Many of those include adding additional structural elements to the summary, like figures, tables or structure in the summary text itself. For example, one of the participants wrote: *"An ideal summary is good enough to fully replace the original (often longer) texts contained in articles that need to be read for exams. The main purpose behind this is speed of learning from my experience. More tables, graphs and visual representations of the study material and*

(a) *Situation (1):* What was the goal of this study activity? (MC)

(b) *Situation (2):* Who made this pre-made summary? (MC, Only if Remembered)

(c) *Situation (3):* The summary was made specifically to help me (and potentially my fellow students) with my study activity (LS, Only if Remembered)



(d) *Audience:* For what type of people was the summary intended? (LS)

(e) *Use (1):* How did this summary help you with your task? (MR)

(f) *Use (2):* Overall, how helpful was the pre-made summary for you? (LS, Only if Remembered)

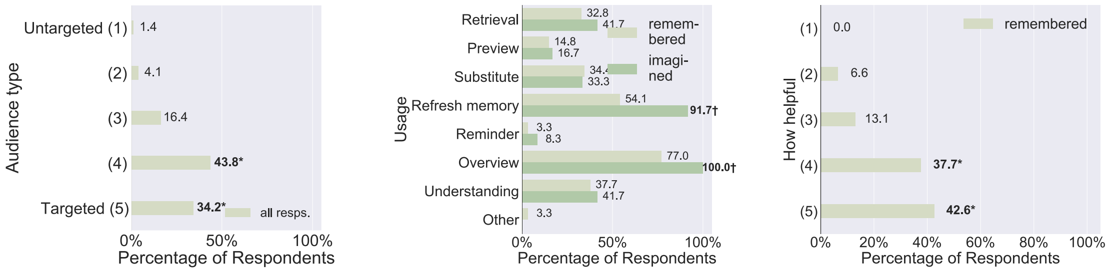


Figure 5: Results for the ***purpose factor*** questions. Specific purpose factor in italics. Answer type in brackets: MC = Multiple Choice, MR = Multiple Response, LS = Likert Scale. ** indicates significance (χ^2), after Bonferroni correction, with $p \ll 0.001$, * with $p < 0.05$. † indicates noteworthy results where significance was lost after correction for the number of tests. If two options are flagged, these options are not significantly different from each other, yet both were chosen significantly more often than the other options.

key concepts / links would improve the summary, as I would faster comprehend the study material." Another participant wrote: *"– colors and a key for color-coding – different sections, such as definitions on the left maybe and then the rest of the page reflects the structure of the course material with notes on the readings that have many headings and subheadings."*

Another theme is the desire to have more examples in the summary. One participant wrote: *"More examples i think. For me personally i need examples to understand the material. Now i needed to imagine them myself"*.

Some participants wrote that they would like a more personalized summary, for example: *"I'd highlight some things I find difficult. So I'd personalise the summary more."* Another participant wrote: *"Make it more personalized may be. These notes were by another student. I might have focussed more on some parts and less on others."*

4.5 Trustworthiness and future features

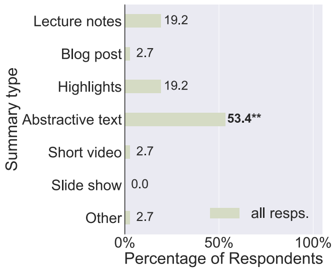
Of all participants, 48.0% indicated that it would not make a difference to them whether a summary is machine- or human-generated, as long as the quality is as good as a human-generated one. This last point is reflected in which types of summaries participants would trust more. People opted significantly more often for a human-generated one. For the future feature questions, *adding more details to the summary* and *answering questions based on the content of the summary* were very popular. We give a full account in Appendix D.

5 Implications and Perspectives

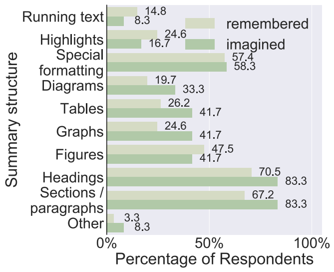
5.1 Future research directions

Our findings have important implications for the design and development of future automatic summarization methods. We present these in Table 2, per context factor. Summarizing, the research developments as summarized in Section 2 are encouraging, yet given that automatic summarization methods increasingly mediate people's lives, we argue that more attention should be devoted to its stakeholders, i.e., to the purpose factors. Here we have shown that students, an important stakeholder group, have different expectations of pre-made

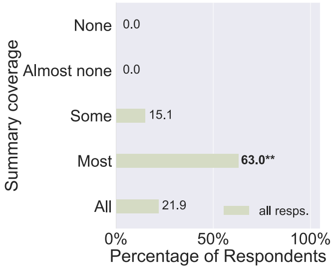
(a) *Format (1):* What was the type of the summary? (MC)



(b) *Format (2):* How was the summary structured? (MR)



(c) *Material:* How much of the study material was covered by the summary? (LS)



(d) *Style:* What was the style of this summary? (MC)

Input Factors
Stronger focus on developing methods that can: • handle a wide variety and a mixture of **different types** of input documents at once; • understand the **relationships** between different input documents; • use the **structure** of the input document(s).
Purpose Factors
• Explicitly define a **standpoint** on the purpose factors in each research project; • Include a comprehensive **evaluation** methodology to evaluate usefulness. We propose this in Section 5.2.
Output Factors
Stronger focus on developing methods that can: • output different summary **styles**, e.g., informative, aggregative or critical. Especially the last two require a **deeper understanding** of the input material than current models have; • explicitly model and understand **relationships** between different elements in the summary and potentially relate this back to the input document(s).

Table 2: Implications for future research directions.

summaries than what most automatic summarization methods offer. These differences include the type of input material that is to be summarized, but also how these summaries are presented. Presumably, this also holds for other stakeholder groups and thus we hope to see our survey used for different target groups in the future.

Datasets. To support these future directions we need to expand efforts on using and collecting a wide variety of datasets. Most recent data collection efforts are facilitating different input factors – the purpose and output factors need more emphasis. Our findings also impact the evaluation of summarization methods. We discuss this next.

5.2 Usefulness as evaluation methodology

Following Spärck Jones (1998) and Mani (2001a), we argue that a good choice of context factors is crucial in producing useful summaries for users. It is important to explicitly evaluate this. The few existing methods to evaluate usefulness are very resource demanding (e.g., Riccardi et al., 2015) or not comprehensive enough (e.g., DUC, 2003; Dorr et al., 2005). Thus, we propose a feasible and comprehensive method to evaluate usefulness.

For the evaluation methodology, we again use the context factors. Before the design and development of the summarization method the intended purpose factors need to be defined. Especially the fine-grained factor *use* is important here. Next, the output factors need to be evaluated on the use factors. For this, we take inspiration from research on simulated work tasks (Borlund, 2003). Evaluators should be given a specific task to imagine, e.g., *writing a news article*, or *studying for an exam*. This task should be relatable to the evaluators, so that reliable answers can be obtained (Borlund, 2016). With this task in mind, evaluators should be asked to judge two summaries in a pairwise manner on their usefulness, in the following format: *The [output factor] of which of these two summaries is most useful to you to [use factor]?* For example: *The style of which of these two summaries is most useful to you to substitute a chapter that you need to learn for your exam preparation?* It is critical to ensure that judges understand the meaning of each of the evaluation criteria – *style* and *substitute* in the example. We provide example questions for each of the use and output factors in Appendix E.

6 Conclusion

In this paper we focused on users of automatically generated summaries and argued for a stronger emphasis on their needs in the design, development and evaluation of automatic summarization methods. We led by example and proposed a survey methodology to identify these needs. Our survey is deeply grounded in past work by Spärck Jones (1998) on context factors for automatic summarization and can be re-used to investigate a wide variety of users. In this work we use our survey to investigate the needs of university students, an important target group of automatically generated summaries. We found that the needs identified by our participants are not fully supported by current automatic summarization methods and we proposed future research directions to accommodate these needs. Finally, we proposed an evaluation methodology to evaluate the usefulness of automatically generated summaries.

7 Ethical Impact

With this work we hope to take a step in the right direction to make research into automatic summarization more inclusive, by explicitly taking the needs of users of these summaries into account. As stressed throughout the paper, these needs are different per user group and therefore it is critical that a wide variety of user groups will be investigated. There might also be within group differences. For example, in this work we have focussed on students from universities in one country, but students attending universities in other geographical locations and with different cultures might express different needs. It is important to take these considerations into account, to limit the risk of overfitting on a particular user group and potentially harming other user groups.

A Overview context factors

Input Factors	**Purpose Factors**	**Output Factors**
Form	***Situation***	***Material***
Structure: How is the input text structured? E.g., subheadings, rhetorical patterns, etc.	*Tied:* It is known who will use the summary, for what purpose and when.	*Covering:* The summary covers all of the important information in the source text.
Scale: How large is the input data that we are summarizing? E.g., a book, a chapter, a single article, etc.	*Floating:* It is not (exactly) known who will use the summary, for what purpose or when.	*Partial:* The summary (intentionally) covers only parts of the important information in the source text.
Medium: What is the input language type? E.g., full text, telegraphese style, etc. This also refers to which natural language is used.	***Audience***	***Format***
Genre: What type of literacy does the input text have? E.g., description, narrative, etc.	*Targetted:* A lot of domain knowledge is expected from the readers of the summary.	*Running:* The summary is formatted as an abstract like text.
Subject Type	*Untargetted:* No domain knowledge is expected from the readers of the summary.	*Headed:* The summary is structured following a certain standardised format with headings and other explicit structure.
Ordinary: Everyone could understand this input type.	***Use***	***Style***
Specialized: You need to speak the jargon to understand this input type.	*Retrieving:* Use the summary to retrieve source text.	*Informative:* The summary conveys the raw information that is in the source text.
Restricted: The input type text is only understandable for people familiar with a certain area, for example because it contains local names.	*Previewing:* Use the summary to preview a text.	*Indicative:* The summary just states the topic of the source text, nothing more.
Unit	*Substitutes:* Use the summary to substitute the source text.	*Critical:* The summary gives a critical review of the merits of the source text.
Single: Only one input source is given.	*Refreshing:* Use the summary to refresh ones memory of the source text.	*Aggregative:* Different source texts are put in relation to one another to give an overview of a certain topic.
Multi: Multiple input sources are given.	*Prompts:* Use the summary as action prompt to read the source text.	

Table 3: Overview of different context factors classes defined by Spärck Jones (1998), with descriptions of the factors within these classes.

B Survey overview

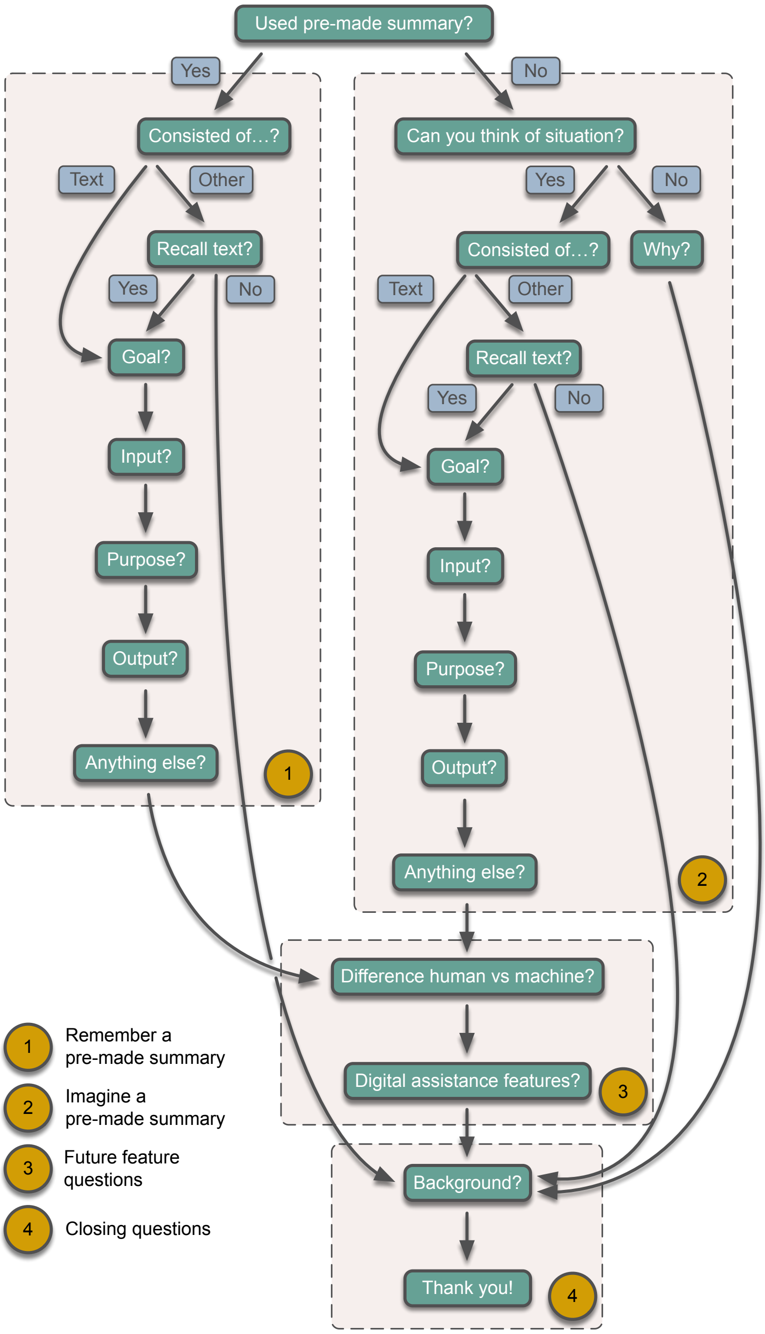

Figure 7: Overview survey design.

C Verbatim survey overview

Table 4: A complete overview of the survey. This table includes the explanation that participants received, as well as all the questions and the answer options. If a question was the start of a branch, the direction of the branch has been written behind the answer options in italic. (This was never shown to the participants.) Note that the survey was performed in SurveyMonkey.[6] The survey had a lay-out as provided by SurveyMonkey, i.e., it consisted of different pages and colors were used to highlight certain important parts in texts.

---

Question Nr.	Question and Answer Options
Q1	**Introduction and Instructions** Thank you for taking the time to fill out this survey! Before you start, please take the time to read these instructions carefully. If you still have any questions after reading the instructions, please send them to `m.a.terhoeve@uva.nl`. We will give away 10 `bol.com` vouchers of 10 euros each among the participants. If you would like to take part in the raffle, you can leave your email address at the end of this survey. **Goal of the study** The goal of this survey is to get insight in how summaries help or can help you when studying. **What the survey will look like** In what follows you will get questions that aim to develop an understanding for: • For which types of study material it is useful to have summaries • How these summaries can help you with your task • What these summaries should look like We expect this survey to take approximately 10 minutes of your time. Use the next button to go to the next page once you have filled out all the questions on the page. Use the prev button to go back one page. **About your privacy** We value your privacy and will process your answers anonymously. The answers of all participants in this survey will be used to gain insight in how pre-made summaries can be helpful for different types of studying activities. The answers will be presented in a research paper about this topic. This will be done either in an aggregated manner, or by citing verbatim examples of the answers. Again, this will all be done anonymously. **I agree that I have read and understood the instructions. I also understand that my participation in this survey is voluntarily.** ☐ I agree

Question Nr.	**Question and Answer Options**
Q2	**Important! Some background knowledge you need to know** Throughout this survey we make use of the term pre-made summary. It is very important that you understand what this means. On this page we explain this term, so please make sure to read this carefully. **Definition pre-made summary** One type of summary is one that you make yourself. Another type of summary is one that has been made for you. In this survey, we focus on this latter type and we call them pre-made summaries. **Who makes these pre-made summaries?** These pre-made summaries can be made by a person, for example your teacher, your friend, a fellow student or someone at some official organisation, etc. The pre-made summaries can also be made by a computer. **What kinds of summaries are we talking about?** There are no restrictions on what these pre-made summaries can look like. On the contrary, that is one of the things we aim to find out with this survey! But, to give some examples, you could think of a written overview of a text book, highlights in text to draw your attention to important bits, blog posts, etc. These are really just examples and don't let them limit your creativity! You can come up with any example of a pre-made summary that is helpful for you. **Yes, I understand what a pre-made summary is!** ☐ Yes
Q3	Please think back to your recent study activities. Examples of study activities can be: studying for an exam, writing a paper, doing homework exercises, etc. Note that these are just examples, any other study activity is fine too. **Did you use a pre-made summary in any of these study activities?** ☐ Yes – *participants are led to Q6* ☐ No – *participants are led to Q4*
Q4	**Can you think of one of your recent study activities where a pre-made summary would have been useful for you?** ☐ Yes – *participants are led to Q25* ☐ No – *participants are led to Q5*

Question Nr.	**Question and Answer Options**
Q5	**Why do you think a pre-made summary would not have helped you with any of your recent study activities?** Open response – *participants are led to Q48*
Start branch of participants who described an existing summary	
	If you have multiple study activities where you used a pre-made summary, please take the one where you found the pre-made summary most useful.
Q6	**The original study material consisted of** ☐ Mainly text – *participants are led to Q8* ☐ Mainly figures – *participants are led to Q7* ☐ Mainly video – *participants are led to Q7* ☐ Mainly audio – *participants are led to Q7* ☐ A combination of some or all of the above – *participants are led to Q7* ☐ I do not know, because I have not seen the study material – *participants are led to Q7* ☐ Other (please specify) – *participants are led to Q7*
Q7	**For now we narrow down our survey to study material that is mostly textual. Do you recall any other recent study activity where you made use of a pre-made summary and where the original study material mainly consisted of text?** ☐ Yes – *participants are led to Q8* ☐ No – *participants are led to Q48*
Q8	**What was the goal of this study activity?** ☐ Studying for an exam ☐ Writing a paper / essay / report / etc. ☐ Doing homework exercises ☐ Other (please specify)
Q9	**Who made this pre-made summary?** ☐ A teacher or teaching assistant ☐ A fellow student ☐ An official organisation ☐ The authors of the original study material ☐ A computer program ☐ I am not sure, I found it online ☐ Other (please specify)

Question Nr.	**Question and Answer Options**
	Now some questions will follow about what the study material that was summarized looked like.
Q10	**What was the length of the study material?** ☐ A single article ☐ Multiple articles ☐ A single book chapter ☐ Multiple book chapters from the same book ☐ Multiple book chapters from various books ☐ A combination of the above ☐ I do not know because I have not seen the study material, only the summary ☐ Other (please specify)
Q11	**How was the study material structured? (Multiple answers possible)** ☐ There was no particular structure - e.g. just one large text ☐ The text contained a title or titles ☐ The text contained subheadings ☐ The text consisted of different chapters ☐ The text consisted of different sections and / or paragraphs ☐ I do not know because I have not seen the study material, only the summary ☐ Other (please specify)
Q12	**What was the genre of the study material?** ☐ Mainly educational (such as a text book (chapter)) ☐ Mainly scientific (such as an academic article, publication, report, etc) ☐ Mainly nonfiction writing (such as (auto)biographies, history books, etc) ☐ Mainly fiction writing (such as novels, short fictional stories, etc) ☐ Other (please specify)
Q13	**How would you classify the difficulty level of the study material?** ☐ Ordinary: most people would be able to understand it ☐ Specialized: you need to know the jargon of the field to be able to understand it ☐ Geographically based: you can only understand it if you are familiar with a certain area, for example because it contains local names
	Now we will ask some questions about the purpose of the pre-made summary that you used.
Q14	**The summary was made specifically to help me (and potentially fellow students) with my study activity.** Strongly disagree ☐ Disagree ☐ Neither agree nor disagree ☐ Agree ☐ Strongly agree ☐ I don't know ☐

Question Nr.	Question and Answer Options
Q15	**For what type of people was the summary intended? Your score can range from (1) Untargetted, to (5) Targetted.** Untargetted: No domain knowledge is expected from the users of the summmary. Targetted: Full domain knowledge is expected from the users of the summmary. (1) ☐ (2) ☐ (3) ☐ (4) ☐ (5) ☐
Q16	**How did this summary help you with your task? (Multiple answers possible)** ☐ The summary helped to retrieve parts of the original study material ☐ I used the summary to preview the text that I was about to read ☐ I used the summary as a substitute for the original study material ☐ I used the summary to refresh my memory of the original study material ☐ I used the summary as a reminder that I had to read the original study material ☐ The summary helped to get an overview of the original study material ☐ The summary helped to understand the original study material ☐ Other (please specify)
Q17	**What was the type of the summary?** ☐ Lecture notes ☐ Blog post ☐ Highlights of some kind in the original study material ☐ Abstractive piece of text, such as a written overview of a text book, an abstract of a paper, etc. ☐ Short video ☐ A slide show ☐ Other (please specify)

Question Nr.	Question and Answer Options
Q18	**How was the summary structured? (Multiple answers possible)** ☐ The summary was a running text, without particular structure ☐ The summary consisted of highlights in the original study material, without particular structure ☐ The summary itself contained special formatting, such as bold or cursive text, highlights, etc ☐ The summary contained diagrams ☐ The summary contained tables ☐ The summary contained graphs ☐ The summary contained figures ☐ The summary contained headings ☐ The summary consisted of different sections / paragraphs ☐ Other (please specify)
Q19	**How much of the study material was covered by the summary?** None of the study material was covered (1) ☐ Almost none of the study material was covered (2) ☐ Some of the study material was covered (3) ☐ Most of the study material was covered (4) ☐ All of the study material was covered (5) ☐
Q20	**What was the style of this summary?** ☐ Informative: the summary simply conveyed the information that was in the original study material ☐ Indicative: the summary gave an idea of the topic of the study material, but not more ☐ Critical: the summary gave a critical review of the study material ☐ Aggregative: the summary put different source texts in relation to one another and by doing this gave an overview of a certain topic ☐ Other (please specify)

Question Nr.	**Question and Answer Options**
Q21	**Overall, how helpful was the pre-made summary for you? Your score can range from (1) Not helpful at all, to (5) Very helpful.** Not helpful at all (1) ☐ (2) ☐ (3) ☐ (4) ☐ (5) ☐ Very helpful
Q22	**Imagine you could turn this summary into your ideal summary. What would you change?** Open response
Q23	**Is there anything else you want us to know about the summary that we have not covered yet?** Open response
Q24	**Is there anything else you want us to know about the original study material that we have not covered yet?** Open response – *participants are led to Q40*
Start branch of participants who described an imagined summary	
	Please take one of these study activities in mind and imagine you would have had a pre-made summary.
Q25	**The original study material consisted of** ☐ Mainly text – *participants are led to Q27* ☐ Mainly figures – *participants are led to Q26* ☐ Mainly video – *participants are led to Q26* ☐ Mainly audio – *participants are led to Q26* ☐ A combination of some or all of the above – *participants are led to Q26* ☐ Other (please specify) – *participants are led to Q26*
Q26	**For now we narrow down our survey to study material that is mostly textual. Do you recall any other recent study activity where you could have used a pre-made summary and where the original study material mainly consisted of text?** ☐ Yes – *participants are led to Q27* ☐ No – *participants are led to Q48*

Question Nr.	Question and Answer Options
Q27	**What was the goal of this study activity?** ☐ Studying for an exam ☐ Writing a paper / essay / report / etc. ☐ Doing homework exercises ☐ Other (please specify)
	Now some questions will follow about what the study material that could be summarized looked like.
Q28	**What was the length of the study material?** ☐ A single article ☐ Multiple articles ☐ A single book chapter ☐ Multiple book chapters from the same book ☐ Multiple book chapters from various books ☐ A combination of the above ☐ Other (please specify)
Q29	**How was the study material structured? (Multiple answers possible)** ☐ There was no particular structure - e.g. just one large text ☐ The text contained a title or titles ☐ The text contained subheadings ☐ The text consisted of different chapters ☐ The text consisted of different sections and / or paragraphs ☐ Other (please specify)
Q30	**What was the genre of the study material?** ☐ Mainly educational (such as a text book (chapter)) ☐ Mainly scientific (such as an academic article, publication, report, etc) ☐ Mainly nonfiction writing (such as (auto)biographies, history books, etc) ☐ Mainly fiction writing (such as novels, short fictional stories, etc) ☐ Other (please specify)
Q31	**How would you classify the difficulty level of the study material?** ☐ Ordinary: most people would be able to understand it ☐ Specialized: you need to know the jargon of the field to be able to understand it ☐ Geographically based: you can only understand it if you are familiar with a certain area, for example because it contains local names

Question Nr.	Question and Answer Options
	Now we will ask some questions about the purpose of the pre-made summary that would have been helpful.
Q32	**For what type of people should the summary ideally be intended? Your score can range from (1) Untargetted, to (5) Targetted.** Untargetted: No domain knowledge is expected from the users of the summmary. Targetted: Full domain knowledge is expected from the users of the summmary. (1) ☐ (2) ☐ (3) ☐ (4) ☐ (5) ☐
Q33	**How would this summary help you with your task? (Multiple answers possible)** ☐ The summary would help to retrieve parts of the original study material ☐ I would use the summary to preview the text that I was about to read ☐ I would use the summary as a substitute for the original study material ☐ I would use the summary to refresh my memory of the original study material ☐ I would use the summary as a reminder that I had to read the original study material ☐ The summary would help to get an overview of the original study material ☐ The summary would help to understand the original study material', ☐ Other (please specify)
	Now we will ask some questions about what the summary should look like and cover.
Q34	**What would be the ideal type of the summary?** ☐ Lecture notes ☐ Blog post ☐ Highlights of some kind in the original study material ☐ Abstractive piece of text, such as a written overview of a text book, an abstract of a paper, etc. ☐ Short video ☐ A slide show ☐ Other (please specify)

Question Nr.	Question and Answer Options
Q35	**What is the ideal structure of the summary? (Multiple answers possible)** ☐ The summary should be a running text, without particular structure ☐ The summary should consist of highlights in the original study material, without particular structure ☐ The summary itself should contain special formatting, such as bold or cursive text, highlights, etc. ☐ The summary should contain diagrams ☐ The summary should contain tables ☐ The summary should contain graphs ☐ The summary should contain figures ☐ The summary should contain headings ☐ The summary should consist of different sections / paragraphs ☐ Other (please specify)
Q36	**How much of the study material should be covered by the summary?** None of the study material should be covered (1) ☐ Almost none of the study material should be covered (2) ☐ Some of the study material should be covered (3) ☐ Most of the study material should be covered (4) ☐ All of the study material should be covered (5) ☐
Q37	**What should the style of this summary be?** ☐ Informative: the summary should simply convey the information that was in the original study material ☐ Indicative: the summary should give an idea of the topic of the study material, but not more ☐ Critical: the summary should give a critical review of the study material ☐ Aggregative: the summary should put different source texts in relation to one another and by doing this give an overview of a certain topic ☐ Other (please specify)

Question Nr.	Question and Answer Options
Q38	**Is there anything else you would want us to know about your ideal summary that we have not covered yet?** Open response
Q39	**Is there anything else you would want us to know about the original study material that we have not covered yet?** Open response
Look out questions	
	Now, let's assume the pre-made summary was generated by a computer. You can assume that this machine generated summary captures all the needs you have identified in the previous questions.
Q40	**Would it make a difference to you whether the summary was generated by a computer program or by a human?** ☐ Yes – *participants are led to Q41* ☐ No – *participants are led to Q43*
Q41	**Please explain the difference.** Open response
Q42	**Which type of summary would you trust more:** ☐ A summary generated by a human, for example a teacher or a good performing fellow student ☐ A summary generated by a computer ☐ No difference
Q43	**Please explain your answer.** Open response
Q44	**Which type of summary would you trust more:** ☐ A summary generated by a human, for example a teacher or a good performing fellow student ☐ A summary generated by a computer ☐ No difference

Question Nr.	Question and Answer Options
	Now imagine that you can interact with the computer program that made the summary, in the form of a digital assistant. Imagine that your digital assistant made an initial summary for you and you can ask questions about it to your digital assistant and the assistant can answer them. Answers can be voice output, but also screen output, e.g. a written summary on the screen. In the next part we would like to investigate how you would interact with the assistant. Please do not feel restricted by the capabilities of today's digital assistants.
Q45	**Please choose the three most useful features for a digital assistant to have in this scenario.** ☐ Summarize particular parts of the study material with more detail ☐ Summarize particular parts of the study material with less detail ☐ Switch between different summary styles (for example highlighting vs a generated small piece of text) ☐ Explain why particular pieces ended up in the summary ☐ Provide the source of certain parts of the summary on request ☐ Search for different related sources based on the content of the summary ☐ Answer specific questions based on the content of the summary
Q46	**Please choose the three least useful features for a digital assistant to have in this scenario.** ☐ Summarize particular parts of the study material with more detail ☐ Summarize particular parts of the study material with less detail ☐ Switch between different summary styles (for example highlighting vs a generated small piece of text) ☐ Explain why particular pieces ended up in the summary ☐ Provide the source of certain parts of the summary on request ☐ Search for different related sources based on the content of the summary ☐ Answer specific questions based on the content of the summary
Q47	**Can you think of any other features that you would like your digital assistant to have to help you in this scenario?** Open response
Background questions	
	Thank you for filling out this survey so far! We would still like to ask you two final background questions.
Q48	**What is the current level of education you are pursuing?** ☐ Bachelor's degree ☐ Master's degree ☐ MBA ☐ Other, please specify

Question Nr.	Question and Answer Options
Q49	**What is your main field of study?** Open response
Thank you!	
	You have come to the end of our survey. Thanks a lot for helping out! We very much appreciate your time.
Q50	**If you would like to participate in the raffle to win a voucher, please fill out your e-mail address below. We will only use this e-mail address to blindly draw 10 names who win a voucher and to contact you if your name has been drawn.** Open response

D Full results trustworthiness and future feature questions

In this section we report the results for the exploratory questions that we asked about the trustworthiness of a summary generated by a machine versus a human, as well as the results for the questions about features for summarization with a digital voice assistant.

We find that participants are divided on the question whether it would make a difference to them whether the summary was generated by a machine or a computer. If we look at all participants together, we find that $48.0.\%$ of the participants answered that it would make a difference, whereas 52.0% answered that it would not. However, if we split the participants based on study background, an interesting difference emerges (Figure 8a). Participants with a background in STEM indicated significantly more often that it would not make a difference to them, whereas the other groups of students indicated the opposite. Almost all participants who answered that it would make a difference said that they would not trust a computer on being able to find the relevant information, i.e., all seemed to favor the human generated summary. Only one participant advocated for the computer-generated summary as a *"computer is more objective."* Almost all participants who said it would not matter to them did add the condition that the quality of the generated summary should be as good as if a human had generated it. One person wrote: *"If the summary captures all previously discussed elements it is effectively good for the same purpose. So then it does not matter who generated it."* This comment exactly captures the motivation of the setup of our survey.

This caution regarding automatically generated summaries is confirmed by the question in which we asked which type of summary participants would trust more – a human-generated one or a machine-generated one. People chose the human-generated summary significantly more often (Figure 8b). This also holds for the participants with a STEM background, which aligns with the responses to the open questions we reported earlier – apparently participants do not fully trust that the condition they raised earlier would be satisfied, namely that only if the machine was just as good as the human, it would not matter for them whether the summary was generated by a machine or a human.

The results for the most and least useful features for a digital assistant in a summarization scenario are given in Figure 8c and 8d. Adding more details to the summary and answering questions based on the content of the summary are very popular features, whereas summarizing parts of the input material with less detail is not.

Lastly, we asked participants whether they could think of any other features that they would like their digital assistant to have in the outlined scenario. A number of participants answered that they would like the digital assistant to generate questions based on the summary, so that they could test their own understanding. For example, one participant said: *"Make questions for me (to test me)"* and another participant had a related comment: *"Maybe the the digital assistant could find old exam questions to link to parts of the summary where the question is related to, so that there is a function to test if you've understood the summary."* Another line of answers pointed towards giving explicit relations between the input material and summary, for example: *"Show links between subject materials and what their relation is"* and another person wrote: *"Dynamic linking from summary to original source is a great added value of generating a summary"*.

E Examples evaluation questions

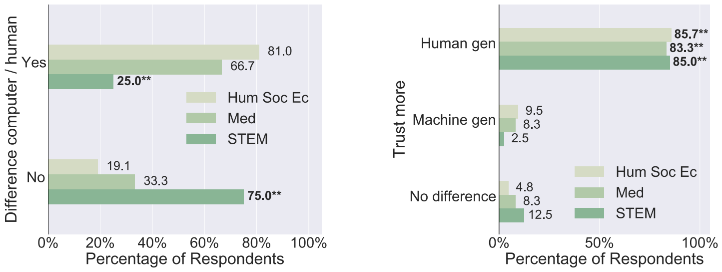
Here we give additional examples for the evaluation questions that can be used for our proposed evaluation methodology. The phrase *"a document that is important for your task"* should be substituted to match the task at hand. For example, in the case of exam preparations, this could be replaced with *"a chapter that you need to learn for your exam preparation"*. Only the questions with the intended purpose factors should be used in the evaluation.

Purpose factor *Use* & Output factor *Style*:

- The *style* of which of these two summaries is most useful to you to *retrieve* a document that is important for your task?
- The *style* of which of these two summaries is most useful to you to *preview* a document that is important for your task?
- The *style* of which of these two summaries is most useful to you to *substitute* a document that is important for your task?
- The *style* of which of these two summaries is most useful to you to *refresh your memory* about a document that is important for your task?

(a) Would it make a difference to you whether the summary was generated by a computer program or by a human? (MC)

(b) Which type of summary would you trust more? (MC)



(c) Please choose the three *most* useful features for a digital assistant to have in this scenario. (MR)

(d) Please choose the three *least* useful features for a digital assistant to have in this scenario. (MR)

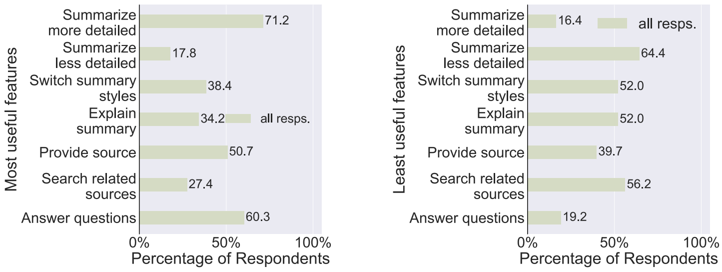


Figure 8: Results for the future feature questions. Answer type in brackets. MC = Multiple Choice, MR = Multiple Response. ** indicates significance (χ^2 or Fisher's exact test), after Bonferroni correction, with $p \ll 0.001$.

- The *style* of which of these two summaries is most useful to you to *prompt* you to read a source text that is important for your task?

Purpose factor *Use* & Output factor *Format*:

- The *format* of which of these two summaries is most useful to you to *retrieve* a document that is important for your task?
- The *format* of which of these two summaries is most useful to you to *preview* a document that is important for your task?
- The *format* of which of these two summaries is most useful to you to *substitute* a document that is important for your task?
- The *format* of which of these two summaries is most useful to you to *refresh your memory* about a document that is important for your task?
- The *format* of which of these two summaries is most useful to you to *prompt* you to read a source text that is important for your task?

Purpose factor *Use* & Output factor *Material*:

- The *coverage* of which of these two summaries is most useful to you to *retrieve* a document that is important for your task?
- The *coverage* of which of these two summaries is most useful to you to *preview* a document that is important for your task?
- The *coverage* of which of these two summaries is most useful to you to *substitute* a document that is important for your task?
- The *coverage* of which of these two summaries is most useful to you to *refresh your memory* about a document that is important for your task?
- The *coverage* of which of these two summaries is most useful to you to *prompt* you to read a source text that is important for your task?

ErAConD: Error Annotated Conversational Dialog Dataset for Grammatical Error Correction

Abstract

Currently available grammatical error correction (GEC) datasets are compiled using essays or other long-form text written by language learners, limiting the applicability of these datasets to other domains such as informal writing and conversational dialog. In this paper, we present a novel GEC dataset consisting of parallel original and corrected utterances drawn from open-domain chatbot conversations; this dataset is, to our knowledge, the first GEC dataset targeted to a human-machine conversational setting. We also present a detailed annotation scheme which ranks errors by perceived impact on comprehension, making our dataset more representative of real-world language learning applications. To demonstrate the utility of the dataset, we use our annotated data to fine-tune a state-of-the-art GEC model. Experimental results show the effectiveness of our data in improving GEC model performance in a conversational scenario.

1 Introduction

In recent years, both researchers and businesses have attempted to build effective educational chatbots to help language learners improve their conversational skills in a second language (primarily English) (Huang et al., 2021). However, many such systems, such as GenieTutor Plus (Huang et al., 2017), use rule-based dialog engines, and thus do not take advantage of recent developments in dialog generation using Transformer models, which have vastly improved the quality of modern chatbots (Liang et al., 2020). Extant dialog systems for conversational language learning can be broadly classified into two types. In the first type, the chatbot serves as a teacher and repeatedly asks the user questions to test acquisition of specific words, syntax, and other pedagogical targets. In the second type, the chatbot serves as a conversational partner, encouraging users to chat with it and, in some cases, providing corrective feedback to learners (Fryer et al., 2020). It is this latter type we hope to improve using our proposed dataset.

Grammatical error correction (GEC) models are needed to generate appropriate corrective feedback for this second type of educational chatbot. However, nearly all current GEC datasets focus on written essays, a domain which differs markedly from conversational speech in both syntax and style. As a result, datasets drawn from written sources, such as student essays, produce poor results when applied to dialog (Davidson et al., 2019). There currently exists one dataset of error-annotated conversational utterances by English second language learners on which researchers can train and evaluate conversational GEC models, the Teacher-Student Chatroom Corpus (Caines et al., 2020); this data is generated in the context of human-human interaction, specifically interactions between a teacher and a second language learner student. However, no similar conversational dataset focuses on the human-machine conversational setting. In this work we seek to address this gap in the available data by developing a high-quality, error-annotated dataset of learner dialog collected from an online educational chatbot.[1] To appropriately annotate our data for language learning applications, we introduce a 3-level grammatical error classification structure in order to categorize errors based on severity. Our motivation for this error classification structure is to give users the opportunity to first focus on improving their most serious grammatical errors. To demonstrate the utility of the proposed dataset, we fine-tune and evaluate a state-of-the-art GEC model using our newly developed dataset.

2 Related Work

As with many NLP tasks, the current state-of-the-art in grammatical error correction involves using large Transformer-based language models such as BERT (Devlin et al., 2019), RoBERTa (Liu et al., 2019), and XLNet (Yang et al., 2019). To evaluate the utility of our dataset, we use Omelianchuk et al. (2020)'s GECToR model, which reframes GEC as a sequence labelling task rather than a monolingual machine translation task. GECToR achieves SoTA results on the test corpus used for the BEA 2019 Shared Task on Grammatical Error Correction (Bryant et al., 2019). Other promising supervised GEC models include those of Stahlberg and Kumar (2021) and Rothe et al. (2021), who achieve SoTA results on the JFLEG (Napoles et al., 2017) and CoNLL-2014 (Ng et al., 2014) GEC datasets, respectively. Both models combine innovative synthetic data generation methods with large pretrained transformer language models.

Recent work related to the development of datasets for grammatical error correction include Napoles et al. (2019) who presents a dataset of native and non-native English writing. Trinh and Rozovskaya (2021) proposes a new parallel dataset of Russian student writing. These datasets add to the growing number of GEC datasets available to the research community. However, as previously mentioned, no GEC dataset that contains chatbot-based human-machine conversational data, in English or any other language, is currently available. We seek to begin closing this gap with the present research.

3 Data Collection

3.1 Data Collection Process

We collected 186 dialogs containing 1735 user utterance turns of open-domain dialog data by deploying BlenderBot (Roller et al., 2020) on Amazon Mechanical Turk (AMT) via LEGOEval. (Li et al., 2021). We decided to deploy BlenderBot, because it is open-sourced and because it has relatively good coherence, and is known for its engagement and human-like conversational qualities.

The AMT crowd-workers who conversed with our bot are L2 English speakers of at least intermediate proficiency. The workers were asked to converse with our chatbot for at least 10 turns (a turn is defined as a bot/user utterance pair) either about movies or the COVID-19 pandemic; we chose these because of their universal experience and subjectivity of the two topics, resulting in a rich and diverse set of utterances in the dataset. Workers interacted with the bot using a typed interface, similar to a messaging app. We plan to expand this to an ASR-driven system as well as to additional conversational topics in future work.

3.2 Data Annotation

After collecting open-domain dialog data, we manually revised each user utterance to correct any non-standard or ungrammatical English usage. A subset of the dialogs are corrected by two annotators to provide multiple corrected targets for system evaluation–the remaining dialogs are corrected by a single annotator. Both annotators are graduate student native speakers of English.

3.2.1 Annotation scheme

We followed an annotation method similar to that proposed in Náplava et al. (2022), in which we asked annotators to revise any sentences containing ungrammatical elements. Our goal was to apply the minimum number of edits needed to make the utterance conform to standard written English while remaining as faithful to the source as possible. With this goal in mind, we designed our annotation scheme to conform to the rules of standard written English with two exceptions: internet shorthand and slang, and short responses which are incomplete sentences; both forms, while not acceptable in formal written English, are frequently considered acceptable in the context of informal dialog. We also made fluency edits (Napoles et al., 2017) of semantic and sentence construction errors, particularly those related to lexical choice, omission, and word order. For example, the source line *"The movie tell about a poor girl that meet a prince and in love for him"*, suffers from non-native-like word choice. We corrected this utterance to *"the movie tells about a poor girl that meets a prince and falls in love with him"*. We made these corrections with the intention of creating ground truth utterances which are as semantically and syntactically similar to the source as possible.

3.2.2 Inter-annotator agreement

We took several steps to ensure that annotators were meeting the goal of revising ungrammatical and disfluent sentences while retaining the semantic content of the source dialog. During our annotation training phase, we had both annotators correct an identical set of 26 dialogs. The annotators then reviewed each other's annotations on this subset and noted specific area of disagreement, which were then discussed with the lead researchers who provided specific instructions on how to resolve these discrepancies. Annotators then repeated the annotations of the same 26 dialogs to ensure that the provided instructions were being followed. During this process, we also asked annotators to note any changes which they believed changed the underlying semantics of a given dialog, so that such changes could be eliminated in subsequent passes. At each stage, we calculated inter-annotator agreement (as described below), and only continued with the annotation of the remaining 160 dialogs once our second-pass agreement levels were on-par with previously reported GEC corpora such as Trinh and Rozovskaya (2021).

For many ungrammatical sentences, there are multiple acceptable ways to correct the error. As a result GEC annotations can be quite variable, and traditional methods of calculating inter-annotator agreement are not informative (Rozovskaya and Roth, 2019). We therefore utilized two metrics for calculating inter-annotator agreement. The first, originally proposed by Rozovskaya and Roth (2010), asks each annotator to review and correct the corrections of the other annotators, and then calculates the percent of sentences which are unchanged on this second pass; these figures are shown as "Judged correct" in Table 1. The second method, used in work such as Trinh and Rozovskaya (2021) calculates the $F_{0.5}$ by setting one annotator as reference and the other as hypothesis; these figures are also provided in Table 1.

Ref	**Judged Correct**	**TP**	**FP**	**FN**	**Prec**	**Rec**	**$F_{0.5}$**
0	95.9%	59	109	57	0.351	0.509	0.374
1	96.2%	59	57	109	0.509	0.351	0.467

Table 1: Annotator agreement by $F_{0.5}$ score. Only dialogs with two annotators are compared. The first column indicates which annotator is selected as reference. The "Judged Correct" column indicates second-pass agreement between annotators.

Level	**Impact on Meaning**	**Error Types**
1	Trivial	Punctuation (excl. apostrophe) & Casing
2	Moderate	Acronyms, Abbreviations, Non-English Internet Slang, & Apostrophe
3	Significant	SV Agreement, Verb Form, Word Confusion, etc.

Table 2: Categorization of grammatical errors.

3.3 Error Types

One of our key goals in developing an error correction model using the proposed dataset is to enable users to focus on specific language skills on which they wish to improve. Since we are dealing with online chat conversations, our data is more casual than the more formal written data seen in previous GEC datasets. Moreover, because our data consists of human-machine conversations involving English language learners of intermediate level, users are assumed to know basic English grammar. Therefore, we wanted to give users the flexibility of choosing to limit feedback, such as only receiving feedback on major lexical and syntactic errors. Specifically, we want to avoid overwhelming users with an excessive number of proposed corrections, and to enable users to improve their conversational skills by first focusing on their most serious errors. Importantly, suggesting an excessive number of corrections could overwhelm a less proficient user or possibly irritate a more proficient participant, resulting in reduced user enjoyment and engagement (Koltovskaia, 2020). To that end, we organized our annotated corrections into a 3-level structure based on a perceived ranking of how errors impact the ability of interlocutors to understand what the user is saying, as shown in Table 2. As such, we focus primarily on lexical, syntactic and usage errors (Ferris, 2011; Touchie, 1986), while leaving mechanical errors to the lowest-priority category. Error priority tags are attached to each edit proposed by the annotators automatically in a post-processing step using a modified version of the ERRANT toolkit (Bryant et al., 2017).

For Level 1, our logic is that conversational partners are generally still able to understand a message when it is missing sentence-final punctuation or when a word is not properly capitalized. Because they are of at least intermediate English proficiency, participants can be assumed to know the underlying rules related to punctuation and capitalization; their errors result rather from inattentiveness (Sermsook et al., 2017) and the informal nature of the conversational genre (Cohen

Example	Message	Error
1	yes, johnny depp, and brad pitt	Punctuation & Casing
2	Ok, what are you talking about? Kkkkkk	Non-English Internet Slang
3	I also like SF movies. It makes me think differently.	Acronym
4	What's your fav movie right now?	Abbreviation
5	IT SEEMS DRAMATIC. ILL WATCH.	Apostrophe
6	She is not on the line now. Maybe its nighttime there.	Apostrophe
7	I'd say you could help Zhou Yu. He's either unable to create a non-broken hit or he's cheating, exploring low-wage workers. What do you think?	Word Confusion
8	It just don't work	SV Agreement
9	I have a friend from the US. We have a conversation and I don't know the word *bangus* in English. So it was hard for me to communicate with her.	Verb Form

Table 3: Examples user utterances with error type from ErAConD dataset.

and Robbins, 1976). Consider Ex.1 in Table 3: the syntactic structure of the sentence makes it clear that the user is listing names of actors despite the lack of capitalization and punctuation.

For Level 2, our logic is that interlocutors are likely able to understand a message despite usage of acronyms, abbreviations, non-English internet slang, or a missing apostrophe. An example of such non-English internet slang is shown in Ex. 2 in Table 3. The use of such forms in text-based online conversation is to be expected, since these types of abbreviations are common in all student writing (Purcell et al., 2013; Thangaraj and Maniam, 2015). However, such cases could potentially lead to misunderstanding, especially when conversing with someone of a different generation or linguistic background. Therefore, we categorize these non-standard forms as moderate "errors" (though they are not errors in the traditional sense). We do not consider these non-standard forms as significant because our assumption is that the writer intentionally chose to use these forms for brevity and in the spirit of informality common in online chat (Forsythand and Martell, 2007).

Finally, we include errors which are likely to result misunderstanding or misinterpretation of a message in Level 3 . As we can see in Ex. 7 in Table 3, the user incorrectly uses the term *non-broken* instead of *unbroken*, and *exploring* instead of *exploiting*. These lexical errors, particularly the latter, are likely to result in misinterpretation of the speaker's intended meaning. Similarly, the user makes a subject-verb agreement error in Ex. 8 and a verb tense error in Ex. 9. In the former, the user mistakenly uses a plural verb for a singular subject, while in the latter, the user uses a present tense verb when a past tense verb is needed. Because these errors relate to some of the most fundamental rules in English grammar, such errors must be addressed promptly. Thus, we treat these errors as "significant" in our annotation scheme.

4 Dataset Statistics

Dialogs	186
User turns	1735
User sentences (source)	2454
Word tokens (source)	24616
Word types	2860
Error annotations	2346.5
Level 3 error annotations	684.5
# of turns per dialog	9.33
# of sentences per turn (source)	1.41
# of tokens per turn (source)	14.19
# of error annotations per turn	1.35
# of Level 3 error annotations per turn	0.39
# of Level 3 error annotations per 100 tokens	2.78

Table 4: Overview of ErAConD dataset.

Table 4 reports statistics related to the composition of the ErAConD dataset. All statistics are based on user turns; we omit turns generated by our dialog system, as these are not relevant to training a GEC system to provide feedback to users. Additionally, we exclude utterances which include only stop phrases (i.e. "stop", "goodbye", etc.) since these are intended to terminate the conversation. Our 3-level structure is reflected in our modified ERRANT (Bryant et al., 2019) toolkit and M2 format. Error type tags are generated from annotated parallel data automatically with our modified version of ERRANT[2], and related figures are averaged across multiple annotators. Inspired by Rozovskaya and Roth (2021), our version of ERRANT also enables users to provide grammatically equivalent edits (i.e. changing "I'm" to "I am"), so that ERRANT can recognize them as identical edits.

As shown in Table 4, Level 3 edits account for 29.17% of all errors, which supports the necessity of our proposed categorization feature. The error distribution in our dataset is comparable to that of essay-based GEC datasets, according to statis-

---

[2] Code is available at `https://github.com/yuanxun-yx/errant`

tics provided in Bryant et al. (2019), with the exception of spelling and morphological (inflection) errors, which are substantially higher. While the higher rate of spelling errors is unsurprising in a conversation dataset, the difference in morphological errors warrants further investigation.

5 Grammar Error Correction Model

To demonstrate the utility of our proposed dataset in improving GEC for the open-domain dialog setting, we use the ErAConD dataset to fine-tune a state-of-the-art GEC model, GECToR (Omelianchuk et al., 2020), which we then test on held-out dialog data. Our results show that ErAConD is useful for adapting GEC models to open-domain dialog.

5.1 Training process

To train a model catered to conversations, we fine-tune the GECToR model[3] proposed by Omelianchuk et al. (2020) on our collected data. The GECToR model is a grammatical error correction model that generates a set of encoded edit operations to correct the input text rather than directly outputting corrected text. In other words, rather than outputting superficially corrected text, the model outputs the operations necessary to convert the uncorrected text to its corrected version. This set of encoded edit operations can then be applied to the original uncorrected text in a post-processing step to generate the final corrected output (Omelianchuk et al., 2020). The GECToR model training pipeline starts with a large pre-trained language model (i.e. XLNet or RoBERTa) that is then fine-tuned on both synthetic and collected data. To test our proposed dataset, we further fine-tune this GECToR model on our data.

We only choose to fine-tune the GECToR model using Level 3 edits in our dataset and ignore the Level 1 and 2 edits so that our model can perform better in real-world pedagogical settings. As previously mentioned, overwhelming students with trivial errors, such as punctuation and capitalization, can decrease user enjoyment and engagement (Koltovskaia, 2020). In future work, we plan to train the GECToR model on targeted conversational data across all stages of the pipeline, and determine which errors to present to the user in a post-processing step. We also plan to integrate conversational context.

5.2 Result and Analysis

Setting	TP	FP	FN	Prec	Rec	$F_{0.5}$
XLNet	72.4	444.6	147.2	0.140	0.330	0.158
FT XLNet	27.1	13.2	191.1	0.683	0.124	0.352

Table 5: Performance of GECToR with each setting. Scores are averaged among 5 runs. Table 7 provides detailed score of every run. XLNet is the baseline GECToR model based on XLNet, and FT XLNet is the fine-tuned GECToR using level 3 edits.

Table 5 indicates the efficacy of our data in terms of improving the performance of the GECToR model. The fine-tuned model outperforms the original in terms of $F_{0.5}$, a metric commonly used in GEC (Omelianchuk et al., 2020). The significant increase in $F_{0.5}$ score results from a massive reduction of false positives. In other words, after we fine-tune GECToR on our dataset, the model produces far fewer edits, which helps improve the precision greatly. This is of particular importance in a GEC model, as model precision is considered more important than recall in GEC tasks since false positives could lead to serious confusion in language learners.

Due to the limited size of the dataset, and the uneven distribution of errors in user utterances, we use 5-fold cross-validation to ensure the reliability of our results. We report the average of five cross-validation runs. One note, we modified ERRANT to allow equivalent edits, our reported results on all models might be slightly higher than original ERRANT-based results.

6 Conclusions and Future Work

We provide the first high-quality, fine-grained error-correction conversation dataset between English second language learner and an educational chatbot. To demonstrate the utility of our dataset, we train and evaluate a SoTA GEC model on the dataset, resulting in a significant improvement in overall model performance for conversational setting. This project lays the groundwork for future work on conversational grammatical error correction (such as adding other dialog domains and incorporating information about the native languages of users) and customized educational dialog system for second language learners.

7 Ethical Considerations

Collecting these dialogs for our dataset is difficult in that it requires substantial commitment from participants. In order to provide as large of a dataset as possible, we utilized the services of Amazon Mechanical Turk as previously mentioned. Given ethical concerns in recent years regarding data acquisition through crowdworkers, we verified that the crowdworkers assigned to our tasks were compensated fairly and treated humanely.

The annotators also examined the dataset to ensure that it does not contain personally identifiable information (which was anonymized) or potentially offensive content (which was removed).

A Appendices

A.1 Annotation Exceptions

Even though they violate the rules of standard English, we left the following types of errors unchanged in our annotated dataset:

1. *Utterances that are not complete sentences.* For example, response utterances such as *Yes*, *Very good*, and *Me too* are considered correct in our annotation due to their prevalence in informal dialog, although they are not correct in formal writing.

2. *Use of common English internet slang and shorthand expressions.* Slang and shorthand expressions such as *lol* ("laugh out loud") and *u* (short for "you") are not only distinctive to online chat conversations, but also reflective of their casual nature. Additionally, they may be language, culture, and even sub-culture specific. While these terms may not be suitable to a more formal register, they are generally acceptable in the context of informal dialog (Forsythand and Martell, 2007); thus, we do not classify such usage as errors.

A.2 Dataset Statistics

As described in Section 4, Table 6 shows the type distribution of edit type in ErAConD. Type labels were generated using our version of ERRANT. Levels of edits were first generated by ERRANT, and then manually checked to label Type 2 edits that are hard to be recognized by code (non-English Internet slangs, acronyms and abbreviations). To take all annotators into consideration, the number of edits was averaged among multiple annotators.

The statistics give us several important insights. First, the number of "significant" errors is slightly

higher than in written GEC datasets, such as NUCLE. This result shows that grammatical errors are relatively rare in both the conversational and written domain. Additionally, the average length of each sentence is significantly shorter than written GEC datasets. Finally, the error rate data supports our tiered categorization of errors, as the frequency of errors would be much higher than non-conversational datasets if all less significant errors, such as capitalization and punctuation, were included.

A.3 Experimental Results

Table 7 is the full version of Table 5. Some details of experiment are mentioned at Section 5.2. 20% of the dialogs were chosen randomly for the test set and the rest were used for training. Then 5-fold cross-validation was applied and the whole process was run 5 times in total, so as to observe the reliability of our results. We used the recommended parameters of XLNet to train and test GECToR. From the table we can see that the variance of performance among these runs is small. The distribution of Level 3 edits in test and train sets for each run is also represented in Table 8.

Semantic Diversity in Dialogue with Natural Language Inference

Katherine Stasaski and Marti A. Hearst
UC Berkeley
`{katie_stasaski, hearst}@berkeley.edu`

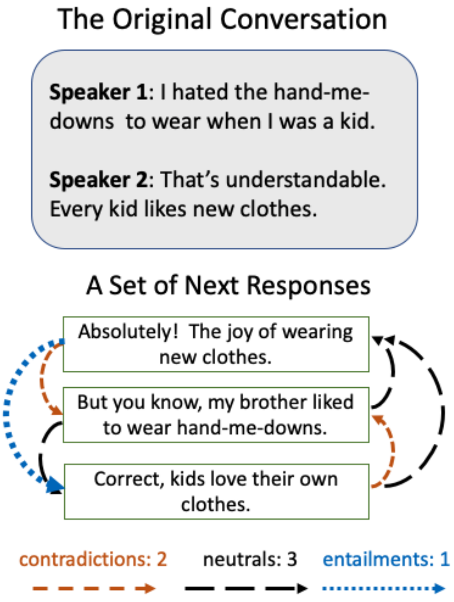
Abstract

Generating diverse, interesting responses to chitchat conversations is a problem for neural conversational agents. This paper makes two substantial contributions to improving diversity in dialogue generation. First, we propose a novel metric which uses Natural Language Inference (NLI) to measure the semantic diversity of a *set* of model responses for a conversation. We evaluate this metric using an established framework (Tevet and Berant, 2021) and find strong evidence indicating NLI Diversity is correlated with semantic diversity. Specifically, we show that the contradiction relation is more useful than the neutral relation for measuring this diversity and that incorporating the NLI model's confidence achieves state-of-the-art results. Second, we demonstrate how to iteratively improve the semantic diversity of a sampled set of responses via a new generation procedure called Diversity Threshold Generation, which results in an average 137% increase in NLI Diversity compared to standard generation procedures.

1 Introduction

Dialogue models often struggle to produce engaging utterances in conversations, tending to generate responses which are common in the training data, such as "OK," "Yeah," or "I don't know" (Li et al., 2016). While these responses are appropriate for a wide variety of contexts, their over-production can result in a dull conversation (See et al., 2019).

An evaluation task has emerged that consists of measuring the diversity of chitchat model responses over a test set. While some past work uses human evaluation to measure model response diversity according to engagingness, specificity, or interestingness (Li et al., 2016; See et al., 2019; Ghandeharioun et al., 2019), several automated metrics have also been proposed to measure diversity of model responses. Some metrics measure *lexical* diversity, typically via n-gram overlap (Li et al., 2016) or computing the BLEU score (Zhu et al., 2018) among model responses generated from the test set. Other past work attempts to measure *semantic* diversity via repurposing sentence similarity metrics (Tevet and Berant, 2021; Zhang et al., 2020a; Cer et al., 2017).



Speaker 1: I hated the hand-me-downs to wear when I was a kid.

Speaker 2: That's understandable. Every kid likes new clothes.

Absolutely! The joy of wearing new clothes.

But you know, my brother liked to wear hand-me-downs.

Correct, kids love their own clothes.

Figure 1: Illustration of NLI Diversity using human responses from DailyDialog++. Contradictions are weighted by 1, entailments by -1, and neutrals by 0, so the score is $(2 \times 1) + (3 \times 0) + (1 \times -1) = 1$.

We propose a new metric aimed at measuring semantic diversity by leveraging a Natural Language Inference (NLI) model to score a set of multiple dialogue model responses for a single conversation, as illustrated in Figure 1. NLI is a three-way classification task to determine whether one sentence entails, contradicts, or is neutral toward a second sentence. We hypothesize that a diverse set of responses for a conversation captures contradictory ways one could respond, which can be measured by the NLI model. We aggregate the contradiction, neutral, and entailment predictions among pairs of

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 85 - 98
July 10-15, 2022 ©2022 Association for Computational Linguistics

responses from the set and combine the predictions into a new diversity metric, called *NLI Diversity*.

We additionally explore two modifications of NLI Diversity. First, because the neutral prediction may be indicative of diversity, we propose Neutral NLI Diversity, where neutral predictions are weighted the same as contradiction predictions. Second, since our Baseline NLI Diversity method does not take into account the *confidence* of the model's prediction, we propose Confidence NLI Diversity, which aggregates the probability mass of the model's predicted class instead of aggregating the number of predictions for each class.

We assess NLI Diversity using Tevet and Berant (2021)'s diversity metric evaluation framework, finding that NLI Diversity is highly correlated both with human judgments of diversity and with the *diversity parameter*, a gold standard diversity value used to generate the set of responses. Confidence NLI Diversity achieves state-of-the-art performance in terms of correlation with semantic diversity. Also, through an ablation study, we find positive, neutral, and negative correlations between human judgments and the number of contradiction, neutral, and entailment predictions, respectively.

We next explore the use of a dialogue model to generate a set of candidate responses with a minimum target level of semantic diversity, such as 10 Contradictions. Our new generation procedure, *Diversity Threshold Generation*, iteratively improves a set of model responses until this intended threshold is reached. If a set of sampled responses does not meet the intended threshold, the lowest-scoring response is thrown out and a new response is sampled until the diversity threshold is reached. We show this procedure results in a more diverse set of responses than the original sampled set, often with only a few resampled responses. Results of automated analysis shows relevancy is maintained from initial to final sets of responses.

In summary, our contributions are:

- A novel diversity metric, NLI Diversity, evaluated using Tevet and Berant (2021)'s framework, that measures semantic diversity and interrogates the relationship between Contradiction and Neutral predictions and diversity,
- Confidence NLI Diversity, a diversity metric which obtains state-of-the-art performance on semantic diversity,
- A new dialogue generation procedure, Diversity Threshold Generation, which continues sampling responses until an intended diversity threshold, defined using NLI Diversity, is reached,
- Experimental results indicating dialogue models are able to generate diverse responses using Diversity Threshold Generation with minimal loss in relevancy.

2 Related Work

Past work has explored lexical and semantic diversity metrics as well as ways of evaluating these metrics. We also draw from work in NLI and generating diverse sets of hypotheses.

2.1 Measuring Model Response Diversity

Traditionally, a model's diversity has been measured in terms of its predictions over the test set (Li et al., 2016), which we call *Test Set Diversity*. In this setup, the model predicts one response for each conversation in the test set (containing n conversations), resulting in n predictions. The diversity measure is computed over these n predictions, resulting in a score over the entire test set.

The notion of diversity we investigate, however, measures the model's ability to generate a *set* of responses for a single conversation (Zhang et al., 2019; Tevet and Berant, 2021), which we call *Multi-Response Diversity*. Instead of generating one response for each of the conversations in the test set, we evaluate a model's ability to generate m responses for each of the n conversations.

As shown by Tevet and Berant (2021), metrics which have been proposed in the *Test Set Diversity* setting can still be applied in the *Multi-Response Diversity* setting, however, by treating each set of m responses as its own "test set" and averaging over the n total sets.

2.2 Diversity Metrics

Lexical diversity metrics measure differences in word choice, as opposed to diversity of content. Li et al. (2016) propose *distinct-n*, which measures the number of unique n-grams generated divided by the total number of n-grams generated in the *Test Set Diversity* setting. Some past work has applied this metric to the *Multi-Response Diversity* setting (Tevet and Berant, 2021). Cao and Clark (2017) propose examining the percent of unique *responses* over the test set. Other past work has proposed using BLEU score over a set of model responses in the *Test Set Diversity* setting (Zhu et al., 2018).

Semantic diversity metrics, on the other hand, compare diversity of the content present in each response. Many of these measures are adapted from semantic similarity scores, since lower similarity can indicate higher diversity (Tevet and Berant, 2021). BERTScore measures the similarity of BERT embeddings for each token in two sentences (Zhang et al., 2020a). Bert-STS assigns a score based on the semantic similarity of two sentences (Tevet and Berant, 2021). The Sent-BERT metric computes cosine similarity between BERT sentence embeddings (Reimers and Gurevych, 2019). Larson et al. (2019) propose identifying diverse paraphrases by identifying embedding outliers.

Other past work has used human evaluation to measure a model's diversity. Li et al. (2016) ask humans to choose the better of two responses based on specificity to the past conversation. See et al. (2019) ask humans to rank dialogue responses on a variety of factors, including interestingness and inquisitiveness. Tevet and Berant (2021) compare participants' ability to judge diversity of a set of responses in two ways: (i) by ranking one response as more diverse than a second response and (ii) by judging the diversity of a single response on a Likert scale, finding that participants were equally able to judge diversity in both conditions. They also find that human judges are better at distinguishing semantic diversity than lexical diversity.

Other past work has incorporated diversity metrics into the dialogue dataset creation pipeline. Stasaski et al. (2020) propose a method which measures the diversity of a crowdworker's contributions compared to a corpus, using that information to determine when to stop collecting data from the worker. This results in a more diverse dataset.

2.3 Evaluation of Diversity Metrics

Tevet and Berant (2021) propose a framework to examine the reliability of diversity metrics. They propose the notion of a *diversity parameter*, which is used to generate a set of model responses, e.g., the p-value in nucleus sampling, which specifies the vocabulary probability distribution cutoff used to restrict sampling to the most-likely words whose combined likelihood $\geq p$. If p is higher, the set of responses should have higher diversity, and vice-versa. This *diversity parameter* is treated as a gold standard for a set of responses' diversity. Diversity metrics assign scores in the *Multi-Response Diversity* condition and are evaluated in terms of correlation to the diversity parameter. They further propose two datasets to evaluate diversity metrics: one which includes model responses and contains varying levels of lexical diversity and one which is human-created and maintains high lexical diversity to allow focused evaluation of semantic diversity.

2.4 Natural Language Inference

Natural Language Inference is a task aimed at predicting whether one sentence contradicts, entails, or is neutral towards a second sentence. Models for NLI are typically trained using one of two datasets: Stanford Natural Language Inference (SNLI) (Bowman et al., 2015) or Multi-Genre NLI (MNLI) (Williams et al., 2018). More recent datasets include FEVER (Thorne et al., 2018; Nie et al., 2019), adapted from a fact-checking dataset, and ANLI (Nie et al., 2020), collected in an adversarial human-in-the-loop procedure. With the rise of transformer architectures, models have achieved high performance on NLI tasks (Liu et al., 2019).

In a dialogue setting, NLI has been used to improve *consistency* between a persona and model responses over the course of a conversation by integrating an NLI-based reward into a reinforcement learning training procedure (Song et al., 2020).

To our knowledge, however, NLI has not been used to measure the diversity of model responses in either the *Test Set Diversity* or the *Multi-Response Diversity* setting.

2.5 Generating Diverse Sets of Hypotheses

While work has only recently begun to explore the task of generating multiple *dialogue* responses to a conversation (Zhang et al., 2019; Tevet and Berant, 2021), past work has explored generating diverse sets of hypotheses in some other application areas. Carbonell and Goldstein (1998) explored using Maximal Mutual Relevance to reduce redundancy without sacrificing relevancy in document selection for summarization. Batra et al. (2012) proposed a greedy iterative algorithm to generate diverse, probable hypotheses for multiple vision tasks. Most related to our work is Gimpel et al. (2013), which applied Batra et al. (2012)'s approach to machine translation, generating a *set* of translations instead of a single translation. In contrast to Gimpel et al. (2013), by holding the sampling procedure constant throughout the iterative process, our method can explore the extent to which diversity can be increased without altering standard decoding practices.

3 NLI Diversity Metric

We propose three diversity metrics in the *Multi-Response Diversity* setting which leverage the predictions of an NLI model. Two metrics (Baseline and Neutral) aggregate the NLI model's class predictions and one metric (Confidence) aggregates the weight of these predictions.

3.1 Baseline NLI Diversity

We propose a new metric, called *Baseline NLI Diversity*, which uses an NLI model's predictions to measure diversity. More formally, for a given conversation, c, and a dialogue generation model M, a set of utterances $u_1, ..., u_n$ is produced by the model. Each pair of utterances is compared in both directions using an NLI model, $NLI(u_1, u_2), NLI(u_2, u_1), ..., NLI(u_n, u_{n-1})$.

The NLI model predicts a distribution over the three potential classes: contradiction, neutral, and entailment. We take the argmax over these classes, resulting in a list of NLI predictions, $NLI_{preds}(NLI(u_1, u_2), ..., NLI(u_{n-1}, u_n))$ of size $n(n-1)$. To produce an overall diversity score for $NLI_{preds}(u_1, ..., u_n)$, we assign each of these classes a value representing their diversity, denoted $NLI_{score}(NLI_{preds}(u_1, ..., u_n))$.

We hypothesize that larger numbers of entailment predictions found in a set of model-generated utterances is indicative of a lack of diversity; similarly, larger number of contradiction predictions is indicative of a larger amount of diversity. Because we want a higher value of NLI_{score} to indicate higher diversity, we assign values as:

$$NLI_{score} = \begin{cases} 1 & \text{if contradiction} \\ 0 & \text{if neutral} \\ \text{-1} & \text{if entailment} \end{cases}$$

The sum of the NLI_{score} values for the set of utterances results in the final NLI Diversity score, formally defined as:

$$Baseline\ NLIDiversity = \sum_{u_i, u_j \in u_1, ..., u_n} NLI_{score}(NLI_{pred}(NLI(u_i, u_j))$$

While the Baseline NLI Diversity metric aggregates all classes, we also investigate the separate number of entailment, contradiction, and neutral predictions in NLI_{preds}, denoted # Entailment, # Contradiction, and # Neutral, respectively.

3.2 Neutral NLI Diversity

Our primary hypothesis is that contradictions indicate diversity and entailments indicate lack of diversity. Because it is unclear what the role of neutrals might be, we explore a version of NLI Diversity which weights neutral and contradiction predictions as equally diverse. This metric is the same as Baseline NLI Diversity except the NLI_{score} used to assign values is:

$$NLI_{score\_neutral} = \begin{cases} 1 & \text{if contradiction} \\ 1 & \text{if neutral} \\ \text{-1} & \text{if entailment} \end{cases}$$

3.3 Confidence NLI Diversity

Because the prior two NLI Diversity metrics do not incorporate the confidence of the NLI model's class predictions, we explore an additional metric which incorporates this value. Letting $conf_{class}(u_1, u_2)$ represent the model's probability mass assigned to the predicted NLI $class$ after $softmax$, the function is defined as: $NLI_{score\_confidence} =$

$$\begin{cases} 1 \times conf_{con}(u_1, u_2) & \text{if contradiction} \\ 0 & \text{if neutral} \\ \text{-1} \times conf_{ent}(u_1, u_2) & \text{if entailment} \end{cases}$$

Intuitively, instead of assigning a 1 value for a contradiction prediction, this metric assigns the probability of the contradiction class. Likewise, instead of a -1 for an entailment prediction, this metric assigns the negative probability mass of the entailment class.

4 Evaluation of NLI Diversity

We evaluate NLI Diversity by computing the correlation between the metric and both human labels and *diversity parameter* labels. Below we first describe the models and data and then present the results of the evaluation.

4.1 Models

We explore two NLI models: a Roberta-large model (Liu et al., 2019) fine-tuned on the Multi-Genre NLI (MNLI) Corpus (Williams et al., 2018)[1] and a Roberta-large model fine-tuned on a combination of MNLI, SNLI, FEVER, and ANLI[2], both

---

[1] `https://huggingface.co/roberta-large-mnli`

[2] `https://huggingface.co/ynie/roberta-large-snli_mnli_fever_anli_R1_R2_R3-nli`

decTest	Mixed Lexical Diversity; Mixed Semantic Diversity; Model Generated
Examples:	
temp 0.28	“I think he is the most awesome guy ever” “He is the most awesome guy ever”
temp 0.55	“The unemployment rate is lower than what it is” “No but it does make it more likely to be higher than what it is”

conTest	High Lexical Diversity; Mixed Semantic Diversity; Human Generated
Examples:	
high lexical and low semantic	“Sorry, but I don’t agree.” “I think you are wrong about that.”
high lexical and high semantic	“Dont be so judgemental, try to see things her way.” “You are right that is insane.”

Table 1: Descriptions of diversity datasets from Tevet and Berant (2021). Corresponding temperature parameter (higher is more diverse) or semantic and lexical diversity levels accompany each example.

containing 300M parameters. We refer to these models as *NLI Diversity – MNLI* and *NLI Diversity – Combined*, respectively. We do not employ additional fine-tuning of these models.

4.2 Data

There are two different English datasets released to evaluate diversity metrics in Tevet and Berant (2021): *conTest* and *decTest*, described in Table 1. The *conTest* dataset is human-created and captures *content*, or *semantic*, diversity independent of *lexical* diversity. Low-diversity examples in this dataset have high lexical diversity but low semantic diversity. This dataset was created by asking crowdworkers to generate sets of utterances with either low or high *semantic* diversity using varied language, in order to keep a high level of *lexical* diversity constant across both conditions.

The *decTest* dataset includes model-generated responses, with diversity controlled by a decoding parameter, such as a temperature parameter. The dataset can include duplicate responses, and does not attempt to mediate lexical diversity; therefore, low-diversity examples in this dataset may reflect *low lexical* as well as *low semantic* diversity.

While the original dataset includes multiple generation tasks, we evaluate on the dialogue task, *respGen*, which is drawn from Reddit conversations (Hashimoto et al., 2019)[3]. There are 200 conversations for each of *conTest* and *decTest* for the *respGen* task, with multiple responses for each conversation (5 for *conTest*, 10 for *decTest*).

4.3 Diversity Parameter Correlation

The *diversity parameter* from Tevet and Berant (2021) represents either a parameter directly used to generate responses via a dialogue model, such as p in nucleus sampling, or a binary value indicating whether crowdworkers were instructed to generate a high- or low-diversity set of responses. A measure which is able to capture diversity will be positively correlated with this diversity parameter.

Table 2 shows Spearman’s correlations between NLI Diversity and the diversity parameter. On the *conTest* semantic diversity dataset, Confidence NLI Diversity achieves the highest correlation of all metrics (0.62) and approaches human performance. Baseline NLI Diversity performs comparably to the top-performing automatic metric from Tevet and Berant (2021), at 0.59 correlation. We note the 95% confidence intervals overlaps between Baseline NLI Diversity, Confidence NLI Diversity, Sent-BERT, and human judgements, indicating a lack of significant differences (see Appendix A). Although Neutral NLI Diversity does relatively poorly on *conTest* (0.24), it is the highest-performing NLI metric on *decTest* (0.72), suggesting that incorporating neutral predictions may capture lexical instead of semantic diversity.

A histogram of Confidence NLI Diversity values for low and high semantic diversity sets of responses is shown in Figure 2. We note the lack of large overlap between the distributions of low and high semantic diversity data. In addition to

---

[3] In the data released from Tevet and Berant (2021), these files are called con_test_200_with_hds_resp_gen.csv and dec_test_200_with_hds_resp_gen.csv for *conTest* and *decTest*, respectively.

Metric	decTest ρ	conTest ρ
Human Performance (absHDS)	**0.81**	**0.63**
distinct-n	**0.89**	0.34
cos-sim	**0.89**	0.33
BERT-STS	0.81	0.46
Sent-BERT	0.80	0.59
BERTScore	0.87	0.49
Baseline NLI Diversity – MNLI	0.58	0.59
Baseline NLI Diversity – Combined	0.39	0.59
Neutral NLI Diversity	0.72	0.24
Confidence NLI Diversity	0.44	**0.62**

Table 2: Spearman's ρ correlations between NLI Diversity metrics and the diversity parameter. Results above the double line are reproduced from Tevet and Berant (2021). Both the best automatic metric and human performance for each dataset are in boldface.

the correlation results in Sections 4.3 and 4.4, this result indicates the Confidence NLI Diversity metric distinguishes between low and high semantic diversity.

The higher correlation to the diversity parameter leads us to choose NLI Diversity - MNLI instead of Combined for all further experimentation.

4.4 Human Correlation

In this subsection, we examine the NLI Diversity metric's correlation to the human annotations collected by Tevet and Berant (2021). Each set of responses in *conTest* and *decTest* is scored by 10 annotators from 1 (not diverse at all) to 5 (very diverse) with half-point increments. We compute correlation with respect to the averaged rating.

In addition to NLI Diversity, we explore the prediction counts for each category. We expect that a higher # Entailment value will be negatively correlated with diversity because the more pairs of responses that entail each other, the more similar the set of responses is. Similarly, we expect that a higher # Contradiction value will be positively correlated with diversity. Since the NLI Diversity metric incorporates both # Entailment and # Contradiction, we would expect this metric to be highly correlated with human judgments as well.

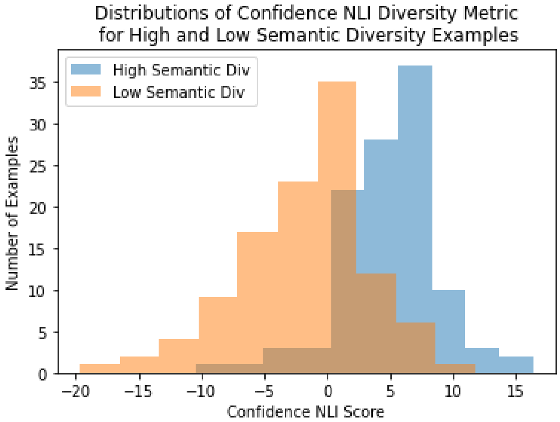


Figure 2: Histogram of Confidence NLI Diversity for high and low semantic diversity examples.

Metric	decTest ρ	conTest ρ
Baseline NLI Diversity	0.48	0.63
Neutral NLI Diversity	**0.69**	0.40
Confidence NLI Diversity	0.41	**0.64**
# Contradiction	0.26	0.46
# Neutral	0.05	–0.08
# Entailment	–0.48	–0.65

Table 3: Spearman's ρ correlation between NLI Diversity metrics (MNLI) and human judgments. Negative values indicate higher # Entailment is *negatively* correlated with diversity.

Spearmean's ρ rank correlation results between our metrics and the human diversity scores are shown in Table 3. The highest-performing correlation for lexical diversity is the Neutral NLI Diversity (0.69). The highest-performing semantic diversity correlation is Confidence NLI Diversity (0.64). Additionally, Baseline and Confidence NLI Diversity correlations are stronger when evaluating with the *conTest* dataset than the *decTest* dataset (an increase of 0.48 to 0.63 for Baseline MNLI and 0.41 to 0.64 for Confidence NLI), indicating these metrics are more correlated with human ratings of semantic diversity than lexical diversity.

Across both datasets, # Entailment is negatively correlated with diversity, # Neutral does not have a strong correlation, and # Contradiction is positively correlated, as hypothesized. This supports our motivation to use NLI as a diversity metric.

5 Diversity Threshold Generation

We have verified that NLI Diversity is both able to capture semantic diversity and aligns with human judgements. We can additionally use NLI Diversity to define a straightforward desired diversity threshold, div_{thresh} for a set of model-generated responses, $u_1, ..., u_n$. For example, we might intend there to be 10 Contradictions within the set. We propose a generation procedure, Diversity Threshold Generation, designed to iteratively increase the diversity of a set of responses for a conversation.

For a conversation, Diversity Threshold Generation begins by sampling n responses. We score the diversity of these responses using a diversity metric, $div\_metric(u_1, ..., u_n)$. If the diversity score falls above div_{thresh}, the process is finished.

If, however, the score falls below div_{thresh}, we identify the model response which contributes *least* to the diversity score by calculating $div\_metric(u_1, ..., u_{n-1})$ for each sub-group of model responses of size $n - 1$. We discard the model response not present in the highest-scoring subgroup and resample a new response. We re-calculate $div\_metric(u_1, ..., u_n)$ and if $div\_metric(u_1, ..., u_n) > div_{thresh}$, the process finishes. We continue resampling until the maximum cutoff of S is reached.

6 Evaluation of Diversity Threshold Generation Method

6.1 Models and Datasets

We experiment with two neural dialogue models, DialoGPT (700M parameters) (Zhang et al., 2020b)[4] and BlenderBot 1.0 (300M parameters) (Roller et al., 2021)[5]. We use the default Transformers implementation for each model (Wolf et al., 2020) and do not fine-tune them. Runtime was between 3 and 36 hours on one Titan-X GPU.

All experiments involve the dialogue model M generating 5 responses for each conversation. The maximum number of samples, S, is set to 20. All experiments are averaged over 10 trials for stability.

We evaluate each model on the development set of two public English conversational datasets : DailyDialog++ (1,028 conversations) (Sai et al., 2020; Li et al., 2017) and EmpatheticDialogues (2,763 conversations) (Rashkin et al., 2019). DailyDialog++ includes 5 human-written responses per conversation, allowing for multi-reference comparison. We split each EmpatheticDialogues conversation at a random turn (consistent for all experiments) for generation. Since BlenderBot supports up to 128 positional embeddings, we pass in the last 128 tokens of the conversation for this condition.

6.2 Metrics

We evaluate three diversity metrics: two semantic diversity metrics, Baseline NLI Diversity (Section 3) and Sent-BERT (Reimers and Gurevych, 2019; Tevet and Berant, 2021), and one lexical diversity metric, distinct-n (Li et al., 2016; Tevet and Berant, 2021). For Sent-BERT, we compute the average negative cosine similarity between BERT sentence embeddings for each pair of responses. Like Tevet and Berant (2021), for distinct-n, we compute the average distinct n-grams from $n \in 1, 2, 3, 4, 5$.

Because Baseline NLI Diversity is more human-interpretable than Confidence NLI Diversity, we use this version for experimentation. For all NLI Diversity experiments, div_{thresh} is achieved when # Contradictions is greater than 10 out of a total of 20 pair-wise comparisons. For both Sent-BERT and distinct-n, however, we do not have a human-specifiable threshold. We use empirical thresholds measured from the sets of 5 human responses for each conversation in DailyDialog++. We choose the 90th percentile for div_{thresh} (0.98 and -0.179 for distinct-n and Sent-BERT, respectively).

We decode using nucleus sampling (p = 0.9), as it has been shown to increase response diversity (Holtzman et al., 2020). However our method could be applied with other decoding procedures.

In order to robustly evaluate Diversity Threshold Generation, we measure both (i) whether Diversity Threshold Generation is able to generate more diverse sets of responses than was originally sampled and (ii) whether the increased diversity comes at the expense of decreased *relevancy* of the responses.

6.3 Diversity Results

We aim to measure whether the diversity of the 5 responses from M increases using Diversity Threshold Generation, compared to the initial 5 sampled responses. Diversity of the starting and ending sets of utterances is measured by Baseline NLI Diversity, distinct-n, or Sent-BERT. We also report the

[5] `https://huggingface.co/transformers/model_doc/blenderbot.html`

Metric	Model	Dataset	Starting Div.	Ending Div.	Num. Sampled
Baseline NLI	DG	Daily	4.11	10.24	6.3
		Emp	3.68	10.11	7.1
	BB	Daily	–5.55	2.51	14.4
		Emp	–8.90	–1.72	16.5
Distinct-n	DG	Daily	0.95	0.98	5.4
		Emp	0.43	0.52	20.0
	BB	Daily	0.61	0.80	20.0
		Emp	0.52	0.71	20.0
Sent-BERT	DG	Daily	–0.26	–0.16	5.2
		Emp	–0.28	–0.16	5.8
	BB	Daily	–0.62	–0.40	19.0
		Emp	–0.71	–0.52	19.7

Table 4: Diversity results of using Diversity Threshold Generation (with a div_{thresh} of 10 # Contradictions for NLI, 0.98 for distinct-n, and -0.164 for Sent-BERT). Num. sampled has a maximum value of 20; DG is the DialogGPT model; BB is BlenderBot.

number of sampled utterances required to reach div_{thresh}.

Results for Diversity Threshold Generation are shown in Table 4. For every condition, we see an increase from starting to ending diversity; for NLI Diversity, this results in an average 137% increase. For most conditions, distinct-n requires more samples than Sent-BERT and Baseline NLI Diversity.

We can use the results of Diversity Threshold Generation to probe differences in the models. In our experimental setup, DialoGPT generates more diverse utterances across all conditions than BlenderBot. The models change by similar proportions from starting to ending diversity using the NLI metric. However, the starting diversity for BlenderBot is far lower than DialoGPT; the negative value for BlenderBot indicates that a large number of entailment predictions were present in the starting response set.

We can also examine differences between the datasets. For instance, we observe lower starting diversities for the Empathetic Dialogues dataset than for DailyDialog++ for both models. Additionally, the number of samples required for EmpatheticDialogues is consistently higher than for DailyDialog++. This is likely because div_{thresh} for both datasets was calculated using human responses from DailyDialog++, since EmpatheticDialogues does not include multiple human responses.

Sampled responses can be seen in Appendix B and results reporting the average overlap from starting to ending sets of responses is in Appendix C. Appendix D includes results using beam search instead of nucleus sampling, and Appendix E reports the stability of Diversity Threshold Generation.

6.4 Relevance Results

Since past work has documented a tradeoff between diversity and relevancy (Zhang et al., 2018), we also report results for the *relevancy* of the starting and ending sets of responses for Diversity Threshold Generation. We use two established relevancy metrics: BLEU Score (Papineni et al., 2002)[6] and BERTScore (Zhang et al., 2020a)[7]. We show results on DailyDialog++, which has multiple human-generated responses for comparison, which is more correlated to human judgements than single-reference evaluation (Gupta et al., 2019).

Results are shown in Table 5. The key takeaway is that the relevancy values remain virtually unchanged when using the Diversity Threshold Generation procedure, according to both BLEU score and BERTScore. The average percent difference is 0.08% for BertScore and 1.1% for BLEU.

7 Discussion

Limitations. While NLI Diversity is highly-correlated with human judgements of diversity, it is limited by the NLI model chosen. Compared to Sent-BERT, the dataset used to train the NLI model is limited in scope. While our experiments showed that an NLI model trained on more datasets (Combined) did not perform better than MNLI, future work can more explicitly explore the effect of more generalized data on NLI Diversity.

This work is limited by automatic evaluation metrics for diversity and relevance. Future work should conduct additional human validation of model responses. More work could also be done to examine cases where the model was not able to generate diverse set, such as when humans also find creating a diverse set of responses difficult.

Future Work. Our results showed Confidence NLI Diversity was highly correlated with both

	BB	0.868	0.867	0.366	0.366

Table 5: Results comparing starting and ending sets of responses from Diversity Threshold Generation to sets of human responses using two relevancy metrics, BERTScore and BLEU score.

human judgements and the diversity parameter, achieving state-of-the-art performance on a semantic diversity dataset. The ablation study deepened this finding, showing that NLI contradiction predictions are especially correlated with diversity. Future work can leverage this finding, e.g., by wording crowdworker instructions to ask for generation *contradictory*, rather than *diverse*, responses.

Our results also show that dialogue generation models are able to improve the diversity of a sampled sets of responses using Diversity Threshold Generation. Diversity Threshold Generation can be used to evaluate future models' capacity to generate multiple diverse responses.

Future work should compare the resulting diverse responses in a conversational context. Studies could be conducted where chatbot users or dialogue writers can choose the way they want the model to respond, similar to Clark and Smith (2021).

8 Conclusion

We propose a novel semantic diversity metric, NLI Diversity, which is highly correlated to human judgments. Confidence NLI Diversity achieves state-of-the-art results on measuring semantic diversity. We propose Diversity Threshold Generation to incentivize production of diverse sets of responses for a conversation. This results in more diverse sets of responses than originally sampled for multiple models, datasets, and metrics while maintaining relevancy, and can also be used to investigate a model's ability to produce diverse responses.

Table 6: Average utterance overlap from starting to ending set of responses using Diversity Threshold Generation on multiple models, datasets, and diversity metrics.

A Confidence Interval Analysis

We perform experimentation using bootstrapping to determine confidence intervals for *conTest* correlations to the diversity parameter. We sample a dataset of 110 elements (50% of the original *conTest* dataset's size) from *conTest* with replacement and compute corresponding Spearman's correlation values using the sampled dataset for Sent-BERT, Baseline NLI Diversity, Confidence NLI Diversity, and human judgements. We repeat this process 1,000 times for stability and calculate 95% Confidence Intervals. The full *conTest* correlation value plotted with these intervals can be seen in Figure 3. While the Confidence Interval values overlap between all 4 conditions, the Confidence NLI Diversity distribution closely matches the human distribution.

B Sampled Responses

Table 7 shows randomly-sampled examples from the DailyDialog++ dataset, created using Diversity Threshold Generation with the DialoGPT model and NLI Diversity as the intended div_metric.

C Average Utterance Overlap

We measure the number of utterances which occur in both the starting and ending sets of responses, called utterance overlap. A high utterance overlap represents a set of responses which did not need to be significantly changed to reach div_{thresh}. For example, an utterance overlap of 4 indicates that only 1 response needed to be resampled (potentially multiple times) from the starting set to reach div_{thresh}. Results are seen in Table 6. Keeping in mind that higher Average Overlap indicates less resampling was needed, we note higher overlap for DialoGPT than BlenderBot 1.0 (with the exception of distinct-n and EmpatheticDialogues).

D Beam Search

We evaluate beam search's ability to generate diverse utterances using Diversity Threshold Generation for DailyDialog++ and NLI Diversity. To compare nucleus sampling to beam search, we generate 25 beams and consider these responses from most to least probable, i.e. if the 5 most likely beams do not satisfy the diversity threshold, we remove the lowest-scoring beam and replace it with the 6th most likely beam. We find the starting NLI Diversity for beam search is -5.05, the ending diversity is 5.35, and an average of 10.97 sampled utterances is required. While the NLI Diversity does improve from the starting to ending set of responses, beam search has a much lower ending diversity than nucleus sampling. While past work has confirmed that nucleus sampling is more *lexically diverse* than beam search using Self-BLEU (Holtzman et al., 2020), our results confirm that nucleus sampling is also able to generate more *semantically diverse* utterances.

E Stability of Procedure

We investigate the stability of Diversity Threshold Generation by measuring the number of samples

Context	Starting Responses	SD	Ending Responses	ED
Speaker 1: Am I too abrupt? Did I scare you? Or you don't want ... **Speaker 2:** No! I have been expecting this moment for a long time . I mean my answer is' yes'. **Speaker 1:** Oh, I'm so happy . I'm interested in your advice.	• I was in a discussion on the internet with a bunch of people. • I've sent you a private message, so if you have any questions or feel like you could use the resources, feel free to send them my way. • Are you an American citizen? • If you have any specific questions about it, I'm happy to answer them. • I'll be in touch!	3	• Are you an American citizen? • I'll be in touch! • Would you like to hear something about the business side of things? • I'd like to recommend you to look at the application, there are lots of important things about it.It.does.nothing to prove anything to you. • You are so adorable. I love that.	10
Speaker 1: Okay, I ' ll take it . By the way, do you have delivery service? **Speaker 2:** You don ' t need to carry the furniture home because we have delivery service. **Speaker 1:** Do you charge for delivery?	• What do you have to worry about? We deliver everything. We take a percentage for any delivery charges. • You can have free shipping if you want • I have a 5 dropoff fee that I pay for. • In the beginning • No. We just get it for free.So, no.	9	• What do you have to worry about? We deliver everything. We take a percentage for any delivery charges. • You can have free shipping if you want • I have a 5 dropoff fee that I pay for. • No. We just get it for free.So, no. • No, there is no charge. I have never actually met the person who bought it.	14

Table 7: Starting and ending responses with corresponding NLI Diversity for DialoGPT, randomly sampled from the DailyDialog++ dataset. SD = Starting NLI Diversity; ED = Ending NLI Diversity.

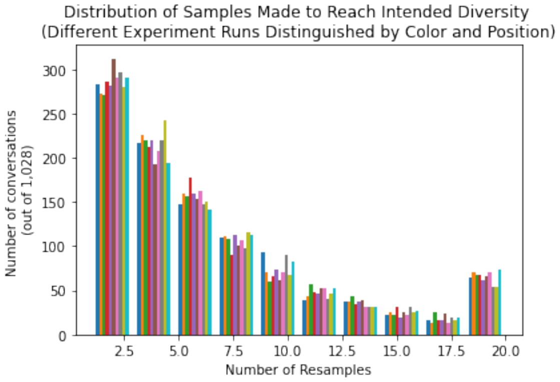

Figure 4: Histogram of number of samples required before reaching intended number of contradictions. Each bar color represents a different run of the experiment.

required before reaching div_{thresh} across multiple runs of the experiment. We present results for NLI Diversity, DailyDialog++, and DialoGPT and observe similar trends across all other conditions.

Figure 4 reports the number of resampled utterances required before reaching the intended number of contradictions. Each bar color represents a different run of the experiment. We do not observe a large difference in number of resamples required between runs of the same condition, indicating that the method is stable. The last bucket contains sets of responses which reached the maximum number of samples, $S = 20$, indicating div_{thresh} could not be reached.

LEA: Meta Knowledge-Driven Self-Attentive Document Embedding for Few-Shot Text Classification

S. K. Hong and **Tae Young Jang**
Samsung SDS, ML Research Center
`{s.k.hong, tae10.jang}@samsung.com`

Abstract

In recent years, NLP has advanced greatly along with the proliferation of pre-trained language models. The pre-trained language models are also properly adapted to downstream tasks when there is sufficient labeled data. However, in real-world applications, we often encounter the deficiency of labeled data. When only given a few instances for a new task, extracting task-aware features from a pre-trained language model regardless of the adaptation is a promising alternative. In the study, we propose a novel embedding transfer method, called LEA, for leveraging pre-trained language models with even only few-shot instances. LEA derives meta-level attention aspects using our new meta-learning framework. We evaluate our method on five text classification benchmark datasets. The results show that the novel method robustly provides the competitive performance compared to recent few-shot learning methods.

1 Introduction

A deficiency of supervised data is often experienced in real-world NLP applications. Few-shot learning aims to yield an AI-driven NLP model capable of recognizing unseen tasks using a few labeled data. Meanwhile, fine-tuning pre-trained models (PTMs) (Howard and Ruder, 2018; Devlin et al., 2019; Lan et al., 2019; Liu et al., 2019) has been the most successful approach in recent years of NLP. Unfortunately, it is still challenging to utilize PTMs (Lee et al., 2019) in few-shot learning.

To address this subtle problem (Sun et al., 2019), we propose a meta-knowledge driven self-attentive embedding transfer method, called LEA (*LEarning-to-Attend*), based on a novel meta-learning framework, through which meta-level attention aspects are derived by encoding how to attend for given tasks. LEA is an efficient and practical method that facilitates the utilization of large-sized PTMs in few-shot learning.

There are the two common transfer learning paradigms in NLP: feature-based transfer (Cer et al., 2018) and fine-tuning (Houlsby et al., 2019). Our approach belongs to the feature-based transfer.

LEA includes two key ideas: (1) construction of a meta-level attention aspects dictionary and (2) inference of the task-specific attention aspects upon the arrival of a new task. The former is a process by which useful meta-level attention aspects across tasks are derived based on a particular PTM via our meta-learning framework. The latter refers to as a task-adaption process, where a subset of task-specific attention aspects is inferred by determining the top-k most relevant attention aspects from the meta-level attention aspects dictionary. While LEA can be applied to a wide variety of downstream tasks, we demonstrate LEA on few-shot text classification problems in the paper.

2 Related Work

Few-shot text classification: In (Geng et al., 2019), INDUCTION is proposed to build class-wise embedding to represent each class using a particular dynamic routing algorithm coalesced with meta-learning. In (Bao et al., 2019), DS is introduced to keep track of underlying word distributions across all available classes and to specify important lexical features for new classes.

Meta-learning: As a metric learning-based method, (Snell et al., 2017) suggested a deep neural network, called a prototype network (PROTO), through which class representations are composed using a learning similarity metric for members of the same class. In (Sung et al., 2018), similar to PROTO, a deep neural network, called a relation network, is proposed to learn a non-linear distance metric rather than the Euclidean distance. In addition, LEO (Rusu et al., 2018) learns a low-dimensional latent embedding of the model parameters such that the classifiers are generated from the latent space into which the tasks are mapped. Frog-

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 99 - 106

GNN (Xu and Xiang, 2021) focuses on all query-support pairs and proposes a multi-perspective aggregation based graph neural network to explicitly reflect intra-class similarity and inter-class dissimilarity.

3 Background

3.1 Problem Setup

Few-shot text classification is a task in which a classifier must be adapted to accommodate new classes using only a few labeled examples. In the literature, this is called a C-way K-shot problem in which K-labeled examples are given for each of the C number of classes. In a meta-learning setting, tasks are divided into a meta-training set ($\mathcal{S}^{tr}$), meta-validation set ($\mathcal{S}^{val}$), and meta-test set ($\mathcal{S}^{test}$) as disjoint sets of classes.

3.2 Model-Agnostic Meta-Learning

Our proposed meta training strategy follows the overall procedure of optimization-based meta-learning (Finn et al., 2017). For a parametric model f_θ, MAML seeks to find task-specific parameters θ_i for any new task τ_i sampled from a particular distribution of tasks. For a particular task $\tau_i \sim p(\tau)$, the task data $\mathcal{D}_{\tau_i}$ consist of $\mathcal{D}_{\tau_i}^{tr}$ and $\mathcal{D}_{\tau_i}^{val}$ during the meta-training phase. MAML alternates between two update processes during meta-training: (1) task-adaptation and (2) meta-optimization.

Task adaptation (or *inner update*): Each task learner updates its own parameters through a gradient descent using the loss evaluated based on its own training data $\mathcal{D}_{\tau_i}^{tr}$ with the initial parameter θ_m given by the outer meta-optimization process. The task-adaptation process is formulated as in Equation 1.

$$\theta_{\tau_i}^{'} \leftarrow \theta_m - \alpha \, \nabla_{\theta_m} \mathcal{L}_{\tau_i}\left(f_{\theta_m}, \mathcal{D}_{\tau_i}^{tr}\right), \qquad (1)$$

Meta-optimization (or *outer update*): The meta-learner updates its parameters through a gradient descent using the loss evaluated by $\mathcal{D}_{\tau_i}^{val}$ with respect to the task-specific parameters $\theta_{\tau_i}^{'}$. The meta-optimization process is formulated as in Equation 2:

$$\theta_m \leftarrow \theta_m - \beta \, \nabla_{\theta_m} \sum_{\tau_i \sim p(\tau)} \mathcal{L}_{\tau_i}\left(f_{\theta_{\tau_i}^{'}}, \mathcal{D}_{\tau_i}^{val}\right), \quad (2)$$

where $\mathcal{L}_{\tau_i}$ denotes a loss function for a task τ_i, and the inner and outer updates are applied through their own standard gradient descent with fixed learning rates α and β, respectively, which are given as hyperparameters.

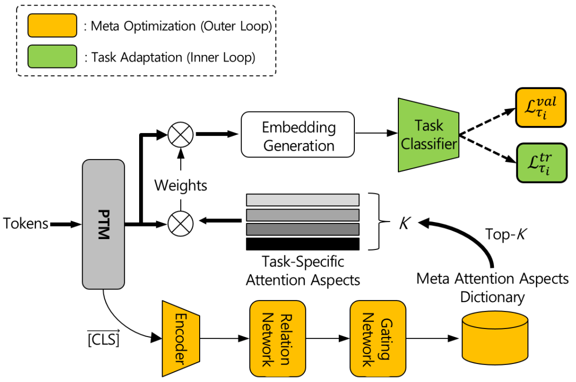

Figure 1: The overall architecture of LEA.

In the meta-testing phase, the meta-learner provides the initial parameters for task-specific model learners. Subsequently, each task learner is individually tailored to find the optimal parameters $\theta_{\tau_i}^{'}$ by applying the above task adaptation process. In this meta-testing, the dataset of task τ_i is given as $\mathcal{D}_{\tau_i} = \left(\mathcal{D}_{\tau_i}^{tr}, \mathcal{D}_{\tau_i}^{te}\right)$.

3.3 Pre-Trained Models

We conducted all experiments with BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019) as the underlying PTMs in the study. Given a text input, a dummy token (CLS) is added to the beginning of the input, and another token (SEP) is added to the end of a sentence. The PTMs end up with providing the corresponding embedding vectors (i.e., denoted as [CLS] and [SEP]) for the artificial tokens as well as embeddings for original tokens for the input text. For downstream classification tasks, the special embedding vector [CLS] is typically used to make a prediction as the representative of an text instance. In this study, the [CLS] vector plays an important role in probing the distinctive properties for an incoming task. In manufacturing a task-specific embedding, we especially utilize the token-level output embeddings of the individual tokens of the jth text instance under a particular task τ_i, which we denote as $H_j^{\tau_i} = [h_{j,1}^{\tau_i}, \ldots, h_{j,L}^{\tau_i}]$. Likewise, the corresponding [CLS] embedding is denoted as $c_j^{\tau_i}$.

4 Proposed Method

The overall architecture of LEA is shown in Figure 1. It represents our meta learning framework for the task-specific feature extraction. It is trained in an end-to-end manner using our proposed meta-learning strategy. The meta training alternates two

Algorithm 1 Our Proposed Meta-Training

    Perform gradient step w.r.t $\phi$
    $\phi \leftarrow \phi - \beta \nabla_\phi \sum_{\tau_i} \mathcal{L}_{\tau_i}^{val}\left(f_{\theta'_{\tau_i}}, \mathcal{E}_{\tau_i}^{val}\right) + \lambda \cdot \Omega$
end while
```

processes: (1) deriving all valid meta-attention aspects across tasks (namely, *meta-optimization*), and (2) choosing a task-specific subset from all the meta-attention aspects for each task (called, *task adaptation*). The high-level operation is described in Algorithm 1.

4.1 Meta Attention Aspects Dictionary

In this study, the meta-level knowledge dictionary maintains all attention aspects derived across tasks $\tau_i \sim p(\tau)$. The concept was inspired by (Lin et al., 2017). The meta-attention aspects in the dictionary are established throughout the meta-optimization process during which it seeks to learn how to attend according to the distribution of tasks. Herein, we define a matrix $W_A \in \mathbb{R}^{A_N \times u}$ as the meta-level attention aspect dictionary. In addition, A_N and u are the total number of attention aspects and dimension of the attention aspect, respectively.

4.2 Top-k Attention Aspects Selection through Gate Network

When a novel task τ_i is given, its related attention aspects, denoted by $W_A^{\tau_i}$, are selectively obtained by assigning the corresponding weights to members of the meta-level attention aspects W_A in the *task-adaptation* process. Here, $W_A^{\tau_i} \in \mathbb{R}^{k \times u}$ indicates the selected k attention aspects of the task τ_i. Note that k and K are different in that the former is the number of topmost relevant attention aspects, whereas the latter, indicates as K-shot, refers to the number of samples in few-shot learning. To do so, we assess the relevance of the task among the meta-level attention aspects W_A. First, each task is fed into an encoding process, which is formulated as follows:

$$e_n^{\tau_i} = \frac{1}{NK^2} \sum_{k_n=1}^{K} \sum_{m=1}^{N} \sum_{k_m=1}^{K} f_{\theta_r}\left(f_{\theta_e}(c_{k_n}^{\tau_i}), f_{\theta_e}(c_{k_m}^{\tau_i})\right), \tag{3}$$

where $e_n^{\tau_i}$ is the representative embedding for the particular class n under a given task τ_i, f_{θ_r} indicates the relation network (Sung et al., 2018), and f_{θ_e} is an encoder network that transforms the delegate embedding [CLS] (denoted as $c_j^{\tau_i}$ for the case of the jth text instance of a specific task τ_i) of a text instance in PTMs (Devlin et al., 2019; Lan et al., 2019; Liu et al., 2019). As a result, the class embedding $e_n^{\tau_i}$ is enforced to encode the pairwise relationship with other classes.

Using the aforementioned class embedding, we attempt to selectively (i.e., top-k) collect task-specific attention aspects for a given task by employing a gating mechanism (Shazeer et al., 2017). The gating output vector is calculated through the following formulation:

$$g_n^{\tau_i} = \text{softmax}\left(G(e_n^{\tau_i}; W_g, W_n, k)\right), \tag{4}$$

where $g_n^{\tau_i}$ is the gating output vector whose number of dimensions must be the same as the size of the meta-attention-aspects dictionary. The gating process G produces a sparse output vector by being parameterized with $\{W_g \in \mathbb{R}^{A_N \times A_N}, W_n \in \mathbb{R}^{A_N \times A_N}, k\}$, where the remaining values except for the k elements are forced to become zeros, and the top-k weights are finally generated through a softmax function.

As a result, we can extract the top-k task-specific attention aspects for the task τ_i. This is formulated as follows:

$$W_A^{\tau_i} = ((W_A)^T g_n^{\tau_i})^T. \tag{5}$$

4.3 Task-Specific Self-Attentive Document Embedding

Here, we perform the self-attentive feature extraction using the aforementioned top-k task-specific attention aspects for a task. We then apply it into the generation of document embeddings for text

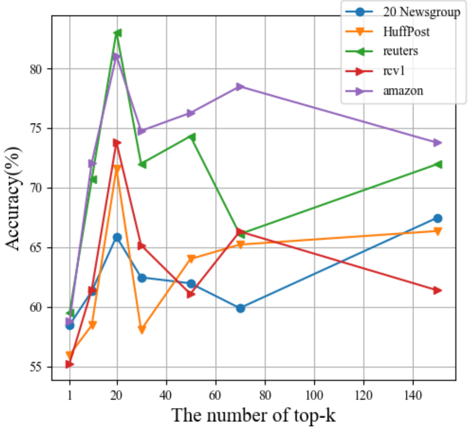

Figure 2: The 5-way 5-shot prediction accuracy depending on the number of top-k attention aspects.

classification. For a text input, we utilize the corresponding embedding vectors for the individual tokens, which are denoted as $H_j^{\mathcal{T}_i} = [h_{j,1}^{\mathcal{T}_i}, \dots, h_{j,L}^{\mathcal{T}_i}]$ for the jth text example of the task $\mathcal{T}_i$. This is formulated as follows:

$$\mathcal{E}_j^{\mathcal{T}_i} = W_A^{\mathcal{T}_i} H_j^{\mathcal{T}_i}, \tag{6}$$

where $\mathcal{E}_j^{\mathcal{T}_i} \in \mathbb{R}^{k \times L}$ is the self-attentive document embedding of the jth input of the task $\mathcal{T}_i$, and $H_j^{\mathcal{T}_i} \in \mathbb{R}^{u \times L}$ is a set of token embedding vectors for the jth instance with L tokens in the task $\mathcal{T}_i$.

For the text classification, we sum $\mathcal{E}_j^{\mathcal{T}_i}$ column-wise and then feed it into a fully connected neural network (denoted as $FC_{\theta'_{\mathcal{T}_i}}$) with the parameters $\theta'_{\mathcal{T}_i}$, which are optimized in the task-adaptation step to make the final predictions.

4.4 Meta-Training Objectives

As noted in Algorithm 1, LEA alternates the following two update steps: (1) task adaptation (or *inner-update*) and (2) meta-optimization (or *outer-update*). The former proceeds as follows:

$$\theta'_{\mathcal{T}_i} \leftarrow \theta'_{\mathcal{T}_i} - \alpha \nabla_{\theta'_{\mathcal{T}_i}} \mathcal{L}_{\mathcal{T}_i}^{tr} \left(f_{\theta'_{\mathcal{T}_i}}, \mathcal{E}_{\mathcal{T}_i}^{tr} \right), \tag{7}$$

where $\theta'_{\mathcal{T}_i}$ indicates the task model parameters, and $\mathcal{L}_{\mathcal{T}_i}^{tr}$ is the classification loss by relying on $\mathcal{E}_{\mathcal{T}_i}^{tr}$ derived from $\mathcal{D}_{\mathcal{T}_i}^{tr}$.

During the meta-optimization step, the groups of parameters $\{W_A, W_g, W_n, \theta_m, \theta_e, \theta_r, \theta_a\}$ are trained in the outer loop with $\mathcal{D}_{\mathcal{T}_i}^{val}$. This is formulated as follows:

$$\phi \leftarrow \phi - \beta \nabla_\phi \sum_{\mathcal{T}_i} \mathcal{L}_{\mathcal{T}_i}^{val} \left(f_{\theta'_{\mathcal{T}_i}}, \mathcal{E}_{\mathcal{T}_i}^{val}, \right) \Big) + \lambda \cdot \Omega \tag{8}$$

where, Ω, as a regularization, includes the term that encourages all attention aspects to have equal importance (Shazeer et al., 2017), and λ is its associated coefficient as usual.

5 Experimental Results

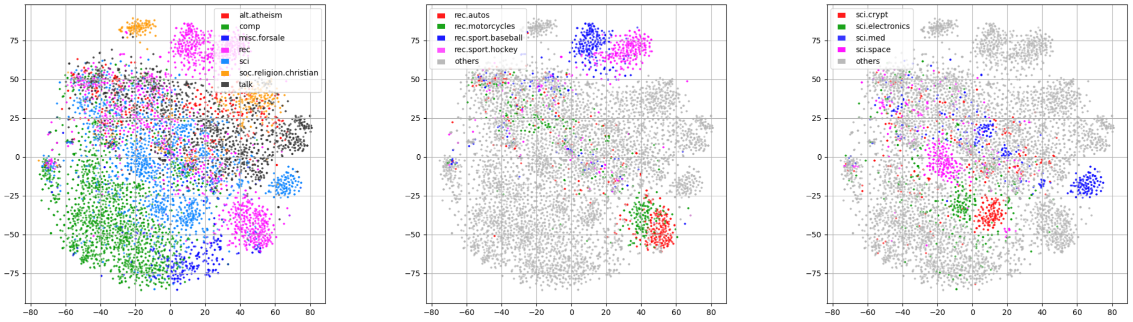
We evaluated LEA on five text datasets — 20 Newsgroup(Lang, 1995), Huffpost headline(Misra and Grover, 2021), Reuters-21578(Lewis., 1997), RCV-1(Lewis et al., 2004), and Amazon product reviews (He and McAuley, 2016) — and compared it with current state-of-art methods. We conducted two different experiments: 5-way 1-shot and 5-way 5-shot all over datasets. The details of the datasets are introduced in Appendix A.1.

5.1 Baselines

In this experiment, we evaluate and compare LEA with six state-of-art methods as follows: Here, **MAML** (Finn et al., 2017) denotes the representative optimization-based meta-learning algorithm, **PROTO** (Snell et al., 2017) indicates the prototype network, **LEO** (Rusu et al., 2018) denotes the meta-learning algorithm using latent embedding optimization, **INDUCTION** indicates the induction network (Geng et al., 2019), **DS** (Bao et al., 2019) denotes few-shot text classification algorithm using the underlying word distributions, and **Frog-GNN** (Xu and Xiang, 2021) denotes the multi-perspective aggregation based graph neural network.

5.2 Overall Performance

We performed all experiments on a frozen BERT$_{BASE}$ (Devlin et al., 2019) as a represen-



(a) (b) (c)

Figure 3: t-SNE plot of task-specific embedding space after task adaptation. (a) Embedding space of seven top-level domains. (b) Same as (a) but highlighted by the four classes in ‘recreation’ domain. (c) Same as (a) but highlighted by the four classes in ‘science’ domain.

tative PTM for LEA and all baselines. As in LEA, **DS** is given the [CLS] embedding and the token embeddings from BERT’s last layer, whereas the other algorithms used the [CLS] embedding of BERT. For the comparison with **Frog-GNN**, we referred to the reported results from (Xu and Xiang, 2021). We additionally applied LEA on RoBERTa$_{BASE}$ (Liu et al., 2019) and fastText (Bojanowski et al., 2017) to verify the applicability of LEA. All performance scores are reported as the average for three repetitions.

As shown in Table 1 and 2, LEA exhibits the competitive performance in both the 5-way 1-shot and 5-way 5-shot, compared to the state-of-the-arts for all the datasets. Namely, the results demonstrate that LEA quickly recognizes how to attend for new tasks using the established meta-attention aspects and provides a robust performance in few-shot text classification problems.

5.3 Hyperparameter Study: Effect of the Number of Top-k Attention Aspects

We also investigate the impact of the number (i.e., k) of task-specific attention aspects. This specific study was conducted on the same frozen BERT$_{BASE}$ as the underlying PTM with the 5-way 5-shot experiment for the all datasets. We fixed the size of the meta attention aspects dictionary to 150 and measured the performances by gradually scaling the k up to 1, 10, 20, 30, 50, 75, 150. As shown in Figure 2, all the datasets exhibit their best performance when setting the top-k attention aspects to 20. This empirical result indicates that each task derives its optimal document embedding by referring only to the most relevant subset rather than exploiting all meta-level attention aspects.

5.4 Task-Specific Document Embedding Visualization

In addition, we plots the task-specific document embeddings and observe the relationships among classes on 20 Newsgroups dataset. To qualitatively characterize the task-specific document embedding space, we split 20 Newsgroup into seven top-level domains, that is, ‘atheism’, ‘computer’, ‘for-sale’, ‘recreation’, ‘science’, ‘religion’, and ‘talk’ and projected them via t-SNE as shown in Figure 3a. Figure 3b shows the relationships between the ‘recreation’ domain composed of four classes and the rest on the space. Figure 3c shows the relationships between the four classes of the ‘science’ domain and the others on the space. These plots demonstrate that LEA produces a structured task-specific embedding space after our task-adaptation step.

6 Conclusion

We hypothesized that a type of task-specific self-attentive mechanism might improve few-shot learning performance, especially when it is prohibitive to fine-tune a large-sized PTM. We have attempted to design a novel embedding transfer method for deriving a meta-level attention aspects dictionary to enable a new task to simply borrow the most relevant attention aspects from the dictionary. As a result, we proposed a novel meta-learning framework for the *learning-to-attend* and showed that LEA is an effective method that facilitates the utilization of large-sized PTMs in few-shot learning.

A Appendix

A.1 Datasets

We introduce the datasets and the split (i.e., train/val/test) which had been maintained in our experiments.

20 Newsgroups is a collection of discourses in newsgroup posts for 20 topics (Lang, 1995).

Huffpost Headlines is a collection of news headlines published in the Huffington Post from 2012 to 2018 (Misra and Grover, 2021). It is composed of 41 topics.

Reuters-21578 is composed of documents that appeared on the Reuters newswire in 1987 (Lewis., 1997). In addition, we use the ApteMod version and discard documents with more than one label to avoid ambiguity, and thus 31 classes remain.

RCV-1 is a set of newswire stories published by Reuters journalists from 1996 to 1997 (Lewis et al., 2004) and comprises 71 topic classes.

Amazon data is a real-world dataset collected from Amazon.com as a set of customer reviews from 24 types of product categories(He and McAuley, 2016). Our goal is to match reviews to their own corresponding product categories.

To train and evaluate the models, we divided each of the aforementioned datasets into a meta-training set ($\mathcal{S}^{tr}$), meta-validation set ($\mathcal{S}^{val}$), and meta-test set ($\mathcal{S}^{test}$) as disjoint sets of classes within the experimental setting. In this work, we used the same split of classes as in (Bao et al., 2019) for the Huffpost headline(Misra and Grover, 2021), Reuters-21578(Lewis., 1997), and RCV-1(Lewis et al., 2004) datasets. Hence, the Huffpost headline is divided into 20, 5, and 16 disjoint classes for meta-training, validation, and test sets.

In terms of Reuters-21678, 15, 5, and 11 disjoint classes are used for meta-training/validation/test sets and 37, 10, and 24 disjoint classes for RCV-1. In Amazon product data, we split the data using rules in (Bao et al., 2019), and its training and validation sets are used for meta-training set. As a result, Amazon product data is divided into 15, and 9 disjoint classes for meta-training and test sets and meta-validation set is not used in Amazon product data. For the 20 Newsgroup dataset, we randomly selected 20 topic classes, and the meta-training set, meta-validation set, and meta-test set contained 10, 5, and 5 disjoint classes, respectively. We summarize the above information in Table 4.

Table 4: Data Splitting

Dataset	# of tr. cls.	# of val. cls.	# of test cls.
20 Newsgroup	10	5	5
HuffPost	20	5	16
Reuters	15	5	11
RCV-1	37	10	24
Amazon	10	5	9

A.2 Implementation Details

We share the breakdown of LEA's implementation. In the encoding process of our experiments, the 768-dimensional [CLS] vector, which is of the same size of the output of the pre-trained BERT-base-uncased, is linearly transformed through f_{θ_e} into a 300-dimensional vector. The relation network, f_{θ_r} is composed of two-layers neural network with ReLU activation and input size is two times of encoder outputs and the size of output is the number of meta-attention-aspects, i.e., 150.

(d)

Figure 4: Visualization of attention weights generated by our model. The texts in (a) and (b) are different samples under a topic *Corporate and Industrial*. (c) and (d) are related to *Markets* and *Economics*.

The gating network, W_g is linear transformation and its size is the number of meta-attention-aspects. For each task classifier, that is, $f_{\theta'_{\tau_i}}$, it is designed as single-layer fully connected neural network. We set the size to 150 for the meta-attention-aspects dictionary, and importantly fixed the number of top-k attention aspects to 20. Table 3 summarizes the above model parameters.

A.3 Training Details and Hyperparameter Tuning

In our work, we train all experiments on a single NVIDIA A100 32G GPU. During the meta-training process, we sampled four tasks with 15 queries from $\mathcal{S}^{tr}$, and it leads to performing task adaptation four times per each meta-optimization update and early stop when the validation loss fails to improve for 20 steps. In validation and test process, we sampled 30 tasks with 15 queries from $\mathcal{S}^{val}$ and $\mathcal{S}^{test}$, and only performed task adaptation using K-shots. After that, the performance of the adapted task model is obtained using queries. We used the Adam optimizer with learning rates of 0.1 and 0.001 in the inner and outer updates, that is, α and β in , respectively. In addition, the coefficient λ of the regularization term was set as 0.0001. We summarize the hyperparameters in Table 5.

A.4 Case Study: Visualization of Attention Weights on Text

Herein, we visualize the heatmaps in some cases to investigate how to assign attention weights to text. Figure 4b demonstrates a termination of stock sale pact, and Figure 4a shows a company growth in terms of consumer products. These were extracted under the *Corporate and Industrial* topic in the RCV-1 dataset and some seminal words such as “agreement”, “contractual” and “receivership” are highlighted to appear in the topic. Figure 4c shows that the Turkish market was closed related to the *Market* topic, and its relevant words such as “Turkish,” “markets,” and “closed” are highly attended as expected. Figure 4d talks about the authority of platinum and gold coins under the *Economics* topic, and the words “US,” “Mint,” “authority,” “gold,” “platinum,” and “coin” are hence highlighted. As shown in these cases, LEA properly captures important words under a certain topic and assigns attention weights to a given text.

Enhancing Self-Attention with Knowledge-Assisted Attention Maps

Abstract

Large-scale pre-trained language models have attracted extensive attentions in the research community and shown promising results on various tasks of natural language processing. However, the attention maps, which record the attention scores between tokens in self-attention mechanism, are sometimes ineffective as they are learned implicitly without the guidance of explicit semantic knowledge. Thus, we aim to infuse explicit external knowledge into pre-trained language models to further boost their performance. Existing works of knowledge infusion largely depend on multi-task learning frameworks, which are inefficient and require large-scale re-training when new knowledge is considered. In this paper, we propose a novel and generic solution, KAM-BERT, which directly incorporates knowledge-generated attention maps into the self-attention mechanism. It requires only a few extra parameters and supports efficient fine-tuning once new knowledge is added. KAM-BERT achieves consistent improvements on various academic datasets for natural language understanding. It also outperforms other state-of-the-art methods which conduct knowledge infusion into transformer-based architectures. Moreover, we apply our model to an industry-scale ad relevance application and show its advantages in the real-world scenario.

1 Introduction

Language models pre-trained by a large text corpus have shown superior performances on a wide range of natural language processing tasks. Many advanced models based on the transformer architectures achieve state-of-the-art results on various NLP benchmarks. Existing literature (Jawahar et al., 2019; Hewitt and Manning, 2019) shows that pre-training enables a model to capture syntactic and semantic information in the self-attention mechanism. However, the attention maps, which record the attention scores between tokens in a self-attention mechanism, are sometimes ineffective as they are learned implicitly without the guidance of explicit semantics (Jain and Wallace, 2019). If the knowledge can be leveraged in a reasonable way to guide the self-attention mechanism, we have a good chance to improve the quality of attention scores as well as the performance of downstream applications.

Recently, there have been multiple attempts for incorporating knowledge into transformer architectures. ERNIE (Zhang et al., 2019) and KEPLER (Wang et al., 2019) utilize both large-scale textual corpora and knowledge graphs to train a representation model in a multi-task learning framework. They need to be retrained from scratch when injecting new knowledge, which is inefficient and can not benefit from existing pre-trained checkpoints. K-Adapter (Wang et al., 2020) integrates additional neural models to capture different kinds of knowledge. It enables adaptation based on pre-trained language models. However, it does not instruct the self-attention mechanism directly and introduces a relatively large number of parameters to the original model.

In this paper, we propose a novel and generic self-attention mechanism enhanced by explicit knowledge to address problems mentioned above. First, we show a failure case of query-ad matching, which motivates us to inject explicit knowledge into self-attention mechanism. In Figure 1, the attention map of a query-ad pair is visualized, and the goal is to judge if the query and ad text are semantically relevant. As shown in the figure, BERT misclassifies this pair as irrelevant, probably because it does not understand the query word *"glipizide"*, which rarely appears in the pre-training corpus. In fact, *"glipizide"* is a kind of medicine and highly related to the word *"Pharmacy"* in ad text, so this case should be classified as relevant. In this case, if we know *"glipizide"* is semantically correlated

---

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 107 - 115
July 10-15, 2022

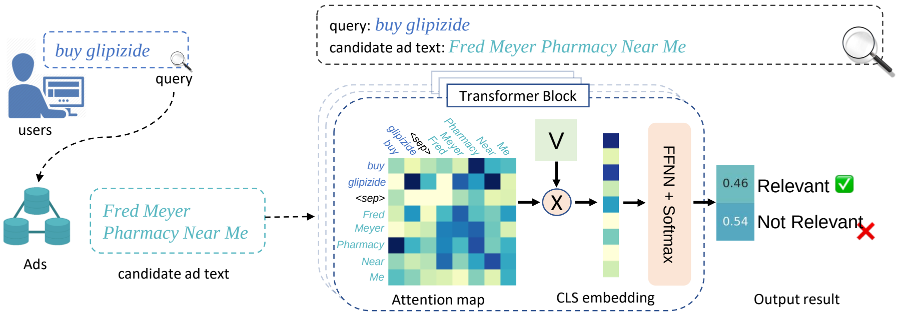

Figure 1: Visualization of attention map from vanilla BERT for a case of query-ad matching

to *"Pharmacy"* as prior knowledge, we can enrich the attention maps accordingly. In addition, terms *"Fred"* and *"Meyer"* are from the same entity, so the attention scores between these two terms should be relatively high. Based on this fact, we believe that simply using language models pre-trained by a general corpus is not enough to meet the satisfaction of a specific application. Thus, our motivation is to inject explicit knowledge into the transformer architecture, which guides the pre-trained language model to perform better adaptation in an efficient fine-tuning procedure.

To address the above motivation, we propose a novel architecture, namely KAM-BERT (Knowledge-assisted Attention Maps for BERT). First, it constructs semantic attention maps based on corresponding relevance functions defined by various kinds of semantic knowledge. Specifically, we consider three kinds of semantic knowledge to guide the self-attention mechanism, i.e., entity, phrase segmentation, and term correlation. Entity and phrase segmentation indicate the cohesion of continuous terms, while term correlation can help to enrich the semantic representation of a sentence. Then, the knowledge infusion procedure is completed by concatenating these attention maps with vanilla self-attention and then performing 2D-convolution for integration. Finally, the result attention maps are served as inputs for value projection, and the rest part is the same as a standard transformer. The KAM-BERT model can be fine-tuned on existing pre-trained checkpoints in a plug and play mode, which is highly efficient in practice.

As illustrated in Section 4, we compare KAM-BERT with BERT and other knowledge-enhanced SOTAs on various natural language understanding tasks, where KAM-BERT shows consistent superiority. Especially, we lift the average score of BERT-Base from 77.5 to 78.7 on the GLUE benchmark. We also demonstrate the advantage of KAM-BERT for knowledge injection on LAMA, a probing benchmark to analyze the factual and commonsense knowledge contained in a model. Furthermore, KAM-BERT is successfully applied to the query-ad relevance scenario in a commercial search engine and shows significant lift in AUC score.

The major contributions of this paper are summarized as follows:

- First, we propose a novel self-attention mechanism enhanced by semantic attention maps, which incorporates knowledge from entity, phrase segmentation, and term correlation. Ablation study will demonstrate the effectiveness of these kinds of semantic attention maps.
- Second, KAM-BERT requires little extra memory and computation cost compared to vanilla BERT and other SOTAs. It can be fine-tuned efficiently on existing language models for a given application. We have successfully applied it to improve the performance of query-ad relevance in a commercial search engine.
- Last but not least, the proposed framework is generic and flexible for infusing various kinds of knowledge into the transformer architecture. Except for the three kinds of knowledge considered in this paper, we will also showcase how to incorporate other kinds of information, such as a knowledge graph. It opens up new opportunities for further exploration.

2 Related Works

After the NLP landmark models Transformer (Vaswani et al., 2017) and BERT (Devlin et al., 2019), many efforts have been devoted to pre-training representation models for natural language and utilizing them to benefit specific NLP tasks. Most of them capture semantic information in the self-attention mechanism implicitly, while recent works demonstrated that injecting explicit knowledge significantly enhanced the performances of downstream tasks. ERNIE (Zhang et al., 2019) makes a preliminary attempt to utilize knowledge graph to improve the performance of knowledge-driven tasks. LIBERT (Lauscher et al., 2019) injects pairs of words with synonym and hyponym relations in WordNet. SenseBERT (Levine et al., 2020) considered word-supersense knowledge by predicting the supersense of the masked word. KnowBERT (Peters et al., 2019) incorporates knowledge bases into BERT through Knowledge attention and re-contextualization. WKLM (Xiong et al., 2019) replaces entity mentions in the original document with names of other entities of the same type, and is trained to distinguish the correct entity mention from random ones. These models are supposed to be retrained when injecting new kinds of knowledge. K-Adapter (Wang et al., 2020) addresses this problem by plugging multiple ways of adapters for different kinds of knowledge. Notably, most of methods above need to be pre-trained from scratch while our method do not. Instead, we inject multiple kinds of knowledge directly into the self-attention maps and support efficient adaptation on a pre-trained language model.

3 KAM-BERT

As illustrated in Figure 2, KAM-BERT injects multiple kinds of knowledge into transformer-based pre-trained models in the form of multi-channel semantic attention maps. Different kinds of knowledge can be extracted independently and infused together into one self-attention map in the transformer architecture. KAM-BERT can be fine-tuned directly from an existing checkpoint of BERT, while additional parameters are initialized randomly and learned in the fine-tuning stage. Thus, it is quite efficient and flexible to incorporate new kinds of knowledge into the model.

Below we first describe the standard self-attention mechanism. Then, we will introduce the generic definition of semantic attention maps, as well as the methodology of multi-channel knowledge infusion which integrates semantic attention maps into transformer models. At last, the generation of different kinds of semantic attention maps will be presented. Note that the time complexity of KAM-BERT is on-par with a vanilla BERT. A detailed analysis can be found in the supplementary material.

3.1 Self-Attention

The representation of a text sequence can be written as $\mathbf{X} \in \mathbf{R}^{N \times C}$, where N denotes the sequence length and C is the word embedding dimension size. A standard Transformer block is composed of a self-attention layer and a position-wise feed-forward layer, while each attention map is generated by a self-attention layer without any other prior knowledge introduced.

The self-attention mechanism plays an important role in the transformer-based model. In a vanilla Transformer, the self-attention map $\mathbf{A^i_{sa}}$ of layer i is calculated by the dimension-normalized dot-product operation.

$$\mathbf{A^i_{sa}} = \text{Self-Attention}(\mathbf{X}) = \frac{\mathbf{QK}^\top}{\sqrt{d}} \tag{1}$$

where d is the dimension of representation vectors. In a vanilla transformer, $\mathbf{A^i_{sa}}$ is then normalized by softmax and fed into position-wise feed-forward layers. In KAM-BERT, the self-attention map $\mathbf{A^i_{sa}}$ is infused with semantic attention maps to calculate the final attention matrix, which will be described in the following sub-sections.

3.2 Semantic Attention Maps

Given a sequence of tokens $\{x_0, x_1, ..., x_{n-1}\}$, the semantic attention map can be defined in a generic form $M \in \mathbb{R}^{n \times n}$, where $M_{i,j} \in [0, 1]$ denotes the attention score from token i to token j, and n is the number of tokens in the current sentence. Then, for a specific kind of knowledge, we need a corresponding relevance function to calculate the attention score, *i.e.*, $M_{i,j} = Relevance(x_i, x_j)$. Note that if x_i denotes a sub-word as in the BERT model, we define $M_{i,j} = Relevance(W(x_i), W(x_j))$, where $W(x_i)$ denotes the entire word which contains the sub-word x_i. For example, BERT will convert a sequence *"I like tacos !"* into a sequence of sub-words, *i.e., {I, like, ta, ##cos, !}*, where *"ta"* and *"##cos"* are sub-words from *"tacos"*, so both $W(ta)$ and $W(\#\#cos)$ denote the word *"tacos"*. In Section 3.4, we will introduce three kinds of semantic attention maps considered in this paper and the generation method for other knowledge-assisted attention maps.

3.3 Multi-Channel Knowledge Infusion

In order to incorporate external knowledge into self-attention, we concatenate semantic attention maps with vanilla self-attention, and then infuse them into a single multi-head attention map using multi-channel 2D-convolutions. Applying 2D-convolution to a self-attention map is first pro-

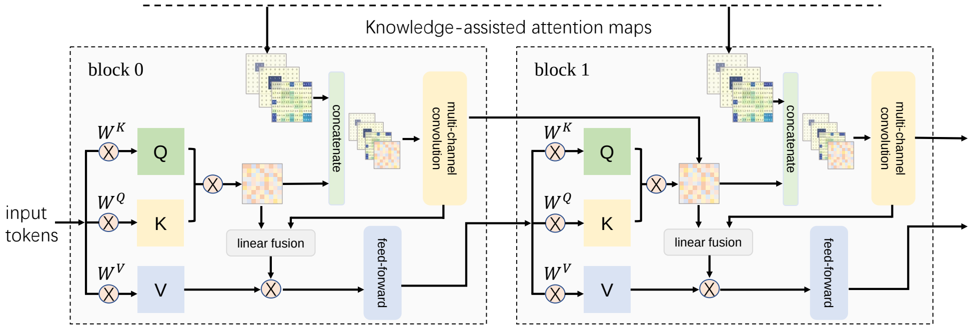
(d) Term correlation



(a) Architecture

Figure 2: Overview of KAM-BERT calculation flow. (a) is our KAM-BERT architecture, (b) (c) and (d) are specific knowledge-assisted attention maps calculated from entity, phrase segmentation and term correlation. We illustrate the first two transformer blocks here.

posed by (Wang et al., 2021) and shows advantages in both NLP and CV tasks. Here we use 2D-convolution to infuse different kinds of knowledge.

First, we perform *Channel Wise Concatenation (CWC)*: the vanilla self-attention map $\mathbf{A}^{\mathbf{i}}_{\mathbf{sa}}$ will be concatenated with each semantic attention map $\mathbf{M_i}$ separately along the channel dimension. Then, a multi-channel 2D-convolution is applied to generate an knowledge-infused attention map, denoted by $\mathbf{A}^{\mathbf{i}}_{\mathrm{sem}}$. The entire process can be formulated as below.

$$\mathbf{A}^{\mathbf{i}}_{\mathbf{sem}} = Conv(CWC(\mathbf{A}^{\mathbf{i}}_{\mathbf{sa}}|\mathbf{M_{1..k}})) \qquad (2)$$

where $\mathbf{M_{1..k}}$ is a set of semantic attention maps obtained by k different kinds of knowledge, including but not limited to the three ones considered in this paper; To infuse different types of knowledge, we apply a standard 2D convolution operation, the output dimension of which is the same as that of $\mathbf{A_{sa}}$. If $\mathbf{A_{sa}}$ has m attention heads, then $\mathbf{A_{sem}}$ will also has m attention heads. We adopt 3×3 kernel for the convolution empirically as it performs better than 1×1 and 5×5 kernels according to (Wang et al., 2021).

At last, we adopt a hyper-parameter α to balance the importance of $\mathbf{A}^{\mathbf{i}}_{\mathbf{sa}}$ and $\mathbf{A}^{\mathbf{i}}_{\mathbf{sem}}$.

$$\mathbf{A}^{\mathbf{i}} = Softmax(\alpha \cdot \mathbf{A}^{\mathbf{i}}_{\mathbf{sem}} + (1-\alpha) \cdot \mathbf{A}^{\mathbf{i}}_{\mathbf{sa}}) \qquad (3)$$

After softmax activation, we get the final self-attention map $\mathbf{A}^{\mathbf{i}}$ with m heads for the i-th layer. Given the self-attention map, the rest components are identical to a vanilla Transformer, which can be calculated as

$$\mathbf{h}^{\mathbf{i}}_{\mathbf{j}} = \mathbf{A}^{\mathbf{i}}_{\mathbf{j}}\mathbf{V}^{\mathbf{i}}, \mathbf{H}^{\mathbf{i}} = (\bigoplus_{j=1}^{m} \mathbf{h}^{\mathbf{j}})\mathbf{W}^{\mathbf{O}}, j \in m. \qquad (4)$$

In detail, we use the obtained attention map $\mathbf{A}^{\mathbf{i}}$ to multiply the value matrix $\mathbf{V}$ in the attention mechanism to get the representation $\mathbf{h}^{\mathbf{j}}$ of the j-th attention head. Next, the outputs of all attention heads from each layer will be concatenated along the embedding dimension. Finally, we multiply this result with a linear transformation matrix $\mathbf{W}^{\mathbf{O}}$ to get the output representation of the i-th KAM-BERT layer. Besides, we add a skip connection from the result attention map in the i-th layer to the self-attention map of the $i+1$ layer to enhance the flow of information between layers.

3.4 Generation of Semantic Attention Maps

The knowledge we inject into KAM-BERT includes entity information, phrase segmentation information, and term correlation information. We consider these three types of knowledge because they reflect language semantics from different perspectives. Entity and phrase represent coherence between adjacent words while term correlations build a semantic bridge for related words which may be far away or even unseen in the current sentence. The first two kinds of knowledge are presented as labeled sequences, and the last one is presented as relationship between tokens. As defined in Section 3.2, a specific kind of knowledge can be transferred to semantic attention maps once the corresponding $Relevance$ function is defined. In the following paragraphs, we will demonstrate how to define $Relevance$ functions for the three types of knowledge used in this paper. Also, we need to emphasize that the proposed framework is generic and is feasible to incorporate other semantic information like a knowledge graph. Thus, we will discuss how to generate other knowledge-assisted attention maps as our future work.

Entity Attention Map Named Entity Recognition (NER) (Nadeau and Sekine, 2007) is a standard task for natural language processing which has been studied for years. Mathematically, a entity extractor transforms the sequence of tokens $\{x_0, x_1, ..., x_{n-1}\}$ into a sequence of labels $\{label_0, label_1, ..., label_{n-1}\}$, where $label_i$ falls into one of three classes, denoting non-entity words, starting words in entities and other words in entities. Based on the labeled sequence, the $Relevance$ function for entity attention map can be defined as

$$Relevance(W_i, W_j) = \begin{cases} 1 & W_i \equiv_E W_j \\ 0 & otherwise \end{cases} \quad (5)$$

where $A \equiv_E B$ denotes A and B belong to the same entity.

Phrase Segmentation Attention Map Similar to the entity attention map, one can highlight the term correlations within the same phrase segmentation to emphasize the locality inductive bias. Syntax tree is a generic source to extract phrases in different semantic levels, which can be generated by a trained syntax parser. In a syntax tree, each internal node represents a phrase segment for a specific level. For example, we can select the parents of leaf nodes in the syntax tree as the root of each sub-tree which represents a phrase. We define the distance of an internal node i to the leaf node as $level(i)$. Thus, the relevance function can be computed by

$$Relevance(W_i, W_j) = \begin{cases} 1 & W_i \equiv_T W_j \\ 0 & otherwise \end{cases} \quad (6)$$

where $A \equiv_T B$ denotes that A and B belong to the same sub-tree at $level(i)$.

Term Correlation Attention Map In computational linguistics, Pointwise Mutual Information (PMI) has been widely used for finding associations between words (Arora et al., 2016). In our work, we adopt PMI to measure the semantic correlations between terms. The PMI of a pair (x, y) from discrete random variables (X, Y) quantifies the discrepancy between the probability of their coincidence given joint distributions and individual distributions. We define the PMI-based relevance function as

$$\begin{aligned} PMI(x; y) &= \log \frac{p(x,y)}{p(x)p(y)} \\ Relevance(W_i, W_j) &= PMI(W_i; W_j)/Z \end{aligned} \quad (7)$$

where Z denotes the normalized factor of PMI matrix. In our experiments, PMI is calculated using a large web corpus. We calculate the probability $p(x, y)$ of a word pair appearing jointly, and the probability of single word appearance is denoted as $p(x)$ and $p(y)$. Finally, we use $\log p(x, y) - \log p(x) - \log p(y)$ to compute the PMI score.

To better incorporate semantic knowledge into attention maps, we further enrich each attention map by adding top k terms which do not appear in the current sentence but hold the highest average PMI scores with terms in the original sentence. Note that we should expand the selected k words to K subwords for BERT. Then the subwords will be appended to the original sentence. After augmentation, the input sentence has $N + K$ words and the shape of an attention map becomes $(N + K) \times (N + K)$, where N and K denote the number of original terms and auxiliary terms respectively (see an example in Fig. 2(d)). In order to align the shapes of different attention maps (including the vanilla self-attention map), we add zero-padding for smaller ones. After passing one transformer layer, the output sequence length is still $N + K$. Note that the auxiliary words are only utilized to enrich the semantics of original word representations, which is done within each transformer layer. Thus, we trim the output sequence length to N before taking it as input to the next transformer layer (while a new round of augmentation will be done in the next layer).

Other Knowledge-assisted Attention Maps. The KAM-BERT framework is generic and can be extended to other kinds of knowledge in future works. For each semantic type, we can define a specific $Relevance$ function to transfer the corresponding information into semantic attention maps. For example, we can define the relevance function for a Knowledge Graph (KG) as:

$$Relevance(W_i, W_j) = \begin{cases} 1 & E(W_i) \equiv_{KG} E(W_j) \\ 0 & otherwise \end{cases} \quad (8)$$

where $E(W_i)$ is the corresponding entity of word or sub-word W_i in a KG, and $A \equiv_{KG} B$ represents that both A and B exist and are adjacent in a KG.

4 Experiments

We briefly introduced the extraction of semantic information in Section 4.1. Then we report experimental results on natural language understand and question answering tasks in Section 4.2 and 4.3 respectively. In Section 4.4, we show evaluation on LAMA, a benchmark especially designed to study how much semantic knowledge is contained in a language model. Experiments on query-ad relevance is described in Section 4.5. At last, we present ablation study in Section 4.6 .

4.1 Semantic Information Extraction

We use Stanza library (Qi et al., 2020) to extract NER information and syntax information. Stanza NER takes one sentence as input and returns the start and end indices of the corresponding named entity in the sentence. While Stanza Parser can extract the corresponding syntax tree for each sentence. We use query-ad logs from a commercial search engine to calculate PMI matrix. These steps gain the knowledge required to generate the semantic attention maps mentioned in Section 3.4.

4.2 GLUE Benchmark

The GLUE benchmark offers a collection of tools for evaluating the performance of models across a diverse set of NLP applications. It contains single-sentence classification tasks (CoLA and SST-2), similarity and paraphrase tasks (MRPC, QQP and STS-B) and pairwise inference tasks (MNLI, RTE and QNLI). We use the default train/dev/test split for each dataset. The hyper-parameters are chosen based on the validation set (refer to appendix for details). After the model is trained, we make predictions on the test data and send the results to GLUE online evaluation service[1] to get testing scores. Note that the original WNLI dataset in the GLUE benchmark is problematic, which causes the evaluation results to be 65.1. In order to make a fair comparison, most papers (Devlin et al., 2019; Liu et al., 2019; Yang et al., 2019) choose to ignore the results of WNLI when calculating GLUE average score.

The scores on all datasets in GLUE benchmark are listed in Table 1. We report test scores on BERT-Base, BERT-Large, RoBERTa related models and their corresponding enhanced models. The performances of BERT-Base, BERT-Large and RoBERTa-Large are reproduced using the official checkpoints provided by corresponding authors.

As shown in the table, our models outperform all corresponding baselines. KAM-BERT-Base achieves an average GLUE score of 78.7, lifting 1.2 scores from standard BERT-Base model with only a few extra parameters introduced to the baseline model. Particularly, the improvements on CoLA datasets are fairly large, showing that our knowledge integration method has good generalization performance for natural language inference and understanding. ERNIE have also added external information such as entity and knowledge graph, but it needs much more time for a joint re-training. As for BERT-Large and its counterpart KAM-BERT-Large, the average improvement on GLUE benchmark is 0.9. We can see that the improvement becomes smaller when the model grows larger, because larger models often capture more semantic knowledge in the pre-training phrase. But incorporating explicit knowledge is still indispensable for achieving a superior performance.

4.3 Question Answering

We conduct experiments on two kinds of question answering tasks, i.e., commonsense QA and open-domain QA. Commonsense QA aims to answer questions with commonsense. We adopt CosmosQA for evaluation, which requires commonsense-based reading comprehension formulated as multiple answer selection. Open-domain QA aims to answer questions using external resources such as collections of documents and webpages. We consider two public datasets for this task, i.e., Quasar-T and SearchQA.

The results of CosmosQA are shown in Table 2. Compared with BERT-Large, KAM-BERT-Large achieves 10.6% improvement in accuracy. KAM-RoBERTa-Large further improves the accuracy of RoBERTa-Large by 5.4%, which indicates that our models has better knowledge inference ability. For open-domain QA, our model also achieves better results compared to corresponding baselines. This because that KAM-based models can make full use of the infused knowledge. At the same time, one can notice that KAM-based models have fewer parameters than K-Adaptor, demonstrating its effectiveness for knowledge infusion. WKLM (Xiong et al., 2019) forces the pre-trained language model to incorporate knowledge from a knowledge graph. This makes WKLM to achieve a better score on QA tasks, but KAM-BERT performs even better than WKLM.

---

4.4 LAMA Benchmark

To further verify whether KAM-BERT better integrate internal knowledge into pre-trained language models, we conduct experiments on LAMA, a widely used benchmark for knowledge probing. LAMA examines models' abilities on recalling relational facts by cloze-style questions. The first place micro-averaged accuracy is used as evaluation metrics. The evaluation results are shown in Table 3. KAM-BERT consistently outperforms corresponding baselines on all tasks. It indicates that KAM-BERT can generate better attention maps with semantic guidance.

4.5 Query-Ad Relevance

Query-ad relevance measures how relevant a search ad matches with a user's search query. Very often queries and ads have words with special meanings, which are not easily understood well by traditional NLP techniques but can benefit from the knowledge-assisted mechanism proposed in this work. Besides, user queries and ads text often contain noises, so evaluation on query-ad relevance task would test our model's robustness and resistance of noise. We compare BERT and KAM-BERT on a large-scale internal dataset of a commercial search engine. As shown in Table 5, our model outperforms corresponding baselines by a large margin, which is statistically significant under 95% confidence interval. One thing to call out is that, although NER and syntax parsing results are nosier comparing to the ones in academic datasets, we still have good improvements on this dataset. This indicates the way we combine those knowledge together makes our model more robust to noisy inputs.

4.6 Model Analysis

In this section, we explore the sensitivity of hyper-parameter α, and then conduct ablation experiments on three types of added knowledge.

Hyper-parameter Analysis The optimal α value after grid search is 0.2, which means that the original attention maps still dominate the token relationships. We chose three tasks from different fields to do ablation study for α. Our model is KAM-BERT-Base, and its performance is shown in Table 4. In three different tasks, setting α to 0.2 achieves the best results. An intuitive understanding is that when α is small, external knowledge plays an unimportant role and cannot participate in

Table 6: Ablation study

Model	Avg	CoLA	SST-2	MRPC	STS-B	QQP	MNLI-m/-mm	QNLI	RTE	WNLI
BERT-Base	77.5	50.1	92.6	88.7/84.3	85.7/84.6	71.0/88.9	83.6/83.2	89.4	**67.9**	65.1
KAM-BERT-Base	**78.7**	**53.7**	**93.2**	**89.2/85.0**	**86.1/84.8**	**71.2/89.4**	**84.3/83.5**	**90.6**	**67.9**	65.1
–KAM-BERT w/o PMI	78.0	52.1	93.0	89.0/84.9	83.5/81.7	71.0/89.1	84.1/83.4	90.2	67.9	65.1
–KAM-BERT w/o Phrase	78.1	53.0	93.1	89.0/84.6	83.2/81.5	71.1/89.1	84.2/83.3	90.5	67.9	65.1
–KAM-BERT w/o Entity	77.7	51.7	92.8	88.9/84.7	82.8/81.0	71.1/88.9	83.8/83.3	89.7	67.9	65.1
–KAM-BERT w/o Conv	78.0	53.1	93.0	89.1/84.9	83.1/81.2	70.8/88.9	84.2/83.3	90.2	67.9	65.1

the entire training process well. With the gradual increase of α, the intervention of external knowledge on the attention map will increase, and the attention relationship in the original sequence will be gradually lost, resulting in the decline of model performance.

Ablation Study For a comprehensive understanding of our model design, we conduct ablation study with the following settings in Table 6. (1) *KAM-BERT w/o PMI*: the PMI-based attention maps are removed; (2) *KAM-BERT w/o Phrase*: the phrase-based attention maps are removed; (3) *KAM-BERT w/o Entity*: the entity-based attention maps are removed. (4) *KAM-BERT w/o Convolution*: the convolution layers for knowledge-assisted attention map integration are removed. Instead, we merge all the attention maps through average aggregation.

The average scores of all ablation experiments are better than BERT, but are relatively worse than KAM-BERT, demonstrating all the components are beneficial for the final performance. At the same time, we observe that after deleting the entity attention map, the score of KAM-BERT drops drastically from 78.7 to 77.7. This shows that the gain brought by entity information is the greatest. In addition, the convolution layer is indispensable for achieving a superior performance.

4.7 Case Study

In Figure 3, we visualize an example of query-ad relevance, where the query is *“buy glipizide”* and ad text is *“Fred Meyer Pharmacy Near Me”*. The darker color in the figure represents a higher attention score. Figure 3(a) is the attention map of vanilla BERT without adding explicit knowledge. When encountering rare words like *“glipizide”*, the self-attention mechanism cannot do a good job to decide which terms should *“glipizide”* attend to. But in Figure 3(b), the attention map of KAM-BERT uses term correlations to learn that *“glipizide”* is a medicine, so it focuses on the medicine-related tokens like *“Pharmacy”* and *“antidiabetic”*.

(c) BERT (d) KAM-BERT

Figure 3: Visualization of attention maps in BERT and KAM-BERT.

Figure 3(c) and 3(d) are the attention maps for the sentence *“The Academy of Fine Arts is located in Northern Maidan.”* We only visualize the key parts due to space limitation. Figure 3(c) shows the attention map for vanilla BERT, and 3(d) is the attention map for KAM-BERT. It can be observed that the terms in the same entity are highly correlated with each other in KAM-BERT, which is more reasonable than vanilla BERT.

5 Conclusion

In this paper, we proposed KAM-BERT, a flexible and efficient approach to inject knowledge into transformer-based pre-trained models. Extensive experiments on GLUE and LAMA benchmark show that our approach outperforms all BERT-Style baselines and achieves new SOTA on QA tasks, suggesting that our models indeed integrate knowledge in an effective manner and have good generalization ability. In future work, we hope to investigate more types of knowledge which can be effectively integrated in our framework.

Abstract

The use of contrastive loss for representation learning has become prominent in computer vision, and it is now getting attention in Natural Language Processing (NLP). Here, we explore the idea of using a batch-softmax contrastive loss when fine-tuning large-scale pre-trained transformer models to learn better task-specific sentence embeddings for pairwise sentence scoring tasks. We introduce and study a number of variations in the calculation of the loss as well as in the overall training procedure; in particular, we find that a special data shuffling can be quite important. Our experimental results show sizable improvements on a number of datasets and pairwise sentence scoring tasks including classification, ranking, and regression. Finally, we offer detailed analysis and discussion, which should be useful for researchers aiming to explore the utility of contrastive loss in NLP.

1 Introduction

Recent years have seen a revolution in Natural Language Processing (NLP) thanks to the advances in machine learning. A lot of attention has been paid to architectures, especially for deep learning, as well as to loss functions. Notably, loss functions based on similar ideas were proposed in unrelated papers in different machine learning fields under different names. This can cause difficulties when solving new problems or when designing new experiments based on previous results. To a greater extent, this applies to "universal" loss functions, which can be applied in different machine learning areas and tasks such as Computer Vision (CV), Recommendation Systems, and NLP. An example of such loss function is the batch-softmax contrastive (BSC) loss, which we will discuss below. For many NLP tasks, it is important to obtain representations of sentences for semantic matching problems, since they can be used for further analysis, e.g., for finding the best answer to a question.

Sentence BERT is a recent popular approach for this (Reimers and Gurevych, 2019): it can be trained with different loss functions, and we show that the choice of a loss function is important. Moreover, we show that it will not be optimal to take the "standard" batch-softmax contrastive loss, which is used for training SimCSE (Gao et al., 2021), a recent alternative to Sentence BERT, and we suggest ways to improve its efficiency. Our contributions can be summarized as follows:

- We study the use of a batch-softmax contrastive loss for fine-tuning large-scale transformers to learn better task-specific embeddings for pairwise sentence scoring tasks.
- We introduce and study a number of novel variations in the calculation of the loss such as symmetrization, incorporating labeled negatives, aligning scores on the similarity matrix diagonal, normalizing over the batch axis, as well as in the overall training procedure, e.g., shuffling, trainable temperature, and sequential pre-training.
- We demonstrate sizable improvements for a number of pairwise sentence scoring tasks such as classification, ranking, and regression.
- We offer detailed analysis and discussion, which would be useful for future research.
- We release our code at `https://github.com/aschern/BSC-loss`

2 Related Work

The contrastive loss was proposed by Hadsell et al. (2006) as metric learning that contrasts Euclidean distances between embeddings of samples from one class and between samples from different classes. Weinberger et al. (2006) suggested the triplet loss, which is based on a similar idea, but uses triplets (*anchor*, *positive*, *negative*), and aims for the difference between the distances for (*anchor*, *positive*) and for (*anchor*, *negative*) to be larger than a margin.

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 116 - 126
July 10-15, 2022

N-pair loss was presented as a generalization of the contrastive and the triplet losses as a way to solve the problem of extensive construction of hard negative pairs and triplets (Sohn, 2016). A batch of N pairs of examples from N different classes is sampled, and the first element in each pair is considered to be an *anchor*. Thus, for each *anchor*, there are one positive and $N-1$ negative pairs. The loss contrasts the distances simultaneously using the softmax function over dot-product similarities. The approach was used successfully in CV tasks.

The same method of Multiple Negative Ranking for training Dot-Product Scoring Models was applied to ranking natural language responses to emails (Henderson et al., 2017), where the loss uses labeled pairs. A similar idea, called *Negative Sharing*, was used to reduce the computational cost when training recommender systems (Chen et al., 2017). Wu et al. (2018) presented an approach with N-pairs like logic, as a Non-Parametric Softmax Classifier, replacing the weights in the softmax with embeddings of samples from such classes. It was also proposed to use L2 normalization and temperature. Yang et al. (2018) used Multiple Negative Ranking to train general sentence representations on data from Reddit and SNLI. Logeswaran and Lee (2018) presented a Quick-Thoughts approach to learn sentence embeddings, which constructs batches of contiguous sets of sentences, and for each sentence, contrasts the next sentence in the text and all other candidates.

A lot of subsequent work focused on maximizing Mutual Information (MI). van den Oord et al. (2018) presented a loss function based on Noise-Contrastive Estimation, called InfoNCE. It models the "similarity" function that estimates the MI between the target (future) and the context (present) signals, and maximizes the MI between temporally nearby signals. If this "similarity" function expresses the dot-product between embeddings, the InfoNCE loss is equivalent to the N-pair loss up to some constants. It was also shown that InfoNCE is equivalent to the Mutual Information Neural Estimator (MINE) up to a constant (Belghazi et al., 2018), which maximizes a lower bound on MI. Deep InfoMax (DIM) (Hjelm et al., 2019) improves MINE, and can be modified to incorporate some autoregression as InfoNCE. However, the effectiveness of loss functions such as DIM and InfoNCE might be primarily connected to MI, rather than to deep metric learning (Tschannen et al., 2020).

The idea gained a lot of popularity in the field of Computer Vision with the advent of SimCLR (a Simple framework for Contrastive Learning of visual Representations), which introduced NT-Xent (normalized temperature-scaled cross-entropy loss) (Chen et al., 2020). It uses self-supervised learning, where augmentations of the same image are used as positive examples and augmentations of different images are used as negative examples. Thus, the task is as follows: for each example in a batch, find its paired positive augmentation. Here, the N-pairs loss is modified with a temperature parameter and with an L2 normalization of embeddings to the unit hypersphere. The loss was further extended for supervised learning as SupCon loss (Khosla et al., 2020), which aggregates all positive examples (from the same class) in the softmax numerator.

Subsequently, similar kinds of loss functions were also introduced to the field of Natural Language Processing (NLP). Gunel et al. (2021) combined the SupCon loss with the cross-entropy loss and obtained state-of-the-art results for several downstream NLP tasks using RoBERTa. Giorgi et al. (2021), Fang and Xie (2020) and Meng et al. (2021) used NT-Xent to pre-train Transformers, considering spans sampled from the same document, sentences augmented with back-translation as positive examples, and sequences corrupted with MLM. Luo et al. (2020) proposed to use NT-Xent in a self-supervised setting to learn noise-invariant sequence representations, where sentences augmented with masking were considered as positive examples. Finally, Gao et al. (2021) introduced the SimCLR loss to NLP under the name SimCSE (Simple Contrastive Learning of Sentence Embeddings), where sentences processed by a neural network with dropout served as augmentations of the original sentences. Here, we explore various ways to use a similar loss function for pairwise sentence scoring tasks.

While the above-described loss functions have different names, they are all based on similar ideas. Below, we will use the name *Batch-Softmax Contrastive* (BSC) loss, which we believe reflects the main idea best. In our experiments below, we will use the "modern" variant of the loss: with temperature, normalization, and symmetrization components (described in more detail in Section 3.1). These components were not used for NLP in combination before.

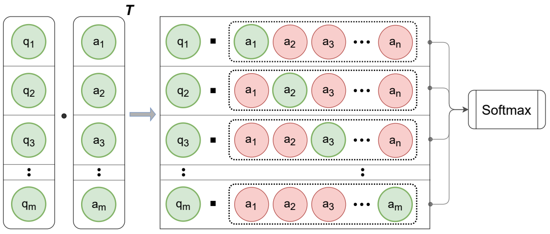

Figure 1: For the set of positives pairs (q_i, a_i), e.g., question–answer, for each q_i, the BSC loss contrasts the scores between q_i and a_i (positive examples) vs. between q_i and a_j for all $j \neq i$ (negative examples) using softmax. Here ▪ denotes the dot-product.

We further introduce a number of novel and important modifications in the definition of the loss and in the training procedure, which make it more efficient, and we show that using the resulting loss yields better task-specific sentence embeddings for pairwise sentence scoring tasks.

3 Method

3.1 Batch-Softmax Contrastive (BSC) Loss

Pointwise approaches for training models for pairwise sentence scoring tasks, such as mean squared error (MSE), are problematic as the loss does not take the relative order into account. For instance, for two pairs with correct target scores (0.4, 0.5), the loss function would equally penalize answers like (0.3, 0.6) and (0.5, 0.4). However, the first pair is better, as it keeps the correct ranking, while the second one does not. This is addressed in pairwise approaches, e.g., in triplet loss, where the model directly learns an ordering. Yet, there is a problem for constructing pairs or triplets in the training set, as it is hard to find non-trivial negatives examples.

Unlike traditional pairwise loss functions, the BSC loss treats all other possible pairs of examples in the batch as "negatives." That is, only positive pairs are needed for training. Consider a batch X of pairs from a question-answering dataset. In general, let $Q_{m\times n}$ and $A_{m\times n}$ be the matrices of embeddings produced by a query model and an answer model. We define the loss function as follows:

$$\begin{aligned}\mathcal{L}_{BSC}(X) &= \mathcal{L}_0(X) + \mathcal{L}_1(X)\\ = &-\operatorname{mean}\left(\log\left(diag\left(\operatorname{softmax}\left(\frac{QA^T}{\tau}\right)\right)\right)\right)\\ &-\operatorname{mean}\left(\log\left(diag\left(\operatorname{softmax}\left(\frac{AQ^T}{\tau}\right)\right)\right)\right)\end{aligned} \tag{1}$$

Here, softmax is applied by rows (Figure 1), and τ is the temperature. Both components can be rewritten, e.g., $\mathcal{L}_0(X)$ can be written as follows:

$$-\frac{1}{m\tau}\sum_{i=1}^{m} q_i^T a_i + \frac{1}{m}\sum_{i=1}^{m}\log\sum_{j=1}^{m}\exp\left(\frac{q_i^T a_j}{\tau}\right) \tag{2}$$

Mathematically, this loss function is similar to the one presented in (Chen et al., 2020). The difference is that we do not use augmentations, and we do not compare q_i to q_j (or a_i to a_j) due to their different nature: we want to compare a question to an answer, not a question to a question or an answer to an answer. Thus, we apply the symmetrization in the formula. So, the difference from SimCSE (Gao et al., 2021) is that we compare not only q_i to all a_j, but also a_i to all q_j in the batch.

Note that, although a frequent short answer may fit multiple questions in a batch, such pairs are considered as "negative" examples in the loss. However, the loss learns Mutual Information (Tschannen et al., 2020), that is $p(q_i, a_i)/(p(q_i)p(a_i))$, and thus it is robust to this false negatives problem.

Early research has already shown the importance of properly configuring and using some BSC loss settings. For example, low temperatures are equivalent to optimizing for hard positives/negatives (Khosla et al., 2020), while L2 normalization of vectors to the unit hypersphere along with temperature effectively weighs different examples (Chen et al., 2020). We further propose a number of important modifications that can have a major impact on the performance for a number of tasks.

3.2 Batch Construction

In computer vision, it is common to use a batch size of 5,000, which in turn would naturally be very likely to contain some hard negative examples. In NLP, fine-tuning Transformers with large batch sizes requires very large amounts of memory. Thus, much smaller batches are used in practice, and it becomes important to make sure these batches do contain some hard negative examples. We achieve this by fixing the content of the batches at each training epoch. Note that this is much simpler than mining hard negatives, as we only need to increase the likelihood that there would be a hard negative example present in the batch, but we do not need to know which particular example in the batch would be hard. Inside the batch, this would be controlled by the temperature parameter.

Example-based shuffling The key idea of this method is to batch several groups, so that within each group all pairs are similar based on their first or their second elements. In this way, each positive pair would be accompanied by hard negatives from the same group and by simpler negatives from the remaining examples inside the batch (which come from other groups). We use the k-nearest neighbors for an input example to form a group for it, and Faiss (Johnson et al., 2021) to quickly find these nearest neighbors in the embedding space. Let the pairs be grouped by their first elements q_i. Algorithm 1 summarizes the proposed method.

Algorithm 1 Example-based shuffling

```
Input: sequence $D$, group size $s$
initialize $R \leftarrow []$   ▷ sequence to store the result
initialize $U \leftarrow \varnothing$   ▷ set of used examples
randomly shuffle $D$
for e in $D$ do
    if e $\notin U$ then
        find the $n$ nearest neighbors of e from $D$
        choose the top $s - 1$ that are not in $U$
        add them and e to $R$ and also to $U$
return reversed $R$
```

Note that in this approach we use two stages in kNN to limit the range of possible candidates and thus to reduce the computational costs (both in terms of time and memory). We first extract the top-n neighbors (for some large n, e.g., 500), and then we take the top-k from them, so that no duplicates appear in the final sequence (for some small $k = 7$). The time complexity of such a check is O(1). If all such neighbors are already used, then only the considered example will be added to the resulting sequence. This case will often arise for the last examples, and thus batches will consist of simple 1-element groups. Therefore, we reverse the sequence to start with these simple batches, as in curriculum learning.

By default, we assume that there should be one positive example for each question/answer (on the diagonal of the matrix), and thus identical neighbors could be optionally filtered. Still, if there are the same q_i in the batch X, the loss definition (eq. 1) does not change. Indeed, let $P_q = \{i \mid q_i = q, (q_i, a_i) \in X\}$, then $\forall i, j \in P_q : (q_i, a_j)$ form a positive pair. According to Khosla et al. (2020), for each q, all $\tilde{q} \in P_q$ should be placed in the softmax numerator and then averaging over all such $\tilde{q}$ should be performed outside the logarithm.

Thus, in $\mathcal{L}_0(X)$ (eq. 2) only the first sum would change as follows:

$$\sum_{i \in P_q} q_i^T a_i \rightsquigarrow \sum_{i \in P_q} \frac{1}{|P_q|} \sum_{j \in P_q} q_i^T a_j$$

$$= \sum_{j \in P_q} \frac{1}{|P_q|} \sum_{i \in P_q} q^T a_j = \sum_{j \in P_q} q_j^T a_j \quad (3)$$

In $\mathcal{L}_1(X)$:

$$\sum_{i \in P_q} q_i^T a_i \rightsquigarrow \sum_{i \in P_q} \frac{1}{|P_q|} \sum_{j \in P_q} q_j^T a_i$$

$$= \sum_{i \in P_q} \frac{1}{|P_q|} \sum_{j \in P_q} q^T a_i = \sum_{i \in P_q} q_i^T a_i \quad (4)$$

In order to select the groups even better, we consider task-specific embeddings. To this end, we apply the current model to encode all pairs at each epoch.

Algorithm 2 Shuffling by words

```
Input: sequence $D$, group size $k$, shingle size $t$
for e in $D$ do
    e.shingle $\leftarrow$ random subset of $t$ words
        of e (ignoring stop-words)
sort $D$ by e.shingle
initialize gID $\leftarrow$ random uint64   ▷ group ID
initialize $s \leftarrow 0$   ▷ current group size
initialize prev $\leftarrow$ first element of $D$
for e in $D$ do
    if e.shingle $\neq$ prev.shingle then
        gID $\leftarrow$ random uint64
    if s $\geqslant$ k then
        gID $\leftarrow$ random uint64
        $s \leftarrow 0$
    e.gID $\leftarrow$ gID
    $s \leftarrow s + 1$
    prev $\leftarrow$ e
sort $D$ by e.gID
return $D$
```

Fast shuffling For extremely large datasets, example-based shuffling is time-consuming even with Faiss; thus, we propose several effective options to perform a less-thorough shuffling. We choose some attribute by which we will group the examples, that is, we guarantee some closeness of the examples. Thus, the examples are close if they share the same words, the same cluster number or the same nearest neighbors.

First, consider the case of words and grouping by the first elements of the pairs (the case of second elements is the same). Algorithm 2 presents the shuffling process. We choose a random word or phrase (shingle) in each element and sort the dataset by these shingles. Since examples with the same shingles will be in a sequence, we assign group IDs sequentially. We split a group if it is too large. Then we shuffle (sort) the dataset by group IDs. The resulting algorithmic complexity is equal to the complexity of two sorts of the dataset.

To produce a shuffle by clusters, we apply the same algorithm, where each sentence is replaced by its cluster number. Thus, each individual shingle is of size $t = 1$. To make a shuffle by nearest neighbors, we create shingles by "sentences," where the words are the positions of the top-k nearest neighbors in the input sequence (for some small value of k). All these approaches, including k-means clustering, can be effectively implemented using MapReduce and parallel computations.

3.3 Labeled Negatives

Usually, when the data size is small, hard negative examples may be hard to obtain even with data shuffling, e.g., when all examples are semantically distant. Nonetheless, if the dataset contains a labeled negative pair with some anchor, then its elements are semantically close by traditional rules of dataset construction. Thus, using such a pair inside the batch, where this anchor is present, will add the necessary hard negative example.

The only change that is added in the loss function is the masking of negative examples—we have no guarantees that the selected negative example is closer to the anchor than the rest of the examples inside the batch. Let y_i be a binary label, where $y_i = 1$ if the i-th pair is positive. Then, we have

$$\mathcal{L}_0(X) = -\frac{1}{m\tau}\sum_{i=1}^{m}\mathbb{1}[y_i = 1] q_i^T a_i + \frac{1}{m}\sum_{i=1}^{m}\mathbb{1}[y_i = 1]\log\sum_{j=1}^{m}\exp\left(\frac{q_i^T a_j}{\tau}\right) \quad (5)$$

3.4 Combo Loss

Theoretically, it is beneficial to use several loss functions for training if they are calculated on the same batch (and thus do not require additional computations). That is, joint training of BSC and MSE losses combines the advantages of pointwise and of pairwise approaches.

This ensures that for positives examples, the values on the diagonal of the dot-product matrix are not only greater than the rest, but are also close to 1 or to some target similarity. Note that here $L_{MSE}(X) = \frac{1}{m}\sum_i^m((q_i^T a_i) - y_i)^2$ for target positive similarities y_i, and thus we do not force all other similarities to zero. At the same time, the BSC loss adds new examples (i.e., "negative" pairs) to the training set.

In order to use the BSC loss when training a model for tasks with non-binary labels, we modify the indicator function in equation (5) as $\mathbb{1}[y_i > t]$, where t is a configurable binarization threshold. Then, we use their convex combination with a configurable hyperparameter $\mu \in (0, 1)$:

$$L(X) = \mu L_{BSC}(X) + (1 - \mu)L_{MSE}(X) \quad (6)$$

3.5 Normalization

L2 normalization of matrices A and B means that $a_i^T b_j$ will be equivalent to cosine similarity. The embeddings can also be normalized by the batch dimension (by coordinates), which can bring additional regularization. In our experiments, we confirm the importance of this, e.g., new representations can be calculated with L2 normalization by coordinates or in a min-max scale.

4 Datasets

NLP tasks that compare pairs of sentences can be roughly divided into three general categories: regression (predicting a similarity score), classification (e.g., similar vs. dissimilar), and ranking (search for the best matches). They differ only by the quality assessment functions, and thus they all can benefit from the above losses.

Note that it is important to calculate the sentence representations for ranking tasks in advance, as when independently calculating the embeddings of the individual elements in the pairs, the inference time of the model becomes linear instead of quadratic. Therefore, we use Sentence-BERT (SBERT), which is trained as a Siamese BERT model, and offers a way to obtain state-of-the-art sentence embeddings, which have been proven useful for a number of tasks (Reimers and Gurevych, 2019; Thakur et al., 2021). At inference time, we first use SBERT to obtain independently a representation for the individual sentences, and then we calculate the cosine similarities between the corresponding embeddings as we construct pairs as part of the process of ranking.

We use a variety of public English datasets and tasks for the evaluation. In particular, we have four ranking tasks (ranking answers to non-factoid questions, ranking questions by their similarity with respect to other questions, ranking comments by their similarity to a given question, ranking fact-checked claims by their relevance with respect to an input claim), two binary classification tasks (paraphrases identification, and duplicate question identification), and one regression task (semantic sentence similarity).

Antique The dataset contains 2,626 non-factoid questions with answer choices (Hashemi et al., 2020), asked by users on *Yahoo! Answers*. There are a total of 34,011 question–answer pairs: 27,422 for training and 6,589 for validation. Each answer is annotated with a relevance score with respect to the question on a scale from 1 to 4 (where 4 denotes the highest relevance), and the task is to rank the answers by their relevance. To model relevance as a cosine similarity, we normalize the scores to the $[0, 1]$ interval. We use Mean Reciprocal Rank (MRR) as the main evaluation measure.

CQA-A This dataset was used in SemEval-2017 Task 3 on Community Question Answering subtask A (Nakov et al., 2017). The goal is to rank the first ten answers in a question thread on Qatar Living, so that *good* answers are ranked higher than *bad* ones. We used the *clean* part of the dataset, which consists of 14,110 and 2,440 labeled question–comments pairs for training and development, respectively. The evaluation measure is Mean Average Precision (MAP). This dataset contains important metadata, e.g., the date and time of the comment, and sorting the comments by time yields a strong baseline; yet, we only use the text. To train the model with the triplet loss, we group the pairs by the first element (anchor).

CQA-B This dataset was developed for SemEval-2017 Task 3, subtask B (Nakov et al., 2017), whose goal was to rank ten potentially related questions by their similarity with respect to an input question. These questions were retrieved from the Qatar Living forum using Google and the input question as a query. We use the clean part of the dataset, which consists of 19,990 training and 5,500 development labeled question-question pairs. The main evaluation measure here is MAP. There is additional information, e.g., the rank of the retrieved question in the Google search results, which we do not use.

PFCC-S Shaar et al. (2020) presented a dataset for detecting Previously Fact-Checked Claims on Snopes (PFCC-S), aimed at facilitating the solution of a fact-checking problem: given an input claim, it asks to rank claims that have been previously fact-checked, so that claims that can help verify the input claim are ranked as high as possible. The dataset has 800 positive input–verified claim pairs for training and 200 such positive pairs for testing, and they are to be matched against a database of 10,369 verified claims. The evaluation is performed in terms of a HasPositive@k metric, which checks whether there is a positive match among the first k results in the ranked list. There are no negative examples in the dataset, but about eight million such pairs can be created. Thus, in order to train models using MSE or triplet loss, we sampled negatives according to the following scheme. First, we encoded all sentences using SBERT (we used the model pretrained on STSb and NLI). Then, we selected the first element in each positive pair as an anchor and we sorted all other examples by their similarity to this anchor. The assumption is that positive examples will be concentrated in the beginning, e.g., among the top-100. Thus, we selected negatives starting from 101 on, logarithmically: on positions $100 + 2^k, k \in \mathbb{N}$. As a result, we obtained many hard negative examples and a small number of easy ones. Finally, we oversampled the positive pairs to correct the balance of positive and negative examples.

Microsoft Research Paraphrase Corpus (MRPC) It was created by Dolan et al. (2004) and contains 5,800 pairs of sentences, extracted from online news sources. Each pair was labeled with a tag indicating whether the sentences are paraphrases (semantically equivalent). There are 3,668, 407, and 1,725 pairs in the training, development, and test subsets. As it is a binary classification task with class imbalance, it is evaluated in terms of F1.

Quora Question Pairs (QQP) Quora presented a dataset containing over 500,000 sentences with over 400,000 lines of potential duplicate questions. Each line has a binary label indicating whether the line truly contains a duplicate pair. Due to the sampling method, which returns mostly positive pairs, the authors supplemented the dataset with negative pairs composed of "related questions." Following Thakur et al. (2021), we sampled randomly 10,000 examples for training, and we used F1 score as the main evaluation measure.

Semantic Textual Similarity Benchmark (STSb) The STS benchmark comprises a selection of English datasets used in the STS tasks organized in the context of SemEval between 2012 and 2017 (Cer et al., 2017). The benchmark comprises 8,628 sentence pairs. The pairs were annotated with similarity scores on a scale from 0 to 5 (with 5 indicating complete equivalence). There are a total of 5,749, 1,500 and 1,379 pairs in the training, in the development, and in the testing split, respectively. The main evaluation measure is Spearman's rank correlation. As for the Antique dataset, here we also normalized the scores to the $[0, 1]$ interval and then we binarized them based on a threshold of 0.6.

5 Experimental Setup

Below, we describe our baselines and hyper-parameter settings.

5.1 Baselines

We used BERT-base uncased in all our experiments to be able to perform direct comparison for tasks such as MRPC, QQP, and STS to previous work (Reimers and Gurevych, 2019; Thakur et al., 2021).

We considered SimCSE (*sup-simcse-bert-base-uncased* checkpoint) (Gao et al., 2021) as an unsupervised baseline as it uses the base version of the BSC loss, which we modified. Below, by *BSC* we will denote using optimal settings in the tables, and variants like *BSC - random shuffle* would mean that instead of these optimal settings, we applied random shuffling.

5.2 Hyperparameters Setting

We set the number of warm-up steps to 10% of the total steps, and we limited the input sequence length to 90 subtokens. We used a batch size of 30 in all tasks, except for Antique and QQP, where we used 50. Note that an order of magnitude larger batch sizes would probably yield better results, but they would also require much more memory. We tried learning rates from {5e-6, 1e-5, 2e-5, 3e-5}, and we selected (on dev) 3e-5 for CQA-B and 2e-5 for all other experiments. We used the AdamW optimizer with the bias correction for the CQA tasks, and without bias correction for the rest. We trained the model for five epochs for Antique, CQA-A and STSb, for six epochs for QQP, MRPC and PFCC-S, and for seven epochs for CQA-B, saving a checkpoint after each one, and we selected the best checkpoint on the development set.

As recommended by Thakur et al. (2021), due to instability, we did seed optimization, running each experiment five times and selecting the best one (on dev). To train with the BSC loss, we used min-max normalization by coordinates with $\tau = 1.2$ for PFCC-S and QQP, standard L2 normalization with $\tau = 0.055$ for CQA-A, $\tau = 0.07$ for CQA-B, and $\tau = 0.1$ for all other tasks (to find the optimal τ, we made it trainable for one run). We applied example-based shuffling to train with the BSC loss. We used a group size of four in MRPC, of five in CQA-B, and of eight in all other tasks. We iterated over μ values from the set $\{0.1, 0.5, 0.9\}$, and we chose $\mu = 0.1$ to train the *combo* approach for CQA-A, MRPC, QQP and STSb tasks, and $\mu = 0.9$ for the other experiments.

Our experiments demonstrated that there is only a minor impact of changing the values of these hyperparameters. For example, the maximum quality drop from μ (0.1 vs. 0.5) is 0.4%, i.e., almost at the noise level, while we obtained gains of up to 10% when using our proposed modifications.

We trained the triplet loss variant from (Reimers and Gurevych, 2019) with `margin` $= 0.6$ for PFCC-S, and `margin` $= 0.5$ for all other tasks. As we have no answers for the test set in MRPC, and no test sets in Antique and PFCC-S, we split the training set into 9:1 to tune the hyper-parameters. The time for training SBERT with the BSC loss (or *combo* loss) was almost equal to the time for training with the standard MSE loss. The most complex example-based shuffling only adds 8% to the training time. Note that it is several times faster than triplet loss, as only positive examples are used for training, and thus the dataset becomes several times smaller. We ran all experiments on a GeForce GTX 1080 GPU Ti. Training SBERT-base took up to ten minutes per epoch depending on dataset size.

6 Results

Below, we describe the evaluation results.

Antique The results are shown in Table 1. Our best approach of combo-training the MSE and the BSC losses outperforms all other variants and the approach proposed in (Hashemi et al., 2020), where specific negative sampling and a triplet loss were used. Besides, the best BSC configuration achieves higher scores than MSE. We can see the importance of using predefined hand-crafted negative examples, which brings additional difficult cases and increases MRR by 0.02.

Approach / Metric	MRR	P@1	nDCG@1
MSE	0.781	0.660	0.769
BSC	0.804	0.680	0.754
BSC - positives	0.784	0.655	0.744
BSC - random shuffle	0.799	0.670	0.754
Combo BSC + MSE	**0.822**	**0.710**	**0.773**
SimCSE (unsup.)	0.681	0.525	0.686
Hashemi et al. (2020)	0.797	0.709	0.713

Table 1: Results for Antique.

Approach / Metric	MAP	MRR	MAP	MRR
MSE	0.869	0.911	0.471	0.513
BSC	0.801	0.867	0.495	0.534
BSC - clusters shuffle	0.787	0.859	0.493	0.534
BSC - random shuffle	0.763	0.828	0.487	0.530
BSC - w/o shuffle	0.816	0.884	0.481	0.532
Combo BSC + MSE	**0.872**	0.912	**0.496**	**0.540**
Triplet loss	0.857	**0.917**	0.475	0.529
SimCSE (unsup.)	0.684	0.735	0.439	0.478
Nakov et al. (2017)	0.884	0.928	0.472	0.501

Table 2: Results for CQA-A and CQA-B.

CQA-A The results for CQA subtask A are shown in Table 2. A comparison with (Nakov et al., 2017) is not very fair, as we did not use the metadata, e.g., the comment position, which was crucial for the best systems. Besides, we use SBERT, which is inferior to a fine-tuned BERT. Nevertheless, our best approach of combo training with MSE and BSC losses yielded competitive results. We further compared different shuffling strategies. The data is ordered by questions, and keeping this order turns out to be best. That is, the model learns to distinguish positive answers for each question from manually selected negative ones and from answers to other questions. Also, note that random shuffling completely eliminates this structure, and MAP drops by 6% absolute. Fast shuffling by 300 clusters, an advanced version of shuffling by words, improves these results. Example-based shuffling finds a data order similar to the initial one, and the quality does not degrade much.

CQA-B The evaluation results for CQA-B are shown in Table 2. Again, we did not use the question position, which is a critically important feature for the best systems. We can see that the BSC loss achieved the best score, noticeably outperforming MSE and triplet losses. The experiments also demonstrate the importance of data order when training with the BSC loss. Since the dataset is small, the model overfits when the original data order is fixed.

Approach / Metric	HP@1	HP@5	HP@50
MSE	0.362	0.508	0.709
BSC	**0.673**	**0.844**	0.899
BSC - 1-dim norm	0.588	0.764	0.899
BSC - no norm	0.608	0.744	0.884
BSC - random shuffle	0.663	0.794	**0.915**
Triplet loss	0.668	0.794	0.899
SimCSE (unsup.)	0.412	0.693	0.849
Shaar et al. (2020)	0.402	0.653	0.784

Table 3: Results for PFCC-S.

Approach / Metric	**MRPC (F1)**	**QQP (F1)**
MSE	89.08	74.29
BSC	86.73	73.13
Combo BSC + MSE	**89.46**	**75.07**
SimCSE (unsup.)	85.43	68.65
Thakur et al. (2021)	87.89 (88.55)	74.97 (79.77)

Table 4: Results for MRPC and QQP.

PFCC-S Table 3 shows the results for PFCC-S (*HP@k* stands for *HasPositives@k*). Note that the scores from (Shaar et al., 2020) are for the pre-trained SBERT without fine-tuning. We observed that even when using oversampling to improve class imbalance, fine-tuning with MSE performed worse than their results. Here, we used only positives examples to train with BSC, and normalizing by the zero dimension. Overall, the approaches using BSC and triplet loss were comparable. However, the dataset size for training with the BSC loss was much smaller, which is also true for MSE. Thus, the BSC loss is faster, and preferable.

MRPC Table 4 shows the results for MRPC. MSE outperformed the BSC loss, but combo achieved a slightly higher F1 score.

QQP The results for QQP are shown in Table 4. We also show results for SBERT and augmented SBERT (in parentheses) from (Thakur et al., 2021). They trained SBERT with MSE using another random training sample, but nonetheless, the F1 score is close to ours. The combo approach outperformed separate training with BSC or MSE.

STSb Table 5 shows the results for STS. It is the only task where combo with the BSC loss was worse than MSE. This could be due to hard negatives not appearing in the batch in any of the shuffling procedures. Moreover, we observed only marginal improvement when fine-tuning with a BSC model initially trained with MSE. However, if it was pretrained with BSC up to overfitting, fine-tuning it with MSE yielded sizable improvements.

Approach / Metric	$\rho \times 100$
MSE	84.80
BSC	83.26
Combo BSC + MSE	84.59
Fine-tuning MSE with BSC	84.95
Fine-tuning BSC with MSE	**85.71**
SimCSE (unsup.)	84.25
Reimers and Gurevych (2019)	84.86

Table 5: Results for STSb: Spearman rank correlation.

7 Discussion

We highlight the following observations:

- Combo-training with BSC and MSE losses generally yields the best results (the only exception is STSb), and it outperforms the triplet loss with advanced negative sampling.

- The order in which the data is presented for training can be critical, as we have seen in the cases of CQA-A and CQA-B.

- The use of labeled negative examples generally improves the results by 1-2% absolute.

- Embedding normalization during training is important. Moreover, it is useful to normalize to the zero dimension (e.g., for PFCC-S).

- A temperature τ of order 0.1 should be used with the standard normalization, and τ of order 1-3 for coordinate normalization.

- A suboptimal setup may hurt performance by over 10%, as was demonstrated for (*i*) filtering out negative examples for which no positives were given in the dataset (Table 1), (*ii*) using poorly formed batches (highest impact in Table 2), (*iii*) suboptimal normalization (Table 3), and (*iv*) wrong temperature value.

- BSC is more suitable for ranking tasks (Antique, CQA, and PFCC-S), but it can help for other tasks (classification and regression tasks, e.g., for MRPC, QQP, and STSb) if applied as pre-training or in joint training with MSE.

Selecting a loss function is important. For instance, if the model optimizes Pearson correlation, it achieves a score of 85.57 on the STS task. Thus, it outperforms almost all considered approaches. Moreover, the combination of such a loss with BSC allows the model to achieve an F1 score of 89.88 in the MRPC task (a classification task).

Finally, we would like to draw a parallel between our work and *Augmented SBERT* (Thakur et al., 2021). When using the BSC loss, some negatives are implicitly added to the dataset. Augmented SBERT adds new examples too and retrieves them using BM25 or Semantic Search samplings. These methods are comparable to our fast shuffling by words (n-grams) and to example-based shuffling, respectively. Moreover, the task-specific model is used to encode the data in both cases. However, we do not need to label such pairs with another model (cross-encoder) due to the BSC loss definition.

8 Conclusion and Future Work

We explored the idea of using a batch-softmax contrastive loss for fine-tuning large-scale pre-trained transformers to learn better task-specific sentence embeddings for pairwise sentence scoring tasks. We introduced and studied a number of variations in the calculation of the loss as well as in the overall training procedure. Our experimental results have shown sizable improvements on a number of datasets and pairwise sentence scoring tasks including ranking, classification, and regression.

In future work, we want to explore new variations of the loss, and to gain better understanding of when to use which variation. We further plan experiments with a larger set of NLP tasks.

Ethics and Broader Impact

We would like to warn that the use of large-scale Transformers requires a lot of computations and the use of GPUs/TPUs for training, which contributes to global warming (Strubell et al., 2019). This is a bit less of an issue in our case, as we do not train such models from scratch; rather, we fine-tune them on relatively small datasets. Moreover, running on a CPU for inference, once the model is fine-tuned, is perfectly feasible, and CPUs contribute much less to global warming.

Acknowledgments

The article was prepared within the framework of the HSE University Basic Research Program. It is also part of the Tanbih mega-project, developed at the Qatar Computing Research Institute, HBKU, which aims to limit the impact of “fake news,” propaganda, and media bias by making users aware of what they are reading, thus promoting media literacy and critical thinking.

NewsEdits: A News Article Revision Dataset and a Document-Level Reasoning Challenge

Alexander Spangher[1], **Xiang Ren**[1], **Jonathan May**[1], **Nanyun Peng**[2]
[1]Information Sciences Institute, University of Southern California

Abstract

News article revision histories provide clues to narrative and factual evolution in news articles. To facilitate analysis of this evolution, we present the first publicly available dataset of news revision histories, *NewsEdits*. Our dataset is large-scale and multilingual; it contains 1.2 million articles with 4.6 million versions from over 22 English- and French-language newspaper sources based in three countries, spanning 15 years of coverage (2006-2021).[1]

We define article-level edit actions: *Addition*, *Deletion*, *Edit* and *Refactor*, and develop a high-accuracy extraction algorithm to identify these actions. To underscore the factual nature of many edit actions, we conduct analyses showing that added and deleted sentences are more likely to contain updating events, main content and quotes than unchanged sentences.

Finally, to explore whether edit actions are predictable, we introduce three novel tasks aimed at predicting actions performed during version updates. We show that these tasks are possible for expert humans but are challenging for large NLP models. We hope this can spur research in narrative framing and help provide predictive tools for journalists chasing breaking news.

1 Introduction

Revision histories gathered from various natural language domains like Wikipedia (Grundkiewicz and Junczys-Dowmunt, 2014), Wikihow (Faruqui et al., 2018) and student learner essays (Zhang and Litman, 2015) have primarily been studied to explore stylistic changes, such as grammatical error correction (Shah et al., 2020) and argumentation design (Afrin et al., 2020). However, deeper questions about content updates and narrative evolution are underexplored: *Which facts are uncertain and likely to be changed? Which events are likely to update? What voices and perspectives are needed to complete a narrative?*

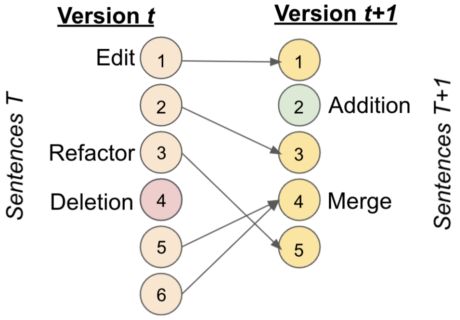

Figure 1: We identify sentence-level operations – *Edit*, *Addition*, *Deletion* and *Refactor* – between two versions of a news article (merges, shown here, and splits are a special cases of *Edits*). We propose tasks aimed at predicting these operations on article versions. We characterize aspects of additions, deletions and edits. We hope *NewsEdits* can contribute to research on narrative and factual development patterns.

Existing edits corpora do not address these questions due to the nature of previously studied domains: as shown in Yang et al. (2017), the distribution of edits in other domains, like Wikipedia, tend to focus on syntax or style edits. In this work, we introduce a novel domain for revision histories, *news article* revision histories which, we show, covers the *updating* of events. Many edits in news either (1) incorporate new information (2) update events or (3) broaden perspectives (Section 3).

Our dataset, *NewsEdits*, contains 1.2 million articles with 4.6 million versions. We develop a document-level view for studying revisions and define four edit actions to characterize changes between versions: sentence *Addition*, *Deletion*, *Edit* and *Refactor* (i.e. the sentence is moved within a document). We introduce algorithms for identifying these actions. We count over 40 million *Edits*, *Additions*, *Deletions* or *Refactors* in *NewsEdits*.

We argue that *news is an important, practical medium to study questions about narrative, factual*

---

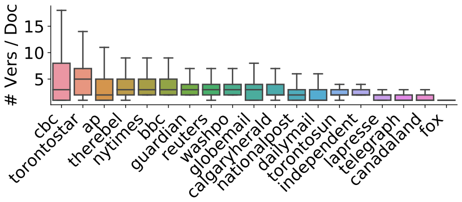

Figure 2: Number of versions per article, by outlet.

and stylistic development. This is because, we hypothesize, there are consistent patterns in the way articles update in the breaking news cycle (Usher, 2018). To prove this hypothesis, we show that updates are predictable. We design three tasks: (1) "predict whether an article will be updated," (2) "predict how much of an article will updated," (3) "predict sentence-level edit actions." We show that current large language model (LLM)-based predictors provide a strong baseline above random guessing in most tasks, though expert human journalists perform significantly better. Our insights are twofold: (a) article updates are predictable and follow common patterns which humans are able to discern (b) significant modeling progress is needed to address the questions outlined above. See Section 4.6 for more details.

Finally, we show that the *NewsEdits* dataset can bring value to a number of specific, ongoing research directions: event-temporal relation extraction (Ning et al., 2018; Han et al., 2019a), article link prediction (Shahaf and Guestrin, 2010), fact-guided updates (Shah et al., 2020), misinformation detection (Appelman and Hettinga, 2015), headline generation (Shen et al., 2017) and author attribution (Savoy, 2013), as well as numerous directions in computational journalism (Cohen et al., 2011; Spangher et al., 2020) and communications fields (Spangher et al., 2021b).

Our contributions are the following:

1. We introduce *NewsEdits*, the first public academic corpus of news revision histories.
2. We develop a document-level view of structural edits and introduce a highly scalable sentence-matching algorithm to label sentences in our dataset as *Addition*, *Deletion*, *Edit*, *Refactor*. We use these labels to conduct analyses characterizing these operations.
3. We introduce three novel prediction tasks to assess reasoning about whether and how an article will change. We show that current large language models perform poorly compared with expert human judgement.

2 The *NewsEdits* Dataset

NewsEdits is a dataset of 1.2 million articles and 4.6 million versions. In Section 2.1, we discuss the sources from which we gathered our dataset. In Section 2.2, we discuss the categories of edit-actions designed to characterize changes between versions, and in Section 2.3, we discuss the algorithm we built to identify these edit-actions.

2.1 Data Collection

We collect a dataset of news article versions. An article is defined by a unique URL, while a version is one publication (of many) to that same URL. We combine data from two online sources that monitor news article updates: NewsSniffer[2] and Twitter accounts powered by DiffEngine.[3] These sources were chosen because, together, they tracked most major U.S., British and Canadian news outlets (Kirchhoff, 2010). Our corpus consists of article versions from 22 media outlets over a 15-year timescale (2006-2021), including *The New York Times*, *Washington Post* and *Associated Press*. Although the median number of updates per article is 2, as shown in Figure 2, this varies depending on the outlet. More dataset details in Appendix E.

2.2 Edit-Action Operations

Since we are interested in how an entire news article updates between versions, we focus on sentence edits (document-level actions), not word edits (sentence-level actions). Identifying that sentences are added and deleted (vs. updated), can help us study the degree of change an edit introduces in the article (Daxenberger and Gurevych, 2012, 2013; Fong and Biuk-Aghai, 2010).

Thus, we define the following sentence-level edit-actions, shown in Figure 1: *Addition*, *Deletion*, *Edit* and *Refactor*. *Additions* should contain novel information and *Deletions* should remove information from the article. *Edits* should be substantially similar except for syntactic changes, rephrased and minimally changed or updated information. Special cases of the *Edit* operation result in sentences that are merged or split without substantial changes. See Section 2.3 for more details.

Refactors are intentionally moved in an article.[4]

---

[2] `https://www.newssniffer.co.uk/`

[3] `https://github.com/DocNow/diffengine`

[4] As an example, in Figure 1, the addition of Sentence 2 in version$_{t+1}$ shifts Sentences 3, 4, 5 down. These are *not* refactors, just incidental moves caused by other operations. However, Sentences 5, 6 in version$_t$ are shifted upwards in

BERT-Based			Subsequence Matching		BLEU-Based	
	Method	F1-Score	Method	F1-Score	Method	F1-Score
Hungarian	TB-mini	88.5	ngram-1	86.0	BLEU-1	86.7
	TB-medium	88.7	ngram-2	88.7	BLEU-2	89.2
	RB-base	88.6	ngram-3	88.5	BLEU-3	88.8
Max	TB-mini	89.0	ngram-4	88.2	BLEU-1,2	88.8
	TB-medium	**89.5**			BLEU-1,2,3	89.1
	RB-base	89.4				

Table 1: F1 scores on validation data for matching algorithms. Left-hand group shows embedding-based methods (TinyBert (TB) and RoBERTa (RB)) with Maximum or Hungarian matching. Middle group shows ngram methods. Right-hand group shows BLEU for different ngram weightings (1,2 and 1,2,3 are uniform weightings over unigrams, bigrams and trigrams).

Refactors are important because, based on the *inverse pyramid*[5] (Pöttker, 2003) of article structure, sentences that are higher in an article are more important (Scanlan, 2003). Thus, *Refactors* give us insight into the changing importance of sentences in a narrative.

2.3 Edit-Action Extraction

To extract these edit-actions, we need to be able to construct a bipartite graph linking sentences between two versions of an article (example graph shown in Figure 1). If an edge exists between a sentence in one version and a sentence in the other, the sentence is an *Edit* (or *Unchanged*). If no edge exists, the sentence is an *Addition* (if the sentence exists in the newer version only) or *Deletion* (if it exists in the older version only). We identify *Refactors* based on an algorithm we develop: in short, we identify a minimal set of edges in the graph which causes all observed edge-crossings. For details on this algorithm, see Appendix F.

In order to construct this bipartite graph, we need a scalable, effective, sentence-similarity algorithm. There is a wide body of research in assessing sentence-similarity (Quan et al., 2019; Abujar et al., 2019; Yao et al., 2018; Chen et al., 2018). However, many of these algorithms measure *symmetric* sentence-similarity. As shown in Figure 1, two sentences from the old version can be merged in the new version.[6] The symmetric similarity between these three sentences would be low, leading us to label the old sentences as *Deletions* and the new one an *Addition*, even if they were minimally edited (for concrete examples, see Table 14). This violates our tag definitions (Section 2.2). So, we need to measure one-way similarity between sentences, allowing us to label merged and split sentences as *Edits*. Our algorithm is an asymmetrical version of the *maximum alignment* metric described by Kajiwara and Komachi (2016):

$$\text{Sim}_{asym}(x,y) = \frac{1}{|x|}\sum_{i=1}^{|x|}\max_{j}\phi(x_i,y_j)$$

where $\phi(x_i,y_j) :=$ similarity between words x_i in sentence x and y_j in sentence y.

We test several word-similarity functions, ϕ. The first uses a simple lexical overlap, where $\phi(x_i,y_j) = 1$ if $lemma(x_i) = lemma(y_j)$ and 0 otherwise.[7] The second uses word-embeddings, where $\phi(x_i,y_j) = Emb(x_i)\cdot Emb(y_j)$, and $Emb(x_i)$ is the embedding derived from a pretrained language model (Jiao et al., 2020; Liu et al., 2019).

Each ϕ function assesses word-similarity; the next two methods use ϕ to assess sentence similarity. *Maximum alignment* counts the number of word-matches between two sentences, allowing many-to-many word-matches between sentences. Hungarian matching (Kuhn, 1955) is similar, except it only allows one-to-one matches. We compare these with BLEU variations (Papineni et al., 2002), which have been used previously to assess sentence similarity (Faruqui et al., 2018).

2.4 Edit-Action Extraction Quality

Although our sentence-similarity algorithm is unsupervised, we need to collect ground-truth data in order to set hyperparameters (i.e. the similarity threshold above which sentences are considered a match) and evaluate different algorithms. To

---

version$_{t+1}$, which is movement that is not caused by other operations. We label this as a *Refactor*.

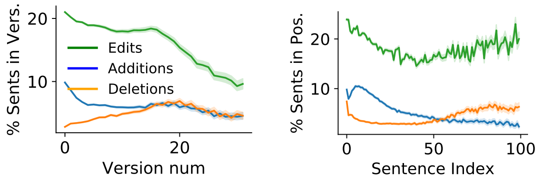
[5] An inverse pyramid narrative structure is when the most crucial information, or purpose of the story, is presented first (Scanlan, 2003).

[6] E.g. "ipsum. Lorem" → "ipsum; and Lorem". Conversly, one sentence can also be split.

[7] We extend this to non-overlapping ngram matches.

	Total Num.	% of Sents.
Edits	26.6 mil.	17.6 %
Additions	10.2 mil.	6.8 %
Deletions	5.4 mil.	3.6 %
Refactors	1.6 mil.	1.1 %

Table 2: Summary Statistics for Sentence Operations



(a) Edit-actions by version (% total in version).

(b) Edit-actions by sentence position (%).

Figure 3: Dynamics of edit actions.

do this, we manually identify sentence matches in 280 documents. We asked two expert annotators to identify matches if sentences are nearly the same, they contain the same information but are stylistically different, or if they have substantial overlap in meaning and narrative function. See Appendix G for more details on the annotation task. We use 50% of these human-annotated labels to set hyperparameters, and 50% to evaluate match predictions, shown in Table 1. Maximum Alignment with TinyBERT-medium embeddings (Jiao et al., 2020) (**Max-TB-medium**) performs best.[8]

3 Exploratory Analysis

We extract all edit actions in our dataset using methods described in the previous section. Statistics on the total number of operations are shown in Table 2. In this section, we analyze *Additions*, *Deletions* and *Edits* to explore when, how and why these edit-actions are made and the clues this provides as to why articles are updated. We leave a descriptive analysis of *Refactors* to future work.

Insight #1: Timing and location of additions, deletions and edits reflect patterns of breaking news and inverse pyramid article structure. How do editing operations evolve from earlier to later versions, and where do they occur in the news article?

In Figure 3a, we show that edit-actions in an article's early versions are primarily adding or updating information: new articles tend to have roughly 20% of their sentences edited, 10% added and few deleted. This fits a pattern of breaking news lifecycles: an event occurs, reporters publish a short draft quickly, and then they update as new information is learned (Hansen et al., 1994; Lewis and Cushion, 2009). We further observe, as is demonstrated in Figure 6 in the appendix, that updates occur rapidly: outlets known for breaking news[9] have a median article-update time of < 2 hours.

	Add.	Del.	Unchang.
Contains Event	38.5	39.3	31.4
Contains Quote	48.4	50.0	39.2
Discourse: Main	4.4	4.9	3.6
Discourse: Cause	29.0	30.2	23.6
Discourse: Distant	63.5	61.4	68.1

Table 3: % *Addition*s, *Deletion*s or Unchanged sentences that contain Events or Quotes, or have news discourse role: Main (main events), Cause (immediate context) or Distant (history, analysis). $F < .01$, $n = 7,368,634$.

An article's later lifecycle, we see, is determined by churn: ≈ 5% of sentences are added and 5% are deleted every version. As seen in Figure 3b, additions and edits are more likely to occur in the beginning of an article, while deletions are more likely at the end, indicating newer information is prioritized in an inverse pyramid structural fashion.

Insight #2: Additions and deletions are more likely to contain fact-patterns associated with breaking news (quotes, events, or main ideas) than unchanged sentences. In the previous section, we showed that the timing and position of edit-actions reflects breaking news scenarios. To provide further clues about the semantics of edit-actions, we sample *Additions*, *Deletions* and unchanged sentences and study the kinds of information contained in these sentences. We study three different fact-patterns associated with breaking news: events, quotes and main ideas (Ekström et al., 2021; Usher, 2018). To measure the prevalence of these fact-patterns, we sample 200,000 documents (7 million sentences) from our corpus and run an event-extraction pipeline (Ma et al., 2021), quote-detection pipeline (Spangher et al., 2020), and news discourse model (Spangher et al., 2021a). As shown in Table 3, we find added and deleted sentences have significantly more events, quotes and *Main-Idea* and *Cause* discourse than unchanged sentences. (See Appendix B for more details.)

Insight #3: Edited sentences often contain updating events. The analyses in the previous sec-

[9] E.g. *Associated Press*, *New York Times* and *Wash. Post*

Event Chains
(attack, killed), (injured, killed), (shot, dead), (shot, killed), (attack, injured), (injured, died), (election, won), (meeting, talks), (talks, meeting), (elections, election), (war, conflict)

Table 4: Selection of top event extracted from edited sentence pairs across article versions.

tions have established that edit-actions both are positioned in the article in ways that resemble, and contain information that is described by, breaking news epistemologies (Ekström et al., 2021). A remaining question is whether the edit-actions change fact-patterns themselves, rather than simply changing the style or other attributes of sentences.

One way to measure this is to explore whether edit-actions update the events in a story (Han et al., 2019b). We focus on pairs of edited sentences. We randomly sample *Edits* from documents in our corpus ($n = 432,329$ pairs) and extract events using Ma et al. (2021)'s model. We find that edited sentence pairs are more likely to contain events (43.5%) than unchanged sentences (31.4%). Further, we find that 37.1% of edited sentences with events contain *different* across versions. We give a sample of pairs in Table 4. This shows that many *within* sentence operations update events.

Taken together, we have shown in this analysis that *factual* updates drive many of the edit operations that we have constructed to describe *NewsEdits* revision histories. Next, we will measure how predictable these update patterns are.

4 Predictive Analysis on NewsEdits

As shown in Section 3, many edit-actions show breaking news patterns, which Usher (2018) observed follow common update patterns. Now, we explore how predictable these operations are, to address whether future work on the fundamental research questions addressed in Section 1 around narrative design is feasible.

In this section, we outline three tasks that involve predicting the future states of articles based on the current state. These tasks, we hypothesize, outline several modeling challenges: (1) identify indicators of uncertainty used in news writing[10] (Ekström et al., 2021), (2) identify informational incompleteness, like source representation (Spangher et al., 2020) and (3) identify prototypical event patterns (Wu et al., 2022). These are all strategies that expert human evaluators used when performing our tasks (Section 4.6). The tasks range from easier to harder, based on the sparsity of the data available for each task and the dimensionality of the prediction. We show that they are predictable but present a challenge for current language modeling approaches: expert humans perform these tasks much more accurately than LLM-based baselines.

In addition to serving a model-probing and data-explanatory purpose, these tasks are also practical: journalists told us in interviews that being able to perform these predictive tasks could help newsrooms allocate reporting resources in a breaking news scenario.[11]

4.1 Task Description and Training Data Construction

We now describe our tasks. For all three tasks, we focus on breaking news by filtering *NewsEdits* down to short articles (# sents $\in$ [5, 15]) with low version number (<20) from select outlets.[12]

Task 1: Will this document update? Given the text of an article at version v, predict if $\exists v + 1$. This probes whether the model can learn a high-level notion of change, irrespective of the fact that different edit-actions have different consequences for the information presented in a news article.

For **Task 1**, $y = 1$ if a newer version of an article was published and 0 otherwise. We sample 100,000 short article versions from *NewsEdits*, balancing across length, version number, and y.

Task 2: How much will it update? Given the text of an article at version v, predict in the next version how many *Additions*, *Deletions*, *Edits*, *Refactors* will occur. This moves beyond Task #1 and requires the model to learn more about *how* each edit-action category changes an article.

For **Task 2**, y = counts of sentence-level labels (*Num. Additions*, *Num. Deletions*, *Num. Refactors*, *Num. Edits*) described in the previous sections, aggregated per document. Each count is binned: $[0, 1)$, $[0, 3)$, $[3, \infty)$ and is predicted separately as a multiclass classification problem. We sample 150,000 short article versions balancing for sources, length and version number.

Task 3: How will it update? For each sentence in version v, predict whether: (1) the sentence itself

---

[10] E.g. "Police to release details of the investigation."

[11] See Appendix A for more details.

[12] The *New York Times*, *Associated Press*, *Washington Post*, *BBC*, *Independent*, *Guardian* and *Reuters* were used, as they are more known for breaking news (Usher, 2018). See Appendix E for more details.

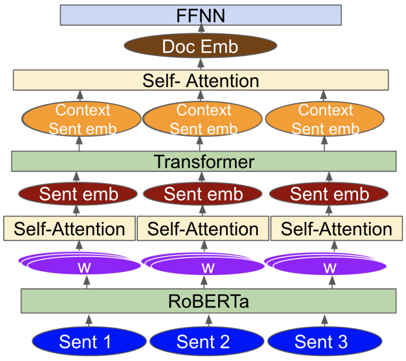

Figure 4: Architecture diagram for the model used for our tasks. Word-embeddings are averaged using **Self-Attention** to form sentence-vectors. A minimal transformer layer is used to contextualize these vectors (+Contextual Layer). In Tasks 1 and 2, self-attention is used to generate a document-embedding vector.

will change (i.e. it will be a *Deletion* or *Edit*) (2) a *Refactor* will occur (i.e. it will be moved either up or down in the document) or (3) an *Addition* will occur (i.e. either above or below the sentence). This task, which we hypothesize is the hardest task, requires the model to reason specifically about the informational components of each sentence *and* understand nuance about structure and form in a news article (i.e. like the inverse pyramid structure (Pöttker, 2003)).

For **Task 3**, y = individual sentence-level labels. Labels are derived for the following subtasks mentioned above: (1) *Sentence Operations* is a categorical label comprising: [Deletion, Edit, Unchanged], expressed as a one-hot vector. (2) *Refactor* is a categorical label comprising: [Up, Down, Unchanged], also expressed as a one-hot vector. (3) *Addition Above* and *Addition Below* are each binary labels expressing whether > 1 sentences was added above or below the target sentence. Because some sentences had *Additions* above and below, we chose to model this subtask as two separate classification tasks. We sample 100,000 short article versions, balancing for sources, length and version number.

For each task, the input X is a document represented as a sequence of sentences. For each evaluation set, we sample $4k$ documents balancing for class labels (some labels are highly imbalanced and cannot be balanced).

4.2 Modeling

We benchmark our tasks using a RoBERTa-based architecture shown in Figure 4. Spangher et al. (2021a) showed that a RoBERTa-based architecture (Liu et al., 2019) with a contextualization layer outperformed other LLM-based architectures like Reimers and Gurevych (2019) for document-level understanding tasks (further insight given in Section 4.6).

In our model, each sentence from document d is fed into a pretrained `RoBERTa Base` model[13] to obtain contextualized word embeddings. The word embeddings are then averaged using self-attention, creating sentence vectors. For **Task 3**, these vectors are then used directly for sentence-level predictions. For **Tasks 1** and **2** these vectors are condensed further, using self-attention, into a single document vector which is then used for document-level predictions. The sentence vectors are optionally contextualized to incorporate knowledge of surrounding sentences, using a small Transformer layer[14] (+Contextualized in Tables 5, 6, 7).

We experiment with the following variations. For **Task 2**, we train with less data ($n = 30,000$ version pairs) and more data ($n = 150,000$ version pairs), balanced as described in Section 4.1, to test whether a larger dataset would help the models generalize better. We also experiment, for all tasks, with freezing the bottom 6 layers of the RoBERTa architecture (+Partially Frozen) to probe whether pretrained knowledge is helpful for these tasks. Additionally, we experiment giving the version number of the older version as an additional input feature alongside the text of the document (+Version).

Finally, for **Tasks 2** and **3**, we attempt to jointly model all subtasksusing separate prediction heads for each subtask but sharing all other layers. We use uniform loss weighting between the tasks. Spangher et al. (2021a) showed that various document-level understanding tasks could benefit by being modeled jointly. For our tasks, we hypothesize that decisions around one operation might affect another: i.e. if a writer deletes many sentences in one draft they might also add sentences, so we test whether jointly modeling has a positive effect.

We do not consider any feature engineering on the input text, like performing event extraction (Ma et al., 2021), even though results in Section 3 show that certain types of edit-actions are more likely to contain events. We wish to establish a strong baseline and test whether models can learn salient features on their own. For more discussion on mod-

---

[13] We used Wolf et al. (2020)'s version, found here `https://huggingface.co/roberta-base`.

[14] Specifically, we initialize a 2-layer, 2-headed GPT2 transformer block to perform autoregressive contextualization.

eling choices and hyperparameter values, see Appendix D.

4.3 Human Performance

To evaluate how well human editors agree on edits, we design two human evaluation tasks and recruit 5 journalists with ≥ 1 year of editing experience at major U.S. and international media outlets.

Evaluation Task 1: We show users the text of an article and ask them whether or not there will be an update. Collectively, they annotate 100 articles. After completing each round, they are shown the true labels. This evaluates **Task 1**.

Evaluation Task 2: We show users the sentences of an article, and they are able to move sentences, mark them as deleted or edited, and add sentence-blocks above or below sentences. They are **not** asked to write any text, only mark the high-level actions of "I *would* add a sentence," etc. Collectively they annotate 350 news articles. After each annotation, they see what edits *actually* happened. The raw output evaluates **Task 3** and we aggregate their actions for each article to evaluate **Task 2**. They are instructed to use their expert intuition and they are interviewed afterwards on the strategies used to make these predictions. (See Appendix G for task guidelines and interviews).

4.4 Results

As shown in Tables 5, 6, and 7, model-performance indicates that our tasks do range from easier (**Task 1**) to harder (**Task 3**). While our models show improvements above **Random**, and **Most Popular**

Topic (↑)	F1	Topic (↓)	F1	y (Add)	F1
U.S. Pol.	38.1	Local Pol.	66.8	[0, 1)	16.2
Business	48.4	War	61.8	[1, 5)	59.7
U.K. Pol.	50.4	Crime	58.3	[5, 100)	0.9

Table 8: Error Analysis: LDA (first two columns): Documents belonging to some topics are easier to predict than others. By label (last column): medium-range growth is easier to predict.

in almost all subtasks, a notable exception is **Task 3**'s *Addition* subtasks, where the models do not clearly beat **Random**. We note that this was also the most difficult subtask for human evaluators.

We observe that +Partially Frozen increases performance on **Task 2**, boosting performance in all subtasks by ≈ 10 points. In contrast, it does not increase performance on **Task 3**, perhaps indicating that the subtasks in **Task 3** are difficult for the current LLM paradigm. Although adding version embeddings (+Version) boosts performance for **Task 1**, it does not seem to measurably increase performance for the other tasks. Finally, performing **Task 2** and **3** as multitask learning problems decreases performance for all subtasks.

In contrast, human evaluators beat model performance across tasks, most consistently in **Task 2**, with on average performance 20 F1-score points above Baseline models. On **Task 3**, human performance also is high relative to model performance. We observe that, despite *Additions* in **Task 3** being the hardest task, as judged by human and model performance, humans showed a ≈ 40 point increase above model performance. Humans are also better at correctly identifying minority classes, with a wider performance gap seen for Macro F1 scores (i.e. see *Sentence Operations*, where the majority of sentences are unchanged).

4.5 Error Analysis

We perform an error analysis on the **Task 2** task and find that there are several categories of edits that are easier to predict than others. We run Latent Dirichlet allocation on 40,000 articles, shown in Table 8.[15] We assign documents to their highest topic and find that articles covering certain news topics (like *War*) update in a much more predictable pattern than others (like *Business*), with a spread of over 26 F1-score points. Further, we find that certain edit-patterns are easier to differentiate, like articles that grow between 1-5 sentences (Table 8). This show us ways to select for subsets of our dataset that are more standard in their update patterns.

The class imbalance of this dataset (Table 2) results in the **Most Popular** scoring highly. To mitigate this, we evaluate on balanced datasets. Class imbalanced training approaches (Li et al., 2020; Spangher et al., 2021a) might be of further help.

4.6 Evaluator Interviews

To better understand the process involved with successful human annotation, we conducted evaluator interviews. We noticed that evaluators first identified whether the main news event was still occurring, or if it was in the past. For the former, they tried to predict when the event would update.[16] For the latter, they considered discourse components to determine if an article was narratively complete and analyzed the specificity of the quotes.[17] They determined where to add information in the story based on structural analysis, and stressed the importance of the inverse pyramid for *informational uncertainty*: information later in an article had more uncertainty; if confirmed, it would be moved up in later versions.[18] Finally, they considered the emotional salience of events; if a sentence described an event causing harm, it would be moved up.[19]

Clearly, these tasks demand strong world-knowledge and common sense, as well and high-level discourse, structural and narrative awareness.[20] Combining these different forms of reasoning, our results show, is challenging for current language models, which, for many subtasks, perform worse than guessing. **+Multitask** performance actually decreases performance for both **Task 2** and **Task 3**, indicating that these models learn features that do not generalize across subtasks. This contrasts with what our evaluators said: their decision to delete sentences often used the same reasoning as, and were dependent on, their decisions to add.

However, we see potential for improvement in these tasks. Current LLMs have been shown to identify common arcs in story-telling (Boyd et al., 2020), identify event-sequences (Han et al., 2019b) and reason about discourse structures (Spangher

---

[15] Topic words shown in Appendix C.

[16] The longer the timespan, the more information they predicted would be added between drafts.

[17] E.g. Generic quotes, say a public announcement, would be updated with specific, eye-witness quotes.

[18] One evaluator called this a *"buried cause"*.

[19] See Appendix G for full interviews.

[20] Evaluators told us they "thought like the AP." The AP, or the *Associated Press*, has a styleguide (Goldstein, 1953) that many outlets use to guide their writing.

et al., 2021a; Li et al., 2021). Further, for the ROCStories challenge, which presents four sentences and tasks the model with predicting the fifth (Mostafazadeh et al., 2017, 2016), LLMs have been shown to perform scene reconstruction (Tian et al., 2020b), story planning (Yao et al., 2019; Peng et al., 2018), and structural common sense reasoning (Chen et al., 2019). These are all aspects of reasoning that our evaluators told us they relied on. Narrative arcs in journalism are often standard and structured (Neiger and Tenenboim-Weinblatt, 2016), so we see potential for improvement.

5 Related Work

A significant contribution of this work, we feel, is the introduction of a large corpus of news edits into revision-history research and the framing of questions around sentence-level edit-actions. Despite the centrality of news writing in NLP (Marcus et al., 1993; Carlson et al., 2003; Pustejovsky et al., 2003; Walker et al., 2006), we know of no academic corpus of news revision histories. Two works that analyze news edits to predict article quality (Tamori et al., 2017; Hitomi et al., 2017) do not release their datasets.[21] WikiNews[22] articles and editor-annotations have been used for document summarization (Bravo-Marquez and Manriquez, 2012), timeline synthesis (Zhang and Wan, 2017; Minard et al., 2016), word-identification (Yimam et al., 2017) and entity salience (Wu et al., 2020). However, we are not aware of any work using WikiNews revision histories. We did not include WikiNews because its collaborative community edits differ from professional news edits.

Since at least 2006, internet activists have tracked changes made to major digital news articles (Hermann, 2006). `NewsDiffs.org`, NewsSniffer and DiffEngine are platforms which researchers have used to study instances of gender and racial bias in article drafts,[23] (Brisbane, 2012; Burke, 2016; Jones and Neubert, 2017; Fass and Main, 2014) shifting portrayals of social events, (Johnson et al., 2016) and lack of media transparency (Gourarie, 2015). These tools collect article versions from RSS feeds and the Internet Archive. Major newspapers[24] and thousands of government websites[25] are being analyzed. We use DiffEngine and NewsSniffer to construct *NewsEdits*.

Wikihow (Anthonio et al., 2020; Bhat et al., 2020) and **Source Code Diffs** (Tan and Bockisch, 2019; Shen et al., 2019; Tsantalis et al., 2018; Silva and Valente, 2017; Marrese-Taylor et al., 2020; Xu et al., 2019) use revision histories from domains and for purposes different than ours. Many tasks have benefited from studying **Wikipedia Revisions**, like text simplification (Yatskar et al., 2010), textual entailment (Zanzotto and Pennacchiotti, 2010), discourse learning (Daxenberger and Gurevych, 2013) and grammatical error correction (Faruqui et al., 2018). However, most tasks focus on word-level edit operations to explore sentence-level changes. Ours focuses on sentence-level operations to explore document-level changes. Research in **Student Learner Essays** focuses on editing revisions made during essay-writing (Leacock et al., 2010; Wang et al., 2020; Zhang, 2020; Zhang and Litman, 2015). Researchers categorize the intention and effects of each edit (Zhang et al., 2017; Afrin et al., 2020), but do not try to predict edits.

6 Conclusion

In this work, we have introduced the first large-scale dataset of news edits, extracted edit-actions, and shown that many were fact-based. We showed that edit-actions are predictable by experts but challenging for current LM-backed classifierss. Going forward, we will develop a schema describing the types of edits. We are inspired by the Wikipedia Intentions schema developed by Yang et al. (2017), and are working in collaboration with journalists to further clarify the differences. This development will help to clarify the nature of these edits as well as focus further directions of inquiry.

7 Acknowledgements

We are grateful to Amanda Stent, Sz-Rung Shiang, Gabriel Kahn, Casey Williams, Meg Robbins, I-Hung Hsu, Mozhdeh Gheini, Jiao Sun and our anonymous reviewers for invaluable feedback. Spangher is grateful for Bloomberg for supporting this research with a PhD fellowship. May is supported by DARPA Contract FA8750-19-2-0500.

8 Ethical Considerations

8.1 Dataset

We received permission from the original owners of the datasets, NewsSniffer and DiffEngine. Both sources are shared under strong sharing licenses. NewsSniffer is released under an `AGPL-3.0 License`,[26] which is a strong "CopyLeft" license. DiffEngine is released under an `Attribution-NoDerivatives 4.0 International` license.[27]

Our use is within the bounds of intended use given in writing by the original dataset creators, and is within the scope of their licensing.

8.2 Privacy

We believe that there are no adverse privacy implications in this dataset. The dataset comprises news articles that were already published in the public domain with the expectation of widespread distribution. We did not engage in any concerted effort to assess whether information within the dataset was libelious, slanderous or otherwise unprotected speech. We instructed annotators to be aware that this was a possibility and to report to us if they saw anything, but we did not receive any reports. We discuss this more below.

8.3 Limitations and Risks

The primary theoretical limitation in our work is that we did not include a robust non-Western language source; indeed, our only two languages were English and French. We tried to obtain sources in non-Western newspapers and reached out to a number of activists that use the DiffEngine platform to collect news outside of the Western world, including activists from Russia and Brazil. Unfortunately, we were not able to get a responses.

Thus, this work should be viewed with that important caveat. We cannot assume *a priori* that all cultures necessarily follow this approach to breaking news and indeed all of the theoretical works that we cite in justifying our directions also focus on English-language newspapers. We provide documentation in the Appendix about the language, source, timeline and size of each media outlet that we use in this dataset.

One possible risk is that some of the information contained in earlier versions of news articles was updated or removed for the express purpose that it was potentially unprotected speech: libel, slander, etc. We discussed this with the original authors of NewsSniffer and DiffEngine. During their years of operation, neither author has received any requests to take versions down. Furthermore, instances of First Amendment lawsuits where the plaintiff was successful in challenging content are rare in the U.S. We are not as familiar with the guidelines of protected speech in other countries.

Another risk we see is the misuse of this work on edits for the purpose of disparaging and denigrating media outlets. Many of these news tracker websites have been used for noble purposes (e.g. holding newspapers accountable for when they make stylistic edits or try to update without giving notice). But we live in a political environment that is often hostile to the core democracy-preserving role of the media. We focus on fact-based updates and hope that this resource is not used to unnecessarily find fault with media outlets.

8.4 Computational Resources

The experiments in our paper require computational resources. All our models run on a single 30GB NVIDIA V100 GPU, along with storage and CPU capabilities provided by AWS. While our experiments do not need to leverage model or data parallelism, we still recognize that not all researchers have access to this resource level.

We use Huggingface RoBERTa-base models for our predictive tasks, and release the code of all the custom architectures that we construct at `https://github.com/isi-nlp/NewsEdits.git`. Our models do not exceed 300 million parameters.

8.5 Annotators

We recruited annotators from professional journalism networks like the NICAR listserve.[28] All the annotators consented to annotate as part of the experiment, and were paid $1 per task, above the highest minimum wage in the U.S. Of our five annotators, three are based in large U.S. cities, one lives in a small U.S. city and one lives in a large Brazilian city. Four annotators identify as white and one identifies as Latinx. Four annotators identify as male and one identifies as female. This data collection process is covered under a university IRB. We do not publish personal details about the annotations, and their interviews were given with consent

Zhe Victor Zhang. 2020. Engaging with automated writing evaluation (AWE) feedback on L2 writing: Student perceptions and revisions. *Assessing Writing*, 43:100439.

A Dataset: Broader Scope

We expect that *NewsEdits*will be useful for a range of existing tasks for revision corpora, such as edit language modeling (Yin et al., 2018) and grammatical error correction (Grundkiewicz and Junczys-Dowmunt, 2014). We also think *NewsEdits* can impact other areas of NLP research and computational journalism, including:

1. **Resource Allocation in Newsrooms** Newsrooms are often tasked with covering multiple breaking news stories that are unfolding simultanesouly (Usher, 2018). When multiple stories are being published to cover breaking news, or multiple news events are breaking at the same time, newsrooms are often forced to make decisions on which journalists to assign to continue reporting stories. This becomes especially pronounced in an era of budget cuts and local-journalism shortages (Nielsen, 2015). We interviewed 3 journalists with over 20 years of experience at major breaking news outlets. They agreed that a predictive system that performed the tasks explored in Section 4 would be very helpful for allowing editors track which stories are most likely to change the most, allowing them to keep resources on these stories.
2. **Event-temporal relation extraction** (Ning et al., 2018) and **Fact-guided updates** (Shah et al., 2020). As shown in Tables 3 and 4, added and edited sentences are both more likely to contain events, and event updates. We see potential for using these sentences to train revise-and-edit (Hashimoto et al., 2018) models.
3. **Misinformation**: Journalists often issue formal *Corrections* when they discover errors in their reporting (Appelman and Hettinga, 2015).[29] We found 14,301 corrections in *added* sentences across the same sample with a custom lexicon.[30] This might be used to help compare malicious campaigns with honest errors (Ferrara, 2017).
4. **Headline Generation** (Shen et al., 2017). Across a sample of 2 million version pairs, we count 376,944, or 17% that have a headline update. Headlines have been used to predict emotional salience (Gupta and Yang, 2019). Modeling edits that result in headline changes can help differentiate salient from non-salient edits.
5. **Authorship Attribution** is the task of predicting which authors were involved in writing an article. We found 2,747 *Contributor Lines*[31] added to articles. This can provide a temporal extension to author-attribution models such as Savoy (2013).
6. **Identifying Informational Needs**: Source inclusion (Spangher et al., 2020) and discourse structures (Choubey et al., 2020; Spangher et al., 2021a) of static articles have been studied. We see this corpus as being useful for studying *when* these narrative elements are added.

Directions that we have not explored, but possibly interesting include: style transfer (Fu et al., 2018), detecting bias in news articles (Mehrabi et al., 2020), cross-cultural sensitivity (Tian et al., 2020a), insertion-based article generation (Lu and Peng, 2021), and framing changes in response to an unfolding story (Spangher et al., 2021b).

B Exploratory Analysis Details

Insight #2 in Section 3 was based on several experiments that we ran. Here we provide more details about the experiments we ran.

Events: We sample of 200,000 documents (7 million sentences) from our corpus[32] and use Eventplus (Ma et al., 2021) to extract all events. We find added/deleted sentences have significantly more events than unchanged sentences.

Quotes: Using a quote extraction pipeline (Spangher et al., 2020), we extract explicit and implicit quotes from the sample of documents used above. The pipeline identifies patterns associated with quotes (e.g. double quotation marks) to distantly supervise training an algorithm to extract a wide variety of implicit and explicit quotes with high accuracy (.8 F1-score). We find added/deleted sentences contain significantly more quotes than unchanged sentences.

News Discourse: We train a model to identify three coarse-grained discourse categories in news text: *Main* (i.e. main story) *Cause* (i.e. immediate context), and *Distant* (i.e. history, analysis, etc.) We use a news discourse schema (Van Dijk, 1983) and a labeled dataset which contains 800 news articles labeled on the sentence-level (Choubey et al., 2020). We train a model on this dataset to score news

---

[29] An example of *misinformation* vs. *disinformation* (Stahl, 2006)

[30] In other words, the corrections were *not* present in previous drafts of the article. See Appendix E.1.4 for examples.

[31] Contribution acknowledgement. Appendix E.1.4 for ex.

[32] We balance for newspaper source, article length (from 5 to 100 sentences), and number of additions/deletions (from 0% of article to 50%)

articles in our dataset.[33] *Then*, we filter to *Addition*, *Deletion*, etc. sentences. We show that added and deleted sentences are significantly more likely than unchanged sentences to be *Main* or *Cause* sentences, while unchanged sentences are significantly more likely to be *Distant*.

C Error Analysis: Continued

As discussed in Section 4.5, we perform Latent Dirichlet Allocation (Blei et al., 2003) to soft-cluster documents. In Table 9, we show the top $k = 10$ words for each topic i (i.e. $\beta^i_{1,...k}$ where $\beta^i_1 > \beta^i_2 > ... > \beta^i_k$).

D Experiment Details

D.1 Modeling Decisions

For **Task 1**, we sample documents in our training dataset, balancing across versions and y and exclude articles with more than 6,000 characters. However, because of the imbalanced nature of the dataset, we could not fully balance.

As is seen in Table 2, +Version, the version number of the old version had a large effect on the performance of the model, boosting performance by over 10 points. We believe that this is permissible, because the version number of the old article is available at prediction time. Interestingly, the effect is actually the opposite of what we would expect. As can be seen in Figure 5, the more versions an article has, the *more likely* it is to contain another version. This is perhaps because articles with many versions are *breaking news* articles, and they behave differently than articles with fewer versions. To more properly test a model's ability to judge breaking news specifically, we can create a validation set where all versions of a set of articles are included; thus the model is forced to identify at early versions whether an article is a breaking news story or not.

For **Task 2**, we first experiment with different regression modeling heads before reframing the task as a classification task. We test with Linear Regression and Poisson Regression, seeking to learn the raw counts. However, we found that we were not able to improve above random in any subtask and reframed the problem as a binned classification problem.

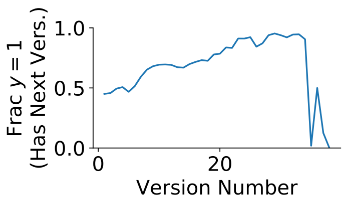

Figure 5: Percentage of the training dataset for **Task 1** which contains $y = 1$, or where another version of the article has been published.

D.2 Hyperparameters and Training

For all tasks, we used pretrained `RoBERTa Base` from Wolf et al. (2020). We used reasonable defaults for learning rate, dropout and other hyperparameters explored in Spangher et al. (2021a), which we describe now. For all tasks, we used AdamW as an optimizer, with values $\beta_1 = .9, \beta_2 = .99, \epsilon = 1e-8$. We used batch-size = 1 but experimented with different gradient accumulations (i.e. effective batch size) $\in [10, 20, 100]$. We did not find much impact to varying this parameter. We used a learning rate of 1e-6 as in Spangher et al. (2021a). Early in experimentation, we trained for 10 epochs, but did not observe any improvement past the 3rd epoch, so we limited training to 5 epochs. We used a dropout probability of .1, 0 warmup steps and 0 weight decay. The embedding dimensionality for the pretrained `RoBERTa Base` we used is 768, and for all other layers, we used a hidden-dimension of 512.

For deriving sentence embeddings, we tested several different methods. We tested both using the `<sep>` token from RoBERTa and averaging the word-embeddings of each word-piece, as in Spangher et al. (2021a), but found that a third method—using self-attention over the word embeddings, or a learned, weighted average—performed the best. We concatenated a sentence-level positional embedding vector, as in Spangher et al. (2021a), with a max cutoff of 40 positional embeddings (i.e. every sentence with an index greater than 40 was assigned the same vector.)

E Dataset Details

Here, we give additional details on the dataset, starting with relevant analyses and ending with technical details that should guide the user on how to access our dataset.

---

[33] We achieve a macro F1-score of .67 on validation data using the architecture described in Spangher et al. (2021a).

U.S. Politics (topic 0)	U.K. Politics (topic 2)	Police *Crime* (topic 5)	Aviation (topic 6)	Tragedy (topic 7)	War (topic 9)	Criminals *Crime* (topic 12)	School (topic 13)	Violence *Crime* (topic 18)
mr	government	police	people	family	killed	court	school	police
president	party	man	airport	died	people	year	year	officers

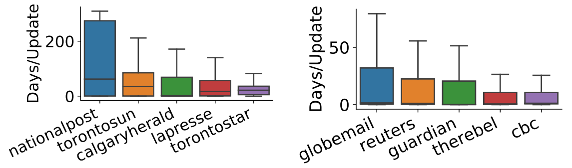
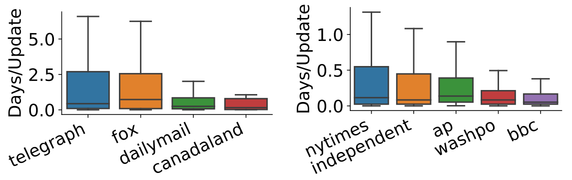
Table 9: Topic Model: Top Topics, selected on the bases of the number of documents they are most-expressed in. Labels are assigned by the researchers post-hoc. Several topics appear to be subsets of a broader *Crime* topic: we note the superclass *Crime* in parentheses. The specific *Crime* topic mentioned in the main body is the Violence topic (Topic 18)



(a) Distribution over days per update, group 1. Median across all sources in this group is 21 days.

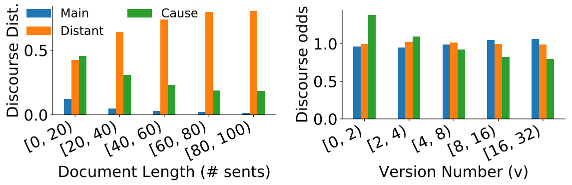
(b) Distribution over days per update, group 2. Median across all sources in this group is .9 days



(c) Distribution over days per update, group 3. Median across all sources in this group is .35 days, or 8.4 hours

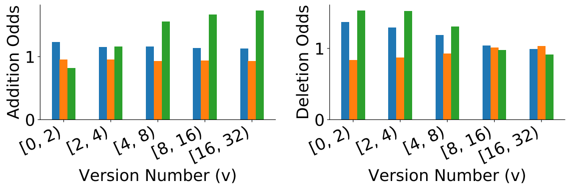
(d) Distribution over days per update, group 4. Median across all sources in this group is .05 days, or 1.33 hours.

Figure 6: Average time between version updates. We break sources into four primary groups with similar update distributions.



(a) Distributions over discourse tags, by article length.

(b) Odds of discourse element, by version. $odds = p(d|v)/p(d|!v)$.



(c) Odds of discourse element in added sentences. $odds = p(d|v,a)/p(d|v,!a)$.

(d) Odds of discourse element in deleted sentences. $odds = p(d|v,del)/p(d|v,!del)$.

Figure 7: Dynamics of news discourse composition size across time. d refers to *discourse label*, v refers to *version* and a, del refer to *is_added*, *is_deleted*

E.1 Additional Analysis

E.1.1 Amount of time between Versions

The amount of time between republication of an article varies widely across news outlets, and has a large role in determining what kinds of stories are being republished. As can be seen in Figure 6, we group sources into 4 categories: (1) Figure 6a, those that update articles over weeks (tabloids and magazines), (2) Figure 6b, those that update articles on a daily basis, on median, (3) Figure 6c, those that update 2-3 times a day, and (4) Figure 6d, those that update hourly, or breaking news outlets.

We are especially interested in rapid updates, because, by limits imposed by this timescale on how much information can be gathered by journalists, these updates are more likely to contain single units of information, updates and quotes. Thus, in our experiments, we focus on *The New York Times*, *Independent*, *Associated Press*, *Washington Post*, and *BBC*. We also include *Guardian* and *Reuters* because they typically compete directly with the previously mentioned outlets in terms of content and style, even if they do not publish as frequently.

E.1.2 Discourse Across Time

We are interested in the dynamics of articles over time. Although this analysis is still ongoing, we seek to understand how, as the article grows through time, the types of information included in it changes.We show in Figure 7a and 7b that in

Unchanged	said, trump, people, president, concerns, government, year
Add/Del	says, senate, law, death, wednesday, monday, tuesday

Table 10: Top Words in Additions/Deletions vs. top words in unchanged sentences.

later versions and longer articles[34] sentences are dominated by *Distant* discourse.

Interestingly, later versions are also more likely to have *Main* and *Cause* discourse added. Based on our annotator interviews, we surmise that this is because, for breaking news, a journalist is frequently trying to assess the causes behind the story. In early drafts, we also see *Main* sentences being removed. This is due to, as the story is updating in early versions, the *Main* event is most likely to be changing.

E.1.3 Top Words

Top Words: We characterize added and deleted sentences by their word usage in Table 10. Words indicating present-tense, recent updates are more likely: day-names like "Monday" or "Tuesday" and the present-tense verb "says" (compared with the past-tense "said" in unchanged sentences).

E.1.4 Collection of Corrections, Authorship

To identify instances of *Corrections* in added sentences, we used the following lexicon:

"was corrected", "revised", "clarification", "earlier error", "version", "article"

Here are some examples of corrections:

- CORRECTION: An earlier version of this story ascribed to Nato spokesman Brig Gen Carsten Jacobsen comments suggesting that after Saturdayś shooting, people would have to be "looking over their shoulders" in Afghan ministries.
- CORRECTION 19 November 2012:An earlier version of this story incorrectly referred to "gargoyles", not "spires".
- Correction 7 March 2012: An earlier version of this story mistakenly said Rushbrook's car had been travelling at 140mph at the time of the crash.

To identify instances of *Contributor Lines*, we use the following lexicon:

"reporting by", "additional reporting", "contributed reporting", "editing by"

Here are some examples of contributor lines:

- Additional reporting by Simon Browning.
- 'The article relied heavily on reporting by Reuters and the BBC, and it cited Reuters in saying that during a visit in October 1989 by Pope John Paul II to South Korea, China had prevented the pope's airplane from flying through Chinese airspace.
- The revelation comes after reporting by The New York Times last week showing that the head of communications at the N.I.H.'s parent agency, the Department of Health and Human Services, also accused federal scientists of using the coronavirus to try to defeat Mr. Trump.
- Additional reporting by Daniel Strauss in Richmond, Virginia, Richard Luscombe in West Palm Beach, Florida, and Ed Pilkington in Essex Junction, Vermont.

E.2 Dataset Tables and Fields

Our dataset is released in a set of 5 SQLite tables. Three of them are primary data tables, and two are summary-statistic tables. Our primary data tables are: `articles`, `sentence_diffs`, `word_diffs`; the first two of which are shown in Tables 12a and 12b (`word_diffs` shares a similar structure with `sentence_diffs`). We compile two summary statistics tables to cache statistics from `sentence_diffs` and `word_diffs`; they calculate metrics such as `NUM_SENTENCES_ADDED` and `NUM_SENTENCES_REMOVED` per article.[35]

The `sentence_diffs` data table's schema is shown in Table 12 and some column-abbreviated sample rows are shown in Table 14. As can be seen, the diffs are calculated and organized on a sentence-level. Each row shows a comparison of sentences between *two adjacent versions of the same article.*[36] Every row in `sentence_diffs` contains index columns: `SOURCE`, `A_ID`, `VERSION_OLD`, and `VERSION_NEW`. These columns can be used to uniquely map each row in `sentence_diffs` to *two* rows in `article`.[37]

---

[34] Version Number has spearman's correlation $r = .335$ with article length.

[35] These summary statistic tables make it convenient to, say, filter `sentence_diffs` in order train a model on all articles that have one sentence added; or all articles that have no sentences removed.

[36] So, for instance, article A, with versions 1, 2 where each version has sentences i, ii, iii, would have 3 rows (assuming sentences were similar): A.1-2.i, A.1-2.ii, A.1-2.iii.

[37] One mapping for `sentence_diffs.VERSION_OLD` = `article.VERSION_ID` and one mapping for `sentence_diffs.VERSION_NEW` = `article.VERSION_ID`.

Table 11: A summary of the number of total number of articles and versions for different media outlets which comprise our dataset. Also shown is the original collection that they were derived from (DE for DiffEngine, and NS from NewsSniffer), and the date-ranges during which articles from each outlet were collected.

E.3 `TAG` columns in `sentence_diffs`

The columns `TAG_OLD` and `TAG_NEW` in `sentence_diffs` have specific meaning: how to transform from version to its adjacent version. In other words, `TAG_OLD` conveys where to find `SENT_OLD` in `VERSION_NEW` and whether to change it, whereas `TAG_NEW` does the same for `SENT_NEW` in `VERSION_OLD`.

More concretely, consider the examples in Table 14b, 14a and 14c. As can be seen, each tag is 3-part and has the following components. **Component 1** can be either **M**, **A**, or **R**. **M** means that the sentence in the current version was **M**atched with a sentence in the adjacent version, **A** means that a sentence was **A**dded to the new version and **R** means the sentence was **R**emoved from the old version.[38] **Component 2** is only present for **M**atched sentences, and refers to the index or indices of the sentence(s) in the adjacent version.[39] Additionally, **Component 3** is also only present if the sentence is **M**atched. It can be either **C** or **U**. **C** refers to whether the matched sentence was **C**hanged and **U** to whether it was **U**nchanged.

Although not shown or described in detail, all **M** sentences have corresponding entry-matches in `word_diffs` table, which has a similar schema and tagging aim.

A user might use these tags in the following ways:

1. To compare only atomic edits, as in Faruqui et al. (2018), a user could filter `sentence_diffs` to sentences where **M..C** is in `TAG_OLD` (or equivalently, `TAG_NEW`). Then, they would join `TAG_OLD.Component_2` with `SENTENCE_ID`. Finally, they would select `SENT_OLD`, `SENT_NEW`.[40]
2. To view only refactorings, or when a sentence is moved from one location in the article to another, a user could filter `sentence_diffs` to only sentences containing **M..U** and follow a similar join process as in use-case 1.
3. To model which sentences might be added, i.e. $p(\text{sentence}_i \in \text{article}_{t+1} | \text{sentence}_i \notin \text{article}_t)$, a user would select all sentences in `SENT_OLD`, and all sentences in `SENT_NEW` where **A** is in `TAG_NEW`.
4. To model the inverse of use-case 3, i.e. which sentences would be removed, or $p(\text{sentence}_i \notin \text{article}_{t+1} | \text{sentence}_i \in \text{article}_t)$, a user would select all sentences in `SENT_NEW`, and all sentences in `SENT_OLD` where **R** is in `TAG_OLD`.

---

[38] i.e. an **A**dded row is not present in the old version and a **R**emoved row is not present in the new version. They have essentially the same meaning and we could have condensed notation, but we felt this was more intuitive.

[39] I.e. in `TAG_OLD`, the index refers to the `SENTENCE_ID` of `SENT_NEW`

[40] or simply look in the `word_diffs` table.

Column Name	Type	Column Name	Type	Column Name	Type
SOURCE	index	TITLE	text	CREATED	text
A_ID	index	URL	text	ARCHIVE_URL	text
VERSION_ID	index	TEXT	text	NUM_VERSIONS	int

(a) DB schema for the `article` table. `SOURCE`, `A_ID` and `VERSION_ID` are the primary key columns.

Column Name	Type	Column Name	Type	Column Name	Type
SOURCE	index	V_NEW_ID	index	TAG_OLD	text
A_ID	index	SENTENCE_ID	index	SENT_NEW	text
V_OLD_ID	index	SENT_OLD	text	TAG_NEW	text

(b) DB schema for the `sentence_diffs` table (`word_diffs` is similar). Table compares *version pairs* of articles. The rows in the table are on the sentence-level; `V_OLD_ID` refers to the index of the old version, `V_NEW_ID` refers to the index of the new version. `TAG_OLD` gives information for how to transition from the old version to the new version; `TAG_NEW` is the inverse.

Table 12: Schemas for two databases central to our content organization scheme.

E.4 Comparison With Other Edits Corpora

Here, we give a tabular comparison with other edits corpora, showing our

F Algorithm Details

In this section, we give further examples further justify our asymmetrical sentence-matching algorithm. The examples shown in Tables 14b, 14a and 14c illustrate our requirements. The first example, shown in Table 14b, occurs when a sentence is edited syntactically, but its meaning does not change.[42] So, we need our sentence-matching algorithm to use a sentence-similarity measure that considers semantic changes and does not consider surface-level changes. The second example, shown in Table 14a, occurs when a sentence is split (or inversely, two sentences are merged.) Thus, we need our sentence matching algorithm to consider many-to-one matchings for sentences. The third example, shown in Table 14c, occurs when sentence-order is rearranged, arbitrarily, throughout a piece. Finally, we need our sentence-matching algorithm to perform all pairwise comparisons of sentences.

F.1 Refactors

To identify which sentences were *intentionally* moved rather than moved as a consequence of other document-level changes, we develop an iterative algorithm based on the idea that a refactor is an intentional sentence movement that creates an edge-crossing. Algorithm 2 givens our algorithm.

```
input  : Article versions $v_{old}$, $v_{new}$, Match Threshold $T$
output : maps $m_{old\to new}$, $m_{old\leftarrow new}$
initialize;
$m_{old\to new}, m_{old\leftarrow new} = \{\}, \{\}$;
// match $v_{old} \to v_{new}$
for $(i, s_i) \in v_{old}$ do
    $d = \max_{s_j \in v_{new}} \mathrm{Sim}_{asym}(s_i, s_j)$
    $j = \arg\max_{s_j \in v_{new}} \mathrm{Sim}_{asym}(s_i, s_j)$
    $m_{old\to new}[i] = j \times \mathbb{1}[d > T]$
end
// match $v_{old} \leftarrow v_{new}$
for $(j, s_j) \in v_{new}$ do
    $d = \max_{s_i \in v_{old}} \mathrm{Sim}_{asym}(s_j, s_i)$
    $i = \arg\max_{s_i \in v_{old}} \mathrm{Sim}_{asym}(s_j, s_i)$
    $m_{old\leftarrow new}[j] = i \times \mathbb{1}[d > T]$
end
```

Algorithm 1: Asymmetrical sentence-matching algorithm. Input v_{old}, v_{new} are lists of sentences, and output is an index mapper. If a sentence maps to 0 (i.e. $d < T$), there is no match. *Sim*$_{asym}$ is described in text.

In English, our algorithm represents sentence matches between two article versions as a bipartite graph. We use a Binary Tree to recursively find all edge crossings in that graph. This idea is based off of the solution for an SPOJ challenge problem: https://www.spoj.com/problems/MSE06H/.[43] We extend this problem to return the *set* of all edge crossings, not just the crossing number.

Then, we filter edge crossings to a candidate

---

[42] Syntactic changes: synonyms are used, or phrasing is condensed, but substantially new information is not added

[43] Solution given here: https://github.com/akhiluanandh/SPOJ/blob/master/MSE06H.cpp.

Corpus	# Revisions	Language	Source	Goal
WiKed Error Corpus	12 million changed sentences	English	Wikipedia	Grammatical Error Correction (GEC)
WikiAtomic-Edits	43 million "atomic edits"[41]	8 languages	Wikipedia	Language Modeling
WiCoPaCo	70,000 changed sentences	French	Wikipedia	GEC and Sentence paraphrasing
WikiHow-ToImprove	2.7 million changed sentences	English	WikiHow	Version prediction, article improvement
NewsEdits	36.1 million changed sentences, 21.7 million added sentences, 14.2 million removed sentences. 72 million atomic edits.	English and French	22 media outlets	Language modeling, event sequencing, computational journalism

Table 13: A comparison of natural langauge revision history corpora.

set, applying the following conditions in order and stopping when there is only one edge crossing left: (1) edges that have the most number of crossings (2) edges that extend the most distance or (3) edges that move upwards. In most cases, we only apply the first and then the second conditions. In very rare cases, we apply all three. In rarer cases, we apply all three and *still* have multiple candidate edges. In those cases, we just choose the first edge in the candidate set. We continue removing edges until we have no more crossings.

G Annotation-Task Descriptions

G.1 Task: Sentence Matching

We give our annotators the following instructions:

> The goal of this exercise is to help us identify sentences in an article-rewrite that contain substantially new information. To do this, you will identiy which sentences match between two versions of an article.
>
> Two sentences match if:
>
> 1. They are nearly the same, word-for-word.
> 2. They convey the same information but are stylistically different.
> 3. They have slightly different information but have substantial overlap in meaning and narrative function.
>
> Examples of Option 3 include (please see the "Examples" section for real examples):
>
> 1. Updating events.
>   - (Ex) The man was presumed missing. → The man was found in his home.
>   - (Ex) The death count was at 23. → 50 were found dead.
>   - (Ex) The senators are still negotiating the details. → The senators have reached a deal.
> 2. An improved analysis.
>   - (Ex) The president is likely seeking improved relations. → The president is likely hoping that hardliners will give way to moderates, improving relations.
>   - (Ex) The storm, a Category IV, is expected to hit Texas. → The storm, downgraded to Category III, is projected to stay mainly in the Gulf.
>   - (Ex) Analysts widely think the shock will be temporary. → The shock, caused by widespread shipping delays, might last into December, but will ultimately subside.
> 3. A quote that is very similar or serves the same purpose.
>   - (Ex) "We knew we had to get it done." said Senator Murphy. → "At the end of the day, no one could leave until we had a deal" said Senator Harris.

(c) Demo 3: Two features shown: (1) Refactoring, or order-swapping, makes sentences appear as though they have been deleted and then added. Swapped sentences are matched through their tags. (2) The last sentence is a newly added sentence and is not matched with any other sentence.

Table 14: Here we show demos of three tricky edge-cases and how our tagging scheme handles them. `Old Tag` annotates a `Old Version` relative to changes in the `New Version` (or “converts” the `Old Version` to the `New Version`). `New Tag` is the inverse. Tag components: **Component 1: M, A, R.** Whether the sentence is **M**atched, **A**dded, or **R**emoved. **Component 2: Index.** If **M**atched, what is the index of the sentence in version that it is matched to. **Component 3: C, U.** If **M**atched, is the sentence **C**hanged or **U**nchanged.

stander. → “I couldn’t stop watching.” said a moviegoer.

Two sentences do not match if:

1. They contain substantially different information.
2. They serve different narrative functions.
3. There is a much better match for one sentence somewhere else in the document.

Things to keep in mind:

- Two sentences might match even if they are in different parts of the document.
- One sentence can match with multiple other sentences, because that sentence might be split up into multiple sentences, each with similar information as parts of the original.
- Sentences don’t have to match.
  - Substantially new information, perspectives or narrative tools might be added in a new version.
  - Substantially old information, perspectives or narrative tools might be removed from an old version.

```
input  : Sentence matches, i.e. edges $e$ between doc $i$ and doc $j$, as a list of tuples:
         $e_i = (s_{i1}, s_{i2}), e_j = (s_{j1}, s_{j2})....$
output : Minimal set of edges $r$ that, when removed, eliminate all crossings.
// Subroutine identifies all edge crossings in $e'$ and returns mapping
   $c = \{e_i \rightarrow [e_j, e_k...], e_j \rightarrow ...\}$ from each edge to all its crossings.
$c = getEdgeCrossings(e)$
while $|c| > 0$ do
    // Find candidate set: all edges with maximum crossings.
    $m = \max_i |c[e'_i]|$
    $e' = e'_i$ where $|c[e'_i]| = m$
    if $|e'| > 1$ then
        // Filter candidate set: all edges $\in e'$ that extend the maximum
           distance.
        $d = \max_i |e'_i[0] - e'_i[1]|$
        $e' = e'_i$ where $|e'_i[0] - e'_i[1]| = d$
        if $|e'| > 1$ then
            // Filter candidate set: all edges $\in e'$ that move up.
            $e' = e'_i$ where $e'_i[1] - e'_i[0] < 0$
        else
    else
end
// Take first element of $e'$ as the candidate to remove.
$t = e'[0]$
$r.push(t)$
// Remove $t$ from $c$ and from all $c[e'_i]$ lists that contain it.
$c = removeEdge(t)$
```

Algorithm 2: Identifying Refactors. We define refactors as the minimal set of edge crossings in a bipartite graph which, when removed, remove all edge crossings.

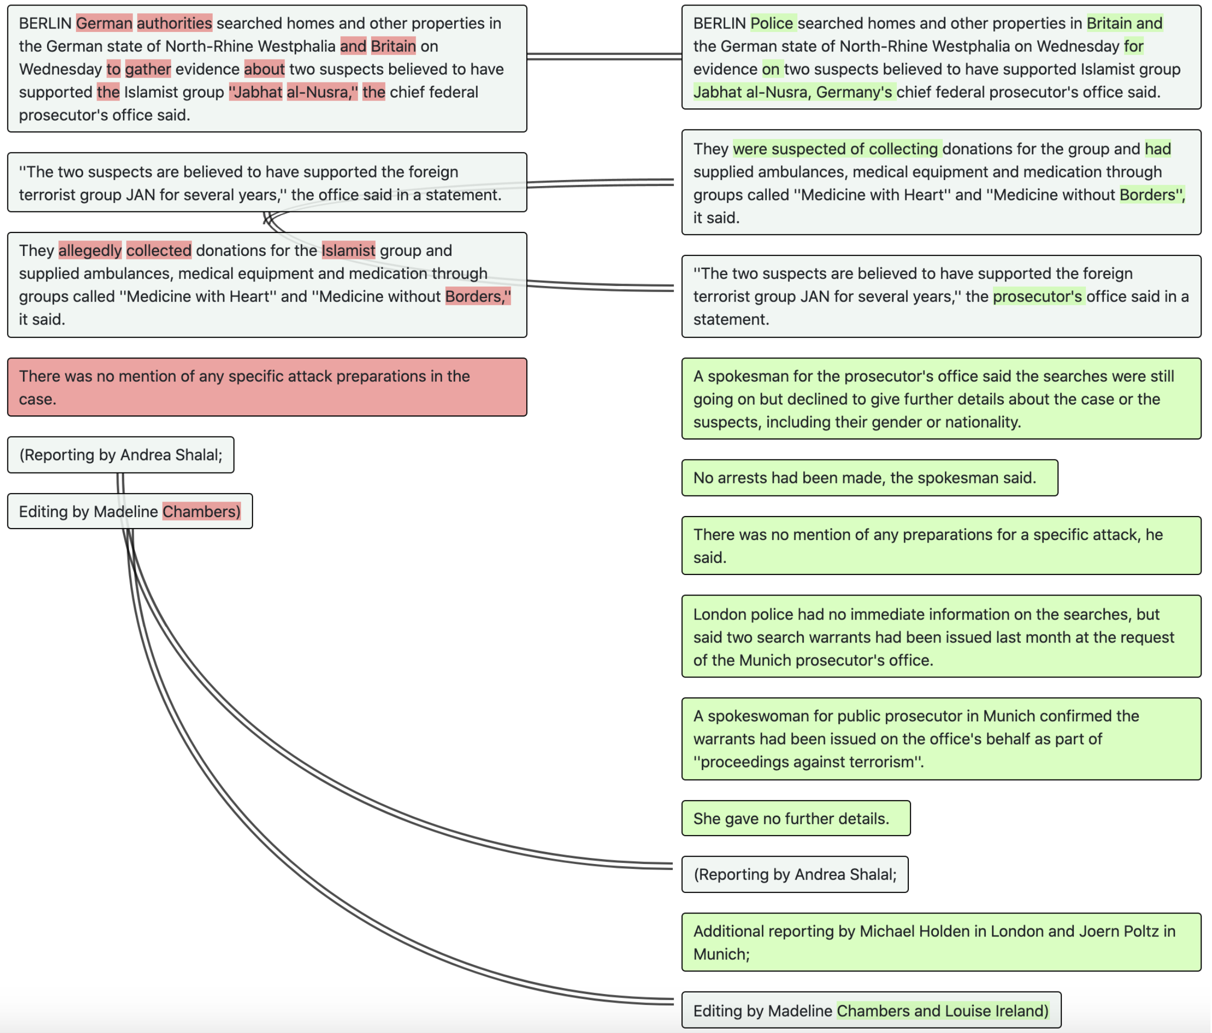
Annotators completed the task by drawing lines between sentences in different versions of an article. An example is shown in Figure 8. We use highlighting to show when non overlapping sequences in the inbox, using simple lexical overlap. If the user mouses over a text block, they can see which words do no match between all textblocks on the other side. Although this might bias them towards our lexical matching algorithms, we do not see them beaking **TB-medium**. This was very helpful for reducing the cognitive overload of the task.

G.2 Task: Edit Actions

In this task, workers were instructed to perform edit operations to an article version in anticipation of what the next version would look like. We recruited 5 workers: journalists who collectively had over a decade of experience working for outlets like *The New York Times*, *Huffington Post*, *Vice*, a local outlet in Maine, and freelancing.

We gave our workers the following instructions.

> You will be adding, deleting and moving sentences around in a news article to anticipate what a future version looks like.
>
> - **Add a sentence either below or above the current sentence** by pressing the Add ↑ or Add ↓ buttons. Adding a sentence means that you feel there is substantially new information, a novel viewpoint or quote, or necessary background information that needs to be present.
> - **Move a sentence by dragging it around on the canvas.** Moving a sentence, (or what we're calling refactoring) means that the importance of a sentence should be either increased or decreased within the article. Please note: refactors are rare!
> - **Delete a sentence by hitting the Delete button.** Deleting an Added sentence just reverses that action—



BERLIN German authorities searched homes and other properties in the German state of North-Rhine Westphalia and Britain on Wednesday to gather evidence about two suspects believed to have supported the Islamist group "Jabhat al-Nusra," the chief federal prosecutor's office said.

"The two suspects are believed to have supported the foreign terrorist group JAN for several years," the office said in a statement.

They allegedly collected donations for the Islamist group and supplied ambulances, medical equipment and medication through groups called "Medicine with Heart" and "Medicine without Borders," it said.

There was no mention of any specific attack preparations in the case.

(Reporting by Andrea Shalal;

Editing by Madeline Chambers)

BERLIN Police searched homes and other properties in Britain and the German state of North-Rhine Westphalia on Wednesday for evidence on two suspects believed to have supported Islamist group Jabhat al-Nusra, Germany's chief federal prosecutor's office said.

They were suspected of collecting donations for the group and had supplied ambulances, medical equipment and medication through groups called "Medicine with Heart" and "Medicine without Borders", it said.

"The two suspects are believed to have supported the foreign terrorist group JAN for several years," the prosecutor's office said in a statement.

A spokesman for the prosecutor's office said the searches were still going on but declined to give further details about the case or the suspects, including their gender or nationality.

No arrests had been made, the spokesman said.

There was no mention of any preparations for a specific attack, he said.

London police had no immediate information on the searches, but said two search warrants had been issued last month at the request of the Munich prosecutor's office.

A spokeswoman for public prosecutor in Munich confirmed the warrants had been issued on the office's behalf as part of "proceedings against terrorism".

She gave no further details.

(Reporting by Andrea Shalal;

Additional reporting by Michael Holden in London and Joern Poltz in Munich;

Editing by Madeline Chambers and Louise Ireland)

Figure 8: Example of Sentence Matching Task. All lines represent sentences that have been matched. When the user hits "Submit", additional coloring is added to the unmatched sentences, which represent *Addition* (green, right) and *Deletion* (red, left) sentences.

we will not record this. Deleting a sentence that is present means you feel it needs to be (a) substantially rewritten (ergo: a new sentence should also be Added), or (b) the sentence no longer applies given new information that was added.

- **Edit a sentence by hitting the Edit button.** Editing a sentence means that the wording might change a little bit due to other changes happening around the sentence or events within the sentence being updated.
- **Leaving a sentence unchanged** means that you don't really expect the sentence to change at all in the next version of the article.

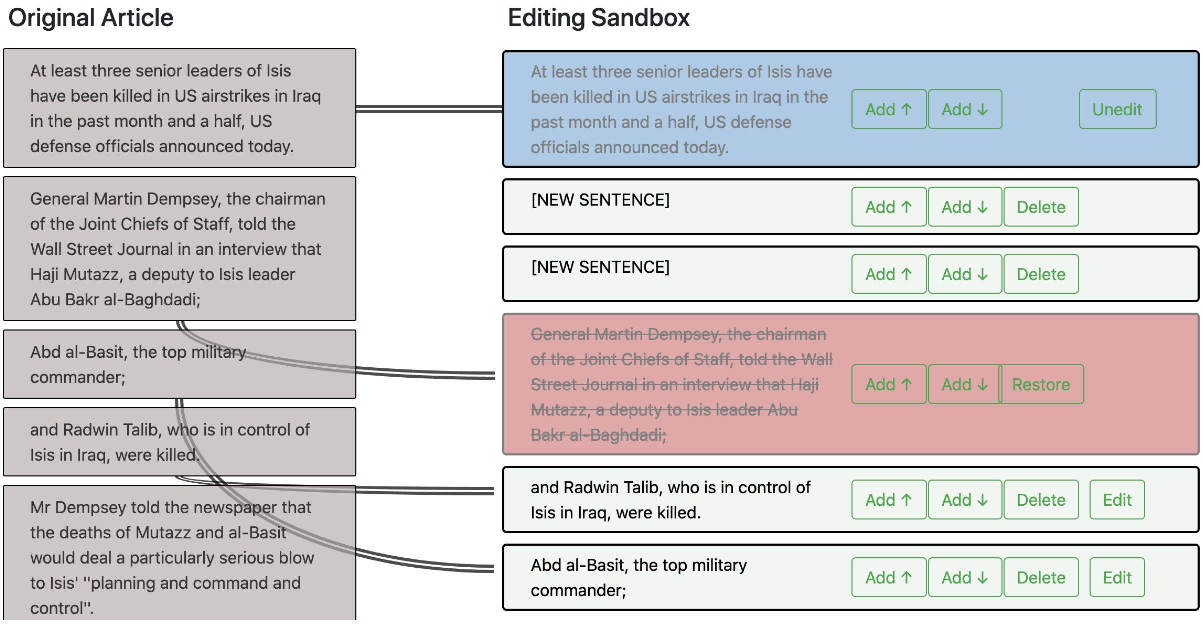
G.3 Annotator Analysis

We seek here to characterize the performance of different expert annotators. We see in Table 15 that there are three workers which do over 30 tasks each. We characterize the per-task accuracy by counting the number of edit-operations per document, and



At least three senior leaders of Isis have been killed in US airstrikes in Iraq in the past month and a half, US defense officials announced today.

General Martin Dempsey, the chairman of the Joint Chiefs of Staff, told the Wall Street Journal in an interview that Haji Mutazz, a deputy to Isis leader Abu Bakr al-Baghdadi;

Abd al-Basit, the top military commander;

and Radwin Talib, who is in control of Isis in Iraq, were killed.

Mr Dempsey told the newspaper that the deaths of Mutazz and al-Basit would deal a particularly serious blow to Isis' "planning and command and control".

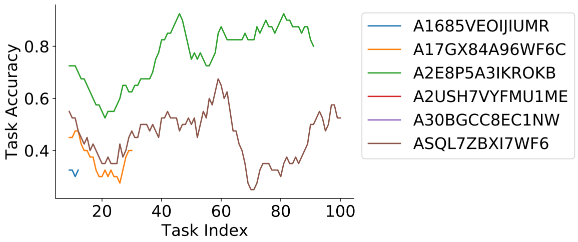

Figure 10: Worker Accuracy over time, by task

seeing if they got the same number as the true number of edits (each expressed as a binned count i.e. low: $[0,1)$ operations, medium: $[1,3)$ operations, high: $[3,\infty)$ operations).

We show that there is a wide variety of performances, in Table 16, with some workers getting over 75% of the operations correct and others getting ≈ 30% correct.

Interestingly, we see that there is a learning process occurring. In Figure 10, we see that workers get better over time as they do more tasks. This indicates that the training procedure of letting them see the edits that actually happened is successful at teaching them the style and patterns the edits will take.

G.4 Annotator Interview 1

This annotator was involved in the Editing task. They edited 50 stories.

1. *What was your general thought process?* Well, my first general though was: "how do I do this update?" Then I thought back to the instructions, and really tried to predict how the AP[44] would update.

I then had to decide what timespan I'd use—in general, I assumed a 24 hour update window, but sometimes it was different. If the story updates 2 hours after news breaks vs. 2 days, it will look very different

Sometimes, I would read the story, try to figure out what the story was about, ask what was missing, what I'd include in a story if I was reporting it fully. A lot of times what I felt were missing were more causal analysis, more quotes, more perspectives.

As I was going through, I almost always decided to edit the lede, and was almost always correct with that. Most leads, I thought, could be

---

[44] The AP, or *The Associated Press*, sets many standards for journalistic writing and reporting cycles.

more efficient, they could incorporate more details from further down in the story into the lede. Also, as stories unfolded, the actor responsible for the event becomes clear, that information will get added to the lede. For example, a building collapses in Manhattan -> faulty beam causes the building collapse. This detail often only becomes apparent afterwards.

What I realized doing this was that there are different genres of breaking news article, and genre matters a lot for how it gets updated. These are the following categories:

(a) Stories where the future is contingent, and you're making predictions in realtime.

ex) A sailor went missing off the isle of Mann. This story is fundamentally about an unknown – will he be discovered or not? This is one of the harder ones to figure out how to update. How it plays out determines how it will be updated. If the search goes on for a long time, you'll have more details, you'll have quotes from his family, conditions on the water. If he's found, this stuff becomes irrelevant. You'll have information about how he gets found, then you'll have information about how many people get updated.

ex) A story was about "Trump is about to make a speech". "Trump expected to speak". I updated it as if event didn't happen yet. But the real update actually contained him speaking. Stories about when multiple futures can happen, without knowing the timescale of the update, are difficult to predict.

I determined whether an event was unfolding by looking for several clues. I looked for certain words: "expected", "scheduled", etc. Usually this signals an event-update. I looked for stories where there's a ton of uncertainty.

Another clue was that the only sources are official statements (ex. "Officials in Yemen say something happened".) The space of possible change increases. You're going to get conflicting reports, eye-witnesses contradicting official statements.

Some articles included direct appeals to readers—"don't use the A4 if you're traveling between London, etc." For crime articles: "if you have any information, please contact agency." This kind of direct appeal is not relevant in the next version.

(b) Past stories when the event is totally in the past.

For these stories, I looked for vagueness of the original article to determine what would be updated. If it's more specific, for example, with exact death toll numbers, information about specific actors and victims, the less it's going to be updated. For these stories, my tendency was to add at least 1-2 sentences of context towards the end of every story. If you're writing for Reuters, you might not need that.

In general, I wanted to see some background, people involved.

The quotes you're getting, are they press releases or are they directly from people? If they more official statements and press releases, then you'll see more updates in the form of specific victim quotes.

One general note: most breaking stories were about bad things. Disasters, crashes, missing people, etc. For a bombing, there's a pretty predictable pattern of expansion. Death toll will get added, more eyewitness accounts. It has an expansionary trajectory.

2. *How did you determine if a sentence needed to be added?* I decided to add anywhere I saw vagueness. I added a lot towards the beginning, right after the nut graf is where I added the most sentences. If I saw a sentence taken from a press release, I added after that, assuming that the journalist would get a more fleshed-out quote from someone.

Often I added [sentences] at the end to add context. I never added something before the lead.

Maybe a story has two ideas, then I'd add sentences to the second half to flesh out a second idea.

Sometimes I thought about different categories of information—quotes, analysis, etc.—and it was obvious if some of that was missing.

3. *How did you determine if a sentence needed to be deleted?*

I very rarely thought things needed to be deleted

One of the challenges of the experiment was that it was hard to indicate how to combine sentences. I got around this by hitting "edit" for sentences that needed to be combined. Then I'd delete ones below, assuming that the edited sentence would include a clause from the sentence below it.

Structural sentences and cues got deleted often. Sentences like "More follows", etc. Nothing integral to the substance of the story.

I noticed that almost always, [informational content of sentences that had been deleted] had been reincorporated.

4. *How did you determine if a sentence needed to be moved up/down?*

I did this by feel, what seemed important. One example: A building collapse in Morocco. A sentence way towards the end had a report about weak foundations, that needed to be brought up. This indicated that the journalist became more confident about something

The inverted pyramid so widely used, in a breaking news it's fairly easy to weight the importance of different elements. Thus, I rarely felt the need to move items upwards.

Sometimes I saw examples of when what was initially a small quote from official was expanded in a later version. Then, it was brought up because the quote became more important. But usually, my instinct would not be to move quotes from officials up.

5. *Did it help to see what actually happened after you finished the task?*

Usually there was 1-2 things that we had done that were basically the same.

A couple of times, [I] was satisfied to see that the updated story made the same decision to switch sentences around.

6. *Any general closing thoughts?*

Most interesting thing was to see how formally constrained journalists and editors are, and how much these forms and genres shape your thought and your work.

There are assumptions get baked into the genres about who's credible, what kinds of things carry weight, sorts of outcomes deserve special attention, a whole epistemic framework.

Even though there's a lot of variation, there's a fair amount of consistency.

I was disappointed that, especially for rapidly expanding stories, the edits were mainly causes and main events. I saw very few structural, causal analyses added to breaking stories. There was some analysis that got added to one story about bombings in the Middle East, but still, not a whole lot about how the specific conflict originated.

G.5 Annotator Interview 2

This annotator was involved in both the editing task and the version-prediction task. They annotated over 100 examples of the first task, and 50 of the second.

1. *What was your general thought process while doing the edits task?*

First, before starting, I made the assumption that every story would need edits, because I think everything could always use more work. In reality, if the article wasn't updated the way it was, I was representing one option. My process was:

(a) Read the whole story, don't make any changes at first.

(b) Then, I would think about what I thought was the most important sentence.

(c) I would often pull that high up into the lede, and then I'd add a sentence before or after.

The factors that determined the most important part of the article were:

(a) Some indication of harm done or the most recent development. I always took "harm done" as the most important part of a story.

For example: Death count—20 people were killed in some explosion vs. a bomb went off here. Moved the "20 people killed" higher because that was a harm ex. Officials are investigating whether so-and-so doctored documents.

(b) Then, I would add/delete and edit based on these. So, I would create a new sentence and edit the next sentence to give more context.

2. *How did you determine if a sentence needed to be added?*

So, after identifying the lede that I described previously, I went through and looked through what parts I felt needed more context or a quote. Getting quotes was very important. Often I identified events that I thought warranted a reaction, acknowledgment, information from a source. If these weren't there, I added a sentence. I didn't keep a checklist of these elements (i.e. "quote", "context", etc.) It was more a gut feeling about what it needed. If I were going back and doing it again, I would write out a checklist.

Often, especially when the news was unpredictable, I would often add a sentence in the beginning saying "I don't know what this sentence is going to be, but it's going to be something". In other words, I was adding context to what the unknown would be. I was able to do this pretty successfully, to predict what context would happen around the unpredictable event.

Where I tried to add more information to flesh out certain unknowns:

(a) If an official said something that needed to be followed up on, I would delete these and add new sentences

(b) I had hoped that the reporter would get that information themselves through eyewitnesses, court documents, etc.

(c) Sometimes an official would give filler quotes like: "we'll have more information later this afternoon". These would be replaced with the actual update.

(d) Context: I would add historical context. How often has something been occurring in this area, etc. Many of real updates did have these contextual sentences.

3. *How did you decide whether a sentence needed to be edited?*

After I decided what would be moved up, I looked at details (dates, people, etc.). Sentences with details were the ones that were most likely to be edited.

4. *How did you determine if a sentence needed to be deleted?*

I deleted sentences that were redundant. I identified filler quotes (e.g. officials saying they'll get more information soon.). These would be deleted when, presumably, more information did come in. Sometimes a quote was redundant to a sentence that was already there. One of the challenges was deciding when to delete or edit a sentence.

5. *How did you determine if a sentence needed to be moved up/down?*

I almost always moved sentences upwards, to the top. As we discussed previously, the top then needs to have room for an update. Again, as we discussed previously, I used harm and recent developments as a metric to decide where to move. The context was also moved around based on when the events took place.

I also tried to focus on recent developments. For example: "Officials are investigating whether so-and-so doctored documents". I would move that to the top. I pulled up the active part of the article to express what was actually happening.

6. *What things did you get wrong?*

I was really bad at predicting stories that were "delete all", "replace all". I struggled more with stories that were about political leaders speaking at an event or speaking at a conference, because these ended up going different ways. Sometimes they made a big announcement that would make headlines, but it was hard to known beforehand what that announcement would be.

For crime, or spot news, it was clearer that an event was unfolding and would have specific updates. By "spot news", I mean stories about crimes, fires, rescues, weather events/disasters, etc. – something unexpected as opposed to articles about events that have been planned, like the example of a political figure speaking at a conference. It was these unexpected events that actually follow more predictable paths when they unfold.

I saw a lot of discrepancies between sentences I chose to edit, and then the actual result was that they got deleted. For example, the death toll was in a sentence, and I'd edit that sentence, but they chose to add a sentence with the same information. The sentence matching algorithm didn't do a good job with informational units that were not at the sentence level.

7. *How did you assess uncertainty in an article?*

Often it was topic-based. I can't think of key indicators that I used to assess uncertainty.

8. *Was really helpful after I made the edits to see what actually happened?*

I tried to balanced this with what my natural instincts were. I did get better over time. I did feel more confident over time. The changes would be more in my decisions to edit vs. add/delete. In my head, I had the same end result in mind, but they edited it and I added a new sentence. I never felt I was widely off

9. *Did you see a lot of analytical pieces? Or mainly breaking news?*

I saw a mix of stuff that was analytical vs. factual. There were certainly more breaking news events, events that were going to happen and change on the same day. However, I did see some day 2 stories. Sometimes, they were updates that were part of an ongoing investigation. The breaking stories and spot news, crime, were the easiest to do. Those ones seem much more formulaic.

10. *What was your general thought process while doing the versioning task? How did you identify versions that updated?*

This one was trickier because I would assume that everything would be updated, everything would be improved. The mindset change that I made was “Will this story itself be edited, or will they write a followup with more information?” Once I made this separation this became easier

11. *What patterns did you observe in this task?*

    The timing of when I thought an update would occur ended up mattering a lot. I paid closer attention to stories that would have updates within the same day or a short period of time. The longer the time-periods between updates, the more likely a new piece would be published instead of an update.

    Again, crime and spot news it was clear — the person was on the scene at this minute, they’d get more information.

    The other giveaways were “so and so is expected to deliver remarks later this afternoon.” It wasn’t quite a preview of the event but it would clearly be updated

    The other thing that made me choose to mark a story as “would be updated” is if there was a key perspective missing or if there was no quotes at all. By “key perspective”, I mean, a key quote from a participant that is usually present in this type of story. For a crime, for example, this included: Law enforcement perspective, witness, family. In general, it means that both sides are represented.

12. *Were there examples that you thought would update that didn’t?*

    There were some with stock figures, quarterly earnings, that I initially thought would be updated, but I had seen the examples that were filled out, but I’d be more accepting that this was a final report and that it’s not going to have any quotes. I became better at identifying which types of pieces wouldn’t have context or quotes.

13. *Anything I may have missed?*

    I tried to flag a couple of articles that transferred over inaccurately. Sometimes there were cases of where one article published to the same URL was something completely different. Sometimes there were calls for subscribing to newsletters or related story links. I deleted ones that were repetitive. This might have influenced results on some articles. These structural updates were annoying.

14. *Could you see solving this kind of prediction task as being useful in a newsroom?*

    I could see it being used as a people management tool. Newsrooms are desperate for any kind of methodology to guide the decisions they make. Deciding who should attack a new story, and who should stay put working on their old piece would help a lot!

Putting the *Con* in Context:
Identifying Deceptive Actors in the Game of Mafia

Samee Ibraheem[*], **Gaoyue Zhou**[*], and **John DeNero**
University of California, Berkeley
`{sibraheem,zhougy_99,denero}@berkeley.edu`

Abstract

While neural networks demonstrate a remarkable ability to model linguistic content, capturing contextual information related to a speaker's conversational role is an open area of research. In this work, we analyze the effect of speaker role on language use through the game of Mafia, in which participants are assigned either an honest or a deceptive role. In addition to building a framework to collect a dataset of Mafia game records, we demonstrate that there are differences in the language produced by players with different roles. We confirm that classification models are able to rank deceptive players as more suspicious than honest ones based only on their use of language. Furthermore, we show that training models on two auxiliary tasks outperforms a standard BERT-based text classification approach. We also present methods for using our trained models to identify features that distinguish between player roles, which could be used to assist players during the Mafia game.

1 Introduction

Correct interpretation of language must take into account not only the meaning of utterances, but also characteristics of the speaker and the context in which their utterances are produced. Modeling the impact of this context on language is still challenging for NLP systems. For example, differences in language identification accuracy, speech recognition word error rates, and translation quality have been observed on the basis of attributes such as a speaker's gender, race, dialect, or role (Blodgett and O'Connor, 2017; Tatman and Kasten, 2017; Tatman, 2017; Stanovsky et al., 2019). Moreover, these systems systematically underperform on data generated by those in the minority, having implications for the ethics and fairness of using these technologies.

This work explores language used for deception: a type of speaker context that is particularly challenging to model because it is intentionally hidden by the speaker. To do so, we collect and release a set of records for the game of Mafia, in which each player is assigned either an honest or a deceptive role. Then, we develop models that distinguish players' roles based only on the text of the players' dialog. We describe two auxiliary tasks that improve classification accuracy over a BERT-based text classifier.

The novel contributions of this paper include:

1. A methodology for collecting records of online Mafia games and a dataset collected from 460 human subjects,
2. Three classification models that can distinguish between honest and deceptive players,
3. An approach for identifying features of the game dialog text that can be used to help identify deceptive players during the game.

The task of identifying deception in dialog is far from solved. Our classification methods, while not accurate enough to reliably identify deceptive players in a game, do show that the text of a dialog in the setting we study does contain information about the roles of the participants, even when those participants are motivated to hide those characteristics by deceiving the listener. Although the models and results described in this work only apply to a particular game setting rather than dialog in general, the approaches we describe are general in character and therefore may inform future work on determining speaker roles from the contents of dialog.

2 Background & Related Work

The game of Mafia is particularly well-suited for the goal of determining whether the deceptive participants in a conversation can be identified from the contents of their utterances.

---

[*] Equal contribution.

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 158 - 168
July 10-15, 2022

2.1 Deception in Language

Humans are a largely collaborative species. However, people sometimes have goals that incentivize them to deceive others. Understanding what cues and interaction styles people adopt when behaving deceptively will be crucial to both developing automated detection and a greater understanding of the complex interactions that people use in deception and revelation. Previous work indicates that people struggle with telling apart lies from truth, especially with deceptive statements (Bond Jr and DePaulo, 2006). This raises the question of what strategies deceptive actors use to avoid detection, as well as what strategies honest actors use to discover deceivers.

Deception is a difficult topic to study, however, because of its inherent complexity: multiple people with different motivations are trying to evaluate one another, while contending with group obligations and accusations, over a period of time that involves planning, taking actions, and responding to others' actions. Moreover, there is a distinction between a falsehood, which is a statement that is not true, a lie, which is a statement that the speaker does not believe, and deception, which is the act of convincing another person to hold a false belief. Whereas falsehoods and lies are properties of statements, deceptive intent is a characteristic of the speaker. Therefore, though deceptive speakers may tell falsehoods and lies, they might also provide truthful statements, and vice versa for honest speakers, thus rendering the truth conditions of individual utterances as unreliable indicators of deception. We are interested in how people solve these dual problems of deceiving and detecting deception, which requires a paradigm wherein we can observe all agents' actions and communication while simultaneously knowing agents' underlying incentives and goals. We thus turn to a game with a rich history of deception research: Mafia.

Previous work on detecting deception from linguistic cues has explored scenarios that either mimic or are taken directly from real-world investigations of potentially deceptive actors. Derrick et al. (2013) showed that deceptive parties take longer to formulate responses and use fewer words in the context of chat-based communication. Burgoon et al. (2003) similarly found that deceivers sent briefer chat messages. Fuller et al. (2011) demonstrated the effectiveness of training classifiers to identify deceptive language in relation to crimes, and found that word quantity was a particularly useful feature. Fornaciari and Poesio (2013) also found surface-level features useful in detecting deceptive statements in a criminal context, specifically through the investigation of Italian court documents, while Mihalcea et al. (2013) found that written lies were easier to detect than transcripts of spoken ones. Abouelenien et al. (2014) took a multimodal approach to deception detection, finding that non-contact approaches were able to match or exceed the performance of those that were more invasive.

2.2 The Game of Mafia

Researchers have also examined deception in games, focusing on settings such as Diplomacy or negotiation over a set of items (Lewis et al., 2017; Niculae et al., 2015). In addition, there has been some work exploring the effects of biased voting on group decision making (Kearns et al., 2009). The game of Mafia specifically has attracted attention, and researchers have analyzed data from various online game communities. Zhou and Sung (2008) discovered differences between deception across cultural communities by analyzing data from an online Chinese Mafia game, Pak and Zhou (2011) used social network analysis to detect deceivers using the epicmafia.com website, and de Ruiter and Kachergis (2018) collected and trained models on a dataset from the online Mafiascum forum. Researchers have also studied the game of Werewolf, a variant of Mafia. Chittaranjan and Hung (2010) used audio information to classify deceptive parties, while Demyanov et al. (2015) used video information. Braverman et al. (2008) and Migdał (2010) developed a mathematical model of the Mafia game, assuming that all votes are cast at random, which allowed them to analyze how mafia and bystander win rates varied with role distribution in a highly controlled version of the game. Bi and Tanaka (2016) showed that under certain conditions, the strategy of mafia pretending to be bystanders is suboptimal.

Most of the deception-oriented games that have been studied in the natural language processing literature provided individual incentives to the players. Mafia allows for the study of patterns of deception that arise when incentives are only at the group level. In addition, whereas using datasets of online Mafia games presents a rich source of deceptive language, the complicated rule sets of games on these forums makes it challenging to isolate specific strategies that participants use to engage in and detect deceptive behavior. In contrast to work using video or audio, we assume that players do not have access to any audiovisual clues about others' roles in order to focus on the role of language. This work takes these factors into account by studying a controlled environment that nonetheless supports the use of complex strategies for deceiving and detecting deceptive behavior.

3 Dataset

A total of 460 English-speaking participants based in the United States were recruited from Amazon Mechanical Turk using the experiment platform Dallinger[1]. Between 4 and 10 participants were recruited for each Mafia game: 1 to 2 participants were designated mafia, and the rest were bystanders. Forty-four of these Mafia games are included in the final analysis. Participants were paid $2.50 for completing the task, plus bonuses for time spent waiting for other participants to arrive in a chatroom to begin the experiment. Waiting was paid at $5/hour.

Upon recruitment, participants were shown a consent form, per IRB approval, followed by an instructional video and accompanying transcript describing how to play the text-based Mafia game using an interface we developed (see Appendix). After they completed a quiz demonstrating they understood the information, they entered a waiting room until the desired number of participants was reached. Participants were then assigned a role (mafioso or bystander) and fake name, after which they began playing the game.

The game dynamics were as follows. Each mafia member was aware of the roles of their fellow mafia members and thus, by process of elimination, knew the roles of the bystanders. However, the bystanders did not know the true role of anyone else in the game. The goal of the mafia was to eliminate bystanders until the number of mafia was greater than or equal to that of the bystanders. The goal of the bystanders was to identify and eliminate all of the mafia members. Since the incentive structure was set up such that bystanders benefited from true beliefs about who the mafia members were, whereas mafia members benefited from false beliefs, bystanders were thus motivated to be honest actors, whereas mafia members were motivated to be deceptive actors in the Mafia game. The game proceeded in phases, alternating between nighttime and daytime (Figure 1). During the nighttime, mafia members could secretly communicate to decide on who to eliminate, after which they discretely voted, and the person with the majority vote was eliminated from the game. If there was a tie, one of the people involved in the tie was randomly chosen to be eliminated. During the daytime, everyone was made aware of who was eliminated during the nighttime, and then all players could openly communicate to decide who to eliminate. All the players then voted publicly, and the person with the majority vote was eliminated and announced to be a bystander or mafioso. Thus, during the nighttime mafia could secretly communicate and eliminate anyone, whereas during the daytime mafia could participate in the voting and communication protocols in the same way as bystanders. The game proceeded until there was a winning faction according to the goals described above.

	M	**B**	**T**
Total #players	87	334	421
Avg #players per game	1.98	7.59	9.57
Std #players per game	0.15	1.21	1.28
Total #utt	770	1392	2162
Avg #utt per game	17.5	31.64	49.14
Std #utt per game	10.45	17.2	24.44
Total #players w/ utt	84	265	349
Perc players w/o utt	0.042	0.958	1

Table 1: Dataset statistics. # is short for *number of*. **M** and **B** denote the mafioso and bystander classes, respectively, while **T** denotes the total number for both groups. The last row shows the distribution of roles among the players with no utterances throughout the game. Note that nearly all of the no-utterance players are bystanders.

From these experiments, we collected a dataset consisting of both mafia and bystander utterances over the course of each game, as well as the participants' voting behavior. Dataset statistics appear in Table 1. Figure 2 displays a snippet of the daytime dialog from one Mafia game. As shown, many utterances are either social interactions (eg. "hi erybody") or discussions about what to do in the game, such as accusations or comments about voting (eg. "I bet it's Mandy...").

Upon further inspection of the data, we can observe several strategies used by mafia members to deceive bystanders:

Figure 1: Mafia experiment screenshot during **(left)** first nighttime phase, with participant as a mafioso, and **(right)** first daytime phase, with participant as a bystander (note that mafia messages are not visible to the bystander).

1. Mafia members may suggest that there is not enough information to decide on who to eliminate, despite their knowledge of everyone's roles (eg. "Should we wait to eliminate someone?" / "It's a little early to tell." / "It's a shot in the dark."),
2. Mafia members may raise suspicion about another player, despite knowing that said player is a bystander (eg. hmm ok analyzing this conversation....I think bianca was a little to flippant in how she was like "sucks to be andrew" haha / I'm going to vote bianca. she's so casual with life and death),
3. Mafia members may invent a false motive and assign that motive to another player, despite knowing that the player is a bystander (eg. It might be Jonathan Kim... killing off Erin who accused him "yesterday").

4 Approach

Given our mafia dataset, there are several tasks that one might address, for example, predicting participants' daytime voting behavior or generating mafia members' nighttime dialog. As our aim is to identify deceptive actors, however, we focus on predicting participants' roles, i.e. bystander or mafioso. Due to the asymmetry in the knowledge available to each group and the goals which incentivize bystanders to increase true belief and mafia members to reduce it, the bystanders are said to take on an honest role in the game, whereas the mafia members take on a deceptive role. To focus on the relationship between language and deception, we ignore voting behavior and consider just the daytime dialog in the game, as only the mafia members were able to converse during the nighttime. As shown in Table 1, since most of the players with no utterances are bystanders, we only consider players who make at least one utterance throughout the game.

To investigate whether linguistic information can be used to identify players' roles, we train and evaluate classifiers that predict the role of a particular player. Since we have a small dataset, we chose to fine-tune pre-trained Transformer models rather than train them from scratch (Vaswani et al., 2017). To predict the role for a player p, we construct an input representation $r(C, p)$ of the full game dialog C that encodes the player of interest p. We develop three approaches which differ in both the dialog representation function r and the modeling approach.

4.1 Standard Classification

Our baseline approach uses a standard BERT-based text classifier (Devlin et al., 2018). To classify player p via the full record of the game C, let boolean variable M_p be true if p is a mafioso. Let T_p be the concatenation[2] of utterances made by p. We train BERT parameters θ_M to predict $P(M_p|T_p; \theta_M)$.

This approach, which provides as input to the classifier only the utterances of the player to be classified, outperformed an alternative representation $r(C, p)$ that included the entire record of all utterances by all players.

---

[2] Utterances are concatenated with an end-of-sentence delimiter after each utterance.

3	2018-11-02 21:00:48.892878	Mandy Smith: C'mon guy
4	2018-11-02 21:00:51.380136	Mandy Smith: I'm nice

Figure 2: Example messages (utterances) in a game. *creation_time* is the time at which the message was sent. The *contents* consists of the name of the sender, as well as the message, separated by a colon and space.

4.2 Auxiliary Tasks

Limiting the input representation r to contain only the speech of the player p being classified is not ideal; correctly interpreting a dialog requires considering all other players' statements as well. We introduce two auxiliary tasks that involve the entire game dialog C:

1. Given all of the prior utterances, is a bystander or a mafia member more likely to have produced the current utterance? (*Utterance Classification*)
2. Given all of the prior utterances, what current utterance would a player produce, given that they are a bystander or a mafia member? (*Utterance Generation*)

We develop a BERT-based classification model for task 1 and fine-tune the GPT-2 language model for task 2 (Radford et al., 2019). Then, we use each of these auxiliary models to classify the role of a particular player p in the game.

4.2.1 Utterance Classification

To classify player p using the auxiliary task of utterance classification, let boolean variable S_i be true if utterance C_i was made by a mafioso (rather than a bystander). Let C be the full record of utterances in the game and $C_{\leq i}$ be the concatenation of all utterances $C_1 \dots C_i$. We train BERT parameters θ_S to predict $P(S_i | C_{\leq i}; \theta_S)$. Finally, let I_p be the set of indices of utterances by player p. M relates to S in that if M_p is true, then S_i is true for all $i \in I_p$. We thus calculate

$$P(M_p | C; \theta_S) \propto \frac{\sum_{i \in I_p} P(S_i | C_{\leq i}; \theta_S)}{N},$$

where $N = |I_p|$.

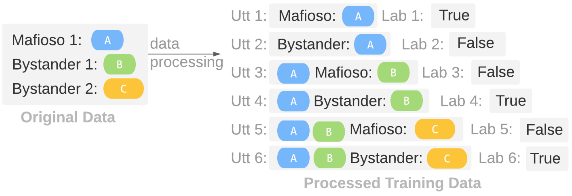

Figure 3: Data processing for fine-tuning BERT. The original data is shown on the left-hand side, while the right-hand side shows the processed data containing two versions of each utterance, one assuming that the target player is a mafioso and one assuming that they are a bystander, with the prior conversation context preceding each and labels corresponding to whether the assumed role matches the actual role of the player.

4.2.2 Utterance Generation

To classify player p using the auxiliary task of utterance generation, we fine-tune GPT-2 to generate utterance C_i conditioned on prior utterances $C_{<i}$ and the role S_i of the speaker that produced C_i. From Bayes' rule, we have $P(M_p|C) \propto P(M_p)P(C|M_p)$. To estimate $P(C|M_p)$, let C_p include all C_i for $i \in I_p$. We make the simplifying assumption that $P(C|M_p) \propto P(C_p|M_p)$, which assumes that the utterances made by players other than p are independent of the role of player p. Then, if M_p is true, S_i is true for all $i \in I_p$, and so,

$$P(C_p | M_p; \theta_C) = \prod_{i \in I_p} P(C_i | C_{<i}, S_i; \theta_C).$$

Using the full dialog C, the final probability of player p being mafioso is calculated as follows:

$$P(M_p|C) = \frac{P(M_p)P(C_p|M_p;\theta_C)}{\sum_{R \in \{M, \neg M\}} P(R_p)P(C_p|R_p;\theta_C)} \tag{1}$$

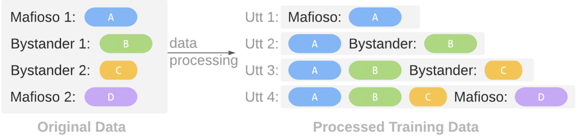

Figure 4: Data processing for fine-tuning GPT-2. The original data is shown on the left-hand side, while the right-hand side shows the processed data containing a version of the corresponding utterance with the prior conversation context preceding.

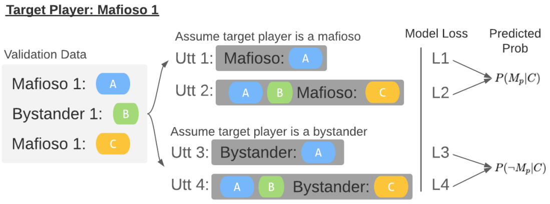

Figure 5: Prediction pipeline for our fine-tuned GPT-2 model. Similar to the pipeline used to produce the training utterances, for prediction, there are now two versions of each, one assuming that the target player is a mafioso and one assuming that they are a bystander. The losses for each utterance of the target player are summed together in order to calculate the mafia and bystander probabilities as described in Equation 1.

4.3 Data Processing

To train models for utterance classification (using BERT) and utterance generation (using GPT-2), we perform data processing procedures on the games' original dataset to create input representations $r(C, p)$ for each player p and obtain our training datasets as shown in Figures 3 and 4. The left side of each figure shows a snippet of a game's data, where "Mafioso" and "Bystander" denote the true roles of the players. The utterances to the right of each figure are training examples used for fine-tuning the BERT and GPT-2 models. Structuring the data in this way provides both the prior context of utterances and the current utterance that happened within this context. This not only gives us the information needed for the auxiliary tasks, but also provides us with more training examples, as we only have 44 games and only 421 players in total, with only 2162 total utterances. Moreover, this mimics the real game scenario from the bystander view in that they can only confirm their own role, but no one else's, which is the appropriate setting for us in which to detect deception.

Figure 5 shows the pipeline for using the GPT-2 model to predict players' roles. Let us assume that the target player for whom we want to predict their role is Mafioso 1. From the original game log on the left, we first perform the data processing scheme from Figure 4 twice, assuming that the target player is a mafioso (top of Figure 5) and a bystander (bottom of Figure 5). Using our trained GPT-2 model, we then obtain a loss for each utterance denoted by L1 through L4. Summing all the losses for each role, as they denote log probabilities, we calculate $P(M_p|C)$ and $P(\neg M_p|C)$ via Equation 1. The target player's role as predicted by the model is finally given by comparing the two probabilities. A similar process is used to calculate $P(M_p|C)$ and $P(\neg M_p|C)$ for the utterance classification BERT model.

5 Experiments

We train three fine-tuned models on the corpus of Mafia game records and compare their performance to a random baseline. The specifications for the baseline and models can be found below, and the results are shown in Table 2.

5.1 Random Baseline

This random classifier classifies each player as a mafioso or a bystander with probabilities equal to the prior distribution of each class, estimated as the ratio of roles across all training games. This serves as a baseline to be compared to for all other methods. In the game setting, this mimics a bystander player with only public information of how many mafia and bystanders are in the game.

5.2 Standard Classification

We initialize the model by loading a pre-trained BERT Base model (12 layers, 768 hidden dimension size, 12 attention heads). We train with a maximum sequence length of 256, which is sufficient for our post-processed dataset, setting the batch size to 16, the learning rate to 1e-5, and the maximum number of epochs to 25.

5.3 Utterance Classification

We initialize the model by loading a pre-trained BERT Base model (12 layers, 768 hidden dimension size, 12 attention heads). We train with a maximum sequence length of 512, which is sufficient for our post-processed dataset, setting the batch size to 5, the learning rate to 5e-5, and the maximum number of epochs to 25.

	Avg Rank	Avg Rank/Game	Accuracy	Maf F1-score	Bys F1-score
Random	19.0	3.4	0.62	0.26	0.74
Std Class	17.9	3.0	0.69	0.4	0.79
Utt Class	14.5	**1.8**	**0.74**	**0.50**	**0.83**
Utt Gen	**11.4**	2.0	**0.74**	**0.50**	**0.83**

Table 2: Experiment results on the validation set for random baseline (**Random**), standard classification (**Std Class**), utterance classification (**Utt Class**), and utterance generation (**Utt Gen**) approaches. Methods that use auxiliary tasks (**Utt Class** and **Utt Gen**) outperform other methods in terms of average ranking overall and per game while also maintaining higher accuracy and F1-score for each class.

5.4 Utterance Generation

We initialize the model by loading a pre-trained 12-layer GPT-2 model with an embedding size of 768. For the dataset, we set the maximum length of each sentence to be 512, which is sufficient for our dataset after post-processing. During training, we set the batch size to be 5 and the learning rate to be 1e-5. We train the model for a maximum of 100 epochs.

5.5 Metrics

These approaches each estimate a probability $P(M_p|C)$ that a player p is a mafioso given the full record of game texts C. In Mafia, bystanders do not declare who is and is not a mafioso, but instead vote each day to eliminate one of the players. Because the act of voting involves choosing one player among them all, a natural metric for evaluating the usefulness of a model is to order all players p from greatest to least $P(M_p|C)$, their probability of being a mafioso under the model, and then to compute the average rank of the true mafia members. Therefore, the first metric in Table 2 is the average ranking of all mafia members when each player is ranked by $P(M_p|C)$ across the entire validation set composed of 5 games. It is also natural to consider player ranking within a single game, so we calculate the average ranking of mafia members within each game as a second metric. Smaller average ranking for mafia members means that the model is able to assign mafia players a high $P(M_p|C)$ relative to bystanders, which is desired.

In addition, we evaluate the accuracy of the classifiers and the F1-score for each class. To calculate these metrics, we first assign the mafioso label to the top k players with the highest $P(M_p|C)$ and the rest of the players with the bystander label, where k is the known number of mafia among all validation games ($k = 10$ in our case). Aside from the ranking metrics, these give further information of the models' quality after utilizing available game information.

5.6 Results and Analysis

We trained all models on 39 training games and evaluated on the remaining 5 validation games. The evaluation results are shown in Table 2. We have a total of 49 players in the validation games, but only considered the 39 players who had spoken at least one utterance throughout the game when calculating the metrics. Players with no utterances are almost exclusively bystanders and are therefore easy to classify without considering language.

First, we see that it is possible to achieve an average rank that is smaller than the random baseline, which demonstrates that there is information in the dialog about the roles of players, despite the fact that mafia members seek to hide their role while conversing. However, standard classification is comparable to random. Next, we observe that both models using auxiliary tasks outperform the standard classifier in rank-based metrics, which demonstrates that the auxiliary tasks provide useful inductive bias for the mafia classification task. Additionally, the accuracy is similar for all approaches, including random classification, which indicates that there is not enough information in the text of a Mafia game for these models to determine players' roles reliably. If the goal of the game were to guess the role of each player individually, then always guessing bystander (i.e. the majority class) would be the best strategy. However, since the goal for the bystanders is to vote to eliminate a mafia member each round, the utterance classification and utterance generation approaches, which achieve the lowest average mafia ranking per game and overall, respectively, are the most favorable.

Note that the precision for the mafia is much lower than that of the bystanders for all models. This is due to the usual lack of information avail-

Prompt	Generated Utterance
lets kill P1.	**M:** sorry P1 :(**B:** hello all
who thinks P3 is Mafia?	**M:** No i'm a bystander **B:** No idea
That sounds suspicious...	**M:** P6 is mafia **B:** Why yall want to eliminate me?
hi team. Hello!. Hi.	**M:** Who is the mob person? **B:** hello

Table 3: Utterances generated by our GPT-2 model given different prompts. **M** and **B** are shorthand for Mafioso and Bystander respectively, and P1, P3, and P6 denote the names of other players in the game.

able to predict that any player is a mafioso, which makes finding the mafia a much harder task than finding bystanders.

6 Discussion

The decoding ability of the GPT-2 model provides us a more straightforward way to understand what the model has learned. Given a prompt sentence, we can use our fine-tuned GPT-2 model to generate what a mafioso and a bystander would say. A few examples are shown in Table 3. From these examples, we inspect the following features that the model might be capturing to distinguish between mafia and bystanders: Feature 1: Referring to other players. Feature 2: Expressing confusion. Feature 3: Referring to others for elimination purposes. Feature 4: Asking for suggestions on who to eliminate.

To confirm that our fine-tuned GPT-2 model captures some of the above features, we hand-label these features on 5 training games and 1 validation game, obtain each player's feature vector, and see whether there exists a correlation between the model's predicted $P(M_p|C)$ for validation players and the similarity of their feature vectors compared to the training set mafioso and bystander players. These feature vectors are shown in Table 4, where each entry denotes the average number of features per player of each role. As an example, for the first column, each mafioso player says 2 utterances having Feature 1 throughout the game on average, while each bystander player says 1.06 utterances having Feature 1 on average. We define the first row as a vector v_1 and the second row as v_2 for future references.

	Feat 1	Feat 2	Feat 3	Feat 4
Mafioso	2.00	0.00	1.30	0.40
Bystander	1.06	0.27	0.65	0.10

Table 4: The average count per role for each of four hand-labeled features (number of references to other players, level of confusion, number of references to other players for elimination, and number of requests for who to eliminate) as identified by our GPT-2 model on 5 training games.

	F1	F2	F3	F4	D(u)	Pred	Truth
P0	4	0	2	0	-5.9	0.98	B
P1	2	0	2	0	-2.1	0.93	M
P2	5	0	5	0	-11.7	0.78	M
P3	2	0	2	0	-2.1	0.63	B
P4	4	2	1	1	-4.1	0.47	B
P5	3	0	2	0	-4.0	0.43	B
P6	0	0	0	0	4.2	0.42	B
P7	1	0	1	0	1.0	0.40	B
P8	0	0	0	0	4.2	0.00	B
P9	0	0	0	0	4.2	0.00	B

Table 5: Features of each player (P0 to P9) in a validation game. For each row, F1 to F4 give the feature vector u for the respective player. $D(u)$ gives the similarity of u compared to the training feature vectors v_1 and v_2. Players are sorted by $Pred$, the probability $P(M_p|C)$ given by our GPT-2 model, and $Truth$ gives the true label for each player (M for Mafioso, B for Bystander). Since P8 and P9 have no utterances throughout the game, as per our heuristic, they are predicted to be bystanders with $P(M_p|C) = 0$.

Table 5 shows the hand-labeled feature vectors for all 10 players in a validation game (first 4 columns, F1 to F4) ranked by the model's predicted $P(M_p|C)$. We define a metric function $D(u) = \|u - v_1\|^2 - \|u - v_2\|^2$ for a validation player's feature vector u. The smaller $D(u)$ is, the closer u is to v_1 than v_2, and hence the more mafia-like they are with respect to players in the training games. We can see that for players of higher rank, their $D(u)$ are negative with larger magnitudes. Referring to the true labels in the rightmost column (M for Mafioso and B for Bystander), the first row also explains how our model can fail to predict the true role of some players: even though this player is a bystander, they act more like the mafia than other bystanders according to these hand-labeled features because they are regularly referencing and accusing other players.

7 Limitations & Potential Risks

We find that we are able to train models to help differentiate players with different roles in the game of Mafia based only on their language use, as well as to identify features that may distinguish between these roles. We also noticed that the mafia were twice as likely to win the Mafia game than were the bystanders. These findings lead us to believe that the bystanders may benefit from being provided hints based on our model's predictions and identified features. However, there are several ethical considerations in regards to using these methods. First, as our model is trained on this particular version of mafia, the specific models trained would not apply to other cases of deceptive language use. Applying these models to out-of-domain data, or even adapting this general approach to new settings, may yield unexpected results. Our experimental results only establish the effectiveness of our approach on the game of Mafia. Future work must evaluate these approaches on other deception detection tasks before they can be safely deployed in real-world scenarios. Next, information that may aid bystanders in detecting deception may also aid mafia members in being deceptive. Though mafia members may attempt to use it for this purpose, because our model is trained to increase true belief, which is directly in line with the bystander goal to identify the truth and against the mafia goal to obscure it, our approach is inherently more useful to bystanders. However, since the models we evaluate are far from perfectly accurate, there is a risk that users using these models for hints would rely too much on their output and thereby be misled. More work should be done to increase the model's performance in order to mitigate this risk.

8 Conclusion

How one uses language depends not only on the content they wish to convey, but also on the context within which they convey it, and speaker attributes such as conversational role contribute to such context. In this work, we leveraged an environment for which roles are explicitly labelled in order to make progress toward the task of deception detection, an essential task to protect users in our increasingly virtual world.

A Mafia Instructions

Below is a transcript of the instructions that were provided to participants before playing the Mafia game in our experiments:

"In this experiment, you will play a version of the party game "Mafia". You are going to play the game of Mafia (also known as Werewolf) with other participants. You are either part of the mafia (a mafioso) or a bystander. The mafia will know who is in the mafia, but the bystanders will not. There will always initially be more bystanders than mafia. There will be one or more mafia members. The goal of the mafia is to eliminate the bystanders one by one until the mafia are equal in number to them. The goal of the bystanders is to correctly guess the identity of the mafia and eliminate them all before the mafia win. There are two phases to this game, nighttime and daytime; at the end of each, a participant is eliminated from the game:

1. In the **nighttime** phase, only the mafia can converse and decide who they want to eliminate. Specifically, if you are a mafioso, you will talk in a chatroom, then use a drop-down menu to select who you want to remove. Mafia will have 1 minute to do this. If there is more than one mafioso and the mafia disagree about who to eliminate, one of the mafia's choices will be selected randomly. If you are a bystander, you will wait out this time, as you are sleeping during the night.

2. Everyone is awake during the **daytime** phase. The participant who was eliminated during the night will be announced: if you were eliminated, you will be sent to the end of the game and compensated. The remaining participants will converse (for 2 minutes and 30 seconds) and decide who to eliminate, where the goal of the bystanders is to eliminate a member of the mafia, and the goal of the mafia is to eliminate a bystander. By the end of this time, everyone needs to select a name from the drop-down menu. (If there are multiple mafia, the mafia will be reminded of each others' names in separate text on this page.) The participant with the most votes will be eliminated, except in the case of a tie, in which a randomly-selected

vote will be eliminated. The eliminated participant and their identity (bystander or mafia) will be announced, and that participant will be sent to the end of the game and compensated.

The game will continue, alternating between nighttime and daytime, until either all of the mafia are removed (*bystanders win!*) or there are equal numbers of mafia and bystanders (*mafia win!*)"

SUBS: Subtree Substitution for Compositional Semantic Parsing

Abstract

Although sequence-to-sequence models often achieve good performance in semantic parsing for i.i.d. data, their performance is still inferior in compositional generalization. Several data augmentation methods have been proposed to alleviate this problem. However, prior work only leveraged superficial grammar or rules for data augmentation, which resulted in limited improvement. We propose to use subtree substitution for compositional data augmentation, where we consider subtrees with similar semantic functions as exchangeable. Our experiments showed that such augmented data led to significantly better performance on SCAN and GEOQUERY, and reached new SOTA on compositional split of GEOQUERY. We have publicly released our code at `https://github.com/GT-SALT/SUBS`.

1 Introduction

Semantic parsing transforms natural language utterances to formal language. Because meaning representations or programs are essentially compositional, semantic parsing is an ideal testbed for compositional generalization. Although neural seq2seq models could achieve state-of-the-art performance in semantic parsing for i.i.d. data, they failed at compositional generalization due to lack of reasoning ability. That is, they do not generalize well to formal language structures that were not seen at training time. For example, a model that observes at training time the questions "*What is the population of the largest state?*" and "*What is the largest city in USA?*" may fail to generalize to questions such as "*What is the population of the largest city in USA?*". This leads to large performance drops on data splits designed to measure compositional generalization (compositional splits), in contrast to the generalization abilities of humans.

To improve compositional generalization in semantic parsing (compositional semantic parsing), prior work focused on incorporating inductive biases directly to models or data augmentation. From the model perspective, some work used neural-symbolic models (Chen et al., 2020), generated intermediate discrete structures (Herzig and Berant, 2020; Zheng and Lapata, 2020), or conducted meta-learning (Lake, 2019). From the data perspective, Jia and Liang (2016) proposed to recombine data with simple synchronous context-free grammar (SCFG), despite not for compositional generalization. Andreas (2019) used some simple rules for data augmentation, where tokens with the same context were considered as exchangeable. Such techniques are still limited since they only leveraged superficial grammars or rules, and failed when there are linguistically rich phrases or clauses.

To fill this gap, we propose to augment the training data of semantic parsing with diverse compositional examples based on induced or annotated (semantic and syntactic) trees. Specifically, we propose to exchange subtrees where roots have similar meaning functions. Since we consider all hierarchies in all trees, deep structures and complex phrases or clauses are considered for data augmentation, which is key for compositional generalization. For instance, in Figure 1, if we exchange subtrees with "*largest*" as meaning function of its root, composition of "*population of the*" and "*largest city in the smallest state in the USA*" results in a new augmented structure "*population of the largest city in the smallest state in the USA*". Although certain substructure substitution methods were explored in other NLP tasks (Shi et al., 2021), subtree substitution with fine-grained meaning functions has been under-explored. Our experiments showed that such augmented data led to significantly better performance on SCAN (Lake and Baroni, 2018)

⋆Equal Contribution. Jingfeng Yang proposed subtree substitution data augmentation for compositional semantic parsing, implemented augmentation and LSTM/BART parsers, and ran SCFG/GECA baselines. Le Zhang induced span trees and ran span-based semantic parsing baseline.

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 169 - 174
July 10-15, 2022

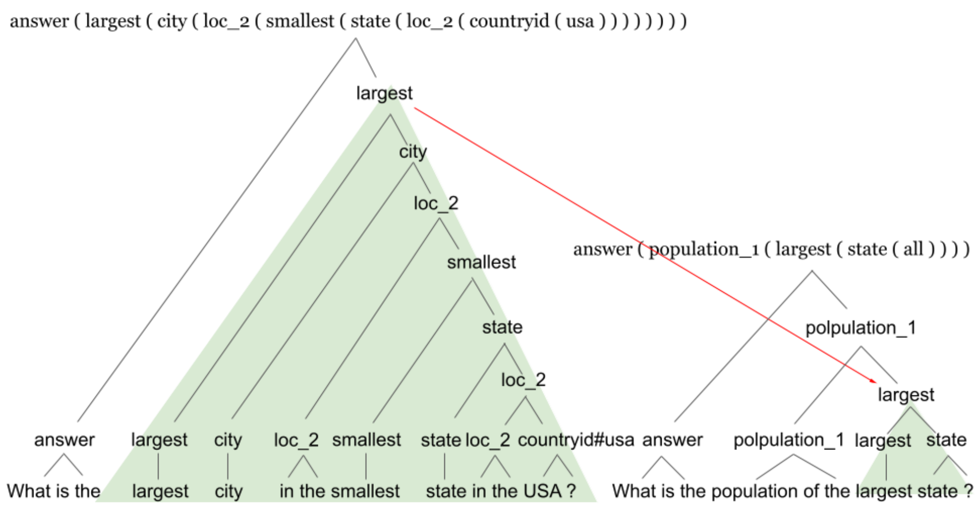

Figure 1: Subtree substitution results in an augmented example. Natural Language: *What is the population of the largest city in the smallest state in the USA ?* Formal Language: `answer ( population_1 ( largest ( city ( loc_2 ( smallest ( state ( loc_2 ( countryid ( usa ) ) ) ) ) ) ) ) )`.

and GEOQUERY, and reached new SOTA on compositional split of GEOQUERY.

2 Methods

Span trees Suppose training set is $\{(x^i, z^i)\}_{i=1}^N$, where x_i is a natural language utterance and z_i is the corresponding program. An utterance x can be mapped to a span tree T, such that program(T)= z, where the deterministic function program($\cdot$) maps span trees to programs (Herzig and Berant, 2020).

As shown in Figure 1, a span tree T is a tree where each node covers a span (i, j) with tokens $x_{i:j} = (x_i, x_{i+1}, \cdots, x_j)$. A span subtree can be viewed as a mapping from every span (i, j) to a single category $c \in C$, where C is a set of domain-specific categories representing domain constants, which include entities (e.g. *countryid#usa* in Figure 1) and predicates (e.g. *loc_2* in Figure 1). The final program can be computed from the span tree deterministically by the function program($\cdot$). Concretely, program(T) iterates over the nodes in T bottom-up, and generates a program $z_{i:j}$ for each node covering the span (i, j). For a terminal node, $z_{i:j} = c$. For an internal node, $z_{i:j}$ is determined by composing the programs of its children, $z_{i:s}$ and $z_{s:j}$ where s is the split point. As in Combinatory Categorical Grammar, composition is simply function application, where a domain-specific type system is used to determine which child is the function and which is the argument. Span trees can be induced by a hard-EM algorithm or semi-automatically annotated. We refer the reader to Herzig and Berant (2020) to see how to obtain span-trees.

2.1 Subtree Substitution (SUBS)

As shown in Figure 1, we consider span subtrees with similar semantic functions as exchangeable. Formally, func($\cdot$) maps a subprogram to a semantic category, and subtrees with the same semantic categories have similar semantic functions. For two data points (x^1, z^1) and (x^2, z^2), if func($z^1_{i_1:j_1}$) = func($z^2_{i_2:j_2}$), we obtain a new augmented (x', z'):

$$x' = x^1_{:i_1} + x^2_{i_2:j_2} + x^1_{j_1:}, z' = z^1 \backslash z^1_{i_1:j_1} / z^2_{i_2:j_2}$$

Definition of func($\cdot$) may vary in different dataset. One straightforward way is to extract the outside predicate in $z_{i:j}$ as its semantic category, which is used on GEOQUERY, such as func(`largest ( state ( all ) ) `)=`largest`.

2.2 Semantic Parsing

After getting augmented data by subtree substitution, we then combine augmented data and the original training data to train a seq2seq semantic parser, where we choose LSTM models with attention (Luong et al., 2015) and copying mechanism (Gu et al., 2016), or pretrained BART$_{\text{Large}}$ (Lewis et al., 2020) as the seq2seq model architecture.

3 Experiments and Results

Dataset We first use SCAN (Lake and Baroni, 2018) as a diagnostic dataset to test the performance of subtree substitution in compositional semantic

	RIGHT	AROUNDRIGHT
LSTM	0.00	1.00 (2800 updates)
LSTM + SUBS	1.00	1.00 (800 updates)

Table 1: Accuracy of diagnostic experiments on SCAN.

	Question	Query
Herzig and Berant (2020)	0.78	0.75
LSTM	0.75	0.58
+ SCFG (Jia et al., 2016)	0.80	0.68
+ GECA (Andreas, 2019)	0.77	0.60
+ SUBS (ours, induced tree)	0.79	**0.72**
+ SUBS (ours, gold tree)	**0.81**	**0.79**
BART	0.91	0.85
+ SUBS (ours, induced tree)	0.91	0.85
+ SUBS (ours, gold tree)	**0.93**	**0.88**

Table 2: Exact-match accuracy on i.i.d. (Question) and compositional (Query) splits of GEOQUERY dataset.

parsing. SCAN is a synthetic dataset, which consists of simple English commands paired with sequences of discrete actions. We use the program version of Herzig and Berant (2020). For instance, "*run right after jump*" corresponds to the program "`i_after ( i_run ( i_right ) , i_jump )`". Also, semi-automatically annotated span trees from Herzig and Berant (2020) are used for subtree substitution. To test compositional semantic parsing, we use the *Primitive right* (RIGHT) and *Primitive around right* (AROUNDRIGHT) compositional splits from Loula et al. (2018), where templates of the form *Primitive right* and *Primitive around right* (respectively) appear only in the test set. In these templates, *Primitive* stands for *jump*, *walk*, *run*, or *look*. For simplicity, func(·) is defined only on `i_right` and `i_left`, where func(`i_right`) = func(`i_left`) = `direction`. That is, all "`i_right`" and "`i_left`" appear as leaf nodes in span trees and they are exchangeable.

We use GEOQUERY dataset to test the performance of subtree substitution in both i.i.d. and compositional generalization for semantic parsing. GEOQUERY contains 880 questions about US geography (Zelle and Mooney, 1996). Following Herzig and Berant (2020), we use the variable-free FunQL formalism from Kate et al. (2005). The i.i.d. split (Question), which is randomly sampled from the whole dataset, contains 513/57/256 instances for train/dev/test set. The compositional split (Query) contains 519/54/253 examples for train/dev/test set, where templates created by anonymizing entities are used to split the dataset, to make sure that all examples sharing a template are assigned to the same set (Finegan-Dollak et al., 2018). As for span trees, we use semi-automatically annotated span trees (gold tree) released by Herzig and Berant (2020). Alternatively, we use the span trees induced by Herzig and Berant (2020)'s span-based semantic parsing, without any human labour.

3.1 Diagnostic Results

Results of diagnostic experiments on SCAN dataset are shown in Table 1, where we use LSTM parser without data augmentation as the baseline. We can see that on the RIGHT split, LSTM seq2seq semantic parser could only achieve zero exact-match accuracy without any data augmentation techniques, which means that the model's compositional generalizibility on the RIGHT split is very poor. After adding our augmented data with subtree substitution, we achieve an exact-match accuracy of 100%. Actually, we got 6660 augmented examples besides the original 12180 training examples. Among all augmented examples, 3351 examples are in the test set, which means 74.87% of 4476 test examples are recovered by subtree substitution. On the AROUNDRIGHT split, using LSTM seq2seq semantic parser could already achieve 100% exact-match accuracy, which means that the model learned from *Primitive right* and *Primitive opposite right* generalize to *Primitive around right* well in our program format "`i_primitive ( i_around ( i_right ) )`". After adding our augmented examples, the parser converged to 100% exact-match accuracy faster, where our method requires around 800 updates to converge while baseline model requires 2800 updates with the same batch size 64.

3.2 Main Results

Table 2 shows the results of experiments on GEOQUERY dataset, where we examined both seq2seq LSTM and $\text{BART}_{\text{Large}}$ parsers. LSTM and BART parsers without any data augmentation are simplest baselines. We also compare with other two data augmentation methods as additional baselines, recombining data with simple SCFG (Jia and Liang, 2016) or using simple rules for Good Enough Data Augmentation (GECA) (Andreas, 2019), which were proven useful for compositional semantic parsing. We can see that on the Question split, adding augmented data from (gold) subtree sub-

	training instances	augmented instances	avg att l	max att l	avg prg l	max prg l
GECA	519	804	8.85	18	15.96	29
SUBS	519	29039	10.43	26	19.33	43

	avg seg l	max seg l	avg att seg l	max att seg l	avg prg seg l	max prg seg l
GECA	1.93	4	-	-	-	-
SUBS	5.99	25	3.98	13	8.01	25

Table 3: Complexity of augmented examples on the Query split of GEOQUERY dataset, which is measured by maximal (max) and average (avg) lengths (l) of exchanged segments (seg) and resulted utterances(att)/programs(prg).

	50	100	200	519
BART	0.64	0.72	0.79	0.85
BART + SUBS	**0.67**	**0.79**	**0.85**	**0.88**

Table 4: Effect of numbers of training examples on compositional split of GEOQUERY.

stitution leads to improvements for both LSTM and BART seq2seq models, suggesting that subtree substitution as data augmentation helps i.i.d generalization for semantic parsing. On the Query split, (gold) subtree substitution achieves more substantial improvements over seq2seq baseline models (absolute 21% and 3% improvements of the exact-match accuracy for LSTM and BART respectively), achieving state-of-the-art results. Moreover, our methods are also better than the two data augmentation baselines. Therefore, subtree substitution is a simple yet effective compositional data augmentation method for compositional semantic parsing. With (induced) subtree substitution, SUBS still achieves improvements for LSTM models.

Analysis of Augmented Data We further examine why subtree substitution could achieve much better performance by analyzing its augmented data. As shown in Table 3, GECA only identifies and exchanges very simple structures, where the average and maximal length of exchanged segments are 1.93 and 4. A closer look at these augmented data shows that nearly all of these segments are simple entities (e.g. STATE: “Illinois”, “Arizona” etc.) or other Nouns (e.g. “area”, “population” etc.). In contrast, subtree substitution can identify and exchange much more complex structures, where the average and maximal length of exchanged segments are 5.99 and 25. For example, *largest city in the smallest state in the USA* and *largest state* are identified as exchangeable. As a result, subtree substitution could produce more complex utterance and program pairs, where the average and maximal length of these resulted utterances are 10.43 and 26, compared with the average (8.53) and maximal (18) length of utterances returned by GECA. Moreover, subtree substitution could generate much more augmented instances, because it can identify more complex structures besides those simple ones identified by GECA. Compared with SCFG, SUBS could also identify complex structures automatically with subtrees, while SCFG only handle simple phrases defined by rules.

Effect of Training Data Size Table 4 shows that with more training examples, models’ performances improve. In all settings, using (gold) subtree substitution boosts the performance of BART. When there are 100 and 200 training examples, the improvement is more significant, demonstrating the effectiveness of SUBS in the few-shot setting.

4 Related Work

Several data augmentation methods have been introduced for (compositional) semantic parsing. Jia and Liang (2016) recombined data by SCFG, and Andreas (2019) used some simple rules to exchange tokens with the same context. However, they leveraged only superficial grammars or rules, which has limited capacity to identify complex structures. Akyürek et al. (2020) learned to recombine and resample data with a prototype-based generative model, instead of using rules. Certain substructure substitution methods have been explored for data augmentation in other NLP tasks (Shi et al., 2021). Dependency tree cropping and rotation within sentence was used in low-resource language POS tagging (Şahin and Steedman, 2019) and dependency parsing (Vania et al., 2019). Dependency tree swapping was explored in low-resource language dependency parsing (Dehouck and Gómez-Rodríguez, 2020), and Universal Dependency features was used for zero-shot cross-lingual semantic parsing (Yang et al., 2021). However, subtree substitution with fine-grained meaning functions has not been examined. Some rule-based data augmentation methods were also explored in table semantic parsing (Eisenschlos et al., 2020; Yang et al., 2022).

To the best of our knowledge, we are the first to explore tree manipulation for semantic parsing.

5 Conclusion

This work proposed to use subtree substitution to compositionally augment the data of semantic parsing to help the compositional generalization. Our method achieved significant improvements over seq2seq models, other data augmentation methods and span-based semantic parsing.

A Training Details

We adapted OpenNMT (Klein et al., 2017) for LSTM model with attention and copying mechanism, while used fairseq (Ott et al., 2019) to implement BART model.

We manually tune the hyper-parameters. For LSTM models, we use one-layer bidirectional LSTM in the encoder side and one-layer unidirectional LSTM in the decoder side. We use dropout with 0.5 as dropout rate and Adam optimizer with a learning rate of 0.001. We use MLP attention and reuse attention scores as copying scores. On GEOQUERY, the batch size is set to 1 sentence without augmented data and set to 64 sentences with augmented data. On SCAN, all batch sizes are 64 sentences. For BART models, we use BART large models. We use Adam as optimizer with a learning rate 1e-5. We use dropout and attention dropout with 0.1 as dropout rate. Also, we use label smoothing with a rate 0.1. Batch sizes are 1024 tokens. Besides, we employ a weight-decay rate 0.01. All the parameters are manually tuned based on the dev performance.

We train all models on NVIDIA A100 SXM4 40 GB GPU. We set the max training epoch to be 100 and select the best performed epoch according to dev performance. Training process on each clause or whole sequence could be finished within 3 hours.

For baselines with other data augmentation methods, we reran GECA and SCFG on this FunQL formalism of GEOQUERY and these splits with annotated span trees. That's why our results are a little different from the reported results in the original paper. We got similar results with their source code and our code on our data, in order to make sure that there is no problem with our results and code.

We got the same denotation accuracy as reported by Herzig and Berant (2020), but we reported exact-match accuracy on Table 2 for fair comparison.

MultiVerS: Improving scientific claim verification with weak supervision and full-document context

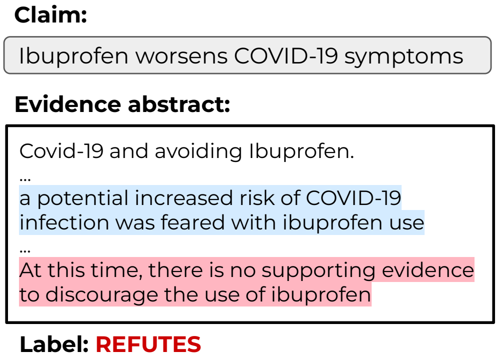
Abstract

The scientific claim verification task requires an NLP system to label scientific documents which SUPPORT or REFUTE an input claim, and to select evidentiary sentences (or *rationales*) justifying each predicted label. In this work, we present MULTIVERS, which predicts a fact-checking label and identifies rationales in a multitask fashion based on a shared encoding of the claim and full document context. This approach accomplishes two key modeling goals. First, it ensures that all relevant contextual information is incorporated into each labeling decision. Second, it enables the model to learn from instances annotated with a document-level fact-checking label, but lacking sentence-level rationales. This allows MULTIVERS to perform weakly-supervised domain adaptation by training on scientific documents labeled using high-precision heuristics. Our approach outperforms two competitive baselines on three scientific claim verification datasets, with particularly strong performance in zero / few-shot domain adaptation experiments. Our code and data are available at `https://github.com/dwadden/multivers`.

1 Introduction

The proliferation of scientific mis- and disinformation on the web has motivated the release of a number of new datasets (Saakyan et al., 2021; Sarrouti et al., 2021; Wadden et al., 2020; Kotonya and Toni, 2020) and the development of modeling approaches (Pradeep et al., 2021; Li et al., 2021; Zhang et al., 2021) for the task of *scientific claim verification*. The goal of the task is to verify a given scientific claim by labeling scientific research abstracts which SUPPORT or REFUTE the claim, and to select evidentiary sentences (or *rationales*) reporting the findings which justify each label.

A common approach to this task is to first extract rationales from the larger document context, and then make label predictions conditioned on the selected rationales. This "extract-then-label" approach has two important drawbacks, which we aim to address in this work. First, the rationales may lack information required to make a prediction when taken out-of-context; for instance, they may contain acronyms or unresolved coreferences, or lack qualifiers that specify the scope of a reported finding (Figure 1 provides an example). Second, the "extract-then-label" approach requires training data annotated with both sentence-level rationales and abstract-level labels. While sentence-level rationale annotations are costly and require trained experts, abstract-level labels can be created cheaply using high-precision heuristics, e.g., the titles of research papers sometimes make claims that are supported by their abstracts.



Claim:

Ibuprofen worsens COVID-19 symptoms

Evidence abstract:

Covid-19 and avoiding Ibuprofen.
...
a potential increased risk of COVID-19 infection was feared with ibuprofen use
...
At this time, there is no supporting evidence to discourage the use of ibuprofen

Label: REFUTES

Figure 1: A claim from the HealthVer dataset, refuted by a research abstract. The sentence in red is a *rationale* reporting a finding that REFUTES the claim. However, this finding cannot be interpreted properly without the context in blue, which specifies that the finding applies to Ibuprofen as a treatment for COVID. MULTIVERS incorporates the full context of the evidence-containing abstract when predicting fact-checking labels.

Motivated by these challenges, we introduce MULTIVERS (**Multi**task **Ver**ification for **S**cience): Given a claim and evidence-containing scientific abstract, MULTIVERS creates a shared encoding of the entire claim / abstract context, using the Longformer encoder (Beltagy et al., 2020) to accommo-

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 175 - 190

date long sequences. Then, it predicts an abstract-level fact-checking label and sentence-level rationales in a multitask fashion, enforcing consistency between the outputs of the two tasks during decoding. This modeling approach ensures that label predictions are made based on all available context, and enables training on instances derived via weak supervision for which abstract-level labels are available, but sentence-level rationales are not.

In experiments on three scientific claim verification datasets, we find that MULTIVERS outperforms two state-of-the-art baselines, one of which has more than 10x the parameters of our system. In addition, we show that training MULTIVERS on weakly-labeled in-domain data substantially improves performance in the zero / few-shot domain adaptation settings. The ability to achieve reasonable performance given limited labeled data is especially valuable in specialized domains, due to the high cost of collecting expert annotations.

In summary, our contributions are as follows:

1. We introduce MULTIVERS, a multitask system for full-context scientific claim verification. MULTIVERS improves fully-supervised fact-verification performance by an average of 11% on three datasets over two state-of-the-art baselines, with improvements of 14% and 26% in the few-shot and zero-shot settings.
2. We present weak supervision heuristics to assign fact-checking labels to two large scientific datasets, and show that training on these annotations more than doubles zero-shot domain adaptation performance.
3. Through ablations and analysis, we demonstrate that our multitask modeling approach achieves our goals of incorporating full-document context into label predictions, and facilitating zero / few-shot domain adaptation.

2 Background

2.1 The scientific claim verification task

We use the definition of scientific claim verification from the SCIFACT task (Wadden et al., 2020), and provide a brief overview of the task here. Other works have cast scientific claim verification as a sentence-level natural language inference (NLI) task; in §4.1, we describe how we process these datasets to be compatible with the task as considered in this work.

Task definition Given a claim c and a collection of *candidate abstracts* which may contain evidence relevant to c, the scientific claim verification task requires a system to predict a *label* $y(c,a) \in \{\text{SUPPORTS}, \text{REFUTES}, \text{NEI}^{1}\}$, which indicates the relationship between c and a for each candidate a. For all abstracts labeled SUPPORTS or REFUTES, the system must also identify *rationales* $R(c,a) = \{r_1(c,a), \ldots, r_n(c,a)\}$, where each $r_i(c,a)$ is a sentence from a that either entails or contradicts the label $y(c,a)$.[2] The rationales may not be self-contained, and may require additional context from elsewhere in the abstract to resolve coreferential expressions or acronyms, or to determine qualifiers specifying experimental context or study population.[3] Examples of these situations are provided in Figure 1 and Appendix A.3.

Evaluation The SCIFACT task reports four evaluation metrics. We have found that two of these metrics are sufficient to convey the important findings for our experiments: (1) *abstract-level label-only* evaluation computes the model's F1 score in identifying abstracts that SUPPORT or REFUTE each claim. Predicting the correct label $y(c,a)$ is sufficient; models do not need to provide rationales. (2) *Sentence-level selection+label* evaluation computes the point-wise product of the model's F1 score in identifying the rationales $R(c,a)$, with the model's abstract-level label $y(c,a)$; this metric rewards precision in identifying exactly which sentences contain the evidence justifying the label. In this work, we refer to these two metrics as "abstract" and "sentence" evaluation respectively.

Retrieval settings For *open* scientific claim verification, the system must retrieve candidate abstracts from a corpus of documents. In the *abstract-provided* setting, candidate abstracts for each claim are given as input. We describe the retrieval settings for all datasets in §4.1.

Supervision settings We consider three supervision settings. In the *zero-shot domain adaptation* setting, models may not train on any in-domain fact-checking data, though they may train on general-domain fact-checking data and other available scientific datasets. In the *few-shot domain adaptation* setting, models may train on 45 claims from the target dataset. In the *fully-supervised* setting, models

---

[1] NEI stands for "Not Enough Info".

[2] This rationale definition is simplified slightly from the one presented in Wadden et al. (2020).

[3] This convention is consistent with related tasks in rationalized NLP for biomedical literature, such as Lehman et al. (2019) and DeYoung et al. (2020).

may train on all claims from the target dataset.

While most existing work on scientific fact-checking has focused on the fully-supervised setting, some recent work has examined the zero-shot setting. Lee et al. (2021) use language model perplexity as a measure of claim veracity. Wright et al. (2022) generate claims based on citation sentences, and verify each generated claim against the abstracts mentioned in the claim's source citation. Given the high potential impact of fact verification systems for specialized domains, combined with the substantial cost of creating these datasets, we believe that the development of techniques for zero / few-shot domain adaptation represents an important area for continued research.

2.2 Scientific claim verification datasets

Several scientific claim verification datasets have been released in the past few years. COVIDFact (Saakyan et al., 2021) and HealthVer (Sarrouti et al., 2021) verify COVID-19 claims against scientific literature. PUBHEALTH (Kotonya and Toni, 2020) verifies public health claims against news and web sources. SCIFACT (Wadden et al., 2020) verifies claims made in citations in scientific papers. CLIMATE-FEVER (Diggelmann et al., 2020) verifies claims about climate change against Wikipedia. In this work, our focus is verifying claims against scientific literature. We therefore perform experiments on the COVIDFact, HealthVer, and SCIFACT datasets. Preprocessing details and summary statistics for these datasets are included in §4.1.

2.3 Models

Motivated in part by the SCIVER shared task (Wadden and Lo, 2021) and leaderboard, a number of models have been developed for SCIFACT (the focus of the shared task). The two strongest systems on the shared task were VERT5ERINI (Pradeep et al., 2021) and PARAGRAPHJOINT (Li et al., 2021), which we adopt as baselines. More recently, ARSJOINT (Zhang et al., 2021) achieved performance competitive with these two systems.[4]

Given a claim c and candidate abstract a, these models make predictions in two steps. First, they predict rationales $\widehat{R}(c, a) = \{\widehat{r}_1(c, a), \dots, \widehat{r}_n(c, a)\}$ likely to contain evidence. Then, they make a label prediction $\widehat{y}(c, f_R(\widehat{R}(c, a))$ based on the claim and predicted rationales, where f_R is a function which creates a representation of the predicted rationales.

While existing models share this general approach, they use different functions f_R to construct rationale representations. For VERT5ERINI, rationale selection and label prediction are performed by two separate T5-3B models, and f_R concatenates the text of the selected rationales. As a result, the label predictor may not have access to all context needed to make a correct label prediction. PARAGRAPHJOINT and ARSJOINT attempt to address this issue by encoding the claim and full abstract (truncating to 512 tokens), and using these representations as the basis for both rationale selection and label prediction. The function f_R consists of self-attention layers over the (globally-contextualized) token representations of the predicted rationales. Thus, PARAGRAPHJOINT and ARSJOINT can incorporate abstract-level context into label decisions. However, the mechanism by which this occurs is more complex than for our proposed system and requires rationale supervision for all training instances.

3 The MULTIVERS model

We propose the MULTIVERS model for full-context claim verification. In §3.1, we describe our modeling approach. Rather than predicting rationales $\widehat{R}(c, a)$ followed by the overall fact-checking label $\widehat{y}(c, f_R(\widehat{R}(c, a)))$, we predict $\widehat{y}(c, a)$ directly based on an encoding of the entire claim and abstract, and enforce consistency of $\widehat{R}(c, a)$ with $\widehat{y}(c, a)$ during decoding. A similar idea has been shown to be effective on sentiment analysis and propaganda detection with token-level rationales (Pruthi et al., 2020). In §3.2, we explain how our approach facilitates few-shot domain adaptation using weakly-labeled scientific documents.

3.1 Full-context claim verification

Long-document encoding Given a claim c and candidate abstract a consisting of title t and sentences $s_1, \dots, s_n$, we concatenate the inputs separated by `</s>` tokens. The `</s>` token following each sentence s_i is notated as `</s>`$_i$:

$$\texttt{<s>}\ c\ \texttt{</s>}\ t\ \texttt{</s>}\ s_1\ \texttt{</s>}_1\ \dots s_n\ \texttt{</s>}_n$$

The model input sometimes exceeds the 512-token limit common to transformer-based language models like BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019); see Table 1 for details on how frequently this occurs. Therefore, we use the Longformer model (Beltagy et al., 2020) as our encoder.

---

[4] Recent progress can be found on the SciFact leaderboard.

We assign global attention to the `<s>` token, as well as all tokens in c and all `</s>` tokens.

Multitask rationale selection and label prediction Given the full-context Longformer encoding, we predict whether sentence s_i is a rationale via a binary classification head, consisting of two feed-forward layers followed by a two-way softmax, on top of the globally-contextualized token $\texttt{</s>}_i$.

Similarly, we predict the overall fact-checking label $\widehat{y}(c, a)$ by adding a three-way classification head over the encoding of the `<s>` token. Since the `<s>` token is trained with global attention, the model makes predictions based on a representation of the entire claim and abstract.

During training, we compute the cross-entropy losses for the label and rationale predictions, and train to minimize the multitask loss:

$$L = L_{\text{label}} + \lambda_{\text{rationale}} L_{\text{rationale}} \tag{1}$$

where $\lambda_{\text{rationale}}$ is tuned on the dev set.

At inference time, we first predict $\widehat{y}(c, a)$ to be the label with the highest softmax score. If the predicted label is NEI, we predict no rationales. If the predicted label is either SUPPORTS or REFUTES, then we predict rationales as all sentences with an assigned softmax score of greater than 0.5. If no sentences have a rationale softmax over 0.5, then we predict the highest-scoring sentence as the sole rationale. In §6.2, we show that this ability to condition the rationale predictions on the label prediction (as opposed to conditioning the label on the predicted rationales) leads to substantial improvement in the zero-shot domain adaptation setting.

Candidate abstract retrieval For datasets that require retrieval of candidate abstracts, we rely on the VERT5ERINI (Pradeep et al., 2021) retrieval system, which achieved state-of-the-art performance on the SCIVER shared task (SCIVER used the SCIFACT dataset for evaluation). This model first retrieves abstracts using BM25 (Robertson and Zaragoza, 2009), then refines the predictions using a neural re-ranker based on Nogueira et al. (2020), which is trained on the MS MARCO passage dataset (Campos et al., 2016).

3.2 Training for domain adaptation

Three types of data are available to train scientific claim verification systems. (1) In-domain fact-checking annotations are the "gold standard", but they are expensive to create and require expert annotators. (2) General-domain fact-checking datasets like FEVER (Thorne et al., 2018) are abundantly available, but generalize poorly to scientific claims (see §6.1). (3) Scientific documents – either unlabeled or labeled for different tasks – are abundant, and high precision heuristics (described in §4.2) can be used to generate document-level fact-checking labels $y(c, a)$ for these data.

We train MULTIVERS as follows: we first pretrain on a combination of general-domain fact-checking annotations, combined with weakly-labeled in-domain data.[5] Then, we finetune on the target scientific fact-checking dataset. The multitask architecture of MULTIVERS is well-suited to this strategy, since the model can be trained on data with or without rationale annotations. When no rationales are available, we set $\lambda_{\text{rationale}} = 0$ in the loss function and train as usual. By contrast, training an "extract-then-label" model on weakly-supervised data requires creating rationale annotations $R(c, a)$, which is quite noisy (see §4.2).

4 Datasets

4.1 Scientific claim verification datasets

We experiment with three scientific claim verification datasets. Table 1 provides a summary of important dataset characteristics. Preprocessing steps and additional statistics can be found in Appendix A. HealthVer and COVIDFact were originally released in an NLI format, pairing claims with (out-of-context) evidentiary sentences. We convert to our task format by identifying the abstracts in the CORD-19 corpus (Wang et al., 2020) containing these sentences.

We use the following terminology: an *atomic* claim makes an assertion about a single property of a single entity, while a *complex* claim may make assertions about multiple properties or entities.

SCIFACT Claims in SCIFACT (Wadden et al., 2020) were created by re-writing citation sentences occurring in biomedical literature into atomic claims, which were verified against the abstracts of the cited documents. REFUTED claims were created by manually negating the original claims. Abstracts that were cited but which annotators judged not to contain evidence were labeled NEI. SCIFACT requires retrieval of candidate abstracts.

HealthVer (Sarrouti et al., 2021) consists of COVID-related claims obtained by extracting snippets from articles retrieved to answer questions

---

[5] We use "pretraining" as shorthand for "training on the target task with out-of-domain and/or weakly-supervised labels."

Dataset	Domain	Claim source	Open	Has NEI	Claim complexity	Negation method	Train claims	Eval claims	> 512 tokens
HealthVer	COVID	TREC-COVID	✗	✓	Complex	Natural	1,622	230	14.9%
COVIDFact	COVID	Reddit	✗	✗	Complex	Automatic	903	313	12.4%
SciFact	Biomed	Citations	✓	✓	Atomic	Human	1,109	300	27.4%
Fever	Wiki	Wikipedia	-	✓	Atomic	Human	130,644	-	33.2%
PubmedQA	Biomed	Paper titles	-	✓	Complex	Automatic	58,370	-	12.1%
EvidenceInference	Biomed	ICO prompts	-	✓	Atomic	Automatic	7,395	-	42.7%

Table 1: Summary of datasets used in experiments. The top group of datasets are scientific claim verification datasets, and the bottom group are for pretraining. Datasets with a ✓ for "Open" require that candidate abstracts be retrieved from a corpus; those with a ✗ provide candidate abstracts as input. Datasets with a ✓ for "Has NEI" require three-way (Supports / Refutes / NEI) label prediction, while those with an ✗ are (Supports / Refutes) only. The "> 512 tokens" column indicates the percentage of claim / abstract contexts that exceed 512 tokens.

from TREC-COVID (Voorhees et al., 2020), verified against abstracts from the CORD-19 corpus (Wang et al., 2020). Claims in HealthVer may be complex. Refuted claims occur naturally in the article snippets. HealthVer provides candidate abstracts for each claim, but some of these candidates do not contain sufficient information to justify a Supports / Refutes verdict and are labeled NEI.

COVIDFact (Saakyan et al., 2021) collects claims about COVID-19 scraped from a COVID-19 subreddit, and verifies them against linked scientific papers, as well as documents retrieved via Google search. Claims in COVIDFact may be complex, and candidate abstracts for each claim are provided. All candidates either Support or Refute the claim. Claim negations were created automatically by replacing salient words in the original claims, and as a result the labels $y(c, a)$ are somewhat noisy (see Appendix A).

4.2 Pretraining datasets

We briefly describe our pretraining datasets and the weak supervision heuristics used to construct them. Detailed descriptions of these heuristics can be found in Appendix A.1.

Fever (Thorne et al., 2018) consists of claims created by re-writing Wikipedia sentences into atomic claims, verified against Wikipedia articles.

EvidenceInference (Lehman et al., 2019; DeYoung et al., 2020) was released to facilitate understanding of clinical trial reports, which examine the effect of an *intervention* on an *outcome*, relative to a *comparator* ("ICO" elements). The dataset contains ICO *prompts* paired with (1) labels indicating whether the outcome *increased* or *decreased* due to the intervention, and (2) rationales justifying each label. We use rule-based heuristics to convert these prompts into claims – for instance "[intervention] increases [outcome] relative to [comparator]".

PubmedQA (Jin et al., 2019) was released to facilitate question-answering over biomedical research abstracts. We use the PQA-A subset, which is a large collection of abstracts with "claim-like" titles – for instance, "Vitamin B6 supplementation increases immune responses in critically ill patients." We treat the paper titles as claims and the matching abstracts as the evidence sources.

To train models requiring rationale supervision, we create weakly-supervised rationales by selecting the sentences with highest similarity to the claim as measured by cosine similarity of Sentence-BERT embeddings (Reimers and Gurevych, 2019). These annotations are not used to train MultiVerS. To estimate the precision of our rationale labeling heuristic, we predict rationales in the same fashion for our supervised datasets and compute the Precision@1 with which this method identifies gold rationales. The scores are relatively low: 49.4, 48.8, and 43.4 for SciFact, COVIDFact, and HealthVer respectively.

5 Experimental setup

We describe our model training procedure, the systems against we compare MultiVerS, and our ablation experiments.

5.1 Model training

Our complete training procedure consists of pretraining on the three datasets from §4.2, followed by finetuning on one of the target datasets from §4.1. We conduct experiments with three different levels of supervision. For *zero-shot* experiments, we perform pretraining only. For *few-shot* experiments, we pretrain followed by finetuning on 45 target examples. For *fully-supervised* experiments, we pretrain and then train on all target data.

Following Li et al. (2021), we found that negative sampling was important to achieve good precision on SCIFACT, which requires document retrieval. We train with 20 negative samples per claim and retrieve 10 abstracts per claim at inference time. Appendix C.3 shows results without negative sampling. For the other datasets, no negative sampling was used. Additional details including batch sizes, learning rates, number of epochs, etc. can be found in Appendix B.

During model development, we experimented with training on all three target datasets combined before predicting on each one, but found that this did not improve performance; see Appendix C.4.

5.2 Baseline systems

We use PARAGRAPHJOINT and VERT5ERINI as baselines. VERT5ERINI is the largest model, with 5.6B parameters. MULTIVERS and PARAGRAPHJOINT are comparably-sized, with 440M and 360M parameters, respectively.

In the fully-supervised setting, we compare against both baselines. For prediction on SCIFACT, we use publicly available model checkpoints as-is. For training on HealthVer and COVIDFact, we use the code provided by the authors, starting from the available checkpoints trained on SCIFACT. Model hyperparameters (learning rate, batch size, epoch number, etc.) for all systems including MULTIVERS were tuned based solely on SCIFACT and not adjusted further. Additional details can be found in Appendix B.4.

Evaluation in the few-shot and zero-shot settings requires pretraining and finetuning as described in §5.1. Due to the expense of pretraining T5-3B, we do not perform these experiments for VERT5ERINI, and compare only against PARAGRAPHJOINT (which shows comparable performance in the fully-supervised setting). We pretrain PARAGRAPHJOINT on the data described in §4.2.

5.3 Ablations

Since PARAGRAPHJOINT and VERT5ERINI differ from MULTIVERS along a number of important dimensions (e.g. model architecture, number of parameters, and base encoder), we conduct ablations to characterize the performance contributions of three key components of MULTIVERS.

Pretraining data We compare the results of three different pretraining strategies. For FEVERSCI, we pretrain on all available data as described in §5.1. For FEVER, we pretrain on FEVER only. For *No-Pretrain*, we perform no pretraining.

Base encoder We compare the performance achieved using LongFormer as the encoder for MULTIVERS, compared to the results when we swap in RoBERTa but keep other settings identical. We use Longformer-large and RoBERTa-large.

Modeling approach We compare three modeling approaches: (1) The *Multitask* approach is the method used by MULTIVERS as described in §3.1. (2) The *Pipeline* approach consists of two separate Longformer modules. The first selects rationales as described in §3.1, but with L_{label} removed from Eq. 1, and the second module predicts a label given the text of the rationales selected by the first module as input. When pretraining on PUBMEDQA, we train on the rationales chosen by Sentence-BERT as described in §4.2. (3) The *Multitask train / Pipeline inference* (MT / PI) approach takes the model trained using the Multitask approach, and performs inference using the Pipeline approach. Specifically, MT / PI is trained to make label predictions based on full abstracts, but must make test-time label predictions based on predicted rationales only. By contrast, the Pipeline model makes label predictions based on gold and predicted rationales at train and test time, respectively.

6 Experimental results

We compare MULTIVERS performance relative to our baseline systems, and present ablation results.

6.1 Main Results

Table 2 compares the performance of MULTIVERS against PARAGRAPHJOINT and VERT5ERINI. A few trends are apparent. First, MULTIVERS outperforms the baselines on all datasets, with relative improvements — averaged over the three datasets and two evaluation methods — of 26%, 14%, and 11% in the zero-shot, few-shot, and fully-supervised settings respectively. We examine possible causes of this improvement in §6.2. Second, while all models score within roughly six points of each other on HealthVer and SCIFACT, variability is much greater on COVIDFact. We suspect that this is due to the automatically-generated nature of COVIDFact negations. Third, we observe that HealthVer appears to be the most challenging dataset of the three. Few-shot abstract-level F1 scores for COVIDFact and SCIFACT are generally

		HealthVer						COVIDFact						SciFact					
		Abstract			Sentence			Abstract			Sentence			Abstract			Sentence

Table 2: Performance of MultiVerS and baselines. In the fully-supervised setting, we compare to ParagraphJoint and Vert5Erini, which exhibit comparable performance. In the zero and few-shot settings, we compare to ParagraphJoint only due to the high cost of pretraining Vert5Erini. We report performance using abstract-level and sentence-level evaluation as defined in §2.1.

within 10 F1 of their fully-supervised values, while the gap is roughly 20 F1 for HealthVer. This may be due to the high complexity of HealthVer claims.

6.2 Ablations

The results of all ablations are shown in Table 3. We report abstract and sentence-level F1 scores in the main text; full results can be found in Table 9 in Appendix C.

In-domain pretraining substantially improves zero / few-shot performance In Table 3a, we compare the performance of models pretrained on FeverSci, Fever, and No-Pretrain. In the zero-shot setting, removing scientific data during pretraining results in a relative performance decrease of 65%, averaged over the three datasets and two evaluation methods. The decrease is driven primarily by very low recall (see Table 9a).

In the few-shot setting, Fever pretraining scores within 4% of FeverSci, while No-Pretrain results in a 39% decrease relative to FeverSci. This suggests that training on a handful of target examples is sufficient to recalibrate a model trained for a different domain, but not to learn the task from scratch. In the fully-supervised setting, Fever pretraining is only slightly worse than FeverSci, while No-Pretrain lags by roughly 9%. Overall, the results indicate that pretraining always helps, and pretraining on weakly-labeled in-domain data helps especially when target data are scarce.

Longformer improves performance on datasets with long documents Table 3b compares the performance of MultiVerS when Longformer and RoBERTa are used as the base encoder. Using Longformer consistently helps on SciFact, but does not help on the other two datasets. This is unsurprising, since 27% of SciFact instances exceed the RoBERTa token limit, compared to less than 15% for the other two datasets (Table 1).

Multitask modeling improves zero / few-shot performance Results comparing our three different modeling approaches are shown in Table 3c. In the zero-shot setting, we find that Multitask performs best, with both MT / PI and Pipeline exhibiting performance drops greater than 50%. The Multitask approach of predicting rationales conditioned on the predicted label leads to improved recall (see Table 9c). Similarly, in the few-shot setting, both Pipeline and MT / PI perform roughly 10% worse than Multitask. Collectively, the results indicate that Multitask makes the best use of the available data when target annotations are limited.

We also find that MT / PI outperforms Pipeline in the zero-shot setting. This supports our intuition from §3.2 that, while training on weakly-supervised *document-level* labels improves zero-shot performance, training on weakly-supervised *sentence-level* rationales (as for Pipeline) leads to worse performance than not training on these rationales (as for MT / PI).

In the fully-supervised setting, Multitask performs best on SciFact, while Pipeline slightly outperforms Multitask on HealthVer and COVID-Fact. MT / PI performs substantially worse than the other approaches on all datasets. We investigate these findings further in §7.1; our results indicate that Pipeline may, in effect, be trained to make predictions based on insufficient evidence.

	Pretraining	HealthVer	COVIDFact	SciFact
Zero	FeverSci	**30.7 / 7.8**	**47.2 / 23.6**	**46.7 / 27.8**
	Fever	1.3 / 0.7	25.2 / 11.2	23.9 / 11.8
Few	FeverSci	**54.7 / 35.7**	69.7 / 37.4	**63.3 / 45.3**
	Fever	53.4 / 31.9	**74.4 / 42.1**	54.5 / 39.0
	No-Pretrain	39.4 / 27.0	67.8 / 22.6	24.2 / 10.8
Full	FeverSci	**77.6** / 69.1	77.3 / **43.7**	**72.5 / 67.2**
	Fever	77.1 / **70.3**	**77.4** / 43.3	67.9 / 61.7
	No-Pretrain	74.5 / 69.7	69.7 / 36.6	63.3 / 58.4

(a) Effect of pretraining data. In-domain pretraining is very effective in the zero- and few-shot settings. In the zero-shot setting, "No-Pretrain" metrics are not shown since this would correspond to no training at all.

	Encoder	HealthVer	COVIDFact	SciFact
Zero	Longformer	30.7 / 7.8	47.2 / 23.6	**46.7 / 27.8**
	RoBERTa	**34.2 / 9.2**	**48.3 / 26.2**	45.2 / 25.9
Few	Longformer	**54.7** / 35.7	69.7 / 37.4	**63.3 / 45.3**
	RoBERTa	51.2 / **36.9**	**72.1 / 41.0**	50.5 / 34.0
Full	Longformer	77.6 / 69.1	77.3 / **43.7**	**72.5 / 67.2**
	RoBERTa	**78.8 / 72.7**	**78.2** / 43.4	67.6 / 62.3

(b) Effect of base encoder. Longformer improves performance on SciFact, which has the largest fraction of instances exceeding the RoBERTa token limit.

	Approach	HealthVer	COVIDFact	SciFact
Zero	Multitask	**30.7 / 7.8**	**47.2 / 23.6**	**46.7 / 27.8**
	Pipe	3.2 / 0.9	19.0 / 10.5	22.5 / 12.8
	MT / PI	4.5 / 1.8	26.7 / 13.5	28.3 / 17.7
Few	Multitask	**54.7 / 35.7**	**69.7** / 37.4	**63.3 / 45.3**
	Pipe	52.8 / 29.5	68.3 / **38.2**	53.0 / 39.9
	MT / PI	46.7 / 32.3	59.3 / 34.1	56.2 / 41.1
Full	Multitask	77.6 / 69.1	77.3 / 43.7	**72.5 / 67.2**
	Pipe	**78.4 / 69.2**	**77.6 / 47.7**	70.9 / 66.2
	MT / PI	70.6 / 64.3	73.3 / 44.0	60.3 / 57.0

(c) Effect of model architecture. The Multitask approach performs best in the zero- and few-shot settings. We examine the fully-supervised setting in detail in §7.1.

Table 3: Ablations examining the effects of pretraining data, base encoder, and modeling approach. Entries are formatted "{Abstract-level F1} / {Sentence-level F1}".

7 Analysis

7.1 Fully-supervised Pipeline performance

In §6.2, we found that the Pipeline approach (but not the MT / PI approach) performed on par with the Multitask approach in the fully-supervised setting. To understand this finding, we collected detailed annotations for 128 claim / evidence instances from the SciFact test set. For each instance, an annotator indicated whether the annotated rationales were "self-contained" — i.e. sufficient to justify the fact-checking label when taken in isolation, or "context-dependent" — i.e. only sufficient when taken in the context of the abstract. Figure 1 and Table 8 provide examples; see Choi et al. (2021) for a detailed discussion of different forms of context-dependence.[6]

	Self-contained			Context-dependent			
Approach	P	R	F1	P	R	F1	%Δ
Multitask	86.1	82.9	84.5	90.3	60.9	72.7	-14.0%
Pipeline	92.4	89.0	90.7	82.4	60.9	70.0	-22.8%
MT / PI	91.8	54.9	68.7	100.0	13.0	23.1	-66.4%
Count	82			46			

Table 4: Performance of the Multitask, Pipeline, and MT / PI modeling approaches on SciFact instances with rationales that are self-contained (can be interpreted in isolation) or context-dependent (must be interpreted in the context of the abstract). Evaluation is performed in the abstract-provided setting. We report abstract-level metrics; sentence-level results are similar. The %Δ indicates the drop in F1 score on context-dependent instances relative to self-contained instances. Multitask suffers the smallest performance loss, while MT / PI suffers the largest.

Table 4 compares the performance of the three modeling approaches on instances with self-contained vs. context-dependent evidence. We find that all approaches have lower performance on context-dependent instances relative to self-contained instances, but the size of the performance drop varies widely. The Multitask approach performs 14.0% worse on context-dependent instances, while the Pipeline approach performs 22.8% worse. Most interestingly, MT / PI performs 66.4% worse, driven predominantly by low recall. The MT / PI model frequently (and correctly) predicts that context-dependent rationales are not sufficient to justify a Supports / Refutes decision. These findings suggest that (1) the Multitask approach is, as expected, best at verifying claims with context-dependent evidence, and (2) the Pipeline approach has, in effect, over-fit to context-dependent rationales and learned to make predictions based on insufficient evidence.

7.2 Performance upper bound

To determine an "upper bound" on the achievable performance of scientific fact-checking models, we

---

[6] Unlike Choi et al. (2021), we do not include the presence of acronyms as "context-dependent," since an acronym can be matched with its expansion based on surface-level textual features. See Appendix C.2 for further analysis of acronyms.

	Abstract			Sentence		
	P	R	F1	P	R	F1
VERT5ERINI	90.7	74.3	81.7	79.6	62.2	69.8
PARAGRAPHJOINT	87.2	64.4	74.1	76.7	55.1	64.1
MULTIVERS	87.4	75.2	80.9	80.5	70.3	**75.0**
Human	94.8	84.1	**89.1**	67.4	67.4	67.4

Table 5: Performance on SCIFACT in the "abstract-provided" setting. Models exceed human agreement as measured by sentence-level F1, but not abstract-level.

assign 151 claim-evidence pairs from SCIFACT for independent annotation by two different annotators. We estimate human-level performance by treating the first annotator's results as "gold," and the second annotator's results as predictions. For comparison, we make predictions using MULTIVERS and our two baseline models, with candidate abstracts provided as input. The results are shown in Table 5. Existing systems already exceed human agreement for sentence-level evaluation, but not abstract-level, indicating that experts tend to agree on the overall relationship between claim and abstract, but may disagree about exactly which sentences contain the best evidence. This constitutes another reason not to rely solely on selected rationales when predicting a fact-checking label: the choice of rationales is itself somewhat subjective.

In addition, these results suggest that one key subtask of scientific claim verification — namely, predicting whether an evidence-containing abstract SUPPORTS or REFUTES a claim — may be nearly "solved" in the setting where (1) the claims are atomic and (2) roughly 1,000 in-domain labeled claims are available for training.

8 Related work

Background on scientific claim verification is covered in §2; we discuss other relevant work here. Nye et al. (2020) have previously observed that document-level context is often required to properly interpret scientific findings.

DeYoung et al. (2020) use an "extract-then-label" pipeline for the original EVIDENCEINFERENCE task. Multitask label prediction and rationale selection was proposed by Pruthi et al. (2020) and applied to sentiment analysis and propaganda detection. As in this work, the authors condition on the predicted label when predicting rationales. Another alternative to supervised rationale selection is to treat rationales as latent variables (Lei et al., 2016; Paranjape et al., 2020).

Long-document encodings for fact verification have been explored by Stammbach (2021), who use Big Bird (Zaheer et al., 2020) for full-document evidence extraction from FEVER. Domain adaptation for scientific text has been studied in a number of works, including Gururangan et al. (2020); Beltagy et al. (2019); Lee et al. (2020); Gu et al. (2021). In those works, the primary focus is on language model pretraining. Here, we focus on training on the target task using out-of-domain and weakly-labeled data.

9 Conclusion

This work points to a number of promising future directions for scientific claim verification. These include applying the approach presented here to develop scientific claim verification models for new scientific sub-domains or other specialized fields given a handful of labeled examples, and extending the task definition to verify claims against longer contexts (e.g. full scientific papers) or larger corpora. Our task formulation also offers an opportunity to study the effects of rationale decontextualization (Choi et al., 2021), especially in cases where models may be making predictions based on insufficient evidence.

In presenting the MULTIVERS system, we addressed two challenges associated with scientific claim verification: incorporating relevant information beyond rationale boundaries by modeling full-document context, and facilitating zero / few-shot domain adaptation through weak supervision enabled by a multitask modeling approach. Our experiments show that MULTIVERS outperforms existing systems across several scientific claim verification datasets. We hope that the task, data, and modeling resources presented in this paper will encourage further work and progress towards the broader goals of identifying and addressing scientific mis- and disinformation.

10 Ethical considerations and broader impact

One long-term goal of research on scientific claim verification is to build systems that can automatically identify mis- and dis-information, which we believe would be socially beneficial given the current prevalence of mis- and dis-information online.

In the shorter term, this work presents two potential risks. First, automated systems for scientific fact-checking are not mature enough to inform real-world medical decisions. We will include a disclaimer with released software to this effect. Second, bad actors could potentially use this work to develop disinformation generators trained to "fool" automated fact-checkers. While this risk cannot be ruled out, we believe that the benefits of publishing this work and making our models available to the community to facilitate further research outweigh the risks that this work will be misused by malicious actors.

A Data processing and statistics

A.1 Data preprocessing

SciFact We use SciFact in its original form, as it was released by the paper authors (Wadden et al., 2020).

HealthVer The HealthVer (Sarrouti et al., 2021) data release available at `https://github.com/sarrouti/HealthVer` appears in NLI format, pairing claims with evidence-containing sentences; the documents from which the sentences were extracted are not provided. We match evidence-containing sentences to their abstracts in the CORD-19 corpus (Wang et al., 2020) using a simple substring search, after normalizing for capitalization and whitespace differences. Evidence for which no match was found in the corpus is discarded.

We then segment the abstracts into sentences. Any sentence in the abstract with a string overlap of $> 50\%$ with the evidence provided in the original data is marked as a rationale. A small number of claims in HealthVer had both supporting and refuting evidence in the same abstract; we remove these claims as well to conform to our task definition. Modeling conflicting evidence is a promising direction for future work.

COVIDFact The COVIDFact data available at `https://github.com/asaakyan/covidfact` is released in a similar format to HealthVer. Like HealthVer, we perform string search over CORD-19 to identify the abstracts containing evidence, and use the same procedure for assigning rationale labels to sentences from the abstract. COVIDFact also includes evidence from sources scraped from the web that are not contained in CORD-19, such as news articles. These sources are not provided with the data release; we discard evidence from non-CORD-19 sources[7].

Refuted claims in COVIDFact are generated automatically by replacing words in the original claim. Based on a manual inspection, we found this process to generate a truly refuted claim roughly a third of the time; in most other cases, it generated a claim that was either ungrammatical or for which the provided evidence was irrelevant. A few cases are provided in Table 6.

FEVER We use the FEVER dataset as-is.

EVIDENCEINFERENCE The EVIDENCEINFERENCE dataset consists of "ICO" (intervention / comparator / outcome) prompts, paired with labels indicating whether the intervention leads to an increase, decrease, or no change in the outcome with respect to the comparator. The dataset is available at `https://evidence-inference.ebm-nlp.com/`. We use templates to convert these prompts to claims. See Figure 2 for an example. Rationale annotations are provided for this dataset. Additional examples of templates are below; the full list will be included in the code release. Refuted claims are generated by swapping "increase" and "decrease" templates.

- **Increase**: [intervention] raises [outcome] relative to [comparator]
- **No change**: [intervention] and [comparator] have very similar effects on [outcome]
- **Decrease**: [intervention] results in a decrease in [outcome], relative to [comparator]

PUBMEDQA We use the PQA-A subset released at `https://pubmedqa.github.io/`, which is filtered for "claim-like" titles. We generate negations by identifying titles with the phrases "does not", "do not", "are not", "is not". "Does not" and "do not" are removed and the relevant verbs are modified to have the correct inflection; for instance "smoking does not cause cancer" is converted to "smoking causes cancer". Similarly, "are not" and "is not" are replaced by "are" and "is".

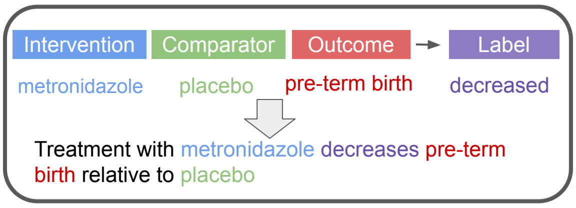

Figure 2: An example showing how an evidence inference prompt (top) can be converted into a claim (bottom) using templates. A refuted claim could be generated by substituting "increases" for "decreases" in the prompt text.

To generate rationales needed to train pipeline models on PUBMEDQA, we employ the following procedure. First, we encode the claim and all abstract sentences using the `all-MiniLM-L6-v2` model from the Sentence-Transformers package `https://www.sbert.net/`. Then, we rank abstract sentences by cosine similarity with the claim and label the top-k sentences as rationales, where k is randomly sampled from $\{1, 2, 3\}$ with a 4:2:1 frequency ratio (this matches the distribution of k in SCIFACT).

A.2 Dataset statistics

Table 7 provides counts showing the number of claim / evidence pairs with each label (SUPPORTS, REFUTES, NEI), in each of our target datasets. Note that a given claim may be (and often is) paired with more than one abstract containing evidence. HealthVer is the largest dataset. COVIDFact is the smallest, in part due to the aggressive evidence filtering described in §A.1.

A.3 Examples of context-dependent rationales

Table 8 provides an example of a context-dependent rationale (as defined in §7.1), as well as an example of a rationale with an undefined acronym. The latter occurs when an acronym appears in a rationale but its full expansion does not; an analysis of undefined acronyms is included in Appendix C.2. The code and data release will contain full annotations indicating which of the 128 human-annotated examples described in §7.1 are context-dependent, and which contain undefined acronyms.

---

[7] Upon request, the paper authors did kindly provide us with scraped evidence documents. Unfortunately, we did not have time to re-run our experiments on these additional sources.

Original claim	**Automatic negation**	**Comment**
Sars-cov-2 reactive t cells . . . are likely expanded by beta-coronaviruses	Sars-cov-2 reactive t cells . . . are not expanded by beta-coronaviruses	Successful negation
Regn-cov2 antibody cocktail prevents and treats sars-cov-2 . . .	On-cov2 antibody cocktail prevents and treats sars-cov-2 infection . . .	Ungrammatical; “On-cov2” isn’t a scientific entity.
. . . immunity is maintained at 6 months following primary infection	. . . immunity is maintained at 6 weeks following primary infection	Not refuted; The original claim entails the negation. Immunity at 6 months implies immunity at 6 weeks.

Table 6: Automatic negations from COVIDFact. Some are successful, in the sense that the attempted negation contradicts the original claim. Others are either ungrammatical or are entailed by the original claim.

Fold	Dataset	SUPPORTS	NEI	REFUTES
Train	SCIFACT	508	485	265
	COVIDFact	299	-	641
	HealthVer	2384	2384	1464
Eval	SCIFACT	113	127	109
	COVIDFact	102	-	215
	HealthVer	374	304	225

Table 7: Evidence distribution by dataset.

A.4 Annotators

In §7, we report an analysis based on annotations performed on the SCIFACT dataset. These annotations were performed by students and / or professional annotators associated with the authors’ research institutions. Annotators were paid between $15 and $20 / hour.

B Modeling details

B.1 Implementation

We implement MULTIVERS using PyTorch Lightning (`https://www.pytorchlightning.ai/`), which relies on PyTorch (`https://pytorch.org/`).

B.2 Model training

Pretraining For pretraining, we train for 3 epochs on FEVER, EVIDENCEINFERENCE, and PUBMEDQA, with the data randomly shuffled. We train on 4 negative samples (i.e. abstracts containing no evidence) per claim, which we find improves precision. We train on 8 NVIDIA RTX 6000 GPUs with a batch size of 1 / gpu (effective batch size of 8), using a learning rate of $1e-5$, using the PyTorch Lightning implementation of the AdamW optimizer with default settings. We initialize from a Longformer-large checkpoint pretrained on the S2ORC corpus (Lo et al., 2020).

Finetuning For finetuning, we train for 20 epochs on the target dataset (SCIFACT, HealthVer, or COVIDFact). For SCIFACT, we train on 20 negative samples / claim. To create “hard” negatives — i.e. abstracts that have high lexical overlap with the claim — we create a search index from 500K abstracts randomly selected from the biomedical subset of the S2ORC corpus. For each claim, we obtain negative abstracts by using the VERT5ERINI retrieval system from §3.1 to retrieve the top-1000 most-similar abstracts from this index, removing abstracts that are annotated as containing evidence, and randomly sampling 20 abstracts to be used as negatives during training.

Since HealthVer and COVIDFact do not have a retrieval step, they do not require negative sampling, and we train on the original datasets as-is.

Retrieval For SCIFACT, we performed dev set experiments retrieving 10, 20, or 50 abstracts / claim, and found that 10 was the best. We use that in our final experiments.

B.3 Model hyperparameters

No organized hyperparameter search was performed. We consulted with the authors of the Longformer paper for suggestions about good model parameters, and generally followed their suggestions.

The loss function in Section 3.1 requires a weight $\lambda_{\text{rationale}}$. This is set to 15 for all final experiments. We informally experimented with values of 1, 5, and 15; no organized hyperparameter search was performed. We selected the learning rate from the values $[9e-5, 5e-5, 1e-5]$.

We performed all experiments with the same random seed, 76, used by invoking the `seed_everything` function in PyTorch Lightning.

All reported results are from a single model run.

B.4 Baselines

VERT5ERINI For prediction on SCIFACT, we use the checkpoint available at

Category	**Example**	
Context-dependent	**Claim:**	Errors in peripheral IV drug administration are most common during bolus administration
	Context:	*OBJECTIVES: To determine the incidence of errors in the administration of intravenous drugs . . .*
	Evidence:	*. . . Most errors occurred when giving bolus doses*
	Explanation:	The evidentiary sentence reporting the finding does not specify the type of error.
Undefined acronym	**Claim:**	Hematopoietic stem cells segregate their chromosomes randomly.
	Context:	*we tested these hypotheses in hematopoietic stem cells (HSCs). . .*
	Evidence:	*. . . indicated that all HSCs segregate their chromosomes randomly.*
	Explanation:	HSCs is an acronym for Hematopoietic stem cells.

Table 8: Examples from the SciFact dataset showcasing rationales that are context-dependent (top example), or include an undefined acronym (bottom example).

https://github.com/castorini/pygaggle/tree/master/experiments/vert5erini. For COVIDFact and HealthVer, we follow the instructions in that repository to convert the data to the required format, and train using the available training code as-is, beginning from the available SciFact checkpoint. We used Google Cloud TPU for training and inference.

ParagraphJoint We use the code available at https://github.com/jacklxc/ParagraphJointModel. For predictions on SciFact, we make predictions using the publicly available checkpoint. For the other two target datasets, we use the training code in the repo without modification.

We used ParagraphJoint as our baseline for zero / few-shot learning experiments, and hence also performed pretraining on ParagraphJoint. The repository provides code to train on the Fever dataset, which we used for pretraining with EvidenceInference and PubmedQA added to the data.

C Additional results and analysis

C.1 Full ablation results

In Table 3, we presented F1 scores for ablations comparing pretraining data, model architecture, and encoder used. Table 9 presents the full results, including precision and recall.

C.2 Performance on rationales with undefined acronyms

In §7.1, we examined the difference in performance on instances with self-contained vs. context-dependent evidence. Here, we show the results of evaluation on instances containing an undefined acronym vs. cases without one. We find that undefined acronyms do not pose a challenge for MultiVerS and Pipeline, but do cause a small performance drop on MT / PI.

C.3 Negative sampling

In §5.1 we described how, for SciFact, we trained on 20 negative abstracts per claim. The effect of training on these additional negative samples is shown in Figure 11. In the abstract-provided setting, negative sampling is not very beneficial. However, when the model must select evidence from retrieved abstracts, precision drops off dramatically without negative sampling. This is worth noting since it suggests that performance reported when models are provided with "gold" candidate abstracts may not offer an accurate estimate of the accuracy these systems would achieve when deployed in a real-world setting, which could require systems to verify claims over hundreds of thousands of documents.

C.4 Cross-dataset generalization

In §5, we discussed how the available scientific fact-checking datasets differ in a number of important respects. Here, we explore whether models trained on one system are able to generalize to another despite these differences. We train MultiVerS on each of our three datasets and then evaluate its performance on the other two. We also train a version of MultiVerS on all three datasets together, and evaluate on each one. Since COVIDFact has no NEI instances, during evaluation we remove all NEI instances from the other two datasets, and evaluate in the abstract-provided setting.

The results are shown in Table 12. The sentence-level evaluation results (Table 12b) indicate that none of the datasets generalize well to each other in their ability to identify rationales. The situation is better for abstract labeling (Table 12a). SciFact and HealthVer each generalize reasonably well to

Abstract

Deep Learning (DL) techniques have been increasingly adopted for Automatic Text Scoring in education. However, these techniques often suffer from their inabilities to explain and justify how a prediction is made, which, unavoidably, decreases their trustworthiness and hinders educators from embracing them in practice. This study aimed to investigate whether (and to what extent) DL-based graders align with human graders regarding the important words they identify when marking short answer questions. To this end, we first conducted a user study to ask human graders to manually annotate important words in assessing answer quality and then measured the overlap between these human-annotated words and those identified by DL-based graders (i.e., those receiving large attention weights). Furthermore, we ran a randomized controlled experiment to explore the impact of highlighting important words detected by DL-based graders on human grading. The results showed that: (i) DL-based graders, to a certain degree, displayed alignment with human graders no matter whether DL-based graders and human graders agreed on the quality of an answer; and (ii) it is possible to facilitate human grading by highlighting those DL-detected important words, though further investigations are necessary to understand how human graders exploit such highlighted words.

1 Introduction

Automatic Text Scoring refers to the task of applying computational techniques to score written text based on certain grading criteria (Alikaniotis et al., 2016). Since its inception (Page, 1966), Automatic Text Scoring has been actively investigated and applied to assist educators in scoring student-written text, e.g., short answer questions and essays, which are often referred to as Automated Short Answer Scoring (ASAS) (Brew and Leacock, 2013) and Essay Scoring (Rodriguez et al., 2019). Driven by the great success of Deep Learning (DL) techniques in various NLP tasks, researchers have endeavored to apply them to construct ASAS systems in recent years (Xia et al., 2020; Sung et al., 2019b,a), some of which displayed performance comparable to human graders. For instance, (Xia et al., 2020) showed that the average performance of an attention-based bidirectional LSTM model could be up to 0.71 (measured by the metric Quadratic Weighted Kappa) in the ASAS competition organized by the Hewlett Foundation, which can be deemed as achieving a substantial agreement with human graders.

Though being effective, DL-based ASAS systems have been widely plagued by the inability to explain how the quality of an answer is graded. The lack of understanding the underlying working mechanism of these systems, beyond question, may stop educators from adopting them in teaching practice as there remain concerns that the use of such ASAS systems might unintentionally encourage students to produce formulaic writings, i.e., writing that is often lengthy and involve complex words, but not much quality content (Wilson et al., 2021; Chen and Cheng, 2008; Wang et al., 2013). Inspired by the research efforts in the broader NLP communities, i.e., those focusing on dissecting complex deep neural net architectures and explaining how they work (Serrano and Smith, 2019; Wiegreffe and Pinter, 2019; Jain and Wallace, 2019; Xie et al., 2020; Sun et al., 2021), in the study presented in this paper we aimed to gain a better understanding of how DL-based ASAS systems work. Specifically, we investigated (i) the alignment between DL-based graders and human graders in terms of the words they think are important in the task of Short Answer Scoring and (ii) whether the important words identified by DL-based graders can be of use to human graders in the marking process. Formally, this study was guided by the following two **R**esearch **Q**uestions:

RQ1 To what extent do DL-based graders align with human graders regarding the words that are important in assessing answer quality?

RQ2 Can the important words identified by DL-based graders be used to facilitate human graders to perform marking?

We conducted two user studies to answer RQ1 and RQ2. For RQ1, with the dataset provided by the Hewlett Foundation, we constructed relatively simple but effective BERT-based graders (i.e., coupling BERT with a single classification layer for prediction), whose performances were comparable to those reported in recent studies (Xia et al., 2020; Surya et al., 2019). To locate words that were essential in determining answer quality, we extracted weights allocated to different input words in the self-attention layers of BERT. Then, we ran a user study to ask human graders to not only score an answer but also annotate the words they believed were important in contributing to or hurting the answer quality. We measured the alignment between BERT-based graders and human graders with the aid of the Jaccard coefficient. Building upon the results of RQ1, we further implemented a randomized controlled trial to investigate whether displaying the important words identified by BERT-based graders can help human graders improve marking accuracy and efficiency to answer RQ2.

In summary, our work contributes to the research on Automated Text Scoring with the following main findings: (i) text spans contained in an answer that increase the answer quality, compared to those decreasing answer quality, are more likely to be identified by human graders; (ii) there exists a certain level of alignment between DL-based graders and human graders regarding the words they think are important in assessing answer quality no matter whether they agree on the quality score of an answer; and (iii) the important words detected by DL-based graders can be potentially used to facilitate human grading, though more research efforts are required to understand how these words are to be utilized by human graders.

2 Related Work

2.1 Automated Short Answer Scoring

As a sub-branch of Automatic Text Scoring, ASAS aims to leverage statistical and machine learning techniques to assess the quality of short answers authored by students in education (Burrows et al., 2015; Xia et al., 2020). Given its important role played in supporting educators to scale up their teaching practices (e.g., to meet the need of marking up to tens of thousands of answers submitted by students and provide informative feedback in a Massive Open Online Course (Pappano, 2012) in a relatively short amount of time), ASAS has been drawing attention from researchers since its inception (Page, 1966). Typically, ASAS can be tackled as either a classification problem (Xia et al., 2020) or a regression problem (Sahu and Bhowmick, 2020). As surveyed in (Bonthu et al., 2021), the approaches used to tackle ASAS often fall into two categories. One is based on traditional machine learning techniques such as SVM (Gleize and Grau, 2013; Mohler et al., 2011; Higgins et al., 2014), K-means (Sorour et al., 2015), Linear Regression (Nau et al., 2017; Heilman and Madnani, 2015; Higgins et al., 2014), and Random Forests (Higgins et al., 2014; Ramachandran et al., 2015; Ishioka and Kameda, 2017), all of which heavily rely on the input of manually-crafted features. For example, Sultan et al. (2016) devised a set of features which were based on a lexical similarity (i.e., similarities between words identified by a paraphrase database (Ganitkevitch et al., 2013)) and monolingual alignment (Sultan et al., 2014), and input the designed features to a ridge regression model to obtain the score of an answer. The other category is based on DL techniques, such as Bi-LSTM (Xia et al., 2020; Kim et al., 2018) and BERT (Sung et al., 2019b), which, in contrast to traditional machine learning approaches, often demonstrate superior performance without the need to engineer human-crafted features. For instance, Sung et al. (2019b) proposed a fine-tuned BERT model for short answer scoring, which outperformed human experts in classifying short answers collected in the subject of psychology.

It has been documented that the use of certain Automated Text Scoring systems in education tends to promote formulaic writing among students, i.e., producing lengthy and complex but not quality content (Wilson et al., 2021; Chen and Cheng, 2008; Wang et al., 2013). As a result, there remain concerns about the ability of these ASAS systems in supporting teachers and instructors (Wilson et al., 2021). To alleviate this issue, some studies were proposed to investigate how ASAS systems work to reach a decision (Higgins et al., 2014), which mainly focused on the ASAS systems powered by traditional machine learning approaches. As an example, Higgins et al. (2014) demonstrated that including syntactically-informed features could boost the predictive performance of an ASAS model, enhancing the model's ability to identify high-quality responses written by students. To our knowledge, it remains largely unexplored the interpretation ability and reliability of ASAS systems powered by up-to-date DL techniques. An exception is presented by (Manabe and Hagiwara, 2021), in which a toolkit named EXPATS is introduced to enable people to visualize not only models based on traditional machine learning techniques but also those based on DL techniques as well as the predictions produced by these models. Our work distinguished itself from previous studies by collecting human-annotated data to inspect how an answer was evaluated by an ASAS system, i.e., comparing the overlap between the important answer words identified by DL-based graders and human graders, to shed light on the extent to which DL-based graders acted like human graders in the marking process.

2.2 Interpretability of Deep Learning Models in NLP

The interpretability and explainability of a predictive model have been widely acknowledged as an essential factor in helping human users understand the validity of a prediction and decide whether to adopt the model for practical use (Jacovi and Goldberg, 2020; Belinkov et al., 2020). In this strand of research, one common method is called *test-based* (Li et al., 2015; Jain and Wallace, 2019; Sun et al., 2020; Lei et al., 2016), which interprets a prediction by identifying relevant parts of input data that drive the prediction, e.g., words contained in a long sentence that play major roles in determining the overall sentimental polarity of the sentence. When it comes to the application of DL-models equipped with attention mechanism (Bahdanau et al., 2014) for NLP tasks, researchers often regard the weights assigned by the attention layer to different parts of input text as indicators of their importance to the model prediction (Mohankumar et al., 2020; Yang et al., 2016; Wang et al., 2016). However, it remains disputable to use attention weights to measure the importance of input text (Wiegreffe and Pinter, 2019; Serrano and Smith, 2019; Jain and Wallace, 2019). For instance, by manipulating attention weights in well-trained models to analyze their influences upon predictions in text classification, Serrano and Smith (2019) concluded that attention weights can only noisily predict the overall importance of different input text to a model prediction and thus should not be regarded as an optional measure for strict importance ranking. On the contrary, Wiegreffe and Pinter (2019) claimed that the feasibility of attention-as-explanation depends on the concrete definition of explanation. In line with this claim, when inspecting a Transformer-based model for non-factoid question answering, Bolotova et al. (2020) extracted the self-attention weights assigned to words in an answer to measure their importance. Similarly, Zou and Ding (2021) analyzed the self-attention weights in three Transformer-based models to investigate whether these models displayed human-like attention in the task of goal-directed reading comprehension. Similar to these studies, we treated the self-attention weights in a BERT-based model as proxies to reveal the importance of different input text, but in the task of ASAS.

2.3 Human Grading

It has been documented that human grading can be affected by various factors, e.g., students' ethnicity (Hinnerich et al., 2011; Van Ewijk, 2011) and gender (Protivínský and Münich, 2018), and the order of answers to be graded Yen et al. (2020). For instance, Protivínský and Münich (2018) showed that teachers' grading was biased towards female students in subjects of mathematics and the native language (Czech), and the observed grading difference was likely due to the different levels of non-cognitive skills (e.g., engagement in the classroom) displayed by female and male students. In a different vein, Yen et al. (2020) demonstrated that human graders spent much less time if they were presented with answers sorted according to their similarities with the marking rubric. Previous research on text reading showed that highlighting can facilitate people to remember and comprehend reading materials (Fowler and Barker, 1974; Lorch, 1989; Lorch et al., 1995; Dodson et al., 2017; Silvers and Kreiner, 1997). Inspired by this, we were interested in investigating whether it can facilitate human graders to score answer quality by highlighting words that DL-based graders identified as important in ASAS.

3 Methods

This study was approved by the Human Research Ethics Committee at Monash University (Project ID 30074). In the following, we first describe the task and dataset based on which we examined the alignment between DL-based graders and human graders, followed by the construction of the DL-based graders. Then, we detailed the setup of the two user studies we implemented to answer RQ1 and RQ2.

3.1 Task, Dataset, and DL-based Graders

This study focused on the ASAS challenge organized by the Hewlett Foundation in Kaggle[1], whose dataset contains over $17,000$ answers written by students of Grade 10 in the US to 10 different question prompts. The subjects of these question prompts include such subjects as science, biology, and English. Notice that each of the question prompts and the corresponding collected answers have their own unique characteristics, e.g., different marking rubrics, scoring scale (some are on $[0, 2]$ and the others are on $[0, 3]$), whether relevant source material was provided, and the average length of answers (ranging from 40 to 60 words). It is worth noting that each of the answers contained in the original dataset was double-scored, i.e., being rated by two independent human graders, and we denoted these scores as *Ground-truth Score1* and *Ground-truth Score2*, respectively, in this study. As specified in the challenge, Ground-truth Score1 is the final score an answer received and also the score that a model should aim to predict. As for Ground-truth Score2, it can be used as a measure of reliability. For instance, researchers can measure the agreements (i) between a model and Ground-truth Score1 and (ii) between Ground-truth Score1 and Ground-truth Score2, and then calculate the difference between the two agreements to gain a rough understanding of the gap between the constructed model and human graders.

In line with previous studies (Xia et al., 2020; Surya et al., 2019; Sung et al., 2019b), we tackled ASAS as a classification problem, i.e., classifying answers to different quality groups. Inspired by the great success of BERT (Devlin et al., 2018) in various NLP tasks, we also used it to construct DL-based graders to score an answer automatically. The model structure is relatively simple, i.e., we only coupled BERT with a single classification layer for prediction and then adapted the model to capture the unique characteristics of this task by fine-tuning on the graded answers. Given the unique characteristics of the different question prompts contained in the dataset, we decided to build a BERT-based grader for each of the question prompts. For each question prompt, we randomly split the answers in the ratio of 8:1:1 as training, validation, and testing sets. The details of the construction process are provided in Appendix A. As suggested by the challenge requirement, we used the metric Quadratic Weighted Kappa (QWK) to measure the performance of DL-based graders, which ranged from 0.660 to 0.891 for the 10 question prompts. As our goal was to investigate that, when a DL-based model was able to achieve a substantial level of performance in assessing answer quality, whether and to what extent it aligned with human graders in the marking process. Thus, we chose only the three question prompts (i.e., Prompt 1, 5, and 6, which were all graded on a scale of $[0, 3]$) in which DL-based graders achieved the best prediction performance (i.e., with QWK 0.831, 0.860, and 0.891, respectively) for the two user studies, as described below.

3.2 Study One

For RQ1, we designed a study to collect answer annotations from human graders, i.e., important words or text spans that human graders believe to increase or decrease the quality of an answer.

Participants. For Study 1, we recruited a total of 20 participants (7 females, 13 males), all of whom had received at least a master's degree, were proficient in English, and were employed by Monash University. In particular, all the participants had certain years of prior teaching experience, i.e., 13 participants less than 3 years, four had 3∼5 years, and three more than 5 years of experience. All participants were informed of the purpose of this study (and also Study 2) and signed consent forms before participating in the studies.

Study Setup. For each question prompt, we randomly selected five answers from each quality level (i.e., scores in the scale of $[0, 3]$) from the testing data set, which resulted in a total of 60 answers. In particular, we developed a grading system to allow participants to not only score an answer but also annotate the words or text spans that they thought important in determining the quality levels. When an-

---

[1] https://www.kaggle.com/c/asap-sas

notating an answer, the participants were required to annotate not only the text spans that *increasing* answer quality but also those *decreasing* answer quality, which were correspondingly denoted as *Positive* and *Negative* text spans in later analysis. We provided the screenshots of the grading system in Appendix C. Each of the 20 participants was required to attend a 90-minute session to grade 30 answers so that we collected a total of 600 assessment scores and annotations from our participants. Every answer was graded by 10 participants. In particular, we assigned the selected answers to the participants in a way that each participant was required to score answers of every quality level. After completion, we compensated each participant with a gift card worth $75 AUD for their time (i.e., $50 AUD per hour, which is comparable to the hourly rate for people with a master's degree in Australia).

Procedure. To ensure the quality of the collected data, we expected the participants to undertake adequate training to understand how they should mark before moving to the actual answer scoring and annotation. Therefore, the grading system we developed provided two modes for participants, i.e., *Practice* for pre-task training and *Actual Task* for actual data collection. Only after finishing the activities scheduled in *Practice*, the participants were allowed to start the *Actual Task*. Both *Practice* and *Actual Task* required a participant to evaluate an answer by following the steps described below. The main difference lied in the sources from which the presented answers were selected, i.e., validation set for *Practice* and testing set for *Actual Task*.

(1) Material Reading. A participant was asked to read a prompt, an article relevant to the prompt (if available in the original dataset), marking rubric, and exemplar answers with scores assigned by human graders (i.e., Ground-truth Score1).

(2) Pre-task questionnaire. The participant was asked to indicate their familiarity, interestingness, and perceived difficulty of the question prompt by answering three questions on a rating scale of $[1, 5]$, which were provided in the Appendix B.

(3) Answer assessment. An answer was presented for the participant to rate its quality. Note that the marking rubric was displayed along with the to-be-graded answer to facilitate the participant to mark.

(4) Answer annotation. The participant was instructed to highlight words and text spans that they identified as important in determining answer quality.

Grading Alignment Measurement. Here, we introduce how we detected the words that DL-based graders paid attention to in the marking process and further measured the overlap between these words and those annotated by the human participants in Study 1. Similar to the work by Bolotova et al. (2020), we extracted the words by calculating weights assigned to each token in the self-attention layers of the adopted BERT model. Specifically, for a token t contained in an answer Ans, its attention weight is calculated as follows:

$$Atn\_Score(t) = \frac{\sum_{i \in Ans} w_{i \to t}}{|Ans|} \quad (1)$$

Here, $|Ans|$ denotes the length of Ans, and $w_{i \to t}$ denotes the attention weight assigned by token i to token t, which can be retrieved and calculated in the attention layers of BERT. In more detail, there were 12 attention heads in the adopted BERT model; we first averaged the weights contained in these attention heads and then retrieved $w_{i \to t}$ in the averaged attention head. In brief, for a token in an answer, we summed up the attention weights from each token contained in the answer to the target token and then normalized the sum by the answer length to obtain the importance of the target token. Then, we could select the top K words with the largest attention weights as the set of important words identified by BERT-based graders. As suggested by Bolotova et al. (2020), we determined the value of K with the aid of a linear regression model, which took the length of an answer as the only input to predict the number of important words it should output. The regression model was trained based on the human-annotated data we collected in Study 1. Then, we followed the approach adopted by Bolotova et al. (2020) and measured their grading alignment by calculating the Jaccard coefficient between the two sets of important words identified by a human grader and a BERT-based grader. We also followed Qu et al. (2019) to exclude stop words from the set of important words before calculating the Jaccard coefficient. The stop words were detected with the aid of NLTK toolkit[2]. We first calculate the Jaccard coefficients over all

---

[2] https://www.nltk.org/

$<$ answer, human grader $>$ data pairs collected in this study and then averaged them as the final measure of the alignment between BERT-based graders and the human graders.

3.3 Study Two

For RQ2, we conducted a randomized controlled experiment to investigate whether human grading could be facilitated by observing highlighted important words detected by DL-based graders.

Participants. We randomly invited 10 out of the 20 participants who had taken part in Study 1 for Study 2. As for the prior teaching experience, seven out of the 10 participants were with less than 3 years, two were between 3 to 5 years, and one with more than 5 years of experience.

Study Setup. The 10 participants were randomly assigned to two groups, i.e., 5 in the control group and 5 in the experimental group. Only the participants in the experimental group were displayed with the highlighted words detected by BERT-based graders. We randomly selected 36 answers from the testing data for participants to mark. It is worth noting that these answers were unseen to the participants in Study 1, and these answers covered all quality levels in all question prompts. Each participant was required to attend a 45-minute session to assess a total of 24 answers. Each answer was assessed by the same number of participants from the control group and the experimental group. Similar to Study 1, every participant was required to score answers of all quality levels. After completion, each participant received a gift card worth $40 AUD to compensate for their time.

Procedure. The procedure of Study 2 only consisted of two main steps from the procedure of Study 1 and the participants did not need to receive pre-task training again, as described below.

(1) Material Reading. Similar to Study 1, we presented participants with all relevant materials to help them get familiar with the task requirement.

(2) Answer Assessment. In this step, the participants in the control group were displayed with answers without any highlighted words. As for the answers presented to participants in the experimental group, the important words contained in these answers, i.e., those detected by applying DL-based graders as described in Section 3.2, were highlighted. It is noteworthy that the participants were informed about (i) the nature of these highlighted words (i.e., important words detected by DL-based graders) and (ii) the reliability of these highlighted words (i.e., some might be helpful for assessing answer quality while the others are not). We used the linear regression constructed in Section 3.2 to determine the number of words that should be highlighted to a participant.

(3) Post-task questionnaire. This step was only for the participants in the experimental group after completing the whole study. The participants were asked to answer two questions on a rating scale of $[1, 5]$ with regard to the usefulness of the highlighted words for marking.

With the completion of the study, we compared the grading performance of the participants in the two groups from two perspectives. One is *accuracy*, which was calculated as the QWK between the participant-provided scores and the ground-truth scores. Here, we regarded that a participant-provided score matched the ground-truth data if it matched either Ground-truth Score1 or Ground-truth Score2 in the original dataset; otherwise, we simply regarded Ground-truth Score1 as the ground-truth. The other is efficiency, which was calculated as the average amount of time that participants spent in scoring answers. The amount of time that a participant used in assessing an answer was computed as the time difference between the moment when the participant entered the screen of the grading system to assess the answer and the moment when the participant clicked to move to grade the next answer.

4 Results

Recall that all answers used in this study were assessed on a grading scale of $[0, 3]$. For the following analysis, we aggregated and denoted the answers whose Ground-truth Score1 is 0 or 1 in the original dataset as *Low quality*, and those of score 2 or 3 as *High quality*.

4.1 Results on RQ1

Table 1 details the fractions of answers with different types of annotations, i.e., positive/negative text spans that increased/decreased answer quality. We observed that 89.3% answers were annotated by our

Table 1: The fraction of answers received different types annotations from the participants in Study 1.

Qulity Level	Low	High	ALL
% Answers with *positive* annotations	53.7	95.3	74.5
% Answers with *negative* annotations	52.3	32.7	42.5
% Answers with annotations	81.3	97.3	89.3

participants, among which 74.5% received positive annotations while only 42.5% received negative annotations. This indicates that text spans contributing to answer quality were more likely to be determined and identified by human graders than those lowering answer quality. This is corroborated by the results in both high-quality and low-quality answer categories. For instance, the fraction of answers with positive and negative annotations were 95.3% and 32.7%, respectively. We can make similar observations in low-quality answers, but the difference was only 1.4%.

Table 2 describes the alignment between BERT-based graders and human graders involved in Study 1, i.e., the Jaccard coefficients between the two sets of the important words identified by them when performing marking. As a baseline for comparison, we selected important words based on randomly-assigned weights and measured their overlap with the important words annotated by human graders (as detailed in the column `RANDOM`). By comparing the results of `RANDOM` and `ALL`, we can conclude that there existed some agreement between BERT-based graders and human graders. When considering both positive and negative annotations, the alignment reached the value of 0.252 (about 69% more than that of randomly-annotated important words, i.e., 0.149). Also, we noticed that the alignment in high-quality answers was more than that in lower-quality answers (0.275 vs. 0.224). When considering only positive/negative annotations for measurement, there was a higher level of alignment in positive annotations than negative annotations (0.251 vs. 0.174). This suggests that DL-based graders and human graders were more likely to agree with each other regarding what makes a good answer than what makes a bad answer. This finding is related to what we observed in Table 1, i.e., human graders made more positive annotations than negative annotations in Study 1. These findings together imply that, to a certain degree, there do exist similarities between the BERT-based graders and human graders in the grading process.

It should be noted that (i) only 40 out of the 60 answers used in Study 1 were correctly assessed by BERT-based graders and (ii) only 342 out of the 600 (about 57%) collected assessment scores provided by our participants were in agreement with the ground-truth (i.e., matching to either Ground-truth Score1 or Ground-truth Score2 in the original dataset). To further investigate grading alignment in different conditions (e.g., BERT-based graders and human graders simultaneously failed to assess the quality of an answer), we further divided the collected data into two groups for analysis, i.e., `G1` consisting of answers for which human graders and BERT-based graders simultaneously delivered correct/incorrect answer scores and `G2` consisting of the other data for which either human graders or BERT-based graders failed to produce correct assessments, as detailed in Table 2. The `G1` alignment was similar to those calculated by taking all answers into account (i.e., the `ALL` column). To our surprise, there also exists an overall alignment of 0.248 between BERT-based graders and human graders in G2. This means, even in the situations where human graders were able to correctly assess the quality of an answer but BERT-based graders failed to do so (or the opposite), there is some overlap between the human-annotated and DL-detected important words. This implies that, in certain cases, even human graders and DL-based graders disagreed on the score value of an answer, they did reach a partial agreement on the words that were important for assessing the answer's quality.

4.2 Results on RQ2

It should be pointed out that 25 out of the 36 selected answers for our participants to grade in Study 2 were accurately scored by BERT-based graders. The reasons we also included the inaccurately-scored answers are two-fold. Firstly, our ultimate goal is to use important words located by BERT-based graders to facilitate human grading in practice. As a DL-based grader is unlikely to derive correct predictions all the time in real-world scenarios, it is very likely that some of the DL-identified plausibly-important words will be presented to human graders in certain cases. Secondly, as demonstrated in Study 1, when BERT-based graders disagreed with human graders regarding an answer's quality, they still had moderate overlap between the important words they identified. Thus, we were interested in investigating whether human graders

Table 2: The overlap between human graders' different types of annotations (i.e., **Pos**itive or **Neg**ative) with the important words detected by BERT-based graders. The column `ALL` includes all collected data for analysis; `G1` includes only the answers that were simultaneously correctly/incorrectly assessed by the two types of graders, and `G2` includes the other data in which either BERT-based graders or human graders did not match to the ground-truth scores. Paired t-tests were applied to examine the difference between `Random` and `ALL` regarding the same type of annotation while unpaired t-tests were adopted to examine the difference between `Random` and (`G1`, `G2`) regarding the same type of annotation. Significant results were marked with either $**$ (if $p < 0.001$) or $*$ (if $p < 0.01$).

	RANDOM			**ALL**			**G1**			**G2**		
Annotation type	Pos	Neg	Pos & Neg	Pos	Neg	Pos & Neg	Pos	Neg	Pos & Neg	Pos	Neg	Pos & Neg
Low quality	0.128	0.123	0.136	** 0.235	** 0.176	** 0.224	** 0.268	* 0.176	** 0.233	** 0.205	0.178	** 0.210
High quality	0.155	0.116	0.160	** 0.261	** 0.170	** 0.275	** 0.256	* 0.173	** 0.273	** 0.267	0.165	** 0.278
Average	0.146	0.120	0.149	** 0.251	** 0.174	** 0.252	** 0.260	** 0.174	** 0.254	** 0.241	* 0.172	** 0.248

Table 3: The participants' grading performance in Study 2. The difference between the two groups regarding their average time spent grading one answer (measured in seconds) was tested to be significant with paired t-test ($p < 0.01$).

Metrics	**Control**	**Experimental**
QWK	0.71	0.74
Avg. time per answer	42.17	54.83

could be facilitated by observing (not necessarily correct) important words identified by BERT-based graders. The grading performances of the participants are given in Table 3, i.e., QWK for accuracy and the average amount of time spent in scoring an answer for efficiency. The results showed that, by highlighting important words detected by BERT-based graders, we could facilitate human grading in terms of grading accuracy. However, contrary to our expectation, the Experimental participants spent roughly 12 more seconds in scoring an answer than the Control participants. This is probably because, as being informed that the highlighted words were identified by a DL-based model and not necessarily useful in discerning answer quality, the participants allocated more time in scrutinizing the answer text to judge its quality. This was partially supported by their responses to questions in the post-task questionnaire, i.e., an average rating of only 3.0 (out of 5.0) was reported regarding whether the participants considered the highlighted words as actually important, but an average rating of 3.8 (out of 5.0) was reported regarding the usefulness of the highlighted words for marking.

5 Discussions and Conclusion

Given the increasing popularity of DL-based Automatic Text Scoring systems in education, this work investigated the interpretability of these systems regarding their alignment with human graders in the task of ASAS. Through two well-designed user studies, we demonstrated that (i) there exists certain alignment between DL-based graders and human graders in terms of the important words they identified for assessing answer quality; and (ii) it is possible to utilize the important words detected by DL-based graders to facilitate human grading.

Though several interesting findings have been enabled, it is not the time yet to advocate that we should incorporate such DL-identified important words into ASAS systems to facilitate human grading due to the following limitations in our study. Firstly, as observed in Study 1, DL-based graders displayed certain agreement with human graders, even in the circumstances of being unable to correctly assess the quality of an answer. It remains unknown what types of words (or concepts) DL-based graders agree/disagree on with human graders. For example, would it be possible that both types of graders tend to hold similar misconceptions (e.g., identifying the same type of plausibly-correct words)? This calls for future research to characterize and analyze the different types of important answer spans identified by DL-based graders and human graders under different circumstances. By doing this, we can potentially derive more insights on how to further improve the prediction performance of DL-based graders. Secondly, and more importantly, it remains unknown the sense-making process the human graders follow to make use of the DL-detected important words. As showed in Study 2, the human graders in the Experimental group neither agreed nor disagreed that the DL-highlighted words were important, but they considered the DL-highlighted words were of value and delivered better grading accuracy (at the cost of a lower grading efficiency). Would it be the case that the highlighted words provoke more in-depth thinking and understanding of an answer among human graders and thus enabling them to better assess the answer quality? This motivates us to conduct further studies to investigate human graders' marking process in using DL-highlighted words in the future.

A BERT-based Grader Construction

We constructed our DL-based graders based on the well-known pre-trained language model BERT (Devlin et al., 2018). Similar to (Sung et al., 2019b), we implemented the BERT-based graders by adopting the pre-trained *bert-base-cased* model (12 layers, 768 neurons in each hidden layer, 12 attention heads, and a total of 110M parameters) with a sequence classification layer on top provided by the Python package Transformers[3]. Then, we fine-tuned the whole model on the training set of each question prompt. It should be noted that only the student-authored answers were used as input to train the model. During model training, the batch size was set to 16, and we selected the number of epoch from $\{1, 2, 3, 4, 5\}$ and the learning rate from $\{1e-5, 5e-5, 1e-4\}$. For the optimizer, we used Adam with decoupled weight decay (i.e., AdamW). To determine the best values for the hyperparameters mentioned above, we trained the models with different combinations of parameter values and selected the best model based on its performance on the validation set for each question prompt. The run time for fine-tuning each BERT-based grader is roughly 1.5 hours (5 epochs, with NVIDIA Tesla P4 GPU). Table 4 details the parameter choices for each constructed model and their corresponding performance (measured by QWK). By comparing QWK1 and QWK2 reported in Table 4, the difference between which can be regarded as the gap between human graders and the constructed BERT-based graders, we can conclude that the BERT-based graders achieved a substantial level of predictive performance in most of the question prompts. Note that the codes for constructing the models can be accessed via `https://github.com/douglashiwo/AttentionAlignmentASAS`.

B Pre-/Post-task Questionnaires

In Study 1, before scoring answers to a question prompt, the participants were required to answer the following three questions to indicate their interest, familiarity, and perceived difficulty of the question prompt on a rating scale of $[1, 5]$:

- To what extent are you interested in the prompt topic? (with 1 being not interested at all and 5 being very interested)

---

[3] https://github.com/huggingface/transformers

Table 4: Performances of the constructed BERT-based graders in different question prompts. QWK1 denotes the QWK between the Ground-truth Score1 and Ground-truth Score2 provided in the orignal dataset, while QWK2 denotes the QWK between the Ground-truth Score1 and the predictions generated by our BERT-based graders.

Prompt ID	**QWK1**	**QWK2**	**Learning rate**	**Epoch**
1	0.950	0.860	5e-5	4
2	0.900	0.716	1e-5	5
3	0.681	0.291	1e-5	5
4	0.683	0.729	5e-5	5
5	0.962	0.891	5e-5	5
6	0.952	0.831	5e-5	5
7	0.959	0.731	5e-5	3
8	0.866	0.660	5e-5	2
9	0.782	0.730	5e-5	3
10	0.887	0.719	1e-5	4

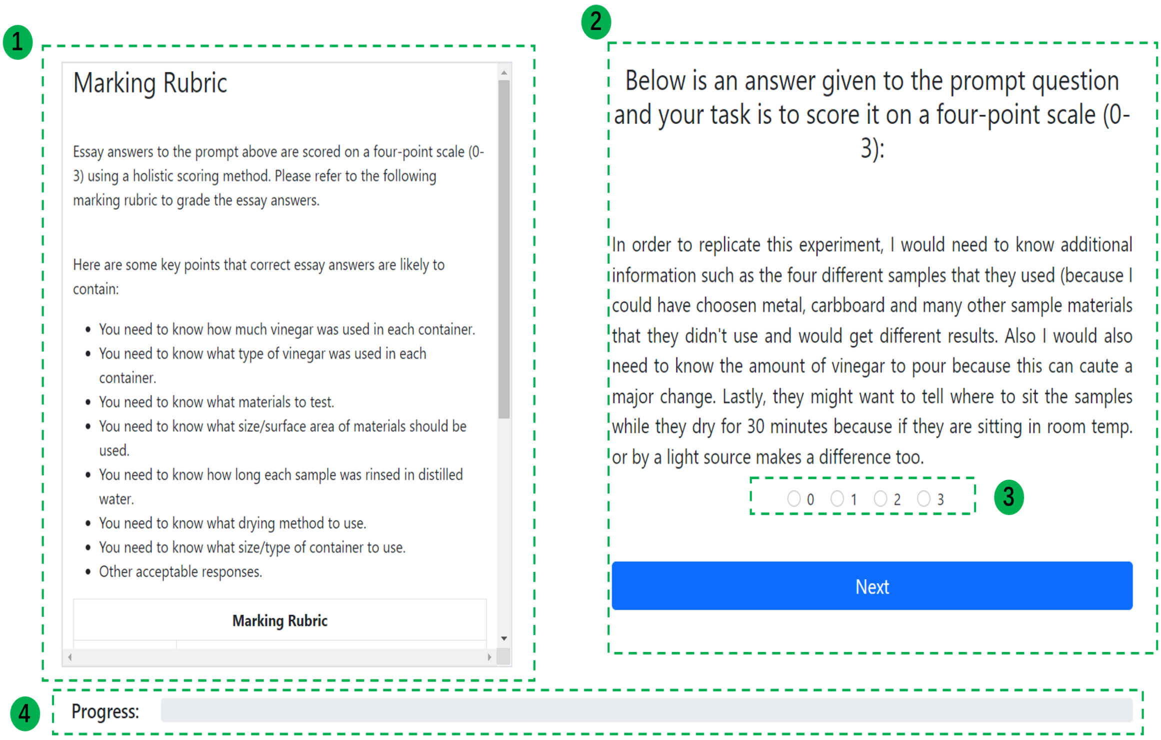
- To what extent are you familiar with the prompt topic? (with 1 being not familiar at all and 5 being very familiar)
- How would you describe the difficulty level of the prompt topic to students of Grade 10 in the US (i.e., the second year in high school)? (with 1 being very easy and 5 being very difficult)

In Study 2, the participants in the Experimental group were required to answer the following two questions to share their opinions regarding the highlighted important words detected by BERT-based graders on a rating scale of $[1, 5]$:

- To what extent do you think the text highlighted by our automatic model grader are actually “important” in determining the quality of an answer? (with 1 being not important at all and 5 being very important)
- To what extent do you think the text highlighted by our automatic model grader helps you grade answers? (with 1 being not helpful at all and 5 being very helpful)

C The Developed Grading System

Figure 1 shows the screen of the developed grading system in which participants scored an answer in Study 1. Figure 2 shows the screen of the developed grading system in which participants annotated an answer after assigning a score value to the answer in Study 1. Figure 3 shows the screen of the developed grading system in which participants in the Experimental group scored an answer in Study 2; the screen that participants in the Control group is similar to Figure 3 but without any answer words being highlighted.



Marking Rubric

Essay answers to the prompt above are scored on a four-point scale (0-3) using a holistic scoring method. Please refer to the following marking rubric to grade the essay answers.

Here are some key points that correct essay answers are likely to contain:

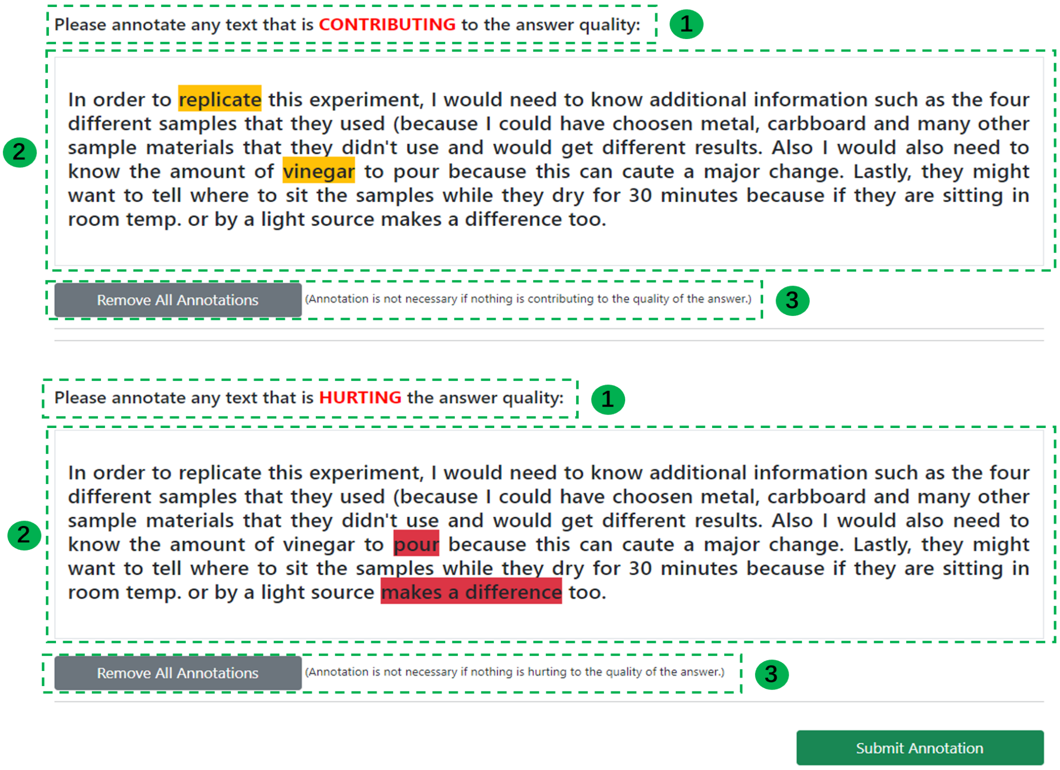
- You need to know how much vinegar was used in each container.
- You need to know what type of vinegar was used in each container.
- You need to know what materials to test.
- You need to know what size/surface area of materials should be used.
- You need to know how long each sample was rinsed in distilled water.
- You need to know what drying method to use.
- You need to know what size/type of container to use.
- Other acceptable responses.

Marking Rubric

Below is an answer given to the prompt question and your task is to score it on a four-point scale (0-3):

In order to replicate this experiment, I would need to know additional information such as the four different samples that they used (because I could have choosen metal, carbboard and many other sample materials that they didn't use and would get different results. Also I would also need to know the amount of vinegar to pour because this can caute a major change. Lastly, they might want to tell where to sit the samples while they dry for 30 minutes because if they are sitting in room temp. or by a light source makes a difference too.

Figure 1: The screen of the developed grading system for a participant to score an answer in Study 1: ① shows the marking rubric to participants; ② shows the instruction and an answer to be graded; ③ shows the score scale (i.e., $[1, 3]$); and ④ shows a participant's overall progress in the study (i.e., how many answers the participant has graded and how many more needs to be graded). After clicking the `Next` button, the participant will enter the next screen to annotate important words contained in the same answer.



Please annotate any text that is CONTRIBUTING to the answer quality:

In order to replicate this experiment, I would need to know additional information such as the four different samples that they used (because I could have choosen metal, carbboard and many other sample materials that they didn't use and would get different results. Also I would also need to know the amount of vinegar to pour because this can caute a major change. Lastly, they might want to tell where to sit the samples while they dry for 30 minutes because if they are sitting in room temp. or by a light source makes a difference too.

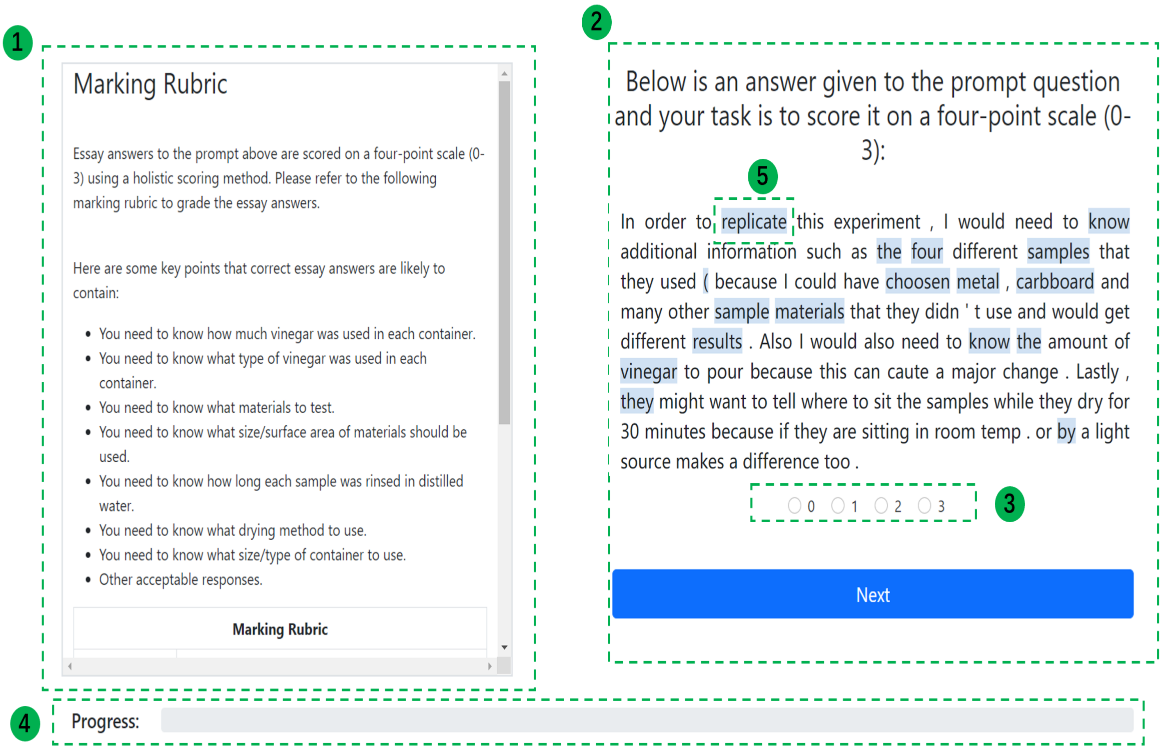
(Annotation is not necessary if nothing is contributing to the quality of the answer.)

Please annotate any text that is HURTING the answer quality:

In order to replicate this experiment, I would need to know additional information such as the four different samples that they used (because I could have choosen metal, carbboard and many other sample materials that they didn't use and would get different results. Also I would also need to know the amount of vinegar to pour because this can caute a major change. Lastly, they might want to tell where to sit the samples while they dry for 30 minutes because if they are sitting in room temp. or by a light source makes a difference too.

(Annotation is not necessary if nothing is hurting to the quality of the answer.)

Figure 2: The screen of the developed grading system for a participant to annotate an answer in Study 1: ① gives annotation instruction to a participant; ② displays the same answer that the participant scored in the previous screen; and ③ allows a participant to remove to all existing annotations and start the annotation from scratch again, and the participant is informed that annotation is not mandatory if she believes that there is nothing contributing/hurting the quality of the answer.



Marking Rubric

Essay answers to the prompt above are scored on a four-point scale (0-3) using a holistic scoring method. Please refer to the following marking rubric to grade the essay answers.

Here are some key points that correct essay answers are likely to contain:

Abstract

Knowledge-grounded dialogue systems are challenging to build due to the lack of training data and heterogeneous knowledge sources. Existing systems perform poorly on unseen topics due to limited topics covered in the training data. In addition, it is challenging to generalize to the domains that require different types of knowledge sources. To address the above challenges, we present PLUG[1], a language model that homogenizes different knowledge sources to a unified knowledge representation for knowledge-grounded dialogue generation tasks. We first retrieve relevant information from heterogeneous knowledge sources (e.g., wiki, dictionary, or knowledge graph); Then the retrieved knowledge is transformed into text and concatenated with dialogue history to feed into the language model for generating responses. PLUG is pre-trained on a large-scale knowledge-grounded dialogue corpus. The empirical evaluation on two benchmarks shows that PLUG generalizes well across different knowledge-grounded dialogue tasks. It achieves comparable performance with state-of-the-art methods in the fully-supervised setting and significantly outperforms other approaches in zero-shot and few-shot settings.

1 Introduction

Recent work has shown that conversational models can be trained in an end-to-end fashion (Gao et al., 2019; Roller et al., 2020; Zhang et al., 2019; Adiwardana et al., 2020). Though such models can generate coherent and natural responses consistent with conversation history, there is still a clear gap between conversational AI agents and humans. The primary reason is that existing dialogue systems lack knowledge of the subject and thus cannot deep dive into specific topics with humans. In order to better incorporate knowledge into dialogue, knowledge-grounded dialogue systems have become increasingly popular.

Dataset	**Knowledge**	**% Topics**
Open-domain		
Wizard of Wikipedia	articles	0.02%
CMU_DoG	articles	0.04%
Recommendation		
REDIAL	tables	15.0%
OPENDIALKG	graph	7.5%

Table 1: Knowledge representation and topic coverage statistics of existing knowledge-grounded dialogue datasets. **% Topics** means the portion of topics or facts in the knowledge database covered by the dataset.

Knowledge-grounded dialogue generation aims to generate informative and meaningful responses based on both conversation context and external knowledge sources. Thus far, researchers have collected knowledge-grounded dialogues for various tasks using crowdsourcing platforms, for instance, open-domain dialogues (Dinan et al., 2019; Zhou et al., 2018) and conversational recommendation dialogues (Li et al., 2018; Moon et al., 2019; Hayati et al., 2020). Workers are asked to base their replies on knowledge from structured knowledge bases (Moon et al., 2019; Tuan et al., 2019) or unstructured documents (Dinan et al., 2019; Zhou et al., 2018; Feng et al., 2020). Taking advantage of recent advances in large-scale language models (Raffel et al., 2019; Lewis et al., 2020a; Guu et al., 2020), researchers have also built knowledge-grounded dialogue systems by fine-tuning such language models in an end-to-end fashion (Shuster et al., 2021; Zhao et al., 2020b; Li et al., 2021).

However, there are two critical challenges in these existing methods. First, it is expensive and time-intensive to collect knowledge-grounded dialogues. As shown in Table 1, most of the datasets

---

[*] Work was done when Yu Li was interning at MSR

[1] **P**re-trained **L**anguage model with a **U**nified knowledge representation for knowledge-**G**rounded dialogues.

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 206 - 218
July 10-15, 2022

only cover a small portion of the knowledge base. Thus, systems which only fine-tune with small training sets generalize poorly on unseen topics in the same knowledge base. Additionally, the formats of knowledge sources vary in different tasks, making the approaches unable to transfer to other domains with different knowledge sources. For example, REDIAL (Li et al., 2018) adopts a movie database as the knowledge source to recommend movies. Techniques on this task exploit the graph structure. It is not easy to adapt such techniques to document-grounded conversation tasks like Wizard of Wikipedia (Dinan et al., 2019).

In this work, we present PLUG, a model that can unify different knowledge formats for knowledge-grounded dialogue generation. First, we convert different knowledge formats (e.g., knowledge graph, knowledge base, and passages) to unstructured text, each using a different retriever. Then we use a pre-trained language model to process them into a unified representation to incorporate the knowledge into dialogue generation. We pre-train PLUG on different knowledge-ground dialogue corpora, including a large-scale open-domain conversation dataset from Reddit. This allows PLUG to learn knowledge in various formats from different tasks, and thus transfer to any knowledge-grounded dialogue task with few-shot learning techniques.

We evaluate the effectiveness of PLUG by applying it to an open-domain knowledge-grounded dialogue benchmark, Wizard of Wikipedia (Dinan et al., 2019), and a knowledge-grounded conversational recommendation benchmark, REDIAL (Li et al., 2018). PLUG achieves results comparable to the state-of-the-art method under a fully-supervised setting. It outperforms other methods on both tasks under zero-shot and few-shot settings, demonstrating that PLUG can be grounded on world knowledge in different knowledge sources and generalize to different downstream tasks.

Our contributions are three-fold: (1) We propose a novel knowledge-based pre-trained language model, PLUG, that can be applied to any knowledge-grounded dialogue tasks; (2) Our model achieves slightly better results than state-of-the-art models in fully-supervised settings and shows promising improvements over the current state-of-the-art in zero-shot and few-shot settings; (3) We present extensive experiments to explore the bottlenecks of the task and the future direction of knowledge-grounded dialogues.

2 Approach

We describe our approach in this section. Figure 1 gives a diagram of our proposed method. We first introduce the background of knowledge-grounded dialogues and the backbone language model in Section 2.1. Then, we formalize the task and introduce the details of PLUG in Section 2.2. Finally, we explain the training process of our PLUG, which includes the pre-training dataset selection and the data pre-processing processes in Section 2.3.

2.1 Background: Knowledge-Grounded Pre-training

Traditional knowledge-grounded dialogue includes three steps: information extraction, knowledge prediction, and response generation. Previous work focuses on developing separate modules (Zhou et al., 2020b). Inspired by the recent success of applying a large-scale pre-trained language model on task-oriented dialogue systems (Peng et al., 2020; Hosseini-Asl et al., 2020), we explore the possibility of using a unified knowledge representation in a large-scale language model. In order to properly manage the task in a sequence-to-sequence setup, we choose T5 (Raffel et al., 2020) as our backbone.

T5 is a sequence-to-sequence pre-trained Transformer (Vaswani et al., 2017) model for transfer learning. It is trained by converting various language tasks into text-to-text tasks. After fine-tuning on a dialogue dataset, T5 can generate fluent and coherent responses. Nevertheless, responses are often too generic because they are not grounded on specific knowledge. PLUG is built on the T5 model but grounded on real-world knowledge during training, making it inherit T5's capability of producing good responses but include more knowledge.

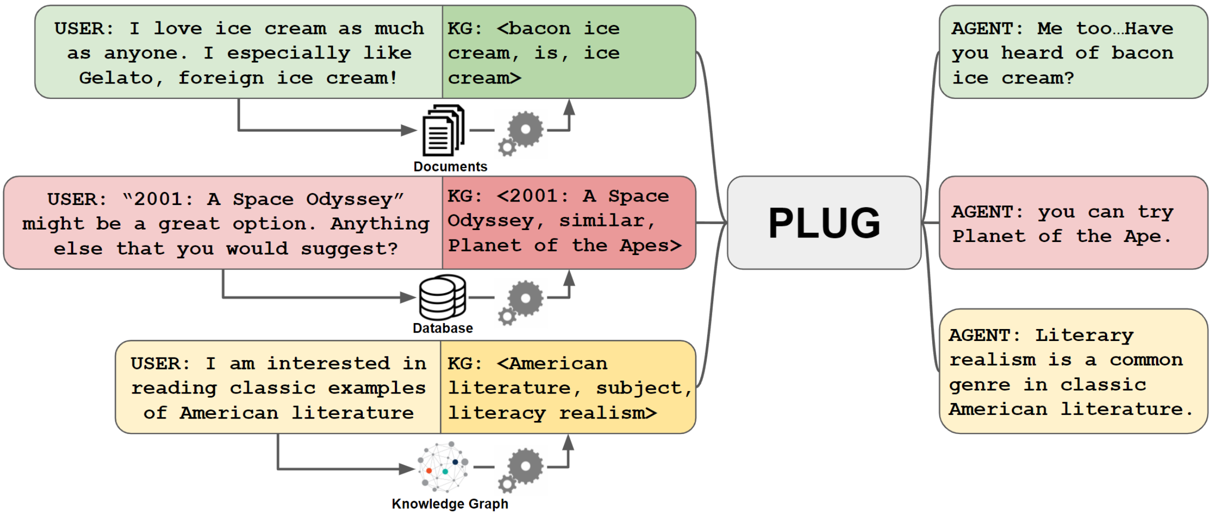
2.2 PLUG

We formulate a knowledge-grounded dialogue as:

$$\mathcal{D} = \{C, R, \mathcal{S}\} \tag{1}$$

where $C = \{C_i\}_{i=1}^{n}$ is a dialogue context, and $R = \{R_i\}_{i=1}^{n}$ is the response in a dialogue that has n turns. $\mathcal{S}$ is the external knowledge source for task t. For each dialogue turn, we can formulate a knowledge-grounded dialogue generation task on a single domain d as $p(R_i|C_i, \mathcal{S})$.

As shown in Figure 1, each task has its own knowledge source (e.g., documents, databases, and knowledge graphs). In order to make all knowledge-grounded dialogue generation tasks



USER: I love ice cream as much as anyone. I especially like Gelato, foreign ice cream!

KG: <bacon ice cream, is, ice cream>

USER: "2001: A Space Odyssey" might be a great option. Anything else that you would suggest?

KG: <2001: A Space Odyssey, similar, Planet of the Apes>

USER: I am interested in reading classic examples of American literature

KG: <American literature, subject, literacy realism>

AGENT: Me too…Have you heard of bacon ice cream?

AGENT: you can try Planet of the Ape.

AGENT: Literary realism is a common genre in classic American literature.

Figure 1: A diagram of PLUG. PLUG homogenizes different knowledge sources in different tasks to a unified knowledge representation. Then it learns to ground response generation on the unified knowledge representation.

able to fit in the text-to-text encoder-decoder framework, we follow T5 to feed each dialogue turn into the language model simply by concatenating the context $C_i = \{c_1, c_2, ..., c_m\}$, and essential knowledge triples $K_i = \{k_1, k_2, ..., k_n\}$ as a token sequence. The essential knowledge is extracted from the knowledge source S and represented as text of triples. We train the model to predict the responses token sequence $R = \{r_1, r_2, ..., r_k\}$. The probability of the responses is formulated as:

$$p(R_i|C_i) = \prod_{t=1}^{k} p(r_t|C_i, K_i, r_1, ..., r_{t-1}) \qquad (2)$$

We will explain how we select and process pretraining datasets in the following sections.

2.3 Model training process

We pre-trained the PLUG model using two datasets, Reddit Conversation (Galley et al., 2018) and OpenDialKG (Moon et al., 2019). We will first present the three-step data cleaning process of Reddit Conversation in Section 2.3.1, then we will introduce OpenDialKG in Section 2.3.2.

2.3.1 Reddit Conversation

Reddit Conversation Galley et al. (2018) is a large-scale open-domain conversation dataset. It extracts the conversation threads grounded on a document from the Reddit data.[2] We only keep the conversations grounded on Wikipedia passages for pretraining to recognize better the knowledge used in the dialogue. Since vanilla document-based dialogue in the dataset does not have a knowledge label for each dialogue turn, we apply a hierarchical information extraction method to obtain the essential knowledge in each turn. Our information extraction method includes three steps: knowledge retrieval, statistical ranking, and semantic ranking.

Knowledge Retriever. We use a knowledge retriever to retrieve all relevant knowledge in a single turn's response. We first extract the title of the grounding Wikipedia passage in the dialogue. Then, we retrieve knowledge triples from a large-scale knowledge graph, DBpedia (Lehmann et al., 2015). Specifically, we query the DBpedia via a public SPARQL endpoint[3] and then collect triples whose subject or object is in the Wikipedia passage in the dialogue. For example, we keep triples <*Barack Obama, alma mater, Columbia University*> and <*Michelle Obama, spouse, Barack Obama*> for the dialogue about Barack Obama. To carry sufficient knowledge to refine in the next step, we retrieve 500 triples for every passage.

Statistical Ranking. After retrieving adequate knowledge, we rank the corresponding triples to refine the knowledge. Specifically, we get the TF-IDF (term frequency-inverse document frequency) value for all the retrieved triples. To find the triples related to the context, we concatenate the dialogue history and the response as the query. Then we compute the cosine similarity between the query and every triple. Because every triple has the Wikipedia passage name as the subject or object, a higher cosine similarity score means the query has more similar text with the distinguished text in the triple.

---

[2] Reddit data dumps: https://files.pushshift.io/reddit/

[3] https://dbpedia.org/sparql

We rank the query-document similarity score and only keep the top-50 triples in this step.

Semantic Ranking. The TF-IDF-based cosine similarity score only counts words overlapping between triples and the query. It will introduce triples whose overlapping words are not meaningful in the context and response. Additionally, the Reddit Conversation dataset is obtained from Reddit conversation threads. It involves many responses that are not grounded on any knowledge. In order to find the triples that have the best semantic similarity with the response and filter out ungrounded responses, in this step, we estimate the semantic similarity score with Sentence-Bert (Reimers and Gurevych, 2019). We rerank the 50 triples from the second step based on the score. Additionally, we abandon the dialogue turns whose best semantic similarity is lower than a threshold because the response cannot find proper knowledge, while we want to pre-train the model with knowledge-grounded turns.

2.3.2 OpenDialKG

To generalize our model to various tasks, we also employ OpenDialKG to enrich our pre-training dataset. OpenDialKG consists of two types of tasks, recommendations and chit-chat, across four domains. Unlike the Reddit Conversation dataset, which needs to find the knowledge grounding in every turn, the original OpenDialKG has a Knowledge graph path label for each dialogue, and a triple label for each dialogue turn. The response is grounded on the labeled triple during data collection. Thus, we use the triple in the dataset as the essential knowledge in our pre-training examples.

3 Experiments

We demonstrate our approach on two different downstream tasks: open-domain knowledge-grounded dialogue and conversational recommendation. Besides the fully-supervised learning setting, we also explore the performance of our approach in few-shot and zero-shot settings. We describe our implementation details in Section A in Appendix.

3.1 Datasets and Knowledge Sources

We test our approach on Wizard of Wikipedia (WoW; (Dinan et al., 2019)) and REDIAL (Li et al., 2018). Basic dataset statistics are listed in Table 2.

Dataset	Train	Valid	Test
WoW	18,430	Seen - 981	965
		Unseen - 967	968
REDIAL	8,004	1,001	1,001

Table 2: Number of conversations in Wizard of Wikipedia (WoW) and REDIAL

Wizard of Wikipedia. This dataset (Dinan et al., 2019) is collected on Amazon Mechanical Turk. Each conversation happens between a “wizard” who has access to knowledge about a specific topic, and an “apprentice” who is interested in the topic. The wizard’s response is grounded on a Wikipedia article in each turn. The data is split as a training set, a validation set, and a test set. The test set has two subsets: Test Seen and Test Unseen. Test Seen contains conversations whose topics are seen in the training set, while topics in Test Unseen are not seen in the training or validation set. To extract the essential knowledge in each dialogue turn, we first keep the top five passages retrieved by the TF-IDF retriever in Shuster et al. (2021). Then we use an Open Information Extraction (OpenIE) annotator[4] to extract the top three triples from the passages as our essential knowledge. The pre-processing is conducted with the code published on ParlAI.[5]

REDIAL. REDIAL (Li et al., 2018) is also collected on Amazon Mechanical Turk. Two crowdworkers, a “movie seeker” and “movie recommender,” are randomly paired. The recommender has access to a movie database and can recommend movies based on movie information, such as actors and movie genres. There are 6,924 different movies mentioned in 51,699 movie slots in the dataset. We follow Li et al. (2018) to split the dataset into training, validation, and test sets. Since recommenders use movie-related knowledge when they recommend movies to seekers, we use it as the essential knowledge for a given turn in this dataset. We experiment with three knowledge sources: (1) We query the movie names mentioned in the dialogue context and retrieve similar movies from the knowledge graph **DBpedia**, mentioned in Section 2.3, and then input the similar movies in a triple format as the essential knowledge. (2) We query the movie names mentioned in the context and retrieve movie comments from **MovieLens**.[6], then use the keywords in the comments as the essential knowledge. (3) We use the output of the recommender

[6] https://grouplens.org/datasets/movielens/

module in **KGSF** (Zhou et al., 2020a), which is the state-of-the-art system on this dataset.

3.2 Baselines

We compare the known best models from different datasets in the following experiments. For the Wizard of Wikipedia dataset, we choose the retrieval-augmented generation (RAG) model from Shuster et al. (2021). It retrieves wiki documents and generates responses based on the documents. We compare PLUG with this document-based generation method to see the impact of our essential knowledge format. We choose the RAG model also using T5 as the baseline for a fair comparison.

For the REDIAL dataset, we choose the current state-of-the-art: KBRD (Chen et al., 2019) and KGSF (Zhou et al., 2020a) as our baselines. Both use a recommender module to predict the recommendation item in the next turn and a generation model to generate the response. All baseline results are from Zhou et al. (2021). To investigate the best performance of our approach, We also use the recommender from KGSF as a knowledge source in our system and compare it with other knowledge sources we mentioned in Section 3.1. As an ablation study, we also explore the performance of vanilla T5 on both tasks to see the performance gain brought by our pre-training process.

3.3 Metrics

For evaluation, we report the performance with standard automatic metrics: BLEU-4 (B4) (Papineni et al., 2002), ROUGE-L (RL) (Lin, 2004), and unigram overlap (F1) of the generated responses. Besides that, for the Wizard of Wikipedia dataset, we follow Shuster et al. (2021) to report the overlapping unigrams between the model's generation and the knowledge on which the human grounded during dataset collection (KF1), attempting to capture whether a model is speaking knowledgeably. On the other hand, for the REDIAL dataset, we follow previous work (Chen et al., 2019; Zhou et al., 2020a; Wang et al., 2021) to report distinct-n (Dist-n) at the sentence level to evaluate the diversity of the model's generation. We also evaluate whether the ground truth movie recommendation can be found in the generated response and report it as the recommendation item recall in responses (Rec).

3.4 Fully-Supervised Results

We first evaluate PLUG with all training examples in the training sets to compare its performance with other state-of-the-art systems. Additionally, we experiment with using golden knowledge in the input to explore the upper bound of our method.

Table 3 shows the Wizard of Wikipedia Test Seen and Test Unseen results. We can see that PLUG with retrieved knowledge achieves better BLEU-4, ROUGE-L, and F1 scores than the RAG method and the model without adding knowledge in the input, on both seen and unseen topics. It suggests that our essential knowledge format helps the model generate responses to ground knowledge better. We also observe that PLUG outperforms the model without pre-training on all metrics, which means our pre-training can boost this task.

We list REDIAL's results in Table 4. We compare our approach to the state-of-the-art systems and T5-Large models without pre-training. Additionally, we include a comparison to models with different knowledge sources as described in Section 3.1. It shows that our best model (PLUG+KGSF) achieves the new state-of-the-art results on the recommendation item recall metric and distinct metrics. This result is understandable given that our approach is built upon pre-trained language models. Similarly, we also observe noticeable performance gains for the pre-training on this task. However, compared to systems with currently available knowledge sources, it is immediately apparent that the system with golden knowledge outperforms the current state-of-the-art on all metrics by a large margin. This huge gap implies that current knowledge retrievers are the main bottleneck for the conversational recommendation task. We will discuss more details in Section 3.7.

Overall, we observe noticeable improvement brought by pre-training on both tasks, but it is less significant than expected. It implies that the knowledge grounding pattern in the response is limited; a complete training set is more than enough for the T5-Large model to learn the generation task. We will discuss more details in zero-shot and few-shot settings in the following subsections.

3.5 Zero-Shot and Few-Shot Results

We focus on zero-shot and few-shot settings because it is more realistic to evaluate dialogue systems. Specifically, we randomly sample 10/50/500 dialogues with different topics from the training sets and observe performance on the complete test sets. We also evaluate under a zero-shot setting. We experiment with knowledge retrieved by exist-

Model	Test Seen BLEU4	ROUGE-L	F1	KF1	Test Unseen BLEU4	ROUGE-L	F1	KF1

Table 4: Fully-supervised results on REDIAL.

ing retrievers on both tasks to set a realistic setting. We compare our models to those without pre-training to explore how our pre-training benefits the model's few-shot learning capability. Wizard of Wikipedia's experiments results are in Figure 2, and REDIAL's results are in Figure 3. Note that for Wizard of Wikipedia, topics in original Test Seen set may not be seen during training in this setting since we only use a small portion of data in the original training set. We use original Test Seen and Test Unseen sets to compare with fully-supervised results. As can be seen in Figure 2 (a)-(c), 3 (a)-(b), PLUG maintains a higher BLEU-4, ROUGE-L, and F1 scores on both tasks when training with less than 500 dialogues. It means PLUG obtains knowledge-grounded generation ability from pre-training and can generalize to different tasks.

Figure 2 (d) shows that models without pre-training achieve a higher knowledge F1 score under a zero-shot setting for the Wizard of Wikipedia dataset. In contrast, it achieves a deficient performance on the language quality-related metrics, which implies that models only copy knowledge words but generate gibberish responses without training. Nevertheless, PLUG still generates knowledge-grounded responses with a lower knowledge F1 score out-of-the-box. This result also suggests that we should only consider knowledge F1 scores when the model has decent scores on language quality metrics.

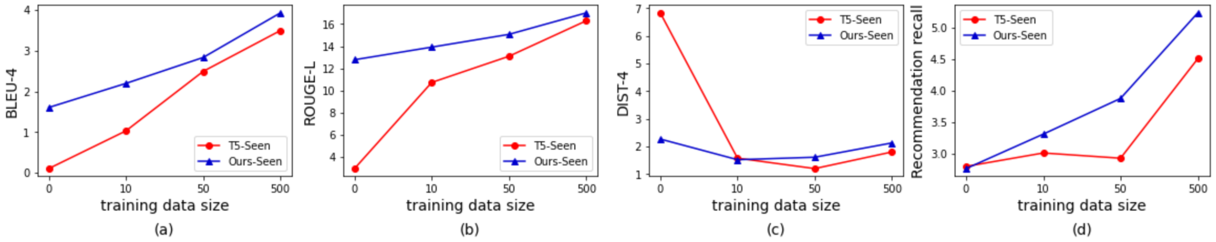
For the REDIAL dataset, Figure 3 (d) shows that there is not as much improvement in recommendation item recall brought by pre-training when compared to BLEU-4 and ROUGE-L on a zero-shot setting. However, we observe a noticeable difference between PLUG and the T5 model, which means PLUG learns to generate with grounded knowledge faster than the T5 model. The unusually high DIST-4 of T5 in Figure 3 (d) is caused by diverse but irrelevant responses. It is also demonstrated by low BLEU-4 and ROUGE-L scores in Figure 3 (a) and Figure 3 (b), and the decrease of DIST-4 when we increase the training data size.

3.6 Human Evaluation

We conduct a human evaluation on Wizard of Wikipedia to assess the overall quality of the responses of our model compared to T5 and RAG[7]. Specifically, we randomly select 100 responses for each model with the same context from Test Seen and Test Unseen. For the few-shot setting, we use the models trained with 50 dialogues. We hire

---

[7] We use the published FiD RAG DPR model at https://parl.ai/projects/hallucination/



(a) (b) (c) (d)

Figure 3: Zero-shot and few-shot results on REDIAL.

workers on Amazon Mechanical Turk to rate models' responses on a 0 - 2 scale with three metrics: Fluency, Coherence, and Knowledge. The order of the systems shown to workers is shuffled to avoid confounding practice effects. Three different workers evaluate each dialogue turn. Table 5 reports average metrics scores. We observe that responses from our fully-supervised model are more fluent and coherent than those from RAG, which benefits from our simple but effective essential knowledge representation. We can also see significant improvement on all metrics for PLUG under a zero-shot setting compared to the T5 model. Performance improvement under the few-shot setting is less than in the zero-shot setting, but PLUG still outperforms T5 on all metrics, which aligns with the result in automatic evaluation. Interestingly, we observe that responses from the model trained with 50 dialogues have already been very fluent and coherent, which is even higher than those from the fully-supervised model. However, responses from the fully-supervised model contain the most appropriate knowledge, which suggests that the model has learned how to generate high-quality responses in a few-shot setting, but it continues to learn how to ground on knowledge with more training samples.

Model	Fluency	Coherence	Knowledge
RAG	1.06	1.08	1.19
T5-Large			
- Zero-shot	0.87	0.98	0.98
- Few-shot	1.26	1.35	1.31
PLUG			
- Zero-shot	1.20**	1.34**	1.25**
- Few-shot	**1.29***	**1.42***	1.39**
- Fully-supervised	1.24**	1.37**	**1.46****

Table 5: Human evaluation results of different models on Wizard of Wikipedia. We test T5 baselines and RAG model against PLUG with $^{**}p < 0.01$, $^{*}p < 0.05$.

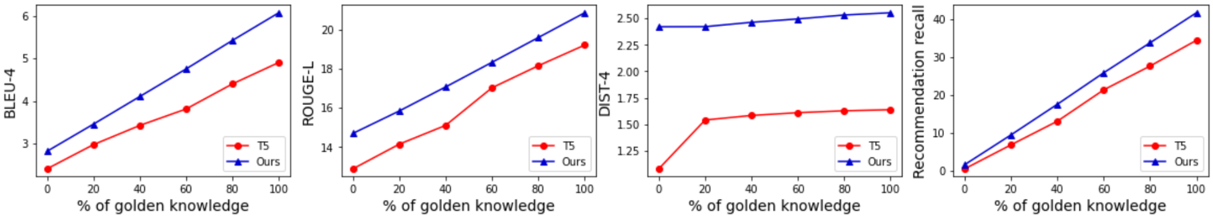
3.7 Discussion and Analysis

To investigate the enormous performance gap between models with golden knowledge and retrieved knowledge in Table 4, we compare the performance of models with different knowledge sources on the REDIAL dataset. Specifically, we mix the golden movies information and the retrieved movie information retrieved in the training/validation/test set to simulate knowledge sources with different recall performances. We experiment with 0/20/40/60/80/100 percent of the golden knowledge. 0 means all training samples includes retrieved knowledge (a flawed knowledge source), 100 means all training samples include golden knowledge (a perfect knowledge source). To have a more realistic setting, we compare the performance of PLUG and T5 under the few-shot setting (trained on 50 dialogues), as shown in Figure 4.

We find that the performance gain for both models is linear with respect to the performance of the knowledge source, whereas PLUG has a better boost on the BLEU-4 score and recommendation recall score. The curve with a higher slope shows the potential benefit from our pre-training method when better knowledge sources are available in the future. Furthermore, the gap on DIST-4 between PLUG and T5 is almost the same as golden knowledge increases, but the DIST-4 of T5 surprisingly drops when no golden knowledge is available. It means that T5 requires a better knowledge source in the training set to generate diverse responses under a few-shot setting, while PLUG has learned that ability in the pre-training process and generates diverse responses out-of-the-box. We also note that the performance boost with a better knowledge source is much more than the generation technology in previous work. This massive gap may shed light on the research direction of knowledge-grounded dialogue tasks for future efforts.

4 Related Work

Knowledge-grounded dialogue is becoming an increasingly important topic, with datasets proposed to model its occurrence on different tasks. Dialogues in these datasets are based on various for-



(a) (b) (c) (d)

Figure 4: Analysis of models with different knowledge sources on REDIAL.

.

mats of knowledge, such as documents in open-domain conversations (Ghazvininejad et al., 2018; Dinan et al., 2019; Gopalakrishnan et al., 2019), movie database in movie recommendation conversations (Li et al., 2018; Hayati et al., 2020), or knowledge graph in recommendation conversations(Moon et al., 2019; Liu et al., 2021b).

One of the principal challenges in knowledge-grounded conversations is incorporating knowledge into dialogue systems. Recent work investigates different techniques of learning a better knowledge representation to fuse knowledge in the response generation process. Ghazvininejad et al. (2018) separately encoded the dialogue history and documents to infuse the response with external world facts. Chen et al. (2019); Wang et al. (2021); Zhou et al. (2020a) joined a knowledge graph representation in a response generation module. Zhu et al. (2017) combined the knowledge from the database with the user intent and fed it into the decoder. Unlike these studies, we use a single encoder for both dialogue context and knowledge.

In order to improve the systems' performance on unseen topics and train knowledge-grounded dialogue in a low-resource setting, researchers investigate pre-training methods for the knowledge-grounded tasks. Zhao et al. (2020a) pre-trained the dialogue generation model with ungrounded dialogues and the knowledge encoder with the Wikipedia dump separately. Li et al. (2020) proposed a pre-trained latent variable model to learn the way that the knowledge is expressed in the response. Liu et al. (2021a) built a document encoder and a dialogue context encoder, then pre-trained them separately in multiple stages. The knowledge encoder in these studies is pre-trained separately and only accepts the same knowledge format, while we pre-train our model with essential knowledge in the text format, thus fitting different knowledge sources in the downstream tasks. Madotto et al. (2020) independently trained adaptors (Houlsby et al., 2019) for different types of knowledge. In comparison, we use a unified essential knowledge representation in our model. Zhao et al. (2020b) and Guu et al. (2020) pre-trained language models with knowledge selection modules but only focused on document-based generation, limiting their models to document-based knowledge sources.

Inspired by the success of pre-trained language models for a variety of natural language processing tasks (Devlin et al., 2019; Radford et al., 2019; Yang et al., 2019; Ma et al., 2021), another line of work investigates learning knowledge through language models' parameters (Petroni et al., 2019; Rosset et al., 2020; Roberts et al., 2020). In our pre-training process, we aim to learn extra knowledge and, more importantly, learn how to generate response grounding on the essential knowledge.

Two recent studies are most closely related to our work. Chen et al. (2020) proposed a pre-trained model for data to text tasks. They unified the knowledge format in the pre-training data and downstream tasks, however only depend on the graph structure and do not work on knowledge-grounded dialogues. Shuster et al. (2021) applied the document retrieval augmentation method (Lewis et al., 2020b) on open-domain knowledge-grounded dialogues. However, they do not do pre-training and rely on Wikipedia documents in the decoder, limiting their model to document-based dialogues. We use unified essential knowledge instead of documents in our pre-training, making our model more generalizable. Our approach can be seen as generalizing both lines of work, and showing for the first time that a pre-trained model is effective for various knowledge-grounded tasks with different knowledge formats.

5 Conclusion and Future Work

We present a knowledge-grounded pre-trained language model PLUG that can be applied to various knowledge-grounded dialogue tasks. It subsumes different knowledge sources into a simple but effective unified essential knowledge representation. Evaluation results on two benchmarks indicate that our model performs better in zero-shot and few-shot settings and can generalize to different knowledge grounded tasks.

As future work, we would like to augment our pre-training datasets with more knowledge sources, and apply our method to other knowledge-grounded tasks such as question answering. Another interesting direction would be to develop better information retrievers since experiments show that the retriever is the main bottleneck in the knowledge-grounded dialogues.

A Implementation Details

We process the Reddit monthly submissions and comments dump from 2011 to 2017, consisting of over 894k knowledge-grounded dialogue turns. As detailed in Section 2.3.1, we set the threshold as 0.35 in the semantic ranking. After filtering with our hierarchical information extraction method, over 321k dialogue turns remain. All dialogue turns in the OpenDialKG dataset are used in the pre-training. Each dialogue turn is processed to form a sequence of tokens consisting of three segments: dialogue context, essential knowledge, and response. We keep the top-three triples/keywords as our essential knowledge in pre-training and downstream tasks. PLUG is implemented with Huggingface Pytorch Transformers[8] (Wolf et al., 2020) and initialized with the 800M-parameter T5 model. We use Adam (Kingma and Ba, 2014) with weight decay for pre-training. Training examples are truncated to ensure a maximal length of 512. Models are pre-trained on 8 Nvidia V100 GPUs until we observe no progress on validation data or up to 20 epochs. The best configuration of hyper-parameters is selected through cross-validated grid-search.

B Ethical Considerations

It is essential to consider potential ethical issues in knowledge-grounded dialogue systems. In our work, PLUG is pre-trained on a large-scale dataset Reddit Conversation, which is crawled from the internet. We follow Galley et al. (2018) to filter out dialogues that have profanity content. However, it is still possible to include inappropriate content in the pre-training dataset. In processing the Reddit Conversation dataset during pre-training, we have carefully designed rules to remove knowledge that has profanity words. Additionally, the T5 model may have seen inappropriate content in its pre-training tasks, and it may generate wrong responses even if we input appropriate knowledge. Considerable additional work is needed to detect profanity content when we generate with a pre-trained language model. In addition to these ethical considerations, we have sought to better conduct our human evaluation by transparently communicating with crowd-workers about data use and study intent and compensating workers at a reasonable hourly wage.

C Human Evaluation Interface

Figure 5 shows the interface of an example in our human evaluation.

---

A user and an agent are chatting with each other. Now it is the agent's turn to reply. Please read the dialog context and rate responses from six agents.

Dialog context:

User: What is your favorite thing to post on Instagram?
Agent: Usually I just photos or videos. Do you know who owns Instagram?
User: No I don't, please tell me.
Agent: it's actually owned by Facebook
User: That cool, what kind of picture do you like to post.
Agent: generally landscape photos. Instagram allows you to use different filters which makes it pretty cool.
User: I used the black and white filter for my dog pictures.

Response 1

Agent: That's a cool filter. Do you have a favorite photo of your dog?

Questions

1. Is the response fluent?

○ 0 - Not fluent

○ 1 - Neutral

○ 2 - Very fluent

CERES: Pretraining of Graph-Conditioned Transformer for Semi-Structured Session Data

Rui Feng[†], Chen Luo[‡], Qingyu Yin[‡], Bing Yin[‡], Tuo Zhao[†] and Chao Zhang[†]

{cheluo,qingyy, alexbyin}@amazon.com

Abstract

User sessions empower many search and recommendation tasks on a daily basis. Such session data are semi-structured, which encode heterogeneous relations between queries and products, and each item is described by the unstructured text. Despite recent advances in self-supervised learning for text or graphs, there lack of self-supervised learning models that can effectively capture both intra-item semantics and inter-item interactions for semi-structured sessions. To fill this gap, we propose CERES, a graph-based transformer model for semi-structured session data. CERES learns representations that capture both inter- and intra-item semantics with (1) a *graph-conditioned masked language pretraining task* that jointly learns from item text and item-item relations; and (2) a *graph-conditioned transformer architecture* that propagates inter-item contexts to item-level representations. We pretrained CERES using ∼468 million Amazon sessions and find that CERES outperforms strong pretraining baselines by up to 9% in three session search and entity linking tasks.

1 Introduction

User sessions are ubiquitous in online e-commerce stores. An e-commerce session contains customer interactions with the platform in a continuous period. Within one session, the customer can issue multiple queries and take various actions on the retrieved products for these queries, such as clicking, adding to cart, and purchasing. Sessions are important in many e-commerce applications, *e.g.*, product recommendation (Wu et al., 2019a), query recommendation (Cucerzan and White, 2007), and query understanding (Zhang et al., 2020).

This paper considers sessions as *semi-structured* data, as illustrated in Figure 1. At the higher level, sessions are heterogeneous graphs that contain interactions between items. At the lower level, each graph node has unstructured text descriptions: we can describe queries by search keywords and products by titles, attributes, customer reviews, and other descriptors. Our goal is to simultaneously encode both the graph and text aspects of the session data to understand customer preferences and intents in a session context.

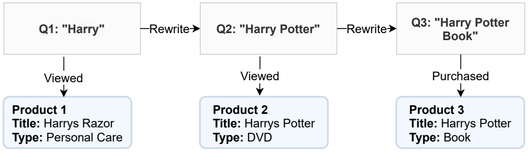

Figure 1: Illustration of a customer session. A session consists of two types of items: queries and products. The customer searched for 3 keywords sequentially and interacted with the products returned by the search engine.

Pretraining on semi-structured session data remains an open problem. First, existing works on learning from session data usually treat a session as a sequence or a graph (Xu et al., 2019; You et al., 2019; Qiu et al., 2020b). While they can model inter-item relations, they do not capture the rich intra-item semantics when text descriptions are available. Furthermore, these models are usually large neural networks that require massive labeled data to train from scratch. Another line of research utilizes large-scale pretrained language models (Lan et al., 2019; Liu et al., 2019; Clark et al., 2020) as text encoders for session items. However, they fail to model the relational graph structure. Several works attempt to improve language models with a graph-structured knowledge base, such as in (Liu et al., 2020; Yao et al., 2019; Shen et al., 2020). While adjusting the semantics of entities according to the knowledge graph, they fail to encode general graph structures in sessions.

We propose CERES (Graph **C**onditioned **E**ncoder **Re**presentations for **S**ession Data), a pretraining model for semi-structured e-commerce session data, which can serve as a generic session encoder that simultaneously captures both intra-

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 219 - 230
July 10-15, 2022

item semantics and inter-item relations. Beyond training a potent language model for intra-item semantics, our model also conditions the language modeling task on graph-level session information, thus encouraging the pretrained model to learn how to utilize inter-item signals. Our model architecture tightly integrates two key components: (1) an *item Transformer encoder*, which captures text semantics of session items; and (2) a *graph conditioned Transformer*, which aggregates and propagates inter-item relations for cross-item prediction. As a result, CERES models the higher-level interactions between items.

We have pretrained CERES using 468,199,822 sessions and performed experiments on three session-based tasks: product search, query search, and entity linking. By comparing with publicly available state-of-the-art language models and domain-specific language models trained on alternative representations of session data, we show that CERES outperforms strong baselines on various session-based tasks by large margins. Experiments show that CERES can effectively utilize session-level information for downstream tasks, better capture text semantics for session items, and perform well even with very scarce training examples.

We summarize our contributions as follows: 1) We propose CERES , a pretrained model for semi-structured e-commerce session data. CERES can effectively encode both e-commerce items and sessions and generically support various session-based downstream tasks. 2) We propose a new graph-conditioned transformer model for pretraining on general relational structures on text data. 3) We conducted extensive experiments on a large-scale e-commerce benchmark for three session-related tasks. The results show the superiority of CERES over strong baselines, including mainstream pretrained language models and state-of-the-art deep session recommendation models.

2 Customer Sessions

A *customer session* is the search log before a final purchase action. It consists of customer-query-product interactions: a customer submits search queries obtains a list of products. The customer may take specific actions, including *view* and *purchase* on the retrieved products. Hence, a session contains two types of items: *queries* and *products*, and various relations between them established by customer actions.

We define each session as a *relational graph* $G = (\mathcal{V}, \mathcal{E})$ that contains all queries and products in a session and their relations. The vertex set $\mathcal{V} = (\mathcal{Q}, \mathcal{P})$ is partitioned into ordered query set $\mathcal{Q}$ and unordered product set $\mathcal{P}$. The queries $\mathcal{Q} = (q_1, \ldots, q_n)$ are indexed by order of the customer's searches. The edge set $\mathcal{E}$ contains two types of edges: $\{(q_i, q_j), i < j\}$ are one-directional edges that connect each query to its previous queries; and $\{q_i, p_j, a_{ij}\}$ are bidirectional edges that connects the ith query and jth product, if the customer took action a_{ij} on product p_j retrieved by query q_j.

The queries and products are represented by textual descriptions. Specifically, each query is represented by customer-generated search keywords. Each product is represented with a table of textual attributes. Each product is guaranteed to have a product title and description. In this paper, we call "product sequence" as the concatenation of title and description. A product may have additional attributes, such as product type, color, brand, and manufacturer, depending on their specific categories.

3 Our Method

In this section we present the details of CERES. We first describe our designed session pretraining task in Section 3.1, and then describe the model architecture of CERES in Section 3.2.

3.1 Graph-Conditioned Masked Language Modeling Task

Suppose $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ is a graph on T text items as vertices, $v_1, \ldots, v_T$, each of which is a sequence of text tokens: $v_i = [v_{i1}, \ldots, v_{iT_i}]$, $i = 1, \ldots, T$. We propose *graph-conditioned masked language modeling* (GMLM), where masked tokens are predicted with both intra-item context and inter-item context:

$$p_{\text{GMLM}}(v_{\text{masked}}) = \prod_{j\text{th masked}} \mathbb{P}(v_{ij} | \mathcal{G}, \{v_{ik}\}_{k\text{th unmasked}}), \tag{1}$$

which encourages the model to leverage information graph-level inter-item semantics efficiently in order to predict masked tokens. To optimize (1), we need to learn token-level embeddings that are infused with session-level information, which we introduce in Section 3.2.2. Suppose certain tokens in the input sequence of items as masked (detailed below), we optimize the predictions of the masked tokens with cross entropy loss. The pretraining framework is illustrated in Figure 3.

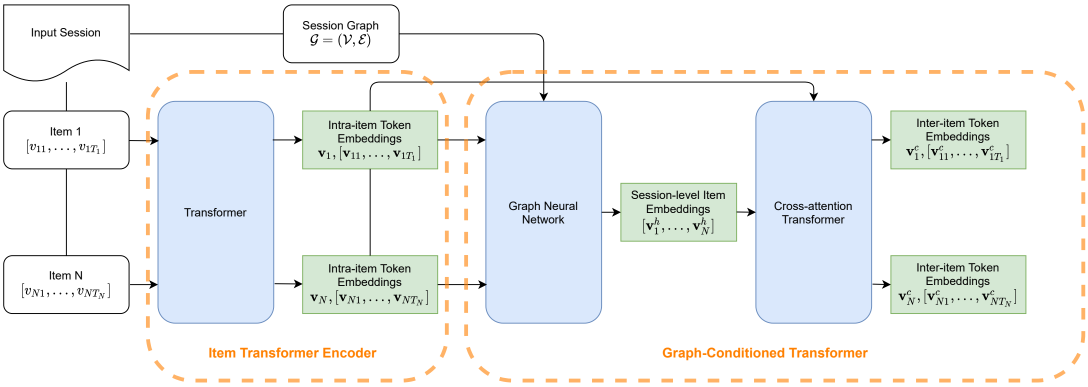

Figure 2: Model illustration. CERES first produces intra-item embeddings in the Item Transformer Encoder. Then, the Graph-Conditioned Transformer aggregates and propagates session-level information to obtain inter-item embeddings.

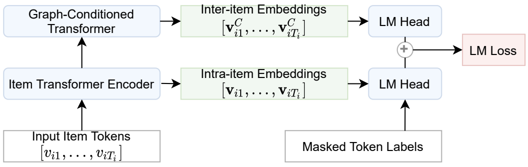

Figure 3: Pretraining framework illustration. CERES learns both inter-item and intra-item embeddings for item tokens for Masked LM and Graph-Conditioned Masked LM. In practice, we find it beneficial to optimize both.

Token Masking Strategy. To mask tokens in long sequences, including product titles and descriptions, we follow (Devlin et al., 2018) and choose 15% of the tokens for masking. For short sequences, including queries and product attributes, there is a 50% probability that a short sequence will be masked, and for those sequences 50% of their tokens are randomly selected for masking.

3.2 Model Architecture

To model the probability in (1), we design two key components in the CERES model: 1) a *Transformer-based item encoder*, which produces token-level intra-item embeddings that contain context information within a single item; and 2) a *graph-conditioned Transformer for session encoding*, which produces session-level embeddings that encodes inter-item relations, and propagates the session information back to the token-level. We illustrate our model architecture in Figure 2.

3.2.1 Item Transformer Encoder

The session item encoder aims to encode intra-item textual information for each item in a session. We design the item encoder based on Transformers, which allows CERES to leverage the expressive power of the self-attention mechanism for modeling domain-specific language in e-commerce sessions. Given an item i, the transformer-based item encoder compute its token embeddings as follows:

$$\begin{aligned}[\mathbf{v}_{i1},\dots,\mathbf{v}_{iT_i}] &= \text{Transformer}_{\text{item}}([v_{i1},\dots,v_{iT_i}]) \\ \mathbf{v}_i &= \text{Pool}([v_{i1},\dots,v_{iT_i}]),\end{aligned} \quad (2)$$

where $\mathbf{v}_{ij}$ is the embedding of the jth token in the ith item, and $\mathbf{v}_i$ is the pooled embedding of the ith item. At this stage, $\{\mathbf{v}_{ij}\}, \{\mathbf{v}_i\}$ are embeddings that only encode the intra-item information.

Details of Item Encoding. We detail the encoding method for the two types of items, queries and products, in the following paragraphs.

Each query $q_i = [q_{i1},\dots,q_{iT_i}]$ is a sequence of tokens generated by customers as search keywords. We add a special token at the beginning of the queries, `[SEARCH]`, to indicate that the sequence represents a customer's search keywords. Then, to obtain the token-level embedding of the queries and the pooled query embedding by taking the embedding of the special token `[SEARCH]`.

Each product p_i is a table of K attributes: $p^1,\dots,p^K$, where p^1 is always the *product sequence*, which is the concatenation of product title and bullet description. Each attribute $p_i^k = [p_{i1}^k, p_{i2}^k,\dots]$ starts with a special token `[ATTRTYPE]`, where `ATTRTYPE` is replaced with the language descriptor of the attribtue. Then, the Transformer is used to compute token and sentence embeddings for all attributes. The product embedding is obtained by average pooling of all attribute's sentence embeddings.

3.2.2 Graph-Conditioned Session Transformer

The Graph-Conditioned Session Transformer aims to infuse intra-item and inter-item information to produce item and token embeddings. For this purpose, we first design a *position-aware graph neural network* (PGNN) to capture the inter-item dependencies in a session graph to produce

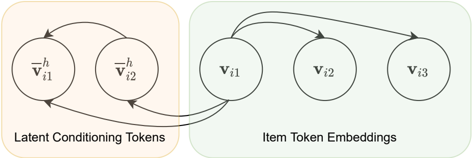

Figure 4: Illustration of cross-attention over latent conditioning tokens. The item token embeddings perform self-attention as well as cross-attention over latent conditioning tokens, thus incorporating session-level information. Latent conditioning tokens perform self-attention to update their embeddings, but do not attend to item tokens to preserve session-level information.

item embeddings. The effect of PGNN is analyzed in Section 4.4. Then conditioned on the PGNN-learned item embedding, we propose a cross-attention Transformer, which produces infused item and token embeddings for the Graph-Conditioned Masked Language Modeling task.

Position-Aware Graph Neural Network. We use a GNN to capture inter-item relations. This will allow CERES to obtain item embeddings that encode the information from other locally correlated items in the session. Let $[\mathbf{v}_1, \ldots, \mathbf{v}_N]$ denote the item embeddings produced by the intra-item transformer encoder. We treat them as hidden states of nodes in the session graph $\mathcal{G}$ and feed them to the GNN model, obtaining session-level item embeddings $[\mathbf{v}^h_1, \ldots, \mathbf{v}^h_N]$.

The items in a session graph are sequential according to the order the customers generated them. To let the GNN model learn of the positional information of items, we train an *item positional embedding* in the same way BERT (Devlin et al., 2018) trains positional embeddings of tokens. Before feeding the item embeddings to GNN, the pooled item embeddings are added item positional embeddings according to their positions in the session's item sequence. In this way, the item embeddings $\{\mathbf{v}^i\}_{i\in\mathcal{V}}$ are encoded their positional information as well.

Cross-Attention Transformer. Conditioned on PGNN, we design a *cross-attention transformer* which propagates session-level information in PGNN-produced item embeddings to all tokens to produce token embeddings that are infused with both intra-item and inter-item information.

In order to propagate item embeddings to tokens, we treat item embeddings as latent tokens that can be treated as a "part" of item texts. for each item i, we first expand $\mathbf{v}^h_i$ to K latent conditioning tokens by using a multilayer perceptron module to map $\mathbf{v}^h_i$ to K embedding vectors $[\mathbf{v}^h_{i1}, \ldots, \mathbf{v}^h_{iK}]$ of the same size. For each item i, we compute its latent conditioning tokens by averaging all latent tokens in its neighborhood. Suppose $N(i)$ is the set of all neighboring items in the session graph, itself included. In each position, we take the average of the latent token embeddings in $N(i)$ as the kth latent conditioning token, $\overline{\mathbf{v}}^h_{ik}$, for the ith item. Then, we concatenate the latent conditioning token embeddings and the item token embeddings obtained by the session item encoder:

$$[\overline{\mathbf{v}}^h_{i1}, \ldots, \overline{\mathbf{v}}^h_{iK}, \mathbf{v}_{i1}, \ldots, \mathbf{v}_{iN_i}]. \tag{3}$$

Finally, we compute the token-level embeddings with session information by feeding the concatenated sequence to a shallow *cross-attention* Transformer. The cross-attention Transformer is of the same structure as normal Transformers. The difference is that we prohibit the latent conditioning tokens from attending over original item tokens to prevent the influx of intra-item information potentially diluating session-level information stored in latent conditioning tokens. Illustration of cross-attention Transformer is provided in Figrue 4.

We use the embeddings produced by this cross-attention Transformer as the final embeddings for modeling the token probabilities in Equation (1) and learning the masked language modeling tasks. During training, the model is encouraged to learn good token embeddings with the Item Transformer Encoder, as better embeddings $\{\mathbf{v}_{ij}\}_{j=1}^{N_i}$ is necessary to improve the quality of $\{\mathbf{v}^c_{ij}\}_{j=1}^{N_i}$. The Graph-Conditioned Transformer will be encouraged to produce high-quality session-level embeddings for the GMLM task. Hence, CERES is encouraged to produce high-quality embeddings that unify both intra-item and inter-item information.

3.3 Finetuning

When finetuning CERES for downstream tasks, we first obtain session-level item embeddings. The session embedding is computed as the average of all item embeddings. To obtain embedding for a single item without session context, such as for retrieved items in recommendation tasks, only the Item Transformer Encoder is used.

To measure the relevance of an item to a given session, we first transform the obtained embeddings by separate linear maps. Denote the transformed session embeddings as $\mathbf{s}$ and item embeddings as $\mathbf{y}$. The similarity between them is computed by cosine similarity $\mathrm{d}_{\mathbf{cos}}(\mathbf{s}, \mathbf{y})$. To finetune the model, we optimize a hinge loss on the cosine similarity between sessions and items.

4 Experiments

4.1 Experiment Setup

Dataset. We collected customer sessions from Amazon for pretraining and finetuning on downstream tasks. 468,199,822 customer sessions are collected from August 1 2020 to August 31 2020 for pretraining. 30,000 sessions are collected from September 2020 to September 7 2020 for downstream tasks. The pretraining and downstreaming datasets are from disjoint time spans to prevent data leakage. All data are cleaned and anonymized so that no personal information about customers was used. Each session is collected as follows: when a customer perform a purchase action, we backtrace all actions by the customer in 600 seconds before the purchase until a previous purchase is encountered. The actions of customers include: 1) search, 2) view, 3), add-to-cart, and 4) purchase. Search action is associated with customer generated query keywords. View, add-to-cart, and purchase are associated with the target products. All the products in the these sessions are gathered with their product title, bullet description, and various other attributes, including color, manufacturer, product type, size, *etc*. In total, we have 37,580,637 products. The sessions have an average of 3.24 queries and 4.36 products. Queries have on average 5.63 tokens, while product titles and bullet descriptions have averagely 17.42 and 96.01 tokens.

Evaluation Tasks and Metrics. We evaluate all the compared models on the following tasks: 1) *Product Search.* In this task, given observed customer behaviors in a session, the model is asked to predict which product will be purchased from a pool of candidate products. The purchased products are removed from sessions to avoid trivial inference. The candidate product pool is the union of all purchased products in the test set and the first 10 products returned by the search engine of all sessions in the test set.

2) *Query Search.* Query Search is a recommendation task where the model retrieves next queries for customers which will lead to a purchase. Given a session, we hide the last query along with products associated with it, *i.e.* viewed or purchased with the removed query. Then, we ask the model to predict the last query from a pool of candidate queries. The candidate query pool consists of all last queries in the test set.

3) *Entity Linking.* In this task we try to understand the deeper semantics of customer sessions. Specifically, if customer purchases a product in a session, the task is to predict the attributes of the purchased product from the rest contexts in the session. In total, we have 60K possible product attributes.

Baselines. The compared baselines can be categorized into three groups:

1) *General-domain pretrained language models* which include BERT (Devlin et al., 2018), RoBERTa (Liu et al., 2019), and ELECTRA (Clark et al., 2020). These models are state-of-the-art pretrained language models, which can serve as general-purpose language encoders for items and enable downstream session-related tasks. Specifically, the language encoders produce item embeddings first, and compose session embeddings by pooling the items in sessions. To retrieve items for sessions, one can compare the cosine similarity between sessions and retrieved items.

2) *Pretrained session models* which are pretrained models on e-commerce session data. Specifically, we pretrain the following language models using our session data: a) *Product-BERT*, which is a domain-specific BERT model pretrained with product information; b) *SQSP-BERT*, where *SQSP* is short for *Single-query Single-Product*. SQSP-BERT is pretrained on query-product interaction pairs with language modeling and contrastive learning objectives. They are used in the same manner in downstream tasks as general-domain pretrained language models. The detailed configurations are provided in the Appendix.

3) *Session-based recommendation methods* including SR-GNN (Wu et al., 2019b) and NISER+ (Gupta et al., 2019), which are state-of-the-art models for session-based product recommendation on traditional benchmarks, including YOOCHOOSE and DIGINETICA; and Nvidia's MERLIN (Mobasher et al., 2001), which is the best-performing model in the recent SIGIR Next Items Prediction challenge (Kallumadi et al., 2021)

To evaluate the performance on these tasks, we employ standard metrics for recommendation systems, including MAP@K, and Recall@K.

4.2 Implementation Details

The implementation details for pretraining and finetuning stages are described as follows.

Pretraining details. We developed our model based on Megatron-LM (Shoeybi et al., 2019). We used 768 as the hidden size, a 12-layer transformer blocks as the backbone language model, a two-layer Graph Attention Network and three-layer Transformer as the conditioned language model layers. In total, our model has 141M parameters. The model is trained for 300,000 steps with a batch size of 512 sessions. The parameters are updated with Adam, with peak learning rate as $3e-5$, 1% steps for linear warm-up, and linear learning rate decay after warm-up until the learning rate reaches the minimum $1e-5$. We trained our model on 16 A400 GPUs on Amazon AWS for one week.

Finetuning details. For each downstream task, we collected 30,000 sessions for training, 3000 for validation and 5000 for testing. For each of the pretrained model, we finetune them for 10 epochs with a maximal learning rate chosen from [1e-4, 1e-5, 5e-5, 5e-6] to maximize MAP@1 on the validation set. The rest of the configuration of optimizers is the same as in pretraining.

4.3 Main Results

4.3.1 Product Search

Table 1 shows the performance of different methods for the product search task. We observe that CERES outperforms domain-specific methods by more than 1% and general-domain methods by over 6% in MAP@1. The second best performing model is Product-BERT, which is pretrained on product information alone.

We also compared with session-based recommendation systems. SR-GNN and NISER+ model only session graph structure but not text semantics; hence they have limited performance because of the suboptimal representation of session items. While MERLIN can capture better text semantics, its text encoder is not trained on domain-specific e-commerce data. While it can outperform general-domain methods, its performance is lower than Product-BERT and CERES. The benefits of joint modeling of text and graph data and the Graph-Conditioned MLM allow CERES to outperform existing session recommendation models.

4.3.2 Query Search

Table 2 shows the performance of different methods on Query Search. Query Search is a more difficult task than Product Search because customer-generated next queries are of higher variance. In this challenging task, CERES outperforms the best domain-specific model by over 7% and general-domain model by 12% in all metrics.

4.3.3 Entity Linking

Table 3 shows the results on Entity Linking. Similar to Query Search, this task also requires the models to tie text semantics (queries/product attributes) to a customer session, which requires a deeper understanding of customer preferences. It is easier than Query Search as product attributes are of lower variance. However, the product attributes that the customer prefer rely more on session information, as they may have been reflected in the past search queries and viewed products. In this task, CERES outperforms domain-specific models and general-domain models by averagely 9% in MAP@1 and 6% in MAP@32 and MAP@64.

4.4 Further Analysis and Ablation Studies

In this section we present further studies to understand: 1) the effect of training data sizes in the downstream task; 2) the effects of different components in CERES for both the pretraining and finetuning stages. following observations:

CERES is highly effective when training data are scarce. We compare CERES with two strongest baselines (BERT, and Product-BERT) when the training sample size varies. Figure 5 shows the MAP@64 scores of these methods on Product Search and Query Search when training size varies. Clearly, the advantage of CERES is greater when training data is extremely small. With a training size of 300, CERES can achieve a decent performance of about 37.55% in Product Search and 36.37% in Query Search, while the baseline models cannot be trained sufficiently with such small-sized data. This shows that the efficient utilization of session-level information in pretraining and fine-tuning stages make the model more data efficient than other pretrained models.

Table 2: The performance of different methods for Query Search, after fine-tuning with 30,000 training sessions.

Graph-Conditioned Transformer is Vital to Pretraining. Without the Graph-Conditioned Transformer in pretraining, our model is essentially the same as domain-specific baselines, such as Product-BERT, which are trained on session data but only with intra-item text signals. While SQSP-BERT has access to session-level information when maximizing the masked language modeling objective, the lack of a dedicated module for GMLM results in worse performance, as shown in the main experiment results.

We could train the Graph-Conditioned Transformer from scratch in the finetuning stage. We present a model called *CERES w/o Pretrain*, which attaches the Graph-Conditioned Session Transformer to Product-BERT as the Item Transformer Encoder. As shown in Figure 6, this ablation method achieves MAP@64 scores of 89.341% in Product Search, 64.890% in Query Search, and 74.031% in Entity Linking, which are below Product-BERT. This shows that the pretraining stage of the Graph-Conditioned Transformer is necessary to facilitate its ability to aggregate and propagate session-level information for downstream tasks.

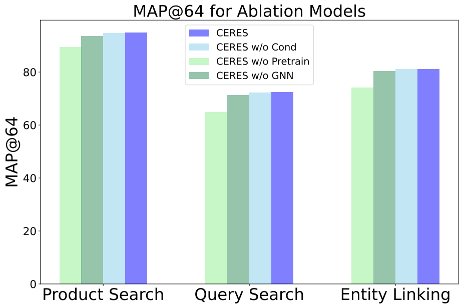

Figure 6: Results on three tasks on ablation models. y-axis represents MAP@64. *CERES w/o Cond* is CERES without the Graph-Conditioned Transformer in the fine-tuning stage. *CERES w/o Pretrain* is CERES without pretraining the Graph-Conditioned Transformer, but instead training it from scratch in the finetuning stage. *CERES w/o GNN* is CERES pretrained without the GNN module.

Graph-Conditioned Transformer Improves Item-level Embeddings. We also present *CERES w/o Cond*, which has the same pretrained model as CERES, but only uses the Item Transformer Encoder in the finetuning stage. The Item Transformer Encoder is used to compute session item embeddings that contain only item-level information, and then takes the average of these embeddings as session embedding. As shown in Figure 6, *CERES w/o Cond* acheives 94.741%, 72.175%, and 81.03% respectively in Product Search, Query Search, and Entity Linking, observing a drop of 0.1% to 0.2% in performance compared with *CERES*. The performance drop is minor and *CERES w/o Cond* still outperforms baseline pretrained language models. Hence, the Graph-Conditioned Transformer in the pretraining stage helps the Item Transformer Encoder to learn better item-level embeddings that can be used for more effective leveraging of session information in the downstream tasks.

Graph Neural Networks Improve Representation of Sessions. In *CERES w/o GNN*, we pretrain a *CERES* model without a Graph Neural Network. Specifically, *CERES w/o GNN* skips the neighborhood information aggregation for items, and uses item-level embeddings obtained by the Item Transformer Encoder directly as latent conditioning tokens. We train and finetune this model with the same setup as CERES. Without GNN, the model's performance is consistently lower than CERES,

Method	map@1	recall@1	map@32	recall@32	map@64	recall@64
BERT	55.609	55.353	66.386	90.511	66.481	95.073
RoBERTa	66.506	65.754	74.516	93.248	74.561	95.438
Electra	62.321	62.365	62.985	68.296	63.122	74.318
Product-Bert	66.827	66.393	74.611	94.404	74.641	96.046
SQSP-Bert	63.942	64.872	72.232	91.241	72.307	94.891
CERES	**75.481**	**75.456**	**81.121**	**95.255**	**81.16**	**96.898**

Table 3: The performance of different methods for Entity Linking, after fine-tuning with 30,000 training sessions.

achieving 93.453%, 71.231%, 80.26% MAP@64 in three downstream tasks, observing a 1.13% performance drop. This shows that GNN's aggregation of information can help item-level embeddings encode more session-level information, improving performance in downstream tasks.

Model Efficiency. CERES has additional few GNN and Transformer layers attached to the end of the model. The additional layers bring ∼20% additional inference time compared to standard BERT with 12 layers and 768 hidden size.

5 Related work

Pretrained language models such as BERT (Devlin et al., 2018), BART (Lewis et al., 2019), ELECTRA (Clark et al., 2020), RoBERTa (Liu et al., 2019) have pushed the frontiers of many NLP tasks by large margins. Their effectiveness and efficiency in parallelism have made them popular and general-purpose language encoders for many text-rich applications. However, they are not designed to model relational and graph data, and hence are not the best fit for e-commerce session data.

Researchers have also sought to enhance text representations in pretrained models with knowledge graphs (Shen et al., 2020; Liu et al., 2020; Yao et al., 2019; Sun et al., 2020, 2021). While these models consider a knowledge graph structure on top of text data, they generally use entities or relations in knowledge graphs to enhance text representations, but cannot encode arbitrary graph structures. This is not sufficient in session-related applications as session structures are ignored.

Many works have been proposed to learn pretrained graph neural networks. Initially, methods were proposed for domain-specific graph pretraining (Hu et al., 2019a,b; Shang et al., 2019). However, they rely on pre-extracted domain-specific node-level features, and cannot be extended to either session data or text data as nodes. Recently, many works have been proposed to pretrain on general graph structure (Hu et al., 2020; You et al., 2020; Qiu et al., 2020a). However, they cannot encode the semantics of text data as nodes.

Contextual information in sessions have been shown beneficial to various related recommendation tasks, such as product recommendation (Wu et al., 2019b; Dehghani et al., 2017; Jannach and Ludewig, 2017; Gupta et al., 2019) and query rewriting (Li et al., 2017; Cucerzan and White, 2007). Many existing session-based recommendation methods seek to exploit the transitions between items (Yap et al., 2012; Rendle et al., 2010; Wang et al., 2018; Li et al., 2017) and considering sessions as graphs (Xu et al., 2019; Ruihong et al., 2021; Wang et al., 2020).

6 Limitations and Risks

This paper limits the application of CERES to session data with text descriptions. CERES has the potential of being a universal pretraining framework for arbitrary heterogeneous data. For example, sessions can include product images and customer reviews for more informative multimodal graphs. We leave this extension for future work.

Session data are personalized experience for customers and could cause privacy issues if data are not properly anonymized. In application, the model should be used to avoid exploitation or leakage of customers personal profiles and preferences.

7 Conclusion

We proposed a pretraining framework, CERES, for learning representations for semi-structured e-commerce sessions. We are the first to jointly model intra-item text and inter-item relations in session graphs with an end-to-end pretraining framework. By modeling Graph-Conditioned Masked Language Modeling, our model is encouraged to learn high-quality representations for both intra-item and inter-item information during its pretraining on massive unlabeled session graphs. Furthermore, as a generic session encoder, our model enabled effective leverage of session information in downstream tasks. We conducted extensive experiments and ablation studies on CERES in comparison to state-of-the-art pretrained models and recommendation systems. Experiments show that CERES can produce higher quality text representations as well as better leverage of session graph structure, which are important to many e-commerce related tasks, including product search, query search, and query understanding.

Attribute	Value
Title	Pour-over Coffee Maker
Bullet Description	Just coffee maker.
Color	N/A
Brand	Chemex
Manufacturer	Chemex
Product Type	Coffee Maker

Table 4: Example Product Table. Each product is guaranteed to have a title. Most products have bullet descriptions, which can be split into multiple entries. Products could have other attributes, such as color, brand, product type, etc. as well.

A Details on Session Data

A.1 Product Attributes.

A product is represented with a table of attributes. Each product is guaranteed to have a product title and bullet description. In this paper, we regard the product title as the representative sequence of the product, called "product sequence". A product may have additional attributes, such as product type, color, brand, and manufacturer, depending on specific products.

A.2 Alternative Pretraining Corpora

In this section we introduce alternative pretraining corpora that encode information in a session, including products and queries, but not treating sessions as a whole.

A.2.1 Product Corpus

In this corpus, we gathered all product information that appeared in the sessions from August 2020 to September 2020. Each product will have descriptions such as *product title* and *bullet description*, and other attributes like *entity type*, *product type*, *manufacturer*, etc. Particularly, bullet description is composed of several lines of descriptive facts about the product. All products without titles are removed. Each of the remaining product forms a paragraph, where the product title comes as the first sentence, followed by the entries of bullet descriptions each as a sentence, and product attributes.

An example document in this corpora is as follows:

```
[Title] product title
[Description] description
[Product Type] product type
[Color] color
```

A.2.2 Single-Query Single-Product (SQSP) Corpus

In this corpus, we treat each session as a document and each query-product pair as a sentence. A query-product pair in the document are the pairs of queries and products that are either viewed or clicked with the given queries. A query-product pair looks like the follows:

```
[SEARCH] search keywords
[TITLE] product title
[DESCRIPTION] description
[ENTITY_TYPE] entity type
```

where the first `[SEARCH]` special token indicates a field of query keywords, and `[TITLE]` indicates fields of product information starting with product tittles. In this corpus, we model the one-to-one relation between queries and products.

A.2.3 Session Corpus

In this corpus, we treat each session as a document and sequentially put text representations of items in a session to the document with special tokens indicating the fields of items. An example document looks like the follows:

```
[SEARCH] keywords 1
[SEARCH] keywords 2 [CLICK]
[TITLE] product 1
[SEARCH] keywords 3
[PURCHASE]
[TITLE] product 2
```

In this example, the customer first attempted to search with *keywords 1* and then modified the keywords to *keywords 2*. The customer then clicked on *product 1*. At last, the customer modified his search to *keywords 3* and purchased *product 2*. In this corpus, session information is present in a document, but the specific relations between elements are not specified. The comparison of different datasets are in Table 5.

A.3 Alternative Pretraining Methods

We introduce the alternative pretraining models.

- **Product-Bert**. It is pretrained on the Product Corpus. Specifically, we treat each product in the Product Corpus as an article. Product titles is always the first sentence, followed by paragraphs of bullet descriptions, which can contain multiple sentences. Then, each additional product attribute is a sentence added after the bullet descriptions.

Corpus	Product Info	Query Info	Relational	Session Context
Product	✓	✗	✗	✗
SQSP	✓	✓	✓	✗
Session-Corpus	✓	✓	✗	✓
Session-Graph	✓	✓	✓	✓

Table 5: Comparision of different pretraining dataset. Product Corpus has access only to product information. SQSP models on the queries and query-product relations, without access to session context. Session Corpus has access to contextual information in a session, but does not model on relations between objects. Session-Graph has access to all information and models on the relational nature of nodes in the session graph.

Product Bert is trained for 300,000 steps, with a 12-layer transformer with a batch size of 6144 and peak learning rate of 1e-3, 1% linear warm-up steps, and $1e-2$ linear weight decay to a minimum learning rate of 1e-5.

- **SQSP-Bert**. It is pretrained on SQSP Corpus. The SQSP Bert uses the same Transformer backbone as Product Bert. Given each query-product pair, SQSP feeds the text pair sequence to the Transformer for token embeddings for masked language modeling loss. In addition to language modeling, for each query-product pair, we sample a random product for the query as a negative query-product pair. The text pair sequence of the negative sample is also fed to the Transformer. Then, a discriminator is trained in the pretraining stage to distinguish the ground-truth query-product pairs and randomly sampled pairs. The discriminator's classification loss should serve as a contrastive loss.

  SQSP Bert is trained with the same configuration of Product Bert.

B Details on Evaluation Metrics

Mean Average Precision. Suppose that for a session, *m* items are relevant and *N* items are retrieved by the model, the *Average Precision* (AP) of a session is defined as

$$\text{AP@N} = \frac{1}{\min(m, N)} \sum_{k=1}^{N} P(k)\text{rel}(k), \quad (4)$$

where $P(k)$ is the precision of the top k retrieved items, and $rel(k)$ is an indicator function of whether the kth item is relevant. As we have at most one relevant item for each session, the above metric reduces to $\frac{1}{r}$, where r is the rank of the relevant item in the retrieved list, and $k = \infty$ when the relevant item is not retrieved. MAP@N averages AP@N over all sessions,

$$\text{MAP@N} = \frac{1}{|\mathcal{S}|} \sum_{s \in \mathcal{S}} \frac{1}{r_s} \quad (5)$$

where r_s is the rank of the relevant item for a specific session s. MAP in this case is equivalent to MRR.

Mean Average Precision by Queries (MAPQ). Different from MAP, MAPQ averages AP over last queries instead of sessions. Suppose $\mathcal{Q}$ is the set of unique last queries, and $S(q), q \in \mathcal{Q}$ is the set of sessions whose last queries are q, then the average precision for one query q is

$$\frac{1}{\sum_{i=1}^{k} \text{rel}(k)} \sum_{k=1}^{N} \min(1, \frac{\sum_{r_s \leq k} \text{rel}(k)}{k}) \quad (6)$$

then we sum over all queries to obtain MAPQ@N.

Mean Reciprocal Rank by Queries (MRRQ). MRRQ averages MRR over session last queries instead of sessions.

$$MRRQ@N = \frac{1}{|\mathcal{Q}|} \sum_{q \in \mathcal{Q}} \max_{s \in S(q)} (r_s) \quad (7)$$

Recall. Recall@N calculates the percentage of sessions whose relevant items were retrieved among the top N predictions.

Political Ideology and Polarization: A Multi-dimensional Approach

Abstract

Analyzing ideology and polarization is of critical importance in advancing our grasp of modern politics. Recent research has made great strides towards understanding the ideological *bias* (i.e., stance) of news media along the left-right spectrum. In this work, we instead take a novel and more nuanced approach for the study of ideology based on its left or right positions on the issue being discussed. Aligned with the theoretical accounts in political science, we treat ideology as a multi-dimensional construct, and introduce the first diachronic dataset of news articles whose ideological positions are annotated by trained political scientists and linguists at the paragraph level. We showcase that, by controlling for the author's stance, our method allows for the quantitative and temporal measurement and analysis of polarization as a multidimensional ideological distance. We further present baseline models for ideology prediction, outlining a challenging task distinct from stance detection.

1 Introduction

Political ideology rests on a set of beliefs about the proper order of a society and ways to achieve this order (Jost et al., 2009; Adorno et al., 2019; Campbell et al., 1980). In Western politics, these worldviews translate into a multi-dimensional construct that includes: equal opportunity as opposed to economic individualism; general respect for tradition, hierarchy and stability as opposed to advocating for social change; and a belief in the un/fairness and in/efficiency of markets (Jost et al., 2009).

The divergence in ideology, i.e., polarization, is the undercurrent of propaganda and misinformation (Vicario et al., 2019; Bessi et al., 2016; Stanley, 2015). It can congest essential democratic functions with an increase in the divergence of political ideologies. Defined as a growing ideological distance between groups, polarization has waxed and waned since the advent of the American Republic (Pierson and Schickler, 2020).[1] Two eras—post-1896 and -1990s—have witnessed deleterious degrees of polarization (Jenkins et al., 2004; Jensen et al., 2012). More recently, COVID-19, the murder of George Floyd, and the Capitol riots have exposed ideological divergences in opinion in the US through news media and social media. With the hope of advancing our grasp of modern politics, we study ideology and polarization through the lens of computational linguistics by presenting a carefully annotated corpus and examining the efficacy of a set of computational and statistical analyses.

Two dimensions: trade and economic liberalism	The U.S. aim is to create a monetary system with enough flexibility to prevent bargain-hungry money from rolling around the world like loose ballast on a ship disrupting normal trade and currency flows. Nixon goals: dollar, trade stability. This must be accompanied, Washington says, by reduction of [trade] barriers ...
One dimension: trade protectionism	The controls program, which Mr. Nixon inaugurated Aug. 15, 1971, has helped to reduce inflation to about 3 percent yearly, and to boost annual U.S. economic growth to more than 7 percent...

Table 1: Excerpts from news article #730567 in COHA (Davies, 2012). The first paragraph advocates for liberalism and the reduction of trade barriers. It also has a domestic economic dimension. The second paragraph, on the contrary, advocates for protectionism and a domestic controls program.

In contrast to studying the bias or the stance of the author of the text via linguistic framing (Kulkarni et al., 2018; Kiesel et al., 2019; Baly et al., 2019, 2020; Chen et al., 2020; Stefanov et al., 2020), we

---

* Equal contribution ordered by first name.

[1] We distinguish ourselves from work that considers other types of polarization, e.g., as a measure of emotional distance (Iyengar et al., 2019) or distance between political parties (Lauka et al., 2018).

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 231 - 243
July 10-15, 2022 ©2022 Association for Computational Linguistics

study the little explored angle that is nonetheless critical in political science research: **ideology of the issue (e.g., policy or concept) under discussion**. That is, in lieu of examining the author's stance, we focus on addressing the at-issue content of the text and the ideology that it represents in the implicit social context. The nuanced co-existence of stance and ideology can be illustrated in the following excerpt:

> *"Republicans and Joe Biden are making a huge mistake by focusing on cost. The implication is that government-run health care would be a good thing–a wonderful thing!– if only we could afford it."* (The Federalist, 9/27/2019)

The author is attacking a liberal social and economic policy; therefore, the ideology being discussed is liberal on two dimensions—social and economic, while the author's stance is conservative. Moreover, our novel approach acknowledges that ideology can also *vary* within one article. In Table 1, we show an example in which one part of an article advocates for trade liberalism, while another advocates for protectionism.

Together, author stance and ideology inform us not only that there is bias in the media, but also which beliefs are being supported and/or attacked. A full analysis of *polarization* (that reflects a growing distance of political ideology over time) can then be derived if *diachronic* data for both author stance and ideology were available. However, while there has been data for the former (with articles from recent years only) (Kiesel et al., 2019), to date, there has been no temporal data on the latter.

In this paper, we present a multi-dimensional framework, and an annotated, diachronic, stance-neutral corpus, for the analysis of ideology in text. This allows us to study polarization as a *state* of ideological groups with divergent positions on a political issue as well as polarization as a *process* whose magnitude grows over time (DiMaggio et al., 1996). We use proclaimed center, center-left and center-right media outlets who claim to be objective in order to focus exclusively and more objectively on the ideology of the issue being discussed, without the subjectivity of author stance annotation. We study ideology within every paragraph[2] of an article and aim to answer the following question: which ideological dimension is present and to which ideological position does it correspond to on the liberal-conservative spectrum.

Our extensive annotation manual is developed by a political scientist, and the data then annotated by three linguists after an elaborate training phase (Section 3). After 150 hours of annotation, we present a dataset of 721 *fully adjudicated* annotated paragraphs, from 175 news articles and covering an average of 7.86 articles per year (excerpts shown in Tables 1, 2, and 3). These articles originate from 5 news outlets related the US Federal Budget from 1947-1975 covering the center-left, center, center-right spectrum: Chicago Tribune (CT), Christian Science Monitor (CSM), the New York Times (NYT), Time Magazine (TM), and the Wall Street Journal (WSJ).

With this data, we reveal lexical insights on the language of ideology across the left-right spectrum and across dimensions. We observe that linguistic use even at word level can reveal the ideology behind liberal and conservative policies (Section 4). Our framework also enables fine-grained, quantitative analysis of polarization, which we demonstrate in Section 5. This type of analysis, if scaled up using accurate models for ideology prediction, has the potential to reveal impactful insights into the political context of our society as a whole.

Finally, we present baselines for the automatic identification of multi-dimensional ideology at the paragraph level (Section 6). We show that this is a challenging task with our best baseline yielding an F measure of 0.55; exploring pre-training with existing data in news ideology/bias identification, we found that this task is distinct from, although correlated with, labels automatically derived from news outlets. *We contribute our data and code at* `https://github.com/bernovie/political-polarization`.

2 Setup

Many political scientists and political psychologists argue for the use of *at least* a bidimensional ideology for domestic politics that distinguishes between economic and social preferences (Carsey and Layman, 2006; Carmines et al., 2012; Feldman and Johnston, 2014).[3] We start with these

---

[2] We use automatically segmented paragraphs since the raw texts were not paragraph-segmented.

[3] It is important to distinguish between ideology and several other concepts. (1) **Partisanship** (party identity) (Campbell et al., 1980): a partisan person changes their ideology when their party changes its ideology, whereas an ideological person changes their party when their party changes its ideology. Partisanship is easily conflated with party ID using a unidimensional conceptualization of ideology, but not with a multi-dimensional one. (2) **Moral foundations**: Haidt et al. (2009) gave an evolutionary explanation of how human

two dimensions while adding a third dimension, "Foreign", when the article tackles foreign issues.

Specifically, our **annotation task** entails examining a news article and annotating each dimension (detailed below) along three levels—*liberal, conservative, neutral*—for each paragraph. The neutral level for every dimension is reserved for paragraphs related to a specific dimension but either (a) contain both conservative and liberal elements that annotators were unable to ascertain an ideological dimension with confidence, or (b) do not portray any ideology. We additionally provide an *irrelevant* option if a dimension does not apply to the paragraph. The three dimensions are:

Social: While the *(1) socially conservative* aspect of this dimension is defined as respect for tradition, fear of threat and uncertainty, need for order and structure, concerns for personal and national security, and preference for conformity, its *(2) socially liberal* counterpart has been associated with a belief in the separation of church and state, tolerance for uncertainty and change (Jost et al., 2009).

Economic: Similarly, while the *(3) economically conservative* aspect of this dimension refers to motivations to achieve social rewards, power, and prestige such as deregulation of the economy, lower taxes and privatization (i.e., being against deficit) spending and advocating for a balanced budget, its *(4) economically liberal* counterpart refers to motivation for social justice and equality such as issues related to higher taxes on rich individuals and businesses and more redistribution.

Foreign: After piloting the bidimensional approach on 300 articles, we find that using only 2 dimensions conflates two important aspects of ideology related to domestic economy and foreign trade. Tariffs, import quotas, and other nontariff-based barriers to trade that are aimed at improving employment and the competitiveness of the US on the international market did not map well onto the bidimensional framework. After consulting several senior political scientists, we adopted a third dimension that dealt with the markets as well as the relations of the US with the rest of the world. While the *(5) globalist* counterpart of this dimension accounts for free-trade, diplomacy, immigration and treaties such as the non-proliferation of arms, its *(6) interventionist* aspect is nationalist in its support for excise tax on imports to protect American jobs and economic subsidies and anti-immigration.

With the annotated data, we demonstrate quantitative **measures of polarization** (Section 5) and introduce the **modeling task** (Section 6) of automatically identifying the ideology of the policy positions being discussed.

3 Data collection and annotation

Raw data Since polarization is a *process* that needs to be analyzed *over time* (DiMaggio et al., 1996), our annotated articles are sampled from a diachronic corpus of 1,749 news articles across nearly 3 decades (from 1947 till 1974). Articles in this corpus are from political news articles of Desai et al. (2019) from the Corpus of Historical American English (COHA, Davies (2012)) covering years 1922-1986. These 1,749 articles are extracted such that: (1) they cover broad and politically relevant topics (ranging from education and health to economy) but still share discussions related to the federal budget to make our annotations tractable[4]; (2) balanced in the number of articles across 5 news outlets with center-left, central, and center-right ideology (c.f. Section 5): Chicago Tribune (CT), Wall Street Journal (WSJ), Christian Science Monitor (CSM), the New York Times (NYT), and Time Magazine (TM). A detailed description of our curation process is in Appendix A.

The raw texts were not segmented into paragraphs, thus we used Topic Tiling (Riedl and Biemann, 2012) for automatic segmentation. Topic Tiling finds segment boundaries again using LDA and, thus, identifies major subtopic changes within the same article. The segmentation resulted in articles with 1 to 6 paragraphs. The average number of paragraphs per article was 4.

Annotation process Our team (including a political science graduate student) developed an annotation protocol for expert annotators using definitions in Section 2. The annotation process is independently reviewed by four political science professors from two universities in the US who are not authors

---

morals, values and traits such as freedom, safety, harm, care, reciprocity, in-group loyalty, authority, equality are formed. Since, some scholars have used these traits to predict ideology whereas others have attempted to understand what traits unites people with the same ideology. (3) **Framing**: frames are used in many ways in political science. They can refer to different ways scholars describe the same information or when scholars talk about different aspects of a single problem (Chong and Druckman, 2007).

[4] Because federal budget stories touch on all aspects of the federal activity, this topic appeals to both liberal and conservative media and thus can provide a good testing ground to showcase our proposed ideological annotation method.

Two dimensions: socially and economically liberal	... Secretary of Defense Robert S. [Mc-Namara] threw his full support today behind the Administration's drive against poverty. ...Mr. Mc-Namara said : "It is the youth that we can expect to be the most immediate beneficiaries of the war on poverty." He said he was endorsing the "entire program" both as a citizen and as a member of the Cabinet. His endorsement came as his fellow Republicans in Congress continued to hammer away at parts of the Administration's antipoverty program. . . .
Two dimensions: socially and economically conservative	The antipoverty program, the Republicans insisted, would undercut the authority of the Cabinet members by making Sargent Shriver a "poverty czar." "I don't see how you can lie down and be a doormat for this kind of operation. "...

Table 2: Excerpts from article #723847 in COHA. Because the first paragraph calls for minimizing income inequality, it is socially liberal; and because advocating for such a program call for an budgetary expenditure, it is also has an economic liberal dimension. The second paragraph advocates for the exact opposites of the positions in the first paragraph. Therefore, it is socially and economically conservative. Sentences most relevant to these labels are highlighted.

Zero dimension	. . . "The committee is holding public hearings on President Eisenhower's Economic Report, which he sent to Congress last week. The Secretary's [Humphrey] appearance before the group provided an opportunity for political exchanges.
One dimension: economically liberal	Senators Paul H. Douglas of Illinois, J. W. Fulbright of Representative Wright Patman of Texas, all Democrats, were active in questioning Mr. Humphrey. The Democrats asserted that the Administration's tax reduction program was loaded in favor of business enterprises and shareholders in industry and against the taxpayer in the lowest income brackets. . . .
One dimension: economically neutral	Senator Fulbright .. declare[d] that the problem was to expand consumption rather than production. ... "Production is the goose that lays the golden egg," Mr. Humphrey replied. "Payrolls make consumers."

Table 3: Excerpts from article #716033 in COHA. The first paragraph is void of ideology. In the second paragraph the topic is anti tax reduction on businesses, thus it is economically liberal. The third paragraph is simultaneously economically conservative and liberal because one speaker is advocating for decreasing tax on businesses and asserting that production gives an advantage to businesses, the other is advocating for decreasing tax on the poor because they need the income and asserting that healthy businesses are the ones who pay salaries for the low income bracket worker.

of this paper; the research area of two of them is ideology and polarization in the US. We will release our full annotation interface, protocol, and procedure along with the data upon publication.

We sampled on average 7.86 articles per year for annotation, for a total of 721 paragraphs across 175 articles. We divided the annotation task into two batches of 45 and 130 articles, the smaller batch was for training purposes.

In addition to the political science graduate student, we recruited three annotators, all of whom are recent Linguistics graduates in the US. The training sessions consisted of one general meeting (all annotators met) and six different one-on-one meetings (each annotator met with another annotator once). During initial training, the annotators were asked to highlight sentences based on which the annotation was performed.

After the annotations of this batch were finalized, the annotators met with the political science student to create ground truth labels in cases of disagreement. Then, the three annotators received the second batch and each article was annotated by 2 annotators. This annotation was composed of two stages to account for possible subjectivity. In stage 1, each annotator worked on a batch that overlapped with only one other annotator. In stage 2, the two annotators examine paragraphs that they disagree, and met with the third annotator acting as consolidator to adjudicate. Tables 1. 3 and 2 are examples of adjudicated annotation in the data.

Agreement To assess the inter-annotator agreement of stage 1, we report Krippendorf's α (Hayes and Krippendorff, 2007) for each dimension for the 135 articles after training and before any discussion/adjudication: economic (0.44), foreign (0.68), social (0.39). The agreements among annotators for the economic and foreign dimensions are moderate & substantial (Artstein and Poesio, 2008), respectively; for social, the 'fair' agreement was noticed during annotation, and additional discussion for each paragraph was then held. Afterwards, 25 more articles were independently annotated and assessed with an α of 0.53. Although the agreements were not perfect and reflected a degree of subjectivity in this task, all dimensional labels were *adjudicated* after discussions between annotators. In total, creating this dataset cost $\sim$150 hours of manual multi-dimensional labeling.

Table 4: Dimensional label counts across all 721 paragraphs in the adjudicated data (there can be multiple dimensions per paragraph).

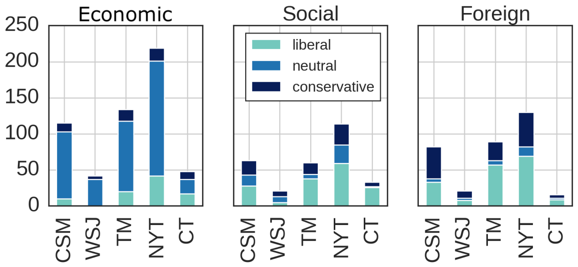

Figure 1: Dimensional label distribution per outlet.

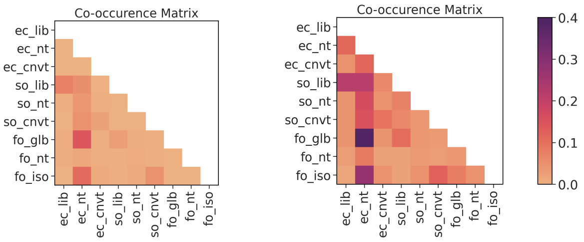

Figure 2: Co-occurrence matrices on the paragraph level (left) and article level (right)

Qualitative analysis of text highlights For the 25 articles used in training, all annotators highlighted the sentences that are relevant to each dimension they annotated. This helped annotators to focus on the sentences that drived their decision, and provided insights to the language of ideology, which we discuss here. On average, 21%–54% of the sentences in a paragraph were highlighted.

We found entities such as “President" and "Congress" were the most prevalent in the highlights, and they tackled social and economic issues combined. This is not surprising as it suggests that when the media quotes or discusses the “President" and “Congress", they do so with reference to more complex policy issues. In contrast, individual congresspeople tackled mostly economic or social issues. This also is not surprising as it suggests that individual congresspeople are more concerned with specific issues. Interestingly, “House" and “Senate" almost always figured more in social issues. This suggest that when news media speaks about a specific chamber, they do so associating this chamber with social issues. Finally, party affiliation was infrequent and was mostly associate with social issues.

4 Ideology analyses

The number of paragraphs per dimension in total is: **Economics (558), Social (291), Forign (338)**, across the 175 articles. In Table 4 we tabulate this for each of the news outlets. Figure 1 shows the dimensional label distributions per outlet for each dimension. Expectedly, the dimensional labels often diverge from proclaimed ideology of the news outlet.

We also analyze the percentage of articles that contain at least one pair of paragraph labels that lean in different directions; for instance, a paragraph with a label of globalist (i.e., liberal) in the foreign dimension and another paragraph with a label of conservative or neutral in the fiscal dimension. The percentage of such articles is 78.3%. Out of these articles, we examine the average proportion of neutral, liberal, and conservative paragraph labels, and find neutral labels have the highest share (43.27%), followed by liberal (33.20%) and conservative (23.53%). In Figure 2 (right), we visualize the percentage of articles where two dimensional labels co-occur within the same article. The figure indicates that ideology varies frequently within an article, showing that a single article-level label will not be fine-grained enough to capture variances within an article.

In Figure 2 (left) we also show paragraph-level label co-occurrence. Unlike the article-level, the co-occurrences are less frequent and we are more likely to observe co-occurrences along the same side of ideology. Still, we see interesting nuances; for example, on both the paragraph and the article level, the economic dimension is often neutral, and this tends to co-occur with both liberal and conservative positions in other dimensions.

Lexical analysis To understand ways ideology is reflected in text, we also look into the top vocabulary that associates with conservative or liberal ideology. To do so, we train a logistic regression model for each dimension to predict whether a paragraph is labeled conservative or liberal on that dimension, using unigram frequency as features. In Table 5 we show the top most left-leaning (L)

Economic	**C:** mr (5.2), tax (5.0), truman (3.7), business (3.3), billion (3.2) **L:** school (-4.3), education (-3.3), commission (-3.2), senator (-3.0), plan (-2.5)
Social	**C:** defense (7.5), tax (4.6), air (4.4), billion (3.9), missile (3.8) **L:** federal (-3.6), wage (-3.6), would (-3.5), policy (-3.2), labor (-2.9)
Foreign	**C:** defense (6.9), force (5.3), north (5.2), air (5.0), vietnam (4.6) **L:** aid (-9.3), economic (-5.5), foreign (-5.3), germany (-4.3), make (-4.1)

Table 5: Words with the most positive and negative weights from a logistic regression model trained to predict liberal/conservative ideology for each dimension.

or right-leaning (R) vocabulary with their weights. The table intimately reproduces our annotation of ideology. For example, words like federal and Senator allude to the fact that the topic is at the federal level. The importance of education and labor to liberals is also evident in the economic and social dimensions in words like school, education, and wage. The importance of the topic of taxation and defense is evident in conservative ideology in words such as tax, business, missile, and force.

5 Polarization

In this section, we demonstrate how our framework can be used to analyze ideological polarization, quantitatively. To say that two groups are polarized is to say that they are moving to opposite ends of an issue on the multi-dimensional ideological spectrum while, at the same time, their respective political views on ideological issues converge within a group, i.e. socially liberals become also economically liberal (Fiorina and Abrams, 2008). In political science when ideology is multidimensional, polarization is often quantified by considering three measures that capture complementary aspects (Lelkes, 2016): (1) **sorting** (Abramowitz and Saunders, 1998) (the extent to which the annotated ideology deviates from an outlet's proclaimed ideological bias); (2) **issue constraint** (Baldassarri and Gelman, 2008) (a correlational analysis between pairs of ideological dimensions); (3) **ideological divergence** (Fiorina and Abrams, 2008) (the magnitude of the distance between two groups along a single dimension). Together these measures describe changes in the ideological environment over time: a *concurrent* increase in all three measures indicates polarization in media.

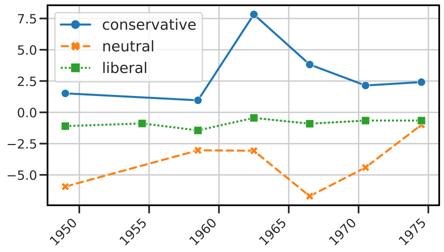

Figure 3: The evolution of the sorting measure, aggregating conservative/neutral/liberal outlets. Moving further away from the zero means articles deviate more from the proclaimed ideology of their outlets.

Limitations: We use only the fully adjudicated data and refrain from using model predictions, since our baseline experiments in Section 6 show that predicting ideology is challenging. Hence, the analysis are demonstrations of what our framework *enables*, which we discuss at the end of this section, and the conclusions are drawn for our annotated articles only. We group our data in four-year periods to reduce sparsity.

Measure 1: Sorting We adapt the sorting principle of Abramowitz and Saunders (1998) to our data and investigate the difference between the proclaimed ideological bias of a news outlet and the ideology of annotated articles from the outlet. To obtain the bias B_j of a news outlet j, we average the ratings of each news outlet across common sites that rates media bias (Adfontes, Allsides, and MBFC), yielding: **CSM (-0.07), CT (0.15), NYT (-0.36), TM (-0.4), WSJ (0.32)** (c.f. Table 8 in Appendix B for ratings from each site).

To obtain the overall ideology $I_i^{(j)}$ of article i from outlet j, we take the average of liberal (-1), neutral (0), and conservative (1) labels across its paragraphs in all three dimensions. Thus, for each 4-year time period with m articles for outlet j, the sorting measure would be the absolute distance of article vs. outlet ideology $|\text{avg}_{i=1}^{m}(I_i^{(j)}) - B_j|/B_j$.

In Figure 3, we plot the sorting measure, averaged across news outlets of the same proclaimed ideological bias. The figure shows that in our sample of articles, the left-leaning news outlets were closest to their proclaimed ideological bias measure over time, whereas the neutral outlets were more liberal before 1957 and after 1964. The right-leaning outlets were more conservative at that time than their proclaimed ideological bias.

Measure 2: Issue constraint This measure refers to the tightness between ideological dimen-

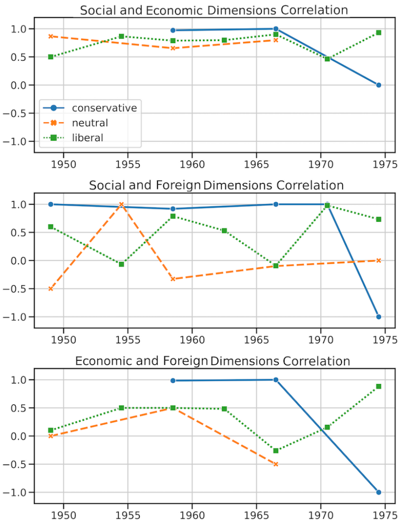

Figure 4: The evolution of the issue constraint measure, stratified by pairs of dimensions. Higher values mean some dimensions correlate more strongly than others. Due to the lack of articles that simultaneously contains social & economic dimensions (1st graph), and economic & foreign dimensions (3rd graph) from conservative outlets their respective blue lines start in 1958.

sions over time (Baldassarri and Gelman, 2008) so as to assess, for example, if socially liberal dimensions are more and more associated with economic liberal dimensions for the news outlets. Concretely, for each article we derive its ideology along a single dimension as the average of paragraph annotations along that dimension. We, then, calculate the Pearson correlation between the article ideology of each pair of dimensions, over all articles from one outlet in the same period.

Results in Figure 4, again averaged across news outlets of the same ideological bias, show that for right-leaning media, the correlation between any two dimensions in the annotated data are largely positive (e.g., economically conservative were also socially conservative) until 1967 or 1970. However, for proclaimed left-leaning and neutral outlets, the correlations fluctuates especially when considering the foreign dimension.

Measure 3: Ideological divergence This measures the distance between two ideological groups on a single dimension (Fiorina and Abrams, 2008). We follow Lelkes (2016) and calculate the bimodality coefficient (Freeman and Dale, 2013; Pfister et al., 2013) per dimension over articles from all news outlets over the same time period. The bimodality coefficient ranges from 0 (unimodal, thus not at all polarized) to 1 (bimodal, thus completely polarized).

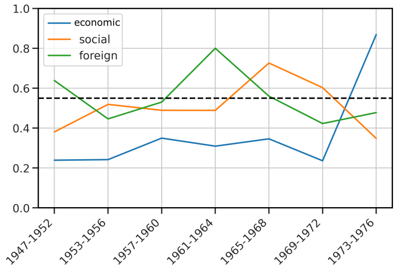

Figure 5: The evolution of the ideological divergence measure stratified by dimension. The dotted line refers to the bimodality threshold (Lelkes, 2016). Higher values mean the ideology of an article along that one dimension is bimodal.

Figure 5 shows the evolution of the ideological divergence measure of every dimension. A bimodality measure assesses whether this divergence attained the threshold for the cumulative distribution to be considered bimodal. Ideological distance, as a result, refers to the three bimodal coefficients. We note, for example, that the foreign dimension crossed this threshold between 1956 and 1968. This means that proclaimed left-leaning and right-leaning outlets grew further apart on foreign issues during this time period.

Discussion Taken together, the graphs indicate that the years between 1957 and 1967 are the most noteworthy. During this period, from our sample of articles, we see that polarization was only present in conservative news media because it (1) sorted, as it was significantly more conservative than its composite bias measure, (2) constrained its issues, as evidence by high positive correlation values, and (3) became increasingly bimodal, as the ideological distance between their positions and those of their liberal counterpart on foreign issues increased over time. While this conclusion applies to only the set of articles in our dataset, the above analysis illustrates that our framework enables nuanced, quantitative analyses into polarization. We leave for future work, potentially equipped with strong models for ideology prediction, to analyze the data at scale.

6 Experiments

We present political ideology detection experiments as classification tasks per-dimension on the paragraph level.

We performed an 80/10/10 split to create the train, development, and test sets. The development and test sets contain articles uniformly distributed from our time period (1947 to 1974) such that no particular decade is predominant. To ensure the integrity of the modeling task, all paragraphs belonging to the same article are present in a single split. The number of examples in the splits for each dimension for the adjudicated data are as follows: for the economic dimension, we had 450 training, 50 development, and 58 test examples. For the social dimension, we had 253 for training, 13 for development, and 25 for testing. For the foreign dimension, we had 266 for training, 33 for development, and 39 for testing.

6.1 Models

Recurrent neural networks We trained a 2-layer bidirectional LSTM (Hochreiter and Schmidhuber, 1997), with sequence length and hidden size of 256, and 100D GloVe embeddings (Pennington et al., 2014).

Pre-trained language models We used BERT-base (Devlin et al., 2019) from HuggingFace (Wolf et al., 2020) and trained two versions, with and without fine-tuning. In both cases we used a custom classification head consisting of 2 linear layers with a hidden size of 768 and a ReLU between them. To extract the word embeddings we followed Devlin et al. (2019) and used the hidden states from the second to last layer. To obtain the embedding of the whole paragraph[5] we averaged the word embeddings and passed this vector to the classification head.

To find the best hyperparameters we performed a grid search in each dimension. For the economic dimension, the best hyperparameters consisted of a learning rate of 2e-6, 6 epochs of training, a gamma value of 2, no freezing of the layers, a 768 hidden size, and 10% dropout. For the social dimension, the best hyperparameters were a learning rate of 2e-5, 12 epochs, a gamma of 4, no freezing of the layers, a 768 hidden size, and 10% dropout. Finally, for the foreign dimension the best hyperparameters consisted of a learning rate of 2e-5, 6 epochs, a gamma of 2, no freezing of the layers, a 768 hidden size, and a 10% dropout.

Focal loss. To better address the imbalanced label distribution of this task, we incorporated *focal loss* (Lin et al., 2017), originally proposed for dense object detection. Focal loss can be interpreted as a dynamically scaled cross-entropy loss, where the scaling factor is inversely proportional to the confidence on the correct prediction. This dynamic scaling, controlled by hyperparameter γ, leads to a higher focus on the examples that have lower confidences on the correct predictions, which in turn leads to better predictions on the minority classes. Since a γ of 0 essentially turns a focal loss into a cross entropy loss, it has less potential to hurt performance than to improve it. We found the best γ values to be 2 or 4 depending on the dimension.

	Econ	Social	Foreign	Average
Majority	0.30	0.23	0.25	0.26
BiLSTM	0.44	0.37	0.33	0.38
BERT no-ft	0.46	0.31	0.53	0.44
+pre-training	0.42	0.32	0.46	0.40
BERT ft	**0.64**	**0.50**	**0.52**	**0.55**
+pre-training	0.56	0.47	0.46	0.49
-focal loss	0.61	**0.50**	0.50	0.54

Table 6: Macro F1 of the models averaged across 10 runs.

Task-guided pre-training. We also explored supervised pre-training on two adjacent tasks that can give insights to the relationship between tasks. We used distant supervision that labeled the ideological bias of each article according to that of its news outlet from `www.allsides.com` (Kulkarni et al., 2018). This procedure allowed us to use the unannotated articles. [6]

6.2 Results

Table 6 shows the macro F1 for each configuration, averaged across 10 runs with different random initializations. The fine-tuned BERT model, with no task-guided pre-training shows the best performance across all 3 ideology dimensions. It is important to note that all the models do better than randomly guessing, and better than predicting the majority class. This shows that the models are capturing some of the complex underlying phenomena in the data. However, the classification tasks still remain challenging for neural models, leaving plenty of room for improvement in future work.

The *BERT ft -focal loss* setting ablates the effect of focal loss against a weighted cross entropy loss. with weights inversely proportional to the distribution of the classes in the dimension. This

---

[5] 99% of the paragraphs in the dataset have $\leq$512 tokens.

[6] We also experimented with pre-training on the dataset from Chen et al. (2020). However, because their dataset starts from 2006 (outside of our time domain), this setting performed poorly.

loss helped get a bump in the macro F1 score of around 0.1 for each dimension compared to an unweighted cross entropy loss. However, the focal loss gave further improvements for 2 of the 3 dimensions. Although task-guided pre-training improved the BERT (no fine-tuning) model for 1 of the 3 dimensions, it led to worse performance than BERT (fine-tuned). The improvement on the no fine-tuning setting indicates that there is a potential correlation to be exploited by the ideology of the news outlet, but such labels are not that informative for multi-dimensional prediction. We hope that this dataset provides a testbed for future work to evaluate more distant supervision data/methods.

7 Related work

In contrast to our multi-dimensional approach that examines the ideology of the issue being discussed instead of the author stance, much of the recent work in computational linguistics has been dedicated to the latter (detection of ideological bias in news media) while collapsing ideology to one dimension (Budak et al., 2016; Kulkarni et al., 2018; Kiesel et al., 2019; Baly et al., 2019, 2020; Chen et al., 2020; Ganguly et al., 2020; Stefanov et al., 2020). The proposed computational models classify the partiality of media sources without quantifying their ideology (Elejalde et al., 2018).

Other researchers interested in the computational analysis of the ideology have employed text data to analyze congressional text data at the legislative level (Sim et al., 2013; Gentzkow et al., 2016) and social media text at the electorate level (Saez-Trumper et al., 2013; Barberá, 2015).

In political science, the relationship between (news) media and polarization is also an active area of research. Prior work has studied media ideological bias in terms of coverage (George and Waldfogel, 2006; Valentino et al., 2009). Prior (2013) argues there is no firm evidence of a direct causal relationship between media and polarization and that this relationship depends on preexisting attitudes and political sophistication. On the other hand, Gentzkow et al. (2016) have established that polarization language snippets move from the legislature in the direction of the media whereas (Baumgartner et al., 1997) have shown that the media has an impact on agenda settings of legislatures.

8 Conclusion

We take the first step in studying multi-dimensional ideology and polarization over time and in news articles relying on the major political science theories and tools of computational linguistics. Our work opens up new opportunities and invites researchers to use this corpus to study the spread of propaganda and misinformation in tandem with ideological shifts and polarization. The presented corpus also provides the opportunity for studying ways that social context determines interpretations in text while distinguishing author stance from content.

This work has several limitations. We only focus on news whereas these dynamics might be different in other forms of communication such as social media posts or online conversations, and the legislature. Further, our corpus is relatively small although carefully annotated by experts. Future work may explore semi-supervised models or active learning techniques for annotating and preparing a larger corpus that may be used in diverse applications.

A Data curation

A diachronic corpus is required to measure and analyze polarization over time (DiMaggio et al., 1996). We collect and annotate data across a long period to address the issue of distributional shifts across years (Desai et al., 2019; Rijhwani and Preotiuc-Pietro, 2020; Bender et al., 2021) and help build robust models that can generalize beyond certain periods.

Additionally, the raw data on top of which we annotate needs to satisfy the following constraints: (1) for human annotation to be tractable, the articles should share some level of topical coherence; (2) for the data to be useful for the larger community, the content should also cover a range of common discussions in politics across the aisle; and (3) the articles should come from a consistent set of news outlets, forming a continuous and ideologically balanced corpus.

We start with the diachronic corpus of political news articles of Desai et al. (2019) which covers years 1922-1986, the longest-spanning dataset to our knowledge. This corpus is a subset of news articles from the Corpus of Historical American English (COHA, Davies (2012)). To extract topically coherent articles, we investigate the topics and articles across multiple LDA (Blei et al., 2003) runs varying the number of topics (15, 20, 30, 50), aiming to arrive at a cluster of topics that share common points of discussion and collectively will yield a sizable number of articles each year from the same news outlets.

The LDA models consistently showed one prominent topic—the federal budget—across 5 news outlets with balanced ideology (c.f. Table 8): Chicago Tribune (CT), Wall Street Journal (WSJ), Christian Science Monitor (CSM), the New York Times (NYT), and Time Magazine (TM). Because federal budget stories touch on all aspects of the federal activity, this topic appeals to both liberal and conservative media and thus can provide a good testing ground to showcase our proposed ideological annotation method. In addition to the core federal budget topic (topic 5 of Table 7), we also include other topics such as health and education that are integral parts of ideological beliefs in the United States, and when discussed at the federal government level, are typically related to the federal budget. The top vocabulary of the cluster is shown in Table 7. In an effort to purge articles unrelated to the federal budget, we selected only those that contain words such as "federal" and "congress", and excluded those that mention state budget, and letters to editors. (Note that during annotation, we also discard articles that are unrelated to the federal budget.) After this curation, the total number of articles is 5,706 from the 5 outlets.

Topic1: Trade	bank, market, farm, loan, export, agricultur, farmer, dollar, food, debt
Topic2: Business	incom, tax, revenu, profit, corpor, financ, treasuri, pay, sale, bond
Topic3: Education	school, univers, educ, student, colleg, professor, institut, teacher, research, graduat
Topic4: Defense	nuclear, missil, weapon, atom, test, energi, strateg, bomb, space, pentagon
Topic5: Economy	budget, billion, economi, inflat, economic, deficit, unemploy, cut, dollar, rate
Topic6: Health/Race	negro, hospit, medic, health, racial, southern, discrimin, doctor, contra, black
Topic7: Industry	compani, contract, plant, steel, coal, wage, railroad, corpor, manufactur, miner

Table 7: Top words from topics selected in our cluster, from the 50-topic LDA model that yielded the most well-deliminated topics.

To account for the sparsity of articles in the first decades and their density in later decades, we narrowed down the articles to the period from 1947 to 1974. We believe this period is fitting because it includes various ideological combinations of the tripartite composition of the American government, Congress and presidency.[10] The total number of articles in the final corpus of political articles on the federal budget from 1947 to 1974 is 1,749.

B Proclaimed ideology of news outlets

	Adfontes	Allsides	MBFC	*Average*
CSM	-.06	0.00	-.16	-.07
CT	-.04	NA	.34	.15
NYT	-.20	-.5	-.4	-.36
TM	-.10	-.5	-.6	-.4
WSJ	.15	.25	.58	.32

Table 8: Ideological bias of news outlets from common references of media bias. We use the average in our analyses.

Abstract

Pretrained language models have significantly improved the performance of downstream language understanding tasks, including extractive question answering, by providing high-quality contextualized word embeddings. However, training question answering models still requires large amounts of annotated data for specific domains. In this work, we propose a cooperative self-training framework, RGX, for automatically generating more non-trivial question-answer pairs to improve model performance. RGX is built upon a masked answer extraction task with an interactive learning environment containing an answer entity **R**ecognizer, a question **G**enerator, and an answer e**X**tractor. Given a passage with a masked entity, the generator generates a question around the entity, and the extractor is trained to extract the masked entity with the generated question and raw texts. The framework allows the training of question generation and answering models on any text corpora without annotation. We further leverage a self-training technique to improve the performance of both question generation and answer extraction models. Experiment results show that RGX outperforms the state-of-the-art (SOTA) pretrained language models and transfer learning approaches on standard question-answering benchmarks, and yields the new SOTA performance under given model size and transfer learning settings.

1 Introduction

Recent studies have shown that language model pretraining provides high-quality text representations and significantly improves neural networks' performance on a variety of natural language processing (NLP) tasks (Peters et al., 2018). Based on the popular Transformer architecture (Vaswani et al., 2017), various language models have been proposed (Devlin et al., 2018; Liu et al., 2019; Clark et al., 2020). These models are pretrained to predict a masked word in a given context from large corpora, and generate a contextual representation that encodes semantic and syntactic information. After finetuning, these representations significantly improve performance on downstream NLP tasks. Although masked language modeling is a powerful self-supervised learning technique, annotation on large-scaled data is still necessary for finetuning on difficult downstream tasks, including extractive question answering (QA)[1] where a large number of labeled question-answer pairs are required as a training corpora.

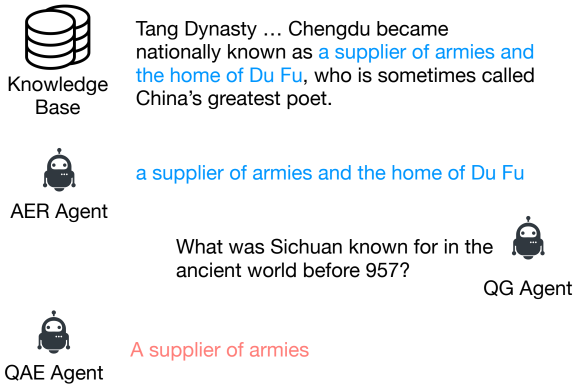

Figure 1: The pipeline of semi-supervised question answering (machine reading comprehension) by RGX. AER (answer entity **R**ecognition) agent recognizes answer entity from a given passage; QG (question **G**eneration) generates a question based on the passage and entity; QAE (question-answering e**X**tractor) extracts answer from the question and passage.

Previous studies showed that the QA models can be improved by training on synthetic question-answer pairs, namely self-training (Sachan and Xing, 2018; Puri et al., 2020; Shakeri et al., 2020; Bartolo et al., 2021). The core step of these work is pretraining a question-answer pair synthesis model on a seed corpus, and apply the generator on target

---

* Work is not related to the employment of the second and fourth authors at Meta and Amazon

[1] Also referred to as machine reading comprehension. The two terms are used interchangeably in this paper.

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 244 - 257
July 10-15, 2022 ©2022 Association for Computational Linguistics

domains to obtain synthetic training data. The QA model learns domain knowledge after finetuning on the synthetic data, and thus the domain adaptation is improved. However, the gap between the pretraining (i.e., seed) and the target corpus still exists, in terms of domain knowledge, question difficulty, and language style. The gap affects the quality of the synthetic training data.

We thus propose a framework that allows cooperative self-training for both QA pair synthesis and question answering to better adapt the synthesis models to the target domain and improve the learning of the QA models. In the framework, we construct a cooperative environment where a question generator and an answer extractor work together to solve a masked entity prediction problem. We first leverage an entity recognizer to mask out an entity in a provided passage. The question generator then outputs a question based on the masked passage. With the generated question and the original, unmasked passage, we train the answer extractor to select the correct answer spans, which are the masked entity. The extractor is also the final model used for extractive QA. To extract the spans accurately, the generator has to provide a good question, and the extractor should select the most likely tokens. We apply an expectation-maximization algorithm to select high-quality QA pairs and update both question generation and answer extraction models to improve the quality of synthetic data and the accuracy of the self-trained QA model based on synthetic QA pairs. We call our algorithm RGX since it incorporates an answer entity **R**ecognizer, a question **G**enerator, and a question-answering e**X**tractor. The RGX pipeline is illustrated in Figure 1.

With RGX, we can train a QA model for any unlabeled target domain given the corresponding text corpora and a labeled QA corpus in a seed domain (either the same or different from the target). By training QA models on synthetic QA data generated by RGX and evaluating the trained model on human-labeled evaluation data, we show that RGX outperforms SOTA approaches in QA benchmark datasets when domain specific human labels are not available during finetuning. In this work, we make the following contributions:

1. We propose a cooperative self-training framework, RGX, which contains an answer entity recognition, question generation, and answer span extraction to automatically generate nontrivial QA pairs on unlabeled corpora.
2. We design a expectation-maximization (EM) synthetic QA selection that identifies difficult but answerable questions without supervision to incrementally train the QA model with challenging examples, and an answer entity recognition (AER) based maximum mutual information (MMI) inference method for question answering.
3. Experiments show that our method significantly outperforms SOTA pretrained QA models and self-training QA baselines.

2 Related Work

Reinforcement learning and self-training have emerged recently for learning language generation in addition to maximum likelihood training. To optimize text generation models directly with non-differentiable objective functions, Rennie et al. (2017) proposed self-critical sequence training (SCST) using a policy gradient (Kakade, 2001; Silver et al., 2014). On the other hand, self-training has been shown to be effective in many tasks, such as machine translation (He et al., 2019), image classification (Xie et al., 2020), and structured database-grounded question answering (Xu et al., 2020).

In the domain of question answering, a question generator can be used for joint answer prediction (Tang et al., 2017; Duan et al., 2017), and synthetic QA data are used for in-domain data augmentation (Sachan and Xing, 2018; Puri et al., 2020; Liu et al., 2020; Klein and Nabi, 2019) and out-of-domain adaptation. Lewis et al. (2019b) and Lee et al. (2020) introduced models for question answering under unsupervised/zero-shot settings. Shakeri et al. (2020) proposed generating synthetic question-answer pairs with an end-to-end model simultaneously. Bartolo et al. (2021) improved the question synthesis by training with difficult QA cases from the AdversarialQA corpus (Bartolo et al., 2020) and fine-grained answer synthesis by multi-model voting. We include more related studies in Appendix A.

In this work, we mainly compare our method with latest baselines, Shakeri et al. (2020) and Bartolo et al. (2021) that reported results on out-of-domain adaptation. Besides improved QA performance, our framework, RGX, differs from the previous work in the following aspects: (1) Our method features reinforced finetuning of the QA

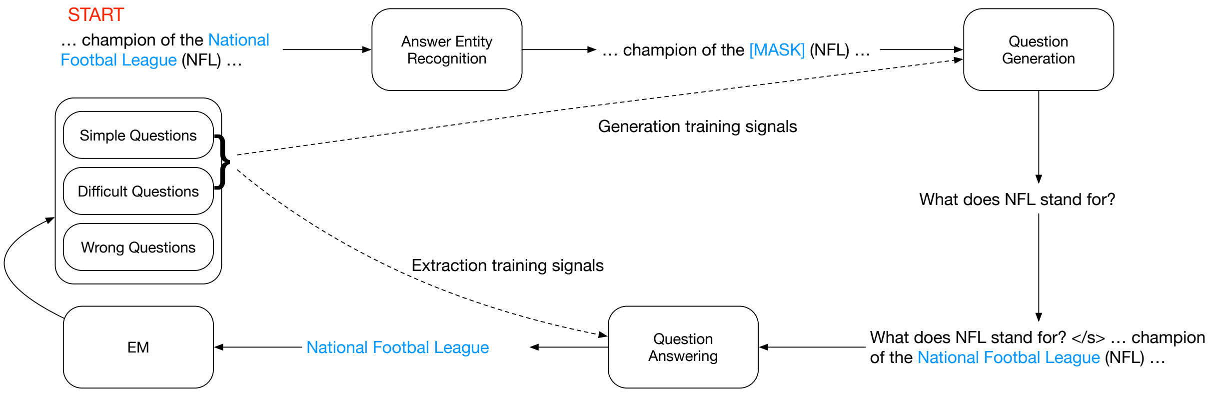

Figure 2: The cooperative learning pipeline for question answering. The pipeline starts from a passage and follows the steps: (1) recognizing a potential answer entity, (2) generating a question asking about the answer entity, and (3) answering the question by extracting the answer span in the passage.

Synthesizer, (2) Our framework supports and improves maximize mutual information inference in test time, and (3) Our work did not use complicated data annotation, e.g. AdversarialQA.

3 RGX Framework

In this section, we first introduce (1) the QA synthesis pipeline, (2) cooperative self-training for both QA synthesis and question answering, and (3) an improved maximum mutual information inference strategy. The self-training pipeline of RGX is shown in Figure 2.

3.1 Data Synthesis

Given a passage p, our goal is generating a set of questions q and answers a for the self-training of the QA model. The RGX model first recognize potential answer entities (AE) in p with an answer entity recognition (AER) model, and then generate question based on the recognized AEs with a question generation (QG) model, and fine-grain the AEs with a pretrained question-answering extraction (QAE) model.

3.1.1 Answer Entity Recognition (AER)

Latest QA synthesis models, QAGen2S (Shakeri et al., 2020) and SynQA (Bartolo et al., 2021), directly generate questions from passages by modeling $P_{qg}(q|p)$. In RGX, we first recognize all potential answer entities in a passage before generating questions for (1) increasing question diversity and coverage, and (2) modeling the mutual information between question generation and answering models in test time. The AER model in trained on the seed QA corpus.

We found that using an off-the-shelf named entity recognition (NER) model pretrained on the CONLL 2003 shared task (Bender et al., 2003) performs poorly as a AER model (shown in our experiments). To learn an effective recognizer, given a passage p and an annotated answer entity e, we select the sentence s containing e from p and train language models to recognize e in s. We tried two models for this task: a BIO sequence tagging model (AER-Tag) and a extractive AER model, which is similar to an extractive question answering model, for easier decoding. The model predicts the start and end positions of the answer entity e. With this method, we get potential answer entities by probabilities of all candidate spans.

3.1.2 Masked Question Generation

With AER, we replace the answer entity e in the passage p with a [MASK] token and obtain the masked passage p^*. We then build a question generator Q (denoted as QG interchangeably) that outputs answerable questions q in natural language with the concatenation of p^* and e as input, i.e., $q = Q([p^*, e])$. We adopt the BART sequence-to-sequence model (Lewis et al., 2019a) as the architecture of Q in our implementation, and we train Q on the question-answer pairs in the seed corpus by maximizing the likelihood of annotated questions.

3.1.3 Answer Extraction as Fine-grained AER

The answer extraction model A (denoted as QAE, question-answering extractor) takes generated question q and the original passage p as inputs. Following the standard extractive QA method, we predict the answers by

$$I_{st}, I_{ed} = A([q, p]) \qquad (1)$$

where I_{st} and I_{ed} stand for the start and end positions of e in p, respectively. We train the QAE model to predict I_{st} and I_{ed} separately with cross entropy losses.

Besides being trained with synthetic QA pairs and evaluated for the final QA performance, the QAE model is also a part of the data synthesis pipeline. After generating questions with the QG model, we use a pretrained QAE model to answer the generated questions. The QAE model recognizes better answers spans than the AER model since it takes questions as additional inputs. As a result, the final synthetic dataset is constructed by selecting generated questions and their corresponding QAE outputs. However, we still found the AER model necessary for generating diverse questions.

3.2 Cooperative Self-training

Although the pretrained models can generate synthetic QA pairs from corpora in unseen domains, there is always a domain shift from the seed QA corpus for pretraining to the target. To efficiently adapt the pretrained models to the new domains, we propose a cooperative self-training algorithm that allows finetuning on the target corpora without additional annotations. The finetuning is based on a three-agent (AER, QG, QAE) cooperative framework, RGX. The pipeline is illustrated in Figure 2 and comprises the following steps:

1. Produce a masked passage by replacing an answer entity selected by AER with the '[MASK]' token.
2. Generate a question asking about the masked entity.
3. Feed the generated question and the original passage into the QAE to predict an answer span.
4. Optimize the QAE model with selected QA pairs.
5. Optimize the QG model with selected QA pairs.

In the proposed pipeline, all the AER, QG, and QAE models need pretraining to provide a reasonable start point for the cooperative self-training. However, the domain gap between the pretraining and the target corpus causes performance degradation. To mitigate the gap, we propose to measure the quality of generated questions and incorporate the measurement in loss functions. The quality is defined in two folds, correctness and difficulty. Firstly, the question should be fluent and answerable, and secondly, it should not be too trivial. To automatically select high-quality generated QA pairs, we introduce a expectation-maximization (EM) method based on QAE losses that learns the question quality without supervision.

3.2.1 Synthetic QA Selection with EM

To select synthetic QA pairs for finetuning, we first divide the generated questions based on the QAE loss for each question into three groups: low-, medium-, and high- loss questions. We can interpret questions with low loss as simple ones that the QAE model can easily answer. Medium-loss questions are challenging for the QAE, while those with high loss usually contain noise (e.g., containing grammatical errors or asking about incorrect answers). If we train the answering model with all questions, the training signal would be very noisy due to the high-loss questions. If we only reward questions that are correctly answered, the generator will converge to a trivial local optima. Thus, we train the QG and QAE model with the low- and medium- loss questions, namely simple and challenging questions. For the entire pipeline to be fully-automatic, we classify a given QA pair into one of the three types described above. Note that simply setting the thresholds as hyper-parameters is difficult since the loss decreases as the QAE model varies with different passages and domains. In order to find the thresholds adaptively, we apply an expectation-maximization (EM) algorithm to bucket synthetic QA pairs for each passage.

We finetune both QG and QAE models with the selected simple and challenging QA pairs. After the training, re-running the RGX pipeline with the finetuned question generation model leads to improved data synthesis. Training the QAE model on the updated synthetic dataset can significant outperform the previous finetuned QAE model.

3.2.2 Maximum Mutual Information QA

Li and Jurafsky (2016) proposed a maximum mutual information (MMI) decoding method for machine translation, and Tang et al. (2017) proposed a MMI method for jointly learning question generation and answering models. There is no previous study to our knowledge that applies MMI inference in test time of question answering that improves the final performance, because (1) modeling $P(q|p, a)$ for all possible answers (spans) a is too inefficient, and (2) Unlike the QAE model that receives loss signals from all words in a given passage, the QG model does not receive loss signal from the passage directly, so $P_{qg}(q|p, a)$ it is less accurate for ranking answer spans.

However, the AER and self-training strategy enable efficient MMI inference for QA,

$$a = \underset{a}{\operatorname{argmax}}[\alpha \log P_{qg}(q|p,a) + \beta \log P_{qa}(a|p,q)]$$

In test time, we run the RGX pipeline for each passage without additional training to get fine-grained AEs and corresponding questions. On the other hand, we take the top span predicted by the QAE model, and the top-k answer entities spans recognized by the RGX pipeline. In practice, we fix $\beta = 1$. We used an adaptive α value by comparing the synthetic question generated by the QG model and the input question. For each answer entity a, we calculate

$$\alpha = \mathtt{max}(1 - \mathtt{abs}(\frac{q_{input}}{q_{gen}} - 1), 0.1)$$

This value normalizes the question probability $p(q|p,a)$ estimated by the QG model, since generated questions from some answer entities is easier than other spans in the same passage, which makes the QG model assign all natural questions a relative low perplexity.

4 Experiments

In this work, we train three modules for building the cooperative self-training environment RGX, i.e., the answer entity recognizer (AER), the question generator (QG), and the question-answering extractor (QAE). We used a BERT (Devlin et al., 2018) model for AER, a BART (Lewis et al., 2019a) model for QG, and an ELECTRA (Clark et al., 2020) model for AER and QAE. To compare with the results reported in Shakeri et al. (2020) and Bartolo et al. (2021), we (1) pretrain question generation and answering models on the seed corpora, (2) generate synthetic QA data on the target domains, (3) finetune QA models with synthetic data, and (4) evaluate the finetuned QA model on human-labeled evaluation sets. The source code and demo are publicly available[2].

4.1 Data

In our experiment work, we leveraged Natural Questions (Kwiatkowski et al., 2019) and SQuAD v1.1 (Rajpurkar et al., 2016) as the seed corpora for pretraining all modules introduced above. To evaluate the performance of the proposed RGX on question answering tasks with different difficulty levels, we conduct experiments on both SQuAD v1.1 (Rajpurkar et al., 2016) and MRQA (Fisch et al., 2019) out-of-domains (BioASQ, TextbookQA, RACE, RelationExtraction, DuoRC, and DROP). In the following sections, we use the term SQuAD to represent the SQuAD v1.1 corpus. For self-training, we sample 3000 passages from the training set of each corpus for data synthesis. More details about the data are provided in Appendix B

4.2 Implementation Details

Pretraining. We pretrain the AER, QG, and QAE models on NaturalQuestions and SQuAD (i.e., the seed) corpora. For NaturalQuestions, we only use the data points containing a short answer. For Cooperative training, we follow the steps described in Section 3.2 for the cooperative training phase.

Self-training. We apply self-training for QG and QAE by finetuning the models on selected synthetic QA pairs using the same method as pretraining. The AER model is fixed after pretraining. The QAE model is finetuned using the official Huggingface (Wolf et al., 2019) training scripts for question answering. We will open-source the RGX framework if the submission is accepted.

Hyperparameters. There are three phases of model training in this work: pretraining on the seed corpora, cooperative adaptation with self-training on the target corpora, and final finetuning on the synthetic data. We adopt most of the hyper-parameters reported in the original BERT (Devlin et al., 2018), BART (Lewis et al., 2019a), and ELECTRA (Clark et al., 2020) papers. We select the final finetuning learning rates from $\{3e-5, 4e-5, 5e-5\}$ and report the highest performance. All the other hyper-parameters are the same as reported in the corresponding papers. For all the phases, we fix $eps = 1e-6$ and $s_w = 2000$, where s_w is the number of warm-up steps, and we apply no weight decays. We use BART-large (406M parameters) and ELECTRA-large (335M parameters) models for our experiments. We run our experiments on 2 Tesla V100 GPUs. Training the QAE models on augmented data takes about 4 hours.

4.3 Experiment Results

We assess the performance of RGX with both semi-annotated and zero-annotated evaluation on unseen domains using exact match (EM) and F1 scores. The exact match metric assesses the percentage of predicted spans that are exactly the same as labeled answers, while the F1 score measure the overall token-level overlap between predicted and labeled

---

[2] `https://github.com/luohongyin/RGX`

answers. In our semi-annotated setting, we use the annotated answer entities in the target corpora but utilize QG to generate questions for obtaining the training question-answer pairs. The labeled questions are not used. We employ no annotation from the target corpora for the out-of-domain task but automatically construct the question-answer training pairs with entities and questions inferred by AER and QG on the corpora.

4.3.1 Semi-annotated Evaluation

The model performance with the pretrained QA model, RGX, and SOTA trained with full-supervision is shown in Table 1.

Models	**EM**	**F1**
Source domain: NQ, Target domain: SQuAD		
ELECTRA-large (NaturalQuestions)	67.8	80.3
RGX	83.1	90.7
–w/o Coop. ST	81.2	89.1
ELECTRA-large (SQuAD)	89.7	94.9

Table 1: The performance of the question answering models in the semi-annotated setting. RGX stands for our cooperative training approach, and Coop. ST stands for cooperative self-training.

Table 1 shows that RGX yields improvement over the pretrained model, approaching the SOTA performance of the fully trained ELECTRA-large-discriminator model. The experiment result suggests that the cooperative learning strategy improves the question generation model with human-annotated answer entities.

4.3.2 Out-of-domain Evaluation

We also evaluate the models in unseen domains, where we do not use any annotated QA for finetuning. We train the QAE models based on the synthetic training data and evaluate the models on the target domains. We compare RGX with latest self-training QA methods, QAGen2S (Shakeri et al., 2020) and SynQA (Bartolo et al., 2021). Since QAGen2S did not report full MRQA results, we implemented our own version. We first present the RGX performance and the results reported by the authors QAGen2S and SynQA, and then conduct ablation study by training different language models on RGX synthetic QA data.

The full evaluation results on MRQA out-of-domains are shown in Table 2, and the experiment setting comparison is shown in table 3. The results show that the models trained with the RGX framework achieve significantly higher EM and F1 scores on most domains, comparing to both pretrained QA models and self-training baselines. The results showed that the RGX model achieves 7.7 and 3.0 average F1 improvement over ELECTRA, the SOTA pretrained language model for QA, by pretraining on NQ and SQuAD respectively. The improvement over previous SOTA self-training QA methods, QAGen2S and SynQA, is also significant on both pretraining corpora, although SynQA applies complicated adversarial QA annotation. The largest gain we got is adapting NQ model to TextbookQA domain, increasing 18.0 EM and 19.4 F1 scores. Note that our model still outperforms all baselines without MMI. The performance on the DROP benchmark drops since DROP requires multi-step reasoning, but the synthetic generation model tends to generate safe question-answer pairs. We also found that without selecting harder questions with SEM in RGX, the performance is significantly lower. These facts indicate that the QA model needs hard training examples for better performance, and explains the good performance of SynQA on DROP. For the same reason, the performance drop led by removing EM from RGX is significantly larger when the QG model is pretrained on SQuAD, since SQuAD questions are more coherent with the context than NQ, and selecting simple questions for RGX training will encourage the model to generate trivial questions, which is harmful for the QA training.

4.4 Analysis

4.4.1 Answer Entity Recognition

We first compare the performance of different AER models and strategies by setting NQ as the source domain and SQuAD 1.1 as the target domain in Table 4. The results showed that the choice of AER model and strategy significantly influences the final QA performance. The low performance of the NER model trained on CONLL shared task suggests the importance of our AER module. We notice that the improvement from the cooperative learning over the pretrained models is higher in the zero-annotation setting than the semi-annotated task. The observation indicates that the model trained with RGX is more robust against the automatically recognized answer entities. More details about the AER methods are shown in Appendix C.

The AER method also enables and improves the maximum mutual information (MMI) inference in test time. Table 2 shows that MMI achieves the

Table 2: The QA performance evaluation on the out-of-domains of the MRQA benchmark. All models used are pretrained on the human-labeled training set from the source domains, and the QA models are finetuned on synthetic data generated based on the unannotated passages of the target domains. The finetuned QA models are evaluated on human-generated evaluation data for each target domains with the exact match (EM) and F1 scores. MMI stands for maximum mutual information inference, EM stands for involving difficult questions with EM selection, and CST stands for cooperative self-training.

Table 4: Comparison of different AER strategies. NER stands for the BERT named entity recognition model trained on the CONLL 2003 shared task. AER-Tag stands for a BIO-based tagging strategy, AER-LM means selecting synthetic QA pairs with lowest QAE losses. AER-EM is the EM-based QA selection strategy applied in our full model.

best performance, and we also show that the MMI accuracy is hurt without AER. Table 5 shows that MMI grounded on AER constantly outperform the ELECTRA model, but grounding on top-k seriously hurts the EM scores. Some invalid answer predictions leads to low question generation perplexities, which makes MMI inference noisy. Table 6 shows that the QG model generated more diverse questions based on the AER outputs.

4.4.2 Synthetic QA Selection with EM

Previous experiments showed that selecting nontrivial synthetic QA pairs is essential for RGX to achieve high performance. Table 2 shows that the performance of cooperative self-trained RGX is much lower than the pretrained baseline without EM. If selecting QA pairs with low perplexities instead of EM, the QA diversity is significantly lower as shown in Table 6, thus makes the QAE model overfit to simple training cases and hurts the QA accuracy. We show questions about the same answer entity being classified into simple, challenging, and difficult types by EM in figure 3. The data points in the plot represents the losses of synthetic QA pairs and the predicted QA type. Based on the highlighted answer entity, question 1 and 2 are predicted as correct questions, while question 3, which has a relatively high QAE loss,

Table 6: The vocabulary sizes and lengths of Annotated and generated questions on SQuAD under both semi- and zero-annotated settings in unseen domains

Context: Despite differences in the spectrum of mutations in CN or CyN, type or localization of mutation only partially determine the clinical phenotype.

Q1: What determines the clinical phenotype of a person with a mutation?
Q2: What determines the clinical phenotype of a mutation?
Q3: What is the only way to determine the clinical phenotype of a mutation?

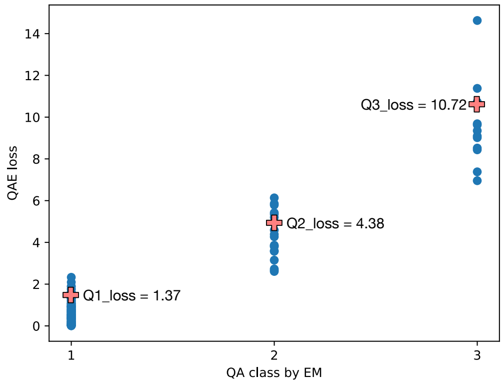

Figure 3: Generated questions about the same answer entity classified into different types by EM. Questions Q1 is answered by the QAE model confidently, while the Q2 is considered more challenging than Q1 since less information is provided. Q3 is an unanswerable questions given the context passage.

is regarded as a wrong question. Note that we only generate one question for each span recognized by the AER model, but different questions might be re-directed to the same AE after QAE fine-graining.

4.4.3 Cooperative Self-training

We found that the cooperative self-training method improves domain adaptation ability of self-trained QA models by increasing both accuracy and diversity of QA synthesis.

Accuracy. We also evaluate the quality of the generated QA pairs without a downstream task by assessing the answer entity hit rate and the BLEU scores of generated questions using the evaluation sets of each domain. The results are shown in Table 7, indicating that RGX find mores human-annotated answer entities, and the generated questions have higher BLEU scores on all domains. The evaluation results show that the synthetic QA pars generated by RGX covers more human annotated answer entities, and the generated questions are more similar to human annotations than the pre-trained question generation model. We also found that tuning the generation model for more than 1 iterations does not result in further improvement, since keeping training language models with their own outputs leads to difficult optimization.

Domain	RGX w/o Coop. ST		RGX	
	Hit	BLEU	Hit	BLEU
BioASQ	68.1	5.9	75.8	12.7
TextbookQA	43.7	7.5	58.2	13.2

RelExt.	47.4	2.8	54.2	3.3
DuoRC	53.5	6.7	60.0	7.5
DROP	73.5	12.3	75.3	9.3

Table 7: Evaluation of the answer hit rates and question BLEU scores of the synthetic data. Hit rate stands for the percentage of human-labeled answer entities in the evaluation passages that are successfully covered by the selected synthetic data generated by RGX.

Diversity. We compare the lengths and vocabulary sizes of the questions and summarize the statistics in Table 6, which shows that the ground-truth questions are longer and more diverse in vocabulary than the generated ones. However, the cooperative self-training, together with AER and EM, improves the vocabulary diversity. We observe a correlation between the vocabulary size and the QA performance reported in Table 1 and 4, presumably because the QAE model requires diverse knowledge for training. Thus, we believe generating more diverse QA pairs with good quality will be a critical next step to improve RGX.

Case Study. An example of a SQuAD passage is shown in Table 8. We list the annotated and generated question-answer pairs by different models. The table shows that the models can recognize rea-

Architecturally, the school has a Catholic character. Atop the Main Building's gold dome is a golden statue of the Virgin Mary. Immediately in front of the Main Building and facing it, is a copper statue of Christ with arms upraised with the legend "Venite Ad Me Omnes". Next to the Main Building is the Basilica of the Sacred Heart. Immediately behind the basilica is the Grotto, a Marian place of prayer and reflection. It is a replica of the grotto at Lourdes, France where the Virgin Mary reputedly appeared to Saint Bernadette Soubirous in 1858. At the end of the main drive (and in a direct line that connects through 3 statues and the Gold Dome), is a simple, modern stone statue of Mary.

Table 8: An example of a passage in the training set of the SQuAD corpus. We list the annotated question-answer pairs, and the question-answer pairs generated by the models pretrained on NQ and finetuned by RGX. The bold texts are annotated or recognized answer entities. Adapting from NQ is difficult since the questions in NQ do not strictly coherent with a given context. More generation examples are shown in Appendix D.

sonable answer entities other than the annotated ones, and RGX generates more natural QAs.

5 Conclusion

We propose a cooperative self-training framework, RGX, consisting of an answer entity Recognizer, a question Generator, and an answer eXtractor, for question generation and answering. We also introduce in the framework an expectation-maximization method that measures the quality of generated questions for reinforced finetuning of the question generation models. Experiments show that RGX significantly outperforms pretrained and self-trained model baselines while adapted to unseen domains, suggesting that RGX is a promising framework for making extractive question answering methods more scalable and less dependent on human annotation.

A More Related Work

Representation learning has been an important topic in NLP area since neural language models were proposed (Bengio et al., 2003). Based on word co-occurrence, Mikolov et al. (2013) and Pennington et al. (2014) proposed language embedding algorithms to model word-level semantics. Recent studies have focused on pretraining contextualized word representations with large-scaled corpora (Peters et al., 2018). State-of-the-art representation models are pretrained with the masked language modeling task (Devlin et al., 2018; Liu et al., 2019; Clark et al., 2020) using the Transformer architecture (Vaswani et al., 2017).

Different variants of masked language models have been investigated to improve performance in downstream tasks. Joshi et al. (2020) leveraged a masked span generation task instead of word prediction. Fei et al. (2020) and Shen et al. (2020) proposed models that learns better syntax knowledge with syntactic distances (Shen et al., 2018) and heights (Luo et al., 2019). Henderson et al. (2019) and Humeau et al. (2019) showed that pretraining language models on dialog corpora perform better on dialog-related downstream tasks, as compared to pretraining on Wikipedia. A span selection pretraining objective is proposed in Glass et al. (2019) to reduce the gap between the pretraining and downstream finetuning stages and to improve the performance on the QA task. Some applications of generated questions are shown in (Lewis et al., 2021; Jia et al., 2021).

In contrast to self-training methods that usually adopt a teacher-student learning strategy, cooperative learning pipelines contain several agents working together to learn as much knowledge as possible. A typical cooperative learning framework is generative adversarial networks (GAN) (Goodfellow, 2016; Goodfellow et al., 2014), where a generator is optimized to confuse a discriminator, and a discriminator is trained to distinguish real examples from generated ones. Sequence GAN is further designed for learning diverse text generation (Yu et al., 2017). Unlike the adversarial learning method where two networks work for opposite goals, other studies proposed learning environments in which different agents learn the same objective functions for language emergence (Lazaridou et al., 2016; Mordatch and Abbeel, 2018; Havrylov and Titov, 2017), including simple natural language, compositional language, and symbolic language.

B Data

The SQuAD v1.1 is the easiest QA corpus used in this paper. The dataset contains $107,785$ question-answer pairs on 536 articles, which are split into passages. Each question is labeled with an answer that can be extracted from the given passage.

The Natural Questions dataset is a large-scale corpus designed for open-domain question answering. The dataset is more challenging than SQuAD. All questions are collected from human search queries and are annotated with long and abstractive answers. Some of the questions are also labeled with a short answer for learning answer-span extraction or reading comprehension. Focusing on the machine reading comprehension task, we select $106,926$ questions labeled with both long and short answers from the dataset for experiments.

For each target domain in MRQA, we collect the corresponding training data and sample 3000 passages for QA synthesis. The number of synthetic QAs varies based on the length of input passages, and is shown in Table 9.

C Answer Entity Recognition Details

In this section, we describe details of the AER methods, which are not covered in detail in previous sections. All AER models are pretrained on the Natural Questions corpus. To solve the sparsity problem, in other words, the passages are long but not all potential question-answer pairs are annotated, we train all following AER models by using the sentence containing the annotated answer entities as inputs, instead of the whole passage. If a sentence in the passage does not contain an annotated answer entity, we do not use it for training.

In this work, we introduce two types of AER methods, tagging based AER (AER-tag) and extraction based AER (AER-Search and AER-Coop). We describe their training and how we use the trained model to recognize answer entities in our experiments.

C.1 AER-Tag

C.1.1 Training

We apply a BIO tagging model for answer entity recognition in the AER-Tab method. We train the model to classify all tokens in the input sentence into three classes,

- B(egin) - the first token of the annotated answer entity
- I(nsize) - other tokens of the annotated answer entity
- O(utside) - tokens that are not a part of the annotated answer entity

C.1.2 Evaluation

Given an input passage, we run the trained BIO tagging model on each of its sentences and greedily predict answer entities. There might be more than one answer entities predicted in each sentence, and we only use the answer entities start with a predicted B tag.

C.2 AER-LM

C.2.1 Training

For AER-LM method, we need to pretrain an extraction-based AER model. We also take a sentence of L tokens containing an annotated answer entity as an example. Using an extraction model, which is similar as our question answering model, we train the model to predict the start and end location of the annotated answer entity. The model outputs a start score and an end score for each token, and predicts the start/end locations by selecting the tokens that are assigned with highest scores. The model is trained with cross-entropy loss, by regarding the extraction task as two L-class classification tasks.

C.2.2 Evaluation

In evaluation, we first run the model on each sentence of the input passages and calculate the start and end scores for each token. For each span $(x_i, x_{i+1}, \ldots, x_j)$ that is not longer than L_{span} tokens, we calculate the span score with

$$s_{ij} = s_{st}^{i} + s_{ed}^{j} \tag{2}$$

where s_{st}^{i} is the start score of the first token of span (i, j), and s_{ed}^{j} is the end score of the last token of the span. In practice, we set $L_{span} = 10$.

To re-rank all possible answer entities, we select top $N_0 = 40$ spans according to s_{ij} for each passage. For all selected answer entities, we generated questions with a pretrained question generator and collect the generation perplexity of the questions. We select $N_{search} = 5$ question-answer pairs with lowest perplexities for the final question-answering finetuning.

C.3 AER-Coop

In AER-Coop, we use the same extraction training method applied in AER-Search, and we also use the s_{ij} scores to select the top $N_0 = 40$ preliminary answer entities for further search. The difference is that we search for final answer entities cooperatively with the pretrained question generator and question answering extractor.

With the question generator and question answering extractor, we re-rank the recognized answer entities with the following score

$$s_{ij}^{c} = \gamma \cdot I_c - p \tag{3}$$

where γ is a large, positive coefficient, p is the perplexity of generated question based on span (i, j), and $I_c = 1$ if the generated question is correctly answered, and otherwise $I_c = 0$.

C.4 Answer Entity Overlapping

We found the extraction-based AER model leads to overlapping problems, since a large start or end score assigned to a token leads to many candidate answer entities start or end at the token. In practice, if an answer entity is selected by the AER-Search and AER-Coop method, we no longer consider any other answer entities that overlap with the selected ones.

D RGX Examples

In this section, we show some examples of our full model. The examples are contained in Table 10.

The National History Museum of Montevideo is located in the historical residence of General Fructuoso Rivera. It exhibits artifacts related to the history of Uruguay. In a process begun in 1998, the National Museum of Natural History (1837) and the National Museum of Anthropology (1981), merged **in 2001**, becoming the National Museum of Natural History and Anthropology. In July 2009, the two institutions again became independent. The Historical Museum has annexed eight historical houses in the city, five of which are located in the Ciudad Vieja. One of them, on the same block with the main building, is the historic residence of Antonio Montero, which houses the Museo Romantico.

When was the national history museum of montevideo founded?

In the 1920s, John Maynard Keynes prompted a division between microeconomics and macroeconomics. Under Keynesian economics macroeconomic trends can overwhelm economic choices made by individuals. Governments should promote aggregate demand for goods as a means to encourage economic expansion. Following World War II, Milton Friedman created the concept of monetarism. Monetarism focuses on using the **supply and demand of money** as a method for controlling economic activity. In the 1970s, monetarism has adapted into supply-side economics which advocates reducing taxes as a means to increase the amount of money available for economic expansion.

Monarism focuses on the relationship between the?

Starting in 2006, Apple's industrial design shifted to favor aluminum, which was used in the construction of the first MacBook Pro. Glass was added in 2008 with the introduction of the unibody MacBook Pro. These materials are billed as environmentally friendly. The iMac, MacBook Pro, MacBook Air, and Mac Mini lines currently all use aluminum enclosures, and are now made of a single unibody. Chief designer **Jonathan Ive** continues to guide products towards a minimalist and simple feel, including eliminating of replaceable batteries in notebooks. Multi-touch gestures from the iPhone's interface have been applied to the Mac line in the form of touch pads on notebooks and the Magic Mouse and Magic Trackpad for desktops.

Who is the designer of the macbook pro?

The city's total area is 468.9 square miles (1,214 km2). 164.1 sq mi (425 km2) of this is water and 304.8 sq mi (789 km2) is land. The highest point in the city is Todt Hill **on Staten Island**, which, at 409.8 feet (124.9 m) above sea level, is the highest point on the Eastern Seaboard south of Maine. The summit of the ridge is mostly covered in woodlands as part of the Staten Island Greenbelt.

Where is the highest point in new york city?

In 1922, the number of supporters had surpassed 20,000 and by lending money to the club, Barça was able to build the larger Camp de Les Corts, which had an initial capacity of 20,000 spectators. After the Spanish Civil War the club started attracting more members and a larger number of spectators at matches. This led to several expansion projects: the grandstand in 1944, the southern stand in 1946, and finally the northern stand in 1950. After the last expansion, Les Corts could hold **60,000 spectators**.

What is the capacity of barcelona's stadium?

On 1 November 2013, international postal services for Somalia officially resumed. **The Universal Postal Union** is now assisting the Somali Postal Service to develop its capacity, including providing technical assistance and basic mail processing equipment.

Who is responsible for supporting the somali postal service?

In addition to membership, as of 2010[update] there are 1,335 officially registered fan clubs, called penyes, around the world. The fan clubs promote Barcelona in their locality and receive beneficial offers when visiting Barcelona. Among the best supported teams globally, Barcelona has the highest social media following in the world among sports teams, with over 90 million Facebook fans as of February 2016. The club has had many prominent people among its supporters, including **Pope John Paul II**, who was an honorary member, and former prime minister of Spain José Luis Rodríguez Zapatero. FC Barcelona has the second highest average attendance of European football clubs only behind Borussia Dortmund.

Who was an honorary member of barcelona football club?

In April 1758, the British concluded the Anglo-Prussian Convention with Frederick in which they committed to pay him **an annual subsidy of £670,000**. Britain also dispatched 9,000 troops to reinforce Ferdinand's Hanoverian army, the first British troop commitment on the continent and a reversal in the policy of Pitt. Ferdinand had succeeded in driving the French from Hanover and Westphalia and re-captured the port of Emden in March 1758 before crossing the Rhine with his own forces, which caused alarm in France. Despite Ferdinand's victory over the French at the Battle of Krefeld and the brief occupation of Düsseldorf, he was compelled by the successful manoeuvering of larger French forces to withdraw across the Rhine.

What did france pay to the prussian monarchy?

Executives at Trump Entertainment Resorts, whose sole remaining property will be the Trump Taj Mahal, said in 2013 that they were considering the option of selling the Taj and **winding down and exiting the gaming and hotel business**.

What is the future of the trump taj mahal?

Vehicles typically include headlamps and tail lights. Headlamps are white or selective yellow lights placed in the front of the vehicle, designed to illuminate the upcoming road and to make the vehicle more visible. Many manufactures are turning to LED headlights as an energy-efficient alternative to traditional headlamps. Tail and brake lights are red and emit light to the rear so as to reveal the vehicle's direction of travel to following drivers. White rear-facing reversing lamps indicate that the vehicle's transmission has been placed in the reverse gear, warning anyone behind the vehicle that it is moving backwards, or about to do so. Flashing turn signals on the front, side, and rear of the vehicle indicate an intended change of position or direction. In **the late 1950s**, some automakers began to use electroluminescent technology to backlight their cars' speedometers and other gauges or to draw attention to logos or other decorative elements.

When did they start putting back up lights in cars?

Abstract

There has been a growing interest in interpreting the underlying dynamics of Transformers. While self-attention patterns were initially deemed as the primary option, recent studies have shown that integrating other components can yield more accurate explanations. This paper introduces a novel token attribution analysis method that incorporates all the components in the encoder block and aggregates this throughout layers. Through extensive quantitative and qualitative experiments, we demonstrate that our method can produce faithful and meaningful global token attributions. Our experiments reveal that incorporating almost every encoder component results in increasingly more accurate analysis in both local (single layer) and global (the whole model) settings. Our global attribution analysis significantly outperforms previous methods on various tasks regarding correlation with gradient-based saliency scores. Our code is freely available at https://github.com/mohsenfayyaz/GlobEnc.

1 Introduction

The stellar performance of Transformers (Vaswani et al., 2017) has garnered a lot of attention to analyzing the reasons behind their effectiveness. The self-attention mechanism has been one of the main areas of focus (Clark et al., 2019; Kovaleva et al., 2019; Reif et al., 2019; Htut et al., 2019). However, there have been debates on whether raw attention weights are reliable anchors for explaining model's behavior or not (Wiegreffe and Pinter, 2019; Serrano and Smith, 2019; Jain and Wallace, 2019). Recently, it was shown that incorporating vector norms should be an indispensable part of any attention-based analysis[1] (Kobayashi et al., 2020, 2021). However, these norm-based studies incorporate only the attention block into their analysis, whereas Transformer encoder layer is composed of more components.

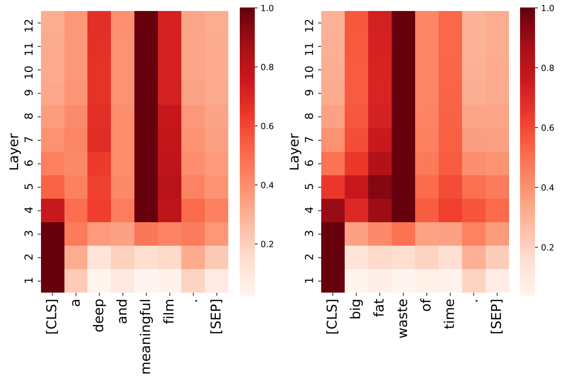

Figure 1: Aggregated attribution maps ($\mathcal{N}_{\text{ENC}}$) for the [CLS] token for fine-tuned BERT on SST2 dataset (sentiment analysis). Our method (GlobEnc) is able to accurately quantify the global token attribution of the model.

Another limitation of the existing analysis techniques is that they are usually constrained to the analysis of single layer attributions. In order to expand the analysis to multi-layered encoder-based models in their entirety, an aggregation technique has to be employed. Abnar and Zuidema (2020) proposed two aggregation methods, *rollout* and *max-flow*, which combine raw attention weights across layers. Despite showing the outcome of their method to be faithful to a model's inner workings in specific cases, the final results are still unsatisfactory on a wide range of fine-tuned models.

Additionally, gradient-based alternatives (Simonyan et al., 2014; Kindermans et al., 2016; Li et al., 2016) have been argued to provide a more robust basis for token attribution analysis (Atanasova et al., 2020; Brunner et al., 2020; Pascual et al., 2021). Nonetheless, the gradient-based alternatives have not been able to fully replace attention-based counterparts, mainly due to their high computa-

tional intensity.

In this paper, we propose a new global token attribution analysis method (GlobEnc) which is based on the encoder layer's output. In GlobEnc, the second layer normalization is also included in the norm-based analysis of each encoder layer. To aggregate attributions over all layers, we applied a modified attention rollout technique, returning global scores.

Through extensive experiments and comparing the global attribution with the input token attributions obtained by gradient-based saliency scores, we show that our method produces faithful and meaningful results (Figure 1). Our evaluations on models with distinct pre-training objectives and sizes (Devlin et al., 2019; Clark et al., 2020) show high correlations with gradient-based methods in global settings. Furthermore, with comparative studies on each aspect of GlobEnc , we find that: (i) norm-based methods achieve higher correlations than weight-based methods; (ii) incorporating residual connections plays an essential role in token attribution; (iii) considering the two layer normalizations improve our analysis only if coupled together; and (iv) aggregation across layers is crucial for an accurate whole-model attribution analysis.

In summary, our main contributions are:

- We expand the scope of analysis from attention block in Transformers to the whole encoder.
- Our method significantly improves over existing techniques for quantifying global token attributions.
- We qualitatively demonstrate that the attributions obtained by our method are plausibly interpretable.

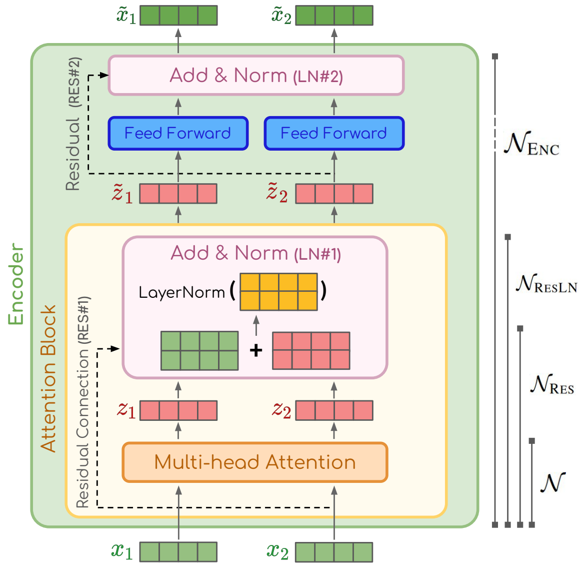

Figure 2: The internal structure of a Transformer encoder layer. We show on the diagram the components that are incorporated by each token attribution analysis method. Our method incorporates the whole encoder ($\mathcal{N}_{\text{ENC}}$) except for the direct effect of the fully connected feed-forward module. Diagram inspired by Alammar (2018).

2 Background

In encoder-based language models (such as BERT), a Transformer encoder layer is composed of several components (Figure 2). The core component of the encoder is the self-attention mechanism (Vaswani et al., 2017), which is responsible for the information mixture of a sequence of token representations ($\boldsymbol{x}_1, ..., \boldsymbol{x}_n$). Each self-attention head computes a set of attention weights $\boldsymbol{A}^h = \{\alpha_{i,j}^h | 1 \leq i, j \leq n\}$, where $\alpha_{i,j}^h$ is the raw attention weight from the i^{th} token to the j^{th} token in head $h \in \{1, ..., H\}$. Therefore, the output representation ($\boldsymbol{z}_i \in \mathbb{R}^d$) for the i^{th} token of a multi-head (with H heads) self-attention module is computed by concatenating the heads' outputs followed by a head-mixing $\boldsymbol{W_O}$ projection:

$$\boldsymbol{z}_i = \textsc{Concat}(\boldsymbol{z}_i^1, ..., \boldsymbol{z}_i^H)\boldsymbol{W_O} \qquad (1)$$

where each head's output vector is generated by performing a weighted sum over the transformed value vectors $\boldsymbol{v}(\boldsymbol{x}_j) \in \mathbb{R}^{d_v}$:

$$\boldsymbol{z}_i^h = \sum_{j=1}^{n} \alpha_{i,j}^h \boldsymbol{v}^h(\boldsymbol{x}_j) \qquad (2)$$

Norm-based attention. While one may interpret the attention mechanism using the attention weights $\boldsymbol{A}$, Kobayashi et al. (2020) argued that doing so would ignore the norm of the transformed vectors multiplied by the weights, elucidating that the weights are insufficient for interpretation. Their solution enhanced the interpretability of attention weights by incorporating the value vectors $\boldsymbol{v}(\boldsymbol{x}_j)$ and the following projection $\boldsymbol{W}_O$. By reformulating Equation 1, we can consider $\boldsymbol{z}_i$ as a summation over the attentions heads:

$$\boldsymbol{z}_i = \sum_{h=1}^{H} \sum_{j=1}^{n} \alpha_{i,j}^h \underbrace{\boldsymbol{v}^h(\boldsymbol{x}_j)\boldsymbol{W}_O^h}_{f^h(\boldsymbol{x}_j)} \qquad (3)$$

Using this reformulation[2], Kobayashi et al. proposed a *norm-based* token attribution analysis method, $\mathcal{N} := (||\boldsymbol{z}_{i\leftarrow j}||) \in \mathbb{R}^{n\times n}$, to measure each token's contribution in a self-attention module:

$$\boldsymbol{z}_{i\leftarrow j} = \sum_{h=1}^{H} \alpha_{i,j}^{h} f^{h}(\boldsymbol{x}_j) \tag{4}$$

They showed that incorporating the magnitude of the transformation function ($f^h(\boldsymbol{x})$) is crucial in assessing the input tokens' contribution to the self-attention output.

Residual connections & Layer Normalizations. Kobayashi et al. (2021) added the attention block's Layer Normalization (**LN**#1) and Residual connection (**RES**#1) to its prior norm-based analysis to assess the impact of residual connections and layer normalization inside an attention block. $\mathcal{N}_{\text{RES}} := (||\boldsymbol{z}^{+}_{i\leftarrow j}||) \in \mathbb{R}^{n\times n}$ is the analysis method which incorporates the attention block's residual connection. The input vector $\boldsymbol{x}$ is added to the attribution of each token to itself to incorporate the influence of RES#1:

$$\boldsymbol{z}^{+}_{i\leftarrow j} = \sum_{h=1}^{H} \alpha_{i,j}^{h} f^{h}(\boldsymbol{x}_i) + \mathbf{1}[i=j]\boldsymbol{x}_i \tag{5}$$

They proposed a method for decomposing LN[3] into a summation of normalizations:

$$\begin{aligned} \text{LN}(\boldsymbol{z}^{+}_{i}) &= \sum_{j=1}^{n} g_{\boldsymbol{z}^{+}_{i}}(\boldsymbol{z}^{+}_{i\leftarrow j}) + \boldsymbol{\beta} \\ g_{\boldsymbol{z}^{+}_{i}}(\boldsymbol{z}^{+}_{i\leftarrow j}) &:= \frac{\boldsymbol{z}^{+}_{i\leftarrow j} - m(\boldsymbol{z}^{+}_{i\leftarrow j})}{s(\boldsymbol{z}^{+}_{i})} \odot \boldsymbol{\gamma} \end{aligned} \tag{6}$$

where $m(.)$ and $s(.)$ are the element-wise mean and standard deviation of the input vector (cf. §A.1). The decomposition can be applied to the contribution vectors:

$$\tilde{\boldsymbol{z}}_{i\leftarrow j} = g_{\boldsymbol{z}^{+}_{i}}(\sum_{h=1}^{H} \alpha_{i,j}^{h} f^{h}(\boldsymbol{x}_i) + \mathbf{1}[i=j]\boldsymbol{x}_i) \tag{7}$$

Accordingly, we can compute the magnitude $\mathcal{N}_{\text{RESLN}} := (||\tilde{\boldsymbol{z}}_{i\leftarrow j}||) \in \mathbb{R}^{n\times n}$, which represents the amount of influence of an encoder layer's input token j on its output token i. Based on this formulation, a context-mixing ratio could be defined as:

$$r_i = \frac{||\sum_{j=1, j\neq i}^{n} \tilde{\boldsymbol{z}}_{i\leftarrow j}||}{||\sum_{j=1, j\neq i}^{n} \tilde{\boldsymbol{z}}_{i\leftarrow j}|| + ||\tilde{\boldsymbol{z}}_{i\leftarrow i}||} \tag{8}$$

Experiments by Kobayashi et al. (2021) revealed considerably low r values which indicate the huge impact of the residual connections. In other words, the model tends to preserve token representations more than mixing them with each other.

3 Methodology

Our method for input token attribution analysis has a holistic view and takes into account almost every component within the encoder layer. To this end, we first extend the norm-based analysis of Kobayashi et al. (2021) by incorporating the encoder's output LN#2. We then apply an aggregation technique to combine the information flow throughout all layers.

Encoder layer output $\neq$ Attention block output. While the RES#1 and the LN#1 from the attention block are included in the analysis of Kobayashi et al. (2021), the subsequent FFN, RES#2, and output LN#2 are ignored (see Fig. 2). Hence, $\mathcal{N}_{\text{RESLN}}$ might not be indicative of the entire encoder layer's function. To address this issue, we additionally include the encoder layer components from the attention block outputs ($\tilde{z}_i$) to the output representations ($\tilde{x}_i$). The output of each encoder ($\tilde{x}_i$) is computed as follows:

$$\begin{aligned} \tilde{\boldsymbol{z}}^{+}_{i} &= \text{FFN}(\tilde{\boldsymbol{z}}_i) + \tilde{\boldsymbol{z}}_i \\ \tilde{\boldsymbol{x}}_i &= \text{LN}(\tilde{\boldsymbol{z}}^{+}_{i}) \end{aligned} \tag{9}$$

We apply the LN decomposition rule in Eq. 7 to separate the impacts of residual and FFN output:

$$\tilde{\boldsymbol{x}}_i = \sum_{j=1}^{n} \Big(g_{\tilde{\boldsymbol{z}}^{+}_{i}}(\text{FFN}(\tilde{\boldsymbol{z}}_{i\leftarrow j})) + g_{\tilde{\boldsymbol{z}}^{+}_{i}}(\tilde{\boldsymbol{z}}_{i\leftarrow j}) \Big) + \boldsymbol{\beta} \tag{10}$$

Given that the activation function between the two fully connected layers in the FFN component is non-linear (Vaswani et al., 2017), a linear decomposition similar to Eq. 7 cannot be derived. As a result, we omit FFN's influence on the contribution of each token and instead consider RES#2, approximating $\tilde{\boldsymbol{x}}_{i\leftarrow j}$ as $g_{\tilde{\boldsymbol{z}}^{+}_{i}}(\tilde{\boldsymbol{z}}_{i\leftarrow j})$. Nevertheless, it should be noted that the FFN *still preserves some influence on this new setting due to the presence of*

---

[2] $\boldsymbol{W}_O^h$ is a head-specific slice of the original $\boldsymbol{W}_O$ projection. For more information about the reformulation process, see Appendix C in Kobayashi et al. (2021)

[3] $\boldsymbol{\gamma} \in \mathbb{R}^d$ and $\boldsymbol{\beta} \in \mathbb{R}^d$ are the trainable weights of LN. Similar to Kobayashi et al. (2021) we ignore $\boldsymbol{\beta}$.

$s(\tilde{\boldsymbol{z}}_i^+)$ *in* $g_{\tilde{\boldsymbol{z}}_i^+}(\tilde{\boldsymbol{z}}_{i\leftarrow j})$. Similarly to Eq. 7, we can introduce a more inclusive layerwise analysis method $\mathcal{N}_{\text{ENC}} := (||\tilde{\boldsymbol{x}}_{i\leftarrow j}||) \in \mathbb{R}^{n\times n}$ from input token j to output token i using:

$$\tilde{\boldsymbol{x}}_{i\leftarrow j} \approx g_{\tilde{\boldsymbol{z}}_i^+}(\tilde{\boldsymbol{z}}_{i\leftarrow j}) = \frac{\tilde{\boldsymbol{z}}_{i\leftarrow j} - m(\tilde{\boldsymbol{z}}_{i\leftarrow j})}{s(\tilde{\boldsymbol{z}}_i^+)} \odot \boldsymbol{\gamma} \tag{11}$$

Aggregating multi-layer attention. To create an aggregated attribution score, Abnar and Zuidema (2020) proposed describing the model's attentions via modelling the information flow with a directed graph. They introduced *attention rollout* method, which linearly combines raw attention weights along all available paths in the pairwise attention graph. The attention rollout of layer ℓ w.r.t. the inputs is computed recursively as follows:

$$\tilde{\boldsymbol{A}}_\ell = \begin{cases} \hat{\boldsymbol{A}}_\ell \tilde{\boldsymbol{A}}_{\ell-1} & \ell > 1 \\ \hat{\boldsymbol{A}}_\ell & \ell = 1 \end{cases} \tag{12}$$

$$\hat{\boldsymbol{A}}_\ell = 0.5\bar{\boldsymbol{A}}_\ell + 0.5\boldsymbol{I} \tag{13}$$

$\bar{\boldsymbol{A}}_\ell$ is the raw attention map averaged across all heads in layer ℓ. This method assumes equal contribution from the residual connection and multi-head attention (See Fig. 2). Hence, an identity matrix is summed and renormalized, giving $\hat{\boldsymbol{A}}_\ell$.

For aggregating the layerwise analysis methods, we use the rollout technique with minor modifications. As many of the methods already include residual connections, we only use Eq. 12 (replacing $\hat{\boldsymbol{A}}_\ell$ with the desired method's attribution matrix in layer ℓ) to calculate the rollout of a given method. However, for methods that do not assume the residual connection, we define a corresponding "Fixed" variation using Eq. 13 that incorporates a fixed residual effect ($r_i \approx 0.5$). **We refer to our proposed global method—aggregating the $\mathcal{N}_{\text{ENC}}$ across all layers by the rollout method—as *GlobEnc*.** In what follows we report our experiments, comparing GlobEnc with several other settings.

4 Experiments

In this section, we introduce the datasets and the token attribution analysis methods used in our evaluations, followed by the experimental setup and results.

4.1 Datasets

All analysis methods are evaluated on three different classification tasks. To cover sentiment detection tasks we use SST2 (Socher et al., 2013), MNLI (Williams et al., 2018) for Natural Language Inference and Hatexplain (Mathew et al., 2021) in hate speech detection.

4.2 Analysis Methods

We use two categories of explainability approaches in our work: ***Weight-based*** and ***Norm-based***.[4] The *Weight-based* approaches employed in our experiments are as follows:

- $\mathcal{W}$: The raw attention maps averaged across all heads (See $\bar{\boldsymbol{A}}_\ell$ in §2).
- $\mathcal{W}_{\text{FIXEDRES}}$: Abnar and Zuidema's assumption; add an identity matrix as a fixed residual to $\bar{\boldsymbol{A}}_\ell$ (see $\hat{\boldsymbol{A}}_\ell$ in Eq. 13).
- $\mathcal{W}_{\text{RES}}$: The corrected version of $\mathcal{W}$ in which accurate residuals are added based on the context-mixing ratios of $\mathcal{N}_{\text{ENC}}$:

$$\hat{r}_i = \frac{\left\|\sum_{j=1,j\neq i}^{n} \tilde{\boldsymbol{x}}_{i\leftarrow j}\right\|}{\left\|\sum_{j=1,j\neq i}^{n} \tilde{\boldsymbol{x}}_{i\leftarrow j}\right\| + \|\tilde{\boldsymbol{x}}_{i\leftarrow i}\|} \tag{14}$$

In order to enforce $\mathcal{W}_{\text{RES}}$ to have a context-mixing ratio equal to $\hat{r}_i$, it is essential to zero-out the diagonal elements (the tokens' attentions to themselves) of $\bar{\boldsymbol{A}}_\ell$ and renormalize it:

$$\begin{aligned} \boldsymbol{A}'_\ell &= (\boldsymbol{I} - \mathbf{diag}\,(\bar{\boldsymbol{A}}_\ell))^{-1}(\bar{\boldsymbol{A}}_\ell - \mathbf{diag}\,(\bar{\boldsymbol{A}}_\ell)) \\ \mathcal{W}_{\text{RES}} &:= \mathbf{diag}\,(\hat{r}_1, \cdots, \hat{r}_n)\,\boldsymbol{A}'_\ell \\ &\quad + \mathbf{diag}\,(1-\hat{r}_1, \ldots, 1-\hat{r}_n)\,\boldsymbol{I} \end{aligned} \tag{15}$$

The *Norm-based* analysis methods, namely $\mathcal{N}$, $\mathcal{N}_{\text{RES}}$ and $\mathcal{N}_{\text{RESLN}}$ were discussed in detail in §2. Our proposed norm-based method $\mathcal{N}_{\text{ENC}}$ was explained in §3. For an ablation study, we introduce $\mathcal{N}_{\text{FIXEDRES}}$ which is $\mathcal{N}$, corrected with a fixed residual similar to $\mathcal{W}_{\text{FIXEDRES}}$[5].

$$\begin{aligned} \hat{\mathcal{N}} &= \left(\frac{||\boldsymbol{z}_{i\leftarrow j}||}{\sum_j ||\boldsymbol{z}_{i\leftarrow j}||}\right) \in \mathbb{R}^{n\times n} \\ \mathcal{N}_{\text{FIXEDRES}} &:= 0.5\,\hat{\mathcal{N}} + 0.5\,\boldsymbol{I} \end{aligned} \tag{16}$$

---

[4] Note that in most of our experiments, we use all these methods within the rollout aggregation technique.

[5] The only difference is that we need to normalize $\mathcal{N}$ before adding an identity matrix.

In §4.5, we will demonstrate our comparative studies between the aforementioned methods and GlobEnc.

4.3 Gradient-based Methods for Faithfulness Analysis

Gradient-based methods are widely used as alternatives for attention-based counterparts for quantifying the importance of a specific input feature in making the right prediction (Li et al., 2016; Atanasova et al., 2020). In this section we discuss the specific gradient-based methods we use, namely saliency, HTA, and our adjusted HTA.

4.3.1 Saliency

Gradient-based saliency is based on the gradient of the output (y_c) w.r.t. the input embeddings ($\boldsymbol{e}_i^0$). One of the most accurate variations of the saliency family is the *gradient×input* method (Kindermans et al., 2016) where the input embeddings is multiplied by the gradients. Thus, the contribution score of input token i is determined by first computing the element-wise product of the input embeddings ($\boldsymbol{e}_i^0$) and the gradients of the true class output score (y_c) w.r.t. the input embeddings. Then, the L2 norm of the scaled gradients is computed to derive the final score:

$$Saliency_i = \left\| \frac{\partial y_c}{\partial \boldsymbol{e}_i^0} \odot \boldsymbol{e}_i^0 \right\|_2 \tag{17}$$

4.3.2 HTA x Inputs

To determine an upper bound on the information mixing within each layer, we use a modified version of *Hidden Token Attribution* (Brunner et al., 2020, HTA). In the original version, HTA is the sensitivity between any two vectors in the model's computational graph. However, inspired by the *gradient×input* method (Kindermans et al., 2016), which has shown more faithful results (Atanasova et al., 2020; Wu and Ong, 2021), we multiply the input vectors by the gradients and then apply a Frobenius norm. We compute the attribution from hidden embedding j ($\boldsymbol{e}_j^{\ell-1}$) to hidden embedding i ($\boldsymbol{e}_i^{\ell}$) in layer ℓ as:

$$\boldsymbol{c}_{i \leftarrow j}^{\ell} = \left\| \frac{\partial \boldsymbol{e}_i^{\ell}}{\partial \boldsymbol{e}_j^{\ell-1}} \odot \boldsymbol{e}_j^{\ell-1} \right\|_F \tag{18}$$

Computing HTA-based attribution matrices is an extremely computation-intensive task (especially for long texts) due to the high dimensionality of hidden embeddings. Hence, we only use this method for 256 examples from the SST-2 task's validation set. It is worth noting that extracting the HTA-based contribution maps for the aforementioned data took approximately 2 hours, whereas computing the maps for the entire analysis methods stated in §4.2 took only 5 seconds.[6]

4.4 Setup

We employ HuggingFace's Transformers library[7] (Wolf et al., 2020) and the BERT-base-uncased model. For fine-tuning BERT, epochs vary from 3 to 5, and the batch size and learning rate are 32 and 3e-5, respectively.[8] We also carried out the main experiment on BERT-large and ELECTRA (Devlin et al., 2019; Clark et al., 2020) where the results are reported at §A.2.

After rollout aggregation of each analysis method, we obtain an accumulated attribution matrix for every layer (ℓ) of BERT. These matrices indicate the overall contribution of each input token to all token representations in layer ℓ. Since the classifier in a fine-tuned model is attached to the final layer representation of the `[CLS]` token, we consider the first row (corresponding to `[CLS]` attributions) of the last layer attribution matrix. This vector represents the contribution of each input token to the model's final decision. As a measure of faithfulness of the resulting vector with the saliency scores, we report the *Spearman's rank correlation* between the two vectors.

4.5 Results

Table 1 shows the Spearman correlation of saliency scores with the aggregated attribution scores from `[CLS]` to input tokens at the final layer. In order to determine the contribution of each component of encoder layer to the overall performance, we report the results for attribution analysis methods discussed in §4.2. Our results demonstrate that incorporating the vector norms, residual connection, and both layer normalizations yields the highest correlation ($\mathcal{N}_{\text{ENC}}$). In what follows, we discuss the impact of incorporating various parts in the analysis.

4.5.1 On the role of vector norms

As also suggested by Kobayashi et al. (2020), vector norms play an important role in determining

w/ **GlobEnc**: [Residual + Layer Norm 1, 2] ($\mathcal{N}_{\text{ENC}}$)	**0.77 ± 0.12**	**0.78 ± 0.09**	**0.72 ± 0.17**

Table 1: Spearman's rank correlation of attribution based importance (aggregated by rollout) with saliency scores for the validation set for the BERT model fine-tuned on SST-2, MNLI, and HateXplain. In fixed residual cases, the context-mixing ratio is roughly 0.5, and in weight-based w/ residual ($\mathcal{W}_{\text{RES}}$), it is corrected with context-mixing ratio of ($\mathcal{N}_{\text{ENC}}$). The numbers are the average on all the validation set examples ± the standard deviation.

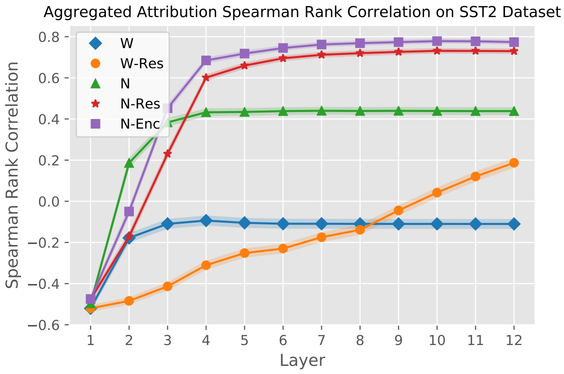

Figure 3: Spearman's rank correlation of aggregated attribution scores with saliency scores across layers. The 99% confidence intervals are shown as (narrow) shaded areas around each line. $\mathcal{N}_{\text{ENC}}$ achieves the highest correlation in almost every layer.

attention outputs. This is highlighted by the significant gap between weight-based and norm-based settings across all datasets in Table 1.

We also show the correlation of the aggregated attention for all layers in Figure 3. The norm-based settings ($\mathcal{N}$ and $\mathcal{N}_{\text{RES}}$) attain higher correlation than the weight-based counterparts ($\mathcal{W}$ and $\mathcal{W}_{\text{RES}}$) almost in all layers, confirming the importance of incorporating vector norms.

4.5.2 On the role of residual connections

Kobayashi et al. (2021) showed that in the encoder layer, the output representations of each token is mainly determined by its own representation, and the contextualization from other tokens' plays a marginal role. This is in contrary to the simplifying assumption made by Abnar and Zuidema (2020) who used a fixed context-mixing ratio of 0.5 (assuming that BERT equally preserves and mixes the representations). This setting is shown as weight-based with fixed residual ($\mathcal{W}_{\text{FIXEDRES}}$) in Table 1. We compare this setting against $\mathcal{W}_{\text{RES}}$ (see §4.2). $\mathcal{W}_{\text{RES}}$ is similar to $\mathcal{W}_{\text{FIXEDRES}}$ (in that it does not take into account vector norms) but differs in that it considers a dynamic mixing ratio (the one from $\mathcal{N}_{\text{ENC}}$). The huge performance gap between the two settings in Table 1 clearly highlights the importance of considering accurate context-mixing ratios. Therefore, it is crucial to consider the residual connection in the attention block for input token attribution analysis.

To further demonstrate the role of residual connections, we utilize the introduced method in §4.2, where we modified the norm-based attentions with fixed residual ($r \approx 0.5$). The comparison of norm-based without any residual ($\mathcal{N}$) and with a fixed residual ($\mathcal{N}_{\text{FIXEDRES}}$) shows a consistent improvement for the latter across all the datasets. This provides evidence on that having a fixed uniform context-mixing ratio is better than neglecting the residual connection altogether.

Finally, when we aggregate the norm-based analysis with an accurate dynamic context-mixing ratio ($\mathcal{N}_{\text{RES}}$), we observe the highest correlation up to

---

[9] As mentioned in §4.2, this analysis method is based on the original experiment by Abnar and Zuidema (2020). Our experiments on SST2 differ from theirs in two aspects: (i) we opted for *gradient*×*input* saliencies, while they used the sum of gradients (sensitivity) (ii) instead of BERT, they used a DistillBERT fine-tuned model (Sanh et al., 2019). However, their reported results in their sepcific setup (Spearman Corr. = 0.14) still yields significantly lower results than GlobEnc.

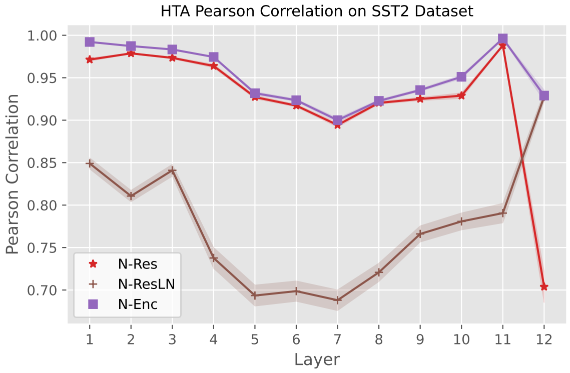

Figure 4: Single layer Pearson correlation of HTA maps with attribution maps. The 99% confidence intervals are shown as shaded areas around each line. $\mathcal{N}_{\text{ResLN}}$ shows considerably less association with HTA.

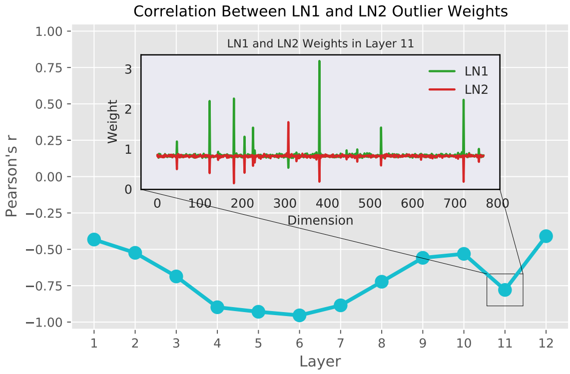

Figure 5: The Pearson correlation between outlier weights of LN#1 and LN#2 across layers. The weight values for layer 11 are shown as well.

		L1	L6	L12	MAX
Indiv.	$\mathcal{N}$	−.50 ± .18	+.28 ± .23	+.40 ± .21	+.41 ± .21
	$\mathcal{N}_{\text{Res}}$	−.48 ± .18	+.29 ± .24	+.41 ± .19	+.41 ± .19
	$\mathcal{N}_{\text{Enc}}$	**−.47 ± .18**	+.29 ± .24	+.41 ± .19	+.41 ± .19
Rollout	$\mathcal{N}$	−.50 ± .18	+.44 ± .20	+.44 ± .20	+.44 ± .20
	$\mathcal{N}_{\text{Res}}$	−.48 ± .18	+.70 ± .14	+.73 ± .13	+.73 ± .13
	$\mathcal{N}_{\text{Enc}}$	**−.47 ± .18**	**+.74 ± .14**	**+.77 ± .12**	**+.78 ± .12**

Table 2: Spearman's rank correlation of attribution-based scores (individual and aggregated by rollout) with saliency scores for the validation set for the BERT model fine-tuned on SST-2. The results are reported for layers 1, 6, 12, and the maximum of all layers. Utilizing rollout aggregation achieves higher correlations than individual layers.

this point, without layer normalization.

4.5.3 On the role of layer normalization

In Table 1 we see a sudden drop in correlations for $\mathcal{N}_{\text{ResLN}}$. Although this method considers vector norms and residuals, incorporating LN#1 in the encoder seems to have deteriorated the accuracy for token attribution analysis. To determine whether this deterioration of correlation in aggregated attributions is also present in individual single layers, we compare the HTA maps as a baseline with the attribution matrices extracted from different analysis methods. Figure 4 shows the correlation of HTA attribution maps with the maps obtained by $\mathcal{N}_{\text{Res}}$, $\mathcal{N}_{\text{ResLN}}$, and $\mathcal{N}_{\text{Enc}}$ methods. The results indicate that $\mathcal{N}_{\text{ResLN}}$ exhibits a significantly lower association.

The question that arises here is that how incorporating an additional component of the encoder (LN#1) in $\mathcal{N}_{\text{ResLN}}$ degrades the results (compared to $\mathcal{N}_{\text{Res}}$). To answer this question, we investigated the learned weights of LN#1 and LN#2. The outlier weights[10] in specific dimensions of LNs are shown to be significantly influential on the model's performance (Kovaleva et al., 2021; Luo et al., 2021). It is interesting to note that based on our observations, the outlier weights of the two layer norms seem to be the opposite of each other. Figure 5 demonstrates the weight values in layer 11 and also the correlation of the outlier weights across layers. The large negative correlations confirm that the outlier weights work contrary to each other. We speculate that the effect of outliers in the two layer norms is partly cancelled out when both are considered.

As shown in Figure 2, the FFN and the second layer normalization are on top of the attention block. However, $\mathcal{N}_{\text{ResLN}}$ does not incorporate the components outside of the attention block. As described in §3, in our local analysis method $\mathcal{N}_{\text{Enc}}$ we incorporate the second layer normalization in the transformer's encoder (Figure 2), thus considering the whole encoder block (except FFN). Overall, our global method, GlobEnc, yields the best results among all the methods evaluated in our experiments. In general, Table 1 suggests that incorporating each component of the encoder will increase the correlation; however, the two layer normalizations should be considered together.

4.5.4 On the role of aggregation

We carried out an additional analysis to verify if incorporating vector norms, residual connection and layer normalizations in individual layers is adequate for achieving high correlations, or if it is also necessary to aggregate them via rollout. Table 2

---

[10] We identify the dimensions where the weights are at least 3σ from the mean as outliers (Kovaleva et al., 2021).

shows the correlation results in different layers for raw attributions (without aggregation) and for the aggregated attributions using the rollout method. Applying rollout method on attribution maps up to each layer results in higher correlations with the saliency scores than the raw single layer attribution maps, especially in deeper layers. Therefore, attention aggregation is essential for global input token attribution analysis.

An interesting point in Figure 3, which shows the correlation of the aggregated methods throughout the layers, is that the correlation curves flatten out after only a few layers.[11] This indicates that BERT identifies decisive tokens only after the first few layers. The final layers only make minor adjustments to this order. Nevertheless, it is worth noting that the order of attribution does not necessarily imply the model's final decision and the final result may still change for the better or worse (Zhou et al., 2020).

4.5.5 Qualitative analysis

To qualitatively answer if the aggregated attribution maps provide plausible and meaningful interpretations, we take a closer look at the attribution maps generated by GlobEnc. Figure 1 shows the GlobEnc attribution of the model trained on SST-2. Each layer demonstrates the [CLS] token's aggregated attribution to input tokens up to the corresponding layer. The example inputs are "a deep and meaningful film." and "big fat waste of time.", both correctly classified by the model. In both cases, GlobEnc focuses on the relevant words for sentiment classification, i.e., "meaningful" and "waste". An interesting observation in Figure 1 is that in the first few layers, the [CLS] token mostly attends to itself while other tokens have marginal impact. As the representations get more contextualized in deeper layers, the attribution correctly shifts to the words which indicate the sentiment of the sentence.[12] More examples from MNLI and SST2 datasets, including misclassified examples are available at §A.3. Our qualitative analysis suggests that GlobEnc can be useful for a reasonable interpretation of attention mechanism in BERT, ELECTRA, and possibly any other transformer-based model.

5 Related Work

While numerous studies have used attention weights to analyze and interpret the self-attention mechanism (Clark et al., 2019; Kovaleva et al., 2019; Reif et al., 2019; Htut et al., 2019), the use of mere attention weights to explain a model's inner workings has been an active topic of debate (Serrano and Smith, 2019; Jain and Wallace, 2019; Wiegreffe and Pinter, 2019). Several solutions have been proposed to address this issue, usually through converting raw attention weights to scores that provide better explanations. Brunner et al. (2020) used the transformation function $f^h(\boldsymbol{x}_j)$ to introduce *effective attentions*—the orthogonal component of the attention matrix in $f^h(\boldsymbol{x}_j)$ null space—to explain the inner workings of each layer. However, this technique ignores other components in the encoder and is computationally expensive due to the SVD required to compute the effective attentions. Kobayashi et al. (2020) incorporated the modified vector and introduced a vector norms-based analysis. This was later extended by integrating residual connections and layer normalization components to enhance the accuracy of explanations (Kobayashi et al., 2021). But, as discussed in §4.5, relying solely on LN#1 does not produce accurate results.

While these methods can be employed for single-layer (local) analysis, multi-layer attributions are not necessarily correlated with single-layer attributions due to the significant degree of information combination through multi-layer language models (Pascual et al., 2021; Brunner et al., 2020). Various saliency methods exist for explaining the model's decision based on the input (Li et al., 2016; Bastings and Filippova, 2020; Atanasova et al., 2020; Wu and Ong, 2021; Mohebbi et al., 2021). However, these approaches are not primarily designed for computing inter-token attributions. To fill this gap, Brunner et al. (2020) proposed HTA, which is based on the gradient of each hidden embedding in relation to the input embeddings. In §4.3.2, we extend HTA to incorporate the impact of the input vectors. However, HTA is extremely computationally intensive. Attention rollout (see §3) and attention flow—which involve solving a max-flow problem on the attention graph—are two aggregation approaches introduced by Abnar and Zuidema (2020), in which raw attention weights (with equally weighted residual weights) are aggregated within multiple layers. We showed that attention rollout does not perform well on the raw

---

[11] $\mathcal{W}_{\text{RES}}$ is the only exception with a constant increase; this method is gradually and artificially corrected by $\mathcal{N}_{\text{ENC}}$ context mixing ratios.

[12] Complete attention maps in Figure A.3 show that, similarly to [CLS], other tokens also focus on sentiment tokens.

attention maps of language models fine-tuned on downstream tasks and that this problem can be resolved by utilizing attribution norms.

6 Conclusions

In this work, we proposed a novel method for single layer token attribution analysis which incorporates the whole encoder layer, i.e., the attention block and the output layer normalization. When aggregated across layers using the rollout method, our technique achieves quantitatively and qualitatively plausible results. Our evaluation of different analysis methods provided evidence on roles played by individual components of the encoder layer, i.e., the vector norms, the residual connections, and the layer normalizations. Furthermore, our in-depth analysis suggested that the two layer normalizations in the encoder layer counteract each other; hence, it is important to couple them for an accurate analysis.

Additionally, using a newly proposed and improved version of Hidden Token Attribution, we demonstrated that encoder-based attribution analysis is more accurate when compared to other partial solutions in a single layer (local-level). This is consistent with our global observations. Quantifying global input token attribution based on our work can provide a meaningful explanation of the whole model's behavior. In future work, we plan to apply our global analysis method on various datasets and models, to provide valuable insights into model decisions and interpretability.

A.1 LN Formulation

$m(\boldsymbol{a}) := \frac{1}{d}\sum_k \boldsymbol{a}^{(k)}$,

$s(\boldsymbol{a}) := \sqrt{\frac{1}{d}\sum_k (m(\boldsymbol{a}) - \boldsymbol{a}^{(k)} + \epsilon)^2}$
where ϵ is a small constant

A.2 More Models

In this section we provide the results for BERT-large and ELECTRA-base. For both models, our method outperforms the previous analysis methods. The results are reported in Tables A.1 and A.2.

A.3 More Examples

Aggregated attributions by different methods throughout layers is shown in Figure A.2. Our proposed method shows more plausible results.

Aggregated attribution map for layer 12 is shown in Figure A.3. In this figure, the effect of each token can be seen on all other tokens and not just the [CLS] token.

More examples for MNLI dataset are shown for BERT-base in Figure A.4, for BERT-large in Figure A.6, and for ELECTRA in Figure A.5. Moreover, misclassified examples of SST2 dataset are shown in Figure A.1.

Abstract

Aspect sentiment triplet extraction (ASTE) is a challenging subtask in aspect-based sentiment analysis. It aims to explore the triplets of aspects, opinions and sentiments with complex correspondence from the context. The bidirectional machine reading comprehension (BMRC) can effectively deal with ASTE task, but several problems remains, such as query conflict and probability unilateral decrease. Therefore, this paper presents a robustly optimized BMRC method by incorporating four improvements. The word segmentation is applied to facilitate the semantic learning. Exclusive classifiers are designed to avoid the interference between different queries. A span matching rule is proposed to select the aspects and opinions that better represent the expectations of the model. The probability generation strategy is also introduced to obtain the predicted probability for aspects, opinions and aspect-opinion pairs. We have conducted extensive experiments on multiple benchmark datasets, where our model achieves the state-of-the-art performance.[1]

1 Introduction

Aspect-based sentiment analysis (ABSA) is an important research area of natural language processing (NLP), which aims to mine fine-grained opinions and sentiments based on a specific aspect. In recent years, it has attracted extensive attention of researchers (Hu and Liu, 2004). ABSA includes three basic subtasks: aspect term extraction (Yin et al., 2016; Li et al., 2018; Ma et al., 2019), opinion term extraction (Liu et al., 2015; Wu et al., 2021), and aspect level sentiment classification (Wang et al., 2016; Chen et al., 2017; Jiang et al., 2019; Zhang and Qian, 2020).

Substantial progress has been achieved in recent studies, integrating multiple subtasks into a more complex task (Chen and Qian, 2020; He et al., 2019; Luo et al., 2019; Zhao et al., 2020). Among them, aspect sentiment triplet extraction (ASTE) (Peng et al., 2020) becomes a subject of great interest, which is also the goal of our work. Many research efforts have been made (Xu et al., 2021; Mao et al., 2021; Chen et al., 2021), for example, using bidirectional machine reading comprehension (BMRC) for ASTE. It handles the task effectively, but problems still remain. In the structure of BMRC, the shared classifiers may lead to query conflicts based on specific context, thus affecting the model performance. Some important strategies are also ignored, such as word segmentation, span matching and probability generation.

In this paper, we present a robustly optimized BMRC method for ASTE. The task is transformed into a machine reading comprehension problem. The complex correspondence between the aspect and opinion is processed through bidirectional query based on specific context. Such relationship can be effectively used to make their extraction mutually beneficial, thus facilitating better prediction of various sentiments. In order to deal with the ASTE task more efficiently, we incorporate the word segmentation and exclusive classifiers, and improve the span matching where the priority rule of the combination of probability and position relationship has been added. We also optimize the generation of probability to avoid its unilateral decrease. Our contributions can be summarized as follows:

- Exclusive classifiers are designed in BMRC, so as to avoid the interference between different question answering steps and the query conflict.
- We further advance the prediction performance by adding word segmentation, improving span matching and probability generation.
- Extensive experiments are conducted on

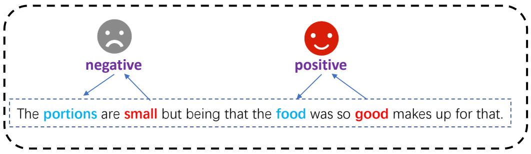

Figure 1: The illustration of ASTE task.

benchmark datasets, where our model achieves the state-of-the-art performance.

2 Methodology

In this section, we briefly review the ASTE task and BMRC model, and then introduce our four improvements in detail.

2.1 Problem Formulation

Given a sentence $W = \{w_1, w_2, ..., w_M\}$ with M tokens, ASTE task is to identify the collection of triplets $T = \{(a_i, o_i, s_i)\}_{i=1}^{|T|}$, where a_i, o_i, s_i and $|T|$ denote the aspect, the opinion expression, the sentiment, and the number of triplets, respectively. For the sentence shown in Figure 1, the collection T is $\{(portions, small, negative), (food, good, positive)\}$.

2.2 BMRC

BMRC can put forward the corresponding query according to the context, and the model then outputs the desired answer.

Forward Query BMRC will query all the aspects based on context; Then, according to the aspect of each prediction, all opinions describing it are queried from the context.

Backward Query BMRC will query all the opinions based on context; Then, according to the opinion of each prediction, all aspects describing it are queried from the context.

Sentiment Prediction Once the aspect-opinion pairs are obtained, the sentiment queries can be constructed to predict the sentiments of the corresponding pairs according to the context.

After that, the sentiments and aspect-opinion pairs are combined into triplets. The whole process is illustrated in Figure 2.

2.3 Word Segmentation

We use the tokenizer based on wordpiece in BERT (Devlin et al., 2019) to segment words into subwords. Wordpiece is a common technique for word segmentation in NLP tasks.

The role of word segmentation has been investigated. Suppose the word *"walking"* is fed into the model, unless it appears many times in the training corpus, the model may fail to handle the word well. When similar words like *"walked"*, *"walker"* or *"walks"* show up, without word segmentation, they will be treated as completely different words. However, if they are subdivided into *"walk ##ing"*, *"walk ##ed"*, *"walk ##er"*, and *"walk ##s"*, their sub-word *"walk"* contains the same semantics which is quite common during training. In this sense, the model is able to learn more information through word segmentation.

2.4 Exclusive Classifiers

Bidirectional queries are performed in BMRC, and the model needs to perform multiple different types of queries based on context. For example, the aspect query in forward query is different from the opinion query in backward query. The former queries all the aspects in the context, while the latter queries all the opinions in the context, requiring different entities. Another example is the aspect query in the forward query and the aspect query in the backward query. Although the entities of the two queries are the same, the latter conveys opinion information and searches for all the aspects described by it, while the former does not carry any context information, namely, all the aspects in the context.

In the original BMRC, all queries share one classifier. However, if different types of queries use the same classifier, it cannot serve any part very well. These different types of queries will interfere with each other and cause the query conflict. By adding exclusive classifiers, each different type of query can use a unique classifier, as shown in Figure 3, which can effectively avoid the problem of query conflict and greatly improve the performance of the model.

2.5 Span Matching

Recently, there is a lot of work to deal with ABSA tasks based on span extraction (Hu et al., 2019; Xu et al., 2021), so does BMRC. After obtaining the predicted value of each position as the start or end position of span through binary classifiers, the predicted value is converted into probability using softmax function (Chen et al., 2021).

When predicting the span, many start and end positions may be predicted. The rule to match them is very important, which will seriously affect the

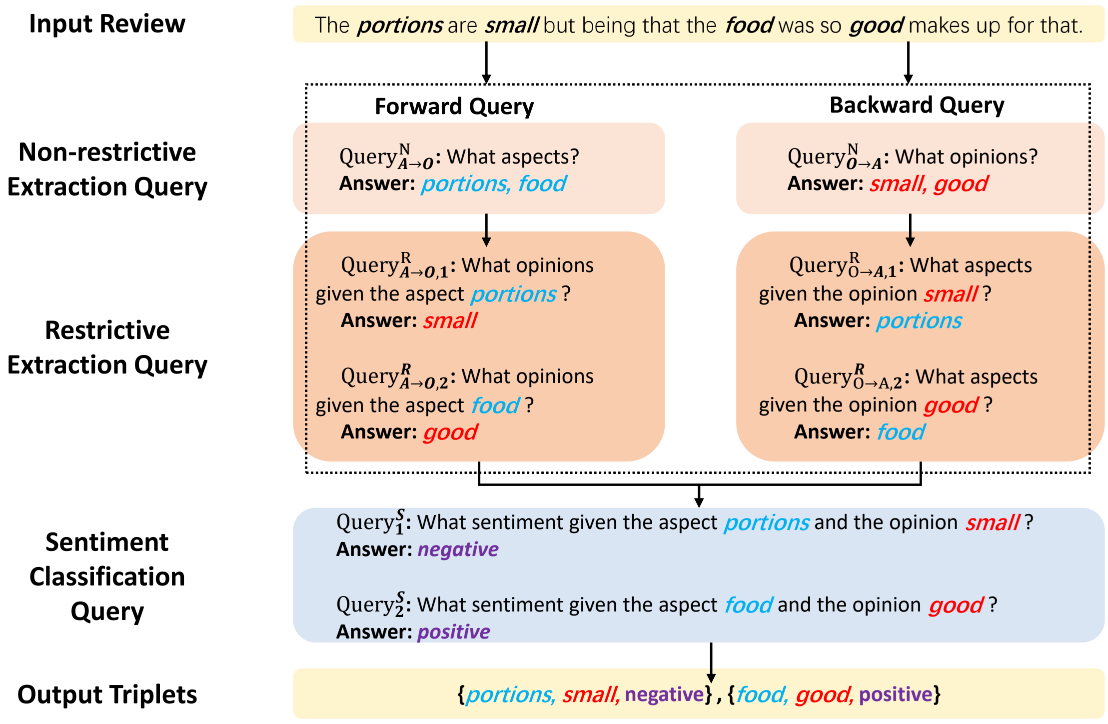

Figure 2: The BMRC framework.

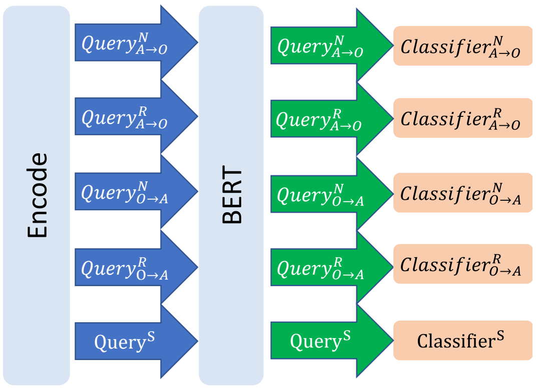

Figure 3: Exclusive classifiers for different queries.

performance of the model. The matching should consider the probability of start and end positions, as well as the relationship between the positions. The former represents the optimistic degree of the model for the position, and the latter is the judgment that the start and end positions of span are as close as possible; the priority of probability is higher. So, the overview of our span matching rule is: make each end position match the start position with the highest probability after the previous end position. If there is a start position with the same probability, select the one whose position is closest to the end position.

2.6 Probability Generation

Once the bidirectional queries and span matching are completed, the aspects, opinions and pairs with corresponding relationship are obtained. In BMRC, the probability product of the start and end positions is taken as the probability of the span, and the probability of pair is the probability product of aspect and opinion. In this way, the probability of pair decreases unilaterally and cannot well represent the prediction of the pair by the model. For example, the probability of the four positions of pair is 0.9, while the probability of pair is $0.9^4 = 0.6561$, which seems not so reasonable.

By probability generation, we can effectively solve the problem of unilateral decrease in the probability of span and pair, so that their probability can better reflect the expectation of the model. The operations are shown in Equation 1 and 2, where we balance the probability of span and pair so that their probability is within the interval of the two related probabilities. It enables us to avoid the unilateral decrease of probability, but keep more appropriate to the expectation of the model.

$$P(span) = \sqrt{P(span_{start}) * P(span_{end})} \quad (1)$$

$$P(pair) = \sqrt{P(pair_{asp}) * P(pair_{opi})} \quad (2)$$

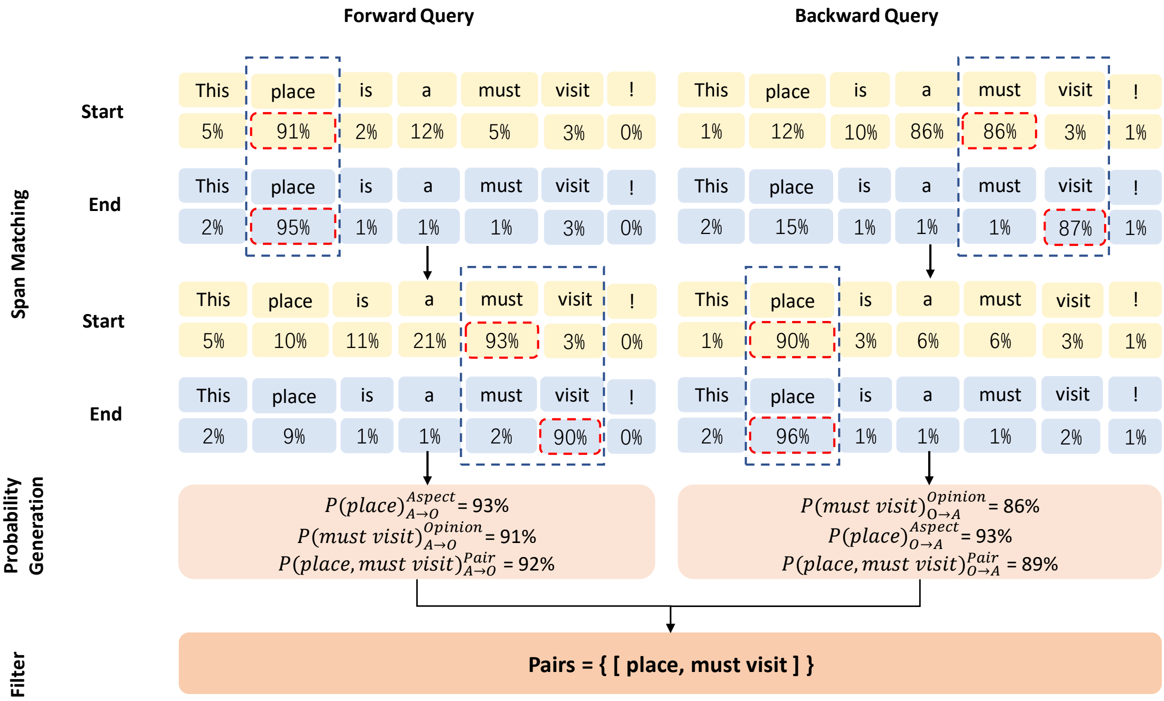

Figure 4: Span matching and probability generation architecture.

In the above equations, $P(\star)$ represents the prediction probability of $\star$. The *span* represents an aspect or opinion, $span_{start}$ and $span_{end}$ represent its start and end positions. The *pair* represents an aspect-opinion pair, $pair_{asp}$ and $pair_{opi}$ represent the aspect and opinion in the pair. For the convenience of comparison, the calculation method of $P(span_{start})$ and $P(span_{end})$ is consistent with BMRC (Chen et al., 2021).

The effects of span matching and probability generation are shown in Figure 4.

3 Experiment

In this section, we introduce information about the experiments, including datasets, evaluation metrics, baselines, experimental results, and ablation study.

3.1 Datasets

We evaluate the model performance on ASTE-Data-v1 (Peng et al., 2020) and ASTE-Data-v2 (Xu et al., 2020), which are popular benchmark datasets for ASTE task. They are derived from Laptop14, Rest14, Rest15, and Rest16 of SemEval shared challenges (Pontiki et al., 2014, 2015, 2016). The ASTE-Data-v2 datasets are the refined data of the previous ASTE-Data-V1 datasets[2].

3.2 Evaluation Metrics

We use precision (P), recall (R) and F1 scores as evaluation metrics to gauge the performance. A triplet prediction is correct only if the aspect, opinion and sentiment are predicted correctly.

3.3 Results

We focus on the ASTE task. The experimental results on ASTE-Data-v1 and ASTE-Data-v2 datasets are shown in Tables 1 and 2, respectively. In order to make a fair comparison with baselines, our F1 scores appear at least three times in the experiments.

It is worth noting that we have achieved state-of-the-art performances on both ASTE-Data datasets, indicating that our improvements further advance the performance of BMRC in dealing with ASTE task. On the Laptop14, Rest14, Rest15, and Rest16 datasets of ASTE-Data-v1, the F1 scores of our model are increased by 2.97, 4.20, 5.61 and 5.52 respectively, compared with the original BMRC. As for ASTE-Data-v2, we also increase the F1 scores of the Strong baseline Span-ASTE (Xu et al., 2021) by 2.74, 0.77, 2.36 and 2.90, respectively. This indicates that our improvement is very significant.

Table 3: The performance of our four improvements on the ASTE-Data-v2 datasets.

3.4 Ablation Experiments

Firstly, we experiment the model without improvement on the ASTE-Data-v2. The model is a reproduction based on BMRC, and then gradually superimposes the four improvements of word segmentation, exclusive classifiers, span matching and probability generation to conduct ablation experiment. This arrangement corresponds to the sequence before and after they contact the data, that is, the data will first pass through word segmentation and enter the model, the prediction value is obtained from the exclusive classifiers, and then span matching is carried out according to it. Finally, the probability generation is used to generate probabilistic representations of aspects, opinions and pairs. The datasets and various parameters of the five experiments are the same. In order to make a fair comparison with baselines, our F1 scores appear at least three times in the experiments. The ablation experimental results are shown in Table 3. Each improvement advances the performance of the model, demonstrating their advantages and effectiveness.

4 Conclusion

In this paper, we propose several improvements on the basis of BMRC for ASTE task, which can effectively deal with the complex correspondence among aspect, opinion and sentiment. In order to deal with the problems of the original BMRC, we add exclusive classifiers and three strategies, including word segmentation, span matching and probability generation. The proposed method is expected to handle complex ASTE task more efficiently. Extensive experiments are conducted to demonstrate the advantages of our improvements.

Abstract

Discovering latent topics from text corpora has been studied for decades. Many existing topic models adopt a fully unsupervised setting, and their discovered topics may not cater to users' particular interests due to their inability of leveraging user guidance. Although there exist seed-guided topic discovery approaches that leverage user-provided seeds to discover topic-representative terms, they are less concerned with two factors: (1) the existence of out-of-vocabulary seeds and (2) the power of pre-trained language models (PLMs). In this paper, we generalize the task of seed-guided topic discovery to allow out-of-vocabulary seeds. We propose a novel framework, named SEETOPIC, wherein the general knowledge of PLMs and the local semantics learned from the input corpus can mutually benefit each other. Experiments on three real datasets from different domains demonstrate the effectiveness of SEETOPIC in terms of topic coherence, accuracy, and diversity.[1]

1 Introduction

Automatically discovering informative and coherent topics from massive text corpora is central to text analysis through helping users efficiently digest a large collection of documents (Griffiths and Steyvers, 2004) and advancing downstream applications such as summarization (Wang et al., 2009, 2022), classification (Chen et al., 2015; Meng et al., 2020b), and generation (Liu et al., 2021).

Unsupervised topic models have been the mainstream approach to topic discovery since the proposal of pLSA (Hofmann, 1999) and LDA (Blei et al., 2003). Despite their encouraging performance in finding informative latent topics, these topics may not reflect user preferences well, mainly due to their unsupervised nature. For example, given a collection of product reviews, a user may be specifically interested in product categories (e.g., "*books*", "*electronics*"), but unsupervised topic models may generate topics containing different sentiments (e.g., "*good*", "*bad*"). To consider users' interests and needs, seed-guided topic discovery approaches (Jagarlamudi et al., 2012; Gallagher et al., 2017; Meng et al., 2020a) have been proposed to find representative terms for each category based on user-provided seeds or category names.[2] However, there are still two less concerned factors in these approaches.

Table 1: Three datasets (Cohan et al., 2020; McAuley and Leskovec, 2013; Zhang et al., 2017) from different domains and their topic categories (i.e., seeds). **Red**: Seeds never seen in the corpus (i.e., out-of-vocabulary). In all three datasets, a large proportion of seeds are out-of-vocabulary.

Dataset	Category Names (Seeds)	
SciDocs (Scientific Papers)	cardiovascular diseases chronic kidney disease **chronic respiratory diseases** diabetes mellitus **digestive diseases** **hiv/aids**	**hepatitis a/b/c/e** mental disorders musculoskeletal disorders **neoplasms (cancer)** neurological disorders
Amazon (Product Reviews)	**apps for android** books **cds and vinyl** **clothing, shoes and jewelry** electronics	**health and personal care** **home and kitchen** movies and tv **sports and outdoors** video games
Twitter (Social Media Posts)	food **shop and service** **travel and transport** **college and university** **nightlife spot**	residence **outdoors and recreation** **arts and entertainment** **professional and other places**

The Existence of Out-of-Vocabulary Seeds. Previous studies (Jagarlamudi et al., 2012; Gallagher et al., 2017; Meng et al., 2020a) assume that all user-provided seeds must be **in-vocabulary** (i.e., appear at least once in the input corpus), so that they can utilize the occurrence statistics or Skip-Gram embedding methods (Mikolov et al., 2013) to model seed semantics. However, user-interested categories can have specific or composite descriptions, which may never appear in the corpus. Table 1 shows three datasets from different domains: sci-

---

[2] In this paper, we use "seeds" and "category names" interchangeably.

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 279 - 290
July 10-15, 2022 ©2022 Association for Computational Linguistics

entific papers, product reviews, and social media posts. In each dataset, documents can belong to one or more categories, and we list the category names provided by the dataset collectors. These seeds should reflect their particular interests. In all three datasets, we have a large proportion of seeds (45% in SciDocs, 60% in Amazon, and 78% in Twitter) that never appear in the corpus. Some category names are too specific (e.g., "*chronic respiratory diseases*", "*nightlife spot*") to be exactly matched, others are the composition of multiple entities (e.g., "*hepatitis a/b/c/e*", "*neoplasms (cancer)*", "*clothing, shoes and jewelry*").[3]

The Power of Pre-trained Language Models. Techniques used in previous studies are mainly based on LDA variants (Jagarlamudi et al., 2012) or context-free embeddings (Meng et al., 2020a). Recently, pre-trained language models (PLMs) such as BERT (Devlin et al., 2019) have achieved significant improvement in a wide range of text mining tasks. In topic discovery, the generic representation power of PLMs learned from web-scale corpora (e.g., Wikipedia or PubMed) may complement the information a model can obtain from the input corpus. Moreover, out-of-vocabulary seeds usually have meaningful in-vocabulary components (e.g., "*night*" and "*life*" in "*nightlife spot*", "*health*" and "*care*" in "*health and personal care*"). The optimized tokenization strategy of PLMs (Sennrich et al., 2016; Wu et al., 2016) can help segment the seeds into such meaningful components (e.g., "*nightlife*" → "*night*" and "*##life*"), and the contextualization power of PLMs can help infer the correct meaning of each component (e.g., "*##life*" and "*care*") in the category name. Therefore, PLMs are much needed in handling out-of-vocabulary seeds and effectively learning their semantics.

Contributions. Being aware of these two factors, in this paper, we study seed-guided topic discovery in the presence of out-of-vocabulary seeds. Our proposed SEETOPIC framework consists of two modules: (1) The *general* representation module uses a PLM to derive the representation of each term (including out-of-vocabulary seeds) based on the general linguistic knowledge acquired through pre-training. (2) The *seed-guided local* representation module learns in-vocabulary term embeddings specific to the input corpus and the given seeds. In order to optimize the learned representations for topic coherence, which is commonly reflected by pointwise mutual information (PMI) (Newman et al., 2010), our objective implicitly maximizes the PMI between each word and its context, the documents it appears, as well as the category it belongs to. The learning of the two modules is connected through an iterative ensemble ranking process, in which the general knowledge of PLMs and the term representations specifically learned from the target corpus conditioned on the seeds can complement each other.

To summarize, this study makes three contributions. (1) *Task*: we propose to study seed-guided topic discovery in the presence of out-of-vocabulary seeds. (2) *Framework*: we design a unified framework that jointly models general knowledge through PLMs and local corpus statistics through embedding learning. (3) *Experiment*: extensive experiments on three datasets demonstrate the effectiveness of SEETOPIC in terms of topic coherence, accuracy, and diversity.

2 Problem Definition

As shown in Table 1, we assume a seed can be either a single word or a phrase. Given a corpus $\mathcal{D}$, we use $\mathcal{V}_\mathcal{D}$ to denote the set of **terms** appearing in $\mathcal{D}$. In accordance with the assumption of category names, each term can also be a single word or a phrase. In practice, given a raw corpus, one can use existing phrase chunking tools (Manning et al., 2014; Shang et al., 2018) to detect phrases in it. *After* phrase chunking, if a category name is still not in $\mathcal{V}_\mathcal{D}$, we define it as **out-of-vocabulary**.

Problem Definition. *Given a corpus* $\mathcal{D} = \{d_1, ..., d_{|\mathcal{D}|}\}$ *and a set of category names* $\mathcal{C} = \{c_1, ..., c_{|\mathcal{C}|}\}$ *where some category names are out-of-vocabulary, the task is to find a set of in-vocabulary terms* $\mathcal{S}_i = \{w_1, ..., w_S\} \subseteq \mathcal{V}_\mathcal{D}$ *for each category* c_i *such that each term in* $\mathcal{S}_i$ *is semantically close to* c_i *and far from other categories* c_j $(\forall j \neq i)$.

3 The SEETOPIC Framework

In this section, we first introduce how we model general and local text semantics using a PLM mod-

---

[3] One possible idea to deal with composite seeds is to split them into multiple seeds. However, there are many possible ways to express the conjunctions (e.g., "*/*", "*()*", "*,*" and "*and*" in Table 1), which may require manual tuning. Besides, simple chunking rules will induce splits that break the semantics of the original composition (e.g., "*professional and other places*" may be split into "*professional*" and "*other places*"). Moreover, even after the split, some seeds are still out-of-vocabulary. Therefore, we propose to use PLMs to tackle out-of-vocabulary seeds in a unified way. In experiments, we will show that our model is able to tackle composite seeds. For example, given the seed "*hepatitis a/b/c/e*", we can find terms relevant to "*hepatitis b*" and "*hepatitis c*" (see Table 4).

ule and a seed-guided embedding learning module, respectively. Then, we present the iterative ensemble ranking process and our overall framework.

3.1 Modeling General Text Semantics using a PLM

PLMs such as BERT (Devlin et al., 2019) aim to learn generic language representations from web-scale corpora (e.g., Wikipedia or PubMed) that can be applied to a wide variety of text-related applications. To transfer such general knowledge to our topic discovery task, we employ a PLM to encode each category name and each in-vocabulary term to a vector. To be specific, given a term $w \in \mathcal{C} \cup \mathcal{V}_{\mathcal{D}}$, we input the sequence "`[CLS]` w `[SEP]`" into the PLM. Here, w can be a phrase containing multiple words, and each word can be out of the PLM's vocabulary. To deal with this, most PLMs use a pre-trained tokenizer (Sennrich et al., 2016; Wu et al., 2016) to segment each unseen word into frequent subwords. Then, the contextualization power of PLMs will help infer the correct meaning of each word/subword, so as to provide a more precise representation of the whole category.

After LM encoding, following (Sia et al., 2020; Thompson and Mimno, 2020; Li et al., 2020), we take the output of all tokens from the last layer and average them to get the term embedding $\boldsymbol{e}_w$. In this way, even if a seed c_i is **out-of-vocabulary**, we can still obtain its representation $\boldsymbol{e}_{c_i}$.

3.2 Modeling Local Text Semantics in the Input Corpus

The motivation of topic discovery is to discover latent topic structures from the input corpus. Therefore, purely relying on general knowledge in the PLM is insufficient because topic discovery results should adapt to the input corpus $\mathcal{D}$. Now, we introduce how we learn another set of embeddings $\{\boldsymbol{u}_w | w \in \mathcal{V}_{\mathcal{D}}\}$ from $\mathcal{D}$.

Previous studies on embedding learning assume that the semantic of a term is similar to its local context (Mikolov et al., 2013), the document it appears (Tang et al., 2015; Xun et al., 2017a), and the category it belongs to (Meng et al., 2020a). Inspired by these studies, we propose the following embedding learning objective.

$$\mathcal{J} = \underbrace{\sum_{d\in\mathcal{D}} \sum_{w_i\in d} \sum_{w_j\in\mathcal{C}(w_i,h)} p(w_j|w_i)}_{\text{context}} + \underbrace{\sum_{d\in\mathcal{D}} \sum_{w\in d} p(d|w)}_{\text{document}} + \underbrace{\sum_{c_i\in\mathcal{C}} \sum_{w\in\mathcal{S}_i} p(c_i|w)}_{\text{category}}, \quad (1)$$

where

$$p(z|w) = \frac{\exp(\boldsymbol{u}_w^T \boldsymbol{v}_z)}{\sum_{z'} \exp(\boldsymbol{u}_w^T \boldsymbol{v}_{z'})}, \quad (z \text{ can be } w_j, d, \text{ or } c_i). \quad (2)$$

In this objective, $\boldsymbol{u}_{w_i}$ (and $\boldsymbol{v}_{w_j}$), $\boldsymbol{v}_d$, $\boldsymbol{v}_{c_i}$ are the embedding vectors of terms, documents, and categories, respectively. $\mathcal{C}(w_i, h)$ is the set of context terms of w_i in d. Specifically, if $d = w_1 w_2 ... w_L$, then $\mathcal{C}(w_i, h) = \{w_j | i - h \le j \le i + h, j \ne i\}$, where h is the context window size.

Note that the last term in Eq. (1) encourages the similarity between each category c_i and its representative terms $\mathcal{S}_i$. Here, we adopt an iterative process to gradually update category-representative terms. Initially, $\mathcal{S}_i$ consists of just a few in-vocabulary terms similar to c_i according to the PLM. At each iteration, the size of $\mathcal{S}_i$ will increase to contain more category-discriminative terms (the selection criterion of these terms will be introduced in the next section), and we need to encourage their proximity with c_i in the next iteration.

Directly optimizing the full softmax in Eq. (2) is costly. Therefore, we adopt the negative sampling strategy (Mikolov et al., 2013) for efficient approximation.

Interpreting the Objective. In topic modeling studies, pointwise mutual information (PMI) (Newman et al., 2010) is a standard evaluation metric for topic coherence (Lau et al., 2014; Röder et al., 2015). Levy and Goldberg (2014) prove that the Skip-Gram embedding model is implicitly factorizing the PMI matrix. Following their proof, we can show that maximizing Eq. (1) is implicitly doing the following factorization:

$$\mathbf{U}_w^T [\mathbf{V}_w; \mathbf{V}_d; \mathbf{V}_c] = [\mathbf{X}_{ww}; \mathbf{X}_{wd}; \mathbf{X}_{wc}], \quad (3)$$

where the columns of $\mathbf{U}_w$, $\mathbf{V}_w$, $\mathbf{V}_d$, $\mathbf{V}_c$ are $\boldsymbol{u}_{w_i}$, $\boldsymbol{v}_{w_j}$, $\boldsymbol{v}_d$, $\boldsymbol{v}_{c_i}$, respectively ($w_i, w_j \in \mathcal{V}_{\mathcal{D}}$, $d \in \mathcal{D}$, $c_i \in \mathcal{C}$); $\mathbf{X}_{ww}$, $\mathbf{X}_{wd}$, and $\mathbf{X}_{wc}$ are PMI matrices.

$$\begin{aligned}
\mathbf{X}_{ww} &= \left[\log\left(\frac{\#_{\mathcal{D}}(w_i, w_j) \cdot \lambda_{\mathcal{D}}}{\#_{\mathcal{D}}(w_i) \cdot \#_{\mathcal{D}}(w_j) \cdot b} \right) \right]_{w_i, w_j \in \mathcal{V}_{\mathcal{D}}}, \\
\mathbf{X}_{wd} &= \left[\log\left(\frac{\#_d(w) \cdot \lambda_{\mathcal{D}}}{\#_{\mathcal{D}}(w) \cdot \lambda_d \cdot b} \right) \right]_{w \in \mathcal{V}_{\mathcal{D}},\, d \in \mathcal{D}}, \\
\mathbf{X}_{wc} &= \left[x_{w,c_i} \right]_{w \in \mathcal{V}_{\mathcal{D}},\, c_i \in \mathcal{C}}, \quad \text{where} \\
x_{w,c_i} &= \begin{cases} \log \frac{|\mathcal{C}|}{b}, & \text{if } w \in \mathcal{S}_i, \\ -\infty, & \text{if } w \in \mathcal{S}_j \ (\forall j \ne i). \end{cases}
\end{aligned} \quad (4)$$

Here, $\#_{\mathcal{D}}(w_i, w_j)$ denotes the number of co-occurrences of w_i and w_j in a context window in $\mathcal{D}$; $\#_{\mathcal{D}}(w)$ denotes the number of occurrences of w

in $\mathcal{D}$; $\lambda_{\mathcal{D}}$ is the total number of terms in $\mathcal{D}$; $\#_d(w)$ denotes the number of times w occurs in d; λ_d is the total number of terms in d; b is the number of negative samples. (For the derivation of Eq. (3), please refer to Appendix A.)

To summarize, the learned local representations $\boldsymbol{u}_w$ are implicitly optimized for topic coherence, where term co-occurrences are measured in context, document, and category levels.

3.3 Ensemble Ranking

We have obtained two sets of term embeddings that model text semantics from different angles: $\{\boldsymbol{e}_w | w \in \mathcal{C} \cup \mathcal{V}_{\mathcal{D}}\}$ carries the PLM's knowledge, while $\{\boldsymbol{u}_w | w \in \mathcal{V}_{\mathcal{D}}\}$ models the input corpus as well as user-provided seeds. We now propose an ensemble ranking method to leverage information from both sides to grab more discriminative terms for each category.

Given a category c_i and its current term set $\mathcal{S}_i$, we first calculate the scores of each term $w \in \mathcal{V}_{\mathcal{D}}$.

$$\begin{aligned} \text{score}_G(w|\mathcal{S}_i) &= \frac{1}{|\mathcal{S}_i|} \sum_{w' \in \mathcal{S}_i} \cos(\boldsymbol{e}_w, \boldsymbol{e}_{w'}), \\ \text{score}_L(w|\mathcal{S}_i) &= \frac{1}{|\mathcal{S}_i|} \sum_{w' \in \mathcal{S}_i} \cos(\boldsymbol{u}_w, \boldsymbol{u}_{w'}). \end{aligned} \tag{5}$$

The subscript "G" here means "general", while "L" means "local". Then, we sort all terms by these two scores, respectively. Each term w will hence get two rank positions $\text{rank}_G(w)$ and $\text{rank}_L(w)$. We propose the following ensemble score based on the reciprocal rank:

$$\text{score}(w|\mathcal{S}_i) = \left(\frac{1}{2}\left(\frac{1}{\text{rank}_G(w)}\right)^{\rho} + \frac{1}{2}\left(\frac{1}{\text{rank}_L(w)}\right)^{\rho}\right)^{1/\rho}. \tag{6}$$

Here, $0 < \rho \leq 1$ is a constant. In practice, instead of ranking all terms in the vocabulary, we only check the top-M results in the two ranking lists. If a term w is not among the top-M according to $\text{score}_G(w)$ (resp., $\text{score}_L(w)$), we set $\text{rank}_G(w) = +\infty$ (resp., $\text{rank}_L(w) = +\infty$). In fact, when $\rho = 1$, Eq. (6) becomes the *arithmetic* mean of the two reciprocal ranks $\frac{1}{\text{rank}_G(w)}$ and $\frac{1}{\text{rank}_L(w)}$. This is essentially the mean reciprocal rank (MRR) commonly used in ensemble ranking, where a high position in one ranking list can largely compensate a low position in the other. In contrast, when $\rho \to 0$, Eq. (6) becomes the *geometric* mean of the two reciprocal ranks (see Appendix B), where two ranking lists both have the "veto power" (i.e., a term needs to be ranked as top-M in both ranking lists to obtain a non-zero ensemble score). In experiment, we set $\rho = 0.1$ and show it outperforms MRR (i.e., $\rho = 1$) in our topic discovery task.

Algorithm 1: SEETOPIC

```
Input: A text corpus $\mathcal{D} = \{d_1, ..., d_{|\mathcal{D}|}\}$, a set of
       seeds $\mathcal{C} = \{c_1, ..., c_{|\mathcal{C}|}\}$, and a PLM.
Output: $(\mathcal{S}_1, ..., \mathcal{S}_{|\mathcal{C}|})$, where each $\mathcal{S}_i$ is a set of
        category-discriminative terms for $c_i$.
1  Compute $\{\boldsymbol{e}_w | w \in \mathcal{C} \cup \mathcal{V}_{\mathcal{D}}\}$ using the PLM;
2  // Initialize $\mathcal{S}_i$;
3  $\mathcal{S}_1, ..., \mathcal{S}_{|\mathcal{C}|} \leftarrow \emptyset$;
4  for $n \leftarrow 1$ to $N$ do
5      for $i \leftarrow 1$ to $|\mathcal{C}|$ do
6          $w_n \leftarrow \arg\max_{w \in \mathcal{V}_{\mathcal{D}} \setminus (\mathcal{S}_1 \cup ... \cup \mathcal{S}_{|\mathcal{C}|})} \cos(\boldsymbol{e}_w, \boldsymbol{e}_{c_i})$;
7          $\mathcal{S}_i \leftarrow \mathcal{S}_i \cup \{w_n\}$;
8  // Update $\mathcal{S}_i$ for $T$ iterations;
9  for $t \leftarrow 1$ to $T$ do
10     Learn $\{\boldsymbol{u}_w | w \in \mathcal{V}_{\mathcal{D}}\}$ from the input corpus $\mathcal{D}$
         and the up-to-date representative terms
         $\mathcal{S}_1, ..., \mathcal{S}_{|\mathcal{C}|}$ according to Eq. (1);
11     $\text{score}_G(w|\mathcal{S}_i)$ and $\text{score}_L(w|\mathcal{S}_i) \leftarrow$ Eq. (5);
12     $\text{score}(w|\mathcal{S}_i) \leftarrow$ Eq. (6);
13     $\mathcal{S}_1, ..., \mathcal{S}_{|\mathcal{C}|} \leftarrow \emptyset$;
14     for $n \leftarrow 1$ to $(t+1)N$ do
15         for $i \leftarrow 1$ to $|\mathcal{C}|$ do
16             $\mathcal{S}_i \leftarrow$ Eq. (7);
17 Return $(\mathcal{S}_1, ..., \mathcal{S}_{|\mathcal{C}|})$;
```

After computing the ensemble score $\text{score}(w|\mathcal{S}_i)$ for each w, we update $\mathcal{S}_i$. To guarantee that each $\mathcal{S}_i$ is category-discriminative, we do not allow any term to belong to more than one category. Therefore, we gradually expand each $\mathcal{S}_i$ by turns. At the beginning, we reset $\mathcal{S}_1 = ... = \mathcal{S}_{|\mathcal{C}|} = \emptyset$. When it is $\mathcal{S}_i$'s turn, we add one term $\mathcal{S}_i$ according to the following criterion:

$$\mathcal{S}_i \leftarrow \mathcal{S}_i \cup \{\mathop{\arg\max}_{w \in \mathcal{V}_{\mathcal{D}} \setminus (\mathcal{S}_1 \cup ... \cup \mathcal{S}_{|\mathcal{C}|})} \text{score}(w|\mathcal{S}_i)\}. \tag{7}$$

3.4 Overall Framework

We summarize the entire SEETOPIC framework in Algorithm 1. To deal with **out-of-vocabulary** category names, we first utilize a PLM to find their nearest in-vocabulary terms as the initial category-discriminative term set $\mathcal{S}_i$ (Lines 1-7). After initialization, $|\mathcal{S}_i| = N$ ($\forall 1 \leq i \leq |\mathcal{C}|$). Note that for an in-vocabulary category name $c_i \in \mathcal{V}_{\mathcal{D}}$, itself will be added to the initial $\mathcal{S}_i$ as the top-1 similar in-vocabulary term.

After getting the initial $\mathcal{S}_i$, we update it by T iterations (Lines 8-16). At each iteration, according to the up-to-date $\mathcal{S}_1, \mathcal{S}_2, ..., \mathcal{S}_{|\mathcal{C}|}$, we relearn embeddings $\boldsymbol{u}_w$, $\boldsymbol{v}_w$, $\boldsymbol{v}_d$, and $\boldsymbol{v}_{c_i}$ using Eq. (1) (Line 10). The two set of embeddings, $\{\boldsymbol{e}_w | w \in \mathcal{C} \cup \mathcal{V}_{\mathcal{D}}\}$ (computed at Line 1) and $\{\boldsymbol{u}_w | w \in \mathcal{V}_{\mathcal{D}}\}$ (updated at Line 10), are then leveraged to perform ensemble ranking (Lines 11-12). Based on the ensemble score $\text{score}(w|\mathcal{S}_i)$, we update $\mathcal{S}_i$ using Eq. (7) (Lines 13-16). After the t-th iteration, $|\mathcal{S}_i| = (t+1)N$ $(\forall 1 \leq i \leq |\mathcal{C}|)$.

Complexity Analysis. The time complexity of using the PLM is $\mathcal{O}((|\mathcal{C}| + |\mathcal{V}_\mathcal{D}|)\alpha_{\text{PLM}})$, where α_{PLM} is the complexity of encoding one term via the PLM. The total complexity of local embedding is $\mathcal{O}(T\lambda_\mathcal{D}(h+|\mathcal{C}|)b)$ because in each iteration $1 \leq t \leq T$, every $w \in \mathcal{D}$ interacts with every other term in the context window of size h, its belonging document, and each category $c_i \in \mathcal{C}$, and each update involves b negative samples. The total complexity of ensemble ranking is $\mathcal{O}(T|\mathcal{V}_\mathcal{D}||\mathcal{C}||\mathcal{S}_i|)$ as in each iteration $1 \leq t \leq T$, we compute scores between each $w \in \mathcal{V}_\mathcal{D}$ and each $w' \in \mathcal{S}_i$ $(\forall c_i \in \mathcal{C})$.

4 Experiments

4.1 Experimental Setup

Datasets. We conduct experiments on three public datasets from different domains: (1) **SciDocs** (Cohan et al., 2020)[4] is a large collection of scientific papers supporting diverse evaluation tasks. For the MeSH classification task (Coletti and Bleich, 2001), about 23K medical papers are collected, each of which is assigned to one of the 11 common disease categories derived from the MeSH vocabulary. We use the title and abstract of each paper as documents and the 11 category names as seeds. (2) **Amazon** (McAuley and Leskovec, 2013)[5] contains product reviews from May 1996 to July 2014. Each Amazon review belongs to one or more product categories. We use the subset sampled by Zhang et al. (2020, 2022), which contains 10 categories and 100K reviews. (3) **Twitter** (Zhang et al., 2017)[6] is a crawl of geo-tagged tweets in New York City from August 2014 to November 2014. The dataset collectors link these tweets with Foursquare's POI database and assign them to 9 POI categories. We take these category names as input seeds.

Seeds used in the three datasets are shown in Table 1. Dataset statistics are summarized in Table 2. For all three datasets, we use AutoPhrase (Shang et al., 2018)[7] to perform phrase chunking in the corpus, and we remove words and phrases occurring less than 3 times.

Previous studies (Jagarlamudi et al., 2012; Meng et al., 2020a) have tried some other datasets (e.g., RCV1, 20 Newsgroups, NYT, and Yelp). However, the category names they use in these datasets are all picked from **in-vocabulary** terms. Therefore, we do not consider these datasets for evaluation in our task settings.

Table 2: Dataset Statistics.

Dataset	SciDocs	Amazon	Twitter
#Documents	23,473	100,000	135,529
#In-vocabulary Terms (After Phrase Chunking)	55,897	56,942	17,577
Avg Doc Length	239.8	119.0	6.7
#Seeds	11	10	9
#Out-of-vocabulary Seeds (After Phrase Chunking)	5	6	7

Following (Sia et al., 2020), we adopt a 60-40 train-test split for all three datasets. The training set is used as the input corpus $\mathcal{D}$, and the testing set is used for calculating topic coherence metrics (see evaluation metrics for details).

Compared Methods. We compare our SEETOPIC framework with the following methods, including seed-guided topic modeling methods, seed-guided embedding learning methods, and PLMs. (1) **SeededLDA** (Jagarlamudi et al., 2012)[8] is a seed-guided topic modeling method. It improves LDA by biasing topics to produce input seeds and by biasing documents to select topics relevant to the seeds they contain. (2) **Anchored CorEx** (Gallagher et al., 2017)[9] is a seed-guided topic modeling method. It incorporates user-provided seeds by balancing between compressing the input corpus and preserving seed-related information. (3) **Labeled ETM** (Dieng et al., 2020)[10] is an embedding-based topic modeling method. It incorporates distributed representation of each term. Following (Meng et al., 2020a), we retrieve representative terms according to their embedding similarity with the category name. (4) **CatE** (Meng et al., 2020a)[11] is a seed-guided embedding learning method for discriminative topic discovery. It takes category names as input and jointly learns term embedding and specificity from the input corpus. Category-discriminative terms are then selected based on both embedding similarity with the category and specificity. (5) **BERT** (Devlin et al., 2019)[12] is a PLM. Following Lines 1-7 in Algorithm 1, we use BERT to encode each input category name and each term to a vector, and then perform similarity search to directly find all repre-

sentative terms. (6) **BioBERT** (Lee et al., 2020)[13] is a PLM. It is used in the same way as BERT. Since BioBERT is specifically trained for biomedical text mining tasks, we report its performance on the SciDocs dataset only. (7) **SEETOPIC-NoIter** is a variant of our SEETOPIC framework. In Algorithm 1, after initialization (Lines 1-7), it executes Lines 9-16 only once (i.e., $T = 1$) to find all representative terms.

Here, all seed-guided topic modeling and embedding baselines (i.e., SeededLDA, Anchored CorEx, CatE, and Labeled ETM) can only take **in-vocabulary** seeds as input. For a fair comparison, we run Lines 1-7 in Algorithm 1 to get the initial representative in-vocabulary terms for each category, and input these terms as seeds into the baselines. In other words, all compared methods use BERT/BioBERT to initialize their term sets.

Evaluation Metrics. We evaluate topic discovery results from three different angles: topic coherence, term accuracy, and topic diversity.

(1) **NPMI** (Lau et al., 2014) is a standard metric in topic modeling to measure *topic coherence*. Within each topic, it calculates the normalized pointwise mutual information for each pair of terms in $\mathcal{S}_i$.

$$\text{NPMI} = \frac{1}{|\mathcal{C}|}\sum_{i=1}^{|\mathcal{C}|}\frac{1}{\binom{|\mathcal{S}_i|}{2}}\sum_{w_j, w_k \in \mathcal{S}_i}\frac{\log\frac{P(w_j,w_k)}{P(w_j)P(w_k)}}{-\log P(w_j,w_k)}, \quad (8)$$

where $P(w_j, w_k)$ is the probability that w_j and w_k co-occur in a document; $P(w_j)$ is the marginal probability of w_j.[14]

(2) **LCP** (Mimno et al., 2011) is another standard metric to measure *topic coherence*. It calculates the pairwise log conditional probability of top-ranked terms.

$$\text{LCP} = \frac{1}{|\mathcal{C}|}\sum_{i=1}^{|\mathcal{C}|}\frac{1}{\binom{|\mathcal{S}_i|}{2}}\sum_{\substack{w_j, w_k \in \mathcal{S}_i \\ j<k}}\log\frac{P(w_j,w_k)}{P(w_j)}. \quad (9)$$

Note that **PMI** (Newman et al., 2010) is also a standard metric for topic coherence. We do observe that SEETOPIC outperforms baselines in terms of PMI in most cases. However, since our local embedding step is implicitly optimizing a PMI-like objective, we no longer use it as our evaluation metric.

(3) **MACC** (Meng et al., 2020a) measures *term accuracy*. It is defined as the proportion of retrieved terms that actually belong to the corresponding category according to the category name.

$$\text{MACC} = \frac{1}{|\mathcal{C}|}\sum_{i=1}^{|\mathcal{C}|}\frac{1}{|\mathcal{S}_i|}\sum_{w_j \in \mathcal{S}_i}\mathbf{1}(w_j \in c_i), \quad (10)$$

where $\mathbf{1}(w_j \in c_i)$ is the indicator function of whether w_j is relevant to category c_i. MACC requires human evaluation, so we invite five annotators to perform independent annotation. The reported MACC score is the average MACC of the five annotators. A high inter-annotator agreement is observed, with Fleiss' kappa (Fleiss, 1971) being 0.856, 0.844, and 0.771 on SciDocs, Amazon, and Twitter, respectively.

(4) **Diversity** (Dieng et al., 2020) measures the *mutual exclusivity* of discovered topics. It is the percentage of unique terms in all topics, which corresponds to our task requirement that each retrieved term is discriminatively close to one category and far from the others.

$$\text{Diversity} = \frac{|\bigcup_{i=1}^{|\mathcal{C}|}\mathcal{S}_i|}{\sum_{i=1}^{|\mathcal{C}|}|\mathcal{S}_i|}. \quad (11)$$

Experiment Settings. We use BioBERT as the

---

[13] `https://huggingface.co/dmis-lab/biobert-v1.1`

[14] When calculating Eqs. (8) and (9), to avoid $\log 0$, we use $P(w_j, w_k) + \epsilon$ and $P(w) + \epsilon$ to replace $P(w_j, w_k)$ and $P(w)$, respectively, where $\epsilon = 1/|\mathcal{D}|$.

PLM on SciDocs, and BERT-base-uncased as the PLM on Amazon and Twitter. The embedding dimension of $\boldsymbol{u}_w$ is 768 (the same as $\boldsymbol{e}_w$); the number of negative samples $b = 5$. In ensemble ranking, the length of the general/local ranking list $M = 100$; the hyperparameter ρ in Eq. (6) is set as 0.1; the number of iterations $T = 4$; after each iteration, we increase the size of $\mathcal{S}_i$ by $N = 3$. We use the top-10 ranked terms in each topic for final evaluation (i.e., $|\mathcal{S}_i| = 10$ in Eqs. (8)-(11)). Experiments are run on Intel Xeon E5-2680 v2 @ 2.80GHz and one NVIDIA GeForce GTX 1080.

4.2 Performance Comparison

Table 3 shows the performance of all methods. We run each experiment 3 times with the average score reported. To show statistical significance, we conduct a two-tailed unpaired t-test to compare SEETOPIC and each baseline. (The performance of BERT and BioBERT is deterministic according to our usage. When comparing SEETOPIC with them, we conduct a two-tailed Z-test instead.) The significance level is also marked in Table 3.

We have the following observations from Table 3. (1) Our SEETOPIC model performs consistently well. In fact, it achieves the highest score in 8 columns and the second highest in the remaining 4 columns. (2) Classical seed-guided topic modeling baselines (i.e., SeededLDA and Anchored CorEx) perform not well in respect of NPMI (topic coherence) and MACC (term accuracy). Embedding-based topic discovery approaches (i.e., Labeled ETM and CatE) make some progress, but they still significantly underperform the PLM-empowered SEETOPIC model on SciDocs and Amazon. (3) SEETOPIC consistently performs better than SEETOPIC-NoIter on all three datasets, indicating the positive contribution of the proposed iterative process. (4) SEETOPIC guarantees the mutual exclusivity of $\mathcal{S}_1, ..., \mathcal{S}_{|\mathcal{C}|}$. In comparison, SeededLDA, Labeled ETM, and BERT cannot guarantee such mutual exclusivity.

In-vocabulary vs. Out-of-vocabulary. Figure 1 compares the MACC scores of different seed-guided topic discovery methods on in-vocabulary categories and out-of-vocabulary categories. We find that the performance improvement of SEETOPIC upon baselines on out-of-vocabulary categories is larger than that on in-vocabulary ones. For example, on Amazon, SEETOPIC underperforms CatE on in-vocabulary categories but outperforms CatE on out-of-vocabulary ones; on Twitter, the gap between SEETOPIC and baselines becomes much more evident on out-of-vocabulary categories. Note that all baselines in Figure 1 do not utilize the power of PLMs, so this observation validates our claim that PLMs are helpful in tackling out-of-vocabulary seeds.

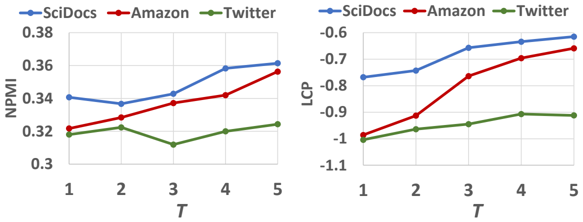
(a) Effect of ρ on NPMI (b) Effect of ρ on LCP



(c) Effect of T on NPMI (d) Effect of T on LCP

Figure 2: Parameter study of SEETOPIC measured by topic coherence.

4.3 Parameter Study

We study the effect of two important hyperparameters: ρ (the hyperparameter in ensemble ranking) and T (the number of iterations). We vary the value of ρ in $\{0.1, 0.3, 0.5, 0.7, 0.9, 1\}$ (SEETOPIC uses $\rho = 0.1$ by default) and the value of T in $\{1, 2, 3, 4, 5\}$ (SEETOPIC uses $T = 4$ by default, and SEETOPIC-NoIter is the case when $T = 1$). Figure 2 shows the change of model performance measured by NPMI and LCP.

Table 4: Top-5 representative terms retrieved by different algorithms for three out-of-vocabulary categories from SciDocs, Amazon, and Twitter. ✓: at least 3 of the 5 annotators judge the term as relevant to the seed. ✗: at most 2 of the 5 annotators judge the term as relevant to the seed.

Method	**Top-5 Representative Terms**
Dataset: SciDocs, Category Name: hepatitis a/b/c/e	
SeededLDA	patients (✗), treatment (✗), placebo (✗), study (✗), group (✗)
Anchored CorEx	expression (✗), gene (✗), cells (✗), genes (✗), genetic (✗)
Labeled ETM	hepatitis b virus hbv dna (✓), serum hbv dna (✓), serum alanine aminotransferase (✗), alanine aminotransferase alt (✗), below detection limit (✗)
CatE	chronic hepatitis b virus hbv infection (✓), hepatitis b e antigen hbeag (✓), hepatitis b virus hbv dna (✓), normal alanine aminotransferase (✗), hbeag-negative chronic hepatitis b (✓)
BioBERT	hepatitis b virus hbv dna (✓), chronic hepatitis b virus hbv infection (✓), hepatitis b e antigen hbeag (✓), hepatitis b virus hbv infection (✓), chronic hepatitis c virus hcv (✓)
SeeTopic-NoIter	hepatitis b virus hbv dna (✓), hepatitis b e antigen hbeag (✓), chronic hepatitis b virus hbv infection (✓), hepatitis b surface antigen hbsag (✓), hbeag-negative chronic hepatitis b (✓)
SeeTopic	chronic hepatitis b virus hbv infection (✓), hbeag-negative chronic hepatitis b (✓), hepatitis c virus hcv-infected (✓), hepatitis b virus hbv dna (✓), chronic hepatitis c virus hcv (✓)
Dataset: Amazon, Category Name: sports and outdoors	
SeededLDA	use (✗), good (✗), one (✗), product (✗), like (✗)
Anchored CorEx	sports (✓), use (✗), size (✗), wear (✗), fit (✓)
Labeled ETM	cars and tracks (✓), tracks and cars (✓), search options (✗), championships (✗), cool bosses (✗)
CatE	outdoorsmen (✓), outdoor activities (✓), cars and tracks (✓), foot support (✓), offers plenty (✗)
BERT	cars and tracks (✓), outdoor activities (✓), outdoorsmen (✓), sports (✓), sporting events (✓)
SeeTopic-NoIter	outdoorsmen (✓), outdoor activities (✓), cars and tracks (✓), indoor soccer (✓), bike riding (✓)
SeeTopic	canoeing (✓), picnics (✓), bike rides (✓), bike riding (✓), rafting (✓)
Dataset: Twitter, Category Name: travel and transport	
SeededLDA	nyc (✗), new york (✗), line (✓), high (✗), time square (✓)
Anchored CorEx	new york (✗), post photo (✓), new (✗), day (✗), today (✗)
Labeled ETM	tourism (✓), theview (✓), file (✗), morning view (✓), gma (✗)
CatE	maritime (✓), tourism (✓), natural history (✗), scenery (✓), elevate (✗)
BERT	maritime (✓), tourism (✓), natural history (✗), olive oil (✗), baggage claim (✓)
SeeTopic-NoIter	maritime (✓), tourism (✓), natural history (✗), scenery (✓), navy (✗)
SeeTopic	wildlife (✓), scenery (✓), maritime (✓), highlinepark (✗), aquarium (✓)

According to Figures 2(a) and 2(b), in most cases, the performance of SeeTopic deteriorates as ρ increases from 0.1 to 0.9. Thus, setting $\rho = 0.1$ always leads to competitive NPMI and LCP scores on the three datasets. Although $\rho = 1$ is better than $\rho = 0.9$, its performance is still suboptimal in comparison with $\rho = 0.1$. This finding indicates that replacing the mean reciprocal rank (i.e., $\rho = 1$) with our proposed Eq. (6) is reasonable. According to Figures 2(c) and 2(d), SeeTopic usually performs better when there are more iterations. On SciDocs and Twitter, the scores start to converge after $T = 4$. Besides, more iterations will result in longer running time. Overall, we believe setting $T = 4$ strikes a good balance.

4.4 Case Study

Finally, we show the terms retrieved by different methods as a case study. From each of the three datasets, we select an out-of-vocabulary category and show its topic discovery results in Table 4. We mark a retrieved term as correct (✓) if at least 3 of the 5 annotators judge the term as relevant to the seed. Otherwise, we mark the term as incorrect (✗).

For the category "*hepatitis a/b/c/e*" from SciDocs, SeededLDA and Anchored CorEx can only find very general medical terms, which are relevant to all seeds in SciDocs and thus inaccurate; Labeled ETM and CatE find terms about "*alanine aminotransferase*", whose elevation suggest not only hepatitis but also other diseases like diabetes and heart failure, thus not discriminative either; BioBERT and SeeTopic, with the power of a PLM, can accurately pick terms relevant to "*hepatitis b*" and "*hepatitis c*". For the category "*sports and outdoors*" from Amazon, SeededLDA and Anchored CorEx again find very general terms, most of which are not category-discriminative; Labeled ETM and CatE are able to pick more specific terms such as "*cars and tracks*", but they still make mistakes; BERT, as a PLM, can accurately find terms that have lexical overlap with the category name (e.g., "*outdoorsmen*", "*sporting events*"), meanwhile such terms are less diverse; SeeTopic-NoIter starts to discover more concrete terms than BERT (e.g., "*indoor soccer*", "*bike riding*") by leveraging local text semantics; the full SeeTopic model, with an iterative updating process, can find more specific and informative terms (e.g., "*canoeing*", "*picnics*", and "*rafting*"). For the category "*travel and trans-*

port” from Twitter, both BERT and CatE make mistakes by including the term “*natural history*”; SEETOPIC-NoIter, without an iterative update process, also includes this error; the full SEETOPIC model finally excludes this error and achieves the highest accuracy in the retrieved top-5 terms among all compared methods.

5 Related Work

Seed-Guided Topic Discovery. Seed-guided topic models aim to leverage user-provided seeds to discover underlying topics according to users' interests. Early studies take LDA (Blei et al., 2003) as the backbone and incorporate seeds into model learning. For example, Andrzejewski et al. (2009) consider must-link and cannot-link constraints among seeds as priors. SeededLDA (Jagarlamudi et al., 2012) encourages topics to contain more seeds and encourages documents to select topics relevant to the seeds they contain. Anchored CorEx (Gallagher et al., 2017) extracts maximally informative topics by jointly compressing the corpus and preserving seed relevant information. Recent studies start to utilize embedding techniques to learn better word semantics. For example, CatE (Meng et al., 2020a) explicitly encourages distinction among retrieved topics via category-name guided embedding learning. However, all these models require the provided seeds to be in-vocabulary, mainly because they focus on the input corpus only and are not equipped with general knowledge of PLMs.

Embedding-Based Topic Discovery. A number of studies extend LDA to involve word embedding. The common strategy is to adapt distributions in LDA to generate real-valued data (e.g., Gaussian LDA (Das et al., 2015), LFTM (Nguyen et al., 2015), Spherical HDP (Batmanghelich et al., 2016), and CGTM (Xun et al., 2017b)). Some other studies think out of the LDA backbone. For example, TWE (Liu et al., 2015) uses topic structures to jointly learn topic embeddings and improve word embeddings. CLM (Xun et al., 2017a) collaboratively improves topic modeling and word embedding by coordinating global and local contexts. ETM (Dieng et al., 2020) models word-topic correlations via word embeddings to improve the expressiveness of topic models. More recently, Sia et al. (2020) show that directly clustering word embeddings (e.g., word2vec or BERT) also generates good topics; Thompson and Mimno (2020) further find that BERT and GPT-2 discover high-quality topics, but RoBERTa does not. These models are unsupervised and hard to be applied to seed-guided settings. In contrast, our SEETOPIC framework joint leverages PLMs, word embeddings, and seed information.

6 Conclusions and Future Work

In this paper, we study seed-guided topic discovery in the presence of out-of-vocabulary seeds. To understand and make use of in-vocabulary components in each seed, we utilize the tokenization and contextualization power of PLMs. We propose a seed-guided embedding learning framework inspired by the goal of maximizing PMI in topic modeling, and an iterative ensemble ranking process to jointly leverage general knowledge of the PLM and local signals learned from the input corpus. Experimental results show that SEETOPIC outperforms seed-guided topic discovery baselines and PLMs in terms of topic coherence, term accuracy, and topic diversity. A parameter study and a case study further validate some design choices in SEETOPIC.

In the future, it would be interesting to extend SEETOPIC to seed-guided hierarchical topic discovery, where parent and child information in the input category hierarchy may help infer the meaning of out-of-vocabulary nodes.

A The Embedding Learning Objective

In Section 3.2, we propose the following embedding learning objective:

$$\mathcal{J} = \underbrace{\sum_{d\in\mathcal{D}}\sum_{w_i\in d}\sum_{w_j\in\mathcal{C}(w_i,h)} \frac{\exp(\boldsymbol{u}_{w_i}^T\boldsymbol{v}_{w_j})}{\sum_{w'\in\mathcal{V}_\mathcal{D}}\exp(\boldsymbol{u}_{w_i}^T\boldsymbol{v}_{w'})}}_{\mathcal{J}_{\text{context}}} + \underbrace{\sum_{d\in\mathcal{D}}\sum_{w\in d} \frac{\exp(\boldsymbol{u}_{w}^T\boldsymbol{v}_{d})}{\sum_{d'\in\mathcal{D}}\exp(\boldsymbol{u}_{w}^T\boldsymbol{v}_{d'})}}_{\mathcal{J}_{\text{document}}} + \underbrace{\sum_{c_i\in\mathcal{C}}\sum_{w\in\mathcal{S}_i} \frac{\exp(\boldsymbol{u}_{w}^T\boldsymbol{v}_{c_i})}{\sum_{c'\in\mathcal{C}}\exp(\boldsymbol{u}_{w}^T\boldsymbol{v}_{c'})}}_{\mathcal{J}_{\text{category}}}. \tag{12}$$

Now we prove that maximizing $\mathcal{J}$ is implicitly performing the factorization in Eq. (3).

Levy and Goldberg (2014) have proved that maximizing $\mathcal{J}_{\text{context}}$ is implicitly doing the following factorization.

$$\boldsymbol{u}_{w_i}^T\boldsymbol{v}_{w_j} = \log\left(\frac{\#_\mathcal{D}(w_i,w_j)\cdot\lambda_\mathcal{D}}{\#_\mathcal{D}(w_i)\cdot\#_\mathcal{D}(w_j)\cdot b}\right), \quad \text{i.e.,}\ \ \mathbf{U}_w^T\mathbf{V}_w = \mathbf{X}_{ww}. \tag{13}$$

We follow their approach to consider the other two terms $\mathcal{J}_{\text{document}}$ and $\mathcal{J}_{\text{category}}$ in Eq. (12). Using the negative sampling strategy to rewrite $\mathcal{J}_{\text{document}}$, we get

$$\sum_{w\in\mathcal{V}_\mathcal{D}}\sum_{d\in\mathcal{D}}\#_d(w)\Big(\log\sigma(\boldsymbol{u}_w^T\boldsymbol{v}_d) + b\mathbb{E}_{d'}\big[\log\sigma(-\boldsymbol{u}_w^T\boldsymbol{v}_{d'})\big]\Big), \tag{14}$$

where $\sigma(\cdot)$ is the sigmoid function. Following (Levy and Goldberg, 2014; Qiu et al., 2018), we assume the negative sampling distribution $\propto \lambda_d$.[15] Then, the objective becomes

$$\sum_{w\in\mathcal{V}_\mathcal{D}}\sum_{d\in\mathcal{D}}\#_d(w)\log\sigma(\boldsymbol{u}_w^T\boldsymbol{v}_d) + \sum_{w\in\mathcal{V}_\mathcal{D}}\#_\mathcal{D}(w)\sum_{d'\in\mathcal{D}}\frac{b\cdot\lambda_{d'}}{\lambda_\mathcal{D}}\log\sigma(-\boldsymbol{u}_w^T\boldsymbol{v}_{d'}). \tag{15}$$

For a specific term-document pair (w,d), we consider its effect in the objective:

$$\mathcal{J}_{w,d} = \#_d(w)\log\sigma(\boldsymbol{u}_w^T\boldsymbol{v}_d) + \#_\mathcal{D}(w)\frac{b\cdot\lambda_d}{\lambda_\mathcal{D}}\log\sigma(-\boldsymbol{u}_w^T\boldsymbol{v}_d). \tag{16}$$

Let $x_{w,d} = \boldsymbol{u}_w^T\boldsymbol{v}_d$. To maximize $\mathcal{J}_{w,d}$, we should have

$$0 = \frac{\partial\mathcal{J}_{w,d}}{\partial x_{w,d}} = \#_d(w)\sigma(-x_{w,d}) - \frac{\#_\mathcal{D}(w)\cdot b\cdot\lambda_d}{\lambda_\mathcal{D}}\sigma(x_{w,d}). \tag{17}$$

---

[15] In practice, the negative sampling distribution $\propto \lambda_d^{3/4}$, but related studies (Levy and Goldberg, 2014; Qiu et al., 2018) usually assume a linear relationship in their derivation.

That is,

$$e^{2x_{w,d}} - \Big(\frac{\#_d(w)\cdot\lambda_{\mathcal{D}}}{\#_{\mathcal{D}}(w)\cdot b\cdot\lambda_d} - 1\Big)e^{x_{w,d}} - \frac{\#_d(w)\cdot\lambda_{\mathcal{D}}}{\#_{\mathcal{D}}(w)\cdot b\cdot\lambda_d} = 0. \tag{18}$$

Therefore, $e^{x_{w,d}} = -1$ (which is invalid) or $e^{x_{w,d}} = \frac{\#_d(w)\cdot\lambda_{\mathcal{D}}}{\#_{\mathcal{D}}(w)\cdot b\cdot\lambda_d}$. In other words,

$$\begin{aligned} &\boldsymbol{u}_w^T\boldsymbol{v}_d = x_{w,d} = \log\Big(\frac{\#_d(w)\cdot\lambda_{\mathcal{D}}}{\#_{\mathcal{D}}(w)\cdot b\cdot\lambda_d}\Big), \\ &\text{i.e., } \mathbf{U}_w^T\mathbf{V}_d = \mathbf{X}_{wd}. \end{aligned} \tag{19}$$

Similarly, for $\mathcal{J}_{\text{category}}$, the objective can be rewritten as

$$\begin{aligned} &\sum_{w\in\mathcal{V}_{\mathcal{D}}}\sum_{c_i\in\mathcal{C}} \mathbf{1}_{w\in\mathcal{S}_i}\log\sigma(\boldsymbol{u}_w^T\boldsymbol{v}_{c_i}) + \\ &\sum_{w\in\mathcal{V}_{\mathcal{D}}} \mathbf{1}_{w\in\mathcal{S}_1\cup\ldots\cup\mathcal{S}_{|\mathcal{C}|}} \sum_{c'\in\mathcal{C}} \frac{b}{|\mathcal{C}|}\log\sigma(-\boldsymbol{u}_w^T\boldsymbol{v}_{c'}). \end{aligned} \tag{20}$$

Following the derivation of $\mathcal{J}_{\text{document}}$, we get

$$\begin{aligned} &\boldsymbol{u}_w^T\boldsymbol{v}_{c_i} = x_{w,c_i} = \log\Big(\frac{\mathbf{1}_{w\in\mathcal{S}_i}|\mathcal{C}|}{\mathbf{1}_{w\in\mathcal{S}_1\cup\ldots\cup\mathcal{S}_{|\mathcal{C}|}}\cdot b}\Big), \\ &\text{i.e., } \mathbf{U}_w^T\mathbf{V}_{c_i} = \mathbf{X}_{wc}. \end{aligned} \tag{21}$$

Putting Eqs. (13), (19), and (21) together gives us Eq. (3).

B The Ensemble Ranking Function

In Section 3.3, we propose the following ensemble ranking function:

$$\text{score}(w|\mathcal{S}_i) = \bigg(\frac{1}{2}\Big(\frac{1}{\text{rank}_G(w)}\Big)^{\rho} + \frac{1}{2}\Big(\frac{1}{\text{rank}_L(w)}\Big)^{\rho}\bigg)^{1/\rho}. \tag{22}$$

Now we prove this ranking function is a generalization of the *arithmetic* mean reciprocal rank (i.e., MRR) and the *geometric* mean reciprocal rank:

$$\begin{aligned} &\lim_{\rho\to 1}\text{score}(w|\mathcal{S}_i) = \frac{1}{2}\Big(\frac{1}{\text{rank}_G(w)} + \frac{1}{\text{rank}_L(w)}\Big); \\ &\lim_{\rho\to 0}\text{score}(w|\mathcal{S}_i) = \Big(\frac{1}{\text{rank}_G(w)}\cdot\frac{1}{\text{rank}_L(w)}\Big)^{1/2}. \end{aligned} \tag{23}$$

The case of $\rho \to 1$ is trivial. When $\rho \to 0$, we aim to show that

$$\lim_{\rho\to 0}\log\text{score}(w|\mathcal{S}_i) = \log\Big(\frac{1}{\text{rank}_G(w)}\cdot\frac{1}{\text{rank}_L(w)}\Big)^{1/2}. \tag{24}$$

In fact, let $r_G = \frac{1}{\text{rank}_G(w)}$ and $r_L = \frac{1}{\text{rank}_L(w)}$.

$$\begin{aligned} \lim_{\rho\to 0}\log\text{score}(w|\mathcal{S}_i) &= \lim_{\rho\to 0}\log\Big(\frac{1}{2}r_G^{\rho} + \frac{1}{2}r_L^{\rho}\Big)^{1/\rho} \\ &= \lim_{\rho\to 0}\frac{\log\big(\frac{1}{2}r_G^{\rho} + \frac{1}{2}r_L^{\rho}\big)}{\rho} \\ &= \lim_{\rho\to 0}\frac{\frac{\frac{1}{2}r_G^{\rho}\log r_G + \frac{1}{2}r_L^{\rho}\log r_L}{\frac{1}{2}r_G^{\rho} + \frac{1}{2}r_L^{\rho}}}{1} \\ &= \frac{\lim_{\rho\to 0}\Big(r_G^{\rho}\log r_G + r_L^{\rho}\log r_L\Big)}{\lim_{\rho\to 0}\Big(r_G^{\rho} + r_L^{\rho}\Big)} \\ &= \frac{\log r_G + \log r_L}{2} \\ &= \log(r_G\cdot r_L)^{1/2}. \end{aligned} \tag{25}$$

The third line is obtained by applying L'Hopital's rule.

Seed-Guided Topic Discovery with Out-of-Vocabulary Seeds

Abstract

Discovering latent topics from text corpora has been studied for decades. Many existing topic models adopt a fully unsupervised setting, and their discovered topics may not cater to users' particular interests due to their inability of leveraging user guidance. Although there exist seed-guided topic discovery approaches that leverage user-provided seeds to discover topic-representative terms, they are less concerned with two factors: (1) the existence of out-of-vocabulary seeds and (2) the power of pre-trained language models (PLMs). In this paper, we generalize the task of seed-guided topic discovery to allow out-of-vocabulary seeds. We propose a novel framework, named SEETOPIC, wherein the general knowledge of PLMs and the local semantics learned from the input corpus can mutually benefit each other. Experiments on three real datasets from different domains demonstrate the effectiveness of SEETOPIC in terms of topic coherence, accuracy, and diversity.[1]

1 Introduction

Automatically discovering informative and coherent topics from massive text corpora is central to text analysis through helping users efficiently digest a large collection of documents (Griffiths and Steyvers, 2004) and advancing downstream applications such as summarization (Wang et al., 2009, 2022), classification (Chen et al., 2015; Meng et al., 2020b), and generation (Liu et al., 2021).

Unsupervised topic models have been the mainstream approach to topic discovery since the proposal of pLSA (Hofmann, 1999) and LDA (Blei et al., 2003). Despite their encouraging performance in finding informative latent topics, these topics may not reflect user preferences well, mainly due to their unsupervised nature. For example, given a collection of product reviews, a user may be specifically interested in product categories (e.g., "*books*", "*electronics*"), but unsupervised topic models may generate topics containing different sentiments (e.g., "*good*", "*bad*"). To consider users' interests and needs, seed-guided topic discovery approaches (Jagarlamudi et al., 2012; Gallagher et al., 2017; Meng et al., 2020a) have been proposed to find representative terms for each category based on user-provided seeds or category names.[2] However, there are still two less concerned factors in these approaches.

Table 1: Three datasets (Cohan et al., 2020; McAuley and Leskovec, 2013; Zhang et al., 2017) from different domains and their topic categories (i.e., seeds). **Red**: Seeds never seen in the corpus (i.e., out-of-vocabulary). In all three datasets, a large proportion of seeds are out-of-vocabulary.

Dataset	Category Names (Seeds)	
SciDocs (Scientific Papers)	cardiovascular diseases chronic kidney disease **chronic respiratory diseases** diabetes mellitus **digestive diseases** **hiv/aids**	**hepatitis a/b/c/e** mental disorders musculoskeletal disorders **neoplasms (cancer)** neurological disorders
Amazon (Product Reviews)	**apps for android** books **cds and vinyl** **clothing, shoes and jewelry** electronics	**health and personal care** **home and kitchen** movies and tv **sports and outdoors** video games
Twitter (Social Media Posts)	food **shop and service** **travel and transport** **college and university** **nightlife spot**	residence **outdoors and recreation** **arts and entertainment** **professional and other places**

The Existence of Out-of-Vocabulary Seeds. Previous studies (Jagarlamudi et al., 2012; Gallagher et al., 2017; Meng et al., 2020a) assume that all user-provided seeds must be **in-vocabulary** (i.e., appear at least once in the input corpus), so that they can utilize the occurrence statistics or Skip-Gram embedding methods (Mikolov et al., 2013) to model seed semantics. However, user-interested categories can have specific or composite descriptions, which may never appear in the corpus. Table 1 shows three datasets from different domains: sci-

[2] In this paper, we use "seeds" and "category names" interchangeably.

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 291 - 302
July 10-15, 2022 ©2022 Association for Computational Linguistics

entific papers, product reviews, and social media posts. In each dataset, documents can belong to one or more categories, and we list the category names provided by the dataset collectors. These seeds should reflect their particular interests. In all three datasets, we have a large proportion of seeds (45% in SciDocs, 60% in Amazon, and 78% in Twitter) that never appear in the corpus. Some category names are too specific (e.g., "*chronic respiratory diseases*", "*nightlife spot*") to be exactly matched, others are the composition of multiple entities (e.g., "*hepatitis a/b/c/e*", "*neoplasms (cancer)*", "*clothing, shoes and jewelry*").[3]

The Power of Pre-trained Language Models. Techniques used in previous studies are mainly based on LDA variants (Jagarlamudi et al., 2012) or context-free embeddings (Meng et al., 2020a). Recently, pre-trained language models (PLMs) such as BERT (Devlin et al., 2019) have achieved significant improvement in a wide range of text mining tasks. In topic discovery, the generic representation power of PLMs learned from web-scale corpora (e.g., Wikipedia or PubMed) may complement the information a model can obtain from the input corpus. Moreover, out-of-vocabulary seeds usually have meaningful in-vocabulary components (e.g., "*night*" and "*life*" in "*nightlife spot*", "*health*" and "*care*" in "*health and personal care*"). The optimized tokenization strategy of PLMs (Sennrich et al., 2016; Wu et al., 2016) can help segment the seeds into such meaningful components (e.g., "*nightlife*" → "*night*" and "*##life*"), and the contextualization power of PLMs can help infer the correct meaning of each component (e.g., "*##life*" and "*care*") in the category name. Therefore, PLMs are much needed in handling out-of-vocabulary seeds and effectively learning their semantics.

Contributions. Being aware of these two factors, in this paper, we study seed-guided topic discovery in the presence of out-of-vocabulary seeds. Our proposed SEETOPIC framework consists of two modules: (1) The *general* representation module uses a PLM to derive the representation of each term (including out-of-vocabulary seeds) based on the general linguistic knowledge acquired through pre-training. (2) The *seed-guided local* representation module learns in-vocabulary term embeddings specific to the input corpus and the given seeds. In order to optimize the learned representations for topic coherence, which is commonly reflected by pointwise mutual information (PMI) (Newman et al., 2010), our objective implicitly maximizes the PMI between each word and its context, the documents it appears, as well as the category it belongs to. The learning of the two modules is connected through an iterative ensemble ranking process, in which the general knowledge of PLMs and the term representations specifically learned from the target corpus conditioned on the seeds can complement each other.

To summarize, this study makes three contributions. (1) *Task*: we propose to study seed-guided topic discovery in the presence of out-of-vocabulary seeds. (2) *Framework*: we design a unified framework that jointly models general knowledge through PLMs and local corpus statistics through embedding learning. (3) *Experiment*: extensive experiments on three datasets demonstrate the effectiveness of SEETOPIC in terms of topic coherence, accuracy, and diversity.

2 Problem Definition

As shown in Table 1, we assume a seed can be either a single word or a phrase. Given a corpus $\mathcal{D}$, we use $\mathcal{V}_\mathcal{D}$ to denote the set of **terms** appearing in $\mathcal{D}$. In accordance with the assumption of category names, each term can also be a single word or a phrase. In practice, given a raw corpus, one can use existing phrase chunking tools (Manning et al., 2014; Shang et al., 2018) to detect phrases in it. *After* phrase chunking, if a category name is still not in $\mathcal{V}_\mathcal{D}$, we define it as **out-of-vocabulary**.

Problem Definition. *Given a corpus* $\mathcal{D} = \{d_1, ..., d_{|\mathcal{D}|}\}$ *and a set of category names* $\mathcal{C} = \{c_1, ..., c_{|\mathcal{C}|}\}$ *where some category names are out-of-vocabulary, the task is to find a set of in-vocabulary terms* $\mathcal{S}_i = \{w_1, ..., w_S\} \subseteq \mathcal{V}_\mathcal{D}$ *for each category* c_i *such that each term in* $\mathcal{S}_i$ *is semantically close to* c_i *and far from other categories* c_j $(\forall j \neq i)$.

3 The SEETOPIC Framework

In this section, we first introduce how we model general and local text semantics using a PLM mod-

---

[3] One possible idea to deal with composite seeds is to split them into multiple seeds. However, there are many possible ways to express the conjunctions (e.g., "*/*", "*()*", "*,*" and "*and*" in Table 1), which may require manual tuning. Besides, simple chunking rules will induce splits that break the semantics of the original composition (e.g., "*professional and other places*" may be split into "*professional*" and "*other places*"). Moreover, even after the split, some seeds are still out-of-vocabulary. Therefore, we propose to use PLMs to tackle out-of-vocabulary seeds in a unified way. In experiments, we will show that our model is able to tackle composite seeds. For example, given the seed "*hepatitis a/b/c/e*", we can find terms relevant to "*hepatitis b*" and "*hepatitis c*" (see Table 4).

ule and a seed-guided embedding learning module, respectively. Then, we present the iterative ensemble ranking process and our overall framework.

3.1 Modeling General Text Semantics using a PLM

PLMs such as BERT (Devlin et al., 2019) aim to learn generic language representations from web-scale corpora (e.g., Wikipedia or PubMed) that can be applied to a wide variety of text-related applications. To transfer such general knowledge to our topic discovery task, we employ a PLM to encode each category name and each in-vocabulary term to a vector. To be specific, given a term $w \in \mathcal{C} \cup \mathcal{V}_{\mathcal{D}}$, we input the sequence "`[CLS]` w `[SEP]`" into the PLM. Here, w can be a phrase containing multiple words, and each word can be out of the PLM's vocabulary. To deal with this, most PLMs use a pre-trained tokenizer (Sennrich et al., 2016; Wu et al., 2016) to segment each unseen word into frequent subwords. Then, the contextualization power of PLMs will help infer the correct meaning of each word/subword, so as to provide a more precise representation of the whole category.

After LM encoding, following (Sia et al., 2020; Thompson and Mimno, 2020; Li et al., 2020), we take the output of all tokens from the last layer and average them to get the term embedding $\boldsymbol{e}_w$. In this way, even if a seed c_i is **out-of-vocabulary**, we can still obtain its representation $\boldsymbol{e}_{c_i}$.

3.2 Modeling Local Text Semantics in the Input Corpus

The motivation of topic discovery is to discover latent topic structures from the input corpus. Therefore, purely relying on general knowledge in the PLM is insufficient because topic discovery results should adapt to the input corpus $\mathcal{D}$. Now, we introduce how we learn another set of embeddings $\{\boldsymbol{u}_w | w \in \mathcal{V}_{\mathcal{D}}\}$ from $\mathcal{D}$.

Previous studies on embedding learning assume that the semantic of a term is similar to its local context (Mikolov et al., 2013), the document it appears (Tang et al., 2015; Xun et al., 2017a), and the category it belongs to (Meng et al., 2020a). Inspired by these studies, we propose the following embedding learning objective.

$$\mathcal{J} = \underbrace{\sum_{d \in \mathcal{D}} \sum_{w_i \in d} \sum_{w_j \in \mathcal{C}(w_i, h)} p(w_j | w_i)}_{\text{context}} + \underbrace{\sum_{d \in \mathcal{D}} \sum_{w \in d} p(d|w)}_{\text{document}} + \underbrace{\sum_{c_i \in \mathcal{C}} \sum_{w \in \mathcal{S}_i} p(c_i|w)}_{\text{category}}, \quad (1)$$

where

$$p(z|w) = \frac{\exp(\boldsymbol{u}_w^T \boldsymbol{v}_z)}{\sum_{z'} \exp(\boldsymbol{u}_w^T \boldsymbol{v}_{z'})}, \quad (z \text{ can be } w_j, d, \text{ or } c_i). \quad (2)$$

In this objective, $\boldsymbol{u}_{w_i}$ (and $\boldsymbol{v}_{w_j}$), $\boldsymbol{v}_d$, $\boldsymbol{v}_{c_i}$ are the embedding vectors of terms, documents, and categories, respectively. $\mathcal{C}(w_i, h)$ is the set of context terms of w_i in d. Specifically, if $d = w_1 w_2 ... w_L$, then $\mathcal{C}(w_i, h) = \{w_j | i - h \le j \le i + h, j \ne i\}$, where h is the context window size.

Note that the last term in Eq. (1) encourages the similarity between each category c_i and its representative terms $\mathcal{S}_i$. Here, we adopt an iterative process to gradually update category-representative terms. Initially, $\mathcal{S}_i$ consists of just a few in-vocabulary terms similar to c_i according to the PLM. At each iteration, the size of $\mathcal{S}_i$ will increase to contain more category-discriminative terms (the selection criterion of these terms will be introduced in the next section), and we need to encourage their proximity with c_i in the next iteration.

Directly optimizing the full softmax in Eq. (2) is costly. Therefore, we adopt the negative sampling strategy (Mikolov et al., 2013) for efficient approximation.

Interpreting the Objective. In topic modeling studies, pointwise mutual information (PMI) (Newman et al., 2010) is a standard evaluation metric for topic coherence (Lau et al., 2014; Röder et al., 2015). Levy and Goldberg (2014) prove that the Skip-Gram embedding model is implicitly factorizing the PMI matrix. Following their proof, we can show that maximizing Eq. (1) is implicitly doing the following factorization:

$$\mathbf{U}_w^T [\mathbf{V}_w; \mathbf{V}_d; \mathbf{V}_c] = [\mathbf{X}_{ww}; \mathbf{X}_{wd}; \mathbf{X}_{wc}], \quad (3)$$

where the columns of $\mathbf{U}_w$, $\mathbf{V}_w$, $\mathbf{V}_d$, $\mathbf{V}_c$ are $\boldsymbol{u}_{w_i}$, $\boldsymbol{v}_{w_j}$, $\boldsymbol{v}_d$, $\boldsymbol{v}_{c_i}$, respectively ($w_i, w_j \in \mathcal{V}_{\mathcal{D}}$, $d \in \mathcal{D}$, $c_i \in \mathcal{C}$); $\mathbf{X}_{ww}$, $\mathbf{X}_{wd}$, and $\mathbf{X}_{wc}$ are PMI matrices.

$$\begin{aligned} \mathbf{X}_{ww} &= \left[\log \left(\frac{\#_{\mathcal{D}}(w_i, w_j) \cdot \lambda_{\mathcal{D}}}{\#_{\mathcal{D}}(w_i) \cdot \#_{\mathcal{D}}(w_j) \cdot b} \right) \right]_{w_i, w_j \in \mathcal{V}_{\mathcal{D}}}, \\ \mathbf{X}_{wd} &= \left[\log \left(\frac{\#_d(w) \cdot \lambda_{\mathcal{D}}}{\#_{\mathcal{D}}(w) \cdot \lambda_d \cdot b} \right) \right]_{w \in \mathcal{V}_{\mathcal{D}},\, d \in \mathcal{D}}, \quad (4) \\ \mathbf{X}_{wc} &= \left[x_{w,c_i} \right]_{w \in \mathcal{V}_{\mathcal{D}},\, c_i \in \mathcal{C}}, \quad \text{where} \\ & x_{w,c_i} = \begin{cases} \log \frac{|\mathcal{C}|}{b}, & \text{if } w \in \mathcal{S}_i, \\ -\infty, & \text{if } w \in \mathcal{S}_j \ (\forall j \ne i). \end{cases} \end{aligned}$$

Here, $\#_{\mathcal{D}}(w_i, w_j)$ denotes the number of co-occurrences of w_i and w_j in a context window in $\mathcal{D}$; $\#_{\mathcal{D}}(w)$ denotes the number of occurrences of w

in $\mathcal{D}$; $\lambda_{\mathcal{D}}$ is the total number of terms in $\mathcal{D}$; $\#_d(w)$ denotes the number of times w occurs in d; λ_d is the total number of terms in d; b is the number of negative samples. (For the derivation of Eq. (3), please refer to Appendix A.)

To summarize, the learned local representations $\boldsymbol{u}_w$ are implicitly optimized for topic coherence, where term co-occurrences are measured in context, document, and category levels.

3.3 Ensemble Ranking

We have obtained two sets of term embeddings that model text semantics from different angles: $\{\boldsymbol{e}_w | w \in \mathcal{C} \cup \mathcal{V}_{\mathcal{D}}\}$ carries the PLM's knowledge, while $\{\boldsymbol{u}_w | w \in \mathcal{V}_{\mathcal{D}}\}$ models the input corpus as well as user-provided seeds. We now propose an ensemble ranking method to leverage information from both sides to grab more discriminative terms for each category.

Given a category c_i and its current term set $\mathcal{S}_i$, we first calculate the scores of each term $w \in \mathcal{V}_{\mathcal{D}}$.

$$\begin{aligned}\text{score}_G(w|\mathcal{S}_i) &= \frac{1}{|\mathcal{S}_i|}\sum_{w' \in \mathcal{S}_i} \cos(\boldsymbol{e}_w, \boldsymbol{e}_{w'}),\\ \text{score}_L(w|\mathcal{S}_i) &= \frac{1}{|\mathcal{S}_i|}\sum_{w' \in \mathcal{S}_i} \cos(\boldsymbol{u}_w, \boldsymbol{u}_{w'}).\end{aligned} \tag{5}$$

The subscript "G" here means "general", while "L" means "local". Then, we sort all terms by these two scores, respectively. Each term w will hence get two rank positions $\text{rank}_G(w)$ and $\text{rank}_L(w)$. We propose the following ensemble score based on the reciprocal rank:

$$\text{score}(w|\mathcal{S}_i) = \left(\frac{1}{2}\Big(\frac{1}{\text{rank}_G(w)}\Big)^{\rho} + \frac{1}{2}\Big(\frac{1}{\text{rank}_L(w)}\Big)^{\rho}\right)^{1/\rho}. \tag{6}$$

Here, $0 < \rho \leq 1$ is a constant. In practice, instead of ranking all terms in the vocabulary, we only check the top-M results in the two ranking lists. If a term w is not among the top-M according to $\text{score}_G(w)$ (resp., $\text{score}_L(w)$), we set $\text{rank}_G(w) = +\infty$ (resp., $\text{rank}_L(w) = +\infty$). In fact, when $\rho = 1$, Eq. (6) becomes the *arithmetic* mean of the two reciprocal ranks $\frac{1}{\text{rank}_G(w)}$ and $\frac{1}{\text{rank}_L(w)}$. This is essentially the mean reciprocal rank (MRR) commonly used in ensemble ranking, where a high position in one ranking list can largely compensate a low position in the other. In contrast, when $\rho \to 0$, Eq. (6) becomes the *geometric* mean of the two reciprocal ranks (see Appendix B), where two ranking lists both have the "veto power" (i.e., a term needs to be ranked as top-M in both ranking lists to obtain a non-zero ensemble score). In experiment, we set $\rho = 0.1$ and show it outperforms MRR (i.e., $\rho = 1$) in our topic discovery task.

Algorithm 1: SEETOPIC

```
Input: A text corpus $\mathcal{D} = \{d_1, ..., d_{|\mathcal{D}|}\}$, a set of
       seeds $\mathcal{C} = \{c_1, ..., c_{|\mathcal{C}|}\}$, and a PLM.
Output: $(\mathcal{S}_1, ..., \mathcal{S}_{|\mathcal{C}|})$, where each $\mathcal{S}_i$ is a set of
        category-discriminative terms for $c_i$.
1  Compute $\{\boldsymbol{e}_w | w \in \mathcal{C} \cup \mathcal{V}_{\mathcal{D}}\}$ using the PLM;
2  // Initialize $\mathcal{S}_i$;
3  $\mathcal{S}_1, ..., \mathcal{S}_{|\mathcal{C}|} \leftarrow \emptyset$;
4  for $n \leftarrow 1$ to $N$ do
5      for $i \leftarrow 1$ to $|\mathcal{C}|$ do
6          $w_n \leftarrow \arg\max_{w \in \mathcal{V}_{\mathcal{D}} \setminus (\mathcal{S}_1 \cup ... \cup \mathcal{S}_{|\mathcal{C}|})} \cos(\boldsymbol{e}_w, \boldsymbol{e}_{c_i})$;
7          $\mathcal{S}_i \leftarrow \mathcal{S}_i \cup \{w_n\}$;
8  // Update $\mathcal{S}_i$ for $T$ iterations;
9  for $t \leftarrow 1$ to $T$ do
10     Learn $\{\boldsymbol{u}_w | w \in \mathcal{V}_{\mathcal{D}}\}$ from the input corpus $\mathcal{D}$
        and the up-to-date representative terms
        $\mathcal{S}_1, ..., \mathcal{S}_{|\mathcal{C}|}$ according to Eq. (1);
11     $\text{score}_G(w|\mathcal{S}_i)$ and $\text{score}_L(w|\mathcal{S}_i) \leftarrow$ Eq. (5);
12     $\text{score}(w|\mathcal{S}_i) \leftarrow$ Eq. (6);
13     $\mathcal{S}_1, ..., \mathcal{S}_{|\mathcal{C}|} \leftarrow \emptyset$;

15         for $i \leftarrow 1$ to $|\mathcal{C}|$ do
16             $\mathcal{S}_i \leftarrow$ Eq. (7);
17 Return $(\mathcal{S}_1, ..., \mathcal{S}_{|\mathcal{C}|})$;
```

After computing the ensemble score $\text{score}(w|\mathcal{S}_i)$ for each w, we update $\mathcal{S}_i$. To guarantee that each $\mathcal{S}_i$ is category-discriminative, we do not allow any term to belong to more than one category. Therefore, we gradually expand each $\mathcal{S}_i$ by turns. At the beginning, we reset $\mathcal{S}_1 = ... = \mathcal{S}_{|\mathcal{C}|} = \emptyset$. When it is $\mathcal{S}_i$'s turn, we add one term $\mathcal{S}_i$ according to the following criterion:

$$\mathcal{S}_i \leftarrow \mathcal{S}_i \cup \{\mathop{\arg\max}_{w \in \mathcal{V}_{\mathcal{D}} \setminus (\mathcal{S}_1 \cup ... \cup \mathcal{S}_{|\mathcal{C}|})} \text{score}(w|\mathcal{S}_i)\}. \tag{7}$$

3.4 Overall Framework

We summarize the entire SEETOPIC framework in Algorithm 1. To deal with **out-of-vocabulary** category names, we first utilize a PLM to find their nearest in-vocabulary terms as the initial category-discriminative term set $\mathcal{S}_i$ (Lines 1-7). After initialization, $|\mathcal{S}_i| = N$ ($\forall 1 \leq i \leq |\mathcal{C}|$). Note that for an in-vocabulary category name $c_i \in \mathcal{V}_{\mathcal{D}}$, itself will be added to the initial $\mathcal{S}_i$ as the top-1 similar in-vocabulary term.

After getting the initial $\mathcal{S}_i$, we update it by T iterations (Lines 8-16). At each iteration, according to the up-to-date $\mathcal{S}_1, \mathcal{S}_2, ..., \mathcal{S}_{|\mathcal{C}|}$, we relearn embeddings $\boldsymbol{u}_w$, $\boldsymbol{v}_w$, $\boldsymbol{v}_d$, and $\boldsymbol{v}_{c_i}$ using Eq. (1) (Line 10). The two set of embeddings, $\{\boldsymbol{e}_w | w \in \mathcal{C} \cup \mathcal{V}_{\mathcal{D}}\}$ (computed at Line 1) and $\{\boldsymbol{u}_w | w \in \mathcal{V}_{\mathcal{D}}\}$ (updated at Line 10), are then leveraged to perform ensemble ranking (Lines 11-12). Based on the ensemble score $\mathrm{score}(w|\mathcal{S}_i)$, we update $\mathcal{S}_i$ using Eq. (7) (Lines 13-16). After the t-th iteration, $|\mathcal{S}_i| = (t+1)N$ ($\forall 1 \le i \le |\mathcal{C}|$).

Complexity Analysis. The time complexity of using the PLM is $\mathcal{O}((|\mathcal{C}| + |\mathcal{V}_\mathcal{D}|)\alpha_{\mathrm{PLM}})$, where α_{PLM} is the complexity of encoding one term via the PLM. The total complexity of local embedding is $\mathcal{O}(T\lambda_\mathcal{D}(h+|\mathcal{C}|)b)$ because in each iteration $1 \le t \le T$, every $w \in \mathcal{D}$ interacts with every other term in the context window of size h, its belonging document, and each category $c_i \in \mathcal{C}$, and each update involves b negative samples. The total complexity of ensemble ranking is $\mathcal{O}(T|\mathcal{V}_\mathcal{D}||\mathcal{C}||\mathcal{S}_i|)$ as in each iteration $1 \le t \le T$, we compute scores between each $w \in \mathcal{V}_\mathcal{D}$ and each $w' \in \mathcal{S}_i$ ($\forall c_i \in \mathcal{C}$).

4 Experiments

4.1 Experimental Setup

Datasets. We conduct experiments on three public datasets from different domains: (1) **SciDocs** (Cohan et al., 2020)[4] is a large collection of scientific papers supporting diverse evaluation tasks. For the MeSH classification task (Coletti and Bleich, 2001), about 23K medical papers are collected, each of which is assigned to one of the 11 common disease categories derived from the MeSH vocabulary. We use the title and abstract of each paper as documents and the 11 category names as seeds. (2) **Amazon** (McAuley and Leskovec, 2013)[5] contains product reviews from May 1996 to July 2014. Each Amazon review belongs to one or more product categories. We use the subset sampled by Zhang et al. (2020, 2022), which contains 10 categories and 100K reviews. (3) **Twitter** (Zhang et al., 2017)[6] is a crawl of geo-tagged tweets in New York City from August 2014 to November 2014. The dataset collectors link these tweets with Foursquare's POI database and assign them to 9 POI categories. We take these category names as input seeds.

Seeds used in the three datasets are shown in Table 1. Dataset statistics are summarized in Table 2. For all three datasets, we use AutoPhrase (Shang et al., 2018)[7] to perform phrase chunking in the corpus, and we remove words and phrases occurring less than 3 times.

Table 2: Dataset Statistics.

Dataset	SciDocs	Amazon	Twitter
#Documents	23,473	100,000	135,529
#In-vocabulary Terms (After Phrase Chunking)	55,897	56,942	17,577
Avg Doc Length	239.8	119.0	6.7
#Seeds	11	10	9
#Out-of-vocabulary Seeds (After Phrase Chunking)	5	6	7

Previous studies (Jagarlamudi et al., 2012; Meng et al., 2020a) have tried some other datasets (e.g., RCV1, 20 Newsgroups, NYT, and Yelp). However, the category names they use in these datasets are all picked from **in-vocabulary** terms. Therefore, we do not consider these datasets for evaluation in our task settings.

Following (Sia et al., 2020), we adopt a 60-40 train-test split for all three datasets. The training set is used as the input corpus $\mathcal{D}$, and the testing set is used for calculating topic coherence metrics (see evaluation metrics for details).

Compared Methods. We compare our SEETOPIC framework with the following methods, including seed-guided topic modeling methods, seed-guided embedding learning methods, and PLMs. (1) **SeededLDA** (Jagarlamudi et al., 2012)[8] is a seed-guided topic modeling method. It improves LDA by biasing topics to produce input seeds and by biasing documents to select topics relevant to the seeds they contain. (2) **Anchored CorEx** (Gallagher et al., 2017)[9] is a seed-guided topic modeling method. It incorporates user-provided seeds by balancing between compressing the input corpus and preserving seed-related information. (3) **Labeled ETM** (Dieng et al., 2020)[10] is an embedding-based topic modeling method. It incorporates distributed representation of each term. Following (Meng et al., 2020a), we retrieve representative terms according to their embedding similarity with the category name. (4) **CatE** (Meng et al., 2020a)[11] is a seed-guided embedding learning method for discriminative topic discovery. It takes category names as input and jointly learns term embedding and specificity from the input corpus. Category-discriminative terms are then selected based on both embedding similarity with the category and specificity. (5) **BERT** (Devlin et al., 2019)[12] is a PLM. Following Lines 1-7 in Algorithm 1, we use BERT to encode each input category name and each term to a vector, and then perform similarity search to directly find all repre-

sentative terms. (6) **BioBERT** (Lee et al., 2020)[13] is a PLM. It is used in the same way as BERT. Since BioBERT is specifically trained for biomedical text mining tasks, we report its performance on the SciDocs dataset only. (7) **SEETOPIC-NoIter** is a variant of our SEETOPIC framework. In Algorithm 1, after initialization (Lines 1-7), it executes Lines 9-16 only once (i.e., $T = 1$) to find all representative terms.

Here, all seed-guided topic modeling and embedding baselines (i.e., SeededLDA, Anchored CorEx, CatE, and Labeled ETM) can only take **in-vocabulary** seeds as input. For a fair comparison, we run Lines 1-7 in Algorithm 1 to get the initial representative in-vocabulary terms for each category, and input these terms as seeds into the baselines. In other words, all compared methods use BERT/BioBERT to initialize their term sets.

Evaluation Metrics. We evaluate topic discovery results from three different angles: topic coherence, term accuracy, and topic diversity.

(1) **NPMI** (Lau et al., 2014) is a standard metric in topic modeling to measure *topic coherence*. Within each topic, it calculates the normalized pointwise mutual information for each pair of terms in $\mathcal{S}_i$.

$$\text{NPMI} = \frac{1}{|\mathcal{C}|}\sum_{i=1}^{|\mathcal{C}|}\frac{1}{\binom{|\mathcal{S}_i|}{2}}\sum_{w_j,w_k\in\mathcal{S}_i}\frac{\log\frac{P(w_j,w_k)}{P(w_j)P(w_k)}}{-\log P(w_j,w_k)}, \quad (8)$$

where $P(w_j, w_k)$ is the probability that w_j and w_k co-occur in a document; $P(w_j)$ is the marginal probability of w_j.[14]

(2) **LCP** (Mimno et al., 2011) is another standard metric to measure *topic coherence*. It calculates the pairwise log conditional probability of top-ranked terms.

$$\text{LCP} = \frac{1}{|\mathcal{C}|}\sum_{i=1}^{|\mathcal{C}|}\frac{1}{\binom{|\mathcal{S}_i|}{2}}\sum_{\substack{w_j,w_k\in\mathcal{S}_i\\ j<k}}\log\frac{P(w_j,w_k)}{P(w_j)}. \quad (9)$$

Note that **PMI** (Newman et al., 2010) is also a standard metric for topic coherence. We do observe that SEETOPIC outperforms baselines in terms of PMI in most cases. However, since our local embedding step is implicitly optimizing a PMI-like objective, we no longer use it as our evaluation metric.

(3) **MACC** (Meng et al., 2020a) measures *term accuracy*. It is defined as the proportion of retrieved terms that actually belong to the corresponding category according to the category name.

$$\text{MACC} = \frac{1}{|\mathcal{C}|}\sum_{i=1}^{|\mathcal{C}|}\frac{1}{|\mathcal{S}_i|}\sum_{w_j\in\mathcal{S}_i}\mathbf{1}(w_j \in c_i), \quad (10)$$

where $\mathbf{1}(w_j \in c_i)$ is the indicator function of whether w_j is relevant to category c_i. MACC requires human evaluation, so we invite five annotators to perform independent annotation. The reported MACC score is the average MACC of the five annotators. A high inter-annotator agreement is observed, with Fleiss' kappa (Fleiss, 1971) being 0.856, 0.844, and 0.771 on SciDocs, Amazon, and Twitter, respectively.

(4) **Diversity** (Dieng et al., 2020) measures the *mutual exclusivity* of discovered topics. It is the percentage of unique terms in all topics, which corresponds to our task requirement that each retrieved term is discriminatively close to one category and far from the others.

$$\text{Diversity} = \frac{|\bigcup_{i=1}^{|\mathcal{C}|}\mathcal{S}_i|}{\sum_{i=1}^{|\mathcal{C}|}|\mathcal{S}_i|}. \quad (11)$$

Experiment Settings. We use BioBERT as the

---

[13] https://huggingface.co/dmis-lab/biobert-v1.1

[14] When calculating Eqs. (8) and (9), to avoid $\log 0$, we use $P(w_j, w_k) + \epsilon$ and $P(w) + \epsilon$ to replace $P(w_j, w_k)$ and $P(w)$, respectively, where $\epsilon = 1/|\mathcal{D}|$.

PLM on SciDocs, and BERT-base-uncased as the PLM on Amazon and Twitter. The embedding dimension of $\boldsymbol{u}_w$ is 768 (the same as $\boldsymbol{e}_w$); the number of negative samples $b = 5$. In ensemble ranking, the length of the general/local ranking list $M = 100$; the hyperparameter ρ in Eq. (6) is set as 0.1; the number of iterations $T = 4$; after each iteration, we increase the size of $\mathcal{S}_i$ by $N = 3$. We use the top-10 ranked terms in each topic for final evaluation (i.e., $|\mathcal{S}_i| = 10$ in Eqs. (8)-(11)). Experiments are run on Intel Xeon E5-2680 v2 @ 2.80GHz and one NVIDIA GeForce GTX 1080.

4.2 Performance Comparison

Table 3 shows the performance of all methods. We run each experiment 3 times with the average score reported. To show statistical significance, we conduct a two-tailed unpaired t-test to compare SEETOPIC and each baseline. (The performance of BERT and BioBERT is deterministic according to our usage. When comparing SEETOPIC with them, we conduct a two-tailed Z-test instead.) The significance level is also marked in Table 3.

We have the following observations from Table 3. (1) Our SEETOPIC model performs consistently well. In fact, it achieves the highest score in 8 columns and the second highest in the remaining 4 columns. (2) Classical seed-guided topic modeling baselines (i.e., SeededLDA and Anchored CorEx) perform not well in respect of NPMI (topic coherence) and MACC (term accuracy). Embedding-based topic discovery approaches (i.e., Labeled ETM and CatE) make some progress, but they still significantly underperform the PLM-empowered SEETOPIC model on SciDocs and Amazon. (3) SEETOPIC consistently performs better than SEETOPIC-NoIter on all three datasets, indicating the positive contribution of the proposed iterative process. (4) SEETOPIC guarantees the mutual exclusivity of $\mathcal{S}_1, ..., \mathcal{S}_{|\mathcal{C}|}$. In comparison, SeededLDA, Labeled ETM, and BERT cannot guarantee such mutual exclusivity.

In-vocabulary vs. Out-of-vocabulary. Figure 1 compares the MACC scores of different seed-guided topic discovery methods on in-vocabulary categories and out-of-vocabulary categories. We find that the performance improvement of SEETOPIC upon baselines on out-of-vocabulary categories is larger than that on in-vocabulary ones. For example, on Amazon, SEETOPIC underperforms CatE on in-vocabulary categories but outperforms CatE on out-of-vocabulary ones; on Twitter, the gap between SEETOPIC and baselines becomes much more evident on out-of-vocabulary categories. Note that all baselines in Figure 1 do not utilize the power of PLMs, so this observation validates our claim that PLMs are helpful in tackling out-of-vocabulary seeds.

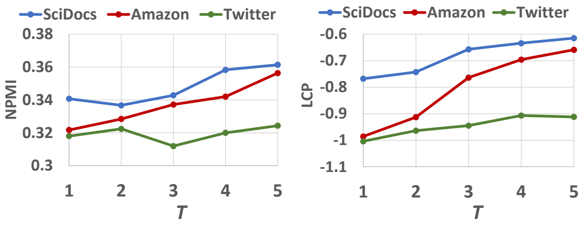
(a) Effect of ρ on NPMI (b) Effect of ρ on LCP



(c) Effect of T on NPMI (d) Effect of T on LCP

Figure 2: Parameter study of SEETOPIC measured by topic coherence.

4.3 Parameter Study

We study the effect of two important hyperparameters: ρ (the hyperparameter in ensemble ranking) and T (the number of iterations). We vary the value of ρ in $\{0.1, 0.3, 0.5, 0.7, 0.9, 1\}$ (SEETOPIC uses $\rho = 0.1$ by default) and the value of T in $\{1, 2, 3, 4, 5\}$ (SEETOPIC uses $T = 4$ by default, and SEETOPIC-NoIter is the case when $T = 1$). Figure 2 shows the change of model performance measured by NPMI and LCP.

Table 4: Top-5 representative terms retrieved by different algorithms for three out-of-vocabulary categories from SciDocs, Amazon, and Twitter. ✓: at least 3 of the 5 annotators judge the term as relevant to the seed. ✗: at most 2 of the 5 annotators judge the term as relevant to the seed.

SeeTopic	chronic hepatitis b virus hbv infection (✓), hbeag-negative chronic hepatitis b (✓), hepatitis c virus hcv-infected (✓), hepatitis b virus hbv dna (✓), chronic hepatitis c virus hcv (✓)
Dataset: Amazon, Category Name: sports and outdoors	
SeededLDA	use (✗), good (✗), one (✗), product (✗), like (✗)
Anchored CorEx	sports (✓), use (✗), size (✗), wear (✗), fit (✓)
Labeled ETM	cars and tracks (✓), tracks and cars (✓), search options (✗), championships (✗), cool bosses (✗)
CatE	outdoorsmen (✓), outdoor activities (✓), cars and tracks (✓), foot support (✓), offers plenty (✗)
BERT	cars and tracks (✓), outdoor activities (✓), outdoorsmen (✓), sports (✓), sporting events (✓)
SeeTopic-NoIter	outdoorsmen (✓), outdoor activities (✓), cars and tracks (✓), indoor soccer (✓), bike riding (✓)
SeeTopic	canoeing (✓), picnics (✓), bike rides (✓), bike riding (✓), rafting (✓)
Dataset: Twitter, Category Name: travel and transport	
SeededLDA	nyc (✗), new york (✗), line (✓), high (✗), time square (✓)
Anchored CorEx	new york (✗), post photo (✓), new (✗), day (✗), today (✗)
Labeled ETM	tourism (✓), theview (✓), file (✗), morning view (✓), gma (✗)
CatE	maritime (✓), tourism (✓), natural history (✗), scenery (✓), elevate (✗)
BERT	maritime (✓), tourism (✓), natural history (✗), olive oil (✗), baggage claim (✓)
SeeTopic-NoIter	maritime (✓), tourism (✓), natural history (✗), scenery (✓), navy (✗)
SeeTopic	wildlife (✓), scenery (✓), maritime (✓), highlinepark (✗), aquarium (✓)

According to Figures 2(a) and 2(b), in most cases, the performance of SeeTopic deteriorates as ρ increases from 0.1 to 0.9. Thus, setting $\rho = 0.1$ always leads to competitive NPMI and LCP scores on the three datasets. Although $\rho = 1$ is better than $\rho = 0.9$, its performance is still suboptimal in comparison with $\rho = 0.1$. This finding indicates that replacing the mean reciprocal rank (i.e., $\rho = 1$) with our proposed Eq. (6) is reasonable. According to Figures 2(c) and 2(d), SeeTopic usually performs better when there are more iterations. On SciDocs and Twitter, the scores start to converge after $T = 4$. Besides, more iterations will result in longer running time. Overall, we believe setting $T = 4$ strikes a good balance.

4.4 Case Study

Finally, we show the terms retrieved by different methods as a case study. From each of the three datasets, we select an out-of-vocabulary category and show its topic discovery results in Table 4. We mark a retrieved term as correct (✓) if at least 3 of the 5 annotators judge the term as relevant to the seed. Otherwise, we mark the term as incorrect (✗).

For the category "*hepatitis a/b/c/e*" from SciDocs, SeededLDA and Anchored CorEx can only find very general medical terms, which are relevant to all seeds in SciDocs and thus inaccurate; Labeled ETM and CatE find terms about "*alanine aminotransferase*", whose elevation suggest not only hepatitis but also other diseases like diabetes and heart failure, thus not discriminative either; BioBERT and SeeTopic, with the power of a PLM, can accurately pick terms relevant to "*hepatitis b*" and "*hepatitis c*". For the category "*sports and outdoors*" from Amazon, SeededLDA and Anchored CorEx again find very general terms, most of which are not category-discriminative; Labeled ETM and CatE are able to pick more specific terms such as "*cars and tracks*", but they still make mistakes; BERT, as a PLM, can accurately find terms that have lexical overlap with the category name (e.g., "*outdoorsmen*", "*sporting events*"), meanwhile such terms are less diverse; SeeTopic-NoIter starts to discover more concrete terms than BERT (e.g., "*indoor soccer*", "*bike riding*") by leveraging local text semantics; the full SeeTopic model, with an iterative updating process, can find more specific and informative terms (e.g., "*canoeing*", "*picnics*", and "*rafting*"). For the category "*travel and trans-*

port” from Twitter, both BERT and CatE make mistakes by including the term “*natural history*”; SEETOPIC-NoIter, without an iterative update process, also includes this error; the full SEETOPIC model finally excludes this error and achieves the highest accuracy in the retrieved top-5 terms among all compared methods.

5 Related Work

Seed-Guided Topic Discovery. Seed-guided topic models aim to leverage user-provided seeds to discover underlying topics according to users' interests. Early studies take LDA (Blei et al., 2003) as the backbone and incorporate seeds into model learning. For example, Andrzejewski et al. (2009) consider must-link and cannot-link constraints among seeds as priors. SeededLDA (Jagarlamudi et al., 2012) encourages topics to contain more seeds and encourages documents to select topics relevant to the seeds they contain. Anchored CorEx (Gallagher et al., 2017) extracts maximally informative topics by jointly compressing the corpus and preserving seed relevant information. Recent studies start to utilize embedding techniques to learn better word semantics. For example, CatE (Meng et al., 2020a) explicitly encourages distinction among retrieved topics via category-name guided embedding learning. However, all these models require the provided seeds to be in-vocabulary, mainly because they focus on the input corpus only and are not equipped with general knowledge of PLMs.

Embedding-Based Topic Discovery. A number of studies extend LDA to involve word embedding. The common strategy is to adapt distributions in LDA to generate real-valued data (e.g., Gaussian LDA (Das et al., 2015), LFTM (Nguyen et al., 2015), Spherical HDP (Batmanghelich et al., 2016), and CGTM (Xun et al., 2017b)). Some other studies think out of the LDA backbone. For example, TWE (Liu et al., 2015) uses topic structures to jointly learn topic embeddings and improve word embeddings. CLM (Xun et al., 2017a) collaboratively improves topic modeling and word embedding by coordinating global and local contexts. ETM (Dieng et al., 2020) models word-topic correlations via word embeddings to improve the expressiveness of topic models. More recently, Sia et al. (2020) show that directly clustering word embeddings (e.g., word2vec or BERT) also generates good topics; Thompson and Mimno (2020) further find that BERT and GPT-2 discover high-quality topics, but RoBERTa does not. These models are unsupervised and hard to be applied to seed-guided settings. In contrast, our SEETOPIC framework joint leverages PLMs, word embeddings, and seed information.

6 Conclusions and Future Work

In this paper, we study seed-guided topic discovery in the presence of out-of-vocabulary seeds. To understand and make use of in-vocabulary components in each seed, we utilize the tokenization and contextualization power of PLMs. We propose a seed-guided embedding learning framework inspired by the goal of maximizing PMI in topic modeling, and an iterative ensemble ranking process to jointly leverage general knowledge of the PLM and local signals learned from the input corpus. Experimental results show that SEETOPIC outperforms seed-guided topic discovery baselines and PLMs in terms of topic coherence, term accuracy, and topic diversity. A parameter study and a case study further validate some design choices in SEETOPIC.

In the future, it would be interesting to extend SEETOPIC to seed-guided hierarchical topic discovery, where parent and child information in the input category hierarchy may help infer the meaning of out-of-vocabulary nodes.

A The Embedding Learning Objective

In Section 3.2, we propose the following embedding learning objective:

$$\begin{aligned}\mathcal{J} = &\underbrace{\sum_{d\in\mathcal{D}}\sum_{w_i\in d}\sum_{w_j\in\mathcal{C}(w_i,h)}\frac{\exp(\boldsymbol{u}_{w_i}^T\boldsymbol{v}_{w_j})}{\sum_{w'\in\mathcal{V}_\mathcal{D}}\exp(\boldsymbol{u}_{w_i}^T\boldsymbol{v}_{w'})}}_{\mathcal{J}_{\text{context}}} + \\ &\underbrace{\sum_{d\in\mathcal{D}}\sum_{w\in d}\frac{\exp(\boldsymbol{u}_w^T\boldsymbol{v}_d)}{\sum_{d'\in\mathcal{D}}\exp(\boldsymbol{u}_w^T\boldsymbol{v}_{d'})}}_{\mathcal{J}_{\text{document}}} + \\ &\underbrace{\sum_{c_i\in\mathcal{C}}\sum_{w\in\mathcal{S}_i}\frac{\exp(\boldsymbol{u}_w^T\boldsymbol{v}_{c_i})}{\sum_{c'\in\mathcal{C}}\exp(\boldsymbol{u}_w^T\boldsymbol{v}_{c'})}}_{\mathcal{J}_{\text{category}}}.\end{aligned} \tag{12}$$

Now we prove that maximizing $\mathcal{J}$ is implicitly performing the factorization in Eq. (3).

Levy and Goldberg (2014) have proved that maximizing $\mathcal{J}_{\text{context}}$ is implicitly doing the following factorization.

$$\begin{aligned}\boldsymbol{u}_{w_i}^T\boldsymbol{v}_{w_j} &= \log\Big(\frac{\#_\mathcal{D}(w_i,w_j)\cdot\lambda_\mathcal{D}}{\#_\mathcal{D}(w_i)\cdot\#_\mathcal{D}(w_j)\cdot b}\Big), \\ \text{i.e.,}\quad \mathbf{U}_w^T\mathbf{V}_w &= \mathbf{X}_{ww}.\end{aligned} \tag{13}$$

We follow their approach to consider the other two terms $\mathcal{J}_{\text{document}}$ and $\mathcal{J}_{\text{category}}$ in Eq. (12). Using the negative sampling strategy to rewrite $\mathcal{J}_{\text{document}}$, we get

$$\sum_{w\in\mathcal{V}_\mathcal{D}}\sum_{d\in\mathcal{D}}\#_d(w)\Big(\log\sigma(\boldsymbol{u}_w^T\boldsymbol{v}_d)+b\mathbb{E}_{d'}\big[\log\sigma(-\boldsymbol{u}_w^T\boldsymbol{v}_{d'})\big]\Big), \tag{14}$$

where $\sigma(\cdot)$ is the sigmoid function. Following (Levy and Goldberg, 2014; Qiu et al., 2018), we assume the negative sampling distribution $\propto \lambda_d$.[15] Then, the objective becomes

$$\begin{aligned}&\sum_{w\in\mathcal{V}_\mathcal{D}}\sum_{d\in\mathcal{D}}\#_d(w)\log\sigma(\boldsymbol{u}_w^T\boldsymbol{v}_d) + \\ &\sum_{w\in\mathcal{V}_\mathcal{D}}\#_\mathcal{D}(w)\sum_{d'\in\mathcal{D}}\frac{b\cdot\lambda_{d'}}{\lambda_\mathcal{D}}\log\sigma(-\boldsymbol{u}_w^T\boldsymbol{v}_{d'}).\end{aligned} \tag{15}$$

For a specific term-document pair (w,d), we consider its effect in the objective:

$$\mathcal{J}_{w,d} = \#_d(w)\log\sigma(\boldsymbol{u}_w^T\boldsymbol{v}_d)+\#_\mathcal{D}(w)\frac{b\cdot\lambda_d}{\lambda_\mathcal{D}}\log\sigma(-\boldsymbol{u}_w^T\boldsymbol{v}_d). \tag{16}$$

Let $x_{w,d} = \boldsymbol{u}_w^T\boldsymbol{v}_d$. To maximize $\mathcal{J}_{w,d}$, we should have

$$0 = \frac{\partial\mathcal{J}_{w,d}}{\partial x_{w,d}} = \#_d(w)\sigma(-x_{w,d}) - \frac{\#_\mathcal{D}(w)\cdot b\cdot\lambda_d}{\lambda_\mathcal{D}}\sigma(x_{w,d}). \tag{17}$$

---

[15] In practice, the negative sampling distribution $\propto \lambda_d^{3/4}$, but related studies (Levy and Goldberg, 2014; Qiu et al., 2018) usually assume a linear relationship in their derivation.

That is,

$$e^{2x_{w,d}} - \Big(\frac{\#_d(w)\cdot\lambda_{\mathcal{D}}}{\#_{\mathcal{D}}(w)\cdot b\cdot\lambda_d} - 1\Big)e^{x_{w,d}} - \frac{\#_d(w)\cdot\lambda_{\mathcal{D}}}{\#_{\mathcal{D}}(w)\cdot b\cdot\lambda_d} = 0. \tag{18}$$

Therefore, $e^{x_{w,d}} = -1$ (which is invalid) or $e^{x_{w,d}} = \frac{\#_d(w)\cdot\lambda_{\mathcal{D}}}{\#_{\mathcal{D}}(w)\cdot b\cdot\lambda_d}$. In other words,

$$\begin{aligned}&\boldsymbol{u}_w^T\boldsymbol{v}_d = x_{w,d} = \log\Big(\frac{\#_d(w)\cdot\lambda_{\mathcal{D}}}{\#_{\mathcal{D}}(w)\cdot b\cdot\lambda_d}\Big),\\ &\text{i.e., } \mathbf{U}_w^T\mathbf{V}_d = \mathbf{X}_{wd}.\end{aligned} \tag{19}$$

Similarly, for $\mathcal{J}_{\text{category}}$, the objective can be rewritten as

$$\begin{aligned}&\sum_{w\in\mathcal{V}_{\mathcal{D}}}\sum_{c_i\in\mathcal{C}}\mathbf{1}_{w\in\mathcal{S}_i}\log\sigma(\boldsymbol{u}_w^T\boldsymbol{v}_{c_i}) +\\ &\sum_{w\in\mathcal{V}_{\mathcal{D}}}\mathbf{1}_{w\in\mathcal{S}_1\cup\ldots\cup\mathcal{S}_{|\mathcal{C}|}}\sum_{c'\in\mathcal{C}}\frac{b}{|\mathcal{C}|}\log\sigma(-\boldsymbol{u}_w^T\boldsymbol{v}_{c'}).\end{aligned} \tag{20}$$

Following the derivation of $\mathcal{J}_{\text{document}}$, we get

$$\begin{aligned}&\boldsymbol{u}_w^T\boldsymbol{v}_{c_i} = x_{w,c_i} = \log\Big(\frac{\mathbf{1}_{w\in\mathcal{S}_i}|\mathcal{C}|}{\mathbf{1}_{w\in\mathcal{S}_1\cup\ldots\cup\mathcal{S}_{|\mathcal{C}|}}\cdot b}\Big),\\ &\text{i.e., } \mathbf{U}_w^T\mathbf{V}_{c_i} = \mathbf{X}_{wc}.\end{aligned} \tag{21}$$

Putting Eqs. (13), (19), and (21) together gives us Eq. (3).

B The Ensemble Ranking Function

In Section 3.3, we propose the following ensemble ranking function:

$$\text{score}(w|\mathcal{S}_i) = \Big(\frac{1}{2}\Big(\frac{1}{\text{rank}_G(w)}\Big)^{\rho} + \frac{1}{2}\Big(\frac{1}{\text{rank}_L(w)}\Big)^{\rho}\Big)^{1/\rho}. \tag{22}$$

Now we prove this ranking function is a generalization of the *arithmetic* mean reciprocal rank (i.e., MRR) and the *geometric* mean reciprocal rank:

$$\begin{aligned}&\lim_{\rho\to 1}\text{score}(w|\mathcal{S}_i) = \frac{1}{2}\Big(\frac{1}{\text{rank}_G(w)} + \frac{1}{\text{rank}_L(w)}\Big);\\ &\lim_{\rho\to 0}\text{score}(w|\mathcal{S}_i) = \Big(\frac{1}{\text{rank}_G(w)}\cdot\frac{1}{\text{rank}_L(w)}\Big)^{1/2}.\end{aligned} \tag{23}$$

The case of $\rho \to 1$ is trivial. When $\rho \to 0$, we aim to show that

$$\lim_{\rho\to 0}\log\text{score}(w|\mathcal{S}_i) = \log\Big(\frac{1}{\text{rank}_G(w)}\cdot\frac{1}{\text{rank}_L(w)}\Big)^{1/2}. \tag{24}$$

In fact, let $r_G = \frac{1}{\text{rank}_G(w)}$ and $r_L = \frac{1}{\text{rank}_L(w)}$.

$$\begin{aligned}\lim_{\rho\to 0}\log\text{score}(w|\mathcal{S}_i) &= \lim_{\rho\to 0}\log\Big(\frac{1}{2}r_G^{\rho} + \frac{1}{2}r_L^{\rho}\Big)^{1/\rho}\\ &= \lim_{\rho\to 0}\frac{\log\big(\frac{1}{2}r_G^{\rho} + \frac{1}{2}r_L^{\rho}\big)}{\rho}\\ &= \lim_{\rho\to 0}\frac{\frac{\frac{1}{2}r_G^{\rho}\log r_G + \frac{1}{2}r_L^{\rho}\log r_L}{\frac{1}{2}r_G^{\rho} + \frac{1}{2}r_L^{\rho}}}{1}\\ &= \frac{\lim_{\rho\to 0}\Big(r_G^{\rho}\log r_G + r_L^{\rho}\log r_L\Big)}{\lim_{\rho\to 0}\Big(r_G^{\rho} + r_L^{\rho}\Big)}\\ &= \frac{\log r_G + \log r_L}{2}\\ &= \log(r_G\cdot r_L)^{1/2}.\end{aligned} \tag{25}$$

The third line is obtained by applying L'Hopital's rule.

SwahBERT: Language Model of Swahili

Abstract

The rapid development of social networks, electronic commerce, mobile Internet, and other technologies has influenced the growth of Web data. Social media and Internet forums are valuable sources of citizens' opinions, which can be analyzed for community development and user behavior analysis. Unfortunately, the scarcity of resources (i.e., datasets or language models) has become a barrier to the development of natural language processing applications in low-resource languages. Thanks to the recent growth of online forums and news platforms of Swahili, we introduce two datasets of Swahili in this paper: a pre-training dataset of approximately 105MB with 16M words and an annotated dataset of 13K instances for the emotion classification task. The emotion classification dataset is manually annotated by two native Swahili speakers. We pre-trained a new monolingual language model for Swahili, namely SwahBERT, using our collected pre-training data, and tested it with four downstream tasks including emotion classification. We found that SwahBERT outperforms multilingual BERT, a well-known existing language model, in almost all downstream tasks.

1 Introduction

Nowadays, online social networking has revolutionized interpersonal communication. The influence of social media in our everyday lives, at both a personal and professional level, has led recent studies to language analysis in social media (Zeng et al., 2010). Especially, natural language processing (NLP) tools are often used to analyze textual data for various real-world applications; mining social media for information about health (De Gennaro et al., 2020), diseases analysis (e.g., COVID-19 (Gao et al., 2020), Ebola (Tran and Lee, 2016)), identifying sentiment and emotion toward products and services, and developing dialog systems (Zhou et al., 2020). Language models have recently drawing much attention as they are known to be effective in many NLP tasks (e.g., text classification, entailment, sequence labeling), but they commonly require a huge amount of data for pre-training and fine-tuning; some models are designed for few-shot learning that does not require much labeled data for fine-tuning, though they still require plenty of pre-training data. As it is expensive and difficult to get the labeled and unlabeled data, the majority of the data are in high-resource languages (HRLs) (e.g., English, Spanish). Unfortunately, other than about 20 HRLs languages, approximately 7,000 low-resource languages (LRLs) in the world are left behind, where most of LRLs are spoken and little written (Magueresse et al., 2020). Africa and India are the main hosts of LRLs, where some languages are spoken by more than 20 million people (e.g., Hausa, Oromo, Zulu, and Swahili). As more data on social media in LRLs, qualified datasets, and publicly available language models will bring many advantages in various fields, such as education (Obiria, 2019), healthcare (de Las Heras-Pedrosa et al., 2020), entertainment (Ahn et al., 2013), and business.

Swahili, a Bantu language, is one of the two official languages (the other being English) of the East African countries such as Tanzania (Petzell, 2012), Kenya, and Uganda. It has been widely spread in African countries not only as a *lingua franca* but also as a second or third language across the African continent and broadly in education, administration, and media. With the rapid development of social networks, electronic commerce, mobile Internet, and other technologies, Swahili is also spreading in online places that result in the growth of Web data. For example, JamiiForum is a popular online platform in Tanzania, and it provides a place to discuss different issues, including political, business, educational, and lifestyle; this means more collected textual data of Swahili is available.

By making use of the online textual data of

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 303 - 313
July 10-15, 2022

Swahili, there are several studies for different tasks (e.g., sentiment classification (Obiria, 2019; Noor and Turan, 2019; Seif, 2016), news classification (David, 2020)). Recently, language models have drawn much attention from the industry and academic world, as the language models brought much better performance (e.g., accuracy) than other existing models. There are few studies that employed the language models for Swahili: named entity recognition (NER) (Adelani et al., 2021) and sentiment classification (Martin et al., 2021). Although these studies have shown successful results, they are limited in that they just borrow the language models (e.g., multilingual Bidirectional Encoder Representations from Transformer (mBERT) (Devlin et al., 2019), Cross-lingual Model-RoBERTA (XLM-R) (Conneau et al., 2020)) pre-trained with other resources (i.e., other languages); in other words, their language models are pre-trained for multiple languages but not dedicated for Swahili. Although such multilingual language models have shown great generalization power across multiple languages, several studies (Bhattacharjee et al., 2021; Tanvir et al., 2021; Vilares et al., 2021) reported that the monolingual models often outperform these multilingual models. There was no study that proposed a monolingual language model for Swahili (i.e., Swahili-specific language model), and the main reason is that Swahili is one of the LRLs, so the existing studies commonly suffered from lack of available data.

In this paper, we focus on the Swahili language. To the best of our knowledge, this is the first study that collects a pre-training dataset and uses it for pre-training of the Swahili-specific language model. We also provide a manually annotated dataset for the emotion classification task. The contributions are summarized as follows.

- Pre-training dataset: we collected Web data from different sources (news sites and social discussion forums) for pre-training the Swahili language model.
- Emotion dataset: we introduce a new Swahili dataset for multi-label emotion classification with six Ekman's emotions: *happy, surprise, sadness, fear, anger, and disgust*.
- Swahili language model: we pre-trained the Swahili language model and compared its performance with other language models on several downstream tasks (e.g., emotion classification, news classification, and named entity recognition (NER)).

2 Background

Most African countries have minority languages that are used by specific ethnic groups (approx. 158 in Tanzania [1]). However they speak different national and official languages of their countries, including native and colonial that can be used in public services such as education, politics, and the media. Swahili is a Bantu language widely spoken in sub-Saharan Africa and acts as the common tongue for most East African (Lodhi, 1993; Amidu, 1995). Many Swahili vocabularies are derived from loanwords, the vast majority from Arabic, but also English, Hindi, Portuguese, and other Bantu languages [2]. As the language grows, new formal and informal vocabularies emerge. The formal vocabularies are used in official documents, whereas the informal vocabularies are mostly used by young adults and on social media platforms (Momanyi, 2009).

Structurally, it is considered an agglutinative language with polysemous features. Its morphology depends on prefixes and suffixes which are syllables (Shikali et al., 2019). A single word is generated with morphemes (i.e., stem, prefixes, and affixes) that will have corresponding inflectional forms. Nouns are divided into classes on the basis of their singular and plural prefixes. Despite its popularity, a limited amount of textual data is available and it is one of the low-resource languages (LRLs). Although there have been a few studies that illustrate the value of NLP (Martin et al., 2021; Obiria, 2019; Gelas et al., 2012), they commonly suffered from the lack of available data.

2.1 Existing dataset of Swahili

To overcome the problem of limited language resource, they have been few datasets for different tasks: new classification dataset, NER dataset, sentiment classification dataset, and emotion classification dataset.

2.1.1 News classification dataset

This dataset [3] is created and shared by a data science competition platform *Zindi* (David, 2020) . It contains a total of 23,266 instances collected from different news websites in Tanzania. There are 6

---

[1] https://www.tanzania.go.tz/home/pages/228

[2] https://en.wikipedia.org/wiki/Swahili_language

[3] https://zenodo.org/record/4300294?ref=hackernoon.com

categories of news: *kitaifa* (national), *kimataifa* (International), *biashara* (finance), *michezo* (sports), *afya* (health), and *burudani* (entertainment). The amount of each category is 10,242 (national), 1,905 (International), 2,028 (finance), 859 (health), 6,003 (sports), and 2,229 (entertainment); so this dataset is highly imbalanced. Kastanos and Martin (2021) applied a deep learning model called Text Graph Convolutional Network (Text GCN) on this dataset and achieved an F1 score of 75.67% for the news classification task.

2.1.2 Sentiment classification dataset

Obiria (2019) collected 886 posts from Twitter and Facebook to analyze the student opinion in Kenyan universities and achieved an accuracy of 83% on binary classification task using support vector machine (SVM) (Hearst et al., 1998). Noor and Turan (2019) extracted 1,087 Twitter texts about demonetization in Kenya and performed ternary sentiment classification with Naive Bayes. They applied various feature extraction methods and obtained an accuracy of 70.8%. Recently, Martin et al. (2021) used a cross-lingual model, mBERT, to perform binary sentiment classification on a social media dataset that they manually annotated, and achieved an accuracy of 87.59%. None of the above datasets are publicly available.

2.1.3 Named entity recognition dataset

This dataset, namely MasakhaNER [4] (Adelani et al., 2021), is created for ten African languages, including Swahili. The news texts are collected from local news sources and annotated using ELISA tool (Lin et al., 2018) by native speakers of each language. The dataset contains a total of 3,006 instances and covers four entities: personal name (PER), location (LOC), organization (ORG), and date & time (DATE) as inspired by the English CoNLL-2003 corpus (Tjong Kim Sang and De Meulder, 2003). The number of entities of each type is 1,702 (PER), 2,842 (LOC), 960 (ORG), and 940 (DATE). They compared three models (e.g., CNN-BiLSTM-CRF, mBERT, and XLM-R) on the NER task, and mBERT and XLM-R achieved 89.36% and 89.46% of an F1 score, respectively.

2.2 Language models

Over the years, models for word representation have been developed and have shown that they are capable of capturing the semantics and syntactic dependencies between words: Word2Vec (Mikolov et al., 2013), Glove (Pennington et al., 2014), and FastText (Bojanowski et al., 2017). As these models do not incorporate context of words, many context-aware language models based on Transformer (Vaswani et al., 2017) were introduced (e.g., Bidirectional Encoder Representations from Transformer (BERT) (Devlin et al., 2019) and XLM-R (Conneau et al., 2020)). These language models are trainable with a monolingual or multilingual dataset. For example, multilingual BERT (mBERT) is trained with a dataset of 104 languages and a shared vocabulary.

Although mBERT has shown its potential in some previous work, several studies reported some limitations of mBERT especially to LRLs: (1) the limited scale of pre-training data (only Wikipedia was used) (Conneau et al., 2020); (2) the small vocabulary size for specific language (Wang et al., 2019). To overcome that, XLM-RoBERTA modifies mBERT by increasing the amount of pre-training data, which increases the shared vocabulary between different languages. It provides a strong improvement over mBERT, however, it is outperformed by monolingual models (Tanvir et al., 2021; Bhattacharjee et al., 2021) due to better representation of morphological language such as Swahili. This is a good improvement since the model can learn morphological information. Another limitation is the nature of pre-training corpora. Most available corpora are extracted from Wikipedia, Bookcorpus, or news blogs which may not be compatible with the task that covers multi-domain such as social media data. In this work, we collect our data from different sources across several domains for our new language model.

3 Dataset

In this section we describe our collected dataset for pre-training and the downstream task of emotion classification. We open our datasets for future use in various studies [5].

3.1 Pre-training dataset

The existing available corpora for Swahili are very small, for example, the Open Super-large

---

[4] https://github.com/masakhane-io/masakhane-ner/tree/main/data

[5] https://sites.google.com/view/swahbert/home

Crawled Aggregated coRpus (OSCAR) database contains about 25 megabytes of the corpus. Using crawler tools, we scraped our own data from different sources such as news Web sites, forums, and Wikipedia. The news Web sites include UN news [6], Voice of America (VoA) [7], Deutsche Welle (DW) [8] and taifaleo [9]. We collected data from *JamiiForums*, which is one of the most popular social media websites in Tanzania founded in 2006. The forum has provided a discussion platform for the public to discuss different issues, including political, business, educational, and lifestyle. Since JamiiForums is a discussion platform, most of its contents are either passages of information or short comments. We collected the passages with more than four logically connected sentences. We removed URL links, usernames, non-textual content (e.g., HTML tags) and filtered out non-Swahili characters (e.g., Latin, Chinese). The size of dataset is about 105MB with 16M words, where a sentence has an average of 27 subword tokens. Most of these platforms contain data that range from 5 to 10 years. The contribution (in percentage) of each source was taifaleo (39.4), UN news (28.6), JamiiForum (10.2), Wikipedia (9.5), VoA (7.2), and DW (5.1).

3.2 Emotion classification dataset

Existing non-Swahili datasets typically use annotation schemes based on Ekman (Ekman, 1992), Plutchik (Plutchik, 1980) or with multiple categories (Demszky et al., 2020). For example, there are English datasets with multiple emotion categories: Affective Text (Strapparava and Mihalcea, 2007) with 11 categories, CrowdFlower with 14 categories, GoEmotions (Demszky et al., 2020) with 27 categories and others (Oberländer and Klinger, 2018). In this paper, to construct a new Swahili dataset for emotion classification, we chose to use 6 emotion categories from Ekman's (Ekman, 1992) scheme: anger (*hasira*), surprise (*mshangao*), disgust (*machukizo*), joy (*furaha*), fear (*woga*), and sadness (*huzuni*). Our dataset is collected from two source types: social media platforms of Swahili and existing emotion datasets of English. The social media platforms include YouTube, JamiiForum [10] and Twitter The conversations and comments on these platforms cover different topics, such as politics, disease outbreaks, and aspects of daily life. We reviewed the dataset and removed profanity towards a specific person or ethnic group. For example, in the sentence '[name] is very stupid, she doesn't act like a leader at all,' we replaced the target name with pronoun. We also selected three existing English datasets with relevant topic coverage and converted them into Swahili using Google translator. The three datasets include: (1) Dailydialog (Li et al., 2017) that reflects daily communication and covers various topics about our daily life, (2) Emotion Cause (Ghazi et al., 2015), and (3) ISEAR (Scherer and Wallbott, 1994) collected from participants from varying cultural backgrounds who complete questionnaires about their experiences and reactions. The Swahili emotion texts obtained from the Google translator were checked and corrected thoroughly by a native Swahili speaker.

Item	Value
# of examples	12,976
# of labels	7 (including 'neutral')
# of text per labels	joy: 2,439 disgust: 3,227 anger: 1,772 sadness: 2,339 fear: 1,116 surprise: 2,305 Neutral: 863
# of labels per examples	1: 92.09% 2: 7.45% 3: 0.46%
Ratio of source	Dailydialog: 13.26% Emotion cause: 13.08% ISEAR: 2.26% Social media: 71.40%
Appx. ratio of taxonomy	Politics: 15% social issues: 80% pandemic: 5%

Table 1: Statistics of Emotion classification dataset.

For the dataset collected from forums of Swahili, two native Swahili speakers were assigned to annotate the emotion labels. These speakers agreed to the consent of serving as annotators and were given an instruction of annotation. They were asked to select one or multiple suitable emotion labels that were expressed in the text, and labeled 'neutral' for unsure texts. The statistics summary is presented in Table 1. We also calculated annotator agreement using Cohen's kappa metric, which computes a score of agreement level between two annota-

tors who each classify N items into C mutually exclusive categories. The scores for each label are joy (0.835), disgust (0.845), anger (0.763), sadness (0.733), fear (0.694), and surprise (0.806). Figure 1 is a heatmap that shows the degree of relationship between emotions. The emotion pair with high intensity (e.g. *hasira* (anger) and *machukizo* (disgust)) has a positive correlation in multi-label emotion.

	anger	disgust	fear	joy	neutral	sadness	surprise
anger	1	0.024	-0.11	-0.19	-0.11	-0.17	-0.14
disgust	0.024	1	-0.16	-0.27	-0.15	-0.21	-0.18
fear	-0.11	-0.16	1	-0.14	-0.082	-0.096	-0.13
joy	-0.19	-0.27	-0.14	1	-0.13	-0.22	-0.21
neutral	-0.11	-0.15	-0.082	-0.13	1	-0.13	-0.12
sadness	-0.17	-0.21	-0.096	-0.22	-0.13	1	-0.2
surprise	-0.14	-0.18	-0.13	-0.21	-0.12	-0.2	1

Figure 1: Pearson correlation matrix for the multi-emotion.

4 SwahBERT

With the collected dataset, we pre-trained the monolingual BERT for Swahili, namely SwahBERT [11]. The SwahBERT basically has the same architecture as the original BERT. This section describes the process of pre-training and fine-tuning of SwahBERT.

4.1 Tokenizer

In mBERT, not all languages have equal content size (Wu and Dredze, 2020), and some languages are dominated; for example, Swahili is only less than 1% of the approximately 120K vocabulary of mBERT. Although it might benefit from high resource languages as Swahili has the same typology (word order) and many loanwords, it would definitely be better to generate a Swahili-specific tokenizer. That is, the multilingual tokenizer often splits the words without considering morphological boundaries (e.g., stem, prefixes, and suffixes), like the sentence in Table 2, so the individual subword units do not have a clear semantic meaning. Swahili is morphologically rich language and polysynthetic language; for example, a word *alimpikia* (cooked for) has a lexical morph {*-pika*}, four grammatical morphs {*a-,-li-, -m-, -i-*} and two in the verb skeletal morphological frame which has the root {*-pik-*}, and bantu end vowel {*-a*} (Choge, 2018). In this paper, to incorporate such linguistic complexity, we try monolingual tokenizers for Swahili with different vocabulary sizes (e.g., 32K, 50K, and 70K) using the WordPiece algorithm [12].

4.2 Training

SwahBERT has 12 encoder blocks and 768 hidden units. We employ two unsupervised pre-training tasks: Masked Language Modeling (MLM) and Next Sentence Prediction (NSP) as described in (Devlin et al., 2019). We conduct experiments by varying the vocabulary size and number of training and warmp steps. Following the pre-training process of (Devlin et al., 2019), we pre-trained SwahBERT in two-phases: uncased was firstly trained for 600K steps using an input length of 128, and then further trained for an additional 200K steps using an input length of 512. Cased models were trained for 600K and 900K steps initially, and an additional 200K and 100K steps in the second phase. The batch size is 32 and 6 for the two-phases, respectively, and the parameters were optimized using the Adam optimizer (Kingma and Ba, 2014) with a warmup over the first 1% of the steps to a peak learning rate of 1e-4.

Table 3 gives the results of pre-training, where it took around 105 hours to complete all phases using two GeForce GTX 1080 Ti GPUs. The best result was obtained with a vocabulary size of 50K for uncased models, while a vocabulary size of 32K was the best for cased models. Compared to the mBERT that has a vocabulary size of 119K, the best vocabulary size of SwahBERT seems small. This is consistent with the vocabulary sizes of other monolingual BERT models; for example, 32K for English, 50K for Estonian, and 30K for Dutch. With the pre-trained models, we put an additional layer on top of the models and fine-tuned them in a supervised way with the labeled datasets for downstream tasks.

5 Experiments

We tested our model on downstream tasks and compared with other models. We put an additional linear layer and an output layer on top of the pre-trained language models, where all models are im-

Table 3: Accuracy and loss of pre-training.

tasks	Total	Train	Development	Test
Emotion	12,976	9,732	1,297	1,947
News	23,266	18,612	2,327	2,327
Sentiment	7,107	5,330	710	1,067
NER	3,006	2,104	300	602

Table 4: The number of instances of the datasets of downstream tasks.

plemented with HuggingFace PyTorch library. During the fine-tuning, the parameters are optimized using the Adam optimizer (Kingma and Ba, 2014) with an initial learning rate of 5e-5 and ϵ parameter of 1e-8. The batch size was set to 32. Table 5 summarizes the averaged F1 scores of language models for different downstream tasks, where all language models are with uncased vocabularies except for SwahBERT_{cased}. Except for the NER task, the SwahBERT outperformed the mBERT for all tasks. The statistic of the datasets is summarized in Table 4, where the emotion classification dataset is introduced in this paper. Among the tasks, all models achieved much better performance in the news classification task, and this might be explained by the fact that the data source of this task is online news documents that may have similar characteristics to the pre-training dataset that is collected from online forums. In the following subsections, detailed results of each task will be described, where the best scores were obtained from three independent experiments.

5.1 Emotion Classification

We use our new dataset for this task and split the dataset into training (75%), development (10%), and test (15%) sets. As shown in Table 5, there is an improvement of 3.94% F1 score from SwahBERT (64.46) compared to mBERT (60.52). The model exhibits the best performance on emotions like joy (0.80), sadness (0.71), and surprise (0.68), as exhibited in Table 6; this is consistent with the fact that these emotions have a lower correlation with other emotions, allowing the models to more easily classify them. For the neutral (0.25) case, we found that there were many instances of incomplete or uncertain expressions, and this caused confusion with other emotions. This is reasonable as 'neutral' might not even exist because people are always feeling something (Gasper et al., 2019). For example, '*Hivi aliyekudanganya hivyo nani?*' (who lied to you that anyway?) was predicted as disgust, while '*Nani aliyekudanganya?*' (who lied to you?) was classified as neutral. As mentioned in (Öhman et al., 2020), such uncertain texts are usually not self-contained since they are reactions to other posts; that is, the emotion will be different whether we consider its context information or not.

tasks	SwahBERT	SwahBERT_{cased}	mBERT
Emotion	64.46	64.77	60.52
News	90.90	89.90	89.73
Sentiment	70.94	71.12	67.20
NER	88.50	88.60	89.36

Table 5: F1 scores (%) of language models on downstream tasks, where NER indicates named entity recognition.

Post: Vifo vya Corona kila kukicha (Corona cases increases everyday) [sadness], <sadness>
Com1: Acha tuu (Yeah...) [sadness], <neutral>
Com2: Kila mtu anaongea lake.. (Everyone is quick to talk what they wish) [disgust], <neutral>
Com3: Popote, mimi na barakoa yangu (anywhere, with my mask) [fear], <neutral>

	SwahBERT			mBERT		
labels	P	R	F1	P	R	F1
joy	0.88	0.73	0.80	0.74	0.71	0.72
anger	0.61	0.43	0.51	0.70	0.32	0.44
sadness	0.68	0.74	0.71	0.69	0.65	0.67
disgust	0.61	0.61	0.61	0.54	0.56	0.55
surprise	0.73	0.64	0.68	0.74	0.66	0.70
fear	0.65	0.61	0.63	0.65	0.56	0.60
neutral	0.30	0.22	0.25	0.33	0.11	0.16

Table 6: Results of emotion classification, where P, R, and F1 indicate precision, recall, and F1 score, respectively.

The annotators made the labels based on the context, whereas the language models predicted labels without the context, and this caused the performance degradation. The example in the box demonstrates how emotions can be affected by contextual information, where emotion with context is represented in [emotion] and emotion of non-context is <emotion>.

5.2 News Classification

We used the existing news classification dataset, and it is split into three sets with a ratio of 80%:10%:10% which is equivalent to 18,612:2,327:2,327 instances. As this dataset has six news categories, this task is a classification on six classes: *kitaifa* (national), *kimataifa* (International), *biashara* (finance), *michezo* (sports), *afya* (health), and *burudani* (entertainment). Table 7 shows the results of SwahBERT and mBERT models. Compared to the existing study of (Kastanos and Martin, 2021) that achieved 75.56% of F1 score using graph convolutional networks (GCN), we observed the improvement of 14.06% and 15.23% F1 scores with mBERT and SwahBERT, respectively. The performance for the 'health' class is relatively lower than others, and the reason might be the data imbalance; the 'health' class has a much smaller amount of instances than other classes, as described in subsection 2.1.1.

5.3 Sentiment Classification

As there is no publicly available dataset for this task, we used our emotion dataset by converting some emotion categories into three sentiment classes: positive, negative, and neutral, where we mapped 'joy' to positive, 'disgust' to negative, and 'neutral' was unchanged. For the neutral class, we extracted additional instances from 'surprise' emotion because 'surprise' can be mapped mid-way of negative and positive (Marmolejo-Ramos et al., 2017). We split the dataset into three sets with ratio 75%:10%:15% equivalent to 5,330:710:1,067. Results are presented in Table 8. We found that SwahBERT outperformed the mBERT with a gap of 3-6% of F1 scores. As we observed in the results of the emotion classification task, the overall performance of sentiment classification task for the 'neutral' class was much lower than the other classes.

	SwahBERT			mBERT		
labels	P	R	F1	P	R	F1
national	0.91	0.92	0.92	0.91	0.91	0.91
sports	0.96	0.97	0.97	0.94	0.98	0.96
entert.	0.89	0.94	0.91	0.85	0.93	0.89
business	0.94	0.85	0.89	0.91	0.82	0.86
Internat.	0.90	0.89	0.90	0.91	0.84	0.88
health	0.50	0.41	0.45	0.47	0.44	0.45

Table 7: News classification results, where P, R, F1 indicate precision, recall and F1-score.

	SwahBERT			mBERT		
labels	P	R	F1	P	R	F1
negative	0.70	0.70	0.70	0.65	0.69	0.67
positive	0.82	0.83	0.82	0.75	0.82	0.79
neutral	0.59	0.60	0.59	0.58	0.48	0.53

Table 8: Sentiment classification results, where P, R, F1 indicate precision, recall, and F1 score.

5.4 Named Entity Recognition

We used MasakhaNER (Adelani et al., 2021) dataset for this task, and it has 70%:10%:20% ratio for training, development, and test set. As shown in Table 5, we did not observe performance improvement of SwahBERT against the mBERT of (Adelani et al., 2021). The biggest reason of this will be the small size of the dataset compared to other downstream tasks, as shown in Table 4. That is, the small NER dataset was not enough for SwahBERT to learn the underlying patterns for NER task, so there was no performance improvement compared to the multilingual language model. We believe that the NER performance of SwahBERT will increase as we keep gathering more NER data.

6 Discussion

We constructed two datasets for the low-resource Swahili language: for the downstream task of emotion classification and pre-training of the new

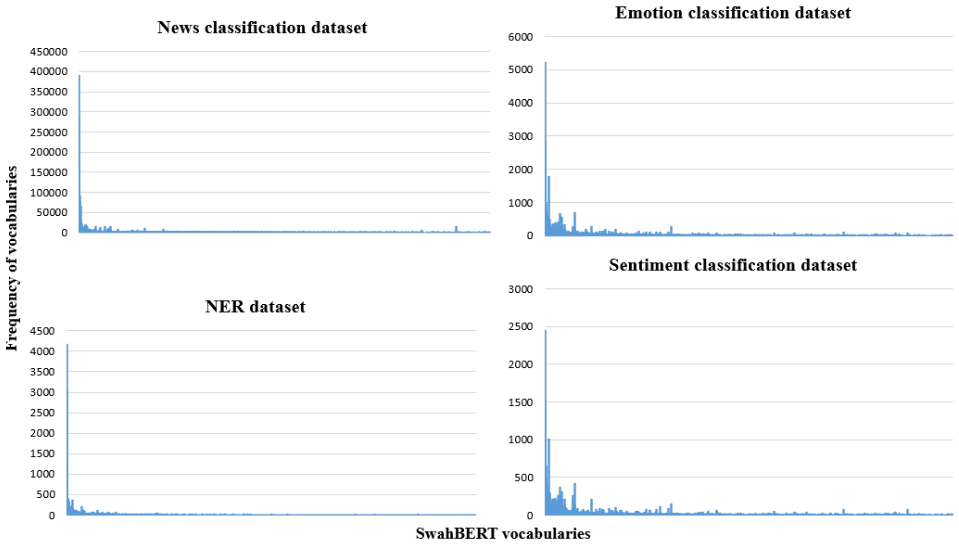

Figure 2: Histogram of downstream task datasets, where the x-axis represents vocabulary words of SwahBERT.

Swahili-specific BERT model. For pre-training purposes, we managed to collect a corpus of about 105 MB. Although the size of our corpus is quite smaller than that of rich-resource languages (e.g., English), the pre-trained SwahBERT has shown great improvement on the downstream tasks. This result is consistent with other previous studies. For example, Micheli et al. (2020) found that well-performing language models can be obtained with a little size of corpora of 100MB. Similarly, in (Martin et al., 2020), experimental results with the language models pre-trained with the 4GB dataset were comparable to those pre-trained with 138GB dataset. However, we believe that plenty of qualified datasets will help to increase the power of language models.

As demonstrated in the experimental results, SwahBERT is generally superior to mBERT in almost all downstream tasks. We believe that our tokenizer with Swahili vocabulary has the biggest contribution to the results. The tokenizer of mBERT works by sharing vocabulary over multiple languages, and this tokenizer tends to split the words without taking into account morphological boundaries (e.g., stem, prefix, and postfix), as shown in Table 2, even though Swahili is a morphologically rich language. The tokenizer of SwahBERT accommodates most single words (e.g., *wanatarajia* (expects), *fursa* (opportunity)) as one and thus helps the model to get better representation.

We examined the characteristics of the datasets by frequency histograms of vocabulary words in the same order as depicted in Figure 2. The emotion classification dataset and the sentiment classification dataset have a similar curve of histogram, and the NER dataset and the news classification dataset seem similar to each other. This explains that the language models (e.g., SwahBERT, mBERT) achieved similar performance (e.g., 88.5% to 90.9% F1 scores) for the news classification and NER tasks, and similar performance (e.g., 60.52% to 71.12% F1 scores) for the emotion classification and sentiment classification tasks. Another interesting point is that SwahBERT showed no improvement in the NER task compared to mBERT. The main reason for this, of course, is the small amount of NER dataset, but we further examined more details by similarity scores between the pre-training dataset and downstream task datasets, as shown in Table 9. The similarity score is computed using a cosine similarity function on word frequencies in datasets. Note that the NER dataset has a much lower score than others, which implies that language models have a smaller chance to learn linguistic patterns for the NER task. This can be resolved if we collect more data for the NER task. We also believe that collecting more qualified data

Tasks	Cosine similarity
News	98.616
NER	52.465
Emotion	84.445
Sentiment	81.543

Table 9: Similarity scores between pre-training dataset and datasets of downstream tasks.

for different tasks in low-resource languages (LRL) will significantly contribute to various future NLP applications (e.g., social network services, news recommendations, etc.).

7 Conclusion

In this study, we introduced our pretraining corpus and annotated dataset for the emotion classification task. The emotion classification dataset contains 7 emotion classes, including neutral, and has approximately 13K instances. We also performed pretraining of monolingual BERT for Swahili, namely SwahBERT, and experimentally compared it with the multilingual BERT (mBERT). The SwahBERT outperformed the mBERT in almost all downstream tasks, where the downstream tasks include emotion classification, news classification, sentiment classification, and NER. Although SwahBERT exhibited superior performance with a relatively smaller pre-training corpus, a more qualified pre-training corpus will definitely contribute to the development of better language models. Therefore, with the growth of the digital platforms for Swahili, we will continue to use the available sources, including native Swahili speakers as annotators, and collect more data from different domains. We hope that this study will facilitate the development of other methodologies and pre-trained language models (e.g., XLM-R) and also aid in social services (e.g., user emotion analysis on forum texts).

Ethical Considerations

The two native Swahili annotators are the authors of this paper, and they receive fair compensation from the project fund. We collected data from a few sources, and all annotated datasets are in Swahili language. We anonymized all texts and confirm that our datasets are allowed to be disclosed for academic purpose according to policies and laws (e.g., UN news[13], Voice of America[14], Deutsche Welle[15], and taifaleo[16]). We gratefully acknowledge a favor of every institute or company that approved of a generous data policy for academic purpose.

Abstract

The rapid development of social networks, electronic commerce, mobile Internet, and other technologies has influenced the growth of Web data. Social media and Internet forums are valuable sources of citizens' opinions, which can be analyzed for community development and user behavior analysis. Unfortunately, the scarcity of resources (i.e., datasets or language models) has become a barrier to the development of natural language processing applications in low-resource languages. Thanks to the recent growth of online forums and news platforms of Swahili, we introduce two datasets of Swahili in this paper: a pre-training dataset of approximately 105MB with 16M words and an annotated dataset of 13K instances for the emotion classification task. The emotion classification dataset is manually annotated by two native Swahili speakers. We pre-trained a new monolingual language model for Swahili, namely SwahBERT, using our collected pre-training data, and tested it with four downstream tasks including emotion classification. We found that SwahBERT outperforms multilingual BERT, a well-known existing language model, in almost all downstream tasks.

1 Introduction

Nowadays, online social networking has revolutionized interpersonal communication. The influence of social media in our everyday lives, at both a personal and professional level, has led recent studies to language analysis in social media (Zeng et al., 2010). Especially, natural language processing (NLP) tools are often used to analyze textual data for various real-world applications; mining social media for information about health (De Gennaro et al., 2020), diseases analysis (e.g., COVID-19 (Gao et al., 2020), Ebola (Tran and Lee, 2016)), identifying sentiment and emotion toward products and services, and developing dialog systems (Zhou et al., 2020). Language models have recently drawing much attention as they are known to be effective in many NLP tasks (e.g., text classification, entailment, sequence labeling), but they commonly require a huge amount of data for pre-training and fine-tuning; some models are designed for few-shot learning that does not require much labeled data for fine-tuning, though they still require plenty of pre-training data. As it is expensive and difficult to get the labeled and unlabeled data, the majority of the data are in high-resource languages (HRLs) (e.g., English, Spanish). Unfortunately, other than about 20 HRLs languages, approximately 7,000 low-resource languages (LRLs) in the world are left behind, where most of LRLs are spoken and little written (Magueresse et al., 2020). Africa and India are the main hosts of LRLs, where some languages are spoken by more than 20 million people (e.g., Hausa, Oromo, Zulu, and Swahili). As more data on social media in LRLs, qualified datasets, and publicly available language models will bring many advantages in various fields, such as education (Obiria, 2019), healthcare (de Las Heras-Pedrosa et al., 2020), entertainment (Ahn et al., 2013), and business.

Swahili, a Bantu language, is one of the two official languages (the other being English) of the East African countries such as Tanzania (Petzell, 2012), Kenya, and Uganda. It has been widely spread in African countries not only as a *lingua franca* but also as a second or third language across the African continent and broadly in education, administration, and media. With the rapid development of social networks, electronic commerce, mobile Internet, and other technologies, Swahili is also spreading in online places that result in the growth of Web data. For example, JamiiForum is a popular online platform in Tanzania, and it provides a place to discuss different issues, including political, business, educational, and lifestyle; this means more collected textual data of Swahili is available.

By making use of the online textual data of

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 314 - 324

Swahili, there are several studies for different tasks (e.g., sentiment classification (Obiria, 2019; Noor and Turan, 2019; Seif, 2016), news classification (David, 2020)). Recently, language models have drawn much attention from the industry and academic world, as the language models brought much better performance (e.g., accuracy) than other existing models. There are few studies that employed the language models for Swahili: named entity recognition (NER) (Adelani et al., 2021) and sentiment classification (Martin et al., 2021). Although these studies have shown successful results, they are limited in that they just borrow the language models (e.g., multilingual Bidirectional Encoder Representations from Transformer (mBERT) (Devlin et al., 2019), Cross-lingual Model-RoBERTA (XLM-R) (Conneau et al., 2020)) pre-trained with other resources (i.e., other languages); in other words, their language models are pre-trained for multiple languages but not dedicated for Swahili. Although such multilingual language models have shown great generalization power across multiple languages, several studies (Bhattacharjee et al., 2021; Tanvir et al., 2021; Vilares et al., 2021) reported that the monolingual models often outperform these multilingual models. There was no study that proposed a monolingual language model for Swahili (i.e., Swahili-specific language model), and the main reason is that Swahili is one of the LRLs, so the existing studies commonly suffered from lack of available data.

In this paper, we focus on the Swahili language. To the best of our knowledge, this is the first study that collects a pre-training dataset and uses it for pre-training of the Swahili-specific language model. We also provide a manually annotated dataset for the emotion classification task. The contributions are summarized as follows.

- Pre-training dataset: we collected Web data from different sources (news sites and social discussion forums) for pre-training the Swahili language model.
- Emotion dataset: we introduce a new Swahili dataset for multi-label emotion classification with six Ekman's emotions: *happy, surprise, sadness, fear, anger, and disgust.*
- Swahili language model: we pre-trained the Swahili language model and compared its performance with other language models on several downstream tasks (e.g., emotion classification, news classification, and named entity recognition (NER)).

2 Background

Most African countries have minority languages that are used by specific ethnic groups (approx. 158 in Tanzania [1]). However they speak different national and official languages of their countries, including native and colonial that can be used in public services such as education, politics, and the media. Swahili is a Bantu language widely spoken in sub-Saharan Africa and acts as the common tongue for most East African (Lodhi, 1993; Amidu, 1995). Many Swahili vocabularies are derived from loanwords, the vast majority from Arabic, but also English, Hindi, Portuguese, and other Bantu languages [2]. As the language grows, new formal and informal vocabularies emerge. The formal vocabularies are used in official documents, whereas the informal vocabularies are mostly used by young adults and on social media platforms (Momanyi, 2009).

Structurally, it is considered an agglutinative language with polysemous features. Its morphology depends on prefixes and suffixes which are syllables (Shikali et al., 2019). A single word is generated with morphemes (i.e., stem, prefixes, and affixes) that will have corresponding inflectional forms. Nouns are divided into classes on the basis of their singular and plural prefixes. Despite its popularity, a limited amount of textual data is available and it is one of the low-resource languages (LRLs). Although there have been a few studies that illustrate the value of NLP (Martin et al., 2021; Obiria, 2019; Gelas et al., 2012), they commonly suffered from the lack of available data.

2.1 Existing dataset of Swahili

To overcome the problem of limited language resource, they have been few datasets for different tasks: new classification dataset, NER dataset, sentiment classification dataset, and emotion classification dataset.

2.1.1 News classification dataset

This dataset [3] is created and shared by a data science competition platform *Zindi* (David, 2020) . It contains a total of 23,266 instances collected from different news websites in Tanzania. There are 6

---

[2] https://en.wikipedia.org/wiki/Swahili_language

[3] https://zenodo.org/record/4300294?ref=hackernoon.com

categories of news: *kitaifa* (national), *kimataifa* (International), *biashara* (finance), *michezo* (sports), *afya* (health), and *burudani* (entertainment). The amount of each category is 10,242 (national), 1,905 (International), 2,028 (finance), 859 (health), 6,003 (sports), and 2,229 (entertainment); so this dataset is highly imbalanced. Kastanos and Martin (2021) applied a deep learning model called Text Graph Convolutional Network (Text GCN) on this dataset and achieved an F1 score of 75.67% for the news classification task.

2.1.2 Sentiment classification dataset

Obiria (2019) collected 886 posts from Twitter and Facebook to analyze the student opinion in Kenyan universities and achieved an accuracy of 83% on binary classification task using support vector machine (SVM) (Hearst et al., 1998). Noor and Turan (2019) extracted 1,087 Twitter texts about demonetization in Kenya and performed ternary sentiment classification with Naive Bayes. They applied various feature extraction methods and obtained an accuracy of 70.8%. Recently, Martin et al. (2021) used a cross-lingual model, mBERT, to perform binary sentiment classification on a social media dataset that they manually annotated, and achieved an accuracy of 87.59%. None of the above datasets are publicly available.

2.1.3 Named entity recognition dataset

This dataset, namely MasakhaNER [4] (Adelani et al., 2021), is created for ten African languages, including Swahili. The news texts are collected from local news sources and annotated using ELISA tool (Lin et al., 2018) by native speakers of each language. The dataset contains a total of 3,006 instances and covers four entities: personal name (PER), location (LOC), organization (ORG), and date & time (DATE) as inspired by the English CoNLL-2003 corpus (Tjong Kim Sang and De Meulder, 2003). The number of entities of each type is 1,702 (PER), 2,842 (LOC), 960 (ORG), and 940 (DATE). They compared three models (e.g., CNN-BiLSTM-CRF, mBERT, and XLM-R) on the NER task, and mBERT and XLM-R achieved 89.36% and 89.46% of an F1 score, respectively.

2.2 Language models

Over the years, models for word representation have been developed and have shown that they are capable of capturing the semantics and syntactic dependencies between words: Word2Vec (Mikolov et al., 2013), Glove (Pennington et al., 2014), and FastText (Bojanowski et al., 2017). As these models do not incorporate context of words, many context-aware language models based on Transformer (Vaswani et al., 2017) were introduced (e.g., Bidirectional Encoder Representations from Transformer (BERT) (Devlin et al., 2019) and XLM-R (Conneau et al., 2020)). These language models are trainable with a monolingual or multilingual dataset. For example, multilingual BERT (mBERT) is trained with a dataset of 104 languages and a shared vocabulary.

Although mBERT has shown its potential in some previous work, several studies reported some limitations of mBERT especially to LRLs: (1) the limited scale of pre-training data (only Wikipedia was used) (Conneau et al., 2020); (2) the small vocabulary size for specific language (Wang et al., 2019). To overcome that, XLM-RoBERTA modifies mBERT by increasing the amount of pre-training data, which increases the shared vocabulary between different languages. It provides a strong improvement over mBERT, however, it is outperformed by monolingual models (Tanvir et al., 2021; Bhattacharjee et al., 2021) due to better representation of morphological language such as Swahili. This is a good improvement since the model can learn morphological information. Another limitation is the nature of pre-training corpora. Most available corpora are extracted from Wikipedia, Bookcorpus, or news blogs which may not be compatible with the task that covers multi-domain such as social media data. In this work, we collect our data from different sources across several domains for our new language model.

3 Dataset

In this section we describe our collected dataset for pre-training and the downstream task of emotion classification. We open our datasets for future use in various studies [5].

3.1 Pre-training dataset

The existing available corpora for Swahili are very small, for example, the Open Super-large

---

[4] https://github.com/masakhane-io/masakhane-ner/tree/main/data

[5] https://sites.google.com/view/swahbert/home

Crawled Aggregated coRpus (OSCAR) database contains about 25 megabytes of the corpus. Using crawler tools, we scraped our own data from different sources such as news Web sites, forums, and Wikipedia. The news Web sites include UN news [6], Voice of America (VoA) [7], Deutsche Welle (DW) [8] and taifaleo [9]. We collected data from *JamiiForums*, which is one of the most popular social media websites in Tanzania founded in 2006. The forum has provided a discussion platform for the public to discuss different issues, including political, business, educational, and lifestyle. Since JamiiForums is a discussion platform, most of its contents are either passages of information or short comments. We collected the passages with more than four logically connected sentences. We removed URL links, usernames, non-textual content (e.g., HTML tags) and filtered out non-Swahili characters (e.g., Latin, Chinese). The size of dataset is about 105MB with 16M words, where a sentence has an average of 27 subword tokens. Most of these platforms contain data that range from 5 to 10 years. The contribution (in percentage) of each source was taifaleo (39.4), UN news (28.6), JamiiForum (10.2), Wikipedia (9.5), VoA (7.2), and DW (5.1).

3.2 Emotion classification dataset

Existing non-Swahili datasets typically use annotation schemes based on Ekman (Ekman, 1992), Plutchik (Plutchik, 1980) or with multiple categories (Demszky et al., 2020). For example, there are English datasets with multiple emotion categories: Affective Text (Strapparava and Mihalcea, 2007) with 11 categories, CrowdFlower with 14 categories, GoEmotions (Demszky et al., 2020) with 27 categories and others (Oberländer and Klinger, 2018). In this paper, to construct a new Swahili dataset for emotion classification, we chose to use 6 emotion categories from Ekman's (Ekman, 1992) scheme: anger (*hasira*), surprise (*mshangao*), disgust (*machukizo*), joy (*furaha*), fear (*woga*), and sadness (*huzuni*). Our dataset is collected from two source types: social media platforms of Swahili and existing emotion datasets of English. The social media platforms include YouTube, JamiiForum [10] and Twitter The conversations and comments on these platforms cover different topics, such as politics, disease outbreaks, and aspects of daily life. We reviewed the dataset and removed profanity towards a specific person or ethnic group. For example, in the sentence '[name] is very stupid, she doesn't act like a leader at all,' we replaced the target name with pronoun. We also selected three existing English datasets with relevant topic coverage and converted them into Swahili using Google translator. The three datasets include: (1) Dailydialog (Li et al., 2017) that reflects daily communication and covers various topics about our daily life, (2) Emotion Cause (Ghazi et al., 2015), and (3) ISEAR (Scherer and Wallbott, 1994) collected from participants from varying cultural backgrounds who complete questionnaires about their experiences and reactions. The Swahili emotion texts obtained from the Google translator were checked and corrected thoroughly by a native Swahili speaker.

Item	Value
# of examples	12,976
# of labels	7 (including 'neutral')
# of text per labels	joy: 2,439 disgust: 3,227 anger: 1,772 sadness: 2,339 fear: 1,116 surprise: 2,305 Neutral: 863
# of labels per examples	1: 92.09% 2: 7.45% 3: 0.46%
Ratio of source	Dailydialog: 13.26% Emotion cause: 13.08% ISEAR: 2.26% Social media: 71.40%
Appx. ratio of taxonomy	Politics: 15% social issues: 80% pandemic: 5%

Table 1: Statistics of Emotion classification dataset.

For the dataset collected from forums of Swahili, two native Swahili speakers were assigned to annotate the emotion labels. These speakers agreed to the consent of serving as annotators and were given an instruction of annotation. They were asked to select one or multiple suitable emotion labels that were expressed in the text, and labeled 'neutral' for unsure texts. The statistics summary is presented in Table 1. We also calculated annotator agreement using Cohen's kappa metric, which computes a score of agreement level between two annota-

4 SwahBERT

With the collected dataset, we pre-trained the monolingual BERT for Swahili, namely SwahBERT [11]. The SwahBERT basically has the same architecture as the original BERT. This section describes the process of pre-training and fine-tuning of SwahBERT.

4.1 Tokenizer

In mBERT, not all languages have equal content size (Wu and Dredze, 2020), and some languages are dominated; for example, Swahili is only less than 1% of the approximately 120K vocabulary of mBERT. Although it might benefit from high resource languages as Swahili has the same typology (word order) and many loanwords, it would definitely be better to generate a Swahili-specific tokenizer. That is, the multilingual tokenizer often splits the words without considering morphological boundaries (e.g., stem, prefixes, and suffixes), like the sentence in Table 2, so the individual subword units do not have a clear semantic meaning. Swahili is morphologically rich language and polysynthetic language; for example, a word *alimpikia* (cooked for) has a lexical morph {*-pika*}, four grammatical morphs {*a-,-li-, -m-, -i-*} and two in the verb skeletal morphological frame which has the root {*-pik-*}, and bantu end vowel {*-a*} (Choge, 2018). In this paper, to incorporate such linguistic complexity, we try monolingual tokenizers for Swahili with different vocabulary sizes (e.g., 32K, 50K, and 70K) using the WordPiece algorithm [12].

4.2 Training

SwahBERT has 12 encoder blocks and 768 hidden units. We employ two unsupervised pre-training tasks: Masked Language Modeling (MLM) and Next Sentence Prediction (NSP) as described in (Devlin et al., 2019). We conduct experiments by varying the vocabulary size and number of training and warmp steps. Following the pre-training process of (Devlin et al., 2019), we pre-trained SwahBERT in two-phases: uncased was firstly trained for 600K steps using an input length of 128, and then further trained for an additional 200K steps using an input length of 512. Cased models were trained for 600K and 900K steps initially, and an additional 200K and 100K steps in the second phase. The batch size is 32 and 6 for the two-phases, respectively, and the parameters were optimized using the Adam optimizer (Kingma and Ba, 2014) with a warmup over the first 1% of the steps to a peak learning rate of 1e-4.

Table 3 gives the results of pre-training, where it took around 105 hours to complete all phases using two GeForce GTX 1080 Ti GPUs. The best result was obtained with a vocabulary size of 50K for uncased models, while a vocabulary size of 32K was the best for cased models. Compared to the mBERT that has a vocabulary size of 119K, the best vocabulary size of SwahBERT seems small. This is consistent with the vocabulary sizes of other monolingual BERT models; for example, 32K for English, 50K for Estonian, and 30K for Dutch. With the pre-trained models, we put an additional layer on top of the models and fine-tuned them in a supervised way with the labeled datasets for downstream tasks.

5 Experiments

We tested our model on downstream tasks and compared with other models. We put an additional linear layer and an output layer on top of the pre-trained language models, where all models are im-

1M	32K (cased)	73.81	98.17	1.2732

Table 3: Accuracy and loss of pre-training.

tasks	Total	Train	Development	Test
Emotion	12,976	9,732	1,297	1,947
News	23,266	18,612	2,327	2,327
Sentiment	7,107	5,330	710	1,067
NER	3,006	2,104	300	602

Table 4: The number of instances of the datasets of downstream tasks.

plemented with HuggingFace PyTorch library. During the fine-tuning, the parameters are optimized using the Adam optimizer (Kingma and Ba, 2014) with an initial learning rate of 5e-5 and ϵ parameter of 1e-8. The batch size was set to 32. Table 5 summarizes the averaged F1 scores of language models for different downstream tasks, where all language models are with uncased vocabularies except for SwahBERT$_{cased}$. Except for the NER task, the SwahBERT outperformed the mBERT for all tasks. The statistic of the datasets is summarized in Table 4, where the emotion classification dataset is introduced in this paper. Among the tasks, all models achieved much better performance in the news classification task, and this might be explained by the fact that the data source of this task is online news documents that may have similar characteristics to the pre-training dataset that is collected from online forums. In the following subsections, detailed results of each task will be described, where the best scores were obtained from three independent experiments.

5.1 Emotion Classification

We use our new dataset for this task and split the dataset into training (75%), development (10%), and test (15%) sets. As shown in Table 5, there is an improvement of 3.94% F1 score from SwahBERT (64.46) compared to mBERT (60.52). The model exhibits the best performance on emotions like joy (0.80), sadness (0.71), and surprise (0.68), as exhibited in Table 6; this is consistent with the fact that these emotions have a lower correlation with other emotions, allowing the models to more easily classify them. For the neutral (0.25) case, we found that there were many instances of incomplete or uncertain expressions, and this caused confusion with other emotions. This is reasonable as 'neutral' might not even exist because people are always feeling something (Gasper et al., 2019). For example, '*Hivi aliyekudanganya hivyo nani?*' (who lied to you that anyway?) was predicted as disgust, while '*Nani aliyekudanganya?*' (who lied to you?) was classified as neutral. As mentioned in (Öhman et al., 2020), such uncertain texts are usually not self-contained since they are reactions to other posts; that is, the emotion will be different whether we consider its context information or not.

tasks	SwahBERT	SwahBERT$_{cased}$	mBERT
Emotion	64.46	64.77	60.52
News	90.90	89.90	89.73
Sentiment	70.94	71.12	67.20
NER	88.50	88.60	89.36

Table 5: F1 scores (%) of language models on downstream tasks, where NER indicates named entity recognition.

Post: Vifo vya Corona kila kukicha (Corona cases increases everyday) [sadness], <sadness>
Com1: Acha tuu (Yeah...) [sadness], <neutral>
Com2: Kila mtu anaongea lake.. (Everyone is quick to talk what they wish) [disgust], <neutral>
Com3: Popote, mimi na barakoa yangu (anywhere, with my mask) [fear], <neutral>

	SwahBERT			mBERT		
labels	P	R	F1	P	R	F1
joy	0.88	0.73	0.80	0.74	0.71	0.72
anger	0.61	0.43	0.51	0.70	0.32	0.44
sadness	0.68	0.74	0.71	0.69	0.65	0.67
disgust	0.61	0.61	0.61	0.54	0.56	0.55
surprise	0.73	0.64	0.68	0.74	0.66	0.70
fear	0.65	0.61	0.63	0.65	0.56	0.60
neutral	0.30	0.22	0.25	0.33	0.11	0.16

Table 6: Results of emotion classification, where P, R, and F1 indicate precision, recall, and F1 score, respectively.

The annotators made the labels based on the context, whereas the language models predicted labels without the context, and this caused the performance degradation. The example in the box demonstrates how emotions can be affected by contextual information, where emotion with context is represented in [emotion] and emotion of non-context is <emotion>.

5.2 News Classification

We used the existing news classification dataset, and it is split into three sets with a ratio of 80%:10%:10% which is equivalent to 18,612:2,327:2,327 instances. As this dataset has six news categories, this task is a classification on six classes: *kitaifa* (national), *kimataifa* (International), *biashara* (finance), *michezo* (sports), *afya* (health), and *burudani* (entertainment). Table 7 shows the results of SwahBERT and mBERT models. Compared to the existing study of (Kastanos and Martin, 2021) that achieved 75.56% of F1 score using graph convolutional networks (GCN), we observed the improvement of 14.06% and 15.23% F1 scores with mBERT and SwahBERT, respectively. The performance for the 'health' class is relatively lower than others, and the reason might be the data imbalance; the 'health' class has a much smaller amount of instances than other classes, as described in subsection 2.1.1.

5.3 Sentiment Classification

As there is no publicly available dataset for this task, we used our emotion dataset by converting some emotion categories into three sentiment classes: positive, negative, and neutral, where we mapped 'joy' to positive, 'disgust' to negative, and 'neutral' was unchanged. For the neutral class, we extracted additional instances from 'surprise' emotion because 'surprise' can be mapped mid-way of negative and positive (Marmolejo-Ramos et al., 2017). We split the dataset into three sets with ratio 75%:10%:15% equivalent to 5,330:710:1,067. Results are presented in Table 8. We found that SwahBERT outperformed the mBERT with a gap of 3-6% of F1 scores. As we observed in the results of the emotion classification task, the overall performance of sentiment classification task for the 'neutral' class was much lower than the other classes.

	SwahBERT			mBERT		
labels	P	R	F1	P	R	F1
national	0.91	0.92	0.92	0.91	0.91	0.91
sports	0.96	0.97	0.97	0.94	0.98	0.96
entert.	0.89	0.94	0.91	0.85	0.93	0.89
business	0.94	0.85	0.89	0.91	0.82	0.86
Internat.	0.90	0.89	0.90	0.91	0.84	0.88
health	0.50	0.41	0.45	0.47	0.44	0.45

Table 7: News classification results, where P, R, F1 indicate precision, recall and F1-score.

	SwahBERT			mBERT		
labels	P	R	F1	P	R	F1
negative	0.70	0.70	0.70	0.65	0.69	0.67
positive	0.82	0.83	0.82	0.75	0.82	0.79
neutral	0.59	0.60	0.59	0.58	0.48	0.53

Table 8: Sentiment classification results, where P, R, F1 indicate precision, recall, and F1 score.

5.4 Named Entity Recognition

We used MasakhaNER (Adelani et al., 2021) dataset for this task, and it has 70%:10%:20% ratio for training, development, and test set. As shown in Table 5, we did not observe performance improvement of SwahBERT against the mBERT of (Adelani et al., 2021). The biggest reason of this will be the small size of the dataset compared to other downstream tasks, as shown in Table 4. That is, the small NER dataset was not enough for SwahBERT to learn the underlying patterns for NER task, so there was no performance improvement compared to the multilingual language model. We believe that the NER performance of SwahBERT will increase as we keep gathering more NER data.

6 Discussion

We constructed two datasets for the low-resource Swahili language: for the downstream task of emotion classification and pre-training of the new

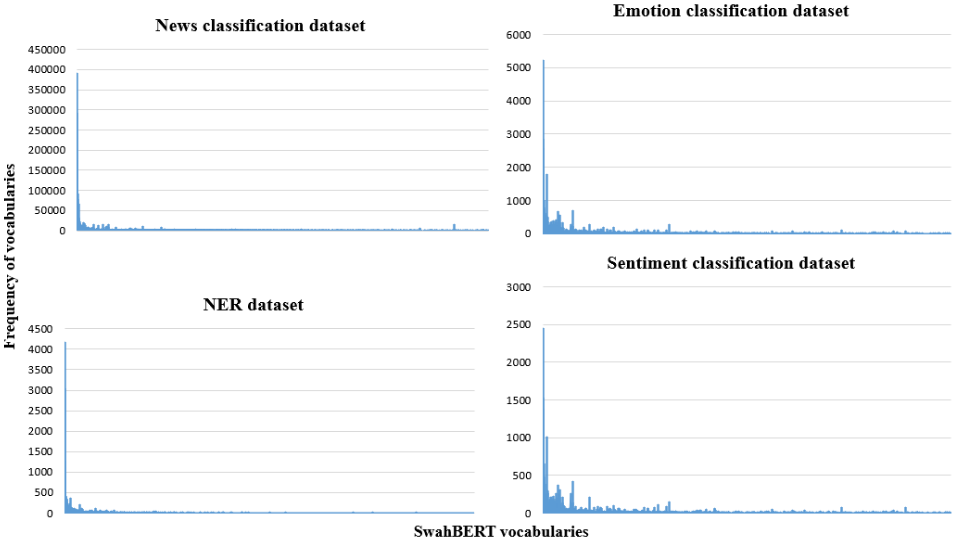

Figure 2: Histogram of downstream task datasets, where the x-axis represents vocabulary words of SwahBERT.

Swahili-specific BERT model. For pre-training purposes, we managed to collect a corpus of about 105 MB. Although the size of our corpus is quite smaller than that of rich-resource languages (e.g., English), the pre-trained SwahBERT has shown great improvement on the downstream tasks. This result is consistent with other previous studies. For example, Micheli et al. (2020) found that well-performing language models can be obtained with a little size of corpora of 100MB. Similarly, in (Martin et al., 2020), experimental results with the language models pre-trained with the 4GB dataset were comparable to those pre-trained with 138GB dataset. However, we believe that plenty of qualified datasets will help to increase the power of language models.

As demonstrated in the experimental results, SwahBERT is generally superior to mBERT in almost all downstream tasks. We believe that our tokenizer with Swahili vocabulary has the biggest contribution to the results. The tokenizer of mBERT works by sharing vocabulary over multiple languages, and this tokenizer tends to split the words without taking into account morphological boundaries (e.g., stem, prefix, and postfix), as shown in Table 2, even though Swahili is a morphologically rich language. The tokenizer of SwahBERT accommodates most single words (e.g., *wanatarajia* (expects), *fursa* (opportunity)) as one and thus helps the model to get better representation.

We examined the characteristics of the datasets by frequency histograms of vocabulary words in the same order as depicted in Figure 2. The emotion classification dataset and the sentiment classification dataset have a similar curve of histogram, and the NER dataset and the news classification dataset seem similar to each other. This explains that the language models (e.g., SwahBERT, mBERT) achieved similar performance (e.g., 88.5% to 90.9% F1 scores) for the news classification and NER tasks, and similar performance (e.g., 60.52% to 71.12% F1 scores) for the emotion classification and sentiment classification tasks. Another interesting point is that SwahBERT showed no improvement in the NER task compared to mBERT. The main reason for this, of course, is the small amount of NER dataset, but we further examined more details by similarity scores between the pre-training dataset and downstream task datasets, as shown in Table 9. The similarity score is computed using a cosine similarity function on word frequencies in datasets. Note that the NER dataset has a much lower score than others, which implies that language models have a smaller chance to learn linguistic patterns for the NER task. This can be resolved if we collect more data for the NER task. We also believe that collecting more qualified data

Tasks	Cosine similarity
News	98.616
NER	52.465
Emotion	84.445
Sentiment	81.543

Table 9: Similarity scores between pre-training dataset and datasets of downstream tasks.

for different tasks in low-resource languages (LRL) will significantly contribute to various future NLP applications (e.g., social network services, news recommendations, etc.).

7 Conclusion

In this study, we introduced our pretraining corpus and annotated dataset for the emotion classification task. The emotion classification dataset contains 7 emotion classes, including neutral, and has approximately 13K instances. We also performed pretraining of monolingual BERT for Swahili, namely SwahBERT, and experimentally compared it with the multilingual BERT (mBERT). The SwahBERT outperformed the mBERT in almost all downstream tasks, where the downstream tasks include emotion classification, news classification, sentiment classification, and NER. Although SwahBERT exhibited superior performance with a relatively smaller pre-training corpus, a more qualified pre-training corpus will definitely contribute to the development of better language models. Therefore, with the growth of the digital platforms for Swahili, we will continue to use the available sources, including native Swahili speakers as annotators, and collect more data from different domains. We hope that this study will facilitate the development of other methodologies and pre-trained language models (e.g., XLM-R) and also aid in social services (e.g., user emotion analysis on forum texts).

Ethical Considerations

The two native Swahili annotators are the authors of this paper, and they receive fair compensation from the project fund. We collected data from a few sources, and all annotated datasets are in Swahili language. We anonymized all texts and confirm that our datasets are allowed to be disclosed for academic purpose according to policies and laws (e.g., UN news[13], Voice of America[14], Deutsche Welle[15], and taifaleo[16]). We gratefully acknowledge a favor of every institute or company that approved of a generous data policy for academic purpose.

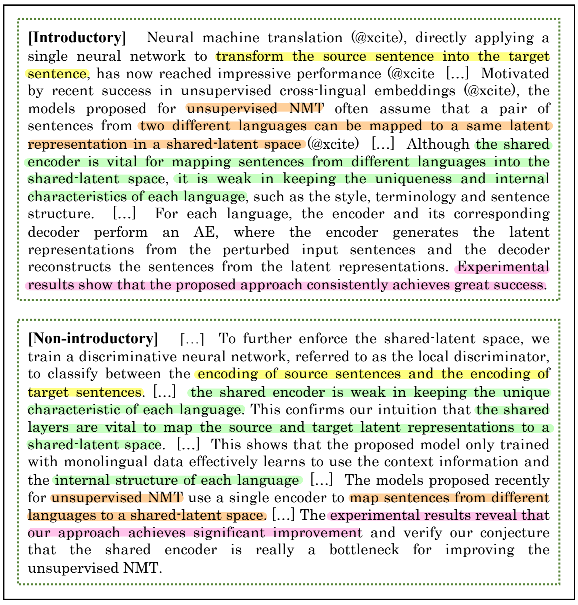
TSTR: Too Short to Represent, Summarize with Details! Intro-Guided Extended Summary Generation

Sajad Sotudeh and **Nazli Goharian**

IR Lab, Georgetown University, Washington DC 20057, USA
{sajad, nazli}@ir.cs.georgetown.edu

Abstract

Many scientific papers such as those in arXiv and PubMed data collections have abstracts with varying lengths of 50–1000 words and average length of approximately 200 words, where longer abstracts typically convey more information about the source paper. Up to recently, scientific summarization research has typically focused on generating short, abstract-like summaries following the existing datasets used for scientific summarization. In domains where the source text is relatively long-form, such as in scientific documents, such summary is not able to go beyond the general and coarse overview and provide salient information from the source document. The recent interest to tackle this problem motivated curation of scientific datasets, arXiv-Long and PubMed-Long, containing human-written summaries of 400-600 words, hence, providing a venue for research in generating long/extended summaries. Extended summaries facilitate a faster read while providing details beyond coarse information. In this paper, we propose TSTR, an extractive summarizer that utilizes the introductory information of documents as pointers to their salient information. The evaluations on two existing large-scale extended summarization datasets indicate statistically significant improvement in terms of ROUGE and average ROUGE (F1) scores (except in one case) as compared to strong baselines and state-of-the-art. Comprehensive human evaluations favor our generated extended summaries in terms of cohesion and completeness.



[Introductory] Neural machine translation (@xcite), directly applying a single neural network to transform the source sentence into the target sentence, has now reached impressive performance (@xcite [...] Motivated by recent success in unsupervised cross-lingual embeddings (@xcite), the models proposed for unsupervised NMT often assume that a pair of sentences from two different languages can be mapped to a same latent representation in a shared-latent space (@xcite) [...] Although the shared encoder is vital for mapping sentences from different languages into the shared-latent space, it is weak in keeping the uniqueness and internal characteristics of each language, such as the style, terminology and sentence structure. [...] For each language, the encoder and its corresponding decoder perform an AE, where the encoder generates the latent representations from the perturbed input sentences and the decoder reconstructs the sentences from the latent representations. Experimental results show that the proposed approach consistently achieves great success.

[Non-introductory] [...] To further enforce the shared-latent space, we train a discriminative neural network, referred to as the local discriminator, to classify between the encoding of source sentences and the encoding of target sentences. [...] the shared encoder is weak in keeping the unique characteristic of each language. This confirms our intuition that the shared layers are vital to map the source and target latent representations to a shared-latent space. [...] This shows that the proposed model only trained with monolingual data effectively learns to use the context information and the internal structure of each language [...] The models proposed recently for unsupervised NMT use a single encoder to map sentences from different languages to a shared-latent space. [...] The experimental results reveal that our approach achieves significant improvement and verify our conjecture that the shared encoder is really a bottleneck for improving the unsupervised NMT.

Figure 1: A truncated human-written extended summary. Top box: introductory information, bottom box: non-introductory information. Colored spans are pointers from introductory sentences to associated non-introductory detailed sentences.

1 Introduction

Over the past few years, summarization task has witnessed a huge deal of progress in extractive (Nallapati et al., 2017; Liu and Lapata, 2019; Yuan et al., 2020; Cui et al., 2020; Jia et al., 2020; Feng et al., 2018) and abstractive (See et al., 2017; Cohan et al., 2018; Gehrmann et al., 2018; Zhang et al., 2019; Tian et al., 2019; Zou et al., 2020) settings. Many scientific papers such as those in arXiv and PubMed (Cohan et al., 2018) posses abstracts of varying length, ranging from 50 to 1000 words and average length of approximately 200 words. While scientific paper summarization has been an active research area, most works (Cohan et al., 2018; Xiao and Carenini, 2019; Cui and Hu, 2021; Rohde et al., 2021) in this domain have focused on generating typical short and abstract-like summaries (Chandrasekaran et al., 2020). Short summaries might be adequate when the source text is of short-form such as those in news domain; however, to summarize longer documents such as scientific papers, an extended summary including 400–600 terms on average, such as those found in extended summarization datasets of arXiv-Long and PubMed-Long, is more appealing as it conveys more detailed information.

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 325 - 335
July 10-15, 2022 ©2022 Association for Computational Linguistics

Extended summary generation has been of research interest very recently. Chandrasekaran et al. (2020) motivated the necessity of generating extended summaries through LongSumm shared task [1]. Long documents such as scientific papers are usually framed in a specific structure. They start by presenting general *introductory information* [2]. This introductory information is then followed by supplemental information (i.e., non-introductory) that explain the initial introductory information in more detail. Similarly, as shown in Figure 1, this pattern holds in a human-written extended summary of a long document, where the preceding sentences (top box inside Figure 1) are introductory sentences and succeeding sentences (bottom box inside Figure 1) are explanations of the introductory sentences. In this study, we aim to guide the summarization model to utilize the aforementioned rationale in human-written summaries. We consider **introductory sentences** as those that appear in the first section of paper with headings such as *Introduction*, *Overview*, *Motivations*, and so forth. As such, all other parts of paper and their sentences are considered as **non-introductory** (i.e., **supplementary**). We use these definitions in the reminder of this paper.

Herein, we approach the problem of *extended* summary generation by incorporating the most important introductory information into the summarization model. We hypothesize that incorporating such information into the summarization model guides the model to pick salient detailed non-introductory information to augment the final extended summary. The importance of the role of introduction in the scientific papers was earlier presented in (Teufel and Moens, 2002; Armağan, 2013; Jirge, 2017) where they showed such information provides clues (i.e. pointers) to the objectives and experiments of studies. Similarly, Boni et al. (2020) conducted a study to show the importance of introduction part of scientific papers as its relevance to the paper's abstract. To validate our hypothesis, we test the proposed approach on two publicly available large-scale extended summarization datasets, namely arXiv-Long and PubMed-Long. Our experimental results improve over the strong baselines and state-of-the-art models. In short, the contributions of this work are as follows:

- A novel multi-tasking approach that incorporates the salient introductory information into the extractive summarizer to guide the model in generating a 600-term (roughly) extended summary of a long document, containing the key detailed information of a scientific paper.
- Intrinsic evaluation that demonstrates statistically significant improvements over strong extractive and abstractive summarization baselines and state-of-the-art models.
- An extensive human evaluation which reveals the advantage of the proposed model in terms of cohesion and completeness.

2 Related Work

Summarizing scientific documents has gained a huge deal of attention from researchers, although it has been studied for decades. Neural efforts in scientific text have used specific characteristics of papers such as discourse structure (Cohan et al., 2018; Xiao and Carenini, 2019) and citation information (Qazvinian and Radev, 2008; Cohan and Goharian, 2015, 2018) to aid summarization model. While prior work has mostly covered the generation of shorter-form summaries (approx. 200 terms), generating extended summaries of roughly 600 terms for long-form source documents such as scientific papers has been motivated very recently (Chandrasekaran et al., 2020).

The proposed models for the extended summary generation task include jointly learning to predict sentence importance and sentence section to extract top sentences (Sotudeh et al., 2020); utilizing section-contribution computations to pick sentences from important section for forming the final summary (Ghosh Roy et al., 2020); identifying salient sections for generating abstractive summaries (Gidiotis et al., 2020); ensembling of extraction and abstraction models to form final summary (Ying et al., 2021); an extractive model with TextRank algorithm equipped with BM25 as similarity function (Kaushik et al., 2021); and incorporating sentences embeddings into graph-based extractive summarizer in an unsupervised manner (Ramirez-Orta and Milios, 2021). Unlike these works, we do not exploit any sectional nor citation information in this work. To the best of our knowledge, we are the first at proposing the novel method of utilizing introductory information of the scientific paper to guide the model to learn to generate

---

[2] We will exchangeably use *(non-)introductory information* and *(non-)introductory sentences* in the rest of this paper.

summary from the salient and related information.

3 Background: Contextualized language models for summarization

Contextualized language models such as BERT (Devlin et al., 2019), and ROBERTA (Liu et al., 2019) have achieved state-of-the-art performance on a variety of downstream NLP tasks including text summarization. Liu and Lapata (2019) were the first to fine-tune a contextualized language model (i.e., BERT) for the summarization task. They proposed BERTSUM —a fine-tuning scheme for text summarization— that outputs the sentence representations of the source document (we use the term source and source document interchangeably, referring to the entire document). The BERTSUMEXT model, which is built based on BERTSUM, was proposed for the extractive summarization task. It utilizes the representations produced by BERTSUM, passes them through Transformers encoder (Vaswani et al., 2017), and finally uses a linear layer with Sigmoid function to compute copying probabilities for each input sentence. Formally, let $l_1, l_2, ..., l_n$ be the binary tags over the source sentences $\mathbf{x} = \{sent_1, sent_2, ..., sent_n\}$ of a long document, in which n is the number of sentences in the paper. The BERTSUMEXT network runs over the source documents as follows (Eq. 1),

$$\begin{aligned} h_b &= \mathbf{BertSum}(\mathbf{x}) \\ h &= \mathbf{Encoder_t}(h_b) \\ p &= \sigma(W_o h + b_o) \end{aligned} \tag{1}$$

where $\mathbf{h_b}$ and $\mathbf{h}$ are the representations of source sentences encoded by BERTSUM and Trasformers encoder, respectively. W_o and b_o are trainable parameters, and p is the probability distribution over the source sentences, signifying extraction copy likelihood. The goal of this network is to train a network that can identify the positive sets of sentences as the summary. To prevent the network from selecting redundant sentences, BERTSUM uses *Trigram Blocking* (Liu and Lapata, 2019) for sentence selection in inference time. We refer the reader to the main paper for more details.

4 TSTR: Intro-guided Summarization

In this section, we describe our methodology to tackle the extended summary generation task. Our approach exploits the introductory information [3] of the paper as pointers to salient sentences within it, as shown in Figure 2. It is ultimately expected that the extractive summarizer is guided to pick salient sentences across the entire paper.

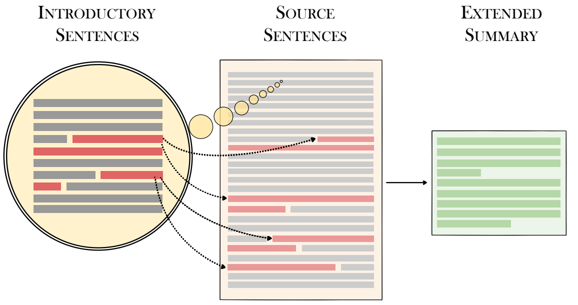

Figure 2: Our model uses introductory sentences as pointers to the source sentences. It then forms the final extended summary by extracting salient sentences from the source. Highlights in red show the salient parts.

The detailed illustration of our model is shown in Figure 3. To aid the extractive summarization model (i.e., right-hand box in Figure 3) which takes in source sentences of a scientific paper, we utilize an additional BERTSUM encoder called Introductory encoder (left-hand box in Fig. 3) that receives $\mathbf{x_{intro}} = \{sent_1, sent_2, ..., sent_m\}$, with m being the number of sentences in introductory section. The aim of adding second encoder in this framework is to identify the clues in the introductory section which point to the salient supplementary sentences [4]. The BERTSUM network computes the extraction probabilities for introductory sentences as follow (same way as in Eq. 1),

$$\begin{aligned} \tilde{h}_b &= \mathbf{BertSum}(\mathbf{x_{intro}}) \\ \tilde{h} &= \mathbf{Encoder_t}(\tilde{h}_b) \\ \tilde{p} &= \sigma(W_j \tilde{h} + b_j) \end{aligned} \tag{2}$$

in which $\tilde{h}_b$, and $\tilde{h}$ are the introductory sentence representations by BERTSUM, Transformers encoder, respectively. $\tilde{p}$ is the introductory sentence extraction probabilities. W_j and b_j are trainable matrices.

After identifying salient introductory sentences, the representations associated with them are retrieved using a pooling function and further used to guide the first task (i.e., right-hand side in Figure 3) as follows,

$$\begin{aligned} \tilde{h}_{top} &= \mathtt{Select}(\tilde{h}, \tilde{p}, k) \\ \hat{h} &= \mathbf{MLP_1}(\tilde{h}_{top}) \end{aligned} \tag{3}$$

---

[3] Introductory information is defined in Section 1

[4] Supplementary sentences are defined in Section 1.

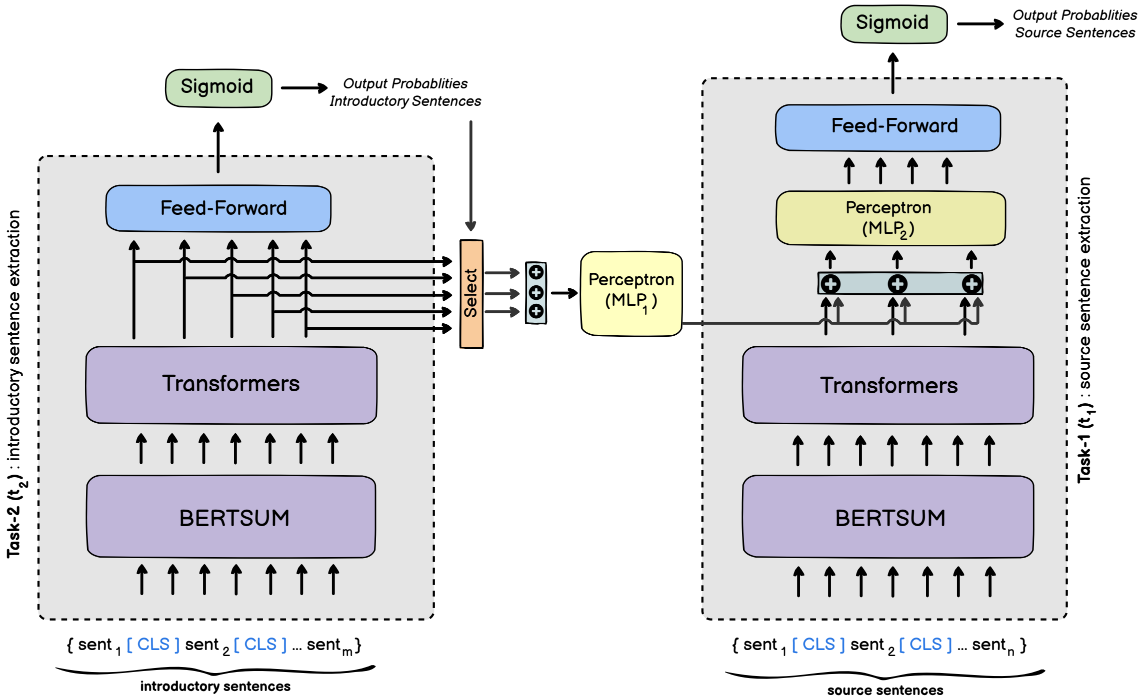

Figure 3: Detailed illustration of our summarization framework. **Task-1 ($\mathbf{t_1}$):** source sentence extraction (right-hand gray box). **Task-2 ($\mathbf{t_2}$):** introductory sentence extraction (left-hand gray box). As shown, the identified salient introductory sentences at training stages are incorporated into the representations of source sentences by the `Select`$(\cdot)$ function (orange box) with $k = 3$. Plus sign shows the concatenation layer. The feed-forward neural network is made of one linear layer.

where `Select`$(\cdot)$ is a function that takes in all introductory sentence representations (i.e., $\tilde{h}$), and introductory sentence probabilities $\tilde{p}$. It then outputs the representations associated with top k introductory sentences, sorted by $\tilde{p}$. To extract top introductory sentences, we first sort $\tilde{h}$ vectors based on their computed probabilities $\tilde{p}$ and then we pick up top k hidden vectors (i.e., $\tilde{h}_{top}$) that has the highest probability. $\mathbf{MLP_1}$ is a multi-layer perceptron that takes in concatenated vector of top introductory sentences and projects it into a new vector called $\hat{h}$.

At the final stage, we concatenate the transformed introductory top sentence representations (i.e., $\hat{h}$) with each source sentence representations from Eq. 1 (i.e., h_i where i shows the ith paper sentence) and process them to produce a resulting vector r which is *intro-aware* source sentence hidden representations. After processing the resulting vector through a linear output layer (with W_z and b_z as trainable parameters), we obtain final *intro-aware* sentence extraction probabilities (i.e., p) as follows,

$$\begin{aligned} r &= \mathbf{MLP_2}(h_i\,;\,\hat{h}) \\ p &= \sigma(W_z r + b_z) \end{aligned} \tag{4}$$

in which $\mathbf{MLP_2}$ is a multi-layer perceptron, influencing the knowledge from introductory sentence extraction task (i.e., $\mathbf{t_2}$) into the source sentence extraction task (i.e., $\mathbf{t_1}$). We train both tasks through our end-to-end system jointly as follows,

$$\ell_{\mathbf{total}} = (\alpha)\ell_{\mathbf{t_1}} + (1-\alpha)\ell_{\mathbf{t_2}} \tag{5}$$

where $\ell_{\mathbf{t_1}}$, and $\ell_{\mathbf{t_2}}$ are the losses computed for introductory sentence extraction and source sentence extraction tasks, α is the regularizing parameter that balances the learning process between two tasks, and $\ell_{\mathbf{total}}$ is the total computed loss that is optimized during the training.

5 Experimental Setup

In this section, we explain the datasets, baselines, and preprocessing and training parameters.

5.1 Dataset

We use two publicly available scientific extended summarization datasets (Sotudeh et al., 2021).

- **arXiv-Long:** A set of arXiv scientific papers containing papers from various scientific domains such as physics, mathematics, computer science, quantitative biology. arXiv-Long is intended for extended summarization task and was filtered from a larger dataset i.e., arXiv (Cohan et al., 2018) for the summaries of more than 350 tokens. The ground-truth summaries (i.e., abstract) are long, with the average length of 574 tokens. It contains 7816 (train), 1381 (validation), and 1952 (test) papers.

- **PubMed-Long:** A set of biomedical scientific papers from PubMed with average summary length of 403 tokens. This dataset contains 79893 (train), 4406 (validation), and 4402 (test) scientific papers.

- **LongSumm:** The recently proposed LongSumm dataset for a shared task (Chandrasekaran et al., 2020) contains 2236 abstractive and extractive summaries for training and 22 papers for the official test set. We report a comparison with BERTSUMEXTMULTI using this data in Table 2. However, as the official test set is blind, our experimental results in Table 1 do not use this dataset.

5.2 Baselines

We compare our model with two strong non-neural systems, and four state-of-the-art neural summarizers. We use all of these baselines for the purpose of extended summary generation whose documents hold different characteristics in length, writing style, and discourse structure as compared to documents in the other domains of summarization.

- **LSA** (Steinberger and Ježek, 2004): an extractive vector-based model that utilizes Singular Value Decomposition (SVD) to find the semantically important sentences.

- **LEXRANK** (Erkan and Radev, 2004): a widely adopted extractive summarization baseline that utilizes a graph-based approach based on eigenvector centrality to identify the most salient sentences.

- **BERTSUMEXT** (Liu and Lapata, 2019): a contextualized summarizer fine-tuned for summarization task, which encodes input sentence representations, and then processes them through a multi-layer Transformers encoder to obtain document-level sentence representation. Finally, a linear output layer with Sigmoid activation function outputs a probability distribution over each input sentence, denoting the extent to which they are probable to be extracted.

- **BERTSUMEXT-INTRO** (Liu and Lapata, 2019): a BERTSUMEXT model that only runs on the introductory sentences as the input, and extracts the salient introductory sentences as the summary.

- **BERTSUMEXTMULTI** (Sotudeh et al., 2021): an extension of the BERTSUMEXT model that incorporates an additional linear layer with Sigmoid classifier to output a probability distribution over a fixed number of pre-defined sections that an input sentence might belong to. The additional network is expected to predict a single section for an input sentence and is trained jointly with BERTSUMEXT module (i.e., sentence extractor).

- **BART** (Lewis et al., 2020): a state-of-the-art abstractive summarization model that makes use of pretrained encoder and decoder. BART can be thought of as an extension of BERTSUM in which merely encoder is pre-trained, but decoder is trained from scratch. While our model is an extractive one, at the same time, we find it of value to measure the abstractive model performance in the extended summary generation task.

5.3 Preprocessing, parameters, labeling, and implementation details

We used the open implementation of BERTSUMEXT with default parameters [5]. To implement the non-neural baseline models, we utilized Sumy python package [6]. Longformer model (Beltagy et al., 2020) is utilized as our contextualized language model for running all the models due to its efficacy at processing long documents. For our model, the cross-entropy loss function is set for two tasks (i.e., $\mathbf{t_1}$: source sentence extraction and $\mathbf{t_2}$: introductory sentences extraction in Figure 3) and the model is optimized through multi-tasking approach as discussed in Section 3. The model with the highest ROUGE-2 on validation set is selected for inference. The validation is performed every 2k training steps. α (in Eq. 5) is set to be 0.5 (empirically determined). Our model includes 474M

---

[5] `https://github.com/nlpyang/PreSumm`

[6] `https://github.com/miso-belica/sumy`

trainable parameters, trained on dual GeForce GTX 1080Ti GPUs for approximately a week. We use $k = 5$ for arXiv-Long, $k = 8$ for PubMed-Long datasets (Eq. 3). We make our model implementation as well as sample summaries publicly available to expedite ongoing research in this direction [7].

A two-stage labeling approach was employed to identify ground-truth introductory and non-introductory sentences. In the first stage, we used a greedy labeling approach (Liu and Lapata, 2019) to label sentences within the first section of a given paper (i.e., labeling introductory sentences) with respect to their ROUGE overlap [8] with the ground-truth summary (i.e., abstract). In the second stage, the same greedy approach was exploited over the rest of sentences (i.e., non-introductory)[9] with regard to their ROUGE overlap with the identified introductory sentences in the first stage. Our choice of ROUGE-2 and ROUGE-L is based on the fact that these express higher similarity with human judgments (Cohan and Goharian, 2016). We continued the second stage until a fixed length of the summary was reached. Specifically, the fixed length of positive labels is set to be 15 for arXiv-Long, and 20 for PubMed-Long datasets as these achieved the highest oracle ROUGE scores in our experiments.

6 Results

6.1 Experimental evaluation

The recent effort in extended summarization and its shared task of LongSumm (Chandrasekaran et al., 2020) used average ROUGE (F1) to rank the participating systems, in addition to commonly-used ROUGE-N scores. Table 2 shows the performance of the participated systems on the blind test set. As shown, BERTSUMEXTMULTI model outperforms other models by a large margin (i.e., with relative improvements of 6% and 3% on ROUGE-1 and average ROUGE(F1), respectively); hence, we use the best-performing in terms of F1 (i.e., BERTSUMEXTMULTI model) in our experiments. Tables. 1 presents our results on the test sets of arXiv-Long and PubMed-Long datasets, respectively. As observed, our model statistically significantly outperforms the state-of-the-art systems on both datasets across most of the ROUGE variants, except ROUGE-L on PubMed-Long. The improvements gained by our model validates our hypothesis that incorporating the salient introductory sentence representations into the extractive summarizer yields a promising improvement. Two non-neural models (i.e., LSA and LEXRANK) underperform the neural models, as expected. Comparing the abstractive model (i.e., BART) with extractive neural ones (i.e., BERTSUMEXT and BERTSUMEXTMULTI), we see that while there is relatively a smaller gap in terms of ROUGE-1, the gap is larger for ROUGE-2, and ROUGE-L. Interestingly, in the case of BART, we found that generating extended summaries is rather challenging for abstractive summarizers. Current abstractive summarizers including BART have difficulty in abstracting very detailed information, such as numbers, and quantities, which hurts the faithfulness of the generated summaries to the source. This behavior has a detrimental effect, specifically, on ROUGE-2 and ROUGE-L as their high correlation with human judgments in terms of faithfulness has been shown (Pagnoni et al., 2021). Comparing the extractive BERTSUMEXT and BERTSUMEXTMULTI models, while BERTSUMMULTIEXT is expected to outperfom BERTSUMEXT, it is observed that they perform almost similarly, with small (i.e., insignificant) improved metrics. This might be due to the fact that BERTSUMEXTMULTI works out-of-the-box when a handful amount of sentences are sampled from diverse sections to form the oracle summary as also reported by its authors. However, when labeling oracle sentences in our framework (i.e., Intro-guided labeling), there is no guarantee that the final set of oracle sentences are labeled from diverse sections. Overall, our model achieves about 1.4%, 2.4%, 3.5% (arXiv-Long), and 1.0%, 2.5%, 1.3% (PubMed-Long) improvements across ROUGE score variants; and 2.2% (arXiv-Long), 1.4% (PubMed-Long) improvements over F1, compared to the neural baselines (i.e., BERTSUMEXT and BERTSUMEXTMULTI). While comparing our model with BERTSUMEXT-INTRO, we see the vital effect of adding second encoder at finding supplementary sentences across non-introductory sections, where our model gains relative improvements of 9.62%-26.26%-16.09% and 9.40%-5.27%-9.99% for ROUGE-1, ROUGE-2, ROUGE-L on arXiv-Long and PubMed-Long, respectively. In fact, the sentences that are picked as summary from the in-

6.2 Human evaluation

While our model statistically significantly improves upon the state-of-the-art baselines in terms of Rouge scores, a few works have reported the low correlation of Rouge with human judgments (Liu and Liu, 2008; Cohan and Goharian, 2016; Fabbri et al., 2021). In order to provide insights into why and how our model outperforms the best-performing baselines, we perform a manual analysis of our system's generated summaries, BertSumExt's, and BertSumExtMulti's. For the sake of evaluation, two annotators were asked to manually evaluate two sets of 40 papers' ground-truth abstracts (40 for arXiv-Long, and 40 for PubMed-Long) with their generated extended summaries (baselines' and ours) to gain insights into qualities of each model. Annotators were Electrical Engineering and Computer Science PhD students and familiar with principles of reading scientific papers. Samples were randomly selected from the test set, one from each 40 evenly-spaced bins sorted by the difference of Rouge-L between two experimented systems.

The evaluations were performed according to two metrics: (1) *Cohesion*: whether the ordering of sentences in summary is cohesive, namely sentences entail each other. (2) *Completeness*: whether the summary covers all salient information provided in the ground-truth summary. To prevent bias in selecting summaries, the ordering of system-generated summaries were shuffled such that it could not be guessed by the annotators. Annotators were asked to specify if the first system-generated summary wins/loses or ties with the second system-generated summary in terms of qualitative metrics. It has to be mentioned that since our model is purely extractive, it does not introduce any fact that is unfaithful to the source.

Our human evaluation results along with Cohen's kappa (Cohen, 1960) inter-rater agreements are shown in Table 3 (agr. column). As shown, our system's generated summaries improve completeness and cohesion in over 40% for most of the cases (6 out of 8 for win cases [10]). Specifically, when comparing with BertSumExt, we see that 68%, 80% (arXiv-Long); and 60%, 66% (PubMed-Long) of sampled summaries are at least as good as or better than the corresponding baseline's generated summaries in terms of cohesion and completeness, respectively. Overall, across two metrics for BertSumExt and BertSumExtMulti, we gain relative improvements over the baselines: 25.6%, 19.0% (cohesion), and 56.5%,

---

[10] Win cases are the ones in which our system wins the baseline(s) in terms of cohesion/completeness.

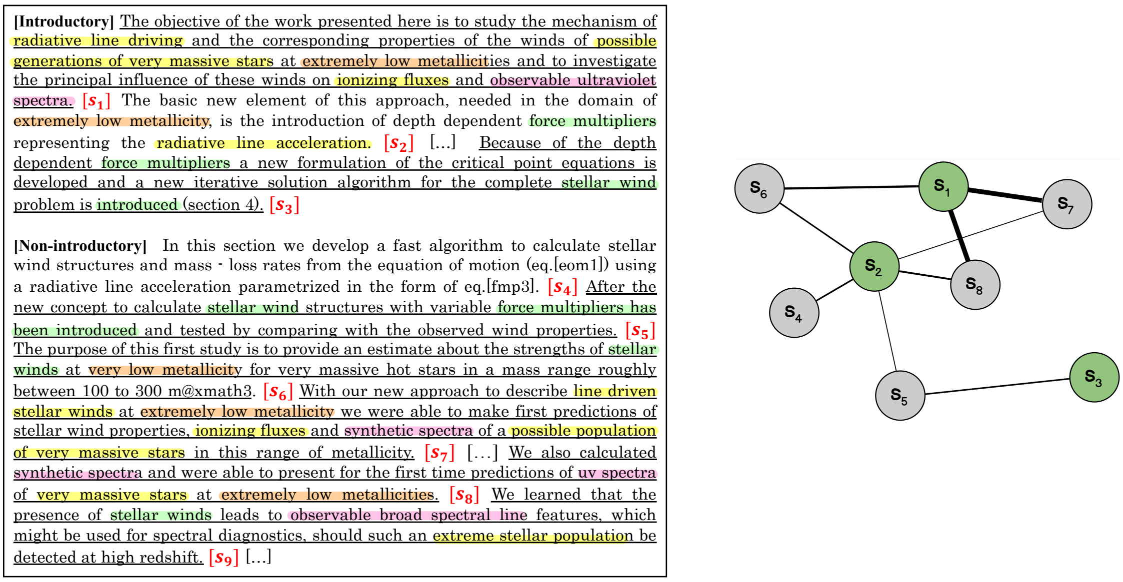
(b)

Table 3: Results of human evaluations over 40 papers sampled from (a) arXiv-Long's, and (b) PubMed-Long's test set. agr. shows inter-rater agreement.



[Introductory] The objective of the work presented here is to study the mechanism of radiative line driving and the corresponding properties of the winds of possible generations of very massive stars at extremely low metallicities and to investigate the principal influence of these winds on ionizing fluxes and observable ultraviolet spectra. [s_1] The basic new element of this approach, needed in the domain of extremely low metallicity, is the introduction of depth dependent force multipliers representing the radiative line acceleration. [s_2] [...] Because of the depth dependent force multipliers a new formulation of the critical point equations is developed and a new iterative solution algorithm for the complete stellar wind problem is introduced (section 4). [s_3]

[Non-introductory] In this section we develop a fast algorithm to calculate stellar wind structures and mass - loss rates from the equation of motion (eq.[eom1]) using a radiative line acceleration parametrized in the form of eq.[fmp3]. [s_4] After the new concept to calculate stellar wind structures with variable force multipliers has been introduced and tested by comparing with the observed wind properties. [s_5] The purpose of this first study is to provide an estimate about the strengths of stellar winds at very low metallicity for very massive hot stars in a mass range roughly between 100 to 300 m@xmath3. [s_6] With our new approach to describe line driven stellar winds at extremely low metallicity we were able to make first predictions of stellar wind properties, ionizing fluxes and synthetic spectra of a possible population of very massive stars in this range of metallicity. [s_7] [...] We also calculated synthetic spectra and were able to present for the first time predictions of uv spectra of very massive stars at extremely low metallicities. [s_8] We learned that the presence of stellar winds leads to observable broad spectral line features, which might be used for spectral diagnostics, should such an extreme stellar population be detected at high redshift. [s_9] [...]

(a) (b)

Figure 4: (a) Our system's generated summary, (b) Sentence graph visualization of our system's generated summary. Green and gray nodes are introductory and non-introductory sentences, respectively. Edge thickness denotes the ROUGE score strength between pair of sentences. Parts, from which sentences are sampled, are shown inside brackets. The summary is truncated due to space limitations. Ground-truth summary-worthy sentences are underlined, and colored spans show pointers from introductory to non-introductory sentences.

46.7% (completeness) on arXiv-Long; and 23.1%, 13.5% (cohesion), and 27.7%, 21.9% (completeness) on PubMed-Long. [11] These improvements, qualitatively evaluated by the human annotators, show the promising capability of our purposed model in generating improved extended summaries which are more preferable than the baselines'. We observe a similar improvement trend when comparing our summaries with BERTSUMEXTMULTI, where 66%, 77% (arXiv-Long); and 58%, 58% (PubMed-Long) of our summaries are as good as or better than the baseline's in terms of cohesion and completeness. Looking at the Cohen's inter-rater agreement, the correlation scores fall into "moderate" agreement range according to the interpretation of Cohen's kappa range (McHugh, 2012).

6.3 Case study

Figure 4 (a) demonstrates an extended summary generated from a sample arXiv-Long paper by our model. The underlined sentences denote that the corresponding sentences are oracle (i.e., summary-worthy), the colored spans denote the pointers from introductory information to non-introductory information, and sentence numbers appear in brackets following each sentence. As shown, our system first identifies salient introductory sentences (i.e., $[s_1]$ and $[s_3]$), and then augments them with important non-introductory sentences. Figure 4 (b) shows the ROUGE scores between pairs of intro-

---

[11] Relative improvement of win rate over lose rate.

ductory and non-introductory sentences. The edge thickness signifies the strength of the ROUGE score between a pair of sentences. For example, introductory sentence $[s_1]$ highly correlates with non-introductory sentence $[s_7]$ as it has a stronger edge (s_1, s_7) thickness. More specifically, $[s_1]$ has mentions of *"radiative line driving"*, *"properties of the winds"*, *"possible generations of very massive stars"*, and *"ionizing fluxes"* which maps to $[s_7]$ with semantically similar mentions of *"line driven stellar winds"*, *"stellar wind properties"*, *"possible generations of very massive stars"*, and *"ionizing fluxes"* [12].

7 Error Analysis

To determine the limitations of our model, we further analyze our system's generated summaries and report three common defects, along with the percentage of these errors among underperformed cases. We found that (1) our end-to-end system's performance is highly dependent on the introductory sentence extraction task's performance (i.e., task $\mathbf{t_2}$ in Figure 3) as identification of salient introductory sentences (i.e., oracle introductory sentences) sets up a firm ground to explore detailed sentences from the non-introductory parts of the paper. In other words, identification of non-salient introductory sentences leads to a drift in finding supplemental sentences from the non-introductory parts. Our model often underperforms when it cannot find important sentences from the introductory part (65%); (2) in underperformed cases, our model fails in selecting motivation, objective sentences from the introductory part, and only identifies the contribution sentences (i.e., describing paper's contributions), such that the final generated summary is composed of contribution sentences, rather than objective sentences. This observation hurts the system in cohesion and completeness (40%); and (3) as discussed, our model matches introductory sentences with sentences from non-introductory parts of the paper. Given that two sentences within a scientific paper might conceptually convey the exact same information, but are just paraphrased of each other, our model samples both to form the final summary as a high semantic correlation exists between them. This phenomenon leads to sampling two sentences that convey the same information without providing more details; hence, information redundancy (35%).

8 Conclusion

In this work, we propose a novel approach to tackle the extended summary generation for scientific documents. Our model is built upon the fine-tuned contextualized language models for text summarization. Our method improves over strong and state-of-the-art summarization baselines by adding an auxiliary learning component for identifying salient introductory information of long documents, which are then used as pointers to guide the summarizer to pick summary-worthy sentences. The extensive intrinsic and human evaluations show the efficacy of our model in comparison with the state-of-the-art baselines, using two large scale extended summarization datasets . Our error analysis further paves the path for future reseacrh.

Abstract

We present a method to control the emotional prosody of Text to Speech (TTS) systems by using phoneme-level intermediate features (pitch, energy, and duration) as levers. As a key idea, we propose Differential Scaling (DS) to disentangle features relating to affective prosody from those arising due to acoustics conditions and speaker identity. With thorough experimental studies, we show that the proposed method improves over the prior art in accurately emulating the desired emotions while retaining the naturalness of speech. We extend the traditional evaluation of using individual sentences for a more complete evaluation of HCI systems. We present a novel experimental setup by replacing an actor with a TTS system in offline and live conversations. The emotion to be rendered is either predicted or manually assigned. The results show that the proposed method is strongly preferred over the state-of-the-art TTS system and adds the much-coveted "human touch" in machine dialogue. Audio samples for our experiments and the code are available at: https://emtts.github.io/tts-demo/

1 Introduction

"The text is like a canoe, and the river on which it sits is the emotion. It all depends on the flow of the river, which is your emotion. The text takes on the character of your emotion."

— Sanford Meisner

In natural language processing, vocabulary and grammar tend to take center stage, but those elements of speech only tell half the story. Affective prosody provides context and gives meaning to words, and keeps listeners engaged. Understanding emotional prosody is central to language and social development. Studies suggest that we show remarkable sensitivity to prosody "even as infants" (Nazzi et al., 1998; Massicotte-Laforge and Shi, 2015). Recently Kraus (2017) shows that voice-only communication likely elicits higher empathic accuracy than even multi-sense modes including facial expressions.

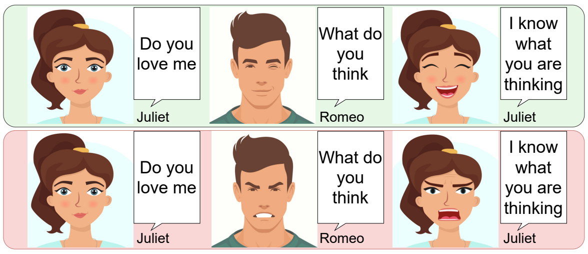

Figure 1: Dialogues can have different meanings despite having the same text. Also, starting with the same emotion, Juliet has different emotions post Romeo's response.

Buchholz (2016) shows that any meaningful spoken dialogue cannot happen without some amount of prosodic matching. As humans, we naturally anticipate and adapt with emotional cues in conversing with others, see Figure 1 for an example. Celebrated trainer Sanford Meisner employed this to develop *Meisner technique* for theatre actors to react naturally to others in the environment as opposed to *method acting*. The importance of emotional prosody in conversations cannot be overstated and TTS models need to fill this gap to make human-like conversations possible in HCI systems.

Mitchell and Xu (2015) study the value of emotional prosody in HCI and emphasize its role in healthcare dialogue systems, improving social interaction skills in people with autism, augmentative and alternative communication devices and gaming narratives. They explain that successfully incorporating expressive speech into HCI, involves two aspects: (a) prosodic emotion recognition and (b) expression of emotional prosody. Considerable effort has been made towards recognizing and predicting the emotional nuances in human dialogues (Kim and Vossen, 2021; Poria et al., 2019b; Zhu et al., 2021; Li et al., 2017; Poria et al., 2021; Vinyals and Le, 2015). However, current TTS systems are

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 336 - 347
July 10-15, 2022 ©2022 Association for Computational Linguistics

yet to improve on rendering emotive or expressive speech for real-world HCI systems.

State-of-the-art TTS systems (Ren et al., 2020; Wang et al., 2017) tend to exhibit average emotions for a given phoneme sequence by taking the mean of utterances from training data. Some efforts towards improving expressiveness (like Battenberg et al., 2019; Karlapati et al., 2020) provide prosody control using a reference clip. Others like Sivaprasad et al. (2021) and Habib et al. (2019) further focused on controllability exposing levers that can be manipulated at inference-time to derive the intended expression. However, the quality and stability of synthesized speech heavily depends on various modeling choices. Emotion or prosody modeling, for example, could pick from numerous available discrete or continuous space representations. The encoder network module chosen might vary in its ability to disentangle prosody from other acoustic features like speaker identity and adaptability to content. For example, those relying on reference clip to replicate prosody might perform poorly when input text is unsuitable for rendering with prosody of reference. Some models feed prosody features with phoneme embeddings directly into the decoder while others use them to predict intermediate features that are used in conditioning the decoder. It is empirically verified (like in Sivaprasad et al., 2021) that intermediate features could be suitably manipulated to bring about the desired change in expression.

We take this direction forward to endow the intermediate feature prediction module with affective state control over the final rendering. We propose *Differential Scaling (DS)* of the predicted intermediates to bring about the required change in emotion. The *DS* module is aimed to effect only emotion as intended while remaining agnostic to all other features like speakers identities or acoustic conditions as seen in train data. We show that this significantly improves the naturalness of the generated speech, while allowing finer control over prosody.

In addition to comparing our model's renderings against various others' from literature for naturalness and emotion control on conventional single utterances drawn from disconnected contexts, we also evaluate them in conversations. We curate data with conversational theatre dialogues and replace an actor with a TTS system. We use its response as a proxy to evaluate the empathic accuracy. In another experiment, we had a theatre director control the emotion levers of our TTS model in a live conversation with the actor to evaluate controllability. As demonstrated in the results, our proposed method significantly improves over existing methods in producing suitable prosodic variation lending closer to human-like conversations. The rest of this paper will elaborate on the following contributions of this work.

- We propose a simple technique of using a *DS* module to better emulate emotions in TTS rendered speech. This works as plug-and-play with both autoregressive and non-autoregressive TTS models that predict prosodic features as an intermediate step.
- Our work extends the literature of training controllable and expressive TTS models with improved empathic accuracy and without specific studio recorded data.
- Finally, we present novel methods and data for evaluating TTS models in real conversations with human subjects. The method of evaluation is a useful step towards filling the gap of emulating emotional speech that needs more work.

2 Related Work

Prosody and conversational speech. Unlike in written text, spoken words contain additional non-verbal information. These cues are collectively termed prosody (Leentjens et al., 1998) that include variations in tone, pitch, energy, duration, accents, intonation, stress, etc. Buchholz (2016) showed that prosodic exchange is unavoidable in human dialogue. Various machine learning methods have been proposed to predict emotion in speech from its prosody variations (Asgari et al., 2014; Kamaruddin and Abdul Rahman, 2013). Variations in pitch accents (Nielsen et al., 2020), for example, lead to a significant difference in how the receiver perceives the content. A sentence (like `I said` **`un`**`lock the door, not lock it` from (Rosenberg and Hirschberg, 2009)) could be delivered both as a statement and a command by merely changing prosody.

Emotion recognition in conversations has gained increasing attention for developing empathetic machines with emotion-tagged multi-modal data publicly available for modeling like (Li et al., 2017; Poria et al., 2019a; Busso et al., 2008). While most methods like (Majumder et al., 2019; Jiao et al., 2019) use a combination of text and speech information, some leverage additional side-information from broader context (Ghosal et al., 2020) and the topic of conversation (Zhu et al., 2021).

In such labeled data, emotion is often represented as a categorical variable over a discrete space following models like Ekman's basic emotions (Ekman, 1992) or the wheel of Plutchik (Plutchik, 1980). This choice is largely owing to the ease of annotating data. Russell (1980) proposed a continuous two-dimensional space as an alternative called valence-arousal model for human emotions. Arousal signifies the intensity of the emotion while valence captures its polarity. It has been extended to add a third dimension of dominance, making it the valence-arousal-dominance (VAD) model. VAD has since been widely used in modelling emotion in music (Grekow, 2016; Rachman et al., 2019), speech (Asgari et al., 2014; Kamaruddin and Abdul Rahman, 2013) and other content (Joshi et al., 2019; Buechel and Hahn, 2017). We use the continuous space representation as it is richer and more convenient to handle in our model. For instance, a continuous space allows the user to change the level of emotion like happy to delighted, sad to depressed, etc., superlatively during synthesis.

Expressive and controllable TTS. Neural TTS systems are now increasingly popular, improving upon older concatenative statistical systems (Michelle and Georgia, 2020) in synthesized speech naturalness. These are broadly sequence-to-sequence networks with an encoder processing the input text or phoneme sequence followed by a decoder that generates the sequence of Mel frames for output speech. Mel frames are then projected into the time domain by a vocoder (van den Oord et al., 2016; Griffin and Lim, 1984) to generate the speech. Decoding could be autoregressive with Tacotron-like models (Wang et al., 2017) or non-autoregressive with Fastspeech-like models (Ren et al., 2019).

Non-autoregressive models are faster at inference than autoregressive models with about comparable naturalness of speech quality (Ren et al., 2020). The trick non-autoregressive models use to generate Mel frames in parallel is to predict the relevant features as an intermediate step and condition the independent decoding of Mels on them. This technique is now increasingly adopted for autoregressive models as well (Wang et al., 2021) to predict features like phoneme duration that improve decoding stability avoiding alignment issues. Our method is compatible with any architecture that predicts prosodic features of pitch, energy, and duration as an intermediate step before decoding.

Going beyond the naturalness of speech, there has been considerable effort to improve the expressiveness of the renderings. Some focused on learning a linear space of variations in speech expressions for selecting a suitable variation at inference time. Wang et al. (2018) learn this space unsupervised by encouraging it to explain all variations in training data not captured in content embedding. A reference encoder maps an input utterance to a style embedding as a linear combination of basis style vectors. Manual analysis is required to understand the prosody feature learned into a basis vector that could include variations like vocal depth or pitch, speaking rate, or even background noise as available in training data. While this offers style control, it does not explicitly learn the prosody variations of interest into the style space. Our work focuses on the same level of control but specifically over the affective state as labeled in some data for supervision.

Sivaprasad et al. (2021) propose a model similar to Wang et al. (2018) with style tokens restricted to valence and arousal. However, the absolute (pitch, energy, duration) feature predictions restrict prosody control, leading to unnatural distortions. Specifically, it skews more towards retaining the speaker's voice identity than the emotion and entangles emotion with other acoustic features. Karlapati et al. (2020) replace the linear style space with a variational reference encoder to generate prosody embedding to condition the decoder. Battenberg et al. (2019) use a similar variational model but instead force its posterior to match that of the reference utterance to copy prosody with a controllable parameter determining the closeness of the match. This trick alleviates certain issues like in pitch-range (Younggun and Taesu, 2019) and transfer to unrelated sentences but exposes a lower degree of control with no explicit levers to operate, as possible in our work.

Habib et al. (2019) propose to learn an explicit latent representation for various prosodic variables, segregating them into explicitly controlable (like affect, speaking rate, etc) and implicit (like intonation, rhythm, stress, etc). While the model offers a

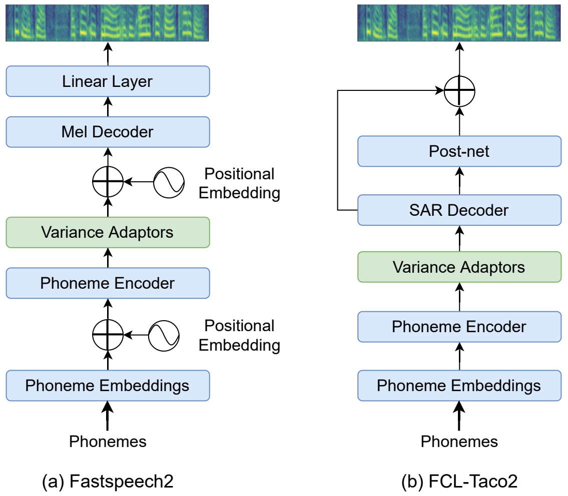

Figure 2: Backbone TTS architectures.

higher degree of explicit control, it requires using a proprietary studio recorded data with utterances reflecting prompted emotions at specified arousal. Dependence on explicit supervision from studio recorded data makes it harder scale this model across languages and other prosodic variations. In contrast, we use publicly available data with emotion labels to train our models.

There are other methods that try to predict suitable prosody features from text content. Raitio et al. (2020) add a prosody encoder module to standard TTS network that predicts certain handcrafted prosody features from text embedding of input. This prosody encoder is used with a small optional bias for affect variations at inference. Hodari et al. (2021) extend this to replace hand-crafting prosody features with explicit training followed by their prediction from text. Karlapati et al. (2021) further enrich the textual context using BERT embeddings and parse-trees. These methods are limited in expressiveness offering no control over rendering emotion that our work focuses on.

3 Model

Our network uses a backbone TTS that can be borrowed from any model which predicts pitch, energy and duration as intermediates features from input phoneme sequence. This network learns to predict the average features for given phonemes. Following the convention in earlier works, we refer to the intermediate features as variances and the module that predicts them as variance adaptor. Prior work improves standard variance adaptors in, say FastSpeech2, by conditioning on emotion variables of valence-arousal in addition to the phoneme sequence to generate expressive speech. We refer to it as Emotional Variance Adaptor (EVA) for which we propose an alternative. Our proposed Differential Scaler (DS) module determines how best to vary the output of the EVA to bring the desired change in emotion. We describe the details of these network choices in this section; specifically, the broader backbone network architecture and the different variance adaptor modules from non-emotive baseline, emotive baseline and our proposal.

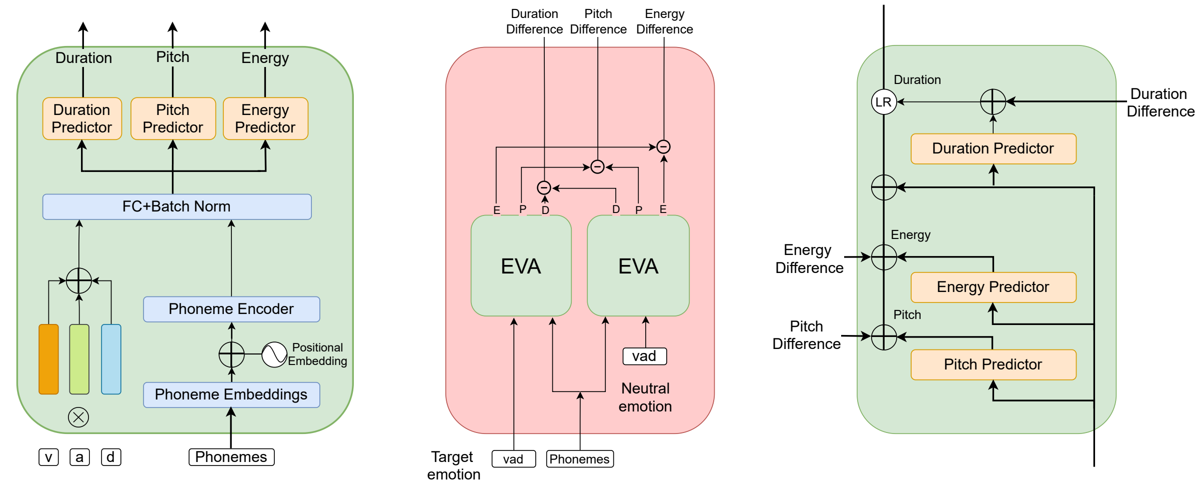
3.1 Backbone

We present experiments with two suitable choices for our backbone systems, FastSpeech2 and FCL-taco2. The backbone has three modules; an encoder, variance adaptor and decoder. The encoder maps an input phoneme sequence to its embedding. Given this representation, the variance adaptor predicts the pitch, energy and duration for each of the phonemes. These intermediate features are processed by the decoder module downstream to return Mel-spectrogram frames. We reuse the encoder and decoder modules as designed in their original architectures without any changes. We refer readers to the respective papers for details of these networks. Wavenet (van den Oord et al., 2016) vocoder is used to map Mel-spectrogram outputs of the decoder to time-domain raw audio.

3.2 Variance adaptor module

Non-emotive baselines. Our baseline models of FastSpeech2 and FCL-taco2 are trained with the variance adaptors as described by their authors. We also train a derivative of the FastSpeech2 with the variance adaptor modified to make predictions at the phoneme-level and not at frame-level. This is to facilitate the phoneme level control of variances. A duration d_π is predicted for each phoneme π, following which the length regulator repeats the hidden state of that phoneme $\dot{\pi}$ times. Also unlike FastSpeech2, we use this length regulator after the predicted pitch and energy are added to the encoder output. We refer to this derivative as FastSpeech2π.

Emotive baseline. Sivaprasad et al. (2021) conditioned the variance adaptor of FastSpeech2 on additional emotion embedding that gives the model control over prosody of the rendered speech. It generates the emotion embedding as a linear weighted combination of the valence and arousal vectors that are learned from data during training. The weights are valence and arousal values as annotated for



(a) Emotional Variation Adaptor (b) Differential Scaler (c) Variance Adaptor

Figure 3: Schematic diagram of the proposed model.

training and can be used as control levers to modify emotion during inference. This emotion variance adaptor (EVA) module generates suitable intermediate features of pitch and energy at frame-level and duration at phoneme-level. These features are consumed by the decoder along with the encoder output in generating Mel frames. While this helps control emotional prosody rendered speech, it leads to a significant drop in perceptual quality and naturalness relative to the baselines. Our contribution is an alternative design of the variance adaptor module that improves upon Sivaprasad et al. (2021)'s FastSpeech2 + EVA model in emotion control and expressiveness and upon the baselines in terms of naturalness.

Differential Scaler. We extend the emotion representation from EVA to include dominance in addition to valence and arousal values. Dominance is the degree of control exerted by an emotion. Including dominance dimension to the emotion space expands the range of emotions the TTS model can express. For example, by introducing this dimension, we can better distinguish outputs for emotions like 'anger and fear' or 'sad and contempt'.

The *Differential Scaler* module further extends EVA to estimate the change in variances necessary for a pronounced effect of the target emotion relative to its neutral counterpart. As shown in Figure 3(b), the variances are estimated using the EVA module for a given phoneme sequence at two different triplets of VAD values. One prediction corresponds to the neutral emotion with VAD values all set to zeros. The other prediction corresponds to the chosen VAD values of target emotion. We take the difference of these two estimates as the direction along which the variances can be varied for the desired change in emotion without affecting other acoustic features. We are implicitly making two assumptions here. Emotion variations are captured as linear transformations in this space and that there is a strong disentangling of emotional prosody with other acoustic features in this space. Results from our empirical evaluation favorably support the above assumptions.

4 Training

Modelling with intermediate features facilitates training the backbone and the variance adaptors independently on different data. We exploit this to train our variance adaptor on scarcely available VAD annotated data while reusing backbone models trained on abundant transcribed speech data.

Backbone. We train two backbone networks FastSpeech2π (non-autoregressive) and FCL-taco2 (autoregressive) on Blizzard 2013 dataset (King and Karaiskos, 2014). It contains 147 hours of Catherine Bayers's speech, reading books in American English. Due to the style of reading, the dataset is rich in expressiveness and spans different combinations of pitch, energy and duration. Both models are trained with Mel loss (mean absolute error between predicted and ground truth Mels), pitch loss, energy loss and duration loss (mean square error between predicted and ground truth features). Both models are trained for 200K iterations using Adam optimizer with warm-up learning rate scheduler and batch size of 16.

EVA. We train EVA on MSP-Podcast corpus

(Lotfian and Busso, 2019) annotated with arousal, valance and dominance values. The corpus consists of around 100 hours speech data but their transcriptions are not available. We generate transcripts using a speech-to-text model. We use Montreal-Forced-Aligner (MFA) (McAuliffe and Sonderegger, 2017) for phoneme alignments. Those transcripts that MFA fails to find a good alignment for are filtered out. The remaining utterances add up to about 71 hours of emotive speech data which we use to train our EVA. We train pitch, energy and duration predictors conditioned on VAD values minimizing only the sum of variance losses. For all the experiments, text transcripts are converted to phonemes using Sun et al. (2019). We generate Mel spectrogram from the audio files similar to Wang et al. (2017). Pitch and energy are computed from the Mel spectrogram and we use MFA for aligning phonemes to train the duration predictor.

5 Experiments and user study

We present three experiments; comparison with prior-art using conventional evaluation metrics, those for emotional consistency with pre-recorded audio, and finally, live conversations with humans.

5.1 Comparisons with prior-art

We compare the proposed approach against four state of the art TTS models. The list includes two non-emotive TTS models (FastSpeech2 and FCL-taco2), one reference-based method (Cai et al., 2021) and one AV conditioned model (FastSpeech2 + EVA). We also compare our method with the modified backbone, FastSpeech2π.

To show the efficacy of DS over EVA module independent of the effect of other interventions, we perform two more comparisons. The first comparison evaluates our model against Fastspeech2 + EVA trained with 'dominance' (on arousal, valence and dominance). The second comparison is made against Fastspeech2π + EVA with the backbone trained on Blizzard (both backbones trained on the same dataset). The first comparison is made on the perceptual-quality and emotional expressiveness while the second comparison is made only for their perceptual-quality.

To evaluate the perceptual-quality/naturalness we compare Mean Opinion Score (MOS) (Chu and Peng, 2006) averaged across forty subjects proficient in English. We synthesize twenty different sentences from the test set using each of the seven models. We prepare user study by picking five samples rendered by each model to make a survey. Annotator rates each sample on a Likert scale of one for 'completely unnatural' to five for 'completely natural'.

To evaluate the emotional expressiveness of the proposed model, we perform two surveys. In the first survey, given a sample, we ask the user to choose the best perceived emotion from a set of four, namely, 'Happy', 'Sad', 'Angry' and 'Fear'. We ask the raters to not judge the textual content and annotate the emotion for each sample based on the rendering alone. In the second survey we evaluate the efficacy of the models to bring about finer control over emotion. We generate two samples with same broader emotion category but with two levels of intensity. The subject now has to identify the sample with higher intensity. For both surveys we generate five samples per emotion and twenty samples for each model. We aggregate the rating across forty proficient English language speakers.

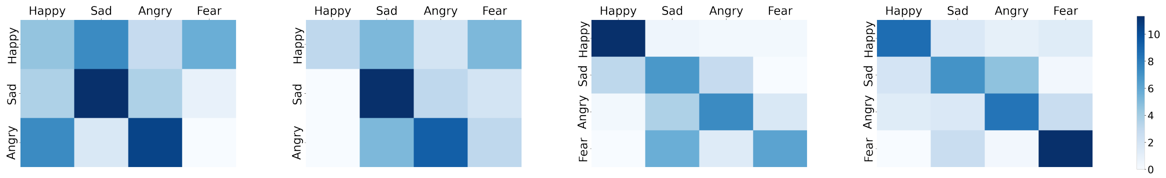
5.2 Emotional consistency in dialogues

Previous efforts in prosody controlled TTS have been evaluated on individual sentences without context. We propose a novel evaluation strategy using excerpts from theater recordings. We replace the audio of one of the actors in the conversation with renderings from a TTS model and have a human subject evaluate it for emotional consistency. The emotion for TTS renderings are chosen manually by a theater director. We compare this with TTS rendered with emotion predicted using TodKat (Zhu et al., 2021) from the dialogues spoken so far. This study consolidates the two aspects of HCI we mentioned in the introduction; prosodic emotion recognition and its expression in TTS utterances.

The dataset is curated using segments from four popular plays, namely, 'Speed-the-Plow', 'Night, Mother', 'Bobby Gould in Hell' and 'Death of a Salesman'. We select 30 dialogue segments collectively from the four plays with an average dialogue length of 90 seconds per segment. Timestamps of segments selected from each play is given in supplementary material. We replace the female voice in the segment with (a) non-emotive TTS model (FastSpeech2π) (b) our model with emotion predicted for each utterance using TodKat and (c) our model with a senior theatre director picking the emotion for each utterance. We randomly pick five

Model	MOS	Finer Control	Coarse Control				
			Happy	Sad	Angry	Fear	Average
FastSpeech2	3.80±0.13	-	-	-	-	-	-
FCL-taco2	3.39±0.14	-	-	-	-	-	-
FastSpeech2π	3.84±0.13	-	-	-	-	-	-
FastSpeech2π + EVA (Blizzard)	2.95±0.14	-	-	-	-	-	-
Cai et al., 2021	3.08±0.16	80.0	22.7	40.9	52.3	-	38.7
FastSpeech2 + EVA (av)	3.01±0.12	81.2	20.0	68.7	52.9	-	47.2
FastSpeech2 + EVA (avd)	3.05±0.17	80.2	37.5	66.6	50.0	33.3	46.8
FCL-taco2 + DS (our model)	3.30±0.14	83.5	90.1	53.3	56.5	46.8	61.8
FastSpeech2π + DS (our model)	**3.91±0.14**	**85.0**	68.4	50.0	59.5	79.1	**64.2**

Table 1: Results for qualitative analysis comparing our model with prior art. The model with (av) only uses arousal and valence for emotion representation while that with (avd) also uses dominance values. See Section 6 for details.



(a) Cai et al. (2021) (b) Sivaprasad et al. (2021) (c) FCL-taco2 + DS (d) FastSpeech2π + DS

Figure 4: Confusion matrices of models performance in the survey to pick the correct emotion. Rows are true emotions and columns are picked emotions. Figure to be viewed in color.

dialogues from the 30 samples in all three settings for each of our surveys. We ask forty raters to rank the three setting in terms of the emotional consistency of the dialogue *i.e.*, to judge the naturalness and aptness of the emotional prosody in the given context.

5.3 Conversation with Meisner trained actor

A Meisner trained actor responds to another actor taking into account his/her behavior. In this experiment, we observe how a Meisner trained actor (Actor M) reacts in a live dialogue initiated by (a) another trained human actor, (b) a non-emotive TTS (FastSpeech2π) and (c) our model (FastSpeech2π + DS). We use the same neutral script with 18 lines in all three cases. We use the behavior of Actor M during interaction with the human as reference. The closeness of Actor M's behavior to this reference while interacting with the two TTS models is used as a measure of the latter's effectiveness in rendering speech expressive enough to evoke an emotive response.

For each of the three scenarios, the conversation is initiated with two different emotional states, viz. (a) highly positive and (b) highly negative. The emotion for our TTS model is chosen live on-the-fly by a theatre director from fourteen bins in the discretized arousal-valence space. The bins are chosen to span the V-shape around high-arousal-high-valence and low-arousal-neutral-valence (Dietz and Lang, 1999). We take majority vote of three listener ratings for each utterance of Actor M on the same discretized arousal-valence space to allow quantitative comparisons.

6 Results

6.1 Comparing with prior art

Naturalness. Table 1 compares the audio quality of the TTS models listed in Section 5.1. It can be seen that the proposed model achieves affective control, without drop in perceived audio quality. In contrast, previous SOTA emotive models (Cai et al. (2021) and FastSpeech2 + EVA) achieve control over emotion at the cost of naturalness (MOS of 3.08 and 3.01 respectively). This result demonstrates the efficacy of using DS module over EVA and validates its ability to disentangle affective features from the acoustic ones. The MOS score of FastSpeech2π improves with addition of DS, as some samples appear more natural when rendered in intended emotions.

Coarse affective control. Results corresponding to emotion detection are presented in Table 1. For each sample, the raters were asked to choose one among the four discrete emotions. On an average, the FastSpeech2π + DS gives best results, outperforming the other models by a significant margin. We observe about 17 and 25.5 improvement in percentage points (pp) over FastSpeech2 + EVA and (Cai et al., 2021) respectively. Figure 4 shows the confusion matrix for this survey. Our models are better at differentiating positive valence emotions from the negative ones. There is still a scope of improvement in distinctly expressing low valence emotions.

Finer affective control. When asked raters to pick the sample from a pair that expresses a particular emotion better, 85% of the times they were able to pick the sample that was actually rendered with a higher arousal value (Table 1). Our best performing model scores 3.8pp over FastSpeech2 + EVA and 5.0pp over (Cai et al., 2021).

Efficacy of DS. To further validate the efficacy of DS (over the EVA), we present evaluations to show that the performance gains occur primarily due to the DS module and not the other interventions. We observe that adding 'dominance' to Fastspeech2 + EVA does not improve its MOS and affective controllability as shown in Table 1. Furthermore, we observe performance drop on Fastspeech2π + EVA when compared against Fastspeech2π + DS when both have their backbones trained on Blizzard dataset (Table 1). The lack of improvement from (Sivaprasad et al., 2021) further highlights that the performance gains by our model does not come from the choice of dataset on which the backbone is trained. Overall, the two experiments conclusively show that DS module is the decisive component that brings the improvements in naturalness and controllability to the proposed TTS system.

6.2 Emotional consistency in dialogues

As described in Section 5.2, we evaluate the emotional consistency of a dialogue when a TTS model replaces an actor in excerpts from a play. Figure 5 shows that emotive models bring significant improvement in emphatic quality of conversations and are picked 80% of the times as the first preference. This result reiterates the hypothesis (Wang et al., 2018) that prosody averaging as in non-emotive TTS is insufficient for emulating emotionally consistent conversations.

Another important observation is how emphatic quality measured as user's first preference falls from 52% to 27% in moving away from hand-picked to model-predicted emotions. This suggests a scope for improvement for emotion prediction models. Nonetheless the results present clear evidence that tying together emotion prediction models to expressive TTS is significantly more preferable to a non-emotive TTS.

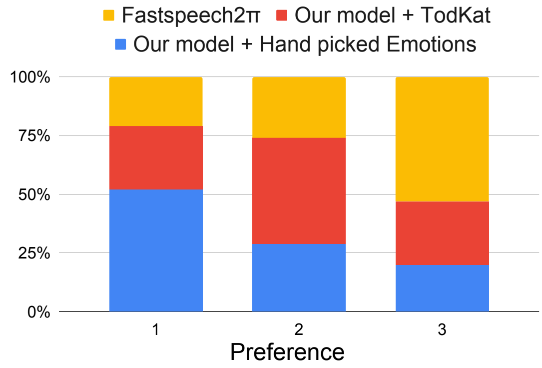


Figure 5: Comparison of emotional consistency in conversations across the three settings described in Section 5.2. Figure to be viewed in color.

This proposed evaluation methodology is more comprehensive and enables assessment of a consolidated conversational system as required in expressive HCI that includes various moving parts like causal emotion recognition in conversation and expressive TTS. This is not feasible with the traditional approach of evaluating on individual sentences drawn from distinct contexts. We argue that this evaluation with contextual dialogues from a conversation is more coherent to humans as reflected in inter-annotator agreement measured by Fleiss's Kappa Score (FKS). FKS goes up by 34% from 0.43 in traditional coarse affective control (Table 1) to 0.58 for our evaluation strategy (Figure 5). We hope this will be useful in a more thorough evaluation of expressive HCI systems.

6.3 Conversation with Meisner trained actor

As mentioned in Section 5.3, we gather the behavioural response of a Meisner trained human actor to TTS systems (emotive and non-emotive) and compare it against his/her reference response to another human actor. We use Pearson's correlation ρ with reference for valence and compare mean-std (μ, σ) for arousal values.

When the conversation was triggered with a positive initial emotion, we had a high ρ(FastSpeech2π+DS, human) of 0.702 for our model compared to negative correlation for non-emotive TTS at ρ(FastSpeech2π, human) of

-0.282. Similarly for a negative initial emotion ρ(FastSpeech2π+DS, human) was high 0.838 relative to low ρ(FastSpeech2π, human) of 0.158.

We find that the average arousal for the human response to our TTS (μ=3.5, σ=1.06) is comparable to a human-human conversation (μ=3.94, σ=0.97), as opposed to the response to a non-emotive TTS (μ=2.55, σ=0.49). This indicates that the range of arousal response elicited from a human actor by our TTS is comparable to a human-human conversation as opposed to that of a prosody unaware TTS.

We also interviewed the human actor about the experience of conversing with the TTS systems. He reported that our TTS gave him "an emotional structure". He felt that the TTS could "dictate the neutral part of the script to change it". He could "remember specific utterances" by our TTS and their emotional content which "drove him" to respond in an emotional manner. In contrast, he reported that the prosody unaware TTS gave "dry answers", made him feel that it was "disinterested", "auto generated" and "did not evoke excitement". He expressed that he "could not have a longer conversation with it".

7 Conclusion

This work presents a novel method that leverages prosodic features (pitch, energy and duration) to modify emotions in the output of a TTS system. Our method is model agnostic and can be used with any TTS backbone that predicts prosodic features in an intermediate step. This method outperforms existing approaches by a significant margin in its ability to accurately render desired emotions, while preserving the naturalness of speech. We curated theatre conversation data to evaluate and show that our prosody-aware TTS better maintains the natural flow of emotions in conversations. Our work shows promise in consolidation of prosodic emotional recognition and expression, a coveted pursuit in the field of HCI. We present further qualitative experiments involving professional theatre artists and demonstrate that the proposed TTS method leads to more human-like conversations. While exposing valence, arousal and dominance values as model levers improves control over the final rendering, in reality it is overwhelming for the user to choose them correctly for a desired output. This is further aggravated by the fact that some sentences cannot be suitably spoken with a chosen set of values, degrading output quality. These are limitations that need to be addressed and appropriately deriving these values from semantics of text input or reference clips could be relevant future directions. Affective control is incomplete without explicit levers on the intonations, which is another limitation to be looked upon in the future work.

8 Ethical concerns

This work shares the same concerns as with others in the domain of TTS systems as discussed by Habib et al. (2019). With TTS outputs getting closer to actual human speech, there could be a potential misuse. The threat of abuse of fake voices is particularly high with similar developments in conjugate areas like computer vision. However, the benefits of improvements to emotive TTS technology could significantly benefit HCI and the corresponding applications to problems in healthcare and other domains. Example applications include healthcare dialogue systems, improving social interaction skills in people with autism and augmentative communication devices. TTS systems synthesizing speech with empathy can ease machine interaction in many touchpoint applications. While the benefits seem to outweigh the concerns at this point, we believe the research community should proactively continue to identify methods for detection and prevention of misuse.

Abstract

Natural language as a modality of interaction is becoming increasingly popular in the field of visualization. In addition to the popular query interfaces, other language-based interactions such as annotations, recommendations, explanations, or documentation experience growing interest. In this survey, we provide an overview of natural language-based interaction in the research area of visualization. We discuss a renowned taxonomy of visualization tasks and classify 119 related works to illustrate the state-of-the-art of how current natural language interfaces support their performance. We examine applied NLP methods and discuss human-machine dialogue structures with a focus on initiative, duration, and communicative functions in recent visualization-oriented dialogue interfaces. Based on this overview, we point out interesting areas for the future application of NLP methods in the field of visualization.

1 Introduction

Natural language as a modality for interacting with visual models enjoys increasing popularity in human-computer interface research in the fields of Human-Computer-Interaction (HCI) and Visualization (VIS) (Yu and Silva, 2020; Srinivasan et al., 2020a; Liu et al., 2021; Narechania et al., 2021; Kim et al., 2021c). At the same time, interest in tasks involving the visual modality has grown strongly in NLP research in recent years (Suhr et al., 2017; Hudson and Manning, 2019; Acharya et al., 2019). While there are common interests and parallel trends in VIS and NLP, research in these fields often adopts different perspectives on what interaction is and how it should be modeled. Broadly speaking, in the VIS community, a lot of research aims to understand **why** users need to interact with a visualization and what users' *intents* are when they interact with a visual model (Dimara and Perin, 2020). Therefore, Brehmer and Munzner (2013) categorize users' data-related intents into *visualization tasks* and introduce a taxonomy to describe them in general terms and compare them among applications. Recent contributions show that different forms of natural language-based interaction prove suitable to support users in accomplishing various visualization tasks. This concerns not only the popular query interfaces, but also, on a broader scale, the provision of recommendations, annotations, explanations, documentations, or for support in analytical conversation. However, the variety of existing visualization tasks benefiting from natural language interaction beyond simple query interfaces has not yet received much attention in the NLP community. On the other hand, modern NLP methods offer enormous potential for modeling multi-modal dialogues in the visualization tasks.

In this survey, we aim to complement the why-oriented perspective of classifying visualization tasks by intent in VIS with the how-oriented dialogue modeling perspective in NLP for works involving natural language interaction. To substantiate the classification of the papers, we first delimit the scope of the survey and explain the methodology employed to derive the selected papers in Section 2. We discuss the taxonomy of abstract visualization tasks by Brehmer and Munzner (2013) as the basis for the classification in Section 3 by explaining **why** interaction with a visualization is performed. Section 4 focuses on **how** interaction is implemented in the works at hand in terms of applied *NLP methods* as well as characteristic *structures* in human-machine dialogue (Bunt et al., 2010). Finally, challenges arising from current approaches are pointed out. As such, the need to compile reliable data sets to support the adoption of deep learning-based NLP methods in the field of VIS yields promising space for future creative work.

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 348 - 374
July 10-15, 2022

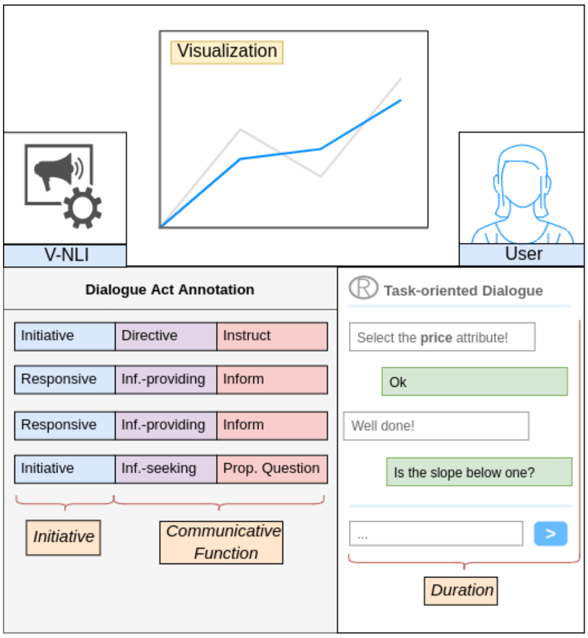

Figure 1: Investigation of dialogue structures as applied in visualization systems based on the DIT++ taxonomy of dialogue acts by Bunt (2009).

Related Surveys. The survey of Shen et al. (2021) considers 55 visualization-oriented natural language interfaces (V-NLI) at the intersection of NLP and VIS. The work focuses on the applicability of natural language interfaces at the different steps of the information visualization pipeline by Kard et al. (1999). The authors discuss query-based language interfaces in detail. Similarly, Özcan et al. (2020) put their focus on querying data visualizations using natural language. However, querying a visualization interface is only one possible language-based interaction among many such as *annotation, description generation, documentation*, and others. Klopfenstein et al. (2017) conduct a more general study on the application of conversational interfaces and derive usage patterns and paradigms for their implementation. Further related work is done at the intersection of Machine Learning (ML) and VIS as by Wu et al. (2021) or Wang et al. (2020), who illuminate where and how ML gains ground in VIS and discuss future directions for applying ML in VIS research. Facing that, we identify substantial ground for a survey that examines current natural language interaction techniques supporting the accomplishment of visualization tasks. Related work in VIS yields comprehensive and well-conducted state-of-the-art surveys focusing on **where** dialogue systems can be integrated into the information visualization pipeline proposed by Kard et al. (1999). This work is complementary in that it illuminates from an NLP perspective **how** visualization-oriented dialogue is structured in terms of *initiative, duration*, and present *communicative functions* within the respective visualization task at hand (see Figure 1). By shedding a light on this we hope to arouse interest in the NLP community for the interesting multi-modal dialogue modeling tasks emerging at the intersection of NLP and VIS.

2 Methodology

For a paper to be included in the survey paper selection, it must meet the following criteria:

- Language-based interaction must be a designated **input/output modality** and some kind of language interface must be provided for it, e.g., a text box or a microphone/speaker.
- Language-based interaction must serve to fulfill or support a main **visualization task**. For example, using natural language for *logging* into an application is **neither** a visualization task **nor** does it support the accomplishment of that task and is, therefore, **not valid**. In contrast, using natural language to *annotate* certain aspects of a visualization **is** considered supportive of achieving the goal of the visualization task and therefore **is valid**.

In addition to contributions that include concrete implementations of interaction scenarios, theoretical papers that discuss design spaces or considerations of language-based interaction possibilities are included. The aim is to explicitly show not only what has already been implemented, but also which interaction possibilities are conceivable and useful in multi-modal visualization-oriented dialogue. The paper selection is made in a two-stage process. First, a set of *seed papers* is derived from conference proceedings of the main conferences in HCI, namely *SIGCHI*, VIS, namely *IEEE VIS, PacificVIS,* and *EuroVIS*, and NLP, namely *ACL* and *EMNLP*, starting from the year 2010 until 2021. The papers are filtered using the keywords *language, visualization, interface* in combination with a semantic embedding map of the abstracts based on Reimers and Gurevych (2019). The exploratory process results in a set of 76 papers. In the second stage, the references of the seed papers are examined and relevant papers that meet the specified criteria are included in the set. This results in a final set of 119 papers. For a detailed insight into the scope of the survey, we refer to Appendix A.

3 Why Users interact with Visualizations

Brehmer and Munzner (2013) introduce a multi-level typology for abstract description and comparison of visualization tasks between applications. An abstract visualization task represents a high-level description of *why* interaction with a visualization application is performed, *how* it is performed, and *what* the input and output of the task are. The *why*-branch of Brehmer and Munzner's typology was chosen primarily for three reasons: First, the high level of abstraction allows to cover a high number of visualization tasks and therefore ensures high representativeness. On the other hand, the modular character of the typology is beneficial for breaking down complex tasks into smaller subtasks in which commonalities can then be identified. In addition, the combination with the *what* and the *how* branch offers the possibility to describe task chains, which can serve as a blueprint for the design of a dialog with the system. The papers are classified on the basis of the **why**-branch of the taxonomy because it distinguishes the tasks taking into account the *goal* to be achieved and thus corresponds to the *goal* definition as also used in goal-oriented dialogue modeling (Bordes et al., 2016; Li et al., 2017; Liu et al., 2018). The why branch spawns the abstract visualization tasks *present, discover, enjoy*, and *produce* illustrated in Figure 2. Following Munzner (2009), **we consider language-based interaction as domain- and interface-independent operations performed by users and/or systems by applying natural language in any kind of representation, e.g, written- or spoken text**. Table 1 shows an overview of the contributions and the respective visualization task to which they are assigned. In the following subsections, concrete tasks involving natural language interaction are presented for each abstract visualization task of the taxonomy. Each section includes a brief definition of the targeted visualization task and a detailed discussion of current related work that addresses it. For a detailed inspection, we refer to Appendix B.

3.1 Present Task

Brehmer and Munzner (2013) define presentation as *'the use of visualization for the succinct communication of information, for telling a story with data, guiding an audience through a series of cognitive operations'*. During this task, natural language is used to complement the presentation of visual findings and results, for data-driven storytelling, or to explain, evaluate and discuss them.

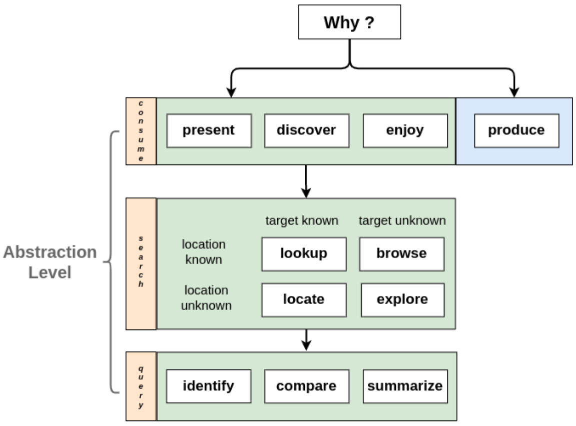

Figure 2: **Why**-branch of the Multi-Level Typology of Abstract Visualization Tasks inspired by Brehmer and Munzner (2013).

Visual Storytelling. Visual storytelling considers the communication of knowledge to a broad audience using visual and textual elements that follow a coherent narrative. The main idea is to match linguistic and visual elements and arrange them consistently within a story. Von Landesberger et al. (2021) study how text and visualization interact with each other in a visual storytelling scenario pointing out that visualizations complement the narrative by providing overview, details, and comparison. Automatic story generation is done by Shi et al. (2021) who leverage the generation of a visual story from spreadsheet input. Natural language text drives the story of a visualization presentation in Kwon et al. (2014); Bryan et al. (2017); Metoyer et al. (2018). Users are guided through the story by interacting with the text segments and the system creates visual animations correspondingly in response.

Explanation Generation. Visualizations offer great potential to create understanding for complex issues among different user groups. In contrast to storytelling, explanation generation is not about assigning a sequence of visual elements to a text-based story, but about automatically explaining given visual facts through natural language texts. Combining text and visualization is used to explain complex processes, e.g., in verbalizing the functionality of ML models (Hohman et al., 2019).

Visualization Task	Subtask	#	Representative Paper(s)
Present	*Visual Storytelling*	6	(Kwon et al., 2014; Metoyer et al., 2018)
	Explanation Generation	3	(Sevastjanova et al., 2018; Hohman et al., 2019)
Discover	*Keyword Search*	15	(Isaacs et al., 2014; Feng et al., 2018; Schleußinger and Henkel, 2018)
	Querying	45	(Setlur et al., 2016; Yu and Silva, 2020; Narechania et al., 2021)
	VQA	3	(Mathew et al., 2021; Chaudhry et al., 2020)
	Browsing	7	(Setlur et al., 2020; Luo et al., 2020; Srinivasan and Setlur, 2021)
Enjoy	*Augmentation*	12	(Srinivasan et al., 2019b; Hullman et al., 2013)
	Description Generation	14	(Obeid and Hoque, 2020; Hsu et al., 2021)
Produce	*Annotation*	7	(Chen et al., 2010b; Ren et al., 2017)
	Documentation	1	(Nafari and Weaver, 2015)
	Visualization Creation	6	(Cui et al., 2020; Fulda et al., 2016)

Table 1: Classification of papers based on the Multi-Level Typology of Abstract Visualization Tasks by Brehmer and Munzner (2013). For the sake of clarity, papers are classified into the most suitable category only, although some works touch on several categories in terms of content. A comprehensive listing can be found in Appendix B.

Sevastjanova et al. (2018) discuss strategies on how to present language explanations during the model inference process and the interaction techniques to be required, such as *details-on-demand, guidance, dialogue*, and *exploration*.

3.2 Discover Task

Using natural language to discover information is one of the most common visualization tasks targeted by V-NLI. Brehmer and Munzner (2013) differentiate between different levels of task granularity such as *discover - search - query* (see Figure 2). The discovery of concepts, objects, and relationships in a visualization depends on the role that the user and the interface take in the visualization-oriented dialogue, as well as on the concreteness of the user's intent. Intents are formulated in oral or written form. Less concrete user intents lead to a more exploratory character of the search. Concrete intents formalized in a query lead to a specific system response. Vague and fuzzy intents are much more difficult to formalize in a single query and must be inferred by the V-NLI through the application of intelligent recommendations or user guidance.

Keyword Search. Discovering information about a visualization by supplementing it with a keyword search interface is examined by Feng et al. (2018). The authors enable the search of visual concepts in a 2D visualization via text input. Further visualization-oriented keyword search interfaces are applied in Chowdhury et al. (2021); Siddiqui and Hoque (2020); Chung et al. (2010). In contrast to that, visual search interfaces take in keywords but focus on displaying results in a way that facilitates visual exploration, as targeted in Wilson et al. (2010); Schleußinger and Henkel (2018); Peltonen et al. (2017). Search history and coverage are tracked and visualized by Isaacs et al. (2014).

Natural Language Querying. Natural language querying is a scenario in which a user formulates a query to a visual model and the system is tasked with outputting a visual response to that query – referred to as *query2viz*. Most of the existing V-NLIs focus on this task. Theoretical work on utterance structures in natural language querying has been done by Srinivasan et al. (2019a, 2021b) finding that utterances mainly target *attribute, chart type, encoding, aggregation*, and *design* aspects of a visual model. Liu et al. (2021); Sun et al. (2014);

Narechania et al. (2021) generate a visualization based on a data table and a natural language query. Yu and Silva (2020) allow query sequences to be specified in a visual exploration workflow.

Ambiguities. Resolving ambiguities and underspecified utterances poses a difficult problem in this visualization task, especially for single-turn query interfaces. Hearst et al. (2019); Tory and Setlur (2019) develop design guidelines for how systems should respond to queries that contain vague modifiers or -user intents by exploring contextual inference strategies. Gao et al. (2015) manage ambiguities in input utterances using visual ambiguity widgets. Setlur et al. (2019) apply inferencing rules based on known syntactic and semantic input structures. Setlur and Kumar (2020) use word co-occurrence in combination with sentiment analysis to determine data attributes and filter ranges associated with the articulated vague property.

Hypothesis Verification. Discovering novel insights from data is usually done by (dis-)validating hypotheses. Choi et al. (2019a,b) study the use of visualizations to prove or disprove natural language hypotheses visually. The user initiates a hypothesis test by formulating it in natural language, and the system indicates the match with the underlying data set by creating a graph that highlights matches/discrepancies in striking green/red colours.

Query Dialogue. Setlur et al. (2016); Aurisano et al. (2016); Bacci et al. (2020) extend the single-turn *query2viz* interaction to a multi-turn interactive visual exploration also referred to as *analytical conversation*. Analytical conversation is the support of visual analysis processes by V-NLI with the aim of inspecting visual features through a visualization-oriented human-machine dialogue, as studied by Turkay and Henkin (2018); Aurisano et al. (2015). In contrast to *visualization creation* (see section 3.4), where visualizations are generated based on natural language text, the manipulation or composition of a visualization in the *query dialog* is used in the sense of a speech act. The produced or manipulated visualization can be seen here as a dynamically generated visual response to a user query with the goal of providing information in the dialog. Setlur and Tory (2017); Hoque et al. (2018) apply pragmatics to visualization-oriented dialogue modeling by taking the dialogue history into account for computing more adequate future responses. Visualization-oriented dialogue assistants have been developed in various forms. General-purpose assistants for driving a visual analytics conversation are proposed by Fast et al. (2018); Kassel and Rohs (2018). Assistants implementing instruction following as in plot manipulation or navigation scenarios process and execute commands in a visualization environment (Shao and Nakashole, 2020; Wang et al., 2021). Multi-modal dialogue assistants combine natural language input in oral or written form with touch gestures (Srinivasan and Stasko, 2018; Kim et al., 2021c; Srinivasan et al., 2020a, 2021a). Sperrle et al. (2020, 2021) study adaptive guidance to support a visual analytics process. Collaborative approaches using mixed-initiative interactions for visual analytics are explored by Hu et al. (2018); Langevin et al. (2018). The potential of competitive visualization-oriented dialogue interfaces for educational purposes is theoretically investigated by Reicherts and Rogers (2020) by examining the role of questions in these dialogues. Kumar et al. (2020b) provide a data set of contextualized dialogue acts in a visual exploration scenario as a basis for training dialogue assistants.

Visual Question Answering. VQA is a well-studied task in Language & Vision (Antol et al., 2015; Yang et al., 2016; Anderson et al., 2018) with the goal to answer questions related to the visual content of images. In VIS, the aim is to answer complex questions related to visual models such as charts or scientific illustrations as in Singh and Shekhar (2020); Chaudhry et al. (2020). Infographics as sophisticated arrangements of visual elements and text are supported by VQA in Mathew et al. (2021). Meeting the high informative standards of response generation required to harness the explanatory purposes of visualizations presents itself as a challenging task.

Browsing. Browsing supports users with a vague or fuzzy data-related intent in discovering visualizations. The idea is to narrow down the user intent through language interaction using text input, multi-step questions, or dialogue and suggest appropriate next steps in the interaction with the visualization. Luo et al. (2018) use keyword input to execute personalized *visualization recommendations*. Other approaches leverage auto-completion in text input (Setlur et al., 2020; Dhamdhere et al., 2017) or use multi-step question procedures to restrict the user's target area (de Araújo Lima and Barbosa, 2020; Luo et al., 2020). Srinivasan and

Setlur (2021) recommend data-related utterances users can use to start a visual analysis or shimmy along. Lee et al. (2021) guide users through a visualization-oriented analytical conversation using insights found in the data similar to Cui et al. (2019).

3.3 Enjoy Task

Brehmer and Munzner (2013) consider enjoying as the *'casual encounter'* with a visualization without having a concrete hypothesis to verify. Natural language enhances the perception of a visualization by displaying additional information such as captions that contextualize the visual experience, as applied in immersive experiences, exhibitions, or museums. Visually impaired people experience visualizations through translation into auditory language.

Augmentation. In augmentation, visualizations are complemented by automatically generated textual elements, such as *labels* or *links*. Srinivasan et al. (2019b); Hullman et al. (2013) augment visualizations with additional facts to substantiate the message to be transmitted. Kandogan (2012) propose the concept of just-in-time augmentation of visual structures during visual analytics to help users understand the structure of the data. Lai et al. (2020) automatically annotate visualizations based on their textual description. Lallé et al. (2021) highlight corresponding elements of a visualization based on tracked gazes of users as they read a text description associated with the visualization. In contrast to that Xia et al. (2020) augment audio podcasts with visual elements. Gao et al. (2014); Latif and Beck (2019) augment map visualizations by automatically mining and linking site-related facts out of articles to their location on the map. Augmentation is also used to textually describe GUI components automatically as a preliminary step for auditory scene description helping visually impaired people interact with visualizations (Chen et al., 2020a).

Visualization Description Generation. Textual descriptions for visualizations are created to complement visual elements during the encounter with a visualization. Spreafico and Carenini (2020); Qian et al. (2021b); Liu et al. (2020) complement visualizations with text analogously to image captioning (Vinyals et al., 2015; Xu et al., 2015). Murillo-Morales and Miesenberger (2020) generate auditory descriptions to make statistical charts accessible to visually impaired people. Hsu et al. (2021) captions scientific illustrations with highly informative labels that meet scientific quality standards. *Summarization* of visualization content into textual form is researched by Demir et al. (2012); Moraes et al. (2014). Bylinskii et al. (2017); Madan et al. (2018) extend this to aggregating infographics into a single descriptive hashtag. Theoretical work on how charts and their descriptions are linked and verbalized by users is carried out in Kim et al. (2021a), where it is found that users tend to retain different amounts of information depending on how prominent the visual feature presented in the caption is.

3.4 Produce Task

Brehmer and Munzner (2013) refer to produce as a *'reference to tasks in which the intent is to generate new artifacts'*. Artifacts generated through natural language interaction are, e.g., *annotations* of objects in a visualization, *scene descriptions*, or *task reports* as used, e.g., in medical visual analysis.

Annotation. Annotating areas of interest, comparing them among each other, and sharing them with colleagues is a common language interaction while working with visualizations (Ren et al., 2017). Chen et al. (2010a,b) leverage touch and click interactions for situated visualization annotation. Latif et al. (2018, 2021) explore the possibilities of linking text and visualization. Sperrle et al. (2019) study the visual annotation of argumentation and how this facilitates analysis. Theoretical work on the sustainable extraction of knowledge from visualization annotations is provided by Vanhulst et al. (2021), who propose a classification framework that enables a structured capture and ordering of annotations.

Documentation. Visualization systems are used by experts, e.g., in the medical domain (Meuschke et al., 2021) to plan and discuss a surgery. Reporting, summarizing, and sharing this visualization-related work is an important task that is an additional burden to the surgeon and therefore should be executed by a machine. Nafari and Weaver (2013, 2015) generate natural language questions from queries executed on a visualization resulting in a natural language translation of the interaction. This leaves a step-by-step report of the interaction finding usage as a report of done work.

Visualization Creation. Visualization creation considers the production of a visual model from a natural language description – also referred to as *text2viz*. Rashid et al. (2021) generate chart visualizations from natural language text input. Collaborative authoring tools assisting users in visualization creation use natural language as an input modality. Cui et al. (2020) provide a tool that generates infographics using natural language statements as input, similar to Qian et al. (2021a). Fulda et al. (2016) design an interactive production process for generating timelines from unstructured text input. Language-based 3D scene generation, also referred to as *text2scene*, which allows users to describe 3D scenes using text without having to learn software tools, is investigated in Coyne and Sproat (2001); Coyne et al. (2012); Ulinski et al. (2018).

4 How Users interact with Visualizations

After discussing **why** users interact with visualizations using natural language, Section 4 provides a complementary discussion of **how** these interactions are modeled. First, in Section 4.1 it is explained which NLP methods are used in these systems. Subsequently, Section 4.2 summarizes the structure of the visualization-oriented dialogues in the analyzed paper set in terms of *initiative, duration*, and present *communication functions* within the respective visualization task.

4.1 NLP Methods

For each paper in the collection, both the NLP methods used, if any, and if named the specific NLP toolkits used for implementation are elaborated. For the sake of clarity, the methods are roughly divided into two areas: *Natural Language Understanding (NLU)* and *Natural Language Generation (NLG)*. The majority of the systems apply standard NLP methods like *tokenization, stemming* or *stop-word removal* to pre-process text inputs, which is why these are not recorded separately. For a detailed inspection, we refer to Appendix C. Figure 3 shows the distribution of applied NLU methods over all papers. *Semantic Parsing*, which relies on rule-based mapping procedures from recognized input tokens to semantic predicates, is predominantly used. Often, *POS-Tagging, Word Embeddings*, and *Named Entity Recognition (NER)* are additionally applied to increase the accuracy of the mapping. For *Word Sense Disambiguation* WordNet, VerbNet or ConceptNet are leveraged. *Speech-to-Text* APIs are a common method used in many systems to enable auditory input. A small number of pioneering systems integrate more sophisticated NLP methods such as *Sentiment Analysis, Vector Search* or *Co-Reference Resolution*. One main reason for the hesitant use of deep learning methods is the high demands on performance and robustness of visualization systems as Dhamdhere et al. (2017) points out. Fluid interaction between user and system in real time is a crucial factor for the success of a visualization application. Adopting state-of-the-art deep learning models to real-time interactions in visualization, e.g., by using *Knowledge Distillation* (Hinton et al., 2015) or *Quantization* (Jacob et al., 2018) leaves space for future work. Figure 4 shows the distribution of applied NLG methods over all papers. *Template-based* language generation is used by the majority of the systems followed by a significantly smaller number of deep learning-based *Seq2Seq Modeling* approaches. Multi-turn systems are predominantly based on rule-based or probabilistic *Dialogue Management*. Only a few systems use the *Text-to-Speech* functionality, as most of the generated responses consist of visual elements. In order to advance the adoption of deep learning-based methods in visualization-related text generation, extensive training data sets are required, as pointed out by Kumar et al. (2020a). There is a

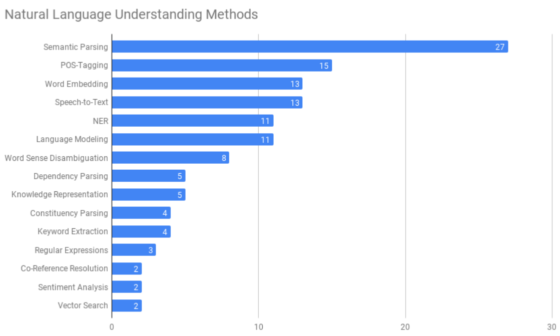

Figure 3: Distribution of NLU methods **over all papers.**

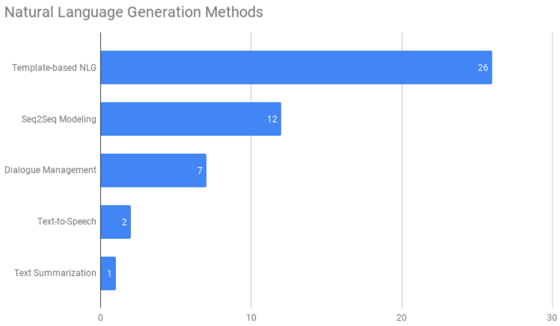

Figure 4: Distribution of NLG methods **over all papers.**

limited number of data sets for *Visualization Description Generation* (Obeid and Hoque, 2020), *Visual Question Answering* (Mathew et al., 2021; Kim et al., 2020) and *Natural Language Querying* (Fu et al., 2020; Srinivasan et al., 2021b; Luo et al., 2021). In particular, the compilation of data sets for emerging dialogue scenarios in *Analytical Conversation, Hypothesis Verification* or collaborative authoring in *Visualization Creation* would motivate the use of deep learning based NLP methods in these tasks. Therefore, generating high-quality data sets for the aforementioned visualization tasks leaves room for future work.

4.2 Dialogue Structures

The study of structures in visualization-oriented dialogue is done with the idea of identifying task-specific patterns, as shown in Figure 5. The structural analysis is based on the work of Bunt (2009) and highlights, in particular, the *initiative, duration*, and *communicative functions* present in the modeled dialogues. For each contribution that provides access to sample data illustrating human-machine dialogue within the paper or supplementary material, the presence of the communicative functions *information providing, information-seeking, commissive*, or *directive* for the user and system is detected. A comprehensive list of allocations is presented in Appendix C. Bunt's DIT++ taxonomy was chosen due to the fact that it focuses on the **function** of the individual speech act. In the context of a visualization task, it is important which function a dialog act fulfills in the successful execution of this task. This manifests itself particularly in the design of dialog agents, where speech acts that are intended to help solve the task must be specified. Other taxonomies focus on the *rhetorical relations* of speech acts to each other, as in Prasad et al. (2008), or the *emotional* information a speech act conveys in the dialogue, as in EmotionML (Schröder et al., 2011). In contrast to the aforementioned taxonomies, Bunt's taxonomy proves suitable in two respects: It allows to understand how current dialogue situations are functionally structured in the visualization context. In this way, patterns can be identified that are common for the respective visualization tasks. From the generation perspective, it allows to specify dialog actions that need to be prepared in certain visualization task contexts in order to support the solution of the visualization task.

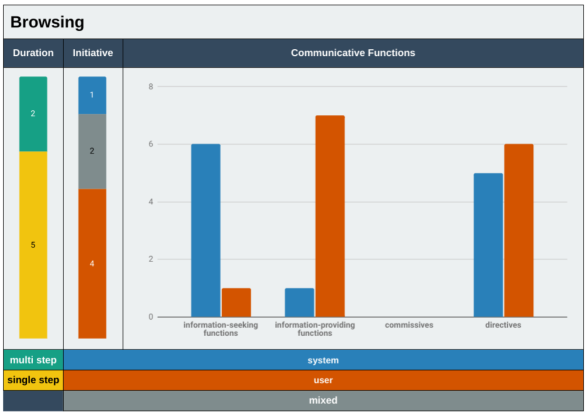

Figure 5: Analysis of *initiative, duration* and *communicative functions* in the sub-task **browsing**.

Present Task. In *Visual Storytelling*, users initiate the interactions which are performed as a sequence of multiple turns triggered through the selection of text phrases. The human-machine dialogue is characterized by the actors complementing each other through text and visual animations as speech acts. Similar to storytelling, the human-machine dialogue in *Explanation Generation* is characterized by a complementing of user input and visualization system output by matching visual and textual elements. Communicating insights found by investigating a visual model is little accompanied by NLP techniques so far compared to other visualization tasks. Template-based story generation systems leave room for innovation in grounding story segments in visualization elements.

Discover Task. The human-machine dialogue in *Keyword Search* is a short, single-turn dialogue characterized by user-initiated text input that is reciprocated by a visual response from the system, similar to *Natural Language Querying*. Keyword-based visualization search relies on text label-only search without including the on-screen representation. This leaves space for grounding abstract visualization concepts like *outliers* or *clusters* in natural language as a promising step towards a generalized visualization search. Keyword search beyond 2D visualizations is an open issue. The modeled dialogue interaction in analytical conversation is a user-initiated dialogue with multiple turns. Visual elements function in the communication as information providers carrying the response. This scenario offers the possibility to apply modern NLP methods to multi-modal dialogues by checking the user's intents and dynamically adapting the user's experience by using the feedback of multiple turns. The implemented systems in *Visual Question Answering* follow a user-initiated, single-turn dialogue approach in which a user question is answered based on textual or visual information the visualization holds. In *Browsing* the initiative in the systems varies between user-, mixed- and system-initiated (see Figure 5) with variable duration. Most approaches focus on high-quality *auto-completion* to lead users, leaving space for innovation in guidance-based dialogue approaches.

Enjoy Task. The predominant features of human-machine dialogue in *Augmentation* are system-initiated single-turn interactions where written or spoken text is used to augment the visual representation. The augmentation of visualizations leaves room for a stronger inclusion of multi-modal interaction triggers such as gazes and gestures in the dialogue conception. *Visualization Description Generation* is characterized by system-initiated single turn systems. *Summarizing* visualizations is a challenge because it requires a high-quality scene description due to the high explanatory potential of visualizations. Particularly visually impaired people benefit from well-designed auditory visualization descriptions, which are a motivation for further improvements.

Produce Task. During *Annotation*, users initiate interactions, which can be continued by system suggestions or completions. Producing artifacts based on a visualization so far relies on template-based authoring tools. *Guidance* and *competition* in *educational contexts*, as well as *the collaboration* of user and system during artifact production, seem to be promising directions for production-supporting human-machine dialogue conception in the future. Authoring tools take the initiative in *Visualization Creation* by suggesting answers or partial task completions. The cooperation with the user appears often in form of a multi-turn production process. *Documentation* is done as a complement of the user's actions, in that the system provides the user with a report of the work performed after or during the user-initiated interaction with a visualization.

5 Conclusion

In this survey, for a renowned taxonomy of abstract visualization tasks, we classified 119 approaches of language-based interaction that support users in pursuing data-related intents. In particular, we shed a light on how the human-machine dialogue is constructed in these works and which NLP methods current V-NLI use. Considering the progress of NLP methods in the field of visualization, we can summarize our work on two main outcomes: A compilation of data sets for the individual visualization tasks seems promising to advance the use of deep learning-based NLP methods; When introducing them, special attention must be paid to performance and robustness aspects due to the high requirements in the VIS area. Finally, the support of visualization tasks through natural language interaction offers a large number of interesting areas for the application of state-of-the-art NLP methods, inviting the NLP and VIS communities to work creatively in the emerging intersection of both fields.

Acknowledgments

We thank the Michael Stifel Center Jena for funding this work, which is part of the Carl Zeiss Foundation-funded project 'A Virtual Workshop for Digitization in the Sciences' (062017-02).

A Scope

Research on visualization-oriented natural language-based interaction is conducted in the VIS, HCI, and NLP communities. For providing an overview of the number of selected contributions per community, the selection set is grouped based on publication venues related to their respective community. Important related work with high subject relevance being derived from other sources is subsumed in the category *Miscellaneous*. The time span of surveyed works is restricted to be between *2010* and *2021*. Next to application papers implementing human-machine interaction theoretical works related to language-based interaction modeling are explicitly included. Table 2 shows the distribution of contributions over community-related venues.

Venues	Papers
Visualization (VIS)	49
Human-Computer-Interaction (HCI)	27
Natural Language Processing (NLP)	9
Miscellaneous	34
Total	**119**

Table 2: Venues of related work

The survey is targeted to touch the intersection of the domains of NLP, HCI and VIS. The scope is defined to reflect on how interaction is modeled and implemented in the different communities as well as to point out how researchers combine different ideas originating from the three fields into work that can be deposited in the intersection of them. For the VIS domain, the most common venues are *IEEE Transactions on Visualization and Computer Graphics* (19) and *Computer Graphics Forum* (5) containing work that is mostly specialized on query-based natural language interfaces. The area of HCI is ostensibly represented by the venue of the *Conference on Human Factors in Computing Systems (SIGCHI)* (14) originating works that consider the interaction aspect and focus on language as a tool that transmits information for reaching a goal. In the NLP domain, the most frequent venue is the *Annual Meeting of the Association for Computational Linguistics (ACL)* (3) including works less visualization-related focusing to a large extent on the dialogue modeling.

B Classification

The contributions are classified based on the Multi-Level Typology of Abstract Visualization Tasks by Brehmer and Munzner (2013). Figure 6 illustrates a distribution of papers over the abstract visualization tasks. The visualization task accommodating the highest number of works considering natural language-based interaction is the task *discover* (70), followed by *enjoy* (26). Contributions supporting *present* (9) and *produce* (14) tasks are less frequent.

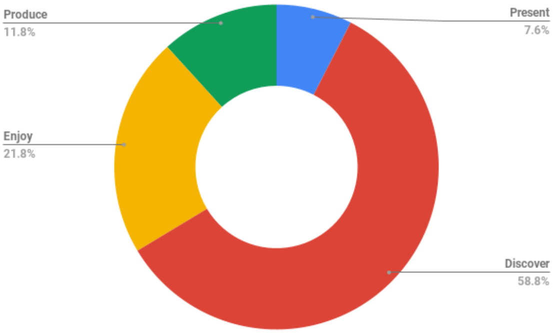

Figure 6: Distribution of papers **over tasks**.

Figure 7 shows the distribution of papers over the inner class sub-tasks. For sake of simplicity, papers are categorized into the single most suitable category only, although some works touch on several categories. *Natural Language Querying* (45) is by far the sub-task with the highest amount of contributions followed by *Keyword Search* (15) and *Visualization Description Generation* (14). Less frequently studied tasks are *Explanation Generation* (3), *Visual Question Answering (VQA)* (3), and *Documentation* (1).

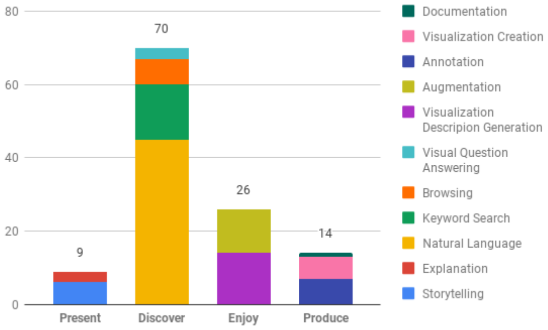

Figure 7: Distribution of papers **over sub-tasks**.

Table 3 contains a comprehensive listing of the classification of the single contributions into the taxonomy by Brehmer and Munzner (2013).

Table 3: Classification of papers based on the Multi-Level Typology of Abstract Visualization Tasks by Brehmer and Munzner (2013).

C Analysis Details

The language-based interaction implemented in the visualization applications is analyzed considering their *initiative, duration* and *communicative functions* present in the human-machine dialogue based on the DIT++ taxonomy of dialogue acts by Bunt (2009). The idea is to create an overview of how the modeled interactions in the respective tasks and sub-tasks are structured. The variables considered in the study and the definitions used for them are explained below. Only contributions that present systems that implement human-machine interaction are part of this examination, theoretical works are excluded. Table 6 contains a comprehensive listing of all contributions evaluated as well as their respective investigation results.

C.1 NLP Methods

For all papers in the selection, the NLP methods used, if any, and if named the NLP toolkits used for implementation are elaborated. For the sake of clarity, the methods are roughly divided into two areas: *Natural Language Understanding (NLU)* and *Natural Language Generation (NLG)*. Due to the fact, that the majority of the systems use standard NLP methods such as *tokenization, stemming*, or *stopword removal* in text pre-processing, these are not recorded separately.

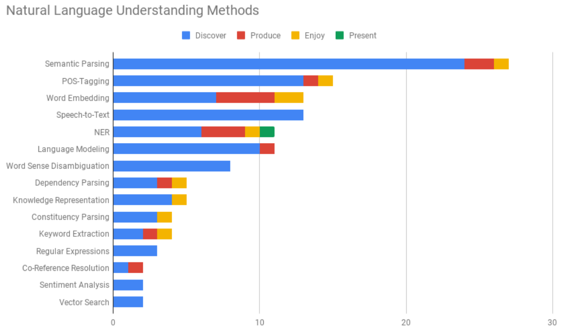

Figure 8: Distribution of NLU methods **per task**.

Figure 8 shows the distribution of applied NLU methods over the four visualization tasks. It can be seen, that in the *discover* task the largest variety of methods is applied. Predominantly used are *Semantic Parsing, POS-Tagging*, and *Speech-to-Text* methods followed by *Language Modeling* and *Word Sense Disambiguation*. Interfaces in *produce* to a greater extend rely on *Word Embedding* and *Named Entity Recognition (NER)*. The *enjoy* task similar to *discover* employs a variety of methods. At *present*, NLU methods are only used to a minor extent.

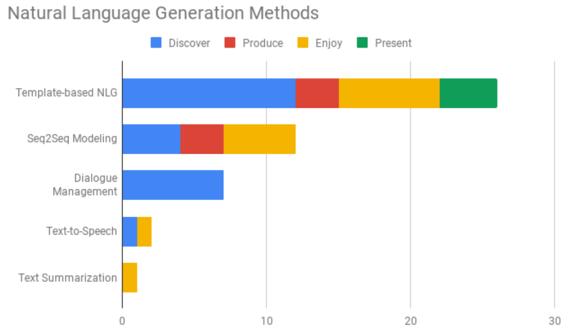

Figure 9: Distribution of NLG methods **per task**.

Figure 9 illustrates the distribution of applied NLG methods over the four abstract visualization tasks. *Template-based NLG* methods are predominantly used to generate text in all tasks at hand. In the *enjoy* task *Seq2Seq Modeling* based on deep learning technologies is primarily used presumably due to the proximity to the common NLP task of *Image Captioning*. The same probably applies to the task of text summarization, which is also carried out. *Dialogue Management* is only applied in *discover*, mostly relying on rule-based or probabilistic modeling methods, e.g., by leveraging *Finite-State-Machine (FSM)* approaches to manage the sequence of dialogue acts. A small number of systems in *discover* and *enjoy* rely on *Text-to-Speech* technologies in the interaction.

NLP Toolkits. An overview of the applied toolkits in NLU is shown in Table 4. Especially *Stanford Core NLP, ANTLR, SpaCy*, and *NLTK* are found to accomplish several tasks. *Word2Vec* is the most popular embedding method, followed by *FastText*. The *Web Speech API* is used primarily because many visualization applications use web technologies. It is striking that many systems rely on *N-gram language models*. In terms of *Word Sense Disambiguation*, WordNet experiences great popularity.

An overview of the applied toolkits in NLG is illustrated in Table 4. The markup language for chatbots *AIML* as well as the *Rasa* toolkit are adopted for *Template-based* text generation, as well as handcrafted *Context-Free-Grammars*. *LL* Parsers* are predominantly applied in the generation of auto-completions. *Seq2Seq Modeling* is experiencing increasing interest expressed through the adoption

NLU Method	Toolkits and Technologies
Semantic Parsing	*ANTLR (4), Context-Free-Grammars(CFG) (3), NLTK (3), Stanford Core NLP (2), AIML (2), IBM Watson, NL4DV Toolkit, SpaCy, Google Cloud Natural Language API, OpenCalais API, Conditional Random Fields (CRF), Wit.ai, Stanford SEMPRE*
POS-Tagging	*Stanford Core NLP (6), SpaCy (3), ClearNLP, Rasa, Compromise JS*
Word Embedding	*Word2Vec (8), FastText (3), GloVe (2), TF-IDF(2), Sent2Vec, BERT Embedding*
Speech-to-Text	*Web Speech API (8), Microsoft Speech API (3), Google Speech API (2), Apple Speech Framework*
NER	*Stanford Core NLP (3), Chrono JS, Google NLP Toolkit, Wikifier, OpenCalais API, TimeML, TERNIP*
Language Modeling	*N-Gram Language Model (6), BERT (4), Bidirectional LSTM (2)*
Word Sense Disambiguation	*WordNet (6), VerbNet, ConceptNet, FrameNet*
Dependency Parsing	*Stanford Core NLP (3), Apache OpenNLP, SpaCy*
Knowledge Representation	*RDF (2), Wolfram Alpha Unit Taxonomy, SIMON*
Constituency Parsing	*ANTLR (2), Stanford Core NLP*
Keyword Extraction	*TF-IDF (3)*
Co-Reference Resolution	*CogCompNLP*
Sentiment Analysis	*Stanford Core NLP, LSTM*
Vector Search	*Word2Vec (2), TF-IDF*

Table 4: NLP Toolkits and Technologies used for NLU and how often they are used in the visualization applications.

of deep learning models such as different variants of *LSTM* and *Transformers*. It is striking that, in addition to ready-made toolkits such as *Rasa* and mark-up languages such as *AIML* for *Dialogue Management*, *Finite-State-Machines* are also predominantly used.

NLG Method	Toolkits and Technologies
Template-based NLG	*AIML, Rasa, LL* Parser, Context-Free-Grammars (CFG), IBM Watson*
Seq2Seq Modeling	*LSTM (3), LSTM+Attention (2), CNN+Conditional Random Fields (CRF) (2), Transformer, M4C, LayoutLM, Image Transformer, Bidirectional LSTM*
Dialogue Management	*Finite-State-Machines (FSM) (2), AIML , Rasa, IBM Watson*
Text-to-Speech	*Microsoft TTS*
Text-Summarization	*PageRank Algorithm*

Table 5: NLP Toolkits and Technologies used for NLG and how often they are used in the visualization applications.

C.2 Initiative

In an interaction, the initiative is taken by the actor that leads or controls the dialogue, e.g., via questions. McTear (2002) classifies initiative into user initiative, system initiative, and mixed- initiative. Litman and Pan (2004) mark, that the initiative within a dialogue determines the set of possible questions and responses of user and system and therefore the outline of the dialogue. Considering the initiator, the classification of McTear (2002) is used as a basis for the classification including the three general categories:

User Initiative. Language-based interactions are classified as user-initiated when the direction of the dialog is determined by the user's actions, in this case, written- or spoken utterances or other text input. The conversation is usually conducted through commands or questions. In addition to prior works (McTear, 2002; Litman and Pan, 2004) considering visualization-oriented dialogue the *data-related intent* depicts an important factor for a user to take the initiative. Exemplary, this happens when users initiate a conversation by formulating a query to discover new insights about a visualization.

System Initiative. System-initiated language-based interactions are determined by natural language utterances generated by the system. The system creates the outline of the interaction towards a previously determined goal. The user is led towards the goal and if the goal is achieved the visualization task is completed. An exemplary case is a system guiding a user in a step-by-step tutorial through the execution of a task, e.g., the identification and elimination of outliers in a visualization.

Mixed Initiative. In mixed-initiated language-based interaction users and systems at different times and to different proportions contribute to the determination of the interaction. In a visualization context both follow a data-related intent but the way there is characterized by negotiation, proposals, and agreement and disagreement. Exemplary this is the case during interactive clustering where user and system propose different divisions of the data space to each other negotiating a good classification for the underlying data.

To carry out the classification an interaction is considered to be *single-initiated* (= user initiative or system initiative only) if **during the whole completion of the visualization task the same actor is initiating**. If the initiative **changes at least once** the interaction is classified as *mixed-initiative* interaction. The scaling of the visualizations is normalized to 100 percent.

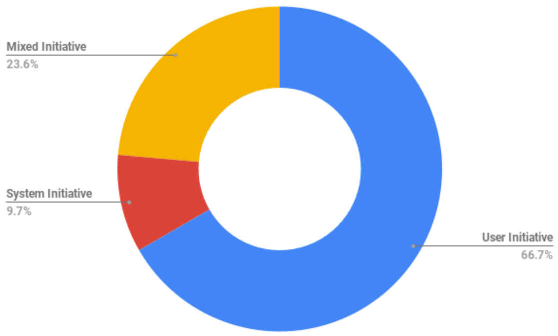

Figure 10: Distribution of initiative **over all papers**.

Figure 10 shows the distribution of initiative over all included papers in the study. In the set of contributions, user-initiated interactions are predominant, followed by mixed-initiative interactions. Only about ten percent of the interactions are system-initiated.

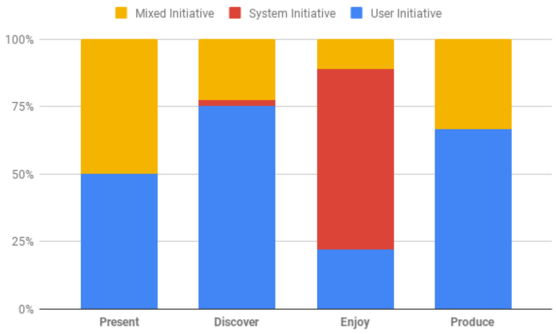

Figure 11: Distribution of initiative **over tasks**.

The distribution of the initiative within the individual visualization tasks is illustrated in Figure 11. In *discover* and *produce* user-initiated interactions are predominant. The *present* task contains a balanced ratio of user- and mixed-initiated interactions. The *enjoy* task is the only task, where system-initiated interactions represent the majority.

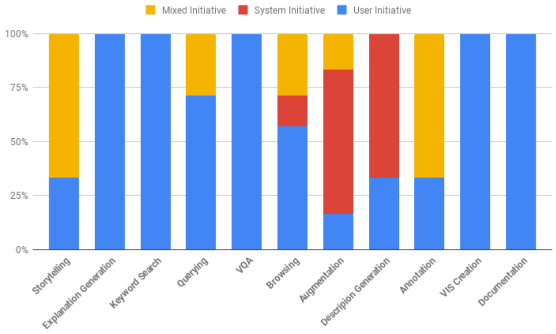

Figure 12: Distribution of initiative **over sub-tasks**.

Figure 12 shows the distribution of initiative within the single sub-task categories. Users initiate the interactions in *Keyword Search, Explanation Generation, VQA, Visualization Creation*, and *Documentation*. System initiative is present in *Augmentation, Visualization Description Generation, and Browsing*. Mixed initiative interaction is modeled in *Annotation, Storytelling* and less frequently in *Natural Language Querying, Browsing*, and *Augmentation*.

C.3 Duration

Within dialogue modeling, natural language-based interactions are modeled as a sequence of dialogue turns. In their survey Deriu et al. (2020) propose a characterization of dialogue system types as task-oriented dialogue systems, conversational agents, and interactive QA systems. The basis for this classification is differences in the dialogue structures supported by the different systems, especially in their duration and task-orientedness. Interactive QA systems are considered task-related single- or multi-turn systems. Task-oriented dialogue systems are considered multi-turn systems with short interaction lengths due to the optimization goal. Conversational agents are classified as non-task-oriented multi-turn systems with long interaction lengths. The decision for single- or multi-turn dialogue systems in a visualization-oriented dialogue is a conceptual one that V-NLI designers have to make concerning the quality measure that is set on the system. Single turn systems, e.g., hold higher risks in failing to resolve ambiguities or vague expressions from a single query than multi-turn systems that can pose requests, but also deliver the result in the quickest possible way.

Depending on the visualization task and sub-task at hand, the interaction structures differ. To carry out a uniform duration classification we consider **the length of the human-machine dialogue, that is modeled by the application** as the decisive criterion. Therefore, **interactions that include more than a single utterance in the calculation of the next response** (e.g. by including the dialogue history in context management) and **interactions that support more than one dialogue turn for users and system respectively** are considered *multi-turn*. An interaction is considered to be *single-turn* **if user and system utter at maximum one utterance respectively in a coherent dialogue**.

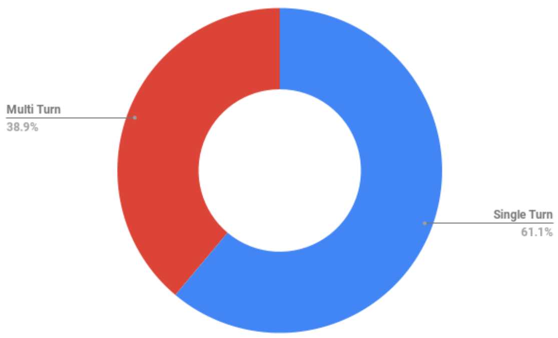

Figure 13: Distribution of duration **over all papers**.

Figure 13 shows that the modeled interactions in almost two-thirds are single turn and one-third are multi-turn.

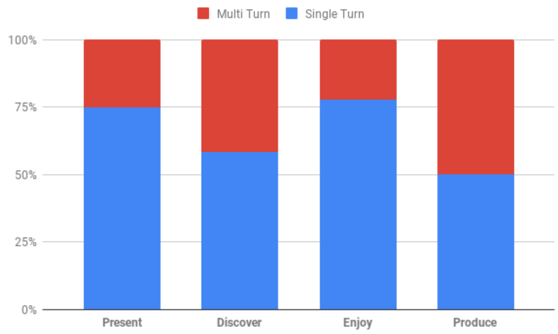

Figure 14: Distribution of duration **over tasks**.

On the task level, in *present* and *enjoy* interactions are predominantly single-turned (see Figure 14). In the *discover* and *produce* task the ratio of multi- to single turn interactions is rather balanced.

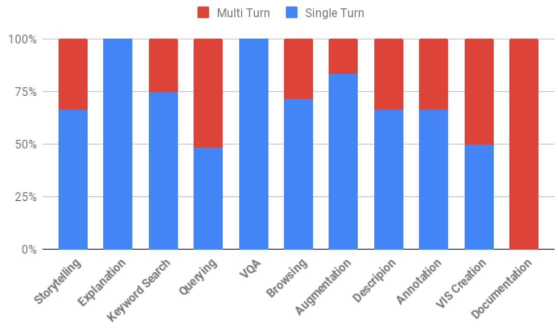

Figure 15: Distribution of duration **over sub-tasks**.

Figure 15 illuminates the distribution of duration on a sub-task level. *Explanation Generation* and *VQA* are modeled in single turn interactions similar to *Keyword Search, Augmentation*, and *Browsing*. Multi-turn interactions are found predominantly in *Natural Language Querying, Visualization Creation*, and *Documentation*.

C.4 Communicative Functions

Bunt (2009) introduces a taxonomy for dialogue act classification. Following that, each individual speech act in a conversation is classified due to the communicative function it carries. On a high level, these general-purpose functions distinguish speech acts as that every individual turn carries either *information providing, information seeking, commissive* or *directive* functionality. Especially since visualization-oriented interactions are multimodal designers of V-NLI have to decide which communicative functions are adopted by visual elements as a complementary modality to language in multi-modal dialogue. The examination of communicative functions in the applications at hand is carried out with the idea in mind of gaining an overview of who holds which share of which communicative function in the modeled dialogues. The aim is to help to better characterize and compare the dialogues in the individual tasks and sub-tasks. For contributions that provide access to exemplary human-machine dialogues either within the paper or the supplemental material the presence of each of the communicative functions *information providing, information seeking, commissive*, or *directive* is detected for user and system respectively (see Table 6). The representation of the identified communicative functions is in absolute quantities for the respective sub-task under consideration.

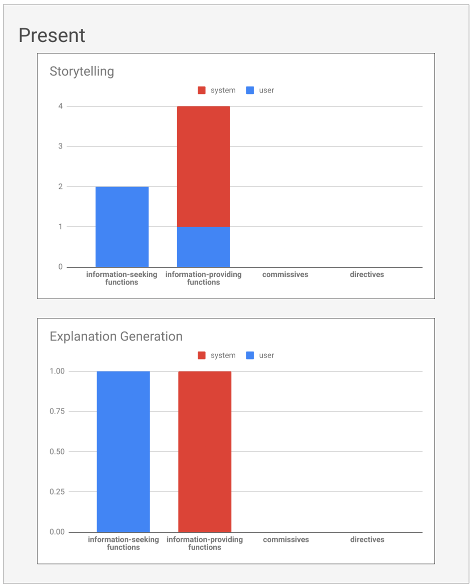

Figure 16: Distribution of communicative functions in task **present**.

Figure 16 shows the characteristic distribution of communicative functions for the task *present* and its respective sub-tasks. It turns out that in these interactions systems predominantly provide users with information. In *Visual Storytelling* the user and the system complement each other in different modalities, textual and visual, to jointly present visual insights in the form of a multi-modal story. *Explanation Generation* is characterized by users who are looking for an explanation for a certain behaviour, which can be understood more easily with the help of a visualization and a generated text description acting as a guide.

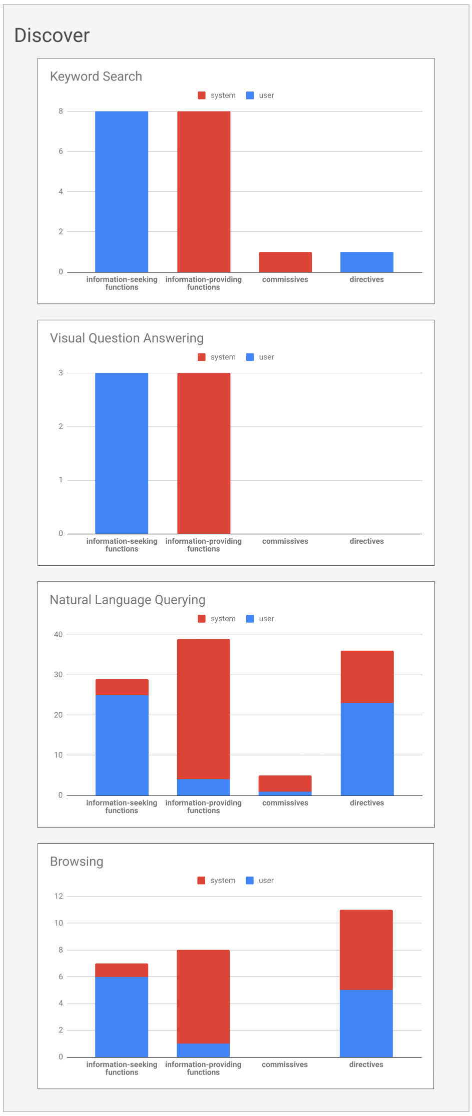

Figure 17: Distribution of communicative functions in task **discover**.

Figure 17 illuminates the shares of communicative functions in the visualization task *discover* and the respective sub-tasks. It shows that interactions in *Keyword Search* and *Visual Question Answering* are predominantly characterized by users seeking information and systems providing those to the user. In *Keyword Search* commissives are occasionally uttered by the system to respond to user-induced directives in dialogue. *Visual Question Answering* follows the classic question-answer scheme in which users bundle their search for information in a question and systems provide textual answers that can be substantiated by the visualization. *Natural Language Querying* and *Browsing* contain a more variable profile of communicative functions which also accommodate higher numbers of directives such as, e.g., system-generated *suggestions* used to pose recommendations to the user in *Browsing* or *commands* in *Natural Language Querying* applied by users to make the system execute an action. Interestingly, commissive utterances occur especially in longer analytical conversations, for example, to confirm the loading of a data set or to acknowledge the perception of a command given by the user. When looking at the distribution of communicative functions in *Browsing*, it becomes clear that the system tries to facilitate the user's entry into visual exploration by providing additional information or directives.

Figure 18: Distribution of communicative functions in task **enjoy**.

The *enjoy* task is characterized through systems providing the user with additional information as well as occasional directives in the *Augmentation* task (see Figure 18). Users occasionally ask for information, but the bulk of the interaction consists of the system presenting information to the user or suggesting directives for future interaction. In *Visualization Description Generation*, the special focus of systems is on providing information to visually impaired people. Describing scenes from a visualization in detail so that visually impaired people can perceive them in their full detail requires high-quality text generation that goes beyond standard image captioning.

Interactions in the context of artifact *production* deliver diverse profiles of communicative functions, as shown in Figure 19. *Annotation* is characterized by users providing information, e.g., in form of text labels and systems that direct the user, e.g., by making *suggestions* where to put those. Interactions in *Visualization Creation* face user and system contributing information as well as systems delivering additional *suggestions* for the next step in the creation process. In *Documentation*, systems provide textual information in form of a report during or after a user interaction with a visual model.

Figure 19: Distribution of communicative functions in task **produce**.

Table 6: Table of references to contributions included in the study sorted according to the abstract visualization task (Task) and sub-task (Sub). Contributions within the same task category share the same color base. Categories the works are evaluated on are duration (Dur), initiative (Init), and present communicative functions (CF), respectively for user (CF - User) and system (CF - System). The individual communicative functions that are investigated are information seeking (IS), information providing (IP), commissives (CM), and directives (DI).

Abstract

This work studies temporal reading comprehension (TRC), which reads a free-text passage and answers temporal ordering questions. Precise question understanding is critical for temporal reading comprehension. For example, the question "*What happened before the victory*" and "*What happened after the victory*" share almost all words except one, while their answers are totally different. Moreover, even if two questions query about similar temporal relations, different varieties might also lead to various answers. For example, although both the question "*What usually happened during the press release?*" and "*What might happen during the press release*" query events which happen after *the press release*, they convey divergent semantics. To this end, we propose a novel reading comprehension approach with precise question understanding. Specifically, a temporal ordering question is embedded into two vectors to capture the referred event and the temporal relation. Then we evaluate the temporal relation between candidate events and the referred event based on that. Such fine-grained representations offer two benefits. First, it enables a better understanding of the question by focusing on different elements of a question. Second, it provides good interpretability when evaluating temporal relations. Furthermore, we also harness an auxiliary contrastive loss for representation learning of temporal relations, which aims to distinguish relations with subtle but critical changes. The proposed approach outperforms strong baselines and achieves state-of-the-art performance on the TORQUE dataset. It also increases the accuracy of four pre-trained language models (BERT base, BERT large, RoBERTa base, and RoBETRa large), demonstrating its generic effectiveness on divergent models.

Paragraph 1: The European Union and the United States have frozen aid to the Palestinian Authority ever since the Hamas-led government took power in March, two months after its upset parliamentary election victory. Abbas's Fatah faction and Hamas labored for months to reach a power sharing agreement that would meet international conditions to lift the siege and end the spiraling crisis, but those talks failed late last month.

Q1: What happened after the victory? (Basic)
A1: frozen took labored failed
Q2: What failed to happen after the victory? (Negated)
A2: agreement meet lift end
Q3: What happened right after the victory? (Constrained)
A3: frozen took labored

Paragraph 2: "The agreement, which was signed by the two governments Thursday, demonstrates Nepal's continuing commitment to development activities in agriculture and forestry," it said in a press release. "These two sectors provide income and employment opportunities for almost 80 percent of Nepal's population," it added.

Q4: What usually happened during the press release? (Common)
A4: said
Q5: What might happen during the press release? (Uncertain)
A5: said added

Figure 1: Examples of temporal reading comprehension. Temporal relations are diverse: Q1-Q5 list examples of possible varieties of temporal relations. Small changes in the question might lead to substantially divergent semantics: replacing *usually* in Q4 with *might* in Q5 leads to different answers. Related events are underlined in the passage.

1 Introduction

Understanding temporal relationships between events in a passage is essential for natural language understanding (Wang et al., 2019; Dong et al., 2019). Temporal reading comprehension (TRC) (Ning et al., 2020) is a natural way to study temporal relations since natural language questions are flexible to capture divergent temporal relations (Zhou et al., 2021). Figure 1 shows several examples of temporal reading comprehension, where given a free-text passage, a system is required to answer temporal questions like "*What usually happened during the press release?*".

A natural solution for temporal ordering understanding is to compare each candidate answer and the referred event in the question and classify their temporal relation into several pre-defined cate-

gories, e.g., UzZaman et al. (2013) defines 13 possible relations such as *after, ends, equal to*. Nonetheless, since temporal relationships vary greatly, it is almost impossible to enumerate all possible relationships. Figure 1 shows several divergent varieties of temporal relations: one might query about *plain after* in Q1, *negated after* in Q2, *constrained after* in Q3, etc. Similarly, a question might query about *usually happen* in Q4, *might happen*, or other relations. Moreover, creating sufficient labels for all such relations is costly and poses great challenges for real-world applications. Therefore, the classification-based approach is incompetent to handle the flexible relations in temporal reading comprehension.

Another paradigm is to formulate it as a reading comprehension problem and directly predict the answer to a question. With the help of large pre-trained language models (e.g., BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019)), such approaches have achieved relatively good performance. However, they still struggle for the temporal reading comprehension task due to the lack of precise question understanding. For example, given the same passage, the BERT model fine-tuned on SQuAD (Rajpurkar et al., 2016) predicts the same answer to the two questions (Ning et al., 2020), "*What happened before a woman was trapped*" and "*What happened after a woman was trapped*". In this case, although the two questions share almost the same words, the only different one between *before* and *after* leads to completely opposite intentions. Moreover, even if two questions query about similar relations, different varieties might also lead to various answers. Take the question Q4 "*What usually happened during the press release?*" and "*What might happen during the press release?*" in Figure 1 as an example. Although they both query about events occurring after *the press release*, the slight difference conveys divergent semantics and leads to different answers.

To tackle these challenges, we propose a novel question answering approach with precise question understanding. Intuitively, temporal ordering questions consist of two elements, referred events, and concerned temporal relations. For example, the question "*What usually happened during the press release?*" can be decomposed into the referred event *the press release* and the concerned relation *usually happen during*. Inspired by this observation, we first encode such questions into two representations, the event vector $\mathbf{h_c}$ and the relation vector $\mathbf{h_r}$. Then we evaluate how well each candidate answer matches the relation $\mathbf{h_r}$ compared to $\mathbf{h_c}$ with a separate MLP module. Such fine-grained representations enable a better understanding of questions by focusing on different elements with different vectors and further provides good interpretability about the reasoning process. More importantly, it empowers the model to capture the semantics of divergent variants of temporal relations. Specifically, we harness an auxiliary contrastive loss that aims to distinguish relations with subtle but critical changes.

We evaluate the proposed approach on the TORQUE dataset and achieve state-of-the-art performance compared to strong baselines. We further testify its effectiveness based on four different models (i.e., BERT base, BERT large, RoBERTa base, RoBERTa large) and demonstrate that precise question understanding can improve the QA accuracy for all models. Ablation study shows that both question representation learning and contrastive loss play a critical role in the approach.

2 Related Work

Temporal machine comprehension is closely related to two areas of works, i.e., machine reading comprehension and temporal ordering reasoning.

2.1 Machine Reading Comprehension

Machine reading comprehension (MRC) (Rajpurkar et al., 2016, 2018) has attracted much attention in recent years. Traditional solutions to MRC tasks focus on utilizing the interaction information between questions and passages via attention-based structures (Kadlec et al., 2016; Dhingra et al., 2017). Later on, pre-trained language models (PLMs), e.g., BERT (Devlin et al., 2019), RoBERTa (Liu et al., 2019), and XLNet (Yang et al., 2019), have been widely used for MRC tasks. With the sheer scale of parameters and the pretraining strategies, PLMs capture more knowledge from the context and have shown outstanding performance on traditional MRC benchmarks.

For more challenging MRC tasks which introduce multi-hop reasoning (Yang et al., 2018), numerical reasoning (Dua et al., 2019), etc., the generic PLMs become not applicable. Recent efforts use graph-based reasoning approaches (Chen et al., 2020) or define specific pretraining training techniques (Raffel et al., 2020) to solve the above challenges. However, existing MRC approaches still struggle for the temporal reading comprehension task due to the lack of temporal relation understanding (Ning et al., 2020). Hence, we propose a novel question answering approach with precise question understanding to tackle this challenge.

2.2 Temporal Ordering Reasoning

Traditional temporal order reasoning tasks (UzZaman et al., 2013; Cassidy et al., 2014; Ning et al., 2018), are often formulated as relation extraction tasks. Given the context passage, the target is to classify the relation between every two events from a predefined relation set, e.g., UzZaman et al. (2013) defines 13 possible relations such as *after, ends, equal to*. Existing solutions can be roughly classified into two categories. The first category focuses on developing the structure of the encoder to capture more temporal information. For example, Cheng et al. (2020) add up a GRU-based dynamically updating structure upon the outputs of the common BERT sentence encoder. The second category focuses on joint learning with external knowledge or some specific constraints. For instance, Ning et al. (2019) significantly improve the extraction performance by joint training temporal and causal relations.

However, the success of the existing approaches is limited to the formulation of the traditional temporal order reasoning tasks, where the events and the candidate temporal relation set are fixed. However, the fixed candidate relation set cannot cover all temporal relations in our daily uses. The most recent released dataset, TORQUE (Ning et al., 2020), formulates temporal ordering reasoning as a machine reading comprehension task. Given a context passage, we need to answer a free-text question about the temporal relations in the context passage. The task is much analogous to our real-world tasks and is more challenging – we need to automatically identify the events and the relations in the free-text question to retrieve the answers from the context passage. To the best of our knowledge, we are the very first to address this challenge.

3 Our Approach

We first introduce the definition of temporal reading comprehension (TRC) and then describe the model architecture consisting of contextual encoder, question understanding, and event relation assessment. Finally, we provide details for the learning and inference process.

3.1 Task Definition

The Temporal Reading Comprehension (TRC) task is defined as follows. Given a passage P which describes a set of events, a system is required to answer a temporal ordering question Q. Here *events* refer to verbs or nouns which define actions or states. A temporal ordering question usually queries events satisfying some concerned temporal relations considering one or more referred events. For example, the first passage in Figure 1 describes events about *Hamas goverment*, and question $Q1$ queries which events have the temporal relation *happen after* with the referred event *the victory*. The answer set A to a question Q could be empty when no events meet the requirement.

3.2 Model Architecture

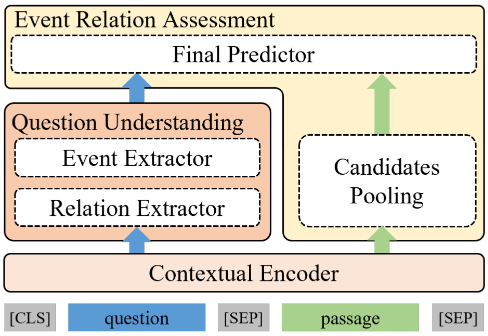

Figure 2: An overview of the proposed model.

Figure 2 depicts the proposed model architecture. Specifically, the passage P and question Q are first encoded by a *contextual-aware encoder*, after which the representations of the question are passed to a *question understanding* module. Finally, each candidate answer is evaluated considering whether it satisfies the concerned relation to the referred event by an *event relation assessment* module.

Contextual Encoder We first encode the passage-question pairs with a pre-trained language model encoder, and here we take BERT as an example. Given a question $Q = [q_i]_{i=1}^{m}$ and a passage $P = [p_i]_{i=1}^{n}$, where m and n are token numbers, we concatenate them into a sequence with the format of *[cls] question [sep] passage [sep]*, which is then fed into the contextual encoder to generate the embeddings,

$$[\mathbf{h_1^q}, ..., \mathbf{h_m^q}, \mathbf{h_1^p}, ..., \mathbf{h_n^p}] = \mathrm{BERT}([q_1, ..., q_m, p_1, ..., p_n]), \tag{1}$$

where $\mathbf{h_i^q}, \mathbf{h_i^p} \in \mathcal{R}^d$ are embeddings for question token q_i and passage token p_i, and d is the embedding size.

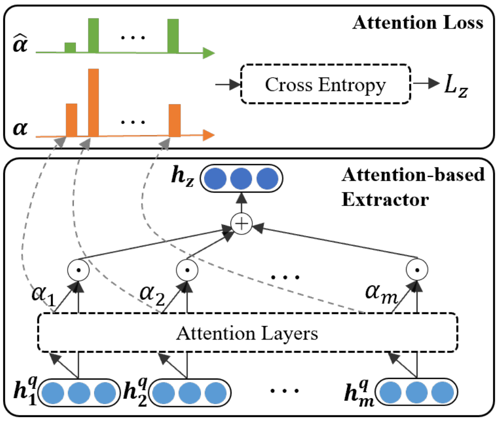

Figure 3: The structure of attention-based event/relation extractor, with attention loss for it.

Question Understanding As discussed in Section 1, precise question understanding plays an essential role in TRC task. Therefore, we propose a question understanding module to achieve that. Intuitively, a temporal ordering question consists of two elements, referred events, and concerned temporal relation. For example, the question "*What usually happened during the press release*" queries the temporal relation *usually happen* to the event *the press release*. A straightforward solution is to decompose the question into two segments directly. However, natural language questions vary a lot, and hard decomposition is risky and might propagate errors to downstream modules, which is verified by experimental analysis in Section 4.5,

Therefore, we design an attention-based extractor to decompose the question implicitly, and obtain two hidden representations, $\mathbf{h_c}$ for the referred event and $\mathbf{h_r}$ for the concerned temporal relation as follows,

$$\mathbf{s_i^{(z)}} = \tanh(\mathbf{W_1^{(z)}} \mathbf{h_i^q} + b_1^{(z)}), \quad z \in \{c, r\} \quad (2)$$

$$\alpha_i^{(z)} = \mathrm{Softmax}(\mathbf{W_2^{(z)}} \mathbf{s_i^{(z)}} + b_2^{(z)}), \quad z \in \{c, r\} \quad (3)$$

$$\mathbf{h_z} = \sum_{i=1}^{m} \alpha_i^{(z)} \mathbf{h_i^q}, \quad z \in \{c, r\} \quad (4)$$

where $\mathbf{W^{(c)}}, \mathbf{W^{(r)}} \in \mathcal{R}^d$, and $b^{(c)}, b^{(r)} \in \mathcal{R}$ are learn-able weights for the extractor, $\mathbf{h_i^q} \in \mathcal{R}^d$ is the embedding for the i-th question token. To effectively learn $\mathbf{h_r}$ and $\mathbf{h_c}$, we employ several auxiliary losses in the training phase, which will be described in section 3.3.

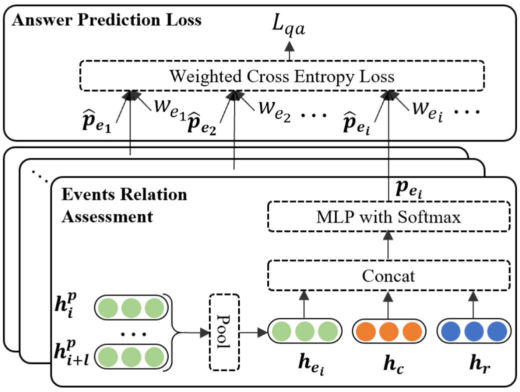

Figure 4: The structure of the event relation assessment, with answer prediction loss for it.

Event Relation Assessment Given the question representations $\mathbf{h_r}$ and $\mathbf{h_c}$, the *event relation assessment* module evaluates how a candidate answer satisfy the relation $\mathbf{h_r}$ with respect to $\mathbf{h_c}$. Let $e = p_i \dots p_{i+l}$ denotes the candidate answer, which consists of l tokens in the passage P. We first get the representation of e by pooling over according token vectors,

$$\mathbf{h_e} = \mathrm{Pool}(\mathbf{h_i^P}, \dots, \mathbf{h_{i+l}^P}). \quad (5)$$

Then we concatenate the representations of the candidate event $\mathbf{h_e}$, question relation $\mathbf{h_r}$, and the question event $\mathbf{h_c}$, and feed it into a two-layer MLP, followed by a softmax function to get the final probability,

$$\mathbf{o_e} = \tanh(\mathbf{W_1^o}[\mathbf{h_e}; \mathbf{h_c}; \mathbf{h_r}] + \mathbf{b_1^o}), \quad (6)$$

$$\mathbf{p_e} = \mathrm{Softmax}(\mathbf{W_2^o} \mathbf{o_e} + \mathbf{b_2^o}), \quad (7)$$

where $\mathbf{W_1^o} \in \mathcal{R}^{3d \times d'}$, $\mathbf{W_2^o} \in \mathcal{R}^{d' \times 2}$, $\mathbf{b_1^o} \in \mathcal{R}^{d'}$, $\mathbf{b_2^o} \in \mathcal{R}^2$ are model parameters, and ; indicates concatenation. $\mathbf{p_e} \in \mathcal{R}^2$ is the probability whether the candidate e satisfies the temporal relation h_r with respect to event h_c.

3.3 Learning Objectives

We employ three learning objectives for model training, including a classification loss L_{qa} function for final answer prediction, and an attention loss L_{att} and a contrastive loss L_{con} for precise question understanding. The overall loss is a weighted combination of all the objectives,

$$\mathcal{L} = w_{qa} L_{qa} + w_{att} L_{att} + w_{con} L_{con}. \quad (8)$$

Answer Prediction Loss The training objective for final answer prediction is defined as,

$$L_{qa} = -\sum_{e \in \mathcal{C}} w_e \hat{\mathbf{p}}_{\mathbf{e}}^T \log \mathbf{p}_{\mathbf{e}}, \tag{9}$$

where $\mathcal{C}$ is the candidate event set, w_e is the weight for candidate e, $\mathbf{p}_{\mathbf{e}} \in \mathcal{R}^2$ is the predicted probability from Eq. (7), and $\hat{\mathbf{p}}_{\mathbf{e}} \in \{0,1\}^2$ is the golden label indicating whether the candidate e belongs to the final answer of the question.

Usually, the candidate set $\mathcal{C}$ is derived by preliminary filtering all unigrams in the passage P. However, some candidates are easy to be classified while others are not. For example, it is easy to classify the word *government* in Figure 1 as a negative answer since it is not an event. In contrast, predicting whether the word *frozen* is the answer for Q1 in Figure 1 is more challenging. Inspired by this observation, we assign weights w_e for candidates in the learning objective, $w_e = 1.5$ if e is an event, and otherwise $w_e = 1.0$. The label of whether a word is an event can be derived when labeling the final answer with little effort, so we can safely assume that we always have such annotation[1].

Attention Loss Besides the answer prediction loss, we also leverage an auxiliary loss to guide the learning of the attention score $\alpha_i^{(c)}$ and $\alpha_i^{(r)}$ defined in Eq. (3). We first derive silver annotation for referred events and concerned relation in a passage using a rule-based approach, which will be detailed in Section 4.2. Let Q_c, Q_r be the set of event and relation tokens according to the silver annotation. Then we have $\hat{\alpha}_i^{(z)} (z \in \{c, r\})$ as the derived attention label,

$$\hat{\alpha}_i^{(z)} = \begin{cases} \frac{1}{|Q_z|}, & \text{if } q_i \in Q_z, \\ 0, & \text{otherwise.} \end{cases} \tag{10}$$

The attention loss is defined as,

$$L_{att} = L_c + L_r, \tag{11}$$

where

$$L_z = -\sum_i \hat{\alpha}_i^{(z)} \log \alpha_i^{(z)}, \quad z \in \{c, r\}. \tag{12}$$

Contrastive Loss As shown in Figure 1, a small change of a question might lead to substantially divergent temporal relations. To this end, we propose to leverage a contrastive loss for precise learning of question relation representations.

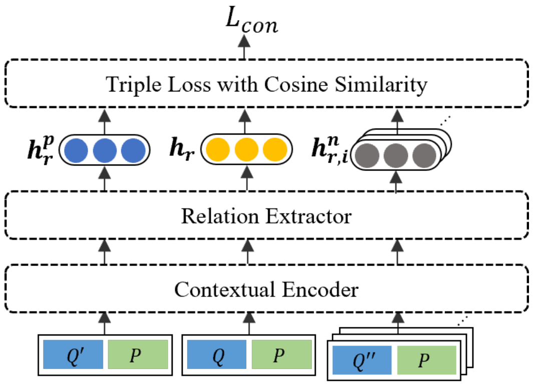

Figure 5: Illustration of the contrastive loss for question understanding.

For the relation representation $\mathbf{h_r}$ of a question Q, we derive a positive vector $\mathbf{h_r^p}$ and a set of negative ones $\{\mathbf{h_{r,i}^n}\}_{i=1}^N$). The positive sample $\mathbf{h_r^p}$ is obtained in two ways. First, we search questions with the same temporal relations but different events, from which we randomly sample one and take its relation representation as $\mathbf{h_r^p}$. Note we can get the silver annotation of events and relations in a question by a rule-based approach. Please refer to section 4.2 for more details. Second, if no such questions can be found, we take the similar approach as in SimCSE (Gao et al., 2021), which applies a different dropout on $\mathbf{h_r}$ and gets a variant of $\mathbf{h_r}$ as $\mathbf{h_r^p}$. We search questions that contain the same events by different temporal relations with respect to Q, and take their relation representations as the negative set $\{\mathbf{h_{r,i}^n}\}_{i=1}^N$).

Given the triple $(\mathbf{h_r}, \mathbf{h_r^p}, \{\mathbf{h_r^n}\})$ for the question Q, its loss is defined as,

$$L_{con}(Q) = -\log \frac{e^{\cos(\mathbf{h_r}, \mathbf{h_r^p})}}{e^{\cos(\mathbf{h_r}, \mathbf{h_r^p})} + \frac{1}{N}\sum_{i=1}^N e^{\cos(\mathbf{h_r}, \mathbf{h_{r,i}^n})}}, \tag{13}$$

where $cos()$ indicates cosine similarity.

3.4 Inference

The inference phase takes three steps. First, we generate a candidate set $\mathcal{C}_p$ for each passage P. Generally speaking, one can take any n-gram in P as a candidate. In temporal relation understanding, we usually take a triggering word as an event candidate. Therefore, $\mathcal{C}_p$ is the set of all unigrams in P. Then, we filter $\mathcal{C}_p$ according to part-of-speech (POS) tagging. Specifically, we use an off-the-shelf POS tagger to tag all words in P, and then keep only verbs and nouns in $\mathcal{C}_p$. Finally, each candidate $e \in \mathcal{C}_p$

---

[1] The TORQUE dataset in our experiment also contains such annotation, and we use it directly in our approach

together with the passage P and the question Q is fed into our proposed model, and e is evaluated according to Eq. (7) and gets its score $\mathbf{p_e}$, where $p_{e,0}$ represents the probability that the candidate matches the question Q. Then we can get the final answer set A as $A = \{e : e \in \mathcal{C}_p \text{ and } p_{e,0} > \tau\}$, where τ is a predefined threshold.

4 Experiments

This section describes an empirical evaluation of our proposed approach. We also provide analysis, ablation studies, and case analysis to demonstrate its effectiveness.

4.1 Settings

Dataset We evaluate the proposed approach on the TORQUE dataset. TORQUE is a temporal reading comprehension benchmark. Each training sample contains a passage and a question requiring understanding temporal relation between events in the passage. Figure 1 shows several examples of training data. The answer to a question consists of an event set A, and A could be empty if no event in the passage satisfies the requirement of the question. In TORQUE, events are defined as event triggers, usually verbs or nouns describing actions or states. There are 3.16k passages with 30.7k questions in total and 2 events for an answer on average. We follow the official split[2] with 80%/5%/15% of data in training/validation/test.

Evaluation Metrics Following Ning et al. (2020)[3], we report three metrics in our experiment, including standard macro F1 and Exact Match (EM) for question answering and consistency score(C). There are multiple annotations for each passage-question pair, which might not always be consistent with each other. We follow the official implementation. Specifically, for each sample, a model's prediction is evaluated according to all annotations, where the largest score is selected and aggregated as the final result.

4.2 Implementation Details

We experiment four pre-trained language models as our contextual encoder, i.e., the base and large model of BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019). The embedding size d is set to 64, d' in Eq (6) and Eq (7) is set to 64. The threshold τ for inference is set to 0.5. In model training, the batch size is set to 16, the dropout rate is set to 0.5. The combination weight w_{qa}, w_{att} and w_{con} in Eq. (8) is set to 1.0, 0.3, and 1.0, respectively. We search the learning rate lr, with grid searching within 3 trials in $lr \in \{0.9 \times 10^{-5}, 1.0 \times 10^{-5}, 1.1 \times 10^{-5}\}$ for the base and large model of RoBERTa, and $lr \in \{4.0 \times 10^{-5}, 5.0 \times 10^{-5}, 6.0 \times 10^{-5}\}$ for the base and large model of BERT. The implementation is based on Python and trained on a Tesla V100 GPU with Adam optimizer for approximately three hours (base model with approximately 110M parameters) and ten hours (large model with approximately 340M parameters). We get the averaged result of three trials for each setting, choose the model with the highest F1 score on the development set, and report the performance on the test set derived from the official online test[4].

Deriving Attention Annotation The relation annotation Q_r for question Q is derived as follows. First, we compile a dictionary for temporal relations, such as *before*, *after*, etc. Please refer to Appendix A.1 for the complete list. Then Q_r is constructed with those words in Q that hit the dictionary. The event annotation Q_c is mainly derived according to the passage P. Particularly, we assume the mentioned event list E in P is known. If a word of Q matches an event in E, it is included in Q_c. Otherwise, if no words of Q hit E, we rely on the relation annotation. Suppose the last relation word is in position k, then $Q_{k+1...n}$ is set as Q_c.

4.3 Main Results

We compare our approach with the baseline (Ning et al., 2020), which takes a passage and the corresponding question as input and applies a one-layer perception on the embedding of each token to predict whether it is the answer of the question or not. The comparison results with four different contextual encoders are shown in Table 1. The table shows that our proposed approach outperforms the baseline on nearly all evaluation metrics. Our model achieves state-of-the-art results with the RoBERTa-large encoder, increasing the F1 score by 1.8% and 0.9% for the dev and test set, respectively. We can see a huge increase for the consistency score (C) on the test set from 34.5% to 38.1%. Using other pretrain language models like BERT-base, our model also improves the performance compared to the baseline approach, by 2.6%, 3.2%, 2.5% in terms of F1, EM, and C score, respectively. Although

there is still a large gap towards the human performance, our model takes a large step compared to the baseline approach, verifying the effectiveness of the proposed approach.

4.4 Ablation Study

Models	**F1**	**EM**	**C**
Our Model	76.1	51.0	38.1
-con	75.8 (-0.3)	49.8 (-1.2)	37.0 (-1.1)
-con -att	75.6 (-0.5)	50.8 (-0.2)	36.6 (-1.5)
-w_e	75.8 (-0.3)	50.6 (-0.4)	37.6 (-0.5)
-all	74.8 (-1.3)	49.7 (-1.3)	34.0 (-4.1)

Table 2: Ablation study on the test set of TORQUE. RoBERTa-large is used as contextual encoder.

We conduct an ablation study to illustrate the effectiveness of each loss in our approach. As shown in Table 2, removing the contrastive loss will lead to a 1.1% drop on consistency value. When we remove both the contrastive and attention loss for question understanding and use mean pooling over the contextual embedding of the whole question token sequence, the macro F1 score and the consistency score decrease by 0.5% and 1.5%, respectively, showing that precise question understanding plays a critical role for TRC. Also, we remove weight w_e in the answer prediction loss in Eq. (9), which results in a 0.3% drop in terms of the F1 score. When all auxiliary loss is removed, which is basically the same as the baseline model with our own implementation, it leads to a huge gap of 1.3%, 1.3%, 4.1% on macro F1, exactly match and Consistency score, respectively. The results of the ablation study indicate that each element of our proposed model is critical for temporal relation understanding.

4.5 Question Representation Analysis

Models	**F1**	**EM**	**C**
w contrastive loss			
attention-based	76.1	51.0	38.1
rule-based	75.8 (-0.3)	50.6 (-0.4)	37.6 (-0.5)
w/o contrastive loss			
attention-based	75.8	49.8	37.0
rule-based	75.6 (-0.2)	48.9 (-0.9)	36.3 (-0.7)

Table 3: Comparison of attention-based and rule-based question representation learning. RoBERTa-large is used as contextual encoder.

As discussed in Section 3.2, a straightforward solution for question understanding is to decompose a temporal ordering question into two parts directly. This section compares our attention-based approach with the hard question decomposition, which obtains the two question vectors $\mathbf{h_r}$ and $\mathbf{h_c}$ by conducting mean pooling over embeddings of tokens in Q_r and Q_c respectively. The comparison results are shown in Table 3. We can see that although the rule-based approach achieves relatively good accuracy, it still underperforms our attention-based approach. For example, when no contrastive loss is employed, the EM score drops by 0.9% when replacing the attention-based representation with the rule-based one. The possible reason is that the rule-based decomposition cannot handle all questions perfectly, and errors in the decomposition will be propagated to downstream modules. For example, "*What could have happened while the announcement was made but didn't?*". "*but didn't*" is a crucial negate in the temporal relation, but the rule-based method might miss it.

4.6 Case Study

Figure 6 shows predicted answers of our model and the baseline for several questions. For the first passage, Questions 1, 2, and 3 inquire about the "*happened after*" temporal relation, but with subtle differences. Q1 is the most common form, which can be answered correctly by both the baseline and our proposed approach. Meanwhile, the baseline model can not capture the negation information

Paragraph: “This decision came after the failure of the dialogue to form a national unity government with the Hamas movement and is the result of the ongoing political and economic siege against the Palestinian people,” he added.

Question & Answers	**Baseline**	**Ours**
Q 1: What happened after the dialogue began?	decision, failure	decision, failure
Q 2: What has not happened after the dialogue began?	No answer	form
Q 3: According to the speaker, what began happening after the dialogue began?	decision, failure	failure

Paragraph: Pakistan's defense ministry Sunday dismissed Indian reports of an alarming increase in cross-border firing in the disputed Kashmir state. "It is a ploy to divert attention from the turbulence in Indian-held Kashmir," a ministry official said.

Question & Answers	**Baseline**	**Ours**
Q 1: What might have started after the reports?	divert, turbulence	divert
Q 2: What might have started before the reports?	increase, turbulence	increase
Q 3: What started before the reports?	increase, turbulence	turbulence

Figure 6: Case study of our approach and the baseline model. Correct answers are marked in blue. Incorrect ones are marked in red. Candidate events in passages are underlined. Both the baseline and our approach use RoBERTa-large as encoder.

in Q2 and fails to predict the correct answer. In Q3 “*happened after*” is constrained by the word *begin*, which confuses the baseline model and leads to partially correct answers. In contrast, our proposed approach can capture these subtle but critical differences and thus makes correct predictions.

For the second passage, our proposed model performs better for all three questions of different temporal types. Q1 and Q2 are variants of uncertain relations, which query about two opposite temporal relations “*started after*” and “*started before*”. The word “*might*” brings uncertainty for the concerned temporal relation, which confuses the baseline model, leading to the wrong prediction for the candidate answer “*turbulence*” for both questions. Q3 queries about a popular temporal relation, and our model can precisely capture the difference between it and two other ones and predict that the candidate event “*increase*” does not meet its requirement since it comes from a controversial report.

4.7 Error Analysis

We randomly sample 100 wrongly predicted question-passage pairs from the validation set, which can be summarized into three categories.

Multi-round Reasoning Sometimes one needs to perform multi-round reasoning to infer the relation between two events, for example, given the passage “*Roughly 40 minutes after the operation began, jubilant soldiers appeared on the rooftop of the residence, flashing the V victory sign. Then Fujimori, who ordered the operation, arrived to tour the residence and embraced the freed hostages.*”, the temporal ordering between “*ordered*” and “*the jubilant soldiers appeared on the rooftop*” is inferred by multi-step reasoning. That is, “*ordered*” happened before “*operation began*”, and “*operation began*” happened before “*solder appeared*”, and thus “*ordered*” happened before “*appeared*”. An advanced reasoning framework is necessary to handle such cases, and we leave it as future work.

Commonsense Knowledge Required The given passage might not provide sufficient information. For example, in the passage “*He was preparing the paperwork for the move, following the course of an absolutely standard transfer. Sadly he killed himself at home in the meantime.*”, although it states that “*preparing the paperwork*” and ““*he killed himself*” happened “*in the meantime*”, commonsense knowledge indicates that *one cannot kill himself and prepare the paperwork at the same time*. So we can infer that “*preparing*” happened before “*killed*”. Incorporating external knowledge is a potential solution for such cases.

Ambiguous Labeling Since the concept of event is not well-defined, it might lead to ambiguous labeling. Considering a passage contains a span “*decision is made*”, some annotators might label *decision* as a candidate event, while others does not. This causes inconsistent labeling, and thus makes it difficult to learn a good predictor.

5 Conclusion and Future Work

Temporal reading comprehension plays a critical role in natural language understanding. In this paper, we propose a precise question understanding method to tackle the TRC problem. Specifically, we encode temporal ordering questions into representations of referred events and concerned temporal relations, based on which candidate answers are evaluated in terms of their temporal relations to the referred events. In addition, a contrastive loss is employed to empower the model to capture essential differences among temporal relations. Experimental results based on four pre-trained models verify the effectiveness of our proposed approach. In the future, we will investigate general approaches to handle more diverse temporal relation understanding problems and improve the passage understanding capability for temporal reading comprehension.

Abstract

This work studies temporal reading comprehension (TRC), which reads a free-text passage and answers temporal ordering questions. Precise question understanding is critical for temporal reading comprehension. For example, the question "*What happened before the victory*" and "*What happened after the victory*" share almost all words except one, while their answers are totally different. Moreover, even if two questions query about similar temporal relations, different varieties might also lead to various answers. For example, although both the question "*What usually happened during the press release?*" and "*What might happen during the press release*" query events which happen after *the press release*, they convey divergent semantics. To this end, we propose a novel reading comprehension approach with precise question understanding. Specifically, a temporal ordering question is embedded into two vectors to capture the referred event and the temporal relation. Then we evaluate the temporal relation between candidate events and the referred event based on that. Such fine-grained representations offer two benefits. First, it enables a better understanding of the question by focusing on different elements of a question. Second, it provides good interpretability when evaluating temporal relations. Furthermore, we also harness an auxiliary contrastive loss for representation learning of temporal relations, which aims to distinguish relations with subtle but critical changes. The proposed approach outperforms strong baselines and achieves state-of-the-art performance on the TORQUE dataset. It also increases the accuracy of four pre-trained language models (BERT base, BERT large, RoBERTa base, and RoBETRa large), demonstrating its generic effectiveness on divergent models.

Paragraph 1: The European Union and the United States have frozen aid to the Palestinian Authority ever since the Hamas-led government took power in March, two months after its upset parliamentary election victory. Abbas's Fatah faction and Hamas labored for months to reach a power sharing agreement that would meet international conditions to lift the siege and end the spiraling crisis, but those talks failed late last month.

Q1: What happened after the victory?
A1: frozen took labored failed
(Basic)

Q2: What failed to happen after the victory?
A2: agreement meet lift end
(Negated)

Q3: What happened right after the victory?
A3: frozen took labored
(Constrained)

Paragraph 2: "The agreement, which was signed by the two governments Thursday, demonstrates Nepal's continuing commitment to development activities in agriculture and forestry," it said in a press release. "These two sectors provide income and employment opportunities for almost 80 percent of Nepal's population," it added.

Q4: What usually happened during the press release?
A4: said
(Common)

Q5: What might happen during the press release?
A5: said added
(Uncertain)

Figure 1: Examples of temporal reading comprehension. Temporal relations are diverse: Q1-Q5 list examples of possible varieties of temporal relations. Small changes in the question might lead to substantially divergent semantics: replacing *usually* in Q4 with *might* in Q5 leads to different answers. Related events are underlined in the passage.

1 Introduction

Understanding temporal relationships between events in a passage is essential for natural language understanding (Wang et al., 2019; Dong et al., 2019). Temporal reading comprehension (TRC) (Ning et al., 2020) is a natural way to study temporal relations since natural language questions are flexible to capture divergent temporal relations (Zhou et al., 2021). Figure 1 shows several examples of temporal reading comprehension, where given a free-text passage, a system is required to answer temporal questions like "*What usually happened during the press release?*".

A natural solution for temporal ordering understanding is to compare each candidate answer and the referred event in the question and classify their temporal relation into several pre-defined cate-

gories, e.g., UzZaman et al. (2013) defines 13 possible relations such as *after, ends, equal to*. Nonetheless, since temporal relationships vary greatly, it is almost impossible to enumerate all possible relationships. Figure 1 shows several divergent varieties of temporal relations: one might query about *plain after* in Q1, *negated after* in Q2, *constrained after* in Q3, etc. Similarly, a question might query about *usually happen* in Q4, *might happen*, or other relations. Moreover, creating sufficient labels for all such relations is costly and poses great challenges for real-world applications. Therefore, the classification-based approach is incompetent to handle the flexible relations in temporal reading comprehension.

Another paradigm is to formulate it as a reading comprehension problem and directly predict the answer to a question. With the help of large pre-trained language models (e.g., BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019)), such approaches have achieved relatively good performance. However, they still struggle for the temporal reading comprehension task due to the lack of precise question understanding. For example, given the same passage, the BERT model fine-tuned on SQuAD (Rajpurkar et al., 2016) predicts the same answer to the two questions (Ning et al., 2020), "*What happened before a woman was trapped*" and "*What happened after a woman was trapped*". In this case, although the two questions share almost the same words, the only different one between *before* and *after* leads to completely opposite intentions. Moreover, even if two questions query about similar relations, different varieties might also lead to various answers. Take the question Q4 "*What usually happened during the press release?*" and "*What might happen during the press release?*" in Figure 1 as an example. Although they both query about events occurring after *the press release*, the slight difference conveys divergent semantics and leads to different answers.

To tackle these challenges, we propose a novel question answering approach with precise question understanding. Intuitively, temporal ordering questions consist of two elements, referred events, and concerned temporal relations. For example, the question "*What usually happened during the press release?*" can be decomposed into the referred event *the press release* and the concerned relation *usually happen during*. Inspired by this observation, we first encode such questions into two representations, the event vector $\mathbf{h_c}$ and the relation vector $\mathbf{h_r}$. Then we evaluate how well each candidate answer matches the relation $\mathbf{h_r}$ compared to $\mathbf{h_c}$ with a separate MLP module. Such fine-grained representations enable a better understanding of questions by focusing on different elements with different vectors and further provides good interpretability about the reasoning process. More importantly, it empowers the model to capture the semantics of divergent variants of temporal relations. Specifically, we harness an auxiliary contrastive loss that aims to distinguish relations with subtle but critical changes.

We evaluate the proposed approach on the TORQUE dataset and achieve state-of-the-art performance compared to strong baselines. We further testify its effectiveness based on four different models (i.e., BERT base, BERT large, RoBERTa base, RoBERTa large) and demonstrate that precise question understanding can improve the QA accuracy for all models. Ablation study shows that both question representation learning and contrastive loss play a critical role in the approach.

2 Related Work

Temporal machine comprehension is closely related to two areas of works, i.e., machine reading comprehension and temporal ordering reasoning.

2.1 Machine Reading Comprehension

Machine reading comprehension (MRC) (Rajpurkar et al., 2016, 2018) has attracted much attention in recent years. Traditional solutions to MRC tasks focus on utilizing the interaction information between questions and passages via attention-based structures (Kadlec et al., 2016; Dhingra et al., 2017). Later on, pre-trained language models (PLMs), e.g., BERT (Devlin et al., 2019), RoBERTa (Liu et al., 2019), and XLNet (Yang et al., 2019), have been widely used for MRC tasks. With the sheer scale of parameters and the pretraining strategies, PLMs capture more knowledge from the context and have shown outstanding performance on traditional MRC benchmarks.

For more challenging MRC tasks which introduce multi-hop reasoning (Yang et al., 2018), numerical reasoning (Dua et al., 2019), etc., the generic PLMs become not applicable. Recent efforts use graph-based reasoning approaches (Chen et al., 2020) or define specific pretraining training techniques (Raffel et al., 2020) to solve the above challenges. However, existing MRC approaches still struggle for the temporal reading comprehension task due to the lack of temporal relation understanding (Ning et al., 2020). Hence, we propose a novel question answering approach with precise question understanding to tackle this challenge.

2.2 Temporal Ordering Reasoning

Traditional temporal order reasoning tasks (UzZaman et al., 2013; Cassidy et al., 2014; Ning et al., 2018), are often formulated as relation extraction tasks. Given the context passage, the target is to classify the relation between every two events from a predefined relation set, e.g., UzZaman et al. (2013) defines 13 possible relations such as *after, ends, equal to*. Existing solutions can be roughly classified into two categories. The first category focuses on developing the structure of the encoder to capture more temporal information. For example, Cheng et al. (2020) add up a GRU-based dynamically updating structure upon the outputs of the common BERT sentence encoder. The second category focuses on joint learning with external knowledge or some specific constraints. For instance, Ning et al. (2019) significantly improve the extraction performance by joint training temporal and causal relations.

However, the success of the existing approaches is limited to the formulation of the traditional temporal order reasoning tasks, where the events and the candidate temporal relation set are fixed. However, the fixed candidate relation set cannot cover all temporal relations in our daily uses. The most recent released dataset, TORQUE (Ning et al., 2020), formulates temporal ordering reasoning as a machine reading comprehension task. Given a context passage, we need to answer a free-text question about the temporal relations in the context passage. The task is much analogous to our real-world tasks and is more challenging – we need to automatically identify the events and the relations in the free-text question to retrieve the answers from the context passage. To the best of our knowledge, we are the very first to address this challenge.

3 Our Approach

We first introduce the definition of temporal reading comprehension (TRC) and then describe the model architecture consisting of contextual encoder, question understanding, and event relation assessment. Finally, we provide details for the learning and inference process.

3.1 Task Definition

The Temporal Reading Comprehension (TRC) task is defined as follows. Given a passage P which describes a set of events, a system is required to answer a temporal ordering question Q. Here *events* refer to verbs or nouns which define actions or states. A temporal ordering question usually queries events satisfying some concerned temporal relations considering one or more referred events. For example, the first passage in Figure 1 describes events about *Hamas goverment*, and question $Q1$ queries which events have the temporal relation *happen after* with the referred event *the victory*. The answer set A to a question Q could be empty when no events meet the requirement.

3.2 Model Architecture

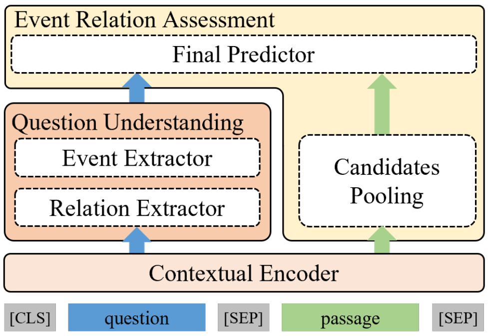

Figure 2: An overview of the proposed model.

Figure 2 depicts the proposed model architecture. Specifically, the passage P and question Q are first encoded by a *contextual-aware encoder*, after which the representations of the question are passed to a *question understanding* module. Finally, each candidate answer is evaluated considering whether it satisfies the concerned relation to the referred event by an *event relation assessment* module.

Contextual Encoder We first encode the passage-question pairs with a pre-trained language model encoder, and here we take BERT as an example. Given a question $Q = [q_i]_{i=1}^{m}$ and a passage $P = [p_i]_{i=1}^{n}$, where m and n are token numbers, we concatenate them into a sequence with the format of *[cls] question [sep] passage [sep]*, which is then fed into the contextual encoder to generate the embeddings,

$$[\mathbf{h^q_1}, ..., \mathbf{h^q_m}, \mathbf{h^p_1}, ..., \mathbf{h^p_n}] = \\ \mathrm{BERT}([q_1, ..., q_m, p_1, ..., p_n]), \tag{1}$$

where $\mathbf{h^q_i}, \mathbf{h^p_i} \in \mathcal{R}^d$ are embeddings for question token q_i and passage token p_i, and d is the embedding size.

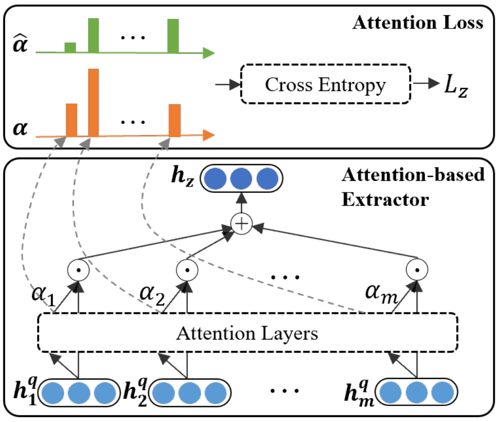

Figure 3: The structure of attention-based event/relation extractor, with attention loss for it.

Question Understanding As discussed in Section 1, precise question understanding plays an essential role in TRC task. Therefore, we propose a question understanding module to achieve that. Intuitively, a temporal ordering question consists of two elements, referred events, and concerned temporal relation. For example, the question "*What usually happened during the press release*" queries the temporal relation *usually happen* to the event *the press release*. A straightforward solution is to decompose the question into two segments directly. However, natural language questions vary a lot, and hard decomposition is risky and might propagate errors to downstream modules, which is verified by experimental analysis in Section 4.5,

Therefore, we design an attention-based extractor to decompose the question implicitly, and obtain two hidden representations, $\mathbf{h_c}$ for the referred event and $\mathbf{h_r}$ for the concerned temporal relation as follows,

$$\mathbf{s_i^{(z)}} = \tanh(\mathbf{W_1^{(z)} h_i^q} + b_1^{(z)}), \quad z \in \{c, r\} \tag{2}$$

$$\alpha_i^{(z)} = \text{Softmax}(\mathbf{W_2^{(z)} s_i^{(z)}} + b_2^{(z)}), \quad z \in \{c, r\} \tag{3}$$

$$\mathbf{h_z} = \sum_{i=1}^{m} \alpha_i^{(z)} \mathbf{h_i^q}, \quad z \in \{c, r\} \tag{4}$$

where $\mathbf{W^{(c)}}, \mathbf{W^{(r)}} \in \mathcal{R}^d$, and $b^{(c)}, b^{(r)} \in \mathcal{R}$ are learn-able weights for the extractor, $\mathbf{h_i^q} \in \mathcal{R}^d$ is the embedding for the i-th question token. To effectively learn $\mathbf{h_r}$ and $\mathbf{h_c}$, we employ several auxiliary losses in the training phase, which will be described in section 3.3.

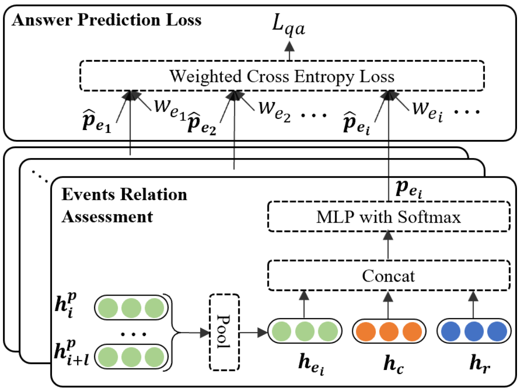

Figure 4: The structure of the event relation assessment, with answer prediction loss for it.

Event Relation Assessment Given the question representations $\mathbf{h_r}$ and $\mathbf{h_c}$, the *event relation assessment* module evaluates how a candidate answer satisfy the relation $\mathbf{h_r}$ with respect to $\mathbf{h_c}$. Let $e = p_i \dots p_{i+l}$ denotes the candidate answer, which consists of l tokens in the passage P. We first get the representation of e by pooling over according token vectors,

$$\mathbf{h_e} = \text{Pool}(\mathbf{h_i^P}, \dots, \mathbf{h_{i+l}^P}). \tag{5}$$

Then we concatenate the representations of the candidate event $\mathbf{h_e}$, question relation $\mathbf{h_r}$, and the question event $\mathbf{h_c}$, and feed it into a two-layer MLP, followed by a softmax function to get the final probability,

$$\mathbf{o_e} = \tanh(\mathbf{W_1^o}[\mathbf{h_e}; \mathbf{h_c}; \mathbf{h_r}] + \mathbf{b_1^o}), \tag{6}$$

$$\mathbf{p_e} = \text{Softmax}(\mathbf{W_2^o o_e} + \mathbf{b_2^o}), \tag{7}$$

where $\mathbf{W_1^o} \in \mathcal{R}^{3d \times d'}$, $\mathbf{W_2^o} \in \mathcal{R}^{d' \times 2}$, $\mathbf{b_1^o} \in \mathcal{R}^{d'}$, $\mathbf{b_2^o} \in \mathcal{R}^2$ are model parameters, and ; indicates concatenation. $\mathbf{p_e} \in \mathcal{R}^2$ is the probability whether the candidate e satisfies the temporal relation h_r with respect to event h_c.

3.3 Learning Objectives

We employ three learning objectives for model training, including a classification loss L_{qa} function for final answer prediction, and an attention loss L_{att} and a contrastive loss L_{con} for precise question understanding. The overall loss is a weighted combination of all the objectives,

$$\mathcal{L} = w_{qa} L_{qa} + w_{att} L_{att} + w_{con} L_{con}. \tag{8}$$

Answer Prediction Loss The training objective for final answer prediction is defined as,

$$L_{qa} = -\sum_{e \in \mathcal{C}} w_e \hat{\mathbf{p}}_{\mathbf{e}}^T \log \mathbf{p}_{\mathbf{e}}, \tag{9}$$

where $\mathcal{C}$ is the candidate event set, w_e is the weight for candidate e, $\mathbf{p}_{\mathbf{e}} \in \mathcal{R}^2$ is the predicted probability from Eq. (7), and $\hat{\mathbf{p}}_{\mathbf{e}} \in \{0,1\}^2$ is the golden label indicating whether the candidate e belongs to the final answer of the question.

Usually, the candidate set $\mathcal{C}$ is derived by preliminary filtering all unigrams in the passage P. However, some candidates are easy to be classified while others are not. For example, it is easy to classify the word *government* in Figure 1 as a negative answer since it is not an event. In contrast, predicting whether the word *frozen* is the answer for Q1 in Figure 1 is more challenging. Inspired by this observation, we assign weights w_e for candidates in the learning objective, $w_e = 1.5$ if e is an event, and otherwise $w_e = 1.0$. The label of whether a word is an event can be derived when labeling the final answer with little effort, so we can safely assume that we always have such annotation[1].

Attention Loss Besides the answer prediction loss, we also leverage an auxiliary loss to guide the learning of the attention score $\alpha_i^{(c)}$ and $\alpha_i^{(r)}$ defined in Eq. (3). We first derive silver annotation for referred events and concerned relation in a passage using a rule-based approach, which will be detailed in Section 4.2. Let Q_c, Q_r be the set of event and relation tokens according to the silver annotation. Then we have $\hat{\alpha}_i^{(z)} (z \in \{c, r\})$ as the derived attention label,

$$\hat{\alpha}_i^{(z)} = \begin{cases} \frac{1}{|Q_z|}, & \text{if } q_i \in Q_z, \\ 0, & \text{otherwise.} \end{cases} \tag{10}$$

The attention loss is defined as,

$$L_{att} = L_c + L_r, \tag{11}$$

where

$$L_z = -\sum_i \hat{\alpha}_i^{(z)} \log \alpha_i^{(z)}, \quad z \in \{c, r\}. \tag{12}$$

Contrastive Loss As shown in Figure 1, a small change of a question might lead to substantially divergent temporal relations. To this end, we propose to leverage a contrastive loss for precise learning of question relation representations.

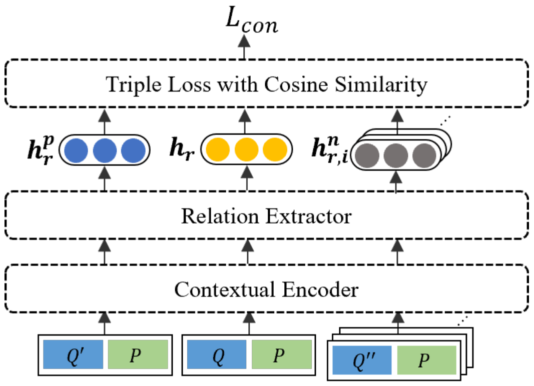

Figure 5: Illustration of the contrastive loss for question understanding.

For the relation representation $\mathbf{h_r}$ of a question Q, we derive a positive vector $\mathbf{h_r^P}$ and a set of negative ones $\{\mathbf{h_{r,i}^n}\}_{i=1}^N$). The positive sample $\mathbf{h_r^P}$ is obtained in two ways. First, we search questions with the same temporal relations but different events, from which we randomly sample one and take its relation representation as $\mathbf{h_r^P}$. Note we can get the silver annotation of events and relations in a question by a rule-based approach. Please refer to section 4.2 for more details. Second, if no such questions can be found, we take the similar approach as in SimCSE (Gao et al., 2021), which applies a different dropout on $\mathbf{h_r}$ and gets a variant of $\mathbf{h_r}$ as $\mathbf{h_r^P}$. We search questions that contain the same events by different temporal relations with respect to Q, and take their relation representations as the negative set $\{\mathbf{h_{r,i}^n}\}_{i=1}^N$).

Given the triple $(\mathbf{h_r}, \mathbf{h_r^P}, \{\mathbf{h_r^n}\})$ for the question Q, its loss is defined as,

$$L_{con}(Q) = -\log \frac{e^{\cos(\mathbf{h_r}, \mathbf{h_r^P})}}{e^{\cos(\mathbf{h_r}, \mathbf{h_r^P})} + \frac{1}{N}\sum_{i=1}^{N} e^{\cos(\mathbf{h_r}, \mathbf{h_{r,i}^n})}}, \tag{13}$$

where $cos()$ indicates cosine similarity.

3.4 Inference

The inference phase takes three steps. First, we generate a candidate set $\mathcal{C}_p$ for each passage P. Generally speaking, one can take any n-gram in P as a candidate. In temporal relation understanding, we usually take a triggering word as an event candidate. Therefore, $\mathcal{C}_p$ is the set of all unigrams in P. Then, we filter $\mathcal{C}_p$ according to part-of-speech (POS) tagging. Specifically, we use an off-the-shelf POS tagger to tag all words in P, and then keep only verbs and nouns in $\mathcal{C}_p$. Finally, each candidate $e \in \mathcal{C}_p$

---

[1] The TORQUE dataset in our experiment also contains such annotation, and we use it directly in our approach

together with the passage P and the question Q is fed into our proposed model, and e is evaluated according to Eq. (7) and gets its score $\mathbf{p_e}$, where $p_{e,0}$ represents the probability that the candidate matches the question Q. Then we can get the final answer set A as $A = \{e : e \in \mathcal{C}_p \text{ and } p_{e,0} > \tau\}$, where τ is a predefined threshold.

4 Experiments

This section describes an empirical evaluation of our proposed approach. We also provide analysis, ablation studies, and case analysis to demonstrate its effectiveness.

4.1 Settings

Dataset We evaluate the proposed approach on the TORQUE dataset. TORQUE is a temporal reading comprehension benchmark. Each training sample contains a passage and a question requiring understanding temporal relation between events in the passage. Figure 1 shows several examples of training data. The answer to a question consists of an event set A, and A could be empty if no event in the passage satisfies the requirement of the question. In TORQUE, events are defined as event triggers, usually verbs or nouns describing actions or states. There are 3.16k passages with 30.7k questions in total and 2 events for an answer on average. We follow the official split[2] with 80%/5%/15% of data in training/validation/test.

Evaluation Metrics Following Ning et al. (2020)[3], we report three metrics in our experiment, including standard macro F1 and Exact Match (EM) for question answering and consistency score(C). There are multiple annotations for each passage-question pair, which might not always be consistent with each other. We follow the official implementation. Specifically, for each sample, a model's prediction is evaluated according to all annotations, where the largest score is selected and aggregated as the final result.

4.2 Implementation Details

We experiment four pre-trained language models as our contextual encoder, i.e., the base and large model of BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019). The embedding size d is set to 64, d' in Eq (6) and Eq (7) is set to 64. The threshold τ for inference is set to 0.5. In model training, the batch size is set to 16, the dropout rate is set to 0.5. The combination weight w_{qa}, w_{att} and w_{con} in Eq. (8) is set to 1.0, 0.3, and 1.0, respectively. We search the learning rate lr, with grid searching within 3 trials in $lr \in \{0.9 \times 10^{-5}, 1.0 \times 10^{-5}, 1.1 \times 10^{-5}\}$ for the base and large model of RoBERTa, and $lr \in \{4.0 \times 10^{-5}, 5.0 \times 10^{-5}, 6.0 \times 10^{-5}\}$ for the base and large model of BERT. The implementation is based on Python and trained on a Tesla V100 GPU with Adam optimizer for approximately three hours (base model with approximately 110M parameters) and ten hours (large model with approximately 340M parameters). We get the averaged result of three trials for each setting, choose the model with the highest F1 score on the development set, and report the performance on the test set derived from the official online test[4].

Deriving Attention Annotation The relation annotation Q_r for question Q is derived as follows. First, we compile a dictionary for temporal relations, such as *before*, *after*, etc. Please refer to Appendix A.1 for the complete list. Then Q_r is constructed with those words in Q that hit the dictionary. The event annotation Q_c is mainly derived according to the passage P. Particularly, we assume the mentioned event list E in P is known. If a word of Q matches an event in E, it is included in Q_c. Otherwise, if no words of Q hit E, we rely on the relation annotation. Suppose the last relation word is in position k, then $Q_{k+1...n}$ is set as Q_c.

4.3 Main Results

We compare our approach with the baseline (Ning et al., 2020), which takes a passage and the corresponding question as input and applies a one-layer perception on the embedding of each token to predict whether it is the answer of the question or not. The comparison results with four different contextual encoders are shown in Table 1. The table shows that our proposed approach outperforms the baseline on nearly all evaluation metrics. Our model achieves state-of-the-art results with the RoBERTa-large encoder, increasing the F1 score by 1.8% and 0.9% for the dev and test set, respectively. We can see a huge increase for the consistency score (C) on the test set from 34.5% to 38.1%. Using other pretrain language models like BERT-base, our model also improves the performance compared to the baseline approach, by 2.6%, 3.2%, 2.5% in terms of F1, EM, and C score, respectively. Although

there is still a large gap towards the human performance, our model takes a large step compared to the baseline approach, verifying the effectiveness of the proposed approach.

4.4 Ablation Study

Models	**F1**	**EM**	**C**
OUR MODEL	76.1	51.0	38.1
-con	75.8 (-0.3)	49.8 (-1.2)	37.0 (-1.1)
-con -att	75.6 (-0.5)	50.8 (-0.2)	36.6 (-1.5)
-w_e	75.8 (-0.3)	50.6 (-0.4)	37.6 (-0.5)
-all	74.8 (-1.3)	49.7 (-1.3)	34.0 (-4.1)

Table 2: Ablation study on the test set of TORQUE. RoBERTa-large is used as contextual encoder.

We conduct an ablation study to illustrate the effectiveness of each loss in our approach. As shown in Table 2, removing the contrastive loss will lead to a 1.1% drop on consistency value. When we remove both the contrastive and attention loss for question understanding and use mean pooling over the contextual embedding of the whole question token sequence, the macro F1 score and the consistency score decrease by 0.5% and 1.5%, respectively, showing that precise question understanding plays a critical role for TRC. Also, we remove weight w_e in the answer prediction loss in Eq. (9), which results in a 0.3% drop in terms of the F1 score. When all auxiliary loss is removed, which is basically the same as the baseline model with our own implementation, it leads to a huge gap of 1.3%, 1.3%, 4.1% on macro F1, exactly match and Consistency score, respectively. The results of the ablation study indicate that each element of our proposed model is critical for temporal relation understanding.

4.5 Question Representation Analysis

Models	**F1**	**EM**	**C**
w contrastive loss			
attention-based	76.1	51.0	38.1
rule-based	75.8 (-0.3)	50.6 (-0.4)	37.6 (-0.5)
w/o contrastive loss			
attention-based	75.8	49.8	37.0
rule-based	75.6 (-0.2)	48.9 (-0.9)	36.3 (-0.7)

Table 3: Comparison of attention-based and rule-based question representation learning. RoBERTa-large is used as contextual encoder.

As discussed in Section 3.2, a straightforward solution for question understanding is to decompose a temporal ordering question into two parts directly. This section compares our attention-based approach with the hard question decomposition, which obtains the two question vectors $\mathbf{h_r}$ and $\mathbf{h_c}$ by conducting mean pooling over embeddings of tokens in Q_r and Q_c respectively. The comparison results are shown in Table 3. We can see that although the rule-based approach achieves relatively good accuracy, it still underperforms our attention-based approach. For example, when no contrastive loss is employed, the EM score drops by 0.9% when replacing the attention-based representation with the rule-based one. The possible reason is that the rule-based decomposition cannot handle all questions perfectly, and errors in the decomposition will be propagated to downstream modules. For example, "*What could have happened while the announcement was made but didn't?*". "*but didn't*" is a crucial negate in the temporal relation, but the rule-based method might miss it.

4.6 Case Study

Figure 6 shows predicted answers of our model and the baseline for several questions. For the first passage, Questions 1, 2, and 3 inquire about the "*happened after*" temporal relation, but with subtle differences. Q1 is the most common form, which can be answered correctly by both the baseline and our proposed approach. Meanwhile, the baseline model can not capture the negation information

Paragraph: “This decision came after the failure of the dialogue to form a national unity government with the Hamas movement and is the result of the ongoing political and economic siege against the Palestinian people,” he added.

Question & Answers	**Baseline**	**Ours**
Q 1: What happened after the dialogue began?	decision, failure	decision, failure
Q 2: What has not happened after the dialogue began?	No answer	form
Q 3: According to the speaker, what began happening after the dialogue began?	decision, failure	failure

Paragraph: Pakistan's defense ministry Sunday dismissed Indian reports of an alarming increase in cross-border firing in the disputed Kashmir state. "It is a ploy to divert attention from the turbulence in Indian-held Kashmir," a ministry official said.

Question & Answers	**Baseline**	**Ours**
Q 1: What might have started after the reports?	divert, turbulence	divert
Q 2: What might have started before the reports?	increase, turbulence	increase
Q 3: What started before the reports?	increase, turbulence	turbulence

Figure 6: Case study of our approach and the baseline model. Correct answers are marked in blue. Incorrect ones are marked in red. Candidate events in passages are underlined. Both the baseline and our approach use RoBERTa-large as encoder.

in Q2 and fails to predict the correct answer. In Q3 “*happened after*” is constrained by the word *begin*, which confuses the baseline model and leads to partially correct answers. In contrast, our proposed approach can capture these subtle but critical differences and thus makes correct predictions.

For the second passage, our proposed model performs better for all three questions of different temporal types. Q1 and Q2 are variants of uncertain relations, which query about two opposite temporal relations “*started after*” and “*started before*”. The word “*might*” brings uncertainty for the concerned temporal relation, which confuses the baseline model, leading to the wrong prediction for the candidate answer “*turbulence*” for both questions. Q3 queries about a popular temporal relation, and our model can precisely capture the difference between it and two other ones and predict that the candidate event “*increase*” does not meet its requirement since it comes from a controversial report.

4.7 Error Analysis

We randomly sample 100 wrongly predicted question-passage pairs from the validation set, which can be summarized into three categories.

Multi-round Reasoning Sometimes one needs to perform multi-round reasoning to infer the relation between two events, for example, given the passage “*Roughly 40 minutes after the operation began, jubilant soldiers appeared on the rooftop of the residence, flashing the V victory sign. Then Fujimori, who ordered the operation, arrived to tour the residence and embraced the freed hostages.*”, the temporal ordering between “*ordered*” and “*the jubilant soldiers appeared on the rooftop*” is inferred by multi-step reasoning. That is, “*ordered*” happened before “*operation began*”, and “*operation began*” happened before “*solder appeared*”, and thus “*ordered*” happened before “*appeared*”. An advanced reasoning framework is necessary to handle such cases, and we leave it as future work.

Commonsense Knowledge Required The given passage might not provide sufficient information. For example, in the passage “*He was preparing the paperwork for the move, following the course of an absolutely standard transfer. Sadly he killed himself at home in the meantime.*”, although it states that “*preparing the paperwork*” and ““*he killed himself*” happened “*in the meantime*”, commonsense knowledge indicates that *one cannot kill himself and prepare the paperwork at the same time*. So we can infer that “*preparing*” happened before “*killed*”. Incorporating external knowledge is a potential solution for such cases.

Ambiguous Labeling Since the concept of event is not well-defined, it might lead to ambiguous labeling. Considering a passage contains a span “*decision is made*”, some annotators might label *decision* as a candidate event, while others does not. This causes inconsistent labeling, and thus makes it difficult to learn a good predictor.

5 Conclusion and Future Work

Temporal reading comprehension plays a critical role in natural language understanding. In this paper, we propose a precise question understanding method to tackle the TRC problem. Specifically, we encode temporal ordering questions into representations of referred events and concerned temporal relations, based on which candidate answers are evaluated in terms of their temporal relations to the referred events. In addition, a contrastive loss is employed to empower the model to capture essential differences among temporal relations. Experimental results based on four pre-trained models verify the effectiveness of our proposed approach. In the future, we will investigate general approaches to handle more diverse temporal relation understanding problems and improve the passage understanding capability for temporal reading comprehension.

Abstract

Cross-lingual question answering is a thriving field in the modern world, helping people to search information on the web more efficiently. One of the important scenarios is to give an answer even there is no answer in the language a person asks a question with. We present a novel approach based on single encoder for query and passage for retrieval from multi-lingual collection, together with cross-lingual generative reader. It achieves a new state of the art in both retrieval and end-to-end tasks on the XOR TyDi dataset outperforming the previous results up to 10% on several languages. We find that our approach can be generalized to more than 20 languages in zero-shot approach and outperform all previous models by 12%.

1 Introduction

Question answering (QA) is an important tool for information search on the Internet. Since it is natural for a person to ask a question to get some information, the QA systems are designed to meet this requirement. QA provides a wide range of tasks, from engineering to cornerstone scientific tasks. Open-domain QA, in this direction, is an interesting example of a problem that connects both: multilingual knowledge sources form differing knowledge and supplement gaps in each specific language. The requirement for modern language models to be cross-lingual is gradually becoming more and more important and is being incorporated into popular benchmarks such as XGLUE (Ruder et al., 2021) or XTREME (Liang et al., 2020), where the systems are evaluated not only by their performance metrics on single language tasks but the ones on many languages.

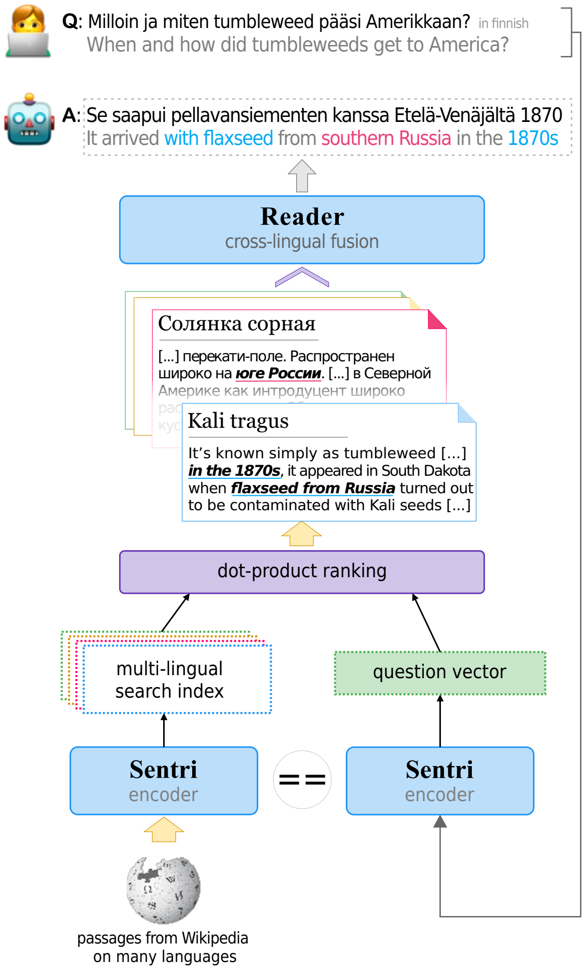

Figure 1: Overview of **Sentri** and a case example of answering a Finnish question using non-Finnish sources. In short, *at the first step* system retrieves information from factoid knowledge sources (*Wikipedia's*) on diverse languages. *In the second step* it fuses the retrieved information regardless of the language of each part, even in the absence of texts on query language. *Finally*, it produces an answer on the query language that aggregates all (as it can) diverse pieces from other languages.

For this particular example, there is no answer[1] in Finnish Wikipedia. One of the reasons is that there aren't many articles in Finnish Wikipedia because Finnish is a **low-resource** language in general. Moreover, the answer can be found in **rich-resources** languages such as English or Russian for example.

Generally, passage retriever is based on the so called dual-encoder, i.e. two independent modules of the same architecture for the question and context encoding. However, in previous works (Qu et al., 2021; Gao and Callan, 2021) authors found out that on the one hand dual-encoder is not noise-resistant and on the other hand large batch training can improve stability of resulting embedding space. For instance, in (Qu et al., 2021; Gao and Callan, 2021) authors used 512×8 and 512×4 respectively.

Ouguz et al. (2021) present DPR-PAQ model combining large semi-supervised corpus for pre-training with the better and larger LM $RoBERTa_{large}$, DPR-PAQ achieves the state of the art results on Natural Questions dataset. Nevertheless, large models and large batch training require abundance of GPU memory. The mentioned models are represent dual-encoder scheme, where two independent encoders are used – one for the questions and one for the passages. To reduce memory usage, we present a system including a single encoder used for both tasks, moreover, we show that the system using single encoder can learn an embedding space better suited for transfer learning and thus improve result in cross-lingual question answering in zero-shot scenario.

The system, we call **Sentri**, achieves a new state of the art on XOR TyDi QA cross-lingual dataset (Asai et al., 2021a) outperforming the previous approaches by 10% on retrieval task and 7% on end-to-end question answering task. In addition, on MKQA multi-lingual dataset (Longpre et al., 2020), which contains translations of Natural Questions to different languages, in zero-shot scenario our system outperforms a strong baseline by 8%.

The overall contribution of this paper is two-fold: (i) we present a system, including single encoder for questions and contexts, that achieves state-of-the-art results in the retrieval and end-to-end tasks of the XOR TyDi dataset, (ii) we provide an analysis of the system behaviour in zero-shot scenario on unseen languages proving the its transferability and lower resource consumption.

The rest of the paper is organized as follows. Section 6 presents an overview of the recent studies on multilingual QA models. Section 2 which details the dataset design choices, outlines the data preparation pipeline and data used for evaluation.

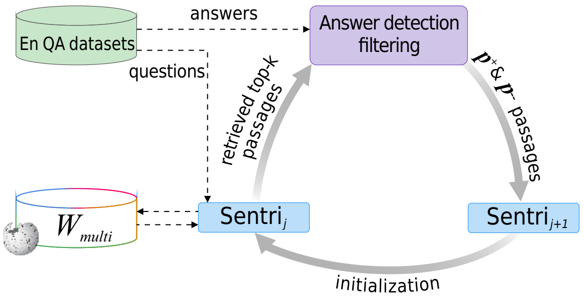

Figure 2: Iterative training framework that adopts the idea of *self-training*. *At first*, we retrieve top-k passages from Wikipedia for each question from the initial QA training set with $Sentri_j$ model. *Secondly*, we select the positive (p^+) passages for each question and treat the rest as hard negative (p^{--}) examples. *Finally* we train the new $Sentri_{j+1}$ model closing a circle.

Section 3 presents the engineering choices and describes the resulting model and its training process. We describe experimental setup and describe the achieved results in Section 4. We provide additional results analysis in Section 5, and Section 7 concludes the paper.

2 Datasets

In this work, we use XOR TyDi and MKQA to evaluate our system onto and several datasets to (pre-)train it.

XOR TyDi (Asai et al., 2021a) is a multilingual open-retrieval QA dataset that enables cross-lingual answer retrieval. The dataset, based on questions from TyDi QA (Clark et al., 2020), articulates three new tasks that involve finding documents in different languages using multilingual and English resources. It consists of questions written by information-seeking native speakers in 7 typologically diverse languages: Arabian, Bengali, Finnish, Japanese, Korean, Russian and Telugu. Answer annotations are retrieved from multilingual document collections. *XOR-Retrieve* is a cross-lingual retrieval task where a question is written in the target language (e.g., Japanese), and a system is required to retrieve an English document that answers the question. XOR-English Span is a cross-lingual retrieval task where a question is written in the target language (e.g., Japanese), and a system is required to output a short answer in English. *XOR-Full* is a cross-lingual retrieval task where a question is written in the target language (e.g., Japanese), and a system is required to output a short answer in the target language. In our work, we concentrate on XOR-Retrieve and XOR-Full

---

[1] There exists only one Wikipedia page on Finnish related to tumbleweed but there is no mention that tumbleweed is an invasive plant in North America.

tasks and use XOR TyDi to train and evaluate our system.

2.1 Training Dataset Pre-processing

Since there are low-resource languages in the XOR TyDi dataset, the task of preparing data is of priority importance. To generate data in different languages, we used NQ and Trivia QA datasets described above. Both NQ and Trivia QA are English language datasets. To use them for training purposes in our setup we had to translate them to the languages of XOR TyDi. The quality of machine translation still does not match the human translation quality in most of the languages and domains. However, questions and answers in NQ and Trivia QA datasets are short and easy to translate.

For each pair of question q and answer a from the datasets, we made translations from English to each language L_i using the **M2M100** model described in (Fan et al., 2020), it is a state-of-the-art model for translation for many languages, including the ones we are interested in. Thus we translated question-answer pairs and we got an aligned dataset. The pairs are not enough, since the open-domain QA task is based on so-called support passages retrieved from some document collection. To overcome this issue we mined the positive and hard negative sample passages for each language L_i. We consider a paragraph from a document to be a positive sample if it is ranked high by a retriever model and includes the answer. We use complicated morphology-aware answer detection technique which we describe in Appendix. If a paragraph is highly ranked but contains no answer, we consider it as a hard negative sample. The resulting statistics and analysis of the training dataset we also present in Appendix.

Information Retrieval We took into account that most XOR TyDi languages have complex morphology and other linguistic features, which makes information retrieval less effective for the models using token comparison. Thus we decided to normalize the morphology for at least the languages, which has publicly available stemmers, namely, Arabic[1], Bengali[2], Korean[3], and Russian[1]. The Telugu language has no publicly available stemmer, but there is a lemmatizer[4], which we used.

For Korean we apply token splitting by the part-of-speech tag, i.e. modifier POS as a *Josa* and *Eomi* are treated as separate tokens. Unfortunately, we have not found accessible stemmers and/or lemmatizers for Japanese and Finnish languages. We use this normalisation to improve positive passage mining for self-training procedure. More details on normalisation could be found in Appendix.

Natural Questions (NQ) (Kwiatkowski et al., 2019) dataset is designed for end-to-end question answering. The questions are mined from real Google search queries and the answers are spans in Wikipedia articles identified by annotators. We use this dataset in two ways. One way is for training and another one is for zero-shot evaluation. The latter option is provided to us by **MKQA** dataset (Longpre et al., 2020). It is a translation of 10 thousand question-answer pairs from NQ to 26 different languages, thus giving us an aligned dataset of 260 thousand question-answer pairs total. The former option is described below.

We also use **Trivia QA** for pre-training of our model. Joshi et al. (2017) presented Trivia QA, a large-scale question-answering dataset that includes so-called evidence documents, allowing one to state a task of information retrieval. Trivia QA includes 95 thousand question-answer pairs authored by trivia enthusiasts and independently gathered evidence documents, six per question on average ending with 650 thousand total triples.

3 Method

The open domain question answering task heavily relies on retrieval from some (possibly more than one) document collections. In the case of the cross-lingual variant of this task, the usage of several (at least two - in English and in a target language) document collections is almost inevitable. We evaluate our model in two cross-lingual setups: using English Wikipedia (W_{eng}) to search for a relevant passage containing the answer to the question or using collection of multilingual reference passages from Arabic, Russian, English, Finnish, Telugu, Bengali, Japanese, Korean Wikipedia (W_{multi}). More formally, given a question q in language L_i, a system retrieves the documents from W_{eng} or W_{multi}, and formulates an answer a. Thus the system could be virtually split to **retriever**, which creates a list of

relevant documents, and **reader**, which generates an answer using the most relevant documents. The sample of the system output is presented on Fig. 1.

3.1 Single Encoder Retriever

We follow common (Qu et al., 2021; Asai et al., 2021b; Ouguz et al., 2021) dual-encoder approach in data representation. The system consists of question encoder $E_q(\cdot)$ and passage encoder $E_p(\cdot)$ which maps text to d-dimensional real-valued vectors. Before run-time, $E_p(\cdot)$ applied to all passages in knowledge source to create search index. To find out relevant passages to certain question system operates a similarity function:

$$\mathrm{sim}(q,p) = E_q(q)^{\intercal} \cdot E_p(p). \tag{1}$$

i.e. similarity between the question and the passage defined by the dot product of their vectors.

In this work we investigate case when $E_q(\cdot) = E_p(\cdot)$ and call this approach as *Single Encoder*. In addition to it, a model with $E_q(\cdot) \neq E_p(\cdot)$ we call *Bi-Encoder* to avoid confusion.

The architecture that utilizes **S**ingle **en**coder approach for re**tri**eval (**Sentri**) shares one encoder for $E_q(\cdot)$ and $E_p(\cdot)$ contrary to bi-encoder which based on two separate models.

Since our model is used in a multi-lingual setting, the choice of multilingual models is natural for base model. We use XLM-RoBERTa (Conneau et al., 2020) (large) in our experiments.

answers	July 16, 2017, August 27 , 2017, July 16 , 2017 ...

Figure 3: An example of overlap in positive passages (p^+) for different instances of a question.

Training Sentri is trained to give positive passages higher scores than negative passages. More specifically, given a question q_i in a language from L together with its positive passage p_i^+ and m negative passages $\{p_{i,j}^-\}_{j=1}^m$ sampled from W_{multi}, we minimize the loss function:

$$\begin{aligned}&\mathcal{L}(q_i, p_i^+, \{p_{i,j}^-\}_{j=1}^m) \\ &= -\log \frac{e^{\mathrm{sim}(q_i, p_i^+)}}{\sum_{j=1}^m e^{\mathrm{sim}(q_i, p_{i,j}^-)} + e^{\mathrm{sim}(q_i, p_i^+)}},\end{aligned} \tag{2}$$

where we aim to optimize the negative log-likelihood of the positive passage against a set of m negative passages.

For each question, we treat other passages in the training batch that do not answer this particular question as negative passages (*in-batch negative trick*, Henderson et al. 2017; Karpukhin et al. 2020) In particular, for batch size n each question can be further paired with $m = n - 1 + n$ negatives (i.e., positive and hard negative passages of the rest questions) without sampling additional negatives. Furthermore, in the case of multilingual data, it helps enforce the cross-lingual ability of the model because of an increasing number of cross-language pairs.

3.2 In-batch False Negatives Filtering

Although the above strategy can increase the number of negatives, some of them may turn out to be false negatives. We analyze the batches generated for the training and found out that different questions in the same batch could have the same positive passages. Since these positive passages are used for in-batch negative training that produces false negative pairs. For English Wikipedia this overlap is significant but not so crucial like for lower resource Wikipedias. For instance, for Natural Questions passages in 44% training triplets (questions, answer, passage) are used more than once in the dataset. The sample of positive passage overlap for NQ is presented on Fig. 3. We use in-batch filtering allowing us to eliminate this overlap from generated batches and thus improve the overall system quality.

3.3 Self-Training

Several works (Qu et al., 2021; Izacard and Grave, 2020a) refer to iterative learning as a source of model quality improvement. We use this idea in the form described below, which we call *self-training*. Fig. 2 presents the framework which we use in this work. $Sentri_j$ model retrieves top-k passages from Wikipedia for each question from the initial QA training set. Then we select the positive (p^+) passages for each question (we know the ones for the initial training set) and treat the rest as hard

Table 1: Performance on XOR-Retrieve task. The best result is given in **bold**, the second best is in *underlined italic*. We note that at extremely **low-resource** languages such as Finnish and Telugu *Sentri* shows consistent performance, similar to results on **moderate-resource** languages such as Russian.

negative (p^{--}) examples. Afterwards, we train new iteration $Sentri_{j+1}$ model using the passages marked up previously. In contrast to (Asai et al., 2021b) we train iteratively only a retrieval part of the whole system.

At stage 0 when there is no trained model available, we use well-known BM25 model (Sanderson, 2010) as a retriever in our experiments. The important feature of this model is that it does not need any kind of training, thus it could be used to retrieve documents from collections in languages with little or no training data.

For Sentri system we report the results for the *second* stage of self-training below. For Bi-Encoder we report results for stages 1 and 2 adding the specifying index.

3.4 Answer Generation

We have experimented with both extractive and abstractive answer generation and found out that abstractive is more profitable. Here we describe the abstractive reader approach we use as primary one. We decided to use the FiD model (Izacard and Grave, 2020a) as a reader model in Sentri for end to end question answering task XOR-Full since it allows us to exclude the translator from a pipeline and to aggregate information in a cross-lingual setup. Since the original FiD model is monolingual, we present extension of this work, multilingual version which we call **MFiD**. To train MFiD, we use several QA datasets, listed in Sec. 2, namely XOR-Full, XOR TyDi, Natural Questions, and Trivia QA datasets, the same ones used for training the retriever part of the Sentri model. For each question from the QA datasets we retrieve top-50 passages from multi-language knowledge source using our retriever model. And then use it for training MFiD as cross-lingual fusion reader. We also experimented with standard extractive reader. The details on extractive approach could be found in Sec. 5.

4 Experiments

We have conducted a series of experiments with number of models, namely these are Sentri model combined with different reader parts and Bi-Encoder model with one or two stages of self-training. Bi-Encoder model is using standard extractive reader (plus machine translation where applicable). The main difference between Sentri and Bi-Encoder, that the latter is based on classic dual-encoder architecture, while the former is using single encoder for questions and paragraphs.

4.1 Results on XOR TyDi

Tables 1 and 2 contain results for our system in retrieval and end-to-end setups, XOR-Retrieve and XOR-Full respectively. These two tables contain the results of the models' evaluation on the development and test parts of the XOR TyDi dataset. It is important to mention that we use name Sentri for our model in both tasks, while in XOR-Retrieve task the reader part is not used, since it is essentially a passage ranking evaluation. Also, you can find results for our models titled as Bi-Encoder$_1$ and Bi-Encoder$_2$ (for first and stages of self-training respectively). As one can see Sentri significantly outperforms these baseline models and existing state-of-the-art models. We provide more detailed analysis in section Ablation Study.

Tab. 1 displays recall scores for 2000 and 5000 first tokens (**R@2kt** and **R@5kt** respectively). That means that we expect to find an answer span in the first l tokens. This metric was proposed

Table 3: Zero-shot cross-lingual retrieval results on MKQA dataset.

in (Asai et al., 2021a) as alternative to more common $Recall@N$ in purpose to make more fair comparison across various models with different passage size used.

Our system outperforms the previous state-of-the-art system in both R@2kt and R@5kt metrics by a wide margin on four languages, namely Arabic, Japanese, Russian, and Telugu. More importantly, our system outperforms the previous system on average for all the languages. Interestingly, self-training improves the results in all the languages, with the intriguing exception of the Russian language. This fact requires an additional investigation, we leave it as future work for now.

Table 2 displays F1, Exact Match (EM), and BLEU scores for the end-to-end setup where given a question in target language L_i and Wikipedia in both English and L_i, a system is required to generate an answer in the target language. F1 measure is computed per token for an answer span. Exact Match compares the golden answer span with the system output for exact equality. BLEU metric, defined as in (Papineni et al., 2002), computes the number of overlapping n-gram between the golden answer and the system output. In this experiment, we see a somewhat different behaviour of the model. Our model outperform previous state of the art system for all languages, with exception for Telugu where CORA model (Asai et al., 2021b) shows insignificantly higher score.

4.2 Zero-Shot Cross-Lingual Transfer

We investigated the transferability across the languages for the trained system. We used the MKQA dataset in similar to the XOR-Retrieve setup, i.e. we retrieved the passages from English Wikipedia, extracted the answer from the top-ranked passage, and translated it with a machine translation model. Here we again use M2M100 model for machine translation task. As a baseline for this task, we utilized BM25 with extractive reader and the machine translation model at the end of pipeline. We selected from MKQA such unseen languages that were not presented to the system during the training process. The achieved results presented in Tab. 3 show that even in such a zero-shot setting our system significantly outperforms both the strong baseline and previous approaches in all languages. Additional details on zero-shot transfer could be found in Appendix.

5 Ablation Study

Sentri model has five important features which differentiate it from the previous work: self-training, a single encoder model for passage and question processing as a retriever, a generative model as a reader, in-batch negative filtering, usage of the machine translated data during the training process.

(I) The effect of the first of mentioned features could be analysed basing on Tab. 1 (upper part of the table, showing results on development set) and 2. Self-training for Bi-Encoder model improves results by 3% on average for the XOR-Full task and about 5% for the XOR-Retrieve task (Bi-Encoder$_1$ vs Bi-Encoder$_2$).

(II) The usage of a single encoder could be estimated as again 3% for the XOR-Full task and about 5-6% for the XOR-Retrieve task (Sentri + ext. reader vs. Bi-Encoder$_2$). In Tab. 4 we demonstrate key motivation of using shared encoder model. We observe that the single encoder approach superior to the Bi-Encoder in terms of memory efficiency and overall performance. With the same size (less than 2% difference) it achieves more than 12% relative improvement or ∼6-7 difference in absolute points in retrieval task. Note that Sentri and Bi-Encoder$_2$ trained in the same setting and same QA datasets except used base model variants (*base* and *large* respectively). We do it for the sake of the matching number of parameters, matched memory consumption and similar training time of both models.

	Base architecture		#params	XOR	
	E_q	E_p	**overall**	**R@2kt**	**R@5kt**
Bi-Encoder$_2$	XLM-R$_{base}$	XLM-R$_{base}$	540 M	45.4	53.9
Sentri	XLM-R$_{large}$ (shared)		550 M	**51.0**	**60.8**

Table 4: Comparison of architectures of *single* and *bi-encoder* models. The single encoder approach significantly outperform dual-encoder one using almost the same memory amount.

	Most-effective top-k	Macro Average **F1**	**EM**	**BLEU**
Sentri + ext. reader + MT	5	16.1	10.1	16.5
Sentri + CORA Reader	15	30.7	-	-
Sentri + MFiD	100	**41.3**	**34.9**	**30.7**

Table 5: Comparison of different reader models.

(III) The replacement of standard extractive reader, i.e. span-tagging model, with a generative one, MFiD model in our case, turned out to add up to 34% of F1 measure (for Japanese) and 25% on average. We observe that with the number of contexts more than 5 performance of extractive reader degrades. Contrary that using more contexts for answer generation can significantly improve model quality. We further evaluate generative reader usage by adding the one described in (Asai et al., 2021b), it uses only 15 top-ranked contexts due to memory constraints. Unlike that, MFiD can use up to 100 top-ranked contexts thanks to the independent processing of passages in the reader's encoder. The results are presented in Tab. 5.

(IV & V) The importance of the last two features could be estimated basing on Tab. 6. While the former one adds up to 2 per cent, the latter is of crucial importance adding up to 20% depending on task and measure.

We could conclude that all the features are important for our approach to present state-of-the-art results in retrieval and end-to-end tasks.

5.1 Languages Used

It is also interesting to know if the system is actually using the data in other languages for answer generation. In other words, if our model is *truly* cross-lingual. The analysis of the top-100 paragraphs for all the questions in validation set of XOR TyDi, namely the breakdown on the languages used, is shown on Tab. 7. As one can see, there are several interesting features could be spotted in the table. The highest self-usage (i.e. when a question and a paragraph are in the same language) percentage is shown by Korean language (almost entirely, 97.6%), with negligible usage of other languages, except English with 1.4%. On the contrary, Finnish language is shown the lowest self-usage of 52.9% with 34.6% usage of English. These two facts could be explained as Korean having unique writing system, thus it has almost nonexistent intersection with other languages in terms. In the contrary Finnish is Latin-based and is in close contact with Swedish language since the Middle Ages, while Swedish is close German language for English. But this speculation has its downside: the second most-used language for Finnish is Japanese (7.4%), which is both unrelated and uses other script. Interestingly, Japanese language is the

	R@2kt		R@5kt	
	MKQA	**XOR**	**MKQA**	**XOR**
Sentri	53.3	51.0	60.3	60.8
Sentri w/o false negative filtering	52.1	49.3	60.1	60.3
Sentri w/o weight-sharing (Bi-Encoder approach)	45.3	45.4	52.9	53.9
Sentri w/o multi-language translations of training set	41.5	30.8	45.8	42.3

Table 6: Ablation experiments on MKQA and XOR development sets.

second language by usage for almost all the languages, including Korean but with only 0.7%. For Telugu the second most used language is Bengali, which is related to it. But surprisingly, the other way around it is almost unused. Another peculiar feature is that Russian language is significant in usage for almost all the languages with exception for Korean. We hypothesise that it is due to the proportion of Russian data in the training set, this language being the second by size in the dataset. It is important to mention that the largest present language is Arabic, but its influence is lower than Russian. The influence of Arabic, Russian, and Japanese need more in-depth future investigation.

6 Related Work

Datasets The cross-lingual question answering datasets were scarce before recent years. Fortunately, these years left us with several publicly available datasets. Lewis et al. (2020) introduced MLQA dataset. It consists of parallel QA pairs in several languages. Liu et al. (2019) have presented XQA dataset, with training set in English and validation and test sets in the other languages. Cross-lingual Question Answering Dataset (XQuAD) benchmark presented in Artetxe et al. (2020). It consists of a subset of 240 paragraphs and 1190 question-answer pairs from SQuAD v1.1 (Rajpurkar et al., 2016) together with their translations into ten languages.

Systems Open-domain question answering task assumes answering factoid questions without a predefined domain (Kwiatkowski et al., 2019). Recent research was focused on creating non-English question answering datasets and applying cross-lingual transfer learning techniques, from English to other languages. Until recently, the availability of appropriate train and test datasets has been a key factor in the development of the field: however, in recent years, many works have focused on the collection of loosely aligned data obtained through automatic translation or by parsing similar multilingual sources. Artetxe et al. (2020) studied cross-lingual transferability of monolingual representations of a transformer-based masked language model.

In most previous approaches the authors use extractive models to generate the actual answer. This could be explained by the mental inertia from SQuAD-like datasets. By SQuAD-like we mean a dataset where labelled data includes an explicitly stated question, a passage, containing an answer, and a span markup for the answer. Such markup was presented for the question answering task called SQuAD in (Rajpurkar et al., 2016). But recently there were presented cross-lingual generation of answers from raw texts. Kumar et al. (2019); Chi et al. (2019) studied cross-lingual question generation. Shakeri et al. (2020) proposed a method to generate multilingual question and answer pairs by a generative model (namely, a fine-tuned multilingual T5 model), it is based on automatically translated samples from English to the target domain. Generative question answering was mostly considered in previous work for long answers datasets. However, FiD model (Izacard and Grave, 2020b) archives competitive results on SQuAD-like datasets, where an answer is supposed to be short text span. For open domain question answering, one of the first approaches named RAG used generative models was presented in (Lewis et al., 2021). A key idea of this RAG model is to process several (top k) passages from the retriever in the encoder simultaneously. The produced dense representations of the passages are used in the decoder for the answer generation, this process is called fusion. Processing the passages independently in the encoder allows a model to scale to many contexts, as it only runs self-attention over one context at a time. FiD model follows this paradigm further improving the results in question generation.

7 Conclusion

Nowadays multi-lingual and cross-lingual problems are coming to the stage once the natural language models become more and more powerful. One of these problems is that where the systems answer the questions using various mutually disjoint language data, as it stated in XOR TyDi task. This task is based on a specific XOR TyDi dataset (Asai et al., 2021a), which ensured such information asymmetry in the different language data. We introduced the cross-lingual system to solve the XOR task. While the XOR TyDi is a challenging test that stimulates cross-linguality in NLP systems, we have outperformed the existing models in two subtasks: XOR-Retrieve and XOR-Full without using external APIs. The first task is a classical passage retrieval task, while the second one is an end-to-end question-answering task. Besides showing the state of the art results on these two subtasks, our system is demonstrated the ability the transfer to the unseen languages in retrieval task, including the languages which were not presented in the pre-trained language model we use as an encoder for the retriever part of our Sentri model. And last we found that the previous works ignored the existence of the morphology in XOR TyDi presented languages, thus missing many results in information retrieval. We propose to solve this issue by using stemming or lemmatization for such languages.

Our system has five differentiating features, which are self-training (using the output of the previously trained models), single encoder (allowing us to reduce the number of parameters about twice in retriever), usage of a generative model to get the question from retrieved passages, in-batch negative filtering, and usage of the machine translated data during the training process. All of these features are proved to make a share in the achieved significant quality improvement demonstrated by our model. Although, our system has several flaws, e.g. passage selection strategy and stemming for the languages, we consider these flaws as our future work. But we hope that current study will foster research in cross-lingual question answering tasks.

A Implementation Details

For our system, we have adapted models from the Huggingface Transformers library (Wolf et al., 2019). We trained the question and passage encoders using the in-batch negative sampling with a batch size of 16, one hard negative per question. We trained the system for 40 epochs with a learning rate of 10^{-5} using Adam, linear scheduling with warm-up and dropout rate of 0.1. For training and validation, we used NQ, Trivia, XOR and TyDi QA datasets. The number of hard negative passages was 32 and 50 for the first and second stages respectively. All experiments were carried out on four nVIDIA V100 GPUs (with 32Gb RAM each).

B Data Distribution

The overall statistics on mined data from the mentioned datasets are available in Tab. 8. As one can see, the data acquired is following the rough pattern: most of the samples come from TriviaQA, the second source is NQ, while the rest comes from XOR TyDi QA. In the perspective of languages the pattern follows the XOR TyDi distribution, with Arabic being the largest non-English language, and Korean being the smallest one.

Table 8: The number of mined samples from training part of Natural Questions, TriviaQA, and XOR TyDi QA datasets

C Effects of Normalisation

Since we are using normalisation for the retrieval, we decided to look into the evaluation process. The metrics used for the evaluation, namely per-token F1, Exact Match, and BLEU, are based on simple token comparison. Such comparison is inefficient for the languages with rich morphology, like Russian or Japanese. So we applied the same normalisation as in retrieval for the generated and gold answers. Table 9 shows the achieved results. As one can see normalisation helps to achieve less strict and thus more informative comparison for the morphology-rich languages. Since Japanese and Finnish are both synthetic agglutinative languages, we suppose that the results on them could also be improved with usage of the stemming/lemmatization, thus improving the cross-lingual average further. Given that we think the usage of some kind of normalisation should be recommended for any cross-lingual QA task including morphology-rich languages.

Table 9: Results for Sentri model with and without normalisation.

D Zero-Shot Cross-Lingual Transfer

In addition to the MKQA results on which were presented in main contents, we used M2M100 model to translate the MKQA English subset to all known to it languages, thus extending MKQA to 98 languages. We provide the results on the this extended dataset in Tab. 10.

E Unseen Languages

We thoroughly analysed the (partially) unseen languages and found out that our system performs reasonably well even for those languages, which are not present in the pre-trained XLM Roberta used as an encoder in our model. The results are presented in Tab. 11. We also provide aggregated results for the unseen on training stage languages and seen in the training stage ones. As one could see, our model performs surprisingly well on the languages which were not presented on any training stage, although the training improves Recall by 12 and 13 per cent on average, while pre-training adds 13.8% of Recall. We think this is another evidence of the great generalizability of the pre-trained language models.

Diversifying Neural Dialogue Generation via Negative Distillation

Yiwei Li, Shaoxiong Feng, Bin Sun, Kan Li
School of Computer Science, Beijing Institute of Technology
{liyiwei,shaoxiongfeng,binsun,likan}@bit.edu.cn

Abstract

Generative dialogue models suffer badly from the generic response problem, limiting their applications to a few toy scenarios. Recently, an interesting approach, namely negative training, has been proposed to alleviate this problem by reminding the model not to generate high-frequency responses during training. However, its performance is hindered by two issues, ignoring low-frequency but generic responses and bringing low-frequency but meaningless responses. In this paper, we propose a novel negative training paradigm, called negative distillation, to keep the model away from the undesirable generic responses while avoiding the above problems. First, we introduce a negative teacher model that can produce query-wise generic responses, and then the student model is required to maximize the distance with multi-level negative knowledge. Empirical results show that our method outperforms previous negative training methods significantly.[1]

1 Introduction

In the past few years, data-driven response generation (Vinyals and Le, 2015; Shang et al., 2015; Vougiouklis et al., 2016) has achieved impressive performance, drawing continuously increasing attention from academia and industry. Conventionally, with the guidance of maximum likelihood estimation (MLE), neural dialogue models are expected to maximize the probability of generating the corresponding reference given any query. Unfortunately, due to the many-to-one phenomenon (see Table 1), a characteristic of the dialogue task (Csáky et al., 2019), these models are prone to produce safe but generic responses (e.g., *I don't know* (Li et al., 2016)), which sets an obstacle for the generative dialogue system to be deployed widely. Some researchers tried to redesign the objective of models to meet the requirement of diverse responses instead of MLE, such as MMI (Li et al., 2016), AdaLabel (Wang et al., 2021), and IAT (Zhou et al., 2021). Besides, several studies (Kulikov et al., 2019; Holtzman et al., 2020) proposed more advanced decoding strategies to alleviate the problem of generic responses. Indeed, the above methods boost the diversity of responses by reminding the model what should be said.

However, inspired by negative training (Kim et al., 2019; Ma et al., 2021), we argue that it is also necessary to tell the dialogue model what not to say. To alleviate the problem of generic responses, He and Glass (2020) negatively updates the parameters when identifying the high-frequency responses. Li et al. (2020a) punishes the behaviors of generating repetitive or high-frequency tokens by using the unlikelihood objective (Welleck et al., 2020).

Although the negative-training based methods enhance the diversity of responses, there still exists two drawbacks: First, they regard high-frequency tokens or utterances as negative candidates. However, the high-frequency response problem is only a sub-problem of the generic response problem (He and Glass, 2020). It means that the responses that are low-frequency but generic will escape from punishment. Even worse, we have observed that some generic responses followed by a low-frequency but meaningless subsequence can avoid being identified as high-frequency, which inevitably sacrifices the fluency of responses (see Analysis). Second, these methods ignore the implicit negative knowledge in neural networks that characterizes negative candidates at multiple levels. We contend that it is more effective to conduct negative training with richer information (e.g., hierarchical representation).

To tackle the above problems and further improve the diversity of responses, we propose a novel negative training paradigm called *Negative Distillation* (ND). Conventional knowledge distil-

---

Proceedings of the 2022 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies, pages 407 - 418
July 10-15, 2022

	Query	Response	Entropy Score
1:	Oh, honey, you made a mistake.	**I don't know** how to do it.	8.61
2:	Would you like regular car wash package?	**I don't know** what you mean.	8.75
3:	I'm looking for the airport. Can you tell me how to get there?	No, sorry. **I don't know**.	10.69
4:	That's cathy. She is pretty, isn't she? She likes dancing. Ask her to dance.	Well, **I don't know**.	12.14
5:	It doesn't matter. You gotta find what she's interested in and go with that.	**I don't know** . . .	6.82

Table 1: The *many-to-one* phenomenon in DailyDialog. All the above five queries have the same **I don't know**-like responses. The corresponding *source entropy* (Csáky et al., 2019) scores are much higher than the median score (0.92) of the whole training set. This phenomenon will lead to the generic response problem.

lation (KD) (Hinton et al., 2015; Jiao et al., 2020) takes the teacher as a positive role model and induces the student to imitate. Differing from that, we train the teacher as a negative role model and remind the student to get rid of those bad behaviors.

Specifically, we first collect a negative training set by using a filtering method called *Source Entropy* (Csáky et al., 2019). This filtering method can retrieve all *many-to-one* cases of the raw dataset. Note that the "one" is usually a generic response. Then, we train a dialogue model on the above subset as the negative teacher. Given queries, the negative teacher can provide a set of negative candidates (i.e., generic and dull responses) that the student is prone to generate, which avoids the first drawback mentioned before. Therefore, the student obtains query-wise bad behaviors for *Negative Distillation*. To conduct the negative update holistically, we design two negative objectives, including soft unlikelihood loss on the prediction layer and reverse square error on the intermediate layer. In this way, the negative distillation fully exploits multi-level negative knowledge to force the student to generate non-generic responses.

Our contributions are summarized as follows:

- We propose a novel and effective negative training paradigm called *Negative Distillation*. It constructs query-wise generic responses as the negative candidates.
- We design two negative objectives to utilize multi-level information to further boost the performance of negative distillation.
- We perform extensive experiments and detailed analysis to verify the effectiveness of the negative distillation framework and the superiority compared with previous negative training methods.

2 Method

In this section, we first introduce the negative teacher, then describe the negative distillation on the prediction layer and the intermediate layer, respectively, and finally present the progressive optimization objective. Algorithm 1 shows the whole training details.

2.1 Background

Dialogue Generation with MLE Take $Q = \{q_1, q_2, ..., q_{T_q}\}$ and $R = \{r_1, r_2, ..., r_{T_r}\}$ as the (*query, response*) pair, where T_q and T_r represent the length of query and response, respectively. The generative dialogue model aims to learn a conditional probability distribution $p_\theta(R|Q)$. The maximum likelihood estimation (MLE) is usually used to train the model, which can also be expressed as minimizing the negative log-likelihood:

$$\mathcal{L}_{\mathrm{MLE}} = -\sum_{i=1}^{T_r} \log p_\theta \left(r_i \mid r_{<i}, Q \right). \qquad (1)$$

Considering one characteristic of the dialogue task, i.e., allowing the response to be varied, the *many-to-one* phenomenon occurs in the dialogue corpora frequently. However, with the MLE-based training, this phenomenon will cause the model to produce generic responses.

Unlikelihood Training Unlikelihood (UL) loss (Welleck et al., 2020) is proposed for the model to address the problem of undesirable behaviors (e.g., repetitive or high-frequency tokens). It forces the model to minimize the probability of generating negative candidates, which is formulated as:

$$\mathcal{L}_{\mathrm{UL}} = -\sum_{i=1}^{T_r} \sum_{r_c \in \mathcal{C}_t} \log(1 - p_\theta(r_c \mid r_{<i}, Q)), \tag{2}$$

where $\mathcal{C}_t$ consists of negative candidates (e.g., overuse frequent words) that are also a sub-set of the vocabulary.

Knowledge Distillation The traditional knowledge distillation (KD) usually transfers useful knowledge from a large and strong teacher network T to a small student network S. The distillation loss is used to align the soften predictions of the teacher and the student, denoted as $f^T(x)$ and $f^S(x)$:

$$\mathcal{L}_{\mathrm{KD}} = \sum_{x \in \mathcal{D}} L\left(f^T(x), f^S(x)\right), \tag{3}$$

where $L(\cdot)$ is a measurement function that calculates the distance of different probability distributions, x is the input text, and $\mathcal{D}$ denotes the training set.

In this work, we replace the positive teacher in vanilla KD with a negative teacher, aiming to provide negative knowledge for the student to conduct negative training and avoid undesirable behaviors.

2.2 Negative Teacher

To improve the diversity of responses, the dialogue model should be told which responses are generic. For negative distillation, a negative teacher is required to produce possible generic responses given any query. In this work, we adopt the widely used Transformer (Vaswani et al., 2017) as the underlying model for both teacher and student. We introduce the *Source Entropy* filtering method (Csáky et al., 2019) to identify and collect the many-to-one cases for the negative training set. The source entropy is defined as:

$$H_{src}(r, \mathcal{D}) = -\sum_{(q_i, r) \in \mathcal{D}} p(q_i|r) \log p(q_i|r), \tag{4}$$

where $p(q_i|r)$ is the conditional probability calculated based on the relative frequency of (*query, response*) pairs, r is a response, q_i is the query corresponding to the response r, and $\mathcal{D}$ represents the raw training set. A higher source entropy indicates that the response r corresponds to more queries, i.e., the *many-to-one* problem is serious. We select the top 50% [2] dialogue pairs (q, r) with a high source entropy as the negative training set $\mathcal{D}_N$, which contains a much higher proportion of generic responses than the raw training set.

After that, we train the teacher N on the negative training set $\mathcal{D}_N$ by Equation 1. The teacher will naturally produce generic responses for any input query. More importantly, it will provide richer negative knowledge for the student, including soft logits in the prediction layer and implicit features in the intermediate layers.

2.3 Negative Distillation

In this section, we conduct the negative distillation for the student based on the multi-level negative knowledge.

ND for Prediction Layer The soften logits in the prediction layer contain more information than the ground-truth labels, such as the similarity between labels (Wang et al., 2021). Therefore, conventional KD transfers knowledge by narrowing the gap between the probability distributions of the teacher T and the student S:

$$\mathcal{L}_{KD} = -\sum_{i=1}^{T_r} \sum_{k=1}^{|\mathcal{V}|} p_T\left(r_i = k \mid r_{<i}, Q\right) \cdot \log p_S\left(r_i = k \mid r_{<i}, Q\right). \tag{5}$$

As for negative distillation, the extra knowledge in soften logits of the negative teacher reflects how to generate dull responses based on the input query. Therefore, we propose a soft unlikelihood loss to maximize the distance between the predictions of the negative teacher N and the student S:

$$\mathcal{L}_{pred} = -\sum_{i=1}^{T_r} \sum_{k=1}^{|\mathcal{V}|} p_N\left(r_i = k \mid r_{<i}, Q\right) \cdot \log\left(1 - p_S\left(r_i = k \mid r_{<i}, Q\right)\right), \tag{6}$$

where p_N and p_S are calculated by:

$$p^i = \frac{\exp\left(z_i/t\right)}{\sum_j \exp\left(z_j/t\right)}, \tag{7}$$

where t is a temperature coefficient that is used to soften the probability distribution over words.

---

[2] Simply the same as Akama et al. (2020)

It should be emphasized that previous negative training methods only use the high-frequency words or phrases with one-hot representation as the targets, which ignores the rich information existing in the soften logits (e.g., the generic words have similar probabilities). In the Analysis section, we demonstrates the superiority of soften logits compared with hard targets (i.e., one-hot representation).

ND for Intermediate Layer In addition to the output knowledge from the prediction layer, there is also some implicit knowledge embedded in the intermediate layers, such as hidden states and attention matrices. To keep the student away from undesirable behaviors (i.e., producing generic responses) more effectively, we further consider the above knowledge into negative distillation. Specifically, the distance between features of the negative teacher and the student should also be increased. In this work, we propose a new measurement function, called mean reverse square error (MRSE), to calculate this distance:

$$\mathcal{L}_{MRSE}(\boldsymbol{A}, \boldsymbol{B}) = \frac{1}{n} \sum_{i=1}^{n} \exp^{-SE(\boldsymbol{A}_i, \boldsymbol{B}_i)}, \quad (8)$$

where $\boldsymbol{A}$ and $\boldsymbol{B}$ are the feature matrices of the negative teacher and the student, respectively, and n is the number of elements of each matrix.

Due to the responses generating in the decoding phrase, we only conduct negative distillation on the intermediate layers of the decoder. For each decoder layer, the negative distillation objective of hidden states is defined as:

$$\mathcal{L}^{l}_{hid} = \mathcal{L}_{MRSE}(\boldsymbol{H}^{l}_{N}, \boldsymbol{H}^{l}_{S}), \quad (9)$$

where $\boldsymbol{H}^{l}_{N}$ and $\boldsymbol{H}^{l}_{S}$ are the output hidden states of the l^{th} decode layer of N and S, respectively.

As the attention weights can learn substantial linguistic knowledge (Clark et al., 2019), it is beneficial for the student to further conduct negative distillation on the attention matrices, which is computed as follows:

$$\boldsymbol{A} = \frac{\boldsymbol{Q}\boldsymbol{K}^{T}}{\sqrt{d_k}}, \quad (10)$$

$$\text{Attention } (\boldsymbol{Q}, \boldsymbol{K}, \boldsymbol{V}) = \mathrm{softmax}(\boldsymbol{A})\boldsymbol{V}, \quad (11)$$

where $\boldsymbol{Q}$, $\boldsymbol{K}$, and $\boldsymbol{V}$ are the matrices of queries, keys, and values, respectively, and d_k is a scaling factor. Following Jiao et al. (2020), the attention matrix $\boldsymbol{A}$ is chosen to calculate the distance rather than its softmax version $\mathrm{softmax}(\boldsymbol{A})$. Similar to Equation 9, the negative distillation objective of attention matrices is formulated as:

$$\mathcal{L}^{l}_{att} = \mathcal{L}_{MRSE}(\boldsymbol{A}^{l}_{N}, \boldsymbol{A}^{l}_{S})), \quad (12)$$

where $\boldsymbol{A}^{l}_{N}$ and $\boldsymbol{A}^{l}_{S}$ are the attention matrices of the l^{th} decoder layer of N and S, respectively.

Output: $S$ : The trained student.
```

2.4 Progressive Optimization

The overall loss, combining the above negative distillation objectives and the MLE objective, is denoted as:

$$\mathcal{L} = (1 - \alpha)\mathcal{L}_{mle} + \alpha(\mathcal{L}_{pred} + \sum^{l} \mathcal{L}^{l}_{hid} + \sum^{l} \mathcal{L}^{l}_{att}), \quad (13)$$

where α is a hyper-parameter that balances the importance of supervised learning and negative distillation. For negative distillation, it would be better that the student has the ability to say something before it is reminded of what not to say. Thus, we perform a progressive distillation that first warms up the negative distillation ratio and then colds it down gradually. Inspired by the derivative of sigmoid function:

$$\sigma'(z) = \sigma(z)(1 - \sigma(z)) = \frac{e^{-z}}{(e^{-z} + 1)^2}, \quad (14)$$

Datasets	Train	Valid	Test	Vocab
DailyDialog	68k	6.8k	6.8k	17,930
OpenSubtitles	200k	20k	10k	21,177

Table 2: Statistics of two dialogue datasets in the experiments.

which shows a trend of gradual rise-fall, we define the balance coefficient α as:

$$\alpha = \lambda * \frac{e^{-z}}{(e^{-z}+1)^2}, \tag{15}$$

where λ controls the peak value and z is calculated by:

$$z(s) = \beta * (s - \gamma), \tag{16}$$

where s is the training step, and β and γ control the telescopic and translation transformation, respectively.

3 Experiments

3.1 Datasets

In our experiments, two widely used dialogue datasets are employed to evaluate the proposed method: **DailyDialog**, which collects conversations that are similar to human daily communication (Li et al., 2017b), and **OpenSubtitles**, which consists of large-scale dialogues extracted from movie subtitles (Tiedemann, 2009). In this work, we focus on the single-turn dialogue generation, thus we pre-process these two datasets into the (query, response) pairs. Table 2 provides the statistics of both datasets.

3.2 Experimental Settings

We take the Transformer-based sequence-to-sequence model (Vaswani et al., 2017) as the underlying model for all approaches. Following the settings of Transformer in Csáky et al. (2019), both encoder and decoder contain 6 layers, in which the self-attention module has 8 attention heads and the number of feed-forward units is 2048. The size of hidden states is set to 512 and the dimension is 64 for query, key, and value. Please refer to Appendix A for more details.

For the proposed approach, both the negative teacher network and the student network have the same settings in terms of the network architecture and hyper-parameters. λ in Equation 15 is set to 4, making the peak value equal to 1. γ is 25600 and β is $6/\gamma$. For the temperature coefficient t, we simply set it to 1.

3.3 Baselines

We compare the proposed negative distillation (**ND**) approach with the standard Transformer, two existing negative training approaches and two extra diversity improving approaches:

- **Standard** The vanilla Transformer-based sequence-to-sequence model with the MLE-based training (i.e., the cross-entropy based loss).
- **NT** (Negative Training) (He and Glass, 2020) During training, it first counts the frequency of all generated utterances and then conducts the negative update based on the high-frequency utterances.
- **UL** (Unlikelihood Training) (Li et al., 2020a) Different from **NT**, it calculates the frequency of all generated words instead of utterances and penalizes the high-frequency words by introducing an unlikelihood loss term.
- **CVAE** (Zhao et al., 2017) A dialogue response generation model using conditional VAE to improve the diversity of generated responses.
- **FACE** (Jiang et al., 2019) It uses the frequency-aware cross-entropy loss to tackle the low-diversity problem.

All the baselines are performed with the same architecture and hyper-parameters as ours. Following He and Glass (2020); Li et al. (2020a), we use greedy search as the decoding strategy for all baselines and our method. We also evaluate the performance with beam search (size 5) and obtain similar results (see 3.6 for details). Details for baselines is describes in Appendix B.

3.4 Automatic Evaluation

Metrics To evaluate whether negative distillation can effectively reduce the generic responses, we adopt **Dist-{1,2,3}** (distinct) (Li et al., 2016) to reflect the lexical diversity of the generated responses. It is a widely used metric that counts the proportion of unique unigrams/bigrams/trigrams. **LF** (low-frequency token ratio) (Li et al., 2020b) further measures the diversity of responses by calculating the ratio of low-frequency words in the generated responses. The threshold of low frequency is set to 100. Besides, it is necessary to verify whether

Models	Dist-1 ↑	Dist-2 ↑	Dist-3 ↑	LF ↑	KL-1 ↓	KL-2 ↓	BLEU-3 ↑	BLEU-4 ↑

Table 4: Results of human evaluations on DailyDialog. Our framework has a higher win rate than baselines.

the models can ensure consistency while improving diversity. So we use **KL-{1,2}** (KL divergence) (Csáky et al., 2019), which measures the distribution distance between the generated and the ground-truth responses, to reflect how well a model can approximate the ground-truth unigrams/bigrams distributions. **BLEU** (Chen and Cherry, 2014) is also reported and it measures n-gram overlap between the generated and the ground-truth references.

Results Table 3 shows the results obtained at the lowest point of the validation loss. We can see that our approach outperforms all baselines in diversity (**Dist** and **LF**) by a significant margin on both datasets, demonstrating that **ND** can effectively alleviate the generic response problem by using multi-level negative information. The **KL** and **BLEU** scores of **ND** are close to or better than **Standard**, which verifies that our method can maintain the consistency of responses while improving its diversity. To some extent, both **NT** and **UL** improve the diversity of words, especially for trigrams, but the low **LF** scores indicate that they reduce the high-frequency words but fail to increase the number of low-frequency's. What's worse, **BLEU** and **KL-2** scores of above two and **CVAE** sharply decline. It suggests that previous negative training approaches and other methods for diversity enhancement may harm the consistency and fluency of responses dramatically, which is not in line with the goals of the dialogue system. Our method obtains similar results with beam search. Please refer to 3.6 for details.

3.5 Human Evaluation

Apart from automatic evaluations, we conduct human evaluations to further verify the effectiveness of our method than previous negative training methods. We randomly select 50 samples from the test set of DailyDialog, and three well-educated annotators are invited to judge which of the responses generated by **ND** and baselines is better (i.e., win, tie or loss) in terms of informativeness, relevance, and fluency. Informativeness reflects how much the information related to the query is contained in the generated response. Relevance reflects how likely the generated response is coherent to its query. Fluency reflects how likely the generated response is produced by human.

Table 4 summarizes the human evaluation results. We can see that the proposed approach is overall better than all baselines. Specifically, **ND** achieves better performance than **Standard** in terms of informativeness and relevance, and remains competitive in fluency. Compared with both **NT** and **UL**, our approach shows significant advantages, especially in fluency. It indicates that their punishment for high-frequency tokens or utterances will lead to a serious non-fluency and inconsistency problem. We use Fleiss's kappa (Fleiss, 1971) to measure the inter-annotator agreement.

3.6 Experimental Analysis

We conduct extensive analysis on DailyDialog to investigate the effectiveness of the negative distillation in more details.

Models	Dist-2	Dist-3	LF	KL-2	BLEU-4
ND	.0678	.1447	.158	.26	.388
w/o $\mathcal{L}_{pred}$	.0529	.1084	.145	.39	.397
w/o $\mathcal{L}_{att}$	.0517	.1032	.138	.26	.392
w/o $\mathcal{L}_{hid}$	.0365	.0677	.109	.62	.380
w/o $\mathcal{L}_{neg}$	.0313	.0576	.102	.53	.395

Table 5: Ablation studies of different negative distillation objectives in **ND**.

Ablation study We study the effects of different negative distillation objectives by ablating the prediction layer distillation (w/o $\mathcal{L}_{pred}$), the attention distillation (w/o $\mathcal{L}_{att}$), the hidden state distillation (w/o $\mathcal{L}_{hid}$), and the whole negative distillation (w/o $\mathcal{L}_{neg}$, i.e. Standard). The results in Table 5 show that all three proposed negative distillation objectives are useful for improving the diversity. The significant decline in w/o $\mathcal{L}_{hid}$ indicates that the negative information in intermediate layers is very important for **ND**. w/o $\mathcal{L}_{att}$ is better than w/o $\mathcal{L}_{hid}$, attributing to the more abundant information in hidden states.

Does *source entropy* work? To verify whether the *source entropy* filtering method can collect the generic responses, we select the top 50% and the bottom 50% of the sorted training set as $\mathcal{D}_t$ and $\mathcal{D}_b$, respectively. Then we train N_t and N_b on the corresponding sub-sets. From Table 6, we can see that N_b outperforms N_t in all the diversity-related metrics, indicating the effectiveness of *source entropy*.

Models	Dist-1	Dist-2	Dist-3	LF
N_t	0.0024	0.0078	0.0134	0.0331
N_b	**0.0040**	**0.0121**	**0.0215**	**0.0444**

Table 6: Effect of the *source entropy* filtering method.

Can the negative knowledge be transferred? We take N_t and N_b as the negative teachers for the students S_t and S_b, respectively. Then we conduct negative distillation on both S_t and S_b. The results in Table 7 demonstrate that S_t obtains more gains in diversity than S_b, indicating S_t gets rid of more negative knowledge. It can be further verified by the results of previous analysis that N_t has more negative knowledge than N_b.

Models	Dist-2	Dist-3	LF	KL-2	BLEU-4
S_t	**0.0678**	**0.1447**	**0.158**	**0.26**	**0.388**
S_b	0.0409	0.0844	0.097	0.40	0.386

Table 7: Effect of negative knowledge.

Models	Dist-2	Dist-3	LF	KL-2	BLEU-4
Standard	.0313	.0576	.102	.53	.395
ND (fixed α)	.0392	.0793	.123	.42	.386
ND	.0678	.1447	.158	.26	.388

Table 8: Effect of progressive distillation.

Models	Dist-1	Dist-2	Dist-3	LF
ND (random target)	0.0040	0.0109	0.0170	0.053
ND (hard target)	0.0136	0.0620	0.1344	0.139
ND (soft target)	0.0145	0.0678	0.1447	0.158

Table 9: Comparison of soft targets, hard targets, and random targets for negative distillation.

Study of soft target To evaluate the superiority of soft targets for negative distillation, we sample responses (i.e., hard target) by greedy search on the predictions of negative teachers for comparison. The results in Table 9 show that ND with soft targets can diversify the responses more effectively, demonstrating the advantages of richer negative information (e.g., the similarity between labels) in soft targets. What's more, we randomly select responses from the negative training set $\mathcal{D}_N$ as negative targets. The sharp decline in performance proves that the negative teacher can produce targeted generic responses.

Effect of progressive distillation In order to verify the effectiveness of progressive negative distillation, we conduct negative distillation with fixed α. The value is obtained by calculating the average of α in Equation 15 across the convergence steps. The results in Table 8 demonstrate that the progressive distillation policy can help the student exploit negative knowledge more effectively. Besides, note that ND with fixed α also outperforms the Standard model.

Models	Dist-1 ↑	Dist-2 ↑	Dist-3 ↑	LF ↑	KL-1 ↓	KL-2 ↓	BLEU-3 ↑	BLEU-4 ↑
Standard	0.0060	0.0238	0.0455	0.068	0.92	0.62	0.375	0.372
NT	0.0077	0.0326	0.0640	0.083	0.76	0.70	0.349	0.334
UL	0.0059	0.0270	0.0570	0.075	0.82	0.95	0.321	0.294
CVAE	0.0022	0.0152	0.0579	0.026	1.60	1.94	0.144	0.087
FACE	0.0074	0.0305	0.0591	0.086	0.73	0.64	0.123	0.077
ND	**0.0108**	**0.0427**	**0.0799**	**0.120**	**0.72**	**0.05**	**0.386**	**0.404**

Table 10: Automatic evaluation results using beam search (size 5) on DailyDialog. Our approach (**ND**) outperform baselines on all the metrics.

Evaluation results with beam search He and Glass (2020) and Li et al. (2020a) choose greedy decoding due to its simplicity and higher diversity than beam decoding. However, we find that both **NT** and **UL** tend to generate long but non-fluent and incoherent responses. So we conduct beam search with adding the length penalty. Table 10 summarizes the results and it shows that both two baselines get better **KL** and **BLEU** scores than using greedy search due to shorter responses. **ND** outperform baselines on all the metrics, confirming the effectiveness of our method.

Input: The phone turns off by itself.

Standard: What's the problem?
NT: I see. Is a part of the most important things. And I'll be happy to keep you there. Is the most important thing for you...
UL: I see. Is not allowed to be a good thing. Birthday. Birthday. - hour are very important......
ND: I am calling to tell you that he is in the right desk.

Input: Well, I bought this skirt here yesterday afternoon. But I got the wrong size. It's too small for my daughter. I wonder if I could refund it.

Standard: That's fine.
NT: That's fine. Your mind and address number. number. And date are available. And so on. Is very simple......
UL: I'm sorry, sir. But you've got to work overtime before you leave the contract. Service is very important. Service. Service usually be late.
ND: I think you have to pay the money.

Table 11: Examples of generated responses.

Case study Table 11 shows some cases generated by the proposed method and baselines. **Standard** prefers generic and meaningless responses. Both **NT** and **UL** tend to generate a short generic sentence followed by a incoherent and non-fluent subsequence. In contrast, **ND** can produce diverse and coherent responses.

4 Related work

Diversity Dialogue Learning There are two lines of work for solving the generic response problem: One line promotes the diversity from positive view, which is outside of our work. Specially, previous work includes MMI (Li et al., 2016), GAN (Li et al., 2017a; Zhang et al., 2018), CVAE (Zhao et al., 2017), BT (Su et al., 2020), FACE (Jiang et al., 2019), AdaLabel (Wang et al., 2021), IAT (Zhou et al., 2021), and Nucleus Sampling (Holtzman et al., 2020). The other line alleviates the generic response problem using negative training. He and Glass (2020) regards frequent response problem as a sub-problem of the generic response problem and conduct negative update for the high-frequency responses during training. Li et al. (2020a) focuses on high-frequency tokens rather than tokens and punishes them by using the unlikelihood objective (Welleck et al., 2020). Both of them handle the generic response problem only from the angle of reducing frequency, thus can not capture all the features of generic replies.

Negative Training for Dialogue Learning Negative training for retrieval-based dialogue learning has been previously extensively studied (Humeau et al., 2020; Nugmanova et al., 2019), while we focus on the dialogue generation in this work. He and Glass (2020) uses negative training to prevent generic and malicious responses in dialogue models. Li et al. (2020a) generalizes unlikelihood to dialogue generation for improving repetition, specificity and coherence. Lagutin et al. (2021) proposes implicit unlikelihood training to minimize repetition. Our work proposes a new negative training paradigm aimed at improving the diversity of dialogue responses while avoiding the problem of poor consistency and fluency of previous work.

5 Conclusion

We present a novel negative training paradigm to improve the diversity of dialogue responses. It formulates the conventional negative training as a knowledge distillation process, which is rarely explored before. The negative teacher can produce the corresponding generic and dull responses given any query, which naturally avoids problems that hinder previous negative training methods. Besides, we further boost the performance of negative distillation by exploiting richer information, i.e., multi-level features. Extensive experiments validate the superiority of our proposed method compared with prior negative training work.

A limitation of our work is that we only focus on the generic response problem. For future work, we will extend the proposed negative distillation to handle other generation problems, such as inconsistency and lacking personas or emotions.

A Details for Implementations

Here are some implementation details of our experiments. Dropout (Srivastava et al., 2014) is used for the self-attention module, the feed-forward layer, and the activation layer, and the rate of all three is set to 0.1. We also use label smoothing (Szegedy et al., 2016) and the smoothing value is 0.1. The batch size is set to 256. We use the Adam optimizer (Kingma and Ba, 2015) and employ the *warm-up* (He et al., 2016) trick to adjust the learning rate during training. The warm-up steps s_{wp} are 128000 and 256000 for DailyDialog and OpenSubtitles, respectively. The learning rate is computed as follows:

$$lr = \frac{2 \cdot \min(\frac{1}{\sqrt{s}}, \frac{s}{\sqrt{s_{\text{wp}}^3}})}{\sqrt{d_{\text{model}}}}, \tag{17}$$

where lr is the learning rate at the s^{th} step of training and d_{model} is the size of hidden states. We implement all approaches with Pytorch 1.7, and conduct all experiments on RTX 3090.

B Baselines

For **NT**, the threshold r_{thres} is set to 1% and the weight coefficient λ_{POS} is set to 1 as the authors' suggestion. For **UL**, we search the mixing hyperparameter α in $[1, 10, 100, 1000]$ and 1000 is selected for its best performance. Both **NT** and **UL** are refined on the well-trained **Standard** model. For **CAVE**, we set the latent size with patience to 256 and 64 for DailyDialog and OpenSubtitles, respectively. And for **FACE**, we use the "output frequency" and "pre-weight" version as the author suggested.

We also compare the proposed method (ND) with AdaLabel (Wang et al., 2021), although AdaLabel alleviates the generic response problem from the perspective of target regularization instead of negative training. The results in Table 12 confirms the superior performance of our method for improving the diversity of generated responses.

Models	Dist-1 ↑	Dist-2 ↑	Dist-3 ↑	LF ↑	KL-1 ↓	KL-2 ↓	BLEU-3 ↑	BLEU-4 ↑
AdaLabel	0.0100	0.0397	0.0757	0.105	0.89	0.59	0.097	0.061
ND	0.0145	0.0678	0.1447	0.158	0.65	0.26	0.381	0.388
AdaLabel	0.0065	0.0259	0.0476	0.064	1.11	0.83	0.109	0.069
ND	0.0108	0.0427	0.0799	0.120	0.72	0.05	0.386	0.404

Table 12: Comparing with AdaLabel by greedy search(Up) and beam search(Down) on DailyDialog. "↑" means higher is better. "↓" means lower is better.

On Synthetic Data for Back Translation*

Abstract

Back translation (BT) is one of the most significant technologies in NMT research fields. Existing attempts on BT share a common characteristic: they employ either beam search or random sampling to generate synthetic data with a backward model but seldom work studies the role of synthetic data in the performance of BT. This motivates us to ask a fundamental question: *what kind of synthetic data contributes to BT performance?* Through both theoretical and empirical studies, we identify two key factors on synthetic data controlling the back-translation NMT performance, which are quality and importance. Furthermore, based on our findings, we propose a simple yet effective method to generate synthetic data to better trade off both factors so as to yield a better performance for BT. We run extensive experiments on WMT14 DE-EN, EN-DE, and RU-EN benchmark tasks. By employing our proposed method to generate synthetic data, our BT model significantly outperforms the standard BT baselines (i.e., beam and sampling based methods for data generation), which proves the effectiveness of our proposed methods.

1 Introduction

Since the birth of neural machine translation (NMT) (Bahdanau et al., 2014; Sutskever et al., 2014) back translation (BT) (Sennrich et al., 2016a) has quickly become one of the most significant technologies in natural language processing (NLP) research field. This is because 1) it provides a simple yet effective approach to advance the supervised NMT by leveraging monolingual data (Edunov et al., 2018) and it also serves as a key learning objective in unsupervised NMT (Artetxe et al., 2018; Lample et al., 2018); 2) back translation even plays a significant role in other NLP research fields beyond translation such as paraphrasing (Mallinson et al., 2017) and style transfer (Prabhumoye et al., 2018; Zhang et al., 2018).

Back translation consists of two steps, namely synthetic corpus generation with a backward model and parameter optimization for the forward model. Various contributions have been made on improving back translation, for instance, iterative back translation (Hoang et al., 2018), tagged back translation (Caswell et al., 2019), confidence weighting (Wang et al., 2019), data diversification (Nguyen et al., 2020). Although these efforts differ in some aspects, all of them share a common characteristic: they employ a default way to generate synthetic data in the first step of BT which is either beam search or random sampling with a backward model. Seldom work studies the consequences of synthetic corpus to back translation and hence it is unclear how synthetic data influences the final performance of BT.

The early study empirically suggests the quality of the synthetic corpus is vital for BT performance (Sennrich et al., 2016a). However, recent studies illustrate better test performance can be achieved by low quality synthetic corpus (Edunov et al., 2018). This contradictory observation indicates the quality of synthetic data is not the only element that affects the BT performance. Hence, this fact naturally raises a fundamental question: *what kind of synthetic data contributes to back translation performance?*

In this paper, we attempt to take a step forward toward the above fundamental question. To this end, we start from a critical objective in semi-supervised learning, which is defined by the marginal distribution of a target language. Then we derive an approximate lower bound of the objective function, which is closely related to the objective of back translation. Corresponding to this lower bound, we theoretically find two related elements for maximizing such a lower bound: quality of syn-

thetic bilingual data and importance weight of its source. Since both elements are mutually exclusive to some extent, it may induce contradictory observation if one judges the BT performance according to a single element. In addition, such a theoretical explanation is supported by our empirical experiments. Furthermore, based on our findings, we propose a new heuristic approach to generate synthetic data whose both elements are better balanced so as to yield improvements over both sampling and beam search based methods. Extensive experiments on three WMT14 tasks show that our BT consistently outperforms the standard sampling and beam search based baselines by a significant margin.

Our contributions are three folds:

1. We point out that importance weight and quality of synthetic candidates are two key factors that affect the NMT performance.
2. We propose a simple yet effective method for synthetic corpus generation, which could better balance the quality and importance of synthetic data.
3. Our experiments prove the effectiveness of the aforementioned strategy, it outperforms beam or sampling decoding methods on three benchmark tasks.

2 Revisiting Back Translation

NMT builds a probabilistic model $p(y|x;\theta)$ with neural networks parameterized by θ, which is used to translate a sentence x in source language $\mathcal{X}$ to a sentence y in target language $\mathcal{Y}$. The standard wisdom to train the model is to minimize the following objective function over a given bilingual corpus $\mathcal{B} = \{(x_i, y_i)\}$:

$$\ell(\mathcal{B};\theta) = \sum_{(x_i,y_i)\in\mathcal{B}} \log p(y_i|x_i;\theta) \tag{1}$$

Recently Sennrich et al. (2016a) propose a remarkable method called **Back Translation (BT)** to improve NMT by using a monolingual corpus $\mathcal{M}$ in target language $\mathcal{Y}$ besides $\mathcal{B}$ and back translation becomes one of the most successful techniques in NMT (Fadaee and Monz, 2018; Edunov et al., 2018). At a high level, back translation can be considered as a semi-supervised method because it leverages both labeled and unlabeled data. Suppose $p(x|y;\pi)$ is the backward translation model whose parameter π is optimized over $\mathcal{B}$, the key idea of back translation can be summarized as the following two steps:

- **Synthetic Corpus Generation:** It firstly back-translates each target sentence $y \in \mathcal{M}$ to $\hat{x}$ obtain a synthetic bilingual corpus $\{(\hat{x}, y) \mid y \in \mathcal{M}\}$ by $p(x|y;\pi)$.
- **Parameter Optimization:** It combines both authentic corpus $\mathcal{B}$ and the synthetic corpus and then optimizes the parameter θ by minimizing the loss

$$\ell(\mathcal{B};\theta) + \sum_{y\in\mathcal{M}} \log p(y|\hat{x};\theta) \tag{2}$$

To make BT more efficient, the standard configuration is widely adopted: each sentence y is required to generate a single source $\hat{x}$ and both two steps are performed for a single pass. We follow this standard in this paper for generality but our idea in this paper is straightforward to apply to other configurations such as (Graça et al., 2019; Hoang et al., 2018; Nguyen et al., 2020).

In the first step, there are two main strategies to generate the synthetic corpus, i.e., deterministically decoding and randomly sampling with $p(x|y;\pi)$. The first strategy aims to search the best candidate as follows,

$$\hat{x}^b = \arg\max p(\hat{x}|y;\pi) \tag{3}$$

The above optimization is achieved by the beam search decoding, which can be regarded as a degenerated shortest path problem with respect to the $\log p(\hat{x}|y;\pi)$ with limited routing attempts. The alternative strategy is random sampling: it randomly samples a token with respect to the distribution estimated by a back-translation model at each decoding step. Such a process can be modelled by,

$$\hat{x}^s = \texttt{rand}\{p(\hat{x}|y;\pi)\} \tag{4}$$

Research Question Prior work points out (Sennrich et al., 2016a) that the synthetic corpus with high quality is beneficial to the final performance of back translation. However, the recent studies (Edunov et al., 2018) find that NMT models with unsatisfactory BLEU score corpus, for instance, the corpus generated by sampling based strategy, also establish the state-of-the-art (SOTA) achievement among back-translation NMT models.

This contradictory fact indicates that the quality of synthetic corpus is not the sole element for back translation. This motivates us to study a fundamental question for back translation: *what kind of synthetic corpus is beneficial to back translation?*

3 Understanding Synthetic Data by Two Factors

To answer the fundamental question presented in the previous section, we first start from the marginal likelihood objective defined on the target language $\mathcal{Y}$, and then we theoretically explain two factors (i.e., quality and importance) that are highly related to the training objective of back translation. Finally, we empirically explain why synthetic corpus with low quality may lead to better performance than synthetic corpus with high quality by measuring both factors.

3.1 Theoretical Explanation

Maximizing marginal likelihood is an important principle to leverage unlabeled data. Therefore, we rethink back translation from this principle because it makes use of target monolingual corpus $\mathcal{M}$. For each $y \in \mathcal{M}$, the marginal likelihood objective can be derived by the Bayesian Equation (5), Jansen Inequality (6), and importance sampling (7) as follows:

$$\begin{aligned}
\log p(y;\theta) &= \log \sum_x p(x)p(y|x;\theta) && (5)\\
&\geq \sum_x p(x)\log p(y|x;\theta) && (6)\\
&= \sum_x p(x|y)\frac{p(x)}{p(x|y)}\log p(y|x;\theta) &&\\
&= \mathbb{E}_{\hat{x}\sim p(\cdot|y)}\left\{\frac{p(\hat{x})}{p(\hat{x}|y)}\log p(y|\hat{x};\theta)\right\} &&\\
&\approx \frac{p(\hat{x})}{p(\hat{x}|y)}\log p(y|\hat{x};\theta) && (7)
\end{aligned}$$

where $p(x)$ is a language model on source language $\mathcal{X}$, $p(x|y)$ is a backward translation model from $\mathcal{Y}$ to $\mathcal{X}$ which serves as the proposal distribution for importance sampling, and $\hat{x}$ is sampled from $p(x|y)$. If $p(x|y)$ is set as the backward model $p(x|y;\pi)$ optimized on $\mathcal{B}$, the last term in Equation 7 is the same as the second term in BT loss (i.e., $\log p(y|\hat{x})$ in Eq. 2), and the unique difference is the multiplicative term called *importance* weight:

$$\mathrm{Imp}(\hat{x};y) = \frac{p(\hat{x})}{p(\hat{x}|y)} \quad (8)$$

The denominator is the candidate conditional probability to target, and the numerator is the candidate distribution on source language distribution. Since $\mathrm{Imp}(\hat{x};y)$ is constant with respect to the parameter θ, maximizing $\log p(y|\hat{x};\theta)$ in BT loss implicitly maximizes $\mathrm{Imp}(\hat{x};y)\log p(y|\hat{x})$, which indicates that back translation aims to implicitly maximize the marginal likelihood objective. More importantly, according to Equation 7 we can find that the following two factors are critical to influence the marginal likelihood $\log p(y;\theta)$:

- **Factor 1:** The quality of $\hat{x}$ as a translation of y corresponding to the $\log p(y|\hat{x};\theta)$ in Eq. 7.
- **Factor 2:** The importance of $\hat{x}$ as a translation of y corresponding to $\mathrm{Imp}(\hat{x};y)$ in Eq. 7.

Theoretically, if $\hat{x}$ is of higher quality and contains more semantic information in y, $p(y|\hat{x};\theta)$ would be higher and thus it would lead to a higher $\log p(y;\theta)$, which is well acknowledged by prior work (Sennrich et al., 2016a; Wang et al., 2019). In particular, if $\hat{x}$ is with higher importance weight, maximizing $\log p(y|\hat{x};\theta)$ is more helpful to maximize $\log p(y;\theta)$. On the contrary, if $\mathrm{Imp}(\hat{x};y)$ is very small, it needs to avoid such a sample $\hat{x}$ from $p(x|y)$, which is essentially the rejection control strategy in importance sampling theory (Liu et al., 1998; Liu and Liu, 2001).

Unfortunately, in practice, both factors are mutually exclusive to some extent: if $\hat{x}$ is with high quality, $p(\hat{x}|y;\theta)$ would be higher as well leading to lower importance weight. This fact can explain the contradictory observation in Sec 2 that BT with high-quality synthetic data sometimes leads to better testing performance, while it may deliver worse performance at other times, which will be later justified in Sec 3.2.

Estimating Two Factors To measure the quality of $\hat{x}$ for each y, it is natural to use the evaluation metric such as BLEU if the reference translation x of y is available. Otherwise, as a surrogate, we use the log likelihood $\log p(\hat{x}|y;\pi)$ of the backward translation model π which is trained on the authentic data $\mathcal{B}$. Similarly, in order to estimate the importance of $\hat{x}$, we train an additional language model $p(x;\omega)$ with GPT (Radford et al., 2018) on a large monolingual corpus for $\mathcal{X}$. In this way, the importance weight is estimated by

$$\mathrm{Imp}(\hat{x}) \approx \frac{p(\hat{x};\omega)}{p(\hat{x}|y;\pi)}$$

Systems	BLEU($\hat{x}$)	$\log p(\hat{x}\|y,\pi)$	Imp.	Test BLEU
beam	**27.20**	**-15.65**	-95.13	32.7
sampling	7.70	-157.62	**-41.86**	34.1
beam*	**18.50**	**-26.66**	-95.07	31.6

* The checkpoint of the backward model for generating synthetic corpus are only trained for 1 epoch. However, its $\log p(\hat{x}|y,\pi)$ is still measured by a standard backward model π.

Table 1: Testing BLEU (on test set), quality (measured by both BLEU and $\log p(\hat{x}|y;\pi)$) and importance (Imp.) estimation of synthetic data (on dev set) with beam search or random sampling on WMT14 DE-EN task.

Systems	BLEU($\hat{x}$)	$\log p(\hat{x}\|y,\pi)$	Imp.	Test BLEU
en-de(en)_beam	**31.90**	**-15.29**	-91.07	29.7
en-de(en)_sampling	10.90	-139.71	**-46.88**	30.0
ru-en(ru)_beam	**33.10**	**-15.49**	-89.71	35.9
ru-en(ru)_sampling	9.50	-155.82	**-47.47**	35.6

Table 2: Testing BLEU (on test set), quality (measured by both BLEU and $\log p(\hat{x}|y;\pi)$) and importance (Imp.) estimation of synthetic data (on development set) with beam search or random sampling on WMT14 EN-DE and RU-EN tasks.

3.2 Empirical Justification

In this subsection, we aim to justify the following statements: 1) encouraging the quality of synthetic corpus may to some extent hurt the performance of BT due to the decrease of importance; 2) judging the testing performance in terms of quality only may be dangerous while it would be meaningful to judge the testing performance by taking into account both factors rather than either factor. To this end, we run some quick experiments on WMT14 datasets whose settings will be shown in Sec 5 later.

We set up two back translation systems with two different options (i.e., beam search and sampling) to generate synthetic corpus by using the best checkpoint of $p(\hat{x}|y;\pi)$ tuned on the development set. Both beam search and sampling based BT systems are denoted by beam and sampling. In addition, we pick another checkpoint of $p(\hat{x}|y;\pi)$ which is trained for only 1 epoch, and we use this weak checkpoint to set up another beam search based BT system, which is denoted as beam*. Table 1 shows BLEU on test dataset, the quality and importance on the development set according to three systems on WMT14 DE-EN task.

In Table 1, beam is better than sampling in the quality of synthetic corpus but its testing performance is worse. This is meaningful because the former relies on the synthetic corpus with lower importance weight according to our theoretical explanation. In addition, when comparing beam with beam*, we can find that beam delivers better testing performance because its quality is better meanwhile its importance weight is almost similar to that of beam*. Table 2 consistently demonstrates that it is meaningless to take into account quality only when evaluating BT. These facts justify our statements and provide an answer to the fundamental question in section 2.

4 Improving Synthetic Data for BT

As shown in the previous section, both importance and quality of synthetic corpus are beneficial to the overall testing performance of back translation. It is a natural idea to promote both factors when generating synthetic corpus such that running BT on such corpus leads to better testing performance. However, this is difficult because both factors are mutually exclusive as discussed in Section 3. In this section, we instead propose two methods (namely data manipulation and gamma score) to trade off both factors in the hope to yield better BT performance.

4.1 Data Manipulation

Since the synthetic data in sampling based BT is of high importance yet low quality whereas the case for the synthetic data in beam search based BT is opposite, we propose a data manipulation method to trade off importance and quality by combining both synthetic datasets. Through balancing the ratio between beam and sampling based synthetic corpora, we expect to find an optimized beam/sampling ratio to further improve NMT model performance.

Specifically, we randomly shuffle $\mathcal{M}$ and divide it into two parts with the first part accounting for γ ($0 < \gamma < 1$); then we generate translations for the first part with beam search while generating translations for the second part with sampling. Formally, we use the following corpus $\mathcal{M}^c$ as the synthetic corpus for BT:

$$\mathcal{M}^c = \{(\hat{x}_i^b, y_i)_{i=0}^k\} \cup \{(\hat{x}_j^s, y_j)_{j=k}^{|\mathcal{M}|}\}$$
$$k = \lfloor \gamma |\mathcal{M}| \rfloor$$

Where $\hat{x}^b$ denotes a translation of y generated by $p(x|y;\pi)$ with beam search and $\hat{x}^s$ is a translation with sampling, $|\cdot|$ means the size of the corpus, and γ is the combination ratio for beam and sampling synthetic corpora. By tuning γ here, one can modify the weightage for the number of beam and sampling sentences, to improve back-translation performance by training models on a combined synthetic corpus.

Although this method is easy to implement, its limitation is obvious. Since each $\hat{x}$ is either from beam search or from sampling, the quality of $\mathcal{M}^c$ is generally worse than that of beam search and its importance weight is generally worse than that of sampling. Consequently, we propose an alternative method in the next part of this section.

4.2 Gamma Score

The key idea to the alternative method is that it employs a score that balances both quality and importance to generate a translation $\hat{x}$ for each $y \in \mathcal{M}$. A natural choice of such a score is defined by the interpolation score as follows:

$$\gamma \log \mathrm{Imp}(\hat{x}; \omega, \pi) + (1-\gamma) \log p(\hat{x}|y; \pi)$$

where γ is used to trade off both factors as in corpus manipulation. With the help of this score, one may optimize the $\hat{x}$ by beam search whose interpolation score is the best among all possible translations of $y \in \mathcal{M}$. Unfortunately, such an implementation leads to limited performance in our preliminary experiments, due to two major challenges.

On one hand, the estimations of quality and importance weight of $\hat{x}$ are not well calibrated, and in particular, quality and importance are mutually exclusive as mentioned before. As a result, beam search with the interpolation score over the exponential space can not guarantee a desirable translation $\hat{x}$ for each y. On the other hand, quality and importance weight of $\hat{x}$ are not at the same scale for different y, it is difficult to balance both factors with a fixed γ in the interpolation score for different y.

To alleviate these issues, we propose a simple method as follows. Specifically, firstly, instead of beam search with the interpolation score, we simply utilize the backward translation $p(x|y; \pi)$ to randomly sample a set of candidate translations which is denoted by $A(y) = \{\hat{x}_i\}_i^N$ ($N = 50$ in this paper as it works well). [1] Then we pick a $\hat{x}_j$ among $A(y)$ according to the balancing score. Secondly, for each $\hat{x}$, we normalize the log values of importance and quality of each candidate by its sequence length, then normalize these values with respect to all N candidates as follows:

$$\tilde{\mathcal{F}}(\hat{x}_i) = \frac{\log\left(\mathcal{F}(\hat{x}_i)\right)/\mathtt{len}(\hat{x}_i) - \mu_{\mathcal{F}}}{\sigma_{\mathcal{F}}} \quad (9)$$

where $\mathcal{F}$ is either importance weight or quality estimations, and $\mu_{\mathcal{F}} = \frac{1}{N}\sum_i \log \mathcal{F}(\hat{x}_i)$ and $\sigma_{\mathcal{F}} = \frac{\sum_i (\log \mathcal{F}(\hat{x}_i) - \mu_{\mathcal{F}})^2}{N-1}$ are mean and variance of N sampled candidates with length normalized. Finally, the Gamma score is defined on the normalized values of importance and quality as follows:

$$\Gamma(\hat{x}_i; \omega, \pi) = \frac{\exp\left(\gamma \tilde{\mathrm{Imp}}(\hat{x}_i; \omega, \pi) + (1-\gamma)\tilde{p}(\hat{x}_i|y, \pi)\right)}{\sum_j \exp\left(\gamma \tilde{\mathrm{Imp}}(\hat{x}_j; \omega, \pi) + (1-\gamma)\tilde{p}(\hat{x}_j|y, \pi)\right)} \quad (10)$$

where $\tilde{\mathrm{Imp}}$ and $\tilde{p}$ are the normalized log value of importance weight and backward translation model $p(\hat{x}|y, \pi)$ as defined in Equation 9.

Once the gamma score in Equation 10 is computed, there are two methods to select $\hat{x}$ from $A(y)$, which are deterministic and stochastic methods. For deterministic selection, we simply select the candidates with maximum gamma score among N translation candidates; and for sampling, we sample a candidate according to its gamma score distribution. These two methods are called gamma selection and gamma sampling in our experiments.

5 Experiments

5.1 Settings

We run all the experiments by using fairseq (Ott et al., 2019) framework. For dataset settings, since datasets WMT14 EN-DE and DE-EN are widely used (Li et al., 2019b; Zhu et al., 2020; Li et al., 2020; Fan et al., 2021; Le et al., 2021), we follow both standard benchmarks and additionally we employ WMT14 RU-EN as the third dataset to validate the effectiveness of the proposed methods. For back translation experiment, we use an equal scale monolingual corpus randomly sampled from Newscrawl 2020 (Barrault et al., 2019) comprising 4.5 million monolingual sentences for DE-EN language pair and 2.5 million for RU-EN direction, thus total 9 million sentences for DE-EN pair and 5 million for RU-EN direction are used. We tokenize the parallel corpus using Mose tokenizer (Koehn et al., 2007), and learn a source and target shared Byte-Pair-Encoding (BPE) (Sennrich et al., 2016b)

---

[1] N-best decoding strategy with $p(x|y; \pi)$ to generate N candidates may be another solution which remains as future work.

Table 3: Data manipulation achieves the almost the same BLEU score as sampling BT.

with 32K types. We develop on newstest2013 and report the results on newstest2014.

As for model architecture, we employ all the translation models using architecture `transformer_wmt_en_de_big`, which is a Big Transformer architecture with 6 blocks in the encoder and decoder, and is widely used as a standard backbone on various NMT research studies. We use the same hyperparameter settings across all the experiments, i.e., 1024 word representation size, 4096 inner dimensions of feed-forward layers, and dropout is set to 0.3 for all the experiments. In addition, for monolingual models, we apply `transformer_lm_gpt` architecture (Radford et al., 2018) on source language side of the corpus without any extra corpus. [2] The detailed hyperparameters used for training translation and language models are shown in Appendix.

For baseline models, we train them for 400K updating steps, and train the models with back-translation data for 1.6M updating steps. We save the checkpoints every 100k updating intervals, and only select the checkpoints with highest develop set performance. As for the back-translation data, we study beam decoding and sampling decoding as baselines since they are the common practice for BT research (Roberts et al., 2020; Wang et al., 2019). We use baseline models' checkpoints at 400K updating steps to generate default beam5 decoding and sampling decoding synthetic corpus without any penalty. For monolingual models, we only select the checkpoints with the best develop set performance. When tuning γ on dev sets for data manipulation methods we select it from $\{0, 1/4, 1/2, 3/4, 1\}$ and the optimal is $\gamma = 1/2$. For the Gamma Score method, γ is tuned among $\{0.1, 0.2, 0.3, 0.4, 0.5\}$ and it is set $\gamma = 0.2$ for all three tasks.

All the experiments are conducted using 8 Nvidia V100-32GB graphic cards without any gradient accumulation or bitext upsampling, and the results in this paper are measured in case-sensitive detokenized BLEU with SacreBLEU[3] by Post (2018).

5.2 Main Results

5.2.1 Results on DE-EN

Data Manipulation We conduct two experiments to study the data manipulation for back-translation NMT model performance using aforementioned corpus with and without authentic corpus.

Table 3 show the data manipulation results compared with baseline. Firstly, for synthetic corpus experiment, we find that even if only monolingual corpus is used, the performance of back-translation NMT model can still be significantly improved to 31.3 from 29.2 by sampling or 27.6 by beam, and it is only 0.7 lower than bitext baseline by BLEU score measure. Secondly, for the experiments with bitext, the best performance by data manipulation only helps the back-translation NMT model achieves almost the same performance with sampling BT. This means data manipulation methods cannot achieve a higher BLEU score than sampling or beam.

Gamma Score In this paragraph, we conduct the experiments based on gamma score method. We conduct both of the methods in this experiment: we select the candidate with highest gamma score for the deterministic method whereas sample the candi-

---

[2] Note that we do not use the pre-trained language models such as GPT-3 or T5 to exclude our gains from large scale monolingual data.

[3] We use the fairseq default shell script `sacrebleu.sh`, with WMT14/full testsets to evaluate the model checkpoints. The sacrebleu output format is BLEU + case.mixed + lang.de-en + numrefs.1 + smooth.exp + test.wmt14/full + tok.13a + version.1.4.13.

Table 5: SacreBLEU score on WMT14 EN-DE and RU-EN testsets. Gamma criterion based methods outperform beam search based and sampling based back-translation NMT models. The result marked with * denotes that it is significantly better than both sampling and beam based BT with $p < 0.001$.

date by gamma score distribution for the stochastic method.

Once again, we use synthetic gamma corpus combined with bitext to train the back-translation NMT models on each corpus, the results are listed in 4. From the table, we can see that our proposed gamma sampling significantly outperforms the sampling based and beam search based back-translation baselines by 0.9 and 2.3 BLEU scores in terms of SacreBLEU. And our two proposed gamma score based methods outperform the data manipulation method as well.

In the rest of the experiments, we report results for both gamma selection and gamma sampling as the proposed methods and their hyperparameter γ for other tasks is fixed to 0.2.

5.3 Results on other Datasets

We conduct the experiments on WMT14 EN-DE and RU-EN for both gamma selection and gamma sampling as well, and table 5 shows that our proposed gamma based methods significantly outperform beam and sampling based back-translation methods on both en-de and ru-en translation for almost 1 and 0.4 BLEU score respectively. Recently, Edunov et al. (2020) point out that BLEU might overlook the contributions from back translation since it poorly correlates with human evaluation on the data generated in back translation scenario. Follow their suggestions, to better reflect the scenario of back translation, we also evaluate our experiment using COMET metric suggested by Rei et al. (2020). The results are shown in table 6 and we can see that the proposed methods perform well in terms of COMET.

Discussion on Efficiency Since our method requires to run sampling with size of 50 to generate synthetic data, its efficiency is about 10x slower than that of beam BT with size of 5 and 50x slower than that of sampling BT with size 1. Luckily, because the bottleneck of BT is not the synthetic data generation but the parameter optimization on both synthetic and authentic data, our overall overhead is less than 0.5x slower than sampling BT. In addition, since decoding is very easy to be parallelized on GPU or CPU machines, the cost of decoding is not a serious issue for our method, which makes it possible to run our method on a large scale dataset.

5.4 Analysis on Synthetic Corpus

In this subsection, we analyze the synthetic corpus of proposed gamma score methods on both sentence level and token level.

Sentence Level We evaluate the back-translation synthetic source sentences by their sentence representations. We use the baseline model to generate the hidden representations at the end-of-speech token as the sentence representation. Here, we compute the singular value spectrum of the representations for different back-translation corpora.[4]

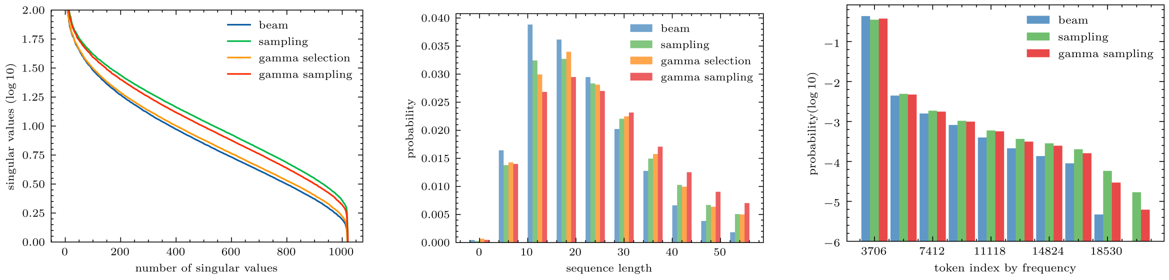
The spectrum is shown in figure 1(a). From the spectrum, sampling has a more uniform distribution whereas beam has the worst variety. Our proposed methods have moderate variety between sampling and beam, and gamma sampling consists of higher linguistic information richness compared with gamma selection.

Figure 1(b) shows the sequence length of the synthetic corpora of different generation methods. Beam generates the shortest synthetic sentences and gamma sampling generates the longest synthetic sentences on average. Between them, sampling and gamma selection generate almost the same sequence length, which means gamma selection candidates provide more learning signals than random sampling under the same length.

Token Level Figure 1(c) is the token frequency histogram, which shows beam has higher probability to decode high frequency tokens while sampling

---

[4] Singular value spectrum analysis is a widely used method to measure the representation distribution. Gao et al. (2019) firstly introduces this method to measure the isotropy of representation, and Wang et al. (2019) directly employ spectrum control for better NMT performance. The idea is, representations of high linguistic variety usually are more isotropic, thus having a relatively uniform singular value distribution. We employ this method here to measure the variety of sentence-level information.



(a) Spectrum (b) Sequence Length (c) Token frequency

Figure 1: Synthetic corpus analysis on singular value spectrum(a), sequence length histogram(b) and token frequency histogram(c).

System	DE-EN	EN-DE	RU-EN
Transformer	51.66	53.35	54.55
Beam BT	49.35	54.61	55.12
Sampling BT	52.71	56.01	54.34
Gamma Selection BT	53.83	**58.22**	**57.03**
Gamma Sampling BT	**53.97**	58.18	56.69

Table 6: COMET metric evaluation results on WMT14 DE-EN, EN-DE and RU-EN datasets. The testset results are in accordance with BLEU metric.

prefers more low frequency tokens.

We also measure the vocabulary size, finding that the proposed gamma sampling shares the same vocabulary size as sampling method. This could be the reason that gamma sampling is based on random sampling for candidates generation.

6 Related Work

This section describes prior arts in back-translation for NMT, data augmentation, and semi-supervised machine translation.

Back-translation NMT Bojar and Tamchyna (2011) firstly proposed back-translation, then Bertoldi and Federico (2009); Lambert et al. (2011) apply back translation to solve the domain adaptation problems in phrase-based NMT systems. Sennrich et al. (2016a) further extend the back translation for training NMT models integrally.

For understanding the back-translation synthetic corpus, Currey et al. (2017) use a copy of target as a pseudo source, and find that NMT model performance can still be improved under the low resource settings. Caswell et al. (2019) propose tagged back-translation to indicate to the model that the given source is synthetic. To further find an optimum back-translation corpus decoding method, Imamura et al. (2018) firstly use sampling based synthetic corpus and find such a stochastic decoding method outperforms beam search on boosting NMT model performance, and Edunov et al. (2018) broaden the investigation of a number of back-translation generation methods for synthetic source sentences. Their contribution shows that sampling or noisy synthetic data gives a much stronger training signal. Graça et al. (2019) reformulate back-translation in the context of optimization and clarifying to improve sampling based decoding method search space, thus proposing N best list sampling. Recently, Nguyen et al. (2020) diversify the training data by multiple forward and backward models translations and combine them with the original datasets.

Data Augmentation for NMT NMT researchers are the pioneers of data augmentation studies since back-translation is a natural type of data augmentation method. (Sennrich et al., 2016a; Norouzi et al., 2016; Zhang and Zong, 2016; Bi et al., 2021). To balance the token frequency in NMT corpus, Fadaee et al. (2017) create new sentences contain low-frequency words. However, as observed by Wang et al. (2018), the improvement across different translation tasks is not consistent, and they invent SwitchOut data augmentation policy. Recht et al. (2018, 2019); Werpachowski et al. (2019) also observe such an inconsistency of variance between training corpus and testing set as well as in the generation tasks. Recently, Li et al. (2019a) try to understand data augmentation from input sensitivity and prediction margin, thus obtaining relatively low variance in generation.

Semi-supervised Machine Translation However, as high quality bitext is always limited and costly to collect, Gulcehre et al. (2015) study methods for effectively leveraging monolingual data in

NMT systems. He et al. (2016) develop a dual-learning mechanism, under such a learning objective, a NMT system is able to automatically learn from unlabeled data, thus improving NMT performance iteratively. Based on iterative learning, Lample et al. (2018) investigates how to learn NMT systems when only large monolingual corpora can be used in each language.

For supervision of models, Gulcehre et al. (2017) employ the target language model hidden states into NMT decoder to further improve performance. Edunov et al. (2020) show that back-translation improves translation quality of both naturally occurring text and translationese according to professional human translators. For supervision of learning corpus, Wu et al. (2019) study both the source-side and target-side monolingual data for NMT.

7 Conclusion

In this work, we answer a fundamental question about synthetic data for back translation. We theoretically and empirically show two key factors namely quality and importance weight of synthetic data play an important role in back translation, and then we propose a new method to generate synthetic data which better balances both factors so as to boost the back-translation performance. For future work, we think it would be of significance to apply our synthetic data generation method to other BT methods or even to more broad NLP tasks such as paraphrasing and style transfer.

A Model Details

The models are optimized using Adam optimizer (Kingma and Ba, 2015), with $\beta_1 = 0.9, \beta_2 = 0.98$. We use the same learning rate schedular as (Vaswani et al., 2017) with maximum learning rate 7×10^{-4}, and 4000 warmup updates. We use the fairseq 10.2 as the framework and the training command as well as the model hyperparameters are listed below,

```
 fairseq-train \
--arch transformer_wmt_en_de_big
--share-all-embeddings
--dropout 0.3
--weight-decay 0.0
--criterion
    label_smoothed_cross_entropy
```

```
--label-smoothing 0.1
--optimizer adam
--adam-betas '(0.9, 0.98)'
--clip-norm 0.0
--lr-scheduler inverse_sqrt
--warmup-updates 4000
--max-tokens 4096
--max-update 1600000
--validate-interval-updates 10000
--save-interval-updates 100000
--lr 7e-4
--upsample-primary 1
```

And the GPT model we employ is only trained on source side of bitext corpus, without extra datasets. The training command line and core settings are listed below.

```
 fairseq-train \
--task language_modeling
--arch transformer_lm_gpt
--share-decoder-input-output-embed
--dropout 0.1
--optimizer adam
--adam-betas '(0.9, 0.98)'
--weight-decay 0.01
--clip-norm 0.0
--lr 7e-5
--lr-scheduler inverse_sqrt
--warmup-updates 8000
--tokens-per-sample 512
--sample-break-mode none
--max-tokens 4096
--update-freq 1
--max-update 1000000
--keep-last-epochs 5
--validate-interval-updates 10000
--save-interval-updates 10000
```

Mapping the Design Space of Human-AI Interaction in Text Summarization

Abstract

Automatic text summarization systems commonly involve humans for preparing data or evaluating model performance, yet, there lacks a systematic understanding of humans' roles, experience, and needs when *interacting* with or being *assisted* by AI. From a human-centered perspective, we map the design opportunities and considerations for human-AI interaction in text summarization and broader text generation tasks. We first conducted a systematic literature review of 70 papers, developing a taxonomy of five interactions in AI-assisted text generation and relevant design dimensions. We designed text summarization prototypes for each interaction. We then interviewed 16 users, aided by the prototypes, to understand their expectations, experience, and needs regarding efficiency, control, and trust with AI in text summarization and propose design considerations accordingly.

1 Introduction

In this era of rapid information consumption, access to high-quality summaries, such as online news highlights and research paper abstracts, is increasingly important. However, summarization is difficult for humans, demanding high cognitive load and expertise (Hidi and Anderson, 1986). Algorithmic approaches can automate summarization but typically underperform humans and require many high-quality human-written summaries for training (Durrett et al., 2016; Huang et al., 2021). AI systems that involve humans typically constrain their input to data preparation (Lloret et al., 2013) or final evaluation (Khashabi et al., 2021) as the first or last step in the summarization workflow. How can humans work together with AI to produce better summaries?

Other text generation tasks, such as machine translation and creative writing, offer inspiration.

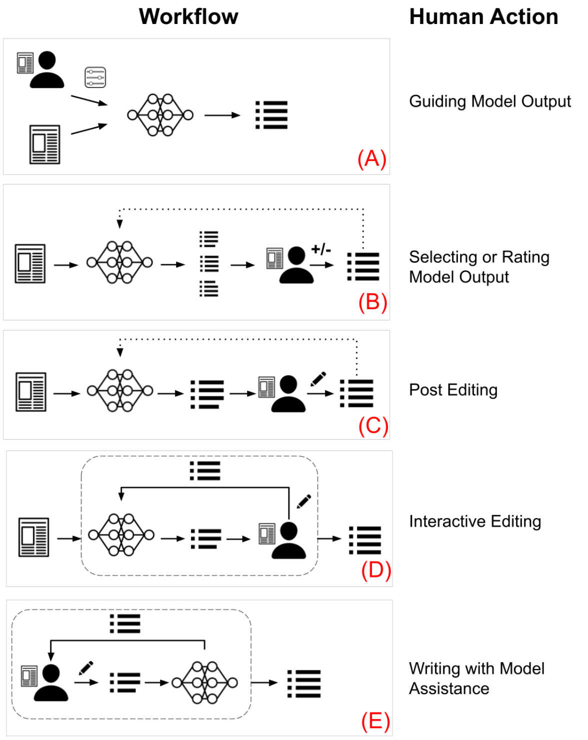

Figure 1: Five human-AI interactions in text generation from Study 1, illustrated as summarization tasks. Explanation of the actions and visual elements are in §2.2.

Beyond being data providers and evaluators, humans can generate text with the assistance of AI. For example, humans can revise AI translation (i.e., "post-editing") (Green et al., 2013) or write with AI suggestions (Clark et al., 2018). These interaction techniques may apply to summarization, yet our understanding of the possible human-AI interactions and how to design for them is incomplete.

To that end, we conducted two studies to explore: **RQ1** What are the different ways that humans and AI can interact in text generation? **RQ2** What are humans' experience and needs with these different types of AI assistance in the context of summarization? For these studies, we took a human-centered approach—focusing on what humans want from AI and how to improve their experience, rather than

improving AI models. In Study 1, we conducted a systematic literature review of 70 papers that involve AI-assisted text generation systems and developed a taxonomy of five different human-AI interactions (Figure 1), including distinct human actions, controls, workflows, and interface features. In Study 2, to explore human experience with these five interactions in the specific context of text summarization, we conducted interviews with 16 users using prototype interfaces that we developed and identified varied user needs regarding efficiency, control, and trust, informing design considerations for AI-assisted text summarization and generation systems.

This work contributes: 1) the first known systematic literature review that provides a taxonomy of human-AI interactions for text generation, 2) an interview user study to understand user experience and needs in each interaction, and 3) an outline of the design space for AI-assisted text summarization and broader text generation systems. This research is a formative, initial exploration that first maps the different types of human-AI interaction for text generation and then surfaces user needs and perceptions for each type in the context of human-AI summarization. Such formative work is crucial for understanding what users might want and need from systems without biasing them by existing implementations—future researchers can use these findings to design and evaluate new human-AI text summarization systems.

2 Study 1: Systematic Literature Review of Human-AI Text Generation

For the first study, We performed a systematic literature review of human-AI text generation and developed a taxonomy of existing interaction types, which differ by the level of human control over the output, whether the AI iteratively updates its output based on human interaction, and whether human or AI initiates the interaction workflow. This study identifies and synthesizes the types of interaction explored in prior work. While we do not contribute any entirely new human-AI interactions for text generation, our taxonomy provides grounding for our second study—exploring user needs and experience with these interactions—as well as future research and design in this space. Future AI/HCI researchers can refer to this taxonomy when designing text generation systems or experiments to select the interaction and design elements that best fit their scenario and to compare findings with prior work toward a more formalized understanding of the space.

2.1 Method

We conducted a comprehensive search on academic papers about human-AI interaction in text generation from online indices and relevant workshops, e.g., ACM Digital Library,[1] arxiv.org,[2] HCI-NLP.[3] With the 692 papers queried from these sources, we manually coded the titles and abstracts against our inclusion criteria (e.g., for the goal of text generation, engaging humans beyond data preparation or evaluation) and identified a final set of 70 papers that describe human-AI interaction (or AI assistance) for the humans' goal of generating text (opposed to offline model training or evaluation). See further details on sources, query methods, inclusion criteria, and analysis process in Appendix A.1.

2.2 Findings: Five Human-AI Interactions in Text Generation

From the 70 papers, we identified five human-AI text generation workflows featuring distinct human actions—guiding model output, selecting or rating model output, post-editing, interactive editing, and writing with model assistance (Figure 1). We present the taxonomy that summarizes our findings in Table 1. For each interaction, we describe the human action, the type of human control, whether the model iterates based on human action, who (human or model) initiates the workflow, and interfaces from literature. We explain the interactions and visual elements in Figure 1 as follows:

Guiding Model Output. Humans can give model guidance to generate text (Figure 1, A). Here, humans are in the driver seat of the generation process with power to initiate and control the final output. Humans provide preferences (illustrated as the slider icon in the figure) to the model. The model takes human input and original text (the document icon) and produces text as the final product (the rightmost four-line summary icon), concluding the interaction with no further iteration. The specific guidance that a human can provide is varied and depends on their ML expertise. Model developers can adjust model parameters such as neural attention

Table 1: A taxonomy of human-AI interaction for text generation: human action, the type of control that humans have over the final output (Human Control), including generating, editing, or selecting/rating AI-generated text, whether the AI iterates, dynamically providing updated outputs based on human interaction (Model Iteration), who (Human or Model) initiates the workflow (Workflow Initiation), and what interfaces are used (Interfaces).

weights and hyperparameters. Alternatively, lay-users can prompt the model using semantic cues (e.g., keywords, topic tags, or descriptive prompts), or specify the style or details of the text (e.g., sentiment or length). Some interfaces support selecting or deselecting what from the input text should be used by the model.

Selecting or Rating Model Output. Humans can select from or rate generated texts (Figure 1, B). The model initiates such workflows by generating candidates of final output (the 3 four-line summary icons). The human does not directly generate text, instead, they have the control to select from or rate the candidates (the "+/-" icon) to support final output. We focus on the case where human input decides which candidate is chosen as the final product, but such feedback can also be used for online model training (e.g., active learning), represented as the dotted arrow going from the final product to the model in the figure.

Post-editing. Post-editing (Figure 1, C)—common in machine translation (Green et al., 2013)—starts with text drafted by AI (the four-line summary icon with an incomplete last line), which humans edit (the pen icon). The workflow concludes when the human finishes editing, without any further iteration by the model, although the edited text can be used for future model training (the dotted arrow going from the final product summary back to the model). In many interfaces, users post-edit AI-generated text in text boxes. Some systems include innovative editing paradigms (e.g., chatbots) and other supports, such as drop-down menus for word or sentence substitution and scaffolds for context (e.g., embedded dictionaries) to aid understanding. Further, productivity supports can reduce workload, such as signalling where edits are needed and automatic error amendment based on users' editing history.

Interactive Editing. Humans can edit text interactively with AI (Figure 1 D). Like post-editing, this dynamic editing interaction is also commonly used in machine translation systems, i.e., "interactive machine translation" (Barrachina et al., 2009). First, the model generates an incomplete draft (the three-line summary icon with a incomplete last line), to which human provides edits. While post-editing would stop at this point, in interactive editing, the model iterates on the human-edited text (the complete three-line summary on the top) to update and generate more text for continued human editing, iteratively and in real-time (the solid line arrow). This iterative human-AI interaction (in the dashed frame) results in the final product. Interactive editing interfaces take many forms. "Prefix-based" edits are specified on a left-to-right phrase by phrase fashion, while the model makes new predictions on the rest of the sentence. In other interfaces, humans edit at arbitrary positions of the AI-generated sentence and the model updates the whole sentence. Some systems offer additional editing support, such as highlighting necessary edits and dropdowns for substitution.

Writing with Model Assistance. Finally, humans can write with AI assistance (Figure 1, E). Humans initiate this workflow and have a high-level control: humans begin writing while the model provides suggestions and can revise their writing based on the suggestions or ignore them. This iterative human-AI interaction (in the dashed frame) generates the final text. In this process, the model iterates, providing additional suggestions based on humans' writing. Assisted writing interfaces include real-time auto-completion, which can happen at the word, phrase, or sentence level. Some systems offer alternative suggestions in dropdowns from which humans choose. Others provide asynchronous suggestions, presented after users have finished writing to reduce distraction.

3 Study 2: Interview Study on AI-assisted Text Summarization

We present a user study in which we evaluated interactions in AI-assisted text summarization with the context of text summarization through interviews aided by prototype interfaces. Our goal is not to prescribe which is "best" but to achieve a qualitative understanding of user needs with each interaction to inform future research and design.

3.1 Prototype Design

We first developed prototype interfaces to represent the five interactions identified in Study 1. We used these prototypes in our user interviews to elicit needs, expectations, and experience around AI-assisted text summarization.

While some prototypes for these interactions exist in the literature for broader text generation tasks, many include additional features and visual design that may affect users' perceptions, therefore, we develop our own set of consistent, simple prototypes for exploring text summarization specifically. Each interactive prototype, implemented in Figma[4] or Google Docs, allowed participants to read an online news document and generate summaries with the support of a hypothetical AI model.

All prototypes were built based on the "Wizard-of-oz" prototyping concept (Kelley, 1983), commonly used in user studies on intelligent systems. This concept allows users to interact with intelligent systems that are not fully implemented; instead, "system outputs" are prepared manually by the research team. This method allows designers of intelligent systems to rapidly test design concepts, understand user experience, and iterate on their design. This method has been used to prototype NLP systems, for example, in the design of chatbots (Zhou et al., 2019; Avula, 2018).

In our study, participants interacted with"Wizard-of-oz" prototypes instead of implemented AI models, so that we could explore human perspectives and user needs for the different interaction types without being limited by model performance or other system characteristics, such as unpredictability and slow updates. Each of our five prototypes used the same original text (a news article from the set used in the warm-up activity, explained in §3.2) that needed to be summarized. The prototypes differed by the interaction interface they supported (from Study 1). Depending on the interaction type, the prototype presented users with "AI-generated" summaries, outputs or suggestions that were pre-defined and written by the research team. While the human-written outputs used in this study might not necessarily imitate the quality and style of AI-generated summaries, outputs, or suggestions, they were intended to provide concrete examples of the interaction types and

---

[4] `https://www.figma.com/`

elicit participant's needs and expectations. Future work should explore how more realistic model outputs affect human perceptions. The specific design of each prototype (and screenshots) are described in the Appendix A.3.

3.2 Method

Participants. We recruited 16 participants (10 females, 6 males, all based in the U.S.) from Upwork[5] with varied professional backgrounds and varied familiarity with the domains of Reddit posts, online news, and U.S. government bills. We intentionally recruited participants who have at least some level of familiarity with text editing or summarization from professional or educational settings, which ensures that participants could speak about for which summarization tasks they desire assistance and describe their needs for such interactions. See Appendix A.2 for demographic details. The study took 2.5 hours, and we paid each participant $60.[6]

Procedure. Each participant first did a 60-minute offline warm-up activity less than 48 hours before the interview, where they summarized six articles (two Reddit posts on scams or finance,[7] two news articles from CNN/Daily Mail,[8] and two U.S. government bills[9]). This activity aimed to expose participants to summarization with articles written in different styles and with varied domain context.

Then, during the 1-on-1 semi-structured recorded video interviews (90 minutes), participants first reflected on their experience in the warm-up summarization tasks and then interacted with all five prototypes, in random order, as users of AI-assisted summarization systems. Participants were shown a news article from the warm-up task (all prototypes used the same article) and also asked to imagine using the prototypes for the other documents from the warm-up. They interacted with the interfaces and received pre-determined outputs that mimicked AI assistance:

1. **Guiding Model Output**: participants could change the desired summary length and style (formal or informal) using sliders and highlight parts of the original text that should be in the summary. We asked participants what additional guidance they wanted to offer to the model.
2. **Selecting or Rating Model Output**: participants chose from three AI-generated summaries.
3. **Post-editing**: participants saw an editable AI-generated summary (text box) and talked through how they would edit it.
4. **Interactive Editing**: given an AI-generated summary (text box), participants chose possible edits to the first sentence (dropdown menu) and then requested the model to update the summary based on those edits. We asked participants to imagine an alternate interface where they could edit anywhere in the summary.
5. **Writing with Model Assistance**: following a "wizard-of-oz" prototyping method (Kelley, 1983), a researcher acted as an AI bot in a Google Doc. As the participants typed their summaries, the "bot" provided suggested next sentences and added comments.

Participants were then prompted to talk through experience with each prototype, including what they liked or disliked regarding efficiency, control, and trust, and how they would improve them. See Appendix A.3 for screenshots of each prototype and A.5 for the interview questions and instructions used in the study. We collected and transcribed 22.6 hours of interview recordings, which were analyzed using thematic analysis (Guest et al., 2011). We performed two rounds of open coding and developed themes reported in the following sections. We refer to participants as P1-16 with gender non-specific pronouns (i.e., they, them). We present findings regarding efficiency, control, and trust—common themes in our interviews and key dimensions in the human-AI interaction literature (Amershi et al., 2019; Shneiderman, 2020). We include additional findings about user expectation and needs in writing summaries in Appendix A.4.

3.3 Findings

3.3.1 General Expectations & Needs

Expectation on AI to improve summarization. The warm-up summarization tasks were challenging and tedious. Summarizing the Government Bills was slow for many due to the unfamiliar domain, jargon, and *"super dry, super repetitive"* (P3) style. Summarizing informally-written and opin-

ionated Reddit posts was also difficult as many were unsure about whether to keep the authors' perspective or summarize neutrally. Therefore, participants hoped that AI could speed up and ease this process. Many envisioned AI-generated summaries as a useful starting point: *"determining where to get started can be a big roadblock for some writers...being able to have that auto-generated summary as your baseline to develop your ideas off I think would be really helpful"* (P13) Further, participants hope to use AI suggestions to improve the content and structure of their writing: *"it gives more of a third party look at things...just kind of compare and contrast it to what I've done, to make sure that I'm on the right track"* (P15).

Different desire for control. Most agreed they at least wanted the ability to proofread the AI-generated summaries, or to *"have the final say"* on whether it was good as a final product (P3). Some said this *responsibility* was a habit of professionalism; others were cautious of the work done by AI and wanted to ensure quality: *"it was drilled into my head that these devices are tools and they can fail...we're always responsible for overseeing what the computer does"* (P7). Beyond simple editing, participants had a varied desire for control. Some felt summarization was *"not necessarily a creative enterprise"* and, therefore, were willing to *"relinquish a little bit of control to AI"* for efficiency (P3), while others wanted to participate in the entire generation process. These participants preferred to compose their own summary using AI strictly as an aid, e.g., *"it would just simply be used as a tool for me, not as something to replace my work"* (P12). Many felt uncomfortable using AI-generated summaries directly or after only proofreading edits due to the sense of *"plagiarism"*, and as a result, wanted the ability to rewrite summaries into their own words. Desired control could also vary by situation. For example, P7 wanted more control when summarizing for the bills because that was a more *"serious and important task,"* while P8 would be more lenient when summarizing the Reddit posts: *"even [the summary] doesn't capture everything, it is good as long as the summary kind of outlines the the key points of the article."*

Need to understand AI to reduce over-reliance and boost trust. Participants were concerned that they might rely on AI too much and lacked confidence to correct it even when it was wrong. For example, P7 felt AI-generated summaries were an *"authority that has given you this thing"*, saying that *"for most people, if presented with something, they're going to go with it."* As a result, users could lose confidence when they disagree with the AI. P8 shared their hesitation to dramatically edit AI-generated summaries: *"it's almost feeling like you're pivoting against the AI...should I question what the AI thinks is important?"* This apprehension might increase when participants are summarizing for unfamiliar or difficult documents. Specifically, some anticipated a lack of trust when summarizing challenging articles because they could not reasonably assess the AI's output: *"I probably wouldn't use it for a lengthier subject that I wasn't familiar with...just because I wouldn't know if the AI was writing something I wanted to write"* (P6).

To foster trust, many wanted information about *how* the AI generated the summaries or suggestions—why the certain information is included and whether there were any hidden presuppositions by the model. For example, P8 said, *"knowing, in a very basic sense, how the AI is generating these summaries, [will] give me a good idea of essentially how much I can trust it."* As the prototypes did not include explanation features, participants noted that they did not trust the AI since they did not understand the mechanism, as P12 put: *"there's too many variables that you don't know. Too many unknowns for me."*

3.3.2 Interaction-Specific Experience & Needs

We report participants' needs and expectations on efficiency, control, and trust when interacting with each of the five interfaces and present a conceptual comparison between the five interfaces in Figure 2.

Guiding Model Output Participants felt this prototype streamlined the summarization process, as they did not need to compose the summary themselves, but only give their preferences: as P6 said, *"I don't have to do quite as much thinking...I don't have to type which takes time."*

Most appreciated the control over the summary generation by adjusting parameters. For example, P8 liked the text highlighting feature, as *"it gives you the amount of control in terms of being able to choose the parts that you think are important."* Many envisioned using the interface to customize the summary for their target audiences. For instance, P6 imagined using it to tailor summary styles for different colleagues: *"with my staff, I*

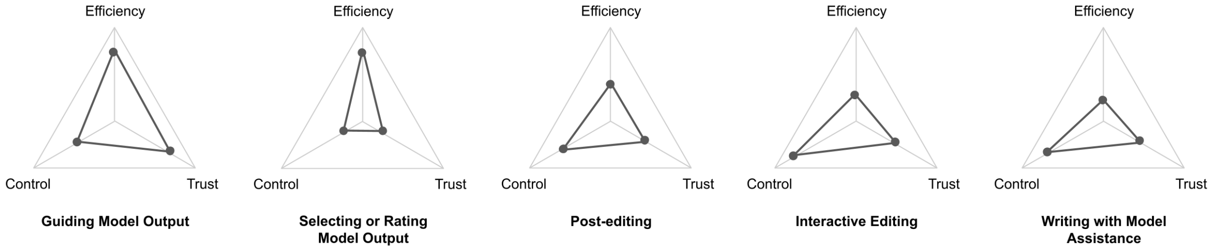

Figure 2: Illustration of participants' perception on level of efficiency, control, and trust with each interaction. These conceptual level charts show a qualitative, rather than precise, comparison between interactions.

would use the short style...for my boss, I might use a longer formal summary to look a little more professional." On the other hand, some were concerned about the lack of editing control: *"it doesn't have as much control as it seems. When you get to this [final] stage, you're stuck with it"* (P7).

Participants felt they had a reasonable understanding of the AI mechanism in this prototype and thus could trust it. Since they could change parameters (e.g., length, style) to experiment with different aspects of the summary, they better understood the process: *"we could [trust it more] maybe because I can play around with it. The long and short allows me to kind of have control"* (P12).

Selecting or Rating on Model Output Most participants thought this interface could make summarization much more efficient, as they only needed to choose the best summary out of a list rather than to write or edit. Participants valued this low workload: *"[it was] gonna summarize the article for me and do all the work...whatever I can use to buy out my part of the labor I am all for."* (P6)

Despite the efficiency advantage, many complained about the lack of control, specifically the inability to influence or edit the AI-generated summaries. For example, some felt that choosing the best might not ensure quality: *"what if three of these are presented, and none of them are really good enough. Then it's just a matter of picking the least bad one"* (P7). Further, since comparing and selecting were simpler tasks than writing or editing, participants paid less attention and thought less critically: *"evaluating already written summaries and trying to decide which one is the best is different from just writing your own summary...I am not like super mentally invested in it, if I were writing my own, I'd very careful with word choices"* (P5).

Many struggled in selection as they did not know how the candidates were generated: *"how do you determine, from an AI standpoint, what information to keep and what information to get rid of? How do you determine the priority as what stays and what goes? Is it biased in any way?"* (P14).

Post-editing Participants were mixed on how much efficiency post-editing would bring. Some thought it could make summarization faster: *"I could just run it through this, and then edit it and change the things that I needed to change. It would save me a lot of time and energy"* (P1). For others, editing unfamiliar text was an equally time consuming task. For instance, P8 would always ensure the summary aligns with their personal writing habits and style, and, therefore, they would spend a lot of effort in editing and customization: *"I feel like it would be just as much work to just write it from scratch...if I'm trying to make it original, I have one less way of being able to word it"* (P8).

Participants were satisfied with the editing control granted by this interface. For instance, P10 shared why they liked it more than the Selecting or Rating on Model Output interaction *"You can edit it to however you'd like. I think the freedom to edit appeals to me a little bit more."*

Similar to other prototypes, participants hoped to see more information on how the AI generated the summary. For example, P16 said it would be helpful to visually see which parts of the article were emphasized in the AI-generated summary, so that they could decide what to focus on. Similarly, P7 imagined a quantifiable way to indicate how much of the content in the summary was matched with the original article. They hoped for *"some advanced algorithms checking to make sure that it did it right"* to decide how much to trust it.

Interactive Editing Participants were more suspicious about this prototype's efficiency compared to the others. They worried that the dynamic updates to the summary might disrupt their existing edits, from P9: *"what if I rewrite the first sentence again, and then it changes everything else. I feel* *like it can really start to ripple."* Real-time model updates also generate new text, creating more editing work: *"with every choice that I have written here, I'm going to have another choice down here to consider whether I want to use or not. It's gonna cause me way too much work"* (P12).

For control, many valued that in addition to editing, they could also experiment with different versions due to the dynamic updates. However, some viewed it pointless to iterate with the AI and would rather complete editing in a single turn: *"it's giving me a choice that I don't necessarily want...I want it to be as close to a final draft as possible, because then my editorial choices are final and have the feeling of finality"* (P3). Participants also worried about unpredictable AI actions that might impact their edits: *"I don't have any idea what the second paragraph is going to be until I make a choice with the wording of the first paragraph"* (P11); *"it is kinda stressful because if you use just one different word, it's going to change the entire thing"* (P15).

To ease this uncertainty, many wanted to understand how the AI updates based on their edits. P5 shared that they tended to discuss with coworkers on how certain choices were made—*"every word is intentional."* And, they hoped to have similar interaction with the AI, *"to know the reasoning behind the changes, the kind of logic flow,"* so that they could make better decisions on what to edit.

Writing with Model Assistance Participants felt that writing and iteratively making improvements based on new model suggestions and comments could be tedious: *"I have to go back and read what it suggests and see if it makes sense for them and for me. I just think it takes you more time to do this"* (P6). Also, from P14, it *"puts more back on the person writing the summary,"* which could introduce writer's block and stress.

Despite of the high control over the final output and whether to take AI's suggestions, participants wanted to control *when* they received assistance during summarization. Many viewed the auto-completion and suggestion intrusive and distracting, especially when they were not ready to receive help: *"it's harder to write when you have constant changes being thrown your way"* (P9). Comparing it with the Interactive Editing interface, P7 found the latter allowed more control over when AI helps: *"since you're pressing a button, you still feel like you have some control. And you have control the timing too, which is important, because, what if you want to think about your first sentence?"*

Similar to other interfaces, participants also wished to know why the AI made certain suggestions, so that they could decide whether and how to follow: *"I am a why person and I like to understand what I am doing. So if you're telling me to change something, you need to give me the reason"* (P6). In addition, some thought auto-completion might amplify human mistakes as it was learning from their writing: *"when I wrote my first sentence, I wasn't confident... And then for the bot to come in with that... it's not going to be a good summary, because I didn't know what I was writing."*

4 Discussion & Design Implications

In the taxonomy, we synthesized five human-AI interactions in AI-assisted text generation. Through interviews, we surfaced user experience and needs with each interaction technique to inform future research and design. Although our user studies focused on summarization specifically, we believe our insights can be used for designing broader text generation systems. We discuss both general and interaction-specific implications as follows.

Offer the post-editing option regardless of interaction type. In general, humans like to have the *"final say"* on AI-generated text. Even when participants' role was choosing model output, they still wanted the option to edit to ensure quality. As such, future human-AI text generation systems should provide editing options for the final output.

Ensure customizable timing of AI-assistance in writing. We found unsolicited auto-completion and suggestions could disrupt users' writing experience. Future AI-assisted writing systems should allow users to easily turn off or adjust any automatic functions to decide when to receive help from AI. For example, users can press a button on-demand, instead of getting automatic suggestions.

Align interactive editing with user expectation. While humans in general like editing support such as dictionary or substitution suggestion, participants were more skeptical about dynamic updates in the Interactive Editing case, as AI may make big changes when they intended to make minor edits. Therefore, they desired to adjust the *extent* of AI-predicted updates based on their intention. Echoing literature on predictable AI systems (Daronnat et al., 2021), future interactive editing systems should consider user expectations and empower users to preview AI actions. Systems could also model human editing intention, perhaps via action history like number and location of edits, and adapt AI actions accordingly to better serve user goals.

Support tailoring text to different audiences. Another use case for AI-assisted writing is to *tailor* generated text to different audiences. For example, Systems with Guiding Model Output interaction allow humans to specify desired style, audience and use cases and generate customized text. Post editing and interactive editing systems can incorporate scaffolds that provide wording and format suggestions tailored for different scenarios.

Address trade-offs between efficiency and control. Guiding models or selecting model outputs are efficient actions, but humans have concerns about the lack of editing freedom and ownership on AI-generated text. Systems that leverage human editing power or support human writing with AI grant more flexibility, but require more effort. Users' needs in efficiency and control vary based on their goals and context. For summarization, participants felt more responsibility and thus desired more control on editing and generation when working on professional tasks or on texts that were perceived to be important (e.g., Government Bills). Future systems should consider these differences and assign different level of controls to users accordingly. For instance, systems can classify tasks based on importance and automate more when generating texts that are less important, while inviting humans to participate more in the generation and editing process for more important tasks.

Foster appropriate trust on AI. Our findings echo literature that humans can both over- and under-rely on AI systems (Bussone et al., 2015; Buçinca et al., 2021). For example, consistent with Bhat et al. (2021), users may view AI-generated text as an authority and be conservative on making edits. Others were uncertain if the AI-generated text or suggestion is reliable, especially when working with important text. Our findings point to the need for *appropriate* trust on AI text generation in general. First, systems should support users to understand *how* the model generates text, so that they can decide whether to rely on it or not. One technique is to allow humans to participate in the model decision process. Systems can refer to the Guiding Model Output interaction and allow users to specify preferences and experiment with different outputs. Systems can also offer explanations to model mechanism, perhaps through visual representations (Zhang et al., 2011; Gehrmann et al., 2019). Second, systems should provide *context support*. Interview participants, regardless of interaction case, had issues working with AI when summarizing Government Bills, as they were unfamiliar with the format and jargon. To this end, systems should equip users with sufficient context, so that they can effectively evaluate AI suggestions and make decisions accordingly. For example, systems can offer embedded dictionaries, resource search, or user Q&A support.

Limitations. We note a few important limitations in our study. First, we scoped our paper specifically to human-AI interactions for the goal of generating text, while we did not study the needs of humans who develop models, annotate data, or consume final outputs from AI. Second, while we performed a formal systematic literature review in Study 1, we may have missed some important papers due to our sampling strategies. Therefore, our taxonomy of human-AI interaction for text generation might not cover all possible interaction types. Third, our interviews were limited in that participants performed only short-term interaction with a hypothetical AI model in predefined scenarios. Users may report different experiences when interacting with real AI models in real-world settings for longer periods of time. That said, our study is a formative first step that aims to ground future research. Future researchers and developers could design human-AI text summarization systems based on our findings and further evaluate the systems in more realistic settings, with realistic model outputs, and through large-scale experiments.

5 Conclusion

While humans are commonly asked to generate training data or evaluate final model output in text summarization, we draw attention to the potential of collaborative human interaction when working with AI. Our study first contributes a taxonomy of five types of human-AI interactions for text generation tasks. We provide insights on user experience and needs around efficiency, control, and trust for the five interactions and design implications, outlining a variety of considerations for researchers, developers, and designers working toward incorporating human users in text generation systems.

A Appendix

A.1 Study 1 Method Details: Data Collection, Inclusion Criteria, and Manual Coding Procedures

We collected academic papers by searching three large online indices: Web of Science[10], Engineering Village[11], and ACM Digital Library[12]. Because this is a rapidly growing field and some relevant papers may not be officially published, we also searched arxiv.org[13] for e-print papers. In addition, we included relevant papers that we encountered in previous research activities and snowballed relevant references (for example, we included papers from the workshops of Hum-eval[14] and HCI-NLP[15]).

The specific keywords we used to query the papers include: 1) A word or phrase about AI: AI OR "artificial intelligence" OR machine OR model; 2) A word or phrase related to human-AI collaboration: collaborate OR interact OR assist OR co-author OR co-write OR co-work OR in-the-loop OR co-create OR “human feedback” OR “human-centered”; and 3) A word or phrase about the task: "text summarization" OR "document summarization" OR "article summarization" OR "text generation" OR "document generation" OR "article generation" OR "caption generation" OR “machine translation” OR “style transfer”. For each keyword, we searched for all of its forms and/or tenses.

The comprehensive search resulted in 692 papers. After a period of team discussion and iteration, we developed the criteria of the papers that we would like to include in our analysis: First, the paper needed to directly contribute to the problem space of text-to-text generation tasks. Papers about image/video caption generation, speech recognition, and speech-based machine translation were excluded. Second, the paper had to contribute an interface, workflow, or user study that involve human-AI collaboration. For this reason, survey papers were excluded. In addition, because our goal was to identify types of human-AI collaboration that were not obvious previously, we intentionally excluded papers that in which the only human-AI collaboration is human evaluation for model generated final results or human generating training data.

The first author and two other authors then independently coded a random sample of 150 papers out of the 692 collected papers for inclusion or exclusion. Specifically, the first author coded all 150 papers, and the other two researchers coded 75 respectively. They reached a high inter-rater reliability by comparing the last two researchers' coding with the first authors' respectively (average Cohen's Kappa = 0.9), validating the inclusion coding strategy. The first author then coded the remaining 542 papers for inclusion or exclusion. This led to 106 papers that met our inclusion criteria. Due to the rapid advancement in natural language generation in the recent ten years (Dong et al., 2021), we believe insights from recent papers would be most relevant to the design and development of future systems and research. Therefore, we excluded papers published earlier than 2011. All these procedures resulted in a final collection of 70 papers selected for analysis.

Finally, we analyzed the 70 papers following the procedures of thematic analysis (Guest et al., 2011), a manual coding method in qualitative research with which researchers iteratively develop themes from qualitative data. The first author conducted two rounds of open thematic coding on the papers, focusing on aspects such as human actions, collaboration goals, and problem domains. During this process, the team discussed, iterated and refined the themes.

A.2 Demographic Details of Study 2 Participants

The demographic details of Study 2 participants can be found in Table 2.

Table 2: Demographic information of Study 2 participants. All the information are self-reported by the participants. All the participants were based in the United States. Column "Experience: summarization" reports their answers to the question "rate the following statement: 'I am experienced in text summarization' on a scale of 1 to 7, with 1 being least experienced and 7 being most experienced." The other columns on experience or familiarity reports their answers to questions in the same format.

A.3 Prototype Interfaces Developed for Study 2 Interviews

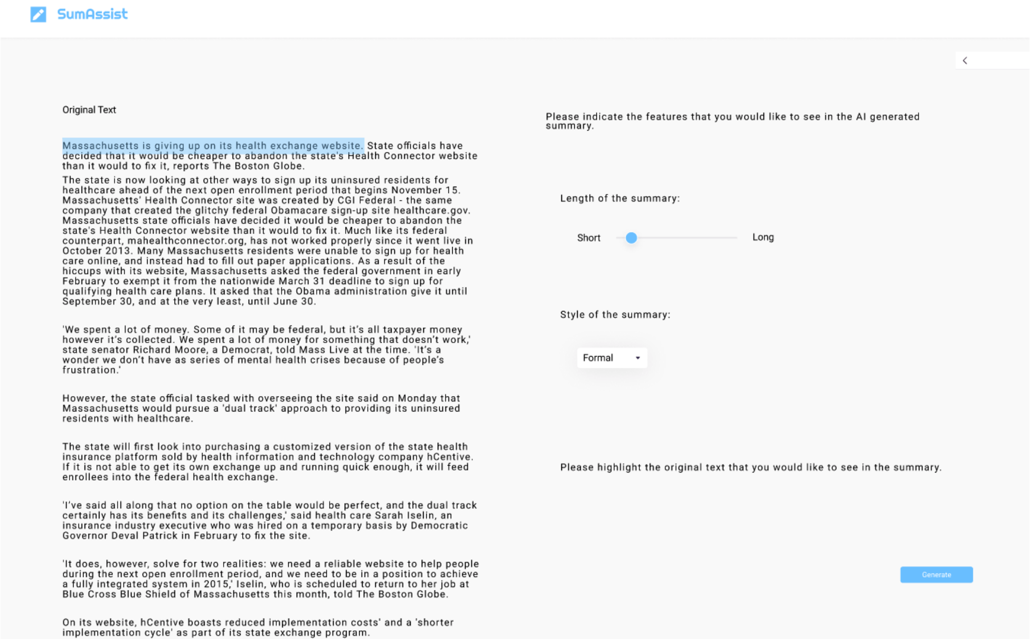
Figure 3-7 show the screenshots of prototype interfaces explained in §3.2. All interfaces except Writing with Model Assistance contain the same original text (a news article from the articles used in the warm-up activity) that needs to be summarized on the left. The representations of different types of human-AI interactions are on the right side of the interface.

A.4 Study 2 Additional Findings: User Expectation and Needs in Writing Summaries

Summarizing with a specific audience in mind. Many participants had a personal template for writing summaries that they learned in school or work. For example, P6 always checked for *"the who, the what, the where, and the why."* P1 looked for *"the who—Who is it about? What was it about? And then what was the outcome?"* and stated that they used the same strategy in all of the summarization tasks in Part 1.

Participants expressed the need to know the target audience of the summary, so that they could determine what kind of information would be useful to them. As P5 said: *"If I don't know who really is my audience in writing these summaries, I don't know what detail would matter to them."* They would also like to customize the summary to suit the needs of different audiences, especially when the original article was less factual and had more room for interpretation, such as the Reddit posts: *"your audiences is going to determine what's important to put in the summary. An attorney is going to perhaps want different information then your common Joe out on the streets. That affects of how something is summarized, you know, because there's always a choice."* (P12)

Support on background knowledge. Participants reported that they faced many challenges in terms of comprehending the original article and writing the summaries. When reading the original articles, many were hindered by the lack of background knowledge. In P10's words, *"it would*



Massachusetts is giving up on its health exchange website. State officials have decided that it would be cheaper to abandon the state's Health Connector website than it would to fix it, reports The Boston Globe.

The state is now looking at other ways to sign up its uninsured residents for healthcare ahead of the next open enrollment period that begins November 15. Massachusetts' Health Connector site was created by CGI Federal - the same company that created the glitchy federal Obamacare sign-up site healthcare.gov. Massachusetts state officials have decided it would be cheaper to abandon the state's Health Connector website than it would to fix it. Much like its federal counterpart, mahealthconnector.org, has not worked properly since it went live in October 2013. Many Massachusetts residents were unable to sign up for health care online, and instead had to fill out paper applications. As a result of the hiccups with its website, Massachusetts asked the federal government in early February to exempt it from the nationwide March 31 deadline to sign up for qualifying health care plans. It asked that the Obama administration give it until September 30, and at the very least, until June 30.

'We spent a lot of money. Some of it may be federal, but it's all taxpayer money however it's collected. We spent a lot of money for something that doesn't work,' state senator Richard Moore, a Democrat, told Mass Live at the time. 'It's a wonder we don't have as series of mental health crises because of people's frustration.'

However, the state official tasked with overseeing the site said on Monday that Massachusetts would pursue a 'dual track' approach to providing its uninsured residents with healthcare.

The state will first look into purchasing a customized version of the state health insurance platform sold by health information and technology company hCentive. If it is not able to get its own exchange up and running quick enough, it will feed enrollees into the federal health exchange.

'I've said all along that no option on the table would be perfect, and the dual track certainly has its benefits and its challenges,' said health care Sarah Iselin, an insurance industry executive who was hired on a temporary basis by Democratic Governor Deval Patrick in February to fix the site.

'It does, however, solve for two realities: we need a reliable website to help people during the next open enrollment period, and we need to be in a position to achieve a fully integrated system in 2015,' Iselin, who is scheduled to return to her job at Blue Cross Blue Shield of Massachusetts this month, told The Boston Globe.

On its website, hCentive boasts reduced implementation costs' and a 'shorter implementation cycle' as part of its state exchange program.

On its website, hCentive boasts reduced implementation costs' and a 'shorter implementation cycle' as part of its state exchange program.

Please select the best summary.

○ The state of Massachusetts has decided not to pour any more money into its Health Connector website. It is now looking into other options ahead of the start of the November 15 health insurance enrollment period. The state officials have decided it would be cheaper for the state to buy a customized version of health and information technology company hCentive's state exchange platform or feed residents into the federal exchange. The state's Health Connector site was created by CGI Federal - the same company that built problematic Obamacare sign up site healthcare.gov.

○ Massachusetts will stop investing into its Health Connector website originally created by CGI Federal. They plan to do so because it would be cheaper to buy a customized version of health and information technology company hCentive's state exchange platform or feed residents into the federal exchange.

○ The state of Massachusetts is now looking into new options for health websites before the November 15 health insurance enrollment period. The state's old Health Connector site was created by CGI Federal - the same company that built problematic Obamacare sign up site healthcare.gov. They wanted a change because it would be cheaper for the state to buy a customized version of health and information technology company hCentive's state exchange platform or feed residents into the federal exchange.

Figure 4: The interface for Selecting or Rating Model Output. Users can chose the final product from three "AI-generated" candidate summaries.

have helped me to have someone explain what that situation was because I had a very hard time understanding the context behind that situation." Related to this was the difficulty in understanding jargon specific to a domain that the participants were unfamiliar with. For example, P13 is unfamiliar with the legislative jargon in the Government Bills but considered they *"are really essential for being able to understand kind of the larger overall picture of the text."* P7 shared that the news article about health website contained technical jargon that *"slows down the process and makes it harder."* Therefore, participants hope to get support for the lack of background knowledge. P15 imagined *"an in-text dictionary* support for explaining jargon.

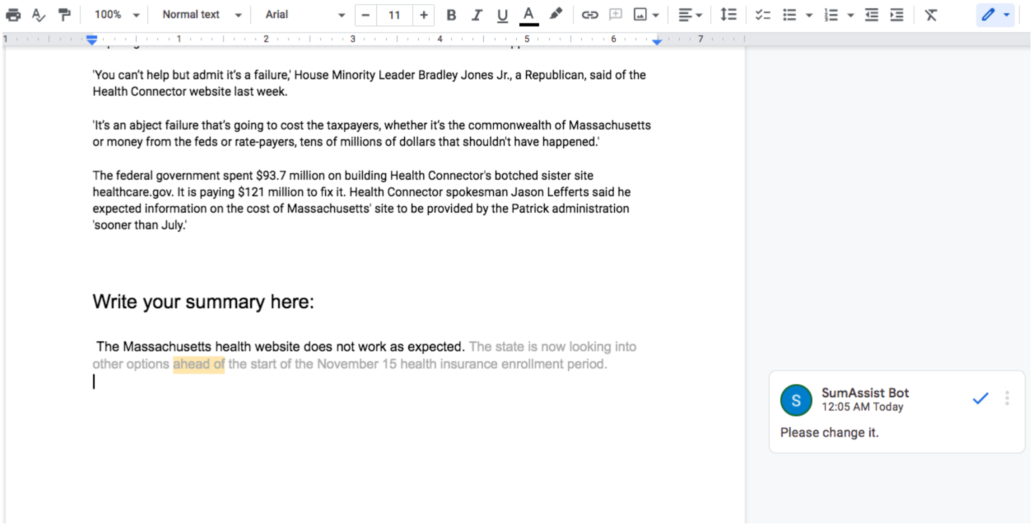
Summarizing formal and informal texts. Participants found summarizing different genres of original text challenging in different ways. Participants who thought comprehending the Government Bills challenging described them as *"super dry, super repetitive,"* (P3) and *"not designed as an article."* (P2) It was difficult to identify the crucial information from a Bill since everything seems important: *"they want you to take all of it away.* (P13) On the other hand, although easy to understand, Reddit posts posed a different challenge due to their informal, unfocused style. For example, in P1’s words, the Reddit posts were *"more of a narrative... there’s no formula to (summarize) them."* Furthermore, many found it challenging to compose the summaries in the same personalized style



'You can't help but admit it's a failure,' House Minority Leader Bradley Jones Jr., a Republican, said of the Health Connector website last week.

'It's an abject failure that's going to cost the taxpayers, whether it's the commonwealth of Massachusetts or money from the feds or rate-payers, tens of millions of dollars that shouldn't have happened.'

The federal government spent $93.7 million on building Health Connector's botched sister site healthcare.gov. It is paying $121 million to fix it. Health Connector spokesman Jason Lefferts said he expected information on the cost of Massachusetts' site to be provided by the Patrick administration 'sooner than July.'

Write your summary here:

The Massachusetts health website does not work as expected. The state is now looking into other options ahead of the start of the November 15 health insurance enrollment period.

SumAssist Bot
12:05 AM Today

Please change it.

Figure 7: The interface for Writing with Model Assistance. In a Google Doc, users can see the original article on the top and they can write their summary under the section “Write your summary here:”. First, the user types a sentence for their summary, then a Bot (played by a researcher who log in with the “SumAssist Bot account”) will insert the next sentence in gray fonts. The Bot will also insert comments on words in the user written sentence and suggest them to make changes.

as the original poster: *"I’m not really familiar with summarizing something in somebody else’s voice or in somebody else’s tone."* (P3) Contrast to the summarization for the Government Bills, described as having *"only one outcome"*, and being *"factual,"* (P7) and *"more direct, more to the point,"* (P10) Reddit posts come with *"an element of opinion to it,"* (P7) and therefore could be summarized through different angles. Some thought they should write in the same perspective as the original poster and preserve the opinions, as P9 said, *"I would make sure I picked up what they were trying to, to lay out."* others considered a summary as a neutral representation of information and thus they had to *"pull the opinions out and give the general message."* (P14)

A.5 Interview protocol and interaction instruction.

Please see the interview protocol and interaction instruction on the next page. Since we need to protect the privacy of our participants, we are not able to share the full interview transcripts.

A.5 Interview Protocol

(§3.3 contains interaction instruction and questions for each of the five prototypes)

1. *Overview*

First of all thank you for spending the time and talking with me today. We are researchers studying how we can help people summarize text. Your participation in this study could help us understand this topic, and contribute to scientific knowledge - ultimately we may publish a research paper about insights from your participation in our study.

2. *Consent*

This interview will last about 90 minutes. I would like to talk to you about your experience with text summarization. You should have already finished the warm-up for the study, and I will ask you questions about it. I will also have you try out some new tools that we developed to support text summarization and ask you questions along the way.

There are no right or wrong answers to my questions. I want to hear your personal experiences and opinions. You also absolutely can decline to answer any of the questions that I ask. At any point if you feel uncomfortable or need to pause or take a break, just let me know.

Everything that is said in this session will be completely confidential and used for research purposes only. Your responses may be published as quotes in a future academic research paper, but no identifiers will tie your username or any other identifiable factors to those responses.

For note-taking purposes, I will record the audio of this call. I will ask you to share your screen while you are trying out our new tools, and I will also record your screen. Feel free to turn off your camera if you don’t like your image to be recorded.

Any questions before we start?

Is it okay if I start studying now?

[if they say yes, start recording]

3. *Interview*

3.1 Opening

To start, could you please tell me a little bit about yourself?

- What experience do you have with writing and editing?

3.2 Reflection on warm-up

Could you please walk me through your experience writing the summaries?

- How did you approach the tasks?
- What were some strategies that you took?
    - How did you decide what to include?
    - How did you decide if a summary is done and good to go?
- What went well?
- What did not go well?
- What were some challenges?
- How do you feel about summarizing the different articles?
    - Which ones were easy? Why
    - Which ones were difficult? Why?
    - How did you approach the different articles differently?

[Pick a the task that they thought as most difficult]
Could you tell me more about your experience finishing this task? Walk me through how you did it.

- Why was this task particularly difficult?
- Did you approach this task differently than other ones?
    - If yes, how? And why?
    - If not, how did your strategy with previous articles work or not work?
- What went well?
- What did not go well?
- What are some challenges?
- What kind of support do you wish to have?
    - Do you want to have the same support for the other tasks? Why or why not?

Did you take any notes or use any external tools or resources?

In general, what kind of support do you wish you could have while summarizing articles?

- Do you want to have different support for different types of articles? Why or why not?

3.3 Interaction with prototypes

Now I am going to have you try out SumAssists, which is a collection of digital tools that we developed to support people to write summaries. I will ask you questions as you try out the tools. Note that some features of the tools are not fully developed yet, so for some parts I need to ask you to imagine your interaction with some features.

I’m now asking you to share your screen to show me your interaction with the tools.

[send them the link to the Figma prototype]

Now you are seeing the original article. This is the same news article about the Massachusetts heath website that you have worked on in Part 1 of the study. You can see 5 different tools that are designed to support you to write the summary for this article.

3.3.1 Selecting or rating model output

[ask the participant to interact with the tool]

What’s your first impression of this tool?
- What do you think it is for?
- How do you want to use it?

This tool provides you three options of AI-generated summaries of this article. You will be able to select the one that you think is the best.

Now please imagine that you are summarizing the article using this tool. Please talk through step-by-step how you are going to do it.
- What do you like about this tool? Why?
- What do you dislike about this tool? Why?
- What is helpful with your summarization process? In what ways?
- What is unhelpful with your summarization process? In what ways?
- How much power of control with the summarization do you feel that you have using this tool? Do you like it this way? Why?
- How much will you rely on this tool while doing the summarization task? Do you like it this way? Why?
  - What type of documents will you rely on this tool
  - How much would you use it
  - Any cases that you wouldn’t want to use it
  - What case you want to totally override it
- How much will you trust the AI-generated summaries using this tool? Do you like it this way? Why?

If we are making this tool available in real life, in what situation do you see yourself using this tool?

Imagining you are summarizing the Reddit posts using this tool, how would your experience be different or similar?

Imagining you are summarizing the government bills using this tool, how would your experience be different or similar?

How would you like to improve this tool?

Let's go back to the main page by clicking on the arrow on the upper right corner.

3.3.2 Post-editing

[ask the participant to interact with the tool]

What's your first impression of this tool?

- What do you think it is for?
- How do you want to use it?

[Debrief them about the tool] This tool provides you with an AI-generated summaries of this article that you can edit on. In the real world you will be able to type and delete any words in this text box on the right just as you are doing normal editing. Right now our implementation doesn't support that. Just imagine you can type and edit the summary.

Now please imagine that you are summarizing the article using this tool. Please talk through step-by-step how you are going to do it.

- What do you like about this tool? Why?
- What do you dislike about this tool? Why?
- What is helpful with your summarization process? In what ways?
- What is unhelpful with your summarization process? In what ways?
- How much power of control with the summarization do you feel that you have using this tool? Do you like it this way? Why?
- How much will you rely on this tool while doing the summarization task? Do you like it this way? Why?
    - What type of documents will you rely on this tool
    - How much would you use it
    - Any cases that you wouldn't want to use it
    - What case you want to totally override it
- Compared to the previous tool, which one do you think would be more helpful? Why?

If we are making this tool available in real life, in what situation do you see yourself using this tool?

- Imagining you are summarizing the Reddit posts using this tool, how would your experience be different or similar?
    - Compared to the previous tool, how do you think this tool would be more or less helpful in this situation?

- Imagining you are summarizing the government bills using this tool, how would your experience be different or similar?
    - Compared to the previous tool, how do you think this tool would be more or less helpful in this situation?
    - If the AI is doing a reasonable job, for longer docs that you may not know as much
    - Are there other text that this tool will be helpful for you to summarize

How would you like to improve this tool?

Let's go back to the main page

3.3.3 Interactive editing

[ask the participant to interact with the tool]

What's your first impression of this tool?

- What do you think it is for?
- How do you want to use it?

[Debrief them about the tool] This tool provides you with an AI-generated summaries of this article. You will be able to edit the first sentence of the summary by selecting in the drop down menu. Once you make the selection and click predict, the rest of the summary will be updated based on your edits on the first sentence.

Now please imagine that you are summarizing the article using this tool. Please talk through step-by-step how you are going to do it.

- What do you like about this tool? Why?
- What do you dislike about this tool? Why?
- What is helpful with your summarization process? In what ways?
- What is unhelpful with your summarization process? In what ways?
- How much power of control with the summarization do you feel that you have using this tool? Do you like it this way? Why?
- How much will you rely on this tool while doing the summarization task? Do you like it this way? Why?
- How much will you trust the AI-generated summaries using this tool? Do you like it this way? Why?
- Compared to the previous tool, which one do you think would be more helpful? Why?

If we are making this tool available in real life, in what situation do you see yourself using this tool?

- Imagining you are summarizing the Reddit posts using this tool, how would your experience be different or similar?

    - Compared to the previous tool, how do you think this tool would be more or less helpful in this situation?

3.3.5 Writing with model assistance

[ask the participant to interact with the tool]

Now this tool is embedded in the Google doc. For this one, please type the summary that you'd like to write for this article.
[Participant type summary]

[SumAssist Bot copies a sentence in gray color once they finish the first sentence]
[SumAssist Bot adds a comment on their first sentence]

If you think the sentence in gray is good, go ahead and keep writing. If you want to edit it, also go ahead. If you don't like it, you can just delete it and write.

[SumAssist Bot copies a sentence in gray color once they finish the first sentence]
[SumAssist Bot adds a comment on their first sentence]
[ask the participant to stop]

This tool is a bot that we built in Google doc and it can suggest next sentences in gray text. It can also comment on the sentence that you wrote as you are writing.

Imagine that you are writing the entire summary with this bot. What do you think the experience would be like?

- What is helpful with your summarization process? In what ways?
- What is unhelpful with your summarization process? In what ways?
- What do you like about this tool? Why?
- What do you dislike about this tool? Why?
- How do you feel about the auto suggestions?

    - How could the auto suggestion be more useful?
- How do you feel about the auto commenting?
    - How could the auto commenting be more useful?
- Would the auto suggestions and comments be annoying? Why and why not?
- How much power of control with the summarization do you feel that you have using this tool? Do you like it this way? Why?
- How much will you rely on this tool while doing the summarization task? Do you like it this way? Why?
- How much will you trust the AI-generated summaries using this tool? Do you like it this way? Why?
- Compared to the previous tool, which one do you think would be more helpful? Why?

If we are making this tool available in real life, in what situation do you see yourself using this tool?

- Imagining you are summarizing the Reddit posts using this tool, how would your experience be different or similar?
    - Compared to the previous tool, how do you think this tool would be more or less helpful in this situation?
- Imagining you are summarizing the government bills using this tool, how would your experience be different or similar?
    - Compared to the previous tool, how do you think this tool would be more or less helpful in this situation?

How would you like to improve this tool?

3.4 General Reflection

In general, which tools that you would most likely be using when you are summarizing articles? Why?

In general, which tools that you would least likely be using when you are summarizing articles? Why?

- For Reddit, news, and government bills respectively?

If you could snap your fingers and create a summarization assistant to help you, how would you like to combine some of these tools?

- And what other features would you like to have?

Towards Robust and Semantically Organised Latent Representations for Unsupervised Text Style Transfer

Sharan Narasimhan **Suvodip Dey** **Maunendra Sankar Desarkar**

Indian Institute of Technology Hyderabad, India

`sharan.n21@gmail.com` `suvodip15@gmail.com` `maunendra@cse.iith.ac.in`

Abstract

Recent studies show that auto-encoder based approaches successfully perform language generation, smooth sentence interpolation, and style transfer over unseen attributes using unlabelled datasets in a zero-shot manner. The latent space geometry of such models is organised well enough to perform on datasets where the style is "coarse-grained" i.e. a small fraction of words alone in a sentence are enough to determine the overall style label. A recent study uses a discrete token-based perturbation approach to map "similar" sentences ("similar" defined by low Levenshtein distance/ high word overlap) close by in latent space. This definition of "similarity" does not look into the underlying nuances of the constituent words while mapping latent space neighbourhoods and therefore fails to recognise sentences with different style-based semantics while mapping latent neighbourhoods. We introduce EPAAEs (Embedding Perturbed Adversarial AutoEncoders) which completes this perturbation model, by adding a finely adjustable noise component on the continuous embeddings space. We empirically show that this (a) produces a better organised latent space that clusters stylistically similar sentences together, (b) performs best on a diverse set of text style transfer tasks than similar denoising-inspired baselines, and (c) is capable of fine-grained control of Style Transfer strength. We also extend the text style transfer tasks to NLI datasets and show that these more complex definitions of style are learned best by EPAAE. To the best of our knowledge, extending style transfer to NLI tasks has not been explored before. [*]

1 Introduction

The Text Style transfer (TST) task is a form of controlled language generation. The goal is to produce fluent style-altered sentences from a given base sentence, while also preserving its style-independent content. The definition of "style" depends on the class labels of the end task. Our work focuses on the unsupervised scenario i.e. performing the training on completely unlabelled corpora. By inducing the latent space organization through input perturbation, TST can be performed using a simple vector arithmetic method (discussed in Section 6).

Background. Several well-known architectures use auxiliary objectives that serve as regularizers to ensure that the latent space geometry is smoothly interpolatable and learns high-level semantic features (refer Appendix D). Inspired by successes in denoising approaches in vision (Creswell and Bharath, 2019; Vincent et al., 2008), we look at input perturbation based approaches for unsupervised style transfer. Unlike text, in vision, freedom exists to finely control the degree of Gaussian "blur" on the continuous input image space. We conjecture that this notion of "controlling blur" may be useful in the text domain as well, serving as our motivation for our chosen model for Input Perturbation. Shen et al. (2020) map "similar" (defined by low Levenshtein distance/ high word overlap) sentences together in the latent space by introducing a simple denoising objective over an underlying Adversarial Autoencoder (AAE) (Makhzani et al., 2015). This noise model includes simple token manipulation

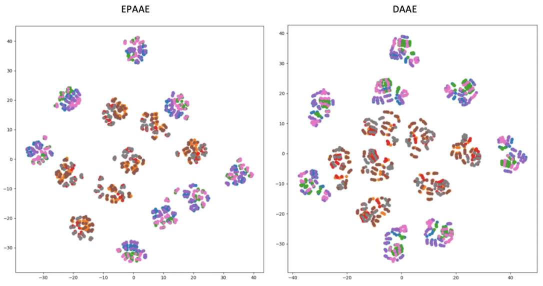

Figure 1: A TSNE plot of encoded latent vectors for all 1950 sentences in the Toy Dataset. EPAAE shows tighter and more organised clustering. Refer to B.1 and B.2 for larger plots with legend.

---

[*] Our code, data and outputs are available at `https://github.com/sharan21/EPAAE`

July 10-15, 2022 ©2022 Association for Computational Linguistics

(token dropout and substitution) with some probability p, to reconstruct the original sentences from the perturbed inputs. We can reason intuitively that discrete word dropout allows sentences with high word overlap (or low Levenshtein distance) to have a higher chance of being perturbed into one another, thereby mapping them close in the latent space during the training time. However, this method allows for stylistically dissimilar sentences, albeit with high word overlap, to be mapped together in the latent space.

Idea. We argue that this negatively impacts the quality of final latent geometry and the results of the subsequent style transfer task. As an alternative, we explore Embedding Perturbation, where a noise vector is sampled, appropriately scaled and added to the embeddings of each input sentence, such that the resultant embeddings are constrained to live inside an E-dimensional hypersphere. The radius of this hypersphere is controllable using a tune-able hyper-parameter ζ. This hypersphere constraint is partially inspired by concepts in adversarial robustness and ensures that each resultant noised word embedding is not altered to the extent of causing the underlying semantics of the sentence to change. We argue that this allows sentences with stylistically similar constituent embeddings to be mapped together, also encouraging the formation of style-preserving latent neighbourhoods (more on this in Section 4). The resulting latent representation from "embedding-perturbed" autoencoders consequently are better semantically organized and stylistically robust, enabling us to perform TST using an inductive method i.e. simple vector arithmetic on latent vectors.

Contributions. We show that this extended model of input perturbation with both discrete and continuous components, allows for overall better quality text style transfer, particularly in its ability to preserve style-independent "content" information. To expand the traditional definitions of styles such as Polarity, Formality, which are based on simple "intra-sentence" attributes, we introduce the "Discourse Style Transfer Task" by salvaging NLI datasets in which the flow of logic between sentences are captured using "Entailment", "Contradiction", and "Neutral" labels. This enables interesting applications such as discourse manipulation in which a pair of sentences agreeing with each other can be made to contradict, and vice versa. We also test our model on fine-grained styles present in the Style-PTB dataset. We empirically show that our model performs the best on a diverse set of datasets with styles ranging from coarse-grained styles (like sentiment) to fine-grained styles (like tenses) and complex inter-sentence styles (like discourse or flow of logic).

2 Related work

Seminal work in TST. Autoencoder based approaches for TST on labelled non-parallel datasets are quite well explored (Shen et al., 2017; Fu et al., 2018). Some techniques involve implicit Style-Content disentanglement of the latent space using Back Translation (Prabhumoye et al., 2018) and adversarial learning (John et al., 2019). Li et al. (2018) achieve disentanglement using simple keyword replacement. Most studies look at simple non-parallel classification datasets, defining their style to be the class label. Studies also look at Syntax-Semantic disentanglement of the latent space (Chen et al., 2019; Bao et al., 2019). A λ_1 penalty is imposed on the log variance of the perturbations to prevent it from vanishing. The latent vacancy problem (Xu et al., 2020) of the $\beta-$VAE is mitigated by introducing auxiliary losses and provided for one of the earliest methods for unsupervised TST. Similar to our work, Rubenstein et al. (2018) introduces the Latent noised AAE (LAAE), Gaussian perturbation is instead added to latent encodings to promote organization. Unsupervised work includes using a language model as a discriminator for a richer feedback mechanism (Yang et al., 2018), allowing it to increase performance in word substitution decipherment, sentiment modification, and related language translation. More seminal work related to autoencoders in the context of Style Transfer is mentioned in Appendix D.

Contemporary work in TST. More recent work, treat the style transfer problem as paraphrase generation and fine-tune pre-trained language models (Krishna et al., 2020). Malmi et al. (2020) trains masked language models or MLMs on the source and target domains to identify input tokens to be removed and replace them with tokens from the target MLM in an unsupervised manner. Liu et al. (2020) uses gradient-based update rules in the continuous latent space z from style and content predictor networks, enabling the transfer of fine-grained styles without using an adversarial approach. Reid and Zhong (2021) performs TST on sentiment and politeness datasets using token editing methods (similar to Li et al. (2018)) using Levenshtein editing operations. Lee et al. (2021) also focuses on enhancing content preservation by introducing a method to remove style at the token level using reverse attention and fuse this content representation with style using a conditional layer normalization technique. Riley et al. (2021) adapts the T5 model (Raffel et al., 2020) for few shot text style transfer by extracting a style representation and performing conditioned decoding, using only a handful of examples at inference time.

3 Method

The underlying language model is a generative auto-encoder which models an input distribution $p(\mathbf{x})$ assumed to be from an underlying latent distribution $p(\mathbf{z})$. A deterministic encoder E representing the distribution $q(\mathbf{z}|\mathbf{x})$, in the form of an RNN, whose output is reparameterized by another distribution $z_i \sim \mathcal{N}(\mu_i(\mathbf{x}), \sigma_i(\mathbf{x}))$ to give the aggregated posterior distribution $q(\mathbf{z})$. Various auxiliary loss functions are used to enforce the learned prior $q(\mathbf{z})$ to match $p(\mathbf{z})$. The Generator G representing $p(\mathbf{x}|\mathbf{z})$, also in the form of an RNN, decodes back the sample from the learnt prior $q(\mathbf{z})$ into its corresponding input from $p(\mathbf{x})$. Gradient descent is applied on the reconstruction loss of the autoencoder given by:

$$\mathcal{L}_{\text{rec}}(\theta_E, \theta_G) = E_{p_{\text{data}}(x)}[-\log p_G(x|E(x))] \quad (1)$$

We use the AAE (Makhzani et al., 2015) as our choice for the underlying generative autoencoder over which the input perturbation techniques were applied. AAE uses a discriminator D to enforce $q(\mathbf{z})$ to match $p(\mathbf{z})$, a standard Gaussian, by learning to distinguish between samples from the two different distributions. This adversarial loss serves as a regularizer for the latent space, giving it the ability the organize itself better for smooth sentence interpolation.

$$\begin{aligned}\mathcal{L}_{\text{adv}}(\theta_E, \theta_D) = \; & \mathbb{E}_{p(z)}[-\log D(z)] + \\ & \mathbb{E}_{p_{\text{data}}(x)}[-\log(1 - D(E(x)))]\end{aligned} \quad (2)$$

The final min-max objective is a sum of the reconstruction loss (given below) and λ weighted adversarial loss:

$$\min_{E,G} \max_{D} \; \mathcal{L}_{\text{rec}}(\theta_E, \theta_G) - \lambda \mathcal{L}_{\text{adv}}(\theta_E, \theta_D) \quad (3)$$

We found empirically that AAEs performed well and were stable during training. On the other hand, β-VAEs required careful tuning of the β hyperparameter to prevent posterior collapse and did not perform as well.

3.1 Finely-controlled continuous noise on embedding space

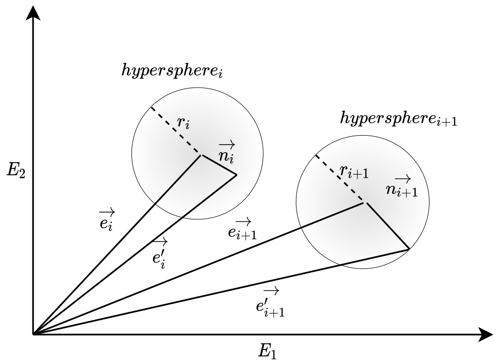

Figure 2: An abstract representation of the continuous embedding noise approach for two arbitrary embeddings e_i and e_{i+1} on an embedding space $E \in R^2$

To further organize the latent geometry of the underlying AAE to encode style-based semantic similarity among sentences, we propose a perturbation-based approach on the continuous embedding space. Word embeddings of dimensionality E, of each input token x_i are denoted as e_i. Consider an input sentence of length l containing tokens $x_0, \cdots, x_{l-1}$ having embeddings $e_0, \cdots, e_{l-1}$ respectively. Our objective is to blur every embedding vector e_i by adding some appropriately scaled noise vector n_i to produce a resultant noised embedding vector e'_i, such that e'_i does not lie too far away from e_i to not change the underlying semantics of the word completely. We do this by ensuring that each new e'_i lives inside an E-dimensional hypersphere. The center of the hypersphere is the original embedding e_i and its radius is defined as $|e_i| * s_i$, where $s_i \in \mathbb{R}^1$ is a random variable sampled from a distribution $P(s)$. $P(s)$ is probability distribution of the form $\mathcal{Y}(\mu = 0, \sigma)$ where $\mathcal{Y}$ is some arbitrarily chosen distribution and σ as function of hyperparameter $\zeta \in R$. This distribution $P(s)$ parameterized by $Y, \zeta)$ models the probability density cloud inside the embedding hypersphere, controlling its radius and interior densities. Figure 1 neatly summarizes the aforementioned embedding perturbation mechanism for a simple example with only two individual word embeddings. In practice, we use a vectorized representation of the above mechanism to blur the embeddings of a mini-batch of sentences of size L in constant O(1) time. The embedding perturbation method is summarized below in a vectorized form:

$$\begin{gathered} z \sim \mathcal{N}(\mu, \sigma^2) \\ \hat{z} = z/|z| \\ s \sim Y(\mu = 0, \sigma^2 = (\zeta/3)^2) \\ n = (s \odot |e|)^T \hat{z} \\ e' = e + n \\ r = \zeta * |e| \end{gathered} \tag{4}$$

where z, $\hat{z}$, s, n and e are vectorized representations of z_i, $\hat{z}_i$, s_i, n_i and e_i respectively for a mini-batch of sentences of size l. $\odot$ and $*$ denote element wise and scalar multiplication respectively. $|x|$ denotes the magnitude of a vector/batch of vectors x. r is the vectorized mini-batch representation of r_i, the expected radius of $hypersphere_i$. We choose the Gaussian distribution as our choice of the probability distribution $\mathcal{Y}$, as on testing it produced the best results[†]. To couple the radius r_i of $hypersphere_i$ to our hyperparameter ζ to enable fine-grained control using ζ, we constrain the probability density of Y to live inside the hypersphere within three standard deviations. To achieve this, we equate 3σ to ζ, and consequently set the variance σ^2 of $\mathcal{Y}$ to be $(\zeta/3)^2$.

3.2 Discrete word dropout probability

The "Denoising Autoencoder" or DAAE (Shen et al., 2020) considered discrete token-level perturbations such as token masking, substitution and deletion. We consider token deletion as discrete noise. Drop probability $p = 0.3$ is found to be the best in both their experiments and ours.

Token deletion is the only type of input perturbation that can alter the number of tokens in a sentence. Any continuous model for input noise cannot mathematically generalize the effects of this kind of discrete word dropout. Furthermore, during our experiments, we find that for some datasets, both discrete and continuous noise components are required to produce the overall best model. In such a case, we first perform token deletion and then subject the leftover token embeddings to perturbation. We refer to this generalized noise model as "Embeddings-Perturbed Adversarial Autoencoder" or "EPAAE" parameterized by ζ and p.

4 Semantic Similarity in Latent Space Neighbourhoods

We contrast and compare the resultant latent space neighbourhoods of DAAEs and EPAAEs.

4.1 Preliminary reasoning

Here, we first investigate the question - *Does token deletion during training group truly put semantically similar sentences together in latent space Z?*. Intuitively we can reason that the answer may be in the affirmative if the drop probability is small. For example, the sentences "The food was good" and "The food was superb" might get perturbed into a common version, i.e. "The food was" and therefore be mapped nearby in Z during training. As analysed and concluded in (Shen et al., 2020), latent neighbourhoods in the latent space of DAAEs successfully cluster sentences with high word overlap (low Levenshtein/Edit distance) together. However, the Levenshtein distance metric is not an accurate measure of the true semantic similarity between sentences. A pair of sentences with high word overlap might convey different ideas w.r.t the underlying style-based semantics of the dataset. For example, in the context of the Yelp dataset, the sentences "The food was good" and "The food was bad" are stylistically opposing (style being polarity in this case) and yet still get mapped close by in Z for DAAEs.

4.2 Testing the hypothesis with a Toy Dataset

We conduct specifically curated experiments on a synthetic dataset to verify our hypothesis that EPAAEs map stylistically similar sentences together.

Details of Toy dataset: Inspired by Yelp, each sentence in this dataset either represents a positive or negative sentiment. It also contains different sentiment independent components, such as the identity of the person and the subject of the review. Each sentence is of the format: "The <*identity_token*> said the <*subject_token*> is <*decision_token*>" where *identity*, *subject* and *decision* token classes are the only variable parameters in each sentence. The entire set of all permutations of these token classes forms the dataset. For example, the decision class is further subdivided into two subclasses, i.e. positive/ negative sentiment,

---

[†] We also tried the uniform distribution with varying values for ζ

Token Class	Sub Classes	Token Options
(0) Identity	(0) Male	boy, man, husband, boyfriend, waiter
	(1) Female	girl, woman, wife, girlfriend, waitress
(1) Subject	(0) Food	food, meal, dinner, breakfast, lunch, pasta, chicken
	(1) Others	service, staff, experience, atmosphere, location, place
(2) Decision	(0) Positive	good, great, excellent, decent, amazing, wonderful, reasonable
	(1) Negative	bad, worst, horrible, spicy, bland, expensive, disgusting, mediocre

Table 1: Structure of token classes and division of subclasses with token options used to create Toy Dataset

DAAE ($p = 0.3$)	**L2 Norm**	**EPAAE** ($\zeta = 3.0$)	**L2 Norm**
the man said the pasta is spicy	0	the man said the pasta is spicy	0
the man said the pasta is good	2.79	the man said the staff is spicy	2.62
the girl said the pasta is spicy	2.88	the man said the pasta is bad	2.69
the man said the pasta is wonderful	2.89	the man said the pasta is bland	2.77
the man said the service is spicy	3	the girl said the pasta is spicy	2.84
the man said the pasta is bad	3.02	the husband said the pasta is spicy	2.89

Table 2: Nearest Neighbour experiment performed on EPAAE and DAAE. Sentences in red indicate dissimilarity in semantics with respect to cluster center

Dataset	**Model**	**Mean L2 Norm for Label Flip**	**Mean Hops for Label Flip**
Toy Dataset	DAAE	**5.725**	14.979
	EPAAE	4.324	**19.587**
Yelp	DAAE	**9.386**	5.850
	EPAAE	8.211	**6.513**
SNLI	DAAE	9.794	3.185
	EPAAE	**10.373**	**3.528**

SciTail	DAAE	10.224	5.750
	EPAAE	**10.676**	**6.253**
PP Removal	DAAE	8.195	6.722
	EPAAE	**8.774**	**7.409**
Tenses	DAAE	7.686	**8.802**
	EPAAE	**10.924**	5.426
Voices	DAAE	6.805	8.367
	EPAAE	**9.657**	**8.726**

Table 3: Quantitative metrics to capture model's ability to preserve style-based semantics inside Latent Neighbourhoods. Bold indicates model with higher value for that corresponding metric in that specific dataset, which is suggestive of ability to better preserve style-based semantics.

each subclass containing 7 and 8 choosable tokens, respectively. The resultant dataset consisted of 1950 sentences. The details of the subclasses and the representative tokens inside each subclass are shown in Table 1. We produce output labels for each sentence by using a 3-bit representation, one bit for each of three token classes, where the values of each bit represent the token label subclass within that class. For example, a label of 5 is encoded as 101 corresponding to a sentence with *Female*, *Food* and *Negative* labels. There are $2^3 = 8$ labels in total labelled 0-7.

Qual. Analysis of Latent space. We consider two models, DAAE with token deletion probability $p = 0.3$ and EPAAE with $\zeta = 2.5$. Both models are initially pre-trained over the unlabelled Yelp dataset. The synthetic dataset is used during inference time only. We encode all 1950 sentences into their respective latent space vectors and use TSNE plots to visualise the latent space of each model (Figure 1). We pick a random *query* sentence, e.g. “The man said the pasta is spicy”, and encode it into Z. We then retrieve the top five nearest encoding to the query and observe their decoded outputs to check for the preservation of style-based semantics (Table 2) around the query. We find that the EPAAE maps the latent neighbourhood such that stylistically similar (positive/negative sentiment in this context) are grouped. This is not the case with the DAAE, evident from Table 2 in which neighbours 1 and 3 have a differing sentiment from the query. This offers an explanation as to why the DAAE is not able to produce tightly confined clusters.

Quant. Analysis of Latent space. To further validate our hypothesis that EPAAEs better preserve style-based semantics in latent neighbours, we generate useful quantitative metrics over a k-nearest neighbours experiment, done on the test split across all datasets. We document these metrics in Table 3. Column 3 conveys the mean distance to the closest neighbour with the opposite label. Column 4 conveys the mean number of hops to reach to the closest neighbour with opposite labels. In all but a few datasets, the DAAE reports a smaller “mean hops for label flip”, supporting our hypothesis that stylistically dissimilar sentences are mapped closer together in the latent neighbour than our proposed model. We also see this trend mostly holds true for the "Mean L2 Norm for Label Flip" metric in Column 4 as well, providing further evidence to our hypothesis.

5 Setup, Datasets and Metrics

5.1 Experimental Setup

Baselines. This work focuses on simple denoising approaches for Unsupervised TST and subsequently constrains our choice of baselines to follow these criteria. We consider three other autoencoder based models for our experimentation, i.e. Denoising AAE (DAAE), Latent-Noised AAE (LAAE) and the β-VAE.

Hyperparameters and Setup. Details on hyperparameter selection can be found in A.2. Other common hyperparameters (detailed in A.1) related to encoder/decoder architectures remained identical across all models. Training is completely unsupervised, and labels are only used during inference time. Details on computation time, number of parameters and infrastructure used can be found in Appendix. E.

5.2 Datasets

In this section, we briefly describe the different kinds of datasets used for experimentation. Further details is provided in in Appendix C.

Complexity of Styles in Datasets: Current studies mainly focus on high-level styles to validate the approaches. To validate our hypothesis that the EPAAE can perform fine-grained style transfer due to semantics learnt from embeddings, we consider three tasks: sentiment, discourse and fine-grained text style transfer. As prepossessing, we remove non-essential special characters and lowercase all sentences. Except for the Yelp dataset, no pruning is done based on sentence length.

Sentiment Style Datasets: We use the preprocessed version from (Shen et al., 2017) of the Yelp dataset. The sentiment labels (positive, negative) were considered as style.

Discourse Style Datasets: To check for the model's ability to alter the discourse or *flow of logic* between two sentences we make use of NLI datasets such as SNLI, DNLI, and Scitail. Each instance in the SNLI dataset (Bowman et al., 2015) consists of two sentences that either contradict, entail (agree) or are neutral towards each other. Similarly, the DNLI dataset (Welleck et al., 2019) consists of contradiction, entailment and neutrality labelled instances. Scitail (Khot et al., 2018) is an entailment dataset created from multiple-choice science exams and the web, in a two-sentence format similar to SNLI and DNLI. The first sentence is formed from a question and answer pair from science exams and the second sentence is either a supporting (entailment) or non-supporting (neutrality) premise.

Fine-grained Style Datasets: The Style-PTB dataset (Lyu et al., 2021) consists of 21 styles/labels with themes ranging from syntax, lexical, semantic and thematic transfers as well as compositional transfers which consist of transferring more than one of the aforementioned fine-grained styles. To check whether the EPAAE can capture fine-grained styles better by leveraging its better organised latent space, we make use of three styles i.e. Tenses, Voices (Active or Passive) and Syntactic PP tag removal (PPR). In the Tenses dataset, each sentence is labelled with "Present", "Past", and "Future". The Voices dataset contains "Active" and "Passive" voices labels and the PPR dataset contains "PP removed" and "PP not removed" labels.

5.3 Automatic Evaluation metrics

Evaluation for text style transfer includes checking for a) Style Transfer accuracy, b) Content preservation metrics and c) Fluency of output sentences. Recent studies show that automatic Evaluation metrics are still an open problem and can be gamed (Xu et al., 2020).

Style Transfer Measure: A pre-trained classifier is used to check the presence of the target label in the output sentence. (Mir et al., 2019) introduces the notion of checking the style transfer intensity apart from just the presence of the target label. While we find this notion intriguing, we wish to first accomplish the style transfer task convincingly for the current set of tasks before assuming a more complex metric.

Content Preservation: In recent work, we observe that models typically struggle more in content preservation and the ability to preserve the contextual meaning of the base sentence. The BLEU score alone does not suffice to correlate strongly with actual qualitative results. To truly validate our hypothesis that EPAAE's are better able to preserve content better, we augment the bucket of standard content preservation metrics [‡]. Apart from the standard of using BLEU between sentences of source and target styles, we borrow evaluation techniques from fields similar to Text Style Transfer such as Machine Translation and Text Summarization, such as METEOR (Banerjee and Lavie, 2005),

---

[‡] To generate all our content preservation metrics, we use the nlg-eval package from: `https://github.com/Maluuba/nlg-eval`

ROUGE-L (Lin, 2004), CIDEr (Vedantam et al., 2015) which have been shown to correlate more strongly with human judgement. Following the study of (Sharma et al., 2017), in which they show BLEU does not necessarily correlate with human evaluations in dialogue response generation, we also adopt Embedding Average, Vector Extrema (Forgues et al., 2014) and Greedy matching score (Rus and Lintean, 2012).

Fluency of generations: Past work measures the perplexity using a pre-trained language model to gauge the fluency or grammatical correctness of the style transferred outputs. (Mir et al., 2019) argues such perplexity calculations for style transfer tasks may not necessarily correlate with a human judgement of fluency. Adversarial classifiers in the form of logistic regression networks are trained with the goal of distinguishing between human-produced and machine produced sentences. These classifiers are then used to score the naturalness of the output sentences. We follow this metric during our evaluation of fluency or naturalness [§]

6 Experiments

In this section, we look at the quantitative and quantitative results for the text style transfer task for four autoencoder models in seven datasets. We use the vector arithmetic method on latent space representations, inspired by (Mikolov et al., 2013) where it showed that word embeddings learnt can capture linguistic relationships using simple vector arithmetic. Analogous to the standard example where "King" - "Man" + "Woman" ≈ "Queen", we manipulate an arbitrary sentence encoding z_x of Style X to Style Y [¶]:

$$z_x = z_y + k(\frac{1}{N_y}\sum_{i=0}^{N_y} z_y^i - \frac{1}{N_x}\sum_{i=0}^{N_x} z_x^i) \tag{5}$$

where z_y^i, z_y^i denotes the latent vector of the i^{th} sentence in style y and x respectively and N_x and N_y represent the number of encoding present in the corpus for style x and y respectively. k is a scaling parameter used to control the style transfer strength. The resultant latent vector is passed through the decoder to produce the output sentence.

6.1 Quantitative Analysis

TST accuracy, content preservation and naturalness were computed on the converted sentences (shown in Table 4, 5, 6). Content preservation metrics can be found from Column 4 onwards. We consider two versions of the EPAAE i.e. only continuous embedding noise, continuous embedding noise + token deletion, and find that in some cases a mixture of both is required for optimal performance. We find that a slightly lowered value p for the EPAAE combined with its optimal ζ parameter outperforms other models as well.

6.1.1 Sentiment TST

Table 4 summarises the results of TST on the Yelp dataset. On visual inspection, there appears to be a general tradeoff between TST% and content preservation metrics. For example, the β-VAE achieves the best TST% but suffers from bad content preservation capability. In this case, we observe that EPAAE ($\zeta = 2.0, p = 0.1$) has the best content preservation capabilities across all metrics and achieves a reasonable tradeoff of TST%=77.1 as well.

6.1.2 Discourse TST

Table 5 summarises the results on four NLI datasets. Similar to the sentiment task, we see that EPAAEs have the best content preservation capabilities as well as the naturalness metric. It achieves this while achieving a comparable TST% as well. β-VAE shows best TST% but again suffers in content preservation. DAAE also display reasonable TST% vs Content preservation tradeoffs but overall cannot match the tradeoffs achieved by EPAAEs. Human evaluations on the SNLI dataset (Table 8) confirm this as well. The TST% achieved by any model in any task peaks at only 60.4% compared to 81.9% in sentiment task, a significant difference that hints at the fact that the Discourse TST task might be intrinsically more complex than sentiment style. Future work that aims to increase performance on the NLI task will be beneficial.

6.1.3 Style-PTB TST

Table 6 summarises the results on three datasets from the Style-PTB benchmark. (Lyu et al., 2021) produces a hierarchy of styles based on transfer difficulty measured by the average token-level ham-

---

[§] We use code and pretrained models from `https://github.com/passeul/style-transfer-model-evaluation` to measure naturalness.

[¶] Simply put, the difference of the means of all vectors in Style Y and X is computed and scaled by a factor k, then added to any arbitrary latent vector with style Y to convert it to style X.

Model	Naturalness	TST Acc.	BLEU-2	METEOR	ROUGE-L	CIDER	Embedding Average	Vector Extrema	Greedy Matching Score

Table 5: Quantitative results of TST experiments on NLI datasets

ming distance between the base and converted sentence. According to this hierarchy Tense inversion, PP removal/addition and Voice change are labelled in ascending order as easy, medium and hard respectively. Our results seem to partially validate this observation, in that the max TST% is obtained on the Tenses dataset (100%). Generally speaking, we also observe that TST has much better performance on fine-grained Style-PTB datasets than sentiment and discourse styles. Similar to before, the EPAAE shows best content preservation at competitive values of TST% as well.

It is also noteworthy to consider the direction of style transfer, particularly in the case of complex styles such as Discourse styles present in NLI datasets. Results and analysis on direction-specific metrics for Discourse TST are presented in Appendix B.2.2.

6.2 Qualitative Analysis

Samples of Output. For qualitative analysis, sample outputs by DAAE and EPAAE for the Yelp, SNLI and Tenses dataset are given in Table B.4. For a full list of qualitative examples on all datasets along with setup details, please refer to Appendix B.2.1.

Varying k for Fine-Grained TST. By varying the value of k in Equation 5, it is possible to finely control the strength of Text Style transfer. We show examples of this for the Yelp (Table B.9) and the SNLI (Table 7) dataset, for the baseline DAAE ($p = 0.3$) and the proposed model EPAAE. For the proposed EPAAE model, the best performing models (specifically in content preservation metrics) were chosen i.e. $zeta = 2.0$, $p = 0.1$ for the Yelp dataset and $zeta = 2.5$ for the SNLI dataset. The chosen qualitative examples highlight the EPAAEs slight superiority in performing fine-grained TST compared to the baseline.

Smooth Interpolation. Sentence interpolation experiments are reported in Appendix B.1, in which latent space points in an interpolation along a specific direction are decoded to gauge the smoothness of the space and its ability to generate coherent sentences

6.3 Human Evaluations

Each human annotator was given a set of base sentences and asked to vote for which model produced the most appropriate corresponding style inverted sentences. Please refer to Appendix A.3 for full details on the setup. Results are shown in Table 8. We observe that the proposed EPAAE model was overall more preferred across all three chosen datasets. This margin was most significant in the case of the SNLI dataset.

7 Conclusion

We introduce the “Embedding Perturbed AAE” or EPAAE and show that it best captures underlying style-based semantic features in the latent space in an unsupervised manner compared to its baselines. By inducing robust latent space organization through embedding perturbation in an unsupervised manner, we also demonstrate the possibility of fine-grained TST, where we can control the strength of the target style. Using a diverse set of datasets with varying formulations and complexities of style, we empirically that EPAAE performs overall best in the text style transfer task, particularly in its ability to preserve style-independent content across all datasets.

8 Future Work and Limitations

Regarding work in TST. We wish to augment existing state of the art methods with embedding perturbation to check if doing so aids performance. We see degrading TST performance in the Entailment to Contradiction Task across all models. Future work will focus on methods to improve this task.

Generally. It is also interesting to further analyse the effects of embedding perturbation to latent representations and resultant properties. A theoretical analysis would be beneficial to cement the use of embedding perturbation in a more general setting. There also remain more important questions that need answering for, e.g. "What if you apply continuous perturbation to hidden states instead of embeddings?", "What is the relation between this type of perturbation and techniques like dropout?". We wish to explore these important questions in the future.

Ethics Statement

Any TST model can be used for nefarious purposes, e.g. performing a "Non-toxic to toxic" modification of text in a real-world setting and causing social harm. Therefore, it is important we keep in mind a code of ethics (e.g. `https://www.acm.org/code-of-ethics`) for usage, research and development in this type of research. We have made all our code open-source and provided all details of experimentation and implementation to the best of our knowledge.

Acknowledgements

We would like to thank the reviewers whose feedback we believe substantially increased the quality of this work. We would like to thank the human annotators for their participation.

Appendix

A Additional details on Text Style Transfer Experiments

A.1 Model Architecture

All baseline models were trained with all underlying architectures apart from their individual objective losses. Bi-directional GRUs were used for the encoder and decoder with input embeddings of size 300, a hidden representation of size 256 and a latent space of size 128. For all models using AAEs as the underlying autoencoder, the discriminator was a single-layered perceptron with 512 units. The ADAM optimiser with β_1, β_2 as 0.5, 0.999 and a learning rate of 0.001. All models were trained for 30 epochs as any more training steps caused the reconstruction loss to dominate and decrease overall performance on the TST task. All input perturbations were disabled in inference time.

A.2 Hyperparameter Selection

For the hyperparameters p, λ_l, and β for the DAAE, LAAE and β-VAE, we fixed the values as 0.3, 0.05, 0.15 respectively. This decision was aligned with the results in Shen et al. (2020), which showed that these values produced the best reconstruction vs BLEU trade-off. We found this to be the case during subjective manual testing as well. λ_{adv} was set to 10 for all models having AAEs as the underlying architecture. For EPAAE, we found that $\zeta \in [2.0, 3.0]$ overall showed the best results across all datasets. Therefore a manual search around this range was conducted to determine the optimal ζ for each dataset.

A.3 Human Evaluations

TST outputs of two models, the baseline DAAE and the proposed EPAAE model, on the Yelp, SNLI and Tenses dataset were considered. The best performing EPAAE was chosen according to the results in Table 4, 5 and 6, particularly with respect to the content preservation metrics (Since TST% were similar across all models). Two hundred sentences (hundred from each base style) were randomly sampled from the test split of each dataset and style inverted (with scaling factor $k = 2$). Six hundred instances (each instance being a base and converted sentence pair) were equally split between three human evaluators. Each evaluator was given the task of labelling all two hundred instances from each dataset. The models were anonymous to evaluators and randomly named as "Model 1" and "Model 2". Each instance was to be labelled by an evaluator with four possible decision outcomes, i.e. "1 is best", "2 is best", "All are bad" and "All are good". For each instance, the majority of three votes from each of the three annotators were taken as the final decision for that corresponding instance. Instances without a majority were marked as "NA". The evaluation guidelines was formulated to consider which model a) successfully transferred the target style b) preserved the style-independent content and c) was overall fluent and grammatically coherent.

B Additional Experiments:

B.1 Sentence Interpolation in Latent Space - Qualitative Examples

We perform sentence interpolation using DAAE and EPAAE, starting from the same input sentence, incrementally moving along the same direction in the latent space in five fixed-size steps. We see that both the baseline and proposed model are able to produce fluent and coherent sentences, indicative of a smoothly populated latent space.

B.2 Text Style Transfer

B.2.1 Qualitative Examples

TST with scaling factor $k = 2$ was performed on DNLI, Scitail datasets as seen in B.5 and B.6 respectively. Similarly, it was also performed on Voices and PP Removal datasets from the Style-PTB benchmark as shown in B.7 and B.8 respectively. The proposed model for each dataset, was chosen to be the EPAAE with best performance in the content preservation metrics (shown in Table 4, 5 and 6). Samples were specifically selected in which at least one of the models was able to generate the ideal, style converted sentence with near-perfect content preservation and coherence. This was done by human evaluators, where both the models were anonymized.

B.2.2 Direction specific Discourse Transfer metrics

Particularly in the case of Discourse Style, it is natural to speculate that the difficulty of style transfer might be sensitive to the direction i.e.

two blond women are hugging one another the women are sleeping	**two blond women are hugging one another the women are sleeping**
two blond women are hugging one another the women are sleeping	two blond women are hugging one another the women are sleeping
three dogs affectionately playing the dogs are sleeping	three dogs affectionately playing the dogs are sleeping
two dogs are playing and wrestling with each other two cats are chasing each other through the house	two dogs are playing and wrestling with each other two cats are chasing each other through the house
two men in wheelchairs crash and they reach for the ball the men are sleeping	two men in wheelchairs crash and they reach for the ball the men are sleeping
three dogs in different shades of brown and white biting and licking each other the dogs are fighting	three dogs in different shades of brown and white biting and licking each other the dogs are fighting

Table B.1: Sentence Interpolation on sentence from **SNLI** dataset (**Left:** EPAAE, **Right:** DAAE)

the report will follow five consecutive declines	**the report will follow five consecutive declines**
the report will follow five consecutive declines	the report will follow five consecutive declines
the report will follow five consecutive declines in full monthly figures	the report follows five consecutive declines
the report followed five consecutive declines	the report followed five consecutive declines
the report follows five consecutive declines	the report will follow five consecutive declines in full monthly figures
the index hits its low 20297 off 2042 points	the report follows five consecutive declines in full monthly figures

Table B.2: Sentence Interpolation performed on the **Voices** dataset (**Left:** EPAAE, **Right:** DAAE)

the soviets had a world leading space program the guests noted	**the soviets had a world leading space program the guests noted**
the soviets had a world leading space program the guests noted	the soviets had a world leading space program the guests noted
the challengers had a big price advantage	the plant had a hairy stem that produced flowers and diminutive seeds
the expansion set off a marketing war	the japanese used 00 of the world s ivory
the uaw was seeking a hearing by the full 14 judge panel	the diplomat added that mr krenz had several things going for him
total return was price changes plus interest income	the japanese used 40 of the world s ivory

Table B.3: Sentence Interpolation performed on the **Tenses** dataset (**Left:** EPAAE, **Right:** DAAE)

Yelp	**Negative to Positive**		**Postive to Negative**	
Base	i had high hopes and they simply could n't have fallen farther	probably wo n't stay here again	the food is always flavorful and filling	food was excellent and service was fast
Converted (DAAE)	the italian flavors and amazing and all really impressive !	certainly here !	the food is not cooked and it was appealing .	food was not the waitress and was slow .
Converted (EPAAE)	i had great prices and everything is exquisite !	definitely stay here !	the food is n't just extremely bland .	food was ok. service was slow and disappointed
SNLI	**Entailment to Contradiction**		**Contradiction to Entailment**	
Base	a man and lady standing on a seesaw at a park . a man and woman are on a seesaw outside	a dog is jumping through the water . tha animal is in the water	a young child in a green shirt is on a carousel . the young child is wearing a blue shirt	three people shopping in an isle in a foreign grocery store . three people look at clothes in the mall
Converted (DAAE)	a man and a woman are on a seesaw at a beach. a man and woman are on a seesaw	a dog is running through the water the animal is running through the water	a young child in a blue shirt is wearing a red shirt and a blue hat a child is on a swing	three people in shopping carts in a shopping mall. three people shopping in a store
Converted (EPAAE)	a man and a woman are sitting on a seesaw at a park. a man and a woman are sitting on a couch	a dog is jumping through the water the animal is flying through the air	a young child in a red shirt is on a green slide. the child is wearing a shirt	three people shopping in a shopping mall in a foreign city. three people shopping in the mall
Tenses	**Future to Past**		**Past to Future**	
Base	miller brewing co and general motors will be included by clients	i will see a possibility of going to 2200 this month	spiegel was 80 controlled	mr deaver had reopened a public relations business
Converted (DAAE)	miller brewing co and general motors were included	i was a math major but i was going at this	42 will be advanced	mr breeden will not be public relations business will say
Converted (EPAAE)	miller brewing co and general motors was included by clients	i saw a possibility of going to 2200 this year	spiegel will be 80 controlled	mr deaver will have reopened a public relations business

Table B.4: Qualitative examples of TST task by DAAE and EPAAE on Yelp, SNLI and Tenses dataset

	DNLI			
Models	**Entailment to Contradiction**		**Contradiction to Entailment**	
	Example 1	Example 2	Example 1	Example 2
Base	i work in a cubicle . i have a hectic job	i have 3 kids . i am the proud parent of 2 boys and 1 girl	i work as a contractor for a cab company . i am a travel agent	i am a ballet dancer . i work as a trauma surgeon
DAAE	i work as a cashier in a supermarket . i am a cashier	i have a wife and two kids . i am a proud us sailor	i work for a online company . i do not have a job	i am a ballet dancer . i work at home editing
EPAAE	i work in a cubicle . i am a skilled craftsman	i have 3 kids . i am a proud mother of two	i work for a cab company . i have been working for many years	i am a ballet dancer . i took ballet lessons when i was a kid

Table B.5: TST task performed on DNLI dataset

Scitail				
Models	**Entailment to Neutrality**		**Neutrality to Entailment**	
	Example 1	Example 2	Example 1	Example 2
Base	most amphibians such as frogs live part of their lives on land and return to water to breed . frogs are amphibians that live part of the time in fresh water and live rest of the time on land	reptiles are found on every continent worldwide with the exception of the polar antarctica . modern members of the reptiles group live in many different habitats and are found on every continent except antarctica	respiratory rate is 40 150 breaths per minute . the normal respiratory rate per minute in adult humans is 12 18 breaths	and was the goddess of earth and sky moon and sun . the sun and the moon appear to be about the same size in the sky because the moon is smaller in diameter and is closer to earth than the sun
DAAE	most amphibians have dual habitats and the remainder on land and live in the first decade of fish and live in the first living things have the time of fresh water and live rest	many species are the most common ancestor in the unk of the same species of birds and mammals have the same species of birds	cardiac output is the amount of breaths per minute the normal respiratory rate per minute the normal respiratory rate per minute in adult humans is 12 18 breaths	the sun and the moon is the closest planet to the sun and the moon is the closest planet to the sun the sun is the closest star
