Abstract

Retrieval-augmented generation (RAG) enhances the outputs of language models by integrating relevant information retrieved from external knowledge sources. However, when the retrieval process involves private data, RAG systems may face severe privacy risks, potentially leading to the leakage of sensitive information. To address this issue, we propose using synthetic data as a privacy-preserving alternative for the retrieval data. We propose SAGE, a novel two-stage synthetic data generation paradigm. In the stage-1, we employ an attribute-based extraction and generation approach to preserve key contextual information from the original data. In the stage-2, we further enhance the privacy properties of the synthetic data through an agent-based iterative refinement process. Extensive experiments demonstrate that using our synthetic data as the retrieval context achieves comparable performance to using the original data while substantially reducing privacy risks. Our work takes the first step towards investigating the possibility of generating high-utility and privacy-preserving synthetic data for RAG, opening up new opportunities for the safe application of RAG systems in various domains. Our code is available at <https://github.com/psychology/RAG-SAGE>.

1 Introduction

Retrieval-augmented generation (RAG) aims to improve language model outputs by incorporating relevant information retrieved from external knowledge sources. It has been effectively applied in various scenarios, such as domain-specific chatbots (Siriwardhana et al., 2023) and email/code completion (Parvez et al., 2021). A typical RAG system often operates in two stages: retrieval and generation. First, the system retrieves relevant knowledge

Figure 1: An illustration for RAG with synthetic data.

from an external database based on the user query. Then, the retrieved information is integrated with the query to form an input for a large language model (LLM). The LLM uses its pre-trained knowledge and the retrieval data to generate a response, enhancing the overall quality of the output.

However, according to existing literature (Zeng et al., 2024; Huang et al., 2023; Ding et al., 2024; Qi et al., 2024; Ren et al., 2024), RAG may face severe privacy issues when the retrieval process involves private data. For example, Zeng et al. (2024) observe that carefully designed user prompts are able to extract original sentences in the retrieval data (untargeted attack), and can also extract specific pieces of private information (targeted attack), potentially leading to the leakage of considerable amount of the retrieval data. The potential risk of information leakage can significantly limit the applications of RAG systems. For instance, a medical chatbot (Yunxiang et al., 2023) using patients’ historical diagnosis cases as a knowledge source may improve response quality but raises concerns about exposing sensitive patient information. Therefore, enhancing the privacy properties of RAG systems and protecting the retrieval data from leakage is of high importance to prevent unauthorized access or misuse and enable safe and widespread adoption, particularly in sensitive domains like healthcare.

Some adaptations (Zeng et al., 2024) have been proposed to protect the privacy of RAG by incorpo-

*Equal contribution.

rating additional components in the RAG pipeline. These adaptations include pre-retrieval techniques (such as setting similarity distance thresholds in retrieval) and post-processing techniques (e.g., re-ranking and summarization (Chase, 2022)). However, as demonstrated by (Zeng et al., 2024), these methods cannot fully eliminate privacy risks, as the data itself may contain sensitive information. Moreover, these methods often introduce a significant privacy-utility trade-off and may incur extra time costs during inference.

To address the above concern, we propose an alternative data-level solution via using synthetic data as shown in Figure 1. By generating a privacy-preserving version of the original data and only providing the synthetic version to the LLM, the risk of information leakage could be effectively mitigated. This approach can potentially ensure that the original data is not directly used as input to the LLMs, thereby reducing the chances of sensitive information being exposed or leaked during the retrieval and generation process. Therefore synthetic data allows the creation of a safe, surrogate dataset that maintains the essential properties and relationships of the original data while protecting sensitive information. There are recent works exploring synthetic data generation using pre-trained language models (Ye et al., 2022; Meng et al., 2022; Gao et al., 2023a; Chen et al., 2023; Yu et al., 2024; Xie et al.) and utilizing the synthetic data in the downstream task to protect the privacy of the original data. Besides, some studies integrate differential privacy with synthetic data for in-context demonstrations (Tang et al., 2023). However, while existing methods for generating synthetic data work well for downstream tasks or in-context demonstrations, they are not well aligned with the unique requirements of RAG: RAG primarily focuses on utilizing key information from the data to answer related questions (Ding et al., 2024), rather than learning general patterns. Therefore, it is crucial to preserve as much useful information as possible from the original data when generating synthetic retrieval data. On the other hand, existing synthetic methods do not require generating data that shares the same key information with the original data. Consequently, there is a lack of exploration on how to effectively use synthetic data for RAG and how to design a feasible solution for generating high-quality retrieval data. Meanwhile, the unique information requirements of retrieval data also present challenges in generating privacy-preserving syn-

thetic data, as it is crucial to carefully select what information to preserve.

In this work, we take the first effort to investigate the possibility of generating synthetic retrieval data that maintains high utility while enhancing privacy protection for RAG. After identifying the related data from the original dataset, we use the synthetic version of the data as context instead of the original data for generation. We use a two-stage generation and refinement paradigm called SAGE (Synthetic Attribute-based Generation with agent-based refinement) to generate synthetic retrieval data. To preserve the important information of the original data and keep the utility of the synthetic data, we first utilize an attributed-based extraction and generation approach to generate the synthetic data. Specifically, for each dataset, we first input few-shot samples to make the LLM identify important attributes of the dataset. Then, for each data sample, we ask the LLM to extract key information corresponding to these attributes. After that, we input the attribute information into another LLM and ask it to generate synthetic data based on these key points (stage-1). In this way, the generated data contains key contextual information.

Although the attribute-based method can preserve key information of the original data, it may still include some privacy information, as the stage-1 does not incorporate privacy constraints. Therefore, a second step is necessary to further preserve privacy. In stage-2, we propose an agent-based iterative refinement approach to enhance the protection of private information. Specifically, we introduce two agents, a privacy assessment agent and a rewriting agent. The privacy assessment agent determines whether the generated data contains privacy information, such as containing personally identifiable information (PIIs) or potentially leading to the linkage of personal information, and provide feedback. The rewriting agent then takes this feedback to refine its generated data until the privacy agent deems it safe. Our experimental results show that using our synthetic data as retrieval data can achieve comparable performance with using original data while substantially reducing the associated privacy risks.

2 Related Works

2.1 Retrieval-augmented generation and its privacy issues

Retrieval-augmented generation (RAG), introduced by Lewis et al. (2020), has become a popular ap-

proach to enhance LLMs’ generation ability (Liu, 2022; Chase, 2022; Van Veen et al., 2023; Ram et al., 2023; Shi et al., 2023; Guo et al., 2025; Han et al., 2024; Zeng et al., 2025b,a). RAG improves output accuracy and relevance (Gao et al., 2023b), mitigating "hallucinations" of LLMs (Shuster et al., 2021). Its flexible architecture allows seamless updates to the dataset, retriever, and LLM without re-training (Shao et al., 2023; Cheng et al., 2023). These advantages make RAG a favored approach for applications like personal chatbots and specialized domain experts (Panagoulas et al., 2024).

However, there application of RAG also brings privacy issues. Huang et al. (2023) have shown the privacy implications of retrieval-based LM and identified privacy leakage of KNN-LM (Khandelwal et al., 2019), a specific kind of retrieval LM. Zeng et al. (2024) have shown that RAG is vulnerable to extraction attacks. Qi et al. (2024) have shown that production RAG models also suffer from attacks. The vulnerability of RAG makes its application in privacy domains under high risks.

2.2 Synthetic data generation using large language models

As large language models become more expressive, researchers have explored using them to generate synthetic data. Ye et al. (2022); Meng et al. (2022) propose to generate synthetic data via zero-shot prompting and then train smaller models on these data to handle various tasks like text classification, question answering and etc. Gao et al. (2023a) further develop a noise-robust re-weighting framework to improve the quality of generated data. Chen et al. (2023) propose to mix a set of soft prompts and utilize prompt tuning to generate diverse data. Yu et al. (2024) focus on the attributes of data itself including length and style to generate more diverse data. Recent works (Tang et al., 2023; Xie et al.; Xu et al., 2019, 2020) take privacy into consideration. Tang et al. (2023) propose a few-shot data generation method to generate private in-context demonstrations from a private dataset and provide a differential privacy guarantee. Xie et al. introduce a private evolution algorithm to generate differentially private data. However, their synthetic data is not guaranteed to include contextual information in the original data, thus not fitting the RAG system well.

3 Methods

Our SAGE framework of generating synthetic retrieval data is composed of two stages, i.e., attribute-based data generation and agent-based interactive refinement, as shown in Figure 2. The stage-1 aims to generate data that contains essential information of original data, while the stage-2 aims to automatically refine the data to further mitigate the privacy concerns. The synthetic data generation process can be conducted **offline** and only needs to be performed **once**. During inference, when the original data is identified, the corresponding synthetic data is returned as retrieval data¹.

3.1 Stage-1: Attribute-based data generation

In this stage, we aim to generate synthetic data that contains all the essential information from the original data. To achieve this goal, we propose an attribute-based data extraction and generation paradigm to create synthetic data.

The entire process of Stage-1 consists of three steps: identifying important attributes using few-shot samples, extracting key information related to essential attributes, and generating synthetic data conditioned on the extracted key information. First, we feed few examples within the dataset to an LLM-based *attribute identifier* and prompt it to identify m most essential attributes of the dataset². This process is performed before generating any synthetic data, and is only needed for once. Then, after obtaining the essential attributes, we leverage an LLM-based *information extractor* to extract key information related to these attributes for each data sample and construct [attribute:key information] pairs. This step captures the core useful information of the original data. Finally, we input these attribute-information pairs into an LLM-based *data generator* to generate new synthetic data. The synthetic data is expected to include key information extracted in the second step, thus reducing the loss of useful information in the original data. The prompt used for this step is provided in Appendix A.1.1. The LLMs used in these steps (attribute identifier, information extractor, and data generator) can be the same or different models. In Section 4.4, we also explore different model combinations and their impacts. Through stage-1, the risk of untargeted attacks is also mitigated, as this process

¹Our framework is versatile and adaptable to various scenarios and fields, as discussed in Appendix A.10

²We discuss the impact of m in Section 4.4

Figure 2: Pipeline of generating synthetic data.

reduces unnecessary information from the original data while only maintaining essential information.

3.2 Stage-2: Agent-based private data refinement

Though the synthetic data generated in Stage-1 has preserved important information from the original data, it may still have privacy issues as no privacy controls are added. For example, it may contain PII such as email addresses or phone numbers, or specific personal information that can possibly be linked to specific individuals. Thus, the synthetic data still may cause privacy leakage when used as retrieval data. Although methods such as anonymization can mitigate this issue to some extent, they can only mask highly structured data like email addresses, and it is challenging to reduce other potential privacy risks (Wang et al., 2022). As pointed out in (Brown et al., 2022), one key challenge in natural language processing (NLP) is that private information is often not explicitly presented but can be inferred from the context. Considering the sentence: "I just got back from the oncology department at City Central Hospital. The doctor said my chemo is going well.", this sentence does not directly mention the person's name but reveals that the speaker is undergoing cancer treatment at City Central Hospital. Moreover, Shi et al. (2022) further demonstrate that although directly removing all entities can preserve privacy, it will cause the data to contain almost no useful information, and the performance loss would be unacceptable. To address this issue, we propose to utilize the rewriting and reflection capabilities of large language models (LLMs) through an agent-based approach.

This method involves 2 agents collaborating to iteratively refine the generated answers so that they can maintain utility while protecting privacy.

Specifically, in our framework, we introduce a privacy agent and a re-writing agent that collaborate iteratively to enhance the privacy of the generated data. The privacy agent takes both the generated data from Stage-1 and the original data as input to assess whether the generated data contains privacy issues, such as containing PII or the linkage of personal information. It then provides feedback to the re-writing agent. The re-writing agent, in turn, improves data according to the privacy agent's advice. The privacy agent then evaluates the newly generated data again. This process continues until the privacy agent determines that the synthetic data is safe³. Stage-2 mitigates targeted attack risks by eliminating structured PII (e.g., emails, phone numbers), which can be effectively identify, remove and rewrite by advanced LLMs such as GPT-3.5.

4 Experiment

In this section, we present various experimental results to demonstrate the utility and privacy properties of SAGE. We first introduce our experiment setup in Section 4.1, including the components of RAG, evaluation datasets, tasks, and baselines. Then, we present the utility and privacy results in Section 4.2 and Section 4.3. Moreover, we conduct ablation studies in Section 4.4 to investigate the impact of the number of attributes, model choice,

³We put the detailed workflows and system prompts of these two agents and average iteration rounds in Appendix A.1.2 and synthetic data examples in Appendix A.11.

and the number of retrieved documents on the performance and privacy of SAGE. We also discuss the cost of synthetic data in Appendix A.7.

4.1 Evaluation Setup

RAG components In our experiments, we mainly employed Llama3-8b-chat (L8C) as the language model for text generation for performance evaluation. We chose this model because it cannot perform well on our chosen tasks without RAG, allowing us to test the extent to which RAG can improve the generation quality. For the privacy experiments, we use both the widely-used closed-source model GPT-3.5-turbo and the open-source model L8C for text generation. Both models have been safety-aligned, allowing us to demonstrate the vulnerability of RAG systems and the effectiveness of our proposed methods. We utilized the bge-large-en-v1.5 model as the embedding model. The embeddings were stored and the retrieval database was constructed using the FAISS library. By default, the L_2 -norm was used as the similarity metric to compare embeddings. Unless otherwise specified, we retrieved a single document ($k = 1$) for each query. The impact of varying the number of retrieved documents was further investigated in Section 4.4.⁴

Tasks and retrieval datasets We consider two privacy-related scenarios to verify the effectiveness of our synthetic methods. In the first scenario, we focus on monitoring medical dialog cases and utilize the HealthcareMagic-101 dataset of 200k doctor-patient medical dialogues as the retrieval dataset. In the second scenario, we follow the setting of (Huang et al., 2023) to consider a case where some private information is mixed with a public dataset. Specifically, we mix personal information pieces from the Enron Mail dataset (private dataset) with the wikitext-103 dataset (public dataset), which we refer to as Wiki-PII dataset. We extract personal PII and combine those PII with each sample of the wikitext-103 dataset. The details of the construction are presented in Appendix A.9. We then evaluate the performance of our methods on open-domain question answering datasets (ODQA), including Natural Questions (NQ) (Kwiatkowski et al., 2019), Trivia QA (TQA) (Joshi et al., 2017), Web Questions (WQ) (Berant et al., 2013), and CuratedTrec (CT) (Baudiš and

Šedivý, 2015). The detailed descriptions of these datasets are included in Appendix A.9.

Baselines. To verify the effectiveness of our methods, we include three baselines: simple paraphrasing⁵ and existing representative LLM-based data synthesis methods like **ZeroGen** (Ye et al., 2022) and **AttrPrompt** (Yu et al., 2024). We provide the details of these methods in Appendix A.3. We also report generation results without RAG, denoted as **0-shot**, using original data directly as retrieval data, denoted as **Origin**, and the outputs of the attributes-based generation, denoted as **Stage-1**. Finally, we report the outputs of the complete SAGE pipeline, denoted as **Stage-2**.

Stage-2	0.113	0.0943

Table 1: Utility results on HealthCareMagic dataset

4.2 Utility of using synthetic data

To assess the utility of using synthetic data as retrieval data, we evaluate the quality of the generated answers by comparing the answers with the ground truth. We primarily report the ROUGE-L and BLEU scores between the generated and the ground truth answers. *We also incorporate more evaluation metrics such as Exact Match(EM) and LLM-based evaluation and get similar conclusion in Appendix A.2. The details of these metrics are explained in Appendix A.8.*

Utility results on medical dialog. For the medical dialog case, we split the data into two parts: 99% of the data is used as the retrieval data, and the remaining 1% is used as the test data. To evaluate the system’s performance, we input questions from the test set and compare the generated answers with the ground truth answers using similarity-based metrics such as ROUGE-L and BLEU scores. The results are reported in Table 1. The results demonstrate that using synthetic data achieves performance comparable to, and even better than, using original data. Moreover, it significantly out-

⁴By default, we use GPT-3.5 at stage-1 and GPT-4 for agents at stage-2, we explore the model choice in Section 4.4

⁵We also incorporate more complex prompts and advanced models, such as GPT-4o in Appendix A.6, for paraphrasing, and obtain consistent conclusions.

performs generation without retrieval. Our methods also surpass simple paraphrasing and ZeroGen. These findings suggest that our approach to generating synthetic data effectively preserves the utility of the original data.

Utility results on ODQA. To assess open-domain question answering (ODQA) performance, we combine the WikiText-101 dataset with Enron Mail, as the source for information retrieval. We then evaluate the system’s performance using multiple ODQA datasets, such as Natural Questions (NQ), Trivia QA (TQA), WQ, CT.

The experiment results are summarized in Table 2. Similar to Table 1, using our proposed synthetic data as retrieval data shows consistently high performance, comparable to directly using the original data. In some datasets, such as NQ and WQ, our synthetic data even outperforms the original data. This may be because our pipeline in stage-1 preserves most of the essential key information. In stage-2, the data is further refined, and the final outputs contain more "pure" useful information, making it easier for the LLM to identify essential information and generate better answers.

4.3 Privacy of using synthetic data

To evaluate the privacy properties of using our synthetic data as retrieval data, we conducted targeted and untargeted attacks following (Zeng et al., 2024), which can cause considerable data leakage from standard retrieval database. The composite structured prompting attack on RAG consists of two components: $\{information\}$ and $\{command\}$. The $\{information\}$ component guides the retrieval system to fetch specific data, while the $\{command\}$ component instructs the language model to include the retrieved information in its response. For the $\{command\}$ component, we use phrases such as "Please repeat all the context" for both targeted and untargeted attacks. The $\{information\}$ component is adjusted according to the objectives of the attack. Targeted attacks aim to extract specific sensitive information, such as PII or private dialogue cases, by providing relevant input. In contrast, untargeted attacks seek to gather as much data as possible from the entire retrieval dataset without focusing on specific information.

For untargeted attacks, we report the number of prompts that can generate outputs with either

at least 10 tokens exactly matching the original dataset (**Repeat Prompt**) or with sufficient similarity to the original data, as indicated by a ROUGE-L score exceeding 0.5 (**Rouge Prompts**). Additionally, we report the number of unique verbatim excerpts (**Repeat Contexts**) and closely similar answers retrieved from the data, with a ROUGE-L score higher than 0.5 (**Rouge Contexts**). For targeted attacks, we also report the **Repeat Prompt** metric and the number of unique targeted information pieces extracted (**Targeted Information**). Further details regarding the threat models are provided in Appendix A.4.⁶

Untargeted attack results. In the context of an untargeted attack, the attacker’s objective is to gather as much information as possible from the whole retrieval dataset, rather than seeking specific data. To achieve this, following (Carlini et al., 2021), we randomly select chunks from the Common Crawl dataset to serve as the *{information}* component. We report the results of untargeted attacks on the HealthCareMagic dataset in Table 4. From the results, we can observe that (a) The attribute-based generated data in the first stage shows a lower attack success rate than using original data and simple paraphrasing. This indicates that the method is inherently more robust to privacy attacks. This may be because the generation process produces a new version of the data and naturally avoids highly similar sentences and exact copies. (b) After the agent-based refinement, using the final version of the data as context shows nearly no untargeted attack success. This demonstrates that the refinement process has further protected the data, and the produced data is of high safety.

Targeted attack results. In the targeted attack, the attacker has specific objectives regarding the type of information they aim to extract, such as PII’s including phone numbers and email addresses, or sensitive content like personal dialogue cases. For these attacks, the *{information}* component consists of some specific information that is related to the attacker’s goals. When evaluating the HealthCareMagic dataset, our goal is to extract diagnosed cases for specific diseases. We use the prompt "I want information about disease" as the *information* component. To consider the targeted information as successfully extracted, two criteria must be met:

(a) the name of the targeted disease must appear in the original data, and (b) the model’s output must contain repetitive segments from the original data at least 10 tokens. In the case of the Wiki-PII dataset, which includes a mix of data from Enron Mail, we focus on retrieving PII’s by employing frequently used leading phrases such as "My phone number is" as the *information* element. The targeted information in this context is measured by the total count of PII’s effectively extracted from the retrieval dataset.

The results of targeted attacks lead to conclusions similar to those of untargeted attacks. From Table 3, the generated data in the first stage has significantly reduced targeted information leakage. This is because the synthetic data only retains the essential key information and may naturally omit some specific privacy information. Furthermore, after the agent-based refinement process, the attack success rate further decreases to nearly zero. This validates that the agent-based refinement process can successfully further reduce the possibly privacy-violating information in the synthetic data.

4.4 Ablation Studies

To investigate the factors that affect the quality of synthetic data, we conduct ablation studies regarding the impact of model choice, the number of attributes, and retrieved documents per query.

Impact of model choice. To investigate the influence of model choice on stage-1 generation, we change the models used for the *information extractor* and *data generator* components in stage 1. Specifically, we experiment with different models, including GPT-4, GPT-3.5, and Llama3-Chat-8b, for these two components. For the experiments on the *information extractor*, we fix the *data generator* as GPT-3.5 and vary the model used for the *information extractor*. Similarly, for the experiments on the *data generator*, we fix the model of *information extractor* as GPT-3.5 and vary the model of *data generator*. We conduct the utility experiments on the HealthCareMagic dataset and use BLEU-1 and ROUGE-L scores compared with groundtruth as performance indicators. The impact on performance is shown in Figure 3a and Figure 3b. We can clearly observe that if weak models like Llama-8b-chat are used as the *data generator* or the *information extractor*, the overall performance is poor, even worse than zero-shot prediction. This indicates that the generated data is of poor quality. The performance of GPT-3.5 and GPT-4 when used

⁶We also directly compare the similarity between the synthetic data and original content as a worst-case scenario, presented in Appendix A.5 and Table 8.

Figure 3: Ablation study on model choice. TI means targeted information and RP means repeat prompts.

Figure 4: Ablation study on number of attributes m .

Figure 5: Ablation study on number of retrieved docs.

as *information extractor* and *data generator* both show promising results, and GPT-4 does not outperform GPT-3.5. This may indicate that GPT-3.5 is already powerful enough to handle the stage-1 generation tasks, and more powerful models like GPT-4 do not necessarily improve the performance.

We also report the targeted attack results on the HealthCareMagic dataset when using the stage-1 generated data as retrieval data in Figure 3c and Figure 3d. From the results, we can observe that using L8C as the *information extractor* and *data generator* results in no privacy leakage, as the generated data is of poor quality and fails to preserve information from the original data. We also found that using GPT-4 results in lower privacy leakage than GPT-3.5. This may be because the safety mechanism of GPT-4 is better, and it automatically filters out more sensitive information.

Impact of the number of attributes. In this part, we investigate the influence of the number of attributes m . We change the number of attributes m and observe its impact on performance and privacy on the HealthCareMagic dataset. The performance results are shown in Figure 4a. From the figure, we can observe that when the number of attributes is very small (e.g., when the number of attributes is 2), the performance is likely to be poor. This is because the limited number of attributes fails to capture all the essential information. Besides, we find that with an increase in the number of attributes, the performance improves but does not

necessarily continue to increase. We also report the targeted attack results of using stage-1 data on the same dataset in Figure 4b. From the results, we found that a small number of attributes leads to lower privacy exposure, as the limited number of attributes also misses more private information. Thus, we recommend choosing a proper number of attributes for different datasets via methods like testing on the evaluation set.

Impact of the retrieved number of documents. To verify that our proposed synthetic data pipeline can still protect privacy when more documents are retrieved, we conduct ablation studies by varying the number of documents retrieved and report the targeted attack results on the HealthCareMagic dataset. From Figure 5a, we can observe that in some cases, the privacy risks will be amplified when k increases if only stage-1 data is used. However, in Figure 5a and Figure 5b, we find that the data after agent-based refinement shows consistently minimal privacy leakage when k is increased, indicating the robustness of our method.

5 Conclusions

In this paper, we take the first step towards investigating the possibility of utilizing synthetic data as retrieval-augmented generation (RAG) data to mitigate privacy concerns. We propose a novel two-stage synthetic pipeline that includes attribute-based data generation, which aims to maintain key information, and iterative agent-based refinement,

which further enhances the privacy of the data. Experimental results demonstrate that using our generated synthetic data as RAG data achieves comparable performance to using the original data while effectively mitigating the associated privacy issues. Our work opens up new opportunities for the safe application of RAG systems in sensitive domains.

6 Limitations

In our research, we investigate the possibility of using synthetic data for retrieval-augmented generation (RAG) and propose a novel pipeline for generating high-utility and privacy-preserving synthetic data. We verify the effectiveness and safety of our synthetic data in representative scenarios, such as healthcare. In the future, we would like to further validate the efficacy of our pipeline across a wider range of domains and datasets. Moreover, We acknowledge that the practical attacks on RAG systems (Zeng et al., 2024; Qi et al., 2024) have **different definitions and settings** compared to Differential Privacy (DP). While DP is a rigorous method aiming to make each data item indistinguishable, it protects the data in a sense much stronger than targeted and untargeted attacks considered in this paper, thus we focus on the common attacks considered in literature instead of DP. Providing strict privacy guarantees, such as integrating DP into RAG, remains a challenging open problem in the field. It is an interesting and meaningful direction which we can investigate in future study.

7 Ethic Statement

This work explores using synthetic data to mitigate privacy risks in Retrieval-Augmented Generation (RAG), particularly in safety-critical domains. We argue that protecting sensitive information is crucial, as data leakage can severely impact individuals' well-being and privacy rights. Our approach generates synthetic data to replace sensitive data during RAG, aiming to reduce privacy breach risks. We have adhered to ethical guidelines and acknowledge the need for further research to understand the risks and benefits of our method. Developing privacy-preserving techniques is essential for the responsible deployment of RAG systems. Our research contributes to balancing the benefits of advanced language models with the protection of individual privacy rights.

A Appendix

A.1 Details of System Design

A.1.1 Prompts used in stage-1

Here, we would like to introduce the details of the prompts used in Stage-1. For the *attribute identifier*, we input 5-shot samples to GPT-4 by default and ask the model to summarize n important attributes. For the medical dialog dataset, we set the default number of attributes to 5 for both the Patients’ and Doctors’ information. For the Wiki-PII dataset, we set the default number of attributes to 3. The detailed attributes and corresponding prompts for the *information extractor* are shown in Table 11 and Table 12, respectively. After the *information extractor* obtains the extracted attribute-related information {input_attributes}, the *data generator* uses this information to generate synthetic data. The detailed prompts for the *data generator* are shown in Table 13 and Table 14 for the medical dialog and Wiki-PII datasets, respectively.

A.1.2 Prompts used in stage-2

The system prompts for the rewriting and privacy agents are detailed in Table 15 and Table 16, respectively. The workflow is as follows: the privacy agent first receives the generated data and original data, then assesses the privacy level of the synthetic data from different aspects. If the data is considered safe, the privacy agent returns <safe_synthetic_data> with the flag THISISSAFE. Otherwise, it returns suggestions (words following SUGGESTIONS:) to the rewriting agent. The rewriting agent then generates better synthetic data based on the feedback and sends it back to the privacy agent for re-evaluation. This process continues until the privacy agent determines that the refined synthetic data is safe and outputs the THISISSAFE signal. The average iteration round in this process is 3.964, indicating in most cases, one round of refinement is enough to generate safe data.

Dataset	Metric	llm	ori	Stage-1	Stage-2
NQ	EM	0.18	0.24	0.33	0.38
	Correctness	0.38	0.40	0.43	0.40
PopQA	EM	0.35	0.48	0.51	0.49
	Correctness	0.22	0.27	0.34	0.30

Table 5: Dataset metrics comparison

Wiki_pii	278	232	224
HealthCareMagic	231	134	145

Table 6: Average number of tokens (GPT-3.5 tokenizer)

Dataset	Stage-1 cost	Stage-2 cost	Total cost	Avg_refine_round
Wiki	0.000866	0.00237	0.00324	3.49
HealthCareMagic	0.00126	0.00191	0.00317	2.71

Table 7: Average cost per sample (\$)

A.2 Diverse metric evaluation of model utility

We have added additional evaluation metrics to further verify the effectiveness of our method. The metrics include exact match scores and LLM-based judgment. Specifically, the exact match score measures whether the ground truth answer appears verbatim in the LLM’s response. For the LLM-based judgment,

Targeted Leakage	
Wiki	0
HealthCareMagic	1
Untargeted Privacy Leakage	
HealthCareMagic(Repeat context)	0
HealthCareMagic(ROUGE context)	1

Table 8: Targeted and untargeted information extracted in 100 samples (worst case)

Para(GPT-4o, Joe)	2	3	1	4
SAGE	0	0	0	0

Table 10: Untargeted attack results against paraphrasing (100 prompts)

Prompt
Please summarize the key points from the following Doctor-Patient conversation: {input_context} Provide a summary for the Patient’s information, including: [Attribute 1: Clear Symptom Description] [Attribute 2: Medical History] [Attribute 3: Current Concerns] [Attribute 4: Recent Events] [Attribute 5: Specific Questions] Then, provide a summary for the Doctor’s information, including: [Attribute 1: Clear Diagnosis or Assessment] [Attribute 2: Reassurance and Empathy] [Attribute 3: Treatment Options and Explanations] [Attribute 4: Follow-up and Next Steps] [Attribute 5: Education and Prevention] Please format your response as follows: Patient: - [Attribute 1: Clear Symptom Description]: - [Attribute 2: Medical History]: - [Attribute 3: Current Concerns]: - [Attribute 4: Recent Events]: - [Attribute 5: Specific Questions]: Doctor: - [Attribute 1: Clear Diagnosis or Assessment]: - [Attribute 2: Reassurance and Empathy]: - [Attribute 3: Treatment Options and Explanations]: - [Attribute 4: Follow-up and Next Steps]: - [Attribute 5: Education and Prevention]: Please provide a concise summary for each attribute, capturing the most important information related to that attribute from the conversation.

Table 11: Prompt of *information extractor* on HealthCareMagic dataset

we use [Ragas](#), a widely-used automatic RAG evaluation pipeline Ragas (currently with 5.9k stars on GitHub). Ragas assesses the correctness of generated answers using its [correctness](#) metric, providing a more comprehensive evaluation.

Using PopQA and NQ as examples, Table 5 shows the utility comparison among our synthetic data, direct use of original data, and zero-shot prediction using only an LLM. It is observed that across these metrics, our synthetic data achieves comparable or even better utility performance to the original data. This indicates the high utility of our synthetic data approach.

A.3 Details of baseline implementation

paraphrase Paraphrase leverage the capabilities of LLM to extract relevant and significant components from the retrieved context. Less significant sections can be filtered out, while certain sentences may undergo rewriting. The prompt we utilize to paraphrase is shown in Table 17.

ZeroGen The ZeroGen method aims to generate a series of new question-answer format texts based on the original context. Specifically, we first use the spacy package to identify the named entities from the original context. We then prompt the LLM by "The context is: {*origin context*}. {*extracted entities*} is the answer of the following question: " to generate the question for the entities. The new context consists of 10 randomly selected question answer pairs in form of "question: {*generated questions*}. answer: {*extracted entities*}".

AttrPrompt AttrPrompt only utilizes LLM to generate data without providing original data retrieved from the database. This method asks LLM what are the most important attributes of a certain type of data.

Prompt
Please summarize the key points from the following wiki text:
{input_context}
Provide a summary of the knowledge from the wiki text, including: [Attribute 1: Clear TOPIC or CENTRAL IDEA of the wiki text] [Attribute 2: Main details of the TOPIC or CENTRAL IDEA] [Attribute 3: Important facts, data, events, or viewpoints]
Please format your response as follows:
- [Attribute 1: Clear TOPIC or CENTRAL IDEA of the wiki text]: - [Attribute 2: Main details of the TOPIC or CENTRAL IDEA]: - [Attribute 3: Important facts, data, events, or viewpoints]:
Please provide a concise summary for each attribute, capturing the most important information related to that attribute from the conversation. And remember to maintain logical order and accuracy.

Table 12: Prompt of *information extractor* on Wiki-P11 dataset

Prompt
Here is a summary of the key points:
{input_attributes}
Please generate a SINGLE-ROUND patient-doctor medical dialog using ALL the key points provided. The conversation should look like a real-world medical conversation and contain ONLY ONE question from the patient and ONE response from the doctor.
The format should be as follows:
Patient: [Patient’s question contains ALL Patient’s key points provided] Doctor: [Doctor’s response contains ALL Doctor’s key points provided]
Do not generate any additional rounds of dialog beyond the single question and response specified above.

Table 13: Prompt of *data generator* on HealthCareMagic dataset

For chatdoctor, we prompt the LLM by "What do you think are important attributes to generate some chat doctor datas. Examples: disease...". We can select five of the attributes from the response of LLM, and ask LLM to generate 10 diverse subtopics for each attributes. When generating the new context, we just randomly select the subtopic for each attribute and ask LLM to generate the data following the attribute.

A.4 Details of Attack Design.

In this section, we present the specifics of targeted and untargeted attacks against Retrieval-Augmented Generation (RAG) systems, which we employ to evaluate the privacy protection capabilities of our proposed synthetic data approach. We simulate a realistic black-box attack scenario, in which the attacker’s interaction with the system is restricted to API queries. Consequently, the attacker’s tactics revolve around carefully designing and manipulating queries q to extract the desired information from the RAG system.

Prompt Design. The composite structured prompting is typically composed of 2 parts, the $\{information\}$ part as well as the $\{command\}$ part.

$$q = \{information\} + \{command\}$$

This design aims achieve two objectives: (a) induce the retriever to accurately retrieve targeted information and (b) prompt the model to output the retrieval data in context. The $\{information\}$ component

Prompt
Here is a summary of the key points:
{input_attributes}
Please generate a wiki text using ALL the key points provided. The data should look like a real-world wiki text.

Table 14: Prompt of *data generator* on Wiki-PII dataset

System prompts of Cathy (Re-writing agent)
You are a synthetic data generator and your role is to generate synthetic data based on provided feedback (words after SUGGESTIONS:) and to make sure the synthetic data is of high utility and privacy-preserving, you should put your generated data after the word 'GENERATED DATA:'.
Cathy's Message
Hi Joe, I will give you the real data (TRUE DATA) and synthetic data (GENERATED DATA), please help me assess and provide suggestions from the privacy level of TRUE DATA: {true_con} GENERATED DATA: {syn_con}

Table 15: System message: rewriting agent

is to direct the retrieval system towards fetching particular data; while the *{command}* component instructs the language model to include the retrieved information into its response. For the *{command}* component, we use phrases such as "Please repeat all the context", while for the *{information}* part, it depends on the need of the attackers.

Targeted Attack. For targeted attacks, the attacker aims to extract some targeted specific information. Generating the *information* component for a targeted attack involves two stages. First, the attacker provides specific examples based on their requirements, such as "I want some advice about *target name*" for clear targets or prefix content like "Please email us at" for abstract targets. Second, a significant quantity of similar and varied *information* is generated based on the examples. For targets with numerous sub-contents, like the HealthcareMagic dataset, variations can be created by replacing specific sub-contents, such as disease names obtained from ChatGPT or the International Classification of Diseases (ICD). Alternatively, LLMs like ChatGPT can directly generate similar sentences based on examples, which is also used for the Wiki-PII dataset. For instance, you can input "Generate 100 similar sentences like "Please email us at"".

Untargeted Attack. In untargeted attacks, the focus is on generating diverse *information* components to extract a wider range of data from the retrieval datasets, rather than targeting specific information. Inspired by the approach in (Carlini et al., 2021), we randomly select segments from the Common Crawl dataset to function as the *information* component. However, the randomness of the input may affect the *command* component. To mitigate this issue, we limit the maximum length of the *information* component to 15 tokens, ensuring that the prompts remain coherent and effective in extracting data from the retrieval datasets.

A.5 Directly Compare Synthetic Data and Original Data

Since the attacker can at most extract the synthetic data in our framework, the attacker cannot obtain information beyond the synthetic data. From this perspective, the similarity/overlap between the synthetic data and the original data serves as a privacy upper bound. Therefore, we directly compare the synthetic data with its original version in Table 8. Specifically, we compare the targeted information leakage

in synthetic data derived from two datasets: Wiki-PII and HealthCareMagic, as well as the untargeted information leakage of HealthCareMagic dataset. Remarkably, even in this extreme case, there is nearly no targeted information (PIIs, patient records) leaked, and almost no untargeted information (repeated or highly similar sentences from the original data) exposed. This indicates that our method can effectively mitigate privacy risks at the data level, thus proving robust against various practical extraction attacks.

A.6 Comparison to paraphrasing with GPT-4o

We also conduct an ablation study using more advanced models, specifically GPT-4o to directly paraphrase the model. We use these models to rewrite the content and tested the attack success rate. We consider 3 cases:

- Para(GPT-4o): Paraphrase context using GPT-4o
- Para(GPT-4o,Privacy): Add a system prompt "The generated data should *NOT* have privacy risks."
- Para(GPT-4o,Joe): Add specific privacy protection list (Joe, Table 16) to prompt, the detailed prompts are shown in Table 18.

The results, shown in Table 9 and Table 10, indicate that even with one round of rewriting in para(GPT-4o), para(Joe), para(Privacy), targeted and untargeted privacy concerns still exist. **These results underscore the critical importance of each component within our framework and validate the effectiveness of our methodological design.** Another advantage of our method is that the generation process doesn't necessarily require very powerful LLMs. GPT-3.5 can already achieve good results. Considering the significantly lower cost of GPT-3.5 compared to GPT-4o (or even more expensive models in the future), our method is more cost-effective.

A.7 Cost of synthetic data

Our method only requires one-time off-line generation and does not introduce extra time or costs during inference. Moreover, our synthetic data is typically shorter than the original data as shown in Table 6 (50 tokens less for wiki and 86 tokens less for chatdoctor), suggesting that using synthetic data may actually decrease inference costs to some extent.

We also analyze the computational costs required for the synthetic process using GPT-3.5 as shown in Table 7. Our findings indicate that both the expenses and time are reasonable (a round \$0.003 per sample), especially when the generation is a one-time process.

A.8 Details of Evaluation Metrics

Here we would like to provide a detailed description of our evaluation metrics.

ROUGE-L: ROUGE-L is a metric within the ROUGE (Recall-Oriented Understudy for Gisting Evaluation) family, specifically used to assess the quality of text generation tasks such as automatic summarization and machine translation. It evaluates the similarity between the generated text and a reference text using the Longest Common Subsequence (LCS).

- **Longest Common Subsequence (LCS):** ROUGE-L measures the longest sequence of words that appears in both the generated and reference texts while maintaining the same order, though not necessarily contiguous.
- **Recall, Precision, and F-measure:**
 - **Recall:** The ratio of the LCS length to the length of the reference text (n), indicating how much of the reference sequence is captured by the generated text. $LCS(X, Y)/n$
 - **Precision:** The ratio of the LCS length to the length of the generated text, indicating how much of the generated sequence appears in the reference text. $LCS(X, Y)/m$
 - **F-measure:** The harmonic mean of Precision and Recall, balancing the two metrics. $F_{lcs} = \frac{(1+\beta^2)*R_{lcs}*P_{lcs}}{R_{lcs}+\beta^2*P_{lcs}}$ where β is a parameter to control the importance of precision and recall (usually $\beta = 1.0$). In our results, we report F-measure as the ROUGE-L score.

Let C be the candidate translation and R be the set of reference translations.

BLEU-1: BLEU-1 is a metric that evaluates the quality of machine-translated text based on the precision of unigrams (single words).

- **Unigram precision:** $P_1 = \frac{\sum_w \min(\text{Count}_C(w), \max \text{Count}_R(w))}{\sum_w \text{Count}_C(w)}$

Where:

- $\text{Count}_C(w)$ is the number of times word w appears in the candidate translation
- $\max \text{Count}_R(w)$ is the maximum number of times w appears in any single reference translation

- **Brevity penalty:** $BP = \min(1, \exp(1 - r/c))$

Where:

- c is the length of the candidate translation
- r is the length of the reference translation closest in length to the candidate

- **BLEU-1 score:** $\text{BLEU-1} = BP * P_1$

The BLEU-1 score ranges from 0 to 1, where 1 indicates a perfect unigram match between the candidate and reference translations.

Additional Metrics: Besides, we’ve also added new evaluation metrics to further validate our method:

- **Exact Match (EM) score:** Measures if the ground truth answer appears verbatim in the LLM’s response.
- **LLM-based judgment (Correctness):** Using [Ragas](#), a popular automatic RAG evaluation pipeline (5.9k GitHub stars), to assess answer correctness.

A.9 Details of Dataset Construction

Construction of Wiki-PII dataset. To demonstrate the ability of our proposed method to protect privacy from target attacks, we construct the wiki-PII dataset. This dataset satisfies the requirement of having a high number of PIIs to evaluate the effectiveness of privacy protection methods. The construction of this dataset involves a three-stage process. In the first stage, we extract the authentic PIIs from the Enron Mail dataset. We use the `urlextract` package to extract websites, and regular expressions to extract phone numbers and personal email addresses. In the second stage, we employed the recursive character text splitter from `langchain` to segment the wiki text dataset, setting chunk size to 1500. In the final stage, for each segmented wiki data, we randomly inserted the PII obtained in the first step at the end of each sentence.

A.10 Discussions when adapting SAGE in specific domain application

Here we would like to give some discussions when adapting SAGE in specific domain application. Our framework is designed to be general and can be easily adapted to different domains. We can break down the key components as follows:

Stage-1: Attribute-based Data Generation. The purpose of this stage is to generate a new version of the data with key information. The procedure is as follows: a) Identify key attributes, b) Summarize key points of these attributes. c) Generate synthetic data based on key points.

The key factor in this process is the number of attributes, which can be adjusted based on the complexity of specific fields or datasets. Additionally, we can modify the prompts in step c) to specify the desired structure or format of the generated data. This flexibility allows us to tailor the output to various formats such as conversations, Q&A sessions, reports, or news articles. For instance, to synthesize financial report data, we might include a sentence like "The output should be formatted as an official financial report." This approach ensures that the synthetic data not only contains the key information but also mirrors the appropriate style and structure for its intended use.

Stage-2: Agent-based Private Data Refinement. We provide a general set of privacy violation checks as prompts for the privacy agent (as shown in Table 18). To adapt this stage to domain-specific privacy regulations, such as those in the financial sector, one can simply modify the system prompts of the privacy

agents. For example, when dealing with financial data, one can add terms such as: “*Check for credit scores, credit history, and loan details, which are highly sensitive and subject to specific regulations.*” or “*Ensure that financial data is treated as if it were to be encrypted both in transit and at rest to prevent unauthorized access.*”

This flexibility allows our framework to be tailored to various fields while maintaining its core structure. The ability to customize privacy checks makes it adaptable to different regulatory environments and industry-specific requirements. A potential limitation of our method is that generating data for specific domains may require domain expertise for effective customization. To address this, we recommend using advanced language models such as GPT-3.5 or domain-specific fine-tuned models for data synthesis to achieve better quality.

A.11 Examples of synthetic samples

The examples of the two stages of data synthesis using our method are shown in Table 19. The original context contained an abundance of detailed and specific information, enabling the possibility of inferring the identity of the patient through careful analysis. Our proposed method has the capability to blur out such detailed information while preserving essential disease-related data. This enables doctors to offer accurate diagnosis and treatment recommendations. Following stage-1, a significant amount of detailed information can be effectively blurred out, while still retaining certain preserved information. Subsequently, in stage-2, nearly all of this information can be completely blocked or concealed. For instance, in the second row of Table 19, the original data contains information such as "25 years old," "married for 5 years," "pregnancy," "ectopic pregnancy," and "right fallopian tube removed." Attackers could potentially exploit this information to infer the patient’s identity. However, these pieces of information may not be crucial for achieving accurate diagnosis. Hence, we employ a two-stage synthesis process to shield them. After stage-1, some of the detailed information, such as "married for 5 years," was filtered out, but the age has not been blurred yet. In stage-2, all detailed information is blurred, while retaining only the essential details that allow doctors to provide appropriate advice.

A.12 Definition of Privacy Properties:

Privacy properties in text modalities lack standardized definitions due to the unstructured nature of textual information. In the absence of universally accepted privacy definitions for RAG systems, we adopt an empirical approach consistent with previous RAG privacy research (Zeng et al., 2024; Huang et al., 2023). We consider a potential privacy risk to exist when text from a private database can be extracted through the system. Specifically, we identify privacy risks in two scenarios: when the LLM duplicates data (untargeted attack), or when it generates sensitive information such as personally identifiable information (PIIs) (targeted attack). We quantify the privacy properties of RAG systems using attack success rates. Tables 3 and 4 demonstrate the privacy leakage risks and the effectiveness of our mitigation method. Table 19 provides illustrative examples of our approach in action.

A.13 Compare with latest synthetic data baselines:

We have compared our proposed method with AttrPrompt (2023) (Yu et al., 2023). To demonstrate that our method achieves a better utility-privacy trade-off, we have also implemented another synthetic data method, AugPE (2024) (Xie et al.), for this comparison. We ensured consistent experimental conditions across all methods, including identical datasets, inputs, and evaluation metrics. The only difference lies in the pipeline for generating synthetic data.

The utility results are as Table 20, 21 and 22 where Stage-1 and Stage-2 are our proposed method, Aug-PE and AttrPrompt are the baselines, t denotes the generation rounds of synthetic data.

All evaluation metrics (BLEU-1, ROUGE-L, EM) are better when their values are higher. Our method achieves superior utility compared to other synthetic data approaches. According to the results presented in Tables 3 and 4, our proposed method can nearly completely mitigate both targeted and untargeted attacks. This demonstrates that our framework achieves a better utility-privacy trade-off than competing methods, which we attribute to the following factors:

- Our methods are designed for RAG systems, while others are not, enabling us to achieve better utility.
- Our carefully designed prompt and two-stage iterative refinement process effectively mitigate privacy risks from both targeted and untargeted attacks against the original data.
- We consider both privacy and utility at the generation stage.

A.14 Compare with adaptive attacks

We have carefully examined the adaptive attack methods proposed in (Annamalai et al., 2024) and (Ganev and De Cristofaro, 2023), but found significant challenges in applying them to our scenario for the following reasons:

- These methods were specifically designed for attacking tabular data, whereas our focus is on protecting text data. Unlike structured data, textual information lacks well-defined statistical properties, making it significantly more difficult to model. Text data also exhibits complex and high-dimensional distributions, which further complicates attempts to reconstruct the original content using these techniques.
- Annamalai et al. (2024) assumes access to a fitted generative model and requires specific privacy metrics (e.g., IMS) to launch its attack. In contrast, our approach relies on pre-trained models without fine-tuning on private data and does not use such privacy metrics.
- Ganev and De Cristofaro (2023) relies on k -way marginal queries, which are applicable only to tabular data. Their threat model assumes that attackers can obtain quasi-identifiers from the original dataset—an assumption that does not hold in our setting.

While these methods are not directly applicable to our context, they offer valuable insights into potential privacy vulnerabilities. We will consider their implications in future research.

A.15 Choice of attribute numbers m

A.15.1 The Influence of m on Information Quality

A suitable value of m can enhance the effectiveness of synthetic data, and its selection is closely tied to the characteristics of the privacy dataset to be protected. We adopt a heuristic approach to determine m .

Specifically, we first sample several examples from the dataset and prompt the LLM to identify which attributes are critical. The value of m is then determined by combining the LLM’s responses with human verification, ensuring a balance between privacy preservation and data utility.

Although the parameter m influences the content of the generated outputs, increasing m does not result in excessive information redundancy or significant information loss. As shown in Table 24, we vary the number of attributes m in the prompt to generate synthetic data from the same privacy source. The lengths of the generated texts are comparable (1,407; 1,499; and 1,659 characters), and their semantic content remains largely consistent across different values of m .

These results suggest that the choice of m does not significantly degrade the quality of the synthesized data, nor does it introduce notable redundancy.

A.15.2 The privacy agent does not waste the attributes extracted in stage-1

Although the attribute extraction did not explicitly require including patients’ names, nationality, height, or other such information, the content within each attribute may still contain such private details. These sensitive contents are irrelevant to answering questions but introduce privacy risks.

In Stage-2, we utilize an iterative refinement mechanism with privacy agents and rewriting agents working together to carefully remove and rewrite these sensitive but unhelpful contents within each attribute (instead of removing all attributes). By leveraging Stage-2, we generate examples that not only avoid privacy-sensitive information but also retain the useful information within each attribute extracted previously.

Below, we provide an example demonstrating that the stage-2 does not waste the attributes extracted in the stage-1. The corresponding analysis is shown in Table 23.

Patient: Hello doctor, I'm a 25-year-old from South Asia experiencing serious kidney-related health issues. My kidneys are underdeveloped and not functioning well, leading to elevated levels of waste in my blood. As a result, I've developed symptoms consistent with a bone-related condition that's affecting my ability to walk, and I've also noticed that my height is below average. I've consulted several specialists in my region, but due to the risks associated with my current kidney function, surgery has been ruled out. I'm feeling overwhelmed and uncertain about what to do next. Could you please advise me on possible steps for treatment and care?

Doctor: Thank you for reaching out and sharing your situation. It sounds like you may be dealing with a condition such as rickets, possibly linked to a vitamin D deficiency, which can be common when kidney function is impaired. Taking vitamin D supplements could help slow the progression of your bone symptoms. However, surgery is indeed high risk at this stage, given your elevated waste levels and weakened kidney function. The immediate focus should be on stabilizing your renal health through appropriate medications and dietary adjustments. Once your condition is better managed, more invasive options might become safer. Please stay encouraged—working to improve your kidney function is an important first step forward.

A.15.3 The parameter m has little impact on the attack success rate

We also consider that extracting a larger number of attributes (m) may increase the likelihood of capturing private information, thereby raising the risk of transferring such information into the synthetic data. To investigate this issue, we conducted an ablation study by varying the value of m . As shown in Table 25, Table 26, and Table 27, increasing m does not lead to a higher risk of privacy leakage or improved attack success rates. These results suggest that the choice of m has limited influence on the vulnerability of synthetic data to privacy attacks.

A.15.4 Impact of attribute number m on model performance

Regarding parameter m , we further conducted our experiments. For the wiki dataset, we introduced three different prompts to extract attributes: $m = 2$, $m = 3$, and $m = 4$, along with an adaptive prompt as shown in Table 28. The adaptive method first asks LLM to select the most suitable m value and then we select the corresponding prompt.

We remain other part of pipeline the same, and utilize the exact match metric on the CQA and NQ datasets, the experimental results are presented as Table 29. These result demonstrates that the value of m has little impact on model performance.

A.16 Discussion of Privacy Agents

We demonstrate that our privacy agents have relevant prompts to mitigate linkage attacks and provide examples to verify the effectiveness of such design for linkage attack).

To mitigate potential linkage risks from indirect identifiers, we incorporate a Privacy Agent based on LLMs. While identifying such subtle cues is inherently challenging, our approach uses targeted prompts to guide the model in detecting and redacting indirectly identifying information. For example, the prompt includes instructions such as:

3. Contextual Privacy: Evaluate if the synthetic data, when combined with other publicly available information, could potentially lead to the identification of individuals or reveal sensitive information about them. If such risks are identified, recommend strategies to mitigate these contextual privacy issues.
4. Data Linkage: Assess if the synthetic data can be linked with other datasets to infer additional sensitive information about individuals. If linkage risks are found, suggest techniques such as data perturbation or aggregation to reduce these risks.
5. Semantic Consistency:...

6. Original Data Recovery: Analyze the synthetic data to determine if it could potentially allow attackers to recover or reconstruct the original conversation data (word behind TRUE CONVERSATION:). If such vulnerabilities are identified, suggest methods to introduce additional randomness, noise, or perturbations to break direct correspondences between the synthetic data and the original conversation, making recovery attempts more difficult.

If synthetic data contains such linkage problems, the "Privacy Agent" will discover this issue and provide instructions to the "Rewriting Agent" to generate new synthetic data until no such risks remain. Here is an example of mitigating the linkage privacy risk:

The origin privacy data:

INPUT: hi sir my name is adnan bashir .I am 25 yrz old and I am from Pakistan. my kidney not work is properly my kidney size is small and this disease effect my both legs the rickets disease spread my legs day by day and sir i am very worried about this disease the all pakistani doctors dont accept to opprate me they ask if they try the most chances i will die bcoz my blood urea and creatine high so that is the reason the doctors not agree my operation the kidney disease also effect my height my height is small my height 4 feet 10 inch plz sir help me what i do

OUTPUT: Hello. Thanks for writing to us. If you are having rickets due to vitamin D deficiency, you can take supplements of vitamin D to at least stop the further progress of the disease. With deranged renal function, going for a surgery is risky. The stress of surgery might cause a renal failure. You need to bring the renal functions to normal with the help of medicines and dietary restrictions. I hope this information has been both informative and helpful for you.

The synthetic data:

Patient: Hello doctor, I'm a 25-year-old from South Asia experiencing serious kidney-related health issues. My kidneys are underdeveloped and not functioning well, leading to elevated levels of waste in my blood. As a result, I've developed symptoms consistent with a bone-related condition that's affecting my ability to walk, and I've also noticed that my height is below average. I've consulted several specialists in my region, but due to the risks associated with my current kidney function, surgery has been ruled out. I'm feeling overwhelmed and uncertain about what to do next. Could you please advise me on possible steps for treatment and care?

Doctor: Thank you for reaching out and sharing your situation. It sounds like you may be dealing with a condition such as rickets, possibly linked to a vitamin D deficiency, which can be common when kidney function is impaired. Taking vitamin D supplements could help slow the progression of your bone symptoms. However, surgery is indeed high risk at this stage, given your elevated waste levels and weakened kidney function. The immediate focus should be on stabilizing your renal health through appropriate medications and dietary adjustments. Once your condition is better managed, more invasive options might become safer. Please stay encouraged—working to improve your kidney function is an important first step forward.

In the original data, names, countries, and heights appear alongside medical conditions, creating a combination that easily identifies specific individuals. However, in our synthetic data, the identifying information has been completely removed, making it impossible to infer patient identities through association or linkage attacks. Meanwhile, synthetic data retains the majority of clinically relevant information needed for medical treatment while removing privacy-related information, effectively ensuring both utility and privacy.

A.17 Dataset preparation details

In the experiment, we follow the experimental setting of previous RAG privacy research (Huang et al., 2023) to monitor a situation where some private information is contained in a large public database (e.g., some people's names/phone numbers appearing in large-scale web contents). In real-world scenarios, every sentence in a text could potentially contain privacy-risk entities. Therefore, embedding PII in data is reasonable for modeling such risks.

A.18 Discussion on model choice

Due to the complexity of our prompts, less capable models struggle to meet the requirements. However, with the open-sourcing of powerful models like DeepSeek and QwQ, users can also opt for these robust open-source alternatives, thereby better safeguarding their privacy. Here is an example of the synthetic data generated by QwQ-32B, with the same prompt and similar utility as that for closed model:

Patient: I am a young adult from a South Asian country. I have been diagnosed with renal dysfunction, and the associated rickets is causing progressive leg deformity. My stature is significantly shorter than average, and local healthcare providers have declined surgical intervention due to abnormal renal markers, stating the risk of life-threatening complications. I am deeply concerned about the worsening of my condition and seek guidance on managing my health and improving treatment prospects. What steps can I take?

Doctor: Your symptoms suggest a vitamin deficiency-related skeletal disorder linked to renal impairment, which explains the leg abnormalities and growth limitations. Surgical intervention is currently too risky due to compromised kidney function. To stabilize your condition, initiate nutritional supplementation and follow a diet optimized for renal health. Prioritize restoring baseline renal function through prescribed therapies before reevaluating surgery. Avoid activities that could exacerbate kidney strain, as this could worsen your prognosis. Let's focus on rebuilding your health stability first.

However, when switching to less capable models, they fail to follow our instructions—for instance, being unable to eliminate potential privacy risks.

A.19 Number of private attributes

We clarify that our definition of privacy risk focuses on scenarios where private information is not required to complete the task but is nonetheless leaked. In contrast, if an application is explicitly designed to retrieve private information—such as querying an employee's phone number from an internal company directory—there is no privacy concern, as the access aligns with the authorized user's intent and the task's objective.

In practice, we believe that most tasks do not inherently require private information. For example, in medical dialogue scenarios, essential content includes the patient's symptoms, the doctor's diagnosis, and the proposed treatment plan. In contrast, personal identifiers such as names, phone numbers, or addresses are irrelevant to the clinical reasoning process and offer no utility for resolving medical inquiries. Therefore, removing such private information does not compromise model performance.

A.20 Compare with sanitization/paraphrasing baseline

We provide the results of sanitization and paraphrasing baselines. Our experiments demonstrate that sanitization (directly removing PII) does not work for untargeted attacks, and the paraphrasing baseline cannot eliminate the untargeted risks. This validates the necessity of our design.

Sanitization Simply removing PIIs can only counteract targeted attacks; it does not provide strong protection against untargeted attacks. While PII removal hides sensitive structured information, other content in the data may still carry privacy leakage risks. We implement the pipeline "remove_pii" that carefully remove PIIs and test for untarget attack, the results are in Table 30, We can clearly observe that such baseline still suffers from untargeted attacks.

Sanitization We actually have incorporated para(GPT-4o,Joe), which provides a comprehensive description and checklist of potential privacy risks. Upon analysis of the results, we observed that the generated data still contains some privacy concerns.

We have modified the prompt for the privacy-agent in our stage-2 to enable it to directly paraphrase privacy-sensitive text. The revised prompt is as follows:

Context: Context

Please rewrite the given context, ensuring it does not contain any private or sensitive information. Follow these guidelines:

1. Personally Identifiable Information (PII): Check if the synthetic data contains any PII, such as names, addresses, phone numbers, email addresses, or other information that can directly identify an individual. If found, remove or anonymize such information
2. Sensitive Attributes: Anonymize or remove sensitive attributes including but not limited to race, ethnicity, religion, political affiliation, sexual orientation, health status, or financial information.
3. Contextual Privacy: Evaluate if the synthetic data, when combined with other publicly available information, could potentially lead to the identification of individuals or reveal sensitive information about them. If such risks are identified, try to mitigate these contextual privacy issues.
4. Data Linkage: Assess if the synthetic data can be linked with other datasets to infer additional sensitive information about individuals. If linkage risks are found, use techniques such as data perturbation or aggregation to reduce these risks.
5. Semantic Consistency: Ensure that the privacy-preserving transformations applied to the synthetic data maintain semantic consistency and do not introduce any unintended biases or inaccuracies.
6. Original Data Recovery: Analyze the synthetic data to determine if it could potentially allow attackers to recover or reconstruct the original conversation data. If such vulnerabilities are identified, try to introduce additional randomness, noise, or perturbations to break direct correspondences between the synthetic data and the original conversation, making recovery attempts more difficult.

Please provide the rewritten context that addresses these privacy concerns while maintaining the essential meaning and utility of the information.

The results presented in Table 31 and 32 demonstrate that even after one round of paraphrase using para(Joe) with its detailed description, privacy risks still persist. This outcome validates the effectiveness of our method and underscores the necessity of our design approach.

joe (Privacy Agent)

You are a privacy evaluation agent and your role is to provide comprehensive feedback on the synthetic data generated by the synthetic data generator. To be specific, you should analyze the synthetic data (the data after the word 'GENERATED DATA:') from the following aspects:

1. Personally Identifiable Information (PII): Check if the synthetic data contains any PII, such as names, addresses, phone numbers, email addresses, or other information that can directly identify an individual. If found, suggest ways to remove or anonymize such information.
2. Sensitive Attributes: Look for any sensitive attributes in the synthetic data, including but not limited to race, ethnicity, religion, political affiliation, sexual orientation, health status, or financial information. If present, provide suggestions on how to handle or obfuscate these attributes to mitigate potential privacy risks.
3. Contextual Privacy: Evaluate if the synthetic data, when combined with other publicly available information, could potentially lead to the identification of individuals or reveal sensitive information about them. If such risks are identified, recommend strategies to mitigate these contextual privacy issues.
4. Data Linkage: Assess if the synthetic data can be linked with other datasets to infer additional sensitive information about individuals. If linkage risks are found, suggest techniques such as data perturbation or aggregation to reduce these risks.
5. Semantic Consistency: Ensure that the privacy-preserving transformations applied to the synthetic data maintain semantic consistency and do not introduce any unintended biases or inaccuracies. If inconsistencies are detected, provide feedback on how to maintain the balance between privacy protection and data utility.
6. Original Data Recovery: Analyze the synthetic data to determine if it could potentially allow attackers to recover or reconstruct the original conversation data (word behind TRUE CONVERSATION:). If such vulnerabilities are identified, suggest methods to introduce additional randomness, noise, or perturbations to break direct correspondences between the synthetic data and the original conversation, making recovery attempts more difficult.

Only if the generated data is completely safe and satisfies all the above privacy requirements and prevents the recovery of the original data, include the word 'THISISSAFE' anywhere in your response to signal the end of the evaluation process. Otherwise, provide detailed suggestions and guidance on how to improve the privacy aspects of the synthetic data (after the word "SUGGESTIONS:") and do not contain the word 'THISISSAFE' in your response.

If the data is deemed safe, please also extract the safe synthetic data (the text after 'GENERATED CONVERSATION:') and return it in the following format:
SAFE_DATA: [BEG]<safe_synthetic_data>[END]THISISSAFE

Note that your job is only to assess the privacy level of generated data, you can answer either suggestions (SUGGESTIONS) or this data is safe (SAFE_DATA: [BEG]<safe_synthetic_data>[END]THISISSAFE), does not provide irrelevant answers.

Table 16: System messages: (privacy agent)

Prompt
Given the following context, extract the useful or important part of the Context.
Remember, *DO NOT* edit the extracted parts of the context.

Table 17: Prompt of paraphrase

Para(Joe)
Context: {Context}
Please rewrite the given context, ensuring it does not contain any private or sensitive information. Follow these guidelines:
1. Personally Identifiable Information (PII): Check if the synthetic data contains any PII, such as names, addresses, phone numbers, email addresses, or other information that can directly identify an individual. If found, remove or anonymize such information
2. Sensitive Attributes: Anonymize or remove sensitive attributes including but not limited to race, ethnicity, religion, political affiliation, sexual orientation, health status, or financial information.
3. Contextual Privacy: Evaluate if the synthetic data, when combined with other publicly available information, could potentially lead to the identification of individuals or reveal sensitive information about them. If such risks are identified, try to mitigate these contextual privacy issues.
4. Data Linkage: Assess if the synthetic data can be linked with other datasets to infer additional sensitive information about individuals. If linkage risks are found, use techniques such as data perturbation or aggregation to reduce these risks.
5. Semantic Consistency: Ensure that the privacy-preserving transformations applied to the synthetic data maintain semantic consistency and do not introduce any unintended biases or inaccuracies.
6. Original Data Recovery: Analyze the synthetic data to determine if it could potentially allow attackers to recover or reconstruct the original conversation data. If such vulnerabilities are identified, try to introduce additional randomness, noise, or perturbations to break direct correspondences between the synthetic data and the original conversation, making recovery attempts more difficult.
Please provide the rewritten context that addresses these privacy concerns while maintaining the essential meaning and utility of the information.

Table 18: Prompts used for Para(GPT-4o, Privacy)

Origin context	Stage-1 context	Stage-2 context
input: my 6 year old son was ill last week with a feeling of general unwellness, he had a runny nose, sore stomach (all over , not restricted to any one area)and also pain in his knee (whicChatDoctore and went, was not constant). We saw the GP who thought it was a viral illness. He got better after about 5 days. He was well for perhaps 2 days and the pain in his tummy started again the night before last. Yesterday morning he wouldnt eat anything before going to school as he said he was full despite not eating his dinner the night before either. Last night he woke from his sleep with a pain in his knee. This morning he seems quite well again. I am wondering if there is any reason for concern. output: Hi, Thank you for asking question on Chat Doctor. Recurrent abdominal pain occurs due to worm infestation, urinary tract infection, Amoebic colitis and several other causes. Try metronidazole for 5 days as well as Albendazole once after food. Syrup containing digestive enzymes may help. Better consult pediatrician to pinpoint the diagnosis. Hope this answer will serve your purposeless feel free to ask any more queries if requiredTake care Chat Doctor. V. Subrahmanyam MD;Disassociate professor of pediatrics	Patient: My 6-year-old son had a runny nose, sore stomach, and pain in his knee last week. He got better after 5 days but the pain in his stomach returned the night before last and he woke up with pain in his knee last night. Is .there any reason for concern? Doctor: Recurrent abdominal pain could be due to worm infestation, urinary tract infection, amoebic colitis, or several other causes. I recommend consulting a pediatrician to pinpoint the diagnosis. For now, try metronidazole for 5 days as well as Albendazole once after food and syrup containing digestive enzymes.'	Patient: My son had a viral illness last week and got better, but the pain in his stomach and knee came back. Should I be worried? Doctor: Recurrent abdominal pain in children can be caused by various conditions, including worm infestation, urinary tract infection, amoebic colitis, and others. I recommend trying metronidazole and albendazole for treatment, and consulting a pediatrician for a more accurate diagnosis and next steps in treatment. Additionally, syrup containing digestive enzymes may help.
input: hi, m 25 years old n married for 5 years i had first normal pregnancy bt unfortunately my baby didnt survived, after again i had ectopic pregnancey due to which my right fellopin tube is removed my periods are also not regular. please advice for solution we are desperate to have our own baby output: Welcome to Chat Doctor there are a lot of issues which u need to take up seriously.first the cause for ectopic pregnancy needs to be given importance cos there are more chances of getting ectopic in subsequent pregnancy.since u have only one fallopian tube u need to examined thoroughly to rule out any congenital defects in the tube and the uterus.I would advise u to go to an infertility clinic and take their advice. u can very much conceive and have your own baby.all the best	Patient: I am a 25-year-old female who has had a normal pregnancy in the past but unfortunately lost the baby. I also had an ectopic pregnancy, which resulted in the removal of my right fallopian tube. My periods are irregular, and my husband and I are desperate to have our own baby. Can you please advise me on what options are available for me to conceive and have a baby? Doctor: Based on your medical history, I advise you to seek examination and advice from an infertility clinic to rule out any congenital defects in the remaining fallopian tube and uterus. You can still conceive and have your own baby. The clinic will be able to identify the cause of your ectopic pregnancy and offer treatment options that can increase your chances of a successful pregnancy in the future. It is important to take their advice and follow-up with them regularly.	Patient: Doctor, I had an ectopic pregnancy resulting in the removal of my right fallopian tube. What can I do to have my own baby? Doctor: I understand your concern. The first step is to go to an infertility clinic to be thoroughly examined to rule out any congenital defects in the tube and uterus. The cause of the ectopic pregnancy needs to be given importance as there are more chances of getting ectopic in subsequent pregnancies. The infertility clinic will provide you with advice on treatment options, and please know that you can very much conceive and have your own baby.
input: Hi, am 35 years old and have been married for 8 of these. For some years now, I can hardly do more than one round of sex. Only one and I cant get it on again. I think my wife is not happy, she would like to have two or three rounds as she tells me her friends do. Infact last night she asked me if it is my body, if am sick, weak or simply not interested in her as much as in the past? Personally, I always thought we had no problem in that department? What is wrong with me? output: Hi, Regular exercise, physical games and yoga can help you. Along with then you can take home-cooked meals, low-fat food. Hope I have answered your query. Let me know if I can assist you further. Take care Chat Doctor. R. Raveen	Patient: I'm a 35-year-old male and I'm having difficulty with sexual performance. My wife is unhappy with our sex life and I can only perform one round of sex. What is wrong with me and how can I improve my sexual performance? Doctor: Regular exercise, physical games, and yoga can help improve your sexual performance. It's normal to have concerns about sexual performance, and there are steps you can take to improve it. Eating low-fat home-cooked meals can also help. It's important to maintain a healthy lifestyle to improve sexual performance.	Patient: I've been having difficulty having more than one round of sex for several years now, and my wife is concerned. Is there something wrong with me? How can I improve my sexual performance? Doctor: Regular exercise, physical games, and yoga can help improve your sexual performance. It's understandable that you're concerned about satisfying your wife sexually, and I want to reassure you that your concerns are valid. In addition to exercise, lifestyle changes such as home-cooked meals and low-fat food can also improve your sexual health. It's important to prioritize your overall health and well-being, as this can have a positive impact on your sexual performance.

Methods	NQ (EM)	CQA (EM)
Stage-1	0.330	0.510
Stage-2	0.380	0.490
Aug-PE, $t = 0$	0.190	0.375
Aug-PE, $t = 1$	0.315	0.430

Table 22: Utility results on NQ and CQA datasets using the Exact Match (EM) metric

Role	Attribute	Present?	Notes
Patient	Clear Symptom Description	Yes	Describes kidney issues, bone symptoms, and short stature
	Medical History	Yes	Mentions underdeveloped kidneys and prior consultations
	Current Concerns	Yes	Expresses feeling overwhelmed and uncertain
	Recent Events	Yes	Recent consultations, surgery ruled out
	Specific Questions	Yes	Asks for advice on treatment and care
Doctor	Clear Diagnosis or Assessment	Yes	Suggests possible rickets due to vitamin D deficiency
	Reassurance and Empathy	Yes	Offers encouragement and understanding
	Treatment Options and Explanations	Yes	Recommends vitamin D, medication, dietary changes
	Follow-up and Next Steps	Yes	Advises stabilizing kidney health before surgery
	Education and Prevention	Yes	Explains relationship between kidney health and bone condition

4	Provide a summary for the Patient’s information, including: [Attribute 1: Clear Symptom Description] [Attribute 2: Medical History] [Attribute 3: Current Concerns] [Attribute 4: Specific Questions or Requests] Then, provide a summary for the Doctor’s information, including: [Attribute 1: Diagnosis or Clinical Impression] [Attribute 2: Empathy and Emotional Support] [Attribute 3: Treatment Plan or Recommendations] [Attribute 4: Follow-up Plan or Next Steps]	Patient: Hello doctor, my name is Adnan Bashir, I’m 25 years old from Pakistan. I’m really worried because my kidneys aren’t working properly — they’re small in size, and my blood urea and creatinine levels are very high. This has also affected my height; I’m only 4 feet 10 inches tall. On top of that, I have rickets that is getting worse and spreading in both my legs day by day. I’ve seen several doctors here, but none are willing to operate on me because they say the surgery is too risky and I could die due to my kidney condition. I don’t know what to do — can you please help me or advise me on what steps I should take? Doctor: Hello Adnan, thank you for sharing your concerns. I understand you’re going through a very difficult time. Based on what you’ve described, it sounds like your rickets may be related to a vitamin D deficiency, and taking vitamin D supplements could help stop its progression. Regarding your kidney issues, you’re right to be cautious — with your current high blood urea and creatinine levels, undergoing surgery would indeed carry a high risk and could potentially lead to renal failure. The most important step right now is to focus on improving your kidney function with proper medication and strict dietary changes under medical supervision. Once your kidney condition stabilizes, other treatment options may become safer to consider. I hope this guidance is helpful to you.
5	Provide a summary for the Patient’s information, including: [Attribute 1: Clear Symptom Description] [Attribute 2: Medical History] [Attribute 3: Current Concerns] [Attribute 4: Recent Events] [Attribute 5: Specific Questions] Then, provide a summary for the Doctor’s information, including: [Attribute 1: Clear Diagnosis or Assessment] [Attribute 2: Reassurance and Empathy] [Attribute 3: Treatment Options and Explanations] [Attribute 4: Follow-up and Next Steps] [Attribute 5: Education and Prevention]	Patient: Hello doctor, my name is Adnan Bashir, I’m 25 years old and from Pakistan. I’m really worried because my kidneys are not functioning properly — their size is small, and my blood urea and creatinine levels are very high. Because of this, doctors here refuse to operate, saying it’s too risky and that I might not survive the surgery. I’ve also developed rickets, which is spreading in both of my legs and affecting my ability to move. On top of that, I have a short height of only 4 feet 10 inches, which I believe is also due to my kidney condition. I’ve been to many doctors, but no one is helping. Please tell me what I should do. Doctor: Hello Adnan, thank you for reaching out and sharing your situation. I understand how difficult and worrying this must be for you. From what you’ve described, it sounds like your rickets may be caused by a vitamin D deficiency, which can be treated with supplements to help stop the disease from progressing further. However, given your significantly impaired kidney function, surgery right now would carry serious risks, including the possibility of kidney failure under the stress of the operation. The best course of action is to first stabilize your renal function through medications and strict dietary management. Once your kidney health improves, doctors can safely consider other treatments. In the meantime, addressing the vitamin D deficiency can help manage the symptoms in your legs. I hope this guidance gives you a clearer direction forward.
6	Provide a summary for the Patient’s information, including: [Attribute 1: Symptom Description] [Attribute 2: Medical History and Comorbidities] [Attribute 3: Lifestyle or Social Factors] [Attribute 4: Current Concerns or Discomfort] [Attribute 5: Recent Health Events or Tests] [Attribute 6: Specific Questions or Expectations] Then, provide a summary for the Doctor’s information, including: [Attribute 1: Diagnosis or Clinical Reasoning] [Attribute 2: Emotional Support and Reassurance] [Attribute 3: Treatment Plan with Rationale] [Attribute 4: Risk-Benefit Communication] [Attribute 5: Preventive Advice or Health Education] [Attribute 6: Next Steps or Monitoring Plan]	Patient: Hello doctor, my name is Adnan Bashir, I’m 25 years old from Pakistan. I’ve been diagnosed with kidney problems—my kidneys are small and not working properly, and my blood urea and creatinine levels are very high. Because of this, several doctors in Pakistan have refused to perform surgery, saying it’s too risky and I might not survive. I’m also suffering from rickets, which is affecting both my legs and getting worse day by day. This condition, along with my kidney disease, has also affected my height—I’m only 4 feet 10 inches tall. I’m extremely worried and don’t know what to do. Can you please advise me on how I can manage my condition and whether there’s any way to stop the progression of my leg disease? Doctor: Hello Adnan, thank you for reaching out and sharing your concerns. Based on what you’ve described, it sounds like your rickets may be related to a vitamin D deficiency, which can be managed with proper vitamin D supplementation to help stop its progression. However, because your kidney function is significantly impaired—as shown by your elevated blood urea and creatinine levels—undergoing surgery right now would carry a high risk, potentially leading to kidney failure. That’s likely why your doctors have advised against it. Before considering any surgical option, it’s essential to stabilize your renal function with the help of medications and strict dietary measures. I understand how difficult and frightening this must be for you, but please know that improving your kidney health is the first step. Focus on managing your condition with medical treatment, and avoid any risky procedures until your health has stabilized.
