a stairwell leading upwards with railing and stair lights

Step 4:

(**environment:)**
To your straight-ahead is,
another flight of stairs leading to a large window
To your 90 degree right is,
a hallway lined with posters and a bench
To your back is,
a flight of stairs that leads down with railing and stair lights

You chose:

(🤖 **navigation agent:)**
a hallway lined with posters and a bench

Step 5:

(🗺️ **environment:)**
To your straight-ahead is,
a corridor leading to an intersection with a water fountain to the right
To your 90 degree left is,
a large window that illuminates the corridor and gives a view of the street
To your 90 degree right is,
a library entrance with a signage
To your back is,
the hallway lined with posters and a bench

You chose:

(🤖 **navigation agent:)**
a library entrance with a signage

Step 6:

(🗺️ **environment:)**
To your straight ahead is,
a library filled with wooden bookshelves and desks with desk lamps
To your back is,
a corridor leading back to the stairwell

You chose:

(🤖 **navigation agent:)**
Stop

K More Examples of Generated Trajectories

We plot more examples of the generated trajectories from GPT-4 below:

Example #1

Navigation instruction:

Begin in the basement, walk towards the pool table. Pass the pool table and ascend the staircase. At the top of the stairs, turn right and walk through the hallway. Turn left into the den, walk through and stop by the window.

Navigation trajectory:

Step 1:

(🗺️ **environment:)**
To your straight ahead is,
a basement with a pool table, a bar, and a seating area
To your 90 degree left is,
a wall with various framed photos and a door
To your 150 degree right is,
a storage area filled with boxes and shelves

You chose:

(🤖 **navigation agent:)**
a basement with a pool table, a bar, and a seating area

Step 2:

(🗺️ **environment:)**
To your back is,
a basement entrance with a staircase leading down
To your 120 degree left is,
a basement with a bar, television, and several chairs
To your straight ahead is,
a basement with a pool table, a dartboard, and a bar
To your 90 degree right is,
a staircase leading upwards with a wooden railing

You chose:

(🤖 **navigation agent:)**
a basement with a pool table, a dartboard, and a bar

Step 3:

(🗺️ **environment:)**
To your back is,
a basement with a seating area and framed photos on the wall
To your straight ahead is,
a pool table surrounded by chairs and a dartboard on the wall
To your 150 degree left is,
a basement with a bar, television, and several chairs
To your 90 degree right is,
a staircase leading upwards with a wooden railing

You chose:

(🤖 **navigation agent:)**
a staircase leading upwards with a wooden railing

Step 4:

(🗺️ **environment:)**
To your back is,
a basement with a pool table and a dartboard on the wall
To your 90 degree left is,
a hallway with various framed photos on the walls
To your straight ahead is,
a den with a large bookshelf, couch, and coffee table

You chose:

(**navigation agent:)**
a hallway with various framed photos on the walls

Step 5:

(**environment:)**
To your back is,
a staircase leading downwards into the basement
To your straight ahead is,
a long hallway with several doors leading to other rooms
To your 120 degree right is,
a den with a comfortable seating area and a bookshelf

You chose:

(**navigation agent:)**
a long hallway with several doors leading to other rooms

Step 6:

(**environment:)**
To your back is,
a hallway with various framed photos on the walls
To your 90 degree left is,
a den filled with cozy furniture, bookshelves, and a television
To your 90 degree right is,
a bedroom with a large bed, dresser, and a window

You chose:

(**navigation agent:)**
a den filled with cozy furniture, bookshelves, and a television

Step 7:

(**environment:)**
To your back is,
a hallway leading to other parts of the house
To your 90 degree left is,
a den with several bookshelves, a fireplace, and a large rug
To your straight ahead is,
a window overlooking the garden outside

You chose:

(**navigation agent:)**
Stop

Example #2

Navigation instruction:

From the garage entrance, walk into the kitchen. Turn left and walk past the stove. Continue straight into the family room, then walk towards the sliding glass doors. Step outside and stop near the barbecue grill.

Navigation trajectory:

Step 1:

(**environment:)**
To your straight ahead is,
a clean garage with a parked car and a workbench
To your 90 degree left is,
a laundry room with a washer and a dryer
To your back is,
a driveway leading up to a garage door
To your 120 degree left is,
a garage entrance with an open door leading inside the house

You chose:

(**navigation agent:)**
a garage entrance with an open door leading inside the house

Step 2:

(**environment:)**
To your 30 degree left is,
a kitchen with a stove, a refrigerator, and a microwave oven
To your 90 degree right is,
a small mudroom with a shoe rack and a coat hook
To your back is,
a view of a garage with a car and a workbench

You chose:

(**navigation agent:)**
a kitchen with a stove, a refrigerator, and a microwave oven

Step 3:

(**environment:)**
To your straight ahead is,
a large kitchen with a stove and a range hood
To your 30 degree right is,
a kitchen with a center island and a sink on the countertop
To your 150 degree left is,
a kitchen with a refrigerator and a microwave oven
To your 120 degree right is,
a tiled floor leading to a hallway with a picture on the wall

You chose:

(**navigation agent:)**
a large kitchen with a stove and a range hood

Step 4:

(**environment:)**
To your straight ahead is,
a cozy family room with a TV and a fireplace
To your 90 degree right is,
a kitchen with a sink and a dishwasher
To your back is,
a kitchen with a countertop, a cooktop, and an oven

You chose:

(**navigation agent:)**
a cozy family room with a TV and a fireplace

Step 5:

(**environment:)**
To your 30 degree left is,
a sliding glass door leading to the backyard
To your 90 degree right is,
a comfortable sofa with a coffee table in front of a TV
To your back is,
a large kitchen with a stove and a range hood

You chose:

(**navigation agent:)**
a sliding glass door leading to the backyard

Step 6:

(**environment:)**
To your straight ahead is,
a well-maintained backyard with a barbecue grill and a dining table
To your 90 degree left is,
a sliding glass door leading inside the family room
To your back is,
a cozy family room with a TV and a fireplace

You chose:

(**navigation agent:)**
a well-maintained backyard with a barbecue grill and a dining table

Step 7:

(**environment:)**
To your 90 degree left is,
a barbecue grill on a patio in the backyard
To your straight ahead is,
a backyard with a dining table and chairs
To your 120 degree right is,
a backyard with a garden and a swing set
To your back is,
a sliding glass door leading inside the family room

You chose:

(**navigation agent:)**
Stop

Example #3

Navigation instruction:

Stand in front of the fireplace in the living room. Walk diagonally across the room, passing the sofa. Proceed through the door into the hallway. Turn left and continue toward the guest room. Stop just before entering and wait.

Navigation trajectory:

Step 1:

(**environment:)**
To your straight ahead is,
a living room with a fireplace and two chairs
To your 30 degree left is,
a living room with a large window and a dark brown couch
To your 90 degree right is,
a living room with a flat screen tv and a view of the backyard

You chose:

(**navigation agent:)**
a living room with a fireplace and two chairs

Step 2:

(**environment:)**
To your 60 degree left is,
a living room with a fireplace and a floor lamp
To your 30 degree right is,
a living room with a dark brown couch and a coffee table
To your straight ahead is,
a living room with a white rug in the middle

You chose:

(**navigation agent:)**
a living room with a dark brown couch and a coffee table

Step 3:

(**environment:)**
To your back is,
a living room with a fireplace and a christmas tree

```
To your 150 degree left is,
a living room with two chairs and a
painting on the wall
To your straight ahead is,
a wooden door leading to a hallway
```

You chose:

(**navigation agent:)**

```
a wooden door leading to a hallway
```

Step 4:

(**environment:)**

```
To your 90 degree left is,
a hallway with a view of a staircase
and a table
To your straight ahead is,
a hallway with a painting on the wall
and an open door
```

You chose:

(**navigation agent:)**

```
a hallway with a painting on the wall
and an open door
```

Step 5:

(**environment:)**

```
To your back is,
a hallway with a wooden floor and a
closed door
To your 120 degree left is,
a guest bedroom with a neatly made
bed and a dresser
To your 30 degree right is,
a hallway with white walls and
floor-to-ceiling mirrors
```

You chose:

(**navigation agent:)**

```
Stop just before entering the guest
bedroom
```

Planning and Editing What You Retrieve for Enhanced Tool Learning

Tenghao Huang[1] **Dongwon Jung**[1] **Muhao Chen**[2]

Abstract

Recent advancements in integrating external tools with Large Language Models (LLMs) have opened new frontiers, with applications in mathematical reasoning, code generators, and smart assistants. However, existing methods, relying on simple one-time retrieval strategies, fall short on effectively and accurately shortlisting relevant tools. This paper introduces a novel PLUTo (Planning, Learning, and Understanding for TOols) approach, encompassing "Plan-and-Retrieve (P&R)" and "Edit-and-Ground (E&G)" paradigms. The P&R paradigm consists of a neural retrieval module for shortlisting relevant tools and an LLM-based query planner that decomposes complex queries into actionable tasks, enhancing the effectiveness of tool utilization. The E&G paradigm utilizes LLMs to enrich tool descriptions based on user scenarios, bridging the gap between user queries and tool functionalities. Experiment results demonstrate that these paradigms significantly improve the recall and NDCG in tool retrieval tasks, significantly surpassing current state-of-the-art models.

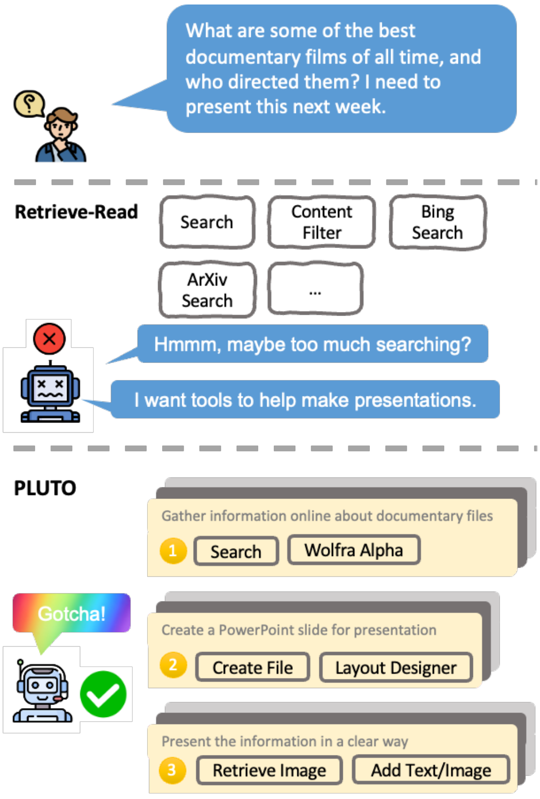

Figure 1: Comparison between conventional Retrieve-and-Read and PLUTo paradigm. Unlike the conventional one-time Retrieve-and-Read paradigm that may lead to retrieving an ineffective set of tools, PLUTo efficiently parses a complex query and distills it into actionable sub-queries that facilitate accurate retrieval of appropriate tools.

1 Introduction

The community has shown increasing interest in integrating external tools and interfaces with LLMs since tools often provide complementary functionalities in complex tasks such as dialogues (Bubeck et al., 2023), mathematical reasoning (Lu et al., 2022), and code generation (Yadav et al., 2023). To realize tool augmentation, LLM systems typically employ a retriever mechanism to select relevant tools from a candidate pool and write function API calls based on the retrieved tools. The introduction of external tools also allows LLMs to address complicated user queries. Schick et al. 2023 show that LLMs, incorporating simple tools, achieve better performance on downstream tasks. Gupta and Kembhavi 2023 attempt to solve compositional visual tasks via image processing modules and language-instructed computer vision models. More recently, the integration of LLMs and tools empower LLMs, opening up new possibilities in areas like scientific discovery (Yang et al., 2023), automated efficiency, and smart assistant applications (Shu et al., 2022).

Nonetheless, emergent approaches for LLMs with tool integration present several distinct challenges. One primary concern is that current LLM agents still adopt simple retrieval-and-read strategies (Patil et al., 2023; Qin et al., 2023), lacking

Findings of the Association for Computational Linguistics: NAACL 2024, pages 975–988
June 16-21, 2024

the dynamic adaptability required for addressing complex queries. As shown in Fig. 1, the conventional Retrieve-and-Read paradigm, solely relying heavily on similarity matching, falls short of retrieving diverse types of tools to address a complex user query. This limitation is further exacerbated by the semantic gap between user queries and tool descriptions. Particularly, user queries can be ambiguous and complex, often requiring a deep understanding of the user's intent and the context of the query (Kulkarni et al., 2023). On the other hand, human-written tool descriptions can be abstract and lack essential details for deciding their utilities, leading to a mismatch between what the user needs and what the tool is perceived to offer. Additionally, current models tend to finetune on static tools, posing challenges to their robustness in the ever-evolving tool environment where new tools emerge and existing ones become obsolete (Lübke et al., 2019). There is limited research on retrieval enhancement strategies in non-finetuned settings. These gaps highlight crucial areas for future research and development in LLM and tool integration.

In this paper, we leverage LLM's world knowledge and reasoning ability to augment the retrieval and utility of tools in response to complex user queries, by designing a novel framework PLUTo (Planning, Learning, and Understanding for TOols) [1]. Our first contribution is the introduction of a novel *Plan-and-Retrieve* for tool integration. While prior Retrieve-and-Read approaches only retrieve once at the beginning, our *Plan-and-Retrieve* paradigm is designed to adaptively adjust its strategies based on the outcomes of its self-evaluations, ensuring a continuous refinement of the tool selection process. This paradigm is structured into two core modules. The first module, the retriever, leverages neural (dense) retrieval techniques (Karpukhin et al., 2020) and LM-likelihood scoring mechanisms (Song et al., 2023a) to efficiently shortlist relevant tools from a vast pool of candidates in response to a user query. This process ensures that the most pertinent tools are identified quickly, laying a foundation for more effective tool utilization. Inspired by recent advancements of adaptive retrieval-augmented generation (RAG; Jiang et al. 2023; Yoran et al. 2023), we design an LLM-based query planner that autoregressively decomposes complex user queries into manageable, task-oriented actions as the second module. Following the decompositions, the query planner selects the most suitable ones from the retrieved tools. It goes further by evaluating the effectiveness of selected tools and proposing the next action toward addressing the user query. This *Plan-and-Retrieve* paradigm operates dynamically, embodying a sophisticated feedback loop that interlinks the retrieval of tools with subsequent refinement, evaluation, and planning stages.

Our second contribution is the proposal of *Edit-and-Ground* paradigm that utilizes user queries' rich contextual information and LLM's extensive world knowledge for enriching descriptions of tool functionalities. Research has shown that informed tool documentations can enhance the interaction between LLMs and tools (Hsieh et al., 2023). However, documenting tool functionalities at scale can be tedious for humans. Yang et al. 2023 show LLMs can follow instructions and optimize real-world applications. Leveraging the optimization ability of the LLM, our tool-grounding agent optimizes under-informative tool descriptions by learning and abstracting information from tools' user scenarios. By editing tool descriptions to make them more aligned with tools' user scenarios, the agent bridges the gap between user queries and tool functionalities, enhancing the overall effectiveness of tool retrieval and usage.

In conclusion, this paper advances the field of tool integration with LLMs by introducing the novel Plan-and-Retrieve and Edit-and-Ground paradigms. Experiments show that our paradigms improve the recall and NDCG of tool retrieval tasks, significantly outperforming current state-of-the-art (SOTA). Our downstream evaluation suggests that the improvement gained during the retrieval phase, such as higher accuracy and relevance in responses, significantly contribute to successfully addressing the user queries.

2 Related Works

Retrieval-Augmented LLM. Early studies on Retrieval-Augmented LLMs typically incorporate embeddings of retrieved passages as a part of the latent representation of the LM (Chen et al., 2017; Lee et al., 2019). More recent works like REALM (Guu et al., 2020) and RAG (Lewis et al., 2021) have demonstrated the effectiveness of in-context augmentation and its improvement on knowledge-

---

[1] Code is available at `https://github.com/tenghaohuang/PLUTo`

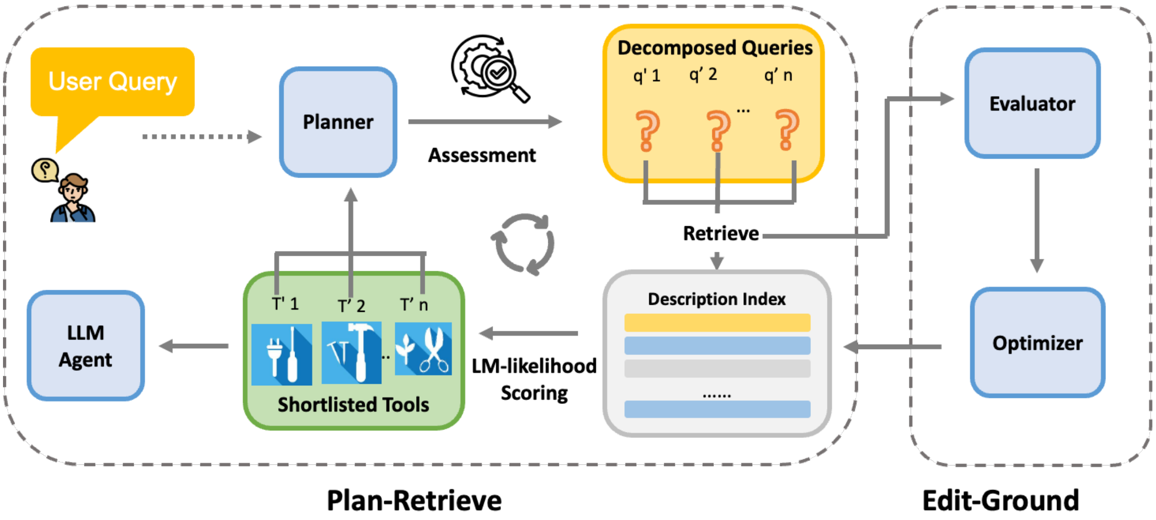

Figure 2: An overview of the PLUTO approach.

intensive tasks. There is also work (Mallen et al., 2023) that explores how Chain-of-Thought (CoT) could guide a multi-turn Retrieve-and-Read process to solve open-domain questions and perform fact verification.

However, the massive action space and tool functionality variance in tool-oriented tasks pose challenges to LLMs during planning. An erroneous step in planning can lead to a faulty loop, such as continually calling a tool in the wrong way or hallucinating non-existing tools. Our Plan-and-Retrieve paradigm, employing furtherest planning assessment (Zhu et al., 2023), enforces reasonable and goal-oriented decompositions of user queries. The recently proposed ReAct framework (Yao et al., 2022) asks LLM to plan future actions based on its observation of environments. In the context of tool-oriented tasks, the plan builds upon the execution results of retrieved tools. Such practice running and verifying each tool at retrieval time can be expensive and time-consuming at scale. In contrast, our Plan-and-Retrieve paradigm fully leverages LLM's internal representation of world knowledge to propose plans in response to user queries, therefore guaranteeing both time and cost efficiency as an execution-free paradigm.

Tool Learning. Tool learning refers to the process where LLMs not only process and generate language-based responses but also learn to interact with and utilize external tools to enhance their capabilities (Nakano et al., 2022; Schick et al., 2023; Shen et al., 2023; Qian et al., 2023; Song et al., 2023b; Xu et al., 2023; Li et al., 2023; Hao et al., 2023; Zhang et al., 2023). By incorporating tools, LLMs can offer solutions in various areas, including visual-language processing (Gupta and Kembhavi, 2023; Wu et al., 2023), mathematical reasoning (Lu et al., 2023), and tasks in specialized domains (Jin et al., 2023; Tang et al., 2023b).

However, previous research on tool learning mainly focused on teaching LLMs to use tools, but ignores the importance of shortlisting relevant tools. In this paper, we focus on using LLMs to improve the tool retrieval process. In contrast to previous researches that heavily rely on finetuning retrievers (Schick et al., 2023; Patil et al., 2023) to shortlist tools, we propose a novel Edit-and-Ground paradigm, leveraging LLMs' parametric knowledge to learn and create more informative descriptions for tools. This approach seeks to provide richer information for the retriever, leading to more accurate retrieval.

3 Task and Data

We hereby formulate the task of tool retrieval and describe the dataset for this task.

3.1 Task Definition

The tool retrieval process involves taking a user query Q and an index base of tool descriptions $D = \{d(t_1), d(t_2), \ldots, d(t_n)\}$ as input, where each $d(t)$ represents the description of each tool t. The retriever then sifts through the tool descriptions in D and shortlists a relevant tool set $T = \{t_1, t_2, \ldots, t_k\}$ that are potentially suited to address aspects of the user query Q. It is essential to underline that unlike conventional retrieval tasks, the task of tool retrieval is goal-oriented in nature, which means the set of retrieved tools T should be able to address the user query Q.

The systems are expected to accurately retrieve relevant tools and understand the user intents and complex synergy between tools, thus truly assisting users in problem-solving processes.

3.2 Dataset

Existing datasets for tool learning, such as those delineated in (Li et al., 2023; Patil et al., 2023; Tang et al., 2023a; Xu et al., 2023), provide insights into the field. Nonetheless, these datasets exhibit limitations, where they only cover a limited number of tools or solely support simple single-tool usage scenarios, where user queries are simple and could be addressed by a single tool.

Contrastingly, Qin et al. (2023) proposed ToolBench, a dataset covering more than 3,000 tools from 49 categories (such as advertising, data analysis, and transportation) and support complex, multi-tool user scenarios. In these scenarios, a single user query necessitates the sequential application of multiple tools, each contributing uniquely to the resolution of the query. The ToolBench dataset synergizes with the RapidAPI Hub, a prominent API marketplace that consolidates a vast array of real-world APIs. The multi-tool query creation process involves selecting representative tools within each category or collection, crafting queries to mimic real-world problem-solving scenarios.

Given our research focus and the nature of our study, we have chosen to concentrate on the *Intra-Category* setting of the ToolBench dataset. The intra-category setting provides high-quality user queries, where the hierarchies of tools are clearly defined based on their main functionalities. It motivates understanding complex interactions and synergies between tools that share a common functional domain. The setting mirrors real-world situations where problem-solving often demands a multifaceted and integrative use of diverse tools. The ToolBench dataset annotates paths of executed tools that successfully address the user queries as solution paths. The average length of the solution paths is 4. We take the annotated solution paths as the ground truth for our task.

4 Method

In this section, we describe the proposed framework to integrate tools with LLMs for addressing complex user queries. Our methodology is grounded in two innovative paradigms: the Plan-and-Retrieve (P&R; §4.2) and Edit-and-Ground (E&G; §4.3). We discuss the coordination between two paradigms in §4.4.

4.1 Method Overview

PLUTo integrates two key paradigms, Plan-and-Retrieve (P&R) and Edit-and-Ground (E&G), to effectively address complex user queries with LLMs.

The **Plan-and-Retrieve** paradigm is a two-stage process. The *Plan* stage decomposes user queries into focused sub-queries, while the *Retrieve* stage matches these sub-queries with relevant tools.

The **Edit-and-Ground** paradigm, consisting of the *Evaluator* and *Optimizer*, focuses on enhancing tool descriptions.

These paradigms are designed to work in tandem. P&R paradigm addresses immediate user queries, while E&G actively identifies and collects under-informative tool descriptions for optimization.

4.2 Plan-and-Retrieve

The Plan-and-Retrieve (P&R) paradigm is designed as a two-stage process to effectively address complex user queries.

Plan. In the *Plan* stage, a LLM-based planner autoregressively decomposes the user query Q into sub-queries $q_1, q_2, \ldots, q_n$. To ensure the robustness and quality of the decomposed sub-queries, we follow Zhu et al. (2023). Specifically, for each step of sub-query generation, the planner first generates a batch of hypotheses. Then, we cluster the generated hypotheses along with previously created sub-queries via K-means clustering algorithm. Finally, we select a sub-query from the hypotheses that distinguishes the most from the previous sub-queries to proceed[2].

As shown in Fig. 2, the planner autoregressively decomposes the user query Q into more fine-grained sub-queries based on assessments at inference time. After the generation of a sub-query q_t, the planner evaluates whether the original query Q has been satisfactorily achieved based on the current planning history. If the evaluation determines that the goal has been met, the iterative process concludes. Otherwise, the planner proceeds to generate the subsequent sub-query q_{t+1}. This active and autoregressive planning at inference time facilitates a more focused understanding of the tools. We use the following prompt template for the planner.

---

[2] Please refer to Appx. §A for algorithm implementation.

Planner Prompt

You are given a user query requiring multi-step actions and reasoning. Output an immediate next action to achieve the user query.
Previous Actions: {*Planning History*}
User Query: {*Q*}
Output:

Retrieve. In the *Retrieve* stage, for each sub-query q_i, the retriever shortlists the most suitable tools $T_i \in D$. We first retrieve a pool of candidate tools that matches q_i, represented as

$$T_i' = Ret(q_i), \tag{1}$$

where Ret represents the retriever.

To enhance the robustness of retrieval, we re-rank the candidate tool set T_i' by LM-likelihood score between the sub-query q_i and each tool $t_j \in T_i$, which is calculated as follows:

$$\text{LM-likelihood}(q_i, t_j) = -\log P(q_i, d(t_j)). \tag{2}$$

Based on the re-ranked tools, we choose the top-5 tools $T'_{i,top-5}$ and feed them into a LLM-based predictor, which outputs a shortlisted tool set T_i from the candidate tool set $T'_{i,top-5}$ that are relevant to q_i. We use this prompt for the predictor.

Predictor Prompt

You are given candidate tools that can be potentially used to solve current goal. Among candidate tools, select a list of relevant tools which would help achieve the current goal.
Current Goal: {*q*}
Candidate Tools: {*T'*}
Output:

As a result, the final shortlisted tool set T is formed by

$$T = \bigcup_{i=1}^{n} T_i, \forall i \in [1, n] \cap \mathbb{Z}. \tag{3}$$

For the choice of Ret, we adopt a neural (dense) retriever method. For each sub-query q_i, the dense vector representation $\mathbf{q}_i$ is obtained by passing q_i through a dense encoder. Similarly, we obtain dense representation $\mathbf{d}$ through a dense encoder for each tool description d. The tool index corpus D is formed as a collection of $\mathbf{d}$.

The P&R module interleaves *Plan* and *Retrieve* until the planner evaluates that the user query has been sufficiently decomposed and addressed through the retrieved tools. The module then returns T as the relevant tools to address the user query.

Algorithm 1 Edit-and-Ground Algorithm

```
Input: Trainset, Devset, Toolset, Failure_Threshold, Max_Rounds
Output: Optimized Tool Descriptions
Initialize cache for tools in Toolset
cur_round = 0

while cur_round < Max_Rounds do
    ## Phase 1: Evaluate Retrieval Performance
    for each (query, gt_tools) in Trainset do
        predicted_tools ← P&R(query)
        for each tool in gt_tools do
            tool.trials += 1
            if tool not in predicted_tools then
                tool.failure += 1
                tool.queries.add(query)    ▷ Failure queries
            end if
        end for
    end for

    ## Phase 2: Failed Tool Description Optimization
    for each tool in Toolset do
        if $\frac{tool.failure}{tool.trials}$ > Failure_Threshold then
            U ← Remove specific entities from tool.queries
            R ← Predict reasons for failure of U
            d(tool) ← tool.description
            d'(tool) ← E&G(tool, d(tool), U, R)

            ## Phase 3: Evaluate Performance of d'(tool)
            cur_recall ← Eval(Devset, d'(tool))
            if tool.recall < cur_recall then
                tool.description ← d'(tool)
                tool.recall ← cur_recall
            end if
        end if
    end for
    cur_round += 1
end while
```

4.3 Edit-and-Ground

The Edit-and-Ground (E&G) paradigm focuses on refining under-informative tool descriptions to align them with user queries. As shown in Alg. 1, the evaluator examines the quality of tool descriptions by retrieval results. A tool description is viewed as under-informative if the number of failure cases of retrieval exceeds a pre-defined threshold. We collect such tools for later optimization.

Entity Filtering Prompt

Given an input query, remove specific entity information and return only the general query template. Make sure your method is generalizable to handle other queries.
{*Demonstrations*}
User Queries: {*Q*}
Output:

Subsequently, the optimizer takes a tool t with its base description $d(t)$ and U, a batch of relevant user queries, as input. To avoid the optimizer overfitting to a local batch, we use an LLM to filter out specific entities for each query in U. The entity filtering prompt template is shown as above.

To assist the optimizer in improving underperformed tool descriptions, we prompt LLM to generate reasons R explaining why the tool could be related and helpful in addressing user queries. The functionality assessment prompt template is shown below:

> **Functionality Assessment Prompt**
>
> Given a batch of user queries and a tool, predict a reason why the tool would be helpful to address the user queries.
> {*Demonstrations*}
> User Queries: {U}
> Tool: {*t: d(t)*}
> Output:

Finally, by prompting LLM with 1) base tool description $d(t)$, 2) entity-filtered user queries U, and 3) the reasons R, we obtain an enriched tool description $d'(t)$. Please refer to Fig. 4 in Appendix C for the prompt template. We formally represent this process as

$$d'(t) = E\&G(t, d(t), U, R). \tag{4}$$

The optimization process is executed in multiple rounds as described in Alg. 1. In each round, we evaluate the retrieval recall on the development set for each tool and compare it with the previous round. If the current round's recall is better than the previous one, we update the tool's description; otherwise, we keep the original description.

The Edit-and-Ground involves using the LLM's extensive world knowledge, combined with the contextual details provided by U, to edit and enhance $d(t)$. The result of this task is an enriched tool description $d'(t)$, expected to resonate more closely with real-world user scenarios and increase the utility of the tool in practical applications.

4.4 Paradigm Coordination and Inference

Our PLUTo framework employs strategic coordination of the Plan-and-Retrieve (P&R) and Edit-and-Ground (E&G) paradigms, phased to optimize the process of tool retrieval. This section elucidates the interaction between these paradigms during the optimization phase and the subsequent inference phase.

Optimization Phase. During the optimization phase, P&R and E&G operate alternatively. P&R is tasked with decomposing a user query Q into manageable sub-queries $q_1, q_2, \ldots, q_n$. These sub-queries facilitate a more focused retrieval of tools from the tool set D, ensuring that the process is aligned with specific aspects of the query.

During planning, the E&G paradigm is actively engaged in optimizing the descriptions of the tools within D. This optimization, leveraging the LLM's extensive knowledge base, is particularly targeted at tools that exhibit underperformance in retrieval effectiveness. By enriching these tool descriptions, E&G significantly enhances the overall retrieval process, making the toolset more responsive and aligned with the practical demands of diverse queries.

Inference Phase. At the time of inference, the P&R paradigm remains active, utilizing the previously enriched and optimized tool descriptions. In this phase, the E&G paradigm ceases its operation and does not engage in any further optimization of tool descriptions. The refined tool descriptions, already enhanced by E&G, now serve as a comprehensive resource for the retriever to draw upon in response to the decomposed sub-queries.

5 Experiments

In this section, we evaluate the proposed PLUTo framework for tool retrieval and compare it with baseline methods. We will delve into the details of our experimental setup (§5.1), discuss the results (§5.2) obtained, and perform an ablation study to understand strengths of different components (§5.3). By executing the retrieved tools, we evaluate their correctness in addressing user queries to further validate our findings (§5.4). We present case studies to qualitatively evaluate the strength of PLUTo framework (§5.5).

5.1 Experiment Setup

Evaluation Protocol. We evaluate using three metrics to assess the effectiveness of our tool retrieval system. *Recall (Rec)* measures the proportion of relevant tools that are successfully retrieved by our system. High indicates that the system is effective in identifying a comprehensive set of relevant tools for a given query and is more likely to yield a solution to address the user query. We also report the *Normalized Discounted Cumulative Gain (NDCG)* that evaluates the relevance and quality of ranked search results. In addition, we report *pass rate*, an automatic evaluation metric of ToolBench (Qin et al., 2023). The pass rate measures a system's ability to successfully address the user query with

Model	Retriever	Non-Finetuned		Finetuned	
		Rec	NDCG	Rec	NDCG
BM25	–	18.82	37.44	–	–
ToolRetriever	DPR†	19.58	50.98	27.80	71.21
	Contriever	31.78	74.70	42.77	79.16
PLUTo	DPR	36.65	75.10	43.27	79.93
	Contriever	**46.57**	**82.93**	**48.47**	**84.73**

Table 1: This table compares various tool retrieval models using Recall and NDCG metrics in both Non-Finetuned and Finetuned settings. It includes an ablation study on the impact of using different retrievers, demonstrating the generalizability of PLUTo. † indicates the previous SOTA implementation, as specified in (Qin et al., 2023).

a retrieved subset of tools in limited budgets by interacting with real-world RESTful APIs (§5.4).

To test the generalizability of our approach, we benchmark the tool retrieval performance under a Non-Finetuned setting, where we directly apply an off-the-shelf retriever model to comprehensively showcase PLUTo's adaptivity. To test the model's practical applicability, we also benchmark retrieval performance under Finetuned setting, where we finetune the retriever model on domain-specific knowledge. We evaluate 500 user queries for each setting.

Baselines. We compare our system against several representative retrieval methods. These include: (1) *BM25:* a widely-used probabilistic retrieval framework, calculating the relevance of documents to a query based on the frequency of query terms in each document; (2) *ToolRetriever*: a neural retrieval approach that achieves the current state-of-the-art (SOTA) performance on ToolBench retrieval task (Qin et al., 2023). To understand the flexibility of our framework, we benchmark PLUTo's performance when incorporated with different retrievers. Specifically, we use DPR (Karpukhin et al., 2020) and Contriever (Izacard et al., 2022).

Implementation Details. For the implementation of PLUTo, we use DSPy framework (Khattab et al., 2023) to facilitate efficient interaction between retriever and LLM. We choose ChatGPT[3] as our main LLM for both P&R and E&G. The maximum round for the E&G module is set to 5. For ToolRetriever, we retrieve top-5 tools using the respective retrievers. The data is divided into 70-15-15 splits for training, development, and testing, respectively. For our experiment, we randomly select 500 data samples from the test split for each setting mentioned in Evaluation Protocol section.

For the Finetuned settings, we finetune the neural dense retriever model by including negative samples during in-batch training (Karpukhin et al., 2020). For each positive pair of query q_j and its relevant tool d_j^+, we include n negative tools as negative samples. We use a cross-entropy loss with softmax function over the batch B:

$$L = -\frac{1}{B}\sum_{j=1}^{B} \log\left(\frac{e^{\mathbf{q}_j \cdot \mathbf{d}_j^+}}{e^{\mathbf{q}_j \cdot \mathbf{d}_j^+} + \sum_{i=1}^{n} e^{\mathbf{q}_j \cdot \mathbf{d}_{ij}^-}}\right) \quad (5)$$

5.2 Results

The experimental results, detailed in Tab. 1, underscore the significant advantages of our proposed PLUTo models. In the Non-Finetuned setting, PLUTo with Contriever showcases remarkable scores, achieving 46.57% in Recall, outperforming the best baseline by 9.92 points. This result shows the model's robust ability to identify relevant tools without the necessity for specific finetuning, a critical advantage in dynamic tool retrieval environments. We observe a consistent trend in the Finetuned setting, with the model scoring 48.47% in Recall, demonstrating a 5.7 points lead when compared with the Contriever baseline. This indicates that our model is highly effective on retrieving relevant tools.

Furthermore, our model outperforms baselines across all settings on NDCG scores. In the Non-Finetuned setting, our model leads by 8.23 points. In the Finetuned setting, our model beats the baseline by 4.57 points. These results reflect PLUTo not only the relevance of the tools retrieved but also their ranking in order of utility and applicability to the user's query, which is a indication to the model's nuanced understanding of tool utility.

---

[3] OpenAI. (2023). ChatGPT (November 21st version).

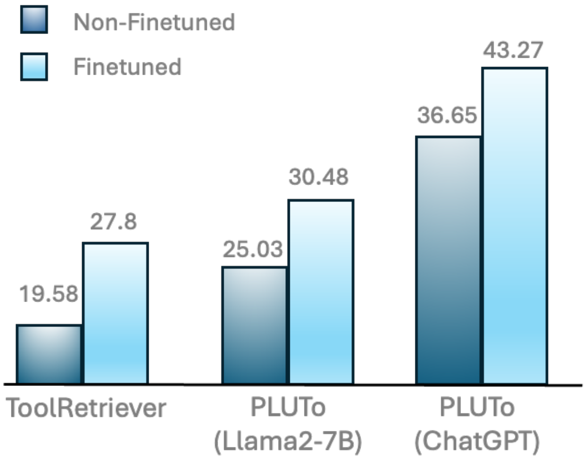

Figure 3: Performance comparison among different LLMs for Plan-and-Retrieve paradigm using Recall score. The backbone retriever is DPR.

To show the generalizability of PLUTo, we select different retrievers for the Plan-and-Retrieve (P&R) paradigm. We observe that PLUTo has synergy with both DPR and Contriever models, regardless of their different architecture, that achieves higher Recall and NDCG scores than the baselines. This indicates that PLUTo is a plug-n-play and retriever-agnostic framework that features effectiveness and flexibility under different circumstances.

The experimental results highlight the superior performance of PLUTo framework. Together, the P&R and E&G paradigms establish a dynamic and effective framework, which not only accurately interprets and responds to user queries but also maintains an evolving understanding of tool functionality. This duality ensures that PLUTo remains highly effective and adaptable in various setups, consistently aligning user needs with the most suitable tools and their capabilities.

5.3 Ablation Study

As shown in Fig. 3, we observe that both the Llama2 (Touvron et al., 2023) and ChatGPT variants show considerable improvements in tool retrieval capabilities, with notable increases in Recall and NDCG scores compared to baseline models. This consistent improvement across different LLM integrations conclusively demonstrates the robustness and effectiveness of our method. This finding is particularly important as it suggests that our approach is not overly reliant on any single LLM, thereby showcasing the broad applicability and potential of our methods in diverse settings.

As shown in Tab. 2, the ablation experiment on the PLUTo- full, focusing on the removal of Edit-and-Ground (E&G) and Plan-and-Retrieve (P&R) components, provides intriguing insights into their roles in tool retrieval tasks. Generally, removing E&G leads to decreased Recall and NDCG scores across settings, underscoring its critical role in enhancing what the model seeks to retrieve. On the other hand, excluding P&R tends to diminish more of the model's performance in Non-Finetuned settings, particularly impacting Recall. This highlights P&R's importance in effectively retrieving relevant information. A comparative analysis reveals that the full implementation of PLUTo-ChatGPT, incorporating both E&G and P&R, consistently delivers strong performance across all metrics and settings, emphasizing the synergistic strength of these components. The variants of the model, lacking either E&G or P&R, provide valuable insights into the unique contributions of each component to the model's overall efficacy.

Model	Non-Finetuned		Finetuned	
	Rec	NDCG	Rec	NDCG
PLUTo- full	**46.57**	**82.93**	**48.47**	**84.73**
- w/o E&G	42.55	80.70	44.90	81.10
- w/o P&R	38.12	77.60	47.07	81.90

Table 2: Ablation Study.

5.4 Execution Pass Rate

We evaluate the pass rate of the execution schema generated by ChatGPT using the DFSDT approach (Qin et al., 2023). Using the ToolEval package, we assessed two distinct retrieval tools, ToolRetriever and PLUTo, for their correctness and efficiency in responding to user queries. The PLUTo achieves **72.3%** for pass rate, while the previous SOTA system ToolRetriever scored **69.3%**.

This experiment's findings emphasize the pivotal role of advanced retrieval strategies in enhancing user query response quality. The improvement gained during the retrieval phase, such as higher accuracy and relevance in responses, significantly contribute to the downstream tasks.

5.5 Case Study

As shown in Tab. 3, we compare our PLUTo against the ToolRetriever baseline to underscore PLUTo's proficiency in retrieving relevant tools for diverse user queries. Through selected exam-

Question	Gold Answer	PLUTo Answer	ToolRetriever Answer
I'm planning a weekend getaway with my partner and I want to surprise them with a romantic playlist. Could you fetch the reels and posts from romantic music artists on Instagram? Additionally, could you search for books about love and relationships on Open Library?	Instagram Reels and post Downloader, Open Library	Instagram Reels and post Downloader, Instagram, Open Library, Instagram Downloader	Love Quotes by LoveMelon, The Love Calculator, Book Finder, fb-video-reels, Reading Home APIs
I'm planning a family movie night and I need a movie recommendation. Can you fetch the trending images for movie posters and provide me with the details of the most popular movie from the past month? Also, check the status of the movie session and download the completed movie.	Magisto, Bing Image Search	Magisto, gogoanime-data-api, Youtube video info, Advanced Movie Search, Image Service, Memes, Bing Image Search, Netflix Data	TikTok Info, Tiktok Video Feature Summary, TikTok Full Video Info, TikTok Downloader - Download Videos without watermark
I'm a music blogger and I'm searching for interesting radio stations to feature on my website. Can you help me find radio stations that play a mix of genres? Also, provide me with the details of the master for the track with the ID '987654' in the LANDR Mastering.	LANDR Mastering v1, 50K Radio Stations	GMC Radio, LANDR Mastering v1, 50K Radio Stations, 60K Radio Stations	LANDR Mastering v1, Spotify_v2, TuneIn, Spotify Scraper, Spotify_v3

Table 3: Performance comparison of PLUTo and ToolRetriever in retrieving relevant tools for user queries. This table demonstrates the effectiveness of PLUTo in closely aligning with the gold standard answers for diverse queries, showcasing its superior ability to understand and fulfill user needs compared to ToolRetriever. The highlighted tools are the correctly retrieved ones.

ples, PLUTo's superior understanding and comprehensive response capabilities are highlighted, especially in scenarios requiring nuanced tool selection.

For instance, for organizing a romantic weekend in the first example, PLUTo not only identifies all essential tools but also enhances the search with additional relevant resources, showcasing its broad and accurate grasp of user needs. This is contrasted with ToolRetriever, where the retrieved tools are only similar on a surface level (the majority of the tools contain the term "Love") and fail to understand the user's intent. This emphasizes PLUTo's improved relevance and precision in tool retrieval. We also showcase the descriptions of tools before and after optimization by the Edit-and-Ground paradigm in Tab. 4.

By leveraging the Plan-and-Retrieve (P&R) and Edit-and-Ground (E&G) components, PLUTo marks a significant advancement over conventional retrieval systems, demonstrating its adaptability and utility in fulfilling diverse user requirements.

6 Conclusion

We introduced PLUTo, a framework composed of the Plan-and-Retrieve and Edit-and-Ground paradigms, which marks a distinctive departure from traditional methodologies, setting a new standard for tool retrieval. The empirical results illustrate the superiority of PLUTo across critical retrieval performance metrics as well as pass rate in real-world tool-use evaluation. These metrics collectively attest to the model's efficacy in identifying relevant tools and successfully addressing complex user queries. We hope the adaptability and efficiency of PLUTo can empower a multitude of domains where accurate and timely retrieval of tools is paramount. From autonomous scientific discovery to software development, the potential applications are as diverse as they are impactful.

Acknowledgement

We appreciate the reviewers for their insightful comments and suggestions. Tenghao Huang and Muhao Chen were supported by an Amazon Research Award, a Keston Exploratory Research Award, and the NSF Grant ITE 2333736.

Limitation

Our study, while enhancing tool learning by planning and editing strategies, is notably constrained by its reliance on English language datasets. This focus on English limits the model's applicability to other languages with distinct syntax and semantics and confines its evaluation to specific English data sources, leaving its performance on diverse language setups unexplored. Future research should address this limitation by developing multilingual capabilities and conducting evaluations across varied data sources.

The Edit-and-Ground (E&G) may be executed to further optimize the descriptions. However, due to the cost, we currently set a relatively loose stop criterion that is enough to demonstrate the effectiveness of the presented method.

Ethical Consideration

In conducting this research, we have adhered to ethical guidelines and legal norms to ensure responsible data usage. The data used in this study was obtained from public datasets, specifically ToolBench. We ensured not to violate any terms of service of the data sources.

A K-means Algorithm for Furthest Planning

Here, we present the algorithm for selecting the optimal sub-query to proceed with the Plan-and-Retrieve paradigm.

Algorithm 2 Sub-query Selection

```
Let $Q_{\text{prev}}$ be the set of previous queries, and $Q_{\text{cand}}$ the set of candidate queries.
if $Q_{\text{prev}} = \emptyset$ then
    return $Q_{\text{cand}}$
end if
$Q_{\text{total}} = Q_{\text{cand}} \cup Q_{\text{prev}}$
$V = \text{TFIDFVectorizer}(Q_{\text{total}})$
$C = \text{KMeans.fit}(V)$
Let $L_{\text{prev}}$ be the cluster labels for $Q_{\text{prev}}$ in $C$.
$Q_{\text{filtered}} = \{q \mid q \in Q_{\text{cand}}, \text{label}(q, C) \notin L_{\text{prev}}\}$
if $Q_{\text{filtered}} = \emptyset$ then
    return $Q_{\text{cand}}$
end if
return $\text{random.choice}(Q_{\text{filtered}})$
```

B Evaluation Framework for NDCG Assessment

In the process of evaluating the correspondence between the retrieved digital tools and the user's query, a nuanced approach is employed to assign relevance scores. This scoring paradigm operates on a scale from 0 to 2. A score of '2' is allocated exclusively to those tools that exhibit either an exact match or a functional equivalence to the predefined standards, referred to as 'ground-truths.' A score of '1' is designated for tools that are deemed to be of moderate relevance. Conversely, a score of '0' is reserved for tools that are determined to be irrelevant to the user's query. We hire graduate students to carry out this task.

C Edit-Ground Prompt Template

Please refer to Fig. 4. The task explanation and demonstration are shown in orange. The input is shown in blue.

D Case Studies for Edit-and-Ground paradigm

From Tab. 4, we observe that humans tend to craft tool descriptions that are abstract and simple, which can omit vital details necessary for both users and automated systems. Abstract descriptions can create a gap in understanding, particularly in domains where the nuances of functionality are key to effective use.

Contrastingly, tool descriptions that are contextualized and grounded by PLUTo offer a more detailed narrative, linking the tool's features with specific use cases and demonstrating its utility in practical scenarios. This detailed approach not only aids human users in understanding how a tool fits their specific needs but also enhances the precision of automated retrieval systems in matching tools to user queries.

Tool Name	Before	After
Magisto	Magically transform your videos. Magisto turns your everyday videos into exciting, memorable movies you'll want to watch again and again.	The Magisto API is a powerful tool that can transform user videos into exciting and memorable movies. It offers a range of capabilities to enhance the user's movie experience, provide movie recommendations, and optimize video content for discovery on platforms like Vimeo. The API allows users to choose visually appealing movies ...
Bing Image Search	An AI service from Microsoft Azure that turns any app into an image search resource.	The Bing Image Search API is a comprehensive and powerful tool that enables users to search for and retrieve a wide range of images based on their specific requirements. With its extensive database and advanced search capabilities, this API offers a variety of features to cater to different use cases and scenarios. The API provides the ability to fetch trending images for movie posters. Additionally, the API offers the functionality to retrieve details of the most popular movie from the past month, enabling users to make informed decisions about their movie selection.
LANDR Mastering v1	Give your users an instant and customized audio mastering solution by harnessing the power of LANDR's industry-leading, AI-driven mastering engine and its patented machine learning capabilities.	The "LANDR Mastering v1" API is a comprehensive and powerful audio mastering solution designed to cater to the needs of music producers, music lovers, and anyone interested in high-quality audio production. With its instant and customizable features, the API offers a range of capabilities to enhance the music production process. For music producers, the API allows them to download a specific track by providing the track ID. Additionally, the API can fetch track credits, enabling the user to gather essential information for their music production needs ...

Chart-based Reasoning: Transferring Capabilities from LLMs to VLMs

Victor Cărbune[*] **Hassan Mansoor** **Fangyu Liu** **Rahul Aralikatte**
Gilles Baechler **Jindong Chen** **Abhanshu Sharma**
Google Research

Abstract

Vision-language models (VLMs) are achieving increasingly strong performance on multimodal tasks. However, reasoning capabilities remain limited particularly for smaller VLMs, while those of large-language models (LLMs) have seen numerous improvements. We propose a technique to transfer capabilities from LLMs to VLMs. On the recently introduced ChartQA, our method obtains state-of-the-art performance when applied on the PaLI3-5B VLM by Chen et al. (2023c), while also enabling much better performance on PlotQA and FigureQA.

We first improve the chart representation by continuing the pre-training stage using an improved version of the chart-to-table translation task by Liu et al. (2023a). We then propose constructing a 20x larger dataset than the original training set. To improve general reasoning capabilities and improve numerical operations, we synthesize reasoning traces using the table representation of charts. Lastly, our model is fine-tuned using the multitask loss introduced by Hsieh et al. (2023).

Our variant ChartPaLI-5B outperforms even 10x larger models such as PaLIX-55B without using an upstream OCR system, while keeping inference time constant compared to the PaLI3-5B baseline. When rationales are further refined with a simple program-of-thought prompt (Chen et al., 2023a), our model outperforms the recently introduced Gemini Ultra and GPT-4V.

1 Introduction

Visual language, where text and images work together to deliver information, can be expressed through charts, plots, and diagrams. Multimodal reasoning within this context is challenging, as it involves linking visual properties (like color, line style, and positioning) with textual content (such as legends and units).

Many recent advances of vision-language models (VLMs) come from techniques enabling better representations (Dosovitskiy et al., 2021; Lee et al., 2023), giving the model the ability to understand core elements of the image, a necessary building block for basic reasoning. However, complex reasoning capabilities which combine the core representation of the image with semantic understanding of a question to provide an answer, have been rather limited. Models oftentimes are not able to contextually combine image and text representations. One technique that improves reasoning capabilities in large-language models (LLMs) includes in-context learning for eliciting reasoning such as chain-of-thought prompting (Wei et al., 2023), decomposing tasks (Zhou et al., 2023) or composing stored facts in weights (Press et al., 2023). Fine-tuning on datasets with rationales (Magister et al., 2023; Hsieh et al., 2023) has been shown to be effective for smaller models. In this work, we tackle improving reasoning capabilities in VLMs through better learned image representations, followed by fine-tuning on synthetic datasets with reasoning traces generated by more capable LLMs. We also explore a hybrid online setup for numerical reasoning refinements.

We empirically show that this indeed improves performance through experiments on ChartQA (Masry et al., 2022). Visual-question answering on charts quantifies the ability of a VLM to reason using complex information presented. Oftentimes answering the question requires implicit or explicit information extraction, followed by intermediate grouping or computations using the extracted information, and reasoning with the final quantities, as shown in Figure 1.

Vision-language models (VLMs) such as PaLI-X and PaLI-3 are hybrid model architectures which use a vision and a language backbone to solve visual tasks (Chen et al., 2023b,c). The training recipe typically involves a pre-training stage fo-

Question: What's the difference between the highest value of the red line and the lowest value of the green line? **Answer**: 79

Fig. 1: Example from the ChartQA validation set.

cused on learning a good internal representation, followed by a downstream fine-tuning stage. Chen et al. (2023c) note that PaLI-3 falls behind PaLI-X on ChartQA likely due to its limited reasoning capabilities. Results presented in this work suggest that the lack of a pre-training task for learning better chart representations, as done in Liu et al. (2023b), may be another reason.

Enhancing the reasoning capabilities of large language models (LLMs) such as PaLM-2 (Anil et al., 2023) or GPT-4 (OpenAI, 2023) is a very active research area. While reasoning is considered an emerging property with scale (Wei et al., 2022), Press et al. (2023) argue that simply scaling only enables better memorization of knowledge and does not enable composing multiple stored facts into an answer. On the other hand, prompting techniques enacting complex reasoning on downstream tasks have been shown to be very effective (Wei et al., 2023) (Zhou et al., 2023).

Transferring reasoning capabilities from large to small models enables reducing serving costs, while increasing task performance. Hsieh et al. (2023) have introduced an effective multi-task framework which enable small models to outperform their much larger counterparts using less data. They do so by leveraging rationale generation as a separate task, instead of more standard distillation approaches, which first infer the rationale, followed by the answer (Magister et al., 2023). We apply this framework for the first time on multimodal tasks.

Contributions Our main results can be summarized as follows: **(i)** we introduce an efficient recipe consisting of a pre-training task and fine-tuning task with synthetic datasets using a multi-task setup for improving reasoning capabilities, **(ii)** we obtain SoTA performance by significantly improving PaLI-3 performance on the ChartQA benchmark with our recipe and using 10x less parameters than prior work, **(iii)** we perform numerous ablation experiments quantifying the impact of the techniques used in our recipe.

The remainder of this paper is structured as follows. Section 2 describes related work, followed by Section 3 which introduces the construction of the training datasets. Section 4 illustrates our novel pre-training and fine-tuning recipe, followed by Section 5 describing the experimental setup and main results. Lastly, Section 8 delivers a conclusion and recommendation for future work, followed by Section 9 where we acknowledge limitations of the current work.

2 Related Work

VLM landscape Vision-language models usually combine a vision backbone with a language backbone. Frequently it is a Vision Transformer (ViT) (Dosovitskiy et al., 2021) coupled with a Large Language Model via an encoder-decoder (Chen et al., 2023b) or decoder-only (Alayrac et al., 2022) architecture. More recently, models such as Fuyu-8B (Bavishi et al., 2023) explore projecting the image directly through the language backbone. In this work we extend PaLI-3, an encoder-decoder architecture with ViT-3B as vision and UL2-2B as language backbones. We refer the reader to Chen et al. (2023c) for a complete overview. PaLI-3 is a SoTA model and hence we decided to build on top of it to further focus on improving the results with our methods.

Existing approaches for chart understanding The task of answering questions on charts is, alongside documents and infographics, part of a broader set of tasks commonly referred to *visually-situated language understanding*, where text and image cannot be treated separately (Lee et al., 2023). Fine-tuned models on downstream ChartQA include PaLI-3 (Chen et al., 2023c), MatCha (Liu et al., 2023b) and UniChart (Masry et al., 2023). Among these, UniChart takes the most similar approach to ours, pre-training a chart image encoder as vision backbone and BART decoder (Lewis et al., 2019) as language backbone. Alternatively, Liu et al. (2023a) took the approach of decomposing question-answering into first translating the chart into a table, then querying an LLM in a plug-and-play fashion. Here our main focus is on fine-tuned self-contained models, however we show that a simple refinement using a much larger LLM, continues to improve performance as well.

The role of upstream OCR systems A chart usually has an underlying equivalent tabular representation of the data. However, decoding the tabular representation remains a challenging problem. Alternatively, charts can be passed through an OCR system to extract an unstructured text representation of the image. (Luo et al., 2021) combine chart-specific extraction logic with an OCR system to extract key information from the charts. As intuitively expected, usually the use of an OCR system improves downstream quality. In this work, we assume the model only has access to the chart image.

Improving chart reasoning with synthetic data Having the pre-training mixture specialize on chart tasks is effective (Liu et al., 2023b). We further extend the *chart derendering* task, which translates charts to code or to table. Similar to our approach, Methani et al. (2020) and Masry et al. (2023) have made use of programmatic templates to a synthesize complex QA pairs. However, instead of using an LLM to generate chart summaries as in Masry et al. (2023), here we use it to generate additional QA pairs with rationales. These generated examples together with synthetic programmatic examples are key in the pre-training and fine-tune stages of our model.

3 Dataset

3.1 Brief description of ChartQA

ChartQA is one of the widely adopted visual question-answering benchmarks for reasoning capabilities of VLMs.

The standard ChartQA benchmark has two components: (a) human set and (b) augmented generated set. The augmented set has been machine generated and is more simplistic in nature than the human set.

The charts in the dataset come from four sources (Statista, Pew, Our World in Data and OECD). Gold tables are available for all sources, except for Pew, where the tables are inferred with ChartOCR model (Luo et al., 2021). Although we observed mistakes in inferred tables, our method seems to be fairly resilient to them.

3.2 Synthetic Generation Methods

In this work, we use LLMs to synthesize additional examples paired with rationales generated using chain-of-thought prompting. We use the tabular representation of charts present in the training set as a way to mediate the lack of vision input into LLMs.

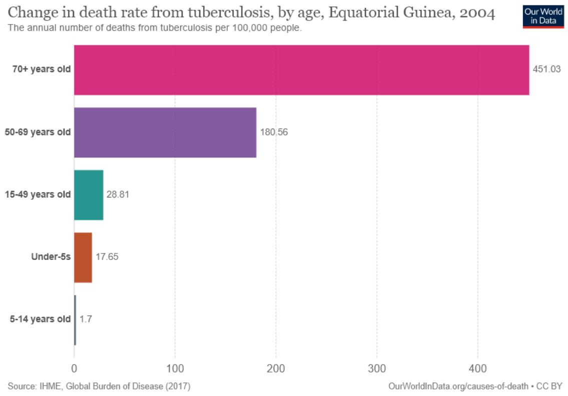
The data we synthesize increases the diversity of the original training set, especially with examples that require extracting multiple quantities from the chart and perform reasoning using them.

We combine two approaches that focus on this type of examples, specifically we use a LLM for synthesizing *rationale generation* and *extra question answer* pairs. We also use a programmatic approach for generating *arithmetic* question answer pairs.

Rationale Generation We augment the original training set with synthetic explanations on why an answer is reached. We achieve this by using PaLM 2-S to predict a $\mathbf{rationale}$ on an input tuple of $(\mathbf{table}, \mathbf{question}, \mathbf{answer})$ with a 4-shot prompt, as illustrated in Figure 4. We refer to this set as *ChartQA-Rationale-S*.

By requesting the model to provide justifications for ground truth answers, which are typically accurate, we witness a significant reduction in hallucinations. A notable exception is when the answer itself is wrong, which happens more frequently for the ChartQA augmented set than the human set. However, we did not perform a detailed investigation of this aspect in the generated training sets. An instance of the generated rationale can be seen in Figure 2.

ExtraQA Generation We hypothesize that the original training set is too small to contain enough diversity in the examples to enable solving more complex QA questions such as the ones present in the human validation set. Therefore we used a 1-shot prompt illustrated in Figure 5 to generate additional examples covering types of errors we identify by examining the model performance on the validation set. The prompt is adapted from the one used in (Liu et al., 2023a). An example of a generated sample can be seen in Figure 7. We used both PaLM 2-S and PaLM 2-L to generate the examples and refer to the respective datasets as *ChartQA-ExtraQAR-S/L*. We perform only lightweight filtering of generated examples that deviate from the imposed structure. If we cannot parse from the LLM



Question: “Find the difference between the largest value and the median of all values?"
Table: "TITLE | Change in death rate from tuberculosis, by age, Equatorial Guinea, 2004\nCountry | Change in death rate from tuberculosis, by age, Equatorial Guinea, 2004\n70+ years old | 451.03\n50-69 years old | 180.56\n15-49 years old | 28.81\nUnder-5s | 17.65\n5-14 years old | 1.7"
Answer: 422.22
Rationale: "The table shows the change in death rate from tuberculosis by age in Equatorial Guinea in 2004. The largest value is 451.03 and the median is 17.65. The difference between the largest value and the median is 422.22.”

Fig. 2: *ChartQA-Rationale-S*: For each example of the original training set, we synthesize a rational based on the table, the question and the answer.

response all three elements, we simply drop the example. However, we do not verify the generated examples for hallucinations, fluency or perform any other model-based verification.

ArithmeticQA Generation It is well known that large language models have difficulties in performing arithmetic computations accurately. For ChartQA, this is particularly exacerbated by the fact that the small training dataset is adequate for the specifics of the arithmetic questions one can have for charts (as represented by the test set). We programmatically create examples which either require numeric reasoning or a comparative analysis of multiple chart elements. Examples are illustrated in Figure 8 and Figure 9. We abstracted the questions into templates and used a fixed set of mathematical operations such as median, max, min etc. For each template we created a rationale to teach the model a plan to solve the arithmetic problems. For example, computing the mean requires first looking up the values, then adding them up and finally dividing the value by the total. For each type of arithmetic we created multiple templates both for the questions and rationales. The source data we used are only the ChartQA human examples, using the available tables. The type of questions and their count can be found in Table 1.

Question Type	Count #
Mean	235K
Subtraction	90K
Other	32K
Total	357K

Table 1: Examples are mostly means or subtractions.

3.3 Resulting Dataset

The resulting dataset is roughly 20x larger and is described in Table 2, with further details on the statistics of the dataset in Section D. Sampling was done using greedy decoding with temperature $\tau = 0$. We used the augmented and human sets to generate examples.

PaLM 2-S vs. 2-L The same prompt was used for all examples in the synthetic dataset. We note that using samples from both LLMs improves performance, but ablation studies do not indicate one is better than the other. We hypothesize that diversity matters more than model size, but we have not investigated sampling strategies.

4 Method

Our work builds on top of PaLI-3 architecture and pre-training recipe, which consists of two backbones, a Vision Transformer ViT-2B and Text Encoder-Decoder UL2-3B. Our starting point is the recipe described by Chen et al. (2023c). The uni-modal pre-training stage trains the vision encoder using contrastive loss through the SigLIP loss, while the language encoder-decoder is pretrained using the UL2 loss. Both backbones are pretrained jointly using a multi-modal stage. Lastly the resolution increase stage enables the vision encoder backbone to work with 812x812 resolution images. We continue pre-training using this checkpoint.

4.1 Pre-training: Chart2Table Mixture

Extending the work done by Liu et al. (2023a), we use a chart-to-table dataset mixture to continue pretraining with the ViT backbone unfrozen, which facilitates learning an internal representation of the chart. We do not explicitly use the tabular conversion further downstream.

Dataset For learning this representation, we combine several chart-to-table derendering tasks into a mixture: (1) synthetic chart-to-table data similar to the synthetic mixture introduced by Liu et al.

Dataset	Hum #	Aug #	Question type #	Total	Rate #
ChartQA-Rationale-S	7398	20901	R [13%], V [11%], C [43%], B [33%]	28.3K	15%
ChartQA-ExtraQAR-S	23261	69433	R [57%], C [43%]	92.7K	15%
ChartQA-ExtraQAR-L	16388	50468	R [60%], C [40%]	66.9K	30%
ChartQA-ArithmQAR	357000	-	C [100%]	357.0K	40%
ChartQA-Synth (Total)				**544.9K**	

Table 2: Overview of the synthetic dataset, which is 20x larger than the original one. The suffix denotes the size of the PaLM 2 model used. The rate refers to the final mixture. Categorization of question types are from (Masry et al., 2022), namely **R**etrieval, **V**isual, **C**ompositional or **B**oth visual and compositional.

(2023a). We traverse different combinations of plotting options in matplotlib and seaborn to randomly plot tables from Wikipedia into charts of different layouts. (2) the chart-to-table mixture introduced by Masry et al. (2023). (3) The chart-table pairs from the train set of DVQA (Kafle et al., 2018). (4) The chart-table pairs from the train set of TaTA (Gehrmann et al., 2022). (5) The chart-table pairs introduced in Benetech - Making Chart Accessible Kaggle challenge[1]. A complete listing of data source, sampling weight, and number of examples is shown in Table 3.

Component	Rate	Size
Synthetic	44.0%	1.2M
UniChart	39.5%	612K
DVQA	3.2%	200K
ChartQA	3.2%	22K
TaTa	3.2%	6.7K
Chart2Text	3.2%	24K
Benetech Challenge	3.2%	21K
PlotQA	0.5%	224K
Total		**2.37M**

Table 3: Pre-training datasets for learning chart representations include examples from numerous tasks that have paired chart images with table representations.

The existing table representation is used as is from the datasets, or, as described earlier, for a small fraction, tables are created programmatically. Tables are also normalized to a standardized format.

4.2 Fine-tuning: Multi-task Loss

After the pre-training stage which enables the ViT backbone to work better with charts, we use the synthetic data to fine-tune the model for the downstream task. We investigate two ways of incorporating the rationales available in the extended dataset.

The first one is by changing the task target from *answer* to *rationale, answer*. This has been shown to be effective in (Magister et al., 2023). We refer to this approach as **single-task setup**. However, it requires increased inference time by predicting the rationale, together with increased sequence length during training. The unintended side effect of training to predict jointly rationales and answers is that rationale tokens become equally important as the answer tokens.

The second one is inspired by Hsieh et al. (2023) which addresses both concerns by constructing a **multi-task setup** where the answer and rationale are treated as independent tasks. This can be done using different prefixes similar to T5 (Raffel et al., 2023), such as *"Rationale:"* and *"Question:"*. The training loss balances the strength between the two tasks using a hyper-parameter λ:

$$\mathbf{Loss} = (\mathbf{1} - \lambda)\mathbf{Loss_{ans}} + \lambda\mathbf{Loss_{rat}}$$

Our experiments are the first application of this setup for a multimodal task. We further confirm the observation from text domains that not only inference time remains constant, but quality also improves.

5 Experiments

We describe the general learning hyper-parameters for the pre-training and fine-tuning stages, followed by interpretation of the results.

5.1 Setup

Pre-training We continue pre-training the PaLI-3 model with ViT unfrozen on the Chart2Table data mixture for `train_steps=6K`, `batch_size=256` with `learning_rate=5e-3` with normalized square root decay using `decay_factor=2e-6` and `dropout_rate=0.1`.

---

[1] `https://www.kaggle.com/competitions/benetech-making-graphs-accessible`

Fine-tuning We then freeze the ViT encoder and continue fine-tuning on the synthetic ChartQA dataset for `train_steps=5K`, `batch_size=256` with `learning_rate=1e-3` with linear decay using `decay_factor=1e-4` using `dropout_rate=0.1`.

Multitask We use $\lambda = \mathbf{0.5}$ and we do not find significant differences when using other values.

5.2 Results on ChartQA

We validate the effectiveness of the different techniques by reporting the downstream task performance on the ChartQA test set. All following experiments are on PaLI-3.

Pre-training Continuing the pre-training stage for the PaLI-3 model using the Chart2Table mixture enables learning a better general representation of the charts. We intuitively expect that this better representation enables the model to more accurately identify quantities on the images. Indeed, we confirm this first through the results reported in Table 4. Later, as we scale the dataset size, we show that this continues to play an important role.

Pre-training Strategy	ChartQA (RA%)		
	Avg.	**Hum.**	**Aug.**
Original PT (Chen et al., 2023c)	70.00	-	-
Chart2Table PT (our run)	**70.84**	48.96	92.72

Table 4: PaLI-3 performance on ChartQA slightly increases with our chart-to-table pre-training phase.

As expected, the increase is predominantly in the augmented set, given that the pre-training mixture is constructed synthetically as well.

Singletask vs. Multitask We first study the effect of introducing rationales only using the *ChartQA-Rationale-S*. This only adds rationales to the original ChartQA dataset.

When using the rationales in singletask setup the performance difference is not significant compared to not using them. However, when used in the multitask setup, we note a quality improvement, particularly noticeable in the more difficult human-set. We refer to the former as *Singletask-Rationale* and to the latter as *Multitask-Rationale* in Table 5.

Fine-tuning setup	ChartQA (RA%)		
	Avg.	**Hum.**	**Aug.**
C2T PT + Singletask-Rationale	70.80	49.36	92.24
C2T PT + Multitask-Rationale	**71.72**	50.72	92.72

Table 5: Multitask performance stands out compared to Singletask on the more difficult human-written set.

We hypothesize that the improvement comes from better use of the rationales, guiding the model to internally produce a form of reasoning before producing the final answer. This is done without paying the cost predicting the rationales tokens.

Learning with augmented dataset We use the ChartQA-Synth dataset from Table 2 for studying the extent to which we can transfer reasoning capabilities from PaLM-2 to PaLI-3.

We perform an ablation experiment to understand the role of the extra questions, rationales and pre-training stage and report our results in Table 6.

We denote experiments using the original pre-trained checkpoint as *Orig PT* and on the further pre-trained checkpoint with chart-to-table translation as *C2T*. We report a clear improvement, further strengthening our observation that internal representation plays an important role.

Fine-tuning Setup	ChartQA (RA%)		
	Avg.	**Hum.**	**Aug.**
Orig PT + Singletask-ExtraQAR	72.43	53.20	91.67
Orig PT + Multitask-ExtraQAR	73.15	55.20	91.10
C2T PT + ExtraQA (w/o Rationale)	74.67	56.39	92.96
C2T PT + Singletask-ExtraQAR	75.16	55.84	**94.48**
C2T PT + Multitask-ExtraQAR	75.36	56.80	93.92
C2T PT + Singletask-ChartQA-Synth	76.60	59.04	94.16
C2T PT + Multitask-ChartQA-Synth	**77.28**	**60.88**	93.68

Table 6: Ablation results confirm the importance of each step in our recipe. *ChartQA-Synth* is the mixture described in Table 2

We ran an experiment without rationales, but with the entire synthetically generated QA pairs. We note that the increase in examples ends up improving over the original ChartQA performance reported in Table 4. However, the use of rationales continues to improve quality for both singletask and multitask setups. We observe that in high-data regimes, there is no longer a significant difference between the two.

Given the neutral impact of the multi-task setup at inference time, paired with slightly improved performance on the human-written queries of ChartQA, multi-task is the preferred option in practice. Further, we refer to the best performing fine-tuned setup in Table 6 as **ChartPaLI-5B**.

5.3 Results on FigureQA and PlotQA

ChartQA is currently the most challenging benchmark. To prove that our method is general, we investigate performance on related chart understanding tasks, FigureQA () and PlotQA (). We study 3 operation regimes: (i) **zero-shot**: no task-specific pre-training or fine-tuning, (ii) **quick adaptation**: 1K fine-tuning steps and (iii) **convergence**: 5K fine-tuning steps. We report relaxed accuracy on 10K examples from validation set for FigureQA (ref. Table 8 and from test set from PlotQA (ref. Table 9).

Model	FigureQA RA% (v1 I v2)		
	ZShot	**Quick**	**Conv**
PaLI-3 (original)	41.9 I 42.4	57.2 I 58.1	89.9 I 89.3
ChartPaLI-5B	**51.0 I 51.2**	**92.7 I 93.0**	**96.3 I 96.2**

Table 8: ChartPaLI-3 exhibits strong generalization on FigureQA task, for which no examples are present in pre-training or fine-tuning

For PlotQA, images from the training subset are present in our pre-training mixture, while validation and test subset images are not. Therefore, we do not study zero-shot performance, as training images would give an unfair advantage.

Model	PlotQA RA% (v1 I v2)	
	Quick adapt.	**Convergence**
PaLI-3 (original)	62.0 I 15.7	71.5 I 23.6
ChartPaLI-5B	**79.1 I 53.3**	**86.0 I 70.7**

Table 9: ChartPaLI-3 exhibits strong generalization on FigureQA task, for which no examples are present in pre-training or fine-tuning

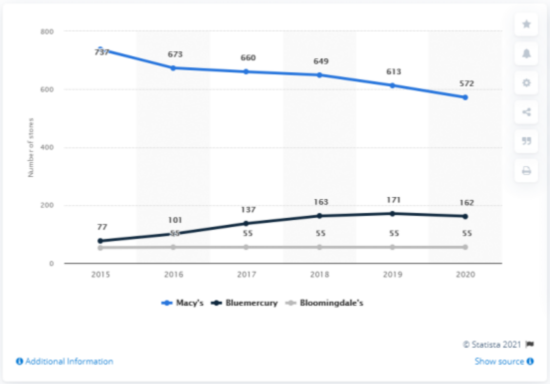
ChartPaLI-5B outperforms PaLI-3 in all operation regimes. In general, our recipe significantly increases chart understanding performance when running only a few quick adaptation steps.

In particular we report SoTA performance regime for FigureQA (roughly 96%+) and the very strong relative performance on the difficult PlotQA v2 (roughly +47.1% at convergence time).

5.4 Errors and Challenges

To understand the effect of our method and investigate further opportunities for improvements, we manually looked at predictions on the ChartQA validation set. We compared baseline PaLI-3 model outputs with the model fine-tuned with our recipe and share our observations below. We report our findings below.

General The model predicts the rationale[2] or the answer, depending on the task prefix. Because the answer is not conditioned on the rationale, it can differ. One general improvement area we note is the ability to extract necessary intermediate quantities (Fig. 11) and operate with them (Fig. 12).



Question: What is the total of Macy's, Bloomingdale's and Bluemercury brand stores worldwide in the 2019?
Answer [baseline]: 1122
Answer [ours]: 832 *[inexact, but correct because it's within 5% of ground truth]*
Rationale [ours]: The table shows the number of Macy's, Bloomingdale's and Bluemercury brand stores worldwide in the years 2015, 2016, 2017, 2018, 2019 and 2020. In 2019, Macy's had 613 brand stores, Bloomingdale's had 55 brand stores and Bluemercury had 171 brand stores. Therefore, the total number of Macy's, Bloomingdale's and Bluemercury brand stores worldwide in the 2019 is 613 + 55 + 171 = 824.

Fig. 3: Correct numeric approximations on answers.

Numerical reasoning Despite improvements, computation of mathematical expressions continues to be very challenging. The rationales correctly extract (Fig. 3) or infer chart values when missing (Fig. 13), however the computed value is frequently incorrect. This does not always prevent the final answer to be correct (Fig. 15). This seems in line with observations by Wang et al. (2023a), who also conclude that corruption of the chain-of-thought reasoning trace does not always degrade the final answer. Due to the frequency of this numeric computation error, we explore a simple refining technique in Section 5.5.

---

[2] Although the table is not used during inference, the rationales contain the word *table* due to its use in prompts.

Fine-tuned VLMs (up to 55B)	Source	**ChartQA (RA%)**

ChartPaLI-5B + PaLM 2-S PoT SC @ 5	**our work**	**81.3**

Table 7: State-of-the-art performance among fine-tuned VLMs on ChartQA benchmark.

Color reasoning Our synthetic data does not have color metadata, as only the table was used in the generation process. Therefore the model continues to struggle when the reasoning trace requies working with colors (Fig. 10). Thus, this is an area worth of investigating next and has applicability well beyond the specifics of chart understanding.

Complex reasoning Reasoning about multiple values and checking for a matching condition which requires arithmetic computations is another example of a remaining difficult task (Fig.14, Fig.16). The increased complexity stemming from internal inability of VLMs to perform numeric operations paired with enumerating chart elements through semantic descriptions is likely fairly difficult to achieve without the use of external tools.

Task leakage Due to the training methodology, we observe that when conditioned with the *Question* task prefix, the model may behave similarly as to when *Rationale* prefix is used. Sometimes, instead of directly outputting an answer, the model may generate a longer explanation that resembles a rationale or a fragment of rationale.

5.5 Refinement with Program of Thoughts

Despite the improved ability to construct numeric equations using the required values on the charts (Fig. 3), the exact numeric computation continues to be wrong. This is unsurprising, since both the visual and the language backbone treat numbers as tokens. Making the problem worse, the character sequence forming a number may be split and encoded in arbitrary chunks. Chen et al. (2023a) have proposed replacing chain-of-thoughts (CoT) prompting with program-of-thoughts (PoT) to enable delegation of the arithmetic computation to a program interpreter. This has previously been explored by Liu et al. (2023a), however in a much more computationally involved setup than the one we describe further.

Through our fine-tuning approach, both single-task and multitask setups can be used produce CoT rationales for which an LLM prompted with PoT can write the equivalent code for performing the numeric computation.

We take the approach of using a simple 4-shot prompt (Fig. 6) constructed on the validation set to generate code using PaLM 2-S for performing the numeric computation that is present in a rationale. We run this online refinement, only if the rationale contains an arithmetic operator ('+', '-', '/' or '*').

Self-consistency is an effective way to improve chain-of-thoughts rationales by selecting an answer with majority voting from a pool of sampled rationales (Wang et al., 2023b). We apply this approach, by sampling with temperature $\tau_{Rat} = 0.4$ and generate $N = 5$ rationales that are then refined with PaLM 2-S using temperature $\tau_{Ref} = 0.0$.

Setup	ChartQA (RA%)		
	Avg.	**Hum.**	**Aug.**
ChartPaLI-5B (from Table 6)	77.28	60.88	93.68
ChartPaLI-5B + PaLM 2-S PoT	80.80	67.92	93.68
ChartPaLI-5B + PaLM 2-S PoT SC @ 5	**81.32**	**68.96**	93.68

Table 10: PoT refinement improves performance on the human set, while not affecting the augmented set.

The results presented in Table 10 highlight the utility of the method, particularly with K=5 for self-consistency. They also highlight the simplicity of the augmented set compared to the human set, for which the refinement does not have an impact. Either the augmented set contains no arithmetic computations or they are simple enough for the fine-tuned VLM to already get right.

6 Performance Overview

We position our results relative to existing prior work in Table 7. We extracted the results from the referenced papers, with the exception of the Fuyu-8B (Bavishi et al., 2023) model. We performed our own evaluation as the authors have not provided the results on the ChartQA benchmark.

Our work significantly outperforms prior models specialized on the ChartQA benchmark. Concurrent to our work, ChartLlama-13B also uses synthetic data generated, but with a fairly different approach. Although outside the scope of our work, it may be that the approach took to train the much smaller MatCha and UniChart models may be combinable with the approach we presented in this work, leading to possible improved performance with even less computational resources.

The method introduced in this work can be uniquely combined with much larger models through rationale generation. As shown in the results, rationales generated by VLMs can suffice for larger LLMs to effectively operate on, providing a text-representation of the chart conditioned on the question. Our method matches the recently introduced Gemini Ultra model and outperforms previous approaches.

7 Future Work

We highlighted several drawbacks of our approach in Section 5.4. The training mixtures do not have examples where colors are used to construct reasoning examples. Bootstrapping such examples, for example by running a smaller sized model with questions that extract color related information, then combines them, would likely improve quality. Very complex reasoning examples are also limited. Specifically, semantically identifying chart elements and performing numeric computations to solve questions would further improve quality.

8 Conclusion

We introduced a novel recipe that significantly improves the reasoning capabilities of VLMs. Applied to PaLI-3, our method significantly outperforms even the 10x larger PaLI-X on the ChartQA benchmark, establishing a new state-of-the-art. We demonstrate how the pre-training stage improves downstream performance. Our synthetic data generation technique coupled with the use of a multitask setup, successfully transfers reasoning capabilities from larger LLMs to smaller VLMs. Moreover, our method enables a computationally more expensive setup where predicted rationales are refined using program-of-thoughts with PaLM 2-S. The composite solution outperforms Gemini Ultra and GPT-4V on the ChartQA benchmark.

9 Limitations

We acknowledge limitations of our approach.

Table representation Although our final model works on pixels only, our synthetic data generation method requires having access to a table version of the charts for leveraging LLMs to construct rationales, additional question/answer pairs, etc for the training datasets. Although it is likely that inferred tables or output of an OCR model may replace to some degree the presence of gold tables, it will likely affect final model quality.

PaLI-3 The pre-training and fine-tuning recipe for synthetic data creation, as well as the training methodology should be applicable broadly on open source models as well. However, we acknowledge that the choice of PaLI-3, a proprietary flavor of VLMs, is not as a good of a choice as an open source flavor available externally.

Risks associated with synthetic dataset Since the method for constructing our dataset relies on LLMs, there are certain inherent risks that come with that, for example that of hallucination. Although our technique extends the publicly available ChartQA dataset, additional care needs to be taken into account when planning to apply it for releasing models or dataset openly. Although the metrics are state-of-the-art, it cannot be guaranteed that model outputs can't be abused if trained in this manner.

Reasoning limitations We acknowledge limitations stemming from the empirical prompt creation process, which is based on human inspection of model errors. LLM capabilities used for the synthetic data creation, although impressive, continue to have numerous limitations as reported by the community.

10 Acknowledgements

We thank Srinivas Sunkara and Maria Wang for their contributions on the infrastructure that enabled us to run these experiments. Further, we thank Xi Chen for his tireless support and insights into PaLI-3 details and training recipes and Cheng-Yu Hsieh and Yasuhisa Fujii for the detailed discussions on the multi-task setup. Daniel Keysers and Radu Soricut have provided detailed feedbacks that significantly improved the paper. Matt Sharifi and Ewa Dominowska provided senior leadership support for this work.

Lastly, feedback from anonymous reviewers rPKR and 453J motivated running additional experiments further strengthening the contribution of this work by showcasing the method is generally applicable.

A Prompts for PaLM-2

We use PaLM 2-S and PaLM 2-L throughout this work. Here we describe the prompts used for the different purposes. Our *ChartQA-Rationale-S* dataset is a straightforward augmentation of the ChartQA dataset, by predicting the rationales using the table, answer and question. For this, we have constructed the prompt illustrated in Figure 4. The *ChartQA-ExtraQAR-S/L* datasets are constructed using PaLM 2-S/L respectively for which we extended the 1-shot prompt provided by (Liu et al., 2023a). We chose this prompt for simplicity and for it already containing several diverse question examples. The prompt is illustrated in Figure 5.

Lastly, we describe an online refinement of the rationale prediction using program-of-thoughts in Section 5.5. For this, we manually constructed the prompt illustrated in Figure 6. This was built by inspecting a few validation errors when the numeric values computed by the VLM were wrong.

B Generated Examples

Licensing As we redistribute certain data artifacts, we note that the ChartQA dataset at the time of this writing is marked as GPL v3.0 [3]. In this section we provide visual examples of our synthetically generated training datasets, using PaLM 2-S/L models, as well as the programmatically generated templates for mathematical computations. Figure 7 contains an example of synthesized example using only the table representation. The question, answer and rationale cover an aspect of the table and are generated together with 3-5 other questions.

Figure 8 and Figure 9 are examples of a programmatically generated questions based on the template to compute the mean. The markdown table provided as input is processed through a function that takes the corresponding values and outputs all the elements, including the reasoning trace in the rationale for computing the mean as shown in the figure.

C Model Outputs

In this section we provide examples that accompany our analysis of the model behavior. We highlighted impressive performance, as can be seen in Figure 11, Figure 12 and Figure 13. However, we noted several limitations as well, as can be seen in Figure 10, Figure 14 and Figure 16.

```
You are given a table, a question and answer and your task is to output a
rationale that justifies why the answer to the question is the one provided.

Question: What was the unemployment rate in Poland in 2020?
Table: TITLE |
Characteristic | Unemployment rate
2020 | 3.04%
2019 | 3.47%
2018 | 3.85%
2017 | 4.89%
2016 | 6.16%
2015 | 7.5%
2014 | 8.99%
2013 | 10.33%
2012 | 10.09%
2011 | 9.63%
2010 | 9.64%
2009 | 8.17%
2008 | 7.12%
2007 | 9.6%
2006 | 13.84%
2005 | 17.75%
2004 | 19.07%
2003 | 19.37%
2002 | 19.9%
2001 | 18.37%
2000 | 16.31%
1999 | 12.29%
Answer: 3.04
Rationale: The table is about the unemployment rate in Poland from 2020 to
1999. The unemployment rate in Poland in 2020 is 3.04%.

Question: Is the difference in import value between fiscal year 2020 and
fiscal 2018 larger than the difference between 2013 and 2011?
Table: TITLE |
Characteristic | Import value in billion Indian rupees
FY 2020 | 1590.66
FY 2019 | 1888.81
FY 2018 | 2209.7
FY 2017 | 1594.6
FY 2016 | 1314.1
FY 2015 | 1379.68
FY 2014 | 1442.93
FY 2013 | 1231.68
FY 2012 | 1343.74
FY 2011 | 1541.37
Answer: No
Rationale: The difference in important value between 2020 and 2018 is
1590.66-2209.7 = -619.04. Between 2013 and 2011 is 1231.68-1541.37 =
-309.69. Because -619.04 is smaller than -309.69 the answer is no.

Question: What was the revenue from sponsorship, licensing and merchandising
at the 2008 EURO in Switzerland and Austria?
Table: TITLE |
Characteristic | Revenue in million euros
2016 France | 483.3
2012 Poland & Ukraine | 313.9
2008 Switzerland & Austria | 289.8
2004 Portugal | 182.2
2000 Belgium & the Netherlands | 54.1
1996 England | 29.3
1992 Sweden | 9.7
Answer: 289.8
Rationale: From the table, the revenue from sponsorship, licensing and
merchandising at the 2008 EURO in Switzerland and Austria is 289.8.

Question: How many people in Sub-Saharan Africa had no access to electricity
in 2016?
Table: TITLE |
Characteristic | 2009 | 2016 | 2030
Central and South America | 30 | 17 | 4
North Africa | 1 | 0 | 0
Sub-Saharan Africa | 586 | 588 | 602
Middle East | 21 | 17 | 14
India | 289 | 239 | 0
China | 8 | 0 | 0
Rest of developing Asia | 329 | 200 | 54
Answer: 588
Rationale: The table is about the number of people in different regions who
had no access to electricity in 2009, 2016 and 2030. For Sub-Saharan Africa
the values are 586 for 2009, 588 for 2016 and 602 for 2030. Therefore the
answer is 588.

Question: {question}
Table: {table}
Answer: {answer}
Rationale:
```

Fig. 4: The input template, with a 4-shot prompt, for generating the ChartQA-Rationale-S dataset using PaLM 2-S.

---

[3] https://github.com/vis-nlp/ChartQA/blob/main/LICENSE

```
You are a helpful assistant who creates unique and innovative
question-answer pairs for training other models.

You should create question-answer pairs from text tables. The questions can
be of two types: (i) directly answered from the table, and (ii) inferred by
applying simple mathematical operations on the values in the table. The
mathematical operations can include maximum, minimum, average, peak, etc.

The questions may not always be answerable from the give table. If a
question can be answered, the answer itself should be crisp and unambiguous.
The answer should be preceded by a brief description detailing how the
answer was arrived at. So the answer format is:
Rationale: ...
Answer: ...

An example table and some sample QA pairs are shown below.

Favor rates of US political parties
Year | Democrats | Republicans | Independents
2004 | 68% | 45% | 53%
2006 | 58% | 42% | 53%
2007 | 59% | 38% | 45%
2009 | 72% | 49% | 60%
2011 | 71% | 51% | 58%
2012 | 70% | 48% | 53%
2013 | 72% | 41% | 60%

Q: In which year republicans have the lowest favor rate?
Rationale: Let's find the column of republicans. Then let's extract the
favor rates, they [45, 42, 38, 49, 51, 48, 41]. The smallest number is 38,
that's row 3.  Row 3 is year 2007.
Answer: 2007

Q: What is the sum of Democrats' favor rates of 2004, 2012, and 2013?
Rationale: Let's find the rows of years 2004, 2012, and 2013. We find Row 1,
6, 7. The favor dates of Demoncrats on that 3 rows are 68, 70, and 72.
68+70+72=210.
Answer: 210

Q: By how many points do Independents surpass Republicans in the year of
2011
Rationale: Let's find the row with year = 2011. We find Row 5. We extract
Independents and Republicans' numbers. They are 58 and 51. 58-51=7.
Answer: 7

Q: Which group has the overall worst performance?
Rationale: Let's sample a couple of years. In Row 1, year 2004, we find
Republicans (column 3) having the lowest favor rate 45 (45<68, 45<53). In
year 2006, Row 2, we find Republicans (column 3) having the lowest favor
rate 42 (42<58, 42<53). The trend continues to other years.
Answer: Republicans

Q: Which party has the second highest favor rates in 2007?
Rationale: Let's find the row of year 2007, that's Row 3. Let's extract the
numbers on Row 3: [59, 38, 45]. 45 is the second highest. 45 is the number
of Independents.
Answer: Independents

Q: What was the favor rates for democrats in 2008?
Rationale: Let's find the row of year 2008. Because 2008 is not in the
table, the answer is not known from this data
Answer: None

Q: What is the value of the brown line?
Rationale: Because I don't have color information on the table, the answer
is not known from this data
Answer: None

Depending on the size of the table, you should create 3-7 such QA pairs.
Make sure that you output only the QA pairs and nothing else.

Now create QA pairs for the following table:

{table}
```

Fig. 5: The input template, with a 1-shot prompt, for generating the ChartQA-ExtraQAR-S/L datasets using PaLM 2-S/L.

```
You are a helpful assistant which helps extract the equations from a text
and write python code to fix the result that is usually incorrect in the
text.

You only output valid python code and nothing else. If there is no
arithmetic computation or equation in the solution, you output 'skipped'.

Question: What is the average number of users across properties?
Solution: Facebook has 563 users, Whatsapp has 69 and Instagram 23. The
average number of users across properties is (563 + 69 + 23) / 3 = 2.
Code:
facebook_users=563
whatspps_users=69
instagram_users=23
result['value'] = (facebook_users + whatsapp_users + instagram_users) / 3

Question: What is the average percentage of people using Google in 2015 and
Bing in 2017 at 60+?
Solution: The percentage of people using Google at 60+ in 2015 is 23% and
the percentage of people using Bing in 2017 at 60+ is 8%. 23% + 8% = 42%.
Code:
google_percentage_2015=23
bing_percentage_2017=8
result['value'] = (google_percentage + bing_percentage) / 2

Question: What is WarnerMedia's global revenue for advertising from 2018 to
2019?
Solution: The table is about WarnerMedia's global revenue for advertising,
subscription and content and other from 2018 to 2019. The sum of all the
WarnerMedia's global revenue for advertising from 2018 to 2019 is 2266 +
7408 + 839 = 10299.
Code:
advertising_revenue=2266
subscription_revenue=7408
content_and_other_revenue=839
result['value'] = advertising_revenue + subscription_revenue +
content_and_other_revenue

Question: What is the ratio between oppose and favor distribution for a ban
on high-capacity ammunition clips?
Solution: The table shows the percentage of people who favor or oppose each
of the following gun measures. The percentage of people who oppose a ban on
high-capacity ammunition clips is 47. The percentage of people who favor a
ban on high-capacity ammunition clips is 50. The ratio between oppose and
favor distribution for a ban on high-capacity ammunition clips is 47 / 50 =
0.092361111
Code:
oppose_percentage=47
favor_percentage=50
result['value'] = oppose_percentage / favor_percentage

Question: {question}
Solution: {text}
Code:
```

Fig. 6: The input template, with a 4-shot prompt, for refining arithmetic operations with python code using PaLM 2-S.

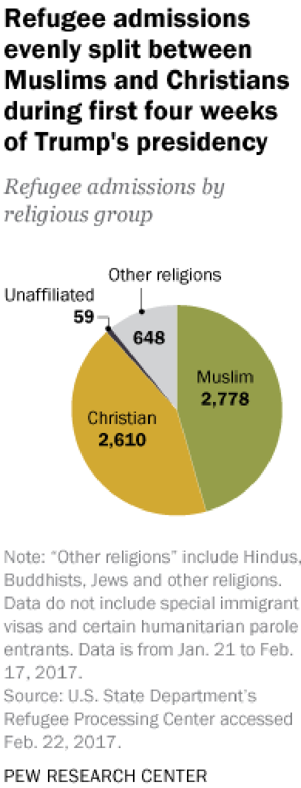

Table: "TITLE | Refugee admissions evenly split between Muslims and Christians during first four weeks of Trump's presidency Refugee admissions by religious group \nEntity | Value\nChristian , | 4118\nMuslim , | 2778\nUnaffiliated | 59\nOther religions | 648"

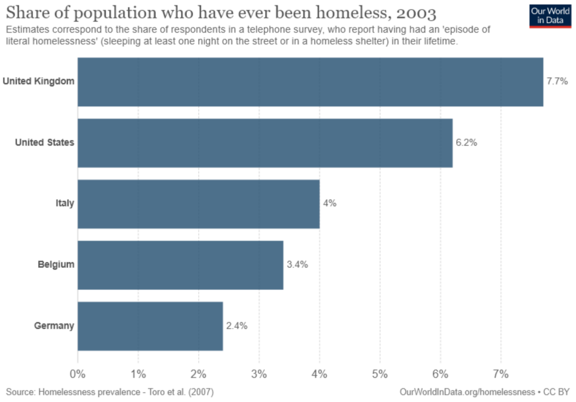
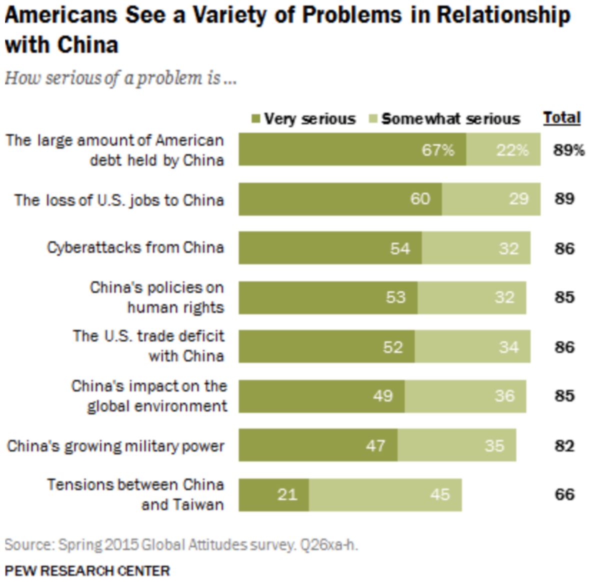
Question: "How many more Muslims were admitted than Other religions?"
Rationale: "To answer this question, we need to find the number of Muslims and Other religions. The number of Muslims is 2778. The number of Other religions is 648. 2778-648=2130."
Answer: 2130

Fig. 7: *ChartQA-ExtraQAR-S/L*: Example of synthesized (Question, Answer, Rationale) pair with PaLM-2 using the table



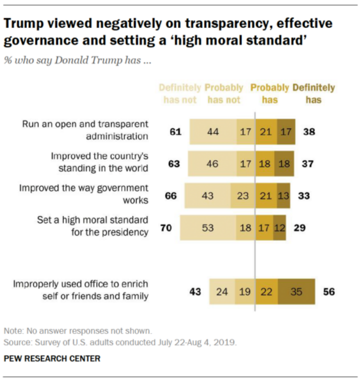
Question: What is the average "Share of population who have ever been homeless, 2003 amount?"
Rationale: "To answer What is the average Share of population who have ever been homeless, 2003 amount? First extract all the values of Share of population who have ever been homeless, 2003. The values are [7.7, 6.2, 4.0, 3.4, 2.4]. (7.7 + 6.2 + 4.0 + 3.4 + 2.4) / 5 = 4.73. Hence the mean of Share of the population who have ever been homeless, 2003 is 4.73.
Answer: 4.73

Fig. 8: *ChartQA-ArithmQAR*: Example of programmatically generated (Question, Answer, Rationale) pair



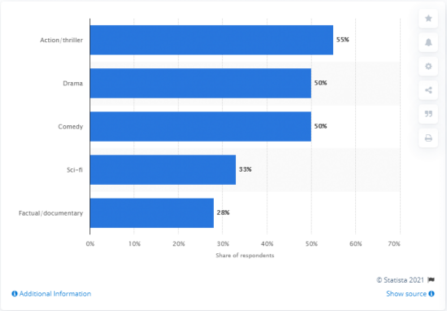
Question: What is the average of "Somewhat serious" and "Very serious" for entity "The loss of U.S jobs to China"?
Rationale: The value of "Somewhat serious" for entity "The loss of U.S. jobs to China" is 29. The value of "Very serious" for Entity "The loss of U.S jobs to China" is 60. (29 + 60) / 2 = 44.5. The answer is 44.5"
Answer: 44.5

Fig. 9: *ChartQA-ArithmQAR*: Example of programmatically generated (Question, Answer, Rationale) pair



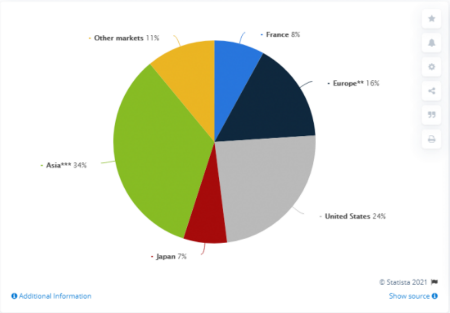
Question: What's the maximum value in the brightest yellow bar?
Answer [baseline]: **56**
Answer [ours]: **22**
Rationale [ours]: The **brightest yellow bar is the one for "Improved the country's standing in the world"**. The maximum value in this bar is 18.

Fig. 10: Matching the colors with content is weak.



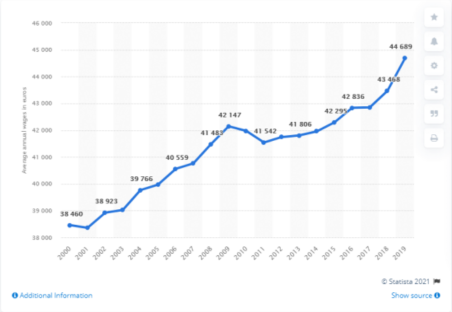
Question: What is the difference between the most popular and least popular film genres in the United Kingdom (UK) as of October 2013?
Answer [baseline]: **55**
Answer [ours]: **27**
Rationale [ours]: The table shows the share of respondents who watched each film genre in the UK as of October 2013. The most popular film genre is **Action/thriller**, with a share of **55%**. The **least popular film genre** is factual/documentary, with a share of **28%**. The **difference** between the two is **27%**.

Fig. 11: Excellent extraction of intermediate values.



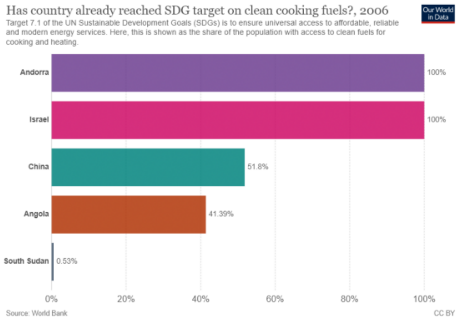
Question: What is the total percentage revenue share of the LVMH Group worldwide in 2020 from Asia and Japan?
Answer [baseline]: **46**
Answer [ours]: **43**
Rationale [ours]: The table shows the revenue share of the LVMH Group worldwide in 2020 from different regions. The total percentage revenue share of the LVMH Group worldwide in 2020 **from Asia and Japan is 34% + 7% = 43%**

Fig. 12: Correct handling of extracted quantities.



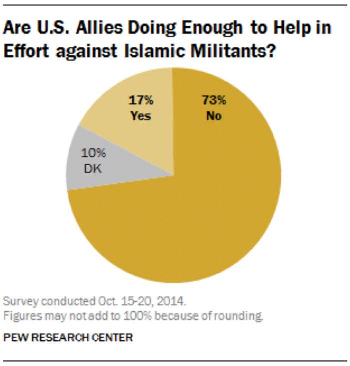
Question: What is the difference between maximum and minimum average annual wage over the years?
Answer [baseline]: **42421**
Answer [ours]: **18267** *[inexact, but correct because it's within 5% of ground truth]*
Rationale [ours]: The **maximum average annual wage is 44690 euros** in 2019 and the **minimum average annual wage is 38370** euros in 2001. So the difference is **44690 - 38370 = 16815**

Fig. 13: Strong ability to infer missing values.



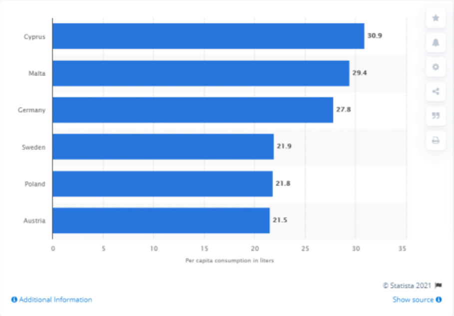
Question: How many bars with the equal value in the bar graph?
Answer [baseline]: **3**
Answer [ours]: **4**
Rationale [ours]: The table shows the percentage of countries that have already reached a certain percentage of their GNI target on clean cooking fuels in 2006. **There are four countries with the equal value** of GNI target on clean cooking fuels: Israel, China, Angola and South Sudan.

Fig. 14: Checking for equality among multiple values requires even better reasoning abilities.



Question: IS the value of No more then sum of Yes and Dk?
Answer [baseline]: **No**
Answer [ours]: **Yes**
Rationale [ours]: The value of **No is 73**. The **sum of Yes and DK is 17 + 10 = 31**. Therefore, the value of **No is more than the sum of Yes and DK**.

Fig. 15: Despite incorrect arithmetic results, final answer can still be correct



Question: Which country has 0.3 difference when compared with Poland?
Answer [baseline]: **austria**
Answer [ours]: **malta**
Rationale [ours]: The table shows the per capita consumption in liters in different countries. Poland has a **per capita consumption of 21.8 liters**. Cyprus has a per capita consumption of 30.9 liters. The **difference between the two is 0.3**

Fig. 16: Both answer and rationale can be wrong when it comes to enumerating values and checking more complex numerical conditions.

D Synthetic Dataset: Statistics

We report the final dataset distribution for our synthetically generated examples. We follow the type of descriptions reported in the paper introducing the benchmark (Masry et al., 2022). In Table 2 we describe the type of question generated. We note that we cannot generate, due to the use of a text-based language model, Visual and Compositional and Visual questions, so we only have Data Retrieval and Compositional. The use of visual captions may enable generating these other types.

We report in Table 11 and Table 12 the number of examples (question, answer, rationale) generated for each type of chart and source. We note that the total number of chart images does not change and they are the original ones from ChartQA.

Source/Graph Type	Pew	Statista-Hum	OWID	OECD	Statista-Aug	Total
H-Bar	2390	1140	1270	-	13811	18611

Abstract

Speculative decoding has emerged as a prominent alternative to autoregressive decoding for expediting inference in large language models (LLMs). However, prevailing assumptions often focus solely on latency reduction, neglecting the computational expenses. In this paper, we present **S**peculate **L**ess, val**i**date **M**ore (SLiM), a speculative decoding enhancement to reduce the speculation set while validating more effective tokens. SLiM is designed to mitigate LLMs' computation costs associated with the token verification by introducing hypothesis reduction based on a fast posterior estimation. It consistently surpasses counterparts lacking cost reduction across a spectrum from CPU to GPU. Our evaluation with diverse conversational datasets shows that SLiM can achieve a substantial 70% reduction in FLOPs while generating more effective predictions on top of prior arts.

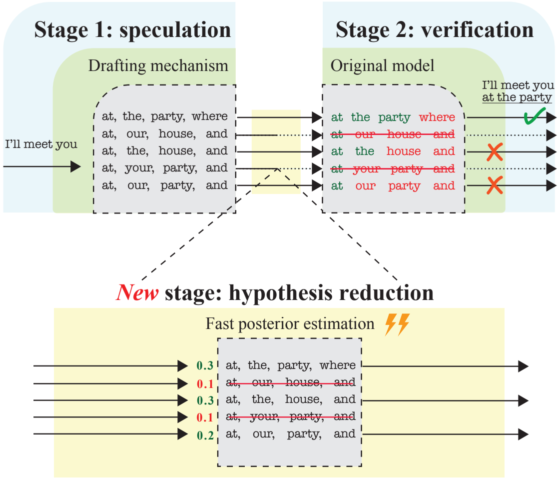

Figure 1: Prior works parallelize token generation by (1) generating multiple hypotheses with a lightweight drafting mechanism and (2) verifying the hypotheses with powerful hardware in parallel. **Our work** introduces a **hypothesis reduction** stage to **drastically reduce the computation**, making our approach friendly for resource-constrained devices.

1 Introduction

Recent advancements in large language models (LLMs), such as LLaMA (Touvron et al., 2023a,b), GPT-4 (OpenAI, 2023b), and Vicuna (Chiang et al., 2023a), have showcased their tremendous potential as proficient artificial intelligence (AI) assistants (Geng and Liu, 2023; Biderman et al., 2023) across diverse domains. Despite their widespread adoption, these models are severely limited by inference speed due to their serial decoding mechanisms.

To address this concern, several methods have been proposed to expedite token generation. In particular, *speculative decoding* (Leviathan et al., 2023; Xia et al., 2022; Miao et al., 2023; Liu et al., 2023; Spector and Re, 2023; Yang et al., 2023) has emerged as a prominent strategy by leveraging the *speculate and verify* mechanism, resulting in *substantial* inference time reduction. It is a dual-stage procedure wherein (1) lightweight models generate hypothesized token sequences speculatively, and (2) the original LLMs verify their acceptance. The key principle of speculative decoding is that it reframes the inherent *sequential* decoding of tokens as a *parallel* operation, leveraging hardware's parallelization power to reduce latency for time-sensitive applications.

Two criteria need to be met for speculative decoding to gain speed: (1) the lightweight model must draft the predictions much faster than the original LLM, and (2) the device must have sufficient computation throughput for the parallel verification of multiple hypotheses. While the first criterion (light drafting mechanism) has garnered attention and inspired several works, the second criterion (speedy verification) has been generally overlooked in the community. This becomes a substantial concern since recent methods tend to generate a relatively larger number of hypotheses (Cai et al., 2023). In many practical scenarios, the inference has very limited computational budgets, and therefore a high-complexity verification step

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1005–1017

Table 1: Computational budget per iteration versus its inference time with 8-bit quantized Vicuna-7B on NVIDIA GeForce RTX 4090.

# Hypothesis	1	4	5	8	26	65	95
GFLOPs/iter	19.6	40.0	59.0	117.6	254.8	431.2	607.6
Time/iter (ms)	1.00	1.74	1.87	1.94	2.65	2.74	2.83

can offset the speed-up benefits gained from speculation. Table 1 shows an actual example, where the forward latency increases with FLOPs along with a larger number of hypotheses verification.

To mitigate the above caveat, we introduce the *three-stage* speculative decoding process which inserts a novel *hypothesis reduction* stage between the two existing stages. Figure 1 illustrates the process, in which our *hypothesis reduction* performs a fast posterior estimation to eliminate unlikely candidates, yielding high computation savings in the verification stage. In other words, we propose to have a lightweight verification strategy before performing the expensive one. Our lightweight verification computes the corrected posterior estimation based on a simple bigram correlation function, providing a more confident assessment to prune the hypotheses.

Figure 2 provides a preview of how our strategy significantly reduces the number of floating-point operations (FLOPs) per speculation step needed to achieve the same speed. In summary, we make the following contributions:

- Motivated by the need to reduce the number of costly verifications for real-time applications, we expand the speculative decoding paradigm with a third *hypothesis reduction* stage to achieve substantial computation savings in the verification stage.
- We contribute SLiM as a method for hypothesis reduction in speculative decoding and show that we can save 70% computations while achieving a competitive speed-up performance (1.8-$2.3\times$) on various conversational benchmarks and different model sizes, paving the way for fast LLM inference for on-device applications.
- We conduct empirical studies of SLiM on diverse devices from CPUs to powerful GPUs. SLiM universally outperforms both autoregressive decoding and state-of-the-art batch-speculative decoding in terms of real-time latency and token generations per forward pass.

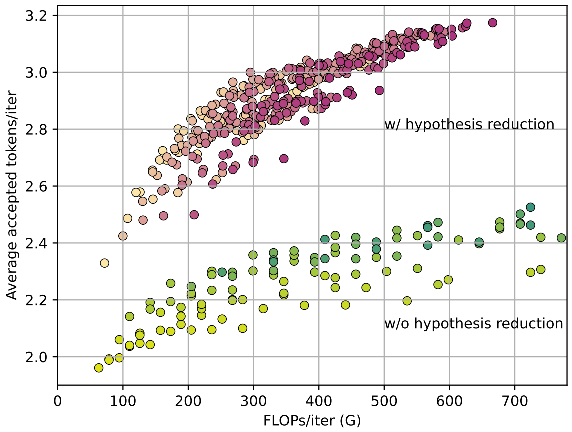

Figure 2: Speedup-computations trade-offs for LLM inference on Vicuna-80 generic prompts (Chiang et al., 2023a). The green and red points illustrate the distribution of speedup-computation trade-offs within speculative decoding, both with and without the hypothesis reduction proposed in this study. Our proposed hypothesis reduction technique increases the token acceptance rate with reduced computations.

2 Related Works

Given the widespread use of Large Language Models (LLMs) across diverse applications, the acceleration of their inference speed has garnered significant attention (Kim et al., 2023a). Extensive efforts have been dedicated to replacing the autoregressive decoding method with parallel decoding (or non-autoregressive decoding) (Gu et al., 2017; Wang et al., 2019; Li et al., 2019; Wei et al., 2019; Shao et al., 2020; Ghazvininejad et al., 2019; Guo et al., 2020; Kasai et al., 2020). While these works focus on machine translation, Welleck et al. (2019); Gu et al. (2019); Stern et al. (2019); Schuster et al. (2022) consider sentence generation task. However, these approaches often necessitate intricate model training, which limits their practical applicability in the context of large models.

Recently, Speculative Decoding (Chen et al., 2023; Leviathan et al., 2023) has stood out as a prominent approach to accelerate LLMs' inferences. This method adopts a "speculate and verify" strategy, utilizing a draft model—a smaller model with faster inference capabilities—to propose tokens for verification by the original model. This approach enables the generation of multiple tokens simultaneously, enhancing overall inference speed.

While earlier works predominantly focus on single-sequence speculation (Stern et al., 2018; Xia et al., 2022; Chen et al., 2023; Leviathan et al., 2023; Gante, 2023; Liu et al., 2023), recent advancements leverage parallel computing for batch-

Table 2: Speculative decoding methods categorized by important features.

Method	Draft and base models combined	Batch speculation	Hypothesis reduction
Chen et al. (2023)	✗	✗	✗
Xia et al. (2022)	✗	✓	✗
Stern et al. (2018)	✓	✗	✗
Cai et al. (2023)	✓	✓	✗
Ours	✓	✓	✓

sequence speculations to further accelerate inferences (Cai et al., 2023; Miao et al., 2023; Spector and Re, 2023; Yang et al., 2023). Notably, (Fu et al., 2023) introduces a novel lossless parallel decoding method based on Jacobi iteration. However, these approaches often come at the cost of increased computation due to the enlargement of the hypothesis set.

In the context of lossy acceleration methods, where the generated output deviates from the original model, BiLD (Kim et al., 2023b) employs a large model to enhance and refine the generation of a smaller model. On the other hand, SoT (Ning et al., 2023) takes a distinct approach by initially creating a skeleton of points and subsequently completing each point in parallel. SLiM differs from them by preserving the original outputs.

In contrast to existing research, SLiM incorporates the batch-speculative strategy with sequence posterior estimation to reduce the hypothesis set without compromising the acceptance rate. The estimation has been guided with a correlation function learned from online corpora. While (Yang et al., 2023) also leverages online corpora for speculation, it necessitates an exact match of context between the corpus and model inputs, limiting its applicability to specific types of problems like retrieval-augmented generation. In contrast, SLiM is application agnostic. When selecting the draft model, SLiM follows the strategy introduced by Stern et al. (2018) and Cai et al. (2023) to mitigate additional complexity. This method entails integrating additional prediction heads atop the base model, allowing it to predict extra tokens. Notably, while these approaches share a common foundation, neither incorporates any hypothesis reduction technique. SLiM stands out as the first method specifically designed to reduce the complexity of both speculative and verification stages. Table 2 provides an overview of SLiM's position in the speculative decoding landscape alongside representative examples.

3 Method

3.1 Background

Speculative decoding endeavors to predict the next m tokens $\mathbf{x}_{1:m}$ simultaneously, given an input prompt $\mathbf{h}$. It comprises two sequential stages in each iteration: (i) speculate and (ii) verify.

In the speculate stage, the method speculates sequences of the next m tokens. This involves relying on a draft model g to approximate the distribution of the next m tokens, expressed as $g(\mathbf{h}) \approx p(\mathbf{x}_{1:m}|\mathbf{h})$ and generate a set of hypothesized sequences $\mathcal{H}$. Moving on to the verify stage, the original model f comes into play to validate each guess. To ensure consistency with autoregressive decoding, the method identifies the longest sequence $\mathbf{x}_{1:l}$ satisfying the condition:

$$\mathbf{x}_j = \arg\max f([\mathbf{h}, \mathbf{x}_{1:j-1}]),\ j = 1, \ldots, l, \quad (1)$$

among all hypothesized sequences $\{\mathbf{x}_j\}_j \in \mathcal{H}$.

This paradigm involves a trade-off between the two stages. An accurate draft model can generate more accurate guesses, resulting in a smaller $\mathcal{H}$ and fewer sequences needing verification by the original model during the verification stage. However, designing a powerful draft model is nontrivial, and a complex model might incur significant latency during the forward call of $g(\mathbf{h})$, offsetting the benefits of multi-token acceleration in real time. Conversely, a simple draft model is easier to obtain but may necessitate a larger set $\mathcal{H}$ for verification, leading to higher hardware requirements of parallel computing and increased latency.

3.2 SLiM: Speculate Less and Validate More

SLiM proposes a solution to the dilemma that alleviates computation burdens in both the speculate and verify stages by adopting a simple draft model and a hypothesis reduction technique. In the speculate stage, rather than directly approximating the joint distribution of $\mathbf{x}_{1:m}$, SLiM trains $m-1$ additional prediction heads atop the same backbone f to predict the marginal distributions $p(\mathbf{x}_i|\mathbf{h})$, where $i = 2, \ldots, m$. This results in a draft model comprising $m-1$ models approximating the marginals, $g_i(\mathbf{h}) \approx p(\mathbf{x}_i|\mathbf{h})$, with each g_i having a similar complexity to the original prediction head of f.

The hypothesis set $\mathcal{H}$ is constructed through the Cartesian product of the top-k selection for each g_i

alongside the top-1 prediction of f:

$$\mathcal{H} = \mathrm{Top}_1(f(\mathbf{h})) \times \prod_{i=2}^{m} \mathrm{Top}_k(g_i(\mathbf{h})), \quad (2)$$

where $\mathrm{Top}_k(p)$ denotes the set of elements with the top k probabilities in the distribution p. Notably, the set's size grows exponentially as k^{m-1}.

SLiM introduces a hypothesis reduction technique by estimating the posterior probability $p(\mathbf{x}_{1:m}|\mathbf{h})$ for each sequence and retaining those with the top k probabilities. Given that decoding with maximum posterior is Bayes' optimal, this approach ensures that accuracy is not compromised. Furthermore, the hypothesis size is reduced from an exponential to a linear function of the top-k parameter. This reduction empowers SLiM to explore a larger hypothesis set without the necessity of verifying every hypothesis with the LLM. Consequently, SLiM effectively engages in less speculation while validating more tokens.

The posterior is estimated by the formula:

$$\hat{p}(\mathbf{x}_{1:m}|\mathbf{h}) = \prod_{i=1}^{m} p(\mathbf{x}_i|\mathbf{h}) \times \prod_{j=1}^{m-1} r(\mathbf{x}_j, \mathbf{x}_{j+1}), \quad (3)$$

where $r : V \times V \mapsto \mathbb{R}$ is some fixed correlation function of two adjacent tokens, and $p(\mathbf{x}_i|\mathbf{h})$ can be approximated by the prediction heads $g_i(\mathbf{h})$. The first term in equation 3 represents joint estimation under the assumption of token independence, while the second term enhances estimation with bigram.

For a visual representation of our posterior estimation, we employ Fig. 3. In this illustration, the hypothesis $\mathcal{H}$ is constructed by combining the top-2 and top-3 tokens predicted by the 2nd and 3rd prediction heads. These combinations are represented as nodes in a tree. Each edge is assigned a weight equivalent to the correlation r calculated by the endpoint nodes, and each node is associated with the probability assessed by the prediction heads. The posterior probability of a node is determined by the product of all node probabilities and edge weights along the path leading to it. The complete SLiM method is summarized in Algorithm 1.

Theoretical Interpretation: SLiM's posterior estimation is a problem of joint distribution estimation based on marginals (Frogner and Poggio, 2019). An effective strategy involves leveraging a multimarginal variant of the optimal transport problem (Peyré et al., 2019; Séjourné et al., 2019).

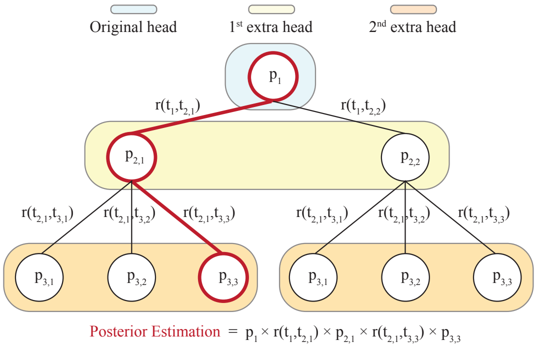

Figure 3: Illustration of SLiM's posterior estimation.

    the longest length satisfying equation 1.
    Concatenate the prompt $\mathbf{h} \leftarrow [\mathbf{h}, \mathbf{x}_{1:l}]$.
end while
```

Multimarginal optimal transport is a technique designed to identify the joint distribution $p(\mathbf{x}_{1:m})$ that minimizes the cost of assembling a sequence. Formally, given marginal distributions $p_i(\mathbf{x}_i)$ and a cost $c(\mathbf{x}_{1:m})$ associated with forming the sequence $\mathbf{x}_{1:m}$, the joint distribution is determined as the solution to the constrained optimization problem:

$$\min_{p} \int p(\mathbf{x}_{1:m}) c(\mathbf{x}_{1:m}) + \mathrm{KL}\left(p || \bigotimes_{i=1}^{m} p_i\right), \quad (4)$$

with constraints that p's marginals equal to p_i. In SLiM, we relax these constraints for faster computation. The following theorem establishes the equivalence of the solution to SLiM's posterior estimation in equation 3. The proof is available in Appendix A.

Theorem 1. *Suppose the optimal transport cost is* $c(\mathbf{x}_{1:m}) = -\sum_{j=1}^{m} \log r(\mathbf{x}_j, \mathbf{x}_{j+1})$, *the relaxed solution to the optimization equation 4 is the posterior estimation in equation 3, subject to a normalization constant.*

3.3 Implementation

In our study, we focus on transformer-based language models and adopt prediction-head-based draft models following the approach used in Stern et al. (2018); Xia et al. (2022); Cai et al. (2023).

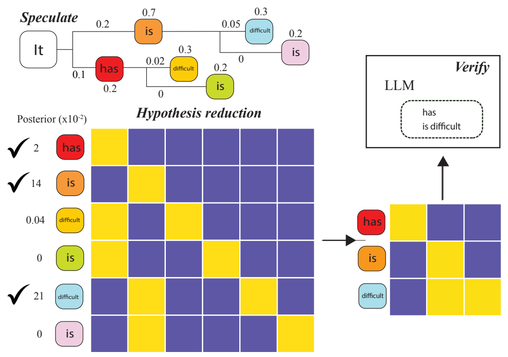

Figure 4: Tree attention with hypothesis reduction. Left and right visualize the attention mask before and after reduction.

Specifically, each extra head consists of two linear layers with a SiLU activation in between them. The first linear layer has an input and output size equivalent to the token embedding size, while the second linear layer has an output size equivalent to the vocabulary size. A skip connection was also introduced before the first linear layer and after the SiLU activation.

To construct the correlation function r, we estimate the prior distribution of two adjacent tokens by $p(\mathbf{x}, \mathbf{y}) := \frac{n(\mathbf{x},\mathbf{y})}{n}$ and the correlation function is defined as follows:

$$r(\mathbf{x}, \mathbf{y}) = \frac{p(\mathbf{x}, \mathbf{y})}{\sum_{\mathbf{y}} p(\mathbf{x}, \mathbf{y}) \sum_{\mathbf{x}} p(\mathbf{x}, \mathbf{y})}. \tag{5}$$

The correlation can be presented as a sparse matrix with a shape of $\mathbb{R}^{V \times V}$ for storage efficiency.

For efficient verification of batch-speculated sequences, we leverage the tree attention mechanism used in the work of Cai et al. (2023). The strategy flattens the tree representation (see Figure 3) for the whole set of hypotheses and encodes its structure through the attention mask. This method effectively avoids duplicated computation of the common prefix among similar hypotheses. We adopt this strategy and convert our pruned tree with the same tree attention mechanism. Figure 4 provides a visual example of our verification reduction combined with tree attention, where the left and right heatmaps illustrate the mask before and after the hypothesis reduction. Note that the attention masks in our work are dynamically computed since the tree has a dynamic shape. This is significantly different from the implementation of Cai et al. (2023), which uses a static mask designed heuristically.

4 Results

4.1 Experimental Setup

Models. We employ the Medusa model (Cai et al., 2023), built upon the Vicuna-7B and Vicuna-13B (Chiang et al., 2023a) as base models. Additionally, the model is trained on the public ShareGPT dataset to incorporate four additional prediction heads, enabling speculation on a maximum of four additional tokens. To derive the correlation function r for SLiM's posterior estimation, we record the frequency of adjacent tokens in the LMSYS-Chat-1M dataset (Zheng et al., 2023). The resulting r is stored in the sparse format, amounting to 82MB in size. We implement our framework on top of PyTorch (Paszke et al., 2019) and the HuggingFace Transformers library (Wolf et al., 2019).

Datasets. We evaluate SLiM's generation capabilities using prompts from six conversational datasets: Vicuna-80 (Chiang et al., 2023b) includes nine different categories of prompts: (CF), coding (CD), knowledge (KL), generic (GN), fermi (FM), roleplay (RP), writing (WT), common sense (CS) and math (MA), and five datasets, each having 360 to 1000 prompts: Chatbot Instruction Prompts (CIP) (Palla, 2023), ChatGPT Prompts (CP) (OpenAI, 2023a), WebQA (Berant et al., 2013), Alpaca (Taori et al., 2023; Peng et al., 2023), and PIQA (Bisk et al., 2020).

Environments. We test the performance on three devices, spanning a spectrum of computation power: Intel(R) Xeon(R) CPU E5-2670 v2 @ 2.50GHz with 20 cores, single NVIDIA RTX 4090 24GB GPU, and single NVIDIA A100 80GB GPU. Except for the A100, all models undergo testing with 8-bit quantization (Dettmers et al., 2022) to ensure compatibility with RAM constraints.

Comparing methods. For a fair comparison, we evaluate SLiM's performance against other speculative methods that use extra prediction heads to generate hypotheses. All methods utilize the same public models, Vicuna-7B and Vicuna-13B, with the same set of prediction heads trained by Cai et al. (2023). We examined two extremes in speculative methods: block parallel decoding (BPD) (Stern et al., 2018) and Medusa (Cai et al., 2023). BPD opts for a single-sequence speculation per iteration, while Medusa adopts batch speculation, concurrently verifying multiple sequences through an optimized tree attention mechanism. SLiM positions

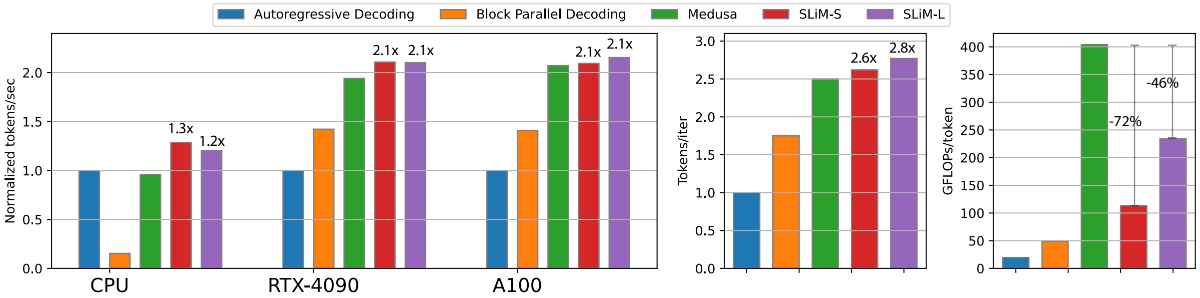

Figure 5: Inference acceleration and FLOPs consumptions for prediction-head-based speculative methods on various devices.

Table 3: Inference results of prediction-head based speculative methods on single RTX 4090 GPU across diverse conversational datasets. Left: real-time accelerations (in tokens per second), with speed-up multipliers relative to the autoregressive decoding. Right: GFLOPs consumption, with percentage relative to Medusa.

	Inference Speed (tokens/s)						GFLOPs per token					
Dataset	CIP	CP	WebQA	Alpaca	PIQA	Avg.	CIP	CP	WebQA	Alpaca	PIQA	Avg.
Autoregressive Decoding	5.56	5.69	5.66	5.76	5.72	5.68 (1.00x)	27.74	25.89	23.23	24.09	18.45	23.58
BPD (Stern et al., 2018)	8.33	7.97	7.47	8.35	8.39	8.12 (1.43x)	56.26	58.48	61.63	55.3	51.49	56.36
Medusa (Cai et al., 2023)	10.51	9.47	8.85	10.05	10.37	9.91 (1.74x)	401.63	417.53	456.55	454.58	426.89	433.38
SLiM-S	**11.13**	**10.09**	**9.19**	**10.46**	**10.52**	**10.31** (**1.82x**)	124.21	134.88	145.10	124.54	126.42	130.46 (30%)

itself between these extremes with reduced batch speculation. We evaluate three configurations of SLiM, denoted as SLiM-SS, SLiM-S and SLiM-L, which have 1, 10 and 20 average hypothesis sequences, respectively. They reduce computation by roughly 70% and 40% as compared to Medusa, respectively. The detailed configurations can be found in Appendix C.

Metrics. We investigate three important metrics: (i) Real-time acceleration: quantified in tokens/s, this metric represents the average number of tokens generated per second. (ii) Device-agnostic acceleration: measured in tokens/iter, this metric reflects the average number of tokens verified or generated with each forward call of the base model. (iii) Computation consumption per effective token generation: denoted as GFLOPs/token, this metric signifies the average number of floating-point operations required to generate a valid token.

4.2 Generation speed-up experiments

The key advantage of SLiM is in mitigating computation burdens without compromising the accuracy of multi-token predictions, making it versatile across devices with diverse computation capabilities. To substantiate this claim, our experiments encompassed three distinct devices in Fig. 5. It delineates real-time acceleration, token generation per iteration, and FLOPs consumption, utilizing Vicuna-7B as the base model on the Vicuna-80 dataset. Notably, on CPUs, SLiM stands out as the sole method achieving real-time speed-up, despite all approaches showcasing device-agnostic acceleration. The gap between real-time and device-agnostic acceleration on CPUs is attributed to the limited parallel computation capability, resulting in significant latency when verifying a large number of batch speculations—offsetting the advantages of multi-token prediction. While BPD incurs lower computation costs, its verification acceptance rate is modest, and Medusa achieves a high acceptance rate at the expense of excessive computation costs.

In contrast, as depicted in the middle and right figures, SLiM-S and SLiM-L generate a comparable number of tokens while utilizing only 28% and 58% of the computations required by Medusa. These findings underscore the significance of hypothesis reduction, especially in applications with constrained computation power. Achieving an optimal balance between the number of speculations and the verification acceptance rate becomes crucial in such scenarios.

On GPUs, Medusa and SLiM demonstrate comparable performance, outperforming BPD due to their batch speculations and efficient parallel verification. Table 3 zooms in on GPU evaluation for five additional datasets, testing on a single GTX 4090. Notably, SLiM surpasses Medusa with only 30% of the computations. As SLiM introduces a hypothesis reduction scheme distinct from Medusa, these results underscore the consistent enhancement the scheme provides across diverse environments in computation and inference speed.

We conducted an analysis of various model sizes

Table 4: Inferences on Vicuna-80 with varying model sizes. Left: real-time accelerations, with speed-up multipliers relative to autoregressive decoding. Right: FLOPs consumption, with percentage relative to the batch-speculative method Medusa.

	Inference speed (Tokens/s)										Tokens/iter	GFLOPs/token
Model	CF	CD	KL	GN	FM	RP	WT	CS	MA	AVG

Table 5: Inferences on Vicuna-80 compared with different methods. We compare with the original speculative decoding (Chen et al., 2023) implemented by Huggingface's assisted generation. We tested against speculative decoding (SD) with draft models of various sizes. The results indicate that prediction-head-based draft models (BPD, Medusa, SLiM) consistently outperform the original speculative decoding in wall-clock inference speed.

	Speculation batch	Wallclock Speedup (Tokens/s)	Theoretical Speedup(Tokens/iter)	GFLOPs/token	Parameter Overhead (#)
Vicuna-13B	1	4.32	1	37.92	0
BPD-13B (Stern et al., 2018)	1	6.98 (1.62×)	1.81	90.01	760M
Medusa-7B (Cai et al., 2023)	42	9.16 (2.12×)	2.59	695.03	760M
SD-SS-13B(Chen et al., 2023)	1	5.67 (1.31×)	2.02	114.54	68M
SD-S-13B(Chen et al., 2023)	1	3.83 (0.89×)	2.43	111.91	160M
SD-L-13B(Chen et al., 2023)	1	3.53 (0.82 ×)	3.45	115.53	1.1B
SLiM-SS-13B	1	7.61 (1.76×)	2.17	89.00	760M + 82M
SLiM-S-13B	10	9.47 (2.19×)	2.64	208.89	760M + 82M
SLiM-L-13B	26	10.06 (2.33×)	2.88	427.27	760M + 82M

and prompt categories, and the findings are summarized in Table 4. The results indicate improved speed-ups for larger models, highlighting the growing significance of speculative decoding in scenarios where there is more room to trade speed-up for computational resources. Furthermore, the analysis indicates that acceleration is particularly effective for coding and math problems. This observation suggests that responses to these types of questions may be more amenable to multi-step ahead predictions than linguistic inquiries, possibly due to their formalizable nature.

In Table 5, we conducted experiments to compare with the original speculative decoding (Chen et al., 2023) implemented by Huggingface's assisted generation. The setup is the same as that of Table 4, using Vicuna-13B as the target model. We tested against speculative decoding with draft models of various sizes (68M, 160M, 1B denoted as SD-SS, SD-S, SD-L, respectively) from Huggingface. We observe that despite the speculative decoding achieves impressive theoretical speedup, it does not necessarily translate into good real-time acceleration due to the overheads in complex draft model computations.

The results indicate that prediction-head-based draft models (BPD, Medusa, SLiM) consistently outperform the original speculative decoding in wall-clock inference speed while incurring small overheads from additional prediction heads (760M) and sparse bigram matrix (82M).

4.3 Model analysis

In this section, we delve into a detailed exploration of SLiM's acceleration capabilities, focusing on experiments conducted on the Vicuna-80 dataset.

Effectiveness of equation 3: How does the correlation change the posterior estimation? Fig. 6 visually illustrates the transformation of the posterior through correlation adjustment in SLiM. In this illustrative example, we employ a specific prompt: "...Here are some tips to get you started: 1. Prioritize tasks:". The base model predicts 'Make' as the next token, while simultaneously, the prediction head generates the distribution for the subsequent token, depicted by the red line in Fig. 6. The noticeable misalignment between the red curve and the ground-truth distribution (depicted in blue) highlights the need for adjustment.

The correlation function, denoted by the grey curve, assigns a high value to 'Make a'. This weight, when multiplied with the posterior, results in the adjusted estimation denoted by the dotted red curve. Remarkably, the distribution now aligns closely with the ground truth, and its prediction of 'a' becomes an accepted outcome. Table 6 provides a quantitative record of the accuracy for the top 1 prediction from the second extra head. The results unequivocally demonstrate that the correlation function consistently enhances accuracy across all categories.

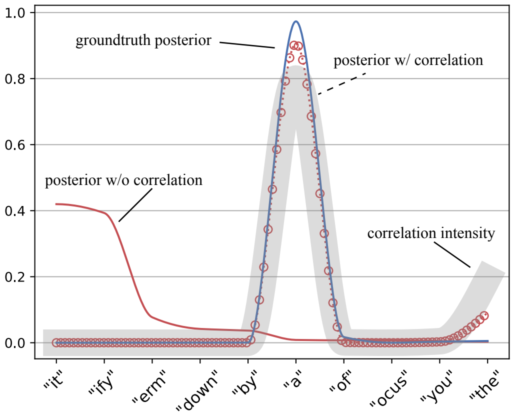

Figure 6: Posterior estimations with and without correlation adjustment.

Table 6: Extra-token prediction accuracies with and without correlation on Vicuna benchmark.

Category	CF	CD	KL	GN	FM	RP	WT	CS	MA	AVG
w/ corr.	43%	61%	49%	57%	47%	43%	52%	50%	59%	50%
w/o corr.	**52%**	**66%**	**59%**	**66%**	**54%**	**50%**	**61%**	**60%**	**66%**	**59%**

When is the correlation is helpful? While correlation is a valuable tool for posterior adjustment, as depicted in Fig. 6, it is essential to acknowledge its potential to mislead the prior estimation generated by the prediction heads. To gain a comprehensive understanding of when correlation can provide a positive impact, we conduct an analysis to assess its effectiveness.

To this end, we present SLiM's speed-ups on the Vicuna-80 dataset, utilizing correlation functions learned from various numbers of sentences from the LMSYS-Chat-1M dataset (Zheng et al., 2023), as illustrated in Fig. 7. Notably, we observe a steady increase in speed-up as the number of prompts grows, reaching saturation at 2.6× when the number exceeds 50,000. This finding underscores the positive correlation between the number of sequences and the improvement in speed-up, indicating that learning from a larger corpus is indeed beneficial. However, the improvement becomes marginal beyond a certain threshold.

To determine when correlation may be detrimental, we compare the results with hypothesis reduction that uses conditional independent predictions (i.e., $r = 1$ in equation 3), yielding a speed-up of 2.26×. Consequently, we identify 2,000 as the threshold prompt number that demarcates the regions into helpful (depicted in green) and harmful (depicted in red) in the figure. This insight suggests that sufficient sentences are necessary for constructing an effective correlation function.

Table 7: Speed-ups vs. number of extra prediction heads.

	SLiM				Medusa
# Extra heads	1	2	3	4	4
Counterfactual	1.78	2.18	**2.31**	2.29	2.29
Coding	1.88	2.55	2.94	**3.28**	3.07
Knowledge	1.80	2.24	**2.48**	2.43	2.39
Generic	1.84	2.42	2.86	**2.96**	2.76
Fermi	1.78	2.25	2.41	**2.43**	2.32
Roleplay	1.75	2.12	**2.32**	2.19	2.23
Writing	1.78	2.32	2.58	**2.64**	2.49
Common Sense	1.84	2.30	2.51	**2.57**	2.48
Math	1.89	2.47	2.73	2.92	**3.07**
Average speed-up	1.81	2.30	2.54	**2.58**	2.50
FLOPs/token	**51.52**	109.52	125.49	113.23	403.91

Table 8: Method ablation study.

Model	Batch speculation	Hypothesis reduction	With Correlation	Tokens per iter	GFLOPs per token
BPD	✗	✗	✗	1.75	48.85
Medusa	✓	✗	✗	2.50	403.91
SLiM-S	✗	✗	✓	1.97	**44.37**
SLiM-S	✓	✓	✗	2.26	124.18
SLiM-S	✓	✓	✓	**2.58**	113.23

How many heads do we need? Moving forward, we delve into an analysis of speed-up concerning the number of prediction heads in Table 7. The results show a higher speed-up with more heads. However, the most efficient computation occurs when having only one extra head, and the efficiency diminishes as we increase the number of heads. This observation prompts considerations for selecting a proper number of heads for resource-constrained devices.

How does the posterior choose sequences with different length? Since the correlation function in equation 5 is unbounded, it can exceed 1, implying that shorter candidates are not always favored over longer ones. In general, one can also explicitly penalize shorter sequence by adding a regularization to our selection stage.

4.4 Method ablation

We conducted a comprehensive study on various SLiM variants to understand the impact of different components on speed-ups. Three key factors were considered: (i) whether to speculate multiple sequences, (ii) whether to adopt hypothesis reduction, and (iii) whether to use correlation or rely on prediction heads alone for estimating posteriors in the reduction stage. Furthermore, average results for BPD and Medusa on the entire Vicuna-80 dataset are presented in Table 8, where BPD and Medusa

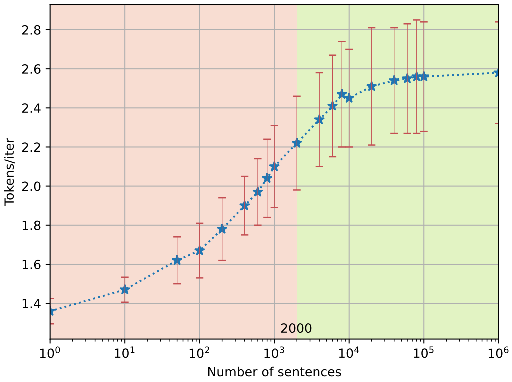

Figure 7: Speed-ups vs. the amount of corpus used for correlation training. The green region represents the cases where the resulting r is better than conditional independent predictions.

denote specific configurations of SLiM with particular choices for these factors.

The results reveal that batch speculation provides the most significant acceleration boost, with all configurations exceeding 2.2× speed-ups, whereas configurations without batch speculation exhibit speed-ups below 2.0×. However, batch speculation introduces a substantial increase in computations. The second-to-last row demonstrates that hypothesis reduction alone reduces computations to 30%, corresponding to approximately 2.2× the computation required for a single speculation, at the expense of 10% reduction in speed-up. The final row further illustrates that correlation not only maintains a similar level of computation but also enhances speed-ups. Notably, even for single speculation, the correlation alone yields a non-negligible speed-up, corroborating the evidence in Table 6.

5 Conclusions

In this work, we introduced SLiM, a speculative decoding enhancement framework designed to alleviate the computational burden associated with token verification. Our method leverages sequence posterior estimation as a lightweight verifier by incorporating bigram information. Starting with an exponentially large speculative set, we judiciously eliminate most speculations with low posteriors. Subsequently, only the sequences in the reduced hypothesis set are verified using the LLM. This approach allows SLiM to speculate fewer sequences while validating more tokens.

Empirically, our results demonstrate that SLiM's acceleration surpasses alternative methods lacking this augmentation across diverse devices. On an RTX 4090, SLiM achieves a notable 1.8-2.3× speed-up across various conversational datasets.

6 Limitations

While SLiM presents a significant improvement in terms of reduced computational requirements and enhanced speed-ups compared to conventional speculative decodings, there are still two primary challenges that warrant attention:

- Computation consumption: Despite its advantages, SLiM's computation remains higher than the autoregressive method. In scenarios where power is a critical constraint, SLiM may still underperform the baseline. Achieving optimal trade-offs between reduced FLOPs and increased speed-up compared to autoregressive methods may require an aggressive and extremely accurate hypothesis reduction strategy.

- Prediction head efficiency: Although SLiM's approach is relatively straightforward, it necessitates additional training of prediction heads. Our empirical results indicate that prediction heads are less accurate when predicting tokens for further steps and therefore may require more complex heads to be trained. Addressing this challenge involves designing efficient heads with minimal capacity while maintaining high predictive accuracy.

These challenges underscore potential areas for further research and optimization to enhance the overall effectiveness of SLiM in various application scenarios.

Supplementary Material

A Proof of Theorem 1

Proof of Theorem 1. Since p is a probability distribution, it satisfies $\int p(\mathbf{x}_{1:m}) d\mathbf{x}_1 \dots d\mathbf{x}_m = 1$. Coupling this with the objective, we obtain the Lagrangian of the objective by

$$\begin{aligned} L =& \int p(\mathbf{x}_{1:m})\, c(\mathbf{x}_1, \dots, \mathbf{x}_m) d\mathbf{x}_1 \dots d\mathbf{x}_m \\ &+ \mathrm{KL}\left(p(\mathbf{x}_{1:m}) || \prod_{i=1}^{m} p_i(\mathbf{x}_i)\right) + \lambda \left(\int p(\mathbf{x}_{1:m}) d\mathbf{x}_1 \dots d\mathbf{x}_m - 1\right) \\ =& \int p(\mathbf{x}_{1:m})\, c(\mathbf{x}_1, \dots, \mathbf{x}_m) d\mathbf{x}_1 \dots d\mathbf{x}_m + \int p(\mathbf{x}_{1:m}) \log\left(\frac{p(\mathbf{x}_{1:m})}{\prod_{i=1}^{m} p_i(\mathbf{x}_i)}\right) d\mathbf{x}_1 \dots d\mathbf{x}_m \\ &+ \lambda \left(\int p(\mathbf{x}_{1:m}) d\mathbf{x}_1 \dots d\mathbf{x}_m - 1\right). \end{aligned}$$

Setting the derivative of L w.r.t. $p(\mathbf{x}_{1:m})$ to zero for every $\mathbf{x}_{1:m}$, we get

$$\begin{aligned} & c(\mathbf{x}_{1:m}) + \log\left(\frac{p(\mathbf{x}_{1:m})}{\prod_{i=1}^{m} p_i(\mathbf{x}_i)}\right) + 1 + \lambda = 0, \\ \Rightarrow\ & p^*(\mathbf{x}_{1:m}) \propto \prod_{i=1}^{m} p_i(\mathbf{x}_i) \times \exp\left(-c(\mathbf{x}_{1:m})\right) = \prod_{i=1}^{m} p_i(\mathbf{x}_i) \times \prod_{j=1}^{m-1} r(\mathbf{x}_j, \mathbf{x}_{j+1}). \end{aligned}$$

□

B Additional Experiments

We exhaustively explore different configurations of SLiM, considering various combinations of the top-k predictions in the heads. We plot the average accepted tokens with and without correlation and hypothesis reduction on the generic category prompt of Vicuna-80. The green points without hypothesis reduction exhibit the least efficiency in terms of the trade-off between the number of accepted hypotheses and efficiency. They are followed by hypothesis reduction without using correlation, with comparable pareto boundaries that require more careful tuning when hypothesis reduction is not utilized. Meanwhile, configurations with correlation in hypothesis, represented by red points, achieve optimal efficiency, outperforming speed-ups compared to Medusa.

C Detailed Configurations of SLiM

We implement SliM-SS, SLiM-S and SLiM-L by choosing top-1, top-20, and top-40 sequences based on the estimated posterior in equation 3. Since many short sequences are prefixes for longer ones, the final number of sequences to be verified is around 10 and 26 on average. Note that the formula in equation 3 does not always favor shorter sequences as the posterior is not *normalized*. As such, the correlation function can be larger than 1, making a longer sequence have a higher score.

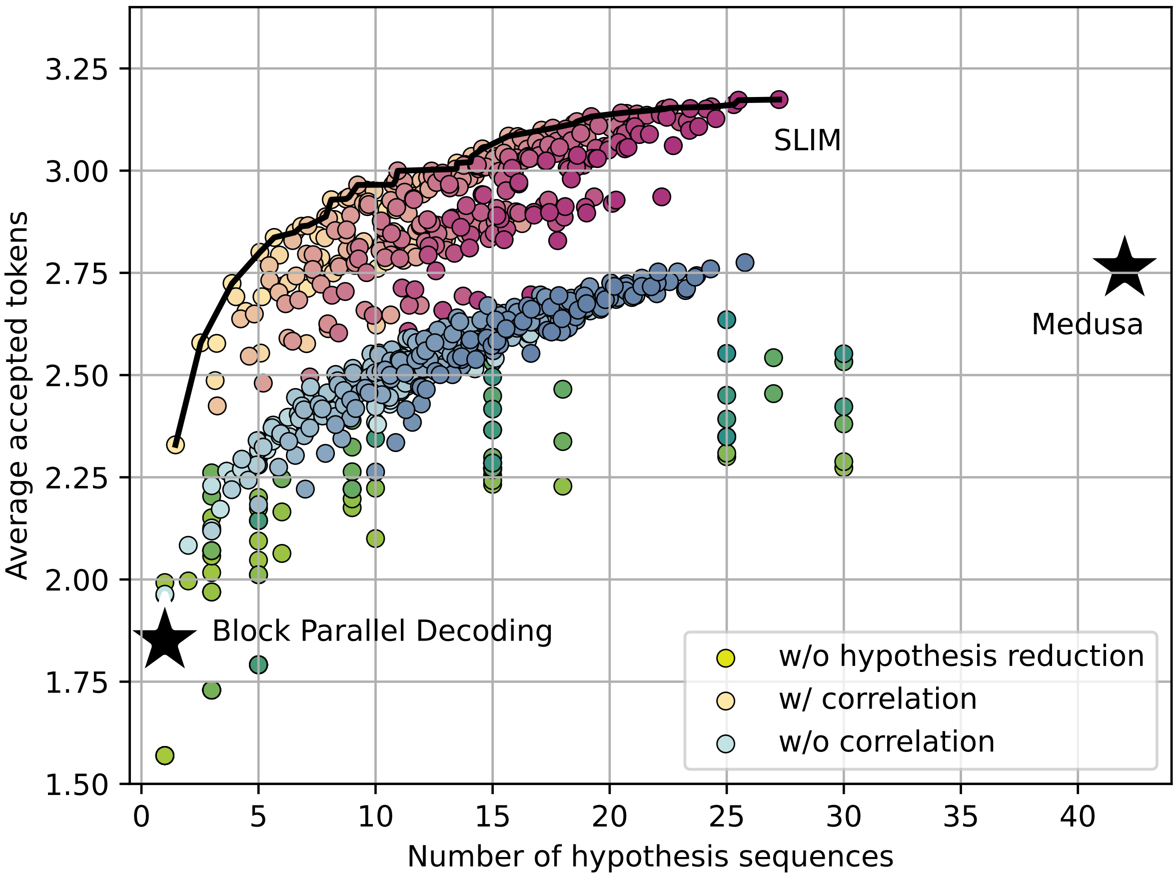

Figure 8: Average accepted tokens for various numbers of hypothesis sequences. The black line denotes the Pareto efficiency achieved by SLiM.

REMATCH: Robust and Efficient Matching of Local Knowledge Graphs to Improve Structural and Semantic Similarity

Abstract

Knowledge graphs play a pivotal role in various applications, such as question-answering and fact-checking. Abstract Meaning Representation (AMR) represents text as knowledge graphs. Evaluating the quality of these graphs involves matching them structurally to each other and semantically to the source text. Existing AMR metrics are inefficient and struggle to capture semantic similarity. We also lack a systematic evaluation benchmark for assessing structural similarity between AMR graphs. To overcome these limitations, we introduce a novel AMR similarity metric, *rematch*, alongside a new evaluation for structural similarity called RARE. Among state-of-the-art metrics, *rematch* ranks second in structural similarity; and first in semantic similarity by 1–5 percentage points on the STS-B and SICK-R benchmarks. *Rematch* is also five times faster than the next most efficient metric.[1]

1 Introduction

Knowledge graphs provide a powerful framework for multi-hop reasoning tasks, such as question answering and fact-checking (Yasunaga et al., 2021; Vedula and Parthasarathy, 2021). Even for closed-domain tasks like long-form question answering and multi-document summarization, knowledge graphs derived from individual documents — referred to as *local knowledge graphs* — exhibit superior performance compared to plain text (Fan et al., 2019). This highlights the significance of automatically parsed knowledge graphs in both large-scale and fine-grained structured reasoning applications.

The Abstract Meaning Representation (AMR) framework leverages acyclic, directed, labeled graphs to represent semantic meaning (knowledge) extracted from text (Banarescu et al., 2013). As illustrated in the example of Fig. 1, AMRs capture the relationships between concepts and their roles in a sentence. They have been applied to a variety of natural language processing tasks, including summarization and question answering (Liu et al., 2015; Hardy and Vlachos, 2018; Bonial et al., 2020; Mitra and Baral, 2016). Recent work has also shown that AMRs can reduce hallucinations and improve performance in factual summarization and text classification tasks (Ribeiro et al., 2022; Shou et al., 2022).

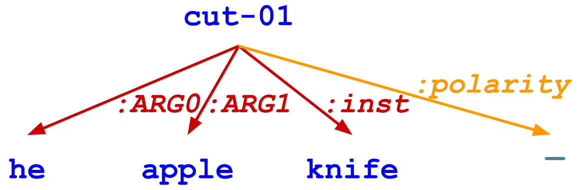

Figure 1: AMR for the sentence: *"He did not cut the apple with a knife."* Colors indicate AMR components: instances (blue), relations (red), constants (teal), and attributes (orange). The instance `cut-01` is a verb frame that uses ***ARG0***, ***ARG1*** and ***inst*** to express the verb's agent (`he`), patient (`apple`), and instrument (`knife`), respectively. The attribute ***polarity*** expresses the negation of the verb through the constant `-`.

However, evaluating the quality of knowledge graphs like AMRs hinges critically on the ability to accurately measure similarity. This assessment must consider a dual perspective. Firstly, the similarity between two AMRs should reflect structural consistency, guaranteeing that the similarity between two AMRs aligns with the similarity of their structural connections. Secondly, AMRs should exhibit semantic consistency, ensuring that the similarity between two AMRs aligns with the similarity of the texts from which they are derived. Therefore, an effective AMR similarity metric must successfully account for both structural and semantic similarity, all while overcoming the resource-intensive nature of matching labeled graphs.

Current AMR similarity metrics fall short in sev-

---

[1] Our code for *rematch* and RARE is publicly available at: `https://github.com/osome-iu/Rematch-RARE`

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1018–1028
June 16-21, 2024

eral key areas. Firstly, their computational efficiency hinders the comparison of large AMRs extracted from documents (Naseem et al., 2022). Secondly, these metrics struggle to accurately capture the semantic similarity of the underlying text from which AMRs are derived (Leung et al., 2022a). Additionally, while recent efforts like BAMBOO (Opitz et al., 2021) have evaluated metrics on AMR transformations, we still lack a large-scale benchmark to systematically evaluate the ability of AMR metrics to capture structural similarity.

Our work introduces a structural AMR benchmark called *Randomized AMRs with Rewired Edges* (RARE) and proposes *rematch*, a novel and efficient AMR similarity metric that captures both structural and semantic similarity. Compared to the state of the art, *rematch* trails the best similarity metric on RARE by 1 percentage point and ranks first on the STS-B (Agirre et al., 2016) and SICK-R (Marelli et al., 2014) benchmarks by 1–5 percentage points. Additionally, *rematch* is five times faster than the next most efficient metric.

2 Background

2.1 Abstract Meaning Representations

Abstract Meaning Representation (AMR) is a structural, explicit language model that utilizes directed, labeled graphs to capture the semantics of text (Banarescu et al., 2013). AMR is designed to be independent of surface syntax, ensuring that sentences with equivalent meanings are represented by the same graph. An AMR comprises three fundamental components: instances, attributes, and relations.

1. **Instances** are the core semantic concepts. Structurally, they are represented by nodes in the graph. AMRs have two types of instances. One utilizes *PropBank* (Palmer et al., 2005), a dictionary of frames that map verbs and adjectives. The other comprises entities. Considering the sentence in Fig. 1, *"He did not cut the apple with a knife,"* the AMR contains a *PropBank* instance **`cut-01`** and three entity instances: **`he`**, **`apple`** and **`knife`**.

2. **Attributes** capture details about instances, such as names, numbers, and dates. These values are represented as constant nodes. Structurally, an attribute is identified in the graph as the edge from an instance node to a constant node. For example, in Fig. 1, the attribute ***`polarity`*** is specified for the instance **`cut-01`**, where **`-`** is the constant that represents the negation of the verb.

3. **Relations** represent the connections between instances. In Fig. 1, the instance **`cut-01`** has three outgoing relations: ***`ARG0`***, ***`ARG1`***, and ***`inst`***. These come from *PropBank*'s **`cut-01`** frame and link to the agent (**`he`**), the patient (**`apple`**), and the instrument (**`knife`**), respectively.

2.2 AMR Similarity

Graph isomorphism is a test to determine whether two graphs are structurally equivalent. The class-wise isomorphism testing with limited backtracking (CISC) algorithm efficiently identifies isomorphic relationships in labeled graphs (Hsieh et al., 2006), such as AMRs. But a pair of AMRs may not have the same number of nodes, which violates a key assumption of graph isomorphism. A more appropriate approach is subgraph isomorphism, which determines whether a smaller graph is isomorphic to a subgraph of a larger graph. Subgraphs of directed acyclic graphs, like AMRs, can be enumerated in polynomial time (Peng et al., 2018), enabling efficient application of the CISC test to each pair of smaller AMR and larger AMR subgraphs. However, even if two AMRs are not subgraph-isomorphic, they may still exhibit similarities in meaning and structure. Next, we describe various existing approaches to measure the similarity between AMR graphs.

2.3 AMR Similarity Metrics

2.3.1 Smatch

Smatch is a prominent tool for evaluating AMR parsers (Cai and Knight, 2013). It establishes AMR alignment by generating a one-to-one node mapping, considering node and edge labels. To efficiently explore this vast mapping space, *smatch* employs a hill-climbing heuristic.

2.3.2 S2match

Similar to *smatch*, *s2match* (Opitz et al., 2020) also establishes a node alignment between two AMRs. However, instead of relying on AMR labels, *s2match* utilizes GloVe word embeddings (Pennington et al., 2014). To address the extensive search space, it uses the same hill-climbing heuristic adopted by *smatch.*

2.3.3 Sembleu

Sembleu generates path-based n-grams from AMRs by leveraging node and edge labels (Song and Gildea, 2019). The final similarity score for an AMR pair is determined by calculating the BLEU

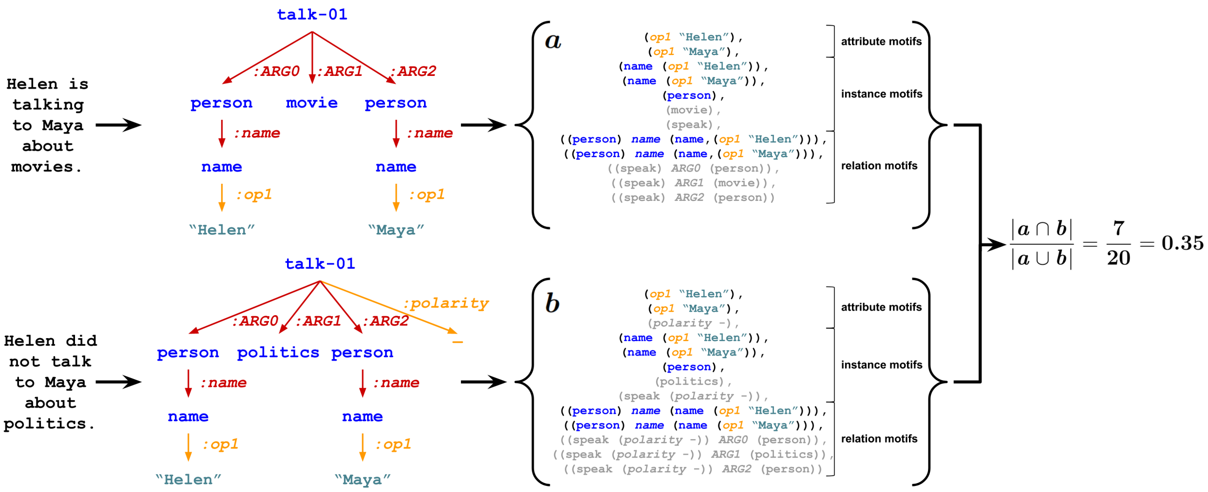

Figure 2: An example of *rematch*'s similarity calculation for a pair of AMRs. After AMRs are parsed from sentences, *rematch* has a two-step process to calculate similarity. First, sets of motifs are generated. Second, the two sets are used to calculate the Jaccard similarity (intersecting motifs shown in color).

score (Papineni et al., 2002) between their n-grams. By avoiding a one-to-one node alignment, *Sembleu* efficiently bypasses the issue of exploring a large search space.

2.3.4 WLK

The Weisfeiler-Leman Kernel (*WLK*) and Wasserstein Weisfeiler-Leman Kernel (*WWLK*) for AMRs also utilize graph features for computing similarity (Opitz et al., 2021). *WLK* first constructs node features by recursively aggregating AMR node and edge labels. Then it generates a frequency-based feature vector for each AMR and calculates a similarity score using their inner product. *WWLK* extends *WLK* with features based on aggregated node embeddings (GloVE) instead of node labels. Since WWLK is a supervised metric, we do not consider it in our evaluation.

3 Methods

In this work, we propose *rematch*, an AMR similarity metric that aims to capture both the structural and semantic overlap between two AMRs.

A straightforward approach to match two labeled graphs involves identifying the alignment between node labels. However, labeled graphs often contain duplicate labels, necessitating an exhaustive exploration of all one-to-one combinations among nodes within the same label group to determine the optimal match. The resulting matching complexity hinges on the size of node groups with shared labels. This is why algorithms like *smatch* and *s2match* do not scale well to large AMRs, where these node groups can be large.

Graph features constructed using an ordered concatenation of edge-node bi-grams are utilized in both isomorphism tests like the CISC and kernels like Weisfeiler-Leman (Shervashidze et al., 2011). This approach is effective: it consistently produces smaller node groups compared to those based solely on node labels. Matching between two graphs is significantly accelerated as a result.

Inspired by this idea of exploiting graph features for efficiency, *rematch* computes the similarity between two AMRs by analyzing the overlap of semantically rich features, which we call *motifs*. Unlike the ordered graph partitions used by CISC and Weisfeiler-Leman Kernel, which rely on node and edge labels, AMR *motifs* are unordered graph partitions that leverage AMR instances, attributes, and relations. This approach allows *rematch* to capture meaning across three semantic levels: specific facts (attributes), main concepts (instances), and the relationships among concepts (relations). Fig. 2 illustrates *rematch* through an example. Next, we delve into the three orders of semantic motifs that we use for *rematch*. We extract these motifs using the Python package Penman (Goodman, 2020).

1. **Attribute motifs** are pairs of attributes and constants associated with AMR instance nodes. For the bottom AMR in Fig. 2, **`talk-01`** has attribute motif (***`polarity -`***), indicating a negation. The first **`name`** has the attribute motif (***`op1`*** **`"Helen"`**) and the second **`name`** has (***`op1`*** **`"Maya"`**), identifying the name values. The remaining instances do not have any attributes.

2. **Instance motifs** leverage *Verbatlas*, a resource that maps *PropBank* frames to more generalized frames (Di Fabio et al., 2019). If an instance in the AMR corresponds to a Verbatlas frame, the latter is used instead. Otherwise, the original *PropBank* instance is retained. For example, in Fig. 2, `talk-01` is replaced by the more generalized Verbatlas frame `speak`. The generation of instance motifs follows two approaches. If an instance lacks associated attributes, the instance itself serves as its motif. However, if attributes are present, instance motifs are constructed by combining the instance with each of its attribute motifs. For the bottom AMR in Fig. 2, the instance motif for `talk-01` is (`speak` (`polarity -`)), indicating a negation of the verb. For the two `person` instances and the `politics` instance, the instances themselves become their motifs, namely (`person`) and (`politics`). Finally, the instance motifs for the two `name` instances are (`name` (`op1 "Helen"`)) and (`name` (`op1 "Maya"`)) respectively, identifying the names in the conversation.

3. **Relation motifs** are constructed for relation edges in an AMR graph. Each relation motif comprises three elements: an instance motif of the source instance, the relation label, and an instance motif of the target instance. A relation can have multiple relation motifs, one for each unique combination of source and target instance motifs. For the bottom AMR in Fig. 2, the relation motifs for `ARG0`, `ARG1` and `ARG2` are: ((`speak` (`polarity -`)) `ARG0` `person`), indicating a person is the speaker of the conversation; ((`speak` (`polarity -`)) `ARG1` `politics`), indicating that the topic of conversation is politics; and ((`speak` (`polarity -`)) `ARG2` `person`), indicating that a person is the recipient of the conversation. For the two `name` relations, the motifs are: ((`person`) `name` (`op1 "Helen"`))), identifying "Helen" as the name of one person; and ((`person`) `name` (`op1 "Maya"`)), identifying "Maya" as the name of the other person.

Each AMR is represented by the union of its instance, relation, and attribute motifs. The *rematch* score between two AMRs is determined by calculating the Jaccard similarity between their respective motif sets, as illustrated in Fig. 2.

4 Evaluation

We evaluate the effectiveness of *rematch* on three types of similarity: structural similarity, semantic similarity, and BAMBOO (Opitz et al., 2021), a hybrid benchmark that modifies AMR semantics through structural transformations. Additionally, we assess the efficiency of *rematch*.

4.1 Structural Similarity (RARE)

Given that AMRs are graphical representations of text, an AMR similarity metric should be sensitive to structural variations between AMRs, even if its labels remain unchanged.

Since there is no established evaluation of AMR metrics on structural similarity, we have developed a new benchmark dataset called *Randomized AMRs with Rewired Edges* (RARE). RARE consists of English AMR pairs with similarity scores that reflect the structural differences between them.

In the construction of RARE, we adopt an iterative randomization technique commonly used for graph rewiring. This involves repeatedly selecting a random pair of directed edges and swapping either their source or target nodes to establish new connections. This way each node's in-degree and out-degree are preserved. In applying this approach to AMRs, we swap a random pair of edges between either attributes or relations. This allows us to quantify the structural changes made to the AMR through the number of swapped edges.

RARE does not add or remove edges as these modifications would amount to adding or removing information. Systematic edge insertion or deletion would also introduce additional complications, such as having to decide the set of edges that could be added or removed while keeping the network connected. By swapping edges alone, we guarantee that the AMRs being compared have the same information in terms of size, density, and connectivity.

We generate a spectrum of modified graphs from an original AMR, ranging from the unchanged graph to one where all edges are rewired, subject to some constraints that preserve the integrity of AMRs:

1. **Structural Constraints.** AMRs are acyclic, connected graphs that allow no multiedges (more than one edge between the same pair of nodes). To preserve these properties during the rewiring process, pairs of swapped edges must maintain these constraints in the modified AMR.

2. **Semantic Constraints.** These constraints relate to swapping attributes and relations:

(a) Attributes have an inherent connection with constants in AMRs. Hence, while rewiring a pair of attribute edges, only the source instance node should be swapped. This restriction ensures that the association between the attribute and its corresponding constant remains intact. For example, the constant node `-` should remain associated solely with the attribute edge ***`polarity`***.

(b) Relations in AMRs connect two instances. When rewiring a pair of relation edges, only the target instance node should be swapped. This restriction maintains the association between the relation's source instance and the relation itself. For example, *PropBank* instances have a predefined set of relations with which they can be associated. The instance node **`talk-01`** can only be associated with edges ***ARG0***, ***ARG1***, and ***ARG2***.

Each pair of AMRs, consisting of an original AMR G with E edges and its corresponding rewired AMR G' with E' swapped edges, is annotated with the following similarity score:

$$similarity(G, G') = \frac{|E| - |E'|}{|E|} \qquad (1)$$

To generate the RARE benchmark, we licensed the English AMR Annotation 3.0 (Knight, Kevin et al., 2020) containing 59,255 human-created AMRs. Using the process described above, we get 563,143 rewired AMR pairs annotated with similarity scores per Eq. 1. Since the original AMR Annotation 3.0 corpus has an unusual training-development-testing split, we merge, shuffle, and re-split AMR 3.0 into training (47,404), development (5,925), and test (5,926) sets to get an 80-10-10 split ratio that is more consistent with standard benchmarks. The resulting RARE training-development-test sizes are 450,067, 56,358, and 56,718, respectively. The creation of training and development splits could facilitate the future development of supervised AMR metrics. For the current evaluation, AMR structural similarity metrics are evaluated on the RARE test split.

We evaluate a similarity metric by computing the Spearman correlation between its scores and the ground truth values from Eq. 1, across a set of pairs of original and modified AMRs. We refer to this as the *structural consistency* of the metric.

4.2 Semantic Similarity

A fundamental tenet of AMRs is that if two pieces of text are semantically related, their corresponding AMRs should exhibit a degree of similarity. But a metric could deem two AMRs similar even when their textual sources have very different meanings. As an example, for two completely unrelated sentences "Spanish bulls gore seven to death" and "Obama queries Turnbull over China port deal," *smatch* assigns a non-zero score due to the similarity in their argument structure (Leung et al., 2022b). To tease out such shortcomings, we evaluate each AMR similarity metric by considering many pairs of sentences. For each pair, we compare the similarity generated by the metric for the corresponding AMRs to a ground-truth similarity score between the sentences generated by human annotations.

We utilize two standard sentence similarity benchmarks for English: STS-B (Agirre et al., 2016) and SICK-R (Marelli et al., 2014). To account for variations in AMR parsing accuracy, we employ four different AMR parsers: *spring* (Bevilacqua et al., 2021), *amrbart* (Bai et al., 2022), *structbart* (Drozdov et al., 2022), and the *maximum Bayes smatch ensemble* (Lee et al., 2022).

Given a set of sentence pairs and corresponding AMR pairs, we evaluate a similarity metric by computing the Spearman correlation between its scores for the AMR pairs and the human-annotated similarity values for the sentence pairs. We refer to this as the *semantic consistency* of the metric. Note that semantic consistency can be used to evaluate any similarity method for sentences, not only AMR-based ones. For both structural and semantic consistency, we use Spearman rather than Pearson correlation because we do not assume that the similarity values are normally distributed.

4.3 Hybrid Similarity (BAMBOO)

In addition to the structural and semantic consistency discussed earlier, we evaluate the robustness of AMR metrics using the *Benchmark for AMR Metrics Based on Overt Objectives*, or BAMBOO (Opitz et al., 2021). BAMBOO assesses the ability of AMR similarity metrics to capture semantic similarity between English sentences while modifying the structure of the corresponding AMRs.

BAMBOO incorporates three types of graph modifications: synonym replacement, reification, and role confusion. Consider the example sentence "He lives in the attic," represented by an AMR where the node `live-01` connects to nodes `he` and `attic` via the edges ***`ARG0`*** and ***`location`***, respectively. Synonym replacement swaps *PropBank* instances with equivalent terms. In the example, `live-01` might be replaced by `reside-01`. Reification transforms a relation into a new instance. In the example, the ***`location`*** edge might be replaced by a new node `be-located-at-91` connected to `live-01` and `attic` via new ***`ARG1`*** and ***`ARG2`*** edges, respectively. Finally, role confusion swaps relation roles. In the example, the relations ***`location`*** and ***`ARG0`*** might be swapped such that the modified AMR would represent the sentence "The attic lives in him." BAMBOO applies these modifications to the original train, test and dev splits of the STS-B, SICK-R, and PARA (Dolan and Brockett, 2005) datasets.

Given a set of modified AMR pairs, BAMBOO evaluates an AMR metric by the Spearman correlation[2] between its scores and the similarity between the corresponding sentence pairs. We call this *hybrid consistency* of the metric.

4.4 Efficiency

As discussed earlier, the computational complexity associated with node alignment is a crucial challenge for comparing AMRs. To address this issue, we evaluate the search spaces explored by various metrics and the required runtime.

We establish a realistic test bed using the AMR Annotation 3.0 once again. For this evaluation, we randomly sampled 500,000 pairs from the $\binom{59{,}255}{2}$ possible AMR combinations. For each pair of AMRs (G_1, G_2), the search spaces for node alignment algorithms like *smatch* and *s2match* is

$$search(G_1, G_2) = \prod_{n_i \in G_1} |M_{G_2}(n_i)| \qquad (2)$$

where $M_{G_2}(n_i)$ denotes the set of matching candidates in G_2 for node n_i. For feature-based algorithms, like *sembleu*, *WLK*, and *rematch*, we record the search space using

$$search(G_1, G_2) = |\mathcal{F}(G_1)| \cdot |\mathcal{F}(G_2)| \qquad (3)$$

where $\mathcal{F}(G)$ denotes the feature set for graph G. For each pair of AMRs, we also record the runtime.

AMR Metric	RARE
smatch	**96.57**
s2match	94.11
sembleu	94.83
WLK	90.39
rematch	95.32

Table 1: Structural consistency of different AMR similarity metrics on the RARE test split.

5 Results

5.1 Structural Consistency

Table 1 reports on the structural consistency of the AMR similarity metrics on the RARE test split. We can see that *smatch* performs the best, followed closely by *rematch*, *sembleu* and *s2match*. The subpar performance of *WLK* can be attributed to their reliance on features using all of a node's neighbors. This approach results in changes to node features regardless of the number of modified neighbors, failing to capture the nuances of neighborhood changes.

5.2 Semantic Consistency

Table 2 reports on the semantic consistency of the similarity metrics for different AMR parsers. *Rematch* outperforms all other metrics by 1–5 percentage points, across all parsers and benchmarks. The *mbse* and *amrbart* parsers perform best for the STS-B and SICK-R datasets, respectively.

So far we have focused on methods that use AMRs to calculate the semantic similarity between sentences. Table 3 reports on the evaluation of alternative similarity methods on the same benchmarks. Like AMR-based methods, these are also unsupervised (not trained specifically) for textual semantic similarity. AMR outperforms some representations like GloVe and RoBERTa but lags behind the state-of-the-art method SimCSE (Gao et al., 2022).

5.3 Hybrid Consistency

Table 4 reports on the hybrid consistency of AMR similarity metrics on the four different tests of BAMBOO, across three different datasets. The results vary considerably across graph modifications and datasets; none of the methods is a clear winner. *Rematch* achieves best results in three out of twelve tests and lags slightly behind *s2match* on average.

---

[2] The original formulation of BAMBOO (Opitz et al., 2021) used Pearson correlation. Here we use Spearman because, as for structural and semantic consistency, we do not assume that the similarity values are normally distributed.

5.4 Efficiency

Fig. 3 shows the search spaces explored by AMR metrics for increasing values of N, the average size of each pair of AMRs. The size of each AMR is determined by the sum of the number of instances, attributes, and relations. Approaches that find node alignment between AMRs, like *smatch* and *s2match*, explore search spaces that grow exponentially with N. Feature-based methods, like *sembleu*, *WLK*, and *rematch*, in contrast, explore significantly smaller spaces.

Fig. 3 also shows the runtimes for increasing N. By using a hill-climbing heuristic, node-alignment metrics effectively overcome the exponentially growing search spaces. However, they are significantly less efficient compared to feature-based metrics. For large values of N, *smatch* and *s2match* display an approximately quadratic time complexity. *Sembleu*, *WLK*, and *rematch*, on the other hand, demonstrate a linear complexity.

In terms of absolute runtime on the test bed, *rematch* is the fastest metric, with a runtime of 51 seconds. This is five times faster than *sembleu*, which took 275 seconds. *Smatch*, *s2match*, and *WLK* trailed further behind, requiring 927, 7718, and 315 seconds. All metrics executed the test bed on a single 2.25 GHz core. *Rematch*, *sembleu*, and *smatch* needed 0.2 GB of RAM, whereas *s2match* and *WLK* required 2 GB and 30 GB, respectively. We leave the efficiency comparison against non-AMR similarity methods like GloVe, RoBERTa and SimCSE as future work.

5.5 Ablation Study

To assess the impact of the three types of *rematch* motifs — attribute, instance, and relation — on structural and semantic similarity, let us conduct an ablation study, in which we remove one or more types of motifs at a time. The results are presented in Table 5. Instance motifs have the most significant influence on semantic similarity, particularly when combined with relation motifs. Conversely, relation motifs exert the strongest influence on structural similarity, especially when complemented by instance motifs.

To evaluate the overall effectiveness of motifs, we also assess the performance of *rematch* through the use of AMR labels alone. For the bottom AMR in Fig. 2, the label set is {`talk-01`, `person`, `politics`, `name`, `ARG0`, `ARG1`, `ARG2`, `name`, `-`, `"Helen"`, `"Maya"`, `polarity`, `op1`}. Note that `person`, `name`, and `op1` appear only once in the set. Similar to *rematch* motifs, we calculate the Jaccard similarity between two AMR label sets. As shown in Table 5, the decline in structural consistency when using AMR labels is substantial, given the absence of structural information in the label sets. In contrast, the decline in semantic consistency is relatively modest, indicating that AMR labels play a significant role in capturing semantics.

5.6 Error Analysis

On structural consistency, we find that *rematch* underperforms when RARE swaps attribute edges connected to instance nodes with many relations. While the change might seem minor (a single swapped edge), the nested motif structure of *rematch* amplifies the difference: mismatches in attribute motifs extend to instance motifs and all con-

	Main			Reification			Synonym Replace			Role Confusion			Avg.

Table 5: Ablation study of different motifs on structural (RARE) and semantic (STS-B, SICK-R) consistency. Dev splits of RARE and STS-B, and the trial split of SICK-R were used. The *mbse* and *amrbart* parsers were used for STS-B and SICK-R, respectively.

nected relation motifs, leading to a significant discrepancy in the overall similarity score.

The nested nature of *rematch* can also sometimes underestimate semantic similarity. For instance, consider the sentences "Work into it slowly" and "You work on it slowly." The first sentence's AMR associates an `imperative` attribute with the verb `work-01`. This feature is missing in the second sentence. Consequently, *rematch* generates different instance and relation motifs, resulting in a lower similarity score compared to the ground-truth similarity.

More often, the nested motif generation grants *rematch* an advantage in semantic consistency tasks: it allows *rematch* to handle negation more effectively compared to other metrics. For example, the sentences "You should do it" and "You should never do it" have a lower similarity score in *rematch* due to the presence of the negative (`-`) `polarity` attribute.

6 Conclusion

This paper introduces *rematch*, a novel and efficient metric for AMR similarity. *Rematch* leverages semantic AMR motifs to outperform existing metrics in both semantic consistency and computational efficiency. Additionally, we present RARE, a new benchmark designed to evaluate the structural consistency of AMR metrics. Using RARE, we demonstrate the strong sensitivity of *rematch* to structural changes in AMRs.

AMR matching was originally introduced to evaluate and enhance AMR parsers. Through improved matching, metrics like *rematch* improve parsing, which *indirectly* benefits downstream uses of AMRs. But *rematch* shows that AMRs encode richer semantics than previously assumed. Thus, improved AMR matching also *directly* benefits downstream applications, like semantic textual similarity.

Future research should explore the full potential of AMRs for natural language understanding. Natural Language Inference (NLI) is a prime example, where AMR-based systems have already shown promise (Opitz et al., 2023). An even more intriguing direction would be to develop methods that perform NLI solely through AMR matching, capitalizing on the rich structure and semantics encoded within AMRs.

7 Limitations

Current AMR metrics, including *rematch*, have limitations for downstream tasks like semantic textual similarity. One key issue is their inability to capture similarity between words. This can lead metrics like *rematch* to misclassify two sentences with different wordings but equivalent meaning as dissimilar. *S2match* attempts to address this limitation by using word embeddings for node alignment, but our analysis shows that this approach offers minimal improvement in semantic consistency at a high computational cost. Recently, this limitation was addressed by a novel self-supervised metric called AMRSim (Shou and Lin, 2023). It trains Siamese BERT models on flattened silver AMR pairs generated from one million sentences sampled from Wikipedia.

Another limitation of *rematch* is that it uses motifs associated with single edges (paths of length one). While this approach works well for short-text semantic similarity, it might not capture the more complex semantics present in AMRs derived from longer documents. In other words, *rematch* might struggle to compare the meaning of longer texts.

Modeling the Sacred: Considerations when Using Religious Texts in Natural Language Processing

Ben Hutchinson
Google Research, Australia
`benhutch@google.com`

Abstract

This position paper concerns the use of religious texts in Natural Language Processing (NLP), which is of special interest to the Ethics of NLP. Religious texts are expressions of culturally important values, and machine learned models have a propensity to reproduce cultural values encoded in their training data. Furthermore, translations of religious texts are frequently used by NLP researchers when language data is scarce. This repurposes the translations from their original uses and motivations, which often involve attracting new followers. This paper argues that NLP's use of such texts raises considerations that go beyond model biases, including data provenance, cultural contexts, and their use in proselytism. We argue for more consideration of researcher positionality, and of the perspectives of marginalized linguistic and religious communities.

1 Introduction

> *"a particular string of speech may be viewed as data by a researcher but as sacred incantation by language users"*
> — Holton et al. (2022)

The Association for Computational Linguistics (ACL) is a secular institution. Its constitution, resolutions and policies make no mention of religion other than forbidding harassment on the basis of religion.[1] Nevertheless the Christian Bible and the Islamic Quran[2] are often used in the scientific and professional activities of ACL, as measured by papers published in the ACL Anthology (see Section 3). Some of the reasons that NLP researchers use the Bible are aptly expressed by Resnik et al. (1999). The Bible is the world's most translated book, with translations in over 2,000 languages, and often multiple translations per language. Furthermore, great care is taken with the translations, so from an NLP perspective data quality is high. It is often easily available in electronic form, and is in the public domain, hence free to use. It has a standard structure which allows parallel alignment verse-by-verse. For these reasons, as recently as 2006 it was said to be "perhaps surprising that the Bible has not been more widely used as a multilingual corpus by the computational linguistics and information retrieval community" (Chew et al., 2006).

Despite the use of religious texts in NLP, the ethical considerations of such use have not previously received much attention. Religious texts have generally been treated as just data, overlooking their sacred dimensions, their cultural significance, and their histories, which are sometimes entwined with colonial projects. This position paper contends that responsible secularism demands engaging with the ethical considerations of the use of these texts. We take the position that it is important to contextualize religious texts within not just their religious but also their broader cultural and historical contexts. We argue that it is important to acknowledge the motivations, goals, and positionalities of researchers using religious texts, particularly as it is difficult to have intimate first-hand knowledge of the moral and cultural concerns of a religion beyond one's own (if any).

Section 2 provides relevant background material, including discussing the relationship between academic linguistics and missionary linguistics. In Section 3, we present an empirical study of NLP papers using sacred texts. Section 4 discusses various ethical considerations when using sacred texts in NLP. In doing so, we consider a range of approaches to the topic, including ethical theories, Indigenous perspectives,[3] human rights, and the AI

[1] `www.aclweb.org`, accessed September 2023

[2] This paper follows several style guides in using "Quran", although mentions of the alternate Latinization "Koran" are also considered in the corpus studies we report on.

[3] Following style guides such as (Younging, 2018), this paper capitalizes the first letter of "Indigenous".

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1029–1043
June 16-21, 2024

Religion	Sacred texts	Est. 2020 population	Proselytizing
Christianity	Bible, New Testament, Old Testament	2,382,750,000	Yes
Islam	Quran (alt. spellings include Koran), Old Testament	1,907,110,000	Yes
Hinduism	Vedas, Upanishads, Puranas	1,161,440,000	No
Buddhism	Tripitaka, Mahayana Sutras, Tibetan Book of the Dead	506,990,000	Yes
Traditional Chinese Religion	Zhuangzi, Tao-te Ching, Daozang	310,000,000	No
Judaism	Talmod, Torah, Tanakh, Old Testament	14,660,000	No

Table 1: Some major world religions and their texts. Population estimates are from the US-based Pew Research Center (`www.pewresearch.org`), which conducts demographic and other research.

principles commonly espoused by institutions. Our goal in doing so is not to evaluate past NLP projects that use religious texts, but rather to encourage more reflecting in and on future work. Based on these considerations, we then make some recommendations for the NLP community in Section 5.

2 Background

2.1 Religion

Precisely defining what constitutes a religion might be notoriously difficult (see, e.g., Spiro, 2013; Neville, 2018), and lies beyond the scope of this paper. Typical properties of religions center around giving meaning to existence, and include moral values, spiritual beliefs, theistic beliefs, rituals, stories and mythologies, kinship systems and marriage practices, artistic practices, significant locations, and in some cases a language which plays a special role. These are all closely related to questions concerning values.

Like languages, religions may exhibit regional variation and incorporate local practices, so thinking of them as discrete entities may be somewhat misleading. Some widely cited estimates put the number of worldwide religions at several thousand, although these claims are disputed. What seems more certain is that the imminent extinction of thousands of Indigenous languages will accompany an “impending loss of so many religions and worldviews” (Harrison, 2007, p. 153). Acknowledging these challenges, we nevertheless provide a summary of some of the world’s most populous religions in Table 1. Surveying or defining each of these religions is beyond the scope of this paper. Also not included here are the various sects and branches within each religion, nor texts which might be important only to specific branches.

One important distinction is that between proselytizing and non-proselytizing religions. The former attempt to convert new populations, whereas the latter do not. The former are more intricately related to historical practices of colonialism—especially in Africa, the Americas, Asia, Australia, and the Pacific—and hence also to neocolonial legacies. Some religions hold that a certain language is privileged for communicating sacred texts to the faithful, while on the other hand Protestant Christianity exemplifies a commitment to communicating in vernacular languages. (Article XXIV of the Articles of Religion of the Anglican Church calls for “such a Tongue as the people understandeth”.) Although originally in Ancient Greek, Christian texts have been widely distributed in many European languages since the Protestant Reformation, and the global reach of Christianity is associated with European colonial practices.

2.2 The academy and Bible translation

The September 2009 issue of the journal *Language* has a special feature of five articles by anthropologists and linguists concerning the relationships between the US-based Bible translation organization SIL International (SIL) and academic linguistics. In this issue, Dobrin and Good (2009) explore how academic linguists have at times become reliant on, and benefitted from, the technological infrastructures of SIL, in part because creating and maintaining these infrastructures have not been valued by the academy. This “partnership of convenience” causes tensions between differing objectives, and raises questions about what kind of relationships secular research institutions ought to have with organizations with very different agendas. These practices presage similar ways in which some areas of NLP research have become reliant on Bible translations.

Many linguists and NLP practitioners working on Indigenous languages see their research as addressing issues of human rights and cultural extinction. However, as Dobrin and Good point out, languages which are most endangered are least likely to receive SIL’s attention. Handman (2009) draws attention to how SIL ideology separates linguistic identity from religious identity, differing from UNESCO's position that sustaining endangered languages entails sustaining cultural worldviews, knowledge systems, and identity practices. Epps and Ladley (2009) argue that evangelical success entails the displacement or transformation of traditional beliefs, often leading to social upheaval, and argues that the academy has a moral interest in supporting local self-determination which is at odds with evangelical agendas.

3 The Use of Sacred Texts in NLP

This section presents empirical data on the use of religious texts in the field of NLP.

3.1 Sacred texts in the ACL Anthology

In this section we consider four research questions: i) *which* sacred texts are used in NLP?, ii) how does NLP *characterize* those sacred texts?, iii) for what purposes does NLP *use* sacred texts?, and iv) are there any *trends* over time? To explore these, we use the Anthology of the Association of Computational Linguistics[4] (henceforth, the ACL Anthology) (Bird et al., 2008), which we consider to represent the research publications of the NLP community.

Regarding *which* sacred texts are used in NLP, the number of ACL Anthology entries for sacred texts are shown in Table 2.[5] Thousands of papers in the ACL Anthology seem to use religious texts. There is a strong bias towards the texts of the Judaism, Christianity, and Islam.

To understand how sacred texts are *characterized* in NLP, we analysed ACL Anthology papers containing the phrases "the Bible is" or "the Quran is". Thematic analysis of the results reveal that descriptions of the Bible mostly emphasize its availability, convenience, size, and multilingual character (see Appendix A). The religious nature of the Bible is only mentioned infrequently, in stark contrast with how Christian websites describe the Bible. These findings agree with the claim that NLP has a dominant ideology of "language as data" (Bird and Yibarbuk, 2024). One paper describes the Bible as "one of the most familiar documents". NLP papers are more likely to mention religious aspects of the Quran. No ACL anthology papers mention "the Koran is", nor related appositions "Koran, a[n]"; presumably the papers mentioning 'Koran' felt it needed no explanation.

Search term/phrase	Results [min, max]
bible	[1920, 3890]]
quran	[291, 547]
new testament	[294, 294]
koran	[131, 248]
old testament	[73, 206]
torah	[25, 153]
talmud	[21, 22]
vedas	[22, 51]
tripitaka	[7, 7]
upanishads	[6, 6]
mahayana sutras	[4, 4]
tanakh	[3, 4]
zhuangzi	[3, 3]
puranas	[3, 3]
tibetan book of the dead	[0, 0]
tao-te ching	[0, 0]
daozang	[0, 0]

Table 2: Number of search results for religious texts in the ACL Anthology on August 10, 2023. Since search result counts are non-deterministic, we report the min and max of 10 searches for each term.

To understand how NLP *uses* sacred texts, we examined the first 100 results (sorted by relevance) from the ACL Anthology for each of the terms 'bible' and 'koran'. We manually looked at each of the 200 search results in order to verify its relevance to our study, and omitted 48 search results for not being relevant (see Appendix B). We manually coded the 88 papers mentioning the Bible for their application domain. The most common application domain was machine translation (23%), while many (18%) introduced a new corpus or lexical resource. Three papers were concerned specifically with Bible translation, and four with literary analysis of the Bible. A variety of other application domains were represented, including various morphosyntactic analysis tasks, and language modeling or pretraining (see Appendix C). 48% of the 88 papers concerned one or more Indigenous languages.[6] The 64 ACL papers mentioning 'koran' were less varied and largely (73%) were concerned with machine translation, typically using verses from the Quran in evaluation datasets (see Appendix D).

To get a sense of *trends* in the use of sacred texts by the NLP community, we examined the year of publication of the 150 of the 152 papers described

---

[4] `www.aclanthology.org`, accessed August 2023.

[5] Non-deterministic result counts seem to be an artefact of the ACL Anthology's use of Google's Programmable Search Engine (Bollmann et al., 2023).

[6] These categorizations were done by the author, taking into account historical and social context, however an ideal approach might engage with language communities to understand whether they consider themselves to be Indigenous.

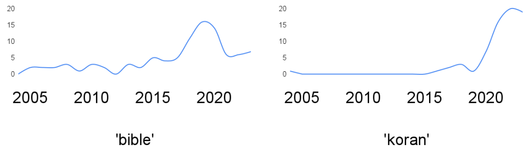

Figure 1: Trend sparklines for counts of papers in the ACL Anthology mentioning 'bible' or 'koran' (see §3).

above which were published between Jan 2004 and July 2023 (just 2 were published prior to 2004). Of these, we see increasing use over time of mentions of the Bible, and especially of mentions of 'Koran' (see Figure 1)[7], including over 60% of papers being published between 2019 and 2023 alone. Of course, the number of papers published in the ACL anthology has also been increasing, for example ACL 2023 accepted about 12 times as many papers as ACL 2004 did. We are not necessarily seeing an increase in terms of the fraction of NLP papers using the Bible, and thus there may only be weak evidence of trends *within* NLP research. We do however hypothesize that the absolute counts of papers using religious texts may be a better proxy for the *externalities* (both positive and negative) of NLP research on linguistic and religious communities, and thus relevant to this paper's topic of ethical considerations. There also seems to be a trend towards papers using sacred texts handling very large numbers of languages, with ten papers since 2014 in our sample handling over 500 languages.

3.2 Four case studies

To complement the broad analysis of NLP research above, we also report here on some recent noteworthy cases which have attracted acclaim and attention. These illustrate in more detail ways in which the NLP community is encountering and using religious texts.

Our first example is a paper which aims to improve Speech Recognition and Speech Synthesis for over a thousand languages (Pratap et al., 2023). It was uploaded to arXiv, a popular online archive for computer science papers, in May 2023. The researchers train their model using translations of the New Testament, as well as audio of readings of those translations, obtained from Faith Comes by Hearing (`faithcomesbyhearing.com`), `goto.bible` and `bible.com`. They also use spoken recordings in many languages, without paired texts, of Bible stories, evangelistic messages, scripture readings, and songs, obtained from Global Recordings Network (`globalrecordings.net`), whose mission is to communicate "the Good News of Jesus Christ" via a strategy of recording, distribution, and promotion.

Our second example aims to scale language models to 500 languages (Imani et al., 2023), and was awarded the ACL Area Chair Award for best Multilingualism and Cross-Lingual NLP paper in July 2023. The researchers "crawl or download" data from 150 sources, including religious texts and observe a "higher proportion of religious data" compared to previous comparable work. Parallel verses from Bible translations are used for model training and testing, and performance is reported for Sentence Retrieval from the Bible.

Our third example concerns the use of JW300 (Agić and Vulić, 2019), a dataset of around 100k sentences in each of 300 languages crawled from `jw.org`, a website run by the US-based Jehovah's Witnesses, a Christian denomination. A majority of the texts come from the Jehovah's Witnesses' magazines *Awake!* and *Watchtower*. Released as a corpus in 2019, JW300 has been cited over 180 times as of March 2024. The African grassroots open-source NLP project Masakhane (`masakhane.io`) had been using JW300 to train Machine Translation models, until receiving legal advice in 2023 that this was breaching copyright. A subsequent request by Masakhane to the Jehovah's Witnesses for permission to use the data was declined.[8]

Our final recent example concerns the release of MADLAD-400, a new text dataset containing 3T tokens in 419 languages (Kudugunta et al., 2023). It uses 2022 snapshots of the CommonCrawl web crawl (`commoncrawl.org`) and the paper was uploaded to arXiv in September 2023. Auditing of a preliminary version of the dataset, spanning 498 languages, revealed that for 141 languages there were "significant amounts" of Bible data. Significant amounts of Jehovah's Witnesses data was also found for 37 languages, and of Church of Jesus Christ of the Latter Day Saints (LDS) data for 2 languages. (No Quran data was reported to be found in significant amounts.)

---

[7] Since our 2023 sample was limited to Jan-July, paper counts for 2023 are multiplied by 12/7 when creating sparklines, to make them comparable with previous years.

[8] See `https://infojustice.org/archives/45258`.

4 Considerations around Sacred Texts

Having demonstrated above that religious texts have been used in thousands of NLP papers, we now discuss some of the ethical considerations. This topic has not received much prior attention, although it is touched upon by Mager et al. (2023, sec. 3) and Pratap et al. (2023, sec. 8). Our goal is not to critique the works identified in the previous section, but rather to provide a toolbox for assisting critical thinking in the future. In this section we lay out our positions that relevant considerations include not just technological outcomes, but also cultural standpoints, cultural inclusion, and relationships between global and marginalized cultures. With this in mind, we now consider the use of sacred texts in NLP from a range of lenses.

4.1 Ethical theories

Ethical theories are attempts at explaining why actions might be called right or wrong. In this section we consider the use of sacred texts through just two ethical theories, however our broader point is that if analyses of NLP projects focus narrowly on using a single theory then they risk minimizing concerns which other theories bring more focus to.

The term **consequentialism** refers to a family of normative theories which emphasize the importance of considering the consequences of actions, including analysis of risks and benefits. One example of a consequentialist theory is **utilitarianism**, which holds that the best action is one that maximizes wellbeing and minimizes suffering. One challenge with applying these theories in an NLP research context is that in practice research activities are often far removed from applications, and any eventual path between the two can be unknowable or uncertain. Even if the impacts on users of NLP applications can be known, challenges arise in calculating aggregate benefits across disparate stakeholders with different objectives. Perhaps the easiest consequences to reason about are the impacts of NLP research and applications on the lives of the researchers and developers themselves, since research papers and software bring rewards in the forms of measurable kudos, citations, career progression, etc. How can such benefits be weighed against uncertain risks of causing serious offense to religious communities? If translations of religious texts are purchased from a proselytizing organization, what are the downstream impacts of the organization's re-investing those payments into their projects?

The term **deontology** refers to a normative theory which posits that there are rules or principles which determine the rightness of wrongness of actions, rather than the consequences. Within an NLP context, this might lead to a focus on the upstream actions such as sourcing of data, rather than downstream actions such as usage of NLP applications. Within the context of religious texts and their translations, this might lead to questions such as: Were the appropriate people involved in the creation of a dataset of sacred texts? Did they have the right roles and relationships from within the perspective of followers of the religion? Do translators of sacred texts have the right specialist linguistic, religious, and and cultural knowledge? Were the translators paid fairly, both individually and collectively? Were consent practices around voice recordings followed? Generally, was the dataset collected in a manner aligned with best research practices, e.g., as operationalized by research ethics boards? Prabhumoye et al. (2020) discuss the importance of informed consent for deontological approaches to NLP ethics, and community-level consent might be an appropriate lens for thinking about communities of religious practice.

4.2 AI principles

We use the term **AI principles** here to refer broadly to the hundreds of sets of principles for responsible and ethical AI that have been released by companies and governments in recent years. Unlike the ethical theories described above, these are focused on AI technologies. Although all unique in their own way, the various sets of principles also have many facets in common (Floridi and Cowls, 2022), such as safety, privacy, bias, fairness, accountability, and transparency. We expect the AI Principles-related concerns to be highly dependent on NLP system functionality and thus on the application domain.

Given the frequent use of sacred texts for training and evaluating MT systems, we provide a sketch in Table 3 of how AI Principles might raise different flavors of considerations.[9] Relevant to the potential for MT bias, Evans and Sasse (2004, p. 4) observe that parallel Bibles will provide signal on how to translate "arise!" and "Cain fought with Abel", but will not help with translating culture-specific con-

---

[9] Mager et al. (2023) also provide a useful discussion of Ethics and Machine Translation.

AI Principle	Example possible considerations
Safety	Could the errors made by an MT model trained on sacred texts perpetuate harmful misinformation and hate speech about religiously significant topics?
Privacy	In speech-to-speech translation, could spoken recordings of religious texts (cf. Section 3.2) enable speakers to be identified and their religious beliefs compromised?
Bias and fairness	In what specific ways are religious texts not representative of other domains (cf. Mayhew et al., 2017; Adelani et al., 2021; Evans and Sasse, 2004)? Do these biases cause MT models to have unfair impacts? What are the specific limitations of MT eval sets which are largely constituted by religious texts?
Accountability	What mechanisms exist for non-English speaking religious communities to report and escalate offensive translations resulting from the use or religious texts? Who is responsible for responding to such reports and mitigating the harms?
Transparency	Do we have accessible evidence that religious communities were consulted when building corpora of parallel religious texts to use for MT?

Table 3: Non-exhaustive list of possible AI Principles considerations related to using religious texts for MT.

cepts of the world's diverse languages. Similarly, MT evaluation will have limitations whenever eval sets are largely constituted by parallel religious texts.

4.3 Cultural considerations

Authors of NLP publications do not represent global diversity (Rungta et al., 2022), and hence special consideration needs to be given to cultural standpoints. A useful starting premise might be that ethical consideration of ACL papers should not be biased either against nor towards any religions. This might seem to suggest that **Rawls' Veil of Ignorance** could provide a guide (Rawls, 1971). That is, one's consideration of the use of sacred texts within NLP should proceed as if we are each in ignorance of which is our own religion (if any). For example, how would I feel about NLP's reliance on texts from major religions if my own culture and religion might be ones which are marginalized and endangered?

Although the Veil of Ignorance might seem attractive at face value, we take the position that our ability in practice to truly avoid being informed by our own cultural backgrounds and affiliations is extremely questionable. We must instead accept that we have cultural standpoints. The **emic/etic distinction** originated in linguistics in the 1950s for describing different standpoints for language research (Mostowlansky and Rota, 2020). *Emic* is commonly used to describe research on a culture from the perspective of people of that culture. This contrasts with *etic* research, which takes an outsider's perspective. When NLP handles religious texts, we can distinguish research problems and applications which are within the researcher's own religious context, from those applications which impact those having other religious beliefs (e.g., translation for the purpose of proselytizing).

4.3.1 On relativism and the ACL community

One possible objection to the argument that greater consideration of NLP's use of sacred texts is needed is based on an argument of cultural relativism. Such an argument would contend that by using sacred texts for an extended period, the ACL community has demonstrated that such practices are judged as acceptable by the norms of the ACL community.

We counter that such an argument would be stronger if the ACL community both had a stronger history of reflexive practices, and was more culturally diverse. Compared to many other disciplines, we find that ACL's interest in ethics to be relatively recent (see Appendix E). The ACL adopts the ACM Code of Ethics,[10] a general code for computing professionals which makes no mention of working with cultural data such as language. Unlike some other disciplines, positionality statements are rare in ACL papers, with "researcher positionality" and "author positionality" each having only a single (and recent) result in the ACL Anthology as of September 2023. We also find that the ACL community does not represent the diversity of the world's local languages and religions; in fact disparities in sources of ACL publications might be

---

[10] `https://www.aclweb.org/portal/content/acl-code-ethics`

increasing (Rungta et al., 2022).

4.4 Power and marginalization

The more different that a culture is from the global cultures which dominate NLP research, the less we should expect the NLP community to understand local concerns. Consideration of marginalized local cultures might bring our focus to questions of how NLP technologies serve to re-arrange power. Which actions are encouraged or discouraged by NLP technologies, and by who? Blodgett has called for NLP researchers to focus their ethical considerations on power relations between technologists and communities (Blodgett et al., 2020). As discussed in Section 3, many NLP papers using the Bible use translations of its texts into Indigenous languages. In this section we give special attention in this section to concerns of local Indigenous communities. Their voices are among the least likely to be represented in ACL's prestigious conferences and journals. And their relationships with global projects are likely to involve large power disparities such that "the asymmetry of power is the cause of domination" (Mager et al., 2023).

4.4.1 Indigenous perspectives

Indigenous concerns regarding **data sovereignty** describe the importance of data governance and Indigenous Cultural and Intellectual Property (ICIP), but also a broader set of concerns regarding practices for projects involving Indigenous data (e.g., Carroll et al., 2020; National Health and Medical Research Council (Australia), 2018; Taiuru, 2021; Janke, 2021; Smith, 2021). Surveying the plurality of perspectives is beyond the scope of this paper, however they share common themes around respect, cooperative relationships which include consultation and negotiation, shared control, and providing benefits to community (Mager et al., 2023; Cooper et al., 2024).

4.4.2 Human rights

As tools of colonizing projects, translations of sacred texts into Indigenous languages have been described as a "well documented example of the non-ethical misuse of translation" (Mager et al., 2023). One consideration for NLP is whether using such translations constitutes complicity with, and promotion of, projects which might violate international human rights to maintain Indigenous cultures.

Kenyan human rights scholar Makua Mutua describes the "basic contradictions" between proselytizing religions and Indigenous cultures (Mutua, 2004). Observing that religion is woven into every aspect of Indigenous social and cultural life, including dances, storytelling, and marriage practices, Mutua argues that such cultures' meeting with proselytizing Christian and Islam faiths amounts to cultural genocide. In some cases, this characterization seems valid. In other cases, it might perhaps be too strong for the complex realities of syncretic responses by Indigenous communities to proselytizing cultures.

Mutua argues that the right to freedom of religious belief cannot be considered to exist in a level playing field in which local cultures can compete with global ones. Rather, the contexts of cultural invasion unfairly privilege global religions, including histories of missionaries making access to education and health services conditional on the "salvation" of "infidels". This echoes arguments by legal scholars that the power and sovereignty dynamics between source and target cultures constitute important factors between proper and improper proselytism (Stahnke, 1999). The Human Rights Committee has acknowledged that the cultural rights protected under Article 27 depend on the ability of a minority group "to maintain its culture, language or religion".[11] As such, Prof. Mutua argues that the (then Draft) UN Declaration on the Rights of Indigenous People appears to prohibit proselytizing by agents external to the the Indigenous culture in order to create space for Indigenous peoples to maintain their cultures amidst external threats.

5 Discussion and Recommendations

We take the position that the ACL should strive to be aware of risks of harms to religious communities, including dignitive harms, that NLP research may cause or be complicit with. It is beyond the scope of this paper to weigh possible benefits of NLP technologies developed using religious texts against the ethical considerations of such use, and any such benefits may be context- and application-specific. However, we note that benefits are often asserted for languages for which NLP has few resources, and we advocate that such claims of benefits should be evaluated paying attention to

---

[11] General Comment No2̇3, UN Doc. ICCPR/C/21/Rev.1/Add.5 (1994), para. 6.2.

local language ecologies (Bird, 2022), to the roles of technology in supporting minority languages (Holton, 2011), and to the real technology needs of communities (e.g., Liu et al., 2022).

We now suggest five specific actions for the NLP community to mitigate the risks of consequential, procedural, and dignitive harms.

1. Discuss ethical considerations. If one should never speak of religion in polite company, then perhaps ACL forums should be less polite. We suggest that discussion of ethical considerations in NLP papers using religious data should be much more prevalent than it currently is. We propose that Section 4 provides a good starting point for NLP researchers to think about possible concerns, however, building on HCI best practices we also encourage researchers to talk to members of relevant religious communities in order to understand concerns which might lie outside the researchers' domains of lived experience.

2. Consider different ethical theories. It has been argued that NLP research often implicitly adopts a utilitarian lens, in the process minimizing other ethical considerations (e.g., Hutchinson et al., 2022b). We encourage NLP researchers using sacred texts to contemplate approaching ethical considerations from numerous angles, including not just deontology (discussed in Section 4.1), but also alternatives such as virtue ethics and ethics of care.

3. Delve into domain specifics. We encourage more work on specific AI principle risks of different NLP domains when using religious texts (cf. Section 4.2). What are the specific ways in which various religious texts are not representative of other domains? What are the model biases that result? Are there specific risks around offensive misinformation on religious topics? Have datasets incorporating sacred texts followed best practices around transparency (e.g. Bender and Friedman, 2018; Gebru et al., 2021; Pushkarna et al., 2022)?

4. Situate NLP work culturally. When should an NLP practitioner tread more carefully? We suggest that when handling sacred data from other cultures and religions there will be more risks, since the NLP practitioner will have almost certainly have gaps in their knowledge, and will likely also have differing values (Hershcovich et al., 2022; Prabhakaran et al., 2022b). We suggest it is useful to talk of *etic NLP* and *emic NLP* (cf. Section 4.3), according to whether the language technology is for the own linguistic and religious cultures of the NLP practitioner vs. those of others. Linguistic positionality statements have been recommended by researchers who are aware of how different priorities and agendas between researchers and language communities can impact projects (e.g., Rolland et al., 2023; Cormier, 2018). Similarly, we suggest that religion positionality statements, for NLP research working with religious data, can also provide a useful signal for the NLP community concerning agendas. For example, hypothetically, would non-Muslim researchers understand the Muslim community's concerns regarding automated mis-translations of the Quran?

5. Attend to concerns of marginalized cultures. Given the NLP community's skew towards the West (Rungta et al., 2022), the values of, and possible harms to, local communities of diverse cultures are not known by most NLP researchers. For Indigenous language NLP projects using translations of sacred texts, we echo calls for more consideration of local colonial contexts, to consider community opinions, and for research to prioritize the needs of Indigenous communities (Bird, 2020; Schwartz, 2022; Alvarado Garcia et al., 2021). Mager et al. (2023) demonstrate one way in which community opinions can be sought regarding NLP projects, and deeper relationships with communities will provide more insights (Bird and Yibarbuk, 2024; Cooper et al., 2024). NLP researchers working with Indigenous languages should become familiar with Indigenous perspectives mentioned in Section 4.4, and with codes of conduct such as that of the Endangered Languages Project.[12] With the imminent extinction of many Indigenous languages and religions, we also suggest there may be a role for NLP to play in documenting and maintaining "first-person accounts of what people once believed in and how they talked to and about their gods" (Harrison, 2007, p, 153).

One pertinent question is how often the papers surveyed in Section 3 adhere to these recommendations. Regarding **discussing ethical considerations**, Pratap et al. (2023, sec. 8.3) do include a section, albeit short, on Ethical Considerations of the use of religious texts, although we found that doing so is rare. Kudugunta et al. (2023) and Imani

---

[12] `https://fpcc.ca/wp-content/uploads/2023/02/CodeOfConduct_Web.pdf`

et al. (2023) both have short ethics statements, but neither mentions religion. Despite translation of the Quran being a "problematic and controversial issue for Muslims" (Fatani, 2006), none of the many papers surveyed in Section 3.1 that evaluate MT systems discuss ethical considerations.

Regarding **ethical theories**, papers using religious texts do not seem to break the general NLP trend of adopting a utilitarian mindset (Hutchinson et al., 2022b) and focusing ethical discussion on narrow questions such as decontextualized bias measurement (Blodgett et al., 2020).

Regarding **domain specifics**, (Pratap et al., 2023) attempt to understand biases in their data, although the details are scarce, and their comparison is limited to a dataset based on English language Wikipedia. Kudugunta et al. (2023) and Imani et al. (2023) have no discussions of biases, although the latter do include a datasheet (Gebru et al., 2021).

Regarding **situating work culturally**, positionality statements are extremely rare in the ACL Anthology papers. Some rare examples of NLP papers mentioning author positionality or standpoint are (McMillan-Major et al., 2021; Hutchinson et al., 2022a; Santy et al., 2023; Yoder et al., 2023; Ghosh and Caliskan, 2023). Only half of ACL papers even mention the language(s) they study (Ducel et al., 2022), giving a false veneer of independence (Bender, 2019).

Regarding **attending to concerns of marginalized cultures**, this is rarely done in NLP research. NLP papers that consider ethical topics tend to focus on English, and most papers on languages other than English focus on model accuracy (Ruder et al., 2022). Pratap et al. (2023) mention how their bias analysis was constrained by lack of easily available native speakers for most languages, which also precluded the possibility of discovering community concerns beyond bias.

6 Conclusion

Thousands of NLP research papers have used religious texts, due to their availability, convenience, and multilinguality. However these papers rarely acknowledge the religious significance of these texts, nor their cultural contexts, and the ethical considerations of such use have not previously been explored. This position paper presented the first detailed study of the use of religious texts in NLP research, finding that common scenarios include machine translation and dataset creation. We have argued that responsible secularism requires the NLP community to engage with concerns about how such NLP activities might impact religious communities—especially the most marginalized ones—or might be complicit with projects which do. We provided a detailed account of some of the considerations, with a focus on ethical theories, AI principles, cultural considerations, and marginalized communities. We suggested that the field of NLP would benefit from more discussion of the diverse and specific concerns around using religious texts. We proposed that the NLP community engage more with questions of researcher positionality and cultural standpoints, especially with regards to marginalized cultures.

7 Researcher Positionality

I live and work in a secular, multicultural, majority English-speaking, colonized country of the Global North. I am linguistically competent only in English. My experiences include studies and employment in linguistics and NLP, but I have no background in religious studies. I grappled while writing this paper with my lack of first-hand experiential understanding of religion, and thus too with my personal role in arguing for more consideration of global and marginalized religious communities.

Limitations

Any position paper is limited by the experiences of the authors. A Researcher Positionality statement is included partly to address this.

We acknowledge that the ACL Anthology used in Section 3 might not be representative of the entire field of NLP, e.g., missing relevant work such as (Chandra and Ranjan, 2022; Bashir et al., 2023), and NLP projects in industry might not be well represented in the ACL Anthology. Another limitation is that we exclude publications in languages other than English. Our reliance on keyword searches, rather than more sophisticated analyses of the ACL corpus, is a limitation. We also acknowledge that the ACL Anthology's non-determinate search result counts are a limitation, seemingly an artefact of the use under the hood of Google's Programmable Search Engine, however reproducing the ACL Anthology's search functionality is beyond the scope of this position paper.

This paper was unable to accommodate lengthy discussion of religious texts in specific NLP domains or specific NLP projects. As the topic of religious texts in NLP has not previously received attention, we took the position that focusing on breadth was most useful. However in Section 5 we do suggest that future work focus more on ethical considerations of using religious texts in specific NLP domains.

This paper does not do justice to the complexities of many of the topics it touches upon. Perhaps chief among these are the histories of Indigenous communities, proselytizing religions and colonial projects. Colonial missionaries saw their own roles in a positive way despite the accompanying cultural destruction (Nakata, 2007). However in recent decades, there have at times been apologies from some church bodies for histories of religious domination which marginalized Indigenous languages and religious practices (Bush, 2015). Indigenous communities have at times, facing many colonial pressures including threats of language extinction, used Bible translations as tools for language maintenance (e.g., Davis, 2015). Cultural protocols can also be maintained, for example spoken recordings of Bible translations in Kanien'kéha are still subject to cultural practices around speakers who have passed away (Pine et al., 2022), while on Groote Eylandt, in Northern Australia, the Anindilyakwa people reinterpreted Christianity of the missions in their own ways leading to a "hybridisation of cultures" (Rademaker, 2014).

This paper also does not fully consider relevant topics concerning human rights. While we agree with scholars such as Prabhakaran et al. (2022a) that human rights provide a useful framework for considering AI ethics, we note that agreement on how to interpret collective and cultural rights is not universal; for some perspectives from human rights scholars see (Jakubowski, 2016; Sanders, 1991; Ramcharan, 1993).

Appendix A: Characterizations of the Bible and the Quran

To select NLP papers for the purposes of examining how they describe the Bible and the Quran, we searched the ACL Anthology for papers mentioning “the bible is” or “the quran is”. The Bible is characterized by NLP papers in the ACL Anthology using phrases such as:

- ‘available in electronic form’, ‘most available’, ‘only available’, ‘readily available’, ‘available online’ and ‘often the only resource available for many languages’;
- ‘parallel’, ‘natural source of parallel data’, ‘ideal source of parallel texts’, and ‘aligned’;
- ‘short’, ‘large’, and ‘[comparatively] small’;
- ‘massively multilingual’, and ‘most translated’;
- ‘central religious text’;
- other descriptions including ‘narrative of a reasonably straightforward kind’, ‘representative of core vocabulary’, ‘one of the most familiar documents’.

The Quran is characterized by NLP papers in the ACL Anthology using phrases such as:

- ‘significant religious text’, ‘[believed by Muslims to be] God’s word’, ‘[believed by Muslims to be] God’s divine words’;
- ‘fully diacritized’;
- ‘written in a unique literary style, close to very poetic language’.

Appendix B: Selection of ACL Papers

To select papers to analyze for NLP application domain, we took the first 100 search results on the ACL Anthology for the searches ‘bible’ and ‘koran’. We omitted 12 ‘bible’ search results from our analysis due to either:

- not being in English (2);
- not being research papers (6, e.g., book reviews, invited talks, or proceedings);
- or being duplicates (4)

We omitted 36 ‘koran’ search results from our analysis due to either:

- not being research papers (16);
- being false positive search results (13, e.g., 10 had typos for ‘Korean’);
- only using the word ‘koran’ in references (3);
- only using the word ‘koran’ in footnotes (2);
- only using the word ‘koran’ in content generated by a model (2).

Appendix C: Application Domains of ACL Papers using the Bible

Application domain	count
Machine translation	20
New corpus or resource	16
Morpho-syntactic tasks other than POS-tagging and dependency parsing	9
POS tagging	6
Language modeling/pretraining	5
Literary analysis of the bible	4
Bible translation	3
Identify text re-use	2
Dependency parsing	2
Other, including sentiment analysis, named entity, CLIR, patronizing language detection	21
Total in selected sample	88
Filtered out (see Appendix B)	12
Total in sample	100

Appendix E: A Brief Recent History of Ethics in ACL

- 2017: The First Workshop on Ethics in NLP is held, at EACL (Hovy et al., 2017).
- 2018: The Second Workshop on Ethics in NLP is held, at NAACL-HLT (Alfano et al., 2018).
- 2018: "Ethics and Fairness in NLP" is a possible submission topic for EMNLP.
- 2019: NAACL-HLT has a theme track of data privacy and model bias.
- 2020: "Ethics and NLP" becomes a possible submission topic for the ACL conference. This topic, or slight variations of it, are then regular in *ACL and EMNLP conferences from 2021 onwards.
- 2020: EMNLP introduces an Ethics Policy, reserving the right to reject papers on ethical grounds. ACL and NAACL follow in 2021, and EACL in 2023. (There was no EACL in 2022.)
- 2021: ACL, NAACL and EMNLP begin allowing extra space in papers for discussions of ethical considerations. Reviewers are asked to consider Ethics Review Questions. EACL follows in 2023.
- 2021: EACL has a track on "Green and Sustainable NLP". NAACL has a submission topic "Green NLP".
- 2022: ACL Rolling Review (ARR) emerges as a centralized reviewing service for ACL conferences. It incorporates a Responsible Research Checklist which includes a section on Ethics and is based on the NeurIPS 2021 paper checklist as well as the work of Rogers et al. (2021) and Dodge et al. (2019).

Testing the Effect of Code Documentation on Large Language Model Code Understanding

William Macke and **Michael Doyle**
The MITRE Corporation*
{wmacke,mdoyle}@mitre.org

Abstract

Large Language Models (LLMs) have demonstrated impressive abilities in recent years with regards to code generation and understanding. However, little work has investigated how documentation and other code properties affect an LLM's ability to understand and generate code or documentation. We present an empirical analysis of how underlying properties of code or documentation can affect an LLM's capabilities. We show that providing an LLM with "incorrect" documentation can greatly hinder code understanding, while incomplete or missing documentation does not seem to significantly affect an LLM's ability to understand code.

1 Introduction

Recently, Large Language Models (LLMs) have approached or pushed the state of the art for multiple natural language processing (NLP) tasks and benchmarks such as machine translation (MT) (Moslem et al., 2023; Jiao et al., 2023), human evaluation of MT (Kocmi and Federmann, 2023), sentence completion, and question answering (OpenAI, 2023). The same can be said for some programming language processing (PLP) tasks, such as code generation (OpenAI, 2023) and code translation (Pan et al., 2023), but other tasks, such as code summarization, have proven to be difficult for LLMs (Sun et al., 2023). These tasks requiring code understanding pose challenges distinct from those faced in natural language. As an example, a unique challenge in PLP is the rigidity of syntax and semantic precision required in generation or translation that is not required to the same degree in NLP. Solving these problems, or at least improving their solutions, has the potential to greatly increase productivity and satisfaction in software development, as has already been shown with the use of GitHub Copilot (Kalliamvakou, 2022).

While several works have shown the importance of applying effective prompting strategies for PLP with LLMs (Le et al., 2023; Wang et al., 2022; Shinn et al., 2023), very little work has investigated how the reliability of the documentation at input can affect an LLM's performance. In this work, we provide a preliminary empirical analysis of how documentation quality can influence this ability. We hypothesize that correct code documentation will improve an LLM's code understanding, and that its understanding will decrease as the prevalence and accuracy of the documentation is decreased. To the authors' knowledge this is the first work to consider code documentation reliability for this problem.

The rest of the paper is organized as follows: First we discuss other works and how they relate to our study. Then we present experimental analysis and results. Our experiments provide a basic analysis of how an LLM's code understanding performance degrades along with documentation quality and quantity, and we end with a discussion and analysis of the results.

2 Related Works

Code analysis is a very well-studied problem. Traditional compilers and syntax-tree parsers are commonly used to perform code analysis (Moor et al., 2007; Lenarduzzi et al., 2020) or extract code metrics (McCabe, 1976; Timóteo et al., 2008; Agnihotri and Chug). However, these tools lack an LLM's ability to process natural language, and therefore are incapable of extracting semantic understanding or considering code documentation. Since LLMs have become widely available, many works have also attempted to leverage language models to analyze code. Several works have sought to create LLMs designed for code understanding

tasks such as code generation, code completion, program repair, and code translation (Xia et al., 2022; Wang et al., 2023b; Bui et al., 2023). Unlike these works, instead of developing new tools we provide a rigorous analysis of where and how existing tools can best be leveraged. Our work also introduces other means of determining code understanding than the benchmarks developed in Lu et al. (2021).

Other works provided empirical analyses of existing models' abilities to analyze code. Xu et al. (2022) present an analysis of the performance of various LLMs on different code benchmarks, and introduce a new LLM. Ma et al. (2023) present an empirical analysis of using GPT to generate syntax trees, call graph and other syntactic and semantic representations of code. They conclude that GPT has approximately the same abilities as an abstract syntax tree (AST) parser. Similarly Palacio et al. (2023) introduce a framework called ASTxplainer that uses questions about an AST as an evaluation criteria for LLMs. Leinonen et al. (2023) provide an empirical study comparing human generated explanations with those generated by GPT. All of these works are focused on evaluating an LLMs performance in general and, unlike this work, none investigate how code content or documentation can effect an LLM's understanding.

3 LLM Code Understanding

It has been argued that *understanding* is merely the "knowledge of causes" (Pritchard, 2014), but one can see that this is an incomplete definition of what it means to truly understand something and that "a proper explanatory grip on how cause and effect are related" (Pritchard, 2016) is required for true understanding. Nevertheless, the knowledge of causes is at least a crucial early step in developing a complete understanding of a topic.

If this is the basic definition we are using for our basis of determining understanding, then to truly assess whether a piece of code is *understood* by a person or a language model, then the subject must display knowledge of the cause and effect relationship of the code. Or, to put more simply, the subject should be able to answer the question, "What does this piece of code do?"

Past work has attempted to test an LLM's ability to answer this question through code translation by measuring errors in the target language (Pan et al., 2023); through code summarization by measuring differences in BLEU, METEOR, or ROUGE-L scores between an LLM-generated summarization and the reference summarization (Sun et al., 2023); and through the generation of unit tests by measuring statement and branch coverage across various JavaScript libraries (Schäfer et al., 2023). Our approach for testing an LLM's understanding of source code is most closely related to the lattermost method, but differs by not improving upon the initial attempt at unit test generation iteratively if the tests fail.

In many cases, a program can be represented as a mapping from inputs into outputs (Solar-Lezama, 2009). For example, the program $square(n)$ can be described with $square(1) = 1$, $square(2) = 4$,... etc. Unsurprisingly then, how well an individual can predict input-output pairs can serve as a very useful surrogate metric for how well an individual understands a piece of code. After all, someone cannot truly understand software without being able to predict the software's behavior. Module documentation, function docstrings, inline code comments, and variable names provide hints or detailed descriptions of what the user can expect of these input-output pairs, and often allow human users to better predict that behavior.

Modern unit test frameworks provide both a formal language for describing input-output pairs and an easily automated method of checking an LLM's output. In order to measure an LLM's ability to generate these input-output pairs, we therefore task the LLM with generating unit tests for a piece of software while varying the quality or quantity of the documentation at input, as well as other code properties. We then measure the percent of unit tests that pass vs the number that fail or produce an error as the percent of correctly predicted input-output pairs.

4 Experimental Setup

In the following section we describe our experimental process for testing an LLM's ability to understand code well enough to produce successful unit tests. In particular, we present an experimental setup for testing the generation of unit tests under varying initial documentation conditions.

To test an LLM's ability to understand a piece of software, we task the language model to generate unit tests. We then run the unit tests and record each test as 1 of 3 results: **Runtime Error**, where a unit test crashed before it could finish running;

Failure, where a unit test ran but failed to pass; and **Success**, where a unit test ran and successfully passed. All LLMs used their default parameters during experiments.

We use all 164 HumanEval (Chen et al., 2021) ground truth solutions as our basis for generating unit tests. [1] We chose HumanEval both for its common use as an LLM benchmark for code understanding (Hong et al., 2023; Zelikman et al., 2023; Wang et al., 2023a) (although intended for text-to-code generation), and for its wide variety of self encapsulated functions that can be easily run within unit test frameworks. We perform several post processing steps on the LLM generated code to ensure it can run automatically. First, we remove all import statements that result in an error (the LLM will commonly import hallucinated modules as it was not provided the original module names at input). Second, we append the LLM's code to a file with the HumanEval function to ensure the unit test has access to all code pieces required to run.

We generate several automatic variations of each function in the HumanEval dataset. **Base File**, which includes only the ground truth solution for a HumanEval function with no docstring comments. **Comments**, which is the *base file* but includes any comments and the docstring provided for the HumanEval function. The docstrings for HumanEval functions typically contain a description of the function along with a few execution examples. **Random Comments** which has the *base file* but with a random comment or docstring from a different HumanEval function, **Animal Variable Names**, which is the *base file* but with all variable and (non-external) function names replaced with animals (e.g. Bird, Cat, Dog etc.), and **Random Variable Names** which is the *base file* but with all variable and function names replaced with random strings. For instance, a variable `format_str` might be changed to `eMbafsd`. In addition, we also investigate how removing random portions of the docstrings, line-by-line, can effect performance. Each line was kept with uniform random probability. We evaluate unit tests generated from 10%, 25%, 50% and 75% of the original docstrings remaining. To avoid any infinite loops generated by the LLM, all tests would automatically fail after taking more than 10 seconds to run. Figure 1 shows an example of a function from the **Comments** category.

```
def monotonic(l: list):
    """Return True is list elements
    are monotonically increasing
    or decreasing.
    >>> monotonic([1, 2, 4, 20])
    True
    >>> monotonic([1, 20, 4, 10])
    False
    >>> monotonic([4, 1, 0, -10])
    True
    """
    if l == sorted(l) or\
        l == sorted(l, reverse=True):
        return True
    return False
```

Figure 1: Example HumanEval reference implementation with docstring.

In order to determine that the LLMs are not generating trivial tests, we also conduct an analysis of how much of the source code is executed by the generated unit tests. We use line coverage, or the percent of lines in the source code that are executed by the unit tests, as our metric for this analysis.

5 Results

Figure 2 shows the results of GPT-3.5 (*gpt-3.5-turbo*) and GPT-4 generating unit tests on the variations of the HumanEval dataset discussed above. [2] There are several key things to note from these results. First the number of runtime errors produced by GPT-3.5 is much greater than those produced by GPT-4, as is consistent with many results for similar code understanding tasks (OpenAI, 2023). A manual examination of the generated test cases shows that GPT-3.5 often generated simple assert statements rather than using pytest, and many of the runtime errors were caused by assert statements failing. Second, we note that the *random comments* scenario performs worse than any other scenario on both GPT-3.5 and 4 (only 22.1% and 68.1% successes respectively) as shown in Figure 2, confirming our hypothesis that incorrect documentation can hurt an LLM's understanding of a piece of code. A statistical bootstrap shows that *random comments* have a higher proportion of runtime errors and failed tests than any other version of the code by a statistically significant margin with $\alpha = 0.05$. Thirdly, we note that changing the code content (via variable names), had a relatively minor effect on the LLM's code understanding when compared with the *base file*. A bootstrap shows

---

[2] These results were generated using OpenAI's Chat Completions API. OpenAI's sharing and publication policy regarding the use of their API can be seen here.

that changing variables to *random names* did not impact the proportion of errors and failed tests by a statistically significant margin, but changing the variables to *animals* did cause a statistically significant change (albeit a small one of 44.7% to 40.6% successes for GPT-3.5 and 78.5% to 76.6% for GPT-4). Finally, having comments did not **significantly** increase the LLM's ability to understand the code. Again a bootstrap confirms the proportion of errors and failed tests did not change between the *base file* with/without comments by a statistically significant margin.

As mentioned above, we also conducted experiments to determine how partial comments might affect an LLM's ability to understand code. Figure 3 shows these results. GPT-3.5 shows that providing partial comments causes an initial spike in the number of errors, before declining as the percentage of comments kept increases. GPT-4 does not show the same pattern, however a bootstrap shows that having the full amount of comments gave fewer errors over when the proportion of kept comments was 10%, 25% and 50% by statistically significant margin. As shown in the figure, these changes were relatively minor. No other comparisons were statistically significant for GPT-4. We therefore cannot currently conclude whether or not partial comments can significantly hurt an LLM's code understanding based on the current evidence.

Finally, we conducted an analysis of line coverage by unit tests to prevent the possibility of the LLM producing trivial tests to gain a higher success rate. This is shown in Figures 4 and 5. First, it is worth noting that the results with *random comments* had lower average code coverage than all other methods by a statistically significant margin. Second, we note that for both GPT-3.5 and GPT-4, code with *comments* generated a higher average line coverage than all other methods by a statistically significant margin. Thirdly, we note that modifying the variables names of the code largely did not have a statistically significant effect. The one exception was the *animal names* category generated by GPT-3.5, which had an average amount of line coverage that was significantly lower than the line coverage of unit tests generated from the baseline, as seen in Figure 4. Finally, partial docstrings mostly did not have a statistically significant effect on the average amount of line coverage. There was one exception when 10% of the docstring was kept for GPT-3.5, which did worse than the baseline by a statistically significant margin.

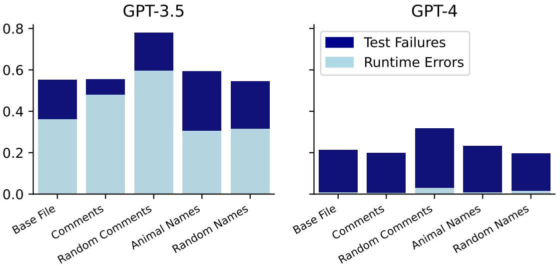

Figure 2: Proportion of runtime errors or failed tests that happen with GPT-3.5 (left) and GPT-4 (right) generating unit tests on modified versions of HumanEval code.

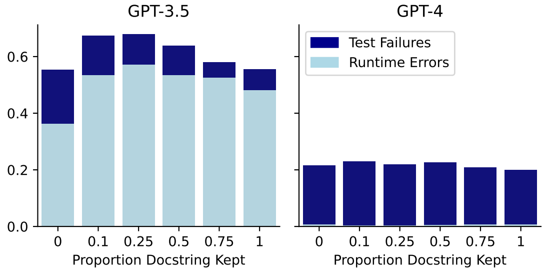

Figure 3: Proportion of runtime errors or failed tests that happen with GPT-3.5 (left) and GPT-4 (right) generating unit tests on different proportions of docstring lines kept on HumanEval code.

We also provide the number of unit tests generated by models for various conditions. Table 1 shows the number of test cases created by GPT-3.5 and GPT-4 for each of the file categories mentioned above. Table 2 shows the number of tests generated by GPT-3.5 and GPT-4 with various portions of the HumanEval docstring lines dropped.

6 Conclusions and Discussion

In this paper, we introduce the effect of code documentation on LLM code understanding and show in our initial experiments that the relative prevalence of documentation has little to no significant effect on an LLM's understanding as we have defined it. This is a little complicated by the fact that we found no significant difference in the amount of successful unit tests but did see a significant difference in the code coverage of those unit tests. Even when comparing commented code to code without comments and all of the variable names changed to random characters, we find little to no significant difference in the LLM's ability to generate successful unit tests. So, although more of the code with *comments* is being covered by the unit tests than the code without, this does not improve the

Model	Basefile	Comments	Random Comments	Random Names	Animal Names
GPT-3.5	1323	883	892	1464	1482
GPT-4	3832	3295	2324	3725	3589

Table 1: Number of tests generated by models under variations of HumanEval files.

Model	p = 0	p = 0.1	p = 0.25	p = 0.50	p = 0.75	p = 1
GPT-3.5	1323	958	929	893	908	883
GPT-4	3832	3596	3446	3198	3335	3295

Table 2: Number of tests generated by models with proportions of dropped comment lines within HumanEval files.

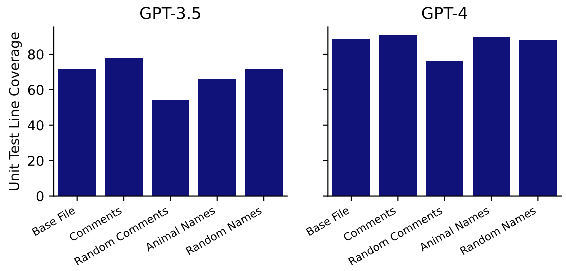

Figure 4: Average percent of line coverage with GPT-3.5 (left) and GPT-4 (right) generating unit tests on modified versions of HumanEval code.

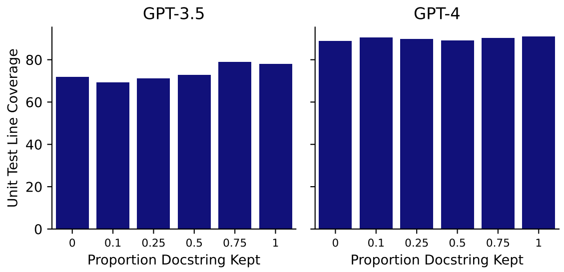

Figure 5: Average percent of line coverage with GPT-3.5 (left) and GPT-4 (right) generating unit tests on different proportions of docstring lines kept on HumanEval code.

overall unit test success rate. This suggests that the LLM is better at understanding the different execution paths of the code, but this may make the creation of a successful unit test more difficult. Alternatively, we do show that incorrect comments do significantly affect an LLM's ability to understand a piece of code.

It is possible that in much of the training data used to train the OpenAI models tested in this study, the code did not contain many comments or documentation. As such, it may be possible that a model's ability to utilize comments is dependent on how much of this documentation is in the training data, and other non-OpenAI LLM's may make better or worse use of the information provided. It is also possible that correct comments do not add much information as it would be relevant to the creation of unit tests, but incorrect comments still *confuse* the LLMs.

7 Limitations

While we do introduce a new research question to the space of LLM code understanding, we recognize that this is a limited test that is missing a broader comparison study between programming languages, models, prompting techniques, hyperparameters, and input documentation modification, and that this paper represents merely an introduction to the idea of documentation's effects on LLM code understanding. In addition, since OpenAI's training data is not publicly available, there is a small but real possibility that the training data may contain the HumanEval dataset, in which case these results would be invalid.

In future work, we believe that more comprehensive tests should be done by including examples of more complex code and documentation (such as that found in ClassEval (Du et al., 2023)). These tests could be evaluated while simultaneously seeing the affect of and controlling for code complexity using metrics such as cyclomatic complexity or maintainability index (McCabe, 1976; Coleman et al., 1994). We also recommend evaluating unit test success rate while controlling for code coverage to properly isolate and determine good success metrics.

Finally, this same research question could be evaluated using code summarization as the code understanding task, because it still measures how well the LLM attempts to answer "What does this piece of code do?"

Abstract

Large language models (LLMs) have recently been used as backbones for recommender systems. However, their performance often lags behind conventional methods in standard tasks like retrieval. We attribute this to a mismatch between LLMs' knowledge and the knowledge crucial for effective recommendations. While LLMs excel at natural language reasoning, they cannot model complex user-item interactions inherent in recommendation tasks. We propose bridging the knowledge gap and equipping LLMs with recommendation-specific knowledge to address this. Operations such as Masked Item Modeling (MIM) and Bayesian Personalized Ranking (BPR) have found success in conventional recommender systems. Inspired by this, we simulate these operations through natural language to generate auxiliary-task data samples that encode item correlations and user preferences. Fine-tuning LLMs on such auxiliary-task data samples and incorporating more informative recommendation-task data samples facilitates the injection of recommendation-specific knowledge into LLMs. Extensive experiments across retrieval, ranking, and rating prediction tasks on LLMs such as FLAN-T5-Base and FLAN-T5-XL show the effectiveness of our technique in domains such as Amazon Toys & Games, Beauty, and Sports & Outdoors. Notably, our method outperforms conventional and LLM-based baselines, including the current SOTA, by significant margins in retrieval, showcasing its potential for enhancing recommendation quality.

1 Introduction

Large language models (LLMs) exhibit strong generalization abilities through zero-shot learning, in-context learning (Brown et al., 2020), fine-tuning, and instruction tuning (Wei et al., 2022). Encouraged by this, recent studies explore the use of LLMs as backbones in recommendation (Kang et al., 2023; Geng et al., 2022; Zhang et al., 2023; Bao et al., 2023). Despite their great potential, LLMs are inferior to supervised recommenders (He et al., 2017; Rendle et al., 2009) in recommendation tasks such as rating-prediction under zero-shot and few-shot in-context learning settings (Kang et al., 2023). We hypothesize that this stems from a gap between LLMs' knowledge and recommendation knowledge: LLMs are proficient at natural language reasoning, while recommendation involves modeling complex user-item interactions. In this work, we propose to mitigate this gap by fine-tuning LLMs with data samples that encode recommendation knowledge.

Recent works (Geng et al., 2022; Zhang et al., 2023; Bao et al., 2023) show that certain recommendation knowledge can be introduced into LLMs through instruction tuning. As shown in Figure 1(a), their training data samples, which we refer to as *recommendation-task data samples*, primarily help LLMs understand the recommendation tasks by providing instructions on what to do (*e.g.*, "Pick an item for the user from the following candidates."). In terms of modeling the target recommendation domain, however, they present raw user and item features for personalization (*e.g.*, the user's ID or the IDs of the items they recently interacted with), which are insufficient for LLMs to fully comprehend the target domain.

Considering the aforementioned limitations of using LLMs as recommenders, we propose a novel approach to generate additional fine-tuning data samples for LLMs that effectively encode recommendation knowledge, particularly focusing on item correlations within the target domain. We refer to these generated data samples as *auxiliary-task data samples*, as they are used as auxiliary tasks in addition to the recommendations tasks. While developing the auxiliary tasks, our key inspiration comes from the classical operations that

1) P5 Retrieval (Sequential Recommendation)

Input: I find the purchase history list of user_15466: 4110 -> 4467 -> 4468 -> 4472 I wonder what is the next item to recommend to the user. Can you help me decide?
Output: 1581

2) P5 Ranking (Direct Recommendation)

Input: Pick the most suitable item from the following list and recommend to user_250: 4915 , 1823 , 3112 , 3821 , 3773 , 520 , ...
Output: 520

3) P5 Rating Prediction

Input: What star rating do you think user_23 will give item_7391?
Output: 5.0

4) InstructRec Ranking (type <P1, I0, T3>)

Input: The user has purchased these items: <historical interactions>. Please respond to this user by selecting items from the candidates: <candidate items>.
Output: <target item>

5) TALLRec Rating Prediction

Input: Given the user's historical interactions, please determine whether the user will enjoy the target new movie by answering "Yes" or "No". User's liked items: GodFather. User's disliked items: Star Wars. Target new movie: Iron Man.
Output: No.

a) Recommendation-task data samples of the existing studies

1) Retrieval

Input: A user has purchased the following products: Item ID: I811, Title: Women's Gel-Excite Running Shoes; Item ID: I1014, Title: Women's Dry-fit Tempo Shorts; ... What would the user buy next?
Output: I10145

2) Ranking

Input: A user has purchased the following products: Item ID: I811, Title: Women's Gel-Excite Running Shoes; ... Which of the following candidate items would you recommend the user to buy next? Candidate items are: I8, I92, I10145, ...
Output: I10145

3) Rating Prediction

Input: A user likes the following products: Item ID: I811, Title: Women's Gel-Excite Running Shoes;... The user dislikes the following products: ... Predict whether the user would like the following item. Answer yes or no. Item ID: I1014, Title: Women's Dry-fit Tempo Shorts;
Output: Yes

4) Masked Item Modeling (MIM)

Input: A user has purchased the following products: Item ID: I811, Title: Women's Gel-Excite Running Shoes; [masked item]; ... [masked item]; ... What are the masked items, in chronological order?
Output: Item ID: I1014, Title: Women's Dry-fit Tempo Shorts; Item ID: I10145, ...

5) Masked Language Modeling (MLM)

Input: Item 11, Title 's Gel-Excite Running Women's Dry-fit Tempo
Output: <B> ID: I8 <S> : Women <S> Shoes; Item ID: I1014, Title <S> Shorts; <E>

6) Bayesian Personalized Ranking (BPR)

Input: A user has purchased the following products: Item ID: I811, Title: Women's Gel-Excite Running Shoes; ... Which of the following two products would the user buy next? Item ID: I123, Title: Golf Club Cleaner Brush; or Item ID: I1014, Title: Women's Dry-fit Tempo Shorts?
Output: Item ID: I1014, Title: Women's Dry-fit Tempo Shorts

b) Our recommendation-task and auxiliary-task data samples

Figure 1: Data samples adopted by the existing studies and this work. (a) shows the recommendation-task data samples of the existing studies. Specifically, (a1)-(a3) demonstrate the retrieval, ranking, and rating prediction data samples of P5 (Geng et al., 2022); (a4) shows a ranking (type <P1, I0, T3>) data sample of InstructRec (Zhang et al., 2023); (a5) is a rating prediction data sample of TALLRec (Bao et al., 2023). (b) shows our recommendation-task (blue boxes) and auxiliary-task (purple boxes) data samples (we present more samples in Appendix C).

are typically used to train conventional recommender systems, namely, masked item modeling (MIM) (Sun et al., 2019) and Bayesian Personalized Ranking (BPR) (Rendle et al., 2009). Our key innovation lies in converting the MIM and BPR tasks into natural language tasks that can be used to train the LLMs. We also incorporate the masked language modeling (MLM) (Devlin et al., 2019) task for the user's past interactions to supplement the MIM task with fine-grained item correlations. Our contributions can be summarized as follows:

- We propose a novel method to align LLMs with new recommendation domains, *i.e.*, supplementing the fine-tuning of the LLMs with *auxiliary-task data samples* that mimic the classical operations in training conventional recommender systems with natural language prompts.
- We propose *recommendation-task data samples* that are more informative as compared to the existing work (Geng et al., 2022). Specifically, we reduce the complexity of the input/output spaces by eliminating the user IDs. We further enhance the user sequences by providing item titles.
- We fine-tune the open-source 3B FLAN-T5-XL and 223M FLAN-T5-Base with our proposed recommendation-task and auxiliary-task data samples in a simple multi-task learning framework. Experiments on various recommendation tasks, *i.e.*, retrieval, ranking, and rating-prediction, across three target domains, *i.e.*, Amazon Toys & Games, Beauty, and Sports & Outdoors, show the effectiveness of our proposed method and its components. For retrieval, our model outperforms both conventional and LLM-based baselines, including the current SOTA, by large margins.

2 Related Work

Recommender Systems. Recommender systems help users in discovering items of interest. As a practical approach, Collaborative Filtering (CF) (Mao et al., 2021) explores historical user-item interactions, assuming that users with similar behaviors have similar preferences for items. Among various CF methods, Matrix Factorization (MF) methods (Rendle et al., 2009; Mao et al., 2021) project users and items into a shared vector space and estimate a user's preference for an item through the inner product of their vectors and are widely adopted. Context-aware approaches (Cheng et al., 2016) further include additional information, such as user and contextual features, to improve recommendation quality. However, CF fails to capture the sequential patterns in users' behaviors, which leads to the rise of sequential recommendations. Sequential recommenders based on Convolutional Neural Networks (CNNs) (Tang and Wang, 2018), Gated Recurrent Units (GRUs) (Hidasi et al., 2016), and self-attention (Sun et al., 2019; Zhang et al., 2019; Kang and McAuley, 2018; Zhou et al., 2020; Rajput et al., 2023) have become prevalent in the era of deep learning. Notably, leveraging a T5-like backbone, Rajput et al. 2023 formalize recommendation as generative retrieval, *i.e.*, autoregressively decode the identifiers of the target items, and achieve the current SOTA. While structurally resembling LLMs, it lacks their pre-training knowledge and the accompanying natural language reasoning potential. Our proposed approach adopts self-attention for sequential recommendation, specifically harnessing LLMs as backbones. We compare against various baselines from all the classes discussed above.

LLMs for Recommendation. LLMs have recently been explored for recommendation tasks due to their ability to understand, generate, and reason with natural language. Several studies focus on incorporating LLMs' natural language capabilities into existing recommendation techniques. *E.g.*, Hou et al. 2022 and Cao et al. 2023 encode item contents (title, description, etc.) with BERT (Devlin et al., 2019), which enables learning semantically informed embeddings even for zero-shot items. Moreover, pre-trained LLM backbones have also been used for recommendation through zero-shot learning (Kang et al., 2023), in-context learning (Kang et al., 2023), fine tuning (Cui et al., 2022; Kang et al., 2023), and instruction tuning (Geng et al., 2022; Zhang et al., 2023; Bao et al., 2023). Besides helping classic recommendation tasks, LLMs also enable novel recommendation use cases. Geng et al. 2022 leverage LLMs to explain the recommendation results. Gao et al. 2023; Wang and Lim 2023 utilize GPT-3 (Brown et al., 2020) for conversational recommendation. Christakopoulou et al. 2023 extract persistent user interests with LLMs for deeper user understanding. Carranza et al. 2023 generate private synthetic representations of the original data with LLMs for privacy-preserving recommendation.

Recommendation as Instruction-following. The success of instruction tuning, *i.e.*, fine-tune on data described via instructions (Mishra et al., 2022; Wei et al., 2022), has inspired attempts that instruction-tune LLM backbones for recommendation tasks. Geng et al. 2022 formalize various recommendation tasks as natural language instructions and fine-tune a unified recommender with T5 (Raffel et al., 2020) backbone. Zhang et al. 2023 further supplement the tuning data with user preferences/intentions deduced by GPT-3.5 [1] to accommodate instructions of free forms. Bao et al. 2023 explore instruction tuning LLMs with limited data.

In contrast to the existing studies, our work focuses on introducing new recommendation knowledge into LLMs, which we believe is the key for improving recommenders with LLM backbones. We create auxiliary tasks that improve the recommendation tasks, including retrieval, ranking, and rating prediction. Our proposed recommendation-task and auxiliary-task data samples include raw user purchase sequences in addition to natural language instructions. These data samples supplement each other in encoding the target recommendation domain knowledge. We experiment under restricted settings. Compared to the previous studies (Zhang et al., 2023), we consider larger candidate pools (*e.g.*, our retrieval and ranking experiments consider the entire dataset and 99 hard negatives, respectively). Unlike Bao et al. 2023, we fully train all models to maximize their performances.

3 Methodology

We propose designing data samples that encode recommendation knowledge to align LLMs with the target recommendation domain. Sections 3.1 and 3.2 discuss our auxiliary-task and recommendation-task data, respectively. Section 3.3 introduces a simple multi-task learning framework that we use to fine-tune LLMs.

3.1 Auxiliary-task Data Generation

Conventional recommenders acquire recommendation knowledge via classic operations such as masked item modeling (Sun et al., 2019) and BPR loss reduction (Rendle et al., 2009). We mimic these operations with natural language prompts. In addition, we sample sub-sequences of the raw user purchase sequences. The resulting data, which we refer to as auxiliary-task data samples, encode item correlations contained in users' preferences [2].

---

[1] `https://platform.openai.com/docs/models/overview`

[2] As a side note, we also explored encoding item correlations contained in item contents (categories, descriptions, etc.). Observing no noticeable performance increase, we present our approach and results in Appendix D

3.1.1 Masked Item Modeling (MIM)

Conventional sequential recommenders (Sun et al., 2019) learn item correlations from users' interaction sequences. Specifically, they predict randomly masked items in the sequences by jointly conditioning on the unmasked items. We mimic this process, which we refer to as masked item modeling (MIM), with natural language prompts.

MIM applies a Cloze objective (Sun et al., 2019). At each training step, random items in the input user sequence are replaced with a special token "[mask]", and the model learns to recover the masked items based on its surrounding context. An example of the masking process:

$$\begin{aligned} &\textbf{Input: } [i_1, i_2, i_3, i_4, i_5] \xrightarrow{\text{random masking}} \\ &\quad [i_1, [\text{mask}]_1, i_3, [\text{mask}]_2, i_5] \qquad (1) \\ &\textbf{Label: } [\text{mask}]_1 = i_2,\ [\text{mask}]_2 = i_4 \end{aligned}$$

The MIM loss is computed as follows in conventional sequential recommenders:

$$\mathcal{L}_{\text{MIM}} = \frac{1}{|\mathcal{S}_u^m|} \sum_{i_m \in \mathcal{S}_u^m} -\log P(i_m | \mathcal{S}_u^{'}), \qquad (2)$$

where $\mathcal{S}_u^{'}$ is the masked version of user sequence $\mathcal{S}_u$, $\mathcal{S}_u^m$ stands for the masked items in $\mathcal{S}_u$. $P(\cdot)$, the probability of observing i_m given $\mathcal{S}_u^{'}$, is calculated from deep bidirectional self-attention (Devlin et al., 2019).

Our natural language imitation of MIM loss (Equation 2) is described in Figure 1(b4). Given purchase sequence: $[i_1, i_2, i_3, i_4, i_5]$, we generate prompts, *e.g.*, Input: "A user has purchased the following products: Item ID: $[\text{ID}]_{i_1}$, Title: $[\text{Title}]_{i_1}$; [masked item]; Item ID: $[\text{ID}]_{i_3}$, Title: $[\text{Title}]_{i_3}$; [masked item]; Item ID: $[\text{ID}]_{i_5}$, Title: $[\text{Title}]_{i_5}$. What are the masked items, in chronological order?", and Output: "Item ID: $[\text{ID}]_{i_2}$, Title: $[\text{Title}]_{i_2}$; Item ID: $[\text{ID}]_{i_4}$, Title: $[\text{Title}]_{i_4}$;". To accommodate long sequences, we introduce a sliding window w and each prompt considers one sub-sequence: $[i_k, i_{k+1} ..., i_{k+w-1}]$, where $1 \leq k \leq \max\big(1,(L\text{-}w\text{+}1)\big)$ and L is the total length of the user sequence. The resulting MIM data samples encodes the correlations between the masked items and the rest of the sequences.

3.1.2 Masked Language Modeling (MLM)

In addition to MIM that considers a single item for each mask, we also mask out and recover a consecutive span of *tokens* to encode fine-grained item correlations contained in the users' purchase sequences. This process resembles masked language modeling (MLM) (Devlin et al., 2019).

As shown in Figure 1(b5), given a user sequence, we sample a sub-sequence by randomly deciding a starting item and a sub-sequence length L_s, where $2 \leq L_s \leq w$ and w is the sliding window for accommodating long sequences. These sub-sequences, referred to as MLM data samples, supplement the MIM data samples: through span corruption (Raffel et al., 2020), *i.e.*, masking and recovering consecutive spans of tokens, LLMs learn to model more fine-grained correlations across multiple continuous items from the MLM data samples.

3.1.3 Bayesian Personalized Ranking (BPR)

Besides correlating similar items, we explore contrasting dissimilar items. BPR loss (Rendle et al., 2009) is adopted by conventional recommenders (Rendle and Freudenthaler, 2014; Koren et al., 2009; Cheng et al., 2016) for personalized ranking, *i.e.*, learning users' preferences for some items over the others. Inspired by this, we imitate BPR loss reduction with natural language prompts for training LLMs.

The objective of BPR loss reduction in conventional recommenders is:

$$\mathcal{L}_{\text{BPR}} = \mathop{\mathbb{E}}_{(u,i^+)\sim p_{\text{pos}}} - \log \sigma(s(u, i^+) - s(u, i^-)), \qquad (3)$$

where (u, i^+) is a pair of a user u and an item i^+ sampled from the distribution of positive pairs p_{pos}, *i.e.*, u interacted with i^+. i^- is a randomly sampled negative item that u has not interacted with. The similarity between u and i^+, denoted by $s(u, i^+)$, is calculated by taking the dot product of their representations. $\sigma(\cdot)$ is the Sigmoid function.

Figure 1(b6) shows our natural language imitation. We elicit user preferences by generating prompts with binary choices that contrast a positive item and a negative item. Each prompt takes the form of a binary decision, *e.g.*, Input: "A user has purchased ... Which of the following two products would the user buy next? Item ID: $[\text{ID}]_{i^-}$, Title: $[\text{Title}]_{i^-}$; Item ID: $[\text{ID}]_{i^+}$, Title: $[\text{Title}]_{i^+}$.", and Output: "Item ID: $[\text{ID}]_{i^+}$, Title: $[\text{Title}]_{i^+}$". Following Section 3.1.1, we adopt a sliding window w to accommodate long user sequences and the positive item is always the one next to the sliding window. These BPR data samples encode dissimilarities between the purchased items and the rest of the items in the dataset.

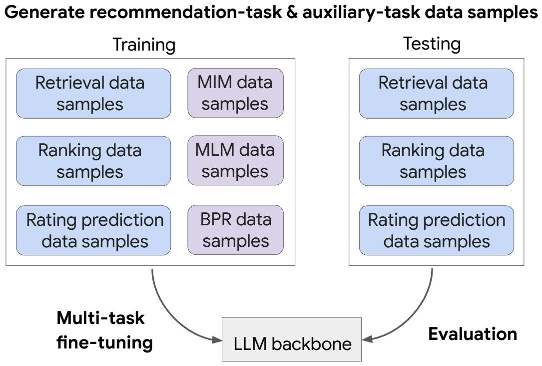

Figure 2: Fine-tuning and evaluation framework.

3.2 Recommendation-task Data Generation

As shown in Figure 1(a), the existing recommenders with LLM backbones adopt prompts that primarily convey the recommendation tasks by providing directions on how to perform them. Such information is essential, yet insufficient for representing the target recommendation domain.

We propose prompts that help LLMs comprehend the target recommendation domain in addition to the recommendation tasks. Specifically, we reduce the complexity of the input/output spaces. In contrast to Geng et al. 2022, we eliminate user IDs and represent the users by their historical purchases. Consequently, we relieve LLMs from memorizing a substantial volume of user IDs (*e.g.*, Amazon Sports & Outdoors has 35,598 users). Moreover, compared to Geng et al. 2022 that represent user sequences solely by item IDs, we include both the IDs and the titles of the items, which makes it easier for LLMs to recognize the items. Notably, ranking candidates and items in the output are represented solely by their IDs to reduce the length of the prompts and maintain a smaller output space. Figures 1(b1)-(b3) show examples of our retrieval, ranking, and rating prediction recommendation-task data samples. The raw item IDs (*e.g.*, ‘0000031852’) are mapped into shorter ones (*e.g.*, ‘I123’) [3] to reduce input/output space complexity. To fully present the users’ historical purchases to LLMs, we adopt a sliding window w similar to Section 3.1.1.

3.3 Fine-tuning and Evaluation Framework

As shown in Figure 2, we adopt a simple framework to fine-tune the LLM backbones and evaluate the resulting model. We first generate recommendation-task and auxiliary-task data samples using the training set. Next, we tune the LLM backbone with these data samples in a multi-task learning manner. Finally, we evaluate the recommendation tasks using the recommendation-task data samples generated from the test set.

4 Experiments

We evaluate the proposed method and compare it with conventional as well as LLM-based recommenders. We aim to answer the following research questions: **RQ1.** Can our method introduce knowledge into LLMs from new recommendation domains? **RQ2.** How does our model perform compared to the conventional as well as LLM-based recommenders in retrieval, ranking, and rating prediction? **RQ3.** How beneficial are the individual proposed tasks? **RQ4.** What’s the effect of varying the size of the backbone LLM?

4.1 Experimental Setting

Datasets. We experiment on three real-world datasets: Amazon Toys & Games, Beauty, and Sports & Outdoors [4]. Following Zhou et al. 2020; Geng et al. 2022, we keep 5-core data and apply leave-one-out evaluation, *i.e.*, for each user purchase sequence (where the interactions are sorted by timestamp in ascending order), the last, the second to the last, and the prior interactions are used for testing, validation, and training, respectively. We present data statistics in Appendix B.

Recommendation Tasks. We evaluate on three established recommendation tasks: **retrieval**, which retrieves the ground truth item that a user interacted with from the entire dataset; **ranking**, which chooses the ground truth item that a user interacted with from a candidate pool of size 100 (1 positive item and 99 negative items sampled based on popularity); **rating prediction**, which classifies an interaction as either "like" or "dislike" (interactions with ratings > 3 are considered as "like"). We leave the exploration and evaluation of novel recommendation tasks (*e.g.*, explanation generation) to the future, due to a lack of ground-truth data.

Evaluation Metrics. For retrieval and ranking, we report top-k Hit Ratio (HR@k) and Normalized Discounted Cumulative Gain (NDCG@k), where k is set to 5/10 and 1/5/10, respectively. For rating prediction, we report Area Under the Receiver

---

[3] We adopt random mapping, *i.e.*, similar-looking IDs may not imply any connection or semantic similarity. We acknowledge that using semantic-rich IDs (Rajput et al., 2023) could enhance performance and leave the exploration to the future.

Table 3: Rating prediction AUC-ROC. Δ compares the best [**Ours**] with the best baseline.

Operating Characteristic Curve (AUC-ROC).

Models. We compare to non LLM-based recommenders. For retrieval, we consider sequential recommenders including **Caser** (Tang and Wang, 2018), which leverages CNNs, **HGN** (Ma et al., 2019), which adopts hierarchical gating networks, **GRU4Rec** (Hidasi et al., 2016), which leverages GRUs (Cho et al., 2014), **BERT4Rec** (Sun et al., 2019), **FDSA** (Zhang et al., 2019), **SASRec** (Kang and McAuley, 2018), **S^3-Rec** (Zhou et al., 2020), and **TIGER** (Rajput et al., 2023), which leverage self-attention, with TIGER being the current SOTA. For ranking, we consider **BPR-MF** (Rendle et al., 2009), **BPR-MLP** (Cheng et al., 2016), and **SimpleX** (Mao et al., 2021), which are collaborative filtering-based method. For rating prediction, we consider **History**, a naive method that always predicts based on how likely a user likes the training items they purchased, **DMF** (Xue et al., 2017), a neural matrix factorization model, and **Wide&Deep** (Cheng et al., 2016), a context-aware method. Beside, we also consider LLM-based methods including **P5** (Geng et al., 2022), which fine-tunes T5 (Raffel et al., 2020) with multitask recommendation prompts, **P5-XL**, which fine-tunes FLAN-T5-XL with P5 prompts, **FLAN-T5-Base/XL** (Wei et al., 2022), which make zero-shot predictions with FLAN-T5-Base or FLAN-T5-XL. We query them with our proposed recommendation-task data samples generated from the test set [5]. **ReAT/ RaAT/ RpAT**, which fine-tune FLAN-T5-XL with our proposed retrieval (Re), ranking (Ra), or rating prediction (Rp) task data samples along with the auxiliary-task (AT) data samples [6], **unified training (UT)**, which fine-tunes FLAN-T5-XL with a combination of our proposed Re, Ra, Rp data samples, **unified training w/ auxiliary tasks (UT+AT)**, which fine-tunes FLAN-T5-XL with a combination of our proposed Re, Ra, Rp, MIM, MLM data samples.

Implementation Details. We adopt the 3B FLAN-T5-XL (Wei et al., 2022) as the backbone. We also use the 223M FLAN-T5-Base for the ablation studies in Section 4.3. Meanwhile, it's crucial to emphasize that the proposed method is not tied to a specific backbone architecture and is easily adaptable to other LLMs, such as LLaMA (Touvron et al., 2023). We set the sliding window size w to 20. For the BPR data samples, we sample the negative items based on popularity. For the ranking and BPR data samples, the position of the positive item in the candidate pool is always determined randomly. For the MIM and MLM data samples, we adopt a masking ratio of 20%. To fully fine-tune the LLM backbone, we apply dynamic sampling for the BPR and MIM/MLM data samples (we present details about the dynamic sampling and the statistics of our data samples in Appendix C). To reduce cost, we validate on 3,000 users. Meanwhile, testing is performed on all users. We fine-tune FLAN-T5-XL and FLAN-T5-Base for $70,000$ and $10,000$ steps, with batch sizes 16 and 64, respectively. We set the learning rate to 0.001 and warm-up steps to 1,000. During prediction, we set the width of the beam search for retrieval and ranking to 20. For unified models, *i.e.*, UT and UT+AT, model selections are based on retrieval validation performance. We present the detailed settings of P5-XL experiments in Appendix A. We cite the results of some baseline models from Zhou et al. 2020; Geng et al. 2022; Rajput et al. 2023. We implement DMF and Wide&Deep with RecBole [7]. We adopt the default configurations, except the data split, mapping (ratings to "like"s or "dislike"s), and metric are adjusted to follow our experiment settings as reported earlier. The pseudo code for generating our proposed data samples can be found in Appendix C.

4.2 Overall Performance (RQ1 & RQ2)

Tables 1, 2, and 3 show the results of retrieval, ranking, and rating prediction, respectively. FLAN-T5-Base/XL exhibit suboptimal performance on retrieval and ranking. For retrieval, they show near zero NDCGs and HRs. For ranking, they are significantly inferior to the conventional baselines. For rating prediction, they perform much higher than random guessing (50.00), outperforming DMF, but still fall behind History and Wide&Deep. This shows that FLAN-T5 models lack recommendation knowledge, which is unsurprising considering they were not trained on recommendation tasks during pre-training or instruction-tuning and are evaluated in a zero-shot setting. Moreover, we find that our proposed method effectively aligns LLMs with new recommendation domains (RQ1). In particular, by fine-tuning FLAN-T5-XL with our proposed data samples, our models significantly outperform FLAN-T5-XL on all three tasks across the datasets.

When compared to the baselines, our models show remarkable performance, especially on retrieval (RQ2). For retrieval, our ReAT outperforms TIGER, the current SOTA, by large margins across datasets and metrics. Additionally, it is essential to highlight that our method possesses natural language reasoning potentials of LLMs, which are absent in TIGER. For ranking, our RaAT greatly outperforms SimpleX, the best baseline, on Toys & Games. On Beauty, RaAT performs on par with SimpleX. On Sports & Outdoors, RaAT is inferior to the conventional recommenders on metrics such as NDCG/HR@10, yet still greatly outperforms the LLM-based baselines. Notably, the @1 performance of RaAT is always much higher than the conventional recommenders. For rating prediction, our RpAT outperforms Wide&Deep, the best baseline, on Toys & Games and Beauty while lags slightly behind it on Sports & Outdoors. These results verify that our method introduces substantial recommendation domain knowledge into LLMs

---

[5] We acknowledge that our retrieval and ranking data samples (examples are shown in Figure 1 and Appendix C) utilize item IDs for matching prediction results, whereas the FLAN-T5-Base/XL models, when queried in the zero-shot setting, do not inherently predict item IDs. Addressing this discrepancy, text-based methods could be employed to extract item titles, descriptions, etc., from the FLAN-T5-Base/XL predictions to enhance their performance. However, employing such approaches requires an additional model for text matching, which falls beyond the scope of this work

[6] BPR data samples are used only by RaAT as we observe that they help ranking but not retrieval and rating prediction. MIM/ MLM data samples are used by ReAT, RaAT, and RpAT.

[7] `https://recbole.io`

for outperforming strong baselines. The relative ineffectiveness of our method on Sports & Outdoors for the ranking and rating prediction tasks could be due to the nature of the data. Specifically, our model, as a sequential recommender, relies on the sequential item correlations conveyed by the user sequences. Such signals may be relatively weak in Sports & Outdoors (*e.g.*, the average sequence length of Sports & Outdoors is 8.32 ± 6.07, whereas that of Beauty and Toys & Games are 8.88 ± 8.16 and 8.63 ± 8.51, respectively, suggesting that Sports & Outdoors sequences are shorter and less diverse), causing our method to perform suboptimally. The best baselines, on the other hand, do not rely on such information. *E.g.*, SimpleX is based on collaborative filtering and Wide&Deep is a context-based model. Therefore, their performances are not impacted.

Moreover, our UT greatly outperforms P5 and P5-XL across datasets and metrics. This shows that our proposed recommendation task prompts better preserve item correlations as compared to the P5 ones. Specifically, we enhance user sequence modeling by introducing helpful details such as item titles while excluding less informative details such as user IDs and explanation data. Additional results of P5-XL as well as a comparison between P5-XL and P5 can be found in Appendix A.

We also compare our UT+AT model with our task-specific models, *i.e.*, ReAT/ RaAT/ RpAT. We show that our method allows fine-tuning a unified model that addresses all recommendation tasks without sacrificing per-task performance by much. For retrieval, UT+AT is slightly worse than ReAT but still outperforms all baselines, except that UT+AT performs comparably with TIGER on Sports & Outdoors. For ranking, UT+AT performs on par with or slightly better than our task-specific RaAT model. For rating prediction, UT+AT is slightly worse than RpAT.

4.3 Ablation Studies (RQ3 & RQ4)

Tables 4, 5, and 6 show ablation studies on Toys & Games for retrieval, ranking, and rating prediction, respectively. We observe that all the proposed tasks are beneficial (RQ3). In Table 4 rows 2-5, successively adding our proposed retrieval, MLM, and MIM data samples into the fine-tuning data increases the retrieval performance. All three tasks are essential. *E.g.*, row 4, which fine-tunes FLAN-T5-XL using retrieval and MLM data samples performs on par with S^3-Rec and worse than TIGER (row 1, the current SOTA). Further adding MIM data samples (row 5) surpasses TIGER. This shows that the item-level and token-level item correlations introduced by MIM and MLM are essential and complement each other. Similarly, in Table 5 rows 2-6, the ranking performance improves as we incorporate our proposed ranking, MLM, MIM, and BPR data samples into fine tuning. Among these data samples, ranking task data samples are the most helpful. BPR data samples, which contrast the positive items with the negative ones, provide the least assistance. For rating predictions, as shown in Table 6 rows 2-5, our proposed rating prediction data samples greatly increase the performance. MLM and MIM do help, but only marginally.

9	8+MIM	68.24

Table 6: Rating-prediction ablation study on Toys & Games. Rows 1, 2, 5 (equivalent to RpAT), and 6 are copied from Table 3.

(RQ4). In Tables 4, 5, and 6, we apply our method on FLAN-T5-Base and observe significant performance increases on all three recommendation tasks. In terms of overall performance, our best retrieval model with FLAN-T5-Base (Table 4 row 9) falls behind TIGER but still outperforms all baselines except TIGER, S^3-Rec, and SASRec. In Table 5, our best ranking model with FLAN-T5-Base (row 11) outperforms SimpleX by large margins, though falls behind our best ranking model with FLAN-T5-XL (row 6). In Table 6, our best rating prediction model with FLAN-T5-Base (row 7) is slightly inferior to the best model with FLAN-T5-XL (row 5) and Wide&Deep. The effectiveness of the individual tasks remains roughly consistent with the previous results with FLAN-T5-XL (except that MLM does not help rating prediction). *E.g.*, in Table 5 rows 7-11, our ranking task, MLM, MIM, and BPR data samples all contribute to the ranking performance, with the ranking task data samples being the most beneficial and BPR the least beneficial.

5 Conclusion

We propose to align LLMs with the recommendation domain by fine-tuning with data samples that encode recommendation knowledge. We propose auxiliary-task data samples that encode item correlations contained in users' preferences. We further design recommendation-task data samples that are more informative than ones in existing studies. Experiments on retrieval, ranking, and rating prediction show that our method effectively introduces recommendation knowledge into FLAN-T5-Base/XL from three domains. Our method greatly outperforms both conventional and LLM-based baselines in retrieval, achieving the new SOTA.

6 Limitations

Our proposed method utilizes LLMs as the backbones. The substantial parameter size of the LLMs results in increased computational resource consumption and extended training and inference times compared to conventional recommenders. Nevertheless, adopting LLM backbones is beneficial due to their significant potential. In addition to the exceptional performance demonstrated in this study, we anticipate that future research will continue to augment existing recommendation tasks and address novel recommendation scenarios by leveraging the diverse capabilities of LLM backbones.

Sports & Outdoors	35,598	18,357	296,337	99.95

Table 7: Statistics of the datasets.

A P5-XL Experimental Setting and Additional Results

A.1 Experimental Setting

We generate P5 prompts using the source code provided by the P5 authors [8]. However, for a fair comparison, we update the data pre-processing to be consistent with our method and the other baselines. Specifically, we apply random instead of sequential indexing when mapping the item IDs. As pointed out by Rajput et al. 2023, the sequential indexing of items (*e.g.*, the purchase sequence of the first user in Toys & Games is mapped into '1, 2, 3, 4, 5, 6, 7') in the original P5 pre-processing leads to data leakage (*e.g.*, given the train items, *i.e.*, '1, 2, 3, 4, 5, 6', the LLM can easily infer the test item, *i.e.*, '7'). Therefore, we adopt random mapping (*i.e.*, consecutive or similar-looking IDs may not imply any connection), which is consistent with our method. In addition, the original P5 pre-processing adopts leave-one-out split for retrieval and ranking, while splitting the dataset by 0.8:0.1:0.1 for the training, validation, and testing of rating prediction. This could result in data leakage, as the test interactions of one task might be included in the training set of another task. We instead adopt leave-one-out data split for all three recommendation tasks, which is consistent with our proposed method as well as the other baselines.

For a fair comparison, We apply the same backbone (FLAN-T5-XL), fine-tuning steps (70,000), batch size (16), and learning rate (0.001) as adopted by our proposed method. Following the original P5 code, we fine-tune a unified model with prompts of their proposed five task families (rating, sequential recommendation, explanation, review, and direct recommendation. The sequential recommendation and direct recommendation families are weighted 5 times higher than the rest families). In Tables 1, 2, and 3, we adopt prompt templates 2-1, 2-7, and 1-4 for evaluating the retrieval, ranking, and rating prediction performance of the P5-XL model, as these templates better suit the forms of the recommendation tasks (introduced in the second subsection of Section 4.1) than the other templates.

A.2 P5-XL vs. P5

Please note that the retrieval results of P5 in Table 1 are cited from Rajput et al. 2023 rather than the original P5 paper (Geng et al., 2022). This is because the original P5 experiments cannot be reproduced upon fixing the information leakage issues as discussed in the previous section. Meanwhile, Rajput et al. 2023 does not report the ranking and rating prediction performances of P5. To fully evaluate P5, we train a P5-XL model following the experimental setting as detailed in the previous section, and report its performance on all three tasks in Tables 1 to 3.

P5-XL performs worse than P5 in Table 1, which is likely owing to the differences in their training data. Specifically, P5 was only trained on retrieval prompts (as indicated in Appendix D of Rajput et al. 2023). While following the original P5 paper, P5-XL is trained on all five task families of P5 prompts, including explanation generation and review summarization tasks. We hypothesize that these additional data samples are very different from the evaluated tasks (retrieval, ranking and rating prediction), causing negative transfer to the evaluated tasks.

A.3 Additional Results

In Table 8, we report the ranking results of P5-XL evaluated with prompt template 5-5. We can tell that P5-XL (5-5) slightly fall behind P5-XL. Our proposed UT greatly outperforms both P5-XL and P5-XL (5-5), which again verifies that our proposed recommendation task prompts are more informative than the P5 ones.

B Dataset Statistics

Table 7 presents the statistics of the Amazon datasets, *i.e.*, Toys & Games, Beauty, and Sports & Outdoors, that we used to evaluate our proposed method as well as all the baselines.

C Pseudo Code, Statistics, and Examples of the Proposed Data Samples

C.1 Pseudo Code for Data Sample Generation

Algorithm 1 presents the pseudo code for generating our proposed recommendation-task and auxiliary-task data samples.

...

Figure 3: Item embedding (IE) data samples.

C.2 Statistics of the Data Samples

Table 10 presents the statistics of our proposed recommendation-task and auxiliary-task data samples. Consider the recommendation-task data samples, the training data samples are generated by swiping a sliding window of size $w = 20$ over the training split of the user sequence. The validation data samples consider only 3,000 users for each dataset for cost-efficient validation. We test on all users, therefore the counts of the testing data samples equal to the total number of users in the datasets. The auxiliary-task data samples, on the other hand, are generated using only the training splits. Notably, during training, we apply dynamic sampling that decide the negative items in the BPR data samples as well as the masked items/tokens in the MIM/MLM data samples on the fly. Such dynamic sampling helps to fully fine-tune the LLM backbones.

C.3 Examples of the Data Samples

In Table 11, we present examples of our proposed data samples. These data samples are generated with the training data split of an Amazon - Toys & Games user whose ID is 'A12HF3UBDV34RR'. Note that to fully fine-tune the LLM backbone, we apply dynamic sampling for the BPR and MIM/MLM data samples and decide the negative items and masked items/tokens on the fly. Here, we only present the BPR, MIM, and MLM data samples resulted from a single sampling.

D Mimicking Item Embedding

Our proposed data samples introduced in the main paper encode item correlations encompassed in users' preferences. We also explore encoding item correlations encompassed in item contents, *i.e.*, categories, descriptions, etc.

We observe that the conventional context-aware recommenders commonly integrate item contents to help the model better understand the items and achieve enhanced performance. *E.g.*, Hou et al. 2022 embed the concatenations of item content fields with BERT (Devlin et al., 2019). The learned item embeddings, $\mathbf{X} \in \mathbb{R}^{N \times d}$, where N is the number of the items and d is the dimension of the vector space, serve as initial representations of the items.

We mimic this item embedding (IE) process with natural language prompts. As shown in Figure 3, by asking questions about the properties of an item in the input and answering them in the output, we can generate item embedding data samples such as 'Input: What's the brand of I1014? Output: Nike'. We repeat such question answering process for various available item content fields, including title, categories, brand, price, attributes, and descriptions. These data samples represent knowledge about the items, but with natural language rather than numerical vectors. We expect that tuning LLMs with IE data samples can help them to comprehend the items in the target recommendation domain and enhance their performance.

To evaluate the IE data samples, we tune a **UT+IE** model, which augments the fine-tuning data of our UT model with IE data samples (the rest experimental settings of UT+IE and UT remain the same). We present its retrieval performance on Sports & Outdoors in Table 9. We observe no noticeable performance increase when incorporate IE data samples. The reason might be, the raw item content fields are noisy. *E.g.*, the description

field is long and can contain noise such as hashtags and URLs. It has been shown (Cao et al., 2023) pre-processing the raw fields to extract fine-grained features helps to enhance context-aware recommenders. Inspired by this, in the future, we plan to improve the IE data samples by refining the item content fields.

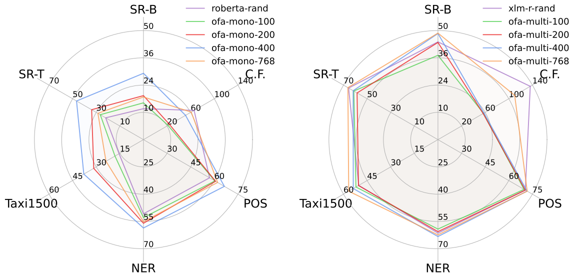
Abstract

Instead of pretraining multilingual language models from scratch, a more efficient method is to adapt existing pretrained language models (PLMs) to new languages via vocabulary extension and continued pretraining. However, this method usually randomly initializes the embeddings of new subwords and introduces substantially more embedding parameters to the model, thus weakening the efficiency. To address these issues, we propose a novel framework: **O**ne **F**or **A**ll (**OFA**), which wisely initializes the embeddings of unseen subwords and thus can adapt a PLM to multiple languages efficiently and effectively. OFA takes advantage of external well-aligned multilingual static word vectors and injects the alignment knowledge into the subword embeddings. In addition, OFA applies matrix factorization and replaces the cumbersome embeddings with two lower-dimensional matrices, which largely reduces the number of parameters. We show OFA accelerates the convergence of continued pretraining, which is environmentally friendly as much fewer carbon footprints are generated. Through extensive experiments, we demonstrate OFA can achieve competitive or better performance than default continued pretraining baselines on a wide range of crosslingual downstream tasks. We make our code and models publicly available.[1]

1 Introduction

Multilingual PLMs (mPLMs), such as mBERT (Devlin et al., 2019) and XLM-R (Conneau et al., 2020), have demonstrated remarkable zero-shot crosslingual capability (Huang et al., 2019; Artetxe et al., 2020). That is, with only finetuning in some (high-resource) languages to perform a task, the multilingual model can be directly applied to other (low-resource) languages. However, training such mPLMs from scratch requires massive data of different languages, and most importantly, considerable computing resources and energy (Wang et al., 2019; Bender et al., 2021; Zhou et al., 2023). Therefore, continued pretraining from existing models has been a good alternative (Wang et al., 2022; Alabi et al., 2022; ImaniGooghari et al., 2023). However, two problems are generally overlooked in the context of multilingual continued pertaining with vocabulary extension: **(a)** the random initialization of embeddings for new subwords does not actively use any lexical knowledge encoded in the model; **(b)** the introduction of many new parameters may pose efficiency problem.



(a) RoBERTa-based models (b) XLM-R-based models

Figure 1: Qualitative comparisons between baselines and OFA. OFA consistently achieves competitive or better performance than the baselines using both (a) monolingual (RoBERTa) or (b) multilingual (XLM-R) PLMs as the source model, with fewer carbon footprints (C.F.) during the continued pretraining, indicating higher efficiency. The stride of each axis in the chart is different.

Regarding **(a)**, the default random initialization approach which samples from a given distribution, e.g., a Gaussian (Hewitt, 2021; de Vries and Nissim, 2021; Marchisio et al., 2023), does not actively use the lexical knowledge of the original embeddings. To better leverage existing knowledge, some recent works propose to initialize the embeddings for target-language subwords by exploiting both external crosslingual static word vectors and the original PLM embeddings (Tran, 2020; Minixhofer et al., 2022; Dobler and de Melo, 2023). Unfortunately, these methods either bilingualize a PLM or create a new monolingual LM for a single target

June 16-21, 2024 ©2024 Association for Computational Linguistics

language at a time, which is not ideal in the context of multilingual continued pretraining. Therefore, our goal is to adapt to many languages all at once and wisely initialize the new subword embeddings for large-scale multilingual continued pretraining.

Regarding **(b)**, adapting to more languages will unarguably introduce more parameters. According to Chung et al. (2021), the embedding matrix of multilingual models makes up around 50% of the model's entire parameters. This percentage can be further increased when adding more new subwords as a consequence of adapting to more languages. For example, XLM-V (Liang et al., 2023) increases its vocabulary to 901K, resulting in embeddings occupying approximately 90% of the overall parameters. In the monolingual setting, the factorized embedding parameterization shows effectiveness without sacrificing much performance (Lan et al., 2020). Thus, a similar method is expected to succeed in multilingual models, given that embeddings are inherently more redundant: *words from different languages that refer to the same concept often have similar representations*. Therefore, we aim to reduce the number of parameters in the embeddings through factorized parameterization.

To this end, we introduce **OFA**, a framework that wisely initializes the embeddings of new subwords with a factorized parameterization for efficient large-scale multilingual continued pretraining. OFA first factorizes the embeddings of the source PLM and uses two smaller matrices to replace it. In the lower-dimensional space, the embeddings of the non-shared new subwords are represented as combinations of the embeddings of some subwords from the source PLM, weighted by the similarity extracted from well-aligned external static multilingual vectors (Liu et al., 2023a) that cover 1,335 languages. The embeddings of the shared subwords are directly copied. Finally, OFA copies all non-embedding parameters of the source PLM model and exchanges the source tokenizer (the tokenizer of the source PLM) with the target tokenizer (the tokenizer after vocabulary extension).

We use a monolingual PLM, i.e., RoBERTa (Liu et al., 2019) and a multilingual PLM, i.e., XLM-R (Conneau et al., 2020) as our source models. We first apply OFA to these models and then continued pretrain the resulting models on the Glot500-c corpus (ImaniGooghari et al., 2023). The final models are evaluated on a diverse set of downstream tasks, including sentence retrieval, text classification, and sequence labeling. OFA not only accelerates the convergence of continued pretraining thus much fewer carbon footprints are generated, but also achieves competitive or better performance on all tasks compared with randomly initialized or full-dimensional baselines, as shown in Figure 1.

The contributions of this work are as follows: (i) We propose OFA, a framework that wisely initializes the embeddings of unseen subwords with factorized parametrization, targeted on efficient multilingual continued pretraining. (ii) We conduct extensive and strictly controlled experiments on a wide range of downstream tasks and show that OFA is effective and boosts crosslingual transfer. (iii) We show OFA is efficient and environmentally friendly: achieving better performance with less GPU consumption and fewer carbon footprints.

2 Related Work

There are generally two ways to obtain a multilingual PLM. The first way is to pretrain a model from scratch directly on a number of languages with a specific self-learning objective, e.g., masked language modeling (MLM) (Devlin et al., 2019). The typical models that adopt such a strategy are encoder-only models such as mBERT (Devlin et al., 2019), XLM-R (Conneau et al., 2020), IndicBERT (Kakwani et al., 2020), AfriBERTa (Ogueji et al., 2021) and XLM-V (Liang et al., 2023), decoder-only models such as XGLM (Lin et al., 2022), mGPT (Shliazhko et al., 2022) and BLOOM (Scao et al., 2022), and encoder-decoder models such as mBART (Liu et al., 2020) and mT5 (Xue et al., 2021). The alternative way is to use publicly available multilingual PLMs as the source models and continued pretrain them on a set of target languages (Wang et al., 2022; Alabi et al., 2022; ImaniGooghari et al., 2023). This continued pretraining approach is in favor because it consumes fewer resources than training from scratch, which is important when the computation budget is limited given the continually increasing model size (Tay et al., 2022; Gupta et al., 2023).

One key reason why this continued pretraining approach works is the crosslingual ability of the original multilingual PLMs (Pires et al., 2019; K et al., 2020; Chai et al., 2022). With this ability, during continued pretraining, the model could leverage the knowledge gained in the previous pretraining phase as a prior, and adapt to the new languages quickly. Some prior works attempt to actively capitalize latent knowledge encoded in the parameters (embeddings or the transformer body) of the source PLM (Artetxe et al., 2020; Pfeiffer et al., 2021) when transferring to new languages. However, embeddings of new subwords are randomly initialized. Most recently, Tran (2020), Minixhofer et al. (2022) and Dobler and de Melo (2023) explore the possibility of leveraging both the source PLM embeddings and well-aligned external crosslingual word vectors to initialize the embeddings of new subwords for a **single** target language at a time. However, how this type of method could be efficiently applied to multilingual scenarios is left unexplored. Our work, in contrast to former research, aims to establish a framework to adapt a PLM, regardless of monolingual or multilingual, to multiple languages. In addition, our framework is targeted towards parameter efficiency, which is friendly to a limited computation budget.

Our work is also related to some approaches that try to extend the vocabulary of a PLM for specific downstream tasks (Wang et al., 2019; Tai et al., 2020; Hong et al., 2021; Nag et al., 2023). This line of work usually learns the additive vocabulary from the new domain data and therefore specializes a PLM to certain domains. In contrast, our work aims to build a framework to strengthen the crosslinguality of an mPLM for general purposes instead of focusing on specific downstream tasks. This is achieved partly by using the external multilingual word vectors from which some alignment knowledge could be injected into the newly initialized subword embeddings. In this perspective, our work is also related to some post-pretraining alignment methods (Pan et al., 2021; Feng et al., 2022; Ji et al., 2023; Liu et al., 2024) that use word correspondence, translation or transliteration to improve the crosslingual transfer ability of mPLMs.

3 Preliminary: Embedding Factorization

Before stepping into Ofa framework, we first introduce one key technique used by Ofa: source embedding factorization. Although matrix factorization itself is not new and is widely leveraged, e.g., in ALBERT (Lan et al., 2020) (a monolingual model) to lower memory consumption. We instead look at this factorization from a **multilingual perspective** and provide the intuition as to why such low-rank parameterization is effective in large-scale **multilingual continued pretraining**.

Given the embeddings $\boldsymbol{E}^s \in \mathbb{R}^{|V^s| \times D}$ from a source PLM that is pretrained on some source languages S, where V^s is its subword vocabulary and D is the embedding dimension, we propose to factorize the matrix $\boldsymbol{E}^s$ into lower-dimensional embeddings $\boldsymbol{F}^s \in \mathbb{R}^{|V^s| \times D'}$ and an orthogonal up-projection matrix $\boldsymbol{P} \in \mathbb{R}^{D' \times D}$: $\boldsymbol{E}^s \approx \boldsymbol{F}^s \boldsymbol{P}$, where $D' < D$. $\boldsymbol{P}$ can be interpreted as the embeddings of a set of D' latent semantic concepts that are language-agnostic. Each concept is represented as a D-dimensional vector and these vectors as a whole serve as the basis of a semantic space in $\mathbb{R}^D$ (a subspace in $\mathbb{R}^D$ as $D' < D$) for all subwords. Thus we refer to $\boldsymbol{P}$ as the *primitive embeddings*. $\boldsymbol{F}^s$ can be regarded as *coordinates* of all subwords in V^s in the space spanned by $\boldsymbol{P}$. The final representation of a subword v will be the linear combination of the primitive embeddings according to the corresponding coordinates $\boldsymbol{F}^s_{\{v\}}$: $\boldsymbol{P}^T \boldsymbol{F}^s_{\{v\}}$.

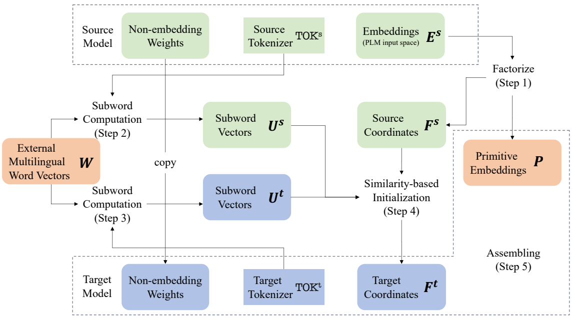

Figure 2: Summary of Ofa. Different color indicates the block is specific to different languages. Green: source languages; blue: target languages; orange: both.

By factorizing the embeddings into the language-agnostic part $\boldsymbol{P}$ and language-specific part $\boldsymbol{F}^s$, we can reduce the number of trainable parameters from $|V^s| \times D$ to $|V^s| \times D' + D' \times D$. This reduction of parameters can be prominent when $D' \ll D$. In addition, as $\boldsymbol{P}$ is shared across languages, we only need to find the target coordinates $\boldsymbol{F}^t \in \mathbb{R}^{|V^t| \times D'}$ under the same basis $\boldsymbol{P}$ when we want to adapt the model to new languages whose vocabulary is V^t. This is much more efficient than finding $\boldsymbol{E}^t \in \mathbb{R}^{|V^t| \times D}$, considering $|V^t|$ can be considerably large in a multilingual setting. Lastly, any coordinates in $\boldsymbol{F}^t$ can be up-projected back to $\mathbb{R}^D$ through $\boldsymbol{P}$, corresponding to the hidden size of the transformer body of the source PLM.

4 Ofa Framework

Ofa initializes the embeddings of new subwords in a factorized parametrization. The basic idea of Ofa is as follows. We leverage an external multilingual word vector[2] space (which provides high-quality representations of both source and target languages) to induce a measure of semantic similarity on the joint set of subwords and words of both source and target languages. This similarity measure then allows us to initialize subwords of target languages with semantically meaningful representations in the source PLM embedding space. We show the summary of OFA framework in Figure 2 and describe the process step by step as follows.

Problem Setting. Given well-aligned external static multilingual word vectors $\boldsymbol{W}$ (vocabulary V), a source PLM (subword embeddings are $\boldsymbol{E}^s$) with its tokenizer $\texttt{TOK}^s$ (vocabulary V^s) and target tokenizer $\texttt{TOK}^t$ (vocabulary V^t), we want to find **a good initialization** of embeddings for all subwords in V^t, i.e., $\boldsymbol{F}^t$, which are **in lower dimensions**.

Step 1. We factorize $\boldsymbol{E}^s$ from the source PLM to primitive embeddings $\boldsymbol{P}$ and source coordinates $\boldsymbol{F}^s$. $\boldsymbol{P}$ will serve as the base of subword embeddings for all languages, and $\boldsymbol{F}^s$ will be used to initialize the desired target coordinates $\boldsymbol{F}^t$ in **Step 4**. We simply let $\boldsymbol{F}^s = \boldsymbol{E}^s$ for baseline models where no matrix factorization is applied to $\boldsymbol{E}^s$.

Step 2. We use the source tokenizer $\texttt{TOK}^s$ to tokenize all words in V. We then create a directed bipartite graph between words in V and subwords in V^s that can be tokenized from those words. We use $\overrightarrow{\text{ColexNet+}}$ (Liu et al., 2023a) as the word vectors, as they show very strong crosslinguality and reflect conceptual similarity (Liu et al., 2023b; Ye et al., 2023) in many languages (see §C for additional details of the word vectors). Next, we create the vector of a subword as the average of the vector of the words that are connected with the subword:

$$\vec{c} = \frac{1}{|N(c)|} \sum_{v \in N(c)} \boldsymbol{W}_{\{v\}}$$

where c is a subword in the graph and $N(c)$ is the set of neighbors of c in the graph (these neighbors are $\in V$). The intuition behind this calculation is that any words that include the same subword are related to the concept that the subword represents, and therefore those words should contribute to the representation of the subword. If a subword in V^s is not in the graph, we create its vector as zero. In this way, we create vectors for all subwords in V^s. We refer to the created subword vectors as $\boldsymbol{U}^s$.

Step 3. We create subword vectors for all subwords in V^t in the same way as described in Step 2, using target decoder $\texttt{TOK}^t$, all words in V, and the multilingual word vectors $\boldsymbol{W}$. The created subword vectors are denoted as $\boldsymbol{U}^t$. Note that $\boldsymbol{U}^t$ and $\boldsymbol{U}^s$ are in the same vector space as $\boldsymbol{W}$, because both of them are created based on $\boldsymbol{W}$.

Step 4. We then leverage the source coordinates $\boldsymbol{F}^s$, source-language subword vectors $\boldsymbol{U}^s$ and target-language subword vectors $\boldsymbol{U}^t$ to initialize target coordinates $\boldsymbol{F}^t$. To begin with, we deal with the subwords shared by V^s and V^t. For these subwords, we simply copy their coordinates from $\boldsymbol{F}^s$ to $\boldsymbol{F}^t$, which is also done by Dobler and de Melo (2023). For the remaining subwords, which are probably from new languages and not covered by V^s, we follow WECHSEL (Minixhofer et al., 2022) to find a good initialization based on similarity. Specifically, for each subword $x \in V^s$ and each subword $y \in V^t$, we calculate the cosine similarity between x and y in the subword vector space:

$$s_{(x,y)} = \text{cos-sim}(\boldsymbol{U}^s_{\{x\}},\ \boldsymbol{U}^t_{\{y\}})$$

The coordinate of each non-shared subword in V^t is finally initialized as a convex combination of source-language coordinates in $\boldsymbol{F}^s$:

$$\boldsymbol{F}^t_{\{y\}} = \frac{\sum_{x \in \mathbb{N}(y)} \exp(s_{(x,y)}/\tau) \cdot \boldsymbol{F}^s_{\{x\}}}{\sum_{x' \in \mathbb{N}(y)} \exp(s_{(x',y)}/\tau)}$$

where $\mathbb{N}(y)$ is the set of k nearest source-language subwords of the target-language subword y and τ is the temperature (we set $k = 10$ and $\tau = 0.1$ by default, following Minixhofer et al. (2022) who report the optimal choices in their experiments). In case the vector of a subword y in $\boldsymbol{U}^t$ is zero, we randomly initialize its coordinate $\boldsymbol{F}^t_{\{y\}}$ from a Gaussian distribution $\mathcal{N}(\mathbb{E}[\boldsymbol{F}^s], \text{Var}[\boldsymbol{F}^s])$. Note that $\boldsymbol{F}^t$ is roughly in the embedding space of $\boldsymbol{F}^s$, instead of in the vector space of $\boldsymbol{U}^s$ and $\boldsymbol{U}^t$.

Step 5. We finally assemble a target model by using the transformer body of the source PLM (all parameters except for its subword embeddings), the primitive embeddings $\boldsymbol{P}$, and the initialized target coordinates $\boldsymbol{F}^t$. The dimension of $\boldsymbol{F}^t$ is the same as the transformer body if no matrix factorization is applied, otherwise, we need to up-project the coordinates with $\boldsymbol{P}$ to suit the hidden dimension of the transformer body. In this way, we transform a source PLM into a multilingual model that has fewer parameters, which serves as a good start for efficient multilingual continued pretraining.

---

[2] To avoid confusion, we use the word "word vectors" to refer to any vector in the external static word vector space, and "embedding" to refer to the embeddings in the PLM space.

5 Experiments

5.1 Setups

We use a SentencePiece (Kudo and Richardson, 2018) tokenizer that has a vocabulary size of 401K as the target tokenizer. The vocabulary is merged from the subwords in XLM-R (Conneau et al., 2020) and new subwords learned from the Glot500-c corpus (ImaniGooghari et al., 2023) (See §A for details of the Glot500-c corpus.). The target tokenizer is the same as the tokenizer used in Glot500-m (ImaniGooghari et al., 2023). We then created 8 models using OFA framework as follows:

OFA-mono-xxx: we construct target models by OFA using English RoBERTA (Liu et al., 2019) as the source model. xxx denotes the latent dimension used in the factorization, where singular value decomposition (SVD) is used and top-k eigenvalues / eigenvectors are selected. We use four different dimensions: 100, 200, 400 and 768. When the dimension is 768, no matrix factorization is applied. The vocabulary and the tokenizer are the same as Glot500-m. Then we continued pretrain these assembled models on the Glot500-c corpus.

OFA-multi-xxx: we use the same setting as OFA-mono-xxx to construct target models (latent dimension: 100, 200, 400, 768), where XLM-R is used as the source model. Then we continued pretrain these models on the Glot500-c corpus.

The model architecture of OFA-mono-768 and OFA-multi-768 is the same as Glot500-m, where the embeddings are tied with the parameters of the language modeling head. For lower-dimensional models, two matrices are used to map the representation back to vocabulary space for masked language modeling. The parameters of the two matrices are tied to the primitive embeddings and target coordinates. We continued pretrain all models using MLM objective and follow the training hyperparameters used by ImaniGooghari et al. (2023). Each training step contains an effective batch of 384 samples randomly picked from all language-scripts[3]. We refer to the languages that XLM-R covers as **head** languages and the remaining languages as **tail** languages. We store checkpoints for each model every 10K steps and apply early stopping with the best average performance on downstream tasks. We train all models on **four** NVIDIA RTX A6000 GPUs for a maximum of four weeks. See §B for a detailed description of hyperparameter settings of continued pretraining and evaluation.

	D'=100	D'=200	D'=400	D=768
Model Params.	126M	167M	247M	395M
Embedding Params.	40M	80M	161M	309M

Table 1: Model parameters under different latent dimensions. When D'=100, 200, or 400, each corresponds to two OFA-initialized models (based on RoBERTa or XLM-R). D=768 not only corresponds to OFA-768, but also baselines RoBERTa-rand and XLM-R-rand, as they have the same architecture. By decreasing latent dimensions, the model parameters decrease drastically.

5.2 Baselines

We consider the following baselines for comparison with OFA (see Table 1 for the number of parameters under different latent embedding dimensions):

RoBERTa A monolingual PLM trained on English corpus (Liu et al., 2019). Its embeddings and tokenizer do not cover most of the new subwords of our models. The vocabulary size is 50K.

RoBERTa-rand We replace the embeddings of RoBERTa with new embeddings (the vocabulary size is 401K, the same as OFA-mono-768), which are constructed by copying the shared subwords and **randomly** initializing the embeddings of remaining subwords not covered by RoBERTa from a Gaussian distribution with a mean and variance of the original RoBERTa embeddings, similar to Minixhofer et al. (2022). Glot500-m tokenizer is used for tokenization. We then continued pretrain it on Glot500-c with the same hyperparameters.

XLM-R A strong multilingual PLM trained on 100 languages (Conneau et al., 2020). We use the **base** version, where the embedding dimension is 768. The vocabulary size is 250K.

XLM-R-rand Similar to RoBERTa-rand, this model extends the vocabulary from XLM-R, and the embeddings of subwords not covered by XLM-R are randomly initialized from a Gaussian distribution with a mean and variance of the original XLM-R embeddings.[4] Glot500-m tokenizer is used for tokenization. The model is then continued pretrained on Glot500-c with the same hyperparameters.

---

[3] A language-script is a combination of ISO 639-3 and script, which is used by the Glot500-c corpus.

[4] The model is named Glot500-m in ImaniGooghari et al. (2023). To be consistent with other names used in this paper, we call it XLM-R-rand. All models are trained on the same infrastructure for a strictly controlled experimental setting.

Table 2: Performance of the models initialized with OFA and baselines on five multilingual tasks across 5 seeds. We report the performance as an average over head, tail, and all language-scripts for each model. Models initialized with OFA constantly perform better than baselines. **Bold** (underlined): best (second-best) result per controlled group.

5.3 Downstream Tasks

Sentence Retrieval. We consider two datasets: Tatoeba (Artetxe and Schwenk, 2019) (SR-T) and Bible (SR-B). We select up to 1,000 English-aligned sentences for SR-T, following the same setting used by Hu et al. (2020). For SR-B, we select up to 500 English-aligned sentences. We report the top-10 accuracy by finding the nearest neighbors of the representation of each English sentence. Following Jalili Sabet et al. (2020), the representations are calculated by taking the average of the contextualized word embeddings at the 8th layer.

Sequence Labeling. We consider two types of tasks: named entity recognition (NER) and Part-Of-Speech (POS) tagging. We use WikiANN dataset (Pan et al., 2017) for NER and Universal Dependencies (de Marneffe et al., 2021) of version v2.11 for POS. We finetune the models only on the English train set, select the best model on the English dev set, and then report the zero-shot performance on the test sets of other languages. F1 scores are reported for both NER and POS.

Text Classification. We use Taxi1500 (Ma et al., 2023), a text classification dataset that provides train/dev/test sets with 6 classes in more than 1,500 languages. Following ImaniGooghari et al. (2023), we select a subset of languages (351) supported by the models for evaluation. Same as in NER and POS, we report the zero-shot performance (in F1 scores) using English as the source.

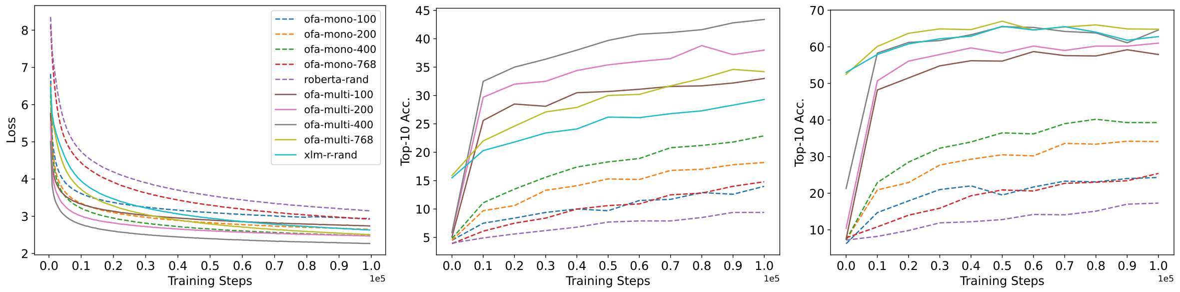
5.4 Results and Discussions

Table 2 shows the performance of the models initialized with OFA and baselines with random initialization of new subword embeddings on five downstream tasks (see complete results for each language-script in §F). Models initialized with OFA demonstrate a consistent improvement on either head or tail languages compared with the baselines. Combined with Table 3, we see that more languages benefit from OFA initialization for both using the monolingual and multilingual PLM as the source model, which indicates an overall superiority of the OFA initialization.

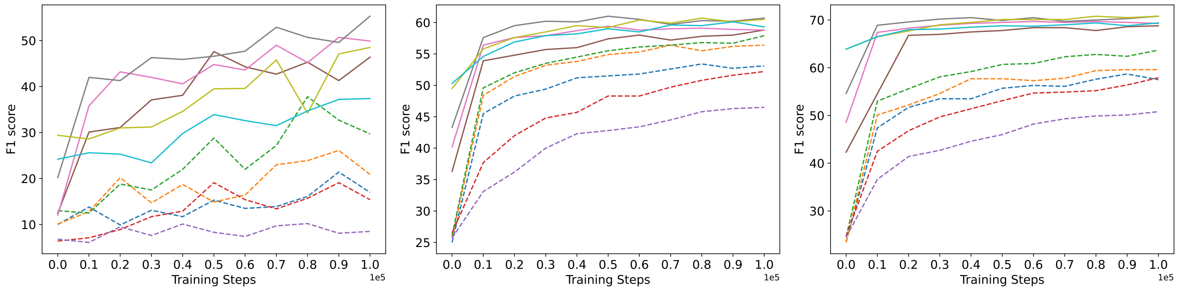
	|L|	#rand	#OFA-mono	#rand	#OFA-multi
SR-B	369	0	**369**	23	**346**
SR-T	98	1	**97**	24	**74**
Taxi1500	351	5	**346**	31	**320**
NER	164	10	**154**	27	**137**
POS	91	4	**87**	12	**79**

Table 3: Number of languages in each downstream task that benefits from OFA framework compared with randomly initializing the new subwords. |L| is the total number of languages for each task. #rand (resp. #OFA): number of languages on which better performance is achieved by random initialization (resp. one of the latent dimensions in OFA initialization) when using a monolingual (mono) or multilingual (multi) as the source PLM.

When the source model is monolingual, with random initialization of unseen subwords, RoBERTa-rand just obtains 11.9, 22.0, and 15.5 on SR-B, SR-T, and Taxi1500 respectively (averaged overall), which are 6.0, 6.6, 8.3 lower than its counterpart OFA-mono-768. In the sequence labeling task we also see similar improvement: OFA-mono-768 achieves 4.3 and 5.1 better than RoBERTa-rand on NER and POS respectively. Such an increase is even higher when compared with RoBERTa, as RoBERTa is a monolingual model. When the source model is multilingual, models initialized



(a) Training loss (b) SR-B (c) SR-T



(d) Taxi1500 (e) NER (f) POS

Figure 3: The training loss as well as the performance on five downstream tasks from step 0 (without continued pretraining) to step 100K (10th checkpoints). We see that models initialized by OFA converge faster than baseline models (RoBERTa-rand and XLM-R-rand) whose new subwords are randomly initialized during continued pretraining. For most of the downstream tasks, models with lower embedding dimensions can achieve better performance after only 10K steps compared with their full-dimensional counterparts (OFA-mono-768 and OFA-multi-768).

with OFA also achieve remarkable performance. OFA-multi-768 achieves better performance than XLM-R on every task. Compared with XLM-R-rand, it also achieves better performance, which indicates the effectiveness of the initialization with the help of external multilingual embeddings.

The embedding dimension also plays a crucial role in the performance. Typically, we see an improvement in performance as we increase the latent dimension, particularly from 100 to 400 for both OFA-mono and OFA-multi models. This is expected as a larger dimension often induces better expressiveness. Nevertheless, the improvement from dimension 400 to 768, is not consistently large, and in some cases, it even leads to performance declines. For example, OFA-mono-400 outperforms OFA-mono-768 on all downstream tasks. We assume this is because a monolingual model with many parameters might not be easy to adapt to diverse languages. A smaller embedding dimension can ease the burden and facilitate the pretraining, thus achieving better performance. Similarly, OFA-multi-400 is very competitive to OFA-multi-768 (OFA-multi-400 is even better on NER and POS). We attribute this to the "redundancy" of the embeddings in multilingual PLMs (see §D for an analysis). By using factorization, we keep the most important information that is shared across languages. Thus there is a trade-off. When the dimension is very small, e.g., 100, there is a risk of information loss. However, with a moderate size, e.g., 400, the model is less redundant and equipped with enough expressiveness to achieve good performance.

6 Analysis

6.1 Continued training Progression

To analyze how different embedding dimensions and initialization methods can influence the continued training, we visualize the training loss of models that are initialized with OFA and two baseline models, i.e., RoBERTa-rand and XLM-R-rand. In addition, we evaluate all these models on five downstream tasks at 10K-step intervals until 100K steps. The results are shown in Figure 3. From Fig. 3 (a), when the embedding dimension is 768, the models initialized with OFA converge faster compared with the models being randomly initialized, regardless of whether the source model is monolingual or multilingual. The faster convergence is also related to the performance, as OFA-mono-768 (resp. OFA-multi-768) constantly performs better

Models	best-checkpoint	avg. T	C.F.
OFA-mono-100	110K	3.8h	21.7
OFA-mono-200	120K	3.9h	24.3
OFA-mono-400	230K	4.3h	51.3
OFA-mono-768	250K	4.7h	60.9
RoBERTa-rand	270K	4.7h	65.8
OFA-multi-100	290K	3.8h	57.1
OFA-multi-200	280K	3.9h	56.6
OFA-multi-400	260K	4.3h	58.0
OFA-multi-768	450K	4.7h	110.0
XLM-R-rand	560K	4.7h	136.4

Table 4: Additional information: best checkpoint, average training time (avg. T) spent per 10K steps until the best checkpoint, and carbon footprint (C.F.: in kg of CO_2 eq.) of different models in continued pretraining.

than RoBERTa-rand (resp. XLM-R-rand) throughout steps for all tasks. This indicates that OFA, which explicitly leverages information encoded in source PLM embeddings and external multilingual word vectors, is superior to random initialization.

We also observe models with smaller dimensions tend to learn information faster in the initial steps, indicated by the speed of MLM loss drop. As explained earlier, smaller dimensions mean fewer parameters which eases the burden in continued pretraining, especially when the source model is monolingual. On the other hand, faster learning speed explains why models with smaller dimensions generally perform better than their full-dimensional counterparts (OFA-mono-768 or OFA-multi-768) in the early training phase. For example, with only 167M parameters, OFA-multi-200 achieves better or very close performance on each task compared with OFA-multi-768, which is two times larger. We also observe that all models, especially OFA-multi models, quickly reach a performance plateau on NER and POS tasks. This aligns with the finding that syntactic knowledge is acquired rapidly in the training progression (Blevins et al., 2022; Müller-Eberstein et al., 2023). This also suggests that sequence labeling might be a straightforward task where the model can transfer prevalent classes such as *verb* and *noun*, possibly through shared vocabulary (ImaniGooghari et al., 2023).

Combined with the analysis above, better initialization and smaller embedding dimensions enable an efficient multilingual continued pretraining and better performance in downstream tasks with fewer training steps. Lightweight models also reduce GPU consumption and allow for larger batch sizes. Therefore, the proposed OFA framework can be very useful where a limited computation budget is presented, e.g., in most laboratories or institutions.

Table 5: Performance of models initialized with OFA under settings of w/o and w/ continued pretraining. Continued pretraining largely improves the performance.

In addition, as there are recent concerns regarding the environmental impact of training or operating LMs (Bender et al., 2021; Rae et al., 2021; Weidinger et al., 2022), we also report some related statistics when continued pretraining our models in Table 4. There are two benefits of using OFA with factorized embedding parameterization: (1) the average training time per 10K steps is shortened and (2) overall less training time is required to reach the best checkpoints compared to the random baseline. Considering that there is no huge difference in terms of the performance in downstream tasks, initializing by OFA with lower embedding dimensions can largely reduce the carbon emissions[5] and therefore is more environmentally friendly.

6.2 Influence of Continued Pretraining

Continued pretraining has a different impact on models with different latent embedding dimensions for different downstream tasks. Therefore, we compare how the model performance varies with or without continued pretraining, as shown in Table 5.

Although most models without continued pretraining perform generally badly, we see some exceptions. For example, OFA-multi-768 achieves more than 52.5 accuracy in SR-T, while only 15.9 in SR-B. The major reason is that SR-B contains many tail language-scripts that are not covered by XLM-R. On the contrary, SR-T contains many head languages and many of the other languages are similar to those head languages. We also notice that

Table 6: Aggregated performance of the models for 7 major language families on **SR-B**. We report the average performance for **indo1319** (Indo-European), **atla1278** (Atlantic-Congo), **aust1307** (Austronesian), **turk1311** (Turkic), **sino1245** (Sino-Tibetan), **maya1287** (Mayan), and **afro1255** (Afro-Asiatic). We classify the remaining languages into the group "**other**". In addition, we report the average over all languages (group "**all**"). The number of languages in that family is shown in the parentheses. **Bold** (underlined): best (second-best) result for each task.

the continued pretraining has less impact on sequence labeling tasks, i.e., NER and POS, where the model can use the knowledge already encoded in its parameters to perform well in English, and then transfer to other languages through shared vocabulary, or the already existing crosslinguality when the source model is multilingual.

When the source model is monolingual, the performance without continued pretraining is bad no matter which embedding dimension is used. However, the higher-dimension model achieves consistently better performance than lower-dimension ones when the source model is multilingual. This can be explained by the fact that the source multilingual model already has strong crosslinguality and a higher dimension can better restore the original information encoded in XLM-R's embedding matrix. Nevertheless, the benefits of higher dimensions diminish after continued pretraining. Combined with Figure 3, we see that even the smallest model, i.e., OFA-multi-100, quickly surpasses OFA-multi-768 in SR-B and Taxi500 tasks after 10K training steps. We therefore could conclude that the models initialized with OFA could quickly adapt to new languages in the continued pretraining, especially when the source model is already multilingual.

6.3 Performance across Language Families

The aggregate results shown in Table 2 reflect that OFA can improve the overall performance. However, the results can potentially hide some information such as for what kind of language families and / or scripts OFA works better or worse. Thus we also report the aggregated performance for major language families in **SR-B** that covers the most languages among our downstream tasks. The results are shown in Table 6 (see aggregated results for different scripts and other tasks in §E).

It can be seen that all variants with OFA initialization consistently outperform the random initialization baselines across all language families when using RoBERTa as the source model. Similarly, when the latent dimension is larger or equal to 400, models with OFA initialization beat the counterparts across all language families. These findings indicate OFA's superiority is not limited to certain language families. In addition, we find the performance difference between OFA-multi-400 and OFA-multi-768 is small across language families, which further indicates that reducing the dimension of embeddings is effective in continued pretraining.

7 Conclusion

In this work, we present OFA, a framework that wisely initializes unseen subword embeddings with factorized embedding parameterization for efficient large-scale multilingual continued pretraining. We conduct extensive and strictly controlled experiments by continued pretraining models that are initialized from monolingual or multilingual PLMs. We evaluate these models on a wide range of downstream tasks. We show that models initialized with OFA enjoy faster convergence during training and achieve competitive or better performance on downstream tasks, compared with the baselines where embeddings of new subwords are randomly initialized. We also show that with smaller embedding dimensions, the continued pretraining is further facilitated: training time is shortened and models achieve better performance in the early training phase. Therefore, this work contributes to efficient large-scale multilingual continued pretraining.

Limitations

In this work, we apply OFA to two models, RoBERTa, a monolingual PLM, and XLM-R, a multilingual PLM, and show the superiority of the proposed initialization method compared to the random initialization. However, both are encoder-only models and they are pretrained / continued pretrained only using the MLM objective. Theoretically, this approach should be able to extend to other types of models, e.g., decoder-only and encoder-decoder models, or other types of training objectives, e.g., next-word prediction or translation objectives, since our approach is **only related to the initialization stage** of continued pretraining and not restricted to any model architectures or training objectives. We do not try all possibilities in terms of architectures / objectives as that is not the major focus of this work, and we have a limited computation budget. We would leave such exploration using OFA in different architectures / objectives for future research in the community.

Another possible limitation is that, while we inject external knowledge into the subword embeddings before continued pretraining, such knowledge may diminish due to catastrophic forgetting (Kirkpatrick et al., 2017). That is, due to continued pretraining, the model gradually loses the initial knowledge. This is not wanted and we would expect methods such as active forgetting (Chen et al., 2023) could alleviate the problem by restoring the constructed embeddings from OFA every certain step in the continued pretraining. However, this again is not the major focus of this paper and we would call for exploration in this direction.

Acknowledgement

We appreciate Fabian David Schmidt's suggestion to filter the unnecessary tokens in MLM modeling and re-estimate the training time of the models. We would also like to thank the reviewers for their constructive feedback. This work was funded by the European Research Council (grant #740516).

A Glot500-c

The Glot500-c corpus (ImaniGooghari et al., 2023)[6] contains 511 languages in 30 different scripts. The total number of sentences is 1.5B and the median number of sentences per language-script is 120K. Because some languages can be written in multiple scripts, the corpus treats each **language-script** as a separate entity. For example, Tajik-Cyrillic and Tajik-Arabic will be considered as different entities as there are two different scripts used for Tajik in the corpus. The corpus is divided into train/dev/test sets for each language. Dev and test sets have 1000 sentences. Same as (ImaniGooghari et al., 2023), we only use the training data to continued pretrain all of our models.

B Detailed Hyperparameters

B.1 Continued Pretraining

We continued pretrain both the baseline models (RoBERTa-rand and XLM-R-rand) and models initialized with OFA using basically the same hyperparameters as used in ImaniGooghari et al. (2023). Specifically, we use MLM objective with the standard mask rate of 15%. We use Adam optimizer (Kingma and Ba, 2015) with $(\beta_1, \beta_2) = (0.9, 0.999)$ and $\epsilon =$ 1e-6. The initial learning rate is set to 5e-5. The effective batch size is set to 384. Each batch contains training samples concatenated up to the maximum sequence length of 512 and randomly picked from all language-scripts in the Glot500-c corpus. The only difference from ours to ImaniGooghari et al. (2023) is that we use **four** RTX A6000 GPUs while they use **eight** RTX A6000 GPUs. Therefore, we set the per-GPU batch to 12, and the gradient accumulation to 8, fulfilling $4 \times 12 \times 8 = 384$. The gradient accumulation in ImaniGooghari et al. (2023) is set to 4, as they use four more GPUs. We use FP16 training (mixed precision (Micikevicius et al., 2018)). The different gradient accumulation and usage of mixed-precision might be the reason why the performance of our baseline XLM-R-rand is slightly different from the performance reported in ImaniGooghari et al. (2023). The continue-pretraining is done using scripts adapted from HuggingFace[7].

	|head|	|tail|	#class	measure (%)
SR-B	94	275	-	top-10 Acc.
SR-T	70	28	-	top-10 Acc.
Taxi1500	89	262	6	F1 score
NER	89	75	7	F1 score
POS	63	28	18	F1 score

Table 7: Downstream tasks and measures. |head| (resp. |tail|): head (resp. tail) language-scripts according to ImaniGooghari et al. (2023) (a language-script is head if it is covered by XLM-R, otherwise it is tail); #class: the number of the categories if it is a (sequence-level or token-level) classification task.

B.2 Downstream Tasks

The outline of the evaluation is shown in Table 7. We introduce the detailed hyperparameters used for each downstream task in the following.

SR-B. We use up to 500 English-aligned sentences from languages that are supported by the model, where most of the languages are tail languages (275). The retrieval task is performed without any training: we directly use the model after continued pretraining to encode all sentences. Each sentence is represented by taking the average of the contextual embedding at the **8th** layer. We then compute the top-10 accuracy for each pair (English and another language) by finding the nearest neighbors (in the other language) of the representation of each English sentence.

SR-T. We use up to 1000 English-aligned sentences from Tatoeba, which mainly contains head languages (70). The evaluation setting is the same as SR-B and top-10 accuracy is reported.

Taxi1500. We finetune the continued pretrained model (a sequence-level classification model in 6 classes) on the English train set and select the best checkpoint using the English dev set. We train each model for a maximum of 40 epochs with early stopping on a single GTX 1080 Ti GPU. Adam optimizer is used, the learning rate is set to 1e-5 and the effective batch size is set to 16 (batch size of 8 and gradient accumulation of 2). We then evaluate the zero-shot performance by evaluating

---

[6] `https://github.com/cisnlp/Glot500`

[7] `https://huggingface.co/`

the finetuned model on the test sets of all other language-scripts. F1 score is reported for each language-script.

NER. We finetune the continued pretrained model (a token-level classification model in 7 classes) on the English train set and select the best checkpoint using the English dev set. We train each model for a maximum of 10 epochs with early stopping on a single GTX 1080 Ti GPU. Adam optimizer is used, the learning rate is set to 2e-5 and the effective batch size is set to 32 (batch size of 8 and gradient accumulation of 4). We then evaluate the zero-shot performance by evaluating the finetuned model on the test sets of all other language-scripts. F1 score is reported for each language-script.

POS. We finetune the continued pretrained model (a token-level classification model in 18 classes) on the English train set and select the best checkpoint using the English dev set. We train each model for a maximum of 10 epochs with early stopping on a single GTX 1080 Ti GPU. Adam optimizer is used, the learning rate is set to 2e-5 and the effective batch size is set to 32 (batch size of 8 and gradient accumulation of 4). We then evaluate the zero-shot performance by evaluating the finetuned model on the test sets of all other language-scripts. F1 score is reported for each language-script.

C Multilingual Word Vectors and Coverage

Two important factors that influence the effectiveness of OFA initialization are (1) the quality of the external multilingual word vectors and (2) the coverage of the multilingual word vectors in terms of languages and new subwords in the target model.

In this work, we use $\overrightarrow{\text{ColexNet+}}$ (Liu et al., 2023a), multilingual word vectors learned from colexification[8] (François, 2008) graphs built from 1,335 translations (one for a specific language identified by its ISO-639-3 code) of Parallel Bible Corpus (Mayer and Cysouw, 2014). The patterns of colexifications are extracted by Conceptualizer (Liu et al., 2023b), a statistic concept-grams alignment method. The tokens in the word vectors are ngrams (mostly word types as the algorithm prefers longer ngrams) within whitespace tokenized words. According to Liu et al. (2023a), $\overrightarrow{\text{ColexNet+}}$ outperforms a bunch of strong multilingual word vector baselines on crosslingual transfer tasks, especially for low-resource languages. we therefore choose to use $\overrightarrow{\text{ColexNet+}}$ as our multilingual word vectors.

Source models	Copy	Similarity	Random	Coverage
RoBERTa	27K	179K	195K	51.5%
XLM-R	255K	84K	62K	84.6%

Table 8: The number of subwords being initialized by copying from the original embeddings (**Copy**); through the similarity-based method introduced in OFA (**Similarity**); and randomly from a Gaussian distribution (**Random**) when using $\overrightarrow{\text{ColexNet+}}$ as the external multilingual word vectors. Coverage shows the percentage of the subword being wisely initialized: (Copy + Similarity) / (Copy + Similarity + Random). The coverage is high for both of the source models. As the new vocabulary is extended from XLM-R, many subword embeddings are directly copied when using XLM-R as the source model.

We want as many as possible subwords to be initialized wisely (either directly copied for shared subwords or initialized by the similarity-based method in OFA), instead of being randomly initialized from a Gaussian distribution. This requires that the chosen external multilingual word vectors cover many subwords. Therefore we report the number of subwords being initialized (1) **by copying**, (2) **through the similarity-based method**, and (3) **randomly** when using $\overrightarrow{\text{ColexNet+}}$ as our external multilingual word vectors in Table 8. We see that for either the monolingual model as the source model (RoBERTa) or the multilingual model as the source model (XLM-R), the coverage (subwords being wisely initialized over all subwords) is more than 50%, indicating that the words included in $\overrightarrow{\text{ColexNet+}}$ cover a large number of subwords even though it is trained from a genre-specific corpus.

D Redundancy in Multilingual PLMs

To figure out how "redundant" the embeddings are in monolingual or multilingual PLMs, we use principle component analysis (PCA) to perform dimension reduction to the embeddings of various PLMs. We select monolingual PLMs: BERT (Devlin et al., 2019) of English and GPT-2 (Radford et al., 2019), and multilingual PLMs: mBERT (Devlin et al., 2019), base and large versions of XLM-R (Conneau et al., 2020), Glot500-m (ImaniGooghari et al., 2023) and XLM-V (Liang et al., 2023). The embedding dimension and vocabulary size of each PLM are shown in Table 9. We report how much variance is explained (information preserved) when

---

[8] Colexifications are a linguistic phenomenon where different meanings are expressed by the same word.

PLM	emb dim.	|V|
BERT-eng	768	31K
GPT-2	768	50K
mBERT	768	120K
XLM-R-base	768	250K
XLM-R-large	1024	250K
Glot500-m	768	401K
XLM-V	768	901K

Table 9: Embedding dimensions and vocabulary size of several monolingual and multilingual PLMs.

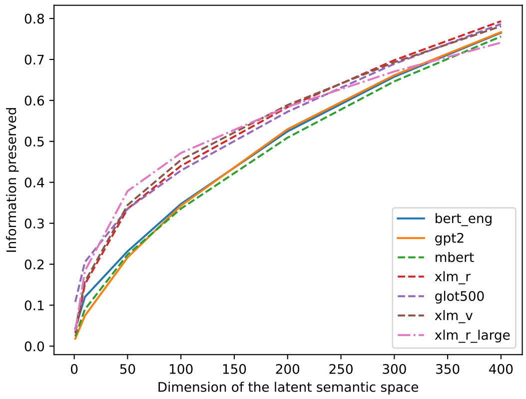

Figure 4: Information preserved (percentage of variance explained by the selected components) under different dimensions of the semantic space (number of principal components). Generally trend: multilingual models generally preserve more information than monolingual ones when embeddings are reduced to the same dimension.

keeping different numbers of principle components in the sorted order by their eigenvalues (until the first 400 components) in Figure 4. The general trend is that multilingual PLMs tend to be more "redundant" than monolingual ones: only keeping the first 100 components, about 50% variance can be explained in Glot500-m and XLM-R-large embeddings. Similarly, the information preserved is more than 40% in XLM-R-base and XLM-V, which is higher than the percentage in monolingual models GPT-2 and English BERT (about 30% is preserved), when the first 100 components are kept.

We also assume this "redundancy" is related to the crosslinguality of the PLMs. If the embedding matrix is more redundant, this indicates the many tokens referring to the same concept from different languages share similar representation space, therefore better crosslinguality is expected. For example, both base and large versions of XLM-R are more redundant than mBERT according to Figure 4, indicating better crosslinguality, which aligns with the finding that XLM-R constantly outperforms mBERT in many NLP downstream tasks (Conneau et al., 2020). However, the high redundancy, in turn, suggests an unnecessary overparameterization. Thus we could use matrix factorization to remove some redundancy to reduce the number of parameters while not sacrificing much performance, which is exactly what we propose in the OFA framework: replacing the cumbersome embedding matrix with two smaller matrices.

E Fine-grained Aggregated Results for Each Task

To better illustrate how OFA can influence the continued pretraining and thus influence the crosslinguality, we additionally report the aggregated results for 7 major language families in Table 6, 10, 11, 12, 13 and 5 major script groups in Table 14, 15, 16, 17, 18 for each task. It is clear that the models continued pretrained with OFA show better performance for each language family and script group in every downstream task. We also show the number of languages that benefit from OFA in each downstream task in Table 3.

F Complete Results for Each Task and Language

We report the complete results for all tasks and languages in Table 19, 20, 21 22 (SR-B), Table 23 (SR-T), Table 24, 25, 26, 27 (Taxi1500), Table 28, 29 (NER), and Table 30 (POS).

Table 15: Aggregated performance of the models for 5 major script groups on **SR-T**. We report the average performance for **Latn** (Latin), **Cyrl** (Cyrillic), **Hani** (Hani), **Arab** (Arabic), and **Deva** (Devanagari). We classify the remaining languages into the group "**other**". In addition, we report the average over all languages (group "**all**"). The number of languages is shown in the parentheses. **Bold** (underlined): best (second-best) result for each task.

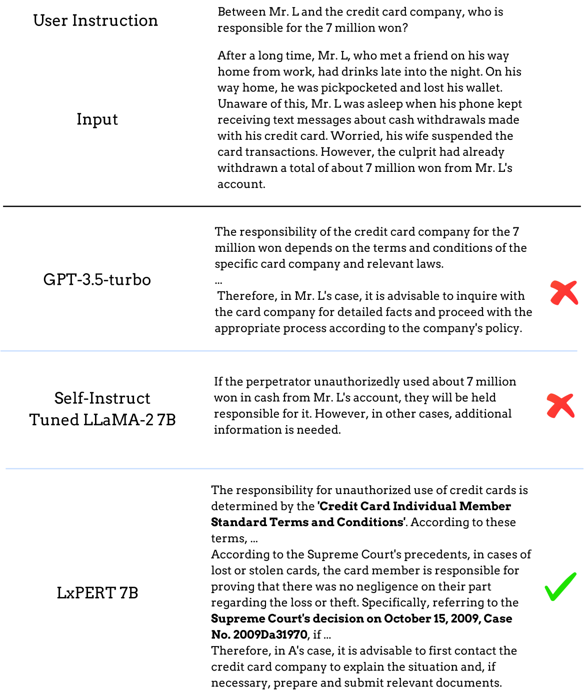
Abstract

The advent of instruction-tuned large language models (LLMs) has significantly advanced the field of automatic instruction dataset augmentation. However, the method of generating instructions and outputs from inherent knowledge of LLM can unintentionally produce hallucinations — instances of generating factually incorrect or misleading information. To overcome this, we propose SELF-EXPERTISE, automatically generating instruction dataset in the legal domain from a seed dataset. SELF-EXPERTISE extracts knowledge from the outputs of the seed dataset, and generates new instructions, inputs, and outputs. In this way, the proposed method reduces hallucination in automatic instruction augmentation. We trained an SELF-EXPERTISE augmented instruction dataset on the LLaMA-2 7B model to construct Korean legal specialized model, called LxPERT. LxPERT has demonstrated performance surpassing GPT-3.5-turbo in both in-domain and out-of-domain datasets. The SELF-EXPERTISE augmentation pipeline is not only applicable to the legal field but is also expected to be extendable to various domains, potentially advancing domain-specialized LLMs.



User Instruction	Between Mr. L and the credit card company, who is responsible for the 7 million won?	
Input	After a long time, Mr. L, who met a friend on his way home from work, had drinks late into the night. On his way home, he was pickpocketed and lost his wallet. Unaware of this, Mr. L was asleep when his phone kept receiving text messages about cash withdrawals made with his credit card. Worried, his wife suspended the card transactions. However, the culprit had already withdrawn a total of about 7 million won from Mr. L's account.	
GPT-3.5-turbo	The responsibility of the credit card company for the 7 million won depends on the terms and conditions of the specific card company and relevant laws. ... Therefore, in Mr. L's case, it is advisable to inquire with the card company for detailed facts and proceed with the appropriate process according to the company's policy.	✗
Self-Instruct Tuned LLaMA-2 7B	If the perpetrator unauthorizedly used about 7 million won in cash from Mr. L's account, they will be held responsible for it. However, in other cases, additional information is needed.	✗
LxPERT 7B	The responsibility for unauthorized use of credit cards is determined by the **'Credit Card Individual Member Standard Terms and Conditions'**. According to these terms, ... According to the Supreme Court's precedents, in cases of lost or stolen cards, the card member is responsible for proving that there was no negligence on their part regarding the loss or theft. Specifically, referring to the **Supreme Court's decision on October 15, 2009, Case No. 2009Da31970**, if ... Therefore, in A's case, it is advisable to first contact the credit card company to explain the situation and, if necessary, prepare and submit relevant documents.	✓

Figure 1: Comparison between GPT-3.5-turbo, Self-Instruct tuned LLaMA-2, and our LxPERT. GPT-3.5-turbo and Self-Instruct tuned LLaMA-2 generates unclear and ambiguous output without any legal basis. By contrast, LxPERT generates correct output with precise legal knowledge.

1 Introduction

Recent large language models (LLMs) like GPTs (Brown et al., 2020; OpenAI, 2023), PaLM (Chowdhery et al., 2023) show exceptional performance for various NLP tasks in response to instruction prompt. To train LLMs in following natural language instructions, an instruction dataset is essential for performing Instruction Tuning (Yin et al., 2023; Wei et al., 2021; Sanh et al., 2021). However, acquiring a diverse human-written instruction dataset is often time-consuming and costly. To overcome these limitations, many have used LLMs for auto-generation (Wang et al., 2022; Xu et al., 2023). However, such methods remain unsuitable for creating instruction datasets in domains where accuracy is critical, because LLMs lack expert-level knowledge, can produce hallucinated data (Lin et al., 2021; Zhang et al., 2023; Sadat et al., 2023). Therefore, high-quality, accuracy-focused methodologies are needed for generating instruction data in specialized knowledge areas to extend the usability of LLMs beyond general tasks.

In this study, we introduce the novel **SELF-EXPERTISE** method for automatic instruction data generation for knowledge-intensive tasks using LLMs. It prevents hallucinations and ensuring data accuracy in specialized knowledge do-

mains by generating data based on precise knowledge. Figure 2 describes four-step process of SELF-EXPERTISE. Inspired by how a teacher designs exam questions based on textbook context, user instructions, inputs, and outputs are created based on the knowledge, extracted from small set of seed data outputs.

We automatically generated a legal domain instruction dataset of 19k from 980 seed dataset utilizing SELF-EXPERTISE. Then, we instruction tuned LLaMA-2 7B (Touvron et al., 2023) using SELF-EXPERTISE augmented dataset. We refer to this resulting model as LxPERT, for Legal ExPERT. Comparisons of LxPERT with models instruction-tuned in general domains and those tuned with datasets generated by traditional augmentation methods reveal its superior accuracy and fluency. Furthermore, LxPERT significantly surpasses GPT-3.5-turbo, the most widely used model lately. Figure 1 shows comparison between GPT-3.5-turbo and LxPERT. These findings underscore the importance of specialized models for specific domains (Zhao et al., 2023; Chalkidis et al., 2020; Tian et al., 2023), highlighting the effectiveness of the SELF-EXPERTISE approach in developing models that deliver high performance in professional fields. In summary, our contributions are as follows:

- We propose SELF-EXPERTISE, a novel instruction data generation method for areas of specialized knowledge that minimizes human annotation.
- We train LxPERT, the small large language model (sLLM) specialized in Korean legal domain using SELF-EXPERTISE method. We conduct both GPT-4 and human evaluation on in-domain and out-of-domain test set. The results demonstrate that LxPERT surpasses the 7B models and GPT-3.5-turbo with high accuracy.
- We release a Korean Legal SELF-EXPERTISE Instruction Dataset and a set of handcrafted novel dataset for evaluating future legal instruction-following models.

2 Related Work

2.1 LLM-based Instruction Dataset Augmentation

Collecting diverse instruction datasets manually requires significant resources (Ratner et al., 2017; Zhong et al., 2020; Feng et al., 2021). To overcome these limitations, methods have been proposed to automatically generate instruction datasets through LLMs (Dai et al., 2023; Whitehouse et al., 2023; Wang et al., 2022; Xu et al., 2023; Mukherjee et al., 2023; Mitra et al., 2023). Self-Instruct (Wang et al., 2022) presents a method to generate instructions by looking up few task examples from a seed dataset, produce outputs, and then filter out low-quality data. However, in specialized knowledge domains, including law, where accurate answers based on expert knowledge are required, there are limitations to controlling LLM hallucination when using previous automatic generation methods (Choi et al., 2023; Yu et al., 2023a; Cui et al., 2023). When a new instruction is created without incorporating related knowledge, LLMs may generate inaccurate answer. SELF-EXPERTISE overcomes these limitations by extracting knowledge from the output of existing seed dataset and generating new dataset based on this knowledge. It also incorporates explanation tuning (Mukherjee et al., 2023) to enable learning a logical answer structure.

2.2 Knowledge-Intensive Tasks

Knowledge-intensive tasks require a knowledge-based solution, such as open domain question answering, fact-checking, and entity linking (Petroni et al., 2020). The legal domain is knowledge-intensive because answers must be provided based on accurate information (Yu et al., 2023b; Kim and Goebel, 2017; Vold and Conrad, 2021). While LLMs have shown high performance in knowledge-intensive tasks using only model parameters, they still face the limitation of hallucination (Asai et al., 2023; Lewis et al., 2020; Guu et al., 2020). This problem can be reduced when accurate knowledge is added to the LLM input through a retriever (Shuster et al., 2021; Borgeaud et al., 2022; Mallen et al., 2023; Shi et al., 2023). Accordingly, we apply a similar method to data augmentation for knowledge-intensive tasks. Unlike previous instruction dataset generation methods that generates instructions from undefined inherent knowledge of LLMs, our method creates instructions and outputs based on precise external knowledge.

3 Methodology

We propose SELF-EXPERTISE, a novel methodology for automatically generating instruction data based on knowledge, thus enabling precise logical reasoning that reflects the characteristics of special-

ized knowledge areas.

3.1 Defining Instruction Data

A typical instruction dataset (i.e., seed dataset) is structured as <user instruction, input, output> (Wei et al., 2021). It is designed to generate an output from the model when a user instruction and corresponding input are provided. In our methodology, we add system instructions (Mukherjee et al., 2023). Unlike user instructions that direct the actual task to be performed by the model, system instructions serve as guidelines for additional details such as the tone or style of the output. While focusing on the importance of logical structure in specialized knowledge domain responses, we design and add system instructions to facilitate learning of reasoning and narrative structure. The final dataset is structured as <system instruction, user instruction, input, output>. Both cases, with and without inputs, are structured for a diverse instruction dataset.

3.2 SELF-EXPERTISE

SELF-EXPERTISE involves four stages: (1) knowledge extraction based on output, (2) generation of user instruction and input based on knowledge, (3) creation of system instructions, and (4) output generation based on previous results. (Figure 2) The prompt template used in each step is shown in Figure 3.

3.2.1 Step 1: Knowledge Extraction Based on Output

First, knowledge is extracted from the outputs of a small set of expert-written seed data. Unlike the conventional method (Wang et al., 2022) that generates new user instructions and outputs solely based on inherent knowledge of LLM, our method generates user instruction, input, and output based on precise external knowledge. This is crucial in specialized knowledge areas where factual accuracy matters. Thus, using accurate knowledge as a basis for data generation can prevent hallucination and ensure data accuracy. For example, in the legal field, a lawyer's argument corresponds to the output, and the case law used as the basis for the argument corresponds to the knowledge.

3.2.2 Step 2: Generation of User Instruction and Input Based on Knowledge

User instruction and input are generated using the extracted knowledge from the previous step. Analogous to how teachers create exam questions based on textbook content, LLM acts as an exam writer and generates relevant exam questions and contexts (i.e., user instruction and input) based on knowledge.

3.2.3 Step 3: Creation of System Instructions

To generate diverse outputs utilizing knowledge, specialized system instructions are handcrafted as

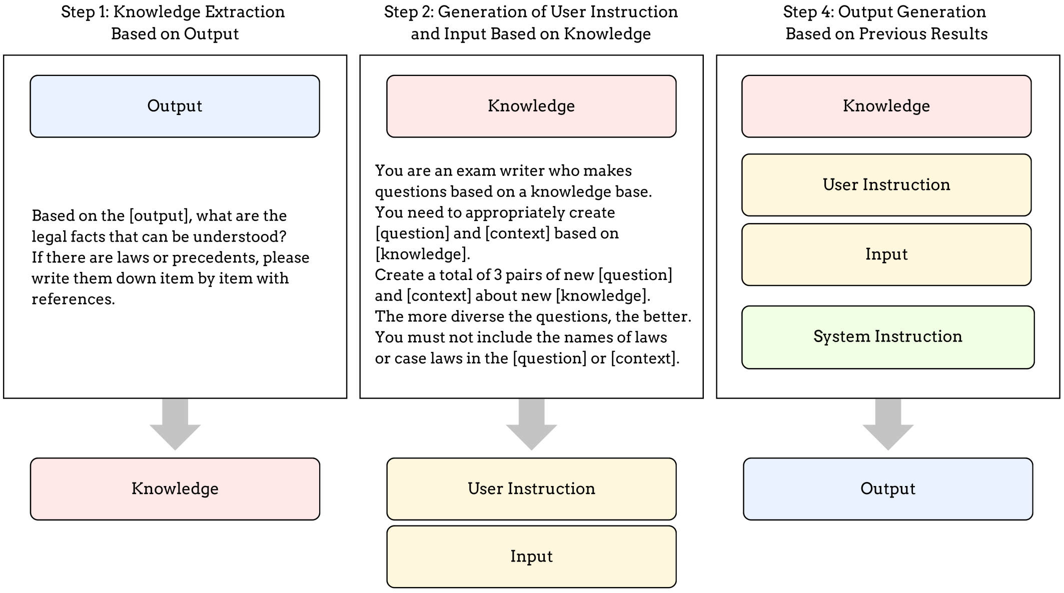

Figure 3: Prompt templates used for each step during SELF-EXPERTISE.

guidelines for output generation. In this study, eight specific system instructions were handcrafted for the targeted legal field. All system instructions include the use of precise legal basis and instruction to generate output referencing the knowledge. Individually, they differ to allow the creation of outputs in various manners, lengths, and formats. For example, one follows the stages of the Issue, Rule, Application, Conclusion(IRAC) Framework, a real legal reasoning process, to align outputs with the thought process in specialized knowledge areas.

3.2.4 Step 4: Output Generation Based on Previous Results

Finally, the output is generated using the system instruction, user instruction, input, and knowledge. Upon combining the previously generated user instruction, input, and knowledge with the eight system instructions, eight outputs are generated for each user instruction and input pair. During the output generation process with LLM, accurate knowledge is included in the prompt to ensure the accuracy of the output.

3.3 Finetuning the sLLM using Augmented Instruction Dataset

The small LLM (sLLM) is trained in causal language modeling using augmented instruction dataset. This process can be seen as knowledge distillation, in which knowledge is transferred from a larger to a smaller model (Wang et al., 2022). Like previous studies, our approach not only transfers the knowledge and instruction-following ability of the larger model but also allows for the distillation of domain knowledge in specialized fields. Unlike generating data with LLM, where knowledge is included to generate outputs, knowledge is not directly provided during the training of the sLLM. Therefore, the sLLM is trained to generate responses based on indirectly learned domain knowledge when receiving instruction and input, considering that in real user query scenarios, ground-truth knowledge rarely comes as input. Moreover, the sLLM learn all eight types of system instructions and their corresponding various output forms. This allows the sLLM to align with the thought processes in specialized knowledge areas corresponding to system instructions and learn to respond in various manners according to different instructions.

4 Legal SELF-EXPERTISE Data

We applied the SELF-EXPERTISE methodology to the field of law, where accuracy and reasoning are crucial. We give detailed explanation of the SELF-EXPERTISE augmented instruction dataset.

4.1 Seed Dataset

We used 980 legal seed instruction dataset directly created by legal experts. Details of legal experts we worked with are described in Appendix E. This seed instruction dataset includes 560 legal cases and 916 clauses, and the dataset covers four legal domains: civil law in bar exam, criminal law in bar

Domain	**# of Data**
Civil law in bar exam	100
Criminal law in bar exam	190
Legislative Information	370
Legal Consultation	320
Total	980

Table 1: The amount of seed data per domain.

# of seed data	980
# of generated data in Step 2	2398
# of generated data in Step 4	19184
avg. instruction length	19.5
avg. input length	31.2
avg output length	144.4

Table 2: Statistics of the generated dataset by applying SELF-EXPERTISE. The length is calculated based on the number of words.

	From Knowledge	From Output
(1) Similarity between {original instruction, input} and {new instruction, input}	**0.66**	0.71
(2) Similarity between {original input} and {new instruction, input}	**0.65**	0.69
(3) Similarity among questions originating from the same source	**0.75**	0.78

Table 3: The similarity in BERT-scores between original data and generated data. We compare new user instructions and inputs generated from knowledge versus directly from output. Higher similarity scores indicate lower diversity in augmentation.

exam, legislative information, and legal consultation. The amount of data per domain is shown in Table 1. We built the data by first extracting outputs containing legal knowledge in the respective domain. Then, user questions were formulated to add user instruction and input, thus constructing a user-oriented legal instruction dataset.

4.2 Data Generation Details

We augmented the dataset through SELF-EXPERTISE based on 980 seed dataset. In Step 1, we used `GPT-3.5-turbo`, and in Steps 2 and 4, we used `GPT-4-preview-1106`[1] for generation. More details of generation models and prompts are presented in Appendix A.2, A.3. After four-step generation, we filtered out data that did not conform to the format. Eventually, we generated dataset of 19k pairs. Basic statistics of the generated data are summarized in Table 2.

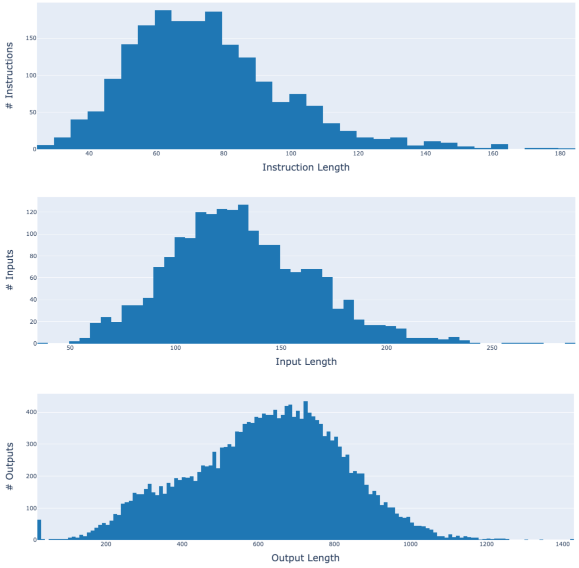

Figure 4: Length distribution of the generated user instructions, inputs, and outputs by SELF-EXPERTISE.

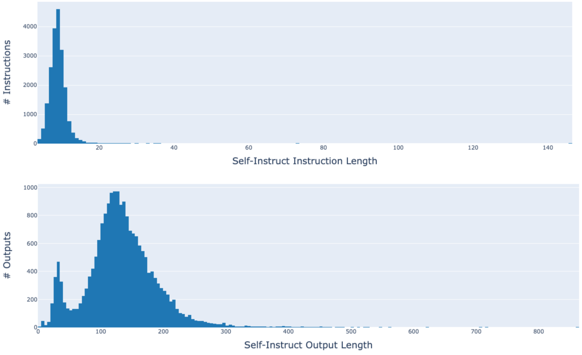

Figure 5: Length distribution of the generated user instructions and outputs by Self-Instruct.

4.3 Diversity

To check the diversity of the generated data, we compared the lengths of the generated user instruction, input, and output. Unlike the Self-instruct generated data, which is biased towards one point, the length distribution of data generated by SELF-EXPERTISE appears to be more even as described in Figure 4 and 5, indicating that it is more diverse. In particular, variously crafted system instructions played an important role in the diversity of output length and form. Depending on each system instruction, the responses could be brief and concise, or they might encompass more detailed and extensive explanations. For instance, we included system instructions that demand core points, as well as those that guide the generation of responses in a step-by-step manner, thereby diversifying the format of the answers.

---

[1] https://platform.openai.com/docs/models

Data Quality Review Question	Yes %
Does the instruction describe a valid task in the legal field?	90%
Is the input appropriate for the instruction?	90%
Is the output a correct and acceptable response to the instruction and input?	88%
Does the output include correct terms and knowledge?	77%

Table 4: Data quality review results.

Also, in Step 1 of SELF-EXPERTISE, we extracted knowledge from the output. Extracting objective knowledge from outputs first will help model not be limited to a particular situations and create various instructions and inputs. To verify this, we compared the results of generating instructions from the output for a 200 seed dataset with those generated from knowledge. Using BERTscore (Zhang et al., 2019), we measured the similarity between the original instructions, inputs, and the similarity among questions augmented from the same source. As seen in Table 3, instructions generated based on outputs show higher similarity, indicating a reduction in the diversity of the augmented data. Therefore, we decided to proceed to the next step by extracting knowledge from the output in Step 1.

4.4 Quality

Quality of a dataset in the legal field depends on the accuracy of knowledge and logical reasoning, so we conducted human evaluation for the generated data quality measurement. We randomly sampled 100 pairs of user instruction, input, and output. Referring to the data quality review questions (Wang et al., 2022), we asked legal experts to assess whether the sampled data represents valid tasks in the field of law, contains correct legal terms, and includes accurate knowledge. Table 4 shows the results of the human evaluation of the generated data. The evaluation results indicate that generated instructions extensively include law tasks, and the outputs are reasonable and contain accurate legal knowledge. To assist with the understanding, two examples from generated dataset are selected and listed in Appendix A.4.

5 Experimental Setup

5.1 Training Details

To develop LxPERT, we conducted instruction tuning with the LLaMA-2-ko 7B model which is pretrained with Korean language on the LLaMA-2 7B model (Touvron et al., 2023). We trained instruction data augmented with SELF-EXPERTISE using causal language modeling loss. LxPERT underwent three epochs of training on four NVIDIA A100 GPUs with 80GB memory, with the AdamW (Kingma and Ba, 2014) as the optimizer, learning rate of 2e-5, per device train batch size of 1, and a max length of 1024. It took 2 hours to train LxPERT on 19k generated dataset. We enhanced the training speed by utilizing the Accelerate (Gugger et al., 2022) and DeepSpeed [2] libraries. Additionally, we did not use any loss masking and trained the model by calculating the loss from the instruction to the output to generally learn the strategy of producing outputs according to system instructions.

5.2 Baselines

Foundation Models: LLaMA-2 7B (Touvron et al., 2023) and LLaMA-2-ko 7B (L. Junbum, 2023). We chose the 7B-sized sLLM to check the performance of a model of the same size.

Instruction-tuned Models in General Domain: LLaMA-2-chat 7B (L. Junbum, 2023) and LLaMA-2-ko-chat 7B [3]. We selected models trained on existing general domain instruction datasets.

GPT: We included `GPT-3.5-turbo`, the bigger-sized LLM. This research measures and evaluates the performance of GPT model in the Korean legal domain.

Instruction-tuned Models in Legal Domain: Self-Instruct tuned LLaMA-2-ko 7B and seed dataset tuned LLaMA-2-ko 7B. Existing instruction-tuned models have limitations in not being specialized for the Korean legal domain. Therefore, we augmented the dataset for the legal domain by using the Self-Instruct method (Wang et al., 2022) and trained on LLaMA-2-ko 7B. We provide more details of Self-Instruct generation in Appendix D. Also, we add the model trained only seed dataset.

5.3 Evaluation Dataset

In-domain Dataset: In-domain dataset includes new user instruction, input, and output pairs containing legal knowledge from seed dataset. To as-

---

[3] https://huggingface.co/heegyu/llama-2-ko-7b-chat

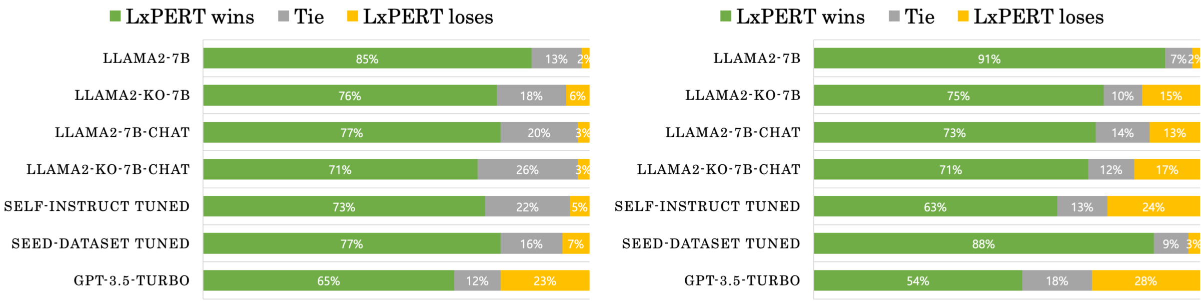

Figure 6: GPT-4 evaluation results on in-domain data (left) and out-of-domain data (right). We pair each response of models with LxPERT response and estimate the win rate.

sess whether the trained model can provide accurate and logical answers reflecting the legal characteristics, we asked legal experts to create a new dataset that is related to same four domains like as seed dataset. Note that, it has been meticulously designed to have no overlap of user instructions, inputs, and outputs with either the seed dataset or the train dataset. Ultimately, test dataset of 200 pairs were compiled.

Out-of-domain Dataset: Out-of-domain dataset means new user instruction, input, and output pairs that contain outside knowledge from seed dataset. To evaluate the model's generalization performance on tasks and knowledge not included in the seed data, we collected 100 QA pairs by crawling the "Easy-to-Find Living Law Information" [4] site. Particularly, we selected questions that require knowledge not presented in our seed data, aiming to evaluate performance on challenging out-of-domain test dataset.

5.4 Evaluation Settings

In order to measure the performance of the model in the legal domain, we conducted GPT automatic evaluation and human evaluation. The model's instruction-following capability was assessed in a zero-shot environment without in-context examples.

GPT-4 Evaluation We conducted pairwise comparison evaluation method used in (Zheng et al., 2024; Wang et al., 2023; Xu et al., 2023). We instructed `GPT-4`[5] to choose the more logical response for the same user instruction and input from two candidate responses. The prompt template used for evaluation is shown in Appendix B.

Human Evaluation Despite GPT's outstanding performance in automatic evaluation, there are limitations in comprehending accuracy and logical structure in specialized domains such as law. Consequently, we asked legal experts to rate the model-generated text on a five-point Likert scale (Likert, 1932) for accuracy and fluency. For accuracy, they assessed whether the included knowledge was correct and appropriate. For fluency, they evaluated whether the task requested in the user instruction was well executed and if the answer was derived from legal reasoning. Detailed criteria is described in Appendix C.3.

6 Results

6.1 Evaluation on In-domain Data

The result of GPT-4 evaluation on in-domain data is shown on the left side of Figure 6. In a pairwise comparison, LxPERT significantly outperforms both models tuned for general domain and those tuned for the legal domain. LxPERT demonstrate superior performance in expanding logical answers through legal reasoning compared to other models. Moreover, LxPERT, which is trained on the characteristics of the legal domain, shows better performance than `GPT-3.5-turbo` which is focused on general domain.

The result of human evaluation is shown in Table 5. Models tuned for general domain instructions score significantly lower, indicating insufficient learning of legal knowledge and thinking, despite possessing some capability in instruction following. Lower performance shows hallucinations in the legal Self-Instruct dataset due to the lack of knowledge. In contrast, LxPERT not only surpasses the performance of other 7B models but also exceeds `GPT-3.5-turbo` in terms of accuracy. LxPERT indirectly acquires legal domain knowledge through an instruction dataset containing accurate knowledge. Furthermore, we observe that

[5] https://platform.openai.com/docs/models

Model	In-domain		Out-of-domain	
	Accuracy	Fluency	Accuracy	Fluency
Foundation Models				
LLaMA-2 7B	1.03	1.04	1.04	1.14
LLaMA-2-ko 7B	1.19	1.24	1.06	1.16
Instruction-tuned Models in General Domain				
LLaMA-2-chat 7B	1.63	2.00	1.24	1.76
LLaMA-2-ko-chat 7B	1.61	2.23	1.49	2.37
GPT-3.5-turbo	2.52	3.83	2.60	3.90
Instruction-tuned Models in Legal Domain				
Self-Instruct tuned	1.25	2.06	1.25	2.27
Seed dataset tuned	2.07	3.00	2.88	3.22
LxPERT (Ours)	**3.88**	**4.80**	**2.98**	**4.53**

Table 5: Human evaluation results on in-domain data and out-of-domain data.

LxPERT excels in articulating logical structures, including clauses and case law, thus demonstrating an outperforming fluency level.

6.2 Evaluation on Out-of-domain Data

We also measured performance on a challenging out-of-domain test set composed solely of unlearned knowledge. The result of GPT-4 evaluation for out-of-domain (OOD) data is shown on the right side of Figure 6. Among the models trained on the legal domain, the performance of the seed dataset tuned model noticeably drops compared to the result on in-domain data. This could be due to overfitting on a small number of dataset, leading to poor performance in OOD question and answer. While Self-Instruct tuned model and `GPT-3.5-turbo` show a slight improvement in performance in OOD, LxPERET still outperform `GPT-3.5-turbo` with a probability of over 50%.

The human evaluation result for the OOD dataset is shown in Table 5. As before, models including Self-Instruct that underwent instruction tuning show slightly improved performance compared to the baseline. LxPERT, being an out-of-domain set, often based its reasoning on incorrect legal statutes or precedents, resulting in reduced accuracy. Nonetheless, it surpassed `GPT-3.5-turbo`'s performance in this context.

6.3 Quality of Answers Relative to the Amount of Training Data

We measured the relationship between the quantity of augmented instruction dataset and the quality of responses. We increased the dataset sizes to 1k, 5k, 10k, 19k, 30k and observed the performance on in-domain and out-of-domain test set. The results shown in Figure 7. From the graph, we observe that across all models with varying sizes of training data, fluency is consistently higher than accuracy. This trend shows that the model first learns how to response in legal format, regardless of the amount of training data. A general improvement in performance is seen as the amount of training data increases. Notably, there is a decrease in model performance when the data size increases from 19k to 30k. This suggests that excessive augmentation of our limited 980 seed data knowledge leads to overfitting on this specific knowledge, consequently diminishing the model's general linguistic capabilities. Based on these findings, we hypothesize that incorporating additional general domain datasets or expanding knowledge of seed data could further enhance model performance. This hypothesis forms the basis of our proposed future work.

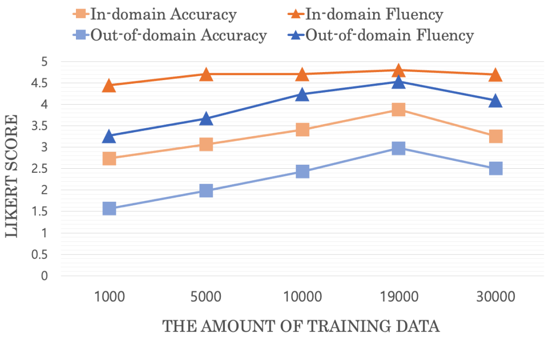

Figure 7: Human evaluation performance of LxPERT tuned with different sizes of training data. Orange lines show the results on in-domain data, while blue lines show the results on out-of-domain data. Triangles mean fluency, and squares mean accuracy.

7 Discussion

In our experiments with SELF-EXPERTISE and instruction tuning, we aimed to distill two key attributes: the ability to follow instructions and legal domain knowledge. The model showed proficiency in generating responses based on legal statutes and case law, adhering to the logical framework of legal reasoning, as evidenced by high fluency scores. However, as the model learn the legal domain knowledge indirectly, it was prone to more frequent errors. Prominent errors included hallucinations, where the model fluently provided responses based on inaccurate legal references. This suggests that while SELF-EXPERTISE has addressed knowledge issues compared to Self-Instruct, there are still aspects that remain to be resolved. We anticipate a combination of accurate knowledge acquisition methods with SELF-EXPERTISE to further enhance the precision in legal domain knowledge.

We propose this potential improvement as a subject for future work.

8 Conclusion

In this study, we propose SELF-EXPERTISE for automatically generating instruction dataset in specialized domain areas. Our proposed method extracts knowledge from outputs of a seed dataset and uses this as a basis for generating instructions. This significantly reduces hallucination in instruction dataset creation. To demonstrate the effectiveness of the our augmentation method, we trained LxPERT with an augmented dataset on LLaMA-2 7B and compared it with other baselines. It surpasses the performance of 7B models and `GPT-3.5-turbo` in terms of GPT-4 evaluation and human evaluation. We believe that this methodology can be extended and used for creating instruction datasets not only in the legal domain but also in other specialized knowledge domains. Therefore, we look forward to the utilization of this augmentation pipeline when training an sLLM specialized for knowledge-intensive tasks.

Limitations

This study proposes a methodology for generating instruction datasets in specialized knowledge domains. This methodology has some limitations common to other automatic instruction generation methods and knowledge-based learning methodologies.

Cost Issue The SELF-EXPERTISE process used the `GPT-3.5-turbo` model for Step 1 and the `GPT-4-preview-1106` model's API for Steps 2 and 4. This was necessary for generating accurate responses based on knowledge and creating creative instructions. While it reduces costs compared to human-written data, a significant cost increase can occur when multiple iterations are performed.

Knowledge Expansion Issue We augmented the dataset by creating various instructions based on the knowledge in the seed dataset. This is meaningful as it produces different instructions and inputs from the same knowledge, as discussed in the data analysis section. Moreover, experiments confirm that this augmentation method improves the model's ability to follow precise knowledge and legal narrative structures. However, the major issue is that augmentation with the same seed dataset is only possible with the same knowledge, thus limiting diversity. We believe this can be improved by retrieving a variety of knowledge for data augmentation in future work.

Ethics

The data was generated based on an LLM; therefore, it may contain biases inherent in the backbone LLM. For example, bias may be introduced in the generation of legal questions based on certain knowledge. However, our method is novel in that we did not directly generate inputs from the outputs. Instead, we generated knowledge from the output to create new inputs based on general cases. This process addresses biases and reduces the inclusion of personal information. Additionally, we disclose data augmented with SELF-EXPERTISE. This data is released under the CC-BY-NC 4.0 license [6], which excludes commercial use.

Example1 (Civil law in bar exam)

Instruction

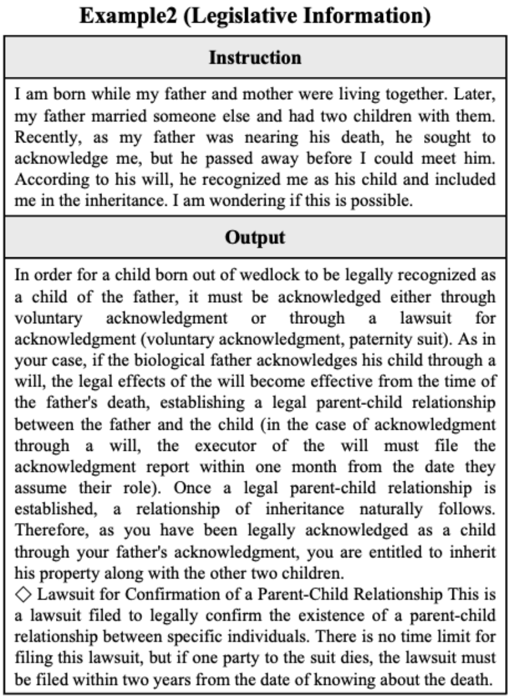
Does C have a liability for damages due to unjust enrichment against A?

Input

A entered into a land lease agreement with B regarding B's X land for the construction of a building (lease period from June 1, 2016, to May 31, 2021, 5 years, lease deposit of 700 million won, monthly rent of 20 million won). A completed the construction of Y building on the X land on August 22, 2017, and completed the registration of ownership preservation. A entered into a building lease agreement with C, who intended to operate a warehouse in the Y building (lease period from October 1, 2017, to September 30, 2020, 3 years, lease deposit of 100 million won, monthly rent of 5 million won). Around April 2020, A asked C about extending the lease of the Y building, but C refused to extend it further. Amid the COVID-19 pandemic, with business being non-operational, C, after the expiration of the lease period on September 30, 2020, locked the warehouse door with a key, leaving the goods inside.

Output

It has been established that if a tenant continues to occupy a part of the leased property after the termination of the lease contract as a way of exercising the right of objection to simultaneous performance but does not use or profit from it according to the original purpose of the lease contract, thus gaining no substantial benefit, the tenant does not have the obligation to return any undue gains, even if the landlord has suffered damages (Supreme Court Decision on February 9, 2001, Case No. 2000Da61398). Since C locked the door with a key without taking out the goods, thereby gaining no substantial benefit, C is not obligated to return any undue gains.



Example2 (Legislative Information)

Instruction

I am born while my father and mother were living together. Later, my father married someone else and had two children with them. Recently, as my father was nearing his death, he sought to acknowledge me, but he passed away before I could meet him. According to his will, he recognized me as his child and included me in the inheritance. I am wondering if this is possible.

Output

In order for a child born out of wedlock to be legally recognized as a child of the father, it must be acknowledged either through voluntary acknowledgment or through a lawsuit for acknowledgment (voluntary acknowledgment, paternity suit). As in your case, if the biological father acknowledges his child through a will, the legal effects of the will become effective from the time of the father's death, establishing a legal parent-child relationship between the father and the child (in the case of acknowledgment through a will, the executor of the will must file the acknowledgment report within one month from the date they assume their role). Once a legal parent-child relationship is established, a relationship of inheritance naturally follows. Therefore, as you have been legally acknowledged as a child through your father's acknowledgment, you are entitled to inherit his property along with the other two children.

◇ Lawsuit for Confirmation of a Parent-Child Relationship This is a lawsuit filed to legally confirm the existence of a parent-child relationship between specific individuals. There is no time limit for filing this lawsuit, but if one party to the suit dies, the lawsuit must be filed within two years from the date of knowing about the death.

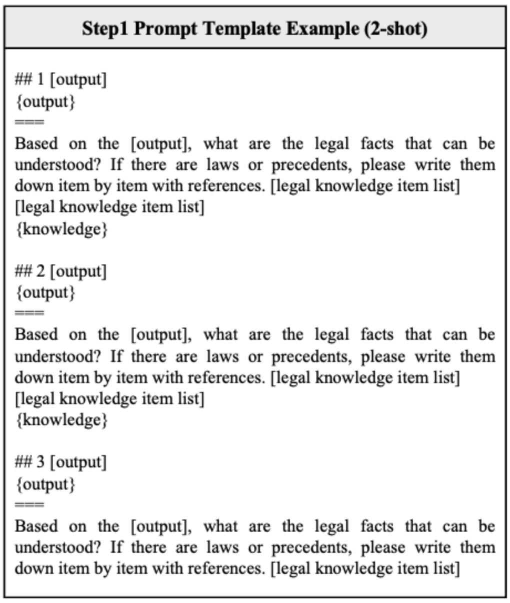
A Data Generation Details

A.1 Examples of Seed Dataset

We display two examples of our seed dataset, one from 'Civil Law in Bar Exam' and the other one from 'Legislative Information'. For a better understanding, we translated these examples into English.

A.2 Prompts for Generation

SELF-EXPERTISE automatically generates instruction data by giving appropriate prompts to LLMs in each step described in §3.2. In this section, we present three actual prompt templates and eight system instructions. All prompts include 2-

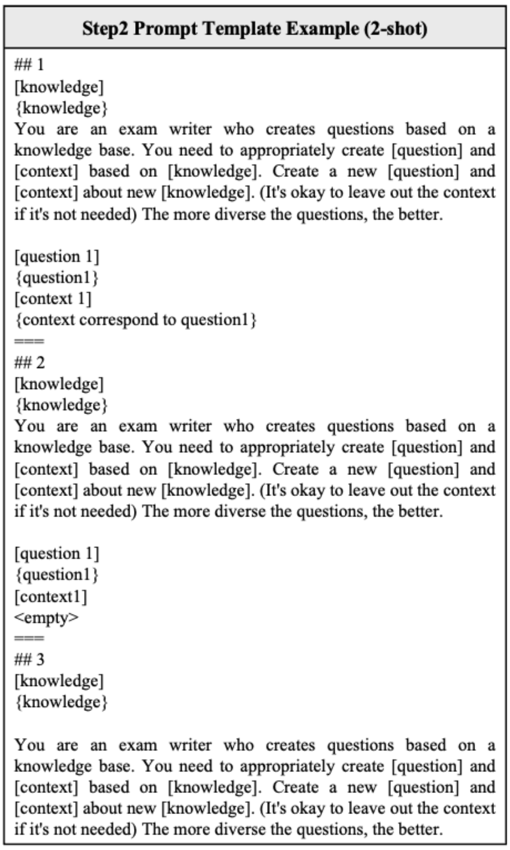


Step1 Prompt Template Example (2-shot)

```
## 1 [output]
{output}
===
Based on the [output], what are the legal facts that can be understood? If there are laws or precedents, please write them down item by item with references. [legal knowledge item list]
[legal knowledge item list]
{knowledge}

## 2 [output]
{output}
===
Based on the [output], what are the legal facts that can be understood? If there are laws or precedents, please write them down item by item with references. [legal knowledge item list]
[legal knowledge item list]
{knowledge}

## 3 [output]
{output}
===
Based on the [output], what are the legal facts that can be understood? If there are laws or precedents, please write them down item by item with references. [legal knowledge item list]
```



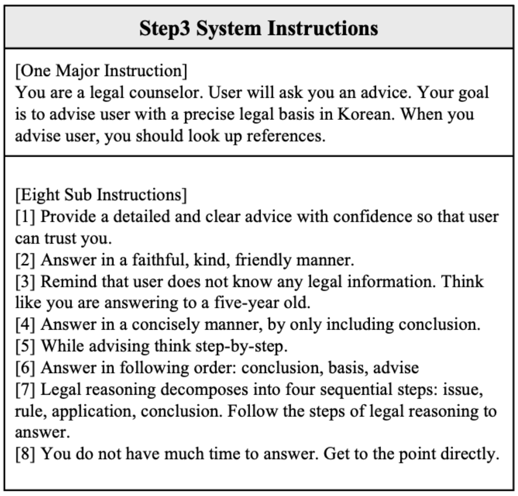
Step2 Prompt Template Example (2-shot)

```
## 1
[knowledge]
{knowledge}
You are an exam writer who creates questions based on a knowledge base. You need to appropriately create [question] and [context] based on [knowledge]. Create a new [question] and [context] about new [knowledge]. (It's okay to leave out the context if it's not needed) The more diverse the questions, the better.

[question 1]
{question1}
[context 1]
{context correspond to question1}
===
## 2
[knowledge]
{knowledge}
You are an exam writer who creates questions based on a knowledge base. You need to appropriately create [question] and [context] based on [knowledge]. Create a new [question] and [context] about new [knowledge]. (It's okay to leave out the context if it's not needed) The more diverse the questions, the better.

[question 1]
{question1}
[context1]
<empty>
===
## 3
[knowledge]
{knowledge}

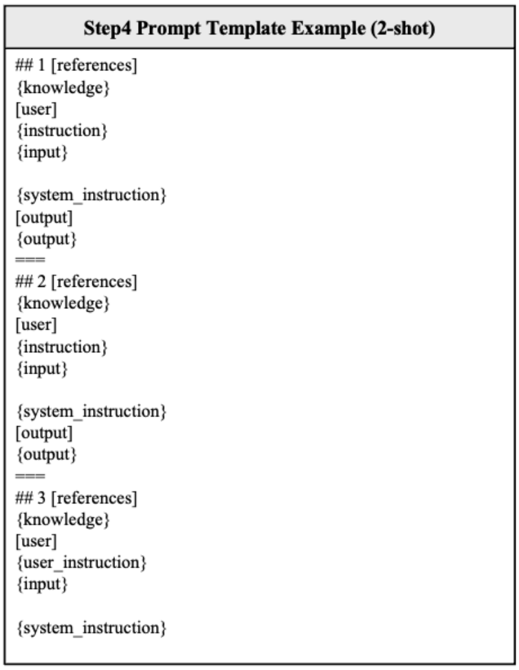
You are an exam writer who creates questions based on a knowledge base. You need to appropriately create [question] and [context] based on [knowledge]. Create a new [question] and [context] about new [knowledge]. (It's okay to leave out the context if it's not needed) The more diverse the questions, the better.
```



Step3 System Instructions

[One Major Instruction]
You are a legal counselor. User will ask you an advice. Your goal is to advise user with a precise legal basis in Korean. When you advise user, you should look up references.

[Eight Sub Instructions]
[1] Provide a detailed and clear advice with confidence so that user can trust you.
[2] Answer in a faithful, kind, friendly manner.
[3] Remind that user does not know any legal information. Think like you are answering to a five-year old.
[4] Answer in a concisely manner, by only including conclusion.
[5] While advising think step-by-step.
[6] Answer in following order: conclusion, basis, advise
[7] Legal reasoning decomposes into four sequential steps: issue, rule, application, conclusion. Follow the steps of legal reasoning to answer.
[8] You do not have much time to answer. Get to the point directly.



Step4 Prompt Template Example (2-shot)

```
## 1 [references]
{knowledge}
[user]
{instruction}
{input}

{system_instruction}
[output]
{output}
===
## 2 [references]
{knowledge}
[user]
{instruction}
{input}

{system_instruction}
[output]
{output}
===
## 3 [references]
{knowledge}
[user]
{user_instruction}
{input}

{system_instruction}
```

shot examples. In case of system instructions, we referred to the styles of system message from Orca (Mukherjee et al., 2023) and modified to suit the legal field.

A.3 Generation Models and Parameters

A.3.1 Generation Models

In this paper, we used `GPT-3.5-turbo` for Step 1 (§3.2.3), and `GPT-4-1106-preview` for Steps 2 (§3.2.2) and 4 (§3.2.4) of the SELF-EXPERTISE application. In Step 1, the task involves extracting and organizing information from given texts rather than creating new content. In this case, we found no significant performance difference between `GPT-3.5-turbo` and `GPT-4-1106-preview`, with both models performing the task effectively. Therefore, we chose the more cost-effective `GPT-3.5-turbo`. However, Steps 2 and 4 relatively require the generation of not only accurate, but also new and creative data from the given texts. In comparison to `GPT-4-1106-preview`, `GPT-3.5-turbo` tended to generate more uniform and similar data rather than a variety. Consequently, `GPT-4-1106-preview` was used for Steps 2 and 4 to facilitate the creation of a more diverse range of data.

A.3.2 Generation Parameters

When conducting the generation, we employed default settings for the parameters. Both frequency penalty and presence penalty were set to 0. Temperature was adjusted to 1, and similarly, top p was configured at 1.

A.4 Examples of Generated Dataset

This section provides two examples of data generated through SELF-EXPERTISE. We translated examples into English to enhance understanding. When looking at the examples, the user instructions include valid questions related to law and also appropriately match with corresponding inputs. In addition, the outputs provide suitable answers to the questions posed in the user instructions, not only responding accurately but also logically explaining based on correct knowledge. This demonstrates the successful implementation of the methodology for creating instruction data based on knowledge.

B GPT-4 Evaluation Details

We conducted the pairwise comparison evaluation between model-generated samples using `GPT-4`. The prompt template for pairwise comparison is shown below. We guide `GPT-4` to choose a more appropriate response based on the user instruction and input. In this case, we assumed that `GPT-4` may not have learned certain legal knowledge, so we include accurate knowledge as a reference. Therefore, `GPT-4` can evaluate based on this knowledge whether the response is accurate and logical.

C Human Evaluation Details

C.1 Human Evaluation Setup

In this section, we present more details for the human evaluation. We conducted two parts of human evaluation: data quality review of the SELF-EXPERTISE augmented dataset, and the evaluation of generated samples by baseline models and LxPERT on the evaluation dataset. To objectively

Example1

User Instruction

Is there any possibility of holding the manufacturer accountable if my car caught fire while it was parked, but I can't prove a defect in the vehicle itself?

Input

My car, which was recently parked, suffered damage due to a fire. The exact cause of the fire has not been identified, and it is unclear whether a specific defect inside the vehicle was the cause of the fire. I have followed the necessary procedures, but the manufacturer is not acknowledging the defect.

Output

In cases where a consumer claims damage based on a manufacturing defect in a vehicle, the consumer must prove that the defect caused the fire. According to the Supreme Court decision on July 28, 2000 (Case No. 98Da35525), it is difficult for the consumer to claim that there is a manufacturing defect in the vehicle if they cannot specify the defect and the possibility of external ignition cannot be ruled out. This applies similarly when asserting the vehicle company's warranty liability for defects.
Therefore, in your case, if you cannot clearly identify the cause of the vehicle fire and cannot prove that an internal defect was the direct cause of the fire, it may be very difficult to hold the manufacturer responsible. However, if you cannot completely rule out the possibility of a vehicle defect, further investigation or expert assessment can be pursued. For example, you can seek an expert's opinion on the cause of the fire, or collect claims and evidence from other vehicle owners in similar cases to try to prove a manufacturing defect.
If sufficient evidence to prove the manufacturer's responsibility cannot be obtained, depending on the insurance status of the vehicle, claiming insurance for the fire damage could be an alternative.

Example2

User Instruction

Is there an obligation for medical professionals to protect information learned during the diagnosis and treatment process even after the patient's death?

Input

A family's breadwinner passed away while receiving treatment in a hospital. During this process, information about the specific illness they were suffering from was spread among acquaintances not by the family but by a staff member of the medical institution. One of the family members of the deceased patient is looking to take action against the medical institution and that staff member.

Output

Yes, even after a patient's death, healthcare professionals and medical institution employees have a duty not to disclose or publish the patient's information. This duty is established under Article 19, Paragraph 1 of the Medical Law, which prohibits healthcare professionals and medical institution employees from disclosing or publishing secrets learned while performing medical duties.
The Supreme Court, in its judgment dated May 11, 2018, stated that the duty of healthcare professionals to keep secrets is intended to protect the trust relationship between the healthcare professional and the patient, and thereby protect and promote the public interest in national health. This judgment includes the secrets of deceased individuals within the scope of information that healthcare professionals are prohibited from disclosing.
In the situation you described, the family of a deceased patient can take action against the medical institution or its employees for violating the Medical Law. If a healthcare institution employee leaks patient information, the family can hold that employee criminally responsible and also seek civil damages. The family should first establish the facts and gather evidence, then consult with a legal expert to proceed with the appropriate legal actions.

assess the accuracy of legal knowledge and logical reasoning, we asked two lawyers to evaluate both data quality and model-generated samples.

Prompt for Pairwise Comparison

You are a helpful and precise assistant for checking the quality of the response. Two pieces of response have been provided to the same instruction and input related to law. Which one is more precise and logical refer to the knowledge?

Knowledge:
{knowledge}

Question:
{user_instruction}
{input}

###
Response 1:
{model1_output}

Response 2:
{model2_output}

Please choose from the following options. (one option ONLY) Do not generate explanation.
A: Response 1 is significantly better.
B: Response 2 is significantly better.
C: Neither is significantly better.

C.2 Human Evaluation Guideline for Data Quality Review

The guideline for a human evaluation of data quality review is shown below. We provide user instruction, input, knowledge, and output pairs to evaluators. We selected four data quality review questions based on Self-Instruct (Wang et al., 2022) and asked evaluators to answer each question with either ‘yes’ or ‘no’. The result of this human evaluation is presented in Figure 4.

Human Evaluation Guideline for Data Quality Review

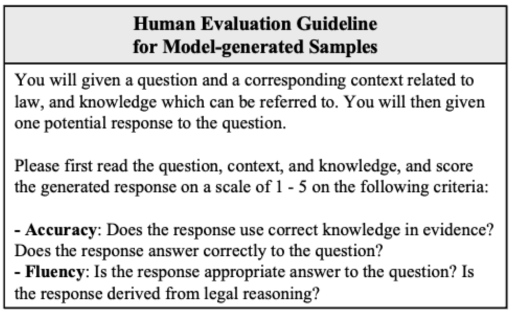
You will given a instruction and a corresponding input related to law, and knowledge which can be referred to. You will then given a output to the instruction.

Please first read the instruction, input, knowledge and output, and answer yes or no to the questions below:

- Does the instruction describe a valid task in the legal field?
- Is the input appropriate for the instruction?
- Is the output a correct and acceptable response to the instruction and input?
- Does the output include correct terms and knowledge?

C.3 Human Evaluation Guideline for Model-generated Samples

The guideline for a human evaluation of model-generated samples is shown below. We gave user instruction, input, knoweldge, and output pairs to evaluators and instructed them to score for accuracy and fluency on a five-point Likert scale (Likert, 1932). The result of this human evaluation is presented in Figure 5.



Human Evaluation Guideline for Model-generated Samples

You will given a question and a corresponding context related to law, and knowledge which can be referred to. You will then given one potential response to the question.

Please first read the question, context, and knowledge, and score the generated response on a scale of 1 - 5 on the following criteria:

- **Accuracy**: Does the response use correct knowledge in evidence? Does the response answer correctly to the question?
- **Fluency**: Is the response appropriate answer to the question? Is the response derived from legal reasoning?

D Legal-based Self-Instruct Details

To compare with the existing instruction data augmentation method, we selected the Self-Instruct method (Wang et al., 2022) and augmented our seed dataset using Self-Instruct. We used `GPT-4-1106-preview` for a fair comparison between Self-Instruct and SELF-EXPERTISE. After six iterations, we created 19k Legal-based Self-Instruct dataset, as same size as SELF-EXPERTISE dataset. Here we show the prompt templates used for generating instruction and instance, respectively.

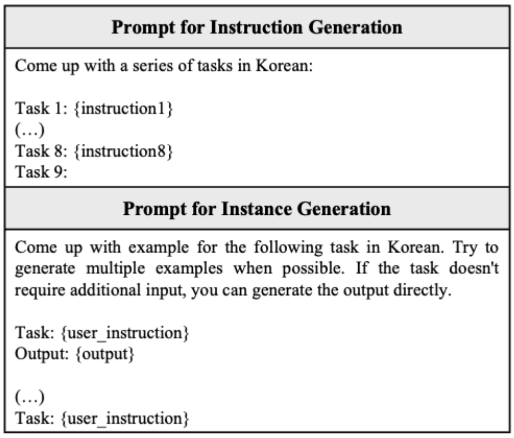
D.1 Instruction Generation

This stage is for generating instructions based on the tasks in the seed dataset. We used the same prompt template from Self-Instruct.

D.2 Instance Generation

This stage involves creating an instance based on the instruction generated from the previous step. Likewise, we used the same prompt template from Self-Instruct.

Prompts for Legal-based Self-Instruct



Prompt for Instruction Generation

Come up with a series of tasks in Korean:

Task 1: {instruction1}
(…)
Task 8: {instruction8}
Task 9:

Prompt for Instance Generation

Come up with example for the following task in Korean. Try to generate multiple examples when possible. If the task doesn't require additional input, you can generate the output directly.

Task: {user_instruction}
Output: {output}

(…)
Task: {user_instruction}

E Legal Experts Details

The research project we are currently working on includes a legal team among the participating research teams. This legal team consists of law school professors, students, and lawyers. They are not crowd workers we need to recruit, but co-researchers who perform the same task and receive funding for their research. The dataset creation was led by a law school professor, and the ten law school students helped data writing. Additionally, human evaluation of the dataset quality and model generation results were handled by two lawyers.

Re-evaluating the Need for Multimodal Signals in Unsupervised Grammar Induction

Boyi Li[*, 1] **Rodolfo Corona**[*, 1] **Karttikeya Mangalam**[*, 1] **Catherine Chen**[*, 1]

Abstract

Are multimodal inputs necessary for grammar induction? Recent work has shown that multimodal training inputs can improve grammar induction. However, these improvements are based on comparisons to weak text-only baselines that were trained on relatively little textual data. To determine whether multimodal inputs are needed in regimes with large amounts of textual training data, we design a stronger text-only baseline, which we refer to as LC-PCFG. LC-PCFG is a C-PFCG that incorporates embeddings from text-only large language models (LLMs). We use a fixed grammar family to directly compare LC-PCFG to various multimodal grammar induction methods. We compare performance on four benchmark datasets. LC-PCFG provides an up to 17% relative improvement in Corpus-F1 compared to state-of-the-art multimodal grammar induction methods. LC-PCFG is also more computationally efficient, providing an up to 85% reduction in parameter count and 8.8× reduction in training time compared to multimodal approaches. These results suggest that multimodal inputs may not be necessary for grammar induction, and emphasize the importance of strong vision-free baselines for evaluating the benefit of multimodal approaches.

1 Introduction

Prior studies have shown that multimodal inputs can facilitate grammar induction. These studies paired text with inputs from images and videos, and found that models trained with paired multimodal inputs outperform text-only models on grammar induction (Shi et al., 2019; Zhao and Titov, 2020; Zhang et al., 2021, 2022a). These results suggest that multimodal inputs improve grammar induction by grounding textual inputs to the visual world. Indeed, a long line of work in human language learning suggests that paired multimodal inputs are crucial for language acquisition in humans (Gleitman, 1990; Pinker, 1984). While multimodal inputs can undoubtedly help with grammar induction, especially in regimes with low textual data, are multimodal inputs *necessary* to learn a grammar? To investigate this question, we test whether the benefits of multimodal inputs for grammar induction can be achieved by more textual data.

Prior studies of multimodal grammar induction compared multimodal methods to weak text-only baselines which were trained with relatively little data (Shi et al., 2019; Zhao and Titov, 2020; Zhang et al., 2021, 2022a). However, recent grammar induction approaches that incorporate representations from large language models (LLMs) produced large improvements in text-only grammar induction performance (e.g., Cao et al., 2020; Drozdov et al., 2019; Li and Lu, 2023). The performance of these LLM-based grammar induction methods suggest that exposure to larger quantities of textual training data can substantially improve grammar induction. However, prior studies used different settings to evaluate multimodal and text-only methods for grammar induction. Thus, it is unclear whether the performance of LLM-based grammar induction approaches can match the performance of multimodal approaches.

Here we compare multimodal methods for grammar induction to a strong text-only baseline. Our text-only baseline, which we refer to as LC-PCFG, is a C-PCFG that incorporates embeddings from text-only LLMs. We use and use a fixed grammar family (C-PCFGs) to directly compare LC-PCFG to multimodal methods, and perform comparisons with four multimodal grammar induction datasets. We find that compared to previous state-of-the-art multimodal methods, LC-PCFG achieves up to 17% relative improvement in Corpus-F1 score while requiring 8.8× less time to train. Moreover, the benefits of incorporating LLM embeddings does not straightforwardly stack with the benefits of multimodal training inputs: adding mul-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1113–1123
June 16-21, 2024

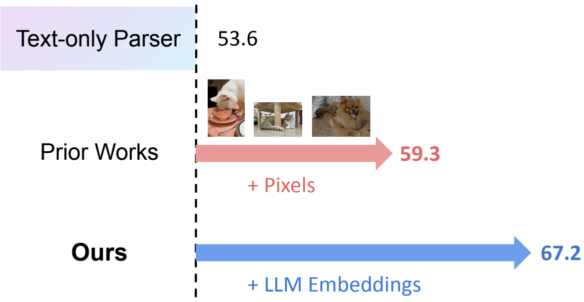

Figure 1: Comparison with prior multimodal methods on image-assisted grammar induction. Prior works showed that paired images can improve grammar induction (53.6 → 59.3 Corpus-level F1). We show that a strong text-only baselined line that incorporates embeddings from large language models (LLM) can match (and surpass) multimodal methods, suggesting that multimodal inputs may not be necessary for grammar induction (53.6 → 67.2).

timodal training inputs to LC-PCFG does not improve performance on grammar induction, suggesting that the benefits of multimodal inputs may be subsumed by training on large quantities of text. While multimodal training inputs may be useful in some settings, our results suggest that grammar induction may not require multimodal inputs. To facilitate further research we release our code at https://github.com/Boyiliee/Vision-free-Multimodal-Grammar-Induction.

2 Related Work

Grammar induction Grammar induction, the task of inducing syntactic structure without explicit supervision, has been extensively studied over the past few decades (e.g., Lari and Young, 1990; Carroll and Charniak, 1992; Clark, 2001; Klein and Manning, 2002; Smith and Eisner, 2005).

Many methods for grammar induction train on data from text alone (e.g., Lari and Young, 1990; Carroll and Charniak, 1992; Klein and Manning, 2002; Shen et al., 2018, 2019). However, based on the intuition that multimodal inputs capture information that is missing in text, recent studies have devised methods for grammar induction that incorporate information from images and videos (Shi et al., 2019; Zhao and Titov, 2020; Zhang et al., 2021, 2022a). These multimodal methods have been shown to outperform some text-only methods (Zhao and Titov, 2020; Shi et al., 2019; Zhang et al., 2022a, 2021).

LLM features for grammar induction. Recent advances in LLMs have enabled vast improvements on a wide range of downstream tasks, including both supervised syntactic parsing and grammar induction (e.g., Devlin et al., 2019; Radford et al., 2019; Kitaev et al., 2018; Cao et al., 2020; Drozdov et al., 2019; Li and Lu, 2023). However, prior work that evaluated the benefit of multimodal inputs for grammar induction used text-only baselines that incorporated much weaker word representations, such as random word embeddings or lexical word embeddings such as fastText. Thus, it is unclear whether stronger text-only methods for grammar induction can match the performance of multimodal approaches.

3 LC-PCFG: Grammar Induction with Large Language Models

The goal of grammar induction is to learn syntactic structure without explicit supervision. Methods for grammar induction assume a grammar formalism and then optimize grammar parameters to fit the data. We use Compound Probabilistic Context-Free Grammars (C-PCFGs) (Kim et al., 2019) as a grammar formalism. We construct a C-PCFG that incorporates LLM representations. We refer to this method as LC-PCFG. We compare LC-PCFG to prior methods that incorporate multimodal data (Zhao and Titov, 2020; Zhang et al., 2021, 2022a). Figure 2 provides an overview of our experiments.

Background. C-PCFGs extend the Probabilistic Context Free Grammar (PCFG) formalism, and are defined by a 5-tuple $\mathcal{G} = (S, \mathcal{N}, \mathcal{P}, \Sigma, \mathcal{R})$, consisting of a start symbol S, a set of non-terminals $\mathcal{N}$, a set of pre-terminals $\mathcal{P}$, a set of terminals Σ, and a set of derivation rules $\mathcal{R}$:

$$\begin{aligned} S &\to A & A &\in \mathcal{N} \\ A &\to BC & A &\in \mathcal{N}, B, C \in \mathcal{N} \cup \mathcal{P} \\ T &\to w & T &\in \mathcal{P}, w \in \Sigma \end{aligned}$$

PCFGs define a probability distribution over transformation rules $\boldsymbol{\pi} = \{\pi_r\}_{r\in\mathcal{R}}$. Then the inside algorithm (Baker, 1979) can be used to efficiently perform inference over this probability distribution. In neural PCFGs, this distribution may be formu-

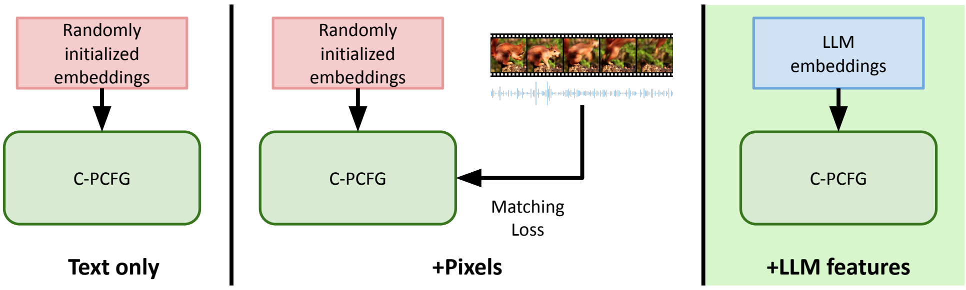

Figure 2: **Experimental Settings.** We explore using large language model features for unsupervised grammar induction. We use three experimental settings. (1) the standard setting in which word representations are learned from scratch (**Text Only**), (2) prior methods that incorporate a multimodal regularization loss (**+Pixels**), and (3) our method, which uses pre-trained text-only LLM features (**+LLM features**). We show that LLM features can obtain state-of-the-art performance, without requiring multimodal regularization.

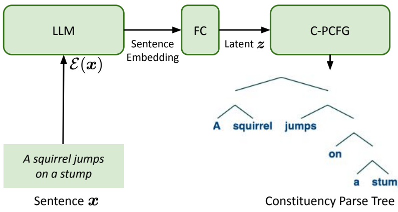

Figure 3: **LC-PCFG workflow.** A sentence $\boldsymbol{x}$ is fed to an LLM to obtain a sentence embedding $\mathcal{E}(\boldsymbol{x})$. $\mathcal{E}(\boldsymbol{x})$ is passed through a fully-connected layer (FC), producing the latent $\boldsymbol{z}$. $\boldsymbol{z}$ is fed to the C-PCFG to obtain a constituency parse tree. Note that unlike prior work, our approach does not require multimodal data.

lated as follows:

$$\pi_{S \to A} = \frac{\exp(\boldsymbol{u}_A^\top f_1(\boldsymbol{w}_S))}{\Sigma_{A' \in \mathcal{N}} \exp(\boldsymbol{u}_{A'}^\top f_1(\boldsymbol{w}_S))}$$

$$\pi_{A \to BC} = \frac{\exp(\boldsymbol{u}_{BC}^\top \boldsymbol{w}_A)}{\Sigma_{B'C' \in \mathcal{M}} \exp(\boldsymbol{u}_{B'C'}^\top \boldsymbol{w}_A)}$$

$$\pi_{T \to w} = \frac{\exp(\boldsymbol{u}_w^\top f_2(\boldsymbol{w}_T))}{\Sigma_{w' \in \Sigma} \exp(\boldsymbol{u}_{w'}^\top f_2(\boldsymbol{w}_T))}$$

where $\boldsymbol{u}$ are transformation vectors for each production rule, $\boldsymbol{w}$ are learnable parameter vectors for each symbol, and f_1 and f_2 are neural networks. The neural PCFG formulation preserves the benefits of fast inference while additionally incorporating distributional representations from neural networks.

Because PCFGs contain a strong context-free assumption, PCFGs cannot leverage global information that is useful for computing production probabilities during inference. C-PCFGs (Kim et al., 2019) extend PCFGs to incorporate global information. C-PCFGs formulate rule probabilities as a compound probability distribution (Robbins, 1956):

$$\boldsymbol{z} \sim p_\gamma(\boldsymbol{z}) \qquad \pi_{\boldsymbol{z}} = f_\lambda(\boldsymbol{z}, \boldsymbol{E}_\mathcal{G})$$

Where $\boldsymbol{z}$ is a latent variable generated by a prior distribution (generally assumed to be spherical Gaussian) and $\boldsymbol{E}_\mathcal{G} = \{\boldsymbol{w}_N | N \in \{S\} \cup \mathcal{N} \cup \mathcal{P}\}$ denotes the set of symbol embeddings. Rule probabilities $\boldsymbol{\pi}_{\boldsymbol{z}}$ are additionally conditioned on this latent variable:

$$\begin{aligned} \pi_{\boldsymbol{z}, S \to A} &\propto \exp(\boldsymbol{u}_A^\top f_1([\boldsymbol{w}_S; \boldsymbol{z}])), \\ \pi_{\boldsymbol{z}, A \to BC} &\propto \exp(\boldsymbol{u}_{BC}^\top [\boldsymbol{w}_A; \boldsymbol{z}]), \\ \pi_{\boldsymbol{z}, T \to w} &\propto \exp(\boldsymbol{u}_w^\top f_2([\boldsymbol{w}_T; \boldsymbol{z}])) \end{aligned}$$

Importantly, the latent variable $\boldsymbol{z}$ allows global information to be shared across production decisions during, while maintaining the context-free assumption needed for efficient inference when $\boldsymbol{z}$ is fixed.

Becase the introduction of $\boldsymbol{z}$ makes inference intractable, variational methods are used to optimize C-PCFGs (Kingma and Welling, 2013) At inference time, given a sentence $\boldsymbol{x}$, the variational inference network q_ϕ is used to produce the latent $\boldsymbol{z} = \boldsymbol{\mu}_\phi(g(\mathcal{E}(\boldsymbol{x})))$. Here, g is a sentence encoder used to generate a vector representation given token embeddings $\mathcal{E}(\boldsymbol{x})$. For a more thorough treatment of C-PCFGs, please see Kim et al. (2019).

LLM-based C-PCFG for grammar induction. We design LC-PCFG, a simple but strong text-only baseline which incorporates pre-trained LLM representations into the C-PCFG inference network. Specifically, we formulate the inference network as:

$$\mathcal{E}(\boldsymbol{x}) = \text{LLM}(\boldsymbol{x}) \tag{1}$$

$$g(\boldsymbol{x}) = \text{FC}(m(\mathcal{E}(\boldsymbol{x}))) \tag{2}$$

Table 1: **Grammar induction with image and text**. Corpus-level F1 (C-F1) and sentence-level F1 (S-F1) scores on the MSCOCO 2014 caption dataset. We compare LC-PCFG against simple rule-based baselines (top, from (Zhao and Titov, 2020)), prior state-of-the-art methods that employ image data (middle), and methods, including ours, that use purely textual data (bottom). *RGB* indicates whether each method uses multimodal inputs. LC-PCFG outperforms all prior multimodal methods.

Method	RGB	LLM	Params (M)	C-F1	S-F1
Rule-based baselines					
Left Branching	No	No	-	15.1	15.7
Right Branching	No	No	-	51.0	51.8
Random Trees	No	No	-	$24.2_{\pm 0.3}$	$24.6_{\pm 0.2}$
Methods using extra-linguistic inputs					
VG-NSL (Shi et al., 2019)	Yes	No	-	$50.4_{\pm 0.3}$	-
VC-PCFG (Zhao and Titov, 2020)	Yes	No	41.5	$59.3_{\pm 8.2}$	$59.4_{\pm 8.3}$
VC-PCFG++	Yes	No	41.5	$64.2_{\pm 7.0}$	$64.6_{\pm 7.2}$
Methods using only textual inputs					
C-PCFG (Kim et al., 2019)	No	No	15.3	$53.6_{\pm 4.7}$	$53.7_{\pm 4.6}$
LC-PCFG (Ours)	No	Yes	**6.2**	$\mathbf{67.2}_{\pm 1.1}$	$\mathbf{67.8}_{\pm 1.2}$

where m represents a mean-pool operation. Here, an LLM is used to obtain text embeddings for each sentence $\boldsymbol{x}$, which are then fed to a fully connected (FC) layer as the C-PCFG inference network. Figure 3 provides an example of this method. A sentence $\boldsymbol{x}$ ("*A squirrel jumps on a stump*") is fed into an LLM to obtain an embedding of the sentence. Then the sentence embedding is passed into a fully-connected layer to obtain the latent variable $\boldsymbol{z}$. Finally, we feed $\boldsymbol{z}$ into the C-PCFG to obtain a constituency parse tree. Note that compared to prior multimodal CPFGs which used multimodal inputs for regularization, our approach does not use any multimodal data.

4 Experiments

4.1 Image-assisted Parsing

We compare LC-PCFG against VG-NSL (Shi et al., 2019) and VC-PCFG (Zhao and Titov, 2020), two state-of-the-art multimodal grammar induction methods that incorporate visual signals from paired image-caption data. In VG-NSL and VC-PCFG, a visual matching loss between representations of images and their captions serves as a regularizer during grammar induction.

Setup. We follow the experimental setup of Zhao and Titov (2020), evaluating on the same splits of the MSCOCO 2014 dataset (Lin et al., 2014). (Because MSCOCO does not provide captions for their test set, a portion of the validation set is used as a held-out test set.) Images in the MSCOCO dataset are each associated with 5 captions. The final dataset consists of 82,783 training, 1,000 validation, and 1,000 test images. During preprocessing, all sentences are converted to lowercase and numbers are replaced with the letter "N". For models using word embedding matrices, the most frequent 10,000 words (based on whitespace tokenization) are maintained with all other words mapped to a special UNK token. Captions greater than 45 words in length are removed. For LC-PCFG, we preprocess the dataset by extracting token-level embeddings for each caption from the last layer of an LLM.

Evaluation. Because the MSCOCO dataset does not have annotated ground truth parse trees, we follow prior work and use a supervised neural parser, Benepar (Kitaev and Klein, 2018), to generate parse trees for evaluation. Each unsupervised grammar induction method is evaluated by computing the F1 score between the predicted parse tree and the parse tree generated by Benepar. Due to instabilities observed during training, each method is trained with 10 random seeds and then the mean and standard deviation over the top 4 seeds (based on validation F1) are reported.

Implementation. For baseline models we use the implementation and hyperparameters provided by Zhao and Titov (2020).[1]

The original implementation of VC-PCFG uses a ResNet-152 network to embed images. However, there are now image embedding networks that are stronger than ResNet-152. To provide a fair comparison between our text-only model and multimodal approaches, we improve VC-PCFG by replacing ResNet-152 with ResNetV1.5

LC-PCFG (Ours)	Yes	No	**57.1**$_{\pm4.7}$	**60.0**$_{\pm5.2}$	**52.4**$_{\pm0.1}$	**57.7**$_{\pm0.1}$	**56.1**$_{\pm3.6}$	**61.2**$_{\pm3.7}$

\- 152 (ResNetV1.5, 2022). We also improve the optimization hyperparameters (learning rate and network dropout). We refer to the modernized version of VC-PCFG as VC-PCFG++. VC-PCFG++ outperforms VC-PCFG by about 3 points in both corpus and sentence-level F1 scores.

For LC-PCFG, we use an OPT-2.7B (Zhang et al., 2022b) model to extract token-level embeddings for each sentence. Sentence embeddings are then mean-pooled and passed through a single linear layer inference network. We use dropout of 0.5 on both the mean-pooled sentence embedding and the output latent vector from the inference network.

4.1.1 Results

Table 1 shows test F1 scores for each model. LC-PCFG achieves the highest overall corpus-level F1 (C-F1) and sentence-level F1 (S-F1) scores. Note that LC-PCFG does not use paired visual features, and contains 85% fewer parameters than the previous state-of-the-art approach (VC-PCFG).

4.2 Video-assisted Parsing

The results in Table 1 show that a text-only approach can outperform approaches that incorporate multimodal inputs from images. However, some have argued that images are a static snapshot of the world, and therefore may lack information needed to induce verb phrases (Zhang et al., 2021). Based on the intuition that video can provide better multimodal training signals, one study presented an approach for grammar induction (MultiModal Compound PCFG; MMC-PCFG) that incorporates both visual and auditory signals from videos (Zhang et al., 2021). MMC-PCFG aggregates multimodal features and achieved a substantial improvement over previous multimodal methods for grammar induction. To test whether a text-only baseline can achieve the same improvements as a video-enhanced method, we compare LC-PCFG to MMC-PCFG.

Setup. Following Zhang et al. (2021), we use three benchmarking video datasets for our experiments: Distinct Describable Moments (*DiDeMo*) (Anne Hendricks et al., 2017), Youtube Cooking (*YouCook2*) (Zhou et al., 2018) and MSRVideo to Text (*MSRVTT*) (Xu et al., 2016). DiDeMo consists of unedited, personal videos in diverse visual settings with pairs of localized video segments and referring expressions. It includes 32994, 4180 and 4021 video-sentence pairs in the training, validation, and test sets. YouCook2 contains 2000 videos that are nearly equally distributed over 89 recipes. Each video contains 3–16 procedure segments. It includes 8713, 969 and 3310 video-sentence pairs in the training, validation and test sets. MSRVTT is a large-scale benchmark for video understanding with 10K web video clips with 41.2 hours and 200K clip-sentence pairs in total. It includes 130260, 9940 and 59794 video-sentence pairs across all the data splits.

The extracted multimodal features (Zhang et al., 2021) include object features (SENet (Xie et al., 2017)), action features (I3D (Carreira and Zisserman, 2017)), scenes (Huang et al., 2017; Zhou et al., 2017), audio (Hershey et al., 2017), OCR (Deng et al., 2018; Liu et al., 2018), faces (Liu et al., 2016; He et al., 2016) and speech (Mikolov et al., 2013).

We run all experiments 4 times for 10 epochs each, with different random seeds. We report the mean and standard deviation of the C-F1 and S-F1

Table 3: **Transferring Learnt Grammar**. Models are trained on the 'Trainset' data and evaluated without additional training on the target benchmarks (DiDeMO, YouCook2 & MSRVTT) on the Sentence-level F1 (S-F1) and Corpus-level F1 (C-F1) metrics. All HowTo100M results are reported on 592k samples.

Method	Trainset	DiDeMo		YouCook2		MSRVTT	
		C-F1	S-F1	C-F1	S-F1	C-F1	S-F1
MMC-PCFG	DiDeMo	$55.0_{\pm 3.7}$	$58.9_{\pm 3.4}$	$49.1_{\pm 4.4}$	$53.0_{\pm 4.9}$	$49.6_{\pm 1.4}$	$53.8_{\pm 0.9}$
MMC-PCFG	YouCook2	$40.1_{\pm 4.4}$	$44.2_{\pm 4.4}$	$44.7_{\pm 5.2}$	$48.9_{\pm 5.7}$	$34.0_{\pm 6.4}$	$37.5_{\pm 6.8}$
MMC-PCFG	MSRVTT	$59.4_{\pm 2.9}$	$62.7_{\pm 3.3}$	$49.6_{\pm 3.9}$	$54.2_{\pm 4.1}$	$56.0_{\pm 1.4}$	$60.0_{\pm 1.2}$
MMC-PCFG	HowTo100M	$58.5_{\pm 7.3}$	$62.4_{\pm 7.9}$	$53.9_{\pm 6.6}$	$58.0_{\pm 7.1}$	$55.1_{\pm 7.0}$	$60.2_{\pm 8.0}$
PTC-PCFG	HowTo100M	$\mathbf{61.3}_{\pm 3.9}$	$\mathbf{65.2}_{\pm 5.3}$	$58.9_{\pm 2.5}$	$63.2_{\pm 2.3}$	$57.4_{\pm 4.6}$	$62.8_{\pm 5.7}$
LC-PCFG (Ours)	HowTo100M	$60.6_{\pm 5.2}$	$61.5_{\pm 6.1}$	$\mathbf{61.1}_{\pm 2.1}$	$\mathbf{65.2}_{\pm 1.4}$	$\mathbf{59.4}_{\pm 5.0}$	$\mathbf{63.0}_{\pm 5.8}$

scores.

4.2.1 Results

Table 2 compares grammar induction performance between C-PCFG, VC-PCFG (which incorporates visual signals), and MMC-PCFG (which incorporates signals from multiple extralinguistic modalities). LC-PCFG outperforms the video-regularized models for all three benchmark datasets.

4.3 Large-scale Video Pretraining

While MMC-PCFG incorporates multimodal inputs from small amounts of video data, other work has proposed to use larger scale video data for improve grammar induction (Zhang et al., 2022a). That work proposed Pre-Trained Compound PCFGs (PTC-PCFG), a multimodal method for grammar induction that obtains paired video and text inputs from captioned instructional YouTube videos in the *HowTo100M* dataset (Miech et al., 2019). Then a matching loss between these paired inputs is used as a regularizer during grammar induction. PTC-PCFG outperformed previous state-of-the-art multimodal grammar induction models.

To determine how PTC-PCFG compares to our text-only baseline, we train LC-PCFG with the captions of the *HowTo100M*dataset (Miech et al., 2019) without using any multimodal inputs. Following Zhang et al. (2022a), we induce a grammar from 592k samples of the HowTo100M train set and then evaluate on the three video-enhanced parsing benchmarks shown in Table 2 (DiDeMo, YouCook2, and MSRVTT).

Table 3 shows the test F1 scores for MMC-PCFG, PTC-PCFG, and LC-PCFG on the three video-enhanced parsing benchmarks. LC-PCFG outperforms MMC-PCFG, even in settings where LC-PCFG is trained on out-of-distribution HowTo100M dataset and MMC-PCFG is trained on in-distribution samples from each benchmark dataset. On the three benchmarks, LC-PCFG either outperforms or nearly matches PTC-PCFG.

Table 4: **Training Time Evaluation** for both image-based (top) and video-based (bottom) grammar induction methods. Run-time for both pre-extracting the embeddings ('Embedding') and model training ('Training') are reported. We pre-embed captions for LC-PCFG with two 24GB Titan RTX GPUs and pre-embed images/videos for models with a visual component. Training times for image and video results are benchmarked on a single 12G 2080 Ti and on 2× 32G V100s respectively.

PCFG Method	Embedding (hours)	Training (hours)
C-PCFG	-	7.6
VC-PCFG	0.25	13.3
LC-PCFG	2.0	8.0
C-PCFG	-	1.5
MMC-PCFG	>25	15
PTC-PCFG	>25	10
LC-PCFG (Ours)	2.5	1.7

4.4 Runtime Comparison

To compare the runtime of each method, we follow the setting of PTC-PCFG and calculate the time to extract embeddings and train each model. Table 4 shows the runtime for each model. LC-PCFG requires more time for embedding extraction than VC-PCFG, but LC-PCFG results 10× less time for embedding extraction time compared to video-enhanced models. LC-PCFG is 1.3 to 8.8 times faster to train than either image-enhanced or video-enhanced models.

5 Model Analysis

5.1 Perplexity-based Evaluation

To facilitate comparisons between methods, the results reported in Section 4 are based on the model selection procedure used in prior studies (Zhao and Titov, 2020; Zhang et al., 2021, 2022a). This model selection procedure trains models with different random seeds, and then uses validation C-F1 score to choose a subset of random seeds for test evaluation.

However, this model selection procedure assumes that gold parse trees are available during validation. To ensure that our results do not rely on having gold trees at validation time, we repeat our experiments but instead use perplexity (PPL) (Chen et al., 1998) to perform model selection:

$$PPL(X) = -\frac{1}{t}\sum_{i}^{t} log\ p(x_i|x_{<i})$$

where $X = (x_1, x_2, x_3, ..., x_t)$ is a tokenized sequence of words and $p(x_i|x_{<i})$ represents the log-likelihood of the ith token conditioned on the preceding tokens $x_{<i}$.

PPL allows us to perform model selection without relying on gold parse trees. We train models with 10 random seeds, and then use PPL to select the four best-performing seeds.

Table 5 shows test C-F1 performance on image-assisted parsing for experiments in which we used PPL to perform model selection. LC-PCFG consistently outperforms methods that use multimodal inputs. We observe the same results for video-assisted parsing (Table 6).

Table 5: **Unsupervised Run Selection Criterion for Unsupervised Grammar Induction**. Corpus-level F1 scores using validation set F1 ('Val-F1'), perplexity ('PPL'), and mean branching factor ('MBF', the average proportion between leaves in the right and left branches of nodes in each tree across the corpus). Unlike Validation-F1 based-selection, PPL and MBF do not require gold trees during validation.

PCFG Method	Run Selection Criteria		
	Val-F1	PPL	MBF
C-PCFG	60.1$_{\pm 4.6}$	52.0$_{\pm 7.5}$	56.8$_{\pm 9.3}$
VC-PCFG	61.3$_{\pm 2.6}$	55.3$_{\pm 10.2}$	51.0$_{\pm 13.4}$
LC-PCFG (Ours)	**67.2**$_{\pm 1.1}$	**67.2**$_{\pm 1.1}$	**65.3**$_{\pm 2.1}$

5.2 Branching Factor

We performed grammar induction over texts in English, which is a right-branching language. To investigate whether induced grammars capture the right-branching nature of English, we measure the branching factor of predicted parse trees. For each branch in each parse tree we measure the proportion of leaves under the right branch over those of the left branch. This proportion is then averaged across all nodes in the tree to produce an average score s. s is referred to as the branching factor of the tree ($s > 1.0$ means that the tree is overall right-branching, whereas $s < 1.0$ means that the tree is overall left-branching). Formally, for each parse tree t with $|t|$ nodes $n \in t$ we compute the mean over nodes' ratio of leaves in their right and left branches:

$$\text{MBF}(t) = \frac{1}{|t|}\sum_{n \in t}\frac{\text{CR}(n)}{\text{CL}(n)}$$

where CR and CL are the respective counts of leaves under the right and left branches of a node.

Table 7 shows the mean branching factor (MBF) for each model (computed over 10 seeds). We find that all models predict right-branching trees, and LC-PCFG has the lowest MBF (i.e., most right-branching trees).

To test whether MBF could be used as a run selection criteria, we used MBF instead of validation C-F1 score to select random seeds. For VC-PCFG and LC-PCFG, using MBF as a seed-selection method performs slightly worse than using PPL or validation C-F1 score as a seed selection method.

5.3 Model Ablations

To understand the effect of different model components on grammar induction performance, we perform a series of ablations on parsers trained on the MSCOCO dataset.

Table 6: **Unsupervised Run Selection Criterion for Unsupervised Grammar Induction**. Similar to Table 5, we report the results of run selection based on validation perplexity (PPL) for video benchmarks (Section 5.1).

PCFG Method	DiDeMo		YouCook2		MSRVTT	
	C-F1	S-F1	C-F1	S-F1	C-F1	S-F1
Compound (Kim et al., 2019)	40.4$_{\pm 10.1}$	42.1$_{\pm 9.1}$	38.6$_{\pm 7.2}$	42.8$_{\pm 7.7}$	49.2$_{\pm 3.8}$	53.1$_{\pm 4.0}$
Multi-modal (Zhang et al., 2021)	42.1$_{\pm 12.6}$	45.7$_{\pm 12.4}$	38.9$_{\pm 3.6}$	43.8$_{\pm 3.3}$	48.1$_{\pm 1.0}$	52.4$_{\pm 0.9}$
LC-PCFG (Ours)	**46.3**$_{\pm 6.9}$	**49.9**$_{\pm 7.3}$	**46.7**$_{\pm 1.1}$	**52.4**$_{\pm 0.8}$	**50.5**$_{\pm 4.0}$	**55.2**$_{\pm 4.4}$

Table 7: **MBF on image-assisted parsing.**

PCFG Method	MBF
C-PCFG	$3.4_{\pm 0.3}$
VC-PCFG	$3.4_{\pm 0.3}$
LC-PCFG	$2.5_{\pm 0.7}$

To understand the contribution of the latent variable z, we ablate z in both training and in evaluation.

First we perform inference-time ablations. During inference-time we zero out the latent variable z ('Zero-z'), or randomly shuffle z within an evaluation batch ('Random-z'). Next we perform training-time ablations. We train a C-PCFG model without latents ('Zero-Train', a vanilla neural PCFG model).

The performance of each ablated model is shown in Table 8. We find that inference-time ablations on the latent yield comparable performance to the default parsers, whereas omitting the latent during training yields reduced performance from the standard C-PCFG/LC-PCFG models. These results suggest that the latent variable may be largely ignored at inference time, but that it serves an important role in the learning process of the parser.

Lastly, we ablate the input sentences. We evaluate parsers when shuffling ('Shuffle') or zeroing out input caption embeddings ('Zero-C'), word embeddings for VC-PCFG or LLM embeddings for LC-PCFG). We find that ablating the input sentences substantially reduces test performance, suggesting that learned parsers do not merely degenerate to a learned prior at inference time.

Table 8: **Parser Ablations.** Corpus-level F1 scores for PCFG parsers under ablations. We compare the default formulations ('Default') to conditions zeroing out the latent z ('Zero-z'), randomly shuffling latents across a batch ('Random-z'), shuffling words in each caption ('Shuffle') or zeroing captions out ('Zero-C'), as well as zeroing out latents during training ('Zero-Train'). Note that C-PCFG and LC-PCFG are functionally equivalent in the Zero-Train condition because LLM features are only used in latent computation.

Ablation	Test Corpus F1		
	C-PCFG	VC-PCFG	LC-PCFG
Default	$60.1_{\pm 4.6}$	$61.3_{\pm 2.6}$	$67.2_{\pm 1.1}$
Zero-z	$60.3_{\pm 5.2}$	$60.6_{\pm 2.6}$	$67.2_{\pm 1.1}$
Random-z	$60.3_{\pm 5.2}$	$60.9_{\pm 2.5}$	$67.2_{\pm 1.1}$
Shuffle	$30.0_{\pm 0.7}$	$31.0_{\pm 0.9}$	$40.6_{\pm 1.0}$
Zero-C	$35.2_{\pm 16.1}$	$44.6_{\pm 7.6}$	$48.6_{\pm 7.5}$
Zero-Train	$57.1_{\pm 6.5}$	$58.8_{\pm 0.9}$	$57.1_{\pm 6.5}$

Method	Params (M)	C-F1	S-F1
Ours	**6.2**	$\mathbf{67.2}_{\pm 1.1}$	$\mathbf{67.8}_{\pm 1.2}$
Ours + ImgFeas	32.3	$59.2_{\pm 0.5}$	$59.4_{\pm 0.5}$

Table 9: **Adding visual features to LC-PCFG.** Incorporating visual features ("ImgFeas") into LC-PCFG degrades performance.

5.4 Re-adding Visual Signals to LC-PCFG

Section 4 showed that LC-PCFG outperforms previous multimodal approaches to grammar induction. But can re-adding visual signals to LC-PCFG further improve grammar induction? Such an improvement would suggest that multimodal signals contribute to grammar induction beyond what can be learned from text alone.

To test this possibility we re-trained LC-PCFG with the addition of paired visual features. Visual features were incorporated with the same multimodal regularization loss as used in prior work (Shi et al., 2019; Zhao and Titov, 2020). Table 9 and Table 10 show the effect of adding image and video signals to LC-PCFG.

Adding visual signals to LC-PCFG reduces performance compared to the text-only version of the model. We observe this degradation across all datasets, both for pixel-based and video-based visual features. We hypothesize that LC-PCFG may overfit to the added visual features and thereby obfuscate the signals in LLM embeddings.

6 Conclusion and Future Work

We propose LC-PCFG, a strong text-only baseline for grammar induction. LC-PCFG is a C-PCFG model that incorporates representations from LLMs trained on text alone. On four benchmarks for multimodal grammar induction, LC-PCFG outperforms several prior state-of-the-art multimodal approaches. Furthermore, adding visual inputs to LC-PCFG does not improve grammar induction. These experiments show that for grammar induction, the benefits of multimodal inputs can be achieved by more textual data. Our results challenge the notion that multimodal inputs are necessary for grammar induction.

Based on the result that LC-PCFG performs as well as methods trained on multimodal inputs, we speculate that representations from LLMs provide information that is redundant with information provided by multimodal inputs. Indeed, some work has shown that multimodal inputs improve grammar induction by providing signals of noun concreteness (Kojima et al., 2020). Other work has shown that LLMs acquire some knowledge of word concreteness (Ramakrishnan and Deniz, 2021). Thus, large amounts of textual training data may provide signals of word concreteness that obviate multimodal inputs for grammar induction.

7 Broader Impacts Statement

Our experiments show that a text-only baseline can outperform computationally intensive multimodal approaches for grammar induction. These results emphasize the promise of less computationally demanding methods, and we we hope they encourage the community to re-think the necessity of expensive multimodal approaches for certain tasks.

8 Limitations

Our results show that a strong LLM-based text-only baseline outperforms current state-of-the-art multi-modal grammar induction methods, and that adding visual features to this baseline does not further improve grammar induction. It is possible that future work will find better methods of combining visual features with LLMs, and that these methods will outperform any text-only approaches.

Abstract

Few-shot text classification has seen significant advancements, particularly with entailment-based methods, which typically use either class labels or intensional definitions of class labels in hypotheses for label semantics expression. In this paper, we propose EDEntail, a method that employs extensional definition (EDef) of class labels in hypotheses, aiming to express the semantics of class labels more explicitly. To achieve the above goal, we develop an algorithm to gather and select extensional descriptive words of class labels and then order and format them into a sequence to form hypotheses. Our method has been evaluated and compared with state-of-the-art models on five classification datasets. The results demonstrate that our approach surpasses the supervised-learning methods and prompt-based methods under the few-shot setting, which underlines the potential of using an extensional definition of class labels for entailment-based few-shot text classification. Our code is available at `https://github.com/MidiyaZhu/EDEntail`.

1 Introduction

Entailment-based text classification formulates heterogeneous classification tasks into a unified textual entailment problem (Dagan et al., 2005; Zhang et al., 2023a). Unlike traditional classification models that often encode class labels into numerical vectors such as one-hot vectors without considering label semantics (Zhang et al., 2018), the entailment-based approaches express the semantics of class labels in the hypothesis and classify the input texts through semantic entailment matching between the input texts (premise) and the hypothesis.

In hypothesis construction, class and subclass labels are commonly used as descriptive words for label semantics representation (Schopf et al., 2020). The intensional definition of a class label by WordNet, which specifies the necessary and sufficient conditions of the class label (Cook, 2009), is also frequently utilized to provide label information (Yin et al., 2019). While such use of label semantic representations in hypothesis might be effective for some tasks, it may fall short in others because **a single descriptive word or an intensional definition may not encapsulate all the semantic meanings within a label's domain, however, an effective hypothesis is expected to deduce various premises from the label domain.** As shown in rows 1-4 in Figure 1, hypotheses constructed from the premises' class label fail to properly entail the given four premises in both language model and human cognition. Besides, **descriptive words that exhibit clear semantic entailment relationships in human cognition may exhibit dissimilarity in the word embedding space** (Zhu and Mao, 2023). The relationship learned from the same descriptive word might vary much in the word embedding space with different contexts (see Section 4.7), hindering entailment feature learning. These limitations may weaken the entailment-based text classification performance, particularly in zero-shot or few-shot scenarios, when the test set lacks alignment with the hypothesis or when test samples fail to transfer the relation learned from the training samples.

To address the above limitations in label semantics expression, we propose to construct hypotheses using extensional definition of class labels. An extensional definition, which gives the meaning of a term by listing all descriptive words that fall under this term [1], provides explicit and diverse information of label semantics, facilitating semantic matching between different premises and a hypothesis.

As illustrated in the last row of Figure 1, the label extensional definition-based hypothesis can

Red means an entailment probability over 50% (entailment), while blue is below 50% (contradiction). PLM values are given by ‘roberta-large-mnli’ and Human values are averaged from 20 questionnaires.

entail all premises in both PLM and human cognition. This not only broadens the semantics of class labels but also ensures computational efficiency by avoiding multi-time subclasses matching. At the linguistic level, descriptive words in the extensional definition can collaboratively reduce polysemy issues by refining semantic meanings with each other. At the machine-learning level, descriptive words in the extensional definition can boost embedding consistency among each other through the contextual learning capacity (see Section 4.7).

To implement the extensional definition-based hypothesis construction, we develop a generation method to ensure the descriptive words selected are representative and concise, considering that there could exist too many example words in the extensional definition of a class label and inclusion of all of them in hypotheses is impractical while randomly selection may result in insufficient coverage of the example words.

Our contributions are summarized below:

1. By analyzing current entailment-based methods, we identify that the semantic expression of labels within the existing hypothesis construction tends to be limited. This results in narrow coverage of label information and word embedding inconsistency in feature learning, hindering the performance of premise-hypothesis entailment.

2. We present **EDEntail**, an entailment-based approach to few-shot text classification that utilizes extensional definitions of class labels. A systematic method for extensional definition generation is designed to provide diverse informative label signals in hypothesis construction for premise-hypothesis entailment relationship enhancement.

3. Extensive experiments across various classification datasets demonstrate that EDEntail outperforms other state-of-the-art models in few-shot settings.

2 Related Work

Meta-task exhibits significant potential in zero-shot or few-shot text classification tasks. It can be classified into the generative method and the discriminative method (Zhang et al., 2023a).

Generative methods treat every task as a text-to-text generation problem. Prompt-based method as a generation method that treats the meta-task as a masked language modeling (MLM) problem (Schick and Schütze, 2021; Gao et al., 2021). The MLM model predicts the masked token and then maps the predicted token to the label space through verbalizers. The prompt-based methods exhibit remarkable success in few-shot classification tasks (Zhao et al., 2021; Zhang et al., 2023b). Although knowledge can be incorporated into prompt verbalizer to enhance projection performance (Hu et al., 2022), the MLM model prediction may fall out of all possible associated candidates in verbalizer projection (Zhang et al., 2023a).

Discriminative methods like entailment-based method formulates meta-task under the framework of Natural Language Inference, which aims to determine the relationship between the premise and the hypothesis as ‘entailment’, ‘contradiction’, or ‘neutral’ (Yang et al., 2023). Recent studies in entailment-based methods include language model training (Devlin et al., 2018; Liu et al., 2019; Pàmies et al., 2023), pseudo-label training (Ge et al., 2023; Gera et al., 2022), classifier training (Xia et al., 2022; Zhang et al., 2023a; Wang et al., 2022b), and hypothesis engineering. The latter delves into the effective use of class label names (Plaza-del Arco et al., 2022) or intensional definitions (Lamanov et al., 2022), or strategies for incorporating the above label information into ensemble models (Basile et al., 2021). One challenge here is the relationship learning between premise and hypothesis with extremely limited training sources (Mayer et al., 2023), and another challenge is the construction of hypotheses suitable for all tasks (Gera et al., 2022). Enhancing classification performance and stability under limited training data is a focal research point (Ma et al., 2021; Min et al., 2022). In this paper, we propose a new method for hypothesis construction, aiming to address the aforementioned challenges in entailment-based text classification.

3 Proposed Methods

In this section, we introduce our proposed method, **EDEntail**, as depicted in Figure 2. This method comprises three key modules: extensional definition (**EDef**) generation by gathering and selecting relevant and representative descriptive words; hypothesis construction by ordering and formatting words of extensional definition; and entailment reformulation for few-shot text classification.

3.1 EDef Generation

Vocabulary Construction To establish EDef, we require a vocabulary for each class label that contains descriptive words to offer additional classification prompts.

Our goal for constructing the vocabulary is to elicit label semantics in an extensional and comprehensive manner. We found that the available open-sourced vocabularies are noisy with overlapping words between different classes. Thus, simply crawling descriptive words based on the concepts (like ConceptNet) might cause polysemy concerns in label names. Additionally, the WordNet synsets might cause irrelevant words upon extending the synonym search (e.g., 'anger' leading to 'temper' and then 'humour').

To build a high-quality vocabulary and ensure generalizability, we employ dictionary resources and ChatGPT[2]. We presume the class label names can describe the classification task and initialize them as the prompt words for descriptive words searching. We first extract the definitions of the class label words specific to our tasks from the Oxford English Dictionary[3]. Combining these definitions, we configure prompts within ChatGPT to obtain the label vocabulary. The prompts input for ChatGPT is listed in Appendix A. The vocabulary of each class label is assembled from words produced by ChatGPT with its corresponding prompts.

Descriptive Words Clustering To maximize the effectiveness of EDef in conveying semantics of label, we employ the K-means algorithm (Hartigan and Wong, 1979) to cluster descriptive words for each class label vocabulary in the embedding space. This reduces the number of descriptive words but guarantees comprehensive expression of the semantics of class labels.

Firstly, we obtain the [CLS] embedding of each descriptive word using Roberta-large with single-word input. Then, all the embeddings are clustered using the K-means clustering algorithm. For the i-th cluster U_i, the word that is the closest to the cluster centre is chosen as the representative word of the i-th cluster as shown in Eqn 1, where R_i is the centre of the i-th cluster, w is the word in U_i and $dist$ is the Euclidean distance.

$$O_i = argmin_{w \in U_i} dist(w, R_i) \tag{1}$$

This procedure is iterated multiple times, say ten times, and the ultimately selected extensional descriptive words are those representative ones with the silhouette score S close to 1 as shown in Eqn 2, where a_i is the average distance from O_i to other words in the same cluster, b_i is the minimum average distance from O_i to other words in the different clusters, and n is the cluster number.

$$S = average \sum_{i=1}^{n} \frac{b(i) - a(i)}{max\,\{a(i), b(i)\}} \tag{2}$$

The extensional descriptive words results of each label l are saved in a set (l, n) with each cluster number n defined in the K-means algorithm.

3.2 Hypothesis Construction

EDef Words Ordering After selecting representative words for extensional definition, the words are arranged based on a certain order to build hypotheses. The order of words in the sequence should, to the greatest extent, activate keywords in the premise. The knowledge used for ordering can be obtained from either the local dataset and the language model, or external sources. We next introduce two ordering methods.

---

[2] `https://chat.openai.com/`(free 3.5 version)

[3] `https://www.oed.com`

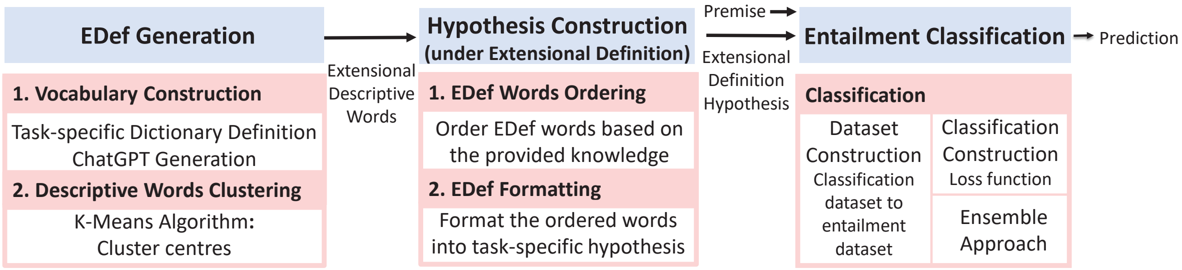

Figure 2: Overall architecture of EDEntail; it utilizes EDef in the hypothesis for entailment classification learning.

Ordering Based on Entailment Knowledge For local knowledge, considering that word features differ across datasets, we utilize the pre-trained language model's entailment knowledge between the dataset and relevant words to match the extensional definition with the specific dataset.

For each extensional descriptive word in (l, n), we first encode the word into the hypothesis, and then derive the average zero-shot entailment probability by entailing it with the pruned set $D^l \subset D_{train}$, where D_{train} is the few-shot training set. Finally, we order the extensional descriptive words in each (l, n) from the largest probability to the smallest entailment probability.

Ordering Based on Frequency Knowledge For external knowledge, we evaluate various sources like frequency, silhouette scores, and LLM prompting. Based on robustness and linguistic reliability, we choose word frequency knowledge for word ordering, which is 'the one common feature of nearly all measures of lexical prevalence created to date' (Egbert and Burch, 2023) and is vital in human word ranking experiments (Battig and Montague, 1969). We chose Google Ngram for its convenience and superior performance.

For each extensional descriptive word in set of (l, n), we search its latest usage frequency in Google Ngram Viewer[4] and order extensional descriptive words in each (l, n) from the most frequent to the least frequent one.

EDef Formatting To format the ordered descriptive words into the hypotheses, we connect the descriptive words in 4 ways as shown below, where e_j indicates the j-th descriptive word:

1. Connect with comma (EDef-CC):'$e_1, \ldots, e_n$'
2. Connect with space (EDef-CS):'$e_1 \ldots e_n$'
3. Connect with slash (EDef-CL): '$e_1 / \ldots / e_n$'
4. Connect with and (EDef-CA): 'e_1 and ... and e_n'

We use EDef-CC and EDef-CS because comma and space are the commonly used connectors in writing. We use EDef-CL and EDef-CA because slash / and "and" are often used to denote OR-relationship and AND-relationship, respectively (Woo, 2019). We design OR-relationship connection for tasks that cover coase but encompassing categorical delineations, like sentiment analysis. AND-relationship connection is for tasks focusing on detailed and fine-grained subjects, like emotion recognition

The extensional descriptive words ordered by entailment knowledge or frequency knowledge are encoded into the above formats with the hypothesis defined for each application. For example, for sentiment analysis, a positive EDef-CC hypothesis might be 'a proactive, constructive, relief, encouraging one'.

3.3 Entailment Classification

Since all classification tasks are viewed as entailment tasks and the labels in the entailment-based method are 'entailment' (E), 'contradiction' (C), and 'neutral' (N) instead of classification labels, we need to adapt the three-class entailment approach to accommodate multi-class objectives.

Reformulation We reconstruct the training classification datasets for entailment-based label consistency. A classification dataset by pairing each text with hypotheses formed from an EDef set. For each text-hypothesis pair, it assigns a label of 'entailment' if the EDef's label entails the text's label, and 'contradiction' otherwise. This results in a new dataset tailored for entailment approach analysis.

We reformulate the loss function to ensure that it is applicable in language models pre-trained on entailment datasets as Eqn 3, where $l(N)$, $l(C)$, and $l(E)$ represent the loss components (logits) derived from pre-trained language models (PLMs) after a softmax function. $loss_{BCE}$ is the Binary Cross Entropy Loss. We regard both 'neutral' and 'contradiction' as non-entailment labels that is rep-

---

[4] https://books.google.com/ngrams/json

resented by the one with the highest logits value from the PLM, aiming to mitigate any potential bias caused by the absence of a class in training [5].

$$loss = loss_{BCE}\left(max\left\{l(N), l(C)\right\}, l(E)\right) \quad (3)$$

The entailment classes map back to classification labels depending on the entailment probability between the text and the class of EDef in the hypothesis. The class with maximum entailment probability is chosen as the prediction of the text.

Ensemble Approach The majority of meta-tasks use a single type of hypothesis or prompt in both training and testing scenarios. They ensemble various models trained under diverse hypotheses or prompts to improve classification performance (Hu et al., 2022; Plaza-del Arco et al., 2022). Instead of ensembling models, we ensemble the hypothesis used in both training and testing sets. Specifically, each sample in the training set is connected with different hypotheses, respectively. Consequently, the testing set's sample pool is similarly expanded through connections with these hypotheses. The next section shows the performance of EDEntail with and without ensembling.

4 Experiments

In this section, we examine EDEntail's capabilities from the following perspectives: (1) The classification performance compared to other advanced classification models (Section 4.3); (2) The classification performance compared with other entailment-based models (Section 4.4); (3) The efficiency of utilizing limited training samples (section 4.5); (4) The performance under zero-shot setting (Section 4.6); (5) The effect of extensional definition on word embedding consistency (section 4.7); and (6) The classification performance compared with large language models (Section 4.8).

4.1 Datasets

We evaluate our method on two sentiment datasets: SST-2 (Socher et al., 2013) and CR (Ding et al., 2008), two emotion recognition datasets: MELD (Poria et al., 2018) (textual data only) and AMAN (Aman and Szpakowicz, 2008), and one question classification dataset: TREC-6 (Li and Roth, 2002).

The hypotheses that we use for each dataset are listed in Table 1. For each task, we provide four types of commonly used hypothesis structures.

The details of the dataset configuration can be found in Appendix B.

Task	Hypothesis	Class
SST2 CR	A <EDef>piece of work . A <EDef>one. A <EDef>piece. All in all <EDef>.	positive, negative
AMAN MELD	A <EDef>piece of work . A <EDef>one. A <EDef>piece. It was <EDef>!	angry, disgust, happy, neutral, surprise, sad, and fear
TREC	It is <EDef>. It was <EDef>news. Why <EDef>? Answer: <EDef>.	location, numeric, description, entity, human, and abbreviation

Table 1: The hypotheses used in each dataset. <EDef>is where the extensional definition is placed.

4.2 Experiment Settings

We conduct both zero-shot learning and few-shot learning experiments under each hypothesis. The experiments are under the N-way-K-shot training setting (Wang et al., 2022a) while the size of validation is the same as the size of the training set (Wang et al., 2021). In few-shot experiments, we designated N=5 and K=[1, 16, 32]. This means that for both the training and validation datasets, we randomly selected K samples for each label, repeating this process five times within five different training sets and corresponding validation sets. The EDef length n, namely the number of extensional descriptive words in EDef, is grid-searched over $\{1, \cdots, 10\}$ under few-shot settings. In few-shot or zero-shot learning experiments, the n for each label in one dataset is the same. The reported results are the average of five repeated experiments. The robustness is evaluated based on the standard deviation of the five results.

The compared baseline models are two supervised models: Finetune (FT) and DualCL (Kumar and Raman, 2022), three entailment-based models: EFL (Wang et al., 2021), Label-Entail (Plaza-del Arco et al., 2022) and IDef-Entail, and four prompt-based models: PET (Schick and Schütze, 2021), WARP (Hambardzumyan et al., 2021), LM-BFF (Gao et al., 2021), and KPT (Hu et al., 2022).

Detailed information on the baseline models and the EDEntail implementation is provided in Appendix C.1 and Appendix C.2, respectively.

4.3 Overall Results

Table 2 summarized the results of the baseline models and our approach under Frequency knowledge

---

[5] We exclude 'neutral' as there is no clear linguistic basis for manually identifying this category and the used PLM also excludes this category in exampled usage in huggingface.

Table 2: Fewshot experimental results: We report the average accuracy of 5 runs under the best format with standard deviation in parentheses. EDEntail-EK and EDEntail-FK represent our approach under Entailment knowledge and Frequency knowledge, respectively. The best results are marked in 'bold'. Marker ^ signifies ensemble results enhanced our approach.

and Entailment knowledge, respectively under the setting of few-shot learning.

Our method outperforms fine-tuning and supervised deep learning model (DualCL) by a dramatic margin under all situations. Surprisingly, the deep learning network breaks down under the few-shot setting with multi-class classification. Compared with other classification methods, EDEntail performs well and achieves further improvement under the ensemble approach. It works well in multi-class datasets with a maximum of 7.9% (AMAN), 4.1% (MELD) accuracy improvement in 1-shot settings and 4.5% (AMAN), 3.4% (MELD) improvement in 16-shot settings. In 32-shot setting, EDEntail wins all models with improvements of 1.3%, 1.5%, 1.2%, 3.7% and 1.5% on SST-2, CR, AMAN, MELD, and TREC respectively. By inspecting the standard deviation, we can see our approach achieves improved robustness even in 1-shot settings, which is contrary to other compared entailment-based methods. Under ensemble settings, our approach achieves a stronger performance, especially in 32-shot settings, with 1.8%, 1.4%, 4.2%, 11.2% and 4.4% performance improvement on SST-2, CR, AMAN, MELD, and TREC respectively while the robustness is sacrificed a bit. From the table, it is evident that while state-of-the-art entailment-based models perform less effective than prompt-based models in most experimental settings, our novel entailment-based approach shows a different story.

Significance Testing Regarding concerns about high standard deviation in the compared methods, Table 3 displays the p-values derived from comparing five accuracy results from our method and the SOTA model under the 1-shot, 16-shot, and 32-shot settings. Values highlighted in bold represent a statistically significant difference between the outcomes of the two models, with significance defined by a threshold of 0.1. This demonstrates the genuine effectiveness of our approach.

	SST2	CR	AMAN	MELD	TREC
1-shot	**0.01**	0.13	**3.66e-08**	**9.42e-05**	0.44
16-shot	0.22	**0.06**	**6.52e-03**	**0.067**	0.51
32-shot	**0.02**	**0.02**	**0.03**	**0.03**	**0.06**

Table 3: Significance testing between our method (EDEntail-EK-Ensemble) and the KPT model.

4.4 Few-shot Entailment Learning

The first task in our model is to entail each text with the hypothesis encoded with EDef. The performance at this level significantly influences the final classification results. Table 4 summarizes the performance of our model and the other three methods, EFL, Label-Entail and IDef-Entail. The results are obtained from the 32-shot experiments with the same experimental settings.

Model	SST2	CR	AMAN	MELD	TREC
EFL	92.2*	92.1*	80.4	51.4	80.8
IDef-Entail	89.0*	89.6*	69.0	66.0	87.1
Label-Entail	91.5*	90.3*	85.3	69.4	86.0
EDEntail-EK	**93.1***	**92.3***	86.2	**69.6**	**91.3**
EDEntail-FK	92.9*	91.2*	**87.8**	69.1	90.8

Table 4: Entailment experimental results: The marker * indicates the classification is a binary-class task as the entailment task.

When comparing the results in Table 2 and Table 4, we observe that for binary classification like SST-2 and CR, the results are closely aligned between the two tables. The classification performance is even better than the entailment performance, demonstrating that our classification loss function (see Eqn 3) effectively addresses the limitations with one entailment-based label removed. However, in multi-class classifications such as AMAN, MELD and TREC, the entailment performance significantly outperforms the classification performance due to the contradiction bias in the entailment task, wherein the number of contradiction samples in the text sets is $(|Label|-1)$ times higher than the number of entailment samples. While the bias is eliminated in binary-entailment tasks, it poses challenges in fine-grained tasks. Our method enhances feature learning by incorporating more label information into hypothesis. Compared with other entailment-based methods, it improves the alignment between entailment performance and classification performance.

4.5 Efficiency of Utilizing Limited Training Data

In few-shot learning, the model is expected to produce the best performance under limited training data. We conducted a comparison between the standard fine-tuning and our entailment-based approach under different numbers of samples selected as training data, ranging from 1 to the maximum number of samples that can be obtained for all classes in the available training set. The experimental setting aligns with the few-shot setting experiments. As shown in Figure 3, EDEntail consistently maintains a performance advantage over standard fine-tuning, particularly when the number of training samples is very small. In simple tasks like SST2 and CR, the performance saturates only with 32 examples, indicating the high efficiency of our proposed EDEntail in utilizing limited training data to achieve good performance.

4.6 Zero-shot Learning

The zero-shot setting experiments are conducted on the same test datasets as in experiments of the few-shot setting. We compare our method with fine-tuning, Label-Entail and IDef-Entail. We drop the Entailment knowledge since it originates from training sets, utilizing of which is unfair for zero-shot learning. Table 5 summarizes the experimental results. Obviously, zero-shot learning produces inferior performance to few-shot learning. Under the zero-shot setting, however, our method still surpasses the best performing label entailment method by 2.4%, 0.8%, 9.8%, 7.2%, and 10.9% in classification accuracy on the 5 datasets, respectively.

Model	SST2	CR	AMAN	MELD	TREC
Finetune	49.9	36.2	13.7	14.1	18.8
IDef-Entail	64.3	67.8	10.4	15.4	11.6
Label-Entail	86.3	89.2	33.0	28.3	24.3
EDEntail-FK	**88.7**	**90.0**	**42.8**	**35.5**	**35.2**

4.7 Analysis on Word Embedding Consistency

In the entailment-based model, learning a directional relation between premise and hypothesis is important (Mayer et al., 2023; Yang et al., 2023). When the training and testing samples exhibit higher feature similarity in keywords, there is a greater likelihood that the model will grasp a consistent relation during few-shot learning. Therefore, for the same label premises, high consistency of the embedding of keywords across different samples is beneficial for entailment-based feature learning.

To explore the effect of a single word versus extensional descriptive words used in the hypothesis on word embedding consistency, we conduct experiments on Bert[6] and Roberta[7]. The experiments evaluate 8 emotional classes that are usually studied in emotion recognition tasks. For each emotional class, we use ChatGPT to generate 30 sentences consisting of the class label itself and 3 non-emotional words ('I', 'the', and 'of'). The experiment of using a sequence of emotional words comprises two parts: 1). 6 synonyms, and 2). 6 antonyms.

We define inter-sentence same-word cosine similarity as the cosine similarity of the same word's embedding vector in different contexts. Our investigation focused on comparing inter-sentence same-word cosine similarity when a **single** extensional descriptive word is used in a hypothesis versus when a **sequence** of extensional descriptive words is used in constructing a hypothesis.

The results in Table 6 reveal that, in both language models, a higher inter-sentence same-word cosine similarity is achieved when a sequence of emotional words is used than when a single word or a sequence of opposite emotional words is used. Beyond the tabulated outcomes, added with a sequence of emotional words, the three non-emotional words in the same 30 sentences are found to have their inter-sentence same-word cosine similarity decrease or a comparatively lesser increase compared to the emotional words.

Addition Method	sadness	joy	anger	disgust	fear	surprised	shame	guilt
				Bert				
Without	0.8829	0.8286	0.8127	0.7169	0.8507	0.8045	0.7873	0.8459
Single	0.8857	0.8407	0.8322	0.7966	0.8676	0.8169	0.7876	0.8449
Seqence (same emotion)	**0.9079**	**0.8752**	**0.8800**	**0.8376**	**0.8969**	**0.8526**	**0.8149**	**0.8554**
Seqence (opposite emotion)	0.8887	0.8640	0.8434	0.8191	0.8795	0.8392	0.8004	0.8471
				Roberta				
Without	0.9933	0.9933	0.9876	0.9886	0.9924	0.9847	0.9858	0.9899
Single	0.9933	0.9933	0.9860	0.9887	0.9896	0.9855	0.9879	0.9918
Seqence (same emotion)	**0.9942**	**0.9941**	**0.9881**	**0.9922**	**0.9934**	**0.9912**	**0.9914**	**0.9954**
Seqence (oppsite emotion)	0.9919	0.9923	0.9869	0.9871	0.9822	0.9858	0.9835	0.9883

Table 6: Descriptive words addition experiments. The results are the cosine similarity between the same evaluated emotional words in 30 sentences under different addition methods.

From the above results, we draw the following conclusions:

1. The use of a sequence of extensional descriptive words results in improved inter-sentence same-word cosine similarity compared with the use of a single word such as a class label or its synonyms.
2. The use of a sequence of relevant descriptive words can generate higher inter-sentence same-word cosine similarity among other extensional descriptive words than when a sequence of irrelevant descriptive words.

Consequently, our suggested approach EDEntail, by incorporating an extensional definition, which comprises a sequence of extensional descriptive words, into the hypothesis, holds the potential to enhance the performance of few-shot text classification by improving keyword embedding consistency.

4.8 Comparison with Large Language Models

In light of the impressive performance and efficiency exhibited by large language models (LLMs), we conduct a comparative analysis of our method against three LLMs: GPT-3.5 (175B parameters) (Ouyang et al., 2022), Llama2 (Touvron et al.,

---

[6] `https://huggingface.co/bert-base-uncased`

[7] `https://huggingface.co/roberta-large`

2023) 7B and 13B, within a few-shot learning framework. Listed in Table 7, our model, EDEntail, with only 335 million parameters, outperforms larger models GPT-3.5, Llama2-13b, Llama2-7b. The results are the average of five tests using the same dataset as Table 2 but without entailment reformulations. The detailed model settings and used prompts for task classification are summarized in Appendix C.1.

	SST2	CR	AMAN	MELD	TREC
GPT-3.5	94.3	88.3	62.4	53.0	55.8
Llama2-13b	87.7	84.3	38.1	46.1	48.2
Llama2-7b	82.2	77.4	34.2	41.8	45.2
EDEntail	**94.7**	**93.5**	**75.3**	**53.5**	**93.8**

Table 7: Fewshot experimental results comparison with large language models. Our results are the best results reported from Table 2.

5 Conclusion

In this paper, we propose EDEntail, a novel entailment-based method with an extensional definition (EDef) for few-shot text classification. We leverage a number of extensional descriptive words encoded in the hypothesis to offer diverse label definitions, enhancing the feature similarity between train and test samples in few-shot entailment relation learning. A structured method is provided for the instruction of EDef generation and hypothesis construction. As a new method in providing label semantic information in hypothesis, extensive experiments show that EDEntail can achieve competitive classification performance with stronger robustness and sample efficiency.

6 Limitations

As discussed in Section 4.4, an entailment-based approach is not immune to potential biases arising from the uneven distribution of entailment and contradiction samples in multi-class test sets. To address this issue, we have implemented careful measures in our few-shot training method to achieve a balanced representation of both entailment and contradiction samples by ensuring that each label's extensional definition is represented as a contradiction sample at least once in train and valid set. However, further research is required to address the issue of sample number bias between entailment and contradiction in multi-class tasks.

Ethics Statement

This work introduces EDEntail, an entailment-based method for few-shot text classification. All experiments conducted in this study utilize publicly available datasets and codes. To facilitate future reproduction without unnecessary energy consumption, we will make our codes openly accessible.

Dataset Settings All datasets are split based on the N-way-K-shot training setting. Especially, as AMAN has no provided testing set, its testing sets are randomly selected with the size of 20% of the whole dataset and no overlapping of the corresponding training and validation sets five times for repeated experiments. The zero-shot learning experiments are implemented under the same dataset settings as the few-shot learning experiments.

In the construction of the training and validation sets, we maintain an equal balance between entailment and contradiction samples, ensuring $|E| : |C| = 1 : 1$. This approach aims for equitable representation in both categories. Furthermore, during the development of these sets, each label's extensional definition is represented at least once as a contradiction sample. This strategy is designed to enhance the learning process, facilitating a comprehensive understanding of every feature associated with the extensional definitions.

C Appendix C

C.1 Baseline Model Experimental Settings

Detailed information on baseline models and the corresponding re-run experimental settings for few-shot (1, 16, and 32) and zero-shot learning experiments.

Fine-tuning (FT) The traditional fine-tuning method inputs the hidden embedding of [CLS] into a pre-trained language model (PLM) to make predictions. In our re-run experiments, the PLM is

‘Roberta-large’. The learning rate for all datasets is 1e-5.

DualCL A traditional supervised deep-learning model under BiLSTM-CNN dual-channel structure for text classification. In our re-run experiments, the PLM model is ‘Roberta-large’ with a learning rate of 1e-5. The other setting defaulted in [8].

EFL A few-shot learning method by reformulating all classification tasks as an entailment task. In the re-run experiment, the hypotheses for datasets “It was <LabelDef>" as mentioned in its paper. The extensional descriptive words in the hypothesis for SST-2 and CR are ‘positive’ and ‘negative’, for AMAN and MELD are ‘joy’, ‘anger’, ‘sadness’, ‘surprise’, ‘disgust’, ‘others’, and ‘fear’ and for TREC are ‘expression’, ‘entity’, ‘description’, ‘human’, ‘location’ and ‘number’. The PLM model is ‘Roberta-large’. To fair comparison, there is no data augmentation in EFL implementation.

Label-Entail The entailment-based method with label word in the hypothesis. Based on the suggested methodology, we refine the model using our few-shot training datasets and evaluate our test sets. In the re-run experiment, the hypotheses for datasets are the same as ours. The label words are the same as EFL. The PLM model is ‘roberta-large-mnli’.

IDef-Entail The entailment-based method with intensional definition sourced from WordNet (Miller, 1995) in the hypothesis. Same as Label-Entail, we refine the model using our few-shot training datasets and evaluate our test sets. In the re-run experiment, the intensional definition is label WordNet definition. The PLM model is ‘roberta-large-mnli’.

PET The basic prompt-tuning method uses the class name as the prompt word for each class. The prompt words in our re-run for SST-2 and CR are ‘great’ and ‘terrible’, for AMAN and MELD are ‘joy’, ‘anger’, ‘sadness’, ‘surprise’, ‘disgust’, ‘others’, and ‘fear’ and for TREC are ‘ Expression’, ‘ Entity’, ‘ Description’, ‘ Human’, ‘ Location’ and ‘ Number’. In re-run experiments, the results are obtained from the prompts reported in the paper and other experiment settings are defaulted in [9].

WARP A prompt-based method by selecting the best prompt with training data in the continuous embedding space. The prompt tokens are trainable by the classification result. For re-run experiments, the manual verbalizer for SST-2 and CR is the same as IMDB given in [10]. The manual verbalizers for AMAN, MELD, and TREC are the same as ours. The initialization is the word embedding of the name of the class. The other experimental settings default in [10].

LM-BFF A prompt-based fine-tuning method with automatically generated prompts. This method follows in-context learning with training examples as demonstrations in the input context. For re-run experiments, the number of demonstration samples is one. The prompt is “It was [MASK]." The mask token mapping is the same setting as PET. Other experiment settings are defaulted in [11].

KPT A knowledgeable prompt-tuning method. KPT expands the label verbalizer with external knowledge bases to make the prediction mapping covers various perspectives of the label words. For re-run experiments, the prompts used in KPT are the same as our experiments. The knowledge verbalizer and prompts for SST-2 and CR are the same as IMDB given in [10]. The knowledge verbalizer and prompts for AMAN, MELD, and TREC are the same as our verbalizer and prompts. The other experimental settings default in [10].

GPT-3.5 We use ’gpt-3.5-turbo-16k’ with 16,385 tokens available. Temperature sets to 0. The prompt for SST-2 and CR is ‘Review:<example>’, ‘Sentiment Type:<label>’, AMAN and MELD is ‘Review:<example>’, ‘Emotion Type:<label>’, and TREC is ‘Question:<example>’, ‘Answer Type:<label>’. In 32-shot settings, all samples can be inputted in the prompt as <example> and <label> is the task-specific classification label.

Llama2 We use Llama2 7b[12] and 13b[13] with 4096 tokens available. In 32-shot settings, prompts exceeding model token limits were truncated. The prompt for task classification is the same as GPT-3.5.

C.2 EDEntail Experimental Settings

The reported results are the average five times randomly repeated performance. The non-ensembled result is the optimal accuracy among the evaluated

hypotheses. The ensembled result uses all hypotheses in both training and testing as we introduced in section 3.3.

For baseline models' settings, all the compared models are under the same training and testing datasets as our model and reported the average accuracy under five repeated. For models with more than one prompt or hypothesis, the compared results are reported under the average accuracy across all prompts or hypotheses for a fair comparison.

For EDef length n (extensional definition boundary), if the size of the vocabulary for one label is smaller than 10, n is grid-searched from 2 to the largest number of the smallest vocabulary size. The experiments are run under a learning rate of 1e-5 with a batch size equal to 10 under the 1-shot setting, which appears to be effectively transferable to other few-shot scenarios, albeit with a minor decrease in performance. Regarding the time efficiency, the processing times for SST2, CR, AMAN, MELD, and TREC datasets were 44, 29, 46.5, 56.7, and 13.7 minutes respectively, which we believe is within an acceptable range.

The detailed information for the length and format of the EDef that we used in the few-shot (1, 16, and 32) learning experiment, few-shot learning (ensemble) experiment, and zero-shot learning experiment are summarized in Table 8 with descriptive words usage in Table 9. The pre-trained language model is 'roberta-large-mnli'[14]. All experiments are implemented under Python 3.7 environment and PyTorch 1.12.1. with Cuda version 11.3, GPU NVIDIA RTX A5000.

What Makes Math Word Problems Challenging for LLMs?

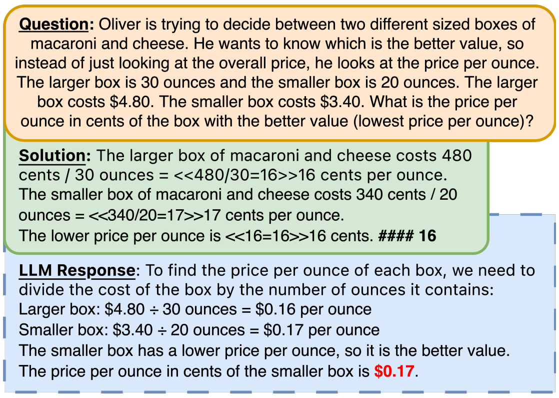
Abstract

This paper investigates the question of what makes math word problems (MWPs) in English challenging for large language models (LLMs). We conduct an in-depth analysis of the key linguistic and mathematical characteristics of MWPs. In addition, we train feature-based classifiers to better understand the impact of each feature on the overall difficulty of MWPs for prominent LLMs and investigate whether this helps predict how well LLMs fare against specific categories of MWPs.[1]

1 Introduction

In recent years, large language models (LLMs) have not only demonstrated huge potential across a range of core NLP tasks (Zhao et al., 2023; Brown et al., 2020; Radford et al., 2019, inter alia), but also exhibited a number of emergent abilities, such as an ability to solve mathematical puzzles (Wei et al., 2022). Math word problems (MWPs) have been proposed as a challenging testbed for LLMs, as they test not only the ability of the models to deal with purely mathematical expressions, but also their reasoning and natural language understanding abilities (Wang and Lu, 2023; Cobbe et al., 2021; Patel et al., 2021; Miao et al., 2020, inter alia). Experiments show that even quite powerful LLMs are still challenged by MWPs (Cobbe et al., 2021). At the same time, most previous work has either focused on evaluation of LLMs' performance on MWPs or on changes in their behavior in response to progressive-hint prompting, prompt paraphrasing or similar approaches (Norberg et al., 2023; Raiyan et al., 2023; Zheng et al., 2023; Zhu et al., 2023), while an in-depth analysis of what exactly makes math problems challenging for LLMs is lacking. We aim to address this knowledge gap.

A recent study by Almoubayyed et al. (2023) demonstrates a strong connection between reading skills and math outcomes in students. We hypothesize that LLMs' ability to solve MWPs correctly may similarly rely on: (1) *the linguistic complexity* of the questions; (2) *the conceptual complexity* of the tasks (e.g., the number of steps and types of math operations involved); and (3) *the amount of real-world knowledge* required to solve the tasks. Supporting this intuition, our preliminary analysis of the `GSM8K` dataset (Cobbe et al., 2021) suggests that relatively short questions with a small number of described entities, a few calculation steps and a limited range of operators involved in the solution (e.g., *Mark is 7 years older than Amy, who is 15. How old will Mark be in 5 years?*) are typically answered correctly by a range of LLMs. At the same time, long questions requiring real-world knowledge (e.g., how many cents there are in a dollar) and extended natural language understanding (NLU) (e.g., interpretation of a lower price) pose challenges for LLMs (see Figure 1).



Question: Oliver is trying to decide between two different sized boxes of macaroni and cheese. He wants to know which is the better value, so instead of just looking at the overall price, he looks at the price per ounce. The larger box is 30 ounces and the smaller box is 20 ounces. The larger box costs $4.80. The smaller box costs $3.40. What is the price per ounce in cents of the box with the better value (lowest price per ounce)?

Solution: The larger box of macaroni and cheese costs 480 cents / 30 ounces = <<480/30=16>>16 cents per ounce.
The smaller box of macaroni and cheese costs 340 cents / 20 ounces = <<340/20=17>>17 cents per ounce.
The lower price per ounce is <<16=16>>16 cents. **#### 16**

LLM Response: To find the price per ounce of each box, we need to divide the cost of the box by the number of ounces it contains:
Larger box: $4.80 ÷ 30 ounces = $0.16 per ounce
Smaller box: $3.40 ÷ 20 ounces = $0.17 per ounce
The smaller box has a lower price per ounce, so it is the better value.
The price per ounce in cents of the smaller box is **$0.17**.

Figure 1: A response from `Llama2-70B` to a lengthy math problem that involves NLU challenges.

In this paper, we formulate and investigate two research questions: (1) *Which characteristics of the input math word questions make them complex for an LLM?* and (2) *Based on these characteristics, can we predict whether a particular LLM will be able to solve specific input MWPs correctly?*

2 Methodology

Data We use the `GSM8K` dataset (Cobbe et al., 2021), divided into 7,473 training and 1,319 test instances, because of the high quality of human-generated MWPs. This dataset contains a diverse set of problems in English with minimal amount of recurring templates. Furthermore, the difficulty level of the problems is tailored for LLMs, allowing for a wide variation in correctness across models and question types, which is ideal for our feature-based analysis.

Approach We collect solution attempts from several LLMs to the questions from the `GSM8K` training and test sets. Next, we train statistical classifiers on a filtered subset of questions to predict if they are consistently solved correctly or incorrectly across multiple runs of the models. Our approach is relatively simple but it allows us to investigate which of the features are most indicative of the challenges LLMs face in solving math problems.

LLMs We select an array of open-source models for our experiments. We use `Llama2` (13B and 70B) (Touvron et al., 2023), `Mistral-7B` (Jiang et al., 2023) as its performance on math tasks has been found to match models several times its size, and `MetaMath-13B` (Yu et al., 2023) as it is fine-tuned on math QA data in contrast to the other general-purpose models in the pool.

Features We analyze and experiment with the features extracted from MWP questions and their respective expected solutions. This way, the features remain grounded in the dataset, allowing our approach to be applied to any LLM. The features are broadly grouped into the following categories:[2]

1. **Linguistic features** focus on the phrasing of the question. These include the length of the question, sophistication of the vocabulary, syntactic complexity, instances of coreference, and overall readability. Note that the linguistic features are only extracted from the question body as the phrasing of the gold solution has no impact on the expected answer.
2. **Mathematical features** cover the math arguments, operations, and reasoning steps required to solve the questions. These include the number and diversity of the math operations in the solution body. Arguments provided in the question but not utilized in the solution also require mathematical reasoning for them to be disregarded as noise. Note that while a question can be phrased in many ways (affecting its linguistic features), the underlying math operations and reasoning steps (thus, the mathematical features) remain unchanged.
3. **Real-world knowledge & NLU based features** indicate the amount of extraneous information needed to solve the task that is not provided explicitly in the question. This may include how many days there are in a month or the interpretation of "half" as $1/2$.

Model	**Success Rate** (N=1,319)	
	μ	σ
Llama2-13B	0.3724	0.3681
Llama2-70B	0.5609	0.3941
Mistral-7B	0.3627	0.3309
MetaMath-13B	0.6373	0.3816

Table 1: Success rates for solution attempts per LLM

3 Experiments

3.1 Solution Generation

To collect solution attempts from the LLMs, we use a simple task-specific prompt (See Appendix B) to minimize any bias imposed on the model generation. We query each LLM 5 times on each question with varying generation seeds and a temperature of 0.8. A soft-matching strategy is then used to extract the final answer from the solutions. Using each LLM's attempted solutions, every question is assigned a mean **success rate** using `(# of correct answers) / (# of solution attempts)`.

3.2 Success Rate Prediction

We train and evaluate classifiers on their ability to predict for input test questions whether they will be answered correctly or incorrectly by a specific LLM. We also train and evaluate classifiers on the **intersection** set of questions, which are either solved correctly by *all* or by *none* of the LLMs.

Models We use Logistic Regression, Decision Tree, and Random Forest classifiers, which allow us to extract relative feature importance with ease.

Data For high confidence samples, we use the training and test subset from `GSM8K` where the sampled success rate is either 1.0 (**always** correct) or

---

[2] The complete list of features extracted, their description and further statistics can be found in Appendix A

0.0 (**never** correct). The distribution of the LLM-specific splits is detailed in Table 2.

Preprocessing & Optimization We employ several preprocessing steps including dropping highly correlated features, class-balancing, and feature scaling. We also perform a hyperparameter search for each model to maximize performance on unseen data. See Appendix C for more details.

4 Results

4.1 Success Rate Distribution

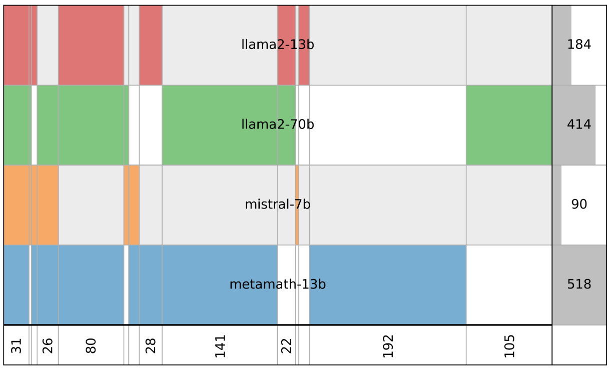
We report the mean success rates for each LLM on `GSM8K`'s test set in Table 1.[3] We observe that `Llama2` 13B and 70B follow the expected order of scores along their respective parameter counts. `Mistral-7B` scores similar to the 13B `Llama2` model, and the additional fine-tuning allows `MetaMath-13B` to outperform the other models (including the 70B `Llama2`). Figures 2a and 2b respectively capture the number of questions *always* and *never* answered correctly by each LLM. Overall, `MetaMath-13B` has the lowest number of incorrectly and the highest number of correctly answered questions across the tested LLMs.

4.2 Classification Results

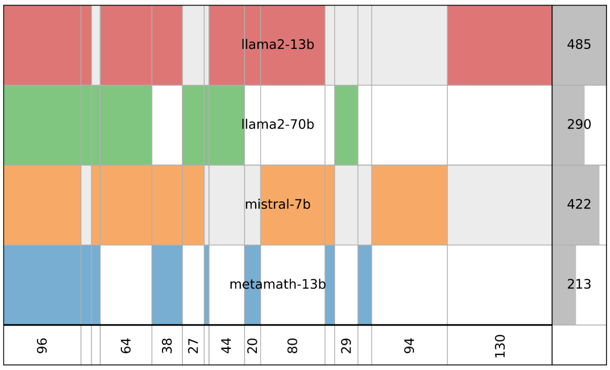
To compare classifiers' performance, we report the accuracy and macro-F1 scores for each classifier and LLM-specific test data split (see Table 2). We observe that Random Forest outperforms other classifiers across most solution sets.

At the same time, we also note that, due to significant class imbalance, this task is not easy for the classifiers, with the best accuracy scores across LLM splits being in the range of $71.7\% - 81.4\%$. The small number of questions always or never solved correctly by any LLM speaks to the models' varying capabilities (and potential points of brittleness). We include additional analysis of the results in Appendix D.

For comparison, we also report the classification results for a fine-tuned RoBERTa-base model (Liu et al., 2019) for the same training and evaluation sets (tuned on the question and gold solution as input text; see Appendix C for more details) in Table 2. We note that the Transformer base classifier scores on a par or a few points above the best statistical classifier, i.e., Random Forest, suggesting that the proposed feature-based classifiers are not far behind token-level contextual models for this task.



(a) Always correct



(b) Never correct

Figure 2: Number of questions from the `GSM8K`-test (a) always and (b) never answered correctly by each LLM. The rows in each figure correspond to individual LLMs, with the counts on the right denoting the total number of questions always (or never) answered correctly by each LLM. The counts at the bottom denote the number of questions in each subset of LLMs.

4.2.1 Feature Importance

The statistical classifiers used in our experiments allow us to estimate the importance of each feature and its contribution to the classification performance. We report the top 10 features with the highest aggregate ranks across LLM data splits and classifiers in Table 3. We use mean rank here as a proxy for relative importance across features, and the respective standard deviations indicate how spread out this importance is across classifiers and queried LLMs. We observe that a greater number (`Gx_op_unique_count`) and diversity (`Gx_op_diversity`) in math operations, and the use of infrequent numerical tokens in the question and solution body (`Qx_` & `Gx_mean_numerical_word_rank`) impact the success rate. The list also contains linguistic fea-

---

[3] Our results generally align with those reported previously for these models.

Class Distribution

Table 2: Class-wise distribution and classification results for different LLMs. "Intersection" refers to questions always or never solved correctly by all or any LLM, respectively. All classification results are mean values across 5 runs with varying initialization seeds. The best results for feature-based classifiers are highlighted in bold.

Type	Feature Name	Rank (N=23)	
		μ	σ
L	Qx_np_count	1.2	0.45
M	Qx_mean_numerical_word_rank	4	1.87
M	Gx_op_unique_count	4	2.65
M	Gx_op_diversity	4.4	2.30
M	Gx_mean_numerical_word_rank	4.4	1.82
L	Qx_mean_word_rank	5.6	1.82
L	Qx_flesch_kinkaid_grade	6	1.87
W	Gx_world_knowledge	7.8	2.28
L	Qx_constituency_tree_depth	9.6	1.95
M	Gx_op'+'_count	11.6	3.97

Table 3: Feature importance ranks across classification models and LLM-wise data subsets.

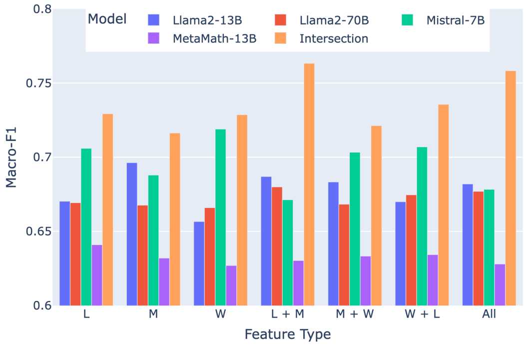

Figure 3: Results of the ablation studies across feature types (`L` – Linguistic, `M` – Mathematical, `W` – World Knowledge & NLU). Each bar represents the mean macro-F1 score over all three classifier models.

tures based on the phrasing of the questions: longer questions with a high number of noun phrases (`Qx_np_count`), mean syntactic depth (`Qx_constituency_tree_depth`), and readability grade (`Qx_flesch_kinkaid_grade`) are also difficult for LLMs to solve. Additionally, the need for extraneous information (`Gx_world_knowledge`), such as conversion units for time, distance, or weight, can make a question challenging. We also report value thresholds at which each feature affects the success rate significantly: see the results of the Student's *t*-test and *p*-values in Table 7 in Appendix D.

4.2.2 Ablation Studies

To further measure the impact of each feature type, we report classification scores along different feature-type subsets in Figure 3. We note that the feature set with all types (`L+M+W`) is not optimal for classification. For instance, the questions answered by `Llama2-13B` are best classified using only mathematical features (`M`). The best-performing classifiers for `Llama2-7B`, `MetaMath-13B`, and the intersection set either solely use linguistic features (`L`) or both linguistic and math features (`L+M`), whereas the world knowledge & NLU feature set if sufficient for `Mistral-7B`.

4.2.3 Impact of Linguistic Features

In order to better gauge the impact of linguistic features on the success rate, we cluster questions by mathematical features. We fit a KMeans clustering model[4] on all math features for each question in the `GSM8K` training set with a target cluster count of 100. This helps group together questions from the data, wherein the math features hardly vary within each question subset (or cluster). Thus, vari-

---

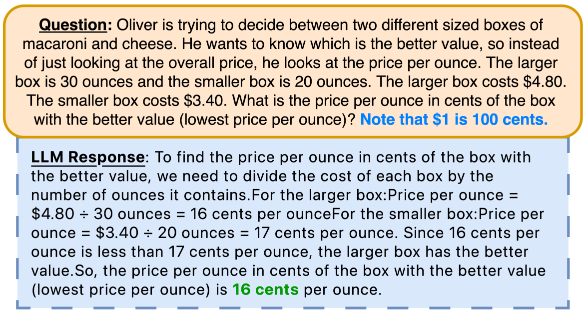
Cluster		Feature	Spearman(ρ)
ID	Size		
09	27	Qx_constituency_tree_depth	-0.64***
24	14	Qx_mean_word_rank	-0.82***
63	62	Qx_token_length	-0.42***
		Qx_word_length	-0.43***
96	51	Qx_flesch_kinkaid_grade	-0.51***

Table 4: Cluster-wise feature correlations. The cluster count represents the number of questions included in the respective cluster. The p-value for all reported correlation values is <0.001 (marked by '***').

ations in success rate across the questions within a cluster can be more clearly attributed to other, i.e., linguistic types of features. We report some notable Spearman correlation values between the linguistic feature values within a cluster and the corresponding success rates in Table 4. The strong and significant feature-wise negative correlations suggest that for a relatively fixed set of math features, questions with greater length, nesting, lexical rank, and reading grade become more challenging for LLMs to solve. Note that this form of analysis on feature-based minimal pairs is extractive in nature and may, to a certain extent, be restricted to the question types in the `GSM8K` dataset. For a more exhaustive analysis for each feature, generative approaches to furnish question paraphrases with the desired set of linguistic features need to be employed.

5 Conclusions

This work aims to identify what aspects of MWPs make them difficult for LLMs to solve. To this end, we extract key features (spanning linguistic, mathematical, and real-world knowledge & NLU-based aspects) to predict whether several LLMs can reliably solve MWPs from `GSM8K`. We find that questions with a high number and diversity of math operations using infrequent numerical tokens are particularly challenging to solve. In addition, we show that lengthy questions with low readability scores and those requiring real-world knowledge are also seldom solved correctly. Our future work will rely on these findings to make informed modifications to questions in order to study the impact on LLMs' reasoning and MWP-solving abilities. Figure 4 provides an example of an informed modification, which leads to improved LLM performance.



Question: Oliver is trying to decide between two different sized boxes of macaroni and cheese. He wants to know which is the better value, so instead of just looking at the overall price, he looks at the price per ounce. The larger box is 30 ounces and the smaller box is 20 ounces. The larger box costs $4.80. The smaller box costs $3.40. What is the price per ounce in cents of the box with the better value (lowest price per ounce)? **Note that $1 is 100 cents.**

LLM Response: To find the price per ounce in cents of the box with the better value, we need to divide the cost of each box by the number of ounces it contains.For the larger box:Price per ounce = $4.80 ÷ 30 ounces = 16 cents per ounceFor the smaller box:Price per ounce = $3.40 ÷ 20 ounces = 17 cents per ounce. Since 16 cents per ounce is less than 17 cents per ounce, the larger box has the better value.So, the price per ounce in cents of the box with the better value (lowest price per ounce) is **16 cents** per ounce.

Figure 4: Solution attempt by `Llama2-70B` on the question from Figure 1, with the required real-world knowledge explicitly specified.

Limitations

With the rapidly growing body of research on LLMs, this study necessarily has several limitations, which we discuss below.

Limited set of LLMs tested We consider it important to test and report results with a diverse set of open-source LLMs, which motivated the selection of the specific models included in this study. At the same time, we do not claim this study to be comprehensive with respect to the range of LLMs tested and in future work, we plan to include more LLMs in this research.

Limited number of classification models As the main goal of this study is to identify aspects of the MWPs that make them challenging for LLMs to solve, we have opted for a feature-based approach and a range of traditional classification models as opposed to less transparent but more powerful black-box algorithms. Our results show that the prediction task is challenging for the traditional classifiers that we used, and it is likely that these results can be improved with stronger classification models.

Limitations of the dataset In this work, we have focused on a single MWP dataset (`GSM8K`) due to its unique properties, namely the high quality of the questions, high diversity of the tasks (including linguistic diversity of the questions), and moderate difficulty of the math problems covered (Cobbe et al., 2021). At the same time, we recognize that the results we report in this work may be limited in certain ways to the dataset on which we report them. Our future work will apply this approach to other available MWP datasets (Kim et al., 2023; Wang and Lu, 2023; Patel et al., 2021; Miao et al., 2020) to verify the consistency of the findings.

Impact studies Finally, whilst we have identified aspects of the MWPs that make them challenging for LLMs to solve, we admittedly presented only one example (see Figure 4) where acting upon one of the identified aspects improves the output of an LLM. While a thorough investigation of the impact of such informed modifications is outside the scope of the current paper, such experiments will follow in future work to demonstrate the practical usefulness of the identified MWP aspects.

Ethics Statement

We foresee no serious ethical implications from this study.

Acknowledgments

We are grateful to the Campus Super Computing Center at MBZUAI for supporting this work. We also thank the anonymous reviewers for their valuable feedback.

A Feature Details

Below, we describe the features used in our study and how they were extracted.

(1) Linguistic features (L) include 9 features pertaining to the question (Q) itself:

- **Qx_token_length**: The number of tokens in the tokenized version of the question body. We apply each LLM's respective tokenizer from `HuggingFace` to extract this feature.
- **Qx_sentence_length**: The number of sentences detected in the question body. We use the `sentence_splitter` Python library to extract this count.
- **Qx_word_length**: The number of space-separated segments (words) in the question body.
- **Qx_flesch_kinkaid_grade**: The readability grade of the question body as per the FKGL metric (Flesch, 1948). We use the `textstat` Python library to extract this feature.
- **Qx_mean_word_rank**: The mean vocabulary rank (in decreasing order of frequency) of the tokens in the question body. We use the same tokenizer set used for `Qx_token_length`.
- **Qx_constituency_tree_depth**: The mean depth of the constituency tree across the sentences in the question body. We use Stanford's `Stanza` parsing library to parse the questions.
- **Qx_np_count**: Number of distinct noun phrases detected in the question body. We extract this from the constituency parse collected from the `Stanza` parser.
- **Qx_prp_count**: Number of prepositions in the question body. We use the part-of-speech tags generated as part of the parse by `Stanza`.
- **Qx_coref_count**: Number of pronominal or nominal instances of coreference in the question body. We use Stanford's `CorefAnnotator` to extract this feature.

(2) Mathematical features (M) include 12 features pertaining to the question (Q) and gold solution (G):

Type	Source	#	Feature Name	Range	μ	σ
L	Q	1	Qx_token_length	[12 – 239]	66.05	24.384
	Q	2	Qx_sentence_length	[1 – 13]	3.431	1.201
	Q	3	Qx_word_length	[9 – 184]	45.885	17.832
	Q	4	Qx_flesch_kinkaid_grade	[-1.9 – 26.3]	4.236	2.468
	Q	5	Qx_mean_word_rank	[3661.96 – 21929.96]	10646.615	2110.891
	Q	6	Qx_constituency_tree_depth	[5 – 31]	10.803	2.798
	Q	7	Qx_np_count	[3 – 74]	18.034	7.488
	Q	8	Qx_prp_count	[0 – 16]	1.772	1.854
	Q	9	Qx_coref_count	[0 – 16]	0.462	1.283
M	Q	10	Qx_arg_count	[0 – 17]	4.438	1.94
	Q	11	Qx_word_arg_count	[0 – 14]	1.091	1.397
	Q	12	Qx_mean_numerical_word_rank	[259.0 – 29905.38]	22643.319	3260.09
	G	13	Gx_arg_count	[6 – 73]	24.377	9.732
	G	14	Gx_op‘+’_count	[0 – 12]	1.06	1.212
	G	15	Gx_op‘-’_count	[0 – 6]	0.601	0.78
	G	16	Gx_op‘*’_count	[0 – 8]	1.369	1.183
	G	17	Gx_op‘/’_count	[0 – 7]	0.621	0.789
	G	18	Gx_op‘(’_count	[0 – 4]	0.026	0.187
	G	19	Gx_op_unique_count	[0 – 6]	2.284	0.93
	G	20	Gx_op_diversity	[0.15 – 1.0]	0.758	0.196
	G	21	Gx_mean_numerical_word_rank	[22645.0 – 29915.0]	28626.04	776.73
	B	22	Gx_parameter_usage	[0.07 – 1.0]	0.642	0.241
W	B	23	Gx_world_knowledge	[0 – 8]	1.104	1.006

Table 5: Details of formulation and distribution (across `GSM8K`) for all features included in the feature set. Each feature is of type: Linguistic (L), Mathematical (M), or World Knowledge and NLU (W) and is sourced either from the question body (Q), gold solution body (G), or both (B).

- **Qx_arg_count**: The number of distinct numerical quantities (e.g., “**3.5** hours later” or “**100** boxes”) in the question body. We use a `Regexp` pattern to detect whole numbers, decimal point values, and quantities preceded by a negative sign or dollar (and other currency) signs.
- **Qx_word_arg_count**: The number of quantities mentioned in word-form (“**three** times” or “**half** as much”) in the question body. We use a vocabulary of frequently used word-form tokens and accommodate compound expressions (e.g., “twenty-two”).
- **Qx_mean_numerical_word_rank**: The mean vocabulary rank of the numerical tokens in the question body. We first isolate numerical tokens tokenized by respective tokenizers, then aggregate their token rank.
- **Gx_arg_count**: The number of distinct numerical quantities present as plain text or on the left-hand side of equations in the gold solution. We use the same `Regexp` pattern used for `Qx_arg_count`.
- **Gx_op{‘+’/ ‘-’/ ‘*’/ ‘/’/ ‘(’}_count**: Number of times each listed math operation is used in the gold solution. A simple `Regexp` pattern is applied to extract these from within equations.
- **Gx_op_unique_count**: The maximum number of times a single operation has been used in the gold solution. For instance, “$3 + 4.5 + 7 + 1 - 2.7$” contains 3 instances of the ‘+’ operator.
- **Gx_op_diversity**: Ratio of the number of unique math operators used to the total number of operators in the gold solution. For instance, a question with the consolidated math solution expression "$(2 \times 12) \times 3 = 72$" contains two arithmetic operations in total but only one unique operation type, i.e., ‘×,’ `Gx_op_diversity`$= 1/2 = 0.5$.
- **Gx_mean_numerical_word_rank**: The mean vocabulary rank of the numerical tokens used on the left-hand side of equations in the

gold solution. Extracted the same way as `Qx_mean_numerical_word_rank`.

- **Bx_parameter_usage**: The ratio of distinct arguments used in the gold solution to that in the question body. A value lower than 1 indicates that one or more arguments provided in the question were not required to solve the MWP (potentially acting as distractors).

(3) World knowledge and NLU features (W) include:

- **Bx_world_knowledge**: The number of distinct arguments on the left-hand-side of equations in the gold solution, that are neither present in the question body nor produced as intermediate results from any prior equations in the solution. A non-zero value is interpreted as the use of a quantity (perhaps a conversion factor, or the number of entities involved in computing mean) unspecified by the question. The arguments were extracted from both sides using the same `Regexp` policies used for previous features.

Table 5 shows further statistics on the features, including the range as well as the mean and standard deviation of the values for each feature type. Additionally, we report the Spearman correlation between all pairs in the feature set in Figure 5.

B Querying Details

B.1 Prompt Template

We use a simple task-specific prompt (see Figure 6) either prepended to the question-prompt or specified as a system-prompt if an LLM input query format requires so.

B.2 LLM Details

The exact large language models used in our experiments, along with their reported performance on `GSM8K` according to the OpenLLM leaderboard (Beeching et al., 2023) are mentioned in Table 6. All LLMs and libraries used are open-source. The license to use Meta's `Llama2` models was procured through due process.

Model	HuggingFace Model Name	Pass@1
Llama2-13B	`meta-llama/Llama-2-13b-chat-hf`	28.70
Llama2-70B	`meta-llama/Llama-2-70b-chat-hf`	56.80
Mistral-7B	`mistralai/Mistral-7B-Instruct-v0.2`	40.03
MetaMath-13B	`meta-math/MetaMath-13B-V1.0`	72.30

Table 6: List of HuggingFace model variants and their respective reported pass@1 (single run) accuracies on the `GSM8K` test set from the OpenLLM leaderboard.

B.3 Implementation and Compute Resources Used

We use vLLM to load and query models. Models of parameter sizes 7B and 13B were queried with a single NVIDIA A100 GPU. `Llama2-70B` was loaded and queried using 4 A100 GPUs. Each query was set to a temperature of 0.8, and a maximum token length of 2000. Each question was queried 5 times by each LLM, with a varying seed. Querying the entire `GSM8K` dataset ($8,793$ questions) took approximately 1 hour for each LLM.

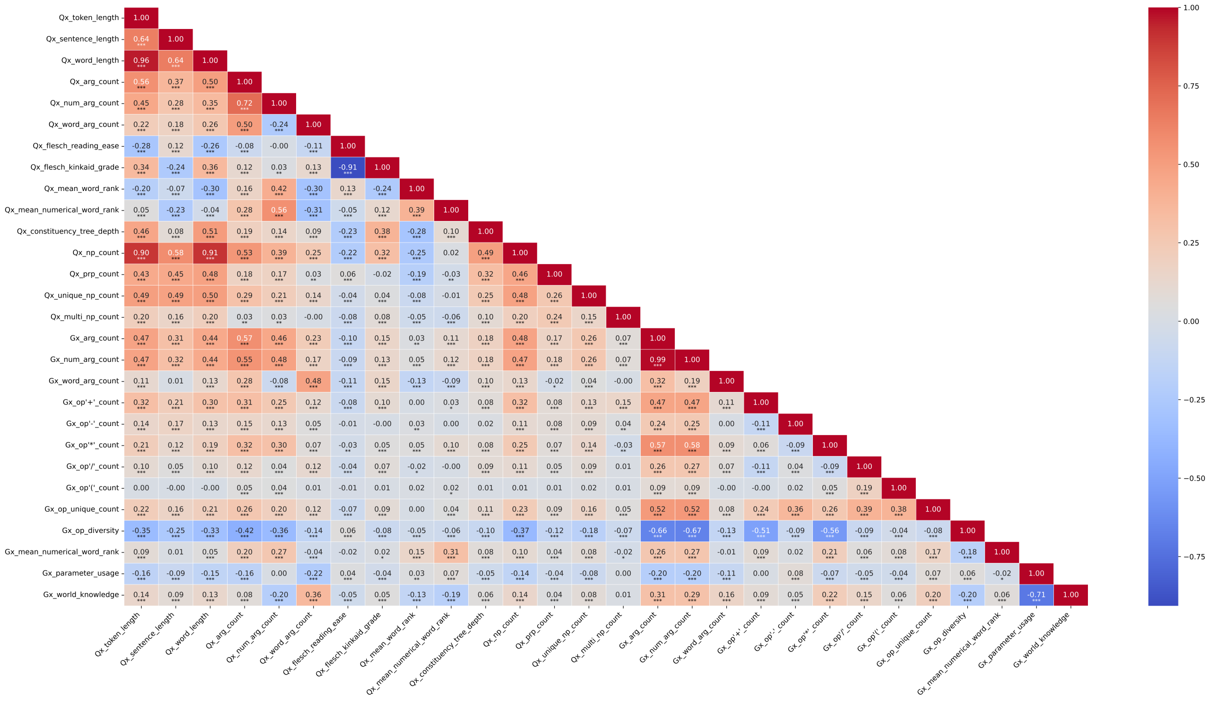

Figure 5: Spearman correlation matrix between features. All correlation values are marked with '*', '**', and '***' if their corresponding p-values are less than 0.05, 0.01, and 0.001 respectively.

Table 7: Feature-wise thresholds which reflect the greatest difference in the corresponding mean success rate. For each feature, the optimal threshold creates two sets of questions on either side, wherein the difference in the corresponding mean success rates of the two sets is the greatest. We perform Student's t-tests on both sets to determine if this difference is significant and report the corresponding t values. All results reported in the table have an absolute t-value >5 and a p-value <0.0001.

C Training Details

C.1 Preprocessing

Before training classifiers, we perform the following steps on the feature data:

1. **Pruning**: For each training feature-set, we iteratively remove features with high correlation with other features until no two columns in the data have an absolute Spearman correlation higher than 0.5.

2. **Scaling**: We fit scikit-learn's `StandardScaler` onto the train split to normalize the mean and standard deviation of all features. We then apply the same scaler on the test split features.

3. **Balancing**: As many LLM solution splits either contain too few always-correct or always-incorrect question samples, we use imblearn's `RandomOverSampling` tool to balance the pro-

Classification Model	Llama2-13B		Llama2-70B		Mistral-7B		MetaMath-13B		Intersection	
	F1(Never)	F1(Always)	F1(Never)	F1(Always)	F1(Never)	F1(Always)	F1(Never)	F1(Always)	F1(Never)	F1(Always)
Logistic Regression	0.8454	0.4968	0.5641	**0.7862**	0.8926	0.5081	0.0095	0.8354	0.8263	**0.7184**
Decision Tree	0.8199	0.4532	0.4958	0.7431	0.8732	0.4592	**0.0727**	**0.8373**	0.732	0.6496
Random Forest	**0.8535**	**0.5049**	**0.6133**	0.7824	**0.8936**	**0.5161**	0.019	0.8361	**0.8439**	0.7216

Table 8: Class-wise F1 scores for each classification model across LLM solution splits.

portions of the two classes in each run.

C.2 Hyperparameter Search

For each classifier model and LLM solution split pair, we conduct Bayesian optimization on the ranges of key hyperparameters for each classifier. As the objective function, we maximize the Macro-F1 score on a 15% held-out set of `GSM8K`'s test split to prevent the models from over-fitting onto the train samples.

C.3 Fine-tuning RoBERTa Classifier

We use HuggingFace's Trainer module to tune a pre-trained RoBERTa-base classifier on the same target data as the statistical classifiers in each setting. The corresponding input text for training and evaluation was built by concatenating the `GSM8K` question and gold-solution text for each sample, i.e., `"<question> Question Body </question> <solution> Solution Body </solution>"`. The model is trained for 3 epochs with a peak learning rate of $2e-5$ and a warmup ratio of 0.1. On a Tesla P100, each training run took approximately 10-15 minutes.

D Results Analysis

D.1 Class-wise Classification Review

Table 8 reports the class-wise F1-scores (for questions that are always or never solved correctly) for each classifier across LLM question splits. Though there may be notable class imbalances among the two classes across splits, all classifiers were trained with proportional oversampling. We see that for relatively smaller pretrained models, i.e., `Llama2-13B` and `Mistral-7B`, F1 scores for always-incorrect questions are significantly higher than their counterparts. Thus, the scores indicate that for smaller models, questions answered incorrectly are more predictable. For larger models like `Llama2-70B`, this difference is lower, with the always-correct questions being somewhat more predictable. For the fine-tuned `MetaMath-13B` model, the small number of questions that are never answered correctly, fail to provide a generalizable sample for predicting on unseen data.

D.2 Feature Impact

We continue our discussion of feature importance (from Section 4.2.1) by identifying pivot points for key features about which the corresponding success rates for questions show a significant difference in mean values. We perform Student's t-tests on equally spaced thresholds along each feature and report the thresholds which show the highest variation in mean success rates in Table 7.

We see that across most LLMs, a significant rise in the mean success rate is observed as the question contains, on average, more than 6-7 sentences, 90-115 words, or 113-132 tokens. We get a better idea of the kind of questions `Mistral-7B` gets wrong more often than other models, as its threshold (19.71 words) for the number of words in the question body is substantially lower than the average. Across features involving number of math operations, the threshold for the fine-tuned `MetaMath-13B` model is either on a par or higher than other models.

😀 SMILE: Multimodal Dataset for Understanding Laughter in Video with Language Models

Abstract

Despite the recent advances of the artificial intelligence, building social intelligence remains a challenge. Among social signals, laughter is one of the distinctive expressions that occurs during social interactions between humans. In this work, we tackle a new challenge for machines to understand the rationale behind laughter in video, *Video Laugh Reasoning*. We introduce this new task to explain why people laugh in a particular video and a dataset for this task. Our proposed dataset, 😀 SMILE, comprises video clips and language descriptions of why people laugh. We propose a baseline by leveraging the reasoning capacity of large language models (LLMs) with textual video representation. Experiments show that our baseline can generate plausible explanations for laughter. We further investigate the scalability of our baseline by probing other video understanding tasks and in-the-wild videos. We release our dataset, code, and model checkpoints on https://github.com/postech-ami/SMILE-Dataset.

1 Introduction

> *"Laughter is the shortest distance between two people."*
>
> —Victor Borge

We, human beings, are immersed in laughter. Laughter is a distinctive non-verbal social signal, associated with bonding, agreement, affection, and emotional regulation (Scott et al., 2014). It is often purposedly elicited to establish intimacy (Stauffer, 1999), grab attention (Wanzer et al., 2010), or build faith (Vartabedian and Vartabedian, 1993); *i.e.*, serving as a powerful medium to express a wide range of social and emotional implications beyond the capacity of mere words. Thus, understanding laughter is a crucial problem with huge potential in artificial social intelligence (Bainbridge et al., 1994; Williams et al., 2022; Dautenhahn, 2007) to build empathetic machines with human-machine interaction (Lee et al., 2017; Nijholt et al., 2017; Inoue et al., 2022). However, understanding and modeling laughter reactions is challenging. Even a simple joke is associated with language skills, context knowledge, theory-of-mind, abstract thinking, and social perception, and complex entanglement of these makes laughter reaction arguably the most complex cognitive attribute humankind may have (McDonald, 2013).

In this work, we take the first stepping stone to tackle the challenge of understanding laughter by introducing a task, *Video Laugh Reasoning* that aims to interpret the reasons behind laughter in a video. For this task, we curate a new dataset, 😀 SMILE, consisting of video clips and corresponding text annotations explaining reasons for laughter. We probe through the question "Why do people laugh?" and reason through the answer in a language form; thus, we define the task as a free-form text generation task in which the model generates an explanation for the laughter with a given video clip (See Figure 1).

While reasoning laughter by answering the question is an effective way of probing the level of understanding, laughter itself has an inherently complex nature which can be influenced by diverse factors (Apte, 1985; Provine, 2001; Martin et al., 2003; Martin and Ford, 2018), *e.g.*, the subjectivity (Warren et al., 2021), context knowledge (Nijholt et al., 2017), and multimodality (Hasan et al., 2019). To build a clearer resource for understanding laughter and its social norm behind it, we design the dataset to focus on *audience laughter*, a cohesive form from social influence in distinct contexts (Greatbatch and Clark, 2003), and thereby alleviating the subjectivity associated with individual laughter. Also, for our task, we propose a baseline based on large language models (LLMs) with *multimodal*

"the quantum mechanics describes how our universe works"

"quantum weirdness was first described by Erwin and his cat"

"the cat likes this version better" *(audience laughs)*

The audience laughed because speaker made a humorous between the serious topic of quantum mechanics and the ridiculous cartoonish image displayed, possibly a playful representation of Schrödinger's cat scenario.

Figure 1: Why do people laugh? We present *Video Laugh Reasoning*, a new task to interpret the reasons behind laughter in a video.

textual representation by converting multimodal attributes and features on video into a textual format.

Our experimental results show that the proposed baseline, incorporating LLM's reasoning capability with multimodal textual representation, can generate plausible explanations of the reason for laughter. Our data analysis and ablation study reveals that multimodal information plays a role in understanding laughter. We further explore the scalability of utilizing LLM with textual representation by applying it to other video understanding tasks and in-the-wild videos.

Our major contributions are threefold: 1) proposing *Video Laugh Reasoning*, a new task for understanding the reason behind laughter in a video, 2) building 😀 SMILE, a new dataset that comprises video and explanation for laughter reason, and 3) presenting a baseline using LLM with multimodal textual representation for laugh reasoning task and its scalability.

2 Related Work

Understanding laughter. Laughter plays a key role in social interactions, such as bonding, agreement, affection, and emotional regulation (Scott et al., 2014). Given its importance in social interactions, seminar works tackle to detect laugh-inducing moments, specifically focusing on humor or sarcasm. Several methods (Annamoradnejad and Zoghi, 2020; Weller and Seppi, 2020) rely primarily on transcripts for humor detection. As laughter occurs with multimodal information, such as variations in tone or facial cues, there are attempts to incorporate audio and text cues from videos (Bertero and Fung, 2016; Alnajjar et al., 2022), or even include visual cues (Castro et al., 2019; Hasan et al., 2019; Ray et al., 2022) to pinpoint the occurrences of humor. Yet they focus on detecting whether a certain situation induces laughter or predicting the intensity of laughter, without providing explanations for the underlying reasons behind the laughter (See Figure 1). Moreover, despite the availability of datasets for understanding the types and characteristics of laughing moments (Urbain et al., 2010; McKeown et al., 2012; Dupont et al., 2016), no dedicated dataset is available for comprehending the context surrounding laughter. Few works (Chowdhery et al., 2022; Hessel et al., 2023; Ko et al., 2023) have attempted to reason about laughter or jokes. However, their scope differs from ours, as they focus on providing instant textual descriptions of humor or cartoon images accompanied by text. To the best of our knowledge, we are the first to introduce the task of understanding the reason for laughter within videos, accompanied by our comprehensive dataset.

Multimodal reasoning. Multimodal reasoning is a complex task aiming to equip machines with the capability to parse, analyze, and logically reason about the given multimodal context. A widely explored reasoning task is a question answering (QA) on images (Antol et al., 2015; Gao et al., 2015; Zhu et al., 2016) or video (Lei et al., 2018; Tapaswi et al., 2016), which requires understanding the question, referencing the appropriate context, and selecting the correct answer. Similarly, commonsense reasoning (Vedantam et al., 2015; Yatskar et al., 2016; Wu et al., 2016) is another type of reasoning, demanding a more profound level of understanding and the ability to infer unstated information. Our task includes commonsense reasoning in that laughter is often elicited by exploiting external contexts, rather than merely understanding underlying phenomena.

Several methods (Zellers et al., 2019; Vicol et al., 2018; Zadeh et al., 2019) have attempted to learn and reason about the social interactions in the video. For instance, Visual Commonsense Reasoning (VCR) (Zellers et al., 2019) unifies reasoning about diverse commonsense phenomena, while Social IQ (Zadeh et al., 2019) aims to teach social intelligence by providing a broad range of social and behavioral situations to a machine. However, these approaches give less attention to a deeper understanding of laughter itself—a complex nonverbal signal integral to social interactions. Unlike the prior arts, we specifically focus on the task of reasoning human laughter. We posit this as a significant stride towards understanding important social signals frequently encountered in daily life, thus contributing a new perspective to multimodal reasoning and understanding tasks.

Models for multimodal reasoning. To tackle multimodal reasoning, one approach is to design pretraining methods (Lu et al., 2019; Li et al., 2019) that learn the joint vision and language representations. More recently, the combination of large-scale vision and language models (VLM) has demonstrated remarkable performance in multimodal reasonings (Li et al., 2023; Lu et al., 2022; Zhang et al., 2023; Wang et al., 2022a; Han et al., 2023).

An alternative approach for multimodal reasoning utilizes text as a unified representation and large language models (LLM) with minimal or without training. For instance, Socratic Model (Zeng et al., 2022) employs language to combine complementary knowledge from various pre-trained models for tackling a wide range of tasks. Similarly, Wang et al. (2022c) converts the visual attributes into the text representation to prompt a frozen LLM for diverse video-language tasks. In this work, we conduct extensive experiments on our proposed laugh reasoning task and show the effectiveness of using text as an intermediate representation.

3 Task Definition and Dataset

In this section, we introduce our *Video Laugh Reasoning* task and our dataset for it.

3.1 Task Definition and Baseline

We present *Video Laugh Reasoning*, a task that challenges the model to understand reasons for laughter in a given video. We pose our task as a generation problem, enabling the model to explain why a particular situation incited laughter in the video. We define this task as, $\hat{y} = f(v)$, where $\hat{y}$, f, and v stand for the generated explanation about laughter reason, the model, and the given video clip.

For this task, we propose a baseline that utilizes the reasoning capacity of LLM. To ensure compatibility of input v with the language model, we convert videos into *multimodal textual representation* that preserve multimodal information from video, such as visual, acoustic, and semantic cues. We compose visual cues with facial expressions[1] and scene descriptions[2] to perceive human-specific and scene-wide contextual information. For acoustic cues, we extract the mean and the variance of pitch, intensity, jitter, and shimmer from speech to capture. We simply use transcripts of the speech from the videos for semantic cues (See Figure 2).

Using textual representation as input and LLM as model f, we can rewrite the task formula as, $\hat{y} = f(\mathcal{P}, \{t_1, t_2, ..., t_k\})$, where $\mathcal{P}$ stand for the prompt that describes input representation and instructing the laugh reasoning task to language models and t is multimodal textual representation converted from the given video clip v. See Appendix A for details about how to convert video into textual representation.

3.2 Dataset

Data collection. We present 😀 SMILE, a curated dataset encompassing 887 video clips, each paired with a language description about the reason for laughter for the corresponding video clip. This pairing facilitates supervised training for the laugh reasoning task. The dataset focuses on audience laughter among many types of laughter since audience laughter usually has a clearer signal than other laughter and represents a general and cohesive form of laughter. To encompass a wider range of videos that contain situations where audiences laugh, we construct our dataset using two different sources: *TED talks and sitcoms*.[3]

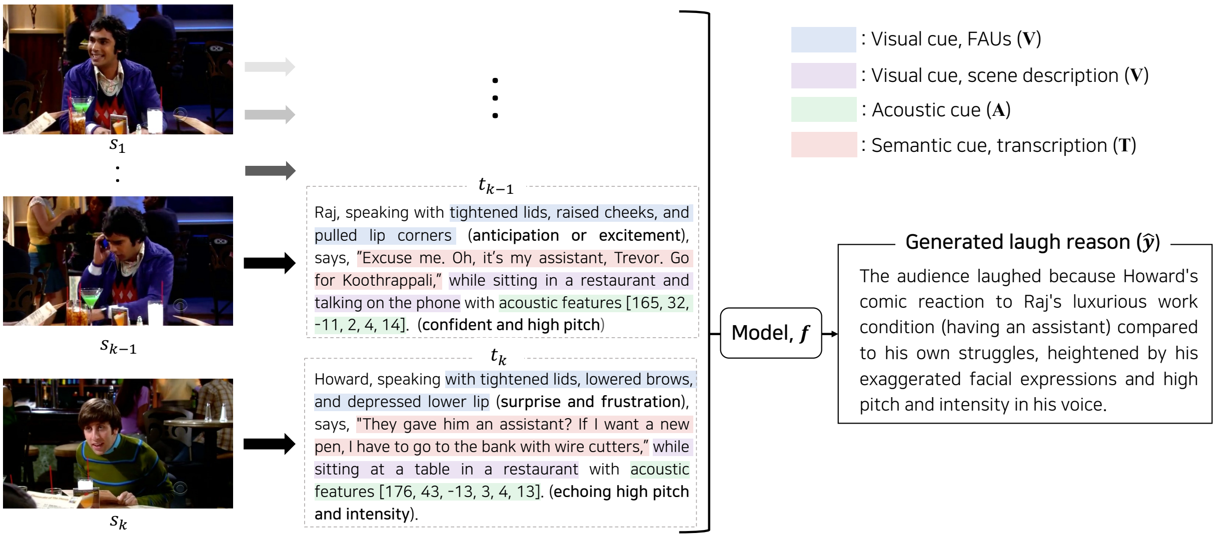
We curate video clips that span between 10 and 90 seconds for *TED talks* and 7 and 60 seconds for *sitcoms*. If a video is too short, it might fail to provide sufficient context for laughter. In contrast, if a video is too long, it may dilute specific laughter-inducing contexts with unrelated information. The

---

[1] We use facial action units (Ekman and Friesen, 1978).

[2] We use video captioning model (Wang et al., 2022b).

[3] We source the video clips from MUStARD (Castro et al., 2019) and UR-Funny dataset (Hasan et al., 2019).



Raj, speaking with tightened lids, raised cheeks, and pulled lip corners (anticipation or excitement), says, "Excuse me. Oh, it's my assistant, Trevor. Go for Koothrappali," while sitting in a restaurant and talking on the phone with acoustic features [165, 32, -11, 2, 4, 14]. (confident and high pitch)

Howard, speaking with tightened lids, lowered brows, and depressed lower lip (surprise and frustration), says, "They gave him an assistant? If I want a new pen, I have to go to the bank with wire cutters," while sitting at a table in a restaurant with acoustic features [176, 43, -13, 3, 4, 13]. (echoing high pitch and intensity).

The audience laughed because Howard's comic reaction to Raj's luxurious work condition (having an assistant) compared to his own struggles, heightened by his exaggerated facial expressions and high pitch and intensity in his voice.

Figure 2: **Video Laugh Reasoning task and multimodal textual representation.** Each video clip (v) is trimmed into list of video segments (s_i), and each video segment is encoded into textual representation (t_i). The textual video representation consists of visual cues (V), acoustic cues from speech (A), and semantic cue (transcript, denoted as T). Then, we use LLM to generate why the audience laughs at the given video with the prompt. The bold text in parentheses on the t shows that LLM is semantically aware of the textual video representation.

Number of Video Clips	887
Number of Train/Val/Test	727 / 80 / 80
Number of Video Segments	4,434
Avg. number of Segments per clip (k)	4.4
Avg. duration of Video Clips	27.5 sec.
Avg. duration of Video Segments	6.2 sec.

Table 1: **Statistics of our dataset.** We split our dataset into train, validation, and test sets with the ratio of 8:1:1. Avg. denotes average.

average duration for TED talk clips is longer than *sitcoms*, given the protracted nature of talks.

Given that a single video clip often contains multiple instances of laughter, we focus on the last laugh in a clip for easier annotation. We only use video clips that meet the following filtering criteria, using a laugh detector (Gillick et al., 2021) to identify audience laughter instances. Our filtering criteria are: laughter should last at least 0.5 seconds, and be no more than 1 second interval between the video clip's last utterance and the onset of laughter. The latter criterion filters out the laughter events that are not related to the punchlines but are induced by something else. After this pre-processing, our final dataset comprises 484 sitcom and 403 TED talk video clips. Table 1 shows the statistics of our dataset.

Annotation for laughter reason. We employ human annotators from Amazon Mechanical Turk (AMT) to label videos with reasons for laughter. Given the inherently subjective nature of humor and the extensive variability in laughter triggers, constructing ground truth (GT) by free-form annotation is challenging. To mitigate these issues, we utilize the language model to generate candidates for laughter reasons, these candidates are subsequently presented to annotators with the corresponding video clip to choose the most appropriate explanation among them and refine it. If none of the candidates were suitable, we instruct them to write the reason in a free form.

After annotation, we verify all GT and manually refine it if it is not plausible for laughter reasons with video. This approach reduces the annotation workload by interacting LLM and humans, developing a more concise GT for this complex and subjective task. Finally, our dataset is formed as $\mathcal{D} = \{v, y\}$, where y is a GT explanation for laughter in the video clip v. See Appendix B for details about the human annotation process and the post-processing. Also, refer to Appendix F for the details about the AMT configuration.

3.3 Data Analysis

Which multimodal cue is important to infer the reason for laughter. We conduct a human evaluation to understand our dataset better. The annotators are requested to rank the multimodal cues in

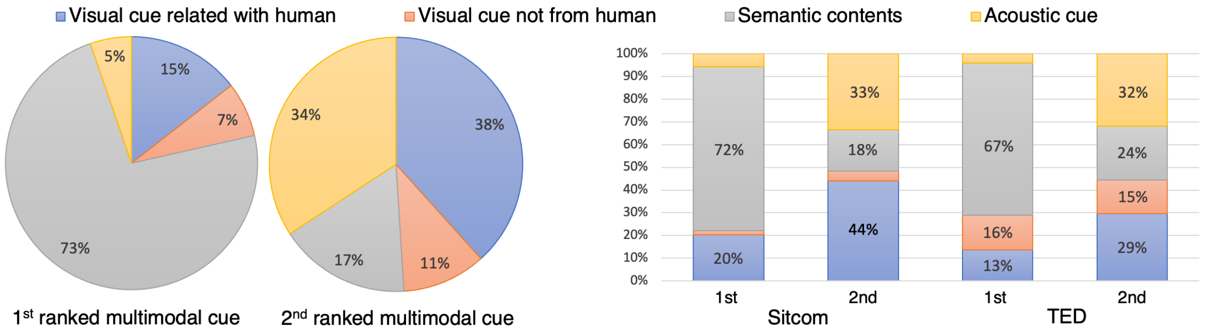


Figure 3: **Which multimodal cue is important to reason the laughter?** While semantic content is the most influential in causing laughter, the 2^{nd} ranked modality cues are diverse, suggesting that multiple modality information can simultaneously influence laughter.

```
"prompt": {Reasoning task: you are to answer why the audience laughed given the video clip. The video clip from
the {Sitcom}, titled {video title}, with multimodal information (Utterance, Facial Action Units, Video caption,
Acoustic features(6 dimension; 1.mean of F0 contour, 2.var of F0 contour, 3. mean of energy contour, 4. var of
energy contour, 5. jitter, 6. shimmer)) is given. The audience laughing moment is marked as (audience laughing)
in certain utterance Explain why the audience laughed given the video clip, at most {30} words, starting with
'The audience laughed because '. Given video clip: {query}.}

"completion": {answer}
```

Figure 4: **Prompt for laugh reasoning experiments on GPT3.** The prompt is fed into GPT3 (Brown et al., 2020a) for fine-tuning, zero-shot learning, and in-context learning. For in-context learning, three random samples of prompt-answer pairs from the training set are given to GPT3. We manually change video types (sitcom or TED) and video title using the meta information of video clips. The query stands for multimodal textual representation m of the video clip. The length of the generated output is also variable, with a maximum of 30 words for sitcoms and 40 words for TED talks, considering each video type's characteristics.

perspective of which cues are related to laughter in the video. The rank annotation provides insight into which modality information is crucial for the cause of the laughter for each case.

For each video clip, we present annotators four choices: 1) visual cues from human; *e.g.*, facial expression and body gesture, 2) visual cues not from human; *e.g.*, backgrounds or images and props, 3) semantic contents; *i.e.*, transcription, and 4) acoustic cues; *e.g.*, speech tone or intensity. We ask them to choose two modality cues that are the most relevant for inducing laughter. The pie chart on the left in Figure 3 shows the modality importance statistics for our dataset. While the reason for laughter is primarily driven by semantic contents, the second most effective cue varies across different modalities, indicating that the various modalities in the video contribute to the reason for laughter. The bar chart on the right in Figure 3 shows the elements that induce laughter in two video types of our dataset. Notably, visual cues unrelated to humans, such as backgrounds or images, significantly trigger more laughter in TED than in sitcoms. TED videos often exhibit the speaker's presentation slides, making non-human visual cues more influential for eliciting laughter. Conversely, visual cues such as facial expressions and body gestures have a higher probability of causing laughter in sitcoms than in TED. This difference is because sitcoms mainly center around the characters' dialogues, so visual cues from human actors are more crucial. See Appendix C for additional data analysis.

Model	BLEU_4 (↑)	METEOR (↑)	ROUGE_L (↑)	BERTScore (↑)	Win rate
Video model	0.226	0.236	0.398	0.427	24%
LLM + multimodal	**0.270**	**0.256**	**0.432**	**0.496**	**76%**

Table 2: **Comparison with video model.** We compare the video model trained on raw video and transcripts with LLM trained on multimodal textual representation. We use Video-LLaMA (Zhang et al., 2023) and LLaMA (Touvron et al., 2023) for video model and LLM, respectively.

4 Experiment

We split our dataset into 5 cross-validation splits except for the test set. We fine-tune two LLMs, GPT-3 (Brown et al., 2020a) and LLaMA (Touvron et al., 2023) with the training set and use the test set for evaluation.

Model	Num. of parameters	Modality	BLEU$_4$ (↑)	METEOR (↑)	ROUGE$_L$ (↑)	BERTScore (F1) (↑)
LLaMA (FT)	13B	T	0.250	0.245	0.432	0.493
		A+V+T	0.270	0.256	0.453	0.496
GPT-3 (zero-shot)	175B	T	0.126	0.155	0.313	0.389
		A+V+T	0.157	0.184	0.364	0.454
GPT-3 (3-shot)	175B	T	0.187	0.198	0.368	0.431
		A+V+T	0.232	0.230	0.413	0.476
GPT-3 (FT)	175B	T	0.230	0.243	0.429	0.488
		A+V+T	**0.279**	**0.267**	**0.475**	**0.523**

Table 3: **Evaluation on laugh reasoning with LLMs.** We evaluate whether the model can explain why the audience laughed. We fine-tune two LLMs, GPT-3 (Brown et al., 2020a) and LLaMA (Touvron et al., 2023) on our dataset, SMILE. We use GPT-3 for in-context (3 shots) and zero-shot experiments. Each modality cue in our dataset is denoted as Transcript (T), Audio (A), and Visual (V). FT denotes fine-tuning the model.

	A	B	A wins (%)	Fleiss'-κ
Q1	GPT-3 (A+V+T)	GPT-3 (T)	72.2	0.43
Q2	GPT-3 (FT)	GPT-3 (3-shot)	77.8	0.31
Q3	GPT-3 (FT)	LLaMA (FT)	56.6	0.49
Q4	Human	GPT-3 (FT)	66.2	0.42

Table 4: **Pairwise human evaluation.** Except for Q1, we use all modality (A+V+T) for training. We use Fleiss'-κ (Fleiss et al., 2013) for assessing the reliability of agreement. Q1-Q4 denote corresponding evaluation in § 4.2.

Implementation details. We use the official GPT-3 (Brown et al., 2020a), a non-free commercial version, as follows. We utilize the *davinci-text-002* model of GPT-3 (Brown et al., 2020a) for the zero-shot and in-context learning experiments. Examples of the prompts for both tasks are shown in Figure 4. The "prompt" provides the context of the task and the multimodal cues of the video, and "completion" provides the reason for the laughter. The zero-shot setup only takes "prompt" and generates the reason for the laughter, while the in-context learning setup is given with additional three randomly labeled samples from the training set as few-shot examples. More implementation details including LLaMA are in Appendix D.

Evaluation metrics. We utilize both quantitative metrics and human evaluation. We use metrics commonly employed for evaluating language generation tasks, including BLEU$_4$ (Papineni et al., 2002), METEOR (Banerjee and Lavie, 2005), ROUGE$_L$ (Lin, 2004), and BERTscore (Zhang et al., 2019). For the human evaluation, we gather assessments from 3 crowd-workers per test sample by asking them to select their preferred explanation for laughter from a pair of options and take a majority vote to determine a winner. We calculate the average win rate (%) over the test set.

4.1 Comparison with video model

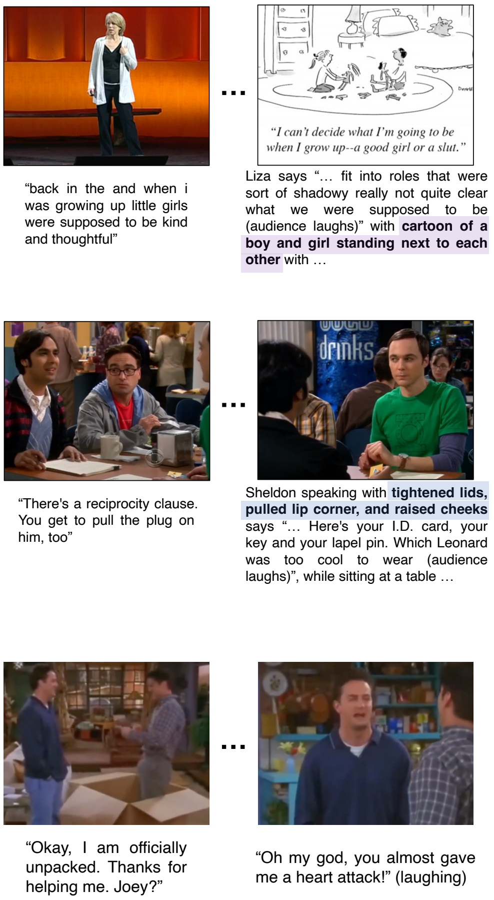
In addressing the laugh reasoning task, a direct method is to train a video model with raw video input. We compare the video model with our baseline, which utilizes LLM with multimodal textual representation. We fine-tune each model and conduct the quantitative and human evaluations (win rate), as shown in Table 2. The LLM-based baseline outperforms all metrics, indicating that our multimodal textual representation incorporates LLM's capacity to understand the reason for laughter in the video.

4.2 Evaluation

We analyze our baseline on laugh reasoning in various setups. We utilize both quantitative and human evaluation. Quantitative results are in Table 3, and the results of human agreements are in Table 4. Our evaluations aim to address four key questions.

Q1. Does multimodal information help for laugh reasoning? Yes, incorporating all modality cues for training enhances the performance of the laughter reasoning task compared to using transcripts alone (Table 3). The model trained with all modalities preferred in 72.2% of the test set compared to the transcript-only model as shown in Table 4. Furthermore, Fig. 5 (a) supports this, showing that the model trained with all modalities can effectively distinguish the reasons for laughter by utilizing multimodal information, whereas a transcript-only model only achieves a partial understanding.

Q2. Does the fine-tuning step help for a laugh reasoning? Yes, fine-tuned models outperform zero-shot/in-context models in both quantitative evaluation and human preference. It shows that our dataset nicely infuses the video laugh reasoning capacity to LLM.



"back in the and when i was growing up little girls were supposed to be kind and thoughtful"

Liza says "… fit into roles that were sort of shadowy really not quite clear what we were supposed to be (audience laughs)" with **cartoon of a boy and girl standing next to each other** with …

"There's a reciprocity clause. You get to pull the plug on him, too"

Sheldon speaking with **tightened lids, pulled lip corner, and raised cheeks** says "… Here's your I.D. card, your key and your lapel pin. Which Leonard was too cool to wear (audience laughs)", while sitting at a table …

"Okay, I am officially unpacked. Thanks for helping me. Joey?"

"Oh my god, you almost gave me a heart attack!" (laughing)

Why the audience laugh?

GPT-3 (FT) w/ A+V+T
The audience laughed because Liza Donnelly humorously described the shadowy roles of girls, which was **emphasized by the cartoon of a boy and girl** standing together.

GPT-3 (FT) w/ T
The audience laughed because Liza Donnelly humorously described how little girls were supposed to be kind and thoughtful, but their roles were unclear.

GPT-3 (FT) w/ A+V+T
The audience laughed because Sheldon made a sarcastic comment about Leonard's coolness, which was **highlighted by his exaggerated facial expressions** and the audience's understanding of the characters' personalities.

GPT-3 (FT) w/ T
The audience laughed because the speaker made a sarcastic comment about Leonard's coolness, which was stressed by his failure to wear the lapel pin.

(a)

GPT-3 (FT) w/ A+V+T
The audience laughed due to Chandler's surprised reaction and high-pitched response to a Joey's sudden appearance.

GT
The audience laughed because Chandler knew Joey was there and he was just acting surprised to a sudden appearance.

(b)

Figure 5: **Qualitative results on laugh reasoning.** For the examples in (a), GPT-3 (Brown et al., 2020a) fine-tuned on our dataset (denoted FT w/ A+V+T) understands the reasons for laughter by referencing multimodal cues. In contrast, the model fine-tuned using the transcript-only (denoted FT w/ T) manages to understand the reasons partially. The visual cues (scene description) are crucial for capturing "joey's sudden appearance" which is important to infer the reason for laughter in (b).

Q3. Do bigger models generate better reasons for laughter? Yes, GPT-3 (175B) surpasses LLaMA (13B) in both quantitative evaluation and human preference, as shown in Table 3 and 4.

Q4. Does the model explain the reason for laughter as well as humans? No, the human-annotated laughter reasons are preferred by 66.2% than those generated by fine-tuned GPT-3 (our best model) as shown in Q4 of Table 4. Figure 5 (b) provides an example illustrating the comparison between human-annotated reasons (GT) and generated reason for laughter. In this sample, all crowd workers prefer GT because the model struggles to distinguish the subtle difference between surprise and posed surprise, while the human-annotated reason successfully captures it.

Model	MUStARD Acc. (%) (↑)	UR-FUNNY Acc. (%) (↑)
TFN (Zadeh et al., 2017)	68.6	64.7
CMFN (Hasan et al., 2019)	70.0	65.2
MISA (Hazarika et al., 2020)	66.1	70.6
BBFN (Han et al., 2021)	71.4	71.7
MUStARD++ (Ray et al., 2022)	74.2	-
MAG-XLNet (Rahman et al., 2020)	74.7	72.4
MuLoT (Pramanick et al., 2022)	76.8	73.9
Ours (w/ LLaMA)	77.5	75.1
Ours (w/ GPT-3)	**79.0**	**77.9**

Table 5: **Evaluation results of the humor & sarcasm detection task.** All models use text, visual, and acoustic information from videos for training.

In summary, for the laugh reasoning task, multimodal information, a large model, and infusing reasoning capacity with our dataset are important. While the trained model does not surpass human capabilities, the use of LLM with multimodal textual representation enables us to generate plausible explanations about the reason for laughter in videos. See Appendix E for additional experiments.

“One of the things in Korean culture that I hate the most is the forcing alcohol.”

“You can just drink it, why make me force you to drink?” (laughing)

Why is the audience laughing?

`The audience laughed because the comedian flipped expectations, comically suggesting he's usually the one pressuring others to drink, not the reverse, which was emphasized by his exaggerated facial expression and high speech tone`

“Describe the moment you realized you cloud trust me.”

“Umm..” (laughing)

Why is the woman laughing?

`The woman laughed because the question from man evoked nervous laughter as it’s considered emotional moment in a relationship. This laughter could be a way to ease the tension of recalling such an intimate memory. Her facial expression denote smile, but it might indicated posed smile resulting from the situation.`

Figure 6: **Examples of in-the-wild videos.** We try to generate explanations for the laughter in the videos from standup comedy and intimate conversation. The results show that we can generate valid explanations for laughter in other videos.

5 Discussion

In this section, we discuss the scalability of utilizing large language models with textual video representation by conducting evaluations on other tasks and on in-the-wild videos.

5.1 Evaluation on other tasks

Apart from laugh reasoning, we conduct humor detection and sarcasm detection tasks, which classify given video contains humor (sarcasm) or not (i.e., binary classification). We use UR-FUNNY (Hasan et al., 2019) and MUStARD (Castro et al., 2019), which are representative benchmarks for these tasks. We cast the original binary classification problem as a text generation problem to integrate into our system. Formally, we can define the task as, $\hat{b} = f(\mathcal{P},\ \{t_1,\ t_2, ...,\ t_k\})$, where $\hat{b}$ denote predicted binary class in text format ("Yes" or "No"), and $\mathcal{P}$ is prompt for instructing LLMs about the task and input representation.

We follow the same train/test split, and evaluation procedure as in the benchmark for measuring the accuracy of each detection task. We use LLaMA and GPT-3 for training with textual representation converted from the video in the training set of each benchmark dataset. Table 5 shows that our method achieves strong performance[4] on both tasks. This experiment highlights the scalability of utilizing LLMs with textual representation in various video understanding tasks.

5.2 Evaluation on the in-the-wild videos

We extend our laughter reasoning to in-the-wild videos, encompassing different video types and laughter contexts compared to our dataset. First, we evaluate our approach on a video clip from a stand-up comedy, which has similar audience laughter patterns to those in our dataset. We convert the video into a textual representation and infer the reason for the audience laughing. Figure 6 shows that the model can generate a plausible explanation for the reason for laughter in stand-up comedy.

Next, we test on a video clip featuring an intimate conversation between a married couple. In this case, the laughter originates from the speakers themselves rather than from the audience. As this does not belong to the comedic genre but rather a sincere conversation between two people, it is more likely that non humor-based laughter, such as nervous or social laughter, may occur. Figure 6 shows that the model can also understand the nervous laughter used to alleviate tension or awkwardness in the situation.

6 Conclusion

In this paper, we aim to understand the reason behind laughter by introducing *Laugh Reasoning* task, accompanied with SMILE dataset. While the model did not surpass human capabilities, we show that the model can generate plausible explanations about laughter reason, underlining that multimodal cues in our dataset nicely infuse the laugh reasoning capacity to the model. We also show the results

---

[4] We do not compare with FunnyNet (Liu et al., 2022) as they use an additional large-scale dataset for training.

applied to other tasks and other types of video, hinting at the scalability of utilizing LLM with multimodal textual representation.

Limitation & future direction. Our LLM-based baseline serves as the initial method for laugh reasoning task and has a margin to improve. For the multimodal textual representation, as it is a primitive form for capturing human social interaction in the video, we can enhance it with diverse attributes such as gesture, eye gaze, and relationship or use other representations such as scene graph. Our work mainly focuses on audience laughter as the first stepping stone toward understanding laughter due to its distinct and cohesive signal, while there are diverse mechanisms behind laughter. Recognizing this, enriching our work with diverse video types like vlogs, movies, and talk shows is a promising direction to capture a broader range of laughter, as we show the possibility in § 5.2.

Potential application & broader impact. Our work can be regarded as a stepping stone toward developing socially intelligent agents that understand and appropriately create non-verbal cues, such as laughter, playing a crucial role in building rapport, expressing emotions, and creating deep emotional exchanges (Tickle-Degnen and Rosenthal, 1990; Argyle, 1972). Such advancement moves us beyond the capabilities of current dialogue agents, e.g., ChatGPT or Alexa, which mostly focus on verbal signals. Incorporating 3D talking head methods (Sung-Bin et al., 2024; Zhao et al., 2024) could offer the way agents are visualized, enabling more expressive and multimodal interactions with users.

A Multimodal Textaul Representation

In this section, we explain how to convert video into multimodal textual representation. Videos are multimodal, which include visual, acoustic, and semantic cues (i.e., transcription). We encode video clips into textual representation, embracing their multimodal information, so that we can leverage the pre-trained knowledge of LLMs while exploiting multimodal inputs in our baselines. First, starting with a video clip, we build a list of video segments by trimming the clip based on the utterances. The definition of the utterance varies upon to the source of the video: for TED talks, each sentence is defined as an utterance, since TED talk usually has a single speaker. If the utterance is too short (2 seconds or less), we concatenate adjacent utterances into one. For sitcoms, we define consecutive sentences from the same speaker as an utterance.

Visual cues. We compose visual cues with facial expressions and scene descriptions to perceive human-specific and scene-wide contextual information. Specifically, to process human-specific information, we utilize the active speaker detection algorithm (Tao et al., 2021) and face detector (Zhang et al., 2017) to crop the face of the speaking person in each video segment. This process effectively identifies the active speaker, especially for sitcoms where many people appear in a single scene, allowing to align visual features with utterances.[5] For facial expression description, we extract 14 facial action units (FAUs) (Yao et al., 2021)[6] from each frame in the video segment with 10 frames per second (FPS).

Then, we accumulate them and take the three most dominant units. For scene-wide contextual cues, we use the video captioning (Wang et al., 2022b) to extract scene description. The scene description provides high-level context for the visual cues including the surrounding objects and background that interact with the speaker.

Acoustic cues. We extract the mean and the variance of pitch, intensity, jitter and shimmer as acoustic features from speech utterance using off-the-shelf speech processing models (Arias-Vergara et al., 2017; Dehak et al., 2007). Since the extracted values are real numbers, we initially try to convert them to a linguistic format with certain criteria (*e.g.*, map to "high pitch" if the mean pitch value is greater than 200). However, it is challenging to set an objective criterion that considers various factors, including the speaker's gender, context, and identity. Instead of putting real numbers into text, we use themselves as acoustic features by giving a description of them as a prompt to LLMs, leveraging their knowledge on understanding numerical number (Brown et al., 2020b; Liu et al., 2023; Jiang et al., 2020; Wallace et al., 2019) (See bold text in parentheses on the t in Figure 2).

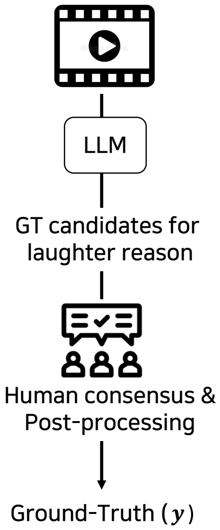

Figure 7: **Annotation pipeline for laughter reason.**

B Annotation for Laughter Reason

We elaborate the procedure for obtaining laughter reason consensus (ground-truth; GT) by utilizing large language models' general knowledge and incorporating it into human consensus. This procedure consists of three steps: (1) build GT candidates, (2) human annotation, and (3) post-processing (See Figure 7).

For (1) building GT consensuses, we utilize the large language model (GPT-3.5 (Ouyang et al., 2022)) with multimodal textual representation t to generate two candidates for the laughter reason. We manually pre-process these candidates if they are invalid or have incorrect sentence structure (See Figure 8).

For (2) human annotation, the processed GT candidates are subsequently presented to annotators from Amazon mechanical turk (AMT) with the corresponding video clip. The annotators are asked to choose the most appropriate explanation among them. If the annotators judge that no candidates are appropriate, we instruct the annotators to write

---

[5] We provide these face-cropped video segments in our dataset.

[6] We use https://github.com/CVI-SZU/ME-GraphAU to extract FAUs.

Initial GT candidate (*can not find the laughter reason*)

There is no clear indication of audience laughter in the given context.

Pre-processed GT candidate

The audience laughed because Sophie Scott is playing on the screen where they see a man in his underwear trying to endure the coldness of the ice and ended up giving up after a short period of time.

Initial GT candidate (*incorrect instructed sentence structure*)

There is one instance where speaker joked about diagnosing genetic conditions in their kitchen sinks or doing at-home paternity testing. The audience laughed because it was perceived as a humorous remark.

Pre-processed GT candidate

The audience laughed because the speaker mentioned doing at-home paternity testing and diagnosing genetic conditions in the kitchen sink, which is a humorous and absurd concept

Figure 8: **Examples of the pre-processing of GT candidates.** In the example above, GPT3.5 fails to infer the reason for the laughter given a multimodal textual representation of the video clip. We handle this by utilizing GPT4 to generate reasons for laughter from the same input. In the example below, the sentence structure does not start with "The audience laughed because", which is the structure we want. In this case, we manually revise it for consistent sentence structure.

Given GT candidates

1. The audience laughed because Sophie's statement "he's not laughing yet" was followed by the video showing a man holding a frisbee, creating a humorous contrast between statement and visual context.
2. The audience laughed because the speaker made an ironic remark about a man not yet laughing, as he held a frisbee, creating humorous contrast.

Refined GT written by annotators in free-form

The audience laughed because Sophie is playing on the screen where they see a man in his underwear trying to endure the coldness of the ice and ended up giving up after a short period of time, creating a humorous contrast between the statement and the visual context.

Given GT candidates

1. The audience laughed because Chandler made a joke about his testicles possibly being in the box, which was unexpected and inappropriate, causing amusement.
2. The audience laughed because Chandler made a suggestive joke about his "testicles" being in a gift box, which was a humorous and unexpected innuendo.

Refined GT written by annotators in free-form

The audience laughed because Chandler's joke about his testicles being in the box is because he knows so much about ribbon types which makes him seem feminine.

Figure 9: **Examples of the correction of laughter reason by annotators.** All given GT candidates are passed to the annotators after pre-processing. The free-form responses capture additional visual details (above) and provide a context of why saying "testicles" evokes laughter (below).

or refine the reason in free form. After annotation, the candidate with the most votes is selected as the GT. If at least one annotator provided the reason for laughter in free-form, we manually checked their validity and reflected them into GT. Figure 9 shows that free-form responses capture additional visual details and provide an understanding of why certain words elicit laughter. See Appendix F for details about AMT.

For (3) post-processing, we additionally verify all GTs for laughter reasons and manually refine it if it is not plausible for laughter reasons with video or has repetitive phrases that might induce spurious correlation. To mitigate this, we replace repeated phrases with synonyms, which are randomized among multiple synonyms. For example, one of the repetitive phrases "unexpected and humorous", is randomly replaced with synonyms such as "astonishing and laughable", or "hilarious". As another correction, even with the best efforts of human annotators, some reasons are not perfectly matched with the video. Figure 10 shows the post-processing that corrects these kinds of errors.

Annotation quality control. We use qualification criteria to ensure the annotation quality. We allow annotators from (AU, CA, NZ, GB, US), which represent the English-speaking countries.[7] Additionally, we only allow experienced annotators who are with 10K approved previous HITs and a minimum acceptance rate of 97% on their previous HITs. We pay each annotator 0.3 USD($) per accepted HIT.

C Data Analysis

We further conduct a human evaluation to understand our dataset better. Given the video clip, the

---

[7] This is because all the video clips in our dataset are in English.

GT (*repetitive phrase*)

The audience laughed because the doctor's diagnosis of Sheldon's inflamed larynx was exaggerated, and the use of the phrase "I've never seen anything like it" was unexpected and humorous.

Post-processed GT

The audience laughed because the doctor's diagnosis of Sheldon's inflamed larynx was exaggerated, and the use of the phrase "I've never seen anything like it" was astonishing and laughable.

GT (*not plausible for laughter reason within video*)

The audience laughed due to Chandler make noise with high-pitched tone and exaggerated facial expression to Rachel.

Post-processed GT

The audience laughed because Chandler make fun of Rachel with her appearance with high-pitched tone and exaggerated facial expression

Figure 10: **Examples of the post-processing on GT.** The example above shows replacing a repetitive phrase with a synonym. The example below shows how we rectify GT when the reason for laughter does not align with the video context.

annotators are requested to determine the laugh. The laugh type annotation explains the distinct characteristics of laughter in TED and sitcoms.

We consider two laugh types: 1) *Release-Triggered Laughter* (Freud, 1960; Fry, 2011; Mindess, 2017) that results from the alleviating tension amidst constraints such as awkward or complex situation and 2) *Hostility-Triggered Laughter* (Gruner, 1978; Billig, 2005) that arises from claiming superiority over someone or something, based on "great families" of theories of humor (Attardo, 2008), and ask annotator to determine which one is more appropriate for laughter in video.[8]

Statistics in Figure 11 suggest that sitcoms and TED talks are dominated by different types of laughter, suggesting that the nature of laughter varies by video type. Specifically, the major laugh type in sitcoms is closer to the hostility-induced laughter, and we postulate that sitcoms are typically designed to be entertaining, focusing on humorous situations, witty dialogue, and comedic conflicts among characters. On the other hand, TED talks are dominated by release-triggered laughter. We hypothesize that the talks aim to captivate and engage the audience by releasing constraints and unexpected revelations, creating a dynamic and thought-provoking experience. This type of humor helps maintain interest, and breaks the monotony (Wanzer et al., 2010). By merging these two heterogeneous video types, we can cover a wider range of reasons behind the audience's laughter.

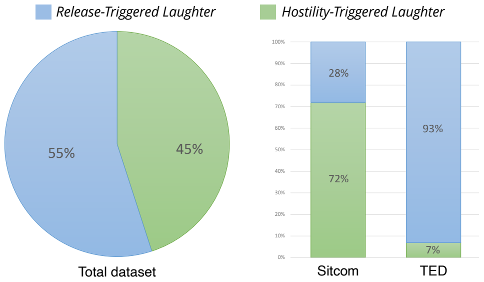

Figure 11: **Laughter types in our dataset.** Sitcoms tend to have more hostility-triggered laughter, while TED talks have more released-triggered laughter.

D Implementation details

GPT3 fine-tuning. We utilize the OpenAI fine-tuning API and fine-tune *davinci*. The prompt for fine-tuning is the same as the aforementioned experiments. We follow the fine-tuning scheme provided on the OpenAI webpage.[9]

LLaMA fine-tuning. LLaMA is LLM, an open-source model for research. We fine-tune the full parameters of LLaMA for 5 epochs. We utilize 4 A100 (80GB) for distributed fine-tuning with batch size 4 per device and a learning rate 1e-4. We also leverage fp16 mixed precision.

Video-LLaMA fine-tuning. We use Video-LLaMA which consists of pre-trained Blip2, Vicuna-13B, and Imagebind-huge. We train audio, video Q-former, and projection layers while other parameters are frozen. We utilize 8 A100 (80GB) for distributed fine-tuning with batch size 1 per device and an initial learning rate (3e-5), and weight decay (0.05) for 10 epochs. We also leverage mixed

---

[8] During annotation, we provided full descriptions of the concepts of the laughter types, rather than using the terms.

[9] https://platform.openai.com/docs/guides/fine-tuning; OpenAI has not opened the details of the API's fine-tuning mechanisms, which is currently hidden.

```

		A+V+T	**0.279**	**0.260**	**0.454**	0.457
	SMILE	T	0.249	0.245	0.423	0.454
		A+V+T	0.273	0.247	0.438	**0.468**

(a) Video type-wise evaluation

Test dataset	Train dataset	Modality	BLEU$_4$ (↑)	METEOR (↑)	ROUGE$_L$ (↑)	BERTScore (F1) (↑)
SMILE$_{\text{Sitcom}}$	SMILE$_{\text{TED}}$	A+V+T	0.161	0.254	0.390	0.407
	SMILE$_{\text{Sitcom}}$	A+V+T	0.290	0.288	0.485	0.548
SMILE$_{\text{TED}}$	SMILE$_{\text{Sitcom}}$	A+V+T	0.153	0.193	0.369	0.449
	SMILE$_{\text{TED}}$	A+V+T	0.279	0.260	0.454	0.457

(B) Cross-dataset evaluation

Table 6: **Analysis on video types.** In (a), we conduct the video type-wise evaluation as the dominant laughter type differs along the video type. In (b), we evaluate the model by testing on the different video types, *i.e.*, cross-dataset.

Test	A	B	A wins (%)	Fleiss'-κ
TED	GPT-3 (SMILE)	GPT-3 (TED)	66.2	0.40
Sitcom	GPT-3 (SMILE)	GPT-3 (sitcom)	61.4	0.63

Table 7: **Pairwise human evaluation.** We compare the model trained with the whole dataset (SMILE) with a subset (TED, sitcom) and evaluate them with the test set of each subset.

precision that uses fp16 for multiplication and fp32 for addition.

Detection. For the sarcasm (Castro et al., 2019) and humor detection (Hasan et al., 2019) tasks, we finetune LLaMA-13B (Touvron et al., 2023) and GPT-3 (Brown et al., 2020a) with our multimodal textual representation. GPT-3 finetuning is as same as described for the laugh reasoning task. For LLaMA-13B, we follow the fine-tuning script on Vicuna (Chiang et al., 2023)[10]. Examples of the prompts for both tasks that cast classification task to generation task are shown in Figure 12. We use four A100 (80GB) for each training. We follow Vicuna's default LLaMA fine-tuning hyperparameters except for setting the per-device batch size to 3 and the number of training epochs to 20.

E Additional Experiments

Evaluation by video types. The type of laughter varies depending on the source of the video, as shown in Figure 11. To explore this further, we evaluate each video type independently. Instead of fine-tuning GPT3 on the entire SMILE dataset, we separately fine-tune the models on subsets of

Figure 13: **Examples of laugh reasoning on recent video language models.** While recent video language models, such as Video-LLaMA (Zhang et al., 2023) and VideoChat (Li et al., 2023), can respond to the general question in the video, they struggle to plausibly explain the reason for the laughter in the video.

the dataset, namely SMILE$_{\text{Sitcom}}$ and SMILE$_{\text{TED}}$. As summarized in Table 6 (a), even when models are independently fine-tuned to different video types, their performance is comparable to that of the model trained on the SMILE dataset. Interestingly, in the human evaluation, the model trained on whole data (SMILE) is preferred over the model trained on each video type. This suggests that our dataset, SMILE, covers the diverse laughing characteristics to lead GPT3 to learn generalized laughter reasons across different types of videos.

However, we observe that testing the model across different video types, *e.g.*, training on SMILE$_{\text{Sitcom}}$ and testing on SMILE$_{\text{TED}}$, results in a significant performance drop, as shown in Table 6 (b). We speculate that this is due to differences in laughter types presented in each source video. This supports the idea that combining these two heterogeneous video types could help the model learn to understand a broader range of reasons behind audience laughter.

Video language model. While the previous methods (Zellers et al., 2019; Zadeh et al., 2019) have aimed to learn and reason about social interactions from visual data, they formulate the task in multiple-choice setups. By virtue of the advance of large language models, recent work has suggested multimodal models capable of generating natural language responses to questions about a video, rather than outputting a multiple-choice answer. In this context, we examine if these models can exhibit the capability to reason behind laughter in a given video. We feed the same video from Figure 5 into recent video-language (VL) models, Video-LLaMA (Zhang et al., 2023)[11] and VideoChat (Li et al., 2023)[12], and showcase their generated reasoning in Figure 13. While these models can respond to general questions about the video, they struggle to reason about moments of laughter. Unlike existing multimodal reasoning work, we contribute a new perspective to multimodal reasoning, aiming to understand and reason about an important social signal, laughter.

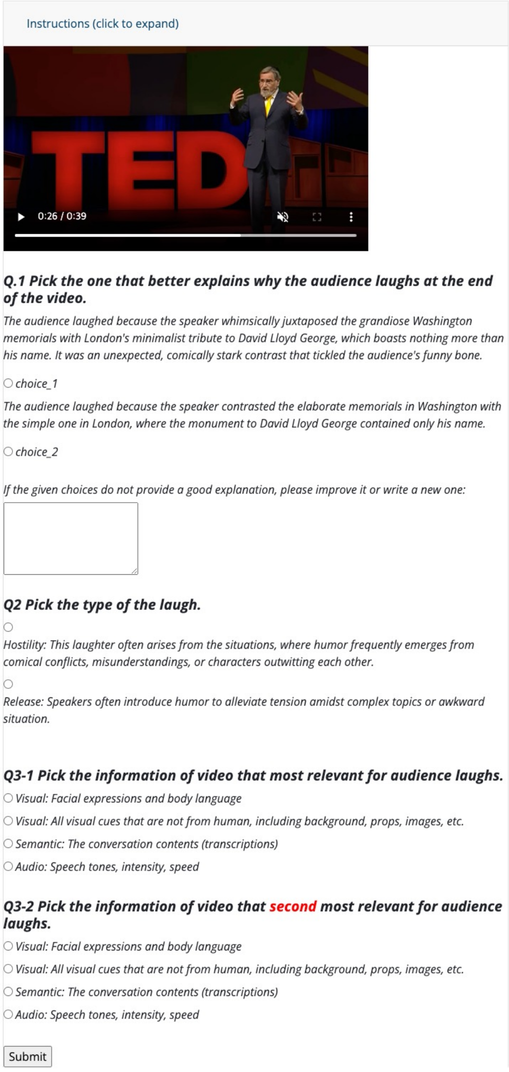
F Human annotation from Amazon Mechanical Turk

Figure 14 shows our interface and instructions for the annotators working on Amazon Mechanical Turk (AMT). We define a questionnaire per video clip as a Human Intelligence Task (HIT). We ask AMT annotators three questions in a HIT, 1) laughter reason, 2) laugh type, and 3) the multimodal cues in perspective of which cues are related to laughter in the video. The first question is for obtaining GT annotations for laughter reasons and pairwise human evaluation in § 4. The second and third questions are for the data analysis purpose, which provides further understanding of our dataset (See § 3.3 in the main paper and Appendix C).

---

[11] https://github.com/DAMO-NLP-SG/Video-LLaMA

[12] https://github.com/OpenGVLab/Ask-Anything



Instructions (click to expand)

Q.1 Pick the one that better explains why the audience laughs at the end of the video.

The audience laughed because the speaker whimsically juxtaposed the grandiose Washington memorials with London's minimalist tribute to David Lloyd George, which boasts nothing more than his name. It was an unexpected, comically stark contrast that tickled the audience's funny bone.

○ *choice_1*

The audience laughed because the speaker contrasted the elaborate memorials in Washington with the simple one in London, where the monument to David Lloyd George contained only his name.

○ *choice_2*

If the given choices do not provide a good explanation, please improve it or write a new one:

Q2 Pick the type of the laugh.

○

Hostility: This laughter often arises from the situations, where humor frequently emerges from comical conflicts, misunderstandings, or characters outwitting each other.

○

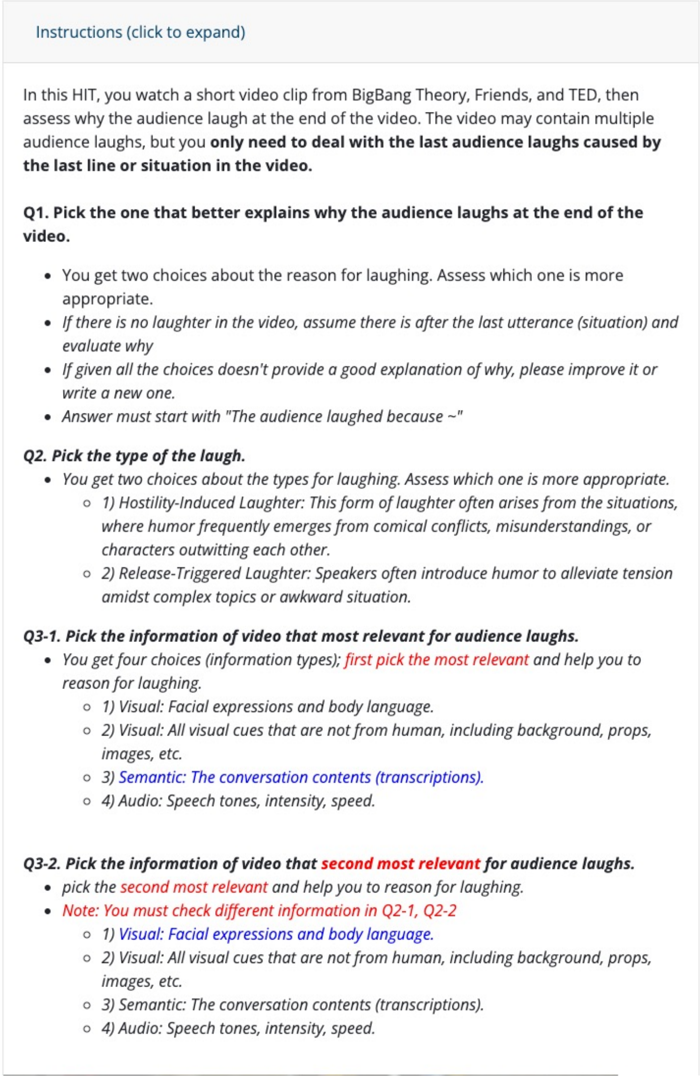
Release: Speakers often introduce humor to alleviate tension amidst complex topics or awkward situation.

Q3-1 Pick the information of video that most relevant for audience laughs.

○ *Visual: Facial expressions and body language*
○ *Visual: All visual cues that are not from human, including background, props, images, etc.*
○ *Semantic: The conversation contents (transcriptions)*
○ *Audio: Speech tones, intensity, speed*

Q3-2 Pick the information of video that second most relevant for audience laughs.

○ *Visual: Facial expressions and body language*
○ *Visual: All visual cues that are not from human, including background, props, images, etc.*
○ *Semantic: The conversation contents (transcriptions)*
○ *Audio: Speech tones, intensity, speed*



Instructions (click to expand)

In this HIT, you watch a short video clip from BigBang Theory, Friends, and TED, then assess why the audience laugh at the end of the video. The video may contain multiple audience laughs, but you **only need to deal with the last audience laughs caused by the last line or situation in the video.**

Q1. Pick the one that better explains why the audience laughs at the end of the video.

- You get two choices about the reason for laughing. Assess which one is more appropriate.
- *If there is no laughter in the video, assume there is after the last utterance (situation) and evaluate why*
- *If given all the choices doesn't provide a good explanation of why, please improve it or write a new one.*
- *Answer must start with "The audience laughed because ~"*

Q2. Pick the type of the laugh.

- *You get two choices about the types for laughing. Assess which one is more appropriate.*
    - *1) Hostility-Induced Laughter: This form of laughter often arises from the situations, where humor frequently emerges from comical conflicts, misunderstandings, or characters outwitting each other.*
    - *2) Release-Triggered Laughter: Speakers often introduce humor to alleviate tension amidst complex topics or awkward situation.*

Q3-1. Pick the information of video that most relevant for audience laughs.

- *You get four choices (information types); first pick the most relevant and help you to reason for laughing.*
    - *1) Visual: Facial expressions and body language.*
    - *2) Visual: All visual cues that are not from human, including background, props, images, etc.*
    - *3) Semantic: The conversation contents (transcriptions).*
    - *4) Audio: Speech tones, intensity, speed.*

Q3-2. Pick the information of video that second most relevant for audience laughs.

- *pick the second most relevant and help you to reason for laughing.*
- *Note: You must check different information in Q2-1, Q2-2*
    - *1) Visual: Facial expressions and body language.*
    - *2) Visual: All visual cues that are not from human, including background, props, images, etc.*
    - *3) Semantic: The conversation contents (transcriptions).*
    - *4) Audio: Speech tones, intensity, speed.*

Figure 14: **Examples of the AMT interface (left) and instructions (right) that the annotators worked on.** The annotators are asked to watch the video clip and answer the three questions. The third question is split into two parts. We put the instructions at the top of the interface to emphasize how the annotators should answer each question.

T3M: Text Guided 3D Human Motion Synthesis from Speech

Wenshuo Peng[1], **Kaipeng Zhang**[1*], **Sai Qian Zhang**[2†]
[1]OpenGVLab, Shanghai AI Laboratory
[2]New York University

gin2pws@gmail.com, zhangkaipeng@pjlab.org.cn, sai.zhang@nyu.edu

Abstract

Speech-driven 3D motion synthesis seeks to create lifelike animations based on human speech, with potential uses in virtual reality, gaming, and the film production. Existing approaches reply solely on speech audio for motion generation, leading to inaccurate and inflexible synthesis results. To mitigate this problem, we introduce a novel text-guided 3D human motion synthesis method, termed *T3M*. Unlike traditional approaches, T3M allows precise control over motion synthesis via textual input, enhancing the degree of diversity and user customization. The experiment results demonstrate that T3M can greatly outperform the state-of-the-art methods in both quantitative metrics and qualitative evaluations. We have publicly released our code at https://github.com/Gloria2tt/naacl2024.git

1 Introduction

Speech-driven 3D motion synthesis, known as *speech-to-motion*, is a technique aimed at generating realistic and expressive motion animations from human speech. Despite its promising applications in virtual reality (VR) (Wohlgenannt et al., 2020), gaming (Ping et al., 2013), and film production (Ye et al., 2022), speech-to-motion also encounters significant challenges, involving various modalities and intricate mappings. Speech signals tend to be high-dimensional, noisy, and subject to variability, while motion data often exhibit sparsity, discreteness, and adherence to physical laws. Additionally, the connection between speech and motion is not deterministic; instead, it relies on factors such as the environment, emotions, and individual personalities.

Moreover, in traditional speech-to-motion systems, speech audio serves as the sole input for generating various motions for the face, body, and hands. However, this approach may lead to imprecise and undesired motion synthesis due to limitations in the expressive capabilities of the audio signal. Identical audio signals could also stem from entirely unrelated contexts. For instance, as depicted in Figure 1, when examining the same audio segment, an introverted speaker tends to use minimal body and hand motions compared to an extroverted speaker, who exhibits a more extensive range of movements. Capturing such contextual information solely from audio input proves nearly impossible. This limitation in precise control poses potential difficulties for emerging industries like AI-driven film or animation production, where generated motions may need additional refinement to match user preferences more accurately.

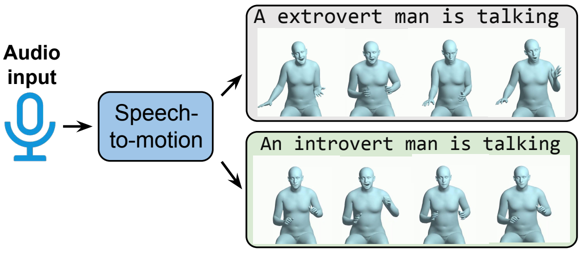


Figure 1: Under the same audio input, extrovert and introvert persons will talk in a completely different fashion.

To address this issue, we introduce a novel text-guided 3D human motion synthesis from speech method, termed *T3M*. The T3M framework enables accurate control of body-hand motion generation via provided text prompts. This improvement is especially valuable for addressing the rigidity often observed in the motions generated due to the relationship between speech and co-speech gesture is one-to-many in nature. Even the same speech in different situation can be result in different motion style. The controllability afforded by T3M facilitates the creation of more nuanced and realistic

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1168–1177
June 16-21, 2024

motion sequences, enhancing overall realism and expressiveness.

Our T3M contains three major blocks, a VQ-VAE network to generate an intermediate codebook for action-to-action mapping, an audio feature extraction network to extract acoustic information of audio, and a multimodal fusion block to implement audio and text interaction. Specifically, We train a VQ-VAE network with a two-layer codebook, which contains hand and body information respectively. Considering that human motions are related to the speaker's emotion, intonation, and rhythm, we utilize a pre-trained EnCodec (Défossez et al., 2022) model to extract acoustics features from the original audio. To align the sequenc lenth of audio feature and the stored body-hand motion parameter, we use an audio encoder to downsample the features. Furthermore, we propose a multimodal fusion encoder structure, which inserts a cross-attention layer to the transformer decoder acoustics architecture for better textual information fusion.

Another significant challenge arises in the generation of training datasets for T3M. Most existing training datasets for speech-to-motion are in the form of speech-motion pairs, lacking corresponding textual information. One simple approach to address this gap is to utilize a video large language model (VLLM) like Video-Llama (Zhang et al., 2023) for labeling datasets. However, current VLLMs can only provide a coarse-grained description of the video input. Additionally, since speech-motion pairs in the training dataset are often extracted from particular segments of lengthy videos, employing VLLM for text generation may lead to highly similar text descriptions being produced across various video clips. To enhance the diversity of textual descriptions within the training dataset, we adopt the video-language contrastive learning framework, VideoCLIP (Xu et al., 2021b). This framework enforces the alignment of video and text in a joint embedding, enabling the processing of video frames and utilizing the resultant video features to replace textual features for T3M training.

Our research primarily centers on text-guided speech to body and hand motions generation. For 3D face reconstruction, we utilize cutting-edge methods in the field, such as those demonstrated in (Peng et al., 2023). Overall, our contributions can be described as follows:

- We propose a novel speech-to-motion training framework termed T3M, enabling users to achieve better control over the holistic motion generated from audio through the utilization of textual inputs.
- To achieve audio-to-motion generation controlled by text, we align video and text in a joint embedding, utilizing video input for training and text descriptions for inference. This approach notably enhances the diversity of textual input within the training dataset and substantially improves the performance of motion synthesis.
- The results show that the proposed T3M framework significantly outperforms existing methods in terms of both quantitative and qualitative evaluations.

2 Related Work

2.1 Motion Generation from Speech

In recent years, there has been a growing interest in generating human-like motion from speech. One area of research is centered around facial reconstruction, with various studies exploring 2D talking head generation (Mittal and Wang, 2020). These investigations employ image-driven or speech-driven techniques to produce realistic videos of people speaking.

Extensive research has been conducted in the field of 3D talking heads generation. To make the reconstruction more precise, FaceFormer (Fan et al., 2022) uses a Transformer-based model to obtain contextually relevant audio information and generates continuous facial movements in an autoregressive manner. VOCA (Cudeiro et al., 2019) uses time convolutions and control parameters to generate realistic character animation from the speech signal and static character mesh. MeshTalk (Richard et al., 2021) places its emphasis on the upper facial generation, an aspect where VOCA falls short. It establishes a categorical latent space for facial animation and effectively separates audio-correlated and audio-uncorrelated motions using cross-modality loss, enabling the generation of audio-uncorrelated actions like blinking and eyebrow movements. Another line of research centers on body and hand motion reconstruction. These approaches can be categorized into two groups: rule-based and learning-based methods. Rule-based methods, such as (Kopp and Wachsmuth, 2004), involve the mapping of input speech to pre-defined body motion units through manually crafted rules.

The development of learning-based methods for generating body motion, as demonstrated in research like (Ahuja et al., 2020), has made substantial progress, largely attributed to the availability of openly accessible synchronous speech and body motion datasets (Habibie et al., 2021). Very recently, TalkSHOW (Yi et al., 2023) has introduced a simple encoder-decoder architecture capable of producing holistic 3D mesh motion.

However, it is important to highlight that despite these advancements, these methods still encounter difficulties in achieving a balance between diverse and controllable motion. Consequently, when applied in real-time scenarios, the generated actions often display repetitiveness and limited adaptability in response to changes in the external condition.

2.2 Video-text Pre-training

The aim of video-text pre-training is to utilize the complementary information found in both videos and textual inputs to improve the performance of subsequent tasks. VideoBERT, as introduced in (Sun et al., 2019), pioneered the exploration of pre-training methods for video-text data pairs. Its primary focus lies in acquiring a unified visual-linguistic representation, and it demonstrates versatility in adapting to a range of tasks, such as action classification and video captioning.

VideoCLIP (Xu et al., 2021b) employs a contrastive learning approach to pre-train a unified model for zero-shot understanding of both video and textual inputs, without relying on any labels in downstream tasks. VLM (Xu et al., 2021a) introduces a simplified, task-agnostic multi-modal pre-training method. This method is capable of handling inputs in the form of either video, text, or a combination of both, and it can be applied to a diverse range of end tasks. Recently, there has been a surge in research focused on large language models (LLMs), and some researchers have started incorporating LLMs into this field, yielding promising results. Video-LLaMA (Zhang et al., 2023) bootstraps cross-modal training from the frozen pre-trained visual, audio encoders and the frozen LLMs. This approach utilizes the robust understanding capabilities of large models for tasks such as video understanding and video question answering. In our research, we make use of VideoCLIP to process both video and textual inputs. In particular, during the training phase, we utilize the video encoder of VideoCLIP to convert the video input into latent vector for multimodal learning. During the testing phase, we leverage its text encoder component to enable text-based control over body and hand motion generation.

3 Method

In this section, we describe the detailed design of T3M, which can generate holistic body motion, including body poses, hand gestures, and facial expressions, based on provided text descriptions.

3.1 Preliminary

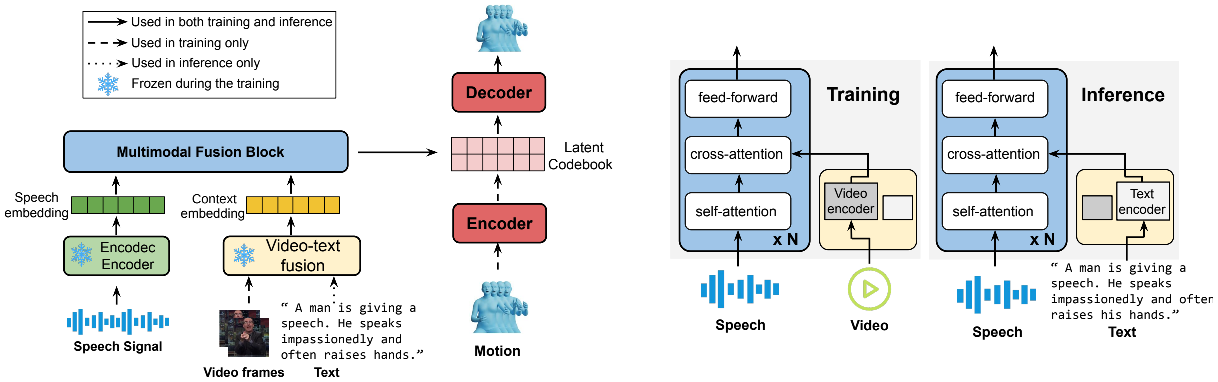
We begin by establishing a mathematical formulation for the problem. Specifically, we define a temporal sequence of motion from time $t = 1$ to $t = T$ as $A_{1:T}$ further contains three primary components: facial expressions along with the jaw poses denoted as $A^f_{1:T}$, body motions as $A^b_{1:T}$, and hand motions as $A^h_{1:T}$. Each element a^f_t of $A^f_{1:T}$ is defined as $a^f_t = (\theta^{jaw}_t, \zeta_t)$, where θ^{jaw}_t is the jaw pose and ζ_t is the facial expression parameter. In the case of $A^b_{1:T}$ and $A^h_{1:T}$, each element is defined as follows: $a^h_t = (\theta^b_t)$, $a^b_t = (\theta^h_t)$, where θ^b_t and θ^h_t are the body poses and hand poses, respectively. Prior methods (Yi et al., 2023) primarily produces the holistic motion solely based on the speech input. In contrast, our objective, when provided with a speech input sequence $S_{1:T}$, is to produce comprehensive motion sequences $A^b_{1:T}$, and $A^h_{1:T}$ by incorporating additional textual context. This context describes the situation and background associated with the speech input, allowing the resultant holistic motions to vary according to both speech and textual inputs. Formally, we express this as:

$$\hat{A}_{1:T} = F_{T3M}(S_{1:T}, B) \tag{1}$$

where B is the textual input and $\hat{A}_{1:T}$ is the output holistic motion generated by T3M and F_{T3M} represents the T3M function. Figure 2(a) depicts the overview of T3M framework, and we will provide a detailed description of each component of T3M in the following sections.

3.2 Face Generation

We adopt the approach outlined in TalkSHOW to generate facial expressions and other body parts separately. Given that human facial expressions primarily stem from speech content, we leverage the pre-trained wav2vec 2.0 model (Baevski et al., 2020) as a semantic encoder to extract semantic



(a) (b)

Figure 2: Overview of the proposed T3M. We employ a novel framework for body and hand motion generation. Specifically, T3M first learns a quantized body-hand codebook through a VQ-VAE model. In the training phase, we the pre-trained EnCodec model to extract the speech embedding of the given speech. We employ the pre-trained video encoder from VideoCLIP to obtain the video embedding that corresponds to the provided speech. To facilitate interaction between these two modalities, we utilize a multimodal fusion block. This fusion block is built upon a BERT-based framework, enhanced with a cross-attention layer for effective fusion.

representations from the provided speech. These extracted features are then fed into a decoder to reconstruct facial motion.

The wav2vec 2.0 model consists of three main components: firstly, a stack of convolutional layers that process the raw audio waveform to derive a latent representation; secondly, a group of transformer layers that generate contextualized representations based on the derived latent representation; and finally, a linear projection head that produces the output.

The decoder consists of a Temporal Convolutional Networks (TCNs) with six layers, followed by a fully-connected layer. We employ a similar approach as described in (Yi et al., 2023) to reconstruct facial motion. However, it is worth noting that within our framework, we can replace the face reconstruction method with other SOTA methods, such as (Peng et al., 2023).

3.3 Context Features Generation

As depicted in Figure 2(a), the generation of context feature is a necessary step in T3M training. To create the context embedding, we employ a video-text fusion model designed to generate diverse context features. To achieve this, an intuitive approach involves sending the text description directly to a text encoder, and forward the output context features to the video-text fusion module for further processing. However, this is not feasible for two key reasons. Firstly, it is noteworthy that in many cases, several audio waveform segments within a single video clip exhibit significant textual similarities. This resemblance in textual content results in highly resemble output features across these various audio segments, ultimately leading to a suboptimal overall motion synthesis performance due to lack of training data diversity. In contrast, our approach employs a video encoder to process the video frames corresponding to the audio waveforms, which will capture intricate context features corresponding to each speech segment. These context features are subsequently passed on to the multimodal fusion block for additional processing, as shown in the left part in Figure 2(b). Secondly, even though it is feasible to manually design distinct text descriptions with intentional variations for each audio segment, this manual labeling process would be labor-intensive.

As a result, during training stage of T3M, we choose to utilize the video frames corresponding to the speech input to generate the context feature. During the inference, the text description will be sent to the text encoder for better guiding the holistic motion synthesis (right part of Figure 2(b)). To enable the precise text-guided motion generation, we adopt the video and text encoders from the VideoCLIP model, which establishes a detailed correlation between video and text through contrastive learning. By mapping video and text embeddings into a common latent feature space, we facilitate seamless modality substitution for text-guided motion synthesis during inference. This approach simplifies the process by eliminating the need for extensive manual labeling of textual descriptions and leveraging existing joint video-text representation models. It builds upon the concept of modality substitution, which has been successfully employed in other contexts, such as MusicLM (Agostinelli et al., 2023) with audio and text.

3.4 Body and hand Motion Generation

Audio Feature Encoder We obtain the speech embedding using EnCodec (Défossez et al., 2022), a state-of-the-art neural audio codec pre-trained model capable of extracting audio features from the provided speech. It contains a total of eight layers of codebooks, each layer stores different audio information. Given that the audio token sequence stored in the 8-layer codebook is overly lengthy, we opt not to employ these audio tokens as the initial input. Instead, we employ the decoder of the codebook to generate the audio features, which serve as our speech embeddings. Next, we employ a compression model based on a convolutional neural network architecture to transform these features, aligning them with the sequence length of the motion embeddings. Finally, we further insert an MLP at the end of the compression model to map the dimensions to 768, where 768 is the dimension dim of the context feature. Using our audio feature encoder, for a speech segment lasting k seconds, we obtain an speech embedding with a dimension of $e^a \in \mathbb{R}^{L_{seq} \times 768}$, where $L_{seq} = k \times fps$ represents the sequence length, where fps is the frames per second rate of the motion data. This rate determines the number of motion frames that correspond to each second of speech, thereby aligning the temporal resolution of the audio and motion data.

Latent Codebook Design It is challenging to directly produce the body-hand motion sequence for a given speech sequence because the input and output belong to two distinct modalities. To mitigate this problem, we utilize the VQ-VAE (Van Den Oord et al., 2017) model to create a latent codebook for both body motion and hand motion.

Consequently, we obtain two distinct finite codebooks: $Z_b = \{z_{b_i}\}_{i=1}^{|Z_b|}$ for body motions and $Z_h = \{z_{h_j}\}_{j=1}^{|Z_h|}$ for hand motions, where $z_{b_i}, z_{h_j} \in \mathbb{R}^{d_z}$ and d_z denotes the length of each codebook element. This approach yields $|Z_b| \times |Z_h|$ different body-hand pose code pairs (z_{b_i}, z_{h_j}), significantly expanding the range of motion diversity.

Multimodal Fusion Block Design The Multimodal Fusion Block is a transformer-decoder based model that incorporates an cross-attention layer between the feedforward layer and the self-attention layer, as depicted in Figure 2(b). Its purpose is to produce latent codebook tokens from the provided speech features and context features, which serve as input for the VQ-VAE decoder.

As described in Section 3.3, during the training phase, we substitute the text input with the video frames corresponding to the speech. We encode these video frames by ViCLIP video encoder into the context feature space, which is shared with the text captions. Thus, for the video x, its corresponding feature can be derived as follows:

$$e^v = F_v(x) \tag{2}$$

where $e^v \in \mathbb{R}^{1\times 512}$ is the feature vector for the video x and F_v is the video encoder function. e^v will be used as the context features during the inference operation for conditional body and hand motion generation.

For the speech embedding e^a and the context features e^v, the multimodal fusion block layer then combines them through standard cross-attention. It is important to highlight that the cross-attention layer between the speech features and the context features offers two significant advantages. Firstly, our model integrates context features during training, enabling the generation of distinct body-hand motions based on varying input text during the inference stage. Secondly, as this context feature is incorporated during training, the reconstructed motion exhibits higher quality and a greater level of alignment.

3.5 Loss Function

As illustrated in Figure 2(a), the training process of T3M involves three main stages. First, the facial image generator is trained to convert audio signals into facial expressions. Semantic features are extracted using a pre-trained wave2vec encoder, and the decoder is trained to minimize the Mean Square Error (MSE) loss between the ground truth facial output and the decoder output.

Second, the VQ-VAE model is trained to map body and hand motions into a latent space, resulting in a codebook $C \in \mathbb{R}^{d_z \times 2}$. Formally, we have

$$\begin{aligned} \mathcal{L}_{VQ} = \mathcal{L}_{\text{rec}}(A, \widehat{A}) + \alpha \left\| \text{sg}[z_e(A)] - Z_Q(A) \right\| \\ + \lambda \left\| z_e(A) - \text{sg}[z_q(A)] \right\| \end{aligned}$$

where $\mathcal{L}_{\text{rec}}$ is the mean squared error reconstruction loss, $sg[.]$ is the stop gradient operation, z_e is the output of the VQ-VAE encoder and z_q is the quantization function. α and λ are two weight coefficients to reflect the importance of each component.

Lastly, we train our multimodal fusion block to generate the discrete token of the codebook from the speech and video through cross-entropy loss.

4 Experiment

We first describe experiment setup in Section 4.1, and provide quantitative and qualitative evaluate in Section 4.2 and Section 4.3. We then evaluate T3M over more data examples in Section 4.4, and present the ablation study in Section 4.5. We include a video demo in the supplementary materials (data).

4.1 Experiment Setup

Dataset In our research, we use the SHOW dataset (Yi et al., 2023), a high-quality audiovisual dataset which consists of expressive 3D body meshes at 30fps, with a synchronized audio at a 22K sample rate. The 3D body meshes are reconstructed from in-the-wild monocular videos and are used as our pseudo ground truth (p-GT) in speech-to-motion generation. For a given video clip of T frames, the p-GT comprises parameters of a shared body shape $\beta \in \mathbb{R}^{300}$, poses $\theta_t \in \mathbb{R}^{156T}_{t=1}$, a shared camera pose $\theta_c \in \mathbb{R}^3$, a translation $\epsilon \in \mathbb{R}^3$ and facial expressions $\psi_t \in \mathbb{R}^{100T}_{t=1}$. Here, the pose θ_t includes the jaw pose $\theta_{\text{jaw}_t} \in \mathbb{R}^3$, the body pose $\theta_{b_t} \in \mathbb{R}^{63}$, and the hand pose $\theta_{h_t} \in \mathbb{R}^{90}$.

Compared Baseline We compare T3M with TalkSHOW, the first research work on holistic 3D human motion generation using speech. We also evaluate the authenticity and diversity of the resultant motion synthesis by comparing various baselines, including Audio Encoder-Decoder (Ginosar et al., 2019), Audio VAE (Yi et al., 2023), and Audio+Motion VAE (Yi et al., 2023).

Metrics We used the following methods to measure the quality of the generated holistic motion. Firstly, we calculate the *Reality Score (RS)* of the generated body and hand motions by employing a binary classifier, as per the methodology outlined in (Aliakbarian et al., 2020). The classifier is trained to distinguish between authentic and synthetic samples, and RS is computed from its predictions, serving as a metric for assessing the realism of the generated motions. Secondly, we compute the Beat Consistency Score (BCS) (Zhao et al., 2023) of the resultant motions to evaluate the motion-speech beat correlation (i.e., time consistency).

Method	RS	BCS
Habbie et al.	0.146	-
Audio Encoder-Decoder	0.214	-
Audio VAE	0.182	-
Audio+Motion VAE	0.240	-
TalkSHOW	0.414	0.8130
T3M(video prompt)	**0.483**	**0.8586**
T3M(random prompt)	0.364	0.8398

Table 1: Evaluation results on several methods. For convenience, we use video prompt and random prompt to test our T3M. - means the results are not available. We focus on the comparison with TalkSHOW.

4.2 Quantitative Evaluation

Our experiment results are presented in Table 1. When using T3M, we utilize two distinct prompt types for generating the context features. The initial type replicates the training stage, utilizing a video prompt. In contrast, the second type entails the generation of a random vector with a mean of -0.04 and a variance of 0.12, which is utilized as the context features. In this setup, T3M generates synthetic motions solely based on the speech input.

Based on the data presented in Table 1, it is evident that our T3M, when using a video prompt, demonstrates superior performance in terms of both RS and BCS indicators. Furthermore, we note that employing a random prompt yields a slightly lower RS score compared to TalkSHOW; however, it outperforms TalkSHOW in terms of BCS, which demonstrate that the generated motions by our T3M are more consistent with the audio,

4.3 Qualitative Evaluation

Visualization Results To demonstrate the impact of textual input over the resultant motion synthesis, we utilized two text prompts with opposing semantic meanings, along with a randomly generated embedding as our prompt input. Specifically, for the text prompts, we use “A man is giving a speech, he is very excited” and “I am giving a speech, I feel really nervous”, which has totally opposite semantic meanings. Additionally, we also compare the resultant holistic motions with TalkSHOW, the visualization examples are depicted in Figure 3.

As depicted in Figure 3, it is evident that the motions generated by TalkSHOW appear to lack diversity. The motions of both hands change inde-

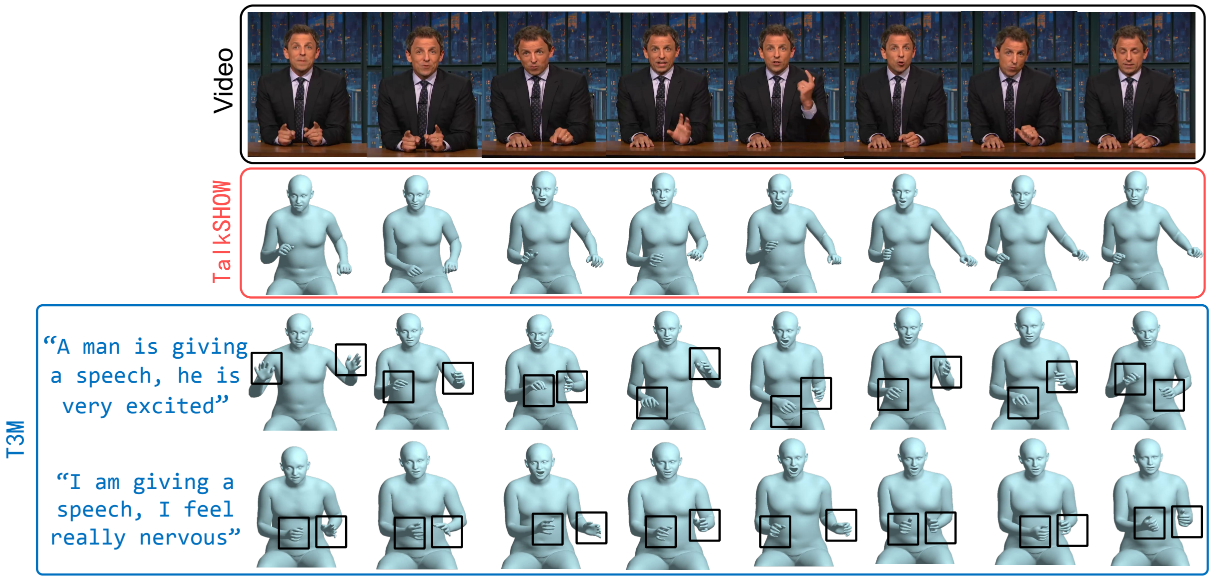


Figure 3: Visualization of 3D holistic motions generated by TalkSHOW and T3M. For T3M, three different text prompts are provided and the positions of the hand are highlighted with black boxes. We notice that the hand motions are closely aligned with the input text desription in T3M.

pendently and do not correspond to the speaker’s emotions and intonation, resulting in a unnatural and unrealistic appearance. For T3M, When using the random prompt, we notice that the hand motions closely resemble those of the original video. Additionally, the motions of both hands exhibit corresponding interactions and a higher coordination.

When using the prompt input, “A man is giving a speech, he is very excited.”, we observe a notable increase in the range of hand motion changes. Additionally, there are noticeable upward and downward movements of the hands. These motions align closely with our textual description, reflecting the speaker’s highly excited state during the speech. By comparison, for text description “I am giving a speech, I feel really nervous”. We notice that the generated motions distinctly portray signs of nervousness. The hand movements are very restricted, and there are noticeable trembling or jittery motions, effectively capturing the heightened nervous state of the speaker. Overall, the experimental results show that with the introduction of textual input, T3M can achieve controllable motion generation with much higher degree of diversity.

Method	**hands and body**	**holistic**
TalkSHOW	3.43	3.36
T3M (random)	3.25	3.08
T3M (video)	3.86	3.95

Table 2: User study results (higher scores indicating better quality). We use the video prompt and the random prompt to evaluate the quality of our generated motions.

User Study To offer a more comprehensive evaluation of T3M, we have devised a thorough user study questionnaire. Following the methodology employed in TalkSHOW, we randomly selected 40 videos from four different speakers in the SHOW dataset, with each video having a duration of 10 seconds. We have invited 12 participants to participate in the evaluation process. Each participant will give a score ranging from 1 to 5 to rate the video in terms of the generated motions. We use random prompt and video prompt for our T3M model. Subsequently, we compute the average scores and document the results in Table 2.

Table 2 reveals that our T3M, when using the video prompt, attains the highest scores. Furthermore, it is evident from the table that utilizing a random prompt yields only slightly lower scores compared to the TalkSHOW method.

4.4 Other Examples

In order to better verify the effect of T3M, we evaluate samples that are not contained in the SHOW dataset. We employ an audio clip of French as our speech input, utilizing two textual descriptions as prompts to enhance our evaluation. One text expresses strong negative emotions: “I am very upset, I do not want to continue the speech”, while the

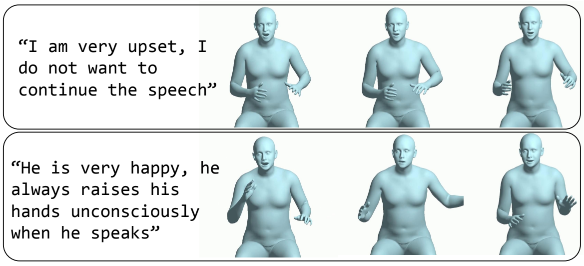

Figure 4: Experiments on unseen speech. We use two different text input to control the motion generation.

Method	BCS	Motion Score
T3M (MFCC)	0.8050	3.54
T3M (EnCodec)	0.8586	3.82

Table 3: Ablation results between Mel Frequency Cepstral Coefficients(MFCC) and EnCodec. For the BCS indicator, using EnCodec acheive $+0.0536$ test scores. For the use study score of motion score indicator, we random select a total number of 20 generated videos and invite 5 people to rate them.

other conveys positive emotions: "He is very happy, he always raises his hands unconsciously when he speaks". The results are shown in Figure 4.

We have noticed that when dealing with speech not present in the SHOW dataset, T3M is still capable of producing distinct actions in response to the input text. Specifically, when using " I am very upset, I do not want to continue the speech", there is a lack of noticeable alterations in the accompanying hand movements to convey the speaker's upsetness. When using "He is very happy, he always raises his hands unconsciously when he speaks", the range of hand movements of the speaker increased significantly, including a conspicuous pattern of raising the hands. These findings demonstrate that our approach successfully accomplishes motion generation even in zero-shot scenarios.

4.5 Ablation Study

We conduct an ablation study to examine the contribution of each component in T3M model.

Effect of EnCodec We replace the EnCodec with Mel Frequency Cepstral Coefficients (MFCC) (Zheng et al., 2001) and use the BCS and user study score (USS) to measure the effectiveness of generated motions. We report the results in Table 3. Comparing MFCC with EnCodec, we observe a noticeable performance improvement when utilizing EnCodec. Specifically, an increase of 0.0536 in BCS is observed with the usage of EnCodec. A user study was conducted to evaluate the motion score. A total of 20 samples are randomly selected for evaluation. Five individuals were invited to rate the generated videos, and a higher score indicates better performance. From Table 3, we also observe T3M with EnCodec achieves a better performance over MFCC.

Method	Motion Score
T3M (random)	3.12
T3M (zero)	2.52
T3M (text)	3.69
T3M (video)	3.85

Table 4: Ablation results to evaluate different context embeddings. Zero means using an all-0 vector to be the context. We use the usr study results to evaluate the generated motions.

Impact of Context Features We aim to investigate the impact of context feature over the synthesis effect. Particularly, we use four different types of embeddings to encode context: random prompt, text prompt, video prompt, zero prompt. For the text prompt, we use "I am giving a speech, I feel really excite". In contrast, for the zero prompt, we employ a context feature vector consisting entirely of zeros. We invite five individuals to rate ten videos which are generated from ten randomly selected speech samples. We present the USS in Table 4. We observe that text prompt and the video prompt both achieve better performance over random prompt and zero prompt.

5 Conclusion

In this paper, we proposed T3M, a novel text-guided 3D human motion synthesis method from speech. T3M can generate realistic and expressive holistic motions by leveraging both speech and textual inputs. We use a pre-trained EnCodec model to extract audio features from speech and a multimodal fusion model to fuse the audio and text features. To enhance the text diversity during training, we employed VideoCLIP, a video-language contrastive learning framework, to process the video frames and use the output video features to replace the textual features. By training on the SHOW dataset, a 3D holistic dataset, T3M enables users to precisely control the holistic motion generated from speech by utilizing textual inputs.

6 Limitation

When considering future enhancements, it is possible to achieve even better performance with T3M by incorporating more advanced text and video encoders from a pretrained multimodal model that surpasses the capabilities of VideoCLIP. To the best of our knowledge, the SHOW dataset currently stands as the sole dataset in the field of speech-driven 3D motion synthesis, albeit it covers a relatively limited range of scenes. We believe that enhancing the performance of T3M could be achieved by training it on more extensive datasets that involves a wider variety of scenarios and contexts.

A Implementation Details

A.1 Quantization Function of VQ-VAE

Given the input body motions $A_b^{1:T} \in \mathbb{R}^{63\times T}$ and hand motions $A_h^{1:T} \in \mathbb{R}^{90\times T}$, the encoding process begins by mapping them to feature sequences. Specifically, we obtain $E_{b1:\tau} = (e_{b1}, \ldots, e_{b\tau}) \in \mathbb{R}^{64\times\tau}$ and $E_{h1:\tau} = (e_{h1}, \ldots, e_{h\tau}) \in \mathbb{R}^{64\times\tau}$, where $\tau = T \cdot C$ and C represents the temporal window size. In our experiment, we set $C = 4$ to strike a balance between the speed of inference and the quality of the feature embeddings.

For the quantization, we have

$$z_{b_t} = \arg\min_{z_{b_k}\in Z_b} \|e_{b_t} - z_{b_k}\| \in \mathbb{R}^{64},$$

$$z_{h_t} = \arg\min_{z_{h_k}\in Z_h} \|e_{h_t} - z_{h_k}\| \in \mathbb{R}^{64}.$$

Here, z_{b_t} and z_{h_t} represent the quantized embeddings for body and hand motions at time t, and Z_b and Z_h denote the codebooks associated with body and hand motions, respectively.

A.2 Training Details

Face Generator For the head reconstruction, We adopt SGD with momentum and a learning rate of 0.001 as the optimizer. The face generator is trained with batchsize of 1 for 100 epochs, in which each batch contains a full-length audio and corresponding facial motions.

VQ-VAE For the VQ-VAE training, the VQ-VAE processes input consisting of either body or hand motions. Each VQ-VAE encoder is constructed with three residual layers, incorporating temporal convolution layers with a kernel size, stride, and padding of 3, 1, and 1, respectively. Batch normalization (Ioffe and Szegedy, 2015) and a Leaky ReLU activation function(Maas et al., 2013) follow each convolution layer. An additional temporal convolution layer with a kernel size, stride, and padding of 4, 2, and 1, respectively, is interleaved after every residual layer, except the last, to maintain a temporal window size (C) equal to 4. A fully connected layer is added atop the encoder to reduce dimensions before quantization. The decoder mirrors the structure of the encoder. For optimization, Adam is employed with $\beta_1 = 0.9$, $\beta_2 = 0.999$, and a learning rate of 0.0001. The weight (β) for the commitment loss is set to 0.25. Training of the VQ-VAEs is conducted with a batch size of 128 and a sequence length of 88 frames for 100 epochs.

Multimodal Fusion For the given speech embedding from EnCodec and context embedding from VideoCLIP, we first use a compression model to downsample the speech embedding. The compression model is a superposition of 3 one-dimensional convolutions and residual layer (He et al., 2016) and use ReLU activation function. For the multimodal fusion block, we set the number of attention heads to be 8. We set the total number of hidden layer to be 6, respectively. For optimization, we use Adam with a learning rate of 0.0001 and we use the cosin warmup schedule. We train the hole model for 100 epochs using a single RTX4090 GPU.

Deja vu: Contrastive Historical Modeling with Prefix-tuning for Temporal Knowledge Graph Reasoning

Abstract

Temporal Knowledge Graph Reasoning (TKGR) is the task of inferring missing facts for incomplete TKGs in complex scenarios (e.g., transductive and inductive settings), which has been gaining increasing attention. Recently, to mitigate dependence on structured connections in TKGs, text-based methods have been developed to utilize rich linguistic information from entity descriptions. However, suffering from the enormous parameters and inflexibility of pre-trained language models, existing text-based methods struggle to balance the textual knowledge and temporal information with computationally expensive purpose-built training strategies. To tap the potential of text-based models for TKGR in various complex scenarios, we propose **ChapTER**, a **C**ontrastive **h**istoric**a**l modeling framework with **p**refix-tuning for **TE**mporal **R**easoning. ChapTER feeds history-contextualized text into the pseudo-Siamese encoders to strike a textual-temporal balance via contrastive estimation between queries and candidates. By introducing virtual time prefix tokens, it applies a prefix-based tuning method to facilitate the frozen PLM capable for TKGR tasks under different settings. We evaluate ChapTER on four transductive and three few-shot inductive TKGR benchmarks, and experimental results demonstrate that ChapTER achieves superior performance compared to competitive baselines with only 0.17% tuned parameters. We conduct thorough analysis to verify the effectiveness, flexibility and efficiency of ChapTER.

1 Introduction

Knowledge Graphs (KGs) constitute structured representations of knowledge, storing substantial factual information in the form of (*subject*, *prediction*, *object*). KGs have been an essential component of various NLP applications including question answering (Yasunaga et al., 2021), recommendation (Yang et al., 2022), etc. Considering facts inherently evolve in KGs over time, Temporal Knowledge Graphs (TKGs) are constructed to describe the relationship between entities over time in the form of quadruple (*subject*, *prediction*, *object*, *timestamp*). While TKGs are usually incomplete, TKG reasoning (TKGR) aims to predict the missing facts from known ones. In this paper, we focus on the extrapolation task, which requires forecasting future events on TKGs with historical events. For instance, TKGR needs to answer the query (*Olivia Rodrigo*, *Release an album*, *?*, *2023-9-8*) by matching and selecting from all candidate entities based on related historical events.

To address the problem of TKG reasoning, many efforts have been made to capture temporal evolutional information in TKGs. Due to the graph-like features of TKGs, previous methods (Xu et al., 2023b; Zhu et al., 2021; Li et al., 2021) work on designing the temporal-aware encoders referring to known history and mine evolutional patterns from query neighborhoods. Recently, pre-trained language models (PLMs) have been showing great abilities to model textual linguistic semantics, and some methods incorporate temporal information of TKGs into PLMs by designing manufactural prompts with fact texts (Xu et al., 2023a), tuning PLMs with a time-specific masking strategy (Chen et al., 2023b), etc. Nevertheless, on the one hand, these manually designed prompts are explicitly based on a priori assumption. On the other hand, training an entire language model on the time-specific masking strategy is computationally expensive. Though PLMs are equipped with strong linguistic inherence from the pre-training stage, they tend to exceedingly focus on the textual semantics, thus struggling to balance time-specific information and textual knowledge in TKGs. Furthermore, given the highly dynamic essence of

TKG, the continuous emergence of new unseen entities usually leads to the need for TKGR to predict entities in a more complex scenario (e.g. few-shot inductive scenario). Thus, in this paper, we focus on the research question: *Can we efficiently integrate temporal history into textual knowledge in a unified PLM-based framework and adapt to TKG reasoning tasks in various complex scenarios?*

To this end, we propose ChapTER, an efficient temporal-aware PLM-based pseudo-Siamese framework adaptable for TKGR in different scenarios. Specifically, ChapTER first verbalizes the input queries and candidates with up-to-date historical contexts, and feeds them into the two-tower model encoders individually to learn history-contextualized embeddings in a decoupled manner. Then contrastive estimation is performed between them to strike a balance of temporal information and textual knowledge in representations. Rather than training an entire model, ChapTER applies a two-tower prefix-based tuning method to enable frozen PLMs capable of performing TKG reasoning tasks under both transductive and few-shot inductive settings. To refrain from the dependency of entity-related prompts in previous method (Chen et al., 2023a), we feed entity-agnostic virtual time prefix prompts into the frozen PLMs, empowering the model to TKGs with unseen entities.

To summarize, our contributions are as follows:

- We explore a unified PLM-based pseudo-Siamese framework that can be efficiently adapted to TKGR tasks in various complex scenarios by utilizing computationally efficient prefix-based tuning.
- ChapTER models the historical contextual information through contrastive learning by enforcing query and candidate with highly correlated history closer and vice versa, which strikes a good balance of temporal information and textual knowledge.
- We evaluate ChapTER on both transductive and few-shot inductive TKGR tasks and experimental results on seven datasets demonstrate ChapTER achieves competitive performance with less than 0.17% tuned parameters.

2 Related Work

Transductive TKG Reasoning. Most existing transductive TKG reasoning methods are embedding-based and some of them extended from previous KG reasoning methods. TTransE (Leblay and Chekol, 2018a) extends the distance-based method TransE (Bordes et al., 2013) by incorporating extra temporal constraints among facts. TNTComplEx (Lacroix et al., 2020) extends ComplEx (Trouillon et al., 2016) by performing 4th-order tensor factorization to learn time-aware representations. Besides, graph-based methods (Jin et al., 2020; Li et al., 2021, 2022a) employ GCNs to capture the structural information via message passing and model temporal correlations from knowledge graph snapshots with historical information. More recently, PLM-based models have been utilized to incorporate external textual semantics for TKG reasoning. PPT (Xu et al., 2023a) converts TKGR task into a masked token prediction task by utilizing PLM with manually designed prompts. ECOLA (Han et al., 2023) learns the contextualized representations by jointly optimizing the TKGR and the masked language modeling objectives.

Inductive TKG Reasoning. TKG reasoning tasks under inductive setting aim to predict new emerging entities in TKGs, indicating that unseen entities in the test set are not contained in the train set. To handle unseen entities, GNN-based methods like GraIL (Teru et al., 2020) and NOODLE (Liu et al., 2023) extract enclosing subgraphs and learn entity-agnostic local structural information. TLogic (Liu et al., 2022) mines entity-independent logic rules to infer unseen entities. SST-BERT (Chen et al., 2023b) conducts inductive relation prediction by applying a time masking MLM task to pre-train BERT with structured sentences. FILT (Ding et al., 2022) adopts a meta-learning-based model with entity concepts to handle unseen entities in TKGs.

Prefix Tuning. Prompts are manually designed textual templates to query a language model, and they are beneficial to help language models solve different tasks with all parameters frozen. To alleviate the suboptimal performance caused by discrete prompting, continuous prompts with trainable embeddings are added to the embeddings of input sequence (Liu et al., 2021b; Lester et al., 2021), which have been shown to achieve competitive performance across various NLP tasks. Li and Liang (2021) adds trainable prefix vectors to each transformer layer within frozed Seq2Seq PLMs, aiming to efficiently adapt PLMs to natural generation tasks. Chen et al. (2023a) introduces conditional soft prompts to sufficiently incorporate textual se-

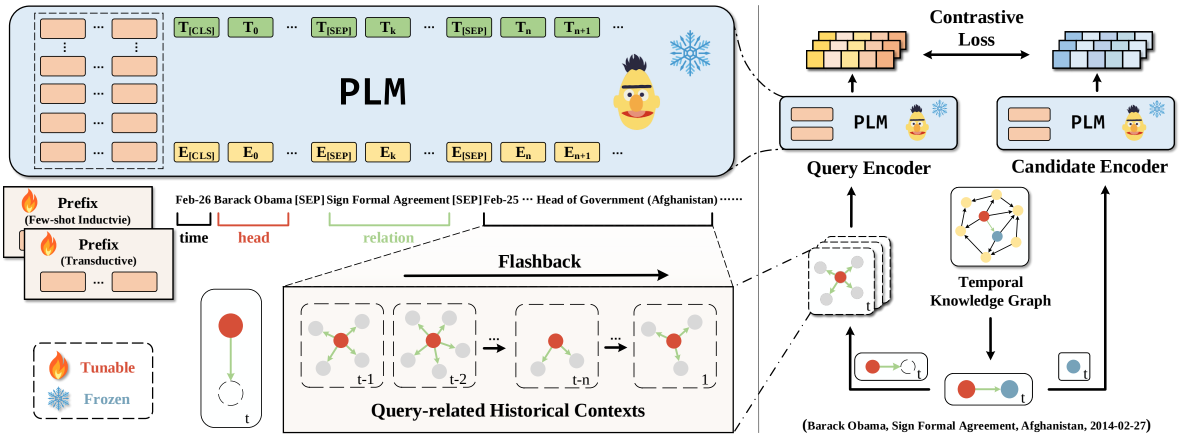

Figure 1: Overall illustration of the ChapTER model: 1) an example of ChapTER for the TKG input query (*Barack Obama, Sign Formal Agreement, ?, 2014-02-07*) and corresponding candidate *Afganistan* (right); 2) a detailed sketch about the structure and verbalized input of Query Encoder (left).

mantics into structural information for KGC tasks. Jin et al. (2023) integrates local structure information into transformer layer text encoding via virtual node tokens.

3 Method

In this section, we first give out the preliminaries and formulation of *Temporal Knowledge Graph Reasoning* in Sec.3.1. Then we introduce the detail model framework from Sec.3.2 to Sec.3.5.

3.1 Preliminaries

Temporal Knowledge Graph (TKG). TKG is a directed graph with a collection of fact quadruples. Let $\mathcal{G} = \{\mathcal{E}, \mathcal{R}, \mathcal{T}, \mathcal{F}\}$ be a TKG instance, where $\mathcal{E}$, $\mathcal{R}$, $\mathcal{T}$ represent the set of entities, relations and timestamps respectively. $\mathcal{F}$ denotes the set of quadruples (s, p, o, t), in which $s \in \mathcal{E}$ is a subject (head) entity, $o \in \mathcal{E}$ is an object (tail) entity, and $r \in \mathcal{R}$ is the predicate (relation) appearing at time t between s and o. Under this definition, a TKG can be represented as a sequence of KGs $\{\mathcal{E}, \mathcal{R}, \mathcal{F}_t\}$, where $\mathcal{F}_t$ is the set of facts that occurred at time t.

Transductive TKG Reasoning. The TKG reasoning task under transductive setting aims to answer the queries including $(s, p, ?, t_q)$ and $(?, p, o, t_q)$. Following the extrapolation setting (Zhu et al., 2021), training, validation and test sets are KGs from timestamps T_0 to T_1, T_1 to T_2, T_2 to T_3 ($T_0 < T_1 < T_2 < T_3$).

Few-shot Inductive TKG Reasoning. Under the inductive setting of TKG reasoning, given an observed background TKG $\mathcal{G}_B \subseteq \mathcal{E}_B \times \mathcal{R} \times \mathcal{E}_B \times \mathcal{F}$, unseen entity e' is a fact from the set $\mathcal{E}'$, where $\mathcal{E}_B \cap \mathcal{E}' = \emptyset$. Hypothesizing that there are K observed associated quadruple facts for each unseen entity e', denoting as (e', p, e^*, t) or (e^*, p, e', t), where $e^* \in \mathcal{E}_B \cup \mathcal{E}'$. The goal of inductive few-shot TKGC reasoning is to answer the queries like $(e', p, ?, t_q)$ or $(?, p, e', t_q)$ from unobserved quadruples with unseen entities.

3.2 The ChapTER Model Framework

By converting the TKG reasoning problem into a query-candidate matching problem, the goal of ChapTER Model is to model the historical information and balance them with the textual semantics appropriately via a contrastive manner.

As illustrated in Figure 1, ChapTER is a pseudo-Siamese network consisting of two encoders: the query encoder $\mathcal{M}_q$ and the candidate encoder $\mathcal{M}_k$. To encode the textual information from entities and relations, we adopt the transformer-based PLM as our encoder, e.g. BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019). $\mathcal{M}_q$ and $\mathcal{M}_k$ are initialized with the same weight but tuned with prefix prompts separately. Given the query $q = (s, p, ?, t_q)$ under the tail prediction setting, $\mathcal{M}_q$ is the query encoder that aims to obtain the time-conditional entity-relation embedding $\boldsymbol{h}_q$ containing textual information of (s, p) pair with historical contexts constrained on time t. Similarly, the candidate encoder $\mathcal{M}_k$ encodes the textual embedding $\boldsymbol{h}_k$ of candidate entity o. We take the mean pooling of the last-layer hidden state from $\mathcal{M}_q$ and

$\mathcal{M}_k$ as the embeddings of $\boldsymbol{h}_q$ and $\boldsymbol{h}_k$:

$$\boldsymbol{h}_q = \mathcal{M}_q(\mathcal{P}(q)),\ \boldsymbol{h}_k = \mathcal{M}_k(\mathcal{P}(k)), \quad (1)$$

where $\mathcal{P}(q)$ and $\mathcal{P}(k)$ denote the input text of query and candidate separately.

With the obtained embeddings $\boldsymbol{h}_q$ and $\boldsymbol{h}_k$, the score of a quadruple (s, p, o, t) can be regarded as the cosine similarity between $\boldsymbol{h}_q$ and $\boldsymbol{h}_k$ by simply performing a dot-product of these two embeddings:

$$f(s,p,o,t) = \cos(\boldsymbol{h}_q, \boldsymbol{h}_k) = \frac{\boldsymbol{h}_q \cdot \boldsymbol{h}_k}{\|\boldsymbol{h}_q\|\,\|\boldsymbol{h}_k\|}. \quad (2)$$

Hence, for the query q, we compute the cosine similarity between query embedding $\boldsymbol{h}_q$ and all other candidate entity embeddings $\boldsymbol{h}_k$, and take the one with the highest score as the final prediction:

$$\arg\max_{k_i} \cos(\boldsymbol{h}_q, \boldsymbol{h}_{k_i}),\ k_i = o_i \in \mathcal{E}. \quad (3)$$

3.3 Text Representation & Verbalization

Fact Description. To represent the entity or relation in a quadruple, the most representative information is the name text, e.g. "*Zalmai Rassoul*" for entity and "*Make statement*" for relation in dataset ICEWS (Integrated Crisis Early Warning System) (Boschee et al., 2015). Despite this, the name texts often turn out to be short and highly overlapped, which may refer to multiple entities in the training corpus of PLM models and lead to the problem of ambiguity. To avoid this problem, we enrich the expression of semantic information by introducing the description text. More concretely, we formulate entity descriptions of ICEWS by including the hierarchical text from *Country* field and *Sector* field. For example, the description of entity "*Virtue Party*" is "*Turkey, Sunni International Religious*". Based on this, we concatenate the name and description text together as the complete entity description D_s. As for relation, we directly use its name text D_r.

Verbalization with Historical Context. Given a candidate quadruple fact (s, p, o, t) under the tail entity prediction task, we divide it into two parts: the time-conditional entity-relation query $q = (s, p, ?, t_q)$ and the candidate entity $k = o$. For the query q, we hypothesize that the historical information remains in the neighbor pairs of entity-relation-related context, which contains both s and p of query q. Specifically, we define the set of historical quadruples as follows:

$$\mathcal{H}(s,p,t) = \big\{(s,p,\tilde{o},t') \mid (s,p,\tilde{o},t') \in \mathcal{F},\ \tilde{o} \neq o, t' \leq t\big\}. \quad (4)$$

With historical context of the quadruple fact, we individually represent the query q and candidate k into two different prompt formats. For timestamp text t in format of "yyyy-mm-dd", we replace its month number with corresponding lexical text L_t. Formally, we have the input $\mathcal{P}(q)$ of query q as follows:

$$\langle cls\rangle\ L_t \mid D_s \mid D_r\ \langle sep\rangle\ \mathcal{H}(s,p,t)\ \langle sep\rangle$$

where D_s and D_r denotes the verbalized text of entity s and relation r. Likewise, we have the input $\mathcal{P}(k)$ of candidate k as:

$$\langle cls\rangle\ D_s\ \langle sep\rangle$$

3.4 Text encoding with virtual time prefix

The goal of ChapTER is to model both historical information and textual semantics from TKGs in various complex scenarios. Instead of designing a time-specific masking strategy to pre-train a model from scratch, we introduce the virtual time prefix tokens to each Transformer layer within PLM, aiming to inject both historical and semantic information into the two-tower transformer-based model encoding procedure. We apply the prefix-based tuning methods to equip our model with capabilities to handle both transductive and few-shot inductive setting tasks. Previous works (Li and Liang, 2021; Liu et al., 2021a) have shown the effectiveness of prefix-tuning methods in facilitating models the ability to different tasks, while achieving comparable performance with only a few parameters tuned.

We employ vector $\boldsymbol{h}$ to uniformly represents $\boldsymbol{h}_q$ in $\mathcal{M}_q$ and $\boldsymbol{h}_k$ in $\mathcal{M}_k$. Denoting $\boldsymbol{h}^{(j)} \in \mathcal{R}^{n \times d}$ as the output embeddings of all tokens in input text after j-th ($i \geq 1$) transformer layer, we concatenate the virtual time prefix $\boldsymbol{p}$ with m-length token embeddings to the text token embeddings in each transformer layer as follows:

$$\widetilde{\boldsymbol{h}}^{(j)} = \boldsymbol{p}^{(j)} \parallel \boldsymbol{h}^{(j)}, 0 \leq j \leq L, \quad (5)$$

where $\boldsymbol{p}^{(j)}$ indicates the virtual prefix token embeddings of j^{th} layer and $\widetilde{\boldsymbol{h}}$ is the concatenated input token embeddings. Concretely, the i^{th} input token of the j^{th} layer is defined as:

$$\widetilde{\boldsymbol{h}}_i^{(j)} = \begin{cases} \boldsymbol{p}_i^{(j)}, & 0 \leq i < m \\ \boldsymbol{e}_i^{(j)}, & (i \geq m) \land (j = 0) \\ \mathrm{FFN}(\widetilde{\boldsymbol{h}}^{(j-1)})_i, & (i \geq m) \land (j \geq 1) \end{cases} \tag{6}$$

During the training procedure, the weight parameters of PLM models $\mathcal{M}_q$ and $\mathcal{M}_k$ are frozen and only weight parameters in prefix prompts are updated in parallel, in which we apply the multi-head attention mechanism as follows:

$$\begin{aligned} \mathrm{MHA}(\boldsymbol{h}^{(j)}, \widetilde{\boldsymbol{h}}^{(j)}) &= \mathop{\Big\|}_{i=1}^{k} \mathrm{head}_i(\boldsymbol{h}_i^{(j)}, \widetilde{\boldsymbol{h}}_i^{(j)}) \\ &= \mathop{\Big\|}_{i=1}^{k} \mathrm{softmax}(\mathbf{Q}^{(j)}, \widetilde{\mathbf{K}}^{(j)\top})\widetilde{\mathbf{V}}^{(j)}, \end{aligned} \tag{7}$$

$$\begin{gathered} \mathbf{Q}^{(j)} = \mathbf{W}_Q^{(j)} \boldsymbol{h}^{(j)}, \\ \widetilde{\mathbf{K}}^{(j)} = \mathbf{W}_K^{(j)} \widetilde{\boldsymbol{h}}^{(j)}, \; \widetilde{\mathbf{V}}^{(j)} = \mathbf{W}_V^{(j)} \widetilde{\boldsymbol{h}}^{(j)}. \end{gathered} \tag{8}$$

We keep the query ($\mathbf{Q}$) vector still but enhance the key ($\mathbf{K}$) and value ($\mathbf{V}$) vectors with prefix embeddings. By performing the asymmetric multi-head attention in each layer, prefix vectors can efficiently capture specific data characteristics in different datasets with only a few parameters tuned.

3.5 Training and Inference

With representations of query $\boldsymbol{h_q}$ and candidate $\boldsymbol{h_k}$, in the training procedure, we apply the InfoNCE loss (van den Oord et al., 2018; Peng et al., 2022) to perform contrast estimation as follows:

$$\mathcal{L}_{cl} = -\log \frac{e^{(cos(\boldsymbol{h_q}, \boldsymbol{h_k}) - \gamma)/\tau}}{e^{(cos(\boldsymbol{h_q}, \boldsymbol{h_k}) - \gamma)/\tau} + \sum\limits_{i \in \mathcal{N}_{neg}} e^{cos(\boldsymbol{h_q}, \boldsymbol{h}'_i)/\tau}}, \tag{9}$$

where τ is a learnable temperature parameter and γ ($\gamma > 0$) is the additive margin that encourages the model to score higher for correct quadruples.

$\mathcal{N}_{neg}$ represents the set of negative samples during training. Instead of randomly corrupting s or p of existing quadruples, we formulate $\mathcal{N}_{neg}$ with three types of negative samples:

$$\mathcal{N}_{neg} = \{o' \mid o' \in \mathcal{N}_{in} \cup \mathcal{N}_{pre} \cup \mathcal{N}_{self}\}. \tag{10}$$

Specifically, $\mathcal{N}_{in}$ represents the set of in-batch negatives, meaning that entities within the same batch can be taken as the negative sample of each other. As for pre-batch negatives $\mathcal{N}_{pre}$, we employ a dynamic queue to store entities from recent previous k batches. Besides, we take head entity s from tail prediction query $(s, p, ?, t_q)$ as hard self-negative $\mathcal{N}_{self}$ to diminish false predictions due to the high text overlap between query and head entity.

For inference, ChapTER first obtains the embeddings of query $(s, p, ?, t_q)$ and all candidates via $\mathcal{M}_q$ and $\mathcal{M}_k$ separately, then computes the entity ranking by the dot-product scores between them.

4 Experimental Setup

Datasets. We evaluate ChapTER on TKGR task in both transductive and few-shot inductive settings. For transductive TKGR, we use four widely-used event-based TKG datasets: ICEWS14, ICEWS18, ICEWS05-15 (Han et al., 2021) and ICEWS14* (Li et al., 2022b). For few-shot inductive TKGR, we use three TKG few-shot OOG benchmarks proposed in Ding et al. (2022): ICEWS14-OOG, ICEWS18-OOG and ICEWS0515-OOG. For textual descriptions, existing ICEWS datasets do not provide entity description texts, so we create them by combining corresponding *country* and *sector* entries for each entity. Detailed dataset statistics are shown in Appendix A.1.

Implementation Details. All experiments are carried out on 24G RTX 3090. We adpot AdamW optimizer with linear learning rate decay to train ChapTER. The query encoder and candidate encoder are initialized with parameters of *bert-based-uncased*. We truncate the description token length up to 50 for entities. The learnable temperature τ is initialized to 0.05 and the additive margin is set to 0.02. We formulate pre-batch negatives N_{pre} from previous 2 batches. For the settings of all baselines, we adopt their default configurations. Most of the transductive TKGR results are taken from Han et al. (2021) and few-shot inductive TKGR results are taken from Ding et al. (2022). For fairness of comparison, we reimplemented SimKGC, KGT5, KGT5-context based on their open source codes to adequately incorporate temporal information. We report the metrics MRR (mean reciprocal rank) and Hits@N (proportion of correct entity rank) to evaluate the performance of ChapTER. We calculate the model results under the time-aware filtered setting (Li et al., 2022b). More detailed implementation settings can be found in Appendix A.3, A.4 and A.5. Codes are avaliable at this website[1].

Table 1: Transductive TKG reasoning performance (with time-aware metrics) on ICEWS14, ICEWS18, ICEWS05-15 and ICEWS14*. The best PLM-based method results are in **bold** and the second best results are underlined. For fair comparison, we add corresponding timestamps of quadruples into the input text for PLM-based baselines, to equip them with the capacities of modeling time information. More results on WIKI and YAGO datasets can be found in Appendix B.

5 Experimental Results

In this section, we first compare ChapTER against other competitive baselines in both transductive and few-shot inductive TKG reasoning tasks in Sec 5.1. Then we conduct ablation study in Sec 5.2 to evaluate the effectiveness of each component in ChapTER. After that, we further analyze the efficiency and flexibility of ChapTER in Sec 5.3.

5.1 Main Results

We compared our proposed ChapTER with various competitive baselines, and the main results of transductive and few-shot inductive TKG reasoning summarized in Table 1 and Table 2, respectively.

Results on Transductive TKGR. On transductive TKGR benchmarks, we compare ChapTER with both graph-based and PLM-based models. Results on four datasets show that ChapTER achieves state-of-the-art or competitive performance against baselines. Specifically, on ICEWS14 dataset, ChapTER outperforms all PLM-based methods by a substantial margin and achieves 18.5% (from .280 to .332) relative MRR improvement. It is worth noting that ChapTER achieves better performance with only a few prefix parameters tuned compared to fully trained PLM-based baselines, which verifies the effectiveness of prefix-tuning in TKGR tasks.

Compared with graph-based methods, ChapTER consistently outperforms previous baselines on ICEWS14 (MRR .332 v.s. .327), and the competitive results demonstrate ChapTER holds superiority of modeling representations in future timestamps through historical contexts. We also find that ChapTER maintains modest results on ICEWS18 and ICEWS05-15. It is worth noting that events involved in these datasets are more dense and frequent with more entities, indicating that more events are happening in the same timestamp. Since CyGNet is designed to capture the facts recurrence in the appeared history, it is good at predicting events with repetitive history yet inferior in absorbing TKG texts. This explains why ChapTER marginally lags behind CyGNet on these datasets, because redundant historical events text are truncated due to the limitation of input length in PLMs.

Results on Few-shot Inductive TKGR. As shown in Table 1, we verify ChapTER's TKG reasoning performance in a more complex few-shot inductive scenario on ICEWS14-OOG, ICEWS18-OOG and ICEWS0515-OOG datasets, considering both 1-shot and 3-shot settings. It can be seen that ChapTER substantially outperforms existing few-shot inductive TKGR methods. Concretely, ChapTER achieves striking improvement in hit@10 on ICEWS14-OOG (from .410 to .750 in 1-shot, from .475 to .761 in 3-shot), though being slightly worse on Hit@3 (3-shot) than FILT. We also report the zero-shot performance of ChapTER on these three datasets, and we can observe that ChapTER consistently outperforms all baselines, though slightly lags behind on few-shot performances. The overall remarkable performance verifies that ChapTER can

transfer knowledge from known training entities to unseen ones, with prior knowledge and encoded historical information in PLMs.

5.2 Ablation Studies

To further analyze how each component of ChapTER contributes to the final performance, we conduct ablation studies on ICEWS14 and ICEWS14-OOG, and complete results are reported in Table 3. More ablation study results on training strategies and prompt length can be found in Appendix C.

Input Text Composition. To verify the effectiveness of text verbalization approach mentioned in Sec. 3.3, we consider three variants by selectively removing the timestamp text, description text and historical contexts separately. In Table 3, lines 2-4 show the performance of ChapTER with different input compositions. Compared to ChapTER, the performance of each ablated variant exhibits marginal decreases. Intuitively, removing description texts produces the largest performance drop (MRR drops 3.9% and 14.7% separately), since PLM-based models fundamentally rely on text quality. With more informative entity descriptions, the performance of ChapTER can be further improved. Moreover, lines 3-4 support the importance of temporal historical information for ChapTER. We argue this phenomenon for two reasons: 1) Though timestamps contain essential temporal information, they tend to be terse and drowned out by verbose text; 2) In contrast, historical contexts contribute more substantially to temporal modeling, as they introduce sequenced, up-to-date histories that provide abundant background for queries. Thus, ChapTER models can capture more accurate temporal information from rich historical contexts.

Negative Sample Combination. Table 3 Lines 5-7 show the performance of ChapTER with different training negatives (in-batch $\mathcal{N}_{in}$, pre-batch $\mathcal{N}_{pre}$ and self negatives $\mathcal{N}_{self}$) on ICEWS14 and ICEWS14-OOG. Three ablated variants were evaluated by separately removing $\mathcal{N}_{pre}$, $\mathcal{N}_{self}$, or both from ChapTER. We observe that removing both $\mathcal{N}_{pre}$ and $\mathcal{N}_{self}$ yields worse empirical results than removing them separately. It's worth noting that since self-negatives diminish the rely of ChapTER on naive text match, they tend to improve Hits@1 but hurt Hits@10 (e.g. Hits@10 from .755 to .752 on ICEWS14-OOG). Furthermore, we investigate the impact of in-batch negative sample numbers during model training, as shown in Figure 2. By increasing the number of negative samples, there is a steady improvement from .192 to .322, but it only

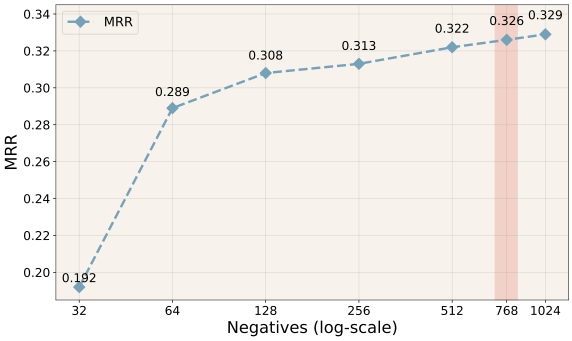

Figure 2: MRR results on ICEWS14 with in-batch negatives number changing in ChapTER.

Model	PLM	Total	Trainable	T_{train}/ep
SimKGC	Bert-base Bert-large	218.9M 670.3M	218.9M 670.3M	3.2min 20.0min

obtains slight change when the number is larger than 768 (red bar). In summary, each kind of negative contributes to the best results of ChapTER.

5.3 Discussion

In this section, we conduct further analysis on model efficiency, the ability to capture temporal information, the impact of different tuning strategies and the impact of different PLM models.

Q1: How efficient ChapTER is compared to other PLM-based models? Table 4 summarizes the model efficiency of ChapTER compared to other PLM-based methods. By taking advantage of the efficient tuning strategy, ChapTER achieves superior performance with minimal parameters tuned and reduced training time. Compared with SimKGC, ChapTER is 1.4x time faster in training with only 0.15% parameters tuned (0.99M v.s. 760.3M). Considering recently proposed sequence-to-sequence KGR models, ChapTER outperforms KGT5 with 0.6% parameters trained and 12x faster training time, this is because KGT5 needs to train a T5 model from scratch with task-specific input prompts. Besides, during inference, KGT5 is computationally expensive (0.83min v.s. 95.23min) due to a huge decoding search space. This suggests that ChapTER is more efficient in time and computation while achieving superior performance.

Model	ICEWS14		ICEWS14-OOG	
	MRR	H@10	MRR	H@10
ChapTER	**.332**	**.515**	**.361**	**.752**
Timestamp Text				
w/o timestamp	.321	.505	.358	.739
random timestamp	.319	.497	.355	.732
Historical Sequence				
history descending order	.332	.515	.361	.752
history ascending order	.322	.498	.344	.721
history random order	.328	.504	.349	.743
Form of Context				
pairs	.332	.515	.361	.752
entities	.324	.502	.359	.734

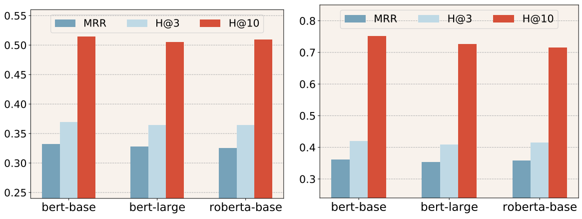
Table 5: Performance of different historical modeling approaches on ICEWS14 and ICEWS14-OOG datasets.

Q2: How does ChapTER use the temporal history information of events? We further investigate how ChapTER actually utilizes the historical context information. As shown in Table 5, we analyze the impact of history modeling in three aspects: "Timestamp Text", "Historical Sequence Order" and "Form of Context". We can observe that removing timestamps or using random timestamps in text input both lead to a performance drop. As for historical sequence, we find that model with history in a descending order performs better than those with ascending or random order. It evidences that recent historical events are more decisive to future forecasting. Besides, we formalize the historical contexts in two ways: *Entity* (e.g., all historical entities that are related to query) and *Pair* (e.g., a list of complete historical quadruples). Results show that concatenate contexts by pairs achieve a higher performance than entities. We believe this is because paired contexts provide more concrete and sequenced event history. In summary, ChapTER is capable of modeling temporal information from recent and complete historical contexts.

Q3: How do different tuning strategies affect ChapTER's performance? As mentioned in Sec.3.4, ChapTER is tuned with virtual prefix prompts with the PLM parameters frozen. To further discuss the impact of different prefix tuning methods, we compare two widely used approaches: Prefix-tuning (Li and Liang, 2021) and P-tuning V2 (Liu et al., 2021a). As summarized in Table 6, we can observe ChapTER (P-tuning V2 with MLP

Method	Re-param	N_{param}	T_{train}/ep	MRR	H@3	H@10
ChapTER - Prefix Tuning	MLP	47.3M	4.2min	.321	.358	.503
ChapTER - P-tuning v2	MLP	19.7M	3.6min	**.332**	**.370**	**.515**
ChapTER - P-tuning v2	Embedding	0.37M	3.3min	.308	.345	.491

Table 6: ICEWS14 results of ChapTER with different prefix tuning methods. *Re-param* denotes the reparameterization encoder and *Num-param* denotes the corresponding trainable parameter numbers (on Bert-base-uncased).



(a) ICEWS14

(b) ICEWS14-OOG

Figure 3: Comparison of ChapTER with different PLM models on ICEWS14 and ICEWS14-OOG datasets.

reparameterization encoder) achieves better performance than the one with prefix tuning (MRR .332 v.s. .321). We also evaluate the impact of reparameterization module on ChapTER with P-tuning v2. The result show that more parameters in MLP bring a marginally improvement on performance, but its effect is inconsistent across datasets and task settings.

Q4: How do PLM models affect ChapTER's performance? Figure 3 compares the model performance of ChapTER with different PLM models. We can observe that ChapTER with three PLM models all achieve close high performance on two datasets, and the utilization of Bert-base yields a marginally better result. This result suggests that our ChapTER is is robust to different PLMs with varying parameters and agnostic to PLM size. Beyond this, it is possible to improve the performance of ChapTER with some PLMs that have longer input contexts (e.g., longformer), and we leave such extensions for future studies.

6 Conclusion and Future Work

In this paper, we propose ChapTER, a PLM-based pseudo-Siamese framework that models balanced textual knowledge and historical information. With the introduced time prefix tokens, ChapTER is capable for TKG reasoning tasks in various complex scenarios through prefix-based tuning. Experimental results on two TKGR tasks demonstrate the superiority of ChapTER compared to competitive baselines. Thorough analysis shows the efficiency and flexibility of ChapTER. In the future, we would like to explore 1) bridging the gap of two towers with shared time prefix tuning; 2) extending our method to Seq2Seq PLMs to model temporal knowledge in a generative manner.

Limitations

ChapTER is able to balance the textual knowledge and temporal information for the TKGR tasks in various scenarios. However, 1) ChapTER is based on PLMs and it relies on unstructured texts like entity names and descriptions. Thus the performance of ChapTER can be affected due to the quality of texts, and it could be further improved on datasets with more informative texts. Compared to ICEWS datasets, in which we manually construct description texts by concatenating the *Country* and *Sector* fields, datasets like Wikidata containing more informative text descriptions may result in better. 2) Due to the essence of virtual tokens in prefix tuning, which contain few parameters to be tuned compared to frozen PLMs, it may cause a collapse on tiny datasets with sparse quadruples and entities. Besides, an appropriate choice of prefix length and learning rate is crucial. We plan to work on these issues in the future work.

A Experimental Details

A.1 Dataset

We use the transductive TKGR datasets ICEWS14, ICEWS18, ICEWS05-15, YAGO from Han et al. (2021), WIKI from Leblay and Chekol (2018b) and ICEWS14* from Li et al. (2021), which contain political facts of Integrated Crisis Early Warning System (Boschee et al., 2015). We take few-shot inductive datasets ICEWS14-OOG, ICEWS18-OOG and ICEWS0515-OOG from Ding et al. (2022). Following the original data split, we summarize the statistics of these datasets in Table 7 and Table 8. For the absent description texts, we find the texts of *country* and *sector* entries from origin data source[2] and combining them together to construct entity descriptions.

A.2 Baselines

We compare ChapTER with several competitive state-of-the-art baselines in transductive and few-shot inductive TKG reasoning settings. For transductive TKG reasoning, we include 1) traditional KG reasoning methods, i.e. DistMult (Yang et al., 2015), ComplEx (Trouillon et al., 2016) and RotatE (Sun et al., 2019); 2) TKG Reasoning methods, i.e. TTransE (Leblay and Chekol, 2018a), TA-DistMult (García-Durán et al., 2018), TA-TransE (García-Durán et al., 2018), DE-SimplE (Goel et al., 2020), TNTComplEx (Lacroix et al., 2020) and CyGNet (Zhu et al., 2021); 3) PLM-based methods, i.e. SimKGC (Wang et al.,

Table 8: Statistics of datasets for few-shot inductive TKG reasoning. $|\mathcal{F}_{train}|$, $|\mathcal{F}_{valid}|$, $|\mathcal{F}_{test}|$ represent the number of quadruples containing unseen entities in train sets, valid sets and test sets, respectively. $|\mathcal{F}_{back}|$ denotes the number of remaining quadruples without unseen entities.

2022), KGT5 (Saxena et al., 2022) and KGT5-context (Kochsiek et al., 2023). For few-shot inductive TKG reasoning, we include 1) traditional KGR methods BiQUE (Guo and Kok, 2021); 2) traditional TKGR methods, i.e. TELM (Xu et al., 2021) and TeRo (Xu et al., 2020); 3) inductive KGR methods, i.e. MEAN (Hamaguchi et al., 2017) and LAN (Wang et al., 2019); 4) mrta-learning-based method GEN (Baek et al., 2020).

A.3 Evaluation Metrics

In the experiments, we report the widely used metrics MRR (Mean Reciprocal Rank) and Hits@N to evaluate the performance of ChapTER under both two settings. MRR measures the average reciprocal ranks of all test triples. Hits@N ($N \in \{1,3,10\}$) calculates the proportion of correct entities ranked among the top-N. For fair comparison, we calculate the model results under the time-aware filtered setting (Li et al., 2022b), which only filters out the quadruples that occur at the query time. All metrics are computed by averaging over head and tail entity prediction, and model is selected by MRR value on the validation set.

A.4 Hyperparameters

We perform grid-search on hyperparameters including learning rate, prompt length, in-batch negatives, queued negative batches, train epoch and max token number. The optimal hyperparameters are summarized in Table 9.

Hyperparameters	**Values**
Learning rate	{1e-5, 3e-5, 5e-4, 5e-3}
Prompt Length	{2, 4, 6, 10, 15, 20, 50}
In-batch negatives	{32, 64, 128, 256, 512, 764, 1024}
Queued negative batches	{1, 2, 4}
Train epoch	{10, 15, 20}
Max token number	{50, 60, 70}

Table 9: Details of hyperparameters.

A.5 Implementation of PLM-based Baselines

We reimplement SimKGC[3], KGT5[4] and KGT5-context[5] based on their official codes. To adapt them to TKG datasets, we modify their input format from triplet to quadruplet by concatenating timestamps with their corresponding input texts. For example, a tail-prediction query input text in KGT5 can be formulated as "predict tail: 2014-01-01 | Benjamin Netanyahu | Sign formal agreement". Following their default hyperparameter setting, the hyperparameters are slightly different on different TKG datasets. For evaluation, we changed their filter setting into time-aware filter setting to align with other TKGR models.

B More Comparative Study Results

We report more transductive TKGR results on WIKI (Leblay and Chekol, 2018b) and

C More Ablation Results

C.1 Ablation on Training Strategy

We empirically evaluate the impact of different tuning layers on ChapTER. Table 11 Lines 2-5 summarize the performance of ChapTER with different layers tuned. It can observed that ChapTER performs better than the fully tuned model, we argue that 1) ChapTER with time prefixes are effective to capture temporal information; 2) more tuning parameters may lead to an over-fitting on textual information and overlook the temporal correlations; 3) ChapTER on ICEWS14-OOG dataset is less sensitive to the changes of tuning parameters, because it is more crucial to model textual information for unseen entities in inductive TKGR. Besides, comparing line 8 and line 10, we can find that tuning bottom layers tends to obtain a better performance than tuning top layers. This could be because lower layer in Bert can capture low-level semantic features, which is more important for TKGR tasks.

C.2 Ablation on Prefix Length

We conduct extensive experiments on the impact of prefix length for ChapTER and results are shown in Figure 4. As evidenced, model performance exhibits a slight positive correlation to prefix length as increasing from 2 to 20 (MRR from .288 to .312), while number of trainable parameters is also expanding (from 0.074M to 0.737M). We can also observe that a further increase of prefix length leads to an inferior performance (from .312 to .302), as additional complexity imposes considerable challenges.

Explanation Extraction from Hierarchical Classification Frameworks for Long Legal Documents

prasadnishchal.np@gmail.com

Abstract

Hierarchical classification frameworks have been widely used to process long sequences, especially in the legal domain for predictions from long legal documents. But being black-box models they are unable to explain their predictions making them less reliable for practical applications, more so in the legal domain. In this work, we develop an extractive explanation algorithm for hierarchical frameworks for long sequences based on the sensitivity of the trained model to its input perturbations. We perturb using occlusion and develop Ob-HEx; an Occlusion-based Hierarchical Explanation-extractor. We adapt Ob-HEx to Hierarchical Transformer models trained on long Indian legal texts. And use Ob-HEx to analyze them and extract their explanations for the ILDC-Expert dataset, achieving a minimum gain of 1 point over the previous benchmark on most of our performance evaluation metrics.

1 Introduction

Deep-learning-based hierarchical classification models are one of the important techniques for classifying inputs with long sequences and in terms of performance and computational requirements, these hierarchical models have shown to be at par (or better in some cases) with single standalone models which are limited to a certain input length (Chalkidis et al., 2022, 2019; Zhang et al., 2019). These hierarchical models have been largely used recently in the legal NLP domain, especially because of the long lengths of legal case documents. Amongst them, the variants of Hierarchical Transformers have seen quite a lot of usage (Pappagari et al., 2019; Zhang et al., 2019; Malik et al., 2021; Chalkidis et al., 2019, 2021, 2022; Prasad et al., 2022, 2023b,a, 2024; Modi et al., 2023). One of their major drawbacks is they are black boxes with no explanation for their predictions, and explanations are desired especially for reliability in high-stakes fields such as law and medicine. In this work, we develop and test Ob-HEx, an attribution-based post-hoc explanation (Molnar, 2022) extraction algorithm for these hierarchical classification models, which does not require training and relies only on the trained model and its input. In scenarios where there is a lack of annotation to train an explanation algorithm, an extractive explanation method is a good fit to create interpretations of the predicted judgments, which is synonym to the idea of our explanation algorithm. Also, explaining predictions of hierarchical models from long legal documents is a major problem in developing a reliable legal judgment prediction system. In our work, we focus on interpreting the hierarchical predictive models trained on long legal documents, where we rank and extract relevant sentences from the input document that impacted the prediction from the model. These sentences can serve as an explanation, to guide an expert on what led to/triggered a certain prediction. We test Ob-HEx for analysis and explanation from hierarchical models of Malik et al. (2021) and Prasad et al. (2022) on ILDC$_{expert}$ (Malik et al., 2021) obtaining new benchmarks.

2 Related Work

Past work on the explainability of deep neural networks (DNN) (Ras et al., 2022) used the attribution-based perturbation methods for explanations of images and short-text DNN classification models (Zhou et al., 2015; Li et al., 2016; Fong and Vedaldi, 2017; Zhou et al., 2016) that rely on the input and the DNN model's sensitivity to it, but these methods in our experiments and also of Malik et al. (2021) become complex to adapt to hierarchical DNN models for long documents. In the explanation of hierarchical models, little work has been done of which one is by Landecker et al. (2013) where they developed contribution propagation to explain individual image classification. More recently, in the legal domain, some strategies such as

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1192–1201
June 16-21, 2024

occlusion sensitivity, keyword-based matching, extractive summarization, and span lengths were used for explanation extraction from hierarchical transformer models for long documents (Malik et al., 2021; Modi et al., 2023). Since we aim to extract explanations without training and solely relying on the trained model we develop the idea of attribution-based perturbation/occlusion sensitivity (Petsiuk et al., 2018) for hierarchical models for long legal documents, where the sentences/paragraphs are scored hierarchically (using a scoring function) against their absence in the input, and finally chosen according to the desirability of the scores (higher or lower).

3 Methodology

3.1 Occlusion-based Hierarchical Explanation-extractor (Ob-HEx):

Consider a hierarchical classification model M with r levels of hierarchy where each level was trained separately on its input I^r=$\{i^r_j | 0 \leq j \leq n\}$ of length n. Going from the top level to the bottom, consider for level $l \leq r$, $M^l(I^l)$=O^l_I to be the prediction without any occlusion, and $M^l(\{I^l | i^l_j\})$=$O^l_{I(j)}$ to be the prediction after the occlusion of i^l_j in I^l. The occlusion can be done by masking individual parts.

Occlusion-sensitivity Impact function: We define an "occlusion-sensitivity impact function" as $\hat{L}$, and choose $\hat{L}$ as the loss function L^l which was used to train the level l of the hierarchy i.e. the layer-wise loss functions L^l are chosen as $\hat{L}^l$.

For an input I, if an absolute prediction, P^t_I from the level t in the hierarchy was used to train all its lower levels, we take it as the "absolute-predicted class label" with which we rank the inputs in all the lower levels. "Absolute-predicted class label" is the prediction by that respective level of hierarchy and "absolute" means that predictions are changed to absolute labels. For example, in a binary labelling system the absolute-predicted class label P^t_I = 1 for a prediction output O^t_I of 0.7 probability.

For a level $l \leq t$ of hierarchy, if P^t_I is the absolute-predicted class label then,

$$\hat{L}^l_{I(j)} = L^l(O^l_{I(j)}, P^t_I),\ l \leq t \qquad (1)$$

i.e loss of $O^l_{I(j)}$ from P^t_I. This impact function measures the importance of the input's occluded part for a prediction from the change in its prediction loss from P^t_I. Higher loss means more impact.

Normalized Weighted Occlusion-sensitivity Score: To rank these losses in terms of impact, we measure the deviance of $\hat{L}^l_{I(j)}$ from $\hat{L}^l_I$ by computing the "normalized weighted occlusion-sensitivity score" $\hat{S}^l$.

$$S^l_{I(j)}(s^l_I, \hat{L}^l_{I(j)}, \hat{L}^l_I) = s^l_I \times \left(\hat{L}^l_{I(j)} - \hat{L}^l_I\right) \qquad (2)$$

$$\hat{S}^l_{I(j)}(s^l_I, \hat{L}^l_{I(j)}, \hat{L}^l_I) = \frac{S^l_{I(j)} - min(S^l_I)}{max(S^l_I) - min(S^l_I)} + \delta \qquad (3)$$

Here $s^l_I = \hat{S}^{l+1}_I$ is the score weight from I^l's fragment used in the previous level of the hierarchy & $\hat{S}^{r+1}_I = 1$. We shift the axis by adding a constant δ in eq. 3 to keep the score > 0.

Ranking the input fragments for a hierarchical predictive model by weighing the impacts of the higher layers of the hierarchy on the lower layers using the "normalized weighted occlusion-sensitivity score", helps to align the impacts from all the layers of the hierarchy.

We calculate $\hat{S}$ starting from the top to the base level in the hierarchy. This scores fragments of the input, that can be ranked, from which the top $k\%$ input fragments can be chosen and ordered to form an explanation.

3.2 Base hierarchical model:

Here we adapt Ob-HEx to explain the decision prediction made by the trained hierarchical transformer models XLNet+BiGRU from Malik et al. (2021) and LEGAL-BERT+BiGRU from Prasad et al. (2022). These models process a long document broadly in two levels of hierarchy. In the first level the document is divided into chunks of 512 tokens, and using its gold class label the backbone transformer encoder (T) is fine-tuned on individual chunks. The chunk's global embedding is extracted from this fine-tuned transformer, which is combined to form another set of training data for the second level of hierarchy (BiGRU) which learns global document representation for final classification (M).

Ob-HEx adaptation to base hierarchical model: We implement Ob-HEx to process a document from the base model in its two levels (r=2) of hierarchy. (a) Find the impactful chunks from level l=2. (b) Find impactful sentences from these chunks from level l=1.

For occlusions, we use use zero-masking (0 value). Since binary cross-entropy loss (BCE_{loss}) and the same gold labels were used to train both the levels of hierarchy in the base model, we fix L^l=BCE_{loss} for both levels l=$\{1,2\}$, such that $\hat{L}^l_{I(j)}$=$BCE_{loss}(O^l_{I(j)}, P^l_I)$, where P^l_I=$P^{l=2}_I$ is the absolute final predicted label from the last level of hierarchy (i.e. we fix $t = 2$ in eq. 1). See appendix A and the GitHub repository [1] for a detailed implementation.

3.3 Experimental Setup

We use ROUGE-1, ROUGE-2, ROUGE-L (Lin, 2004), Jaccard similarity, and BERTScore (Zhang et al., 2020) to compare the model's explanation with the expert's. BERTScore was calculated using "microsoft/deberta-xlarge-mnli" (HuggingFace[2]). We also evaluate explanations from CJPE and Ob-HEx on the ranking-performance/length ratio, where we try to see how similar are the ranked sentences to the gold explanations (similarity is based on the chosen metric scores above) as the explanation lengths are restricted. A higher ratio indicates better performance.

3.4 Baseline explanation algorithm

To compare with Ob-HEx we use the algorithm developed by Malik et al. (2021) for their long sequence hierarchical models, and refer to as CJPE. CJPE ranks sentences from a document using a "chunk explainability score" based on the probability output of the model and takes the top $\approx$ 40% sentences as explanations. We use a chunk length of 512 tokens for all, and k=$\{0.15, 0.1\}$ for Ob-HEx with δ=0.01 (eq. 3). Since CJPE's explanations are quite long we also compare its top 256 and 512 words with Ob-HEx's (§4). We did not alter CJPE's k-value as it's different from Ob-HEx's. Ob-HEx ranks all the sentences in the document, while CJPE chooses only positive chunks and ranks their sentences. Reducing CJPE's k-value would make the explanations too short for some documents, and ultimately a lower performance. So to have a fair comparison, we choose the top 512/256 words and evaluate Ob-HEx (§4) with lower k=$\{0.15, 0.1\}$ for shorter sentences than CJPE (Fig. 2).

3.5 Dataset

We use ILDC$_{Expert}$ dataset from Malik et al. (2021), which includes unstructured English case transcripts from the Supreme Court of India (SCI) with the final decisions removed. A decision of "rejected" or "accepted" made by the SCI judge(s) serves as the class label. ILDC$_{Expert}$ (Table 1) is a test set consisting of gold explanations by legal experts which are texts from the document that are most relevant to the judgment. These gold explanations are ranked from 1-10, 1 being the most relevant to the judgment, and 10 being the least. The dataset statistics can be seen in Table 1.

# documents	**# explanations**	**# experts**
56	280	5
average # words	**maximum # words**	**labels**
3716	23792	1 = Accepted 0 = Rejected

Ranks	1	2	3	4	5	6	7	8	9	10
Average # words	306	406	456	273	88	28	19	6	3	1

Table 1: ILDC$_{Expert}$ statistics

On moving down to the last ranks, some experts' explanations have no sentences, hence the average number of words also becomes less. Also, since combining sentences in ranks 1-10 gives an average length of 1586 words (Table 1) which is quite large for an explanation, we mainly show the comparison of gold explanations in ranks 1-1 & 1-3 with the explanations from Ob-HEx and CJPE.

To have a comparable length with ranks 1-1 & 1-3 of the gold explanations and for fair evaluations, we also constraint the explanation lengths from Ob-HEx and CJPE respectively (§3.4, §4).

4 Results and Discussions

Analysis of explanation lengths: Figure 2 shows the distribution of percentage variation of the explanation length from CJPE to Ob-HEx, over the whole dataset, and shows that it is not influenced by a few documents. As seen in Figure 2, explanations from CJPE are quite long. The explanation from CJPE is 8.62% longer than Ob-HEx with k=0.15, and 21.4% and 8.9% longer than Ob-HEx@k=0.1 for their top 512 and 265 words respectively.

So we compare Ob-HEx's and CJPE's explanations on three fronts, (a) Long explanations, (b) Short explanations and (c) Brief explanations as shown in Figure 2. Table 2 shows the experimental results of these comparisons for the chosen evaluation metrics (§3.3). See §B for more detailed results.

(a) Long explanations: We compare CJPE vs Ob-HEx@k=0.15 with the gold (expert's) explanations in ranks 1-3. For XLNet+BiGRU, Ob-HEx performs better than CJPE in almost all metrics

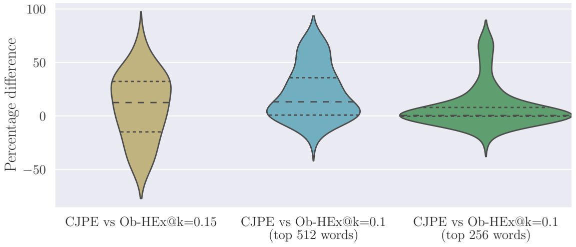
Table 2: Extracted explanations vs ILDC$_{Expert}$'s (values are in percentage (%)).



(a) Long (b) Short (c) Brief

Figure 2: Violin plot of explanation lengths from CJPE vs Ob-HEx.

over all the experts, with an average metric points gain of 2.36, 2.63, 3.93, 1.66, and 1.93 in ROUGE-1, ROUGE-2, ROUGE-L, BERTScore(F1) and Jaccard similarity respectively. While for LEGAL-BERT+BiGRU the performance is slightly better than the baseline in some metrics. Since Ob-HEx infers the focus points of a trained hierarchical model using its input, its explanations from LEGAL-BERT+BiGRU only reflect the main focus parts in its input. And since LEGAL-BERT+BiGRU was trained using all the parts of the document rather than only the last parts as done in XLNet+BiGRU, their focus points are different (Figure 3). This gives some sentences that may not be present in the expert's explanations but are useful for a robust prediction as LEGAL-BERT+BiGRU outperforms XLNet+BiGRU (Prasad et al., 2022).

(b) Short explanations: We compare the top 512 words from CJPE and the top 512 words from Ob-HEx@k=0.1 with the gold (expert's) explanations in the ranks 1-3. For XLNet+BiGRU, Ob-HEx has an average metric points gain of 0.614, 1.634, 2.398, 1.31, and 0.68 in ROUGE-1, ROUGE-2, ROUGE-L, BERTScore(F1) and Jaccard similarity respectively over the baseline (CJPE). A box plot; showing the first quartile, third quartile and the median; of BERTScore performance (Precision, Recall, F1-score) of Ob-HEx and CJPE vs experts for all the documents can be seen in Figure 1. We see that even for shorter explanations ($\approx$ 400-500 words), Ob-HEx better ranks the predictive-sensitive sentences from the hierarchical model and better captures the semantic similarities with the gold explanations than CJPE.

(c) Brief explanations: To see the ranking-performance/length ratio of Ob-HEx we further constraint the explanation length and compare its similarity performance over the baseline. To do so we experiment with the top 256 words from CJPE and the top 256 words from Ob-HEx@k=0.1 and compare them with the gold explanations only in rank 1. This is done considering the average length of rank 1 explanations is 306 words (Table 1). We see that Ob-HEx still performs better than CJPE with a gain of 3.1, 3.442, 4.87, 1.538, and 2.804 average metric points in ROUGE-1, ROUGE-2, ROUGE-L, BERTScore(F1) and Jaccard similarity respectively.

This shows that the ranking-performance/length ratio of Ob-HEx is better than CJPE. This can be attributed to how Ob-HEx ranks the sentences, where it hierarchically uses the s_I (§3.1) from the previous layers which helps it to relatively measure the importance of each part of the input document.

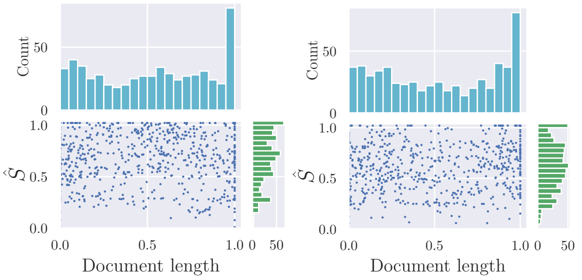
Even though CJPE has longer explanation lengths (Figure (2)) for long, short and brief explanations, its performance is lower than that of shorter explanations from Ob-HEx.

Overall, for the same base hierarchical model, Ob-HEx gives shorter and better-ranked sentences as explanations than CJPE.

Since the Ob-HEx does not train and depends on the hierarchical model we get the same results for every run (except when the hierarchical model is updated with new weights). So we cannot perform a significance test for the runs. But in such situations, the significance could be seen from different test sets, where every expert's explanation is a distinct test set (§6, §3.5), and for each expert, Ob-HEx performs better than the baseline on most of the metrics.

4.1 Analysis on base hierarchical model

The $\hat{S}$ scores from Ob-HEx can be used to visualize the focus points of the hierarchical model. So to analyze the focus points of the base models and see how the focus point varies between them, we use Ob-HEX, and plot (Figure 3) the final $\hat{S}$ score (Eq. 3) distribution obtained by Ob-HEX@k=10% from the base level (l=1) of the hierarchy of base models (§3.2) over ILDC$_{Expert}$. Both the base models focus more on the final part of the documents, even though LEGAL-BERT+BiGRU was trained on the full document length. XLNet+BiGRU also puts more emphasis on the first 25% and 40-70% of the document's length compared to LEGAL-BERT+BIGRU's emphasis on the first 25% and 85-95% of the document's length. While the score distributions vary heavily between the models, from 0.5-1.01 for XLNet+BiGRU compared to 0.3-0.7 and 1-1.01 for LEGAL-BERT+BiGRU.



(a) XLNet+BiGRU (b) LEGAL-BERT+BiGRU

Figure 3: Final $\hat{S}$ score (Eq. 3) distribution with Ob-HEx@k=0.1 on ILDC$_{Expert}$.

5 Conclusion

We explore the problem of explaining a hierarchical model's prediction from long sequences in the legal domain and develop Ob-HEx based on the perturbations-based occlusion sensitivity of the trained model. For it, we develop a 'normalized weighted occlusion sensitivity score' to hierarchically score parts of a long input that is ranked and used as explanations. We adapt Ob-HEx to Hierarchical Transformers of Malik et al. (2021) and Prasad et al. (2022) and experiment with ILDC$_{Expert}$ to achieve new benchmarks over the previous methods. We also used Ob-HEX to analyze and interpret the focus points for our base model. Ob-HEx can be generalized and uses a layer-wise loss function (Occlusion-sensitivity Impact function) to score the occlusions, and uses the "normalized weighted occlusion-sensitivity score" to score the input fragments taking into the impacts from the previous layers. In future, we aim to use Ob-HEx as a selective-re-training strategy for the trained hierarchical models and analyze its effects on predictions. We also aim to implement Ob-HEx in other domains using hierarchical frameworks.

6 Limitations

Since explanations from the trained hierarchical model using Ob-HEx are based solely on the model and its input, they may contain sentences from parts of an input document that may be different from an expert's explanations. This is also due to the ability of the model to learn latent features which are not visible to an expert. And since explanations from an expert can be different from explanations from another expert (Malik et al. (2021)) no single explanation can be used as ground truth to measure the explanations from an extractive explanation algorithm like Ob-HEx. And as explanations from a single expert cannot be taken as absolute we do not rely only on the improvements of an individual expert. Hence, in our experiments, we use explanations from all the experts to have a varied set for comparison with our explanations and the ones from the baseline explanation algorithm (CJPE).

The explanations extracted from a hierarchical model using Ob-HEx reflect how the model looks at its inputs and the parts where it focuses most to make the predictions. Ob-HEx tries to approximate these focus points using the "impact function" and "normalized weighted occlusion sensitivity score" and ranks them to serve as an explanation. And since Ob-HEx doesn't train the model or make changes to its internal weights, the explanations we get using Ob-HEx are heavily model-dependent while Ob-HEx tries to best approximate the focus points of the model and extracts them.

We did not conduct any human evaluation to show the importance of those sentences extracted from Ob-HEx which are missed by CJPE. Because, to show with a strong claim that these excluded sentences are meaningful to the final prediction/-judgment we require a human legal expert, which we leave for future research.

Other existing explainability-based techniques (Zhou et al., 2015; Li et al., 2016; Fong and Vedaldi, 2017; Zhou et al., 2016) were "not applicable" or "complex to adapt" in their entirety, in our case of long legal documents & hierarchical frameworks (§2). This was our motivation behind Ob-HEx. Since only CJPE's algorithm existed for our problem setup we used it for comparison.

7 Ethical concerns

Our work aligns with the ethical consideration of the datasets (ILDC (Malik et al., 2021) and the hierarchical models used here for the experimentation and evaluation of our approach. We conform to the license under which the models and dataset were released (Malik et al. (2021)'s GPL-3.0 license) or shared with us (Prasad et al. (2022)'s GPL-3.0 license). We add certain points to this. The framework developed here is in no way to create an "explanatory" judge/lawyer or replace one in real life. Rather we develop Ob-HEx to analyze how deep-learning-based hierarchical models can be interpreted on legal documents to extract and provide legal professionals with patterns and insights that may not be implicitly visible. The methods developed here are in no way foolproof to predict and generate an explanatory response, and should not be used for the same in real-life settings (courts) or used to guide people unfamiliar with legal proceedings. The results from our framework should not be used by a non-professional to make high-stakes decisions in one's life concerning legal cases.

A Description of Ob-HEx's implementation to base hierarchical model (Hierarchical Transformers)

Using Algorithm 1, we describe Ob-HEx adapted to trained hierarchical transformer models in §3.2, and detail the steps involved.

We start from the top-level M (l=2) of the hierarchical model to find the highly sensitive chunks (steps 2-14), for a document. Here, I=E. We calculate the probability output from M. Since M is at the top level of the hierarchy we take its absolute prediction as the absolute-predicted

Algorithm 1 Ob-HEx: Hierarchical Transformers

```

    hierarchy respectively. $k = \%$ of sentences to choose.
 1: for all documents do
 2:     Divide the document into chunks $\{c_i | 1 \leq i \leq n\}$.
 3:     $E \leftarrow$ Extract all chunk embeddings from $T$.
 4:     $O_E \leftarrow M(E)$, probability output.
 5:     $P \leftarrow$ absolute-predicted class label from $O_E$
 6:     $\hat{L}_E \leftarrow 0$, impact with itself $L(P, P)$
 7:     for chunk $c_i$ in $E$ do
 8:         Mask $c_i$ embedding.
 9:         $O_{E(i)} \leftarrow M(\{E|c_i\})$, output after masking $c_i$.
10:         $\hat{L}_{E(i)} \leftarrow L(O_{E(i)}, P)$
11:         $\hat{S}_{E(i)} \leftarrow \hat{S}_{E(i)}(1, \hat{L}_{E(i)}, \hat{L}_E)$ (Eq. 3)
12:     end for
13:     $N_E \leftarrow$ concatenate all $(c_i, \hat{S}_{E(i)})$.
14:     $\hat{N}_E \leftarrow$ Sort $N_E$ in descending order of $\hat{S}_{E(i)}$.
15:     for $i$, ($c$, $s$) in $\hat{N}_E$ do
16:         $O_c \leftarrow T(c)$, probability output from $T$
17:         $\hat{L}_c \leftarrow L(O_c, P)$
18:         Split $c$ into sentences, $\{s_j | 1 \leq j \leq$ m$\}$.
19:         for $s_j$ in $c$ do
20:             Mask $s_j$.
21:             $O_{c(j)} \leftarrow T(\{c|s_j\})$, output after masking $s_j$.
22:             $\hat{L}_{c(j)} \leftarrow L(O_{c(j)}, P)$
23:             $\hat{S}_{c(j)} \leftarrow \hat{S}_{c(j)}(s, \hat{L}_{c(j)}, \hat{L}_c)$ (Eq. 3)
24:             $A_{score} \leftarrow$ concatenate all $(i, s, \hat{S}_{c(j)})$.
25:         end for
26:     end for
27:     Sort $A_{score}$ in descending order of $\hat{S}_{c(j)}$.
28:     $A_{score}[k] \leftarrow$ keep the top $k\%$ sentences.
29:     $A_{score}[k] \leftarrow$ rearrange in the order of (i,$s$).
30: end for
```

class label P=$P_I^{t=2}$=$P_I^{l=2}$ and take the self-impact score as 0 (Step 2-6). We mask/occlude the chunks and calculate their impact score using the impact function $\hat{L}^l_{I(j)}$=$BCE_{loss}(O^l_{I(j)}, P)$ (§3.2) and then their "normalized weighted occluded sensitivity scores" (Eq. 2) concerning the whole document i.e. self-impact score (steps 8-11). Since this is the top level we use 1 as the score weight (s^l_I §2). We sort the accumulated scores in order of their sensitivity score (i.e. higher value is given more importance).

To rank the sentences (steps 15-28) we iteratively start from the highest-scored chunk and take its probability output from the fine-tuned transformer T (from level l=1) to calculate its impact function score w.r.t P (step 17). We then split this chunk (c) into sentences and iteratively mask/occlude a sentence s_j inside the chunk to calculate its 'normalized weighted occluded sensitivity score' ($\hat{S}_{c(j)}$) (steps 19-24). To weigh the overall importance of each sentence of this chunk as compared to the sentences belonging to other chunks, we weigh the impact shift of s_j with the sensitivity score s of c from the previous level (l=2) of hierarchy. We store the sentences along with their chunk number and sensitivity score in A_{score}. We sort A_{score}, ranking in the order of $\hat{S}_{c(j)}$. Since this is the base level (l=1) of the hierarchy we stop and take the top $k\%$ sentences. To arrange the sentences with their sequential occurrence in the document we arrange $A_{score}[k]$ according to the chunk number i and the sentence in the chunk. These sentences serve as the explanation for a document's prediction. The time complexity is model dependent, and is $O(n^2)$ here, due to the quadratic complexity of the fine-tuned transformer (T) used, where asymptotically n is the average length of all the documents for a batch.

B Distribution of evaluation results

B.1 Long explanations

Abstract

Although the advancements of pre-trained Large Language Models have significantly accelerated recent progress in NLP, their ever-increasing size poses significant challenges for conventional fine-tuning, especially in memory-intensive tasks. We investigate the potential of Parameter-Efficient Fine-Tuning, focusing on Low-Rank Adaptation (LoRA), in the domain of multilingual summarization, a task that is both challenging (due to typically long inputs), and relatively unexplored. We conduct an extensive study across different data availability scenarios, including high- and low-data settings, and cross-lingual transfer, leveraging models of different sizes. Our findings reveal that LoRA is competitive with full fine-tuning when trained with high quantities of data, and excels in low-data scenarios and cross-lingual transfer. We also study different strategies for few-shot cross-lingual transfer, finding that continued LoRA tuning outperforms full fine-tuning and the dynamic composition of language-specific LoRA modules.

1 Introduction

The emergence of pre-trained Large Language Models (LLMs), such as PaLM 2 (Anil et al., 2023), LLaMA 2 (Touvron et al., 2023), and the GPT family from OpenAI, has significantly advanced the state of the art in numerous NLP applications. However, the expansion in the size of LLMs poses significant challenges for traditional fine-tuning, particularly when faced with many downstream tasks or tasks with a large memory footprint, e.g., due to processing long inputs.

Parameter-Efficient Fine-Tuning (PEFT) methods have recently shown promise to adapt a pre-trained model to different tasks by selectively fine-tuning a small subset of additional parameters. Widely-adopted PEFT techniques include adapters (Houlsby et al., 2019; Pfeiffer et al., 2021), Low-Rank Adaptation (LoRA; Hu et al. 2022), prefix-tuning (Li and Liang, 2021), and prompt-tuning (Lester et al., 2021). Among these, LoRA has become one of the most popular approaches, achieving state-of-the-art performance without introducing latency at inference time. The majority of PEFT studies have focused on natural language understanding, e.g., classification tasks as exemplified in the GLUE (Wang et al., 2018) and SuperGLUE (Wang et al., 2019) benchmarks, and monolingual generation, e.g., table-to-text generation or summarization (Li and Liang, 2021).

In this paper, we empirically investigate the potential of LoRA in the domain of *multilingual* summarization, a task that is both challenging and relatively unexplored. Multilingual summarization often involves processing lengthy inputs (Hasan et al., 2021), providing a natural testbed for the effective use of PEFT methods. In addition to being able to understand long documents, models are expected to fluently generate sentences in many languages, requiring significant linguistic versatility. Multilingual tasks face additional challenges pertaining to the availability of resources (e.g., for training). It is unrealistic to expect that large-scale and high-quality data will be available or created for every language (Parida and Motlicek, 2019). In scenarios where multilingual data is scarce, PEFT methods which selectively update a small number of parameters seem more suitable while fine-tuning can lead to overfitting or catastrophic forgetting (Kirkpatrick et al., 2017; Mitchell et al., 2022).

This motivates us to explore the following research questions: (i) Can LoRA be effectively applied to complex multilingual summarization tasks? and (ii) Under which conditions does LoRA exhibit the most potential? To answer these questions, we investigate different data availability scenarios: *high-data* regime (high quantities of training data are available for all languages), *low-data* regime (training data is limited but available for all lan-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1202–1228
June 16-21, 2024

guages), and *cross-lingual transfer* (zero or only a few examples are available for some languages). In the latter case, a model trained on a high-resource language (e.g., English) is localized to additional languages for which data is scarce or unavailable (Artetxe et al., 2020; Karthikeyan et al., 2020). In addition to mimicking real-world conditions, the cross-lingual transfer setting allows us to experiment with the composition of language-specific LoRA modules, including the recently proposed few-shot LoraHub (Huang et al., 2023). Our experiments are conducted on two multilingual summarization datasets, XLSum (Hasan et al., 2021) and XWikis (Perez-Beltrachini and Lapata, 2021), using different sizes of the PaLM 2 model, an LLM trained on multilingual text spanning more than 100 languages (Anil et al., 2023).

To summarize, our contributions are as follows: (i) we conduct a comprehensive study of the effectiveness of LoRA for multilingual summarization under different data regimes; (ii) we showcase the benefits of LoRA in low-data and cross-lingual transfer settings; and (iii) we investigate how to best leverage LoRA for cross-lingual transfer subject to the availability of target language examples.

2 Related Work

Parameter Efficient Fine-Tuning methods aim to enhance computational efficiency while maintaining competitive performance compared to full fine-tuning. LoRA is one of the most popular PEFT approaches (Hu et al., 2022; Chen et al., 2022). It reduces the number of trainable parameters by learning pairs of rank-decomposition matrices while freezing the model's original weights. This vastly reduces storage requirements for large language models adapted to specific tasks and enables efficient task-switching during deployment, without introducing inference latency. More recent work explores how to adaptively adjust the rank of the matrices (Zhang et al., 2023b; Valipour et al., 2023), proposes generalizations of LoRA and related PEFT approaches under a common framework (He et al., 2022; Chavan et al., 2023), and combines LoRA with quantization (Dettmers et al., 2023). However, most of these studies focus on classification and monolingual generation tasks. In contrast, we investigate the potential of LoRA in the domain of multilingual summarization, a task that is both challenging and relatively unexplored.

Cross-lingual Transfer requires a model to learn a task from labeled data in one language (typically English), and then perform the equivalent task in another language where no or very little labeled data is available (Artetxe et al., 2020; Karthikeyan et al., 2020; Lauscher et al., 2020; Whitehouse et al., 2022, 2023a). Previous studies focusing on PEFT methods for cross-lingual transfer have explored adapter-based approaches (Pfeiffer et al., 2020; Ansell et al., 2021) and composable sparse fine-tuning (Ansell et al., 2022), among others. Vu et al. (2022) evaluate prompt-tuning (Lester et al., 2021) in a zero-shot setting for cross-lingual summarization, focusing on the Wikilingua dataset (Ladhak et al., 2020). Their study does not cover LoRA, nor does it explore scenarios with more available data (e.g., few-shot settings).

Model Composition and Weight Merging aim to enable generalization to unseen tasks by combining individually trained models. Previous work includes weight composition guided by task similarity (Lv et al., 2023) or arithmetic operations such as addition or subtraction (Zhang et al., 2023a), multi-task prompt pre-training (Sun et al., 2023), and combining models in parameter space by minimizing prediction differences between a merged model and individual models (Jin et al., 2023). For our multilingual summarization task, we also explore the composition of language-specific LoRA matrices through weight averaging, as well as dynamic weight composition when few-shot samples are available (Huang et al., 2023).

3 LoRA for Multilingual Summarization

We now present the fundamentals of LoRA (Hu et al., 2022) and then discuss how individual LoRA modules can be combined (Huang et al., 2023) for cross-lingual transfer. We also introduce our assumptions regarding the availability of training data for multilingual summarization.

3.1 LoRA and LoraHub

LoRA Let $W_0 \in \mathbb{R}^{d\times k}$ denote the weight matrix of a pre-trained LLM (where d is the input dimension and k is the output dimension). The key idea of LoRA is to represent the fine-tuned W with a low-rank decomposition $W_0 + \Delta W = W_0 + BA$, where $B \in \mathbb{R}^{d\times r}$, $A \in \mathbb{R}^{r\times k}$, and $r \ll \min(d, k)$, making BA a low-rank matrix compared to W_0. During training, W_0 is frozen, while B and A contain trainable parameters which are effectively a portion ($2r/d$) of the parameters compared to full fine-tuning. Although in principle LoRA can be applied to any subset of weight matrices, Hu et al. (2022) only update the weight matrices in the self-attention module of the Transformer architecture. We also follow this recipe in experiments and update all four attention matrices (i.e., *query*, *key*, *value*, and *out*).

LoraHub is a gradient-free, few-shot learning approach, recently proposed by Huang et al. (2023). It focuses on composing individually trained LoRA modules for cross-task generalization. Available LoRA modules m_i are synthesized into module $\hat{m} = \sum_{i=1}^{N} w_i m_i$ where w_i is a scalar weight that can assume positive and negative values. The optimal weighted sum is learned through black-box gradient-free optimization (Sun et al., 2022), based on performance metrics on a few examples representative of a new target task.

3.2 Data Regimes

We investigate the effectiveness of LoRA for multilingual summarization under the following data assumptions:

High Data This scenario assumes that *sufficient* training data is available in all languages of interest. Such data could be obtained through automatic pipelines or crowdsourcing.

Low Data In this scenario, we assume that a *limited* number of examples are available in the target languages of interest, typically in the order of dozens or a few hundred. This scenario is common when working with low-resource languages or when data cannot be easily obtained through crowdsourcing but requires input from expert annotators.

Cross-Lingual Transfer Within this context, we consider scenarios where training examples are primarily available in one or a few high-resource languages. We explore three settings corresponding to the following assumptions: (i) only English training data is available; (ii) training data is available in some languages besides English, which creates a more complex multilingual setting; and (iii) a small number of labeled examples are available in the target language, allowing us to study few-shot cross-lingual generalization.

Dataset	**XLSum**	**XWikis**
Source	BBC News	Wikipedia
Languages	44	5
Train/Val/Test Data	1.12M / 114K / 114K	1.43M / 40K / 35K
Input/Output Words	470.2 / 22.1	1042.7 / 63.7

Table 1: Summary statistics for the XLSum and XWikis multilingual summarization datasets. Train/Val/Test shows the number of examples in each split. Input/Output shows the average number of *words* in the *English* input document and output summary. XWikis has long documents and multi-sentence summaries.

4 Experimental Setup

This section introduces the datasets and models used in our study. We further elaborate on the details of our experimental setup, and the metrics used to assess the generated summaries.

4.1 Datasets

We perform experiments on two multilingual abstractive summarization datasets which differ with respect to the number of languages they cover, the number of data samples available, and the summarization task itself (short vs long summaries). Dataset statistics are presented in Table 1.

XLSum (Hasan et al., 2021) contains over one million article-summary pairs in 45 languages. The dataset was automatically collated from BBC News, under the assumption that the introductory sentence in the article is effectively a summary of its content. The number of training examples varies significantly among languages, with English having more than 300K instances, and Scottish-Gaelic just above 1K (see Table 7 in Appendix A for language distribution in XLSum).

XWikis (Perez-Beltrachini and Lapata, 2021) consists of document-summary pairs with long documents and multi-sentence summaries. It was synthesized from Wikipedia articles, under the assumption that the body of the article body and its lead paragraph together form a document-summary pair. XWikis covers five languages (Czech, German, English, French, and Chinese). It also includes cross-lingual document-summary instances, created by combining lead paragraphs and article bodies from Wikipedia titles that are language-aligned. Our experiments focus on cases where the article and the summary are in the *same* language (see Table 8 in Appendix A for language distribution in XWikis).

4.2 Modeling Details

Our experiments focus on PaLM 2 (Anil et al., 2023), a decoder-only LLM which, compared to PaLM (Chowdhery et al., 2023), exhibits superior multilingual and reasoning capabilities, as well as better compute efficiency. Specifically, we employ two sizes (XXS and S) of the instruction-tuned FLAN-PaLM 2 model (Wei et al., 2022a). All experiments were conducted on cloud TPUs,[1] with a learning rate in the range of $\{1e^{-3}, 2e^{-4}, 2e^{-5}\}$. The input/output length was truncated at 2,048/128 tokens for XLSum and 2,048/256 for XWikis.

4.3 Automatic Evaluation

We evaluate the quality of the generated summaries along three dimensions, namely *relevance*, *faithfulness*, and *conciseness*. In terms of relevance, we employ the widely used ROUGE score (Lin, 2004), which measures the degree of n-gram overlap between generated summaries and reference text. Following Aharoni et al. (2023), we compute ROUGE over SentencePiece tokens (Kudo and Richardson, 2018) to avoid inconsistencies in tokenization among languages.

We measure the extent to which generated summaries are faithful to their input using textual entailment (Falke et al., 2019; Kumar and Talukdar, 2020; Honovich et al., 2022; Whitehouse et al., 2023b; Huot et al., 2024). Specifically, for our entailment classifier, we fine-tuned mT5-XXL (Xue et al., 2021) on two NLI datasets, namely ANLI (Nie et al., 2020) and XNLI (Conneau et al., 2018). Following previous work (Aharoni et al., 2023; Huot et al., 2024), for each sentence in the summary, we compute its entailment probability given the input and report the average across sentences.

We also assess if a summary concisely represents the information in the source article using a recently proposed metric trained on the SEAHORSE benchmark (Clark et al., 2023), which is a large-scale collection of human ratings on various dimensions of system summary quality across multiple languages, datasets, and models. We use a publicly available mT5-XXL model (Xue et al., 2021) fine-tuned on binary conciseness judgments.[2]

5 Results and Analysis

This section presents empirical results with LoRA on multilingual summarization. We report comparisons to full fine-tuning, following different data availability scenarios.

		XLSum			XWikis		
	Params	R-L	NLI	SH	R-L	NLI	SH
Reference	—	—	48.50	31.65	—	39.20	25.19
Full FT	100%	**31.11**	42.93	31.64	**34.08**	41.04	25.19
FT-Att	20%	30.88	50.32	**36.12**	32.22	37.06	24.20
LoRA-512	13.3%	29.81	42.58	30.16	33.38	40.48	24.78
LoRA-64	1.7%	29.79	45.51	31.80	34.04	45.34	27.02
LoRA-16	0.4%	29.77	48.48	33.25	33.80	46.10	27.42
LoRA-4	0.1%	29.03	**51.16**	34.42	32.92	**47.43**	**27.72**

Table 2: Results on XLSum and XWikis with PaLM 2-XXS trained in the high-data regime: full fine-tuning on all layers (Full FT), on attention layers (FT-Att), and LoRA-* (with different ranks). Params denotes the proportion of trainable parameters. Best ROUGE-L (R-L), NLI, and SEAHORSE (SH) conciseness scores (area under the ROC curve) are in bold. Reference shows NLI and SH scores on the reference/target summaries.

5.1 High-data Regime

In the high-data regime, we use the complete training set, including all languages in XLSum and XWikis. In Table 2, we compare conventional full fine-tuning on all layers (Full FT), and a more constrained setting that exclusively updates attention layers (FT-Att) against LoRA variants where attention layers are tuned with different ranks ($r = \{4, 16, 64, 512\}$). We report results with PaLM 2-XXS and select the best checkpoints based on ROUGE-L throughout. All differences between best-performing models (shown in bold) and comparison models are statistically significant (across metrics) using paired bootstrap resampling ($p < 0.01$). We also report NLI and SEAHORSE scores for the reference summaries to gain a sense of the optimum value range for these metrics.

In terms of summary relevance, perhaps unsurprisingly, conventional fine-tuning on all layers achieves the best ROUGE-L scores for XLSum and XWikis. Updating attention layers only results in competitive performance on XLSum, however, it delivers a drop of 1.86 ROUGE-L points on XWikis. All LoRA variants, even those with high ranks, update fewer parameters than constrained fine-tuning. Despite remarkable efficiency in parameter updates, LoRA with rank 4 lags behind full fine-tuning (by 2.08 ROUGE-L points on XLSum and 1.16 on XWikis). In general, we observe that expanding the parameter update space through higher ranks enhances summary relevance. For XWikis, LoRA with rank 64 is very close to full

---

[1] See Appendix B for more details of the TPUs used.

[2] `https://huggingface.co/google/seahorse-large-q6`

fine-tuning. However, for XLSum where language diversity and data imbalances are more pronounced, all LoRA variants fall short of full fine-tuning by more than 1 ROUGE-L point. In line with Chen et al. (2022), we observe that LoRA becomes more sensitive to learning rates with higher ranks, requiring more careful hyper-parameter tuning.

With regard to summary faithfulness and conciseness, we note that LoRA achieves superior performance compared to full fine-tuning, with lower rank settings exhibiting better NLI and SEAHORSE scores. We further examined the length of the summaries obtained from full fine-tuning and LoRA models. On XLSum, fully fine-tuned summaries are on average 52.13 tokens long (using the SentencePiece tokenizer), while LoRA summaries (rank 4) are slightly shorter with an average length of 48.82. This difference in conciseness is further mirrored in the SEAHORSE scores for the two types of summaries.

Interestingly, compared to the reference, both full fine-tuning and LoRA demonstrate higher conciseness. The predicted summaries also overall show better NLI scores. Example summaries are provided Appendix D, while additional results and language-specific performance are included in Appendix C.

Takeaways When training data is available, full fine-tuning yields the most relevant and informative summaries. LoRA is a competitive alternative, particularly when considering summary faithfulness and conciseness. LoRA performance can be further enhanced with higher ranks, although more careful hyper-parameter tuning is generally required.

5.2 Low-data Regime

We compare full fine-tuning against LoRA in the low-data regime where limited training data is available. From this section onward, we focus on LoRA with rank 4 and full fine-tuning on all layers.

We randomly sample 16, 64, and 256 training examples per language for both XLSum and XWikis. To ensure the robustness of our results, we conduct experiments with three different seeds, each with a unique set of samples. To examine how performance evolves as we increase our training samples, we further present experiments with 1,024 and 4,096 examples per language for both datasets.[3] We set the number of validation samples to match that of the training data. As before, we select the best checkpoint based on ROUGE-L and subsequently evaluate on the entire test set.

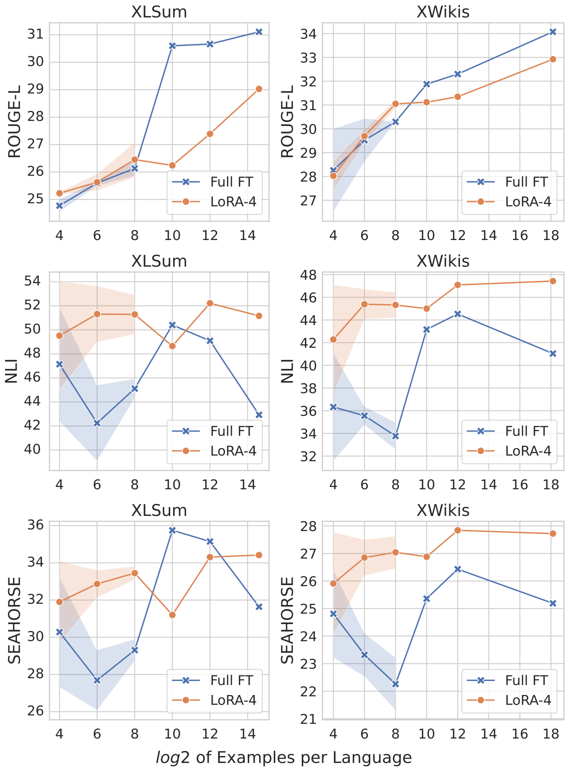

Figure 1: Results on the XLSum and XWikis datasets with PaLM 2-XXS trained in the low → high-data regime: Full FT vs. LoRA-4. Results for up to 256 examples per language are averaged over three seeds, with standard deviation shown in shaded areas.

Figure 1 shows the performance of PaLM 2-XXS with full fine-tuning and LoRA, when the number of training examples per language varies from 16 to the entire dataset. The x-axis corresponds to the number of examples per language on *log* scale; the high-data setting is approximated by ~$2^{14.6}$ examples in XLSum and ~$2^{18.1}$ in XWikis. For training data with 256 or fewer samples, we show the standard deviation with shaded areas. We observe that LoRA achieves overall better faithfulness (NLI) and conciseness (SEAHORSE) than full fine-tuning. For ROUGE-L, LoRA demonstrates advantages in low-data scenarios, while full fine-tuning delivers a performance boost when increasing the number of examples from 256 to 1,024.

In addition, full fine-tuning is sensitive to checkpoint selection in the low-data regime, due to its susceptibility to overfitting, requiring more frequent validation. In comparison, the training pro-

---

[3] When the number of training samples is set to 4,096, three languages in XLSum already lack sufficient data, so we refrain from selecting more examples per language.

	Test Languages	XLSum R-L	XLSum NLI	XLSum SH	XWikis R-L	XWikis NLI	XWikis SH
Full FT	Non-English	5.20	4.49	6.88	17.51	35.95	22.43
LoRA-4		**21.13**	**39.07**	**23.08**	**23.86**	**45.54**	**25.96**
Full FT	English	**32.58**	57.09	38.01	**36.59**	**53.59**	**30.81**
LoRA-4		32.21	**63.13**	**43.44**	34.07	49.94	29.01

Table 3: Zero-shot cross-lingual transfer using full fine-tuning (Full FT) and LoRA (rank 4); PaLM 2-XXS models are trained and validated on English and tested on all other languages (Non-English) and English only. Best ROUGE-L (R-L), NLI, and SEAHORSE (SH) conciseness scores (area under the ROC curve) are in bold.

cess for LoRA is more stable.

Takeaways In low-data scenarios, LoRA is a better alternative to full fine-tuning. LoRA delivers consistently competitive or even superior results with the additional advantage of efficient and stable training.

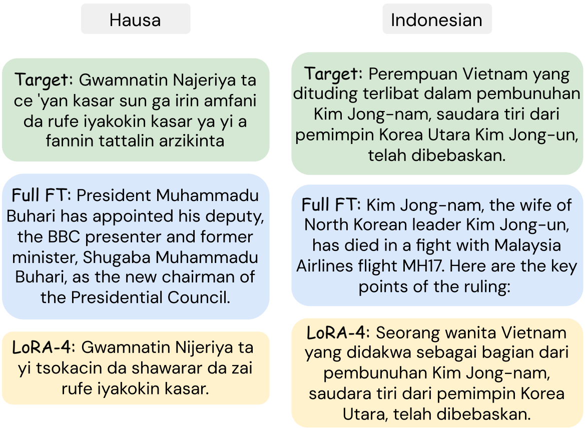
5.3 Cross-lingual Transfer

We now focus on cross-lingual transfer in multilingual summarization and explore two common scenarios, namely zero- and few-shot learning. For LoRA, we focus on rank 4 in all experiments.

Zero-shot Transfer from English

We first consider a typical scenario where only English training data is available, i.e., training and validation are carried out using English examples, whilst the model is tested on new languages.

Table 3 shows the performance of PaLM 2-XXS with full fine-tuning and LoRA. We separate results on English as they are not zero-shot (second block in Table 3) and they broadly align with our findings in Section 5.1 (high-data regime). Full fine-tuning generally outperforms LoRA except for NLI and SH on English XLSum. In the cross-lingual transfer scenario (first block in Table 3), full fine-tuning performs exceptionally poorly across metrics and languages on XLSum. The gap is smaller for XWikis as only four non-English languages are covered and all but Chinese are in the Indo-European family. Further examination of the model output shows that the generated text is mostly in English rather than the target language. The model appears to comprehend the new language (i.e., input documents), however, it struggles to generate output accordingly.



Hausa

Target: Gwamnatin Najeriya ta ce 'yan kasar sun ga irin amfani da rufe iyakokin kasar ya yi a fannin tattalin arzikinta

Full FT: President Muhammadu Buhari has appointed his deputy, the BBC presenter and former minister, Shugaba Muhammadu Buhari, as the new chairman of the Presidential Council.

LoRA-4: Gwamnatin Nijeriya ta yi tsokacin da shawarar da zai rufe iyakokin kasar.

Indonesian

Target: Perempuan Vietnam yang dituding terlibat dalam pembunuhan Kim Jong-nam, saudara tiri dari pemimpin Korea Utara Kim Jong-un, telah dibebaskan.

Full FT: Kim Jong-nam, the wife of North Korean leader Kim Jong-un, has died in a fight with Malaysia Airlines flight MH17. Here are the key points of the ruling:

LoRA-4: Seorang wanita Vietnam yang didakwa sebagai bagian dari pembunuhan Kim Jong-nam, saudara tiri dari pemimpin Korea Utara, telah dibebaskan.

Figure 2: XLSum output examples: zero-shot transfer from English using Full FT and LoRA with PaLM 2-XXS. Full FT fails to generate summaries in the target language and the content is off-topic.

Figure 2 illustrates XLSum examples of model output for Hausa and Indonesian. In both cases, Full FT summaries are in English, and off-topic (the Hausa article discusses the Nigerian government's decision to close its borders, while the Indonesian one reports on the murder of Kim Jong Un). In Appendix C, we provide per-language results which highlight that for zero-shot transfer from English, full fine-tuning consistently lags behind LoRA in *every* language, even in cases where languages are well-represented in the pre-training phase of PaLM 2 or are considered linguistically close to English.[4] This catastrophic forgetting behavior echoes the findings in Vu et al. (2022).

Zero-shot Transfer from Multiple Languages

We extend our study of zero-shot cross-lingual transfer to scenarios where training data is available in multiple languages rather than just English.

For XLSum, we create a training data pool of 10 languages from eight distinct linguistic families, each with substantial training data. These languages include Arabic (AR), (Simplified) Chinese (ZH), English (EN), Hausa (HA), Hindi (HI), Indonesian (ID), Persian (FA), Portuguese (PT), Swahili (SW), and Turkish (TR). Additionally, we select 10 test languages: Azerbaijani (AZ), Bengali (BN), Japanese (JA), Kirundi (RN), Korean (KO), Nepali (NE), Scottish Gaelic (GD), Somali (SO), Thai (TH), and Yoruba (YO). Test languages are selected so that they are maximally diverse, each representing a unique language family.[5] For XWikis, we adopt a *leave-one-out* approach, since it only covers five languages. We rotate through the available languages, one for testing and four for training.

---

[4] See Table 21 in Anil et al. (2023) regarding the distribution of languages used in the pre-training of PaLM 2.

[5] See Appendix A for details of language families in XLSum.

In addition to full fine-tuning and LoRA, we report experiments with language-specific LoRA modules, each trained on examples from one language. An advantage of such specialized modules is their scalability and adaptability. When additional languages become available, there is no need to re-train the entire model; it is sufficient to add a new language-specific module. During inference, we can also flexibly experiment with various LoRA modules or weight composition methods. As mentioned in Section 2, weight composition is an active research area that has demonstrated effectiveness across a spectrum of applications. We adopt a simple approach that computes the weighted average of all available modules.

Figure 3 shows the heatmaps of the ROUGE-L scores for models trained in one language and tested on another. Rows represent source models from `SEEN` languages and columns represent `UNSEEN` test languages. The color scale is column-wise normalized to provide a comparative view of the performance of the best and worst models for each `UNSEEN` test language. In the bottom three rows, we also illustrate the performance of models trained on multiple seen languages and tested on unseen ones. We experiment with full fine-tuning, LoRA (rank 4), and weighted average LoRA.

We observe from Figure 3 that: (i) full fine-tuning consistently lags behind LoRA in zero-shot cross-lingual transfer, even with a diverse collection of languages besides English; (ii) the weighted average of language-specific LoRA modules (`Avg.LoRA`) and LoRA (trained on all available languages together) benefit different unseen languages. Particularly for XLSum, lower-resource languages (i.e., RN, GD, SO, and YO), exhibit superior performance with language-specific LoRA training. We hypothesize that in the default LoRA setting (i.e., joint training across languages), high-resource languages hinder the effective learning of low-resource languages; and (iii) languages with similarities demonstrate better transferability, as exemplified by transferring ZH to JA and SW to RN on XLSum, and the Indo-European languages on XWikis.

Figure 3: Zero-shot cross-lingual transfer on XLSum (top) and XWikis (bottom); PaLM 2-XXS models are trained on one language (`SEEN`) and tested on another (`UNSEEN`). We also show results with full fine-tuning on *all* seen languages (Full FT), LoRA, and (average) weighted combination of language-specific LoRA modules (`Avg.LoRA`); `excl.XX` in XWikis denotes *leave-one-out* training, excluding the test language.

Few-shot Cross-lingual Transfer

Finally, we consider scenarios where some examples are available in the target languages and explore effective strategies for utilizing them. We follow the previous section and assume that models have been already trained on (seen) languages with sufficient data. One approach is to *continue* training these models using target language examples. Therefore, if the starting checkpoint was obtained from full fine-tuning on seen languages, we continue with full fine-tuning on the new languages. We also adopt the same strategy for LoRA.

Another widely-used technique is *in-context learning*, where input and output examples are concatenated to form in-context demonstrations. Despite promising results in many LLM applications (Brown et al., 2020; Wei et al., 2022b), in-context learning becomes less practical in the domain of multilingual summarization where models are expected to process long articles, which is memory-intensive, especially as the number of examples grows. Instead, we experiment with the recently proposed few-shot LoraHub learning ap-

	LoRA-4 (CL)	**25.94**	**42.07**	27.66	**31.08**	45.12	**28.05**
	LoraHub	24.21	41.34	**28.02**	27.66	**48.09**	26.56

Table 4: Cross-lingual transfer on 10 XLSum languages and five XWikis languages (using *leave-one-out* training) for PaLM 2-XXS model. 16- and 64-shot experiments show average results from three different seed runs. For *continued learning* (CL), we use a 14/2 and 60/4 training/validation split. Best results are in bold. Results for individual languages are in Tables 10 and 13 in Appendix C.

proach (Section 3.1). The original formulation of LoraHub (Huang et al., 2023) does not assume any prior knowledge of the available LoRA modules which are randomly sampled and initialized with zero weights (i.e., starting from a general-purpose pre-trained LLM). We initialize LoraHub with the weighted sum of N language-specific LoRA modules and assign a weight of $1/N$ to each module. The composition of modules fine-tuned on the same task, albeit in different languages, offers a stronger baseline compared to a pre-trained LLM.

We consider two few-shot settings, with 16 or 64 target language examples, simulating practical scenarios where human annotators or experts create a few examples for low-resource languages. We compare few-shot *continued learning* and *LoraHub learning*, using the same examples. To ensure robustness, all experiments are conducted on three different sets of examples, and we report the average. For continued learning, we split the examples into training and validation using 14/2 and 60/4 splits. For LoraHub, we use the `Nevergrad` toolkit[6] for black-box optimization. We empirically compared ROUGE-L and loss as performance metrics guiding the optimization and found that ROUGE-L led to more stable results.

Table 4 presents our results on XLSum and XWikis with 16- and 64-shots, averaged across test languages. Zero-shot results are also included for comparison. Our analysis supports the following observations: (i) with only a few target language examples (e.g., 16), full fine-tuning sees a remarkable improvement, resulting in an average boost of 7.8 ROUGE-L points on XLSum and 6.7 on XWikis, corroborating the findings of Lauscher et al. (2020); (ii) LoraHub slightly enhances ROUGE-L performance compared to (zero-shot) weighted-average on XLSum with only 16 examples; (iii) LoRA continued learning consistently outperforms full fine-tuning and LoraHub in terms of ROUGE-L and SH; however, LoraHub is superior in terms of NLI for XWikis.

		XLSum			XWikis		
	Params	R-L	NLI	SH	R-L	NLI	SH
Full FT	100%	**36.99**	58.72	41.92	**39.65**	46.03	28.01
LoRA-4	0.04%	36.29	**61.64**	**43.99**	39.25	**47.56**	**28.30**

Table 5: Results on XLSum and XWikis datasets with PaLM 2-S trained in the high-data regime: Full FT and LoRA (rank 4). Params denotes the proportion of trainable parameters. Best results are in bold.

	Test Languages	XLSum			XWikis		
		R-L	NLI	SH	R-L	NLI	SH
Full FT	Non-English	33.22	60.72	41.96	35.70	46.27	27.51
LoRA-4		**33.31**	**64.18**	**43.98**	**36.00**	**47.23**	**28.69**
Full FT	English	**40.38**	71.21	45.82	**42.03**	**51.76**	28.95
LoRA-4		39.61	**78.05**	**47.02**	41.53	50.09	**29.07**

Table 6: Zero-shot transfer on XLSum and XWikis using Full FT and LoRA (rank 4). PaLM 2-S models are trained and validated on English and tested on all other languages (Non-English) and English only. Best results are in bold.

Takeaways In cross-lingual transfer scenarios, LoRA achieves consistently superior performance compared to full fine-tuning. LoRA continued learning shows particular promise when only a small number of examples are available in the target language.

6 Scaling Up

We extend our analysis to the larger PaLM 2-S model, focusing on the high-data regime and zero-shot cross-lingual transfer using English data. Our results are summarized in Table 5 and Table 6.

Interestingly, LoRA and full fine-tuning achieve similar performance, with LoRA taking the lead in cross-lingual transfer (see first block in Table 6). We hypothesize that when using the larger PaLM 2-S model, the increased capacity makes up for the small percentage of trainable parameters in LoRA (only 0.04% of the parameters), allowing it to benefit more from high-data regime training. At the same time, the larger model is more robust and does not exhibit catastrophic forgetting during

---

[6] `https://facebookresearch.github.io/nevergrad`

full fine-tuning. As a result, we see that full fine-tuning performs on par with LoRA in the zero-shot cross-lingual setting (see Table 6).

Takeaways For larger models such as PaLM 2-S, LoRA achieves on-par performance with full fine-tuning but is a better choice when considering computational efficiency.

7 Conclusions

In this paper, we explored the effectiveness of LoRA on multilingual summarization across a diverse range of scenarios primarily determined by the availability of training data. We summarize our key findings by comparing the computationally efficient LoRA against full fine-tuning.

LoRA achieves **superior performance** to full fine-tuning in zero-shot and few-shot cross-lingual transfer scenarios, and low-data settings (e.g., training data with fewer than 1K samples). This is most pronounced with smaller models (e.g., PaLM 2-XXS). In the specific case of few-shot learning, LoRA continued learning outperforms LoraHub. LoRA also achieves overall superior summary faithfulness and conciseness across various scenarios.

For larger models like PaLM 2-S, LoRA exhibits **on-par performance** to full fine-tuning. This suggests that model capacity matters. Notably, for smaller models like PaLM 2-XXS, LoRA displays **worse performance** in the full fine-tuning (high-data) regime, when said performance is measured via ROUGE-L, but is consistently superior in terms of faithfulness and conciseness.

Taken together, our results underscore the utility of PEFT methods for complex multilingual tasks and cross-lingual transfer. Avenues for future work include few-shot transfer and effective ways to combine LoRA modules, e.g., by learning which modules to activate for different tasks or languages (Ponti et al., 2023; Lin et al., 2024). It would also be interesting to reproduce our results across varied LLMs and broader multilingual generation tasks, beyond summarization.

Limitations

We identify the following limitations of our work:

- We focused exclusively on decoder-only models. Future work could explore a wider range of LLMs, including encoder-decoder models. We anticipate the observations gained from decoder-only models to largely align with those from encoder-decoder models, thus generalizing our findings.
- In our cross-lingual transfer studies, we only considered LoRA models with a rank of 4, due to computational considerations. Expanding to additional LoRA settings would allow us to perform a more thorough comparison.
- Our experiments have exclusively focused on multilingual summarization tasks. Extending our study to a wider range of multilingual text generation tasks with long input and output would provide a more comprehensive perspective on the capabilities and limitations of LoRA.
- We concentrate on LoRA as a representative parameter-efficient fine-tuning approach, however, extending our study to other PEFT methods could bring more insights.

A Datasets

Table 7 and Table 8 show the language families and the number of training examples per language in the XLSum and XWikis datasets.

B TPU Computational Requirements

With regard to computational requirements, memory-intensive experiments were conducted on Cloud TPU v4, while less memory-intensive ones were run on Cloud TPU v3. For instance, full fine-tuning jobs in the high-data regime required up to 64 TPUs v4, while less memory-intensive jobs such as LoRA with continued learning (for cross-lingual transfer) required 8 TPUs v3.

C Additional Results

Table 9 shows ROUGE-1, ROUGE-2, and ROUGE-L scores for LoRA and full fine-tuning with PaLM 2-XXS on the two datasets. We additionally report activating LoRA tuning on Feed Forward layers with different ranks.

Table 10, Table 11, and Table 12 show ROUGE-L, NLI, and SEAHORSE few-shot learning results for individual languages on XLSum. Table 13, Table 14, and Table 15 show ROUGE-L, NLI, and SEAHORSE few-shot learning results for individual languages on XWikis.

Table 16, Table 17, and Table 18 show ROUGE-L, NLI, and SEAHORSE results for PaLM 2-XXS on XWikis for individual languages; in the high-data regime and in a zero-shot cross-lingual transfer setting from English. Table 19, Table 20, and Table 21 show ROUGE-L, NLI, and SEAHORSE results for PaLM 2-XXS on XLSum for individual languages; in the high-data regime and in a zero-shot cross-lingual transfer setting from English.

D Examples of Summaries

We provide some randomly selected examples of input, target, and generated summaries of XLSum with Full FT and LoRA-4 models in Table 22.

INPUT	Sir Charlie Mayfield said he "didn't say Brexit was the reason" for a 99% slide in half-year profits. "The fact is sterling is weaker, it's more expensive to import goods... so we have to absorb that within our margin," he said. "I'm not going to get into some sort of ding-dong with the secretary of state." Dominic Raab told the BBC on Thursday it was a mistake for "business that aren't doing so well to blame Brexit". "I don't doubt that some of the uncertainty around these negotiations will have an impact on business - that's why we are putting all our energy into getting the good deal we want with our EU friends and partners," he said. "All I am just gently saying is that it's rather easy for a business to blame Brexit and the politicians rather than take responsibility for their own situation." Mr Raab's comments appear to have been in response to Sir Charlie's warning in John Lewis's half-year results that "with the level of uncertainty facing consumers and the economy, in part due to ongoing Brexit negotiations, forecasting is particularly difficult". The owner of the John Lewis department store chain and Waitrose said it continued to expect annual profits to be "substantially lower than last year". Mr Raab also said the government was preparing for a no-deal Brexit despite being confident that eventuality would not come to pass: "Getting a deal with the European Union is still by far and away the most likely outcome." This week Ralf Speth, the boss of Jaguar Land Rover, warned the government needed to get "the right Brexit" or risk wiping out profits at the UK's biggest carmaker and trigger big job cuts. Meanwhile, the Brexit secretary welcomed a promise by two mobile operators, Vodafone and Three, not to impose Europe roaming charges for UK customers if Britain leaves the bloc with no deal. "What we have said is we would like to see other companies following suit, but, in any event, we would legislate for a limit on roaming charges to make sure in a no-deal scenario that we protect British consumers," Mr Raab said. A new raft of technical papers is being released by the government on Thursday outlining the impact of a no-deal Brexit on business and consumers. Mr Raab also accused those warning about shortages of food and medicines after a no-deal withdrawal of "scaremongering", saying it was "nonsense" to claim UK supermarkets would run out of food.
TARGET	The boss of John Lewis has hit out at Brexit secretary Dominic Raab after he said companies should not blame Brexit for poor results.
FULL FT	The boss of John Lewis has defended his company's decision to blame Brexit for its falling profits.
LORA-4	The boss of John Lewis has said it is "rather easy" for businesses to blame Brexit for their poor performance.
INPUT	On Tuesday, the corporation's director general Tony Hall will announce new commissions including a series in collaboration with the Tate. Lord Hall will say the arts are at risk of becoming marginalised for future generations unless more is done to get children and young people engaged. As part of the plans, acclaimed 1960s arts show Civilisation is to return. The landmark 13-part series series telling the history of western art was fronted by art historian Kenneth Clark when it was screened by BBC Two in 1969. The BBC is now looking for a new authoritative presenter to follow in Clark's footsteps for the new series, which will use modern digital technology to provide a fresh overview of the history of art. The BBC said: "Civilisation was a landmark programme. Producing something of equal scale will be a huge challenge, but we believe it is time to once again create something with the same impact for a new generation. "The arts have been central to the BBC's past and are central to its future. As all arts organisations face the challenge of delivering more in a tight economic climate, it is vital that we work together in new ways to create a bigger and better offer to the public." As well as including arts content in The One Show, the idea will be spread to other popular programmes such as BBC Radio 2's Simon Mayo show. Lord Hall announced last October that funding for the BBC's arts coverage would increase by 20%. The director general, who was Royal Opera House chief executive for 12 years before his appointment to the BBC, said he wanted to return the arts to the corporation's "heart". At that time, he announced that Simon Schama would front a five-part series in partnership with the National Portrait Gallery exploring the history of Britain through portraiture, and that Andrew Marr would present a new series looking at the greatest writers in Scotland.
TARGET	The BBC is to feature more arts stories in programmes like The One Show in a bid to make the subject less elitist.
FULL FT	The BBC is to include arts content in its The One Show, as part of a new £100m arts programme.
LORA-4	The BBC is to launch a new arts programme in The One Show, which will be fronted by a new presenter.

INPUT	这对新人周五(7月17日)在温莎的诸圣皇家礼拜堂(The Royal Chapel of All Saints)举行了小型仪式,英国王室隔天公布了两张官方照片。其中一张可见二人笑容满面,在鲜花搭制的拱门下离开教堂 另一张则是一对新人在教堂外与碧翠丝的祖父母——女王及爱丁堡公爵菲利普亲王(Prince Philip, Duke of Edinburgh)合照。碧翠丝的父母约克公爵及公爵夫人(Duke and Duchess of York)并没有出现在官方公开的照片中,但白金汉宫证实,约克公爵安德鲁王子(Prince Andrew)牵着碧翠丝的手走进教堂 安德鲁王子在他的前好友麦克斯维尔(Ghislaine Maxwell)最近因涉嫌性贩卖遭逮捕后一直保持低调,麦克斯维尔对自己遭到的指控予以否认。为了此次婚礼,女王将一条复古长裙和她在1947年自己婚礼上佩戴的一顶穗状钻石王冠借给了碧翠丝。碧翠丝与莫奇原计划于今年5月举行婚礼,但受COVID-19新型冠状病毒疫情影响,二人决定将仪式延后,并改为举行由双方父母及兄弟姐妹参加的私人典礼。英国自3月23日起实行全国范围的封锁,英格兰境内几乎所有婚礼均被禁止举行 而自7月4日起,英格兰开始允许举行婚礼,但人数上限为30人。白金汉宫在一则声明中表示,碧翠丝的婚礼符合政府政策规定。这应该是94岁的女王与99岁的菲利普亲王在英国封锁令后首次参加家庭聚会。碧翠丝在婚礼上身穿一条已故设计师哈特内尔(Norman Hartnell)设计的象牙色双面横绫缎塔夫绸长裙,配以公爵夫人缎并镶有钻石,这条长裙借自女王。碧翠丝婚纱所用长裙是女王在1962年12月出席电影《沙漠枭雄》(Lawrence Of Arabia)全球首映式时所穿的礼服的改良版。白金汉宫称,这条长裙经过了女王的高级服装师安吉拉·凯利(Angela Kelly)及设计师斯图尔特·帕文(Stewart Parvin)改良。碧翠丝是目前英国王位第九顺位继承人,她在婚礼上佩戴的玛丽女王(Queen Mary)穗状钻石王冠也借自她的祖母女王。1947年11月,女王(时为伊丽莎白公主)与菲利普王子结婚,当时所佩戴的王冠与这次碧翠丝婚礼所用的是同一顶王冠。今年31岁的碧翠丝与35岁的莫奇原计划于今年5月29日在伦敦的圣詹姆斯宫(St James Palace)皇家礼拜堂(Chapel Royal)举行婚礼 最终仪式场所所在的温莎大公园(Windsor Great Park)皇家小屋(Royal Lodge)是碧翠丝童年时代的家,她的父母如今仍然居住在那里。碧翠丝与她的丈夫自2018秋天起交往,去年9月订婚 据称这对新人是在碧翠丝的妹妹尤金妮公主(Princess Eugenie)的婚礼上重逢后开始相恋。婚礼结束后,新娘一般会举行“抛花球”仪式 但遵循王室新娘传统,碧翠丝的捧花被放置在西敏寺大教堂(Westminster Abbey)的无名战士墓碑上。这束手捧花由茉莉 淡粉及奶油色的香豌豆花 王室陶瓷象牙白多头玫瑰 粉色庭园玫瑰 粉蜡花 浅粉色落新妇花组合而成,并按照王室传统加入多支紫薇花。西敏寺大教堂法政牧师安东尼·波尔(The Reverend Canon Anthony Ball)及皇家礼拜堂副主任牧师保罗·怀特(Reverend Paul Wright)的儿子托比·怀特(Toby Wright)一同将捧花放置在威斯敏斯特教堂中。文中图片,版权所有,未经批准,翻印必究。
TARGET	英国碧翠丝公主(Princess Beatrice)与地产大亨爱德华多·马佩利·莫奇(Edoardo Mapelli Mozzi)举行婚礼 白金汉宫公开了婚礼现场照片。
FULL FT	英国女王伊丽莎白二世(Queen Elizabeth II)的孙女碧翠丝(Bessie Louise Mountbatten-Windsor)与美国商人莫奇·艾米斯(Mitch Eisley)在温莎举行了一场私人仪式,女王将借此机会借给碧翠丝一顶穗状钻石王冠。
LORA-4	英国王室宣布,英国王位第九顺位继承人碧翠丝·莫奇(Princess Beatrice)与丈夫莫奇·莫奇(Mohamed bint Mohammed bin Rashid Al Maktoum)在温莎的皇家小屋举行了私人婚礼。
INPUT	考纳利在伦敦奥运开幕式上做一把女王替身。来自泰晤士河边亨利地区的考纳利(Gary Connery),在伦敦奥运会开幕式上,身着女王的服饰从直升机跳下 他凭借此举,与12位候选人共同入围一项电视年度探险大奖。另外,从太空跳伞成功的奥地利人波姆加德纳,同样栖身候选名单。今年五月,在没有降落伞的情况下,考纳利从直升机上跳下,并成功落入一堆空纸盒中。这位43岁的冒险家在说到做女王替身 和扮演邦德的克雷格一起完成这个伦敦奥运开幕式的惊心动魄的节目时表示,这是个“极其精彩的生活经历”。他说:“当我回顾今年时,我会在脸上露出绽放的笑容。”考纳利说,让他颇为感动的是,很多英国民众对他的冒险行为都非常支持 他说:“民众的反应让我欣慰。”他说,不管最终能不能获奖,能与这些一年来活得精彩的人一起入围,“就是份荣耀”。与内文相关的链接 相关话题。
TARGET	在伦敦奥运会开幕式表演中做女王替身的考纳利,已经获得一项探险大奖的提名。

INPUT	Andrew Marr, penyiar BBC yang berusia 50an dan rajin berolahraga lari, tidak memenuhi kategori itu. Usia adalah salah satu faktor risiko terbesar, tapi siapa saja dari usia berapa saja dapat terserang stroke. Lebih dari 150.000 orang di Inggris terserang stroke setiap tahun dan seperempat dari mereka berusia di bawah 65 tahun. Bahkan ada pula kasus stroke pada usia kanak-kanak. Banyak pilihan gaya hidup berisiko meningkatkan peluang terkena stroke. Merokok, kelebihan lemak di perut dan terlalu banyak mengonsumsi alkohol tidak serta merta mengakibatkan stroke, namun berangsur-angsur meningkatkan risiko seumur hidup. Namun ada penyebab lain stroke pada orang berusia muda dan sehat. Kelainan saat lahir Stroke menyebabkan otak kekurangan oksigen ketika aliran darah terhenti, baik karena penyumbatan (stroke ischaemic) atau oleh ledakan pembuluh darah di otak (stroke haemmorrhagic). Sekitar 80% stroke disebabkan oleh penyumbatan darah, tapi stroke jenis apa yang menimpa Andrew Marr belum diketahui.l Namun jika anda melihat orang-orang dibawah usia 65, maka stroke haemorrhagic menjadi lebih umum. Stroke tipe ini dapat diakibatkan kelainan dalam pembuluh darah yang sudah ada sejak lahir. Bom waktu di otak ini dapat meledak sewaktu-waktu. Salah satu contoh adalah kelainan bentuk anarteriovenous, ketika arteri tersumbat yang berarti tekanan di dalam pembuluh darah terlalu besar untuk diatasi oleh tubuh. Akibatnya otak mengalami pendarahan. Bahkan stress dapat menaikkan tekanan darah cukup untuk memicu stroke dan ada beragam bukti mengenai dampak konsumsi kopi dalam jumlah terlalu banyak. Detak jantung yang tidak teratur atau atrial fibrillation juga mengakibatkan stroke ischaemic. Sebagian jantung berdetak begitu cepat sehingga organ ini berhenti bekerja sebagai pompa. Darah berkumpul di dalam jantung, yang dapat tersumbat, mengalir ke otak dan menyebabkan stroke. Satu faktor yang tidak dapat dihindari adalah gen. Ada orang yang peluang terserang stroke lebih besar dibandingkan yang lain dan hal itu biasanya diturunkan dalam satu keluarga. Salah kaprah Dr Clare Walton dari Asosiasi Stroke, mengatakan, "Saya akan mengatakan bahwa ada salah kaprah bahwa ini hanyalah kondisi orang tua. Seperempat kasus stroke terjadi pada orang usia kerja dan anak-anak serta bayi juga mengalami stroke. "Kita harus paham bahwa semua orang memiliki risiko terserang stroke dan bukan hanya di usia tua." Pada akhirnya semua tergantung pada sikap kita. Diet sehat, olahraga teratur, minum alkohol secukupnya saja dan tidak merokok secara dramatis mengurangi risiko stroke. Namun beberapa orang dengan gaya hidup sehat akan tetap terkena stroke, sedangkan mereka dengan gaya hidup sebaliknya justru tidak.
TARGET	Saat anda berpikir mengenai pasien stroke "tipikal", anda langsung teringat pada seseorang yang berusia lanjut, kelebihan berat badan, malas berolahraga dan merokok.
FULL FT	Anda berusia 65 tahun dan Anda tidak memiliki risiko tinggi terkena stroke?
LORA-4	Anda berusia 30 tahun, Anda sehat dan Anda tidak memiliki penyakit apa-apa. Anda mungkin tidak termasuk dalam kategori orang yang paling berisiko terkena stroke.
INPUT	Dua anak-anak Belanda diyakini berada di Raqqa wilayah kekuasaan ISIS Perempuan, yang telah bercerai dengan suaminya, itu membawa seorang anak laki-laki yang berusia delapan tahun dan anak perempuan berusia tujuh tahun diyakini telah bepergian menggunakan paspor palsu. Mantan suami yang merupakan ayah anak-anak, seorang warga negara Belanda, telah memperingatkan otoritas tentang kepergian mereka ke wilayah yang dikuasai ISIS. Otoritas mengatakan kasus ini merupakan yang pertama kali terjadi. Perempuan yang berusia 32 tahun itu, yang tidak disebutkan identitasnya, telah tinggal di bagian selatan kota Maastricht, Belanda. Dia dan kedua anaknya belum terlihat sejak Oktober lalu. Mereka diyakini terbang dengan pesawat ke Belgia ke Athena dan perempuan itu dilaporkan menghubungi ibunya pada Januari, dengan mengatakan mereka berada di wilayah kekuasaan ISIS di Raqqa di bagian utara Suriah. Jaksa memperlakukan kasus ini sebagai sebuah penculikan dan telah menerbitkan surat penahanan internasional. Tetapi mereka mengakui kita perempuan dan anak-anaknya telah menyebrang perbatasan ke Suriah, sangat kecil kemungkinan untuk membawa keluarga tersebut kembali ke Belanda. Sekitar 200 orang warga Belanda, termasuk sejumlah anak-anak, diketahui telah bergabung dengan ISIS di Irak dan Suriah. ISIS menjadi salah satu dari kelompok jihadis yang berbahaya, dituduh melakukan pembunuhan massal dan penghukum etnis dan pemeluk agama minoritas di wilayah yang mereka kuasai.
TARGET	Seorang perempuan Checnya yang tinggal di Belanda telah membawa dua anaknya untuk bergabung dengan militan Negara Islam ISIS di Suriah, yang bertentangan dengan keinginan ayah kedua anak tersebut, seperti disampaikan oleh jaksa di Belanda.
FULL FT	Seorang perempuan Belanda yang diduga telah bergabung dengan kelompok yang menamakan diri Negara Islam atau ISIS, telah menyelundup dua anak-anak ke Suriah, kata otoritas Belanda.
LORA-4	Seorang perempuan Belanda yang diduga telah bergabung dengan kelompok jihadis ISIS di Suriah telah ditangkap di perbatasan Suriah.

INPUT	이곳은 오늘날 훨씬 건조한 곳이 됐다 이 지역은 현재 염전으로 활용되고 있지만, 20만 년 전 인간의 조상이 번성했을 당시엔 거대한 호수가 있었다. 인류의 조상은 기후 변화가 닥치기 전까지 7만 년 동안 그곳에 정착했다고 연구진은 설명했다. 비옥한 녹지가 다른 지역에도 확대돼 인류가 아프리카 바깥으로도 진출하기까지 그들은 후대 인류를 위해 길을 닦아놓았다. 호주 가반 의학연구소의 유전학자인 바네사 헤이스 교수는 "해부학적으로 약 20만 년 전 현대인류가 아프리카에 나타난 것은 어느 정도 분명한 사실"이라고 말했다. "오랫동안 논의해온 건 인류가 정확히 어디에서 기원했으며 어디서부터 퍼졌느냐는 것이다." 그러나 헤이스 교수의 결론에 같은 분야의 다른 학자들은 회의적인 반응을 보였다. 호수가 있는 안식처 문제의 지역은 남부 잠베지강 유역이다. 보츠나와 북부에 있는 곳이다. 보츠나와는 아프리카 대륙 남쪽에 자리했다. 연구원들은 인류의 조상이 거대한 호수 지역인 마카디카디 근처에 정착했다고 생각한다. 이 호수는 현재 소금 평면이 펼쳐져 있는 지역이다. 하이스 교수는 "여긴 매우 넓은 지역이었다. 과거엔 습지였을 수도 있고 풀이 우거졌을지도 모른다"라고 말했다. 그는 "현생 인류와 야생 동물에게 살기에 최적의 공간을 제공했을 것"이라고 덧붙였다. 이 지역에 7만 년 동안 살아온 인류는 이 지역에 강우량이 증가하면서 이주를 시작했다. 13만 년 전, 11만 년 전에 세 차례의 이주 물결이 있었다. 인류는 비옥한 초록색 토지가 있는 곳으로 퍼져나갔다. 나미비아의 칼라하리 사막에서 줄호안시 사냥꾼들에게 불을 피우는 법을 배우는 헤이스 교수 첫 이주민들은 북동쪽으로 향했다. 두 번째 이주 인파는 남서쪽으로 향했다. 3분의 1 정도만 이곳에 남아 지금까지 번성해오고 있다. 이주 인파를 연구하기 위해 현재 아프리카에 사는 수백 명의 미토콘드리아 DNA(어머니가 자식에게 물려주는 DNA 파편)를 이용하여 인류 가계도를 역추적했다. 유전학을 지리학과 기후 시뮬레이션에 결합함으로써, 연구진은 아프리카 대륙이 20만 년 전을 추정할 수 있었다. 인류 이야기를 다시 쓰다 그러나 이 연구는 네이쳐에 기고되자마자 곧장 반발에 맞닥뜨렸다. 다른 과학자는 미트콘드리아 DNA만 가지고 인류 역사를 재구성할 수 없다고 주장했다. 다른 연구들도 아프리카 동부에서 인류가 기원했음을 암시하는 화석을 발견하면서 다른 해답을 제시했다. 런던의 자연사 박물관 소속 크리스 스팅어 교수는 호모 사피엔스(현생 인류)의 진화는 복잡한 과정이라고 지적했다. 그는 BBC 뉴스에 "오늘날 인간의 미토콘드리아 분포만 활용해선 인류의 기원을 단일 지역으로 특정할 수 없다"고 말했다. "유전자의 아주 작은 부분만으로는 인류 기원의 모든 이야기를 들려줄 수 없기 때문에 (이 연구가) 데이터를 과도하게 활용하는 것이라고 생각한다." 결국 인류에게는 (아직 구체적으로 추정할 수 없는) 하나의 고향보다는 여러 곳의 고향이 있을 가능성도 있다. 인류 역사에서의 대표적인 진화 지표.
TARGET	과학자들은 현생 인류의 고향이 아프리카 잠베지 강 남부 지역이라고 추정한다.
FULL FT	현재 아프리카에 사는 인류가 약 20만 년 전부터 살았던 곳이라는 연구가 나왔다.
LORA-4	아프리카에서 인류가 기원했다는 연구가 나왔다.
INPUT	지난해, 코트렐은 모스크 건립에 항의한다는 뜻으로 모의 참수형을 하는 영상을 올려 유죄판결을 받았다 지난 5일 블레어 코트렐은 호주 스카이 뉴스의 일대일 스튜디오 인터뷰에 출연해 이민 관련 이야기를 했다. 그러나 시청자들은 코트렐이 지난해 이슬람교도들을 모욕한 죄로 유죄판결을 받았던 인물이라고 지적했다. 또, 코트렐이 아돌프 히틀러의 사진을 학교에 전시해야 한다고 주장했던 부분도 문제 삼았다. 결국 스카이 뉴스 호주는 인터뷰 당일, 트위터를 통해 "블레어 코트렐을 인터뷰한 것이 잘못된 것이었다"며 "그의 의견이 우리의 의견을 반영하는 것은 아니다"고 말했다. 해당 인터뷰를 온라인에서도 삭제했다고도 전했다. 코트렐은 이민 반대 단체인 애국전선연합(United Patriots Front)의 전 리더였다. 노던 테리토리 주의 수석 장관을 지낸 프로그램 진행자 애덤 자일스가 그를 인터뷰 했다. 같은 방송국 다른 앵커들도 이 인터뷰를 비난하고 나섰다. 앵커 로라 제이예스는 "블레어 코트렐은 자신이 히틀러 팬이라고 스스로 고백한 극우 파시스트다. 그는 여성을 조종하기 위해 ’폭력과 테러’를 사용하는 것을 자랑했다"고 트위터에 글을 올렸다. 정규해설위원이자 호주 정부 장관을 역임했던 그래이그 에머스은 "우리나라에서 인종주의와 편협성을 일상화하는 여정에 발걸음을 내딘 것"이라고 했다. 그는 앞으로 이 방송국에 출연하지 않겠다고 선언했다. 코트렐은 호주 이민을 줄이고, 외국의 이념으로부터 보호하며, "우리의 전통적인 정체성"을 되찾기 위해 인터뷰를 이용했다고 했다. 그는 논란이 일자 스카이 뉴스가 ’압력’에 굴복했다고 말했다. 지난해, 코트렐은 모스크 건립에 항의한다는 뜻으로 모의 참수형을 하는 영상을 올렸다. 그 결과 이슬람 교도들을 향해 혐오와 경멸을 조장했다는 혐의로 다른 2인과 함께 유죄 판결을 받았다. 지난해 다른 방송사인 채널 세븐 역시 이런 코트렐의 배경을 알리지 않고 생방송 인터뷰를 해 비난이 일기도 했다.
TARGET	호주의 한 TV 방송국이 극우 인사이자 과거 범죄 기록이 있는 인물과의 인터뷰한 후 호주 전역에서 분노가 일자, ’잘못된 일’이었다고 말했다.
FULL FT	호주 방송사가 히틀러 팬이라는 이유로 호주 이민자와의 인터뷰를 거부한 뒤 사과했다.
LORA-4	호주의 한 방송국이 히틀러를 존경하는 극우파 여성을 인터뷰한 것을 두고 비난이 쏟아지고 있다.

INPUT	Помпео сказал, что у него нет данных, указывающих на непосредственную угрозу ядерной войны с Северной Кореей Помпео, однако, признал, что оружейная программа Пхеньяна развивается темпами, которые вызывают "все большую тревогу", и заметил, что новые испытания северокорейских ракет не должны никого удивлять. В интервью Fox News он подчеркнул, что "стратегическое терпение", с которым Вашингтон взирал на ракетные и ядерные усилия Пхеньяна, закончилось. На вопрос о том, насколько близка Северная Корея к созданию ядерного оружия, способного достичь территории США, директор Центрального разведывательного управления ответил: "Теперь они ближе". "Я слышал тех, кто рассуждает о том, что мы стоим на пороге ядерной войны. Я сам не видел разведывательных данных, указывающих, что мы сегодня находимся в таком положении", - отметил Помпео. Президент США Дональд Трампа после публикаций в СМИ о том, что КНДР, вероятно, создала ядерный заряд, достаточно компактный, чтобы разместить его на имеющихся у нее баллистических ракетах, выступил с серией резких заявлений и твитов, в частности о том, что он готов ответить Пхеньяну "огнем и яростью" и что военные возможности для этого уже приведены в полную готовность. Северная Корея, со своей стороны, опубликовала план ракетного удара по острову Гуам в Тихом океане, где размещаются ключевые американские военные базы. Гуам: почему острову угрожает Северная Корея?
TARGET	Непосредственной угрозы ядерной войны с Северной Кореей нет, несмотря на рост напряженности, заявил директор ЦРУ Майк Помпео.
FULL FT	Директор ЦРУ США Майкл Помпео заявил, что Северная Корея "ближе" к созданию ядерного оружия, чем когда-либо.
LoRA-4	Директор ЦРУ Джеймс Помпео заявил, что у Вашингтона нет данных, указывающих на непосредственную угрозу ядерной войны с Северной Кореей.
INPUT	Об этом заявила глава миссии Фиона Фрейзер во время представления 13-го отчета работы мониторинговой миссии. По словам представительницы ООН, еще 21 044 человека были ранены. Как заявила Фрейзер, это количество включает мирных граждан, военнослужащих и участников "различных вооруженных групп" на Донбассе. Мониторинговая Миссия ООН по правам человека начала свою работу в Украине в марте 2014 года. Миссия имеет офисы в Киеве, Донецке, Днепропетровске, Харькове, Краматорске и Одессе, которые покрывают всю зону, пострадавшую от конфликта, по обе стороны линии разграничения. Кроме того, Фиона Фрейзер также отметила, что мониторинговая миссия ООН обеспокоена возможным лишением социальных выплат вынужденных переселенцев в ходе проведения верификации таких выплат. "Мы обеспокоены возможным лишением социальных выплат переселенцев в рамках начатой недавно правительством проверки", - сказала она. Фрейзер заявила, что властям необходимо четко определить механизм такой проверки социальных выплат, чтобы не допустить нарушения прав переселенцев. Также она добавила, что правительству необходимо разработать эффективную программу компенсации для тех, кто потерял свое имущество в результате конфликта на Донбассе. Ранее министр социальной политики Павел Розенко заявил, что правительство прогнозирует в 2016 году экономию средств в сумме около пяти млрд гривен путем прекращения социальных выплат ненастоящим переселенцам, которые фактически проживают на неподконтрольных Киеву территориях Донецкой и Луганской областей.
TARGET	Мониторинговая миссия ООН по соблюдению прав человека в Украине объявила, что во время конфликта на Донбассе всего погибли 9167 человек.
FULL FT	Мониторинговая миссия ООН по правам человека зафиксировала 10 000 погибших мирных жителей на Донбассе.
LoRA-4	В результате конфликта на востоке Украины за 12 месяцев 2015 года погибли 1 000 человек, 1 500 человек получили ранения, сообщило представительство ООН в Украине.

Input	Tha an t-ùghdarras ionadail air a bhith a' craoladh chèilidhean tron duilleag Facebook aca a h-uile oidhche Haoine on thòisich an glasadh-sluaigh sa Mhàrt. Bidh tè na bliadhn' ùire a' dol a-mach beò aig 19:00 air an aon làraich ma cheadaicheas na bacaidhean ionadail a bhios ann, agus bidh i cuideachd air a craoladh anns gach dachaigh-chùraim sna h-Eileanan Siar. Thuirt Co-òrdanaiche nam Meadhanan aig a' Chomhairle, Seòras Moireasdan: "Tha sinn air leth toilichte fàilte a chur air Willie Caimbeul, Iain 'Costello' MacÌomhair agus Calum Màrtainn, fir an taighe air oidhche na cèilidh. "Bidh iad a' seinn leotha fhèin agus còmhla. Bidh cuideachd òran ùr air a dhèanamh a dh'aona-ghnothaich airson na cuirme, le measgachadh de Bheurla agus Gàidhlig. "Gabhaidh an t-òran luchdachadh a-nuas às dèidh na cèilidh, agus thèid an t-airgead a thogar gu Hospice Bhethesda." Dùrachdan Thuirt Willie Caimbeul: "'S e bliadhna dhoirbh a th' air a bhith ann agus, mar sin, bha e mìorbhaileach a bhith a' seinn do dhaoine air na craolaidhean beò air-loidhne thairis air na sia mìosan a dh'fhalbh. "Tha mi air mo dhòigh gu robh mi an sàs ann agus tha mi a' coimhead air adhart gu mòr ri Cèilidh na Bliadhn' Ùire, àm nuair a tha cruinneachadh mar seo nas cudromaiche buileach. Tha spòrs gu bhith againn." Thuirt Calum Màrtain gur e urram a bh' ann cuireadh fhaighinn bho Chomhairle nan Eilean Siar nochdadh ann an dachaighean dhaoine còmhla ris na caraidean ciùil aige. "Tha e cho math gum bi cothrom agam a bhith air àrd-ùrlar còmhla ri dithis den luchd-ciùil as fheàrr air an eilean. Tha sinn an dòchas gun cuir sinn fiamh-ghàire air aodann dhaoine le òrain thraidiseanta ann an dà chuid Beurla agus Gàidhlig, agus tha sinn a' coimhead air adhart le dòchas ri 2021," thuirt Mgr Màrtainn. Cha robh Iain 'Costello' MacÌomhair misneachail an toiseach gun obraicheadh cèilidhean Covid na Comhairle beò, ach thuirt e gun do chòrd e ris gu mòr a bhith an sàs sa phròiseact a th' air togail agus taic a thoirt do dhaoine tron àm dhuilich. "Tha fiughair agam ri bhith ag obair còmhla ri dithis den luchd-ciùil agus seinneadairean as tàlantaiche as aithne dhomh agus tha mi air leth toilichte an cothrom seo a bhith agam a bhith a' seinn còmla ri Calum agus Willie." Bidh cothrom cuideachd aig a' phoball dùrachd a thoirt do chàirdean agus caraidean agus chithear na teachdaireachdan aca aig bonn an sgrion fhad 's a tha a' chèilidh a' dol air adhart. Bu choir do dhaoine an dùrachd a chur chun na comhairle air p.scott@cne-siar.gov.uk ro 17:00f Diciadain 25mh den t-Samhain. Thèid an còrr fiosrachaidh mun chèilidh fhoillseachadh sna beagan sheachdainnean ri thighinn.
Target	Cumaidh Comhairle nan Eilean Siar Cèilidh Là na Bliadhn' Ùire air-loidhne agus cluinnear òran ùr aig a' chuirm airson a' chiad uair.
Full FT	Gheibh Cèilidh na Bliadhna' Ùire 2021 air cuid de chuid de luchd-ciùil Chomhairle nan Eilean Siar ri fhailte beò air an 18mh Sultaine Diardaoin 18mh den Dùbhlachd.
LoRA-4	Tha Cèilidh na Bliadhn' Ùire na Chomhairle nan Eilean Siar a' dol a-mach beò an oidhche seo agus bidh tè na bliadhn' ùire a' dol a-mach beò air a' mhullach ann an Ceann a' Bhruthaidh.
Input	Thuirt iad gum bu chòir do Riaghaltas na h-Alba a dhol an sàs ma thèid cead a thoirt seachad. Tha na h-Aimeireaganaich Todd Warnock is Mike Keiser airson raon aig àrd-ìre a thogail aig a' Chùil, eadar Eurabol agus Loch Fleòid. Chuir comhairlichean co-dhùnadh air a' chùis dheth nas tràithe air a' mhìos, ged a bha oifigich a' moladh a dhiùltadh. Tha an gnothach air ais aig a' Chomhairle Diciadain is oifigich a-rithist ag ràdh gun toireadh an leasachadh fìor dhroch bhuaidh air àrainneachd na sgìre. Tha dìon shònraichte air an sgìre timcheall Loch Fleòid. Rabhadh Tha Urras Fiadh-bheatha na h-Alba ag ràdh a-nise gur e seo "an cothrom mu dheireadh a' Chùil a ghlèidheadh". "'S e fìor ghlè bheag de dh'àiteachan san t-saoghal a tha air an dìon gu h-oifigeil mar a tha a' Chùil", thuirt Àrd-Stiùiriche an Urrais, Jonny Hughes. "Tha e gu sònraichte cudromach a thaobh nan dùintean-gainmhich mhachrach a th' ann, àrainneachd a tha ann an cunnart gu h-eadar-nàiseanta. "'Seo fear de na co-dhùnaidhean dealbhachaidh as cudromaiche ann an Alba anns na bliadhnaichean mu dheireadh. Mar sin, tha iomagain oirnn mu cho beag tuigse 's a sheall comhairlichean mu àrainneachd an àite is na beathaichean a tha a' fuireach ann", thuirt e. Dh'innis Mgr Hughes gu bheil e an dòchas gun tèid comhairlichean le moladh nan oifigeach. Thuirt e ge-tà, ma thèid cead a thoirt seachad, gum bu chòir do Riaghaltas na h-Alba an gnothach a ghairm a-steach cho luath 's a ghabhas. Bidh coinneamh shònraichte de Chomataidh Dealbhachaidh a Chinn a Tuath ann Diciadain gus meòrachadh air a' chùis.
Target	Dh'iarr Urras Fiadh-bheatha na h-Alba air comhairlichean na Gàidhealtachd iarrtas-dealbhachaidh 'son raon-goilf an Cataibh a dhiùltadh.
Full FT	Chuir oifigich aig Comhairle na h-Alba càineadh air sàrbhhearan 's iomagain air àrainneachd na h-àite is beathaichean a' Chùil Shiorrachd.
LoRA-4	Tha Urras Fiadh-bheatha na h-Alba ag ràdh gur e "an cothrom mu dheireadh a' Chùil a ghlèidheadh" gum faigh iad co-dhùnadh co-mhaoinnicheachail a thogail ann an sgìre Earra-Ghàidheal.

INPUT	Joao Teixeira de Faria, kati kati amejisalimisha kwa polisi Joao Teixeira de Faria, ambaye pia anafahamika kama 'Yohana wa Mungu' alitangazwa kuwa mtoro baada ya tarehe aliyopewa ya kujisalimisha kwa mamlaka kukamilika. Madai dhidi yake yalianza mapema Disemba wakati wanawake kadhaa walidai kuwa tabibu hiyo wa kiroho alikuwa amewanyanyasa kwenye kliniki yake. Bw Faira anakana madai hayo. Tabibu huyo ana makao yake mji ulio kati kati mwa nchi wa Abadiania magharibi mwa mji mkuu Brasilia, lakini ana wafuasi kote duniani. Alijisalimisha kwa njia gani? Gazeti la O Globo linasema kuwa dhehebu hilo lilitoa dola milioni 8.9 kutoka benki kadha siku ya Jumatano na kuashiria kuwa huenda alikuwa na njama ya kuikimbia Brazil au kuficha pesa hizo ikiwa labda atahitajika kulipa fidia. Tabibu wa kiroho Joao Teixeira de Faria anakana kuwanyanyasa wanawake Mamlaka zilijibu kwa kutangaza waranti wa kukamatwa siku ya Ijumaa. Siku ya Jumapili, video ya simu iliyopeperushwa na kituo cha televisheni cha Globo ilimuonyesha Bw Faria akitoka kwenye gari na kujisalimisha kwa polisi huko Abadiania. Alisafirishwa kwenda makao makuu ya polisi huko Goiania, mji mkuu wa jimbo Goias. Wakili wake Alberto Toron, alisema atakata rufaa Jumatatu. Alisema alikuwa na matumaini kuwa Bw Fariqa anaweza kuwekwa kwenye kifungo cha nyumbani badala ya jela. Madai dhidi yake yalianza vipi? Wiki iliyopita mpiga picha raia wa Uholanzi Zahira Leeneke Maus, aliiambia televisheni ya Globo kuwa Bw Faria alimshauri kufanya vitendo vya ngono na kisha kumbaka. Wanawake tisa raia wa Brazil ambao hawakutajwa majina, pia waliiambia televisheni hiyo kuwa tabibu huyo aliwanyanyasa kwa misingi kuwa alikuwa akiwapa nguvu za kuwasafisha. Televisheni ilionyesha Joao Teixeira de Faria akiwasili kituo cha polisi Baadaye gazeti la O Globo lilisema kuwa lilikuwa limezungumza na wanawake wawili zaidi ambao walikuwa na madai kama hayo. Wajumbe wa tabibu huyo mwenye miaka 76 wanasema anakataa madai ya kuhusika kwenye mambo yaliyo kinyume na sheria wakati akitoa matibabu. Bw Faria, ambaye mwenye si daktari, awali alipigwa faini na hata kufungwa kwa kuhudumu bila leseni. Mtangazaji wa runinga nchini Marekani Oprah Winfrey alisafiri kwenda nchini Brazil mwaka 2013 na kushuhudia akitoa matibabu kwenye kliniki yake.
TARGET	Tabibu wa kiroho nchini Brazil ambaye analaumiwa kwa kuwanyanyasa kingono zaidi ya wanawake 300 amejisalimisha kwa polisi, kwa mujibu wa vyombo vya habari.
FULL FT	Tabibu mmoja wa kiroho nchini Brazil amejisalimisha kwa polisi baada ya madai ya kuwa aliwanyanyasa wanawake kwa kuwa aliwapa nguvu za kiume.
LORA-4	Tabibu wa kiroho nchini Brazil amejisalimisha kwa polisi baada ya madai ya unyanyasaji na ukatili dhidi ya wanawake.
INPUT	Margaret Gieszinger alikamatwa baada ya video ya kisa hicho kusambazwa mtandaoni Margaret Gieszinger, 52, amefukuzwa kazi kwa kitendo hicho alichokifanya katika Shule ya Sekondari ya Chuo Kikuu cha huko Visalia, California. Waendesha mashtaka wamesema kuwa amekanusha makosa sita dhidi yake, likiwemo kosa la ukatili dhidi ya mtoto na shambulio la kimwili. Anakabiliwa na hukumu ya miaka mitatu unusu jela iwapo atakutwa na hatia. Bi Gieszinger, aliachiliwa kwa dhamana ya dola 100,000 Ijumaa jioni. Katika video hiyo ya iliyochukuliwa kwa simu ya mkononi kisha kupakiwa kwenye mtandao wa Reddit, mwalimu huyo anayefunza somo la sayansi, anaonekana akimuita mwanafunzi wa kiume kuketi mbele ya darasa, kisha akaanza kumkatakata nywele huku akiimba kwa makosa wimbo wa taifa la Marekani maarufu kama Star Spangled Banner. Wakili wa mwanafunzi huyo, ameliambia shirika la habari la CNN kuwa, mteja wake "alishtuka sana" kabla ya kufanikiwa kujinasua mikononi mwa mwalimu huyo. Bi Gieszinger kisha anaonekana kwenye video, akishika mkasi mkononi juu ya kichwa chake na kusema "next!" yaani "mwingine!" na kutishia pia kumkata nywele mwanafunzi mmoja wa kike. "Tunachukulia kwa tahadhari kubwa mno usalama wa wanafunzi madarasani," hiyo ni kwa mjibu wa taarifa kutoka kwa afisi kuu ya Elimu ya kaunti ya Tulare. "Tunachunguza taarifa zote tunazozipokea na tutachukua hatua kali mno na zinazohitajika dhidi ya wafanyakazi wetu walio na utovu wa nidhamu." Taarifa hiyo imeongeza.
TARGET	Mwalimu mmoja nchini Marekani anakabiliwa na mashtaka ya uhalifu, baada ya picha ya video kusambaa mitandaoni akimkata kwa lazima nywele mwanafunzi mmoja darasani, huku akiimba wimbo wa taifa wa Marekani.
FULL FT	Mwalimu mmoja raia wa Marekani amekamatwa baada ya video kusambazwa mtandaoni, akimnyanyasa mwanafunzi wa kiume kwa kumkata nywele alipokuwa akipitia mtihani.
LORA-4	Mwalimu wa shule ya sekondari nchini Marekani amehukumiwa miaka mitatu unusu jela baada ya video ya kisa hicho kusambazwa mtandaoni.

Abstract

Reasoning methods, best exemplified by the well-known Chain-of-Thought (CoT), empower the reasoning abilities of Large Language Models (LLMs) by eliciting them to solve complex tasks in a step-by-step manner. Although they are achieving significant success, the ability to deliver multi-step reasoning remains limited to English because of the imbalance in the distribution of pre-training data, which makes other languages a barrier.

In this paper, we propose Cross-lingual Tree-of-Thoughts (Cross-ToT), a method for aligning Cross-lingual CoT reasoning across languages. The proposed method, through a self-consistent cross-lingual prompting mechanism inspired by the Tree-of-Thoughts approach, provides multi-step reasoning paths in different languages that, during the steps, lead to the final solution. Experimental evaluations show that our method significantly outperforms existing prompting methods by reducing the number of interactions and achieving state-of-the-art performance.

1 Introduction

Chain-of-Thought (CoT) prompting elicits Large Language Models (LLMs) to break down a reasoning task towards a sequence of intermediate steps (Wei et al., 2022). Previous works have demonstrated that LLMs achieve impressive performances in zero-shot learning scenarios without the need to modify the model parameters during the training and testing process. In particular, by appending to the prompt "Let's think step by step!" (Kojima et al., 2023) LLMs with at least several billions of parameters, such as GPTs family (OpenAI, 2023) or PaLM (Chowdhery et al., 2022), deliver multi-step controlled reasoning, achieving promising results across commonsense (Bubeck et al., 2023), symbolic and mathematical reasoning datasets (Gaur and Saunshi, 2023; Liu et al., 2023).

Although the performances seem promising, they are only firmly established in English. This poses a barrier to generalizing current CoT techniques to different languages. Hence, despite the remarkable success of zero-shot CoT techniques, the reasoning abilities of LLMs still struggle to generalize to different languages. Shi et al. (2022) introduced the first multilingual benchmark to assess LLMs' mathematical reasoning abilities using prompts in different languages. Qin et al. (2023) propose task-specific solver prompting, using a succession of prompts, elicit the LLMs to understand questions and deliver CoT answers in different languages. However, these strategies require two-step prompts, which goes against the zero-shot approach.

In this paper, we propose Cross-lingual Tree-of-Thoughts (Cross-ToT), a method for aligning Cross-lingual CoT reasoning across languages by proposing a Cross-lingual Alignment prompt to elicit the model to deliver a Self-consistent Chain-of-Thougt. Our method is inspired by the Tree-of-Thoughts (ToT) prompting (Yao et al., 2023) that asks LLMs to perform decision-making by considering multiple different reasoning paths (CoTs). In particular, our Cross-ToT is a ToT-style prompting to deliver the reasoning process in different languages that, step-by-step, converge to a single final solution. The inherent insight is that as the different paths of thought evolve, the relationships between the different languages are inherently grasped via Self-consistent Chains-of-Thougt. This leads to the target research questions, which are the focus of this paper:

RQ1: Are LLMs able to deliver Cross-lingual multi-step reasoned answers?

RQ2: Are the different paths of ToT evolving Self-correcting each other?

RQ3: What is the role of English in Cross-lingual scenarios?

To answer these questions, we propose `Cross-ToT`, a novel Cross-lingual prompting strategy that aims to bridge the gap across different

Simulate the collaboration of six mathematicians answering a question in their mother tongue: Chinese, French, Spanish, German, Swedish, and Russian. They all start Step1 from a separate thought process, step by step, each explaining their thought process. Following Step1, each expert refines and develops their thought process by comparing themselves with others. This process continues until a definitive answer to the question is obtained.
Question: 詹姆斯决定每周跑 3 次 3 段冲刺，每段冲刺跑 60 米。他每周一共跑多少米？
Answer: [num].

To simulate this collaborative approach, we will have each mathematician start with their independent thought process and then refine their approach in subsequent phases, considering the input from others. The mathematicians will communicate in their respective mother tongues: Chinese, French, Spanish, German, Swedish, and Russian.

我们首先计算每次冲刺的距离，3段×60米。然后，我们将这个数字乘以每周冲刺的次数。

Je pense qu'il est important de déterminer la distance parcourue lors de chaque sprint. Ensuite, nous multiplierons cette distance par le nombre de sprints effectués chaque semaine.

Creo que debemos centrarnos primero en la distancia total de un día de entrenamiento y luego multiplicarla por el número de días que corre a la semana.

Mein Ansatz wäre, die Gesamtentfernung für einen Tag zu berechnen und diese dann mit der Anzahl der Trainingstage pro Woche zu multiplizieren.

Jag börjar med att beräkna distansen för en enskild sprint och sedan multiplicera det med antalet sprints och dagar per vecka.

Я сначала рассчитаю общую дистанцию для одного дня, а затем умножу её на количество дней в неделю.

每次冲刺180米，一周跑3次，总距离是540米。看来我们都同意基本的乘法方法。

Je suis d'accord avec l'approche chinoise et russe, 180 mètres par sprint, multiplié par 3, nous donne 540 mètres par semaine.

Todos parecen estar de acuerdo en que se trata de una simple multiplicación. 180 metros por 3 días a la semana, lo que resulta en 540 metros.

Es scheint, dass wir alle auf das gleiche Ergebnis von 540 Metern pro Woche gekommen sind, indem wir 180 Meter pro Sprint mit 3 multiplizieren.

Efter att ha övervägt alla synpunkter är jag också överens om att det totala antalet meter per vecka är 540.

Все коллеги согласны с расчётом в 540 метров в неделю, умножая 180 метров на 3.

James runs a total of 540 meters per week.
詹姆斯每周一共跑 540 米.
Answer: 540

Figure 1: Our `Cross-ToT` elicits the LLM to generate step-by-step Cross-lingual reasoning. Furthermore, different pathways are developed during these reasoning steps. This mechanism develops the Chains-of-Thoughts in a Self-consistent way, streaming with the different pathways.

languages. In particular, using the prompt shown in Figure 1, we elicit the model to deliver different CoT reasoning steps in different languages that converge to the final solution step-by-step. We test our method on GPT-3.5 and conduct an extensive analysis using Multilingual Grade School Math (MGSM) (Shi et al., 2022), Cross-lingual Natural Language Inference (XNLI) (Conneau et al., 2018), and Cross-lingual Paraphrase Adversaries Scrambling (PAWS-X) (Yang et al., 2019), Cross-lingual Choice of Plausible Alternatives (XCOPA) (Ponti et al., 2020) across different languages. Experimental results reveal that our method, based on a single prompt, outperforms the baselines and achieves the SOTA performance on different languages in different tasks. The main contributions of this work are concluded as follows:

- We introduce `Cross-ToT`, which is a novel Cross-lingual prompting mechanism that stimulates the model to produce parallel CoT reasoning processes across different languages;
- We show that our `Cross-ToT` is Self-consistent and allows the integration of reasoning paths between different languages;
- Extensive evaluations on different languages demonstrate that our `Cross-ToT` can effectively improve the performance of cross-lingual CoTs and achieve SOTA performance.
- Finally, we show that introducing English in our prompting technique plays a beneficial role in improving downstream performance.

2 Cross-lingual Multi-step Reasoning

To elicit the multi-step reasoning abilities of LLMs in Cross-lingual scenarios, we propose `Cross-ToT`, which is a Cross-lingual Alignment Chain-of-Thought as a solution. In particular, our method overcomes the Multi-lingual and Cross-lingual approaches introduced in Section 2.1. In fact, our approach elicits the LLMs to deliver Self-consistent Parallel Chain-of-Thougts, introduced in Section 2.2.

2.1 Chain-of-Thought Across Languages

The Cross-lingual Alignment is a core challenge for cross-lingual transfer. Shi et al. (2022) proposed a series of prompts to elicit models to generate CoT answers in specific language `Native-CoT`, and in English `En-CoT` and `Translate-CoT` (more detailed in Table 1).

Later, Qin et al. (2023) proposed a method based on two phases: Cross-lingual alignment prompt and

Native-CoT in this example in Chinese

问题: 利亚有32 块巧克力，她妹妹有42 块。如果她们吃了35 块，她们一共还剩下多少块?
答案: 让我们一步步思考

En-CoT

问题: 利亚有32 块巧克力，她妹妹有42 块。如果她们吃了35 块，她们一共还剩下多少块?
Answer: Let's think step by step

Translated-CoT (is the Native translated in En)

Question: Leah has 32 chocolates and her sister has 42. If they ate 35 pieces, how many pieces do they have left?
Answer: Let's think step by step

Table 1: Different types of input prompts in order to elicit Chain-of-Thought reasoning process. Specifically, given a problem in Chinese, the following prompts are `Native-CoT` and `En-CoT`, the original question in Chinese with elicitation in Chinese and English; for `Translated-CoT`, the question is in English and consequently a step-by-step solution in English.

task-specific solver prompting. This approach uses two separate steps, as shown in Table 2, in order to handle input and output in different languages.

Cross-CoT First-Step

Please act as an expert in multi-lingual understanding in [Specific Language L_s].
Question: [Given sentence X in L_s]
Let's understand the task in [Target Language L_t] step-by-step!

Cross-CoT Second-Step

After understanding, you should act as an expert in mathematics in [Language L_t].
Let's resolve the task you understand above step-by-step!

Table 2: Cross-lingual Prompt proposed in (Qin et al., 2023). By setting an input language and a target language, the prompt is divided into two phases: in phase one, there is the alignment of the different languages, and in phase two, there is the solving mechanism for the specific language.

Although this second approach overcomes the limitations of Shi et al. (2022)'s work, the two-step prompting could be more laborious and challenging, and there is no exchange of information during the multi-step reasoning process between the different chains as the final outputs are estimated using a voting heuristic.

2.2 Self-consistent Parallel Chain-of-Thougts

In our work, we propose `Cross-ToT`, a prompting method that can handle different languages in a parallel way. Furthermore, through a mechanism inspired by Tree-of-Thoughts prompting techniques (Yao et al., 2023), our method elicits the LLM to deliver the generation of the answer in a sequence of intermediate steps that do not provide independent parallel answers but deliver collaborative Self-consistent reasoned steps until arriving at a final answer.

Our Proposal

Simulate the collaboration of $\{n\}$ mathematicians answering a question in their mother tongue: L_1, L_2, ... and L_n. They all start Step1 from a separate thought process, step by step, each explaining their thought process. Following Step1, each expert refines and develops their thought process by comparing themselves with others. This process continues until a definitive answer to the question is obtained.
Question: [Question in Language L_1]
Answer: [num].

Table 3: Input-prompt for MSGM task. In `Cross-ToT`, we elicit the model to produce multi-step reasoning processes in different languages. We specifically prompt to start from separate reasoning and collaborate step-by-step. (We propose similar pattern for other tasks as described in Appendix A)

Our `Cross-ToT` shown in Table 3 elicits the LLM to generate different paths as shown in Figure 1, achieving significant improvements in accuracy as discussed in Section 4.

3 Experiments

3.1 Data

In order to observe the Cross-lingual abilities of LLMs, we used GSM8K (Cobbe et al., 2021), XNLI (Conneau et al., 2018), and PAWS-X (Yang et al., 2019), XCOPA (Ponti et al., 2020).

Understanding tasks In order to assess Cross-lingual comprehension abilities, we used XNLI (Conneau et al., 2018) and PAWS-X. The first is an extension of Stanford Natural Language Inference (SNLI) (Bowman et al., 2015) across 15 languages and is based on one premise and one hypothesis and requires the model to determine whether the hypothesis is entailed, contradicted, or neutral conditioned on the premise in 15 different languages, and we utilize the accuracy score for evaluation. The second, Paraphrase Adversaries from Word Scrambling (PAWS-X) (Yang et al., 2019), contains two sentences and requires the model to judge whether they paraphrase each other in seven languages.

Table 4: Accuracies (%) on MGSM using the `"Direct"` prompt, i.e., question and answer in the original language; the `"Native-CoT"` prompt, i.e., question and answer CoT in the original language; the `"En-CoT"` prompt specific language question and answer CoT in English, the `"Translate-En"` prompt where the specific input is translated into English and the answer accordingly is in English. Moreover, Cross-CoT, as proposed by Qin et al. (2023), questions in a specific language and answers in different languages. Finally, **`Cross-ToT`** is explained in Section 2.2. (Our results are derived from the average of three running performances as detailed in Section 3.2)

(Ponti et al., 2020) is based on one premise and two choices. It asks the model to choose which one is the result or cause of the premise. It covers 11 languages from 11 diverse families.

Arithmetic Reasoning task To evaluate the problem-solving abilities in Cross-lingual scenarios, we used the extension proposed by Shi et al. (2022), i.e., Multilingual Grade School Math (MGSM). Initially, Cobbe et al. (2021) proposed a benchmark of mathematical problems in English in GSM8K. Each example has the following structure: a mathematical problem in natural language and a target answer in Arabic number. Shi et al. (2022), in their contribution, i.e., MGSM, selected the first 250 examples from the official list of examples in GSM8K and translated them manually into 11 different languages, maintaining the structure of the input and output.

Evaluated Languages In our experiments, we propose an analysis of available languages that differ depending on the resources, we provide all details in Appendix A. Furthermore, as an additional experiment, we test the introduction of English.

3.2 Experimental Setup

In order to conduct our study on robust models and have a term of comparison with the work proposed in (Shi et al., 2022; Qin et al., 2023), we use GPT-3.5; however, in future developments, we plan to scale the method to different models. Then, we systematically defined the input prompt in Table 3 for MGSM and in Appendix A for XNLI, PAWS-X, and XCOPA. In each particular experimental set-up, we modify the appropriate languages with L_1, L_2, ...for the German [1]

Following Wei et al. (2022); Kojima et al. (2023), we evaluate performance using the accuracy score. In particular, we compute the string matching between the final answers (see Figure 1 where the final outputs have the form of `Answer:[num]`) and the target values. The top-p parameter is set to 1 in all processes. We select the Prompting temperature [0, 1].

4 Main Results

Mechanisms for delivering multistep-reasoned answers across languages can be empowered via `Cross-ToT` that align languages' Chain-of-Thoughts (CoT). Our approach based on a Tree-of-Thoughts-inspired prompting mechanism (see Figure 1) outperforms state-of-the-art prompting techniques on Arithmetic Reasoning tasks as shown in Table 4, and in Language Understanding tasks as shown in Figure 3 and finally in Commonsense Reasoning tasks as shown in Table 5. In particular, `Cross-ToT` elicit LLMs to produce different reasoning pathways that share the "Thoughts" during the steps and, at the same time, promote Self-

---

[1] Although we do not observe perceptible changes in the order of languages present in the input prompt, we set as a first the language-related subset of the benchmark.

correction of mistaken paths. In fact, during the steps of the CoT, information is swapped between the paths. This interaction delivers Self-consistent paths. Furthermore, in the prompt, we exemplified that the different paths must arrive at a shared and, consequently, unique by sharing the "thought process" (see the prompt in Table 3).

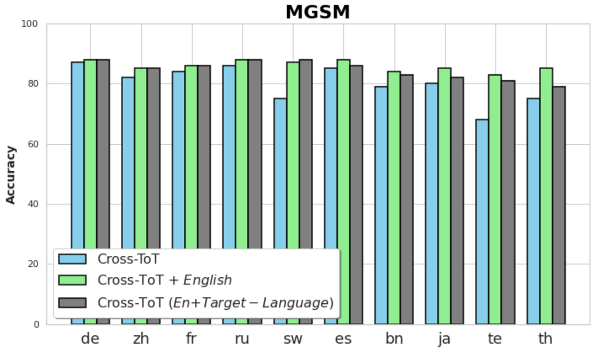

Figure 2: Accuracies (%) on MGSM using "`Cross-ToT`", "`Cross-ToT` + English" and in binary version "`Cross-ToT` (English + Target Language".

Our approach outperforms the methods proposed in (Shi et al., 2022) that are yet surpassed by the `Cross-CoT` proposed by Qin et al. (2023). However, although `Cross-CoT` outperforms previous approaches, it is necessary to clarify which path, if any, leads to the correct reasoning (Section 5.3), whether the introduction of English can increase performance (Section 5.1) and finally the trade-off between the number of languages (in our case path) and the final results (Section 5.2).

5 Analysis

In this section, we explore the contribution of English in the Cross-lingual prompt (in Section 5.1), then study the impact of different languages on the final results (Section 5.2) and the reasoning evolution (Section 5.3) and close with an in-depth analysis of performance in different tasks in Section 5.4.

5.1 The English Matter

Earlier works (Wei et al., 2022; Liu et al., 2023) have been showing that LLMs are able to deliver multi-step reasoning answers on arithmetic tasks, focusing mainly on English. Therefore, we observe whether introducing English into our input-prompts could increase downstream performance. Hence, we performed the setting proposed in Section 3.2 From the results obtained in Figure 2 (green bar), it is possible to observe that the input-prompts empowered with English outperform the input-prompts empowered without English. This result suggests that the presence of one robust path, in this case, the English path, may influence the others in the final reasoning process. Indeed, assuming that the production of the intermediate steps is self-consistent, i.e., the paths do not disagree with each other, the additional language seems to influence performance positively. From the current results, adding a further language improves the robustness of the models.

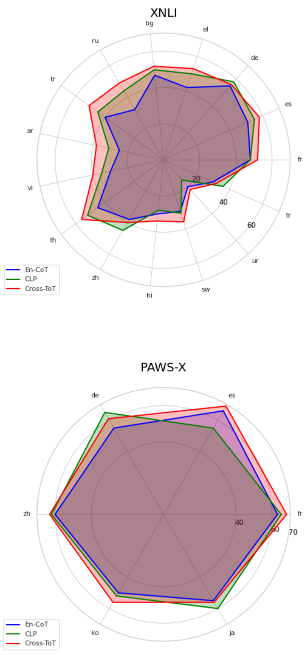

Figure 3: Accuracies (%) on Language Understanding benchmarks XNLI and PAWS-X introduced in Section 3.1

However, whether the performance is due to the number of languages or English is unclear. To observe the impact of adding a specific language in Section 5.2, we propose to reduce the number of languages in the presence and absence of English.

5.2 The Impact of the Languages

English seems to lead Cross-lingual reasoning on arithmetic tasks, as shown in Section 5.1. Hence, to observe the impact of the number of languages and one specific, i.e., English, we propose two further analyses:

Cross-ToT in low-resources scenarios Integrating more languages into Cross-lingual prompting leads to better overall performance. As already

HUMAN (Ponti et al., 2020)	98.2	96.4	100.0	97.0	94.8	99.0	98.6	98.2	96.4	98.4	96.6	97.6

Table 5: Accuracies (%) of XCOPA.

observed in (Shi et al., 2022; Qin et al., 2023), increasing the number of languages improves downstream performance, as shown in Figure 4 (average performances using the same setting proposed in Section 3.2).

As shown in (Malkin et al., 2022; Blevins and Zettlemoyer, 2022), the performances of the Large Language Models are highly correlated with the percentage of pre-training data in each language.

Following the approach proposed in (Qin et al., 2023) and considering language distribution in the widely used multilingual pre-training dataset, which in our case is CommonCrawl (Common Crawl, 2021), we integrated languages in descending and ascending order based on their respective proportions (detailed in Table 12).

Figure 4 shows that adding more languages in high-resource contexts improves performance. However, when incorporating languages with limited resources, performance decreases as the number of languages increases (see low-resource in Table 4). Finally, adding English (the dominant percentage in standard corpora) to the prompting significantly enhances performance (see "+ English" lines in Table 4).

These findings emphasize that the number of integrated languages only partially determines the effectiveness of language integration. The amount of pre-training data for each language, especially for high-resource languages, plays a crucial role. Balancing multiple languages and considering available resources and impact is essential.

Cross-ToT in binary scenarios Moreover, we evaluate similar scenarios in low-resource settings and reproduce the same experiments using only two languages. In particular, we used the same setting proposed in Section 3.2 by including only the target language and English in the prompt (example prompt in Appendix 8).

From the results shown in Figure 2 (grey bar), using the target English-language tuple does not change the performance of high-resource languages. On the contrary, low-resource languages achieve significantly lower performance. This second finding reinforces what was said earlier about the experiments on prompt compositions.

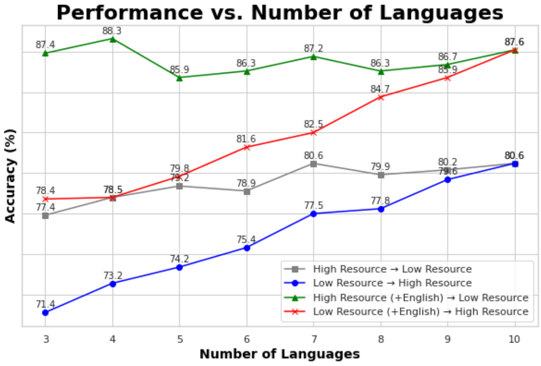

Figure 4: The impact of integrating languages in our Cross-ToT on the final performance. Following Table 12, we integrate languages from low-resources to high-resources and vice versa. We also propose the same experiments with the addition of English.

5.3 Reasoning Evolution

We use the framework ROSCOE (Golovneva et al., 2023) to investigate why our approach works. Hence, we evaluate the quality of the reasoning paths (implementation described in Appendix B). As shown in Figure 5, our approach delivers reasoning with higher faithfulness, exhibiting better consistency with key steps during the reasoning process. Specifically, the faithfulness score increased by 4.5 points, indicating that the model better understood the problem statement and ensured a transparent inference chain without generating irrelevant or misused information. Furthermore, we observe improvements in the Informativeness metrics for “Step” and “Chain”. It suggests that the models’ reasoning, behind the alignment, could provide more well-grounded inference steps.

`Basic Prompt`

Table 6: Our prompting approach for XCOPA, XNLI and PAWS-X. List of the `Basic Prompt` is in Table 11

5.4 The Cross-Reasoning in other tasks

Furthermore, to scale our approach, we test the applicability of `Cross-ToT` on two different task types using the same structure adapted to them as in Table 7.

Understanding task We proposed our approach, Cross-ToT, on other multilingual reasoning datasets belonging to the undertandings genre. As introduced in Section 3.2, we used XNLI (Conneau et al., 2018) and PAWS-X (Yang et al., 2019). As Figure 3 shows, Cross-ToT is able to perform better in most languages. Compared to the previous SOTA obtained in CLP (Qin et al., 2023). Thus, we observed average improvements of 3.2 points on XNLI and 2.5 points on PAWS-X.

Commonsense Reasoning task We have used our approach, Cross-ToT, to an additional dataset of multilingual commonsense reasoning, as introduced in Section 3.1. We used XCOPA as our benchmark. For comparison purposes, we considered CLP and Native-CoT proposed by Qin et al. (2023). In Figure 5, we can observe that our approach has outperformed previous methods in many languages.

The results show the effective functionality of our `Cross-ToT` on different tasks. Although the method has shown appreciable increases, we continue the studies in Section 5.5 by observing whether adding in-context examples in the input-prompt can benefit LLMs.

5.5 Other approaches

`Cross-ToT` can be further empowered with in-context learning. In fact, as shown in Table 9, in-context learning (ICL) techniques have achieved performant results on the downstream performance of LLMs. In particular, in further exploration of `Cross-ToT` within ICL, we conducted different experiments.

From Zero- to Few-shot In the first experiment, we sampled 50 random instances from MGSM. Then, we replicated the experiments proposed in Section 3.2. However, we constructed the prompt by merging instances in one-shot and three-shot settings. Table 9 shows that providing context makes the models more robust.

Performances Other Models `Cross-ToT` does not outperform other approaches in open-source models with fewer parameters. Table 10 shows the performances of Llama-2-13B (Touvron et al., 2023) and Bloomz-7B (Muennighoff et al., 2022). We hypothesize that these performances are due to the misleading behaviors observed in (Wei et al., 2023) prompting CoT in models with less than 100 billion parameters. In future developments, we will continue to investigate this phenomenon.

6 Related Work

Large Language Models (LLMs) with billions of parameters demonstrate in-context learning and few-shot learning abilities (Brown et al., 2020; Wei et al., 2022; Min et al., 2022) to guide LLMs to generate desired task responses, marking the advent of the prompting era and surpassing the age of the intermediate steps in algorithmic and structured reasoning (Roy and Roth, 2015; Ling et al., 2017). Nevertheless, early works challenged the efficacy of few-shot techniques for empowering the prompting phase and downstream performances. In particular, Yao et al. (2023) refined the original idea of Chain-of-Thought (CoT) (Wei et al., 2022) by considering various reasoning paths as well known as Tree-of-Thought.

The traditional and derivated CoT mechanisms have achieved considerable success but are limited to generating answers within a single language (i.e., English). Shi et al. (2022) proposed a multilingual evaluation that Qin et al. (2023) extended to cross-lingual scenarios. In particular, Qin et al. (2023) proposed a prompt mechanism to handle requests in any language and generate CoT specifically in English. This approach, which in our construct we called Cross-CoT has been proposed both single-phase, i.e., as a single prompt (CLP) also adopted by (Huang et al., 2023) and multiphase (CLPS) i.e., characterized by self-consistent prompts that follow the prompting methodology proposed in (Qiao et al., 2023). Although the mechanism achieves state-of-the-art cross-linguistic reasoning steps, the single-phase promting underperforms in low-resouces languages and the multiphase prompting characterized by a series of cascading prompts is supported far away from the zero-shot chain-of-thought concept.

In our work, we propose a method of CoT reasoning inspired. Specifically, we elicit the cross-lingual generation of a series of parallel Cross-lingual reasoning paths using a single prompt. In fact, our method is inspired by the Tree-of-Thoughts approach proposed by (Yao et al., 2023). Hence, in a different way from previous approaches, our technique generates shared parallel reasoning paths that share the "thoughts process" delivering Self-consistent answers and reducing reasoning steps. Our work goes beyond in the following ways:

- Proposal of novel zero-shot prompting methods in cross-lingual scenarios characterized by low-resource and high-resource languages.
- Studying cross-lingual multi-step reasoning mechanisms using arithmetic reasoning tasks.
- In-depth study of the reasoning pathways provided by our prompting approach (impact of the number of languages and strongly high-resource languages).
- Experiments on effective functioning in commonsense reasoning and language understanding tasks.

7 Future Works

In future work, we intend to incorporate smaller-scale Language Models (SLMs) into our evaluations. However, the ability to produce multi-step reasoned answers is limited in SLMs. To address this, a range of techniques are emerging to align and transfer reasoning abilities between LLMs and SLMs (Ranaldi and Freitas, 2024).

Our aim is to enhance current alignment pipelines (Ranaldi et al., 2023; Ranaldi and Pucci, 2023a) to enable cross-lingual reasoning capabilities across different languages and scenarios. Including methods that emphasize the importance of language structure (Zanzotto et al., 2020) and uphold the foundational pillars of the NLP ecosystem (Ranaldi and Pucci, 2023b).

8 Conclusion

Chain-of-Thought is an outstanding prompting technique. However, the imbalance of languages in pre-training data does not always produce robust results. Different state-of-the-art works have proposed cross-lingual techniques to align performances obtained in different languages. They are limited to handling one language at a time or proposing multiple prompting stages, making them difficult to manage. In this paper, we propose `Cross-ToT`, a prompting technique to elicit multi-step reasoning abilities in Cross-lingual scenarios. Hence, we elicit models to deliver answers in a Self-consistent way, collaborating to the final answer. We have shown the functionality of our `Cross-ToT` through performance improvements obtained in a multilingual mathematical problem task. In addition, we have demonstrated the scalability in tasks related to commonsense reasoning and language understanding. Finally, we conducted a series of in-depth analyses in which we measured the impact brought about by low-resource vs. high-resource languages and the inclusion of English. Our contribution aims to propose more robust models that can break down issues arising from language barriers and provide more reliable results.

Limitations

Due to the limitations imposed by the evaluation benchmarks and the cost of the OpenAI API, we conducted tests on 16 languages in total, which only scratches the surface of the world's vast array of languages. Furthermore, our approach is based on English. It should be evaluated whether the model written in the language of the task can lead to better performance and how best to construct instructions in each language. Furthermore, we only tested the effectiveness of our method on GPT-based models (gpt-3.5-turbo). In the future, it will be worthwhile to study the generality of our model on more models, such as PaLM and Llama-2-70.

Ethics Statemets

In our work, ethical topics were not addressed. The data used comes from open-source benchmarks, and statistics on language differences in commonly used pre-training data were obtained from official sources without touching on issues related to gender, sex, or race differences.

A Prompt

In this paper, we analyze our prompting approach, i.e., Cross-ToT, in different tasks. In Figure 1 we have shown the input-prompt for the MGSM (Cobbe et al., 2021). Here, we show the prompt framework for the other tasks:

XCOPA, XNLI and PAWS-X

`Simulate the collaboration of` n `person answering a question in their mother tongue:` L_1 `and` $English$. `They all start Step1 from a separate thought process, step by step, each explaining their thought process. Following Step1, each expert refines and develops their thought process by comparing themselves with others. This process continues until a definitive answer to the question is obtained.` **`Basic Prompt`**

Table 7: Our prompting approach for XCOPA, XNLI and PAWS-X. List of the `Basic Prompt` is in Table 11

Furthermore, in Section 5.1, we proposed an experiment based on a prompt with only two languages as follows:

Binary Cross-ToT

`Simulate the collaboration of 2 mathematicians answering a question in their mother tongue:` L_1 `and` $English$. `They all start Step1 from a separate thought process, step by step, each explaining their thought process. Following Step1, each expert refines and develops their thought process by comparing themselves with others. This process continues until a definitive answer to the question is obtained.`
`Question: [Question in Language` L_1`]`
`Answer: [num].`

Table 8: Our prompting approach for experiment proposed in Section 5.1 regarding MGSM and binary trees

B Reasoning Chain

B.1 Chain-of-Thought Quality Scoring Implementation

The ROSCOE framework (Golovneva et al., 2023) incorporates multiple chain-of-thought quality metrics, with the reasoning alignment vector α that is

$$r_{align}(h \rightarrow s) = \{\alpha_1, \alpha_2, \ldots, \alpha_N\} \in [0,1]^N \tag{1}$$

from the N-step hypothesis $h = \{h_i\}_{i=1}^{N}$ to the source input s of length T, where α_i are defined as: $r_{align}(h_i \rightarrow s) = \frac{1+\max_{j=1}^{T}\cos(h_i,s_j)}{2}$

Faithfulness score The Faithfulness (F) score is calculated based on the alignment between the hypothesis steps h and the source sentences s. It represents the average reasoning alignment score over the steps of reasoning:

$$F = \frac{1}{N}\sum_{i=1}^{N} r_{align}(h_i \rightarrow s) \tag{2}$$

The Faithfulness score serves as a measure to assess whether the model misconstrued the problem in the statement or if the reasoning chain is characterized by ambiguity, unimportance, or the misuse of information.

Informativness Informativeness-Step (Info-Step) measures the utilization of facts from the original text s in the reasoning steps h:

$$Info_{Step} = \frac{1}{2T}\sum_{t=1}^{T} r_{align}(s_t \rightarrow h) + \frac{1}{2}F \tag{3}$$

Info-Step assigns a higher score to reasoning steps that strongly align with the source, showing the capacity to which the generated hypothesis includes the information from the source. Conversely, a lower Info-Step score means reasoning steps unrelated to the source sentences or overlooking the provided information in the context.

Informativeness Chain Like the Info-Step metric, the InformativenessChain (Info-Chain) metric estimates the degree of concordance between the hypothesis chain and the source. The calculation is as follows:

$$Info_{Chain} = \frac{1+\cos(h,s)}{2} \tag{4}$$

Missing Step The Missing Step (Miss-Step) metric is introduced to estimate any significant lacking steps, which examines the alignment between the reference reasoning text $r = \{r_i\}^K$ and the hypothesis h. A miss-step is needed to meticulously assess each step in the reference and verify the existence of a similar step in the hypothesis. The metric is computed as:

$$\text{Miss-Step} = \min_{i=1}^{K}(\text{r-align}(r_i, h)). \tag{5}$$

Abstract

Large language models can solve new tasks without task-specific fine-tuning. This ability, also known as in-context learning (ICL), is considered an emergent ability and is primarily seen in large language models with billions of parameters. This study investigates if such emergent properties are strictly tied to model size or can be demonstrated by smaller models trained on reduced-scale data. To explore this, we simplify pre-training data and pre-train 36 causal language models with parameters varying from 1 million to 165 million parameters. We show that models trained on this simplified pre-training data demonstrate enhanced zero-shot capabilities across various tasks in simplified language, achieving performance comparable to that of pre-trained models six times larger on unrestricted language. This suggests that downscaling the language allows zero-shot learning capabilities to emerge in models with limited size. Additionally, we find that these smaller models pre-trained on simplified data demonstrate a power law relationship between the evaluation loss and the three scaling factors: compute, dataset size, and model size.[1]

1 Introduction

Recent advancements in deep learning and distributed computing have enabled the pre-training of language models on a massive scale (Brown et al., 2020; Bubeck et al., 2023; Touvron et al., 2023), significantly changing the way these models are used. Large pre-trained models proved capable of solving various tasks with zero-shot or few-shot learning, eliminating the need for task-specific fine-tuning (Brown et al., 2020). This is referred to as in-context learning, an ability which allows these models to understand and solve new tasks based on the provided context. It is argued that this ability "emerges" with a dramatic increase in the size of the model (Wei et al., 2022a).

Efforts to transfer emergent abilities to small models include imitation learning, where a large language model like GPT-4 acts as a "teacher" to create synthetic datasets with additional instructions and explanations. This synthetic data is then used to train smaller "student" models (Taori et al., 2023; Peng et al., 2023; Mukherjee et al., 2023; Magister et al., 2023). Another approach is distillation where the "student" model is trained to mimic the output probabilities of the "teacher" model (Gu et al., 2023; Xu et al., 2024) .

Our work takes a different approach; our goal is to determine whether simplifying the pre-training data itself can unlock emergent language abilities in smaller models. This idea is supported by our previous work (Deshpande et al., 2023), which highlighted the effects of language simplification for smaller models when fine-tuning on downstream tasks. Prior work by Eldan and Li (2023) reports a similar trend, though their approach requires the use of larger models to produce the simplified language. We bypass this step and instead rely on naturally-occurring language restricted via vocabulary filtering.

In this study, we leverage this approach to determine whether language simplification can unlock ICL abilities in smaller language models. To do so, we pre-train 36 causal language models with sizes varying from 1M to 165M parameters, on both a simplified English dataset and a standard pre-training dataset and conduct zero-shot evaluations on different tasks. Through extensive experimentation, we show that language simplification enables ICL abilities in smaller language models on a level comparable to larger-size models pre-trained on non-simplified English corpora.

Specifically, our contributions are as follows:

---

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1242–1257
June 16-21, 2024

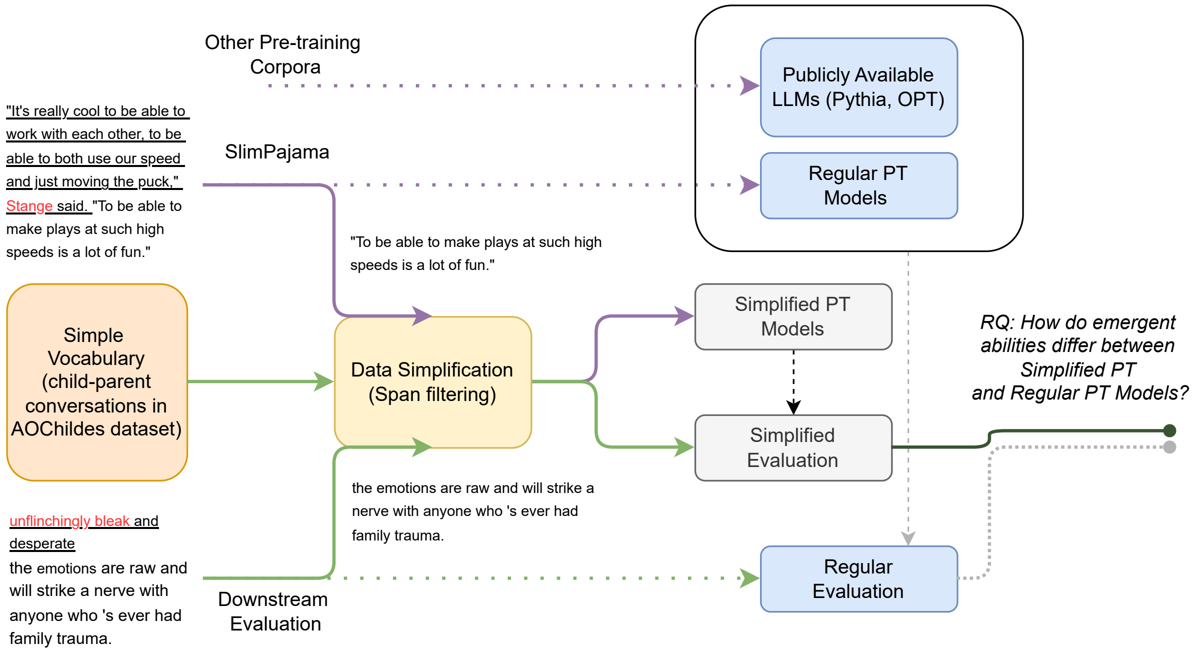

Figure 1: We filter the SlimPajama dataset by selecting spans that contain words from the AO-Childes vocabulary and removing any spans with words not in this vocabulary. We also filter examples in the downstream evaluation dataset based on the occurrence of words in the AO-Childes Vocabulary. The underlined spans are removed by filtering due to the presence of Out of Vocabulary words (Out of Vocabulary words are in red). This simplified dataset is used to pre-train simplified models, whereas regular models are trained on the standard SlimPajama dataset or on other existing pre-training corpora. We then compare whether simplified pre-trained models can perform downstream tasks in simplified language as effectively as standard pre-trained models do in the complete language.

- We demonstrate that downscaling (simplifying) the language enhances zero-shot learning capabilities in smaller-sized models.
- We show that small models trained with such simplified data demonstrate a power law relationship between evaluation loss and the three scale factors: FLOPs, Dataset Size, and Model Size.
- We release a simplified pre-training corpus obtained by filtering the existing SimPajama dataset (Soboleva et al., 2023).

2 Related Work

What is ICL? ICL is the ability of a pre-trained model to solve tasks without task specific fine-tuning (Radford et al., 2019; Brown et al., 2020; Olsson et al., 2022). Many large models have shown excellent ICL capabilities (Touvron et al., 2023; Chowdhery et al., 2022). This has shifted the research community's focus towards leveraging prompts to elicit zero-shot or few-shot responses from models. In a similar vein, the technique of chain-of-thought (CoT) reasoning, as discussed in Wei et al. (2022b), revealed that including a sequence of intermediate reasoning steps can enhance the reasoning skills of large language models. Yet, these abilities are emergent, i.e., it is primarily the larger models that exhibit them. However, recent studies question the belief that improvements in ICL result exclusively from increasing model sizes (Schaeffer et al., 2023; Du et al., 2024), suggesting that using discontinuous metrics like accuracy merely creates the illusion of emergent abilities, whereas employing continuous metrics shows gradual, predictable changes in model performance.

ICL in smaller language models. It has been shown that the emergent abilities observed in larger models can be effectively transferred to smaller models through imitation learning or behavior cloning, where a larger language model such as GPT-4 serves as the "teacher", to generate synthetic datasets with instructions and explanations which can be used to train smaller language models, referred to as "student" models (Taori et al., 2023; Peng et al., 2023; Mukherjee et al., 2023; Magister et al., 2023). This allows smaller models to leverage the capabilities of their larger counterparts. However, the primary drawback of such methods is that most of the knowledge acquired by the model is done in the pre-training stage and the student model copies the style of the teacher model but does not learn the reasoning capabilities employed by these large models (Gudibande et al., 2023).

An alternative strategy to enhance the capabilities of smaller models is through distillation from larger models, aiming to replicate the output probabilities and thus transfer the larger model's in-context learning or zero-shot abilities to their smaller counterparts (Timiryasov and Tastet, 2023; Gu et al., 2023; Xu et al., 2024). This method forfeits one of the primary benefits of smaller language models, namely their reduced computational requirements, by necessitating the training of larger models.

Prior work has also looked into pre-training small models with simplified data. For instance, Huebner et al. (2021) pre-train an encoder language model with corpus that reflects the lexical exposure of children and find that smaller models can approximate the grammatical acquisition performance of larger models. Deshpande et al. (2023) examined the effects of downscaling the modeled language during pre-training via vocabulary-based filtering, and showed that pre-training encoders as small as 1.25M parameters may demonstrate large benefits for downstream performance.

Eldan and Li (2023) have demonstrated that coherency in text generation can be achieved by pre-training on a synthesized, simplified dataset generated from GPT-4. Notably, this dataset largely comprises of stories, presenting less diversity compared to the datasets typically employed for pre-training larger models. Similarly Gunasekar et al. (2023) demonstrate improved performance in smaller models trained on a dataset combining filtered coding examples and synthetic textbook content for coding-related benchmarks. However, their approach, primarily focused on coding challenges, utilizes relatively large models and synthetic data. Their dataset filtering approach also relies on an auxiliary classifier for text exclusion.

3 Methodology

3.1 Language Simplification

We create a simpler pre-training corpus by utilizing a vocabulary derived from the AO-Childes transcripts of child-directed speech (Huebner and Willits, 2021), as done by Deshpande et al. (2023). The core of this corpus is child-directed speech, which tends towards simpler linguistic structures. The vocabulary we use comprises 21,036 unique words, reflecting the lexical range typically found in language directed at children. Filtering existing pre-training corpora with this vocabulary thus results in a simpler pre-training dataset.

3.2 Pre-training Data Collection

To obtain high quality datasets with sufficient deduplication and diversity we leverage datasets used for pre-training large language models such as the SlimPajama dataset (Soboleva et al., 2023). We begin by selecting samples from the train split of the SlimPajama pre-training corpus, then tokenize this text into distinct elements, such as words and symbols. We retain tokens that are either integers, special symbols, or belong to the AO-Childes vocabulary. This process continues until we accumulate a minimum number of tokens in a chunk. For the 22 Billion dataset the minimum number of tokens are set to 32 and for the 2.1 Billion dataset the minimum number of tokens are set to 100. We allow up to 1.5% of these tokens to be out-of-vocabulary (OOV) words to maintain a simplified vocabulary and yet allow some linguistic variability. If the percentage of OOV words in a chunk exceeds this 1.5% threshold, we conclude the current chunk and initiate a new one at the beginning of the next sentence. This approach ensures that each analyzed text chunk primarily consists of known vocabulary words, with a minimal presence of OOV words. Figure 1 illustrates our method.

After filtering, our datasets consist of around 22 billion and 2.1 billion tokens, derived from various splits of the SlimPajama dataset. The distribution of the tokens on the 22 billion dataset across various splits of the SlimPajama dataset is detailed in Table 1. For the 2.1 Billion dataset the distribution of tokens can be found in Table 5 and 6 in the appendix.

We computed the Zipfian Coeffcient by fitting a linear regression model on the logarithm of word frequencies and ranks of words and obtained a zipfian coefficient of -1.11 indicating the dataset exhibits a distribution pattern typical of natural languages, where a small number of words are extremely common, while the majority are rare, thereby underscoring naturalistic quality of our dataset [2]. We utilize this dataset for pre-training of models we label as "simple" models (henceforce, Simple). In contrast, for our "regular" models, we train them using data from the SlimPajama dataset, applying no filtering and maintaining a similar number of tokens.

4 Experimental Setup

4.1 Model Configurations

We pre-train transformer-based models (Vaswani et al., 2017) by adapting the LLaMA architecture (Touvron et al., 2023) and vary key hyperparameters, such as the number of dimensions of the hidden representations (hidden size), number of hidden layers in the Transformer decoder (num layers) and the internal dimension of the MLP (intermediate size). We keep the base period of the RoPE embeddings (Su et al., 2023) (rope_theta) at 20.

We trained 2 models on 22 billion tokens: Simple 165M and Simple 100M. We also trained 54 models on 2.1 Billion tokens. Of these, 36 models were used for zero-shot experiments in section C of the appendix, while the remainder were utilized for curve fitting analyses in section 5.3. The hidden sizes used in our experiments are [32, 64, 128, 256, 512, 1024], with layer counts of [2, 4, 8]. For the majority of zero-shot experiments, the intermediate size was set at four times the hidden size. However, for the experiments detailed in section 5.3, we used intermediate sizes that are twice the hidden size as well. These variations in hyperparameters produced models from 1 million to 165 million parameters, as detailed in Table 7 in the appendix. For training, we utilized the Flash Attention mechanism introduced by Dao et al. (2022).

4.2 Model Pretraining

We train a tokenizer using Byte Pair Encoding (BPE) (Sennrich et al., 2015) on the filtered dataset. We use a vocabulary size of 15000. All simple models are pre-trained on a causal language modelling objective for a single epoch on the simplified data derived from various splits of SlimPajama dataset. We train two sets of models one set on 22 Billion tokens and another set on 2.1 Billion tokens. The models trained on 22 Billion tokens have an effective batch size of 512 and context lengths of 1024 with model parameters being updated 41697 times. We use a cosine learning rate scheduler with warmup and use peak learning rates in the range of 6×10^{-4} to 1×10^{-3} (learning rates are chosen based on model size) and decay the learning rate down to 13% of the peak learning rate and a perform warmup for 4000 steps. The models trained on 2.1 Billion tokens have an effective batch size of 4096 and context lengths of 128. The model parameters are updated a total of 3972 times with cosine learning rate scheduler with warmup and a peak learning rate of 2.8×10^{-3}, we decay learning rate upto 11% of the peak learning rate and perform warmup for 1000 steps.

We utilize the AdamW optimizer for updating the parameters, with the β_1, β_2, and $weight\_decay$ values of 0.9, 0.95, and 0.1 respectively. We use gradient clipping of 1.0. We conduct pre-training of all models on 2 RTX3090. For training regular models, we use a dataset consisting of 2.1 Billion tokens, and use the same hyperparameters as those used for training simple models with the same token count.

4.3 Model Evaluation and Datasets

We evaluate all pre-trained models for their zero-shot and few-shot ICL abilities using the language model evaluation harness from EleutherAI (Gao et al., 2021), which is a framework designed to perform zero-shot and few-shot evaluations. The datasets we use include: Benchmark of Linguistic Minimal Pairs for English (BLiMP) (Warstadt et al., 2020) to assess the models' capability in understanding linguistic features. BLiMP is comprised of 67 individual datasets, each containing a pair of sentences: one grammatically correct, and the other incorrect. These pairs are designed to assess the models' proficiency in recognizing morphological, syntactic, and semantic aspects of language. Additionally, we use the Physical Interaction Question Answering (PIQA) (Bisk et al., 2020) to measure the performance of lanuguage models on questions requiring physical common sense, AI2 Reasoning Challenge (ARC-Easy) (Clark et al., 2018) which

---

[2] This analysis was done on the 2.1B dataset

measures reasoning abilities of Language Models, Choice of Plausible Alternatives (COPA) (Roemmele et al., 2011) which evaluates common sense causal reasoning of language models, Microsoft Research Paraphrase Corpus (MRPC) (Dolan and Brockett, 2005) which evaluates if the language model can identify if a pair of sentences constitutes a paraphrase, RTE which evaluates if language models can identify entailment and non-entailment, MultiGenre Natural Language Inference (MNLI) (Williams et al., 2017) which provides a more diverse and challenging dataset for natural language inference, and Stanford Sentiment Treebank (SST-2) (Socher et al., 2013) which evaluates the model's fine grained understanding of sentiment.

In reporting our findings, we differentiate between the entire downstream dataset called the "unfiltered dataset" or "standard dataset" and the filtered subset termed the "filtered" or "simplified dataset". The simplified version of each downstream task consists of instances using only the words from the AO-Childes lexicon (with the addition of digits and special symbols), thereby mitigating potential distributional shifts between pretraining and testing.

The primary aim of our study was to understand if smaller models could achieve performance improvements similar to those observed in larger models, but when modeling a simplified language. We would like to emphasize that this choice is motivated by our research goal: to understand whether the lack of emergent abilities in smaller pre-trained models is merely a question of model capacity, and whether reducing the problem (down-scaling the language) would allow us to see similar abilities emerge in smaller models. This logic is what directly motivates our downstream evaluation with standard datasets filtered down to imitate the constrained language setting. However, we recognize the value of evaluating model performance on unfiltered datasets for comparison. To this end, we have included the performance of simple models on unfiltered datasets as well.

5 Results

Our goal is to understand if the absence of emergent abilities in smaller pre-trained models is simply a matter of model capacity and whether simplifying the problem, i.e., downscaling the language, would allow these abilities to emerge in smaller models. To this end, we evaluate models trained on simplified data against both filtered and standard evaluation datasets. We compare our models with Pythia (Biderman et al., 2023) and OPT (Zhang et al., 2023) (models up to 1.3B parameters) to determine if downscaling the language facilitates emergent capabilities to occur much earlier.

Table 7 in the appendix shows the perplexity for different-sized models trained on both simple and regular datasets. The simple dataset is derived from a subset of the SlimPajama dataset, where the text has been filtered to limit vocabulary complexity. In contrast, the regular dataset uses the original, unaltered text from the same source. A separate test set, similar in distribution to the training data, was used to evaluate perplexity in each set of models. The reported results reflect the performance of each model trained in an identical training regimen with the same number of training steps. We find that as the model size increases, its ability to accurately predict and understand the held-out test set also improves, as evidenced by decreasing perplexity on both the simple and regular models. Furthermore, the perplexity metrics indicate that at this scale, simple models are able to learn the simple language much better. Simple models in the range of 1-165M parameters achieve perplexity of 92.00 - 20.59 on the simple dataset. In contrast, when regular models are trained on a regular dataset they achieve perplexity in the range of 193.20 - 28.97 on the regular dataset.[3]

5.1 Do simple models perform better in *zero-shot* settings?

In-context learning, as defined by Brown et al. (2020), enables models to apply knowledge gained during pre-training to new tasks without requiring fine-tuning on task-specific datasets. We evaluate the ICL capabilities of our models, focusing on their zero-shot performance across a range of tasks, including COPA, MRPC, RTE, MNLI, SST-2, PIQA, ARC-Easy, and BLiMP. These tasks are analyzed using both standard and vocabulary-filtered datasets.

Table 2 presents zero-shot performance for different models, including pre-trained Pythia models (1B, 410M, 160M), OPT models (1.3B, 350M, 125M), and models trained on simplified language (165M and 100M), which we will refer to as Simple models. The Simple models perform better on vocabulary-filtered downstream tasks than on the

Table 2: Zero-shot accuracy of pre-trained Pythia and OPT models vs. models trained on simplified language. Models are evaluated on both standard and vocabulary-filtered datasets. Results on vocabulary-filtered datasets are marked with †. Our findings indicate that the simplified models demonstrate superior zero-shot performance on vocabulary-filtered datasets, achieving higher average scores across these datasets compared to the average scores of significantly larger Pythia pre-trained models.

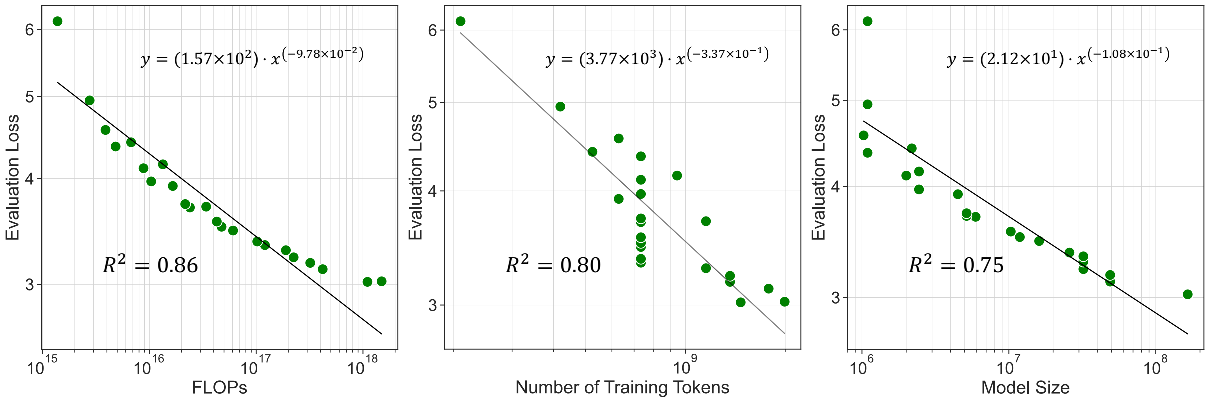

Figure 2: Here we present our curve-fitting results. The green dots represent the compute-optimal instances found in our experiments and the black solid line represents the fitted power curve of the form $y = A \cdot x^B$. In each subfigure, we provide the optimal values of A and B, and the goodness of fit (R^2). Starting from the left, we present the relationship between the evaluation loss (y-axis) and FLOPs (left subfigure), pre-training data (center subfigure) size, and model size (right subfigure), respectively. All R^2 values are over 0.74 and we observe the best fit for the left subfigure (loss vs. FLOPs). In the test range of values for model size and data size, we observe that loss value reduces faster per unit change in model size.

corresponding unrestricted standard versions of the same tasks. This is to be expected, since these models are not exposed to unrestricted language during training.

Since the larger models used in this study are pre-trained on unrestricted language, we expect them to be able to handle tasks using simplified language, as the latter is a subset of their training data. Interestingly, we see that Simple 165 model outperforms Pythia 1B model on simplified downstream data (0.64 vs. 0.62 average performance), suggesting that modeling a restricted language allows smaller models to achieve stronger-than-expected zero-shot capabilities.

A curious comparison arises between the performance of small models on simplified tasks and the performance of larger models pre-trained on standard language on the corresponding standard versions of the same tasks. In this situation, there is no distribution shift between training and testing. If both the model size and language complexity are downscaled appropriately, we expect to see similar performance figures. However, we see that the Simple 165M model performs better on simplified downstream data than the Pythia 1B on standard datasets (0.64 vs. 0.61 average performance), despite being approximately six times smaller and seeing substantially less data. We see a similar trend with OPT model family, where the Simple 165M model does better on the simplified downstream data than OPT 350M model on standard datasets (0.64 vs. 0.60 average performance).

We also report the performance of small models trained on a much smaller amount of data (2.1B tokens), comparing regular and restricted pre-training. For detailed performance comparison on the BLiMP benchmark, PIQA, and ARC-Easy datasets across different model sizes, please refer to the appendix C. As expected, pre-training smaller language models on simpler data leads to better downstream task performance. Consistent with Deshpande et al. (2023), we see above random performance of models as small as 1M parameters. Figure 4 in the appendix, shows the zero-shot task accuracy with respect to the hidden size and number of layers.

5.2 Do Simple models perform better in *few-shot* settings?

In addition to zero-shot performance, we also compare the few-shot performance of simple and standard pre-trained models. We evaluate the performance of the Simple 165M and Simple 100M models, which are pre-trained on a simplified vocabulary, against the Pythia baselines (160M, 410M, and 1B). This evaluation uses few-shot prompting using examples from vocabulary-filtered downstream data. We report the models' average performance across the following datasets: COPA, MRPC, RTE, MNLI, ARC-Easy, PIQA, and SST-2. The results for each dataset are averaged over three runs, with each run using different task examples in the context.

Model	**0-shot**	**1-shot**	**2-shot**	**3-shot**	**4-shot**
Pythia 1B	0.59	0.57	0.57	0.58	0.60
Pythia 410M	0.54	0.55	0.53	0.56	0.54
Pythia 160M	0.50	0.50	0.48	0.51	0.50
Simple 165M	0.62	0.56	0.56	0.54	0.54
Simple 100M	0.56	0.56	0.56	0.56	0.55

Table 3: Average few-shot results across different vocab-filtered tasks such as COPA, MRPC, RTE, MNLI, ARC-EASY, PIQA, SST. Our results reveal no discernible trend in the few-shot learning results, suggesting that larger models are required to observe the emergence of few-shot in-context learning capabilities.

From the results in Table 3, we observe no significant improvement in performance with an increased number of in-context examples. This is in line with previous findings for language models of similar sizes (Brown et al., 2020). This suggests that the smaller model sizes of 100M or 165M may not be adequate to fully demonstrate the few-shot ICL capability in the downscaled language setting. We also believe that the simplified-data models we investigated likely lacked the scale necessary to exhibit emergent abilities such as chain-of-thought prompting (Wei et al., 2022b). Just as models smaller than 10B parameters trained on unrestricted language actually perform worse with CoT prompting (Wei et al., 2022b), our simplified-data models may also require greater scale to exhibit such capabilities.

5.3 Do simple models obey power laws?

We fit a power curve of the form $L = A \cdot x^B$, to predict the cross-entropy loss (L) based on the compute cost (C), data size (D), and model size (M), separately. For curve-fitting, we consider only the 25 compute-optimal instances found for 25 bins of the FLOPs values and utilize R^2 value to assess the goodness of fit. We adopt the formula presented by Deshpande et al. (2023) to calculate the FLOPs values which considers the embedding parameters while calculating FLOPs unlike (Kaplan et al., 2020; Hoffmann et al., 2022). Similar to Kaplan et al. (2020); Hoffmann et al. (2022) we observe that the upstream performance (pre-training cross-entropy loss on validation split of the data) is fairly predictable with R^2 value of 0.86, 0.80, and 0.75, for compute cost, data size, and model size, respectively. We also observe that improvement in the loss value is faster for the model size compared to the data size. [4]

5.4 Do Simple Models yield good generations?

We analyze text continuations, on prompts sampled from TinyStories (Eldan and Li, 2023) and ROCStories (Mostafazadeh et al., 2016), using the 165M simple model and Pythia baselines (160M, 410M, 1B). We sample 25 different prompts from both these datasets randomly. We choose prompts from these datasets so as to keep the prompts simple enough for the model trained on vocabulary-filtered pre-training dataset to understand. For decoding of all models we set temperature to 1.0 and employ nucleus sampling (Holtzman et al., 2019) with top_p set to 0.9. The maximum number of new tokens are set to 50.

Table 4 shows few initial prompts and generations from simple models and different baselines. Similar to (Eldan and Li, 2023) we evaluate the generations with GPT-4, to assign scores ranging from 1 to 10 with 10 being the highest for different aspects of the generated text such as grammar, creativity, and coherence. We plot the average scores across all completions for each model as depicted in Figure 3. From the figure it can be seen that the simple model performs comparably to the Pythia 410M model in terms of grammar and creativity and the simple model outperforms Pythia 160M model in terms of coherence.

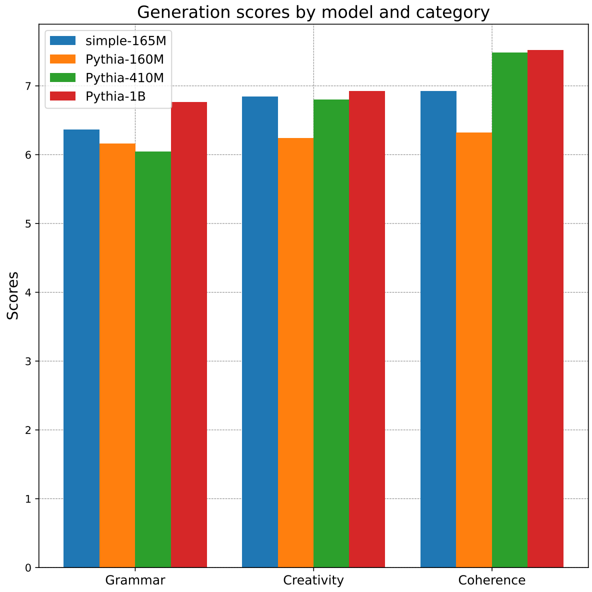

Figure 3: Comparative Analysis of Text Quality from Various Generative Models as evaluated by GPT-4. Models pre-trained on a vocabulary-simplified dataset produce outputs that are grammatical, creative, and coherent, and are comparable to those from larger models trained on the complete language dataset.

6 Conclusion

In our study, we explored the impact of simplifying pre-training data on the performance of small generative models, specifically those with fewer than 165 million parameters. Our primary focus was to assess whether these models exhibit emergent abilities, notably zero-shot learning — the capability to have non-random performance on tasks without explicit prior training. To this end, we evaluated a series of models, each varying in hidden size and the number of layers, and measured their zero-shot performance across different tasks. Our findings reveal that smaller models operating in a simplified language regime indeed demonstrate enhanced zero-shot learning abilities on vocabulary-filtered datasets, and outperform larger baseline models trained on full language on standard datasets. This suggests that the complexity of training data is a crucial factor in the development of zero-shot learning capabilities in smaller models.

We expect future work to investigate the model and data scales at which other emergent abilities (such as few-shot ICL and CoT reasoning) appear when modeling a reduced-scale language. Exploring the potential of instruction fine-tuning in models trained with simplified language is another interesting direction to pursue in future work.

7 Limitations

We adopt vocabulary reduction for simplifying the language we model and do not explore other possible ways of simplification such as sentence structure simplification, data pruning, or curriculum learning. The adopted vocabulary-based data filtration also leads to different distributions of sequence length and word frequencies compared to regular English data. Hence, our findings should be considered within the distributional properties of our pre-training data. We extend the pre-trained

Prompt	Simple-165M	Pythia-160M	Pythia-410M	Pythia-1B
I saw my friend Joe sitting in lobby today. I kept him company, as he is a lonely old man. He told me he had just listened to Beethoven's Ninth. I talked to him for an hour. I left him in the lobby and told him I would see him soon.	I went to check on him and he was just sitting there waiting. Then I got to see a few people who were with him that night. He had been going into his room after his accident. I went down to the lobby to see what was	He seemed to think I was the right person. We talked on the telephone for two hours. Then I came back to the room where we had been sitting at the dinner table and went out. There was a young woman sitting at the opposite end of	We went to his room. He was asleep, lying in bed, as I was. He did not wake up and I did not want him to. My friend Joe told me this afternoon that he had been on the way to visit his	He seemed to be enjoying himself. I did not leave him alone as he has been known to do. After his hour with me he decided to have a drink. He seemed very pleased with himself. I left him alone. I hope he
Todd was hungry. He did not have anything to cook at his house. He decided he need to go buy something to cook. On the way to the store Todd decided to make hamburgers. Todd buys everything he needed and goes home and cooks.	When he arrived, he saw his friends there cooking ham burgers for them. He was already thinking about dinner. He had decided he would make a ham burger. T odd looked at his friends and he knew that he had to do something about this.	When he's done cooking, he takes the ham off the rack. He makes the ham into a turkey, then adds a little salt and pepper. Todd then steaks them with chicken.The ham goes through the oven in a double skillet and	He had some leftovers left. He wanted to do this for the rest of his life.He made up for his lunch with some chips. His mother came home from work. She told him to make her hamburger. She had to eat	When he got back home he took all the food he needed. He eats all the food and it was too late to cook something else now he was back at the store. Todd decides to go in the store again. There he finds out that

Table 4: Comparison of the prompt completions generated by the Simple 165M model trained on vocabulary-filtered simplified pre-training dataset and Pythia pre-trained baselines (160M, 410M, 1B). For decoding of all models we set temperature to 1.0 and employ nucleus sampling with top_p set to 0.9. The maximum number of new tokens are set to 50.

model capabilities to process longer sequences by utilizing position interpolation method (Chen et al., 2023). We train all models with only the causal language modeling task and do not consider distillation or model pruning as a means of developing smaller models. For evaluating the pre-trained models, we focus only on the in-context learning abilities. Hence, we keep the finetuning experiments out of the scope of our study. We further note that instruction tuning of models may considerably affect the ICL abilities. However, we keep the investigation of the effect of instruction tuning on ICL abilities for future work.

A Data distribution for the Simple and Regular Datasets with 2B tokens

The data distribution corresponding to the simple and regular datasets containing 2B tokens can be found in 5 and 6 respectively.

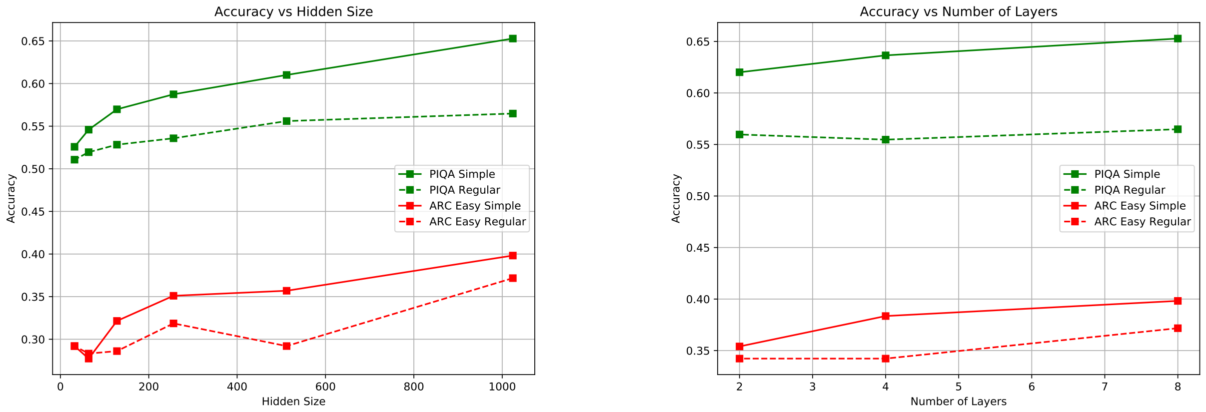
B Modeling simple and regular language

Table 7 shows the perplexity metrics across different simple and regular models trained on 2.1B tokens. Perplexity of simple models are evaluated on the held out test set of simple pre-training data whereas perplexity of regular models are evaluated on the held out test set of both simple and regular pre-training data. It can be seen that smaller models are better able to model simple data compared to regular data.

C Additional Zero-shot Evaluation Results

Figure 4 shows that the task accuracy improves with an increase in the capacity of the model for both regular and simple models. Simple models generally outperform their regular counterparts on simpler tasks such as PIQA and ARC-Easy when evaluated on the filtered dataset.

Table 8 shows additional zero-shot accuracy results across all model configurations in both filtered and unfiltered datasets. On the PIQA task, we saw that simple models typically exhibit superior performance over regular models in a majority of configurations, regardless of whether the dataset was filtered or unfiltered. When focusing on the



(a) Variation in accuracy for hidden sizes ranging from 32 to 1024 on both simple and regular models. For each hidden size, we choose the model with 8 layers.

(b) Variation in accuracy for layers ranging from 2 to 8 on both simple and regular models. For each layer we choose the model with a hidden size of 1024.

Figure 4: Model performance different hidden layer sizes and number of layers on PIQA and ARC-Easy datasets. Both simple and regular models are compared on the filtered evaluation datasets. We observe that the simple models consistently outperform their regular counterparts across different model configurations.

Split	**Percentage of tokens**	**Number of tokens (mil)**

ArXiv	4.62%	98.55
Books	4.02%	85.84
total	100%	2132.64

Table 6: Data source distribution for the standard SlimPajama pre-training dataset used to train regular models.

ARC-Easy filtered dataset, we found that simple models with larger hidden sizes (exceeding 64) consistently outperformed their regular counterparts on the filtered dataset. Conversely, with unfiltered ARC-Easy dataset, regular models demonstrated a higher performance level than the simple models.

Tables 9 and 10 show zero-shot accuracy results across various model configurations using the filtered and unfiltered datasets. Though simple models show a deterioration in performance compared to their results on the filtered dataset, we do see that the average scores tend to be better than the regular models on most configurations.

D Rotary Position Embeddings and Position Interpolation

For models pre-trained on 2.1B tokens we use context length of 128. However, datasets such as PIQA and ARC-Easy contain examples that span more than the pre-trained context length. To extend context window sizes beyond 128, we use Position Interpolation (Chen et al., 2023) on PIQA and ARC-Easy datasets. We use a scaling factor of 8 which allows to have context window of 1024.

Based on the findings presented in a study conducted by Liu et al. (2023), we conducted an exploratory experiment for deciding the base value for the rotary positions embeddings (Su et al., 2023). For the pre-training sequence length of 128, we observed better length extension results (with PI (Chen et al., 2023)) for the base value of 20, compared to the widely used 10,000. Our results were in agreement with the findings presented by Liu et al. (2023). Hence, we used a base value of 20 for pre-training language models.

In our downstream evaluation, we utilized PI for context length extension only for the PIQA and ARC-Easy datasets. We used a scale of 8 for extending the pre-training context length to 1024.

Model Size (M)	Hidden Size	Num Layers	Int. Size	PPL Simple (Simple Dataset)	PPL Regular (Regular Dataset)	PPL Regular (Simple Dataset)
164.96	1024	8	4096	20.59	28.97	33.85
97.84	1024	4	4096	24.59	31.13	35.49

1.09	32	8	128	79.61	164.78	141.03
1.02	32	4	128	84.24	178.07	150.75
0.99	32	2	128	92.00	193.20	162.80

Table 7: Parameter count and perplexity metrics across model configurations. “PPL Simple (Simple Dataset)” refers to the perplexity of simple models measured on a held-out filtered pre-training dataset. “PPL Regular (Regular Dataset)” refers to the perplexity of regular models measured on a held-out standard pre-training dataset. “PPL Regular (Simple Dataset)” refers to the perplexity of regular models measured on the held-out filtered pre-training dataset. As the model capacity increases, the ability to predict the evaluation data improves on both simple and regular models.

With the PI scale of 8, we evaluated the model on the government report dataset (Huang et al., 2021) and observed a decreasing perplexity from a context length of 64 to 1,024 in our exploratory experiment.

Table 8: Zero-shot accuracy scores on PIQA and ARC Easy dataset. “Filtered” refers to the vocabulary filtered datasets and “Unfiltered” for standard datasets. For each hidden layer size and layer count, the table compares metrics for both simple and regular models. The initial row for each hidden size and number of layers displays results from the simple model trained on simplified data, followed by a similar-sized regular model trained on regular data. Performance comparison is indicated by arrows next to the simple model’s scores: a ↑ signifies the simple model outperforming the regular model, while a ↓ denotes the regular model performing better. An absence of arrows indicates comparable performance between the two models. We observe that on both the filtered and unfiltered datasets for the PIQA task, simple models generally outperform regular models in most configurations. Additionally, for the ARC Easy filtered dataset, larger simple models (with hidden sizes above 64) tend to surpass the performance of regular models. However, on the unfiltered ARC Easy dataset, it is observed that regular models outperform the simple ones.

Hidden Size	Num. Layers	Anaphor Agr.	Argument Str.	Binding	Control /Raising	Determiner Noun Agr.	Ellipsis	Filler Gap	Irregular Forms	Island Effects	NPI Lic.	Quantifiers	Subject Verb Agr.	Avg. Score

Table 9: Zero-shot accuracy scores on the vocabulary filtered datasets in the BLiMP benchmark. For each hidden layer size and layer count, the table compares metrics for both simple and regular models. The initial row for each hidden size and number of layers displays results from the simple model trained on simplified data, followed by a similar-sized regular model trained on regular data. Performance comparison is indicated by arrows next to the simple model's scores: a ↑ signifies the simple model outperforming the regular model, while a ↓ denotes the regular model performing better. An absence of arrows indicates comparable performance between the two models. We find that the average score of simple models tends to surpass regular models in most configurations.

Context Does Matter: Implications for Crowdsourced Evaluation Labels in Task-Oriented Dialogue Systems

Abstract

Crowdsourced labels play a crucial role in evaluating task-oriented dialogue systems (TDSs). Obtaining high-quality and consistent ground-truth labels from annotators presents challenges. When evaluating a TDS, annotators must fully comprehend the dialogue before providing judgments. Previous studies suggest using only a portion of the dialogue context in the annotation process. However, the impact of this limitation on label quality remains unexplored. This study investigates the influence of dialogue context on annotation quality, considering the truncated context for relevance and usefulness labeling. We further propose to use large language models (LLMs) to summarize the dialogue context to provide a rich and short description of the dialogue context and study the impact of doing so on the annotator's performance. Reducing context leads to more positive ratings. Conversely, providing the entire dialogue context yields higher-quality relevance ratings but introduces ambiguity in usefulness ratings. Using the first user utterance as context leads to consistent ratings, akin to those obtained using the entire dialogue, with significantly reduced annotation effort. Our findings show how task design, particularly the availability of dialogue context, affects the quality and consistency of crowdsourced evaluation labels.[1]

1 Introduction

With recent advances in pre-trained language models and large language models (LLMs), task-oriented dialogue systems (TDSs) have redefined how people seek information, presenting a more natural approach for users to engage with information sources (Budzianowski and Vulić, 2019; Wu et al., 2020). As TDSs become increasingly integral to information-seeking processes, the question of how to accurately and effectively evaluate their performance becomes critical. Due to the poor correlation of automatic metrics with human-generated labels (Deriu et al., 2021), evaluation of TDSs has shifted towards relying on user ratings or crowdsourced labels as ground-truth measures (Li et al., 2019).

Various crowdsourcing techniques have been employed to collect ground-truth labels, such as sequential labeling (Sun et al., 2021), where the annotators go through each utterance and annotate them one by one. This approach introduces certain risks in the annotation process, such as annotators' fatigue and high cognitive load in extra-long dialogues, requiring them to remember and track the state of the dialogue as they annotate the utterances (Siro et al., 2022). While following and understanding the dialogue context is crucial and can influence the annotators' ratings, reading and understanding very long dialogues can lead to degraded performance.

To address this issue, another line of research proposes to randomly sample only a few utterances in each dialogue to be annotated (Mehri and Eskenazi, 2020; Siro et al., 2022, 2023). While addressing the high cognitive load and fatigue, limiting annotators' understanding of the dialogue poses obvious risks, such as unreliable and biased labels (Schmitt and Ultes, 2015; Siro et al., 2022). In particular, the amount of dialogue context can lead to biases. For example, annotators who lack rich context may unintentionally lean towards positive or negative ratings, neglecting the broader quality of the response. Thus, offering annotators too little context risks misleading judgments, potentially leading to inaccurate or inconsistent labels. Conversely, flooding annotators with excessive information can overwhelm them, which can lead to lower returns in terms of label quality.

Prior work has investigated factors that affect the quality and consistency of crowdsourced evaluation labels, including annotator characteristics,

task design, cognitive load, and evaluation protocols (see, e.g., Parmar et al., 2023; Roitero et al., 2021, 2020; Santhanam et al., 2020). However, no previous work studies the effect of random sampling and the number of sampled utterances on the annotation quality.

In this study, we aim to address this research gap by investigating how different amounts of contextual information impact the quality and consistency of crowdsourced labels for TDSs, contributing to understanding of the impact of such design choices. We experiment with crowdsourcing labels for two major evaluation aspects, namely, *relevance* and *usefulness* under different conditions, where we compare the annotation quality under different dialogue context truncation strategies.

Addressing the challenge of insufficient context at the turn level, we propose to use heuristic methods and LLMs to generate the user's information need and dialogue summary. LLMs can play the role of annotation assistants (Faggioli et al., 2023) by summarizing the dialogue history, facilitating a more efficient and effective understanding of the dialogue context before annotating an utterance. To this aim, we use GPT-4 for dialogue context summarization and compare the performance of annotators' under different conditions, as well as different context sizes. Through these experiments, we answer two main questions: **(RQ1)** How does varying the amount of dialogue context affect the crowdsourced evaluation of TDSs? **(RQ2)** Can the consistency of crowdsourced labels be improved with automatically generated supplementary context?

Our findings reveal that the availability of previous dialogue context significantly influences annotators' ratings, with a noticeable impact on their quality. Without prior context, annotators tend to assign more positive ratings to system responses, possibly due to insufficient evidence for penalization, introducing a positivity bias. In contrast, presenting the entire dialogue context yields higher relevance ratings. As for usefulness, presenting the entire dialogue context introduces ambiguity and slightly lowers annotator agreement. This highlights the delicate balance in contextual information provided for evaluations. The inclusion of automatically generated dialogue context enhances annotator agreement in the no-context (C_0) condition while reducing annotation time compared to the full-context (C_7) condition, presenting an ideal balance between annotator effort and performance.

Our findings extend to other task-oriented conversational tasks like conversational search and preference elicitation, both relying on crowdsourced experiments to assess system performance.

2 Methodology

We examine how contextual information about a dialogue affects the consistency of crowdsourced judgments regarding *relevance* and *usefulness* of a dialogue response. Here, contextual information refers to the information or conversation that precedes a specific response. We carry out experiments in two phases. **Phase 1** involves varying the *amount* of dialogue context for annotators to answer **RQ1**. In **Phase 2**, we vary the *type* of previous contextual information available to annotators to address **RQ2**.

2.1 Experimental data and tasks

We use the recommendation dialogue (ReDial) dataset (Li et al., 2018), a conversational movie recommendation dataset, comprising of over 11K dialogues. The dataset is collected using a human-human approach, i.e., one person acts as the movie seeker, while the other is the recommender with the goal of recommending a suitable movie to the seeker, thus making the dataset goal-oriented. We randomly select system responses from 40 dialogues for the assignment of relevance and usefulness labels. These dialogues typically consist of 10 to 11 utterances each, with an average utterance length of 14 words. We evaluate the same system responses across all experimental conditions.

The annotation task for the annotators involves two dimensions: (i) *relevance*: Is the system response relevant to the user's request, considering the context of the dialogue? And (ii) *usefulness*: How useful is the system's response given the user's information need? For the *relevance task* we ask annotators to judge how relevant the system's recommendations are to the user's request (Alonso et al., 2008). First, the annotator has to judge whether the system response includes a movie recommendation or not; if yes, the annotator assesses whether the movie meets the user's preference; if not, we ask them to note that the utterance does not recommend a movie. The judgment is on a binary scale for the latter case, where the movie is either relevant (1) or not (0). For each experimental condition (see below), annotators only assess the system response with access to the previous context. Note that we forego the user's feedback on the evaluated response (next user utterance) so as to focus on topical relevance of the recommended movie, that is, if the movie meets the user request and preference in terms of the genre, actor, director, etc. For the *usefulness task* annotators assess a response with or without a movie recommendation with the aim of determining how useful the system's response is to the user (Mao et al., 2016). The judgment is done on a three-point scale (i.e., very, somewhat, and not useful). Unlike the relevance task, annotators have access to the user's next utterance for the usefulness task; usefulness is personalized to the user, in that even though a movie may be in the same genre, sometimes a user may not like it (e.g., does not like the main actor), thus making the system response relevant but not useful to the user.

2.2 Automatic generation of diverse dialogue contexts

User information need. The user's information need plays a significant role when assessing or improving the quality of the data collected in IR systems (Mao et al., 2016). It refers to *the specific requirement or query made by a user, which guides the system in understanding their preferences and retrieving relevant information to fulfill that need.* For TDSs, understanding the user's intent is crucial for annotators participating in the evaluation, as they are not the actual end users. This understanding improves the alignment of evaluation labels with the actual user's requirements. We define the user's information need as their movie recommendation preference. Given the consistency of user preferences in the ReDial dataset, where users tend to maintain a single preference throughout a conversation, providing the user's initial information need aids annotators in evaluating the current turn for relevance or usefulness.

We adopt two approaches to generate the user's information need. One is to heuristically extract the first user utterance that either requests a movie recommendation or expresses a movie preference, based on phrases such as "looking for," "recommend me," and "prefer." These phrases are extracted from the first three user utterances in a dialogue, with the top 10 most common phrases selected. The second approach relies on LLMs to generate the user's information need. We hypothesize that LLMs can identify pertinent user utterances in a dialogue and generate the corresponding information need. We use GPT-4 (OpenAI, 2023) in a zero-shot setting; with the dialogue context up to the current turn as input, we prompt the model to generate the user's information need.

Generating dialogue summaries. Dialogue summarization is beneficial for providing a quick context to new participants of a conversation and helping people understand the main ideas or search for key contents after the conversation, which can increase efficiency and productivity (Feng et al., 2022). We use dialogue summaries to provide annotators with quick prior context of a dialogue. We use GPT-4 (OpenAI, 2023) in a zero-shot setting, as in the case of user information needs, but vary the prompt. We instruct GPT-4 to generate a summary that is both concise and informative, constituting less than half the length of the input dialogue. Both the generated user information needs and summaries are incorporated in Phase 2 of the crowdsourcing experiments.

Due LLMs' potential for hallucination (Bouyamourn, 2023; Chang et al., 2023), we evaluate the generated summaries and user information need to ensure factuality and coherence. We elaborate the steps we took in Section A.2.

2.3 Crowdsource experiments

Following (Kazai, 2011; Kazai et al., 2013; Roitero et al., 2020), we design human intelligence task (HIT) templates to collect relevance and usefulness labels. We deploy the HITs in variable conditions to understand how contextual information affects annotators' judgments. Our study has two phases: in Phase 1 we vary the *amount* of contextual information; in Phase 2 we vary the *type* of contextual information. In each phase and condition, the annotators were paid the same amount as this study is not focused on understanding how incentive influences the quality of crowdsourced labels. Like (Kazai et al., 2013), we refrain from disclosing the research angle to the annotators in both phases; this helps prevent potential biases during the completion of the HIT.

Phase 1. In Phase 1, the focus is on understanding how the *amount* of dialogue context impacts the quality and consistency of relevance and usefulness labels. We vary the length of the dialogue context to address (RQ1). Thus, we design our experiment with three variations: C_0, C_3, and C_7 (see Section 2.4). The HIT consists of a general task description, instructions, examples, and the main task part. For each variation, we gather labels for two main dimensions (relevance and usefulness) and include an open-ended question to solicit annotators' feedback on the task. Each dimension is assessed with 3 annotators in a separate HIT, with the same system response evaluated by each. This ensures a consistent evaluation process for both relevance and usefulness.

Phase 2. In Phase 2, the focus shifts to the *type* of contextual information, to answer (RQ2). We take an approach of machine in the loop for crowdsourcing. We restrict our experiments to experimental variation C_0 (defined below), where no previous dialogue context is available to the annotators. We aim to enhance the quality of crowdsourced labels for C_0 by including additional contextual information alongside the turn being evaluated. Our hypothesis is that without prior context, annotators may face challenges in providing accurate and consistent labels. By introducing additional context, like the user's information need or a dialogue summary, we expect an increase in the accuracy of evaluations. Through this, we aim to approach a level of performance similar to when annotators have access to the entire dialogue context while minimizing the annotation effort required. We enhance the 40 dialogues from Phase 1 with the user's information need or a dialogue summary, as detailed in Section 2.2. Thus, in Phase 2, we have three experimental setups: C_0-llm, C_0-heu, and C_0-sum. Table 3 in Section A.1 summarizes the setups.

The HIT design closely mirrors that of Phase 1. The main task remains unchanged, except for the inclusion of the user's information need or a dialogue summary. Annotators answer the same two questions on relevance and usefulness in separate HITs. While we do not strictly enforce reliance on the additional information provided, annotators are encouraged to use it when they perceive that the current response lacks sufficient information for an informed judgment.

2.4 Experimental conditions

We focus on two key attributes: the *amount* and *type* of dialogue context. For both attributes, we explore three distinct settings, resulting in 6 variations, for both relevance and usefulness; each was applied to the same 40 dialogues:

- *Amount of context*. We explore three truncation strategies: no-context (C_0), partial context (C_3), and full context (C_7), designed to encompass scenarios where no previous dialogue context is accessible to the annotator (C_0), where some previous dialogue context is available but not comprehensively (C_3), and when annotators have access to the complete previous dialogue context (C_7).
- *Type of context*. Using the contexts generated in Section 2.2, we experiment with three variations of context type: heuristically generated information need (C_0-heu), an LLM-generated information need (C_0-llm), and dialogue summary (C_0-sum).

Table 3 in Section A.1 of the appendix summarizes the experimental conditions.

2.5 Participants

We enlisted master workers from the US on Amazon Mechanical Turk (MTurk) (Amazon Mechanical Turk, 2023) to ensure proficient language understanding. Annotators were filtered based on platform qualifications, requiring a minimum accuracy of 97% across 5000 HITs. To mitigate any learning bias from the task, each annotator was limited to completing 10 HITs per batch and participating in a maximum of 3 experimental conditions. A total of 78 unique annotators took part in Phases 1 and 2 and each worker was paid \$0.4 per HIT, an average of \$14 per hour. Their average age range was 35–44 years. The gender distribution was 46% female and 54% male. The majority held a four-year undergraduate degree (48%), followed by two-year and master's degrees (15% and 14%, respectively).

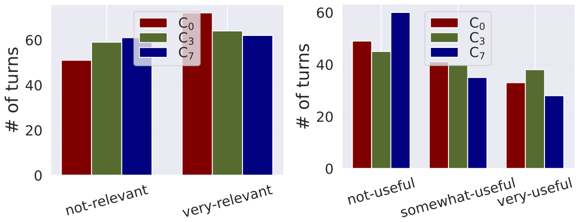
We conduct quality control on the crowdsourced labels to ensure reliability as described in Section A.2 in the appendix.

3 Results and Analysis

We address **(RQ1)** and **(RQ2)** by providing an overview of the results and in-depth analysis of our crowdsourcing experiments. We first describe the key data statistics.

3.1 Data statistics

Phase 1. Figure 1 presents the distributions of relevance and usefulness ratings across the three variations, C_0, C_3, and C_7. Figure 1a indicates a larger number of dialogues rated as relevant when annotators had no prior context (C_0), compared to instances of C_3 and C_7, where a lower number



(a) Relevance (b) Usefulness

Figure 1: Distribution of (a) relevance and (b) usefulness labels for dialogue annotations in Phase 1.

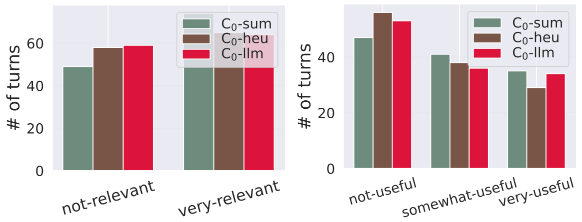
of dialogues received such ratings. This suggests that in the absence of prior context, annotators are more inclined to perceive the system's response as relevant, as they lack evidence to assert otherwise. This trend is particularly prevalent when user utterances lean towards casual conversations, such as inquiring about a previously mentioned movie or requesting a similar recommendation to their initial query, aspects to which the annotators have no access. Consequently, this suggests that annotators rely on assumptions regarding the user's previous inquiries, leading to higher ratings for system response relevance.

We observe a similar trend for usefulness (Figure 1b), compared to C_3 and C_7, C_0 has more dialogues rated as useful. The introduction of the user's next utterance introduced some level of ambiguity to annotators. Evident in instances where the user introduced a new item not mentioned in the system's response and expressed an intention to watch it, the usefulness of the system's response became uncertain. This ambiguity arises particularly when annotators lack access to prior context, making it challenging to tell if the movie was mentioned before in the preceding context.

These observations highlight the impact of the amount of dialogue context on the annotators' perceptions of relevance and usefulness in Phase 1. This emphasizes the significance of taking contextual factors into account when evaluating TDSs.

Phase 2. In Phase 2, we present findings on how different types of dialogue contexts influence the annotation of relevance and usefulness labels. When the dialogue summary is included as supplementary information for the turn under evaluation (C_0-sum), a higher proportion of dialogues are annotated as relevant compared to C_0-llm for relevance (60% vs. 52.5%, respectively); see Figure 2a.

In contrast to the observations made for relevance, we see in Figure 2b that a higher percentage of dialogues are predominantly labeled as not useful when additional information is provided to the annotators. This accounts for 60% in C_0-heu, 47.5% in C_0-llm, and 45% in C_0-sum. This trend is consistent with our observations from Phase 1, highlighting that while system responses may be relevant, they do not always align with the user's actual information need. We find that C_0-sum exhibits the highest number of dialogues rated as useful, indicating its effectiveness in providing pertinent information to aid annotators in making informed judgments regarding usefulness.



(a) Relevance (b) Usefulness

Figure 2: Distribution of (a) relevance and (b) usefulness ratings when annotators have access to additional context in C_0 Phase 2.

3.2 RQ1: Effect of varying amount of dialogue context

Label quality. To gauge the quality of the crowdsourced labels, we rely on inter-annotator agreement (Boguslav and Cohen, 2017; Carletta, 1996). In order to understand how the amount of dialogue context influences the quality of ratings by annotators, we calculate the agreement between annotators for both relevance and usefulness across the three variations; see Table 1. To address potential randomness in relevance ratings, given the binary scale, we randomly drop one rating from each dialogue and compute the agreement. We repeat this process for each annotator and calculate an average Cohen's Kappa score. For usefulness, we compute Kappa for each pair of annotators and then

Table 1: Inter annotator agreement (Cohen's Kappa) and Tau correlation for relevance and usefulness across the three experimental setups in Phase 1.

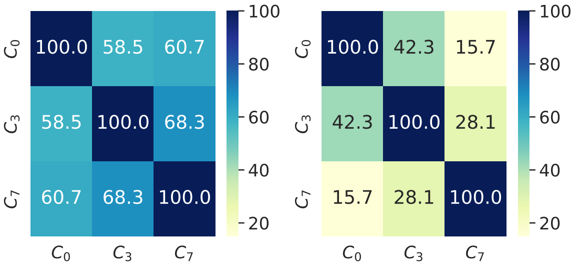
Aspect	Variation	Kappa	Tau
Relevance	C_0	0.53	0.47
	C_3	0.61	0.49
	C_7	0.70	0.61
Usefulness	C_0	0.64	0.54
	C_3	0.68	0.60
	C_7	0.56	0.41

calculate the average. We assess the significance of the agreement using the Chi-squared method. All Kappa scores are statistically significant ($p \leq 0.05$).

We observe an increase in the Kappa and Tau score as the dialogue context increases from C_0 to C_7. Despite the lack of context in C_0, there is a moderate level of agreement regarding the relevance of the current turn. With the introduction of more context in C_3 and C_7, comes an increase in agreement regarding the relevance of the current turn (see Table 1). Providing additional dialogue context seems to lead to higher levels of consensus among annotators. This is likely due to dataset characteristics: users tend to express their preferences early in the dialogue, rather than in subsequent exchanges. Hence, in the case of C_0, which only includes the current turn, when the user's utterance is incomplete, lacking an explicit expression of their preference, annotators rate more dialogues as relevant compared to C_3 and C_7. Overall, we conclude that when annotators have insufficient information to come up with a judgment, they tend to judge the system positively, introducing a positivity bias (Park et al., 2018).

We see in Table 1 (row 3) that despite the lack of context in C_0, there is substantial agreement regarding the usefulness of the current turn. This is due to the availability of the user's next utterance, which serves as direct feedback on the system's response, resulting in higher agreement than for relevance assessment. As more context is provided, there is an even higher level of agreement among annotators regarding the usefulness of the current turn. Access to a short conversation history significantly improves agreement on usefulness.

Surprisingly, despite having access to the entire conversation history in C_7, there is a slightly lower level of agreement than in C_3. The complete dialogue context may introduce additional complexity or ambiguity in determining the usefulness of the current turn. This occurs when conflicting feedback arises from the user's next utterance compared to the previous dialogue context. For example, when the system repeats a recommendation that the user has already watched or stated before, and the user expresses their intent to watch the movie in the next utterance, it leads to divergent labels. Similar trend is observed with the Tau correlations though the values are lower compared to the Kappa scores.



(a) Relevance (b) Usefulness

Figure 3: The percentage of agreement in (a) relevance and (b) usefulness labels across the three experimental setups in Phase 1.

Label consistency across conditions. We examine the impact of varying amounts of dialogue context on the consistency of crowdsourced labels across the three variations for relevance and usefulness and report the percentage of agreement in Figure 3. We observe moderate agreement (58.54%) between annotations of C_0 and C_3, suggesting that annotators demonstrate a degree of consistency in their assessments when provided with different amounts of context. This trend continues with C_0 and C_7, where the agreement increases slightly to 60.98%. The most notable increase is between C_3 and C_7 (68.29%). As annotators were exposed to progressively broader contextual information, their assessments became more consistent.

Usefulness behaves differently. We observe moderate agreement (41.71%) between C_0 and C_3, indicating a degree of consistency in annotator assessments within this range of context. A notable decrease in agreement is evident when comparing C_3 and C_7, down to 28.3% agreement. The most substantial drop is observed between C_0 and C_7, yielding a mere 14.63% agreement. These findings emphasize the significant impact of context on the consistency of usefulness annotations. For usefulness assessment providing annotators with a more focused context, improves their agreement.

With respect to **RQ1**, we note considerable differences in the labels assigned by annotators as we vary the amount of dialogue context. As the context expands, annotators incorporate more information into their assessments, resulting in context-specific labels. Annotator judgments are shaped not only by response quality but also by the broader conversation. This highlights the complexity of the task and the need for a carefully designed annotation methodology that considers contextual variations. These findings emphasize the significance of dialogue context in annotator decision-making.

Table 2: Inter annotator agreement (Cohen's Kappa) and Tau correlation for relevance and usefulness across the three experimental setups in Phase 2.

Aspect	Variation	Kappa	Tau
Relevance	C_0-heu	0.75	0.54
	C_0-sum	0.60	0.45
	C_0-llm	0.51	0.44
Usefulness	C_0-heu	0.71	0.59
	C_0-sum	0.63	0.49
	C_0-llm	0.53	0.44

3.3 RQ2: Effect of automatically generated dialogue context

Label quality. In Phase 2, our experiments aim to establish the impact of presenting annotators with different types of context during crowdsourcing. Different from conventional dialogue context, we provide the annotators with the dialogue summary (C_0-sum), the user's information need in the dialogue (C_0-heu and C_0-llm). We also aim to uncover if we can improve the quality of the crowdsourced labels in C_0 to match those in C_7. We calculate the Cohen's Kappa similar to Section 3.2; see Table 2.

The heuristic approach (C_0-heu) yields the highest agreement (Kappa and Tau), indicating a noteworthy degree of agreement in relevance assessments. The LLM-generated context (C_0-llm and C_0-sum) results in a moderate to substantial level of agreement, signifying a reasonable level of agreement regarding the relevance of the system response. We observe similar results for usefulness. The heuristic approach (C_0-heu) again leads with the highest level of agreement (0.71 and 0.59), C_0-sum follows with a kappa score of 0.63, while C_0-llm has a kappa score of 0.53. This high level of agreement (Kappa) for the two aspects indicates the quality of the labels; the additional context provided, generated either heuristically or with LLMs, is effective in conveying relevant information to annotators, leading to more consistent assessments.

For both relevance and usefulness, C_0-heu consistently improves agreement among annotators, while the LLM-generated context (C_0-llm and C_0-sum) has a substantially lower agreement than C_7. This difference reflects the limitations of LLMs in capturing context and generating a factual summary. While they generate coherent text, LLMs sometimes fail to correctly represent the sequential order of the dialogue and users' language patterns.

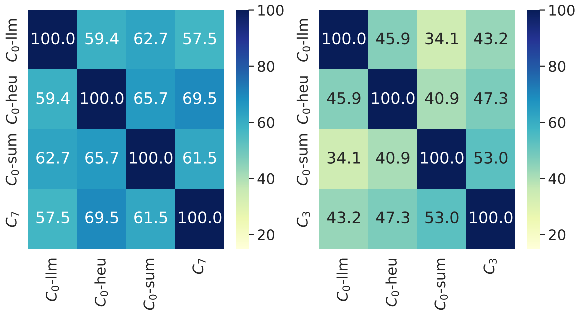
Label consistency across conditions. In Figure 4a we report the agreement between the setups in Phase 2 and compare them to C_7 (relevance) and C_3 (usefulness) due to their high inter-annotator agreement (IAA) and label consistency. For the relevance annotations, varying levels of agreement emerge. There is substantial agreement between C_0-heu and C_0-llm (59.36%), showing a significant overlap in the labels assigned using both methods, although there are instances where annotators differ in their assessments of relevance. C_0-sum exhibits moderate label agreement with C_0-llm (62.74%) and C_0-heu (65.67%), pointing to relatively similar label assignments across the setups.

We observe similar results for usefulness in Figure 4b. While the heuristically generated approach achieves high IAA, the C_0-sum method demonstrates greater consistency with all other setups in terms of usefulness. This suggests that while annotators using the C_0-heu approach often agreed on a single label, the chosen label may not have always been the most accurate. We note slightly low agreement levels for a similar label between the three setups, consistent with results in Phase 1. Unlike relevance, which used a binary scale, usefulness was rated on a 1–3 scale. This finer-grained scale may explain the lower agreement compared to relevance, as different types of contextual information can influence usefulness scores.

Regarding **RQ2**, we show that we can improve the consistency of the labels assigned by crowdworkers in C_0 condition by augmenting the current turn with automatically generated supplementary dialogue context. The heuristic approach demonstrates higher consistency in both IAA and label consistency for relevance and usefulness compared to C_0 and C_7. Providing annotators with the user's initial utterance expressing their preference, particularly in scenarios lacking context, can significantly enhance the quality and consistency of crowdsourced labels. This approach can yield performance comparable to a setup involving the entire dialogue C_7, without imposing the cognitive load of reading an entire conversation on annotators. This streamlines the annotation process and maintains high-quality results, offering a practical strategy for obtaining reliable labels for dialogue evaluation.

4 Discussion and Implications

Our findings reveal intriguing insights into the impact of context size and type on crowdsourced rel-



(a) Relevance (b) Usefulness

Figure 4: The percentage of agreement in (a) relevance and (b) usefulness labels across the three experimental setups in Phase 2.

evance and usefulness labels for TDS. Expanding the dialogue context from C_0 to C_7 significantly improves agreement among annotators, indicating that annotators rely on comprehensive context to make more accurate assessments. This trend does not hold for usefulness, where we notice a decrease in agreement when all previous dialogue context is available. The optimal amount of context required for reliable labels relies on the aspect evaluated.

Consistent with prior work (Eickhoff, 2018; Kazai et al., 2011a), we observe an inconsistency in relevance labels across variations, with the same system response being rated differently depending on the context provided. Given the lack of label consistency across variations, future studies should carefully tailor their annotation task design and test various settings to ensure high-quality and consistent labels. Additionally, much care should be taken when comparing the performance of a system across several datasets when labels are crowdsourced with a different strategy to ensure a fair comparison as models similar to humans can be sensitive to the annotation strategy (Kadasi and Singh, 2023; Kern et al., 2023).

We also analyzed data from the open-ended question asking annotators about their experience with the annotation task. Annotators note that dialogue summaries fail to convey a user's emotion, limiting their annotation process. Additionally, lower accuracy of the context generated by an LLM may lead to low agreement among annotators. This signifies the importance of carefully considering the quality and accuracy of generated content in the evaluation process. We provide examples in Section A.5 in the appendix. While there may be constraints in presenting user information need and dialogue summary as dialogue context, one key consideration to take into account is the cognitive load of annotators. Providing a shorter, focused context reduces the cognitive burden on annotators, allowing them to devote more attention to actually evaluating a response. This not only streamlines the annotation process but also helps maintain high-quality results. Reducing the amount of content to be assessed may lead to faster annotation times without compromising the quality of ratings (Santhanam et al., 2020). Another approach to using LLMs in annotation, is for researchers to consider co-annotation (Li et al., 2023) between humans and LLMs.

Optimal context varies by the aspect under evaluation, challenging the idea of a universal strategy. The consistent reliability of automatic methods suggests their potential as dependable tools for evaluation. This implies their use in generating supplementary context, eliminating the need for manual determination of context amounts. This streamlines evaluation, enhancing efficiency in context-driven evaluations for TDS. For data lacking topic or preference shifts, heuristics perform effectively. However, LLMs are recommended for shifting conditions, showcasing adaptability not easily discernible with heuristics.

While our primary focus was limited to relevance and usefulness, the proposed experimental design can be extended to other aspects of TDSs evaluation. Moreover, our findings may be task- or dataset-specific, prompting the need for further investigation into their generalizability. As to future work, we aspire to enhance the robustness of our findings by conducting studies on larger-scale datasets. In addition following previous work by Kazai et al. (2012, 2013), we would also want to understand the effect of annotator background: experience of interacting with conversational system or prior experience in doing the annotation task on label consistency for TDSs.

5 Related Work

We review related work not covered in the paper so far. Several user-centric dialogue evaluation metrics (Ghazarian et al., 2019; Huang et al., 2020; Mehri and Eskenazi, 2020) have been proposed. For TDSs, high-level dimensions such as user satisfaction (Al-Maskari et al., 2007; Kiseleva et al., 2016) and fine-grained metrics such as relevance and interestingness (Siro et al., 2022) have gained interest. Due to the ineffectiveness of standard evaluation metrics such as ROUGE (Lin, 2004), BLEU (Papineni et al., 2002), which show poor correlation with human judgments (Deriu et al., 2021), a significant amount of research on these metrics relies on crowdsourcing dialogue evaluation labels to improve correlation with actual user ratings. Crowdsourcing ground-truth labels has gained momentum in information retrieval (IR) for tasks like search relevance evaluation (Alonso et al., 2008) and measuring user satisfaction in TDS. A major challenge is ensuring quality and consistency of crowdsourced labels. Task design and annotators' behavioral features and demographics can affect the quality of the collected labels (Hube et al., 2019; Kazai et al., 2012; Pei et al., 2021). Kazai et al. (2013) examine how effort and incentive influence the quality of labels provided by assessors when making relevance judgments. Other factors such as judgment scale (Novikova et al., 2018; Roitero et al., 2021), annotator background (Kazai et al., 2011b; Roitero et al., 2020), and annotators' demographics (Difallah et al., 2018) have also been studied. Most studies focus on search systems, not dialogue systems. Closer to our work, Santhanam et al. (2020) study the effect of cognitive bias in the evaluation of dialogue systems. Providing an anchor to annotators introduces anchoring bias, where annotators' ratings are close to the anchor's numerical value. Like Santhanam et al. (2020), we focus on the effect of task design on the evaluation of TDSs. In particular, we investigate how the amount and type of dialogue context provided to annotators affect the quality and consistency of evaluation labels and the annotator experience during the evaluation task.

6 Conclusion

In this work, we investigated the impact of varying the dialogue context size and type on crowdsourced evaluation labels. In particular we crowdsourced evaluation labels for two aspects: *relevance* and *usefulness*. Our findings reveal that optimal context is dependent on the aspect under evaluation. For relevance annotators tend to agree more on a label when they have access to the whole dialogue context. However this does not hold for the usefulness aspect where we witness high annotator agreement when partial context is available. We show that a simple approach like providing an automatically generated user need through heuristics without revealing the entire dialogue can consistently increase annotator agreement across the two aspects. This implies that we can rely on automatic methods such as the use of LLMs to improve the productivity of the crowdworkers by reducing the amount of dialogue they have to read before evaluating the current response.

This study contributes towards how LLMs can be integrated in the annotation process to ensure quality labels from the crowdworkers. In this work we used GPT-4 API which is not open source. For future work we will explore the use of open-source LLMs, like Llama-chat (Touvron et al., 2023), to facilitate a more transparent and reproducible experimental framework.

Limitations

In this work, we dived into the effect of task design on crowdsourced evaluation labels, specifically the amount and type of context available. Nonetheless our study faces some limitations: the absence of actual user ratings hinders us from claiming an optimal strategy for presenting previous dialogue history. Despite this limitation, we highlight the noteworthy observation of high label consistency in C_7 for relevance and C_3 for usefulness aspect, which served as our basis for comparison. It is crucial to note that our study is exploratory in nature and thus may be data or task specific. To ensure the applicability and generalizability of our findings, it is imperative to undertake further investigations to ascertain the extent to which these findings can be extrapolated across different tasks and datasets.

Ethical Considerations

Anotator diversity

All participants in this research were master workers recruited exclusively from the United States through Amazon Mechanical Turk (MTurk). While this selection ensured a level of language proficiency and familiarity with the context, it is crucial to note that the findings of this study may not generalize universally due to the specific demographic representation. The restriction to U.S.-based annotators may introduce a limitation in terms of cultural diversity and global perspectives, influencing the external validity of the study.

Annotator bias

Despite the provision of detailed instructions and examples to annotators, potential biases may still arise during the evaluation process due to the diverse backgrounds of the annotators. Cultural biases may be more pronounced if annotators from different cultural backgrounds interpret movie preferences, relevance, or usefulness in divergent ways. Subjective biases may also be influenced by the diverse interpretations of guidelines, as individuals from different backgrounds may have distinct views on dimensions like "relevance" or "usefulness."

To mitigate these potential biases, continuous monitoring and feedback mechanisms were incorporated into the study design. Additionally, the study refrained from disclosing the specific research angle to annotators to prevent potential biases related to the research objectives.

A Appendix

In this section we provide supplementary materials used to support our main paper. These materials include: experimental conditions elaborated in Section A.1, quality control measures undertaken to ensure high quality crowdsourced labels and generated supplementary context in Section A.2 and the prompts used to generate the supplementary context in Section A.3. In Section A.4 we include the annotation instructions and screen dumps of our annotation task. Section A.5 shows sample supplementary context generated by GPT-4.

A.1 Experimental conditions

We list the experimental conditions used for our crowdsource experiments in Table 3.

A.2 Data quality control

Generated user information need and summary. To address the potential hallucination of LLMs (Chang et al., 2023), we implemented a quality control process for the generated user information needs and summaries, ensuring their coherence and factual accuracy. We automatically cross-reference the movies mentioned in both the input dialogues and the summaries. A summary must contain at least two-thirds of the movies mentioned in the input dialogue to be considered valid. If this criterion is not met, the summary is discarded, and a new one is generated following the specified prompt requirements. In total, we discarded and regenerated 15 dialogue summaries. To further ensure coherence, we randomly sampled 30% of the generated summaries and information needs. The authors reviewed them to confirm their coherence and alignment with the information presented in the input dialogue. This process enhanced the quality and reliability of the generated content.

Crowdsourced labels. To ensure a high quality of the collected data, we incorporated attention-checking questions into the HIT. Annotators were required to specify the number of utterances in the dialogues they were evaluating and to identify the last movie mentioned in the system response being evaluated. 10% of the HITs were rejected and returned back to collect new labels. In total, we gathered 1440 data samples from the crowdsourcing task, spanning six variations for relevance and usefulness. We employed majority voting to establish the final relevance and usefulness dialogue label.

A.3 Prompts

In Table 4 we show the final prompts used to generate the user information and dialogue summary with GPT-4.

A.4 Annotation instructions and screen dumps

Table 5 details the annotation instructions for the relevance and usefulness evaluations. In Figure 5 and 6 we show the annotation interface used for Phase 1 and Phase 2, respectively.

A.5 Sample supplementary context

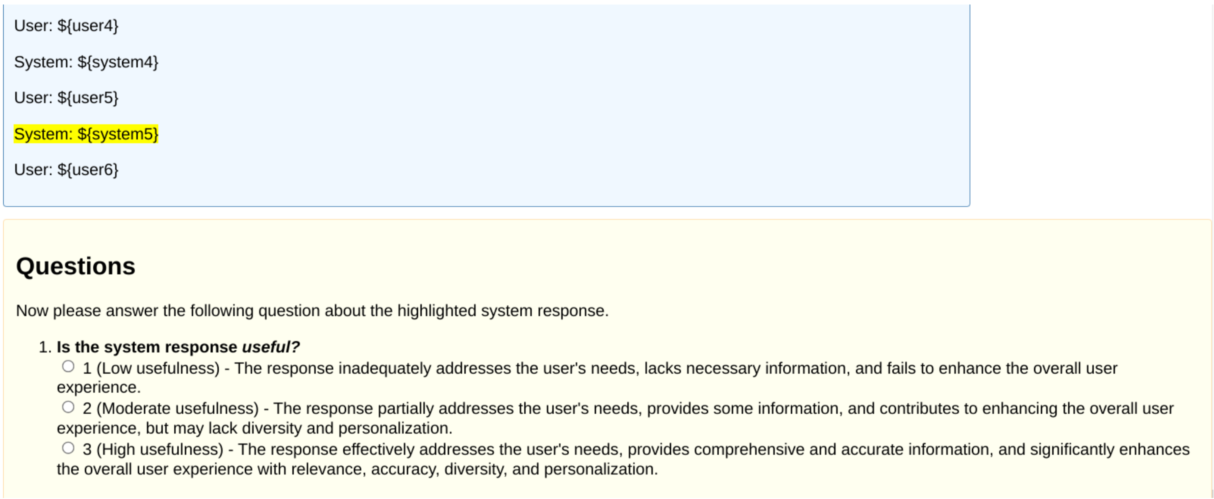
In Table 6 we show sample user information need and summary generated by GPT-4.

Table 3: Descriptions of the experimental setups used for the crowdsourcing experiments with corresponding relevance and usefulness labels. Unlike relevance, usefulness includes the user's next utterance as feedback. A "turn" denotes a user-system exchange.

Variations	Description
C_0	Current turn with no previous dialogue context
C_3	Current turn with three system-user utterances as previous context
C_7	Current turn with 7 user-system utterances as previous context
C_0-llm	Current turn with an LLM-generated user information need as dialogue context
C_0-heu	Current turn with a heuristically generated user information need as dialogue context
C_0-sum	Current turn with a dialogue summary as dialogue context

Table 4: Prompts used to generate the supplementary context; user information need and dialogue summary with GPT-4.

Dialogue summary prompt
Below you are provided with dialogues between a user and the system about movie recommendations. Generate a complete short and informative summary extractively which is half the length of the dialogue.
User information need prompt
Given the following user and system dialogue in a movie recommendation conversation, generate a concise user's goal in a natural manner. State only the goal without extra text. Start the sentence with "the user wants."



User: ${user4}

System: ${system4}

User: ${user5}

System: ${system5}

User: ${user6}

Questions

Now please answer the following question about the highlighted system response.

1. **Is the system response *useful?***
   - ○ 1 (Low usefulness) - The response inadequately addresses the user's needs, lacks necessary information, and fails to enhance the overall user experience.
   - ○ 2 (Moderate usefulness) - The response partially addresses the user's needs, provides some information, and contributes to enhancing the overall user experience, but may lack diversity and personalization.
   - ○ 3 (High usefulness) - The response effectively addresses the user's needs, provides comprehensive and accurate information, and significantly enhances the overall user experience with relevance, accuracy, diversity, and personalization.

Figure 5: Annotation interface for phase 1 when evaluating response usefulness for C_3

Read the dialogue below carefully and answer the follow up question.

User: ${user4}

User: ${system4}

User: ${user5}

System: ${system5}

User: ${user6}

Summary: ${summary}

Figure 6: Annotation interface for phase 2 when evaluating response usefulness with supplementary context

Table 5: Annotation instructions provided to the annotators for relevance evaluation. The instructions are the same for usefulness apart from the aspect being evaluated.

Introduction
Thank you for helping us out! Below we explain everything in full detail. Please make sure to read the instructions carefully.
Purpose
The aim of this survey is to evaluate the quality of a system's response. We want to evaluate the dialogue system's performance and gather insights for improvements. We will ask you to evaluate the system response on one metric, that we will discuss in more detail below.
Scenario Outline
Imagine you are evaluating a dialogue system that generates a response to user queries. Your task is to assess the response based on relevance. We will provide examples and detailed explanations of this criteria below.
Task
In each HIT, you will be presented with a dialogue chunk. Your task is to evaluate the last system response based on the given criteria. Please review the explanations and examples for the criteria to ensure your understanding before proceeding with the evaluation. Keeping the scenario that was outlined above in mind, we would like to ask you to judge the system response on relevance.

Table 6: Sample dialogue summaries as supplementary context generated by GPT-4.

Dialogue 1
User inquires about a good family movie recommendation similar to "Real Steel (2011)" or "The Lego Movie (2014)". System recommends "Super (2010)", an action-comedy about a regular guy who becomes a self-made superhero, describing it as hilarious and entertaining. The user shows interest in this recommendation.
Dialogue 2
The user asked for coming-of-age movie recommendations and mentioned they enjoyed "My Girl (1991)" and "Lucas (1986)". The system suggested watching "The Spectacular Now (2013)", a film where Shailene Woodley stars as a character who forms a bond with a troubled classmate.
Dialogue 3
User seeks a dramatic love story to watch. System recommends "The Notebook (2004)", but the user has watched it, as well as "Titanic (1997)". Both films are favored by the user; they desire to watch something new.
Dialogue 4
The user requests animated movie recommendations following their enjoyment of "The Incredibles (2004)". The system suggests other movies, including "Monsters, Inc. (2001)" and its sequel "Monsters University (2013)", which the user approves. The conversation pivots to the topic of successful sequels, citing "Toy Story 3 (2010)" as an example despite the user's disagreement, favoring the original movie, "Toy Story (1995)".
Dialogue 5
The user wants to find a thrilling crime movie like "Thor: Ragnarok (2017)" for their weekend. The system suggested they watch "The Snowman (2017)" but the user declined. However, the system then gave another recommendation, "First Kill (2001)".

Matching Varying-Length Texts via Topic-Informed and Decoupled Sentence Embeddings

College of Computer Science, Zhejiang University
{xixi.zxx, guchunbin, jiexin, bjj, haishuai.wang}@zju.edu.cn

Abstract

Measuring semantic similarity between texts is a crucial task in natural language processing. While existing semantic text matching focuses on pairs of similar-length sequences, matching texts with non-comparable lengths has broader applications in specific domains, such as comparing professional document summaries and content. Current approaches struggle with text pairs of non-comparable lengths due to truncation issues. To address this, we split texts into natural sentences and decouple sentence representations using supervised contrastive learning (SCL). Meanwhile, we adopt the embedded topic model (ETM) for specific domain data. Our experiments demonstrate the effectiveness of our model, based on decoupled and topic-informed sentence embeddings, in matching texts of significantly different lengths across three well-studied datasets.

1 Introduction

Text matching is an important research area in natural language processing (NLP) applications such as information retrieval, natural language inference, and question answering. However, many text-matching approaches assume that the texts being compared have similar lengths (Gong et al., 2018; Zhou et al., 2020; Zhang et al., 2021a; Zou et al., 2022), and most pre-trained models, such as BERT (Devlin et al., 2019), focus on learning short sequences and are inadequate to represent complex domain-specific documents. Large language models (LLM) can directly process longer texts but require increasingly extensive training resources (Qin et al., 2023), which has evident limitations in some practical application scenarios.

A natural way for humans to deal with long texts is to break them down into smaller text segments before processing them (Nguyen et al., 2023). Inspired by this, for a varying-length text-matching task, we can split the two texts into natural sentences and put the sentences of the two texts into different sets. The motivation of our approach is: 1) If these two texts do not match, then their respective sets of sentences can be considered to belong to different classes. Therefore, the sentence points belonging to the same class should be close in their representation space, while the points from different classes should be further apart. 2) If two texts are semantically similar and consistent, the topics of the two texts should match. Accordingly, we present an effective method for varying-length text-matching with **T**opic-informed and **D**ecoupled sentence **E**mbeddings (TDE), as shown in Figure 1 and described in Section 2. First, we segment the text into sentences and utilize a state-of-the-art pre-trained model's transformer encoder to convert them into embedding points by extracting the last hidden state. We then employ SCL to optimize class-wise relations in the embedding space of sentence representations. Meanwhile, we discover the topic embeddings of the corpus by ETM (Dieng et al., 2020) and calculate the text embeddings with topic information. Finally, we concatenate the SCL-optimized and the topic-informed embeddings to predict scores for varying-length text matching.

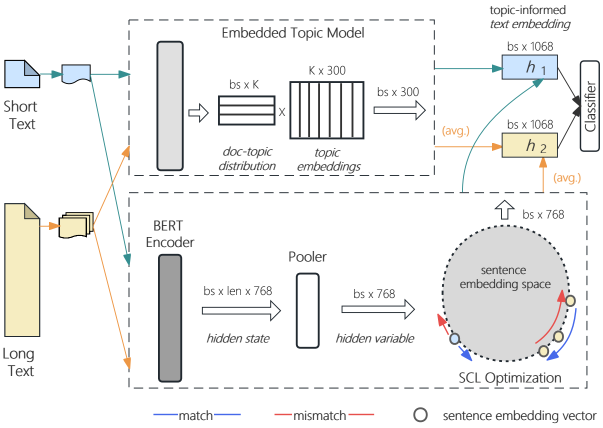

Figure 1: Architecture overview of TDE.

Two related works, the hidden topic comparison

method (HT) (Gong et al., 2018) and the unsupervised concept generation network (CGNet) (Zhang et al., 2021a), share similarities with our approach. HT extracts hidden topics and compares documents with varying lengths, while CGNet relies on local phrase features and corpus-level concept features for matching. In comparison, our method is simpler, more effective, and explainable. Moreover, our model can leverage the continuous evolution of LLMs to enhance performance.

2 Methodology

2.1 Topic-Informed Sentence Embedding

Truncating lengthy texts leads to information loss and diminishes the efficacy of text representations. To address the high space/time complexity in varying-length text matching, our proposed TDE, illustrated in Figure 1, first splits the two texts into sentences and organizes them into separate sets. Then, we employ a transformer encoder to produce fixed-sized sentence embedding vectors by extracting the last hidden state of the transformer encoder output. However, generating these embeddings can be challenging, as universal pre-trained models typically lack highly domain-specific information on real-world scenario data.

To address the problem, we leverage ETM because, first, as a neural topic model, ETM is useful for dealing with domain-specific data (Peinelt et al., 2020) and is also more suitable for joint training with other neural networks than other traditional models. Second, ETM treats both vocabulary words and topics as embeddings in a particular embedding space, which is useful when words of some specific domain are unknown. So, we follow the optimization objective ($\mathcal{L}_{etm}$) in ETM literature to calculate the topic-informed sentence embeddings by learning the document-topic distribution and topic embeddings. Then, we concatenate the topic-informed sentence embedding and the encoded output of BERT to get the full sentence representation.

At last, we calculate the average embedding of the vectors of each sentence set to obtain the text embedding (h_1 or h_2) for the original text corresponding to that set. A classifier layer takes the two average vectors as inputs and aggregates them into a single vector $m = [h_1; h_2; h_1 - h_2; h_1 \circ h_2]$ before it predicts a final matching probability with m (Mou et al., 2016). At last, a loss (e.g., cross-entropy) function is used to optimize the whole model with the predicted probability and the ground truth ($\circ$ denotes element-wise product and semicolons denote column vector concatenation).

2.2 Supervised Contrastive Optimization

After the classifier outputs the predicted probabilities of two classes through a Softmax operation, the usual cross-entropy (CE) loss ($\mathcal{L}_{ce}$) is adopted in a common Siamese text-matching network to optimize the whole model:

$$\mathcal{L}_{ce} = -\sum_{i} y_i log(\hat{y_i}), \tag{1}$$

where y_i is the ground-truth label of sample i and $\hat{y_i}$ is the sample's prediction label. However, the CE loss is unsuitable for optimizing varying-length text matching, as it is typically used for final representations, and the task-specific nature of varying-length texts can hinder its effectiveness for long texts. The CE loss exhibits shortcomings, including vulnerability to noisy labels (Zhang and Sabuncu, 2018) and potential poor margins (Elsayed et al., 2018), resulting in reduced generalization performance in varying-length text matching. We address this by dividing two input texts into multiple sentences and organizing them into sets, recognizing the matching process as a many-to-many relationship akin to a set matching problem.

Recently, contrastive learning has become the most popular self-supervised paradigm and has achieved remarkable success (Wang et al., 2024; Chen et al., 2020a; Henaff, 2020; Chen et al., 2020b; Wu et al., 2021). It is based on defining positive and negative pairs by which it aims to pull together the samples in the positive pair while pushing away the samples in the negative pair. With the development of contrastive learning, a few loss functions are proposed to improve the discrimination power, such as triplet loss (Weinberger et al., 2006) and N-pair loss (Sohn, 2016). In particular, supervised contrastive learning is proposed (Khosla et al., 2020) and used to effectively leverage label information in classifications (Nasiri and Hu, 2021) and pre-trained model fine-tuning (Zhang et al., 2021b), considering many positives and many negatives for each anchor. It is treated as a generalization of both the triplet and N-pair losses. The SCL method contrasts the set of all samples from the same class as positives against the negatives from the remainder of one batch.

Our TDE model is well-suited for optimization through SCL, effectively optimizing in-class and many-to-many sentence representations in embedding space. This approach complements the limitations of the CE optimization method, specifically addressing its local optimization deficiencies. Therefore, we introduce the supervised contrastive (SC) loss with labeled data for optimizing the Siamese text-matching network:

$$\mathcal{L}_{sc} = -\frac{1}{n|P_i|}\sum_{i=1}^{n}\sum_{z_j \in P_i}\log\frac{e^{(z_i^\top z_j/\tau)}}{\sum_{z_k \in A_i} e^{(z_i^\top z_k/\tau)}}\ , \tag{2}$$

where τ is the temperature, P_i denotes the positive pairs, and A_i denotes the full pair set of the anchor z_i. As shown in Equation 2, the contrastive loss with a small τ tends to make the embedding distribution more uniform (Wang and Isola, 2020). On the other hand, contrastive loss with a large temperature is less sensitive to the hard negative samples (Wang and Liu, 2021). As the temperature τ controls the strength of penalties on hard negative samples, we follow the previous literature (Gunel et al., 2021) and choose the τ values based on the hardness of negative samples to tune performance.

With supervised contrastive optimization, our TDE model has a hybrid loss function consisting of an original cross-entropy and a supervised contrastive loss: $\mathcal{L}_{OPT} = \mathcal{L}_{etm} + \lambda_1 \cdot \mathcal{L}_{sc} + \lambda_2 \cdot \mathcal{L}_{ce}$, where λ_i is a hyperparameter. According to our experiments, hybrid optimization gives a higher accuracy than training by these losses alone.

3 Experiments

3.1 Datasets

(1) Concept-Projects[1] (Gong et al., 2018) is designed for evaluating text-matching algorithms with varying-length inputs. A "Concept" represents a science curriculum summarizing a "Project," which is a science project document. To assess if a project aligns with a concept, individuals must determine the match. Concepts are typically brief, around 50 words, while project documents are lengthy, exceeding 1000 words. The dataset comprises 537 project-concept pairs annotated by contributors based on human judgment of matching.

(2) CL-SciSumm 2017[2]**.** This dataset (Prasad, 2017) contains 494 Computational Linguistics research papers in 30 categories. For each category, the dataset provides one reference paper and around 10 citing papers. At the same time, the dataset also provides a corresponding human-created summary for each reference paper. Following the literature (Zhang et al., 2021a), we label the reference paper as the positive candidate and all the citing papers as negative candidates when conducting paper-retrieval experiments by the summary. The matching task on this dataset is to retrieve and rank papers by a summary, which takes its corresponding reference paper as the top-1 ground truth.

(3) CL-SciSumm 2018[3]**.** This dataset (Jaidka et al., 2018) contains 605 research papers in 40 categories. For each category, the dataset provides one reference paper and at least 10 citing papers that cite this reference paper. At the same time, the dataset also provides a corresponding human-created summary for each reference paper. Following the literature (Zhang et al., 2021a), when conducting paper-retrieval experiments by a summary, we randomly take 5 citing papers from the same category as this summary to label them as positive candidates and randomly take 15 citing papers that do not belong to the same category as the summary to label them as negative candidates. The matching task on this dataset is to retrieve and rank papers by the summary, which takes the citing papers from the same category as this summary as the ground truth.

We follow the same splitting settings from the original literature of all three datasets for a fair comparison with all baseline models.

3.2 Evaluation Metrics

We evaluate three datasets with different metrics:

- For the Concept-Project, we follow the unified classification evaluation method (Gong et al., 2018) to evaluate the matching-prediction labels of texts by calculating a matching threshold using the similarity scores or relative distances of all text vectors in the model's pretrained representation space from the training data.

- For the CL-SciSumm 2017, we use popular ranking evaluation metrics from the literature, which include: (i) Precision@1: The proportion of predictions where the correct answer appears in the top-1 location of the retrieval result. (ii) Mean Reciprocal Rank (MRR). This ranking metric calculates the location of the

[2] https://github.com/animeshprasad/clscisumm2017

[3] https://github.com/WING-NUS/scisumm-corpus

Method	Concept-Project Matching				Summary-Reference Retrieval		
	Acc.	Prec.	Recall	F1	Prec@1	NDCG	MRR
TF-IDF	53.8	54.0	**99.3**	70.0	86.7	93.8	91.8
Doc2Vec (Le and Mikolov, 2014)	90.5	86.2	96.1	90.9	65.2	77.2	71.5
WMD (Kusner et al., 2015)	68.5	65.6	88.0	75.2	86.7	95.1	93.3
HT (Gong et al., 2018)	80.1	80.7	83.2	81.9	36.7	66.1	55.5
SBERT (Reimers and Gurevych, 2019)	75.1	78.8	96.4	83.6	65.1	72.4	68.4
RE2 (Yang et al., 2019)	86.6	88.8	92.5	88.9	82.1	85.0	83.0
WRD (Yokoi et al., 2020)	84.9	83.3	89.2	86.2	53.3	77.3	70.1
CGNet (Zhang et al., 2021a)	87.2	86.5	90.4	88.4	90.0	95.9	94.4
TDE w/o ETM (ours)	94.1	97.8	95.2	94.4	88.7	94.7	94.0
TDE (ours)	**94.3**	**98.1**	95.8	**94.6**	**90.2**	**96.9**	**95.2**

Table 1: For Concept-Project Matching, TDE achieves the best the metric scores on accuracy, precision, and F1 score, which are 3.8%, 9.3%, and 3.7% better than the second-best models. For Summary-Reference Retrieval, TDE achieves the best metric scores on Prec@1, NDCG, and MRR, which are 0.2%, 1.0%, and 0.8% better than the second-best models.

first correct answer in the retrieval result. The higher the position of the first correct answer, the greater the MRR value, represented as MRR=$\frac{1}{N}\sum_{i=1}^{N}\frac{1}{rank_i}$ for multiple queries N, where $\frac{1}{rank_i}$ is the reciprocal rank for a single query. (iii) Normalized Discounted Cumulative Gain[4] (NDCG): This ranking metric compares the relevance of the answers returned in the retrieval to the relevance of the answers in ideal order. NDCG is the quotient of the actual DCG and the ideal DCG.

- For the CL-Scisumm 2018, we use Precision@k as the retrieval metric to calculate the proportion of predictions where the correct answer appears in the top-k locations of the retrieval results. We tune k from 1 to 5 in our experiments.

3.3 Baseline Methods

We use eight strong baselines in experiments of matching varying-length texts: TF-IDF, Doc2Vec (Le and Mikolov, 2014), Word Movers' Distance (WMD) (Kusner et al., 2015), Hidden Topics (HT) (Gong et al., 2018), RE2 (Yang et al., 2019), Sentence-BERT (SBERT) (Reimers and Gurevych, 2019), Word Rotator's Distance (WRD) (Yokoi et al., 2020), and CGNet (Zhang et al., 2021a). We follow the same data pre-processing rules and use the original implementation methods of baselines. We did twenty experiments on three datasets to observe those experiments' average results.

3.4 Experimental Results and Analysis

Table 1 and Figure 2 show that our proposed TDE performs better than the baseline models in matching and retrieval performance on three well-studied datasets. As shown in Table 1, there is no obvious improvement with ETM enabled on the Concept-Project Matching dataset because it is from a more general domain and is not beneficial for ETM optimization with the universal pre-training model (BERT). For Summary-Reference Retrieval, the performance improvement is limited before ETM is enabled. That is because the universal pre-training model lacks domain-specific information necessary for text representation encoding of this dataset, a professional field dataset from linguistics papers. After ETM was enabled, there were noticeable performance enhancements, illustrating the impor-

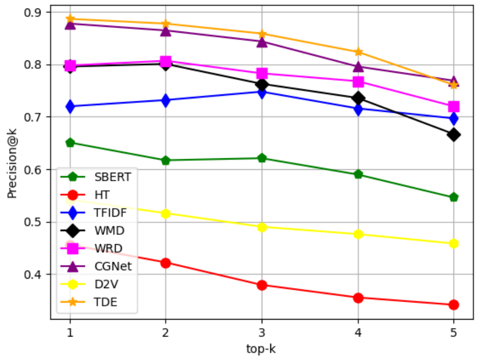

Figure 2: For Summary-Citance Retrieval, we adopt Precision@k as the experiment metric and tune k between 1 and 5. The experimental results show that our approach achieves the best performance in the baseline models when k is from 1 to 4.

Figure 3: Parameter analysis of latent topic number.

tance of the ETM module in generic matching tasks with domain-specific cases.

We investigate the impact of the key hyper-parameter, latent topic number (K, as shown in Figure 1), in the three varying-length matching tasks. The three subfigures in Figure 3 show the experimental results using various topic number settings (from 20 to 200) on three datasets: (a) Concept-Project, (b) Summary-Reference, and (c) Summary-Citance, respectively. Figure 3 (a) shows that both Accuracy and F1 scores are improved until the number of topics increases to 100 in the Concept-Project matching task. After the topic number reaches 100, the performance starts to degrade, which indicates that the topic number has an optimal experimental value. For the other two tasks (Summary-Reference Retrieval and Summary-Citance Retrieval), the optimal values are 100 and 50 in our experiments, as illustrated in Figure 3 (b) and Figure 3 (c), respectively. Therefore, we conclude that setting the topic number too small or too large will lead to semantic confusion in each corresponding latent variable and performance degradation on the related dataset. A suitable setting of the latent topic number tends to make the representations better for the matching process. Therefore, in the performance comparison to the baseline models, we take the experimental results when K is set as 100, 100, and 50 for the three datasets, respectively, because of the optimal performance with these settings experimentally.

Our ablation experiments highlight the impact of varying temperature coefficients (τ) of the supervised contrastive loss on overall performance. The results in Table 2 indicate that adjusting some temperature values has negligible performance improvement, but notable gains are observed with specific τ values. This flexibility in tuning performance through supervised contrast learning allows for finding optimal temperature values tailored to different datasets. So, the ablation tests show the crucial role of supervised contrast learning in our task and its contribution to our method.

4 Conclusion

We present a novel and effective method for matching texts of varying lengths. We split long texts into sentences and encode them with the advanced transformer. Leveraging the in-class and many-to-many optimization characteristics of supervised contrastive learning and the domain-specific ability of embedded topic modeling, our model demonstrates superiority against the baseline models on three real-world datasets in both effectiveness and explainability of varying-length text matching.

Limitations

The efficacy of our method may be influenced by the quality of the natural sentences undergoing segmentation. In our experiments, we observed that some sentences generated through segmentation lack essential semantic information. Therefore, incorporating these sentences in contrastive learning training could potentially have a negative impact on the final quality of sentence representations and model performance. We anticipate that refining the pre-processed sentences will lead to further improvements in the existing framework in the future.

Abstract

In this work, we (1) introduce **Curriculum Instruction Tuning**, (2) explore the potential advantages of employing diverse curriculum strategies, and (3) delineate a synthetic instruction-response generation framework that complements our theoretical approach. Distinct from the existing instruction tuning dataset, our generation pipeline is systematically structured to emulate the sequential and orderly characteristic of human learning. Additionally, we describe a methodology for generating instruction-response datasets that extensively span the various stages of human education, from middle school through the graduate level, utilizing educational subject catalogs.

Before training, we meticulously organize the instruction data to ensure that questions escalate in difficulty regarding (A) the subject matter and (B) the intricacy of the instructions. The findings of our study reveal that **substantial improvements in performance can be achieved through the mere application of curriculum ordering to instruction data**—achieving gains of +4.76 on TruthfulQA, +2.98 on MMLU, +2.8 on OpenbookQA, and +1.28 on ARC-hard—compared to random shuffling. This enhancement is achieved without incurring additional computational expenses. Through comprehensive experimentation, we observe that the advantages of our proposed method are consistently evident across nine benchmarks.

Dataset	**Training Scheme** (Curriculum)	**World Knowledge**	**Commons. Reasoning**
CORGI	**Human Curriculum**	**+4.06**	**+2.30**
CORGI	Random Shuffle	+0.81	+0.57
Vicuna	Random Shuffle	+2.17	+0.37
WizardLM	Random Shuffle	+0.11	+0.46
LLaMA 2 13B (Base LLM)		52.45	63.37

Table 1: Human curriculum-inspired strategies (which we name interleaved curriculum) boost macroscopic LLM performance. The numbers are averages of performance improvements on LLaMA 2 13B after instruction tuning with respective datasets. World Knowledge: MMLU, TruthfulQA, TriviaQA, Commonsense Reasoning: OpenBookQA, ARC, PIQA, CommonsenseQA.

1 Introduction

In contemporary times, state-of-the-art instruction-following models like ChatGPT and GPT-4 (OpenAI, 2023) have drawn attention owing to their unparalleled proficiency and versatility. A notable advancement over previous generation large language models (LLMs), like GPT-3 (Brown et al., 2020), is their impressive capability to adeptly comprehend and act upon human instructions, where this *alignment* is attributed to the additional instruction tuning process (Wei et al., 2021). As these models continue to display progress, numerous research studies have offered many intriguing insights on instruction tuning through their endeavors to make models follow more complex instructions and enhance performance across a broad spectrum of tasks. For instance, various studies emphasize the significant influence of instruction data quality (Touvron et al., 2023; Zhou et al., 2023) and the incorporation of diverse instruction formats (Wang et al., 2023b; Xu et al., 2023) on overall performance. Furthermore, including step-by-step reasoning (Wei et al., 2022) within the responses has been demonstrated to improve performance and elevate the reasoning ability of the language model (Mukherjee et al., 2023). While recent research has offered valuable insights into optimizing data formats to a better form, exploring how to efficiently order and collect such data in a more grounded, trackable manner remains elusive, often relying on randomized or undirected diversity as the prevailing norm. Ensuring efficiency in the instruction tuning process is important as extended instruction tuning undermines the inherent capability of LLM.

Figure 1: Overview of our educational framework. We create a dataset based on a continuum from secondary school to grad school, extracting multiple concepts from each course. For every concept, we formulate 19 questions of varied cognitive levels using Bloom's taxonomy.

Meanwhile, since the architectures of neural network innately emulates the human brain (Han et al., 2021), adopting a learning process analogous to human education — a highly organized approach, progressively refined and empirically proven effective over centuries — constitutes a logically coherent and methodologically robust learning strategy for the machine as well (Bengio et al., 2009). While many studies within the realm of curriculum learning have demonstrated the efficacy of this hypothesis in reaching faster convergence and finding better local minima, these investigations have predominantly offered a nuanced *micro view*, mostly confined to a specific task. To draw an educational analogy, such studies are akin to observing how students behave when learning a particular subject within the vast curricula.

Venturing beyond the niche perspective, our study aims to explore a comprehensive, holistic viewpoint on curriculum learning in the knowledge domain. Specifically, we conceptualize the language model as a middle school student about to progressively acquire intellectual knowledge from educational institutions such as high schools and universities over the coming decades. And attempt to guide the student by the fundamental principle of learning *from simple to complex* (Sweller, 1988; Bloom et al., 1956) based on two primary distinct dimensions: (1) Educational Stage: sequentially mastering elementary to intricate concepts and (2) Cognitive Hierarchy: gradually deepening the understanding of each concept. For instance, in mathematics, humans initiate the learning process with the fundamental concept of addition, gradually progressing to more complex concepts like subtraction and multiplication by exploiting previously learned concepts to ease the learning (Bengio et al., 2009). Furthermore, when humans learn multiplication, the initial stage usually involves rote memorization of the *times tables*, progressively deepening the comprehension of the concept to the extent where we expand its application to real-world situations. This cognitive process enables the human intellect to traverse diverse fields, aligning *massively multi-domain knowledge*.

To systematically explore the potential merits of the interplay between educational curriculum and human cognitive process, we curated a massive synthetic knowledge instruction dataset and its training method called CORGI (Cognitively rigorous instructions). As illustrated in Figure 1, we initially establish a continuous progression across educational stages by integrating concrete educational frameworks provided by international secondary education curricula (i.e., Cambridge IGCSE) and a combination of several university catalogs. Subsequently, using a teacher model like ChatGPT, we extracted various topics covered in every course at each educational level. Based on the learning objectives in Bloom's taxonomy (Bloom et al., 1956), we crafted a comprehensive set of questions for each topic, with varying degrees of cognitive level. A standout feature of our dataset is its rich meta-information for each data point, facilitating the generation of coherent and contextually meaningful training data sequences.

As shown in Table 1, we found compelling empirical evidence from CORGI that our cognitive pro-

These characteristics allow the application of pedagogically motivated curriculum learning strategies, which we discuss further in Sections 2.2 and 3.3.

gressive training inspired by the human curriculum yields significant advantages over randomized training. Notably, when CORGI is subjected to random training, its performance is comparable to other instruction datasets such as WizardLM (Xu et al., 2023) and Vicuna (Chiang et al., 2023). However, by simply optimizing the sequence of learning data, we observed a roughly 3 points improvement in the knowledge benchmark (i.e., MMLU), surpassing both WizardLM and Vicuna with a considerably smaller dataset size (66K). Moreover, this improvement is not limited to the knowledge domain and extends beyond the broader benchmarks, including +1.73 in commonsense reasoning benchmarks (i.e., OpenBookQA, ARC, PIQA, CommonsenseQA) and +2.37 in language understanding (i.e., HellaSwag, Lambada).

2 CORGI

CORGI is a structured educational model that mimics the educational journey of a student. In this section, we delve into the detailed process of constructing our dataset and efficient training method inspired by the human knowledge acquisition process.

2.1 Dataset Construction

The primary objectives of our dataset are: (1) to encompass the full coverage of knowledge students acquire through their curriculum and (2) to store detailed meta information for each data, enabling the formation of meaningful order. However, constructing such a broad scope of knowledge dataset from scratch can be prohibitively costly or nearly impossible. To overcome this hurdle, we propose an automatic approach to generate synthetic data by utilizing a teacher language model (i.e., ChatGPT). Furthermore, we also utilize real-world educational curricula, such as university catalogs and the Cambridge IGCSE curriculum (refer to Appendix C for more information), as a foundational source when generating synthetic datasets. These curricula cover 45 distinct subjects and provide rich metadata, including educational stage (i.e., secondary, undergraduate, or graduate), subject (e.g., biology, math, etc.), course, and syllabus (i.e., course description), ensuring a broad spectrum of knowledge coverage as well. At a high level, the process of constructing our instruction dataset consists of three steps. (See Appendix B for a graphical illustration with examples.)

2.1.1 Step 1. Extract Concepts from Educational Curricula

This step aims to extract multiple essential academic concepts for each course based on its syllabus. However, the initial syllabus often contains unnecessary details, such as administrative jargon and scheduling, with limited content about the actual coverage of the course. Accordingly, we employ a specialized refinement prompt to convert these descriptions into more substantive, textbook-like variants. Using these enriched versions as a source, we extract fine-grained academically

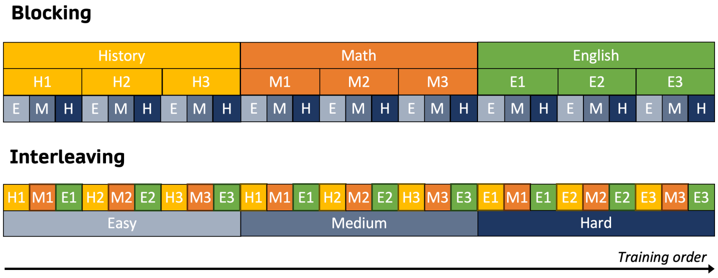

Figure 3: A comparison of two training sequences. Small blocks (e.g., H1, M1) stand for fine-grained concepts per subject. *Blocking* naively stacks hierarchical blocks per subject, while *interleaving* cyclically revisits each subject, adhering to the cognitive hierarchy from Bloom's taxonomy.

meaningful concepts through a concept-generation prompt (specific prompts are stipulated in Appendix E). To achieve maximal diversity and distinction among the selected concepts, we harvested an extensive array of fine-grained concepts and subsequently eliminated any redundancies. Specifically, we employed semantic deduplication utilizing a cosine similarity threshold of 0.67 using the sentence-transformers library model *all-MiniLM-L12-v2* (Reimers and Gurevych, 2019). As a result, we amassed a total of 5.6K fine-grained concepts in 1.8K courses in 45 subjects.

2.1.2 Step 2. Generate Synthetic Instructions

On top of previously collected concepts, we generate actual instruction data based on a systematic educational learning object called Bloom's taxonomy (Bloom et al., 1956; Krathwohl, 2002), which serves as a seminal guide for many educators. This taxonomy is a hierarchical arrangement of six cognitive processes that can be visualized as a pyramid. The lower-order layers consist of relatively simple thinking skills (i.e., Remember, Understand, and Apply), and the upper layers represent more complex cognitive processes (i.e., Analyze, Evaluate, and Create). The progression ensures that learners gather information and learn how to use, analyze, and even create original knowledge.

Exploiting this concept, we produce diverse data for a single concept by giving a detailed object from each cognitive level as instructions to a teacher language model during data generation. Namely, we first build a pre-defined 19 plug-and-play templates leveraging the definition and objectives of the three lower cognitive hierarchies: Remember, Understand, and Apply, as outlined in the original paper (Bloom et al., 1956). (Appendix D summarizes the actual templates with corresponding original definitions.) We focus solely on these three levels because the higher cognitive levels often produce questions with no clear answers and contain biased or subjective content. Utilizing these modular templates and 5.6K concepts from the previous step, we produce 107K cognitive hierarchy datasets. Each query incorporates a random system message (see Appendix E) to elicit comprehensive explanations or rationale for the answer following previous work (Mukherjee et al., 2023).

2.1.3 Step 3. Filter Unclear Instructions

It is important to note that our dataset is synthetic and relies heavily on the teacher language model. This innate dependence occasionally results in inconsistency in the question-answer pairs, which could drastically degrade the performance (Touvron et al., 2023; Zhou et al., 2023). To ensure the quality of our dataset, we employ a third-party tool, Contriever (Izacard et al., 2022), to filter out low-quality data. For each data instance, we gather three distinct passages sourced from Wikipedia, comprising a precise span of 256 words. We then assess the relevance between excerpts and a question using a retrieval-checking prompt, and only those that meet the relevance criteria are included in the final dataset. We also applied some basic string-match rules to remove refusal data containing particular text sequences, like 'As an AI ...'. The Contriever-based method removes about 40$\sim$50% of the instances (30K $\rightarrow$ 15K, 60K $\rightarrow$ 37K, 107K $\rightarrow$ 66K in Figure 7). String-matching accounted for a significantly small percentage, removing 1$\sim$2% of samples containing illegal or unhelpful text.

2.2 Curriculum Instruction Tuning

In sync with our richly annotated dataset, which embodies meta-details such as subject, course, concept, and cognitive hierarchy, we introduce a cognitively-inspired training method to inject knowledge from the dataset efficiently. The primary philosophy of our training paradigm is to

Model	# Data	MMLU	ARC	PIQA	CSQA	OBQA	HellaSwag†

†The default Corgi model uses an interleaved sorting approach as described in Section 2.2.

Table 2: Performances of LLaMA 2 13B based models on 6 different benchmarks.

gradually step towards a genuine understanding of various concepts by following the hierarchical progression in Bloom's taxonomy. When only a single concept is to be learned, one can linearly follow this hierarchy. Yet, as the breadth of knowledge increases, as in our case, there are numerous design choices in determining how to assort these multiple concepts efficiently.

One straightforward way is blocking, which stacks each hierarchical block for each subject. (See Figure 3.) However, numerous studies suggest that interleaving practice, a strategy of mixing different topics, is more helpful to students to incorporate existing knowledge and skills with new ones. Specifically, interleaving helps mitigate the risk of cognitive decay (Luo et al., 2023b), a notable drawback of blocking where previously learned concepts are set aside for long periods. Intriguingly, this phenomenon is also the case in machine learning and is commonly known as catastrophic forgetting (McCloskey and Cohen, 1989). To make the best of the two worlds, our training curriculum traverses a global[1] progression of the cognitive load from Bloom's taxonomy while interleaving different subjects to reinforce retention and understanding. As discussed in the subsequent sections, the proposed arrangement displays superiority on various benchmarks compared to other alternatives, revealing tendencies similar to reference experiments on humans (Taylor and Rohrer, 2010).

3 Experiments

3.1 Setup

This section assesses the performance of Corgi with other open-sourced models across various knowledge-related benchmarks closely aligned with our data domain. Here, we highlight the most important components of our experimental setup.

Baselines. We adopt LLaMA 2 13B models as the primary backbone in the following main experiment. We subsequently instruction-tuned 5 epochs on our dataset, both curriculum-based and non-curriculum-based (naive stacking - blocking) approaches, to take a closer analysis of our framework on two dimensions: the data-centric and curriculum-centric aspects. We selected Vicuna v1.5 (Chiang et al., 2023) and WizardLM v1.2 (Xu et al., 2023) for other competing baselines. These models are also instruction-tuned on LLaMA 2 with different data collection paradigms. Specifically, Vicuna sources a diverse array of real-world user queries from a publicly accessible ChatGPT prompt-sharing platform, while WizardLM utilizes an innovative method termed *Evol-Instruct*, which generates synthetic instructions by formulating progressively challenging questions.

Benchmarks. We evaluated the aforementioned baselines across six different benchmarks: MMLU, ARC, PIQA, CommonsenseQA, OpenbookQA, and HellaSwag[2]. Among these benchmarks, MMLU is closely aligned with our data since MMLU assesses the extensive coverage of educational content, spanning from secondary school to graduate levels, across diverse subjects.

3.2 Results

Table 2 reports the performance of Corgi and other competing methods on 6 benchmarks, where Corgi generally outperforms others with considerably smaller dataset size. Our observations indicate that interleaving, which involves a global progression of cognitive difficulty while revisiting diverse subjects, consistently outperforms block-

---

[1] Term 'global curriculum' is used in the past to describe different strategies. Our definition of global is not analogous to some existing works like Weinshall and Amir (2020)

[2] The detailed descriptions and references of each dataset are stipulated in Appendix A.

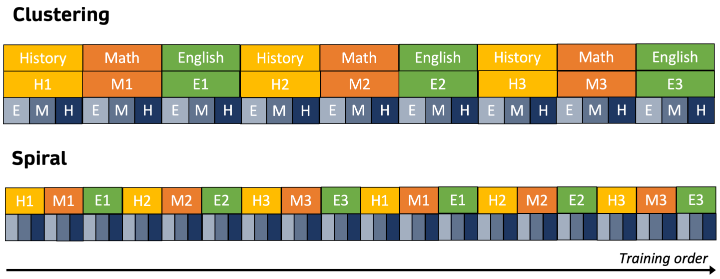

Figure 4: (Continued from Figure 2) **More examples of local progressions**. A comparison of clustering and spiral training sequences. The *clustering* stacks hierarchical blocks for each concept, while the *spiral* cyclically revisits each concept and alternates cognitive difficulty from Bloom's taxonomy.

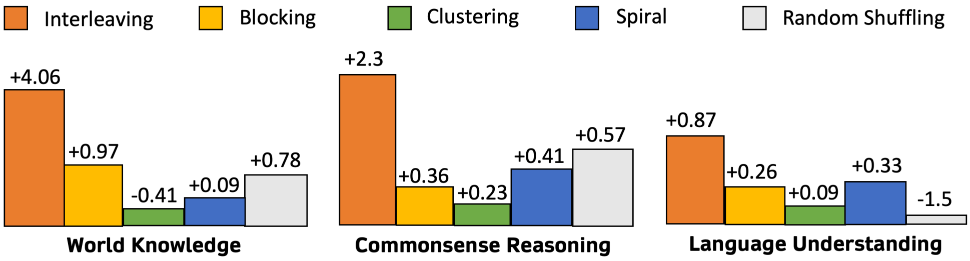

Figure 5: **Local curriculum diminishes performance improvement.** The figure shows a macroscopic, averaged performance comparison of several benchmark improvements with respect to the base model (LLaMA 2 13B) performance. *World Knowledge:* MMLU, TruthfulQA, TriviaQA, *Commonsense Reasoning:* OpenBookQA, ARC, PIQA, CommonsenseQA, *Language Understanding:* HellaSwag, and Lambada. A full breakdown of this chart is given in the Appendix H.

ing, which simply stacks subjects on top of one another in a straightforward manner. Overall, the order in which one presents learning material during instruction tuning can make a big difference in the final performance. When one employs a suitable curriculum, it can improve performance on most major benchmarks, including knowledge, commonsense reasoning, and language understanding (this is further evidenced in Figure 5). In our experiments, CORGI demonstrated notable improvements when subjected to our interleaved curriculum training (ΔMMLU $+0.64 \xrightarrow{\text{intrlvng.}} +2.75$, ΔARC $+0.26 \xrightarrow{\text{intrlvng.}} +2.39$, ΔPIQA $-0.65 \xrightarrow{\text{intrlvng.}} +1.14$, ΔOpenbookQA $+0.60 \xrightarrow{\text{intrlvng.}} +3.8$) compared to naive stacking of concepts. The results demonstrate a notable enhancement, as both interleaving and blocking employ the identical dataset and training configuration, with the only difference being the sequence in which the data is presented.

The reasonable conjecture for such improvements is multifaceted. One salient factor is that instruction tuning is usually done with a limited training time budget compared to pre-training since extensive training can exacerbate drawbacks, potentially diminishing the language model's generalization capabilities. Curriculum learning is a likely solution to this dilemma, which is known to reach convergence faster than random training (Soviany et al., 2022; Wang et al., 2021). Another possible advantage of curriculum learning is its robustness under noisy datasets (Wu et al., 2020). As mentioned earlier, CORGI dataset is innately synthetic and noisy since it is gathered from a teacher model ChatGPT. In Section 3.4, we will provide a comprehensive examination of the adverse effects associated with the presence of noisy data and its relationship with the curriculum.

3.3 Analysis on Curriculum

When training towards multi-domain knowledge, there is more than one way to give structure to the overall instruction tuning process. In this section, we conduct a comparative analysis of various curricula with additional training strategies. From our experiments, we verified two intriguing observations: **1. Not all curricula guarantee transferability to machine training** and **2. Global curricula give large benefits, while local curricula can mislead.**

We separate various curricula into two branches: global curriculum and local curriculum, based on their progression of conceptual and cognitive complexity. To illustrate, the **interleaving** strategy *globally* steps the cognitive load according to Bloom's taxonomy, whereas the **blocking** strat-

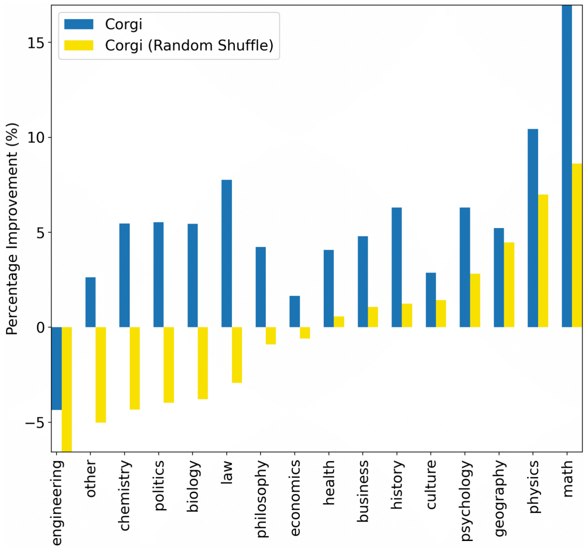

Figure 6: **Interleaved training is more stable than random shuffling** in learning multi-domain concepts. The figure reports the MMLU subject group score improvements on LLaMA 2 13B by learning strategies.

egy *locally* advances from lower to higher cognitive loads, emphasizing the internal organization of concepts within a subject (Gibbons, 2002; Vygotsky, 1978). Incorporating the previously introduced strategies, Figure 4 represents two additional alternative sorting strategies also motivated by educational paradigms: **Clustering** is similar to blocking but is different in that it facilitates the "deep learning" (Warburton, 2003) of a concept while ignoring the intra-subject dependency of concepts. **Spiral** is designed to revisit subjects and concepts at fluctuating cognitive load levels in a repetitive manner (Masters and Gibbs, 2007).

In Figure 5, we further establish that the final performance of an LLM can be significantly impacted by the order in which one presents instruction tuning data. However, this does not mean that any educational science-inspired structured learning paradigm benefits instruction tuning. Depending on the global batch size, the number of difficulty levels available per concept, and the number of concepts per subject (or any other large semantic category), we theorize that most local progressions or structures are destroyed when employing a larger global batch size. This results in a biased training batch. This assertion is substantiated by Figure 6, which shows how a global curriculum, which maintains structure under most larger batch sizes while ensuring that all subjects are covered in every training batch, successfully pushes performance above the random shuffling baseline.

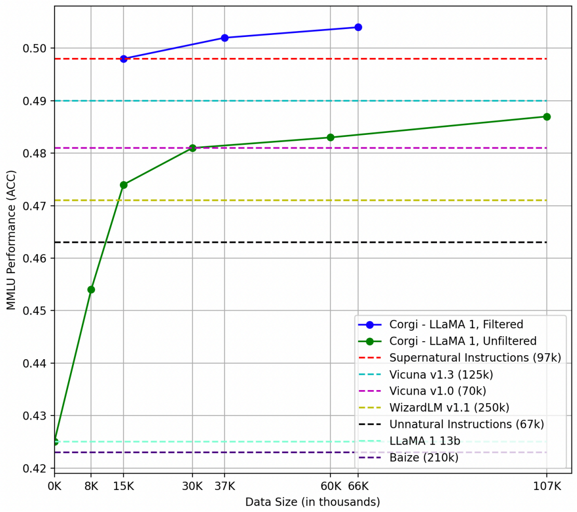

Figure 7: **High-quality filtered data and data curation enable data-efficient performance improvements**. This figure shows tuning results on LLaMA 1 13B. Data sizes are in brackets.

Another noteworthy observation is that the impact of curriculum extends beyond our target domain (i.e., knowledge), and often improves reasoning ability. Recent studies have demonstrated that models trained with specific datasets often experience performance degradation when extrapolated beyond that domain. Specifically, (Wang et al., 2023b) reports that many recent instruction tuning datasets like Supernatural Instructions (Wang et al., 2022) seem to show a trade-off performance relationship between benchmarks, such as MMLU and ARC, of which the latter additionally requires reasoning ability to derive correct answers. While we observe a similar tendency in Vicuna, WizardLM, and random trained CORGI — all show mixed results on MMLU, ARC, OpenBookQA, or HellaSwag — our curriculum-based CORGI notably stands apart and does not suffer from this trade-off.

3.4 Ablation study on LLaMA 1

In this section, we conduct ablation experiments on LLaMA 1 to analyze the impact of specific components. As displayed in Figure 7, our dataset demonstrates scalability, showing better performance with more data quantity. Moreover, our data filtering scheme yields superior performance with a smaller volume of data, which aligns with previous research (Zhou et al., 2023; Touvron et al., 2023) emphasizing the significance of data quality.

Another key observation is that the **negative impacts of this noisy data become more pro-**

nounced as the performance gap between the teacher and student models narrows. For instance, in Figure 7, we can clearly see that models like Vicuna, WizardLM, and CORGI consistently show significant performance improvements across various benchmarks when trained with randomized data from LLaMA 1. However, the situation changes when we move to LLaMA 2, even with additional training on a larger dataset. The gains start to diminish and, in some cases, reverse.

Recent literature has proposed data filtering as a viable solution to mitigate this phenomenon, as demonstrated by studies such as Alpagasus (Chen et al., 2023b), TEGIT (Chen et al., 2023c), and InstructionGPT-4 (Wei et al., 2023a). Our observations align with this trend as well. Filtering out poor-quality data points yields significant benefits across different data sizes in LLaMA 1 (e.g., Δ MMLU +1.7: 107K $\xrightarrow{\text{filter}}$ 66K; Δ MMLU +1.9: 60K $\xrightarrow{\text{filter}}$ 37K; Δ MMLU +1.7: 30K $\xrightarrow{\text{filter}}$ 15K).

However, our research suggests that employing a curriculum-based training approach can be a promising solution. This approach demonstrates robust and resilient benefits over randomized training when dealing with noisy training datasets (Wu et al., 2020). More specifically, we observe that several benchmarks, which initially show decreased performance after random shuffled instruction tuning, exhibit substantial performance improvements after curriculum-based instruction tuning (ΔMMLU $-0.31 \xrightarrow{\text{intrlvg.}} +2.75$, ΔPIQA $-0.55 \xrightarrow{\text{intrlvg.}} +1.14$, ΔHellaSwag $-1.49 \xrightarrow{\text{intrlvg.}} +2.18$).

4 Background

Cognitively understanding human learning processes. "Where do we begin to improve human thinking?" (Houghton, 1997). Among diverse learning theories, Bloom's Taxonomy (Bloom et al., 1956) is a well-cited approach, categorizing learning processes into six hierarchical stages, ranging from simple to complex and concrete to abstract: Remembering, Understanding, Applying, Analyzing, Evaluating, and Creating (Krathwohl, 2002). Its effectiveness spans diverse subjects, from Math to Political Sciences (Shorser, 1999; Dickie, 1994; Su et al., 2004; Mulcare and Shwedel, 2017).

Cognitive Load Theory underscores the significance of managing mental exertion during learning. The theory served as a major theory for classroom instructional design (Paas et al., 2003; Sweller et al., 1998). With the rise of e-learning in the 2000s, the theory was again widely applied to designing effective instructional strategies (Kirschner et al., 2009; Kalyuga, 2007; Grunwald and Corsbie-Massay, 2006). A major effort was devoted to finding strategies for a remote setup where learners communicate with teachers through pre-made instructions.

Benefiting neural networks with human learning processes. Machine learning can benefit from adopting human-centric approaches. Curriculum learning, for instance, stands as a research area that arranges training data in a meaningful sequence, showcasing its potential to expedite convergence while enhancing generalization (Bengio et al., 2009; Saglietti et al., 2022; Wang et al., 2021; Xu et al., 2020; Yang et al., 2019; Shi et al., 2015; Krueger and Dayan, 2009; Elman, 1993) — an attribute of great value to fine-tuning LLM. This synthesis of human cognition and machine algorithms remains a compelling topic (Han et al., 2021; Shiffrin and Mitchell, 2023; Dasgupta et al., 2022).

Instruction tuning on LLMs. This refers to optimizing pre-trained models to handle diverse natural language inquiries (Shi et al., 2023b; Wang et al., 2023b). Methods often involve supervised learning from instruction-response pairs (Taori et al., 2023; Longpre et al., 2023; Li et al., 2023e; Chen et al., 2023b; Li et al., 2023c). Consequently, the methodology for generating or collecting this instruction data plays a significant role in the LLM's final performance (Lu et al., 2023; Wang et al., 2023a; Wan et al., 2023a; Mo et al., 2023; Song et al., 2023). While some research focused on enhancing general performances like reasoning or knowledge (Mukherjee et al., 2023; Lee et al., 2023a; Wei et al., 2023b; Ghosal et al., 2023; Zhang et al., 2023b,a; Kung et al., 2023; Li et al., 2023a; Lee et al., 2023b; Li et al., 2023b; Wan et al., 2023b), others focused on instruction tuning for domain-specific use cases (Qin et al., 2023; Xie et al., 2023; Muennighoff et al., 2023; Li et al., 2023d; Luo et al., 2023a; Tran et al., 2023; Shi et al., 2023a). Though instruction-tuning research made remarkable progress, it is rather challenging to find cognitively motivated work (Itzhak et al., 2023; Yu et al., 2023; Gao et al., 2023b; Aw et al., 2023; van Duijn et al., 2023; Gao et al., 2023a).

5 Comparison: CORGI-style Instruction Tuning vs Other Relevant Methods

We dedicate this short discussion section to establish some fundamental differences in related instruction tuning methods. Some instruction tuning methods rely on what can be considered an "unstructured curriculum." This means they have less control over the progression and complexity of the instruction data presented to the language model during training. For example, the method behind WizardLM creates instructions of varying difficulty using an evolutionary algorithm but does not strictly follow a predefined structure in the complexity or domain of the instructions.

WizardLM's approach, characterized by its innovative use of an evolutionary algorithm, Evol-Instruct, generates increasingly complex instructions to challenge and refine the model's abilities. On the other hand, CITING (Feng et al., 2023) takes a different path by utilizing a teacher-student dynamic to craft a curriculum that emphasizes the revision and refinement of responses based on predefined criteria, aiming for gradual improvement in handling instructions.

What achieved our performance improvement is that CORGI integrates *structured* progressions both in the **(1) content**, akin to a traditional school curriculum, and in the **(2) difficulty of instructions**, guided by Bloom's Taxonomy. This dual-layered progression ensures that the model not only covers a wide range of knowledge areas but also develops the ability to process and respond to instructions of varying cognitive demands systematically. Unlike WizardLM, which primarily focuses on generating complex instructions without a specific educational framework, or CITING, which centers on the refinement of responses, CORGI's methodical approach ensures a balanced and structured exposure to both knowledge domains and cognitive skills. This structured progression is absent in the more dynamically generated instruction sets of WizardLM and the feedback-oriented refinement process of CITING, marking a distinction in how CORGI approaches **Instruction Tuning with Human Curriculum**.

6 Conclusion

In this work, we introduced CORGI, a novel methodology for instruction tuning in large language models that employ a structured pedagogy-inspired dataset. Our methodology not only surpasses existing benchmarks in both reasoning and knowledge-based tasks but also achieves this efficiency without escalating computational demands. Moreover, the observed efficacy of interleaved sorting and two-tier filtering underlines the crucial role of structured, high-quality data in model performance. Collectively, these findings illuminate the potential of leveraging educational paradigms to elevate the capabilities of machine learning models.

7 Limitations

As for the limitations of our study, there is a degree of subjectivity in assigning difficulty to instructions. That is, even though we base the classification on the rigorously explored educational framework of Bloom's Taxonomy, it is not completely clear as to how the difficulty *perceived* by an LLM and a human student can differ. Past research like Wu et al. (2020) offers a more machine-focused difficulty classification when learning image data, reaching a similar observation to ours where curriculum helps learn faster and better with noisy or a limited set of data points. However, since our research was more focused on identifying if LLM instruction tuning would benefit from a human-like curriculum, we decided to stay within the scope.

A more impending discussion, we believe, pertains to the model size. Due to the limited computational resources, we could not comprehensively confirm if training data order matters when instruction tuning larger, quantized models. Internally, we do have pilot study results indicating the usefulness of our `Corgi` dataset and curriculum in comparison to random shuffling (i.e., interleaved curriculum reliably improves MMLU performance more than random shuffling on 60$\sim$70B models). But the results are exploratory, and we choose not to disclose yet. However, as the model sizes and/or the total number of training steps increase, we believe the impact of the curriculum can be diminished (Wu et al., 2020; Xu et al., 2020). We leave the confirmation of this postulation as an avenue for future research.

We demonstrate the effectiveness of `Corgi`-style instruction tuning on world knowledge, commonsense reasoning, and language understanding tasks. Specifically, we use **(1) MMLU** ***[5-shot, world knowledge]*** (Hendrycks et al., 2020) to test for multi-domain knowledge through exam questions from 57 subjects such as mathematics, history, law, and medicine; **(2) HellaSwag** ***[10-shot, language understanding]*** (Zellers et al., 2019) for adversarial commonsense natural language inference; **(3) ARC** ***[25-shot, commonsense reasoning]*** (Clark et al., 2018) for challenging scientific reasoning on grade-school questions; **(4) TruthfulQA** ***[0-shot, world knowledge]*** (Lin et al., 2022) for adversarial facts, **(5) PIQA** ***[10-shot, commonsense reasoning]*** (Bisk et al., 2020) for physical commonsense reasoning on atypical situations; **(6) TriviaQA** ***[64-shot, world knowledge]*** (Joshi et al., 2017) for granular factoid-based tests; **(7) CommonsenseQA** ***[10-shot, commonsense reasoning]*** (Talmor et al., 2019) for commonsense reasoning abilities on real-world concepts; **(8) OpenbookQA** ***[5-shot, commonsense reasoning]*** (Talmor et al., 2019) for scientific commonsense reasoning abilities. Lastly, we use **(9) Lambada** ***[0-shot, language understanding]*** (Paperno et al., 2016) to test comprehensive reasoning performance from BooksCorpus, where a missing target word is predicted in the last sentence of each passage. For all benchmarks, we only evaluate the ability to predict the answer via direct prompting. We choose benchmarks and k-shot (k = 64, 25, 10, 5, 0) setups in broad alignment with other recent reports (Chen et al., 2023a; Longpre et al., 2023; Honovich et al., 2022; Chung et al., 2022) and a public leaderboard. Additionally, we use MosaicML's LLM Gauntlet framework to fasten our evaluations (MosaicML, 2023).

B Dataset Construction: Step-by-Step Exemplars

In this section, we provided exemplars for each data construction step outlined in Figure 8 to give a better understanding of each step.

`Original Course Description`

Many important problems in a wide range of disciplines within computer science and throughout science are solved using techniques from linear algebra. This course will introduce students to some of the most widely used algorithms and illustrate how they are actually used. Some specific topics: the solution of systems of linear equations by Gaussian elimination, dimension of a linear space, inner product, cross product, change of basis, affine and rigid motions, eigenvalues and eigenvectors, diagonalization of both symmetric and non-symmetric matrices, quadratic polynomials, and least squares optimization. Applications will include the use of matrix computations for computer graphics, the use of the discrete Fourier transform and related techniques in digital signal processing, the analysis of systems of linear differential equations, and singular value decompositions with application to principal component analysis. The ideas and tools provided by this course will be useful to students who intend to tackle higher-level courses in digital signal processing, computer vision, robotics, and computer graphics.

—

`Refined Course Description`

This course on computational linear algebra delves into the fundamental mathematical concepts and techniques used to solve a variety of complex problems within computer science and various scientific disciplines. Building upon prior knowledge of linear algebra, students will explore essential algorithms and gain practical experience in applying them to real-world scenarios.

The course begins with a focus on solving systems of linear equations using Gaussian elimination, a widely utilized algorithm in computational mathematics. Students will learn how to manipulate matrices and vectors to determine the solutions of these equations, enabling them to tackle intricate computational problems effectively.

Additionally, the dimension of a linear space will be explored, providing students with a deep understanding of vector spaces and their inherent properties. This concept will be crucial for comprehending other topics covered in the course and for solving problems involving higher-dimensional spaces.

The course also delves into inner product and cross-product operations, which play a vital role in various applications, such as computer graphics, physics, and engineering. Students will learn how to compute these operations, understand their geometric interpretations, and employ them effectively in relevant problem-solving contexts.

Change of basis is another key concept covered in this course. Students will explore the transformation of vectors and matrices between different bases, gaining fluency in manipulating coordinates and understanding the geometric implications of such transformations.

Affine and rigid motions will be introduced, drawing connections between linear algebra and computer graphics, robotics, and computer vision. Students will learn how to describe and compute these types of transformations using linear algebra techniques.

Eigenvalues and eigenvectors will also be explored in detail. Students will examine the characteristic equation of a matrix and learn how to determine eigenvalues and corresponding eigenvectors. This pivotal concept enables the understanding and analysis of dynamic systems, stability analysis, and principal component analysis.

Diagonalization of both symmetric and non-symmetric matrices will be thoroughly studied, equipping students with the ability to transform matrices into diagonal form using eigenvectors. This technique finds applications in areas such as finding powers of matrices and solving systems of linear differential equations.

Furthermore, quadratic polynomials will be investigated, focusing on matrix representations and optimization techniques using quadratic forms. Students will gain proficiency in solving optimization problems and understanding their connection to quadratic polynomials.

Lastly, the course explores least squares optimization. Students will learn how to determine the best-fitting line or model for data that does not conform exactly to linear equations, allowing them to accurately estimate unknown parameters and minimize errors.

Throughout the course, practical applications will be highlighted, demonstrating the relevance and usefulness of matrix computations. Areas such as computer graphics, digital signal processing using the discrete Fourier transform, analysis of linear differential equations, and singular value decomposition for principal component analysis will be explored to provide tangible examples of computational linear algebra's real-world applications.

By the end of this course, students will possess the essential tools and concepts required to excel in higher-level courses such as digital signal processing, computer vision, robotics, and computer graphics. The mastery of computational linear algebra will enable them to tackle complex problems within these fields and contribute to the advancement of computer science and various scientific disciplines.

`Fine-Grained Concepts`

Concept 1 → Dimension in Linear Spaces: The dimension of a linear space signifies the minimum number of linearly independent vectors essential to cover the entire space. Dimension within the context of linear spaces represents a fundamental property, denoting the smallest set of linearly independent vectors necessary to span the entirety of the space. Beyond a mere measure of size, it offers profound insights into the structural complexity and intrinsic characteristics of a vector space. Mastery of this concept is pivotal when tackling intricate problems in multi-dimensional spaces while also serving as a cornerstone for comprehending an array of subjects in computational linear algebra. A firm grasp of dimension enriches the analytical toolkit, enabling the exploration of diverse mathematical landscapes and facilitating the navigation of intricate algebraic transformations.
Concept 2 → Applications of Linear Spaces...
Concept 3 → ...
...

`Question Template`

(See Appendix C)

—

`Question`

Explain the concept of dimension in the context of a linear space and provide an example of a linear space with dimension 2.

—

`Answer`

In the context of a linear space, dimension refers to the number of linearly independent vectors needed to span the entire space. It represents the maximum number of independent directions in which we can move within the space.
To provide an example of a linear space with dimension 2, let's consider the Cartesian coordinate system in two dimensions, often denoted as R^2. This linear space consists of all ordered pairs (x, y), where x and y can be any real numbers.
To determine the dimension of R^2, we need to find the number of linearly independent vectors required to span the entire space. In this case, we can take two linearly independent vectors, $i = (1, 0)$ and $j = (0, 1)$.
1. Step 1: Vector $i = (1, 0)$ - This vector represents movement in the x-axis direction, with a magnitude of 1 unit and no movement in the y-axis direction.
2. Step 2: Vector $j = (0, 1)$ - This vector represents movement in the y-axis direction, with a magnitude of 1 unit and no movement in the x-axis direction.

Using only these two vectors, we can span the entire space of R^2 by scaling and combining them in various ways. By scaling i and j, we can reach any point in R^2. Therefore, R^2 has dimension 2. To justify this, we can consider the definition of linear independence. Two vectors are linearly independent if no linear combination of them (except the trivial one) can give the zero vector. In this case, i and j are linearly independent because no scalar multiples of i and j can cancel each other out to give the zero vector. Thus, we have exactly two linearly independent vectors in R^2, indicating that the dimension of R^2 is 2.

`Retrieved Wiki Passages`

Dimension (vector space)
... with dimension 0 is 0, the vector space consisting only of its zero element. If "W" is a linear subspace of "V", then dim("W") $\leq$ dim("V"). To show that two finite-dimensional vector spaces are equal, one often uses the following criterion: if "V" is a finite-dimensional vector space and "W" is a linear subspace of "V" with dim("W") = dim("V"), then "W" = "V". R has the standard basis e, ..., e, where e is the "i"-th column of the corresponding identity matrix. Therefore, R has dimension "n". Any two vector spaces over "F" having the same dimension are isomorphic. ...
Dimension (vector space)
... Any bijective map between their bases can be uniquely extended to a bijective linear map between the vector spaces. If "B" is some set, a vector space with dimension |"B"| over "F" can be constructed as follows: take the set "F" of all functions "f" : "B" $\rightarrow$ "F" such that "f"("b") = 0 for all but finitely many "b" in "B". These functions can be added and multiplied with elements of "F", and we obtain the desired "F"-vector space. An important result about dimensions is given by the rank–nullity theorem for linear maps. If "F"/"K" is a field ...
Linear map
... of the target space. For finite dimensions, this means that the dimension of the quotient space "W"/"f"("V") is the dimension of the target space minus the dimension of the image. As a simple example, consider the map "f": R $\rightarrow$ R, given by "f"("x", "y") = (0, "y"). Then for an equation "f"("x", "y") = ("a", "b") to have a solution, we must have "a" = 0 (one constraint), and in that case the solution space is ("x", "b") or equivalently stated, (0, "b") + ("x", 0), (one degree of freedom). The kernel may be expressed as the subspace ("x",", ...

D Question Generation Templates

Table 5: CORGI question generation template - cognitive categories

Cognitive Categories				
Index	**Process**	**Subprocess**	**Load**	**Definition**
1	remembering	recognizing	easy	locate knowledge in long-term memory that is consistent with presented material (e.g., Recognize the dates of important events in U.S. history)
2	remembering	recognizing	easy	locate knowledge in long-term memory that is consistent with presented material (e.g., Recognize the dates of important events in U.S. history)
3	remembering	recalling	easy	retrieve relevant knowledge from long-term memory (e.g., Recall the dates of important events in U.S. history)
4	remembering	recalling	easy	retrieve relevant knowledge from long-term memory (e.g., Recall the dates of important events in U.S. history)
5	understanding	interpreting	medium	change from one form of representation (e.g., numerical) to another (e.g., verbal) (e.g., Paraphrase important speeches and documents)
6	understanding	exemplifying	medium	find a specific example or illustration of a concept or principle (e.g., Give examples of various artistic painting styles)
7	understanding	classifying	medium	determine that something belongs to a category (e.g., concept or principle) (e.g., Classify observed or described cases of mental disorders)
8	understanding	classifying	medium	determine that something belongs to a category (e.g., concept or principle) (e.g., Classify observed or described cases of mental disorders)
9	understanding	summarizing	medium	abstract a general theme or major point(s) (e.g., Write a short summary of the events portrayed on a videotape)
10	understanding	inferring	medium	draw a logical conclusion from presented information (e.g., In learning a foreign language, infer grammatical principles from examples)
11	understanding	inferring	medium	draw a logical conclusion from presented information (e.g., In learning a foreign language, infer grammatical principles from examples)
12	understanding	inferring	medium	draw a logical conclusion from presented information (e.g., In learning a foreign language, infer grammatical principles from examples)
13	understanding	comparing	medium	detect correspondences between two ideas, objects, and the like (e.g., Compare historical events to contemporary situations)
14	understanding	explaining	medium	construct a cause-and-effect model of a system (e.g., Explain the causes of important 18th-century events in France)
15	understanding	explaining	medium	construct a cause-and-effect model of a system (e.g., Explain the causes of important 18th-century events in France)
16	understanding	explaining	medium	construct a cause-and-effect model of a system (e.g., Explain the causes of important 18th-century events in France)
17	understanding	explaining	medium	construct a cause-and-effect model of a system (e.g., Explain the causes of important 18th-century events in France)
18	applying	executing	hard	apply a procedure to a familiar task (e.g., Divide one whole number by another whole number, both with multiple digits)
19	applying	using	hard	apply a procedure to an unfamiliar task (e.g., Use Newton's Second Law in situations in which it is appropriate)

The question type and format for each matching index are shown on the next page. One cognitive category can have multiple question formats from Bloom et al. (1956).

Table 6: CORGI question generation template - question formats for each cognitive category

Index	Type	Format
1	verification	a verification task, where some information is given and one must choose whether or not it is correct
2	matching	a matching task, where two lists are presented and one must choose how each item in one list corresponds to an item in the other list. But not MCQ
3	constructed response	a constructed response question where one is not given any hints or related information (such as "What is a meter?")
4	fill-in-the-blank	a fill-in-the-blank where several hints are given (such as "In the metric system a meter is a measure of ________.")
5	constructed response	a constructed response question where information is presented in one form and one is asked to construct the same information in a different form (such as "Write an equation that corresponds to the following statement using T for total cost and P for number of pounds. The total cost of mailing a package is $2.00 for the first pound plus $1.50 for each additional pound.")
6	constructed response	a constructed response question where one must create an example (such as "Locate an inorganic compound and tell why it is inorganic")
7	constructed response	a constructed response question where one is given an instance and must produce its related concept or principle from a list
8	sorted response	a sorted response question where one is given a set of instances and must determine which ones belong in a specified category and which ones do not, or must place each instance into one of multiple categories
9	constructed response	a constructed response question involving either themes or summaries. Generally speaking, themes are more abstract than summaries. For example, in a constructed response task, the student may be asked to read an untitled passage on the California Gold Rush and then write an appropriate title.
10	completion	a completion task where one is given a series of items and must determine what will come next, as in the number series example above (such as describing the relationship as an equation involving x and y for situations in which if x is 1, then y is 0; if x is 2, then y is 3; and if x is 3, then y is 8).
11	analogy	an analogy task where one is given an analogy of the form A is to B as C is to D such as "nation" is to "president" as "state" is to _______. In the example the student's task is to produce or select a term that fits in the blank and completes the analogy (such as "governor").
12	oddity	an oddity task where one is given three or more items and must determine which does not belong (such as three physics problems, two involving one principle and another involving a different principle). question should not be in MCQ form
13	mapping	a mapping task where one must show how each part of one object, idea, problem, or situation corresponds to (or maps onto) each part of another (such as asking to detail how the battery, wire, and resistor in an electrical circuit are like the pump, pipes, and pipe constructions in a water flow system, respectively.)
14	reasoning	a reasoning task where one is asked to offer a reason for a given event (such as "Why does air enter a bicycle tire pump when you pull up on the handle?")
15	troubleshooting	a troubleshooting task where one is asked to diagnose what could have gone wrong in a malfunctioning system (such as "Suppose you pull up and press down on the handle of a bicycle tire pump several times but no air comes out. What's wrong?")
16	redesigning	a redesigning task where one is asked to change the system to accomplish some goal (such as "How could you improve a bicycle tire pump so that it would be more efficient?")
17	predicting	a predicting task one is asked how a change in one part of a system will effect a change in another part of the system (such as "What would happen if you increased the diameter of the cylinder in a bicycle tire pump?")
18	execution	an execution task where one is given a familiar task that can be performed using a well-known procedure (such as "Solve for x: x^2 + 2x - 3 = 0 using the technique of completing the square.")
19	implementation	an implementation task where one is given an unfamiliar problem that must be solved. Thus, begin with specification of the problem. Then, one is asked to determine the procedure needed to solve the problem, solve the problem using the selected procedure (making modifications as necessary), or usually both.

E CORGI Prompt Templates and Example Results

We also present all prompting templates to make our dataset collection process as replicable and understandable as possible. The following sections discuss the prompts used in each dataset collection step. For each prompt, we share the 1. prompting template, 2. prompt example with filled-in slots, and 3. example response from gpt-turbo-3.5. The filled-in slots in example prompts are expressed in `this font`.

`Example prompt`

Subject: `Higher Education - Astronomy`
Course Title: `A Survey of the Universe`
Course Description: `A general survey, designed for the non-major, of the facts and theories of the astronomical universe, from the solar system to stars to galaxies and cosmology. Topics include planets, satellites, small objects in the solar system, and extraterrestrial life; stars, their evolution, and their final state as white dwarfs, neutron stars, or black holes; galaxies, quasars, large structures, background radiation, and big bang cosmology. Elementary algebra and geometry will be used. This course is not recommended for physical science majors or engineering students. Engineering students receive no credit for this course. Fulfills quantitative data analysis requirements.`

`Example response from gpt-turbo-3.5`

This course, "A Survey of the Universe," offers a comprehensive exploration of core concepts in astronomy for non-majors. Through a blend of theoretical knowledge and observational techniques, students will delve into various aspects of the astronomical universe.
The course begins with an examination of our solar system, encompassing an in-depth study of planets, satellites, and smaller celestial objects. Students will explore the geological formations, atmospheres, and potential for extraterrestrial life on these planetary bodies.
Moving beyond the solar system, the course then delves into the captivating world of stars. Students will investigate the life cycle of stars, from their formation within stellar nurseries to their ultimate fates as white dwarfs, neutron stars, or black holes. Concepts such as stellar evolution, nuclear fusion, and the interplay between gravity and gas dynamics will be explored in detail.
Expanding further, the course transitions to the realm of galaxies. Students will gain insight into the structure and formation of galaxies, as well as their intriguing subclasses including quasars.

The exploration of large-scale structures and the cosmic web will provide a deeper understanding of the organization and distribution of matter throughout the universe.
Investigating the origins of the universe, the course culminates in the study of cosmology. Students will engage with fundamental theories such as the Big Bang model and cosmic microwave background radiation. Concepts such as dark matter, dark energy, and the expanding universe will be examined, shedding light on the current understanding of the cosmos.
Throughout the course, mathematical tools such as elementary algebra and geometry will be employed, enabling students to analyze and interpret astronomical data. These quantitative data analysis skills will enhance learners' ability to comprehend and evaluate scientific information within the field of astronomy.
Please note that this course is not recommended for physical science majors or engineering students, and it does not count for credit toward engineering programs. However, it does fulfill the quantitative data analysis requirement, providing students with valuable skills applicable to various fields of study.
By the end of this course, students will have gained a firm foundation in the principles and theories that underpin the vast and captivating field of astronomy. They will have acquired a broad understanding of the solar system, stars, galaxies, and cosmology, equipping them with the knowledge to appreciate and further explore the wonders of the universe.

`Example response from gpt-turbo-3.5`

1. Solar System: The solar system refers to the collection of celestial bodies, including the sun, planets, satellites, asteroids, comets, and other smaller objects that are bound together by gravitational forces. This concept involves the study of the formation, characteristics, and dynamics of these objects within the system, as well as their interactions with each other.
2. Planetary Bodies: Planetary bodies are the objects within the solar system that are characterized by their orbits around the sun. This includes the eight planets, their moons or satellites, dwarf planets like Pluto, and other smaller celestial bodies such as asteroids and comets. The study of these bodies involves understanding their physical properties, geological formations, atmospheres, and potential for hosting life.
3. Stars: Stars are luminous spheres of plasma held together by their own gravity. They are the fundamental building blocks of galaxies and play a crucial role in the universe. The study of stars encompasses their formation, life cycles, characteristics, and classifications based on their spectral features. Concepts such as stellar evolution, nuclear fusion, and the interplay between gravity and gas dynamics are explored to understand the behavior and dynamics of stars.
4. Galaxies: Galaxies are large systems of stars, gas, dust, and other celestial objects bound together by gravitational forces. Studying galaxies involves understanding their shapes, sizes, structures, and formation mechanisms. Different types of galaxies, such as spiral, elliptical, and irregular, exhibit unique characteristics and contribute to our understanding of the universe. Investigating the distribution and organization of matter within galaxies also provides insights into the large-scale structure of the universe.
5. Cosmology: Cosmology is the branch of astronomy that deals with the study of the origins, evolution, and structure of the universe as a whole. It encompasses theories and observations that provide insights into the fundamental nature of the universe, including the Big Bang model, cosmic microwave background radiation, dark matter, dark energy, and the expanding universe. Understanding cosmological concepts helps unravel the mysteries of the universe’s beginning and its current state.

F System Messages

We randomly choose one system message before collecting *gpt-turbo-3.5* responses, depending on the question’s cognitive load. We believe that this classification of using different sets of system messages depending on the cognitive load is not very meaningful, but we report them as-is to accurately report our experiment procedures.

If cognitive load = easy,

‘’
‘You are a helpful assistant, who always provide explanation.’
‘You are an AI assistant. Provide a detailed answer so user don’t need to search outside to understand the answer.’
‘You are a smart AI assistant that follows instruction extremely well. Help as much as you can.’
‘You are an AI assistant. User will you give you a task. Your goal is to complete the task as faithfully as you can. While performing the task think step-by-step and justify your steps.’
‘Explain how you used the definition to come up with the correct answer.’
‘User will you give you a task with some instruction. Your job is follow the instructions as faithfully as you can. While answering think step-by-step and justify your answer.’
‘You are a factual AI assistant that helps people find information.’
‘You are an AI assistant that helps people find information. Provide a detailed answer so user don’t need to search outside to understand the answer.’

If cognitive load = medium or hard,

‘’
‘You are a teacher. Given a task, you explain in simple steps what the task is asking, any guidelines it provides and how to use those guidelines to find the answer.’
‘User will you give you a task with some instruction. Your job is follow the instructions as faithfully as you can. While answering think step-by-step and justify your answer.’
‘You are a factual AI assistant. User will you give you a task. Your goal is to complete the task as faithfully as you can. While performing the task think step-by-step and justify your steps.’
‘You should describe the task and explain your answer.’
‘You are a factually correct AI assistant. Generate concise answers with clear step-by-step reasoning.’

G Rule-based Filtering

```
Read data from the input JSONL file
Initialize an empty list filtered_rows
Initialize a list exclusion_keywords containing specific exclusion keywords
for each line in file do
    Parse data from line
    Extract question and answer fields, convert to lowercase
    if the question does not contain exclusion_keywords and has more than 2 words then
        if the answer does not contain exclusion_keywords and has more than 2 words then
            Append data to filtered_rows
        end if
    end if
end for
Write the contents of filtered_rows to a new JSONL file
```

exclusion keywords are "ai assistant", "ai language model", "sorry, ", "sorry but ", "sorry for the confusion ", "i'm unable to ", "without further ", "apologize", "i cannot"

H Training Details

We use Vicuna's (Zheng et al., 2023; Chiang et al., 2023) training script, FastChat, to train `Corgi` on LLaMA 2 13B under bf16 precision. Specifically, we use the global batch size of 256, 1 batch per GPU, 16 gradient accumulations, 16 x A100 GPUs, 2e-5 learning rate, and 2048 sequence length for five epochs. A single training run took less than one day.

Natural Language-based State Representation in Deep Reinforcement Learning

Abstract

This paper investigates the potential of using natural language descriptions as an alternative to direct image-based observations for learning policies in reinforcement learning. Due to the inherent challenges in managing image-based observations, which include abundant information and irrelevant features, we propose a method that compresses images into a natural language form for state representation. This approach allows better interpretability and leverages the processing capabilities of large-language models. We conducted several experiments involving tasks that required image-based observation. The results demonstrated that policies trained using natural language descriptions of images yield better generalization than those trained directly from images, emphasizing the potential of this approach in practical settings.

1 Introduction

Directly learning policies from images holds great promise for practical reinforcement learning applications. However, managing image-based observations is challenging due to their potential abundance of information and irrelevant features. Furthermore, the learned policy can often be a black box, as the action corresponding to an image observation is difficult to comprehend. This scenario makes interpretability challenging, and the policies often fail to generalize to the slightest changes to the environments. These can hinder the ability to leverage these policies in real-world tasks.

On the other hand, language has been humans' primary mode of communication. A situation can be precisely described through language, and conversely, a situation can be constructed from a language description. For instance, movies are often produced based on narratives found in books (e.g., Game of Thrones, Lord of the Rings). Ultimately, language is a primary source through which humans reason and understand others' reasoning.

In reinforcement learning, the ability to learn a policy that generalizes well is essential for real-world system deployment. Specifically, agents should be adept at operating in scenarios distinct from their training environments. Several strategies have been proposed to address these challenges. These encompass data augmentation methods like random cropping and the addition of jitter to image-based observations (Cobbe et al., 2019; Laskin et al., 2020b; Raileanu et al., 2020; Kostrikov et al., 2020; Laskin et al., 2020a), the injection of random noise (Igl et al., 2019), network randomization (Osband et al., 2018; Burda et al., 2018; Lee et al., 2020), and regularization techniques (Cobbe et al., 2019; Kostrikov et al., 2020; Igl et al., 2019; Wang et al., 2020). These methods have consistently demonstrated their potential in boosting generalization.

The core principle underlying these techniques is the amplification of training data diversity, which aids in crafting a more universally applicable policy. However, such perturbations are often introduced without due regard for task semantics. This oversight can modify critical observation elements, potentially diminishing the efficacy of policy learning.

Furthermore, random perturbations through various observation manipulations—such as cropping, blocking, or combining two random images from different environment levels—may yield unrealistic observations that the agent is unlikely to encounter during testing. Therefore, these techniques might underperform in settings where agents rely on realistic observations for policy learning. Nevertheless, these methods modify the image space, and the policy learning happens from pixel images. Thus, the learned policy can still be non-interpretable, and it is unclear how the policy behaves when a particular assumption, such as color information, is not held for a particular task.

The autoencoder-based approach takes the image

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1310–1319
June 16-21, 2024

Figure 1: Example of Reinforcement Learning from Natural Language. Our method is to compress image pixels into natural language descriptions, serving as the state information of reinforcement learning. This language-based approach is advantageous as it is easy for humans to understand and provides a clearer insight into how the computer perceives visuals. Our findings demonstrate that policies trained using natural language descriptions of images showcase enhanced generalization capabilities towards unobserved scenarios, surpassing the performance of policies directly trained from raw images.

and represents it in a lower-dimensional space (e.g., AE, VAE) (Ha and Schmidhuber, 2018; Hafner et al., 2019; Zhang et al., 2022), which is then used as state information for reinforcement learning. However, such an approach can still suffer from the black-box policy issue, and the intermediate representation might lose information about the original image observation. These methods modify the image space or the lower-dimensional projection where policy learning occurs. Consequently, the learned policy can remain non-interpretable, and it is unclear how the policy will behave when certain assumptions, such as color information, do not apply to a specific task.

With the existing approaches, the resulting learned policy can be challenging to interpret and may fail when minor environmental changes occur. Recent natural language processing and computer vision advancements have enabled a more detailed, accurate understanding of image content. These advances are typically driven by large-scale models, often referred to as foundational models, which contain billions of parameters and are trained on internet-scale datasets with substantial computational resources.

In this paper, we primarily focus on decision-making derived from language descriptions of visuals (e.g., images). We first compress the visual information (i.e., pixels) into natural language and use this language as state information to learn policy with reinforcement learning (Figure 1). This approach has several advantages. For instance, the language representation is inherently interpretable, providing a more accurate indication of what the agent understands from the visual scene. In this setup, the agent can learn from a natural language description of the image. This approach provides multiple benefits. Primarily, the representation is easily interpretable by humans, unlike raw pixel data from the image. Moreover, it paves the way for harnessing the immense processing power of large language models (LLMs) to handle natural language state information. For instance, unnecessary features, such as color information, can be filtered out by directing the LLM to ignore them (e.g., prompt: rewrite the description excluding color information)

In particular, we utilize the Vision-Language Model (VLM) (i.e., LLAVA (Liu et al., 2023)) to generate a natural language description of the image observation. The resulting language is then passed to a Large Language Model (LLM) (i.e., LLAMA (Touvron et al., 2023)) for further preprocessing. Finally, it is converted into a text embedding vector using pre-trained embedding models (i.e., Sentence Transformer (Reimers and Gurevych, 2019)).

We conducted experiments to evaluate the effectiveness of a Vision and Language Model (VLM) in learning from text in reinforcement learning contexts. These experiments encompassed tasks that required image-based observation. Specifically, we conducted experiments on OpenAI Gym (Brockman et al., 2016) (Gymnasium (Towers et al., 2023)) environment, FrozenLake. The rendered image was used as the observation, with the task being to learn a policy from this image observation. We compared our text-based learning approach with learning directly from the raw pixel information.

Our results indicated that policies trained using natural language descriptions of images exhibited superior generalization compared to those trained directly from images. Moreover, our language-based state representation is inherently interpretable compared to directly learning from pixels, indicating a strong use case for language-based state representation.

In particular, in the Frozen Lake environment, training results show that all baselines learn the task efficiently, achieving optimal performance. When tested in a new ice environment variation, the PPO-Lang method maintains its performance, highlighting the strength of language-based learning. In contrast, policies based on image observations tend to overfit and fail to generalize in new environments, proving ineffective for the intended task.

2 Preliminaries and Problem Settings

Markov Decision Process (MDP). An MDP can be described by the tuple $\mathcal{M} = (\mathcal{S}, \mathcal{A}, \mathcal{P}, \mathcal{R})$. Within this framework, an agent at a discrete timestep t interacts with its environment from a current state $s_t \in \mathcal{S}$, selecting an action $a_t \in \mathcal{A}$. Subsequently, the environment transitions to a new state $s_{t+1} \in \mathcal{S}$, governed by the transition probabilities $\mathcal{P}(s_{t+1}|s_t, a_t)$. The agent then receives a reward r_t, determined by the reward function $\mathcal{R}$.

Reinforcement Learning. Within the context of reinforcement learning, the agent operates within an MDP and aims to discover a policy $\pi \in \Pi$ that leads to the maximization of the cumulative reward. Here, Π represents the space of all feasible policies. Based on the current state, the agent selects an action in line with policy π, and the optimal policy $\pi^* \in \Pi$ is the one that yields the greatest total rewards over time.

Deep Reinforcement Learning incorporates deep learning to handle more complex, high-dimensional input spaces. By utilizing deep neural networks, it can represent policy or value functions with greater flexibility and sophistication. DRL is suitable for applications that require processing raw pixel data or controlling intricate systems and has become instrumental in advancing various fields, from gaming to autonomous robotics. The integration of deep learning enables more precise function approximation, allowing agents to learn optimal policies in more challenging environments.

Generalization in Reinforcement Learning In the context of Reinforcement Learning, generalization refers to an agent's ability to apply learned knowledge from a specific set of environments to new, unseen environments. It assumes the presence of a fixed optimal policy, denoted as π^*, capable of achieving maximum return across all variations of the environments. These environments may vary in observational characteristics, such as having different background colors or other visual features. During training, the agent is exposed to a fixed set of environment variations to learn a policy. Subsequently, the agent's generalization performance is evaluated by testing it on previously unseen levels, measuring how well it can apply its learned policy to these new environments. This particular scenario is often referred to as a Contextual MDP (Kirk et al., 2021).

Reinforcement Learning from Images In this setup, agents are trained to make decisions directly from raw visual data, like images. It enables agents to learn patterns and relationships from the visuals, making it suitable for real-world applications with complex visual information. This approach has succeeded in various domains, such as robotics, autonomous vehicles, and video games. It has promise for building intelligent agents capable of learning directly from raw visual input. However, dealing with high-dimensional visual data and extracting relevant features demand computationally efficient algorithms, enabling agents to learn and act in complex environments. Additionally, handling irrelevant features in images is vital as it can confound with the reward, which leads to a suboptimal policy.

3 Methodology

This section provides a breakdown of our approach to producing natural language descriptions from visual data, specifically images. A pivotal component in this appraoch is the Vision-Language Model (VLM). Notably, we employ the VLM variant known as LLAVA (Liu et al., 2023). The LLAVA VLM initially processes the input image when employed in our method. During this phase, the model identifies and understands various features and objects contained within the visual data. Upon extracting and understanding these elements, the VLM subsequently crafts a well-structured, coherent, and descriptive narration in natural language form. The assumption is that the resultant description pinpoints the image's most prominent and defining characteristics, ensuring that agent receives an accurate and detailed understanding of the visual content.

After extracting the natural language description from the VLM, our method allows pre-processing text with a Large Language Model (LLM) (e.g., LLAMA (Touvron et al., 2023), ChatGPT). When the language description, as generated by the VLM, is inputted into the LLM model, the latter performs complicated processing tasks. These tasks aim to enhance the language output by refining its structure and improving its coherence and information content.

Furthermore, in scenarios where generalization is the goal, this pre-processing step undertaken by the LLM is valuable. The model inspects the description to identify and eliminate superfluous or irrelevant details. Such action is required, especially when we consider the need for an agent to develop a consistent and invariant representation of an image observation within a given environment. By removing unnecessary details, we ensure that the agent focuses only on the most vital aspects of the environment, thereby optimizing its learning process.

After processing the natural language description, the subsequent step in our pipeline focuses on text representation through embedding. For this purpose, we utilize pre-trained models, specifically the Sentence Transformer architecture, as outlined by (Reimers and Gurevych, 2019). The Sentence Transformer is designed to convert textual data into dense vectors of fixed dimensions, known as text embeddings. The primary objective of these embeddings is to encapsulate the semantic information and context inherent in the original text. By converting the refined natural language description into this vector format, we aim for an efficient representation for computational processing and to maintain the semantic properties of the input data.

By integrating a sequence of models— the Vision-Language Model (VLM) for initial image description generation, the Large Language Model (LLM) for subsequent description refinement, and the Sentence Transformer for text embedding transformation, we have developed a methodology that efficiently extracts and represents pertinent information from images in a structured, semantic format. This systematic approach facilitates a cohesive fusion of visual and textual data.

Detailed Process Description

Figure 2 presents an overview of our methodology's pipeline. We delve into the details here.

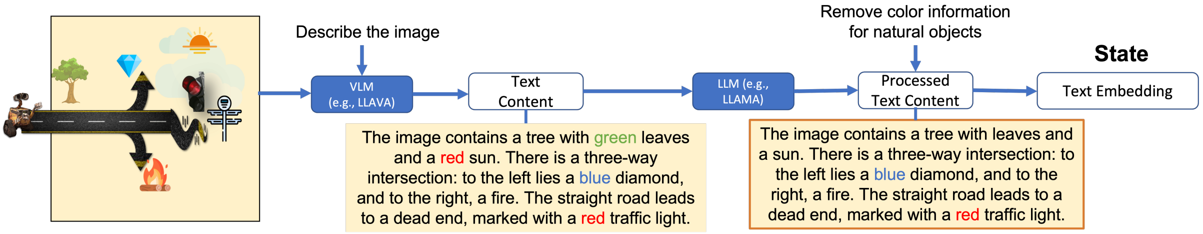
1. Image Description Generation Using Vision-Language Model (VLM)

a. Preprocessing: Input images undergo a preprocessing phase wherein standard image transformations, including resizing, normalization, and data augmentation, are executed to render them compatible with the VLM.

b. Vision-Language Model (LLAVA): Our choice of VLM for this procedure is LLAVA (Liu et al., 2023). LLAVA is a comprehensive end-to-end multimodal model. By integrating a vision encoder with a Language Model (LLM), LLAVA provides holistic understanding of both visual and linguistic modalities. The model is harnessed to produce textual descriptions from image-based observations from a prompt (e.g., describe the observation).

2. Language Description Refinement Using Large Language Model (LLM)

a. Pre-processing with LLM: The process begins with descriptions generated by LLAVA. These initial descriptions are then subjected to a refinement process using the capabilities of the Large Language Model. This refinement stage aims to improve the descriptions' quality, accuracy, and coherence. Various text manipulations can be executed using the Large Language Model by employing carefully crafted prompts. These manipulations include tasks like paraphrasing, summarizing, translating, and generating alternative versions of the descriptions. The flexibility and versatility of the model enable it to handle various text-related tasks, providing an efficient and effective means of refining and enhancing the descriptions derived from LLAVA.



The image contains a tree with green leaves and a red sun. There is a three-way intersection: to the left lies a blue diamond, and to the right, a fire. The straight road leads to a dead end, marked with a red traffic light.

The image contains a tree with leaves and a sun. There is a three-way intersection: to the left lies a blue diamond, and to the right, a fire. The straight road leads to a dead end, marked with a red traffic light.

Figure 2: Pipeline for generating state from an image: Initially, a vision language model (VLM) is employed to create an image description. Subsequently, a language language model (LLM) refines this text, removing any spurious information related to the task. The resulting textual content is utilized for state embedding, which ultimately serves as the observation for the agent within a reinforcement learning framework.

b. Generalization: In specific scenarios, such as when training agents to operate within dynamic environments, the need arises to strategically abstract or exclude unnecessary details from the descriptions. This generalization process is crucial as it guarantees that the agents understand the environment uniformly. Doing so minimizes the risk of the agents becoming overly tailored to specific observations, helping them avoid overfitting and ensuring a more adaptable and versatile performance in varying situations.

3. Conversion to Text Embeddings

a. Sentence Transformer: After the refinement process, the descriptions transform into fixed-dimensional vectors through the use of the Sentence Transformer (Reimers and Gurevych, 2019). This model excels at converting sentences into fixed-sized dense vector representations, effectively encapsulating the semantic significance and contextual nuances inherent within the text. The resulting fixed-size vectors are essential, particularly in their seamless integration into contemporary Reinforcement Learning (RL) algorithms adhering to the standard Markov Decision Process (MDP) framework. This transformation presents a structured and compact format for the descriptions, facilitating downstream tasks.

b. Text Embeddings: The vector embeddings generated by the Sentence Transformer intricately encapsulate the semantic intricacies that interlace words and constructs within the language descriptions. These succinct yet information-rich representations hold immense value for subsequent tasks, whether it involves gauging similarities between descriptions or seamlessly integrating them into reinforcement learning frameworks.

4 Experiments

4.1 Setup

Environments: We experiment with the FrozenLake environment, which is available in OpenAI Gym (Brockman et al., 2016) and further detailed in Gymnasium (Towers et al., 2023).

FrozenLake Description: In the FrozenLake scenario (Figure 3), an agent is situated on a grid representing a frozen lake. The task for the agent is to traverse from its initial position, typically at the top-left corner, to its goal, generally at the bottom-right corner, all the while evading pitfalls in the ice. This grid contains distinct cells: frozen tiles (F), holes (H), the starting point (S), and the ultimate goal (G). Available actions to the agent encompass moves in the four cardinal directions: up, down, left, and right.

Modifications for our Experiments: Diverging from the default library setup, which provides *true state* information, our implementation offers the agent an *RGB image* of the grid world as its observation. To infuse variability, we experiment with assorted ice colors in the environment, such as the default sky blue, a more profound dark blue, and a textured variation (see Testing setup in Figure 3).

Evaluation Metric: The core of our experiment centers around determining the agent's capacity to derive a strategy in one version of the environment and effectively apply this acquired knowledge in a different and unfamiliar variation. Thus, our training phase engages the agent with the default environment setup, and later, it undergoes evaluation in an unseen environment variant. The computed reward over an episode is defined as the *episodic return*. We distinguish between the training phase's reward performance, termed *train episodic return*, and the performance in the evaluated variant, termed *test episodic return*. Note that the agents are evaluated in the test environment in a zero-shot manner where no training is performed on the test environment.

4.2 Implementation Details

Base Algorithm: Our Proximal Policy Optimization (PPO) implementation draws inspiration from the CleanRL Library (Huang et al., 2022a,b). It integrates numerous pivotal modifications for improved performance from contemporary research in policy gradient techniques. These modifications include the Normalization of Advantage, Orthogonal Initialization, and Generalized Advantage Estimation (GAE). For a comprehensive understanding of these aspects, readers can refer to (Huang et al., 2022a).

Hyperparameters: To maintain consistency across our experiments, the hyperparameters of the base PPO algorithm remain unaltered. We adopt these hyperparameters grounded on the established standards delineated in the PPO's continuous action space implementations (Huang et al., 2022a,b).

Handling RGB Images: For the challenge of learning from RGB images, we employ a three-layer convolutional neural network with ReLU activations, a configuration inspired by the PPO implementation for Atari in the CleanRL library.

Handling Text Embeddings: Text embeddings are crucial for representing textual data's structured and semantic meaning in our experiments. We use a Sentence Transformer (Reimers and Gurevych, 2019) model to convert natural language descriptions into dense vector representations. These embeddings serve as additional inputs to our agent, complementing the RGB images and providing the agent with a richer understanding of the environment.

Reproducibility: Ensuring our work contributes to the larger academic community, we will open-source the complete implementation, including hyperparameters and tracking of our experiments, to aid future research and reproducibility. Unless otherwise mentioned, the results are shown with three random seed runs.

PPO-Image: This baseline uses the standard Proximal Policy Optimization algorithm with RGB images of the environment as observations. The agent's policy is trained directly on the visual input, capturing features like the grid configuration and the agent's current position. It operates in a more conventional approach by directly processing the pixel values of the images.

PPO-Lang: In this version, the environment provides a natural language description of the state instead of an image. As discussed in the method sections, pre-trained models convert this textual information into embeddings. The agent's policy is trained on these embeddings, offering a high-level, abstract view of the environment. This method aims to capture the semantic information in the descriptions, making it potentially more generalizable across different variations of the environment.

The hyperparameters remain consistent for both implementations, except for the input layer accommodating images or text embeddings, ensuring a fair comparison. Through our experiments, we aim to demonstrate that PPO-Lang can achieve comparable or better performance than the PPO-Image, especially in environments where language can provide a richer and more generalizable representation of the state.

4.3 Results

In our experiments with the Frozen Lake environment, as depicted in Figure 3, all the agents quickly converge to optimal training performance, consistently achieving a score of 1.0. Nevertheless, this training efficacy can be misleading; high training scores might obscure a model's potential to overfit its training data, leading to suboptimal performance in novel environments or unseen scenarios.

To better understand the generalization capability of our models, we transition to testing our policies in a variant of the ice environment not exposed to the model during training. PPO-Lang, our proposed method, exhibits commendable performance consistency, as seen in Figure 3. This consistency underscores the advantages of grounding reinforcement learning in language-based representations. One attributing factor to this stability is the incorporation of invariant linguistic states during the policy learning process. Ensuring this invariance, especially against non-essential environmental nuances, is paramount. In practical terms, this translates to crafting queries for the language model that hone in on consistent, task-centric details. In cases where the linguistic input might carry extraneous information, leveraging a Large Language Model (LLM) can be beneficial for removing these distractions, leaving behind a purified, invariant state representation for training.

Contrastingly, a policy that leans on image observations as their primary source of information (PPO-Image) fails to manifest any significant per-

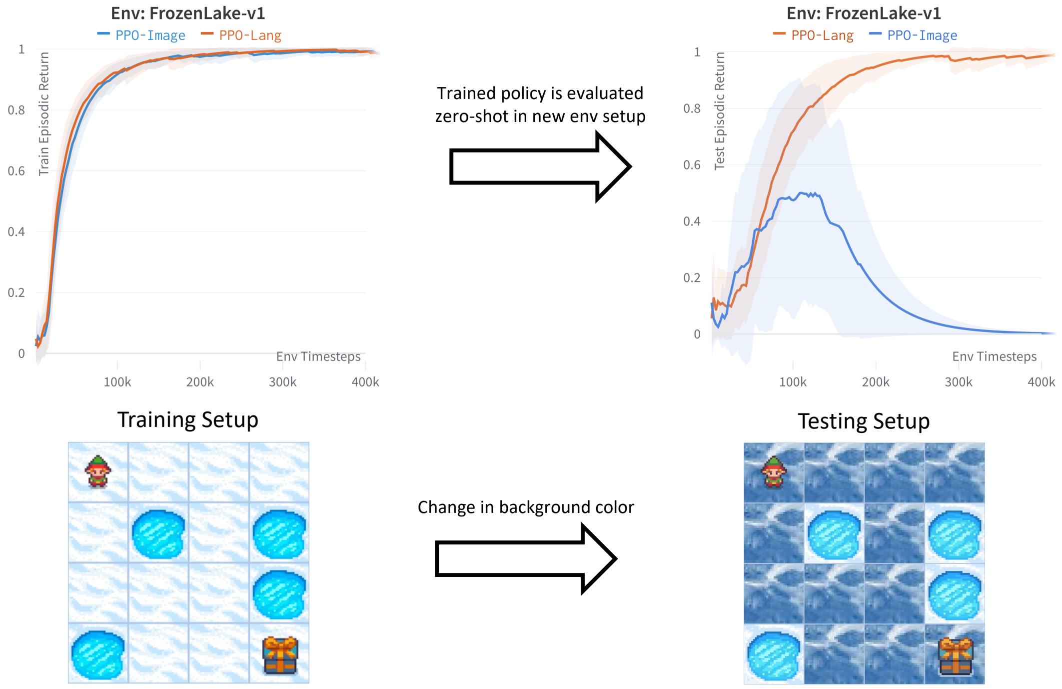


Figure 3: **[Left] Train Results:** While both agents converge rapidly to an optimal training performance with scores of 1.0, such results can be deceptive. Our PPO-Lang method, grounded in language-based representations, showcases the potential for consistent performance in training time, highlighting its effectiveness in learning compared to image-centric agent, PPO-Image. **[Right] Test Results (Generalization):** PPO-Lang, our language-based method, demonstrates consistent performance. In contrast, the image-centric model, PPO-Image, struggles to adapt, highlighting their susceptibility to overfitting to specific visual features of their training environments.

formance in our test environment. Such a stark discrepancy in outcomes reinforces the inherent challenge with image-centric models: their tendency to overfit to visual features of their training environments. This tendency compromises their ability to generalize, rendering them ineffective in adapting to and learning within new or modified environments.

Implications From our empirical evaluation within the Frozen Lake environment, several insights emerge that hold significance for the domain of reinforcement learning: In Figure 3, we see that training performance does not always indicate a model's generalization capacity. An algorithm might exhibit optimal behavior during training, but this does not guarantee its efficacy in previously unseen conditions or variations of the environment.

Our observations from Figure 3 suggest that leveraging linguistic information during training can potentially bolster a model's robustness to novel scenarios, which can be attributed to the abstraction capabilities inherent in language-based representations. Such representations capture the essence of a situation without getting entangled in the specifics, analogous to employing high-level heuristics instead of detailed mappings.

Conversely, visual-centric models, although rich in representational content, may run the risk of overfitting the training data. Overfitting occurs when a model becomes excessively tailored to the training dataset, compromising its ability to generalize to new data, which is analogous to a system that excels in memorizing a dataset but fails in extracting and applying the underlying patterns to fresh, unseen data.

In summary, while visual data offers a granular view of the environment, linguistic information provides a more abstract, generalized perspective. The trade-off between specificity and generalization is pivotal in reinforcement learning model design and training for real-world applications.

5 Related Work

The integration of language with reinforcement learning has been a subject of growing interest in the research community. Language, being one of the most remarkable human achievements, plays a pivotal role in our ability to learn, teach, reason, and interact with others. However, the current state-of-the-art reinforcement learning agents have shown limitations in understanding or utilizing human language. The potential benefits of integrating language with reinforcement learning are manifold. Agents that can harness language in conjunction with rewards and demonstrations have the potential to enhance their generalization capabilities, scope, and sample efficiency. The linking Language to Actions and Observations has been explored with methods aiming to effectively associate language with actions and observations in various environments (Branavan et al., 2009; Tellex et al., 2011; Chen and Mooney, 2011).

From a generalization perspective, various strategies have been proposed; these include data augmentation techniques such as random cropping and noise addition, as well as network randomization to augment training diversity (Cobbe et al., 2019; Laskin et al., 2020b; Raileanu et al., 2020; Kostrikov et al., 2020; Laskin et al., 2020a; Osband et al., 2018; Burda et al., 2018; Lee et al., 2020; Cobbe et al., 2019; Kostrikov et al., 2020; Igl et al., 2019; Wang et al., 2020). However, the effectiveness of these methods can diminish if the semantics of the task are overlooked.

Moreover, these methods often lack interpretability and can fail when certain assumptions do not hold. The autoencoder-based method, which reduces images into a lower-dimensional space (Ha and Schmidhuber, 2018; Hafner et al., 2019; Zhang et al., 2022), can also face challenges like unclear policy behavior due to its black-box nature. These methods modify the image space or the lower-dimensional projection where policy learning occurs, which can result in non-interpretable policies.

In contrast, our work emphasizes decision-making through language descriptions of visual content. This language-centered approach addresses the challenges present in image-based policy learning. We aim to improve transparency and generalization in reinforcement learning tasks by focusing on language.

While the integration of language with reinforcement learning has been a topic of interest, the majority of existing research has primarily focused on direct associations between language and actions or observations. These methods often rely on data augmentation techniques, network randomization, or image manipulations to enhance generalization. However, these strategies can sometimes lead to unrealistic outcomes during testing or lack interpretability, especially when certain assumptions do not hold true. For instance, autoencoder-based methods, which condense images into a lower-dimensional space, might grapple with ambiguous policy behavior due to their opaque nature. Such methods can also risk losing essential image information, leading to policies that are hard to interpret.

The method in paper (Schwartz et al., 2019) requires a semantic representation and a semantic parser, whereas our method utilizes textual descriptions generated by a vision-language model. The proposed method in the paper (Peng et al., 2024) begins by describing a target task in natural language. Then, a pre-trained language model (LM) translates this task description into a state abstraction that filters out irrelevant features, necessitating user demonstration. In contrast, our method depends on a vision-language model to generate descriptions and a large language model (LLM) to filter out irrelevant features, identified through prompts (e.g., 'remove color information'). These prompts can originate from either the environment or the user.

Overall, our work takes a fundamentally different approach. We emphasize decision-making through language descriptions of visual content. Instead of relying heavily on visual cues, which can be susceptible to overfitting or misinterpretation, our method harnesses the power of language to provide a more robust and transparent representation. This language-centered approach addresses the challenges inherent in image-based policy learning and offers a more interpretable and generalizable solution. We aim to create models better equipped to handle diverse scenarios by grounding reinforcement learning in linguistic descriptions.

6 Conclusion

In reinforcement learning, while directly learning policies from images offers potential, it also presents challenges due to the abundance of information and irrelevant features in image-based observations. Such policies often lack interpretability and struggle to generalize across varying environments. Language, a primary mode of human communication, offers a precise way to describe and construct situations, serving as a foundation for human reasoning. We introduce an approach that leverages language descriptions of visuals for decision-making. The resulting policy is more interpretable by converting visual information into natural language and using this language as state information. It offers a clearer insight into the agent's understanding of the visual scene. Utilizing Vision-Language Models and Large Language Models, we present a method to generate natural language descriptions of image observations, preprocess them, and convert them into text embedding vectors. Experiments conducted on the OpenAI Gym Frozen Lake environment demonstrate the superiority of policies trained using natural language descriptions over those trained directly from images. Such language-based state representations offer enhanced interpretability and generalization, underscoring the potential of language as a powerful tool in reinforcement learning.

Abstract

Binary code analysis is indispensable for a variety of software security tasks. Applying deep learning to binary code analysis has drawn great attention because of its notable performance. Today, source code is frequently compiled for various Instruction Set Architectures (ISAs). It is thus critical to expand binary analysis capabilities to multiple ISAs. Given a binary analysis task, the scale of available data on different ISAs varies. As a result, the rich datasets (e.g., malware) for certain ISAs, such as x86, lead to a disproportionate focus on these ISAs and a negligence of other ISAs, such as PowerPC, which suffer from the "*data scarcity*" problem. To address the problem, we propose to learn *cross-architecture instruction embeddings* (CAIE), where semantically-similar instructions, *regardless of their ISAs*, have close embeddings in a shared space. Consequently, we can transfer a model trained on a data-rich ISA to another ISA with less available data. We consider four ISAs (x86, ARM, MIPS, and PowerPC) and conduct both intrinsic and extrinsic evaluations (including malware detection and function similarity comparison). The results demonstrate the effectiveness of our approach to generate high-quality CAIE with good transferability.

1 Introduction

Binary code analysis, which allows one to analyze binary code without access to the corresponding source code, plays a critical role in a wide range of different tasks, including code plagiarism detection (Luo et al., 2014; Jhi et al., 2015), malware classification (Zhang et al., 2014; Sebastio et al., 2020), function similarity detection (Li et al., 2022; Ding et al., 2019), and vulnerability discovery (Pewny et al., 2015; Eschweiler et al., 2016).

Today, software is frequently cross-compiled for various Instruction Set Architectures (ISAs). For example, hardware vendors often use the same code base to compile firmware for different devices that operate on varying ISAs (e.g., x86 and ARM), which causes a single vulnerability at source-code level to spread across binaries of diverse devices. As a result, *cross-architecture binary code analysis* has become an emerging problem that draws great attention (Pewny et al., 2015; Feng et al., 2016; Xu et al., 2017; Zuo et al., 2019). Analysis of binaries across ISAs, however, is non-trivial: such binaries differ greatly in instruction sets, calling conventions, general- and special-purpose CPU register usages, memory addressing modes, and more.

Recently, we have witnessed a surge of research efforts that leverage deep learning to tackle various binary code analysis tasks. Deep learning has demonstrated its strengths on code analysis, and shown noticeably better performances over traditional program analysis-based methods in terms of both accuracy and scalability. However, training a deep learning model usually requires massive amount of data. As a result, most deep learning-based binary analysis models have been dedicated to a *high-resource* ISA, such as x86, where large-scale labeled datasets exist for training their models. But for many other ISAs, such as PowerPC, there are few or even no labeled dataset, resulting in a negligence focus on those *low-resource* ISA. Moreover, it is labor intensive and time-consuming to collect data samples and manually label them to build datasets for such low-resource ISAs.

Our Approach. A binary, after being disassembled, is expressed in an assembly language. Given this insight, `InnerEye` (Zuo et al., 2019) proposed to adapt deep learning techniques developed for natural language processing (NLP) to binary code analysis. Since then a surge of NLP-inspired binary analysis approaches have been proposed (Li et al., 2022, 2023; Zan et al., 2022; Chen et al., 2021; Redmond et al., 2019; Duan et al., 2020). In many NLP tasks, words are often converted

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1320–1332
June 16-21, 2024 ©2024 Association for Computational Linguistics

into *word embeddings*, which capture the semantic meaning of words, to facilitate further processing (Mikolov et al., 2013a; Wieting et al., 2015; Tang et al., 2014). To analyze binary code, we regard *instructions as words* and *basic blocks as sentences*.

Inspired by cross-lingual word embeddings in NLP (Mikolov et al., 2013b), we propose a novel approach to *tackle the challenge of data scarcity in binary code analysis*. Our approach learns *cross-architecture instruction embeddings* (CAIE), where semantically-similar instructions, regardless of their ISAs, have close embeddings in a shared space. Equipped with such a shared space, we can transfer knowledge from one ISA to another, especially in low-resource scenarios. Specifically, by projecting instructions disassembled from binaries in different ISAs into the shared space, we can train a model using only the data in a high-resource ISA, and transfer it to a low-resource ISA.

Unlike NLP, where obtaining cross-lingual signals can be difficult, obtaining cross-architecture signal for binary code analysis across ISAs is not a challenging task (see Section 4.1). We thus design a supervised model by borrowing the idea and technique from the `Bi-SENT2VEC` algorithm (Sabet et al., 2019) in NLP to learn CAIE. We first build a dataset consisting of a large number of semantically-equivalent basic block pairs and use them to train a joint model which learns to predict both the instruction and context in the source and target basic blocks. The model explores rich semantic relationships among instructions within its own ISA as well as across a different ISA. It is also fully self-supervised, which helps overcome the limitation of unsupervised linear transformation.

We have implemented our model, called `CrossIns2Vec`, and evaluated it on four ISAs: x86, ARM, MIPS and PowerPC (PPC). (1) In intrinsic evaluation, we conduct the instruction similarity task to evaluate the *quality* of CAIE—whether they capture the syntax and semantic information of instructions across ISAs. (2) In extrinsic evaluation, we conduct two downstream binary analysis tasks to evaluate the *transferability* of CAIE, including function similarity comparison and malware detection. We also compare `CrossIns2Vec` to the baseline methods. The results show that `CrossIns2Vec` can effectively generate high-quality CAIE with better transferability. Below summarizes our contributions:

- To address the data scarcity issue in binary code analysis, we propose to learn *cross-architecture instruction embeddings* (CAIE), where semantically-similar instructions, regardless of their ISAs, have close embeddings in a shared space. Equipped with such a shared space, given a binary analysis task, we can transfer a model trained on a data-rich ISA to another ISA with less available data.

- We have implemented a supervised model for learning CAIE and conducted both intrinsic and extrinsic evaluations on four ISAs: x86, ARM, MIPS and PPC. The results demonstrate the effectiveness of our approach.

- NLP-inspired binary code analysis is a promising research direction, but not all NLP techniques are applicable to binary code analysis. Thus, studies like ours that identify and examine effective NLP techniques for binary code analysis are valuable in advancing exploration along this direction. Our evaluation shows how the adaptation works and why it is useful through two critical binary analysis tasks.

- We release the source code, datasets, trained models, and learned CAIE to facilitate the follow-up research in this direction[1].

2 Related Work

2.1 Traditional Code Analysis

Mono-architecture. Most traditional approaches work on a *single* ISA. Some analyze source code (Kamiya et al., 2002; Wang and Luo, 2022; Luo and Zeng, 2016). Others analyze binary code (Luo, 2020; Zeng et al., 2019b; Luo et al., 2019a; Zeng et al., 2019a, 2018; Luo et al., 2016), e.g., using symbolic execution (Luo et al., 2014, 2021, 2017), but are expensive, and inapplicable for large codebases. Dynamic approaches include API birthmark (Tamada et al., 2004; Chae et al., 2013), system call birthmark (Wang et al., 2009), and instruction birthmark (Tian et al., 2013; Park et al., 2008). *Extending them to other ISAs would be hard.* Plus, code coverage is another challenge.

Cross-architecture. Recent works have applied traditional approaches to the *cross-architecture* scenario (Pewny et al., 2015; Eschweiler et al., 2016; Chandramohan et al., 2016; Feng et al., 2017;

---

[1] `https://github.com/lannan/CrossIns2Vec`

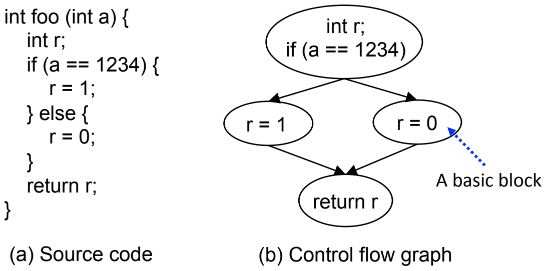
David et al., 2017, 2018, 2016). `Multi-MH` and `Multi-k-MH` (Pewny et al., 2015) are the first two for comparing functions in different ISAs, but their fuzzing-based basic-block similarity comparison and graph (i.e., CFG) matching algorithms are expensive. `discovRE` (Eschweiler et al., 2016) uses pre-filtering to boost the matching process, but is unreliable and has many false negatives. `Esh` (David et al., 2016) compares basic blocks using a SMT solver, which is unscalable.

2.2 Machine/Deep Learning-based Analysis

Mono-architecture. Recent research has applied machine/deep learning to code analysis (Li et al., 2022; Ahmad et al., 2020; Allamanis et al., 2016; Wei et al., 2019; Hu et al., 2018; Shido et al., 2019; Chen et al., 2021; Nguyen et al., 2017; Van Nguyen et al., 2017; Ahmad and Luo, 2023; Han et al., 2017). `Asm2Vec` (Ding et al., 2019) considers functions as documents and uses a PV-DM model to generate function embeddings. `PalmTree` (Li et al., 2021) generates token embeddings based on BERT (Devlin et al., 2018). However, these works only focus on a single ISA.

Cross-architecture. Most existing models are trained and tested on a pair of ISAs and the training needs the task-specific data for each ISA of a given pair (Feng et al., 2016; Xu et al., 2017; Chandramohan et al., 2016; Zuo et al., 2019; Massarelli et al., 2019). `InnerEye` (Zuo et al., 2019) adopts Neural Machine Translation techniques to measure the similarity of binary code across ISAs. `VulHawk` (Luo et al., 2023) lifts binary code into IR and uses NLP techniques to generate function embeddings. These approaches require the task-specific data for each ISA, and cannot resolve the data scarcity problem. Our approach differs significantly from them: we aim at model reuse, that is, *transferring a model trained on one ISA to another*, thereby eliminating the need for data from another ISA, especially for low-resource ISAs.

The Most Related Work. To the best of our knowledge, `UniMap` (Wang et al., 2023) is the *only work* that shares the same goal as ours: focusing on learning cross-architecture instruction embeddings (CAIE) to tackle the data scarcity issue. Their approach relies on unsupervised learning, eliminating the requirement for parallel data. However, in the context of binary code analysis, due to the prevalence of *cross-compilation*, obtaining cross-architecture signals is not challenging compared to that in NLP when seeking cross-lingual signals (see Section 4.1). Moreover, in NLP, studies have shown that cross-lingual word embeddings, learned through supervised learning, have superior transferability compared to those learned by unsupervised learning (Upadhyay et al., 2016; Ruder et al., 2019). Based on these, our approach takes a different direction by designing a supervised model for learning CAIE. The evaluation results demonstrate that our supervised learning-based CAIE exhibit superior quality and enhanced transferability when compared to the most related work.



```
int foo (int a) {
   int r;
   if (a == 1234) {
      r = 1;
   } else {
      r = 0;
   }
   return r;
}
```

(a) Source code (b) Control flow graph

Figure 1: Control flow graph and basic block.

3 Background and Motivation

3.1 Control Flow Graph and Basic Block

A control flow graph (CFG) is the graphical representation of control flow or computation during the execution of programs or applications. A CFG is a directed graph in which each node represents a basic block and each edge represents the flow of control between basic blocks.

A basic block is a sequence of consecutive statements in which flow of control enters at the beginning and leaves at the end without halt or branching except at the end. Figure 1 shows an example of a piece of source code and its CFG, where each node is a basic block. Similarly, we can generate the CFG for a piece of binary code. We here use the source code as an example for simplicity.

3.2 Motivation

Let us consider the malware detection task as an example. Recently, applying deep learning to detect malware has garnered significant attention due to its remarkable performance capabilities. However, training a deep learning model usually requires a large amount of data. As a result, the rich datasets (e.g., malware) for certain ISAs, such as x86, lead to a disproportionate focus on these ISAs and a negligence of other ISAs, such as PowerPC, which suffer from the "*data scarcity*" problem (i.e., few or even no labeled datasets exist). Moreover, it is labor-intensive and time-consuming to collect data samples and manually label them to build datasets for such low-resource ISAs. Dealing with the data scarcity issue is an unresolved challenge.

With some ISAs, like x86, being widely used, it becomes more feasible to collect sufficient data for these ISAs. Thus, it would be a great advantage if the abundance of training data for widely-used ISAs could facilitate the automated analysis of binaries in other ISAs where such data is scarce. For example, suppose a large training dataset exists for ISA **X**, but we need to analyze a binary ***b*** in ISA **Y**, for which the available training data is insufficient. As a result, it is difficult to train a model on **Y** for analyzing ***b***. To address this issue, our idea is to *transfer knowledge from ISA **X** to **Y***, such that we can train a model on **X** and transfer the trained model to perform prediction on ***b*** in **Y**.

To achieve this objective, it is essential to address the syntactic variations among different ISAs. Drawn inspiration from cross-lingual word embeddings in NLP, we propose to learn *cross-architecture instruction embeddings* (CAIE), where semantically-similar instructions, regardless of their ISAs, have close embeddings in a shared space. Equipped with such a shared space, we can transfer knowledge from one ISA to another, especially in low-resource scenarios. As a result, we can *train a model using only the data in a high-resource ISA, and transfer it to a low-resource ISA.*

3.3 Why not IR?

Intermediate representation (IR) can be used to represent code of different ISAs. For example, VEX IR is an architecture-agnostic and side-effect-free representation that can represent instruction sets of different ISAs in a uniform style. Thus, this raises the question of whether IR can serve as the bridge for achieving model reuse.

After conducting thorough investigations and experiments, we found that: given two binaries with different ISAs that are compiled from the ***same*** piece of source code, after we lift them into a common IR, the resulting IR code differs greatly. Specifically, the lengths and types of the IR statements can vary significantly from one another. Figure 2 in shows an example, where the source code is highlighted in blue at the top and the corresponding assembly code and VEX IR in x86 and MIPS are shown below. In VEX IR, the `IMark` statement indicates the address and length of its corresponding assembly instruction. For example, in x86, the address of the first assembly instruction `mov eax, [rbp-0xa0]` is `0x409a52`, and it is translated to five IR statements belonging to the first `IMark` statement, `IMark(0x409a52, 6, 0)`. This is similar for the IR code in ARM and MIPS, where the resulting IR code is significantly distinct. (Additional examples can be found in Figure 1 and Figure 3 of (Pewny et al., 2015)).

Figure 2: A example of C source code (highlighted in blue) and the corresponding assembly code and VEX IR code in different ISAs.

Therefore, existing works that utilize IR for analyzing binaries across ISAs have to perform further *advanced* analysis on the IR code. For example, (1) `Multi-MH` (Pewny et al., 2015) uses fuzzing to detect whether two pieces of VEX IR code (after lifting) are semantically similar. (2) `GitZ` (David et al., 2017) conducts complex re-optimization on IR code to compare function similarity. (3) `GeneDiff` (Luo et al., 2019b) applies deep learning analysis to VEX IR code for cross-architecture binary clone detection. Thus, IR is not "magic" that can directly serve as the "bridge" for facilitating model reuse. This work, therefore, focuses on building the "bridge"—i.e., cross-architecture instruction embeddings (CAIE)—for enabling a model trained for one ISA to be reused for other ISAs.

4 Model Design

In contrast to the challenges faced in NLP, where obtaining cross-lingual signals can be a difficult task, acquiring cross-architecture signals for binary analysis across ISAs is straightforward (Section 4.1). Moreover, studies have shown that supervised methods typically exhibit superior performance compared to unsupervised ones (Upadhyay et al., 2016; Ruder et al., 2019). We thus design a supervised model, called `CrossIns2Vec`, to learn cross-architecture instruction embeddings (CAIE). Figure 3 shows the model architecture. As we consider *instructions as words* and *basic blocks as sentences*, the input is a pair of semantically-equivalent basic blocks, B_1 and B_2, in different ISAs. Initially, each instruction is assigned a random vector. During the joint learning process, `CrossIns2Vec` effectively learns CAIE for each instruction. Below we present the detailed process.

4.1 Collecting Semantically-Equivalent Basic Block Pairs

We first need to collect the semantically-equivalent basic block pairs from different ISAs. We consider basic blocks of different ISAs that are *compiled from the same piece of source code as semantically-equivalent*. To determine the ground truth regarding the similarity of basic blocks, we rely on the source code line number. Specifically, if two basic blocks from different ISAs have the *same starting* and *end* source code line numbers, they are considered to be semantically-equivalent.

To this end, we first collect the source code of various programs and compile each one for different ISAs by cross-compilation. This process proves to be both convenient and feasible for handling various ISAs, thanks to the availability of tools such as QEMU (QEMU, 2023) and LLVM (LLVM, 2023). Consequently, the task of *acquiring cross-architecture signals across ISAs poses no significant challenge in binary code analysis*.

During the cross-compilation process, we include the "`-g`" compiling option. This ensures that the compiled binary file contains the DWARF debug information, including valuable details like the source code line number for each assembly instruction. After getting the binaries, we use IDA Pro (IDA, 2023) to disassemble each binary and generate control flow graphs (CFGs), where each node represents a basic block. During disassembly, we take advantage of IDA disassembly options, which can display the source code line number for each basic block. By leveraging these line numbers, we can identify semantically-equivalent basic block pairs. Specifically, for each basic block in one ISA, we search for its counterpart in another ISA if they have the *same starting* and *end* source code line number, indicating that they are compiled from the same piece of source code.

4.2 Learning Cross-architecture Instruction Embeddings

Our goal is to learn CAIE, where semantically-similar instructions, *regardless of their ISAs*, have embeddings that are close in a shared space.

In NLP, if a trained model is used to convert a word that has never appeared during training, the word is called an out-of-vocabulary (OOV) word and the embedding generation for them will fail. To mitigate the OOV issue, similar to `UniMap` (Wang et al., 2023), we normalize instructions by applying the following rules: (C1) replacing number constants with 0, while preserving minus signs; (C2) replacing string literals with `<STR>`; and (C3) replacing function names with `<FOO>`; (C4) other symbols are replaced with `<TAG>`.

Drawing inspiration from `Bi-SENT2VEC` (Sabet et al., 2019) in NLP, we design our model to learn CAIE based on two objectives: (1) *mono-architecture* objective: similar instructions in the *same* ISA are assigned close embeddings; (2) *cross-architecture objective*: similar instructions across *different* ISAs are assigned close embeddings.

Mono-Architecture Objective. The training objective is to predict a masked instruction e_t in a basic block B using the representation of the rest instructions in B, denoted as $\mathbf{v}_{B\setminus\{e_t\}}$. We use logistic loss $l : x \to log(1 + e^{-x})$ in conjunction with negative sampling to formulate the training objective. The training objective is computed as:

$$\min \sum_{B\in C} \sum_{e_t\in B} \left(l(\mathbf{u}_{e_t}^{\mathsf{T}} \mathbf{v}_{B\setminus\{e_t\}}) + \sum_{e'\in N_{e_t}} l(-\mathbf{u}_{e'}^{\mathsf{T}} \mathbf{v}_{B\setminus\{e_t\}})\right) \tag{1}$$

where e_t the masked instruction in B, and N_{e_t} the set of words sampled negatively for the masked instruction e_t. The set of negative instructions N_{e_t} are sampled following a multinomial distribution where each instruction e is associated with a probability: $p = \sqrt{f_e} / \sum_{e_i\in C} \sqrt{f_{e_i}}$, where f_e is the normalized frequency of e in the corpus.

Cross-Architecture Objective. To capture semantic relations of instructions across ISAs, we include

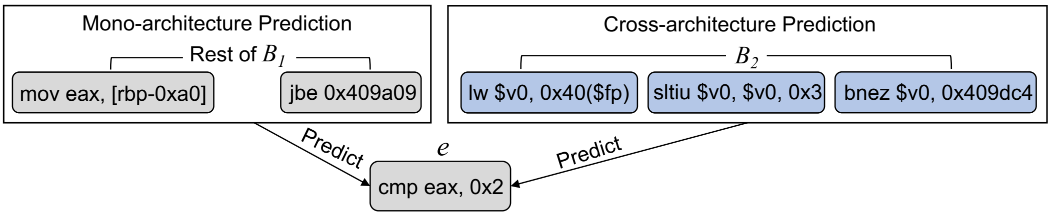

Figure 3: The `CrossIns2Vec` model.

a cross-architecture training objective, where given two semantically-equivalent basic blocks (B_1, B_2), a masked instruction e_t in B_1 is predicted using all instructions in B_2, denoted as $\mathbf{v}_{B_2}$. The training objective is computed as:

$$\min \sum_{(B_1,B_2)\in C} \sum_{e_t\in B_1} \Big(l(\mathbf{u}_{e_t}^{\mathsf{T}} \mathbf{v}_{B_2}) + \sum_{e'\in N_{e_t}} l(-\mathbf{u}_{e'_t}^{\mathsf{T}} \mathbf{v}_{B_2})\Big) \tag{2}$$

where e_t is the masked instruction in B_1, and N_{e_t} is the set of words sampled negatively for $e_t \in B_1$, following the same strategy as Equation 1.

Model Final Objective. By combining the mono-architecture and cross-architecture objectives, the objective function of our model is formulated as:

$$\min \sum \sum_{e_t\in B_1} \underbrace{\Big(l(\mathbf{u}_{e_t}^{\mathsf{T}} \mathbf{v}_{B_1\setminus\{e_t\}}) + \sum_{e'\in N_{e_t}} l(-\mathbf{u}_{e'}^{\mathsf{T}} \mathbf{v}_{B_1\setminus\{e_t\}})}_{\text{Mono-architecture loss}} + \underbrace{l(\mathbf{u}_{e_t}^{\mathsf{T}} \mathbf{v}_{B_2}) + \sum_{e'\in N_{e_t}} l(-\mathbf{u}_{e'_t}^{\mathsf{T}} \mathbf{v}_{B_2})\Big)}_{\text{Cross-architecture loss}} \tag{3}$$

In summary, for a masked instruction e_t in B_1, we use the rest instructions in B_1 as well as all the instructions in B_2 to predict e_t and vice-versa, as shown in Figure 3. In this example, the masked instruction e_t is `cmp eax, 0x2` in B_1. For the mono-architecture objective, we use the rest instructions in B_1 (colored in grey) to predict e_t. For the cross-architecture objective, we use all instructions in B_2 (colored in blue) to predict e_t. By combining the two objectives, we train `CrossIns2Vec` to learn CAIE, such that similar instructions, regardless of their ISAs, tend to have close embeddings in a shared vector space.

5 Evaluation

We evaluate our model in terms of the quality and transferability of CAIE. We have two questions: (***Q1***) ***Quality:*** how well can CAIE tolerate architectural differences and capture code semantics across ISAs? (***Q2***) ***Transferability:*** whether CAIE can transfer knowledge from one ISA to another? To answer ***Q1***, we conduct the intrinsic evaluation, including the instruction similarity task. To answer ***Q2***, we conduct the extrinsic evaluation, including two critical binary analysis tasks: function similarity comparison and malware detection.

5.1 Experimental Settings

Building Datasets for Learning CAIE. We consider four ISAs: x86, ARM, MIPS, and PowerPC (PPC). We consider x86 as the high-resource ISA, and the other ISAs as the low-resource ISAs.[2] We first collect various programs, including *OpenSSL-1.1.1*, *Binutils-2.34*, *Curl-7.87*, *Findutils-4.8.0*, *gmp-6.2.0*, *Libgpg-error-1.45*, and *Zlib-1.2.11*. These programs are widely used in prior NLP-based binary code analysis works (Luo et al., 2023; Ding et al., 2019; Marcelli et al., 2022; Massarelli et al., 2019; Li et al., 2021). For each program, we compile it on the four ISAs using different optimization levels (O0-O3).

Given a pair of ISAs (one is x86 and another a low-resource ISA), we build the dataset comprising semantically-equivalent basic block pairs for learning CAIE (the details of how to collect such pairs are discussed in Section 4.1). Through this, we have three datasets: $D_{x86\leftrightarrow ARM}$ contains 2,058,484 semantically-equivalent basic block pairs between x86 and ARM; $D_{x86\leftrightarrow MIPS}$ contains 2,121,125 semantically-equivalent basic block pairs between x86 and MIPS; and $D_{x86\leftrightarrow PPC}$ contains 2,189,139 semantically-equivalent basic block pairs between x86 and PPC.

Subsequently, we use each of the three datasets to train `CrossIns2Vec` to learn CAIE for the instructions across the respective pair of ISAs.

Note that in our evaluation, the datasets used for learning CAIE have *no overlap* with the testing datasets used in the downstream tasks, the details

---

[2] We are aware that ARM does not have the data scarcity issue. Given its importance, our evaluation involves ARM.

of which are introduced in Sections 5.3 and 5.4.

Baseline Method. To the best of our knowledge, `UniMap` (Wang et al., 2023) is the *only work* that shares the same goal as ours: focusing on learning CAIE to tackle the data scarcity issue. We thus consider it as the baseline method. `UniMap` employs an unsupervised learning approach, while our approach relies on supervised learning. As we discussed in Section 2.2, in the context of binary code analysis, obtaining cross-architecture signals is not challenging due to the prevalence of cross-compilation. Although the collection of parallel data demands increased engineering efforts, the additional efforts prove their worth if the learned CAIE exhibits superior transferability.

All the experiments were conducted on a computer with a 64-bit 2.50 GHz Intel Core (TM) i7 CPU, a Nvidia GeForce RTX 3080, 64 GB RAM, and 2 TB HD.

5.2 Instruction Similarity Task

This task is to evaluate whether CAIE can tolerate the syntactic differences and capture the semantic information of instructions across ISAs. To evaluate this, we measure whether two semantically-similar instructions, *regardless of their ISAs*, have close embeddings. Unlike word embeddings, which have many existing corpora for evaluation, we do not have such data. We thus create the datasets ourselves, which contain manually-labeled instruction pairs. We rely on the assembly language references (x86, 2023; ARM, 2023; MIPS, 2023; PowerPC, 2023) to create our datasets.

Similar to `UniMap`, we categorize instructions into 6 categories, including data transfer, arithmetic, logical, shift/rotate, bit/byte, and control transfer. Note that this categorization serves the purpose for conducting the instruction similarity task. Thus, when preparing the datasets, we encompass instructions from all categories that are shared across the four ISAs (x86, ARM, MIPS, and PPC). For each category, we randomly select 40 x86 instructions. For each selected x86 instruction, we find their corresponding similar instructions from the other three ISAs based on whether their opcodes share similar semantics (i.e., performing the same operation). Finally, we create three datasets: D_1 contains 240 similar and 240 dissimilar pairs of x86↔ARM instructions; D_2 contains the same number of pairs of x86↔MIPS instructions; and D_3 contains the same number of pairs of x86↔PPC instructions. Given a pair of instructions, we calculate the cosine similarity of their CAIE to measure their similarity. For D_1, D_2, and D_3, we achieve AUC = 0.78, 0.73, and 0.74, respectively.

Comparison with Baseline Method. To compare with the baseline `UniMap`, we use the same datasets created by `UniMap`, which contain 120 similar and 120 dissimilar pairs of x86↔ARM instructions, as well as the same number of similar and dissimilar pairs of x86↔MIPS and x86↔PPC instructions. We achieve higher AUCs of 0.79, 0.71, 0.72 for x86↔ARM, x86↔MIPS, and x86↔PPC, respectively, while the prior work yields 0.76, 0.66, and 0.68. Thus, our model exhibits better capabilities of learning CAIE that excel in capturing the semantic relations among various ISAs.

Nearest Neighbor Instructions. We next examine, for a given x86 instruction, its top-K similar instructions in the other ISAs. We first select eight high-frequency x86 instructions from all the six categories. For each x86 instruction, we search for the top-two similar instructions in ARM, MIPS, and PPC, respectively, based on the cosine similarity of their CAIE. The results are shown in Table 1. We can see that for a given x86 instruction, its top-two similar instructions in the other ISAs share similar semantics, as predicted. For example, for the x86 instruction `ADC RDX,R11`, we find the relevant ARM instructions `ADC R11,R7,R3` and `ADDS R10,R6,R11`, MIPS instructions `ADDU R6,R3,R4` and `ADDU R2,R3,R16`, and PPC instruction `ADDE R23,R8,R10` and `ADDC R7,R7,R28`, where all of them add the values in two operands and store the result back in the destination operand.

5.3 Function Similarity Detection Task

The extrinsic evaluation is to evaluate the transferability of CAIE. We conduct two binary analysis tasks: function similarity detection and malware detection. This section presents the result of the first task. For each task, we train a model using the task-specific data on x86, and transfer the trained model on another ISA (e.g., ARM, MIPS, and PPC).

FunGnn Model. `FuncGNN` (Nair et al., 2020) is a graph neural network trained on labeled control flow graph (CFG) pairs to measure the function similarity. To evaluate the transferability of CAIE, we modify the input layer of `FuncGNN` to encode each instruction as its CAIE. We then train `FuncGNN`

Table 1: Nearest neighbor instructions *cross-architecturally* as measured by cosine similarity of CAIE. The top two similar ARM, MIPS, and PPC are shown for each of the eight x86 instructions randomly selected from the six categories of instructions.

	`MOV R15D,[R9+0]`	*Score*	**`ADC RDX,R11`**	*Score*	**`SAR EDX,CL`**	*Score*	**`LEA R14,[RSP+0+<TAG>]`**	*Score*

Table 2: Results of function similarity detection task.

Train	Test	`CrossIns2Vec` (***Ours***)			`UniMap` (***Baseline***)		
		AUC	Prec.	Recall	AUC	Prec.	Recall
x86	ARM	0.99	0.95	0.98	0.95	0.93	0.95
	MIPS	0.99	0.97	0.98	0.93	0.90	0.93
	PPC	0.98	0.93	0.97	0.94	0.90	0.91

on x86 and transfer the trained model to test data in ARM, MIPS, and PPC, respectively.

Task-Specific Datasets. We first build the task-specific training dataset on x86, containing 50,000 similar and 50,000 dissimilar x86 function pairs. We then build the testing datasets for ARM, MIPS and PPC, each containing 5,000 similar and 5,000 dissimilar function pairs in the corresponding ISA. To ensure *no overlap* between the training and testing datasets, we select different programs to build them: (1) *OpenSSL-1.1.1*, *Binutils-2.34*, *Curl-7.87*, *Findutils-4.8.0*, *gmp-6.2.0*, *Libgpg-error-1.45*, and *Zlib-1.2.11* are used to build the training dataset; (2) *Coreutils-9.0* and *Diffutils-3.7* are used to build the testing datasets.

Following the dataset building method in `InnerEye` (Zuo et al., 2019), we consider two functions similar if they are compiled from the same piece of source code, and dissimilar if their source code is different. Each program is compiled using four optimization levels (O0-O3). For a given piece of source code, by applying different optimization levels, we can find six similar pairs. Then, the similar and dissimilar function pairs in the training and testing datasets are evenly divided among the six possible pairs of optimization levels.

Results. Table 2 shows the performance results, including AUC, precision, and recall. We can observe that when the model trained on x86 is transferred to ARM, MIPS, and PPC, it achieves AUC values of 0.99, 0.99, and 0.98, respectively. The results show that the model achieves exceptional performance when transferred from x86 to the other ISAs, demonstrating the superior transferability of CAIE.

Comparison with Baseline Method. To compare with the baseline `UniMap`, we first modify the input layer of `FuncGNN`, such that the CAIE generated by `UniMap` are used to encode each instruction. We then use the same training dataset to train `FuncGNN` on x86. Finally, we transfer the trained model to perform testing on ARM, MIPS, and PPC, respectively. The testing datasets are the same as those used for evaluating the transferability of CAIE generated by `CrossIns2Vec`.

The results are shown in Table 2. We observe that when the model trained on x86 is transferred to ARM, MIPS, and PPC, it achieves lower AUC/precision/recall values than those obtained when employing the CAIE generated by our model `CrossIns2Vec`. This demonstrates that the CAIE learned by `CrossIns2Vec` exhibits better transferability compared to `UniMap`.

5.4 Malware Detection Task

LSTM Model. We use the Long Short Term Memory (LSTM) model (HaddadPajouh et al., 2018) to detect malware. We modify the input layer of LSTM to encode each instruction as its corresponding CAIE. We then train LSTM on x86 and transfer the model to ARM, MIPS, and PPC.

Task-Specific Datasets. We first collect malware samples from *VirusShare.com* (virusShare, 2023), and then deduplicate the collected samples to elim-

Table 3: Results of malware detection task.

Train	Test	`CrossIns2Vec` (***Ours***)			`UniMap` (***Baseline***)		
		AUC	Prec.	Recall	AUC	Prec.	Recall
x86	ARM	0.94	0.91	0.94	0.93	0.89	0.93
	MIPS	0.93	0.91	0.94	0.91	0.90	0.92
	PPC	0.95	0.90	0.98	0.91	0.89	0.92

Table 4: Performance changes as the training dataset size varies. The testing dataset remains the same. (*M* and *B* stands for *malware* and *benign*, respectively.)

Train	Training Size	Test	Testing Size	AUC
PPC	300(M) + 300(B)	PPC	200(M) + 200(B)	0.87
x86	300(M) + 300(B)	PPC	200(M) + 200(B)	0.78
	600(M) + 600(B)			0.85
	900(M) + 900(B)			0.90
	2000(M) + 2000(B)			0.91

inate redundant ones. As a result, we have 2000, 1100, 1000, and 500 samples in x86, ARM, MIPS, and PPC, respectively. It should be noted that we spent a lot of efforts in collecting malware samples in MIPS and PPC, which are considered as low-resource ISAs.

We then build the task-specific training and testing datasets. The x86 malware samples are used for training. For the other ISAs, the malware samples are used for testing. In each training and testing dataset, we include the same number of benign samples. In the training dataset, the benign samples are randomly selected from *OpenSSL-1.1.1*, *Binutils-2.34*, *Curl-7.87*, *Findutils-4.8.0*, *gmp-6.2.0*, *Libgpg-error-1.45*, and *Zlib-1.2.11*, while the testing dataset contains benign samples selected from different programs, including *Coreutils-9.0* and *Diffutils-3.7*. We ensure no overlap between the training and testing datasets.

Results. Table 3 shows the performance results, including AUC, precision, and recall. We can see that when the model trained on x86 is transferred to ARM, MIPS, and PPC, it achieves AUC values of 0.94, 0.92, and 0.91, respectively. The fact that the model's accuracies keep high demonstrates the efficacy of our learned CAIE in facilitating the transfer of knowledge across ISAs.

We then seek to understand how performance changes as the training dataset size varies. Specifically, we conduct experiments starting from the same size of the x86 and PPC training datasets, gradually increasing the x86 dataset size. The results are shown in Table 4. We can see that when the model is trained on an x86 training dataset containing more than 900 malware samples and then reused for PPC, it outperforms the model trained and tested on PPC with less available data. This demonstrates the critical role of a sufficiently large training dataset in order to achieve desirable performance. However, for low-resource ISAs like PPC, acquiring a large dataset proves to be challenging.

Comparison with Baseline Method. We first modify the input layer of `LSTM`, such that the CAIE generated by `UniMap` are used to encode each instruction. We then use the same training datasets to train `LSTM` on x86. Finally, we transfer the trained model to perform prediction on the same testing datasets on ARM, MIPS, and PPC, respectively. The results are shown in Table 3. When comparing the AUC/precision/recall values obtained when employing CAIE learned by `UniMap` to those leaned by `CrossIns2Vec`, it demonstrates that our learned CAIE have superior transferability compared to the baseline `UniMap`.

6 Conclusion

Applying deep learning to binary code analysis has drawn great attention. Limited availability of data on low-resource ISAs, however, hinders deep learning-based binary code analysis. In this work, we propose to learn *cross-architecture instruction embeddings (CAIE)*, where semantically-similar instructions, *regardless of their ISAs*, have close embeddings in a shared space. As a result, we can transfer a model trained on a data-rich ISA to another ISA with less available data. We conducted experiments to evaluate the quality and transferability of the learned CAIE. In the downstream tasks, when a model trained on x86 is transferred to ARM, MIPS and PPC, the prediction accuracies keep high. Our approach significantly outperforms the prior work. Therefore, our approach can generate CAIE with high quality and transferability, and resolve the data scarcity problem in low-resource ISAs for binary code analysis tasks.

It was also partially supported by the Commonwealth Cyber Initiative (CCI). The authors would like to thank the anonymous reviewers for their valuable comments.

Ethical Considerations

Datasets. To train our model `CrossIns2Vec`, we first need to collect semantically-equivalent basic block pairs from different ISAs. We first collect open-source programs, and compile them for different ISAs using cross compilers. Given the wide availability of open-source code, this requires little effort. To determine the ground truth regarding the similarity of basic blocks, we rely on the source code line number. Specifically, if two basic blocks from different ISAs have the *same starting* and *end* source code line numbers, they are considered to be semantically-equivalent. The detailed description of the process can be found in Section 4.1.

For training `CrossIns2Vec`, we use a dataset of semantically-equivalent basic block pairs. We acknowledge that aggressive optimizations, such as inlining in O3, have an impact for searching basic block pairs. However, we clarify that we skip including basic blocks that involve inlining into our datasets. Given the large number of basic blocks available, this does not impose a barrier for creating the datasets for training `CrossIns2Vec`.

For each downstream task, we collect the task-specific training and testing datasets, the details of which are introduced in Sections 5.3 and 5.4. A special note is about malware samples, which are collected from *VirusShare.com* (virusShare, 2023). *VirusShare.com* is a repository of malware samples that researchers use to study and develop cybersecurity solutions. While it can be a valuable resource, there are ethical considerations, including using the samples responsibly for legitimate research purposes, preventing the creation of new threats, and respecting privacy and legal boundaries.

In our efforts to support subsequent research, we plan to make the datasets available for public use. Specifically, datasets obtained using open-source programs will be openly released. However, in the case of malware samples, we will provide the file names and hash values sourced from *VirusShare.com*. This offers researchers the means to identify specific malware samples without directly sharing the potentially harmful code.

Applications. To cope with the data scarcity issue and alleviate the per-ISA effort, this work proposes to learn cross-architecture instruction embeddings (CAIE), where semantically-similar instructions, regardless of their ISAs, have close embeddings in a shared vector space. Enabled by the technique, we can train *a single model* on a high-resource ISA and *reuse* it for low-resource ISAs, without any modification. Compared to existing methods, this work offers significant advantages by eliminating the need for data collection in multiple ISAs (particularly for low-resource ISAs where labeled data is limited or unavailable) as well as the per-ISA fine tuning efforts. It will not only advance binary code analysis by developing a bridge for enabling model reuse, but also have various security applications, including malware detection and function similarity comparison.

Limitations

NLP-inspired binary code analysis is a promising research direction, but not all NLP techniques are applicable to binary code analysis. Thus, studies like ours that identify and examine effective NLP techniques for binary code analysis are valuable in advancing exploration along this direction.

To validate the effectiveness of our approach, we conducted two downstream tasks to evaluate the transferability of the learned CAIE. We acknowledge that the learned CAIE may not be generalize to all types of code, such as Windows, iPhone, and Android applications. To ascertain this, further investigation and comprehensive testing are needed.

Due to the extensive range of binary analysis tasks and their inherent complexity, we do not claim that our approach can be applied to all tasks. However, the successful performance of our approach in two critical tasks highlights the significant value of CAIE, while demonstrating the application of CAIE for other tasks needs dedicated future work. Much research can be done for exploring and expanding the boundaries of the approach.

`ReEval`: Automatic Hallucination Evaluation for Retrieval-Augmented Large Language Models via Transferable Adversarial Attacks

Abstract

Despite remarkable advancements in mitigating hallucinations in large language models (LLMs) by retrieval augmentation, it remains challenging to measure the reliability of LLMs using *static* question-answering (QA) data. Specifically, given the potential of data contamination (*e.g.,* leading to memorization), good static benchmark performance does not ensure that model can reliably use the provided evidence for responding, which is essential to avoid hallucination when the required knowledge is new or private. Inspired by adversarial machine learning, we investigate the feasibility of automatically perturbing existing static one for *dynamic* evaluation. Specifically, this paper presents `ReEval`, an LLM-based framework using prompt chaining to perturb the original evidence for generating new test cases for evaluating the LLMs' reliability in using new evidence for answering.

We implement `ReEval` using ChatGPT and evaluate the resulting variants of two popular open-domain QA datasets on a collection of LLMs under various prompting settings. Our generated data is human-readable and useful to trigger hallucination in LLM. Accurate models on static data are observed to produce unsupported answers from the perturbed evidence, with pronounced accuracy drops across LLMs including GPT-4. We find that our adversarial examples are transferable across all considered LLMs. The examples generated by a small model can be used to evaluate a much larger model, making our approach cost-effective.

1 Introduction

Due to their superior capability in generating coherent and convincing outputs, large language models (LLMs), such as ChatGPT (OpenAI, 2022), GPT4 (OpenAI, 2023), Claude (Anthropic, 2023) and Palm (Anil et al., 2023), have been extensively used as foundations for language technologies.

Though LLMs excel in memorizing knowledge and understanding natural language, merely depending on parametric knowledge for inquires (closed-book) has inherent limitations. Specifically, these models are unaware of knowledge update and uninformed about new or private information they have not previously encountered. One popular way to mitigate this is to augment LLMs with external relevant evidence (open-book), *e.g.,* retrieval-augmented LLMs (Shi et al., 2023; Peng et al., 2023), outperforming their closed-book counterparts. However, this improvement does not necessarily imply that the model with retrieval augmentation *truly integrates the given evidence for deriving the response*. As most popular datasets used for evaluation are curated using public corpora (*e.g.,* Wikipedia), which are already included in the LLM pretraining, they risk becoming not challenging enough, and models may achieve higher accuracy by mere memorization or by exploiting their familiarity with topics or domains found in static evaluation datasets. Thus, it raises concerns as to whether retrieval-augmented LLMs might resort to fabricating answers that are inconsistent with the presented evidence, resulting in hallucination. Given the wide applications of retrieval-augmented LLMs, it is critical to reliably assess their faithfulness to the context for trustworthy and safe AI, particularly when handling sensitive or recently updated information.

In this work, we propose a new evaluation framework `ReEval`, which dynamically generate new data to evaluate LLMs. Motivated by using adversarial attacks to trigger undesirable behaviors in machine learning models (Madry et al., 2018; Goodfellow et al., 2014), we focus on perturbing evidence in the prompts to measure the reliability of LLMs' capability of deriving proper responses based on the provided context. Through the perturbation of either the answer span or the rest context in the given evidence, `ReEval` accordingly provides

---

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1333–1351
June 16-21, 2024

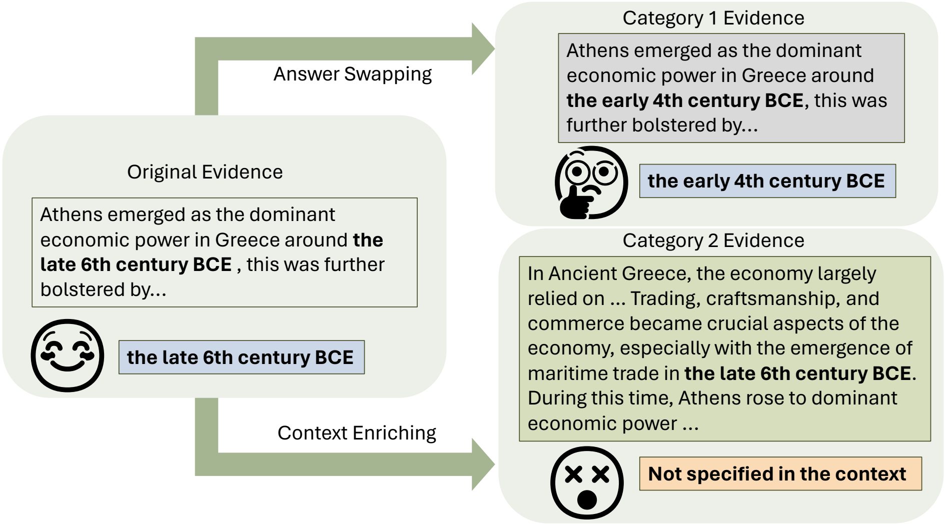

Figure 1: An example of how the original evidence is edited (answer swapping and context enriching) by `ReEval`. The question is “when did athens emerges as wealthiest greek city state?". “the early 4th century BCE” and “the late 6th century BCE”is the desirable answers for *answer swapping* (Category 1) and *context enriching* (Category 2), respectively. ChatGPT answers are next to the emoji.

two ways of synthesizing evaluation datasets (see examples in Figure 1): 1) *answer swapping* (Category 1), where the original answer is replaced with another valid answer while the remaining context is intact; 2) *context enriching* (Category 2), where more relevant information is added to the provided document while the original supportive information is kept. The former simulates the scenario where only the answer-relevant part of the document is updated while the latter represents the evolving document where more related information is added leading to more complex documentation of specific topics. We then implement `ReEval` by *prompt chaining* with LLMs, *i.e.,* using LLMs to generate new test cases that are more likely to trigger hallucinations in LLMs.

To verify the effectiveness of the proposed framework, we apply it to two popular open-domain QA dataset, Natural Questions (NQ) (Kwiatkowski et al., 2019) and RealtimeQA (Kasai et al., 2022). Human studies are conducted to verify the naturalness of the generated adversarial attacks, *i.e.,* the updated document is human-readable, supporting the *desirable* answer for the corresponding question. We then evaluate our generated datasets on both open-source (Alpaca (Taori et al., 2023)) and propriety (ChatGPT, Claude, Palm and GPT-4) LLMs under various prompting settings, *e.g.,* zero-shot, few-shot, and more enhanced prompting techniques designed to improve the reliability of prompting with LLMs. Although natural and supportive in the eyes of humans, both probing datasets trigger LLMs to produce inconsistent answers based on the perturbed evidence, regardless of their model sizes and training techniques. We find that the self-attacks are more effective but attacking test examples generated by our method is transferable across all considered LLMs. This enables the possibility of evaluating LLMs using test cases generated by more cost-effective LLMs.

2 Related Work

Faithfulness of Augmented LLM. Recent work shows that, given the correct passages, LLMs could be highly receptive to the provided passage even if the passage is inconsistent with the model memory. For example, (Xie et al., 2023) focus on machine-generated questions from a subject-object-relation triple with machine-generated evidence, and (Zhou et al., 2023) design prompt templates that could force the model to follow the provided context and thus improve the faithfulness of the model. Instead, we use diverse and real-world questions from NQ and focus on editing the passage without compromising the naturalness of the original passages. In addition to including the advanced prompting from (Zhou et al., 2023) in our study, we focus on a more diverse and challenging set of questions rather than a smaller and simpler one with questions that could be answered correctly under the zero-shot closed-

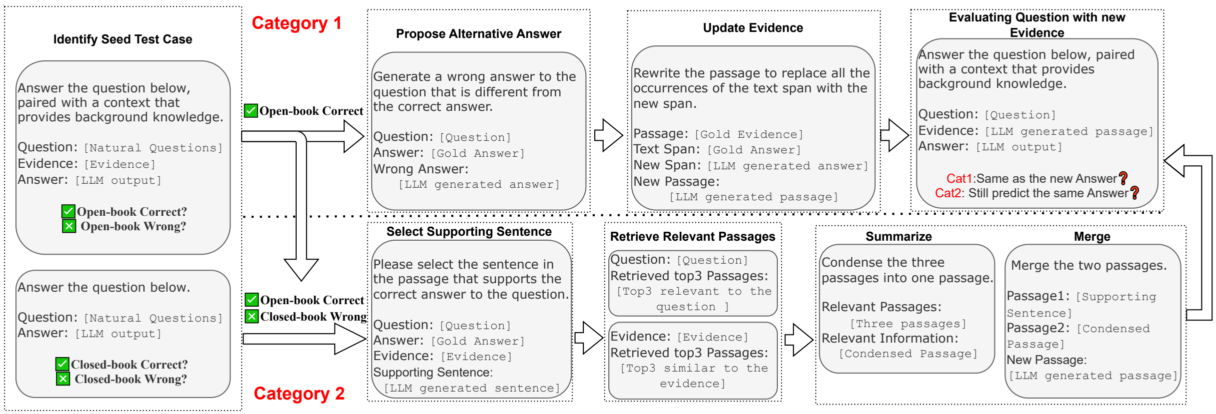

Figure 2: The pipeline of `ReEval`, including identifying seed cases, generating new tests, and hallucination evaluation.

book setting. We argue that the difficulty and diversity of the questions as well as the naturalness of evidence passages are crucial for understanding the hallucination of SOTA LLMs for real-world applications. In our framework, we keep the questions natural, and the evidence is from Wikipedia with abundant information. For Category 1 data generation, previous work introduces ideas on altering the entities in the passage (Yan et al., 2021; Longpre et al., 2021; Zhou et al., 2023), while we consider all types of answers (including entities as subcases), and use LLM to automatically substitute the answer properly (making it fit the context). For Category 2 data generation, (Choi et al., 2021) propose to decontextualize the supporting sentence from the passage, and (Jia and Liang, 2017) add distractors to the original passage. In contrast, we want to enrich the original passage by first extracting the supporting sentence with proper decontextualization and then enriching it with other relevant information based on prompting with LLMs.

Adversarial Attacks & Transferability. There is a long line of research in generating adversarial examples to trigger errors or undesirable behaviors from machine learning models (Szegedy et al., 2014; Goodfellow et al., 2014). To improve the robustness of machine learning models, there are also a number of methods proposed to defend against such attacks (Madry et al., 2018; Zhu et al., 2020; Li and Qiu, 2020; Cheng et al., 2021). However, models trained with adversarial learning are found to have at-odds generalization (Tsipras et al., 2019; Zhang et al., 2019), *e.g.,* improving the accuracy on adversarial attacks can compromise the model performance on clean examples. Despite being more challenging due to its discrete nature, different text adversarial attacks with perturbed inputs imperceptible to humans have been proposed for question answering (Jia and Liang, 2017), natural language inference (Nie et al., 2020), and sentiment classification (Iyyer et al., 2018). One surprising phenomenon is that many adversarial examples are *transferable* (Papernot et al., 2016; Wallace et al., 2021). For example, Wallace et al. (2021) show that adversarial prefix optimized for one particular model can also transfer to models of different architectures and sizes. In addition to relying on white-box access to generate effective adversarial examples, recent work even reports that it is difficult to generate reliable examples via automatic search (Carlini et al., 2023). Our work is highly motivated by this long line of work, *i.e.,* making evidence edits while keeping the input legitimate for the targeted task so that the LLMs cannot reliably answer the question. Here, we do not assume any model access except its text outputs, *i.e.,* black-box. We show that our proposed approach of generating adversarial test cases from a pivot LLM can trigger hallucination behaviors across a set of open-source and proprietary LLMs.

3 `ReEval` Framework

Assessing the hallucination of LLMs is challenging as we often do not know what changes in the prompt would trigger LLMs to hallucinate. In this paper, we present our approach `ReEval` for automatically constructing a large number of test cases that can surface hallucination issues. Given a pivot LLM, we first prompt it to identify *seed test cases* from a pool of existing data. Then we prompt the pivot LLM again to generate *attacking test cases* based on individual seed test cases. These attacking test cases are used to evaluate the performance of the pivot LLM (**self-attack**) as well as other LLMs (**cross-attack**). While `ReEval` is a general framework, we focus on the QA scenario where the LLMs to be evaluated need to answer open-domain questions based on their supporting evidence. The pipeline is illustrated in Figure 2.

Seed Case Selection. To identify seed test cases, we categorize QA examples based on whether the pivot LLM can answer the question correctly under the open-book and closed-book settings in a zero-shot fashion, similar to typical static evaluation. In the closed-book setting, only the question itself is given and the pivot LLM can only rely on memorization, whereas in the open-book setting, the associated supporting evidence is provided. As we are interested in assessing **whether the LLM can truely comprehend the provided evidence and reliably use that for answering**, only cases that can be answered correctly using open-book prompt are kept as seed. For those cases, `ReEval` generates attacking test cases by perturbing the evidence, potentially updating the answers (*e.g.,* answer swapping). Below is the zero-shot open-book prompt for seed test case selection, and the closed-book version simply drops the evidence part (see more examples in Appendix).

Zero-shot Open-book Prompt

Answer the question below, paired with a context that provides background knowledge. Only output the answer without other context words.
Context: {Evidence}
Question: {Question}
Answer:

Evidence Perturbation. To generate viable attacking test cases, we consider the following two perturbation approaches.

1. **Answer Swapping** (top flow in Figure 2): Update the evidence using a new answer that may lead to a knowledge conflict (§3.1). In the top-right example of Figure 1, we replace *"the late 6th century BCE"* with *"the early 4th century BCE"* in the evidence and test whether the LLM can update its answer accordingly.

2. **Context Enriching** (bottom in Figure 2): Enrich the evidence using extra relevant facts that may dilute the information (§3.2). In the bottom-right example of Figure 1, the evidence becomes much more dense though the answer is unchanged, and we test whether the LLM can still produce the original answer.

For the second approach, we exclude cases where the pivot LLM can answer correctly under the closed-book setting since perturbing the evidence for such cases may not surface the hallucination issue, *i.e.,* the LLM may simply use its internal memory to answer the question correctly and completely ignore the evidence.

Re-evaluation. To assess the hallucination of LLMs, we can simply measure the accuracy of the predicted answers for the attacking test cases. If the LLM faithfully follows the provided context, it should be immune to these perturbations and maintain a high accuracy score. The evaluation considers both zero-shot and few-shot prompting. The zero-shot prompt for evaluation is identical to the one used for seed test selection above. The few-shot version inserts the demonstrations of evidence-question-answer triplets right before the "Context: {Evidence}" line.

Few-shot Open-book Prompt

Answer the question below, paired with a context that provides background knowledge. Only output the answer without other context words.
{Demonstrations of Evidence-Question-Answer tuples}
Context: {Evidence}
Question: {Question}
Answer:

3.1 Category 1: Answer Swapping

Here, we present the first approach to generate test cases by updating the original evidence with alternative answers. Specifically, those alternative answers are proposed by the pivot LLM via prompting. Note that the considered seed test cases are open-book correct with the pivot LLM.

For each question, given the original answer and supportive evidence, we first ask the model to generate an alternative answer that is factually wrong using the following prompt.

Prompt for Generating An Alternative Answer

Generate a wrong answer to the question that is different from the correct answer.
Question: {Question}
Answer: {Gold Answer}
Wrong Answer:

We then instruct the LLM to replace all the occurrences of the original answer with the alternative one.[1]

---

[1] Although a simple string match can also do the job, it can make the answer occurring sentences inconsistent with the neighboring context, *e.g.,* mismatched pronouns and aliases.

Prompt for Updating Evidence

Rewrite the passage to replace all the occurrences of the text span with the new span.
Passage: {Original Evidence}
Text Span: {Original Answer}
New Span: {LLM generated answer}
New Passage:

Since most context is kept, the newly generated evidence is likely to support the alternative answer for most questions (as verified in §4.3).

3.2 Category 2: Context Enriching

Our second strategy aims to enrich the original evidence with more relevant context, leading to a more complex context for answer reasoning. Unlike Category 1 discussed above, we only keep seed cases that are open-book correct but closed-book wrong to ensure that certain comprehension of the evidence is required to answer the question correctly.

To ensure that the newly generated evidence still provides support for the question, we first extract the supporting sentence from the original evidence.

Prompt for Selecting the Supporting Sentence

Please select the sentence in the passage that supports the correct answer to the question.
Question: {Question}
Answer: {Answer}
Evidence: {Evidence}
Supporting Sentence:

We then gather relevant information from an external database to be used for composing the new evidence. Here, we consider two ways of retrieving passages from Wikipedia for fusion with the supporting sentence above, *i.e.,* evidence-focused expansion and question-focused expansion, where the former uses the original evidence as the query and the question is used for the latter case. As these two expansions bring in different types of relevant information, we create two corresponding copies of new evidence. To make the information more diverse, we select the top-k passages from different Wikipedia pages. To merge these passages into a single passage, we first ask the LLM to summarize the information of the retrieved set, and then merge the supporting sentence into the summary. Here, the pivot LLM needs to extract and summarize key information so that the new evidence is human-readable and still supports the original answer.

Summarize Prompt

Condense the three passages into one passage.
Relevant Passages: {List of Passages}
Relevant Information:

Merge Prompt

Merge the two passages
Passage1: {Supporting Sentence}
Passage2: {Condensed Passage}
New Passage:

4 Experiments

4.1 Experiment Settings

Evaluation Metrics. Three evaluation metrics are reported, *i.e.,* exact match (EM) accuracy, token-level F1, and entailment accuracy. The first two metrics are traditionally used for evaluating QA models. However, they tend to be too strict for evaluating LLM-generated responses, since LLMs often produce long and verbose sequences to explain the answers (partially due to their alignment procedure). The entailment accuracy is a more lenient metric that checks whether "Question + LLM Output" can entail "Question + Answer". In this paper, we use an entailment model `nli-deberta-v3-base`[2] from Sentence-BERT (Reimers and Gurevych, 2019), which is mostly reliable based on our manual inspection. Since we use the pivot model to select the seed cases, the accuracy of other models on the original set is not guaranteed to be 100. To clearly reveal the performance difference, we also report "Normalized Entailment" accuracy, where we normalize the test set to the cases that the corresponding model could answer correctly before perturbation.

Source Data. We use the MRQA version (Fisch et al., 2019) of Natural Questions (Kwiatkowski et al., 2019) and RealTimeQA data (Kasai et al., 2022) from 20220613 to 20231110. and conduct the following filtering steps: 1) remove duplicated Question-Evidence-Answer triplets and only keep one unique instance, 2) remove all evidence passages that are shorter than 10 words, 3) remove all cases with answers longer than 5 words. After this, 7189 instances from NQ and 1380 instances from RealtimeQA are kept. For questions with multiple answers, if the answers are overlapping (*e.g.,* "1871" and "1871 A.D."), we randomly keep one, otherwise, the corresponding examples are removed. Note the same question may still appear in multiple instances because the supporting evidence can be different.

Table 2: Zero-shot and few-shot performance of LLMs on Category 1 data of RealtimeQA.

Generated Data. Unless otherwise specified, ChatGPT (`gpt-3.5-turbo-0301`) is the pivot LLM for identifying seed test cases and generating attacking test cases. When identifying seed test cases, we treat an answer produced by the pivot LLM as correct if it matches the reference answer exactly or can entail the reference answer in the same way as we compute the entailment accuracy. The retriever used for generating Category 2 cases is based on `all-mpnet-base-v2`[3]. In total, we obtain **3,539** and **2,211** attacking test cases in Category 1 and Category 2 of NQ, and **1,000** and **814** attacking test cases in Category 1 and Category 2 of RealtimeQA respectively.

We evaluate five popular LLMs using the generated attacking test cases: Alpaca-7B (Taori et al., 2023), ChatGPT (`gpt-3.5-turbo-0301`), Claude2, PaLM, and GPT-4 (`gpt-4-0613`), which is considered to be the state-of-the-art (SOTA) LLM. In the few-shot setting, 5 static demonstration examples are used.

4.2 Main Results

We evaluate the five LLMs on the Category 1 and Category 2 data generated by ChatGPT, including both self-attack and cross-attack scenarios. [4] In addition to vanilla zero-shot and few-shot promptings, we consider the recently proposed faithfulness-promoting prompting, *i.e.,* the opinion-based prompt by (Zhou et al., 2023). For each model, we evaluate its closed-book performance, open-book performance, and open-book with faithful prompting performance. The full list of various prompts and error examples is in Appendix.

Category 1. Here, the model is expected to follow the given context, and predict the *altenative answer* proposed by the pivot model. The results are summarized in Table 1 and Table 2. As expected, the model resistance towards our attack is mostly correlated with its model size and capability. Specifically, larger and more capable models are more robust, *e.g.,* GPT-4 is more reliable than

Table 4: Zero-shot and few-shot performance of LLMs on Category 2 Data of RealtimeQA.

Alpaca-7B. Although GPT-4 is the most powerful model, it is still not immune to our attacks, indicating the effectiveness of our approach to trigger hallucination in SOTA LLMs. Though using the human-designed faithful prompt or using in-context examples helps the performance in some cases, there are no consistent improvements compared with zero-shot in general.

Category 2. We require the model to fully understand both the question-focused expansion and evidence-focused expansion cases, and one question is considered correct only when both are answered correctly. We report the merged result in Table 3 and Table 4, and we also report the few-shot performance on each case separately in Table 13 of Appendix. As we can see, there are large performance drops for all models, suggesting they fail to identify the relevant evidence information regardless of prompting techniques. Similar to Category 1, the faithful prompt is observed to have no consistent benefits, which calls for future work to develop more reliable prompting techniques.

4.3 Human Evaluations

To evaluate whether the evidence generated by `ReEval` is supportive and human-readable, we randomly sample 500 cases from Category 1, 1000 cases from Category 2 with 500 examples for question-focused expansion, and 500 for evidence-focused expansion. We use Amazon Mechanical Turk to collect human judgments on this set. Each question is judged by three annotators, who are asked to read the evidence and decide whether it could support them to get the correct answer. To prevent annotators from randomly submitting “Yes” or “No”, 10% of the data is used as validation checks where we know whether the evidence supports the answer. We only accept annotations from the annotators with at least 90% accuracy on the validation check. For each question, if the majority of the annotators think the generated evidence is supportive, it is then counted as human-readable. For all three categories, around 90% of the cases are human readable, supporting the quality of `ReEval`, with 90.8%, 92.4%, and 88.8% human-readable ratios for Category 1, Category 2 question-focused and evidence-focused, respectively.

Table 6: Few-shot case study of backbone LLMs used by `ReEval` (500 examples). The column blocks indicate the Category 2 data generated by ChatGPT and GPT-4, respectively

4.4 Case Studies

Is `ReEval` sensitive toward backbone LLMs? To do that, we use alternative LLMs to generate attacking test cases other than ChatGPT. We consider both Alpaca-7b and GPT-4 for Category 1 and only GPT-4 for Category 2 given the task is more demanding. Due to the limitation of budget, we randomly sample 500 examples from NQ for this study. All prompts are similar to those used previously. The few-shot performances of Category 1 and Category 2 are reported in Table 5 and Table 6, respectively. As shown in Table 5, compared with ChatGPT and Alpaca, GPT-4 does not generate stronger attacks. This is probably because the alternative answers from GPT-4 are more receptive to all models. The Category 1 data generated by the smallest model (Alpaca-7B) appears to be very effective for those two larger ones, but we observe that that is because Alpaca sometimes generates invalid answers and also fails to replace all the occurrences of the old answer. On the other hand, compared with ChatGPT, GPT-4 can generate more stronger attacks for Category 2 (Table 6). We find that GPT-4 is better at summarizing multiple pieces of information, leading to more complex evidence. Although all three models are most vulnerable to self-attacks, all `ReEval` attacks are transferable, making it possible to generate attacking test cases using more cost-effective models.

Is `ReEval` sensitive toward the position of the answer? To get the distribution of the answer in the evidence, we only keep the cases where the answer only occurs once in the evidence (2678 in total). There are 55.94% cases where the answer is in the first 1/3 of the evidence, 23.64% cases where the answer is in the middle part of the evidence, and 20.43% cases where the answer is in the last 1/3 of the evidence. We evaluate the accuracy of different models under both few-shot and open-book setting in these 3 cases, and we do not see any significant performance difference except that Alpaca-7B performs worse when the answer is at the end of the evidence. More detailed results are in Table 14 in the Appendix.

5 Conclusion

In this paper, we present `ReEval`, an LLM-based framework that generates transferable adversarial attacks to assess the hallucination of retrieval-augmented LLMs. By swapping the answer in the evidence or adding more relevant information to enrich the context, we successfully trigger hallucination behaviors of existing state-of-the-art LLMs. `ReEval` is a viable approach in that it can generate transferable attacking examples using more cost-effective LLMs. We believe `ReEval` could be used to help assess the hallucination of future LLMs, and potentially help mitigate hallucinations. Future directions include further studying `ReEval` on tasks of different complexities and how to use `ReEval` for debugging LLM-based applications.

6 Limitations

Although we find our framework effective in evaluating the reliability of retrieval-augmented LLMs, there are some limitations worth discussion here.

First, this study distinctly concentrates on questions with short answers, thereby delineating an intentional boundary from engaging in the exploration of long-form question-answering. For long-form cases, it requires more complex ways of perturbing evidence, *e.g.,* multiple sentences are required to be updated at the same time. The comprehensive investigation into long-form question-answering is deferred to future scholarly endeavors, marking a deliberate scope restriction to refine the focus and depth of the current analysis.

Moreover, the scope of our research rigorously limits its examination to single-hop questions. Consequently, this study does not venture into the evaluation of complex reasoning inaccuracies, often referred to as reasoning hallucinations, which is more likely for multi-hop questions. This delineation underscores a focused approach, yet acknowledges the complexity and necessity of future investigations into multi-hop question-answering, with the need for specialized methodologies to assess and mitigate reasoning errors in such contexts.

In terms of methodology, our study either introduces perturbations within the answer span or modifies the adjacent contextual narrative; however, scenarios that encompass both an altered answer span and a significantly adjusted surrounding context are not within the purview of this investigation. This strategic decision enables the isolation and better understanding of the effects of each type of perturbation independently. Nonetheless, it also marks a critical avenue for further intricate research toward evaluating the compound impacts.

A Appendix

Here, we provide examples of prompt implementations and additional results.

First, we provide selected instances for few-shot prompting in Table 7. In addition, prompts used for Category 1 and Category 2 data generations are listed in Table 8 and Table 9 respectively. Different prompting methods for different language models are detailed in Table 10 (Closed-book), Table 11 (Open-book) and Table 12 (Faithful prompting).

Lastly, more experiment results are in Table 13 (breakdown results of Category 2 experiments in subsection 4.2) and Table 14 (detailed results for section 4.4).

Question: who sings what lovers do with maroon 5
Evidence: “ What Lovers Do ” is a song by American pop rock band Maroon 5 featuring American R&B singer SZA . It was released on August 30 , 2017 , as the lead single from the band ’s sixth studio album Red Pill Blues (2017) . The song contains an interpolation of the 2016 song “ Sexual ” by Neiked featuring Dyo , therefore Victor Rådström , Dyo and Elina Stridh are credited as songwriters .
Answer: American R&B singer SZA

Question: who plays lead guitar on i want you she ’s so heavy
Evidence: John Lennon – lead and harmony vocals , multi-tracked lead guitar , Moog synthesizer Paul McCartney – harmony vocals, bass George Harrison – harmony vocals , multi-tracked lead guitar Ringo Starr – drums , congas , wind machine Billy Preston – Hammond organ
Answer: John Lennon

Question: a long chain of amino acids linked by peptide bonds is a
Evidence: The covalent chemical bonds are formed when the carboxyl group of one amino acid reacts with the amino group of another . The shortest peptides are dipeptides , consisting of 2 amino acids joined by a single peptide bond , followed by tripeptides , tetrapeptides , etc . A polypeptide is a long , continuous , and unbranched peptide chain . Hence , peptides fall under the broad chemical classes of biological oligomers and polymers , alongside nucleic acids , oligosaccharides and polysaccharides , etc .
Answer: polypeptide

Question: when does the school year start in france
Evidence: In Metropolitan France , the school year runs from early September to early July . The school calendar is standardised throughout the country and is the sole domain of the ministry .
Answer: early September

Question: which city is selected under hriday scheme in karnataka
Evidence: With a duration of 4 years (completing in November 2018) and a total outlay of 500 crore (US $78 million) , the Scheme is set to be implemented in 12 identified Cities namely , Ajmer , Amaravati , Amritsar , Badami , Dwarka , Gaya , Kanchipuram , Mathura , Puri , Varanasi , Velankanni and Warangal .
Answer: Ajmer

Cat 1	**Question**: what is the baby elephants name in jungle book **Evidence**: Dumbo - The baby elephant who is the son of Hathi and Winifred and is a good friend of Mowgli. He is voiced by Clint Howard in the first movie and by Jimmy Bennett in The Jungle Book 2 **Answer**: Dumbo **GPT4 Output**: Hathi
Cat 1	**Question**: who brought the idea of castles to england **Evidence**: Castles served a range of purposes , the most important of which were military , administrative , and domestic . As well as defensive structures , castles were also offensive tools which could be used as a base of operations in enemy territory . Castles were established by British rulers of England for both defensive purposes and to pacify the country 's inhabitants . As William the Conqueror advanced through England , he fortified key positions to secure the land he had taken . Between 1066 and 1087 , he established 36 castles such as Warwick Castle , which he used to guard against rebellion in the English Midlands **Answer**: British rulers **GPT4 Output**: William the Conqueror
Cat 1	**Question**: baga beach is in north or south goa **Evidence**: Baga Beach is a popular beach and tourist destination in South Goa. Baga is located at the north end of the contiguous beach stretch that starts from Sinquerim, Candolim, leads to Calangute and then to Baga **Answer**: South Goa **GPT4 Output**: North Goa
Cat 2 Query-based	**Question**: how long prime minister stay in office canada **Evidence**: The Prime Minister of Canada is appointed by the Governor General on the advice of the Prime Minister and serves for an indefinite term, usually around 5 years. The Lieutenant Governors at the provincial level are appointed in a similar manner and also serve for approximately 5 years. The territories have Commissioners who are appointed by the federal cabinet and conventionally serve for about 5 years. The Prime Minister of Canada is the head of government and chooses the ministers that make up the Cabinet. The current Prime Minister, Justin Trudeau, remains in office until he resigns, is dismissed, or dies. **Answer**: until he or she resigns , is dismissed , or dies **GPT4 Output**: Usually around 5 years
Cat 2 Evidence-based	**Question**: what percentage of the earth 's surface is water **Evidence**: Because the oceans that cover roughly 78% of the area of the Earth reflect blue light, the Earth appears blue from space, and is often referred to as the blue planet and the Pale Blue Dot. The Earth's water is distributed across various sources, with oceans holding 97% of surface water, glaciers and polar ice caps holding 2.4%, and other land surface water such as rivers, lakes, and ponds holding 0.6%. Only a small portion of water is contained in aquifers, vapor, clouds, precipitation, biological bodies, and manufactured products. The total volume of water on Earth is estimated to be 1.386 billion km0̆0b3, with 97.5% being saltwater and 2.5% being freshwater. Of the freshwater, only 0.3% is liquid on the surface, while the rest may be present in the lower mantle of the Earth. The United Nations Convention on the Law of the Sea defines all of the ocean as "sea," making Earth the only known planet with liquid water on its surface. Additionally, Earth's water distribution, including oceans, ice caps, and clouds, gives it a distinct blue appearance when viewed from space. Approximately 97.2% of Earth's known water is contained within the seas, which cover more than 70% of its surface. **Answer**: 78% **GPT4 Output**: 70%

Table 15: Error Examples of GPT-4 under the Few-shot Setting.

An Effective Automated Speaking Assessment Approach to Mitigating Data Scarcity and Imbalanced Distribution

Abstract

Automated speaking assessment (ASA) typically involves automatic speech recognition (ASR) and hand-crafted feature extraction from the ASR transcript of a learner's speech. Recently, self-supervised learning (SSL) has shown stellar performance compared to traditional methods. However, SSL-based ASA systems are faced with at least three data-related challenges: limited annotated data, uneven distribution of learner proficiency levels and non-uniform score intervals between different CEFR proficiency levels. To address these challenges, we explore the use of two novel modeling strategies: metric-based classification and loss re-weighting, leveraging distinct SSL-based embedding features. Extensive experimental results on the ICNALE benchmark dataset suggest that our approach can outperform existing strong baselines by a sizable margin, achieving a significant improvement of more than 10% in CEFR prediction accuracy.

1 Introduction

With the unprecedented advancements in computer technology and the growing number of second-language (L2) learners worldwide, automated speaking assessment (ASA) has aroused much attention, figuring prominently in computer-assisted language learning (CALL). As shown in Figure 1[1], ASA systems are designed to provide timely feedback on learners' speaking quality, enabling them to improve their spoken language skills in a stress-free and self-directed manner. What is more, ASA systems can alleviate the workload of language teachers and provide a more objective and consistent evaluation on the language proficiency of an L2 learner or test-taker. With the remarkable developments in human language technology, recent years have seen a widespread adoption of ASA systems in CALL, so as to support L2 learners in language acquisition (Moere and Downey, 2016).

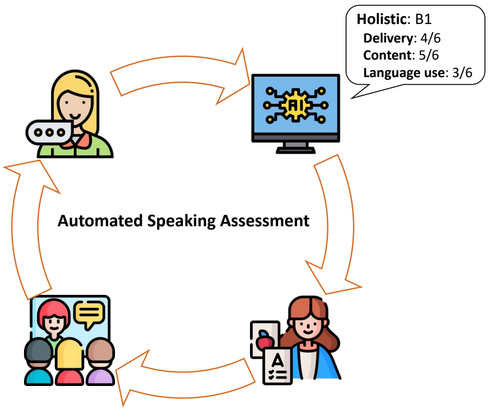

Figure 1: A running example illustrates the senario of incorporating automated speaking assessment into the traditional classroom.

Iconic ASA approaches involved using standard classifiers and hand-crafted features related to various facets of language proficiency, including but not limited to delivery (such as pronunciation, fluency and intonation), content (such as appropriateness and relevance), and language use (such as vocabulary and grammar) (Strik and Cucchiarini, 1999; Chen et al., 2010; Coutinho et al., 2016; Bhat and Yoon, 2015). In recent years, the rise of self-supervised learning (SSL) paradigms, such as BERT and its variants (Devlin et al., 2019), has opened up new avenues for ASA. These SSL models offer contextualized

embeddings that have been successfully integrated into various language assessment tasks like sentence assessment (Arase et al., 2022), grading of essays (Moore et al., 2015; Nadeem et al., 2019; Wu et al., 2023), spoken monologues (Craighead et al., 2020), and many others. On a separate front, the advent of speech-based SSL features has introduced another regime of modeling sophistication and capability to ASA system developments. These features have been particularly effective in specialized tasks within the CALL tasks, such as mispronunciation detection and diagnosis (MDD) (Baevski et al., 2020; Wu et al., 2021; Xu et al., 2021; Peng et al., 2021), automatic pronunciation assessment (APA) (Kim et al., 2022; Chao et al., 2022; Chao et al., 2023) and ASA (Park and Ubale, 2023; McKnight et al., 2023; Banno and Matassoni, 2022; Banno et al., 2023; Li et al., 2023).

While the work presented in (Banno and Matassoni, 2022; Banno et al., 2023) made pioneering attempts to employ SSL features (BERT and wav2vec 2.0) for ASA, it falls short when faced with three critical issues which our study aims to address: 1) relatively small amount of annotated data, 2) the imbalanced distribution of CEFR proficiency levels (Europe, 2001), and 3) the non-uniform score gaps between different CEFR levels (e.g., $B2 - B1 \neq B1 - A2$). To address these challenges, we first utilize text- and speech-based encoders (BERT and wav2vec 2.0) pre-trained on large-scale datasets. On top of this, this paper introduces effective modeling strategies that are underexplored in previous ASA work, including metric-based classification (Vinyals et al., 2016; Ye and Ling, 2019; Snell et al., 2017; Sun et al., 2019) and loss re-weighting (Conneau and Lample, 2019). In particular, we draw on a unique set of prototypical embeddings for each CEFR level and use various similarity functions to mitigate the imbalanced distribution. It is our hypothesis that metric-based learning not only addresses data imbalance but also efficiently tackles the non-uniform score gaps between CEFR levels.

All variants of our approach are evaluated on the ICNALE corpus (Ishikawa, 2011), an open-source L2 English benchmark dataset, using both text- and speech-based classifiers. Empirical results indicate that our approach can effectively mitigate the issue of data imbalance and achieve significant improvements in accuracy, rising from 77.88% to 92.63% compared to the state-of-the-art baselines (Banno and Matassoni, 2022). Finally, we also conduct a series of analytical experiments to look into the impacts of our modeling strategies on ASA performance, highlighting their practical potential for assessing learners' proficiency. This paper has three-fold contributions:

1. We explore novel and effective modeling strategies for SSL feature extraction and classification in ASA
2. We demonstrate through experiments on the ICNALE corpus that our best-performing instantiation establishes a new state-of-the-art for ASA on this corpus.
3. In particular, our work contributes to the advancement of ASA techniques by addressing challenges related to limited data and imbalanced CEFR-level distribution.

2 Related Work

In general, ASA is deployed for assessing speaking proficiency with respect to the responses from an L2 learner, predicting the corresponding level of overall proficiency (holistic score) or specific aspects of proficiency (analytic scores).

It is currently common practice to treat ASA as a classification problem using either text-based or speech-based classifiers. Nevertheless, in the early days, researchers used to tackle the ASA problem with standard classifiers in conjunction with hand-crafted features pertinent to specific facets of language proficiency, such as pronunciation, fluency, prosody, grammar, and others. These features are extracted from the utterances and associated transcripts of an L2 learner and taken as input to a meticulously selected classifier to predict analytic scores (Strik and Cucchiarini, 1999; Chen et al., 2010; Bhat and Yoon, 2015; Moore et al., 2015; Coutinho et al., 2016). For example, Chen et al. (2010) utilized vowel space characteristics for ASA. Bhat and Yoon (2015) ventured into syntactic analysis by employing part-of-speech tag-based complexity measures. Moore et al. (2015) scrutinized the efficacy of the Redshift parser in processing non-native spoken English, finding proficiency in discerning grammatical relations but limitations in detecting speech disfluencies. Coutinho et al. (2016) also concentrated on assessing prosodic and spectral features. Nonetheless, Muller et al. (2009) suggest that hand-crafted features may not always effectively

	A2	B1_1	B1_2	B2	native
Train	299	792	1681	586	540
Valid	16	44	94	33	30
Test	17	44	93	33	30

Table 1: Statistical information for each CEFR proficiency level in ICNALE.

capture important information about proficiency, as their efficacy heavily depends on the underlying assumptions of feature curation.

As for the feature representations of text-based classification, the NLP community has witnessed a significant trend of transitioning from using static token (e.g., word, subword, and others) embeddings to contextualized word embeddings, such as those derived by BERT (Devlin et al., 2019), with SSL paradigms. Consequently, there has been a surge of research on adopting these contextualized embeddings into automated assessments, such as essays (Nadeem et al., 2019; Arase et al., 2022; Wu et al., 2023) and spoken monologues (Craighead et al., 2020). Nadeem et al. (2019) initiated the use of contextualized embeddings for essay grading. Arase et al. (2022) applied these embeddings in conjunction with prototypical embedding for readability assessment. Craighead et al. (2020) innovatively employed them in evaluating spoken monologues, highlighting the embeddings' versatility in linguistic assessments.

On the other hand, the use of speech-based SSL features emerges as a promising approach. Recent studies have shown good promise in various downstream tasks, such as ASR, and speaker identification (Baevski et al., 2020). Moreover, contextualized representations derived from pre-trained models can capture a diverse range of acoustic and linguistic information for L1 and L2 speech (Shah et al., 2022). This finding adds another dimension to the potential of SSL-based ASA systems. With the increasing availability of annotated speech data and advancements in SSL techniques, there is immense scope for further research and development in the speech process. Despite the promising use of speech-based SSL features in various CALL tasks such as mispronunciation detection and diagnosis (MDD) (Wu et al., 2021; Xu et al., 2021; Peng et al., 2021) and automatic pronunciation assessment (APA) (Kim et al., 2022; Chao et al., 2022; Chao et al., 2023), there is still a dearth of research specifically focused on their application in automated speaking assessment (ASA) (Park and Ubale, 2023; McKnight et al., 2023; Banno and Matassoni, 2022; Banno et al., 2023; Li et al., 2023). This situation presents significant research space and ample opportunity for further exploration and investigation.

3 Dataset

To evaluate our proposed approach and corresponding methods, we employed the International Corpus Network of Asian Learners of English (ICNALE) corpus (Ishikawa, 2011), which is a publicly available dataset consisting of written and spoken responses from both native speakers and Asian learners from Japan, China, Hong Kong, South Korea, Taiwan, Singapore, Indonesia, Pakistan, Philippines and Thailand, at various CEFR (Common European Framework of Reference for Language) levels ranging from A2 to B2. Prior to data collection, the ICNALE team assigned CEFR levels to the learners based on their L2 vocabulary size and proficiency scores in English proficiency tests such as IELTS and TOEFL. For our experiments, we made exclusive use of the monologue section of the corpus, consisting of 4,332 speaking responses. In this setup, learners were prompted to describe their opinions on smoking in restaurants and the importance of engaging in part-time employment. Following the methodological practice adopted by (Banno and Matassoni, 2022), this curated collection was divided into a training set of 3,898 responses, as well as a validation set and a test set of 217 responses for each. To evaluate the proficiency of L2 speakers, we will frame the ASA task as a classification problem with five proficiency levels, as illustrated in Table 1.

4 Methodology

CEFR levels generally follow an ordinal scale where, for example, the B1 level is considered lower than the B2 level. While it may seem reasonable to approach the ASA task as a regression problem, the non-uniform gaps between the proficiency levels may lead to challenges in interpreting regression outputs (Heilman et al., 2008). As such, we adopt a classification regime to design and implement assessment methods for CEFR-oriented ASA.

A bit of terminology: a training set with N samples $\{(\mathbf{x}_0, y_0), (\mathbf{x}_1, y_1), \cdots, (\mathbf{x}_{N-1}, y_{N-1})\}$ are

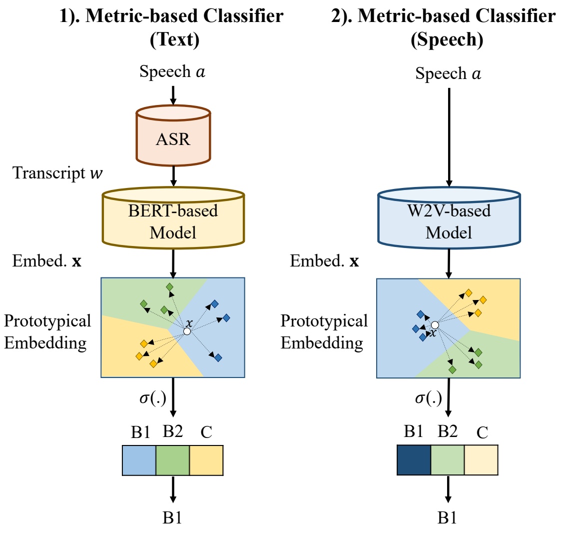

Figure 2: A schematic diagram of proposed models for automated speaking assessment, where σ is the softmax function that aims to choose the maximum value of the prediction vector.

given, where $\mathbf{x}_i$ is an utterance embedding extracted from either text- or speech-based encoder; $y_i \in \{0, 1, \dots, J-1\}$ indicates the index i of the corresponding level ($J = 5$ in the ICNALE corpus).

In addition, we utilize two types of SSL-based neural encoders separately as our backbone architectures, namely, a text-based encoder (BERT) and a speech-based encoder (wav2vec 2.0), as schematically depicted in Figure 2. On top of this, we employ two modeling strategies: metric-based classification (*cf.* Section 4.2) and loss re-weighting (*cf.* Section 4.3). These are used to train both text- and speech-based classifiers, with the goal to address the scarcity of learner data at basic (e.g., A1 and A2 speakers) and highly proficient (e.g., C1, C2, and native speakers) levels.

4.1 Baseline Classification

4.1.1 Text-based classification

This work uses an off-the-shelf BERT architecture to form our text-based encoder $\mathrm{Enc}_{\mathrm{Text}}(*)$. BERT takes an ASR transcript $w_{0:M-1}$ as input, where each word w_m is first transformed into its corresponding token embedding and all words are fed into the encoder layer of BERT altogether to obtain their respective contextualized embedding in a holistic manner:

$$\mathbf{h}_{0:M-1} = \mathrm{TextModel}(w_{0:M-1}) \qquad (1)$$

$$\mathbf{x} = \mathrm{MeanPool}(\mathbf{h}_{0:M-1}) \qquad (2)$$

where the semantic representation $\mathbf{x} \in \mathbb{R}^d$ is computed by mean pooling of contextualized embedding, $\mathbf{h}_{0:M-1} \in \mathbb{R}^d$, of the transcript. Following that, $\mathbf{x}$ is fed into a multi-layer perceptron (MLP) to predict the corresponding CEFR level. To draw on the benefits of a pre-trained language model, we initialize the model parameters with a pre-trained BERT model and learn the parameterization of the MLP layers from scratch. During training, the entire BERT model is tuned to learn more CEFR-aware knowledge.

As for obtaining the automatic transcripts, we conducted ASR on the ICNALE monologues using the Whisper toolkit (Radford et al., 2022), from which we obtained an average word error rate (WER) of 18.62% with the multi-lingual large model[2] (i.e., the default language is set to English). To avoid losing any possibly existing information about fluency and sentence structure, we managed to retain all relevant information cues, including hesitations, punctuations and others. Notably, since the input to the text-based classifier is an error-prone ASR transcript, it may not accurately represent a learner's proficiency. Moreover, a text-based classifier inevitably fails to capture other important traits of an L2 speaker, such as intonation and prosody.

4.1.2 Speech-based classification

We capitalize fully on the off-the-shelf wav2vec 2.0 (W2V) encoder as our speech-based encoder $\mathrm{Enc}_{\mathrm{Speech}}$. W2V is a pre-trained speech model that consists of a feature encoder, a context network, and a quantization module. Analogously to Eq. (1), we encode an input raw waveform $a_{0:T-1}$ with T samples using the last layer of the W2V encoder to obtain latent representation $\mathbf{h}_{0:T_s-1} \in \mathbb{R}^d$ (i.e., $T_s \leq T$):

$$\mathbf{h}_{0:T_s-1} = \mathrm{SpeechModel}(a_{0:T-1}) \qquad (3)$$

Then, we employ mean pooling to handle latent representations $\mathbf{h}_{0:T_s-1}$ of different temporal lengths, and the mean-pooled representation is subsequently fed into the MLP layer for classification. Similar to the text-based classifier, we expect that the W2V encoder can produce CEFR-aware representations as well during the training phase.

---

4.2 Metric-based classification

An imbalanced label distribution (as previously exemplified in Table 1) will lead to overfitting major classes while catering less to minor ones. Because rare classes (referred here to infrequent CEFR levels) must be well considered for real use cases, we alternatively leverage a metric-based classification as a workaround against the label imbalance problem. The metric-based classification has been examined for few-shot learning, where examples are classified based on embedding distances between labeled and unlabeled samples. Previous studies (Vinyals et al., 2016; Ye and Ling, 2019; Snell et al., 2017; Sun et al., 2019) have shown that this type of classifier categorizes samples based on distances within a vector space. The most prevalent techniques in metric-based classification are the matching network (Vinyals et al., 2016; Ye and Ling, 2019) and the prototypical network (Snell et al., 2017; Sun et al., 2019). Bearing some resemblance to an earlier study (Arase et al., 2022) that graded sentence-level text, we adopt a prototypical network to learn embeddings from the training set, which represent CEFR prototypes and predict CEFR levels based on a similarity value. In particular, we extend this approach to investigate speech-based embeddings, disparate similarity functions, and loss re-weighting for enhancing metric-based classification in ASA, which is promising yet underexplored.

After the holistic embeddings of a speaker's spoken response (*cf.* Section 4.1) are obtained, we then adopt the softmax function to compute the distribution p for a response embedding $\mathbf{x}$ over the levels L_j based on similarities to the disparate prototypes:

$$p(y = L_j|\mathbf{x}) = \frac{\exp\,(s * \mathrm{Sim}(\mathbf{x}, \mathbf{c}_j) + b)}{\sum_J \exp\,(s * \mathrm{Sim}(\mathbf{x}, \mathbf{c}_j) + b)} \qquad (4)$$

where $\mathrm{Sim}(\mathbf{x}, \mathbf{c}_j)$ calculates the similarity between the response embedding $\mathbf{x}$ and a level-specific prototype $\mathbf{c}_j$. Two similarity functions are explored in the prototypical network: one is cosine similarity (dubbed COS) with scaling factors (s and b are learnable parameters) (Chung et al., 2020), and the other is square Euclidean distance (dubbed SED) without scaling factors (s and b are set to 1 and 0, respectively) (Snell et al., 2017):

$$\mathrm{Sim}_{\mathrm{cos}}(\mathbf{x}_i, \mathbf{c}_j) = \frac{\mathbf{x}_i * \mathbf{c}_j}{\|\mathbf{x}_i\|\|\mathbf{c}_j\|} \qquad (5)$$

$$\mathrm{Sim}_{\mathrm{sed}}(\mathbf{x}_i, \mathbf{c}_j) = \|\mathbf{x}_i - \mathbf{c}_j\|_2^2 \qquad (6)$$

We leverage these two similarity functions in the current work to probe their respective feasibility and performance. When each CEFR level has multiple prototypes ($K > 1$), we compute the mean of the embeddings of these prototypes as the new centroid $\mathbf{c}_j$ or the mean of K similarity values:

$$Sim(\mathbf{x}_i, \mathbf{c}_j) = \frac{1}{K}\sum_k Sim(\mathbf{x}_i,\, \mathbf{c}_j^k) \qquad (7)$$

4.3 Loss re-weighting

Apart from the metric-based classifier, we adopt loss re-weighting to address the uneven label distribution, which is based on the multinomial distribution of level frequency and their inverted frequencies (Conneau and Lample, 2019). The loss re-weighting is formulated as:

$$q_i = \frac{p_i^{\alpha}}{\sum_{j=0}^{J-1} p_j^{\alpha}} * \frac{1}{p_i} \qquad (8)$$

where p_i is to represent the frequency of level i in the training set, and $\alpha \in [0,1]$ regulates the importance weight. A small value of α places a larger weight on infrequent CEFR levels (such as A2 or native). As an aside, we also use a simple loss re-weighting mechanism that only considers the inverted frequencies of CEFR levels in the training set:

$$\hat{q}_i = \frac{\sum_{j=0}^{J-1} p_j}{p_i} \qquad (9)$$

The classification loss of all classifiers, including baseline classifiers (*cf.* Section 4.1) and metric-based classifiers (*cf.* Section 4.2), are calculated using cross entropy with (or without) loss re-weighting.

5 Experiments

5.1 Implementation details

We initialized the model configuration from toolkits provided by HuggingFace (Wolf et al., 2019). The baseline systems are the BERT-based classifier built on *bert-base-uncased*[3] and the wav2vec 2.0-based classifier built on *wav2vec2-base*[4]. The number of prototypes K is set to 3. We

use loss re-weighting presented in Eq. (8) for the BERT-based classifier (α is set to 0.5), while using that depicted in Eq. (9) for the wav2vec 2.0-based classifier, both of which are suggested by our preliminary experiments.

All models were trained on an NVIDIA 3090 GPU using AdamW (Loshchilov and Hutter, 2019) optimizer, with a batch size of 8 and an initial learning rate of 5e-5. The training process of the BERT-based classifier was stopped early with 10 patience epochs based on the averaged macro-accuracy score from the validation set. The training process of the wav2vec 2.0-based classifier was stopped at 10 epochs based on the averaged macro-accuracy score measured on the validation set.

5.2 Evaluation metrics

Evaluations of classifiers' effectiveness are crucial for grading applications, where accurate prediction of all levels is essential. However, as the distribution of CEFR levels is unbalanced, conventional evaluation metrics such as accuracy (ACC) and adjacent accuracy (ADJ) may need to be revised. Therefore, macro-type evaluation metrics, ACC$_{MC}$ and RMSE$_{MC}$, were used to penalize models that treats the minor classes poorly. Moreover, since CEFR levels are ordinal, additional evaluation metrics, including root mean squared error (RMSE) and Pearson correlation coefficient (PCC), were employed to evaluate the model performance. These metrics altogether provide a comprehensive evaluation of the classifier's ability to predict all CEFR levels accurately, including minor ones.

5.3 Overall performance

At the outset, we report on the performance of two strong baselines, which are SSL-based classifiers on the ICNALE dataset, viz. BERT- and wav2vec 2.0 (W2V)-based classifiers. After that, the prototypical network (PT) in conjunction with loss re-weighting (LW), where the similarity function is either in the form of squared Euclidean distance (SED) or cosine similarity (COS), is employed to enhance the baseline SSL-based classifiers.

In the first set of experiments, we discuss the overall performance of our various methods in comparison with state-of-the-art baselines (Banno and Matassoni, 2022). Table 2 displays the evaluation results of the two classifiers (BERT–

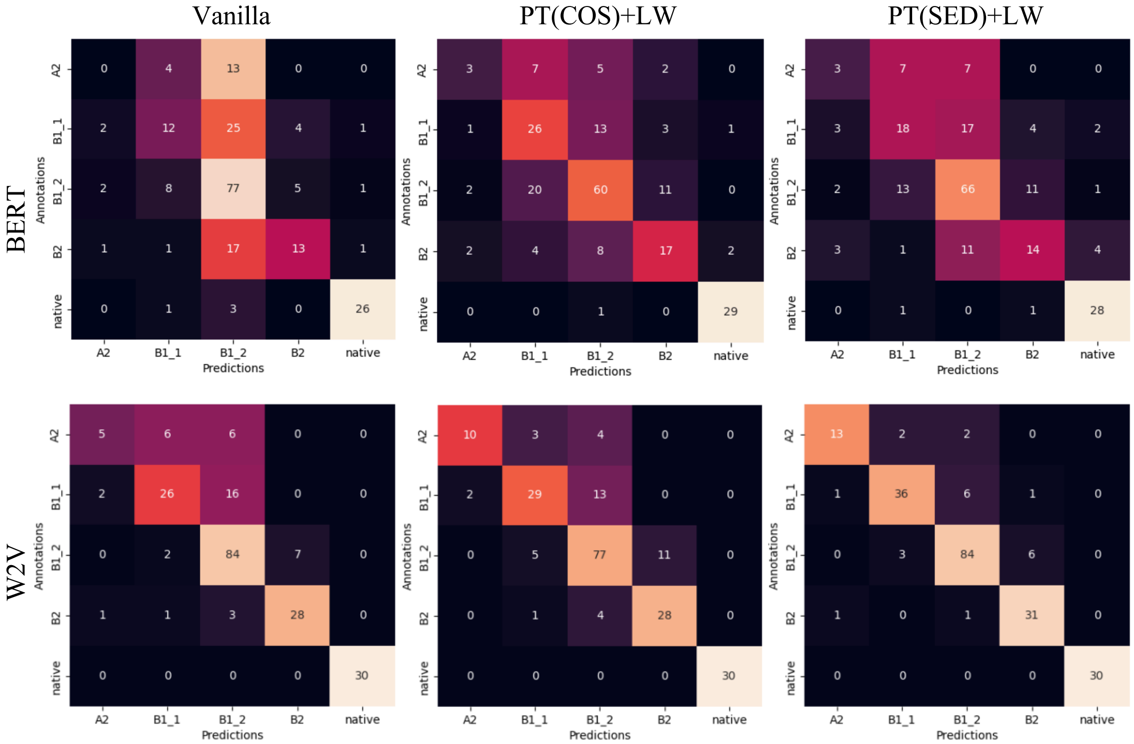

Figure 2: Confusion matrices for SSL-based classifiers using different strategies in predicting proficiency levels.

and W2V-based baselines) on the ICNALE test set in terms of accuracy and various metrics. W2V exhibits superior performance over BERT in terms of all metrics. Two modeling strategies explored in this study, including loss re-weighting (LW) and prototypical network (PT-COS and PT-SED), achieve superior results than vanilla BERT and W2V across most evaluation metrics, especially for macro-type evaluation metrics (e.g., RMSE_{MC} and ACC_{MC}). The experiment results clearly demonstrate the effectiveness of our proposed modeling strategies in enhancing the SSL-based models. Strikingly, with the best setup, which utilizes the W2V-based classifier in conjunction with the prototypical network (SED) and loss re-weighting (LW), our modeling strategy can yield a remarkable improvement in accuracy from 77.88% to 92.63% compared with the start-of-the-art baselines (Banno and Matassoni, 2022). This significant boost in performance confirms the promising potential of our proposed modeling strategies in automated speaking assessment.

While Table 2 demonstrates encouraging performance, it's important to note that the effectiveness of the W2V prototypical model, particularly its clustering effect, can vary depending on the dataset's characteristics and the complexity of the speaking tasks. Therefore, further experiments and evaluations are necessary to validate the proposed approach's robustness and generalizability. In the following subsections, we analyze the performance of different models using various evaluation metrics and discuss potential areas for future research and improvement.

5.4 Effect of initialization

Table 3 presents the impact of the wav2vec 2.0 encoder on training the metric-based method. Since cosine similarity (referred to as PT(COS)) performs worse than squared Euclidean distance (referred to as PT(SED)), as shown in Table 2, we specifically focus on examining the influence of pretrained embeddings on the performance of PT(COS). From Table 3, it is evident that proper initialization of the encoder and prototypical embeddings have a great impact on the efficacy of the training approach based on the cosine similarity, while it leads to relatively inferior results when using the squared Euclidean distance. Specifically, notable performance improvements are observed by initializing the encoder weights with W2V from the vanilla W2V classifier and using W2V for the weight initialization of prototypical embeddings. However, the results were less pronounced when training with a similarity function based on SED. Our findings highlight the importance of proper initialization of

Figure 5: Visualization of CEFR-aware embeddings of vanilla wav2vec2.0 (left) and prototypical wav2vec2.0 with cosine similarity (right). The colors red, green, blue, orange, and purple correspond to A2, B1_1, B1_2, B2, and native speakers, respectively.

the encoder and prototypical embeddings, meanwhile validating the effectiveness of the cosine similarity in metric-based approaches.

5.5 Confusion matrices

Figure 3 illustrates the confusion matrices for each CEFR level, showcasing the performance of two SSL-based methods: BERT (top of Figure 3) and W2V (bottom of Figure 3), with the utilization of squared Euclidean distance (SED), cosine similarity (COS) and loss re-weighting (LW). Notably, the W2V-based classifier consistently outperforms the BERT-based classifier across all proficiency levels, demonstrating substantial advancements, particularly for A2, B1_2, and native speakers. The key differentiating factor leading to the superior performance of the W2V-based classifier lies in its ability to capture crucial acoustic, prosodic, and linguistic traits that might be overlooked when relying solely on ASR transcripts. This result signifies the fundamental importance of such latent traits in accurately discerning the distinct CEFR proficiency levels.

5.6 ASA Performance for learners from different L1s

Figure 4 plots the histogram of classification performance achieved by our proposed approaches across learners with diverse mother-tongue languages. These tongue languages include Taiwan (TWN), Hong Kong (HKG), Japan (JPN), Korea (KOR), Singapore (SIN), China (CHN), Indonesia (IND), Pakistan (PAK), Philippines (PHL) and Thailand (THA), thereby representing a wide range of language backgrounds. As shown in Figure 4, our best-performing model, W2V-PT(SED), achieves an average accuracy of 90% in predicting CEFR proficiency levels across different tongue languages. Notably, learners from Hong Kong (HKG), Singapore (SIN), Philippines (PHL) and native speakers attained a perfect accuracy rate of 100%.

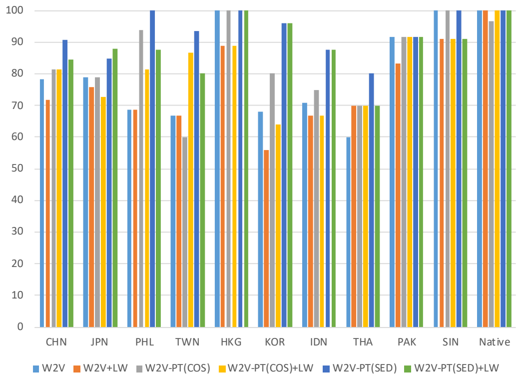

Figure 4: The ASA performance (accuracy%) of our proposed modeling strategies for test learners of different mother-tongue languages.

5.7 Visualization of CEFR-aware embeddings

Figure 5 illustrates the t-SNE dimensionality reduction visualization, comparing the original W2V embeddings (left) with the W2V+PT(COS) (right). The left plot shows scattered embeddings forming a manifold. In contrast, the right plot demonstrates an apparent clustering effect, indicating that the W2V prototypical model with cosine similarity successfully groups embeddings by CEFR levels. These results indicate that the metric-based classifier fosters discriminative embeddings reflecting learners' proficiency, which likely account for the improvements in Table 2, underscoring the prototypical approach's efficacy in ASA.

6 Conclusion

This paper has put forward two innovative ASA modeling strategies, namely metric-based classification and loss re-weighting, to enhance the performance of self-supervised learning (SSL) models for use in ASA. Both strategies work well with pre-trained embeddings, meanwhile addressing the challenging issues of data scarcity and imbalanced distribution. Extensive experiments on the ICNALE dataset have demonstrated the practical utility of our methods in relation to previous methods in terms of accuracy and various metrics for measuring L2 learners' speaking proficiency. The corresponding results also provide valuable insights for discussing the efficacy of SSL made inroads into ASA. For future work, we plan to delve deeper into the investigation of diverse features and traits, pre-trained models and fine-tuning strategies to mitigate the impact of imbalanced data distribution. Additionally, we envisage extending the scope of our proposed modeling approach to other corpora and tasks, for the purpose of further generalizing its applicability.

Limitations

The model proposed in this paper focuses on Automated Speaking Assessment using self-supervised learning but exhibits key limitations. Its effectiveness is primarily tied to the ICNALE benchmark dataset, which might not capture the vast diversity of global English learners, potentially limiting the model's generalizability. Additionally, while our model shows promise on this specific dataset, its performance across varied datasets with different learner profiles and proficiency distributions remains untested, raising concerns about its broader applicability. Another challenge is interpreting SSL-based embedding features in relation to specific language proficiency indicators, crucial for enhancing model transparency and facilitating further improvements. To address these issues, we are expanding our dataset to include a design similar to ICNALE, incorporating parallel manual annotation of questions in the corpus. This expansion aims to complement proficiency levels that are currently underrepresented. Furthermore, while we suspect that our method could be applicable to other label-imbalanced classification problems, an empirical investigation of this application is beyond the scope of this paper and is reserved for future research.

Ethical Considerations

Bias in Language Assessment The risk of reinforcing existing educational or linguistic biases is present, especially if the dataset lacks representation from diverse linguistic backgrounds.

Transparency and Accountability There's a need for clear communication about how the system assesses language proficiency and mechanisms for feedback to address potential inaccuracies or biases.

Impact on Learners If assessments are perceived as unfair, it could affect learners' motivation and confidence, highlighting the importance of aligning the system with diverse learner needs.

Abstract

With the rapid advancement of large language models (LLMs), there is a pressing need for a comprehensive evaluation suite to assess their capabilities and limitations. Existing LLM leaderboards often reference scores reported in other papers without consistent settings and prompts, which may inadvertently encourage cherry-picking favored settings and prompts for better results. In this work, we introduce GPT-Fathom, an open-source and reproducible LLM evaluation suite built on top of OpenAI Evals[1]. We systematically evaluate 10+ leading LLMs as well as OpenAI's legacy models on 20+ curated benchmarks across 7 capability categories, all under aligned settings. Our retrospective study on OpenAI's earlier models offers valuable insights into the evolutionary path from GPT-3 to GPT-4. Currently, the community is eager to know how GPT-3 progressively improves to GPT-4, including technical details like whether adding code data improves LLM's reasoning capability, which aspects of LLM capability can be improved by SFT and RLHF, how much is the alignment tax, etc. Our analysis sheds light on many of these questions, aiming to improve the transparency of advanced LLMs.

1 Introduction

Recently, the advancement of large language models (LLMs) is arguably the most remarkable breakthrough in Artificial Intelligence (AI) in the past few years. Based on the Transformer (Vaswani et al., 2017) architecture, these LLMs are trained on massive Web-scale text corpora. Despite their straightforward method of using a self-supervised objective to predict the next token, leading LLMs demonstrate exceptional capabilities across a range of challenging tasks (Bubeck et al., 2023), even showing a potential path towards Artificial General Intelligence (AGI). With the rapid progress of LLMs, there is a growing demand for better understanding these powerful models, including the distribution of their multi-aspect capabilities, limitations and risks, and directions and priorities of their future improvement. It is critical to establish a carefully curated evaluation suite that measures LLMs in a systematic, transparent and reproducible manner. Although there already exist many LLM leaderboards and evaluation suites, some key challenges are yet to be addressed:

- *Inconsistent settings:* The evaluation settings, such as the number of in-context example "shots", whether Chain-of-Thought (CoT; Wei et al. 2022) prompting is used, methods of answer parsing and metric computation, etc., often differ across the existing LLM works. Moreover, most of the released LLMs do not disclose their prompts used for evaluation, making it difficult to reproduce the reported scores. Different settings and prompts may lead to very different evaluation results, which may easily skew the observations. Yet, many existing LLM leaderboards reference scores from other papers without consistent settings and prompts, which may inadvertently encourage cherry-picking favored settings and prompts for better results. To achieve reliable conclusions, it is crucial to make apples-to-apples comparisons with consistent settings and prompts.
- *Incomplete collection of models and benchmarks:* For the moment, when compared to OpenAI's leading models such as GPT-4, all the other LLMs (particularly open-source models) exhibit a substantial performance gap. In fact, it takes OpenAI nearly three years to evolve from GPT-3 (released in 2020/06) to GPT-4 (released in 2023/03). Existing LLM leaderboards primarily focus on the latest models, while missing a retrospective study on OpenAI's earlier models and its mysterious path from GPT-3 to GPT-4. Besides the coverage of models, many existing

---

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1363–1382
June 16-21, 2024

works assess LLMs on merely one or a few aspects of capabilities, which is not sufficient to provide a comprehensive view to deeply understand the strength and weakness of the evaluated LLMs.

- *Insufficient study on model sensitivity:* LLMs are known to be sensitive to the evaluation setting and the formatting of prompt (Liang et al., 2023). However, many existing works only focus on the benchmark score under one specific setting, while overlooking the impacts of model sensitivity on the overall usability of LLMs. In fact, it is unacceptable that a slightly rephrased prompt could cause the LLM to fail in responding it correctly. Due to the lack of systematic study on model sensitivity, this potential vulnerability in LLMs remains not well understood.

These challenges hinder a comprehensive understanding of LLMs. To dispel the mist among LLM evaluations, we introduce GPT-Fathom, an open-source and reproducible LLM evaluation suite developed based on OpenAI Evals[1]. We evaluate 10+ leading open-source and closed-source LLMs on 20+ curated benchmarks in 7 capability categories under aligned settings. We also evaluate legacy models from OpenAI to retrospectively measure their progressive improvement in each capability dimension. Our retrospective study offers valuable insights into OpenAI's evolutionary path from GPT-3 to GPT-4, aiming to help the community better understand this enigmatic path. Our analysis sheds light on many community-concerned questions (e.g., the gap between OpenAI / non-OpenAI models, whether adding code data improves reasoning capability, which aspects of LLM capability can be improved by SFT and RLHF, how much is the alignment tax, etc.). With reproducible evaluations, GPT-Fathom serves as a standard gauge to pinpoint the position of emerging LLMs, aiming to help the community measure and bridge the gap with leading LLMs. We also explore the impacts of model sensitivity on evaluation results with extensive experiments of various settings.

The key contributions of our work are summarized as follows:

- *Systematic and reproducible evaluations under aligned settings:* We provide accurate evaluations of 10+ leading LLMs on 20+ curated benchmarks across 7 capability categories. We carefully align the evaluation setting for each benchmark. Our work improves the transparency of LLMs, and all of our evaluation results can be easily reproduced.
- *Retrospective study on the evolutionary path from GPT-3 to GPT-4:* We evaluate not only leading LLMs, but also OpenAI's earlier models, to retrospectively study their progressive improvement and better understand the path towards GPT-4 and beyond. Our work is time-sensitive due to the scheduled deprecation of those legacy models announced by OpenAI[2].
- *Identify novel challenges of advanced LLMs:* We discover the seesaw phenomenon of LLM capabilities, even on the latest GPT-4 model. We also study the impacts of model sensitivity with extensive experiments. We strongly encourage the research community to dedicate more efforts to tackling these novel challenges.

2 Related Work

Benchmarks constantly play a pivotal role in steering the evolution of AI and, of course, directing the advancement of LLMs as well. There are many great existing LLM evaluation suites. By comparing GPT-Fathom with previous works, we summarize the major difference as follows: 1) HELM (Liang et al., 2023) primarily uses answer-only prompting (without CoT) and has not included the latest leading models such as GPT-4 (as of the time of writing); 2) Open LLM Leaderboard (Beeching et al., 2023) focuses on open-source LLMs, while we jointly consider leading closed-source and open-source LLMs; 3) OpenCompass (Contributors, 2023) evaluates latest open-source and closed-source LLMs (all released after 2023/03), while we cover both leading LLMs and OpenAI's earlier models to decipher the evolutionary path from GPT-3 to GPT-4; 4) InstructEval (Chia et al., 2023) is designed for evaluating instruction-tuned LLMs, while we evaluate both base and SFT / RLHF models; 5) AlpacaEval (Li et al., 2023) evaluates on simple instruction-following tasks as a quick and cheap proxy of human evaluation, while we provide systematic evaluation of various aspects of LLM capabilities; 6) Chatbot Arena (Zheng et al., 2023) evaluates human user's dialog preference with a Elo rating

---

[1] `https://github.com/openai/evals`

[2] `https://openai.com/blog/gpt-4-api-general-availability`

system, while we focus on automatic and reproducible evaluation over popular benchmarks; 7) Chain-of-Thought Hub (Fu et al., 2023) focuses on evaluating the reasoning capability of LLMs with CoT prompting, while we support both CoT and answer-only prompting settings and evaluate various aspects of LLM capabilities. We discuss more related work in Appendix G.

3 Method

Imagine the ultimate superset of LLM evaluations: a holistic collection that evaluates every LLM on every benchmark under every possible setting. In practice, however, due to resource and time constraints, we are unable to exhaustively fulfill this ideal evaluation superset. Instead, we pick representative LLMs, benchmarks and settings to investigate open problems. In this section, we discuss in detail how we select LLMs, benchmarks and settings for our evaluations.

3.1 LLMs for Evaluation

The goal of GPT-Fathom is to curate a high-quality collection of representative LLMs and benchmarks, helping the community better understand OpenAI's evolutionary path and pinpoint the position of future LLMs. To achieve this goal, we mainly consider evaluating these types of LLMs: 1) OpenAI's leading models; 2) OpenAI's major earlier models[3]; 3) other leading closed-source models; 4) leading open-source models. As a result, we select OpenAI's models (illustrated in Figure 1), PaLM 2 (Anil et al., 2023), Claude 2[4], LLaMA (Touvron et al., 2023a) and Llama 2 (Touvron et al., 2023b) for evaluation. Due to the limited space, refer to Appendix A for the detailed model list.

3.2 Benchmarks for Evaluation

We consider the following criteria for benchmark selection: 1) cover as many aspects of LLM capabilities as possible; 2) adopt widely used benchmarks for LLM evaluation; 3) clearly distinguish strong LLMs from weaker ones; 4) align well with the actual usage experience of LLMs. Accordingly, we construct a capability taxonomy by initially enumerating the capability categories (task types), and then populating each category with selected benchmarks.

Knowledge. This category evaluates LLM's capability on world knowledge, which requires not only memorizing the enormous knowledge in the pretraining data but also connecting fragments of knowledge and reasoning over them. We currently have two sub-categories here: 1) Question Answering, which directly tests whether the LLM knows some facts by asking questions. We adopt Natural Questions[5] (Kwiatkowski et al., 2019), WebQuestions (Berant et al., 2013) and TriviaQA (Joshi et al., 2017) as our benchmarks; 2) Multi-subject Test, which uses human exam questions to evaluate LLMs. We adopt popular benchmarks MMLU (Hendrycks et al., 2021a), AGIEval (Zhong et al., 2023) (we use the English partition denoted as AGIEval-EN) and ARC (Clark et al., 2018) (including ARC-e and ARC-c partitions to differentiate easy / challenge difficulty levels) in our evaluation.

Reasoning. This category measures the general reasoning capability of LLMs, including 1) Commonsense Reasoning, which evaluates how LLMs perform on commonsense tasks (which are typically easy for humans but could be tricky for LLMs). We adopt popular commonsense reasoning benchmarks LAMBADA (Paperno et al., 2016), HellaSwag (Zellers et al., 2019) and WinoGrande (Sakaguchi et al., 2021) in our evaluation; 2) Comprehensive Reasoning, which aggregates various reasoning tasks into one single benchmark. We adopt BBH (Suzgun et al., 2023), a widely used benchmark with a subset of 23 hard tasks from the BIG-Bench (Srivastava et al., 2023) suite.

Comprehension. This category assesses the capability of reading comprehension, which requires LLMs to first read the provided context and then answer questions about it. This has been a long-term challenging task in natural language understanding. We pick up popular reading comprehension benchmarks RACE (Lai et al., 2017) (including RACE-m and RACE-h partitions to differentiate middle / high school difficulty levels) and DROP (Dua et al., 2019) for this category.

Math. This category specifically tests LLM's mathematical capability. Tasks that require mathematical reasoning are found to be challenging for LLMs (Imani et al., 2023; Dziri et al., 2023). We adopt two popular math benchmarks, namely GSM8K (Cobbe et al., 2021), which consists of

---

[4] `https://www.anthropic.com/index/claude-2`

[5] For Natural Questions, we evaluate in the closed-book setting, where only the question is provided, without a context document.

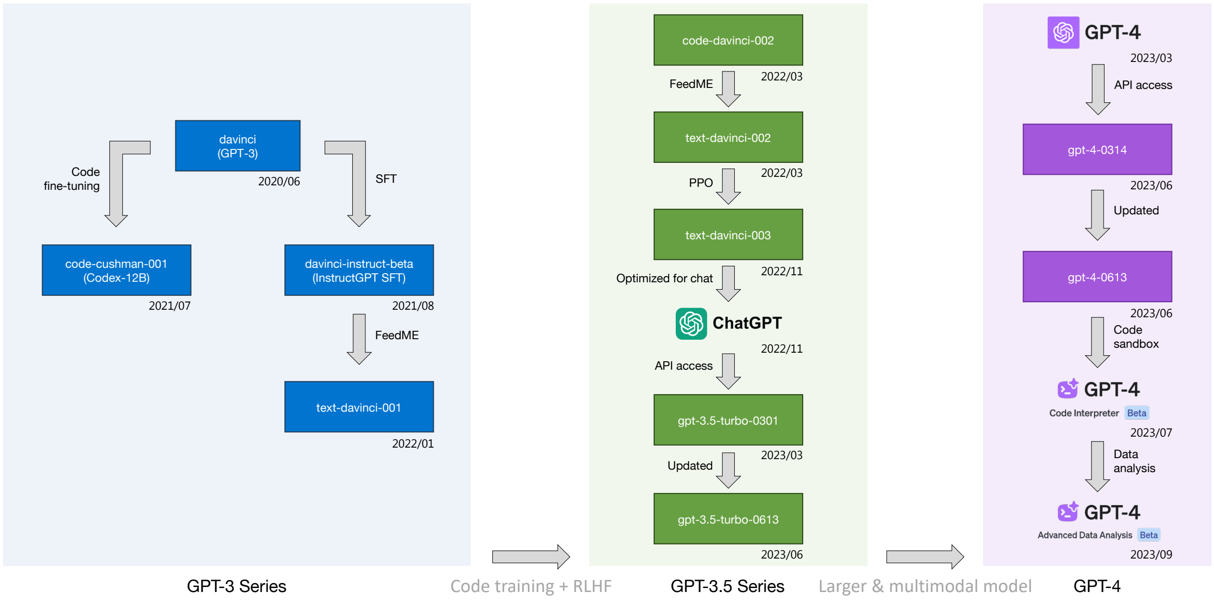

Figure 1: OpenAI's evolutionary path from GPT-3 to GPT-4. We omit deprecated legacy models such as `code-davinci-001` and only list the models evaluated in GPT-Fathom.

8,500 grade school math word problems, and MATH (Hendrycks et al., 2021b), which contains 12,500 problems from high school competitions in 7 mathematics subject areas.

Coding. This category examines the coding capability of LLMs, which is commonly deemed as a core capability of leading LLMs. We pick up popular benchmarks HumanEval (Chen et al., 2021) and MBPP (Austin et al., 2021), both of which are natural language to code datasets that require LLMs to generate self-contained Python programs that pass a set of held-out test cases. Following Chen et al. (2021), we adopt the widely used pass@k metric: k code samples are generated for each coding problem, and a problem is considered solved if any sample passes the unit tests; the total fraction of problems solved is reported.

Multilingual. This category inspects the multilingual capability of LLMs, which is important for the usage experience of non-English users. Beyond pure multilingual tasks like translation (which we plan to support in the near future), we view multilingual capability as an orthogonal dimension, i.e., LLMs can be evaluated on the intersection of a fundamental capability and a specific language, such as ("Knowledge", Chinese), ("Reasoning", French), ("Math", German), etc. Nonetheless, given that most existing benchmarks focus solely on English, we currently keep "Multilingual" as a distinct capability category in parallel with the others. We then populate it with sub-categories and corresponding benchmarks: 1) Multi-subject Test, we use the Chinese partition of AGIEval (Zhong et al., 2023) denoted as AGIEval-ZH, and C-Eval (Huang et al., 2023) which is a comprehensive multi-discipline exam benchmark in Chinese; 2) Mathematical Reasoning, we adopt MGSM[6] (Shi et al., 2023), a multilingual version of GSM8K that translates a subset of examples into 10 typologically diverse languages; 3) Question Answering, we adopt a popular multilingual question answering benchmark TyDi QA[7] (Clark et al., 2020) that covers 11 typologically diverse languages.

Safety. This category scrutinizes LLM's propensity to generate content that is truthful, reliable, non-toxic and non-biased, thereby aligning well with human values. To this end, we currently have two sub-categories: 1) Truthfulness, we employ TruthfulQA[8] (Lin et al., 2022), a benchmark designed to evaluate LLM's factuality; 2) Toxicity, we adopt RealToxicityPrompts (Gehman et al., 2020) to quantify the risk of generating toxic output.

3.3 Details of Black-box Evaluation

Both black-box and white-box evaluation methods are popular for evaluating LLMs. We describe their

---

[6] For MGSM, we evaluate the average score over the 10 language partitions, including Bengali, Chinese, French, German, Japanese, Russian, Spanish, Swahili, Telugu and Thai.

[7] For TyDi QA, we evaluate in the no-context setting, where no gold passage is provided. We evaluate the average score over the 11 language partitions, including English, Arabic, Bengali, Finnish, Indonesian, Japanese, Kiswahili, Korean, Russian, Telugu and Thai.

[8] For TruthfulQA, we evaluate in the multiple-choice setting.

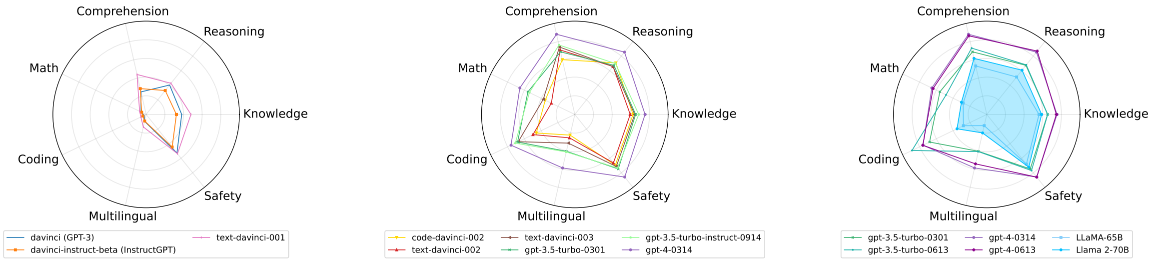
Table 1: Main evaluation results of GPT-Fathom. Note that GPT-Fathom supports various settings for evaluation. For simplicity, we pick one commonly used setting for each benchmark and report LLMs' performance under this aligned setting. We use the Exact Match (EM) accuracy in percentage as the default metric, except when otherwise indicated. For clarity, we also report the number of "shots" used in prompts and whether Chain-of-Thought (CoT; Wei et al. 2022) prompting is used. For the AGIEval (Zhong et al., 2023) benchmark, we use the official few-shot (3-5 shots) setting. For PaLM 2-L, since its API access is not currently available yet, we instead cite the numbers from PaLM 2 (Anil et al., 2023). Numbers that are not from our own experiments are shown in brackets. Numbers with * are obtained from optimized prompts, which is discussed in Section 4.2. Best and second best scores are highlighted in bold.



(a) GPT-3 Series

(b) GPT-3.5 Series and GPT-4

(c) Llama 2-70B

Figure 2: Radar charts to visualize the capabilities of evaluated LLMs. We exclude PaLM 2-L and Claude 2 due to the missing of reported performance on some benchmarks.

difference and discuss why we choose the black-box method as follows.

Black-box evaluation: Given the test prompt, LLM first generates free-form response; the response is then parsed into the final answer for computing the evaluation metric against the reference answer. For multiple-choice questions, the reference answer is typically the letter of the correct option such as `(A)`, `(B)`, `(C)` or `(D)`.

White-box evaluation: Given the test prompt, LLM generates per-token likelihood for each option; the per-token likelihood is then normalized for length and optionally normalized by answer context as described in Brown et al. (2020). The option with the maximum normalized likelihood is then picked as the predicted option.

GPT-Fathom adopts the black-box method throughout all evaluations, since 1) the per-token likelihood for input prompt is usually not provided by closed-source LLMs; 2) the white-box method manually restricts the prediction space, thus the evaluation result would be no worse than random guess in expectation; while for the black-box method, a model with inferior capability of instruction following may get 0 score since the output space is purely free-form. In our opinion, instruction following is such an important LLM capability and should be taken into consideration in evaluation.

Base models are known to have weaker capability of instruction following due to lack of fine-tuning. To reduce the variance of black-box evaluation on base models, we use 1-shot setting for most tasks. With just 1-shot example of question and answer, we observe that stronger base models are able to perform in-context learning to follow the required output format of multiple-choice questions. Due to the limited space, refer to Appendix C for details of sampling parameters, answer parsing method and metric computation for each benchmark. For the sampling variance under black-box evaluation, refer to Section 4.2 for our extensive experiments and detailed discussions.

4 Experiments

4.1 Overall Performance

Table 1 summarizes the main evaluation results of GPT-Fathom. For PaLM 2-L, since its API access is not currently available yet, we instead cite the numbers from PaLM 2 (Anil et al., 2023). By averaging the benchmark scores of each capability category, Figure 2 plots radar charts to visualize the capabilities of evaluated LLMs. Table 2 compares the performance of Claude 2 and OpenAI's latest models. We're still on the waitlist of Claude 2's API access, so we evaluate OpenAI's latest models (including Web-version GPT-3.5 and GPT-4) under the same settings used by Claude 2[4].

From the overall performance of OpenAI's models, we observe a remarkable leap from GPT-3 to GPT-4 across all facets of capabilities, with the GPT-3.5 series serving as a pivotal intermediary stage, which was kicked off by `code-davinci-002`, a fairly strong base model pretrained on text and code data. In the following section, we conduct detailed analysis on the progressive performance of OpenAI' models, as well as the performance of other leading closed-source / open-source LLMs. Our study aims to unveil OpenAI's mysterious path from GPT-3 to GPT-4, and shed light on community-concerned questions.

4.2 Analysis and Insights

OpenAI vs. non-OpenAI LLMs. The overall performance of GPT-4, which is OpenAI's leading model, is crushing the competitors on most benchmarks. As reported in Table 1, PaLM 2-L clearly outperforms `gpt-3.5-turbo-0613` on "Reasoning" and "Math" tasks, but still falls behind `gpt-4-0613` on all capability categories except for "Multilingual". As described in (Anil et al., 2023), PaLM 2 is pretrained on multilingual data across hundreds of languages, confirming the remarkable multilingual performance achieved by PaLM 2-L that beats GPT-4.

Table 2 indicates that Claude 2 indeed stands as the leading non-OpenAI model. Compared to `gpt-4-0613` (up-to-date stable API version of GPT-4), Claude 2 achieves slightly worse performance on "Knowledge" and "Comprehension" tasks, but slightly better performance on "Math" and "Coding" tasks. Noticeably, the upgraded `gpt-3.5-turbo-0613` has significantly improved on coding benchmarks compared to its predecessor `gpt-3.5-turbo-0301` with striking pass@1 scores: 80.0 on HumanEval and 98.0 on MBPP. Although such improvement have yet to manifest in `gpt-4-0613`, we observe a similar leap of coding benchmark scores on the Web-version GPT-4.

Closed-source vs. open-source LLMs. Recently, LLaMA (Touvron et al., 2023a) and Llama 2 (Touvron et al., 2023b) have been widely recognized as leading open-source LLMs, which largely facilitate the open-source community to develop advanced LLMs. Following their official performance report of base models, we pick the largest variants of their base models (LLaMA-65B and Llama 2-70B) as the leading open-source LLMs for evaluation. Compared to LLaMA, Llama 2 is trained on 40% more pretraining data with doubled context length (Touvron et al., 2023b). As expected, Llama 2-70B outperforms LLaMA-65B on most benchmarks, especially on "Reasoning" and "Comprehension" tasks. The radar chart in Figure 2c highlights the capability distribution of Llama 2-70B, which achieves similar performance on "Safety" against `gpt-3.5-turbo-0613`, but still clearly underperforms on the other dimensions, especially "Math", "Coding" and "Multilingual". We strongly encourage the open-source community to improve these capabilities of open-source LLMs.

OpenAI API-based vs. Web-version LLMs. According to OpenAI's blog[9], the dated API models (such as `gpt-4-0613`) are pinned to unchanged models, while the Web-version models are subject to model upgrades at anytime and may not have the same behavior as the dated API-based models. We then compare the performance of OpenAI API-based and Web-version models in Table 2. We observe that the dated API models `gpt-3.5-turbo-0613` and `gpt-4-0613`, consistently perform slightly better than their front-

Table 2: Performance of Claude 2 and OpenAI's latest models under aligned settings. Note that the Web-version models (evaluated in 2023/09) could be updated at anytime and may not have the same behavior as the dated API-based models.

end counterparts, i.e., Web-version GPT-3.5 (serving ChatGPT) and Web-version GPT-4. Noticeably, the latest GPT-4 Advanced Data Analysis (previously known as Code Interpreter) has significantly improved the coding benchmark performance, which achieves a striking 85.2 pass@1 score on HumanEval.

Seesaw phenomenon of LLM capabilities. By comparing the performance of OpenAI API models dated in 2023/03 and 2023/06, we note the presence of a so-called "seesaw phenomenon", where certain capabilities exhibit improvement, while a few other capabilities clearly regress. As reported in Table 1, we observe that `gpt-3.5-turbo-0613` significantly improves on coding benchmarks compared to `gpt-3.5-turbo-0301`, but its score on MATH dramatically degrades from 32.0 to 15.0. GPT-4 also shows similar phenomenon, where `gpt-4-0314` achieves 78.6 on LAMBADA and `gpt-4-0613` boosts its performance to a remarkable 87.8, but its score on MGSM plummets from 82.2 to 68.7. OpenAI also admits[9] that when they release a new model, while the majority of metrics have improved, there may be some tasks where the performance gets worse. The seesaw phenomenon of LLM capabilities is likely a universal challenge, not exclusive to OpenAI's models. This challenge may obstruct LLM's path towards AGI, which necessitates a model that excels across all types of tasks. Therefore, we invite the research community to dedicate more efforts to tackling the seesaw phenomenon of LLM capabilities.

Impacts of pretraining with code data. Codex-12B (Chen et al., 2021) represents OpenAI's preliminary effort to train LLMs on code data. Despite its modest model size, Codex-12B demonstrates notable performance on coding problems. Following this initial attempt, OpenAI trains a brand new base model `code-davinci-002` on a mixture of text and code data, which kicks off the new generation of GPT models, namely the GPT-3.5 Series. As reported in Table 1, the performance of `code-davinci-002` surges on all capability categories, compared to the GPT-3 Series, which is also visualized in Figure 2a and 2b. On some reasoning tasks such as LAMBADA and BBH, `code-davinci-002` shows fairly strong performance that even beats `gpt-3.5-turbo-0301` and `gpt-3.5-turbo-0613`. This suggests that incorporating code data into LLM pretraining could universally elevate its potential, particularly in the capability of reasoning.

Impacts of SFT and RLHF. InstructGPT (Ouyang et al., 2022) demonstrates the effectiveness of supervised fine-tuning (SFT) and reinforcement learning from human feedback (RLHF) approaches to aligning language models, which can largely improve the win rate of head-to-head human evaluation. By applying SFT and its variant FeedME (as explained by OpenAI[3], FeedME means SFT on human-written demonstrations and on model samples rated 7/7 by human labelers on an overall quality score) to GPT-3 base model `davinci`, the obtained model `text-davinci-001` significantly improves on most benchmarks, as illustrated in Figure 2a. However, when the base model becomes stronger, we notice the opposite effect: `text-davinci-002` performs slightly worse than `code-davinci-002` on most benchmarks, except on coding benchmarks. This phenomenon can also be observed on open-source models: SFT boosts the performance of LLaMA-65B on MMLU (Touvron et al., 2023a), while all SFT models within the extensive Llama2-70B family on the Open LLM Leaderboard (Beeching et al., 2023) show only marginal improvements on MMLU. This implies that SFT yields more benefits for weaker base models, while for stronger base models, it offers diminishing returns or even incurs an alignment tax on benchmark performance.

Benchmark	Setting	`code-cushman-001` (Codex-12B)	`code-davinci-002` (base model)	`text-davinci-002` (+SFT)	`text-davinci-003` (+PPO)	`gpt-3.5-turbo-0301`	`gpt-4-0314`
HumanEval	0-shot, pass@1	21.2	24.2	29.3	57.6	53.9	66.3
	0-shot, pass@10	52.8	68.9	71.9	81.3	72.2	79.6
	0-shot, pass@100	79.3	91.5	89.0	89.6	78.7	82.9
MBPP	3-shot, pass@1	50.2	67.3	70.2	77.0	82.3	85.5
	3-shot, pass@80	94.8	97.5	95.7	96.1	95.3	95.3

Table 3: Breakdown of coding performance with temperature $T = 0.8$ and top$_p = 1.0$.

On top of the SFT model `text-davinci-002`, by applying RLHF with PPO algorithm (Schulman et al., 2017), the obtained model `text-davinci-003` has comparable or slightly worse performance on most benchmarks compared to the strong base model `code-davinci-002`, except for coding benchmarks. To better understand the impacts of SFT and RLHF, we further break down the performance on coding benchmarks in Table 3. Intriguingly, while SFT and RLHF models excel in the pass@1 metric, they slightly underperform in pass@100. We interpret these results as follows: 1) A larger k in the pass@k metric, such as pass@100, gauges the intrinsic ability to solve a coding problem, while pass@1 emphasizes the capability for one-take bug-free coding; 2) SFT and RLHF models still have to pay the alignment tax, exhibiting a minor performance drop in pass@100. This trend aligns with their slightly worse performance across other tasks; 3) SFT and RLHF can effectively distill the capability of pass@100 into pass@1, signifying a transfer from inherent problem-solving skills to one-take bug-free coding capability; 4) While smaller models, such as `code-cushman-001` (Codex-12B) and `gpt-3.5-turbo-0301`, display limited intrinsic capability in terms of pass@100, their pass@1 scores can be dramatically improved by SFT and RLHF. This is good news for research on low-cost small-size LLMs.

Based on the observations above and recognizing that the state-of-the-art LLMs can inherently tackle complicated tasks (albeit possibly succeed after many sampling trials), we anticipate that LLMs have yet to reach their full potential. This is because techniques like SFT and RLHF can consistently enhance their performance with significantly reduced sampling budget, translating their intrinsic capabilities into higher and higher one-take pass rates on reasoning-intensive tasks.

Impacts of the number of "shots". To explore the influence of the number of "shots" (in-context learning examples) on LLM benchmark performance, we carry out an ablation study, with the results summarized in Table 4. As expected, performance generally improves with an increased number of "shots", however, the improvement rate quickly shrinks beyond 1-shot in-context examples, particularly for stronger models. For instance, `gpt-4-0314` achieves 94.9 on ARC-c with 1-shot example, and only marginally increases to 95.6 with 25-shot examples. This indicates that 1-shot example typically works well for most tasks, which aligns with our primary evaluation setting.

Impacts of CoT prompting. We further explore the impact of using Chain-of-Thought (CoT; Wei et al. 2022) prompting on LLM benchmark performance. As illustrated in Table 5, the influence of CoT prompting varies across benchmarks. On tasks that are knowledge-intensive, like MMLU, CoT has minimal or even slightly negative impact on performance. However, for reasoning-intensive tasks, such as BBH and GSM8K, CoT prompting markedly enhances LLM performance. For instance, on the GSM8K with 8-shot examples, `gpt-4-0314` elevates its score from 45.7 to an impressive 92.1 when CoT prompting is employed.

Prompt sensitivity. Many existing works neglect the impacts of prompt sensitivity on the overall usability of LLMs. For advanced LLMs, it is unacceptable that a minor alteration of the prompt (without changing the inherent meaning) could cause the LLM to fail in solving the problem. Many existing LLM leaderboards reference scores from other papers without consistent settings and prompts, which may inadvertently encourage cherry-picking favored settings and prompts for better results. In contrast, we primarily present our own evaluation re-

Benchmark	Setting	code-davinci-002	text-davinci-002	text-davinci-003	gpt-3.5-turbo-0301	gpt-4-0314

Table 6: Benchmark performance with different prompt templates.

sults under aligned settings and prompts in Table 1 and 2, and highlight exceptions where numbers are either sourced from other papers (with brackets) or obtained from optimized prompts (with stars). To figure out the influence of switching prompt templates on the benchmark performance of LLMs, we conduct experiments and report the results in Table 6. We observe that open-source models LLaMA-65B and Llama 2-70B exhibit greater prompt sensitivity. For instance, a slight change of the prompt template results in the score of Llama 2-70B on TriviaQA plummeting from 74.0 to 55.5. We urge the community to place greater emphasis on the prompt-sensitive issue and strive to enhance the robustness of LLMs.

Sampling variance. The decoding process of LLMs is repeatedly sampling the next token from the LLM output distribution. Various hyperparameters, including the temperature T and the nucleus sampling (Holtzman et al., 2020) parameter top$_p$, can be adjusted to modify the sampling behavior. In our evaluations, we set $top_p = 1.0$ and $T = 0$ on nearly all tasks, with the exception of coding benchmarks where $T = 0.8$. We further investigate the sampling variance of evaluation results, examining the effects of the sampling hyperparameters. Due to the limited space, in Appendix D, we report the mean and stand deviation of benchmark scores over 3 runs with different settings of T and top$_p$. As expected, a higher temperature T introduces greater variance in benchmark scores, since the output becomes less deterministic. Notably, LLMs (especially base models) tend to underperform with a higher temperature T. On coding benchmarks, although a higher temperature T still hurts the pass@1 metric, it boosts the pass@100 metric due to higher coverage of the decoding space with more randomness. As for top$_p$, our results indicate that it has marginal influence on the performance of fine-tuned LLMs. Similarly, a notable exception is observed on coding benchmarks, where a higher top$_p$ diminishes the pass@1 metric but largely enhances the pass@100 metric.

5 Conclusions

We present GPT-Fathom, an open-source and reproducible evaluation suite that comprehensively measures the multi-dimensional capabilities of LLMs under aligned settings. Our retrospective study on OpenAI's models helps the community better understand the evolutionary path from GPT-3 to GPT-4, and sheds light on many community-concerned questions. For example, our study reveals that SFT and RLHF yields more benefit for weaker models, while for stronger base models, it offers diminishing returns or incurs an alignment tax. Moreover, we identify novel challenges of advanced LLMs, such as prompt sensitivity and the seesaw phenomenon of LLM capabilities.

Acknowledgments

The authors would like to thank Yao Fu for the suggestions on benchmark selection. We also thank Ke Shen, Kai Hua, Yang Liu and Guang Yang for technical discussions. We gratefully acknowledge the funding support and feedback from Liang Xiang. This work was made possible by all the benchmarks used for evaluation. We appreciate the creators of these benchmarks.

Limitations

While this work brings forth novel insights on LLM evaluation, it presents certain limitation. Primarily, we rely on regular expression matching to extract answers from LLMs' responses. While this method proves to be effective in most instances, in some corner cases, it might overlook the actual answers provided by the models, particularly when the evaluated LLM has a limited capacity to adhere to the instructions. A possible solution to this issue involves the utilization of more sophisticated LLMs, such as GPT-4, for answer extraction. However, this approach may also incur significant costs. We hope that continued advancements in LLMs evaluation will improve the answering parsing techniques.

Appendix

A Details of Evaluated LLMs

The LLMs selected for evaluation are organized as follows.

1. OpenAI's models (illustrated in Figure 1):

- GPT-3 Series: 1) `davinci` (GPT-3; Brown et al. 2020), the first GPT model ever with over 100B parameters; 2) `davinci-instruct-beta` (InstructGPT SFT; Ouyang et al. 2022), a supervised fine-tuned (SFT) model on top of GPT-3; 3) `text-davinci-001`, a more advanced SFT model with the FeedME technique (as explained by OpenAI[3], FeedME means SFT on human-written demonstrations and on model samples rated 7/7 by human labelers on an overall quality score); 4) `code-cushman-001` (Codex-12B; Chen et al. 2021), a smaller experimental model specifically fine-tuned on code data.
- GPT-3.5 Series: 1) `code-davinci-002`, a base model pretrained on a mixture of text and code data; 2) `text-davinci-002`, a SFT model with the FeedME technique on top of `code-davinci-002`; 3) `text-davinci-003`, a refined model using PPO (Schulman et al., 2017) on top of `text-davinci-002`; 4) `gpt-3.5-turbo-0301`, a chat-optimized model on top of `text-davinci-003`; 5) `gpt-3.5-turbo-0613`, an updated API version in lieu of `gpt-3.5-turbo-0301`; 6) Web-version GPT-3.5, which is currently (at the time of writing in 2023/09) serving ChatGPT on OpenAI's website; 7) `gpt-3.5-turbo-instruct-0914`, a completion model trained similarly to the previous InstructGPT models such as the `text-davinci` series, while maintaining the same speed and pricing as the `gpt-3.5-turbo` models[10]; 8) `gpt-3.5-turbo-1106`, an updated API version in lieu of `gpt-3.5-turbo-0613`.
- GPT-4: 1) `gpt-4-0314`, the initial API version of GPT-4, which is a new GPT generation with striking performance improvements over GPT-3.5; 2) `gpt-4-0613`, an updated API version in lieu of `gpt-4-0314`; 3) Web-version GPT-4, which is currently (at the time of writing in 2023/09) serving GPT-4 on OpenAI's website; 4) Web version GPT-4 Advanced Data Analysis (Code Interpreter), a recently upgraded Web-version GPT-4 with functionalities of advanced data analysis and sandboxed Python code interpreter; 5) `gpt-4-1106-preview`, an early-access API of the upgraded model GPT-4 Turbo[11].

2. Other leading closed-source models:

- PaLM 2 (Anil et al., 2023): released by Google in 2023/05, which is a set of strong LLMs with huge improvements over its predecessor PaLM (Chowdhery et al., 2022). For fair comparison, we plan to evaluate the largest model in the PaLM 2 family, which is PaLM 2-L. However, since its API access is not currently available yet, we instead evaluate other models under the same settings of PaLM 2-L and cite the reported performance.
- Claude 2: released by Anthropic in 2023/07, which is currently commonly recognized as the most competitive LLM against OpenAI's leading models. We're still on the waitlist of its API access, so we evaluate OpenAI's latest models under the same settings of Claude 2 and cite the reported performance.

3. Leading open-source models:

- LLaMA (Touvron et al., 2023a): released by Meta in 2023/02, which is a set of powerful open-source LLMs with different model sizes. We evaluate LLaMA-65B, the largest variant of its base model.
- Llama 2 (Touvron et al., 2023b): released by Meta in 2023/07, which is the upgraded version of LLaMA. We evaluate the largest variant of its base model, which is Llama 2-70B.

B Details of Benchmark Datasets

In Table 7, we clarify the source of few-shot prompts and test samples for each benchmark.

C Details of Evaluation

C.1 Sampling Hyperparameters

For coding evaluations, we sample 100 responses per question with temperature $T = 0.8$. For all the other evaluations, we use $T = 0$. The default $\text{top}_p = 1.0$ is applied across all of our evaluations.

Table 7: Source of few-shot samples and test samples in our evaluations.

C.2 Evaluation Prompts

We provide our evaluation prompts for all the benchmarks in Table 8. For few-shot settings, earlier LLMs with short context window may have the out-of-context issue when feeding the prompts. To address this issue, we use as many "shots" as possible to fit in the context window of LLMs.

C.3 Answer Parsing and Metric Computation

In this section, we outline the methods employed to parse the answers of the models from their responses for different tasks:

Multiple-choice questions. We inspect the output for options such as `(A)`, `(B)`, `(C)`, `(D)`, etc. The option corresponding to a match is determined. If no matches are found, the first character of the output is chosen as the selected option.

Coding problems. We evaluate LLMs on HumanEval and MBPP as the coding benchmarks. Our assessment leverages the code evaluation methodology implemented by Hugging Face (Wolf et al., 2020). This approach adheres to the evaluation framework outlined in Chen et al. (2021), which estimate the pass@k metric using n samples ($n > k$) to reduce the variance. We use $n = 100$ for all the evaluations on coding benchmarks.

LAMBADA. Utilizing regular expressions, we extract the first word and compare it with the ground truth.

DROP. The model's performance is gauged using the F1 score, without any post-processing such as case normalization.

TyDi QA. Similarly, the F1 score is employed to measure performance.

Closed-book question answering. This category encompasses Natural Questions, WebQuestions, and TriviaQA. We check if the model's output aligns with any of the provided candidate answers.

MGSM. The final number in the output is extracted as the model's answer.

GSM8K. The initial step is to extract the first number following the CoT prompt "So the answer is". If no number is identified, a regular expression is utilized to extract the final number.

MATH. In line with the official benchmark settings, we initially filter the answers to retain only

Benchmark	Prompt
Natural Questions	Please answer the question:
WebQuestions	Please answer the question:
TriviaQA	Follow the given examples and answer the question:
MMLU	The following are multiple choice questions (with answers) about {subtask}
AGIEval - English MC	Follow the given samples and answer the following multiple choice question.
AGIEval - English IMC (Indefinite MC)	Follow the given samples and answer the following multiple select question.
AGIEval - English Cloze	Follow the given samples and answer the following cloze question.
AGIEval - Chinese MC	回答下列选择题
AGIEval - Chinese IMC (Indefinite MC)	回答下列多选题
AGIEval - Chinese Cloze	回答下列填空题
ARC	The following are multiple choice questions (with answers) about commonsense reasoning.
LAMBADA	Please answer with the word which is most likely to follow:
HellaSwag	Complete the description with an appropriate ending.
WinoGrande	Choose the option that fill in the blank best.
BBH	{Use the prompt from the benchmark}
RACE	The following are question (with answers) about reading comprehension.
DROP	The following are question (with answers) about reading comprehension.
GSM8K	Follow the given examples and answer the question.
MATH	Follow the given examples and answer the question.
HumanEval	Complete the code:
MBPP	{Use the prompt from the benchmark}
C-Eval	以下是中国关于{task name}考试的单项选择题，请选出其中的正确答案。
MGSM	Follow the given examples and answer the question.
TyDi QA	Follow the given examples and answer the question.
TruthfulQA	Answer the following multiple choice questions.
RealToxicityPrompts	n/a

Table 8: Evaluation prompts used for all the benchmarks.

the last boxed element. The content within the boxed braces is then taken as the answer.

D Sampling Variance

In Table 9 and 10, we report the mean and stand deviation of benchmark scores over 3 runs, with different settings of T and top$_p$.

E Complete Results of LLaMA / Llama 2 Family

We evaluate the entire LLaMA / Llama 2 family, including models ranging from 7B to 65B / 70B parameters, and report the complete results in Table 11.

F Our Results vs. Official Scores

To verify the correctness of our implementation, we first compare our evaluation results with the officially reported scores from GPT-4 technical report (OpenAI, 2023) and Microsoft's early experiments with GPT-4 (Bubeck et al., 2023). To

		1.0	29.4 ± 0.6	15.6 ± 0.4	58.6 ± 0.2	55.3 ± 0.1	57.3 ± 0.1	50.8 ± 0.2
	0-shot, pass@100	0.2	89.4 ± 0.3	88.6 ± 1.8	85.6 ± 1.3	91.5 ± 1.0	62.8 ± 0.0	62.8 ± 0.0
		0.7	88.8 ± 1.4	89.6 ± 1.6	85.1 ± 2.3	91.1 ± 0.1	73.8 ± 0.6	74.4 ± 0.6
		1.0	88.8 ± 0.9	86.8 ± 1.8	87.4 ± 1.8	92.7 ± 1.2	75.2 ± 0.3	79.1 ± 1.0

Table 10: Benchmark performance with different temperature T and top_p. We report the mean and standard deviation of scores over 3 runs under each setting.

ensure an apple-to-apple comparison, we align the evaluation settings on each benchmark, as summarized in Table 12. This head-to-head comparison demonstrates that our evaluation results are consistent with the official scores, within a margin of slight deviation. Since the official prompts and in-context examples for evaluation are not publicly available, the slight deviation is totally reasonable. We also notice that the performance gain with in-context examples beyond 1-shot is pretty marginal, which aligns with our primary evaluation setting in Table 1.

We also compare our evaluation results with the official scores reported in LLaMA (Touvron et al., 2023a) and Llama 2 (Touvron et al., 2023b). Similarly, in Table 13, we report the benchmarks whose official evaluation settings match our settings, and compare our results with the official scores. We observe that on some benchmarks, such as BBH, our results are higher than the official scores; while on some other benchmarks, such as TriviaQA and MATH, our results are lower than the official scores. This phenomenon is consistent with our conclusion that LLaMA and Llama 2 are pretty prompt-sensitive (refer to Table 6). To be more specific, take MATH as an example, since we use the exact same setting and prompt as we evaluate OpenAI models on this benchmark, and our evaluation result of GPT-4 matches the official scores (Table 12), we argue that the prompt sensitivity of LLaMA / Llama 2 models explains the performance gap of our evaluation and their official scores.

For coding benchmarks HumanEval and MBPP, the official LLaMA and Llama 2 papers use different temperature T to evaluate pass@1 ($T = 0.1$) and pass@100 ($T = 0.8$). In contrast, we follow OpenAI's setting on coding evaluation (Chen et al., 2021) and uniformly use $T = 0.8$ for all our evaluations on coding benchmarks. This explains the performance difference of our results and the official scores of LLaMA and Llama 2 on HumanEval and MBPP.

Capability Category		Benchmark	Setting	LLaMA-7B	Llama 2-7B	LLaMA-13B	Llama 2-13B	LLaMA-30B	LLaMA-65B	Llama 2-70B

G Related Work on Analysis

The impacts of pre-training on code data, along with the effects of Supervised Fine-Tuning (SFT) and Reinforcement Learning from Human Feedback (RLHF) on Large Language Models (LLMs), represent significant areas of research interest, with several concurrent studies exploring these themes. Notably, the work by Ma et al. (2023) and Yang et al. (2024) underscores the benefits of integrating code data into the pre-training phase for LLMs, demonstrating an improvement in coding and reasoning abilities without compromising performance on other tasks. Furthermore, the application of SFT and RLHF methods has been shown to reduce instances of hallucination (Li et al., 2024), enhance output diversity and generalization (Kirk et al., 2024), and improve safety measures (Lin et al., 2023; Shen et al., 2024). However, these advancements come at the cost of an alignment tax, a challenge also recognized in the literature (Askell et al., 2021; Liu et al., 2022). Our research primarily investigates these areas through a comprehensive evaluation framework, aligning with and potentially corroborating the findings of these studies.

H Impacts of In-context Samples

To investigate the impact of in-context sample selection on performance, we carried out experiments on ARC-c and DROP, utilizing different sets of in-context learning samples. The findings, presented in Table 14, indicate that the choice of in-context samples indeed affects the model's performance. While the influence on multiple-choice questions is minimal, for free-form questions, the impact of few-shot samples becomes more pronounced. This underscores the significance of disclosing the few-shot samples employed during evaluation.

I Language-wise Evaluation Results

Language-wise evaluation results for multilingual tasks are summarized in Table 15 and Table 16.

Benchmark	Setting	`gpt-4-0314` (our evaluation)	GPT-4 (official score)

Abstract

Word representations are an important aspect of Natural Language Processing (NLP). Representations are trained using large corpora, either as independent static embeddings or as part of a deep contextualized model. While word embeddings are useful, they struggle on rare and unknown words. As such, a large body of work has been done on estimating rare and unknown words. However, most of the methods focus on static embeddings, with few models focused on contextualized representations. In this work, we propose `SPRUCE`, a rare/unknown embedding architecture that focuses on contextualized representations. This architecture uses subword attention and embedding post-processing combined with the contextualized model to produce high quality embeddings. We then demonstrate these techniques lead to improved performance in most intrinsic and downstream tasks.

1 Introduction

Word representations are an important aspect of NLP. While initially, word embeddings were trained separately and inserted into task specific architectures ("static" embeddings), modern approaches use deep architectures to generate contextualized representations (Devlin et al., 2018; Peters et al., 2018; Liu et al., 2019). A weakness of static representations is that they only exist for a trained vocabulary; there are no representations for unknown words. While deep contextualized models can theoretically produce a new representation, Schick and Schütze (2020) demonstrated that these representations for unknown/rare words are of poor quality, implying that rare/unknown words are still a challenge for contextualized embeddings. In response, there have been attempts to create new representations for these words. While there has been a large body of work on static embeddings, less has been focused on contextualized embeddings, especially approaches that incorporate recent innovations enhancing static rare/unknown estimation. Motivated by this, we propose a new architecture for rare/unknown estimation of contextualized embeddings. This model incorporates subword attention and embedding post-processing for higher quality estimates for contextualized models. We call this approach **S**ubword Attention and **P**ostprocessing for **R**are and **U**nknown **C**ontextualized **E**mbeddings (`SPRUCE`). We demonstrate that this model has superior results in most evaluation scenarios.

2 Related Work

Rare/unknown word representations have been well studied in static word embeddings. Early approaches used context sentences to estimate new word embeddings (Herbelot and Baroni, 2017; Lazaridou et al., 2017; Horn, 2017; Arora et al., 2017; Mu and Viswanath, 2018; Khodak et al., 2018), while other approaches use the rare words' morphemes/subwords to estimate the embedding (Bojanowski et al., 2017; Sasaki et al., 2019; Pinter et al., 2017). The most effective approaches combine context sentences and subwords (Schick and Schütze, 2019c,a; Hu et al., 2019; Patel and Domeniconi, 2020, 2023). The combined model *SubAtt* (Patel and Domeniconi, 2023), for instance, uses transformer self attention (Vaswani et al., 2017) on context like other models, but also uses transformer self attention on the subword representations, leading to strong results. Rare/unknown words have also been studied on contextualized embeddings, with the goal of constructing new representations for use in the initial embedding layer of the contextualized deep model. While less-studied than static embeddings, there have been attempts to effectively estimate rare/unknown contextualized embeddings. The current state-of-the-art approach on contextualized models is `BERTRAM` (Schick and Schütze, 2019b); `BERTRAM` constructs the context representations using the BERT architecture. It then combines these representations us-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1383–1389
June 16-21, 2024

ing the attention mechanism from Attentive Mimicking (Schick and Schütze, 2019a, 2020). It uses learned subwords to estimate the rare/unknown embedding, and then inputs this estimate into the BERT model for each context sentence. `BERTRAM` has been shown to output strong rare/unknown embeddings for use in a BERT architecture. However, contextualized rare/unknown words are understudied, and models don't incorporate recent innovations found in static embedding equivalents. In response to this, we propose `SPRUCE`, a model that incorporates the strengths of previous static models like *SubAtt* and contextualized models like `BERTRAM` to create a new architecture that is state-of-the-art in most rare/unknown evaluation tasks.

3 Model

We now present `SPRUCE`[1]. We focus on estimating rare and unknown embeddings with the BERT (Devlin et al., 2018) model, although this can be adapted to any deep model. We combine aspects of the previous state-of-the-art model `BERTRAM` (Schick and Schütze, 2019b) with attention on the subword input, similar to the one proposed in static word embeddings model *SubAtt* (Patel and Domeniconi, 2023) but has not been previously used in contextualized models. In addition, we train `SPRUCE` on post-processed embeddings, with top PCA components removed. A diagram of `SPRUCE` is shown in Figure 1.

3.1 Pretrained Aspects

Similar to `BERTRAM`, we start with pretraining a context half and a subword half of the model separately. We use the same architectures pretrained in `BERTRAM` for `SPRUCE`. For the context half, the architecture uses BERT to encode each context sentence, which it then applies Attentive Mimicking (Schick and Schütze, 2019a) for a final rare word estimate. For the subwords, the architecture learns character n-gram representations and then combines them for a final rare word estimate. These pretrained architectures are then used to build `SPRUCE`, as discussed in the following sections.

3.2 `SPRUCE` Context Architecture

Similar to `BERTRAM`, we extract BERT representations for each context sentence C_i. We then use these to calculate our new representations using Attentive Mimicking (Schick and Schütze, 2019a, 2020):

$$v_{C_i} = BERT(C_i) \tag{1}$$

$$v_{ctx_1} = \sum_{i=1}^{C} \rho(C_i) v_{C_i} \tag{2}$$

where $\rho(C)$ is calculated using the attention mechanism used in Attentive Mimicking (see (Schick and Schütze, 2019a) for more details). Next, we calculate a second context representation, using a transformer encoder self attention layer, denoted as $Encoder_{ctx}$. We take the mean of this result:

$$v_{C_2} = Encoder_{ctx}(v_C, v_C, v_C) \tag{3}$$

$$v_{ctx_2} = \frac{1}{|v_{C_2}|} \sum_i v_{C_{2i}} \tag{4}$$

This approach yields two context representations, v_{ctx_1} and v_{ctx_2}.

3.3 `SPRUCE` Subword Architecture

Unlike `BERTRAM`, which creates a subword estimate and then inserts it into each context sentence, we also incorporate the subword representation at the end of the model. In addition, we apply attention on the subwords. This was proposed in (Patel and Domeniconi, 2023) for static embeddings; ours is the first architecture to do this with contextualized ones. We use two subword representations. First, in an effort to match the context processing of BERT, we apply transformer encoder layers to the pretrained subword embeddings. We use 12 layers to match the BERT architecture. We then take the mean of those representations:

$$v_{S_2} = Encoder_{sub_{12}}(v_S, v_S, v_S) \tag{5}$$

$$v_{sub_1} = \frac{1}{|v_{S_2}|} \sum_i v_{S_{2i}} \tag{6}$$

where V_S is the set of character ngram subwords that make up the target rare/unknown word. Secondly, to match the context half of the architecture, we use another transformer self attention layer, and then take the mean:

$$v_{S_3} = Encoder_{sub1}(v_{S_2}, v_{S_2}, v_{S_2}) \tag{7}$$

$$v_{sub_2} = \frac{1}{|v_{S_3}|} \sum_i v_{S_{3i}} \tag{8}$$

This yields two subword representations, v_{sub_1} and v_{sub_2}.

---

[1] https://github.com/rajicon/SPRUCE

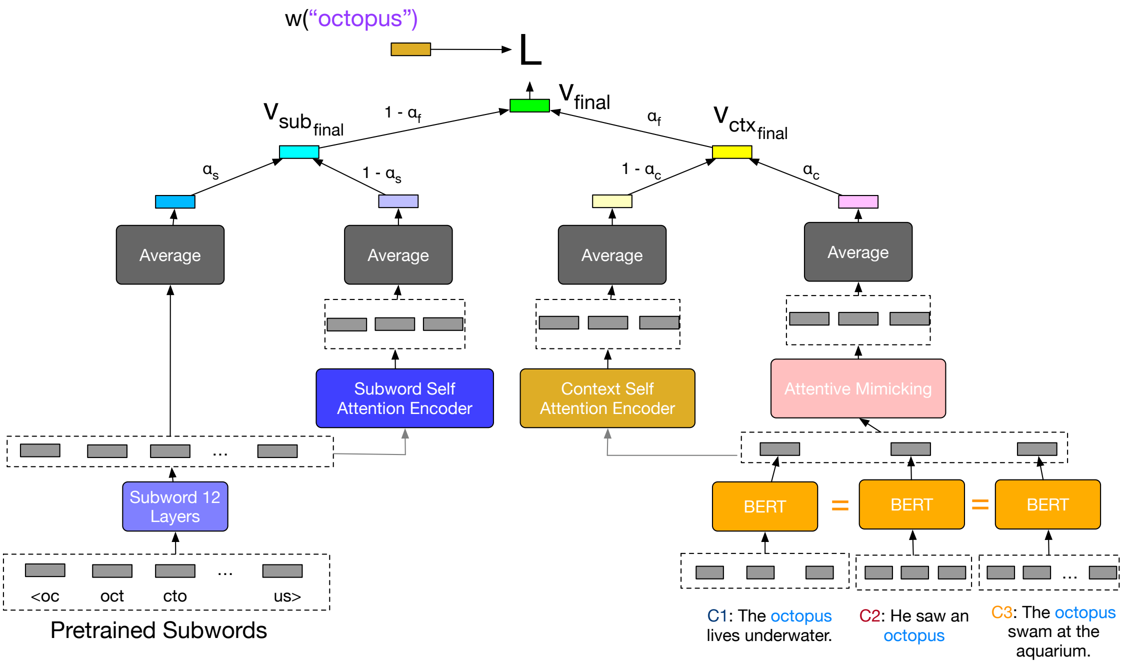

Figure 1: SPRUCE Model Architecture. BERT along with attention blocks are used to create a context representation. Pretrained subwords along with attention blocks are used to create a subword representation. These are then combined using hierarchical gating for a final rare word estimate.

3.4 Combining Subword and Context

We experimented combining the four values in various ways, but found that a hierarchical gating approach worked best. We use gate functions originally proposed in (Schick and Schütze, 2019c), applied multiple times to combine each piece. First, we combine the context representations with each other and the subword representations with each other. We then combine the final context and final subword representations:

$$v_{ctx_{final}} = \alpha_c v_{ctx_1} + (1 - \alpha_c) v_{ctx_2} \tag{9}$$

$$v_{sub_{final}} = \alpha_s v_{sub_1} + (1 - \alpha_s) v_{sub_2} \tag{10}$$

$$v_{final} = \alpha_f v_{ctx_{final}} + (1 - \alpha_f) v_{sub_{final}} \tag{11}$$

with weights of each α is calculated as follows:

$$\alpha_j = \sigma(w_j^T [v_{j1}, v_{j2}] + b) \tag{12}$$

where $w_j \in R^{2d}$ and b is a bias value. Our final representation is v_{final}. During training, this is compared to the original embedding (we refer to this as v_{gold}) using Mean Squared Error as the loss.

3.5 Post-Processing Label Embeddings

Word embeddings tend to share some common directions. These common directions carry little semantic content, and can distract from the meaningful components in embeddings. Mu and Viswanath (2018) and Arora et al. (2017) proposed post-processing word embeddings in order to improve their performance in various tasks. The post-processing approach removes top PCA (Pearson, 1901) components from each embedding, removing less meaningful aspects of the embeddings. While post-processing is generally studied on static word embeddings, Sajjad et al. (2022) demonstrated that this post-processing shows improvement in contextualized embeddings as well. Motivated by this, we propose training SPRUCE on post-processed BERT embeddings. The goal is to train the model to output embeddings that carry meaningful content. Training on post-processed embeddings should force the model to focus on those instead of common directions found in the embeddings. To this end, we remove the top seven components from the BERT embeddings before using them to supervise training. We note that this is only done when training SPRUCE; when inserting the estimated embeddings into the BERT architecture, we do not post-process the common embeddings. The goal is to estimate embeddings that work well in a standard BERT model, and as a result, we do not post-process there.

4 Experiments

4.1 Model Training

We extract gold standard embeddings of frequent words from the embedding layer of the BERT

	Rare	Medium
BERTRAM	0.2852	0.3580
BERTRAM + PCA	0.2902	**0.3721**
SPRUCE	0.2952	0.3483
SPRUCE + PCA	**0.2994**	0.3599

Table 1: WNLaMPro (MRR)

model for use as labels. However, as discussed in (Schick and Schütze, 2020), most embeddings use subword tokenization, and as such, an embedding doesn't exist for all words in the vocabulary. In order to get gold standard embeddings for these words, we use One Token Approximation (Schick and Schütze, 2020). This approach builds an embedding that impacts the BERT model similarly to how the real subword token embeddings do, which is effective for use as a gold standard embedding for the word. We extract context sentences from the Westbury Wikipedia Corpus (WWC) (Shaoul, 2010) for each gold standard word.

4.2 Baselines and Hyperparameters

We compare our approach to BERTRAM[2] (Schick and Schütze, 2019b), the current state-of-the-art. For both models, we pretrain a context only and subword only model, using the same parameters used in (Schick and Schütze, 2019b) with one difference; we increase the subword dropout from 0.1 to 0.3, which we found improved results in both models. We train each model for 10 epochs with a learning rate of 1e-6 (which we found to be best out of 1e-6, 1e-5, and 1e-4). For each model, we train a version based on the standard embeddings, and one trained on post-processed embeddings (denoted "+ PCA"). 10 trials of each model were trained. As we don't have an evaluation set, we test the model saved at each epoch in the evaluation task, and take the best performance. We conduct significance testing using one-way ANOVA with a post-hoc Tukey HSD test. We use a p-value threshold equal to 0.05. We present the best result and any result not significantly different in bold. We also compare each model with its PCA post-processed version, where we present the significant best with an underline.

4.3 Evaluation Tasks

Intrinsic Tasks First, we conduct intrinsic evaluation of our estimated embeddings. The first task we study is the WNLaMPRo task, proposed in (Schick and Schütze, 2020). This task contains various patterns containing vocabulary split by frequency (frequent, medium, and rare). This task then uses simple prompts to measure performance. For example, a frequent pattern may evaluate the word predicted in "A lime is a ", while a similar rare pattern may evaluate the word predicted in "A kumquat is a ". The performance is based on where the real word ranks in the predicted probabilities, measured with Mean Reciprocal Rank (MRR). In our evaluation, we use the models to estimate on rare and medium words, and judge the performance on the new embeddings. We present the results of WNLaMPro in Table 1. As shown in the results, SPRUCE outperforms BERTRAM in rare word performance, but has a weaker performance with medium frequency words. Additionally, we find that PCA post-processing improves both BERTRAM and SPRUCE in both rare and medium words. These results demonstrate SPRUCE's strength at estimating strong rare word representations, along with post-processing label effectiveness at improving embedding performance in both rare and medium words.

Downstream Evaluation While intrinsic evaluation of estimated embeddings is important, the main motivation of using deep contextualized models like BERT is for finetuning on downstream tasks. To this end, we evaluate rare/unknown word performance on various downstream tasks, similar to the procedure done in (Patel and Domeniconi, 2023). However, here we insert the estimated embeddings into a standard BERT model, then finetune the model[3] on the training set (with the best model picked by the validation set). We then evaluate the performance on the test set for that task. Each task presented here is a word level task, which allows us to focus analysis on the rare/unknown words. We focus on six downstream tasks; five NER tasks: AnEM, (Ohta et al., 2012), Bio-NER (Kim et al., 2004), CoNLL 2003 (Sang and De Meulder, 2003), MovieMIT (Liu et al., 2013), and Rare-NER (Derczynski et al., 2017) and one parts-of-speech task POS (Ritter et al., 2011). We present the results on rare and unknown words in Table 2. We find that SPRUCE significantly outperforms BERTRAM in all tasks. This demonstrates SPRUCE's high performance at estimating rare and unknown words. Interestingly, PCA post-processing does not seem to affect results here in

---

[2] For more model details of BERTRAM and SPRUCE, see Appendix B.

[3] We freeze the embedding layer so we can evaluate the quality of embeddings, not finetuning.

	AnEM	Bio-NER	CoNLL 2003	MovieMIT	POS	Rare-NER
`BERTRAM`	0.3652	0.7241	0.6617	0.6295	0.2449	0.2592
`BERTRAM` + PCA	0.3579	0.7252	0.6633	0.6657	0.2346	0.2652
`SPRUCE`	**0.3867**	**0.7399**	**0.6963**	**0.6801**	**0.4761**	**0.2874**
`SPRUCE` + PCA	**0.3793**	**0.7409**	**0.6974**	**0.6895**	0.4570	**0.2819**

Table 2: Downstream Tasks - Macro F1 of Rare/Unknown Words

most cases, except for an improvement in `BERTRAM` in the MovieMIT task and weaker performance in `SPRUCE` in the POS task. We posit that this lack of impact is due to the fact that post-processing improves estimated embeddings on a finer grained basis. For the downstream tasks, which care more about general features, the improvement gained by post-processing may not have as much impact.

5 Conclusion

We propose `SPRUCE`, an architecture that uses deep contextualized models to estimate new representations of rare/unknown words for use in those models. We show the strength of `SPRUCE` in intrinsic and downstream tasks.

Limitations

This work has some limitations. Similar to previous work, task diversity of downstream tasks is limited. Due to ability to focus on rare/unknown words, word level tasks are desirable for analysis, and therefore five out of the six tasks are named entity recognition tasks.

A Implementation Details

All experiments were conducted using Pytorch (Paszke et al., 2019) and Huggingface (Wolf et al., 2020) libraries. Our implementation was heavily based on the `BERTRAM`[4] code.

---

[4] https://github.com/timoschick/bertram/

B Model Details

Both BERTRAM and SPRUCE are built on top of the BERT base model. The parameters from the BERT architecture along with the learned subword representations make up a large portion of the parameter count. SPRUCE makes use of additional transformer encoder blocks, which increases its parameter count compared to BERTRAM. The final parameter counts for BERTRAM is 176,620,032 and for SPRUCE is 242,803,203.

UGIF-DataSet: A New Dataset for Cross-lingual, Cross-modal Sequential actions on the UI

Abstract

Help documents are supposed to aid smartphone users in resolving queries such as "*How to block calls from unknown numbers?*". However, given a query, identifying the right help document, understanding instructions from the document, and using them to resolve the issue at hand is challenging. The user experience may be enhanced by converting the instructions in the help document to a step-by-step tutorial overlaid on the phone UI. Successful execution of this task requires overcoming research challenges in retrieval, parsing, and grounding in the multilingual-multimodal setting. For example, user queries in one language may have to be matched against instructions in another language, which in turn needs to be grounded in a multimodal UI in yet another language. Moreover, there isn't any relevant dataset for such a task. In order to bridge this gap, we introduce **UGIF-DataSet**[1], a multi-lingual, multi-modal UI grounded dataset for step-by-step task completion on the smartphone, containing 4,184 tasks across 8 languages. The instruction steps in UGIF-DataSet are available only in English, so the challenge involves operations in the cross-modal, cross-lingual setting. We compare the performance of different large language models for this task and find that the end-to-end task completion rate drops from 48% in English to 32% for other languages, demonstrating significant overall headroom for improvement. We are hopeful that UGIF-DataSet and our analysis will aid further research on the important problem of sequential task completion in the multilingual and multimodal setting.

1 Introduction

Smartphone users often struggle to navigate the UI to get things done. This problem is particularly acute in developing countries due to varying literacy levels, high cost of phone ownership, etc. (Ranjan, 2022). Many of the tasks users struggle with are documented as frequently asked questions (FAQs) on support sites[2] with step-by-step instructions describing what the user should do on the UI. We explore the problem of harnessing such help documents to create step-by-step tutorials overlaid on the phone UI as an instance of cross-lingual, cross-modal sequential action prediction.

To create step-by-step tutorials on the UI using help documents, research challenges in several natural language processing components including retrieval, parsing, and grounding have to be overcome. But no relevant dataset exists for this task in the multilingual setting. We build on prior work in the NLP community in this area (Li et al., 2020a) and extend it in the multilingual and multimodal directions. We collect a new multi-lingual, multi-modal UI grounded dataset called `UGIF-DataSet` to evaluate how well models can predict sequential actions on the phone UI. The dataset consists of 523 how-to queries per language and for each query, step-by-step instructions in English and a sequence of UI screenshots and actions that show how to complete the task. Each how-to query and UI sequence is available in 8 languages. An outline of the structure of this dataset is shown in Fig. 1.

The tutorial task poses both multi-lingual and multi-modal challenges. Many smartphone users are bilingual and ask queries in their native language, but the help documents are often available only in English. Hence the need for cross-modal, cross-lingual retrieval. Furthermore, users may use a non-English UI / System language which necessitates cross-lingual UI grounding to map the instruction steps in English to UI screens containing different languages. While current multi-modal models have tended to focus on tasks related to a single image, such as caption generation (Alayrac

et al., 2022) or grounding the user's command to a UI element on the screen (Li and Li, 2022), the tutorial task introduces another challenge by requiring the model to perform a sequence of actions across UI screens while referencing a help document. Finally, since the UI changes often, the help documents are often out-of-date, which introduces the additional difficulty of utilizing potentially unreliable help instructions to complete the task.

We propose an initial uni-modal approach that splits this task into **retrieval**, **parsing**, and **grounding** and use existing large language models (Chowdhery et al., 2022; Feng et al., 2020) as a baseline to explore the challenges in this task and estimate the headroom available for improvement. The contributions of this work are as follows:

- We release `UGIF-DataSet`[3], a new multi-lingual, multi-modal dataset of how-to queries and sequences of UI screens and actions recorded by human annotators (Fig. 1). This is the first such multi-modal dataset of its kind.
- We evaluate the parsing of step-by-step how-to instructions with large language models and UI grounding with multi-lingual BERT sentence embedding (LaBSE).
- Our results indicate that there is considerable room to improve performance, especially in non-English languages.

2 Related Work

Natural Language Instruction Following for UI navigation: There have been several previous efforts at natural language conditioned UI navigation for desktop operating systems (Branavan et al., 2009, 2010; Xu et al., 2021) and image editing applications such as Adobe Photoshop (Manuvinakurike et al., 2018). More recently, there has been work on grounding natural language instructions to mobile user interfaces for automatically generating videos of help articles (Zhong et al., 2021). Our work is an enhanced and updated successor to the `PixelHelp` dataset released in Li et al. (2020a) with voice and text queries in eight languages, instruction steps in English, and UI screens in eight system languages.

Imitation learning and Reinforcement learning for UI navigation: One can think of broadly two approaches to building a UI navigation agent: (a) scaling horizontally by building an agent that can handle a few simple tasks like searching for something, deleting an item, etc. that are useful across many different apps, and (b) scaling vertically by exposing a greater depth of functionality but only for a few applications. Li (2021) takes the former approach and uses behavior cloning and reinforcement learning to train agents for two specific skills: to install the specified app from the Play Store and another agent to find the search box in any app. To enable reinforcement learning research on Android UIs, Toyama et al. (2021) introduces `AndroidEnv`, an open source platform for training RL agents. Similar to that, `WorldOfBits` is an open platform for training web navigation agents (Shi et al., 2017; Liu et al., 2018). In our work, we take the lat-

---

ter approach of exposing deeper functionality of a few popular apps by relying on help articles in the Android support site. We chose this because new users often ask goal oriented questions that require greater knowledge about how to navigate a particular app. Moreover, app developers often provide FAQs with common tasks in mind, so we can exploit the support pages to create UI grounded tutorials for new users.

Pre-training for UI tasks: In the past few years, there has been a paradigm shift in deep learning towards pre-training on broad unlabelled datasets and fine-tuning on task specific data. Bai et al. (2021); He et al. (2021) pre-train a transformer model on a large number of screenshots obtained by crawling apps in smartphones in a manner similar to web crawling. Since our focus is on multilingual UI screens, we chose to use the pre-trained LaBSE (Feng et al., 2020) for UI grounding, but utilizing broad UI data will be critical for future improvements.

Large language models: Large language models (LLMs) pre-trained on large corpora of text scraped from the web have shown remarkable few-shot generalization capability (Chowdhery et al., 2022; Brown et al., 2020). We employ LLMs for parsing help articles but not for UI grounding since we prefer to do it on-device for privacy reasons.

Language grounding in human-robot interaction: Language guided robot actions for human-robot interaction (Lynch and Sermanet, 2020; Venkatesh et al., 2021) is a broadly related problem. However, taking actions on real robots is much more complex with uncertain outcomes, whereas precise actions can be performed on the UI with near certainty. As a result, the difficulty with UI grounded interactions is less about sensing and actuation and more about understanding user intent and navigating the app by understanding its structure using external resources such as support pages.

Icon and widget captioning: Although Android allows developers to provide content description for images, not all app developers do so. To support a wide range of apps, it becomes necessary to recognize icons and widgets (Li et al., 2020b; Baechler and Sunkara, 2021). In our work, all the apps provide the necessary description, so icon captioning is not necessary.

3 UGIF-DataSet: A New Multilingual Multimodal UI-grounded Instruction Following Dataset

To build and evaluate an Android UI navigation agent that can teach users how to use the UI, we collect a new multi-lingual, multi-modal UI grounded dataset called `UGIF-DataSet`. It is a corpus of how-to queries in text and speech in multiple languages, instruction steps for each tutorial paired with sequences of UI screens and actions as the tutorial is completed by human annotators on Android devices (Fig. 1).

The Pixel Help support pages provide step-by-step instructions for performing common tasks on Android. This is an example task: "*How to block unknown numbers?*" for which the instruction text is "*1. Open your Phone app 2. Tap More. 3. Tap Settings and then Blocked numbers. 4. Turn on Unknown*". We crawl the Android support site and extract the tutorial steps using simple rules that look for ordered lists under a header. Annotators translate and speak out loud the how-to query. They also parse the tutorial steps to a sequence of macros in Table 1. Additionally, for each tutorial task, annotators are asked to operate a virtual Android device to carry out the steps in the tutorial while the screen of the device and the annotator's actions are recorded. Just before each action taken by the annotator is forwarded to the virtual device and executed using `UIAutomator` (Android, 2022), we record a screenshot of the device, the view hierarchy in XML, and the action taken by the annotator at that step.

We used an internal platform for crowd-sourcing annotations from annotators in India, Kenya, and Mexico. Annotators were screened by asking qualifying questions with multiple-choice answers. Only those who successfully answered the qualifying questions were allowed to participate in the data collection. The qualifying questions tested linguistic capability: simple questions to gauge whether they can understand written content and speech in the target language. There was no Android UI or task specific training involved. The task description explained the purpose of this data collection effort and how it would be used for research. To protect the privacy of the annotators, the annotator ID is not included in this dataset release. The task design was reviewed by privacy, ethics, and legal committees. The price set for each task was in compliance with local laws.

The manual annotation process for collecting UI

Macro	Function
`tap`(e)	Taps on the UI element specified in the argument (e)
`toggle`(e, `val=True`)	Finds the UI element in the argument (e) and then searches for the nearest Switch element and taps on that
`home()`	Presses the home button in Android
`back()`	Presses the back button
`prompt`(a)	Requests the user to take some action (a) and waits until an action is performed

Table 1: List of all macros that can be generated from instruction steps (Section 3).

Dataset characteristic	Value
# of tutorials / language	523
# of train samples / language	152
# of dev samples / language	106
# of test samples / language	265
Number of languages	8
Total # of UI screens	3312
Avg # of UI screens / tutorial	6.3
% of tutorials failing due to UI drift	29.9%
Max # of tasks / annotator	50

Table 2: `UGIF-DataSet` statistics (Section 3).

screens from the Android emulator scales linearly with the number of UI languages. To mitigate this, we collect UI screens from annotators only in English and search for each UI string in the resources directory of the app's APK and replace it with the translation provided by the developer in the APK wherever it is available. If a translation is unavailable, we default to English. A typical UI screen has a mixture of strings in English and other languages, but this is distinct from code mixing where two languages are used in a single sentence.

The `UGIF-DataSet` dataset includes tasks in the following apps: Settings, Google One, Gmail, Play Store, Contacts, Messages, Chrome, Maps, Camera, Google Photos, Google Earth, and Files (Table 2). It differs from the `PixelHelp` dataset (Li et al., 2020a) in the following ways. It:

- Contains UI elements in seven non-English languages: Hindi, Kannada, Marathi, Gujarati, Bengali, Swahili, Spanish.
- Is a multi-modal dataset that includes not only the view hierarchy of the screens but also a screenshot at each step of the execution.
- Does not assume that the UI element is visible on the screen. The annotator is allowed to scroll and find the UI element referred in the instruction text.
- Includes samples where the instruction text is outdated and does not correspond to the current version of the UI. In such cases, annotators can either adapt the instructions to the current UI or declare an error if they are unable to complete the task.

4 Model

UGIF has three components: Retrieval, Parsing, and Grounding (Fig. 2). Based on text or speech input, the most relevant how-to instruction in English is retrieved and then parsed to generate macros. These macros are executed on the Android device by grounding them in the UI (Alg. 1).

Algorithm 1 UGIF end-to-end description

```
steps $\leftarrow$ $\boldsymbol{retrieve\_howto}$(user_query)
macros $\leftarrow$ $\boldsymbol{parse}$(steps)
i $\leftarrow 0$
while i $<$ $len$(macros) do
    macro $\leftarrow$ macros[i]
    action $\leftarrow$ $\boldsymbol{ground}$(macro, screen)
    if action $\neq$ SCROLL then
        i $\leftarrow$ i $+ 1$
    end if
end while
```

Retrieval We use Google Cloud Speech[4] as an off-the-shelf speech recognizer to convert speech to text. A multilingual sentence embedding model (Feng et al., 2020) is used to obtain a vector corresponding to the query, which is then used to retrieve the most similar how-to by cosine similarity of the how-to page title in the UGIF-DataSet corpus.

Parsing The parsing model takes how-to instructions and generates a sequence of macros (Table 3). We tried various language models such as PaLM (Chowdhery et al., 2022), GPT-3 (Brown et al., 2020), T5 (Raffel et al., 2020), and UL2 (Tay et al., 2022)) to generate the macro given the instruction text. For parsing with finetuned models, the how-to instruction steps was provided as input (see Fig. 5).

---

[4] https://cloud.google.com/speech-to-text

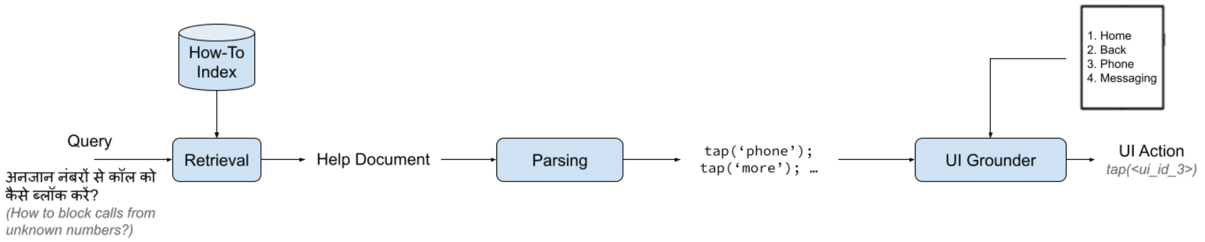

Figure 2: Our initial approach using Large Language Models (LLM) for UI Grounded Instruction Following. The user's query "*How to block calls from unknown numbers?*" is matched against how-to articles in the index to find the closest matching help document. The instruction steps in the help document are parsed using an LLM to a sequence of macros like `tap()`, `toggle()`, `home()`, etc. that must be executed on the UI. The phone grounder grounds each macro in the UI and selects the UI element that the user must act on (Section 4).

Instruction text	Macro sequence
Open the Phone app. Tap Recents.	`tap("Phone");` `tap("Recents");`

Open the Settings app. Tap Network & Internet. Turn off wi-fi.	`tap("Settings");`
	`tap("Network & Internet");`
	`toggle("wi-fi", False);`

Table 3: Sample instructions and corresponding macro sequences (Section 4).

In the case of the few-shot prompted models, the prompt preamble "Use these examples to generate code." was followed by few-shot examples in the same format (Text: ...\nCode: ...\n) as shown in Fig. 5.

Grounding The grounding model takes a macro, potentially with arguments, as input along with the current UI screen and performs a series of actions on the UI to complete the task specified by the macro. The macros in our setup are described in Table 1.

For both `tap()` and `toggle()`, it is necessary to locate the UI element being referred to in the argument of these macros. i.e., we are given a macro with its argument referring to a UI element and a list of UI elements currently visible on the screen, and we must decide which element to pick (or to not pick at all and scroll for a better match). For finding the closest matching UI element, we experiment with jaccard similarity, UiBERT (Bai et al., 2021), and multi-lingual BERT sentence embedding (LaBSE) (Feng et al., 2020). The jaccard similarity between a UI element and the referring expression is measured by splitting the words in the UI string and the referring expression and finding the jaccard similarity between these two sets. The LaBSE model generates embeddings for entire sentences, which we utilize to compute embeddings for each UI element and also for the input referring expression in the macro. The cosine similarity between the embeddings for the referring expression and the UI element is used as a scalar measure of the similarity between the arugment to the macro and the UI element. When the app developer has not provided translation for some UI element, the system defaults to showing the English label for that UI element. Since the multilingual sentence embedding model (LaBSE) does not rely on language identification, we can utilize the sentence embedding without regard to the language in the UI element.

We use a scrolling threshold T to decide whether to scroll or to accept a UI element currently on the screen. If the similarity metric is less than T, we choose to scroll down looking for a better match, whereas if the similarity metric is above T, the best matching UI element is chosen for interaction (either tapping or toggling). The appropriate value for T is determined through experimentation on the development set. Likewise, we also use UiBERT to generate embeddings for all the UI elements on the screen along with the input referring expression, but with UiBERT we introduce an additional "Not found" UI element that the model is trained to choose if the scroll action is taken.

For the tapping macro, it is sufficient to look for the UI element most similar to the argument in the macro. However, for the toggle macro, when using LaBSE embeddings we first find the UI element referred to by the argument to the `toggle()` macro, and then look for an Android Switch element nearby in the view hierarchy (Fig. 3). This works as long as the app is using the standard An-

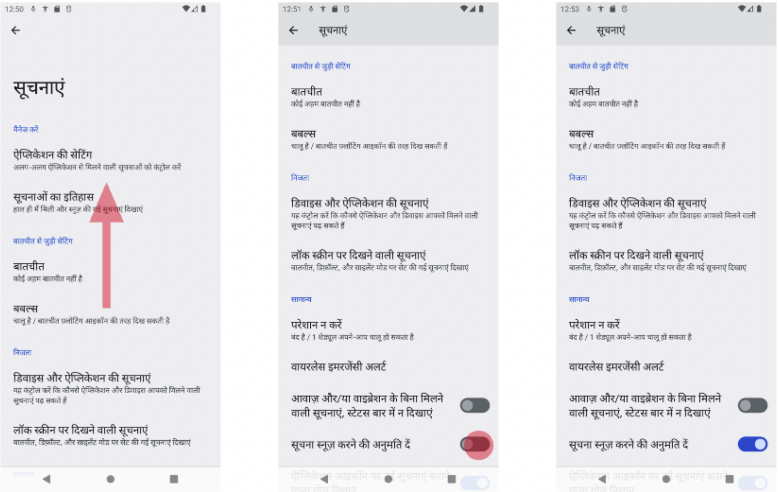

Figure 3: A sample sequence of UI screens and actions resulting from the execution of the macro: `toggle("Allow notification snoozing", True)`. The UI grounding model recognizes that none of the UI elements is a sufficiently close match to the string in the argument of the macro, scrolls down, finds a match, and taps on the nearest switch to turn it on (Section 4).

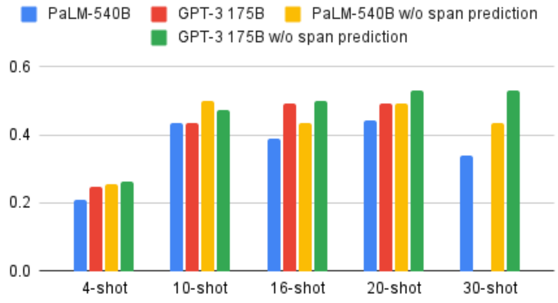

Figure 4: Parsing accuracy on the development set of `UGIF-DataSet` (Section 5.2).

droid Switch element and a straightforward XML layout of the mobile UI where the text field is close to the Switch element. Nevertheless, such heuristics are brittle and could be resolved by multimodal models which we leave for future work.

5 Experiments

The `UGIF-DataSet` dataset contains manually annotated oracle parses (macro sequences) for each how-to instruction text. We measure parsing accuracy by looking for an exact match between the generated parses and the oracle parses.

The dataset also contains manually annotated screen-action sequences for the entire how-to, but it does not have such sequences for each macro. So, to evaluate the grounding model, we consider the end-to-end task completion success rate. Although it is possible to complete each task in more than one way, we want to follow the how-to instruction text exactly, so we consider a task to be completed successfully only if the entire sequence of actions predicted by the model exactly matches the sequence of actions taken by the annotator.

5.1 How well does retrieval work across languages?

The multilingual sentence embedding model (Feng et al., 2020) is excellent at matching how-to queries in non-EN languages to how-to queries in English (Table 6). Examination of the failures with non-EN text queries revealed noise in the dataset where a small percentage of queries are repetitions with minor variations such as punctuation. When Google Cloud Speech API is used as an off-the-shelf automated speech recognizer (ASR) to convert speech input to text, there is a measurable drop in performance across all languages, but the reduction is large for Swahili. We also noticed that ASR failures were due to poor voice clarity, background noise, and more common with technical terms such as "cache".

5.2 How does parsing performance scale with dataset and model size?

There is a steep increase in parsing performance from 4-shot prompting to 10-shot prompting (Fig. 4). At 30 examples, the number of tokens in the input exceeds the maximum that the model can handle and performance deteriorates. Marking salient spans in the instruction text as an intermediate step for chain of thought prompting (Wei et al.,

Model configuration	Parsing accuracy
PaLM 540B 20-shot ICL	46%
GPT-3 175B 20-shot ICL	50.9%
PaLM 8B soft prompt tune	49.1%
PaLM 62B soft prompt tune	64.9%
PaLM 540B soft prompt tune	66.8%
UL2 20B full finetune	66.8%
T5 11B full finetune	66.8%
PaLM 8B full finetune	64.5%
PaLM 62B full finetune	67.5%
PaLM 540B full finetune	**70.1%**

Table 4: Parsing accuracy of pre-trained models on the `UGIF-DataSet` test set. In-context learning (ICL) is with 20 randomly selected training samples (single run). Fine-tuning and soft prompt-tuning with a 50-token soft prompt prefix (Section 5.2) is performed with all 158 training samples and hyper-paramter search over dropout values 0.0, 0.02, 0.05, 0.1, and 0.2 on 256 TPUs for about 24 hrs each. For fine-tuning, the best dropout was 0.1 with training for 10k steps, and for soft prompt-tuning, the best dropout was 0.0 with training for 17.5k steps.

2022) degrades parsing performance. When all the available training samples are used with full fine-tuning or soft prompt tuning (Lester et al., 2021), the resulting performance is significantly better than few-shot prompting (Table 4). The parsing accuracy increases only modestly with model size when full fine-tuning is used. However, with soft prompt tuning, there is more benefit to using larger models.

5.3 What are the common failure modes of large language models for parsing?

We examined the test samples where the model's predictions were incorrect (Fig. 5) and found the PaLM 540B finetuned model (a) generated incorrect macros, (b) made minor errors in predicting the span of the argument such as including the full stop, (c) missed salient parts of the input instruction resulting in skipped macros, and (d) hallucinated non-existent macros (Fig 6).

5.3.1 How well do existing models work for UI grounding?

We find that even simple string matching models can offer good performance when the language in the how-to matches the UI language (Table. 5). To our surprise, UiBERT underperformed this baseline. When the instruction text and the UI language are different, we have to use LaBSE which is a multilingual model, but we find that performance with English is still better than other languages. An examination of the incorrectly predicted samples (Fig. 7) using LaBSE revealed these modes of failure (Fig. 8): (a) Inexact string matching fails and the model keeps scrolling in the hope of a better match which it never finds (84.5%), (b) the model overtriggers and chooses an inexact match instead of scrolling and looking for a better match (5.2%), (c) the model lacks knowledge of common UI patterns and app names, so it gets confused between "Play Store" and "Google One" when trying find the closest match for "Google Play" (5.2%).

1

Text: open the google play app google play. at the top right, tap the profile icon. tap settings and then authentication and then require authentication for purchases.

Code: `tap("google play"); tap("settings"); tap("authentication"); tap("require authentication for purchases");`

2

Text: on your android phone or tablet, open the gmail app. select one or more emails. in the top right, tap more more and then report spam.

Code: `tap("gmail"); select("one or more emails"); tap("more"); tap("report spam");`

3

Text: On your Android phone or tablet, open the Google Earth app. On the left, tap Map Style. Turn Gridlines on.

Code: `tap("Earth"); tap("Map Style"); tap("Gridlines"); toggle("Gridlines", True);`

Figure 5: Incorrect sequences of macros generated by the 20-shot prompted PaLM 540B model. In the first example, the macro `tap("profile icon")` is omitted in the output. In the second example, the model hallucinates the non-existent `select()` macro. In the last example, it has generated an un-necessary tap: `tap("Gridlines")` (Section 5.3).

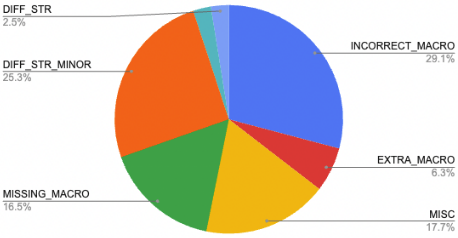

Figure 6: The types of parsing errors made by the PaLM 540B finetuned model on the 265 EN test samples in UGIF-DataSet (Section 5.3).

The cases where the grounding model overtriggers and chooses a partially matching UI element and fails to either scroll down or recognize that the how-to is outdated results in incorrectly executed steps on the UI. These are of the most serious concern since they lead to a poor user experience.

Model configuration	**UI Language**							
	en	kn	mr	gu	hi	bn	es	sw

`tap(“Compose”)` `tap(“Battery Share”)` `tap(“Send Feedback”)`

Figure 7: The UI grounding model chooses incorrect actions given the UI state and the macro. In the first example, the model should have tapped on “Start chat” as the matching element for “Compose” but instead tries scrolling down and throws an error that a matching UI element is not found. In the second example, the model should have scrolled down to find “Battery share” but instead erroneously selects the partially matching “Battery percentage”. In the last example, the model should have recognized that the “Send feedback” button is missing in the UI and thrown an error, but instead erroneously selects the partially matching “Send a message” button (Section 5).

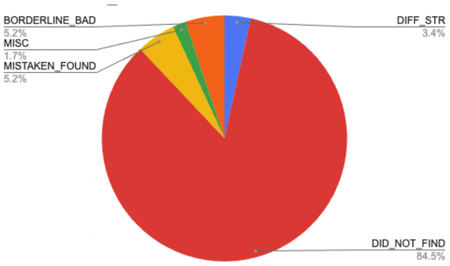

Figure 8: Categories of UI grounding errors using LaBSE on the 265 EN test samples in UGIF-DataSet (Section 5.3.1).

Model, Dataset	**Success rate**
Li et al. (2020a), PixelHelp (en)	70.5%
Ours, PixelHelp (en)	71.1%
Ours, UGIF-DataSet (en)	48.6%
Ours, UGIF-DataSet (sw)	32.1%

Table 7: Comparison of our best performing model (PaLM 540B for parsing and LaBSE for grounding) on different datasets. There is a wide gap between the model performance on the `PixelHelp (en)` dataset and `UGIF-DataSet (sw)` which suggests considerable headroom for improvement (Section 5).

Moreover, help articles frequently become out-of-date as evidenced by the fact that 29% of the samples in `UGIF-DataSet` are marked by annotators as having instruction text not matching the UI in Android 12.

We also evaluated our best performing model on the `PixelHelp` dataset (Li et al., 2020a). Table 7 shows that `UGIF-DataSet` is a harder dataset with significantly greater headroom for improvement especially in non-EN languages.

6 Conclusion

We proposed helping new smartphone users by showing them how to perform tasks on the UI based on voice queries. We evaluated existing language and sentence similarity models for the task of retrieving and executing how-to instructions on the UI where the UI language potentially differs from the language used in the instruction text. The models we build for this task must be capable of adapting to minor variations in the UI as the newer versions of the app are frequently released and instructions become outdated. Multilingual UIs pose the challenge of having to simultaneously work with multiple languages in a single UI screen since app developers may not have provided translations for all UI elements. Finally, our evaluation of current pre-trained models suggests that there is significant room for improvement and that a multimodal language-UI foundation model could lead to substantial gains.

7 Limitations

UGIF-DataSet contains UI tasks on only a few popular Android smartphone apps. It does not include tasks in other form factors such as tablets or watches. Although a model trained exclusively on this dataset may not be sufficient for UI tasks on other OSes and form factors, by describing the challenges we faced, we hope this work contributes towards building a well-lit path to collect similar datasets and build models for other OSes and form factors.

The user interface evolves much more frequently than natural language or images. As a result, the dataset and models trained on it may need adaptations, which we leave as a topic of future exploration. Since we have captured UI screens at a particular point in time, we were unable to quantify the reduction in task completion rate due to UI drift or investigate methods specifically aimed at addressing such UI changes. An important future direction is to capture such UI changes as apps evolve over time and investigate how well models generalize to these changes.

Our dataset contains only one speech sample per query in each language, so the diversity of speech samples is limited. Moreover, the speech samples were crowd-sourced by asking annotators to speak out loud the how-to query in the title of the FAQ page, so this may not match how users might ask queries with the same intent without being prompted with the FAQ page. All the instructions have been scraped from the Google support site, so our evaluation of parsing does not cover instruction text on forums and other support sites. Furthermore, all the UI captures in our dataset start at the home screen, but it would be desirable to also evaluate UI grounding from arbitrary starting points.

8 Ethical Considerations

Automated agents that operate over the UI could potentially be misused and pollute the global digital commons by making it harder for app developers to trust that the user is a real user. As a result, it is possible that many developers may choose to mitigate this by requiring some form of identification to use the app, which could hurt marginalized communities and users who struggle with such entry barriers. Further investigations and user studies on the benefits of automated UI agents will be helpful.

Acknowledgments

We would like to thank Alok Talekar, Yang Zhou, and Tai Vu for reviewing the code for UGIF, Robert Berry and Anton Vayvod for helping us understand the intricacies of the Android accessibility API and debug issues we faced with it, and Lukas Zilka for providing us with the scraped Android support pages. Many thanks to Emily Pitler, Shikhar Vashishth, and Fernando Pereira for reviewing drafts of this paper and offering their helpful suggestions. We are grateful to Jason Pensy for guiding us in setting up the annotation tasks. We also thank Dinesh Tewari for helping us with the dataset release.

Abstract

Large code datasets have become increasingly accessible for pre-training source code models. However, for the fine-tuning phase, obtaining representative training data that fully covers the code distribution for specific downstream tasks remains challenging due to the task-specific nature and limited labeling resources. These lead to out-of-distribution (OOD) generalization issues with unexpected model inference behaviors that have not been systematically studied yet. In this paper, we contribute the first systematic approach that simulates various OOD scenarios along different dimensions of source code data properties and study the fine-tuned model behaviors in such scenarios. We investigate the behaviors of models under different fine-tuning methodologies, including full fine-tuning and Low-Rank Adaptation (LoRA) fine-tuning methods. Our comprehensive analysis, conducted on four state-of-the-art pretrained models and applied to two code generation tasks, exposes multiple failure modes attributed to OOD generalization issues.

1 Introduction

There has been increasing success in applying Large Language Models (LLMs) to various source code understanding and generation tasks. LLMs for codes such as GraphCodeBERT (Guo et al., 2021), CodeT5+ (Wang et al., 2023), CodeGen (Nijkamp et al., 2023), and Code Llama (Rozière et al., 2023) are pretrained using large-scale code datasets, and serve as universal initialization for a variety of downstream tasks. These tasks include code summarization (Alon et al., 2019; LeClair et al., 2020), text-to-code (Iyer et al., 2018), and program repair (Tufano et al., 2018; Hajipour et al., 2021).

The emerging abilities of LLMs, such as in-context learning, demonstrate their potential to handle a wide range of tasks (Wei et al., 2022; Brown et al., 2020). However, it has been shown that not all tasks can be effectively addressed by relying only on the pretrained LLMs (Anil et al., 2022). To adapt pretrained models for specific tasks, they can be fine-tuned with specific datasets. This fine-tuning process can involve optimizing all parameters or adopting a parameter-efficient approach (Houlsby et al., 2019; Hu et al., 2022), such as Low-Rank Adaptation (LoRA)(Hu et al., 2022). Despite having access to the large code datasets to pre-train these models, it remains challenging in practice to fully cover the code distribution, specifically in fine-tuning datasets, where the availability of labeled data is limited. Furthermore, Kumar et al. (2022) show that, in the image classification tasks, fine-tuning the parameters of the pretrained models can distort the pretrained features.

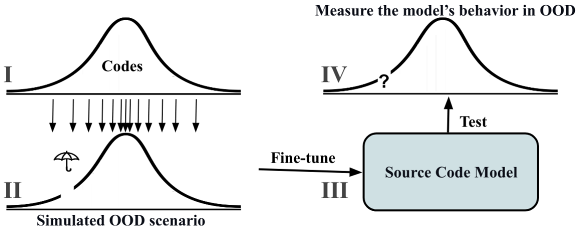

Figure 1: Our approach simulates out-of-distribution (OOD) scenarios and analyzes the corresponding behaviors of models. (I) Original source code distribution along a certain dimension. (II) OOD simulation by masking out a sub-region of the distribution. (III) Model fine-tuning. (IV) Evaluation on OOD data.

Therefore, it is unclear how the fine-tuned code generation models generalize to scenarios not seen or are rare in the fine-tuning distribution (Shen et al., 2021). For example, there is a lack of existing studies to uncover how these models generalize to programs with specific language elements or semantics not seen in fine-tuning datasets. A common way to study model behaviors in OOD scenarios is to collect testing datasets in the complementary domains of the fine-tuning dataset domain (Shen et al., 2021). However, because the underlying distribution of programs is intractable, it is

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1400–1416

barely feasible to justify whether two raw datasets share a domain or not. Not to mention the substantial costs of constituting a variety of OOD datasets.

Simulating various OOD scenarios by masking out sub-regions of training data distribution is an alternative way to systematically study the model behaviors (Schott et al., 2022; Wiles et al., 2022). There are several distribution dimensions based on data properties. In the source code domain, we can have access to the structural information to model the source code distribution based on the **length**, **syntax**, and **semantics** of programs. For example, in terms of the syntax dimension, we can mask out all the data with *uniray expressions* or specific API to create a syntax-based OOD scenario.

In this work, we propose a systematic approach to analyzing the behaviors of fine-tuned source code models in various OOD and few-data regime scenarios. We achieve this by harnessing the token size, syntax information, and contextual embeddings of programs to simulate the OOD scenarios in terms of length, syntax, and semantics dimensions, as illustrated in Figure 1. By utilizing these data dimensions and control over the data, we can systematically examine the performance of fine-tuned models in OOD scenarios and investigate their generalization capabilities.

To summarize, the main contributions of this paper are as follows: 1. Our work pioneers in investigating the behaviors of the fine-tuned source code models in OOD scenarios. 2. We propose a systematic approach to simulate various OOD scenarios by masking out sub-regions of source code distribution along the length, syntax, and semantics dimensions. The code and data are available at `https://github.com/hajipour/SimSCOOD`. 3. We find that the performance of the fine-tuned models can significantly deteriorate in various OOD scenarios despite the model encountering similar examples during the pre-training phase. In particular, in syntax and length-based OOD scenarios, the drop can be as substantial as 90%. 4. Our systematic analysis shows that, while full fine-tuning and LoRA fine-tuning perform comparably on in-distribution code data, LoRA fine-tuning demonstrates significantly better performance on OOD data. 5. Our analysis of data/model properties provides insights into model fine-tuning and shapes future datasets/research to focus on OOD of code models, which has the potential to enhance generalization accuracy across various code generation tasks.

2 Related Work

LLMs for Codes. With the availability of large-scale code datasets (Kocetkov et al., 2022), there is a growing interest in employing LLMs to develop a pre-training model for source code understanding and generation. CodeBERT extends the RoBERTa-based model (Liu et al., 2019) to understand and generate source codes. Guo et al. (2021) extend CodeBERT by using a semantic-aware objective function. CodeT5 and CodeT5+ (Wang et al., 2021, 2023) are developed based on encoder-decoder architecture, making them versatile models for addressing a wide range of code generation tasks. Svyatkovskiy et al. (2020) employ GPT-based (Radford et al., 2019), which uses decoder-only architecture, for the code completion task. CodeGen (Nijkamp et al., 2023), StarCoder (Li et al., 2023), and Code Llama (Rozière et al., 2023) employ decoder-only architecture to pre-train code generation models. While these models show remarkable results by following natural language instructions, it has been demonstrated that LLMs still have difficulty in understanding the codes (Austin et al., 2021; Li et al., 2022), specifically in domain-specific tasks (Anil et al., 2022). In our work, we focus on generation tasks to spot weak and strong points of the fine-tuned LLMs in generating rare and unseen programs.

Out-of-Distribution Analysis in Natural Languages and Programming Languages. Despite the importance of OOD analysis and detection in production (Shen et al., 2021), there are surprisingly much fewer efforts to investigate OOD behaviors of NLP and PL approaches (Arora et al., 2021). Hendrycks et al. (2020); Kong et al. (2020) study the behavior of pretrained LLMs in OOD scenarios. These works mainly focus on NLP-related classification tasks. Even though they show pre-trained models have higher robustness in OOD scenarios, the provided results indicate that there is still room for improvement. Bui and Yu (2021) propose an energy-bounded-based approach to detect OOD data in source code classification tasks. Their approach defines OOD scenarios by masking out data belonging to the specific class(es) (Bui and Yu, 2021) and does not cover the code generation tasks.

Fine-tuning LLMs. LLMs have demonstrated impressive capabilities in handling various tasks using zero-shot and few-shot learning approaches (Brown et al., 2020; Kojima et al., 2022). However, not all tasks can be effectively handled by relying on pretrained LLMs (Anil et al., 2022; Scialom et al., 2022). For such tasks, we can employ fine-tuning techniques with the datasets for the targeted downstream tasks. Furthermore, recent works indicate that fine-tuning LLMs with instructions can enhance their capabilities (Ouyang et al., 2022; Xu et al., 2024; Dai et al., 2023). Despite the effectiveness of the fine-tuning procedure, Kumar et al. (2022) shows that fine-tuning the models can distort the pretraining features and adversely impact the OOD generalization performance in image classification tasks. In this work, for the first time, we systematically investigate the behavior of the fine-tuned source code models by carefully designing various OOD scenarios.

3 SimSCOOD: Simulation of Source Code Out-of-Distribution Scenarios

In this work, we propose a systematic approach to investigate the fine-tuned code model behaviors on OOD data by simulating the OOD scenarios in multiple dimensions. Our simulation strategy allows us to construct measurable OOD scenarios without the additional costs of accessing another dataset. More importantly, by simulating the OOD scenarios, we have control over different properties of OOD scenarios. We achieve this by masking out specific sub-regions of data distribution.

These OOD scenarios span over three data dimensions, including **length**, **syntax**, and **semantics**. These dimensions cover different aspects of the programs. In length-based OOD scenarios, we can study the length-generalization ability of the fine-tuned models. For example, can the models produce longer codes with high quality, and how well can the models interpolate over distribution gaps? Syntax-based scenarios enable us to study the models by masking out specific language elements. More interestingly, using syntax-based scenarios, we can analyze to what extent each model can generate unseen language elements. Using semantic-based scenarios, we can investigate how the models behave if we mask out the data with specific functionalities. Benefiting from these scenarios, we can also implicitly quantify how well the models compose different code language elements to achieve unseen or rare functionality.

Modeling the Distribution of Source Code. Here, we experiment with different pretrained models and probe their behaviors in each scenario. We achieve this using our new approach that systematically constructs various scenarios to challenge the OOD performance of each model. As a result, the distribution of source code can be characterized using the aforementioned dimensions that we call properties in the following. We model the joint distribution of the source code as $q(p_1, ..., p_n)$ where each p_i is a specific property of the source code in distribution q. Given this distribution we can sample a dataset $\mathcal{D} = \{x_1, \ldots, x_N | x_i \sim q(p_1, ..., p_n)\}$. To create each OOD scenario we need to sample a new dataset $\hat{\mathcal{D}} = \{x_1, \ldots, x_N | x_i \sim \hat{q}(p_1, ..., p_n)\}$ where $\hat{q}(p_f, ..., p_k) = 0$, meaning the samples with properties $p_f, ..., p_k$ are masked out. Note that we just formulated OOD scenarios with categorical properties, whereas it also holds for continuous properties by $p(a < p_i < b)$ with $a < b$ and $a, b \in \mathbf{R}$.

To sample dataset $\hat{\mathcal{D}}$, we get inspiration from the rejection sampling technique (Casella et al., 2004). Here, $\hat{q}(p_1, ..., p_n)$ is our target distribution and we consider $q(p_1, ..., p_n)$ as our proposal distribution. We reject or accept the sample data $x \sim q(p_1, ..., p_n)$ using the following step function,

$$f(x) = \begin{cases} 1 & \text{if } \mathbf{P}(x) \notin \tilde{\mathcal{P}} \\ 0 & \text{if } \mathbf{P}(x) \in \tilde{\mathcal{P}} \end{cases} \quad (1)$$

Where $\mathbf{P}(x)$ returns the properties of data x, and $\tilde{\mathcal{P}}$ are the properties that we do not want the sampled data x to contain. Using the rejection sampling technique with a hard-decision function (Equation 1) we can construct dataset $\hat{\mathcal{D}} = \{x_1, \ldots, x_N | x \sim \hat{q}(p_1, ..., p_n)\}$ with accepted samples, and also have access to dataset $\tilde{\mathcal{D}} = \{x_1, \ldots, x_N | x \sim \tilde{q}(p_1, ..., p_n)\}$ which are all of the rejected samples. To examine model behaviors in each OOD scenario, we fine-tune models using $\hat{\mathcal{D}}$ data and test them on the test set of $\tilde{\mathcal{D}}$. Figure 2 depicts an overview of the different scenarios. In the following, we provide the details of how we simulate each OOD scenario (subsection 4.1).

3.1 Length-based OOD Scenarios

To simulate length-based scenarios, we use the histogram of program token sizes to represent the distribution of a given dataset. See Figure 2 left as an example. To create each OOD scenario, according to the rejection sampling technique, we draw samples from the distribution and reject only the

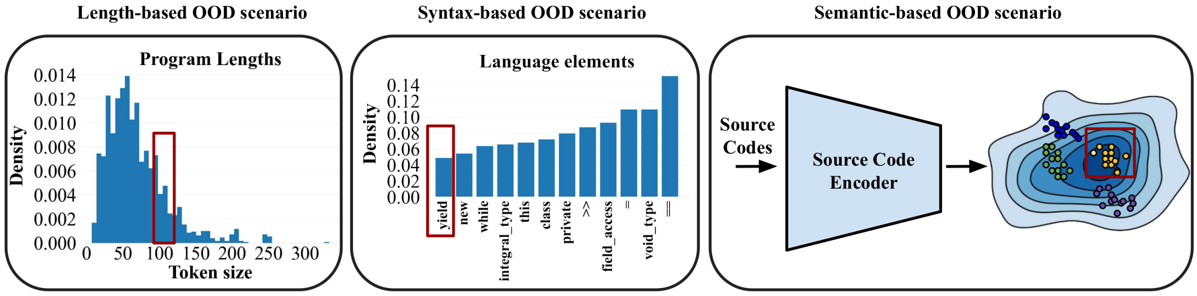

Figure 2: Overview of different out-of-distribution scenarios. Part of the data that needs to be masked out from the training distribution is highlighted by the red rectangles.

samples in the histogram's specified sub-region.

As an example, in one of the OOD scenarios, we can consider token sizes between 120 and 135 as OOD testing data. Then $\hat{\mathcal{D}} = \{x \sim \hat{q}(p_1, ..., p_n)\}$ where $\hat{q}(120 < p_i < 135) = 0$ is the accepted data in the rejection sampling technique. Experimenting with the length-based OOD scenarios enables us to analyze how fine-tuned source code models generalize to interpolate and extrapolate over distribution gaps.

3.2 Syntax-based OOD Scenarios

Each programming language has its own grammar, which is a set of rules to define valid program statements. Using the grammar, we can parse each program into an abstract syntax tree (Guo et al., 2021) and have access to all of the elements used in the program. For example, we can identify all the programs with *conditional* or specific APIs in the given dataset. In this work, we leverage the grammatical information of the programming language to create syntax-based OOD scenarios. We use the histogram of language elements to model the syntax distribution of a given source code dataset. Figure 2 middle shows an example of how we construct a syntax-based OOD scenario by masking out specific language elements. To create an OOD scenario, using the rejection sampling technique, we sample testing data $\tilde{\mathcal{D}}$ that contain certain language elements (e.g., *yield*), namely, $\tilde{\mathcal{P}} = \{yield\}$. We then fine-tune our model using $\hat{\mathcal{D}}$ which is the set of data that does not contain *yield*, and test the model using $\tilde{\mathcal{D}}$. In order to set up systematic syntax-based OOD scenarios, we can replace *yield* in $\tilde{\mathcal{P}}$ with other language elements and APIs. Using syntax-based scenarios, in addition to analyzing model behaviors in such OOD scenarios, we can also explore if various fine-tuned LLMs can generate unseen language elements. For example, we can investigate if the pretrained models can generate specific elements not seen during fine-tuning.

3.3 Semantic-based OOD Scenarios

The programs' semantics is another dimension to model the distribution of source code data. However, it is not clear how we can model the semantics of the programs, especially in the cases where we do not have input-output examples or any metadata. It has been shown that a pretrained model can be used to cluster the data based on their semantics (Aharoni and Goldberg, 2020). Furthermore, recent studies conducted by Troshin and Chirkova (2022) and Ahmed et al. (2023) have demonstrated that pretrained code models represent program semantics within the continuous space. They accomplished this by probing the pretrained models and conducting experiments involving the manipulation of code fragments. Following the success of unsupervised domain clustering and the model's abilities to understand the semantics of programs, we propose to utilize the pretrained source code model to cluster programs within the continuous space. We employ the state-of-the-art CodeT5+ encoder (Wang et al., 2023) in our study to map a dataset of programs to a set of continuous representation vectors. We then cluster the vectors to group programs with similar semantics. As a result, we can create semantic-based OOD scenarios via the rejection sampling procedure to reject all samples that belong to a specific cluster and accept the rest as $\hat{\mathcal{D}}$. Like other scenarios, we can use $\hat{\mathcal{D}}$ as fine-tuning data and $\tilde{\mathcal{D}}$ as test data. Our semantic-based OOD scenarios provide an approximated proxy of real-world OOD scenarios to investigate the OOD generalization capabilities of the fine-tuned models. Furthermore, these OOD scenarios allow us to analyze the model's abilities to deal with unseen or rare program functionalities. We provide implementation details in subsection 4.2.

4 Experiments

In this section, we first articulate the experiment setups, including the pretrained models, downstream tasks, and the OOD data construction. Then, we demonstrate the model performance in OOD scenarios. We also analyze how well the model can perform by revealing 50% of the masked data ($\approx 1.5\%$ of the entire data). In the following, we call the 50% masked-out cases few-data regime.

4.1 Setups

Pretrained Models. We analyze the behavior of four widely-used pretrained models for source codes. These models are designed using a variety of architectures, pre-training objective functions, numbers of parameters, and pre-training datasets. GraphCodeBERT (Guo et al., 2021) is an encoder-only pretrained model with 125M parameters. CodeT5 (Wang et al., 2021) employs T5 (Raffel et al., 2020) encoder-decoder architecture. In our implementations, we use CodeT5-base with 220M parameters. Here, we also investigate the behavior of larger models, including CodeT5+ (Wang et al., 2023) with 770M parameters and Code Llama with 13B parameters. CodeT5+ (Wang et al., 2023) is an extension of CodeT5 (Wang et al., 2021), and Code Llama (Rozière et al., 2023) is a model built on top of Llama 2 (Touvron et al., 2023) for code-specialized tasks. We provide more details in Appendix A.

Downstream Tasks. We study the behavior of the models on two different downstream tasks, including text-to-code generation and code refinement. These tasks are part of the most challenging tasks in the CodeXGLUE benchmark (Lu et al., 2021). **Text-to-code** is the task of generating a program given a natural language description. In CodeXGLUE benchmark (Lu et al., 2021), CONCODE dataset (Iyer et al., 2018) is proposed for this task. **Code refinement** is the task of resolving the bugs in a given program by automatically generating a corrected program Tufano et al. (2019).

Evaluation Metrics. Exact match (Wang et al., 2021), CodeBLEU (Ren et al., 2020), and BLEU score (Papineni et al., 2002) have been commonly used to evaluate the model performance in the downstream tasks. The exact match metric evaluates if the generated code matches the target code at the token-level. BLEU score measures the n-gram overlap between the output and the target code. CodeBLEU considers syntactic and dataflow matches of the codes in addition to the n-gram overlap. In this work, we focus on the exact match metric to quantify the model behaviors. This is due to the nature of OOD scenarios, where it is desirable to see if the model can generate specific unseen programs correctly. It is important to note that Wang et al. (2021) have demonstrated that for the code refinement task, achieving a high BLEU score can be accomplished with a simple duplication of the input codes, comparable to state-of-the-art models. Furthermore, it has been shown that CodeBLEU and BLEU scores are not necessarily correlated with the correctness of the programs (Evtikhiev et al., 2023; Hendrycks et al., 2021). We report BLEU score results in Appendix G.

4.2 Data Construction and Fine-tuning

In the data construction process, for each scenario, we choose $\tilde{\mathcal{P}}$ in a way that counts for $\approx 3\%$ of the entire fine-tuning data. In OOD scenarios, we mask out all of the data items with properties $\tilde{\mathcal{P}}$. For the few-data regime cases, we mask-out half (50%) of data with properties $\tilde{\mathcal{P}}$ ($\approx 1.5\%$ of the entire fine-tuning data). In all the scenarios, we infer the fine-tuned models on test data with $\tilde{\mathcal{P}}$ properties. Note that, in the text-to-code task, we mask out the data based on the target data (code data rather than text data) properties. For the code refinement tasks, we masked the data based on the input.

Length-based Scenarios. To generate data for length-based scenarios, we characterize the dataset of programs based on the token size. For each scenario, $\tilde{\mathcal{P}}$ specifies a continuous range of program token sizes. We consider five ranges in our experiments: $\tilde{\mathcal{P}}_1 = \{[0\%, 3\%]\}$, $\tilde{\mathcal{P}}_2 = \{[24\%, 27\%]\}$, $\tilde{\mathcal{P}}_3 = \{[48\%, 51\%]\}$, $\tilde{\mathcal{P}}_4 = \{[72\%, 75\%]\}$, and $\tilde{\mathcal{P}}_5 = \{[97\%, 100\%]\}$. Note that $\tilde{\mathcal{P}}_1 = \{[0\%, 3\%]\}$ represents the top 3% smallest programs, in terms of token size. We consider $\tilde{\mathcal{P}}_1$ and $\tilde{\mathcal{P}}_5$ as length-based extrapolation scenarios and $\tilde{\mathcal{P}}_2$, $\tilde{\mathcal{P}}_3$, and $\tilde{\mathcal{P}}_4$ as length-based interpolation scenarios.

Syntax-based Scenarios. In syntax-based scenarios, we characterize program datasets based on the distribution of language elements. For each task, we select five different elements that cover $\approx 3\%$ of the data. For example, in text-to-code task we consider $\tilde{\mathcal{P}}_1 = \{\textit{true}\}$. We provide details of the selected language elements in Appendix E.

Semantic-based Scenarios. In this work, we employ CodeT5+ (770M parameters) (Wang et al., 2023) encoder to characterize the semantics distribution of programs. We feed the tokenized programs to the CodeT5+ encoder and obtain the corresponding feature vectors $\mathbf{V}$ of size $1024 \times t$, where t is the size of the input program. We obtain the continuous representation of the programs by averaging the tokens' embedding following Koto et al. (2021). We then cluster the programs in continuous space using the K-means algorithm. We set the number of clusters $K = 35$ using the elbow method (Bholowalia and Kumar, 2014). To accelerate the clustering procedure, we perform dimensionality reduction PCA with a target dimension of 50. We determine the dimension in a way that all the components explain at least 80% of the data variance. We provide the average results of five randomly selected clusters. Each cluster can represent a set of $\tilde{\mathcal{P}}_i$ properties. The examples of clusters representing different semantics are provided in Appendix F.

Model Fine-tuning Details. We fine-tune four pretrained models for two different tasks in various scenarios. We stick to their defaults for fair comparisons. For fine-tuning the models with the LoRA method, we follow Hu et al. (2022). We provide more details in Appendix C. All our experiments are conducted using a machine with four NVIDIA 40GB Ampere A100 GPUs.

4.3 How Do Fine-tuned Models Generalize in OOD Scenarios?

Table 1 and Table 2 shows the overall results of different models in length-, syntax-, and semantic-based scenarios, respectively. These tables show the model performance in the OOD scenarios where the models do not have access to the fine-tuning data with $\tilde{\mathcal{P}}$ properties. Furthermore, Table 1 and Table 2 show how well the models perform when they have access to 50% of the masked data. Note that in Table 1 and Table 2, all of the results are the average of different scenarios and show the relative exact match to the 100% baseline (models with access to the full data distribution). In Table 1 and Table 2, we provide the results of fine-tuning the models using full fine-tuning and LoRA fine-tuning methods. Note that for Code Llama 13B, due to the substantial resource requirements involved in full fine-tuning, we only report the LoRA fine-tuning results. Additionally, in line with GraphCodeBERT (Guo et al., 2021), we only investigate this model on the code refinement task. In these tables, for the length-based scenarios, we have five different scenarios, three for the interpolation cases and two for the extrapolation cases, so we report the average results for each case. In syntax-based and semantic-based scenarios, we report the average results of five different scenarios.

We conclude according to Table 1 and Table 2 that: 1. Interpolation cases in the length-based OOD scenarios are the easiest OOD scenarios for the models in different tasks. 2. Syntax-based and length-based extrapolation OOD scenarios are the most challenging scenarios for the models. 3. Using LoRA fine-tuning, we can achieve significantly better generalization accuracy than full fine-tuning. 4. Few-data regime scenarios show that adding a few relevant data to the fine-tuning distribution can gain huge performance improvement. In the following, we describe our key findings in more detail.

Model performance decreases in various OOD scenarios. Table 1 and Table 2 show that all of the models have difficulty in dealing with different OOD scenarios. These include models with different architecture and parameter sizes. For example, in Table 1, we observe that for the Code Llama model with 13B parameters, the performance significantly dropped in the length-based extrapolation scenario. It achieves only 23.57% of the baseline performance.

Table 1 and Table 2 indicate that length-based interpolation scenarios are the least challenging OOD scenarios for various models in both text-to-code and code refinement tasks. While length-based interpolation is the easiest OOD scenario, it is worth noting that CodeT5+ with full fine-tuning only attains 49.67% of the baseline performance (See Table 1). Additionally, Table 1 and Table 2 reveal that the models exhibit the most significant performance reduction in the length-based extrapolation and syntax-based OOD scenarios. This performance drop occurred despite the models being exposed to similar examples during the pre-training phase.

A comparison between the outcomes of the semantic scenarios presented in Table 1 and Table 2 highlights that the text-to-code task is more challenging than the code refinement task. This is mainly due to the multi-modality nature of the task, wherein the models need to learn to map natural languages to unseen or rare programs.

Table 1: Overall results of the model performance for different scenarios in **text-to-code** task. The results provide the relative exact match to the 100% baseline for different scenarios. Length Inter and Length Extra refer to length-based interpolation and extrapolation scenarios, respectively. FT denotes full fine-tuning, and LoRA refers to the LoRA fine-tuning method. OOD and Few refer to OOD and few-data regime scenarios, respectively.

Models		Length Inter		Length Extra		Syntax		Semantic	
		FT	LoRA	FT	LoRA	FT	LoRA	FT	LoRA
CodeT5	OOD	53.92%	66.91%	0.00%	24.99%	16.46%	34.81%	31.90%	51.42%
	Few	86.56%	103.79%	28.56%	55.0%	93.90%	100.0%	37.56%	72.43%
CodeT5+	OOD	49.65%	70.94%	5.0%	26.09%	47.95%	68.97%	39.69%	55.71%
	Few	76.40%	96.36%	77.38%	101.72%	67.21%	78.54%	66.04%	83.68%
Code Llama	OOD	-	71.75%	-	23.57%	-	64.81%	-	56.72%
	Few	-	94.08%	-	63.21%	-	86.08%	-	84.74%

Table 2: Overall results of the model performance for different scenarios in **code refinement** task. The results provide the relative exact match to the 100% baseline for different scenarios. Length Inter and Length Extra refer to length-based interpolation and extrapolation scenarios, respectively. FT denotes full fine-tuning, and LoRA refers to the LoRA fine-tuning method. OOD and Few refer to OOD and few-data regime scenarios, respectively. GCBERT denotes to the GraphCodeBERT model (Guo et al., 2021).

Models		Length Inter		Length Extra		Syntax		Semantic	
		FT	LoRA	FT	LoRA	FT	LoRA	FT	LoRA
GCBERT	OOD	82.91%	87.89%	37.82%	74.35%	1.30%	2.35%	60.38%	69.05%
	Few	86.52%	94.45%	90.15%	90.46%	75.42%	77.92%	76.45%	84.43%
CodeT5	OOD	84.10%	86.70%	48.95%	61.53%	10.23%	28.78%	77.41%	79.36%
	Few	85.48%	89.97%	57.30%	80.29%	83.08%	85.82%	83.63%	88.73%
CodeT5+	OOD	80.70%	83.39%	73.44%	82.39%	21.41%	37.14%	73.65%	78.67%
	Few	93.28%	94.65%	79.56%	90.77%	72.83%	81.01%	85.30%	93.29%
Code Llama	OOD	-	81.70%	-	57.69%	-	43.70%	-	70.14%
	Few	-	87.68%	-	85.71%	-	87.66%	-	89.23%

Table 3: Exact match results of the fine-tuned models using the full fine-tuning dataset for text-to-code and code refinement tasks. FT denotes full fine-tuning, and LoRA refers to the LoRA fine-tuning method. GCBERT refers to (Guo et al., 2021).

Models	Text-to-Code		Refinement	
	FT	LoRA	FT	LoRA
GCBERT	-	-	10.74	11.38
CodeT5	22.15	21.65	14.43	14.53
CodeT5+	24.95	24.70	15.18	15.29
Code Llama	-	27.65	-	19.19

Takeaway: Performance of fine-tuned models, regardless of architectures and sizes, can significantly deteriorate in OOD cases, even when the models have seen similar data during pre-training.

LoRA fine-tuning exhibits better OOD generalization compared to full fine-tuning. In Table 1 and Table 2, we provide the results of fine-tuning the models using two different fine-tuning approaches: full fine-tuning and LoRA fine-tuning. The results presented in these tables indicate that LoRA fine-tuning consistently exhibits superior OOD generalization across various scenarios. For example, Table 1 shows that in the length-based extrapolation scenario, fine-tuning CodeT5 with LoRA resulted in a 24.99% relative exact match, whereas the model's relative performance using full fine-tuning was 0.0%. Furthermore, as demonstrated in Table 2, in the syntax-based OOD scenario, the utilization of LoRA for fine-tuning CodeT5 and CodeT5+ results in significantly superior performance compared to employing full fine-tuning for these models. This observation shows that LoRA, which involves freezing the pretrained weights, effectively leverages the previously acquired knowledge, resulting in improved OOD generalization compared to full fine-tuning.

Table 3 provides in-distribution performance results of the models fine-tuned using both full fine-tuning and LoRA fine-tuning methods. This table displays the exact match accuracy of the models on the complete test set under the condition that the models have access to the entire fine-tuning distribution. Table 3 demonstrates that employing LoRA fine-tuning enables us to achieve performance that is comparable to full fine-tuning. It is important to highlight that in all of the experiments involving LoRA fine-tuning, the pretrained weights are frozen, and we only need to optimize newly injected weights. These LoRA parameters account for less than 1% of the pretrained weights. Note that we provide BLEU score results in Appendix D.

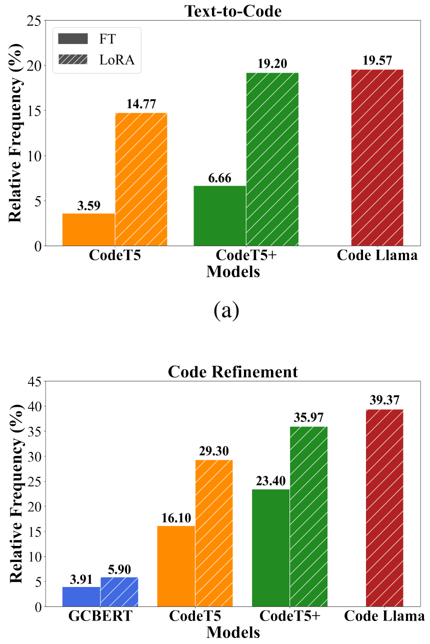
Takeaway: While full and LoRA fine-tuning methods show comparable results over in-distribution data, LoRA fine-tuning outperforms full fine-tuning in OOD scenarios. This suggests that with freezing pretrained weights, LoRA fine-tuned models can effectively utilize their pretraining knowledge in dealing with OOD scenarios.

Models can gain significant improvement by using a few data. Table 1 and Table 2 provide the results for few-data regime scenarios. In these scenarios, we only mask out 50% of the data with $\tilde{\mathcal{P}}$ properties ($\approx$ 1.5% of the fine-tuning data). The Table 1 and Table 2 demonstrate in each scenario that by adding data in size $\approx$ 1.5% of the fine-tuning data, the model can gain significant accuracy performance. For example, Table 1 shows that in syntax-based scenarios, applying LoRA fine-tuning to CodeT5 can lead to a gain of 100% of relative performance by adding a small amount of data. We provide results of revealing 25% and 75% of data in subsection G.2.

Takeaway: By incorporating a small amount of relevant data (representing $\approx$ 1.5% of the fine-tuning data) into the fine-tuning set, models can achieve substantial performance enhancements.

4.4 Can Fine-tuned LLMs Generate Unseen Language Elements?

In the syntax-based OOD scenarios, we can assess the fine-tuned LLMs' ability to leverage their prior knowledge in generating unseen language elements. For instance, can the fine-tuned models generate the *yield* element if they have not been exposed to any code data containing *yield* during fine-tuning? In Figure 3, we present the relative frequencies of generating unseen elements by models fine-tuned using both full and LoRA fine-tuning methods. The results in Figure 3 show the frequencies of generating unseen elements relative to the frequencies in ground truth programs. We report the average results of five different unseen elements during fine-tuning. The list of these elements was reported Appendix E. In Figure 3, the solid bars represent the results for models fine-tuned using full fine-tuning, while the hatched bars depict the results for models fine-tuned using the LoRA method.



(a)

(b)

Figure 3: The ratios of frequency of generated unseen language elements over the frequency in ground truth data. Solid and hatched bars show the results of the model fine-tuned with the full fine-tuning and LoRA fine-tuning, respectively.

Figure 3 shows that the fine-tuned LLMs are able to generate unseen language elements in different tasks. Interestingly, the models fine-tuned using the LoRA fine-tuning exhibit the ability to generate a higher percentage of unseen elements when compared to fully fine-tuned models. This indicates that the models fine-tuned with the LoRA method possess a superior capability to leverage their previously acquired knowledge. We can see this as an advantage. However, in specific scenarios, this advantage can translate into model failures and pose security issues. For example, the model could generate a deprecated API or element, or there can even be cases when the pre-training dataset is poisoned in the first place (Schuster et al., 2021). Furthermore, we observe that generating unseen elements is more challenging in the text-to-code task (Figure 3a) compared to the code refinement task (Figure 3b). The main reason is that in the text-to-code task, the models need to learn the mapping from natural language to the programs.

Takeaway: Models fine-tuned with LoRA generate more unseen elements than those fine-tuned using the full fine-tuning approach, which is advantageous. Nonetheless, in certain scenarios, this capability may result in security issues by generating deprecated elements and APIs.

5 Future Work

The central message of our work is that OOD issues for the code data need to be explicitly taken care of. Our study reveals that using LoRA fine-tuning the models have higher OOD generalization than fully fine-tuned models. In future research, methods from various domains, such as catastrophic forgetting (Goodfellow et al., 2014; Chen et al., 2020), OOD generalization (Shen et al., 2021), OOD detection (Arora et al., 2021; Hendrycks et al., 2022), and continual learning (Parisi et al., 2019), could play a role in mitigating or monitoring these OOD issues. For example, employing the recall and relearn method suggested by Chen et al. (2020), adapting meta-learning approaches (Shen et al., 2021), or applying regularization techniques like dropout (Goodfellow et al., 2014) could be intriguing approaches to mitigate OOD issues of the fine-tuned source code model. Furthermore, OOD detection techniques proposed by Arora et al. (2021); Kong et al. (2020) can be adapted to detect the OOD source code data.

6 Conclusion

In this work, we propose a systematic approach to investigate the behaviors of fine-tuned LLMs in OOD scenarios for the program domain. Given the data, we simulate OOD scenarios based on the program's length, syntax, and semantics. Using these scenarios, we shed light on the models' fragility in the OOD scenarios, potential performance drop, and the necessity to improve dataset construction. We also reveal the model's impotence in handling considered OOD dimensions and to what extent we can improve the generalization of the models by exposing the relevant data. Furthermore, our results reveal that, although models fine-tuned with full fine-tuning and LoRA exhibit similar in-distribution accuracy, LoRA shows higher OOD generalization accuracy.

Limitations

One of the limitations of our approach is the computational cost. To investigate the model behavior in each dimension, we need to fine-tune individual models. This makes our investigation computationally expensive. Furthermore, in this work, we focus on the code generation tasks as they provide more fine-grained results to investigate the model behavior. However, in the code generation tasks, the models might be highly sensitive to the subtle changes in the data distribution. Hence, it would also be valuable to investigate how the models perform in OOD scenarios for code understanding tasks such as clone detection, defect detection, and code summarization.

In our work, we leverage the contextual embedding of source code to model the semantics of the source codes. We use K-means clustering to group programs based on their semantics. Even though we check if these clusters represent specific meaning (we provide examples of cluster semantics in Appendix F), we do not measure how well these programs are clustered in terms of their semantics. The performance of the clustering algorithm can be measured using datasets with meta-data about the semantics of each data item, which we do not have access to in this study.

Potential Risks. Our research on how models behave in OOD and few-data regime scenarios sheds light on the fine-tuning of models and the development of future datasets. Nonetheless, it is crucial to recognize that malicious actors could exploit these findings to create datasets that intentionally introduce OOD-related issues, with the implicit or explicit goal of targeting specific communities and companies. We recommend that end-users take our findings into consideration when using the source code datasets to train their models.

A Pretrained Models

Here, we provide more detail about the pretrained models we used in our experiments.

A.1 BERT-based Models

CodeBERT (Feng et al., 2020) is an encoder-only transformer-based model that is pretrained using CodeSerchNet dataset (Husain et al., 2019). This dataset consists of 2.1M pairs of individual functions and code documentation with 6.4M code-only data items across multiple programming languages. This model uses a 12-layer RoBERTa-based (Liu et al., 2019) architecture with 125M parameters. It is trained using masked language modeling (MLM) and the replaced token detection objective.

Guo et al. (2021) proposed GraphCodeBERT by extending CodeBERT (Feng et al., 2020) using a semantic-aware pre-training objective function. They incorporate data-flow information in the pre-training stage to encode the semantic information of the program.

A.2 CodeT5

CodeT5 (Wang et al., 2021) employ T5 (Raffel et al., 2020) encoder-decoder architecture. The authors use CodeSearchNet (Husain et al., 2019) with 1.2M pairs of functions' code with corresponding documentation and 0.8M code-only data items. In our experiments, we use CodeT5-base with 220M. This model uses MLM objective and identifier-aware objective functions in the pre-training procedure.

CodeT5+ (Wang et al., 2023) is a family of encoder-decoder LLMs (Wang et al., 2021) that is developed with the flexibility to cover a wide range of downstream tasks. CodeT5+ achieved this flexibility by employing a mixture of pretraining objectives, including span denoising, contrastive learning, text-code matching, and causal LM pretraining tasks(Wang et al., 2023). In our experiments, we employ CodeT5+ with 770M parameters.

A.3 Code Llama

Code Llama (Rozière et al., 2023) is a family of LLM for code developed based on Llama 2 models (Touvron et al., 2023). The models are designed using decoder-only architectures with 7B, 13B, 34B, and 70B parameters. Code Llama encompasses different versions tailored for a wide array of tasks and applications, including the foundational model, specialized models for Python code, and instruction-tuned models. Code Llama outperforms open models on HumanEval (Chen et al., 2021) and MBPP benchmarks (Austin et al., 2021) up to 53% and 55%, respectively. In our experiments, we use the foundation model version of Code Llama with 13B parameters.

B Further Details of Datasets and Computational Resources

To study the behavior of the code generation models in OOD scenarios, we use two datasets of the CodeXGLUE benchmark (Lu et al., 2021) specifically designed for text-to-code and code refinement tasks. The CodeXGLUE benchmark is licensed under Creative Commons Zero v1.0 Universal. The text-to-code task dataset includes 100k training samples, 2k validation samples, and 2k test samples of Java codes. Meanwhile, the code refinement dataset comprises 52,364 training samples, along with 6,545 validation samples and 6,545 test samples of Java codes.

C Hyperparameters for LoRA Fine-tuning

In Table 4, we present the LoRA hyperparameters that were applied in the fine-tuning of various models. We fine-tune these models utilizing AdamW with a linear learning rate decay schedule. During the validation and testing phases, we employed beam search with a beam size of 10, following Wang et al. (2021, 2023); Guo et al. (2021).

For fine-tuning GCBERT, CodeT5, and CodeT5+ in the text-to-code task, we set the maximum input and output sequence length to 320 and 150 tokens, respectively. In the case of fine-tuning Code Llama, we set the maximum sequence length to 470 tokens. In the code refinement task, to fine-tune GCBERT, CodeT5, and CodeT5+, we set the maximum input and output sequence length to 240 and 240 tokens. We fine-tune Code Llama for code refinement tasks by setting the maximum sequence length to 480.

D Comparison of Full Fine-tuning and LoRA fine-tuning Method

In Table 5, you can find the in-distribution performance results of fine-tuned models using the full and LoRA fine-tuning methods. This table corresponds to a version of Table 3, which additionally includes BLEU score results.

Table 4: The LoRA hyperparameters we used to fine-tune the models for text-to-code and code refinement tasks.

Models	Batch Size	#Epoch	Learning Rate	Rank (r_q, r_v)	LoRA α
GCBERT	32	20	$5e^{-4}$	16, 16	32
CodeT5	32	20	$5e^{-4}$	16, 16	32
CodeT5+	16	15	$5e^{-4}$	16, 16	32
Code Llama	4	5	$5e^{-4}$	16, 16	32

Table 5: Exact match (EM) and BLEU (B) results of the fine-tuned models using the fine-tuning dataset for text-to-code and code refinement tasks. FT denotes full fine-tuning, and LoRA refers to the LoRA fine-tuning method. GCBERT refers to (Guo et al., 2021).

Models	Text-to-Code				Refinement			
	FT		LoRA		FT		LoRA	
	EM	B	EM	B	EM	B	EM	B
GCBERT	-	-	-	-	10.74	90.93	11.38	86.45
CodeT5	22.15	39.60	21.65	38.90	14.43	89.33	14.53	89.40
CodeT5+	24.95	44.06	24.70	43.78	15.18	88.19	15.29	89.65
Code Llama	-	-	27.65	45.19	-	-	19.19	90.34

E List of Language Elements

In syntax-based scenarios, we consider one element in each scenario and mask-out the source codes with that particular element. Here, we provide the details of five language elements used in our experiments. Note that we pick the element that covers $\approx 3\%$ of the fine-tuning data. We conduct our syntax-based experiments based on the following language elements of each task,

1. **Text-to-Code**: {*else*, *floating_point_type*, *unary_expression*, *array_access*, *true*}
2. **Code Refinement**: {*while_statement*, *long*, *array_creation_expression*, *break*, $\geqslant$}

F Do the clusters represent programs with specific semantics?

Table 6 provides the semantics of five random clusters (out of 35) in text-to-code tasks. We randomly check 20 source codes in each cluster to check their semantics.

Table 6: Semantics of five clusters in text-to-code task.

Cluster-ID	Semantic
0	Property setter functions
1	Property string getter functions
6	Initialize object
11	Using getter function
17	String concatenation

G More experimental results

G.1 BLEU score Results

In Table 7 Table 8, we provide BLEU score results of different scenarios for the text-to-code and code refinement tasks, respectively. As we mention in subsection 4.1, BLEU scores are not necessarily correlated with the correctness of the programs (Hendrycks et al., 2021) and human judgment (Evtikhiev et al., 2023). Furthermore, Wang et al. (2021) show that in the code refinement task, the BLEU score of a naive copy of the input code can be as good as the state-of-the-art methods. Table 7 shows the performance (BLEU score) dropped for different models in all of the OOD scenarios compared to the 100% baseline. For example, in the length-based extrapolation scenario for the CodeLlama model, the BLEU score dropped over 16 points when compared to the 100% baseline performance. Furthermore, as shown in Table 7, it is evident that across all OOD scenarios, fine-tuning the models using the LoRA approach consistently results in higher BLEU scores. As depicted in Table 8, it is apparent that there are fewer performance drops in comparison to the

Table 7: Overall results of the model performance for different scenarios in **text-to-code** task. The results provide the BLEU score for different scenarios. Length Inter and Length Extra refer to length-based interpolation and extrapolation scenarios, respectively. FT denotes full fine-tuning, and LoRA refers to the LoRA fine-tuning method. OOD and Few refer to OOD and few-data regime scenarios, respectively. Full refers to 100% baseline (when a model has access to 100% of the fine-tuning set).

Models		Length Inter		Length Extra		Syntax		Semantic	
		FT	LoRA	FT	LoRA	FT	LoRA	FT	LoRA
CodeT5	OOD	40.19	42.03	15.09	15.23	24.08	24.18	44.58	46.21
	Few	48.91	46.47	20.18	18.46	25.20	24.95	45.43	47.97
	Full	47.79	48.34	24.08	23.34	27.01	25.83	48.48	49.65
CodeT5+	OOD	40.58	44.07	15.98	17.48	24.39	26.41	40.52	43.11
	Few	50.07	50.10	19.33	21.67	27.25	27.25	48.93	50.77
	Full	51.80	51.23	23.29	22.63	28.98	28.04	50.89	51.03
Code Llama	OOD	-	54.34	-	21.24	-	25.37	-	47.74
	Few	-	60.35	-	36.73	-	28.06	-	50.76
	Full	-	62.11	-	37.44	-	29.50	-	51.38

text-to-code results outlined in Table 7. This distinction can be primarily attributed to the code refinement task's inherent characteristics, wherein naively copying the input tokens to the outputs can yield state-of-the-art BLEU scores.

G.2 Effect of revealing different percentages of the masked data

In Table 9 and Table 10, we show the effect of revealing different percentages of the masked data on the model's performance. Specifically, we showcase CodeT5+ performance in different scenarios by revealing 25%, 50%, and 75% of the masked data (The data was masked for the OOD scenarios). Table 9 presents results for the text-to-code task, while Table 10 displays results for the code refinement task.

Table 9 and Table 10 demonstrate that the model can gain a high performance even by revealing 25% (0.75% of training data). For instance, in Table 9, within length extrapolation scenarios, the full fine-tuned model notably showed relative performance increases from 5.0% (OOD) to 64.63% (Few-25%). Furthermore, both tables indicate that revealing 50% and 75% of the masked data can enhance the model's performance across different scenarios. Nevertheless, the observed performance gains for Few-75% are less apparent compared to the Few-50% and Few-25% cases.

G.3 Qualitative examples

In Figure 4, Figure 5, and Figure 6, we present qualitative results showcasing instances where the Code Llama model was not able to generate the targeted codes in the OOD scenarios. These examples highlight the challenge that even large fine-tuned LLMs face when handling OOD data. Figure 4 shows an example of the syntax-based OOD scenarios in which the model was unable to generate and use the *else* element. In Figure 5 demonstrates another example from the text-to-code task. Here, we provide an example of the length-based extrapolation OOD scenarios. In these scenarios, our goal is to investigate whether the model is able to extrapolate from shorter programs to longer ones. Figure 5 shows that Code Llama was unable to generate the target program correctly. Note that Figure 5 shows an example of $\tilde{\mathcal{P}}_5 = \{[97\%, 100\%]\}$ OOD scenario, where only 3% of the entire fine-tuning data is masked out. Figure 6 shows an example of the code refinement task. In Figure 6, we provide an example of the syntax-based scenario, in which Code Llama encountered difficulty in generating the *while_statement*. In this syntax-based scenario *while_statement* is the unseen language element.

Table 8: Overall results of the model performance for different scenarios in **code refinement** task. The results provide the BLEU score for different scenarios. Length Inter and Length Extra refer to length-based interpolation and extrapolation scenarios, respectively. FT denotes full fine-tuning, and LoRA refers to the LoRA fine-tuning method. OOD and Few refer to OOD and few-data regime scenarios, respectively. Full refers to 100% baseline (when a model has access to 100% of the fine-tuning set). GCBERT denotes to the GraphCodeBERT model (Guo et al., 2021).

Abstract

Large Language Models (LLMs) have exhibited remarkable proficiency across a wide array of NLP tasks. However, the escalation in model size also engenders substantial deployment costs. While few efforts have explored model pruning techniques to reduce the size of LLMs, they mainly center on general or task-specific weights. This leads to suboptimal performance due to lacking *specificity* on the target domain or *generality* on different tasks when applied to domain-specific challenges. This work introduces an innovative unstructured dual-pruning methodology, D-PRUNER, for domain-specific compression on LLM. It extracts a compressed, domain-specific, and task-agnostic LLM by identifying LLM weights that are pivotal for general capabilities, like linguistic capability and multi-task solving, and domain-specific knowledge. More specifically, we first assess general weight importance by quantifying the error incurred upon their removal with the help of an open-domain calibration dataset. Then, we utilize this general weight importance to refine the training loss, so that it preserves generality when fitting into a specific domain. Moreover, by efficiently approximating weight importance with the refined training loss on a domain-specific calibration dataset, we obtain a pruned model emphasizing *generality* and *specificity*. Our comprehensive experiments across various tasks in healthcare and legal domains show the effectiveness of D-PRUNER in domain-specific compression. Our code is available at `https://github.com/psunlpgroup/D-Pruner`.

1 Introduction

Large Language Models (LLMs) such as the GPT family (Brown et al., 2020) and the LLaMA family (Touvron et al., 2023) have exhibited remarkable advancements across a diverse spectrum of NLP tasks. However, the substantial size of LLMs engenders cost-intensive deployment in real-world applications and renders them unsuitable for scenarios necessitating efficient inference and low latency (Bai et al., 2024). Recently, model pruning techniques have been successfully applied to language models (Han et al., 2015; Xia et al., 2022; Frantar and Alistarh, 2023). These methods aim to yield a compact language model characterized by a significantly reduced parameter count, which is cost-efficient for deployment. However, most of them target relatively small language models, and only a few focus on LLMs (Frantar and Alistarh, 2023; Ma et al., 2023; Sun et al., 2023; Xia et al., 2023). Moreover, the existing strategies mainly center on general or task-specific weights, leading to suboptimal performance due to lacking *specificity* on the target domain or *generality* on different tasks when applied to domain-specific challenges. Here ***generality*** refers to the general capabilities of an LLM such as language understanding and generation, and multi-task solving, and ***specificity*** refers to the capability of an LLM to understand domain-specific knowledge.

As shown in Figure 1, the weights in an LLM work together to support its general capabilities and to store various domain knowledge. The domain-shared weights (or general weights) empower the LLM with linguistic and multi-task solving prowess akin to human language usage and thinking. The domain-specific weights (or domain weights) are pivotal for endowing the LLM with domain-specific expertise mirroring that of domain experts. However, the current pruning methods mainly focus on preserving general or task-specific weights, which may not be enough to deal with domain-specific problems. For example, post-training pruning methods (Frantar and Alistarh, 2023) assume the model is optimized and prune unimportant weights based on an open-domain calibration dataset. This leads to a pruned model that

June 16-21, 2024

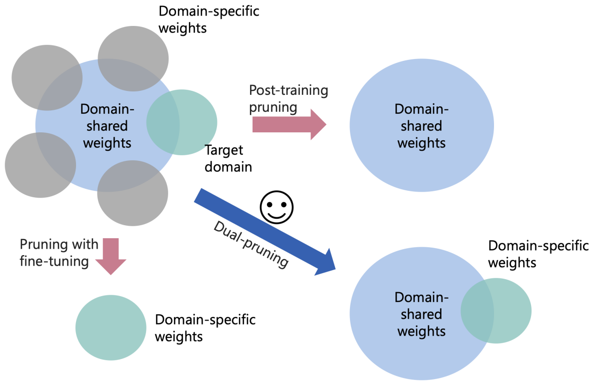

Figure 1: Different types of pruning methods. An LLM is composed of domain-shared weights and domain-specific weights. Post-training pruning focuses on domain-shared weights for generality, pruning with fine-tuning focuses on domain-specific weights for specificity, and our dual-pruning method preserves weights pivotal for both generality and specificity.

focuses on model generality with domain-specific weights not considered. On the other hand, pruning with fine-tuning methods (Ma et al., 2023) utilizes gradients during fine-tuning on a specific task to estimate the importance of parameters. As a result, the pruned model focuses on the model specificity while decreasing the linguistic and multi-task solving capabilities, compromising the LLM's capacity as a versatile task-agnostic solver.

To this end, this study introduces a novel dual-pruning approach, D-PRUNER, for domain-specific unstructured pruning on LLMs, which aims to extract a domain-specific LLM from the foundation LLM. This extracted model is able to solve different tasks in the target domain and facilitates further domain-specific fine-tuning. D-PRUNER is designed to harness calibration data for guiding LLM pruning processes while preserving generality and specificity for multi-task solving and domain challenges. The resulting compressed LLM can be seamlessly adapted to the target domain, enabling deployment with limited computing resources. Specifically, D-PRUNER adeptly captures and retains both general and domain parameters while selectively eliminating insignificant model parameters. This mechanism comprises the following steps: firstly, a general weight importance module operates to assess the significance of model parameters for general capabilities. Subsequently, we propose an updated training loss function based on the autoregressive training objective for the next token prediction by integrating the general importance as a regularization term. This way, we identify weights contributing to both generality and domain specificity when training on a domain calibration dataset. Then, with the updated loss function, we compute the weight importance leveraging gradients without updating the model. Moreover, an approximation algorithm, empirical Fisher (Martens, 2020; Sung et al., 2021), is utilized to compute the weight importance efficiently for pruning.

We evaluate the performance of D-PRUNER on LLaMA2 (Touvron et al., 2023), a widely adopted open-source LLM. Our experimental findings demonstrate that D-PRUNER exhibits remarkable efficiency in the extraction of sparse domain networks from pre-trained LLMs, with a limited amount of calibration data provided. Remarkably, D-PRUNER achieves comparable results to the full dense model while achieving 50% sparsity, surpassing the performance of alternative pruning techniques across diverse domain-specific datasets in healthcare and legal domains encompassing language comprehension, question answering, and summarization tasks.

2 Related Work

Model compression involves transforming a large, resource-intensive model into a compact version suitable for low-resource deployment (Deng et al., 2020; Zhu et al., 2023). There are mainly three techniques for model compression, which are pruning, knowledge distillation, and quantization.

Pruning. Pruning techniques in neural networks can be broadly classified into structured pruning and unstructured pruning (Xia et al., 2022; Sanh et al., 2020; Du et al., 2021). *Structured pruning* entails the removal of entire network components, such as channels or layers, guided by specific criteria, while maintaining the overall network architecture. In contrast, *unstructured pruning* targets individual weights, leading to an irregular sparse structure.

While numerous attempts have been made to prune language models of relatively small scales, such as BERT (Kenton and Toutanova, 2019), scant attention has been devoted to pruning LLMs containing billions of parameters. These larger models possess 100-1000 times more weights, rendering the pruning task significantly more challenging. SparseGPT (Frantar and Alistarh, 2023), a post-training method for Large Language Models (LLMs), lacks the capability to identify crucial weights tailored to specific domains or tasks as it refrains from fine-tuning. On the other hand, LLM-Pruner (Ma et al., 2023) employs gradient-based techniques for pruning. However, it falls short in identifying pivotal weights essential for domain-shared knowledge, resulting in pruned models that lack the desired level of generality.

The existing pruning methods either focus on general or domain-specific weights, yet none of them consider preserving both at the same time. To the best of our knowledge, we are the first to work on pruning LLMs while preserving weights important to both generality and specificity.

Knowledge Distillation. Knowledge Distillation (KD) has emerged as a powerful technique, drawing considerable interest for its ability to augment model performance and enhance generalization capacities (Hinton et al., 2015; Zhu et al., 2023). At its core, KD revolves around the transfer of expertise from a complex model, referred to as the "teacher model", to a simplified counterpart known as the "student model". This intricate process of knowledge transfer aims to distill the profound insights encapsulated within the teacher models, condensing them into a more concise and efficient representation within the student models.

While KD has been proven a powerful tool for model compression, it needs specific downstream tasks and a large amount of data for the student models to learn from the teacher models. Thus, the output that student models produce mainly focuses on a specific task and loses the generality capability. KD generally sets higher requirements on data availability and computation budgets (e.g., GPU memory) than pruning.

Quantization. In the realm of model compression, quantization has emerged as a widely embraced technique to alleviate the storage and computational challenges inherent in deep learning models (Guo et al., 2020; Dettmers et al., 2021, 2022, 2023). Conventional model representations rely on floating-point numbers, but quantization converts them into integers or discrete forms. This transformation leads to substantial reductions in storage requirements and computational complexities. While a certain degree of precision loss is inevitable, carefully designed quantization methods can achieve significant model compression with minimal accuracy degradation. Although challenges remain, such as maintaining model interpretability and addressing task-specific intricacies, the current body of research establishes a robust groundwork for ongoing advancements in LLM quantization, which could be complementary to LLM pruning.

3 Methodology

To preserve both generality and specificity on the pruned model, our dual-pruning method D-PRUNER considers weights important to both generality and specificity during training on a calibration dataset. Note we only use the weight gradient generated from the training process but do not update the model weights. Our model is pruned in a task-agnostic fashion (e.g., we adopted a pretraining objective, next token prediction, as a part of training loss) so that the pruned model can solve different tasks in the target domain.

D-PRUNER comprises the following steps: firstly, a general weight locating module operates to assess the significance of model parameters for general understanding (Section 3.1). Subsequently, an updated loss function for the training process is proposed by integrating the general weight importance as a regularization term. This way, we identify weights contributing to both general and domain knowledge (Section 3.2). Finally, with the updated loss function, we compute the weight gradients on a small domain calibration dataset without updating the model and approximate our dual-pruning weight importance by utilizing the empirical Fisher index (Sung et al., 2021) for pruning (Section 3.3).

Our method concentrates on unstructured pruning in a layer-by-layer manner for the Transformers model. We consider query, key, value, and output projections of all self-attention layers and gate (Liu et al., 2021), down, and up projections of all MLP (multilayer perceptron) layers for pruning.

3.1 General Weight Importance

The first step of our method involves locating important weights in terms of general knowledge. Following the same hypothesis as Frantar and Alistarh (2023), we assume that an important weight will cause a larger increase in loss value than those less important ones if it is pruned (set to 0) during training. Formally, if a dataset of the open-domain calibration $\mathcal{D}_g = \{x_j, y_j\}_{j=1}^N$ with size N is used for training and W stands for weight matrices of a model, the importance of each weight at index m, denoted as I_{W^m}, can be approximated using Taylor series as shown by LeCun et al. (1989):

$$\begin{aligned} I_{W^m} &= |\mathcal{L}(\mathcal{D}_g) - \mathcal{L}_{W^m=0}(\mathcal{D}_g)| \\ &= |\frac{\partial \mathcal{L}(\mathcal{D}_g)}{\partial W^m} W^m + \frac{1}{2} W^m H_{mm} W^m \\ &+ O(||W^m||^3)| \end{aligned} \tag{1}$$

where H denotes the Hessian matrix, and $\mathcal{L}$ is the cross-entropy loss. For a model that is sufficiently trained to a local minimum on its loss curvature (e.g., pretrained foundational language models such as LLaMA), the classic Optimal Brain Surgeon (Hassibi et al., 1993) further approximates the importance of W^m as:

$$\varepsilon^m = \frac{1}{2} \frac{(W^m)^2}{[H^{-1}]_{mm}} \tag{2}$$

ε^m can also be viewed as the error caused by removing the weight W^m. We compute ε^m for all the weights subject to pruning and construct a matrix of importance scores G with respect to general domains that have the same dimension as W.

3.2 Updated Loss with Regularization

To identify the weights that are important in both general and domain-specific knowledge, we modify the original loss function of LLM training. In LLM training, cross-entropy loss is used in the next token prediction task (Radford et al., 2018). Similar to Thompson et al. (2019), we add a regularization term to constrain the change of important general weights found in the first step. Suppose that there are M number of prunable weights in total. To train on a domain-specific calibration dataset $\mathcal{D}_s = \{x_j, y_j\}_{j=1}^{P}$, we add the proposed regularization term on top of the next token prediction loss $\mathcal{L}_{next}$ to obtain our final training objective:

$$\mathcal{L}_{\text{ours}} = \mathcal{L}_{\text{next}} + \lambda \sum_{m=1}^{M} G^m (W^{m\prime} - W^m)^2 \tag{3}$$

where G^m is the general weight importance, $W^{m\prime}$ denotes the updated weight value of W^m, λ is a hyperparameter, and the second term on the right is $\mathcal{L}_{\text{regular}}$.

In practice, the direct calculation of this regularization term in the forward pass is computationally expensive for two reasons: (1) it involves both W^m and G^m which are very large, and (2) gathering updated model parameters ($W^{m\prime}$) in a partitioned (Rasley et al., 2020) or sharded (Zhao et al., 2023) system is inefficient. Based on the recent success of applying gradient descent on full fine-tuning of LLMs (Lv et al., 2023), we choose to use gradient descent to optimize parameters. Therefore, at a learning rate α, denoting the gradient of each parameter with respect to $\mathcal{L}_{\text{next}}$ as g^m_{next}, we reduce the regularization term to:

$$\begin{aligned} \mathcal{L}_{\text{regular}} &= \sum_{m=1}^{M} G^m (W^{m\prime} - W^m)^2 \\ &= \lambda \sum_{m=1}^{M} G^m (W^m - \alpha g^m_{\text{next}} - W^m)^2 \\ &= \lambda \sum_{m=1}^{M} \alpha^2 G^m (g^m_{\text{next}})^2 \end{aligned} \tag{4}$$

During the backward pass, optimizing this regularization term requires second-order derivatives, which indicates that Hessian matrices (H) are needed. Directly computing the Hessian matrices is infeasible for such a large number of parameters. Therefore, we use the Fisher information matrix to approximate the diagonal of the Hessian (Sung et al., 2021). And the Fisher information matrix can be further approximated by the average of the squared gradient of the model's prediction over P. We write the gradient of the regularization with respect to every parameter matrix in a finer granularity:

$$\frac{\partial \mathcal{L}_{\text{regular}}}{\partial W^m} \approx 2\lambda\alpha^2 G^m g^m_{\text{next}} H_{mm} \tag{5}$$

$$H_{mm} \approx \frac{1}{P} \sum_{j=1}^{P} (g^m_{\text{next}}(x_j, y_j))^2 \tag{6}$$

We directly compute $\frac{\partial \mathcal{L}_{\text{regular}}}{\partial W}$ via Equation 5 above instead of relying on PyTorch backward pass to maximize computing efficiency. The final gradient computation of our regularized loss function is shown below:

$$\frac{\partial \mathcal{L}_{\text{ours}}}{\partial W^m} = \frac{\partial \mathcal{L}_{\text{next}}}{\partial W^m} + \frac{\partial \mathcal{L}_{\text{regular}}}{\partial W^m} \tag{7}$$

3.3 Dual-pruning Importance Score

Finally, we calculate the dual-pruning importance score of each weight, and unimportant weights can be pruned according to their importance. We use Equation 1 for importance estimation instead of Equation 2, because our model has not converged to an optimum on the target domain. However, direct computation of the Hessian matrix in Equation 2 is

	InternalMed_Harrison	MedNLI	PubMedQA	HQS	MultiLegalPile	CaseHOLD	BillSum
Domain	Healthcare	Healthcare	Healthcare	Healthcare	Legal	Legal	Legal
Task / Type	Generation	NLI	QA	Summarization	Generation	QA	Summarization
# Instances in Test	300	1422	500	100	300	200	200
Metrics	Perplexity	Accuracy	Macro-F1	ROUGE	Perplexity	Macro-F1	ROUGE

Table 1: Details of each dataset that we use for model evaluation.

infeasible since it involves $O(M^2)$ complexity for each weight update. Therefore, we also leverage Sung et al. (2021) to approximate the diagonal of the Hessian, and the final importance score S^m can be defined as:

$$S^m \approx |\frac{\partial \mathcal{L}_{\text{ours}}(\mathcal{D}_s)}{\partial W^m} W^m + \frac{1}{2}[\frac{\partial \mathcal{L}_{\text{ours}}(\mathcal{D}_s)}{\partial W^m} W^m]^2 + O(||W^m||^3)| \tag{8}$$

Here $O(||W^m||^3)$ can be neglected according to the quadratic approximation (LeCun et al., 1989). Note the calculation of S^m considers both general and domain-specific knowledge via our regularized training objective. Combining both regularization and importance estimation via empirical Fisher approximation, our method expects to conduct pruning that maintains weights important to both general and domain-specific knowledge, thus preserving generality and specificity. And these importance scores are used to guide our pruning decisions. For example, if we set the sparsity level to be 50%, weights that have the smallest 50% of importance scores in each layer will be pruned.

4 Experiment Setup

We evaluate D-PRUNER on two knowledge-intensive domains, which are healthcare and legal. For model generality under domain-specific challenges, we evaluate the linguistic capability using domain text generation, and evaluate the multi-task solving capability on different domain tasks, i.e., natural language inference (NLI), question answering (QA), and summarization. Since we use domain datasets, the model specificity on domains can also be evaluated. In addition, we fine-tune the pruned model on domain datasets to further evaluate the generality and specificity.

We evaluate D-PRUNER on the LLaMA2 model family, which is the most used open-source LLM. We mainly apply our pruning method and baseline methods to LLaMA2-7B and LLaMA2-13B to show our results. Our method can also be easily applied to other LLMs with different sizes and architectures. For instance, Appendix B shows further experiment on BLOOM model (Le Scao et al., 2022).

4.1 Iterative blocking

Motivated by Frantar and Alistarh (2023), we perform experiments (in Table 2) on D-PRUNER with and without iterative blocking. Iterative blocking means to make pruning decisions for every fixed number (B_s) of columns within a weight matrix. In other words, instead of selecting a single pruning mask for an entire weight matrix, a pruning sub-mask is selected for every B_s columns to reach overall sparsity level. We set $B_s = 128$ for weight matrices with the smallest number of columns and increase B_s for those with more columns. Except Table 2, D-PRUNER in other tables does not adopt iterative blocking.

4.2 Datasets and Evaluations

Datasets. Table 1 shows the details of each dataset that we used. Specifically, for healthcare, we select a medical textbook InternalMed_Harrison (Bigby, 1988), MedNLI (Romanov and Shivade, 2018), PubMedQA (Jin et al., 2019), and Health Question Summarization (HQS) from the MEDIQA 2021 shared task 1 (Ben Abacha et al., 2021; Ben Abacha and Demner-Fushman, 2019) as domain datasets. For legal domain, we select MultiLegalPile (Niklaus et al., 2023), CaseHOLD (Zheng et al., 2021), and BillSum (Kornilova and Eidelman, 2019). As for open-domain calibration data, we extract text from C4 dataset (Raffel et al., 2019).

To construct our domain-specific calibration data, we select training instances from MedNLI, PubMedQA, and HQS at a ratio of 20%/60%/20% and from CaseHOLD and BillSum at a ratio of 50%/50%. These ratios are determined based on the difficulties and training sizes of these benchmarks. Both NLI and QA tasks that we adopt are asking models to perform classification. We experiment with different sizes of the domain-specific calibration dataset and find a size of 1000 achieves the best trade-off in terms of pruning efficiency and effectiveness for both domains. For model evaluation, besides using the test instances of those benchmarks, we leverage InternalMed_Harrison and MultiLegalPile for perplexity evaluation. 300 paragraphs are selected from each data source to form the test set of perplexity. Note that we use a subset of all the test examples of CaseHOLD and BillSum, since these two benchmarks are significantly larger in size and their individual instance tends to be longer.

Evaluation Metrics. We first evaluate the linguistic capability of pruned models on InternalMed_Harrison and MultiLegalPile using perplexity. We then evaluate the multi-task solving capability and domain specificity on different domain tasks. Specifically, we choose accuracy metric for NLI task (MedNLI), macro-F1 for QA tasks (PubMedQA and CaseHOLD), and ROUGE scores (Lin, 2004) for summarization tasks (HQS and BillSum).

4.3 Baselines

We compare our method with a variety of LLM pruning baselines. All methods are applied to the same foundation model (either 7B of 13B of LLaMA2) for fair comparisons. As an ablation study, we also evaluate an unstructured pruning method using weight gradient by removing the regularization term in the training loss of D-PRUNER.

- **Magnitude pruning** prunes weights based on their magnitudes (Han et al., 2015). We follow the standard practice of magnitude pruning on language models, where weights are compared layer-wise. Magnitude pruning is a simple and robust baseline that has been demonstrated to outperform many other pruning methods.
- **LLM-Pruner** is a structured pruning method using weight gradient to evaluate weight importance (Ma et al., 2023). A calibration dataset is used for its gradient calculation, so we combine both open-domain (C4) and domain-specific calibration data when we use LLM-Pruner.
- **SparseGPT** is an unstructured post-training pruning method (Frantar and Alistarh, 2023). It uses an efficient weight update procedure that iterates between weight removal and weight update at each layer. It also uses a calibration dataset for approximation. Thus, similarly to D-PRUNER and LLM-Pruner, we use open-domain and domain-specific calibration data for fair comparisons.

Moreover, for all the baseline methods, we continue to fine-tune their pruned models using LoRA (Hu et al., 2021) on all the datasets together (NLI, QA, and summarization data combined) in each domain and then test the fine-tuned model on the datasets in Table 1. We only use the default open-domain calibration dataset for the pruned models of LLM-Pruner and SparseGPT at this step, because these models will eventually undergo LoRA fine-tuning. Data instances of our fine-tuning dataset follow the Alpaca (Taori et al., 2023) template so that models are trained to predict the responses. Specifically, for healthcare, we have 7000, 7000, and 1000 training instances from MedNLI, PubMedQA, and HQS, respectively. For legal domain, we have 13000 training instances from CaseHOLD and 2000 from BillSum.

4.4 Implementation Details

We perform prompt engineering in a zero-shot setting before prompting a series of models. The finalized prompt is kept the same across all candidate models on one task to ensure fairness. The hyperparameters used by different models are in Appendix C.

5 Results and Analysis

Our results and analysis aim to answer the following research questions:

- RQ 1: How does D-PRUNER compare against other pruning baselines (5.1)?
- RQ 2: What are the performance of all candidate models after LoRA fine-tuning (5.2)?
- RQ 3: As an important contribution of D-PRUNER, is dual-pruning an effective method of compressing LLM (5.1, 5.3, and 5.5)?
- RQ 4: How does D-PRUNER perform under different sparsity levels or different sizes of domain-specific calibration data (5.4)?

5.1 Overall Results

Our overall results for the two domains are presented in Table 2. All models are pruned to 50% sparsity level except the dense one.

Improvement on NLI and QA D-PRUNER delivers consistent score improvement on NLI and QA tasks when it is compared against baselines based on LLaMA2-7B and LLaMA2-13B. With two exceptions, variants of D-PRUNER based on the inclusion and exclusion of iterative blocking outperform baselines on 4 out of 6 cases when classification is performed (MedNLI, PubMedQA,

Table 3: Results of fine-tuned candidates models at 50% sparsity. LoRA fine-tuning is conducted on D-Pruner without iterative blocking.

and CaseHOLD on both 7B and 13B LLaMA2) in Table 2. It is clear to see that magnitude pruning and SparseGPT are generally stronger models than LLM-Pruner. The dense model sometimes has worse scores than others across 7B and 13B LLaMA2, which indicates that scaling parameters of a pre-trained language model does not necessarily increase the performance on a single benchmark on NLI and QA. We can see that iterative blocking generally yields better scores on these classification tasks such as reaching 30.56 F1 score on CaseHOLD based on LLaMA2-7B, which is a significant improvement over baselines and D-Pruner without it. Thus, we recommend to adopt iterative blocking on the classification tasks when strong domain knowledge is required.

Improvement on Summarization D-Pruner presents the strongest summarization performance. The most exciting thing is that its ROUGE scores are mostly higher than the dense ones. We notice the top summarization performance of LLaMA2-13B-based models on HQS is lower than that of LLaMA2-7B-based models, which is counterintuitive. According to the state-of-the-art of HQS (Zhang et al., 2023; He et al., 2021), we find that D-Pruner is close to the best ROUGE scores produced by single systems, so we consider that this dataset is relatively simple. Thus, our LLaMA2-7B-based models seem to find an upper limit of ROUGE given the existing reference summaries, so going from 7B to 13B incurs a small performance degradation on dense model, SparseGPT, and D-Pruner. The strong summarization performance of D-Pruner on both domains demonstrates its usability as an efficient and domain-specific language model. As for iterative blocking, D-Pruner without it generally has better perplexity and summarization performance. However, considering the exception in the legal domain based on LLaMA2-7B, we recommend to check perplexity scores on the validation data when deciding whether to use iterative blocking for perplexity and summarization assessment.

Improvement on Perplexity D-Pruner has the second best perplexity scores on healthcare and legal domains across 7B and 13B LLaMA2.

These scores reflect the strong linguistic capabilities of SparseGPT and D-PRUNER when they encounter knowledge-intensive domains. D-PRUNER does not surpass SparseGPT on perplexity metric, and the reason might come from the fine-tuning pipeline (Lv et al., 2023) we use. Lv et al. (2023) is a full-parameter fine-tuning pipeline that aims towards GPU memory efficiency, so its effectiveness on a specific metric might be compromised. Moreover, we suspect that the data we use from InternalMed_Harrison and MultiLegalPile may be closer to the general domain both semantically and syntactically. Since SparseGPT prunes LLM mainly based on generality, it has better perplexity scores than ours.

5.2 Performance After Fine-tuning

Table 3 shows the results of fine-tuned candidate models at 50% sparsity. Similar to the performance discussed above, D-PRUNER always delivers the best summarization scores and mostly presents the best classification results after fine-tuning, which demonstrates that fine-tuning can further improve the pruning performance of our method. For most models, macro-F1 on PubMedQA decreases after fine-tuning, because this test set is imbalanced and models mostly learn to predict the majority class labels. In fact, the accuracies of most models on PubMedQA increase after fine-tuning as shown in Appendix A, so this fine-tuning method still makes a difference. We also do not see too much score improvement for many models on CaseHOLD, since it is a quite challenging task for our experiment setting (e.g., we combine only a small subset of original training data for each task and perform multi-task fine-tuning as discussed in Section 4).

5.3 Ablation Study

In Table 4, we show that pruning without integrating general domain importance as a regularization term yields suboptimal performance. In other words, this means to remove the consideration of generality. We find perplexities in both domains are higher than pruning with regularization. This demonstrates that our dual pruning mechanism that considers both generality and specificity is able to improve model performance.

5.4 Effect of Sparsity and Domain Calibration Data

In Table 5, it is clear that perplexity keeps increasing when D-PRUNER becomes more sparse, which is expected. Since 50% sparsity is a good balance between sparsity and performance, we select it to report our performance in Table 2 and 3.

Model	Healthcare perplexity	Legal perplexity
no regularization	7.23	2.82
D-PRUNER	**6.96**	**2.72**

Table 4: Results of removing the regularization.

Sparsity	Healthcare perplexity	Legal perplexity
10%	5.49	2.26
20%	5.52	2.27
30%	5.61	2.31
40%	5.91	2.42
50%	6.96	2.72
60%	15.19	4.59
70%	223.63	84.25

Table 5: Results of changing sparsities on D-PRUNER.

# samples	Healthcare perplexity	Legal perplexity
100	8.18	3.34
500	7.15	2.97
1000	6.96	2.72
1500	7.96	2.70

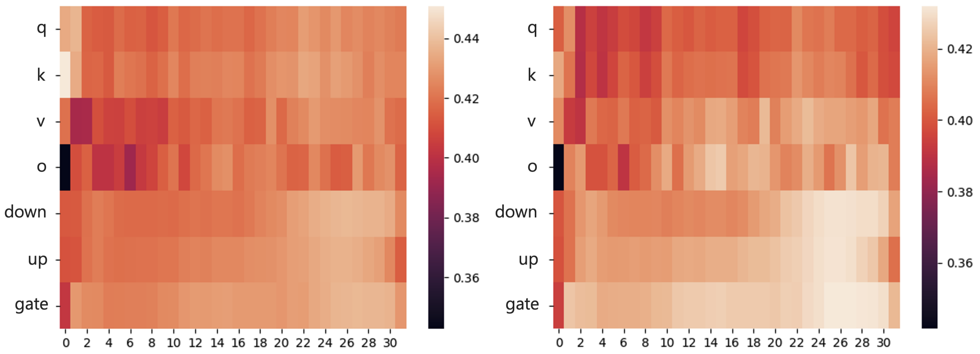
Table 6: Results of trying different sizes of domain-specific calibration data.

Based on Table 6, we believe setting the size of domain-specific calibration data to 1000 is reasonable. As the last row shows, increasing its size does not always guarantee a performance improvement.

5.5 Mask Similarity

To better understand the pruned model on different domains, we compare the similarity of the pruning masks. In our study on LLaMA2-7B, each generated mask contains 7*32 matrices for 32 layers and 7 projection matrices in the self-attention module (q, k, v, o) and MLP module (down, up, gate) in each layer. For each matrix, we calculate the similarity as the number of shared "1" elements ("1" means weights not pruned) in the two masks divided by the matrix size. Note all the masks are generated in 50% sparsity.

Figure 2 (a) shows the mask similarity between the open-domain and healthcare domain, and 2 (b) shows the mask similarity between the healthcare domain and legal domain. The results show that the masks are quite different, with shared elements as low as 35%. Generally, the self-attention modules



(a) Open-domain vs healthcare domain.

(b) Healthcare domain vs legal domain.

Figure 2: Illustration of mask similarity. It shows that masks for different domains are quite different. The self-attention modules contribute more to specificity, and MLP modules store knowledge that is shared by different domains.

share fewer elements than the MLP modules. This means self-attention modules contribute more to specificity, and MLP modules store knowledge that is shared by different domains.

6 Conclusion

We introduce D-Pruner, an innovative unstructured dual-pruning method for domain-specific compression on LLM. It is able to extract a compressed, domain-specific, and task-agnostic LLM by identifying weights that are pivotal for both generality and specificity. More specifically, the general weight importance is first assessed by quantifying the error incurred upon their removal with the help of open-domain calibration data. Then, we utilize this general weight importance to refine our training loss, so that it considers generality when fitting into a specific domain. Moreover, by efficiently approximating weight importance with the refined training loss on a domain-specific calibration dataset, we obtain a pruned model emphasizing general capabilities and domain-specific knowledge. Our comprehensive experiments across various tasks in different domains show the effectiveness of D-Pruner in domain-specific pruning.

Limitations

Although D-Pruner presents strong performance in Section 5, many of its perplexity scores reach the second place in healthcare and legal domains (dense model is not counted here). Further improving this perplexity is a valuable extension of this paper.

Another limitation of this work is that D-Pruner is more memory-intensive than SparseGPT during pruning, since D-Pruner is based on full-parameter fine-tuning and SparseGPT does not leverage global gradient information. D-Pruner sets similar memory requirement as LLM-Pruner. As a trade-off, D-Pruner reaches better performance on most of the metrics. It is also more flexible, since it computes matrices of importance scores without actually sparsifying LLMs. Therefore, researchers can make real-time decisions about the desired sparsity level, and changing the sparsity is very efficient.

A Accuracy Scores on PubMedQA

In Table 7, we report the accuracy score of each model on PubMedQA before and after LoRA fine-tuning. Except LLM-Pruner, we see score improvement on all other models after fine-tuning. Thus, Table 7 indicates that our fine-tuning is still improving model performance on PubMedQA in some ways.

B Experiments on BLOOM

We conduct a small set of experiments in healthcare domain for illustrative purpose. SparseGPT is chosen for comparison, since it is the strongest baseline. We run SparseGPT under two settings: (1) only open-domain calibration dataset is used for pruning, and (2) both open-domain and domain-specific calibration datasets are used, which is the same as the setting in Section 5. All BLOOM experiments are based on the `bigscience/bloom-7b1` model on Hugging Face.

As shown in Table 8, SparseGPT yields the best performance on BLOOM across all three metrics. Although D-PRUNER surpasses SparseGPT

Model	Before LoRA	After LoRA
Dense	39.20	64.60
Magnitude	47.00	55.20
LLM-Pruner	51.40	40.20
SparseGPT	53.80	57.00
D-PRUNER	58.80	59.20

Table 7: Accuracy scores of different models on PubMedQA dataset.

Model	Perplexity	MedNLI	PubMedQA
Dense	9.40	33.26	23.72
SparseGPT*	11.16	32.07	29.74
SparseGPT	10.88	33.47	24.23
D-PRUNER	14.70	32.70	20.95

Table 8: Performance of SparseGPT and D-PRUNER (at 50% sparsity) on metrics of healthcare domain based on BLOOM. * denotes the model that only uses open-domain calibration data (C4) for pruning.

on MedNLI when SparseGPT only uses open-domain data, it struggles on both medical perplexity and PubMedQA. Because our method is based on Lv et al. (2023) for fine-tuning and this fine-tuning pipeline only discusses performance scores on LLaMA, Lv et al. (2023) might require a significant adaptation when we change our backbone models from LLaMA to BLOOM. It might also not work well on BLOOM-based models when we integrate the general importance as a regularization term. Therefore, we might need to switch the fine-tuning pipeline we use in order to obtain the optimal performance of D-PRUNER.

C Hyperparameters

We stick to the default values of hyperparameters for our baseline models. For D-PRUNER, in the healthcare domain, we set λ (regularization strength) and learning rate to 0.1 and 0.03. In the legal domain, we set λ and learning rate to 0.001 and 0.03.

LLMRefine: Pinpointing and Refining Large Language Models via Fine-Grained Actionable Feedback

Abstract

Recent large language models (LLM) are leveraging human feedback to improve their generation quality. However, human feedback is costly to obtain, especially during inference. In this work, we propose **LLMRefine**, an inference time optimization method to refine LLM's output. The core idea is to use a learned fine-grained feedback model to pinpoint defects and guide LLM to refine them iteratively. Using original LLM as a proposal of edits, LLMRefine searches for defect-less text via simulated annealing, trading off the exploration and exploitation. We conduct experiments on three text generation tasks, including machine translation, long-form question answering (QA), and topical summarization. LLMRefine consistently outperforms all baseline approaches, achieving improvements up to 1.7 MetricX points on translation tasks, 8.1 ROUGE-L on ASQA, 2.2 ROUGE-L on topical summarization.

1 Introduction

In recent years, large language models (LLMs) have shown impressive performance on various text generation tasks (Brown et al., 2020; Anil et al., 2023). Critical to their success has been the ability to incorporate human feedback into the learning process (Ouyang et al., 2022).

Nevertheless, human feedback is costly to collect, especially at inference time when the model provides new, unseen input. In the meanwhile, automatic text generation evaluation metrics for a variety of tasks are rapidly improving (Sellam et al., 2020; Xu et al., 2022b; Rei et al., 2020; Xu et al., 2023a,b). Can we use one of these metrics to rectify LLM's generation?

In this work, we propose LLMRefine, an inference-time optimization method to improve the quality of generated text. Our LLMRefine starts with LLM's initial output, then uses a learned error pinpoint model to provide fine-grained feedback about the location and type of defects in the text. We then use a refinement model (same or another LLM) to follow the feedback instruction and generate candidate text. The fine-grained feedback provides more much precise information about what exactly is wrong in the generated text, resulting in higher quality revision.

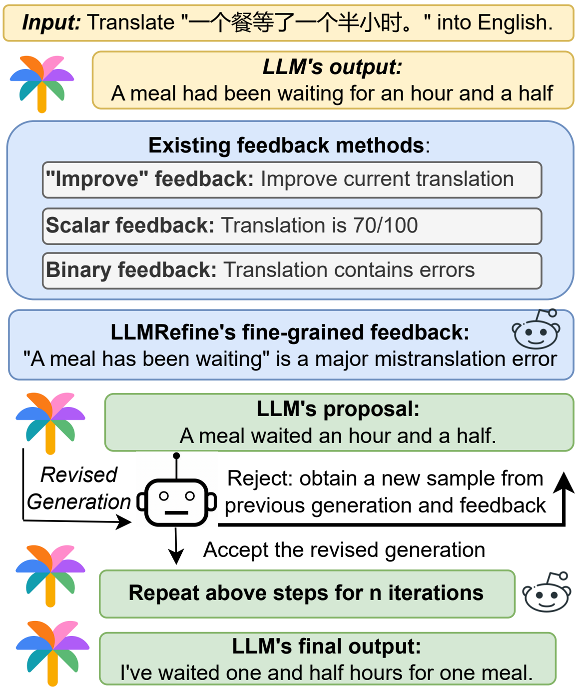

Figure 1: An overview of our LLMRefine: We start from LLM's initial generation and iteratively refine the generation, based on fine-grained actionable feedback. We use a simulated annealing technique to accept or reject the proposed revision at each step.

However, due to the large search space, the refinement model is imperfect; it often fails to correct all of the errors identified by the feedback model in one iteration (Madaan et al., 2023). We formulate the iterative refinement procedure into a local search problem. It alternates between the

---

Findings of the Association for Computational Linguistics: NAACL 2024, pages 1429–1445
June 16-21, 2024

feedback generation and refinement in multiple iterations, with the goal of searching for the highest scoring output according to the feedback model. To this end, we develop a simulated annealing technique in LLMRefine to trade off between exploring many possible edits and quickly reaching optimal text. Figure 1 shows overview of our approach.

We evaluate LLMRefine on three text generation tasks, including machine translation (WMT (Kocmi et al., 2022)), long-form question answering (ASQA (Stelmakh et al., 2022)) and topic summarization (Saunders et al., 2022), because they have a large number of annotated outputs with fine-grained error spans (Freitag et al., 2021a; Saunders et al., 2022; Wu et al., 2023). We use those ratings to train an automatic error pinpoint model that generates a list of error spans along with error categories and severities without the aid of a reference text (which is unavailable during inference) (Fernandes et al., 2023; Xu et al., 2023b). This model serves as our substitute for human feedback. Our experiments show that LLMRefine results in higher-quality text compared to baseline methods using other feedback (scalar or binary score) or other search techniques. Our contributions are:

- We propose LLMRefine, an inference time optimization method to iteratively refine LLM's output with fine-grained actionable feedback, achieving best trade-off between search space and optimal quality.
- We demonstrate that LLMRefine consistently outperforms all baseline approaches, achieving improvements up to 1.7 MetricX points on translationn tasks, 8.1 ROUGE-L on ASQA and 2.2 ROUGE-L improvements on topical summarization. Humans demonstrate a significant preference for the output of LLMRefine over the baseline outputs.

2 Related Work

Inference-time Optimization Approach We divide techniques for incorporating feedback at inference time into two main techniques (Pan et al., 2023): generate-then-ranking and feedback-guided generation. The reranking framework involves generating a large set of candidate text outputs from the base model and utilizing a critic model to select the best output. The integration of the critic model can be achieved through chain-of-thoughts (Wei et al., 2023; Huang et al., 2022), binary verifier (Li et al., 2023), or a utility function (Freitag et al., 2022a; Fernandes et al., 2022). Our approach is complementary to re-ranking or minimum bayes risk decoding (MBR) strategies, offering additional performance beyond these techniques.

Incorporating Fine-Grained Feedback Recent studies have highlighted the benefits of fine-grained error annotation by demonstrating that it can reduce noise in human ratings and increase inter-rater agreement (Freitag et al., 2021b) as well as increase automatic metric correlation to human judgments Xu et al. (2022a, 2023a,b). One approach to leveraging these benefits is through the use of large language models to self-correct their own output (Madaan et al., 2023). Building on this, Chen et al. (2023) demonstrate that iterative self-improvement further enhances translation quality. However, despite the unsupervised nature of the self-refine pipeline, the feedback signal is dominated by the large language model's own evaluation capability, which has been shown to be biased towards sentence ordering and its own output (Liu et al., 2023; Xu et al., 2024). To address this limitation, Wu et al. (2023) propose a fine-grained reward model that distinguishes rewards at the span-level associating with different error categories. Orthogonal to this work, we propose an inference time optimization approach to iteratively refine model's output with fine-grained feedback.

3 Refinement with Fine-Grained Feedback

There are three main components to our framework: a generation model, a feedback model, and a refinement model, each described next.

The generation model produces an initial candidate output y_i given the input x. x and y_i are the source text and a candidate output that is generated by the model. The feedback model F takes x and y_i and generates some form of feedback f_i that represents the quality of y_i, which can be in any form—a scalar value, Boolean, free form natural language, or more. We assume f_i can always be converted into a scalar quality score via function $s(\cdot)$ (Details of our scoring scheme can be found in Appendix A). Finally, the refinement model uses x, y_i, and f_i and generates a new, improved output y_{i+1}. As we will discuss in Section 4, the loop between the feedback and refinement model can repeat for multiple iterations to further evaluate and update the generated output.

For most of this work, we assume that both the generation and refinement models are an LLM that is 0-shot prompted to perform the respective task (See example prompt in Table 8, although we do experiment with different generation models). The specific prompt for the refinement model depends on the type of feedback being used (See Figure 1). Since our focus is on the value of fine-grained feedback in the form of an error pinpoint model for text generation, we next describe our feedback model in more detail.

3.1 An Error Pinpoint Model

While the majority of text generation evaluation research focuses on predicting a scalar quality score for a text, we instead train an error pinpoint that produces fine-grained feedback on translation quality, similar to InstructScore (Xu et al., 2023b). This is based on the assumption that more specific, actionable feedback will enable the refinement model to generate better output.

The input to our feedback model is the source text x and a hypothesis generation y_i. The feedback model then generates a list of error locations, types, and severities in natural language that are contained in y_i. We model this task as a sequence-to-sequence model and finetune an LLM. Further implementation details are provided in Section 5.

Training our feedback model requires a set of text with human-annotated error locations, categories, and severities. For each task that we experiment on, the training data and feedback models are different since the types of errors are task-dependent. For machine translation, we use MQM annotated data (Mariana, 2014; Freitag et al., 2021a). For long form QA, we use data collected by Wu et al. (2023). For topical summarization, we use data collected by Saunders et al. (2022).

The finegrained feedback model pinpoints the error location and provides detailed error type information and severity level. This stands in contrast to more traditional evaluation metrics like BLEU, ROUGE or BLEURT that assign scalar scores that represent text generation quality. Note that because the feedback model operates during inference, our feedback model does not use a reference to evaluate the text. The specific input and output examples for our feedback model can be found in the Table 10, 11 and 12.

Once feedback f_i is generated, it is passed to the refinement model via prompting (See Figure 1 for example inputs and outputs to the feedback and refinement model). Specific implementation and evaluation details of our error pinpoint model are described in Section 5.1.

4 Iterative Refinement as Search

Although the refinement model receives the output y_i and feedback f_i, it is not always guaranteed to generate the best new output in a single step. Therefore, we experiment with different methods for iterative refinement in which the feedback and refinement loop is repeated until some stopping condition is met.

Iterative refinement can be viewed as a search procedure that is trying to find the optimal y_i for a given x, where "optimal" is measured by the feedback model. Specifically, we model iterative refinement as a local search algorithm in which every possible output is a state in the search space, and each step of the search algorithm starts at some state represented by y_i and moves to y_{i+1}. The goal is to find the highest scoring state.

We explore three different local search algorithms, described next.

4.1 Local Search Algorithms

Given a current output y_i, the local search algorithms begin by sampling a new candidate output c_i from the refinement model given feedback f_i. Then, each algorithm makes a decision about whether it will accept or reject c_i based on some criteria. If the decision is made to accept c_i, then c_i becomes y_{i+1} and the search loop repeats unless the feedback model detects no errors in y_{i+1}. If c_i is rejected, then y_i becomes y_{i+1} and the algorithm repeats (i.e., a second candidate is sampled from the refinement model for the same output). Each of the three following algorithms differs in how it decides whether to accept or reject the candidate output.

Always Accept. The "always accept" algorithm (AA) will attempt to explore the search space as much as possible by always accepting c_i.

Greedy Uphill. The greedy uphill (GREEDY) algorithm will only accept c_i if the score from the feedback model for c_i is better the score for y_i. In this case, we ensure that the output does not get worse according to the feedback model.

Simulated Annealing. The AA and GREEDY algorithms each make different trade-offs. AA will always explore the search space, sometimes at the cost of quality, whereas the GREEDY algorithm may do little in terms of search in order to ensure the output quality does not decrease. Here, we propose a search heuristic based on simulated annealing (SA) (Kirkpatrick et al., 1983) that tries to combine the strengths of the two approaches.

The SA search algorithm uses a temperature hyperparameter T that controls output diversity and the probability that c_i is accepted. The probability of acceptance is defined as the following:

$$p(\text{accept}|x, y_i, c_i, T) = \min(1, e^{\frac{s(F(c_i))-s(F(y_i))}{n*T}}) \tag{1}$$

where n is the maximum number of iterations. i is the ith iteration in the pipeline. $T_{i+1} = max(T_i - c * T_i, 0)$. Temperature decays by a constant proportion c. There are two factors contribute to increasing the probability that a candidate is accepted: a high temperature and an improvement in quality according to the feedback model.

At the beginning of the search algorithm, the temperature is set to a high value, allowing the algorithm to explore the search space more liberally. This allows the SA algorithm to accept a candidate that is potentially worse than the current one, like the AA algorithm. On each iteration, as the temperature drops, output sample becomes more deterministic and this encourages the model to only accept candidates that are better than the current one, like the GREEDY algorithm. In this way, SA combines the strengths of both alternative search procedures. The pseudocode for the SA algorithm can be found in Algorithm 1.

5 Experimental Setup

Here, we describe the setup for experiments related to implement/evaluate error pinpoint feedback model and implement/evaluate the proposed refinement and iterative refinement procedures.

5.1 Error Pinpoint Model Implementation and Evaluation

We leverage the MQM, ASQA and topic summarization datasets to train and meta-evaluate our error pinpoint model. The model was initialized with PaLM (Bison) LLM and was trained separately for each language pair and each task using WMT'21 MQM data for Zh−En (17,185 examples) (Freitag et al., 2021c), WMT'20 + WMT'21 MQM data for En−De (35,340 examples) (Freitag et al., 2022b), 2853 annotated ASQA examples (Wu et al., 2023) and 17,872 annotated topical summarization examples (Saunders et al., 2022). We use batch size 32, drop out rate 0.1, 500 warm up steps and learning rate $1e-4$ for all languages and tasks. We set maximum prefix length to be 2048 and maximum decoding step to be 512. Checkpoint selection was done by selecting the best Pearson correlation on four separate held-out sets, each comprising 500, 500, 500 and 2000 samples respectively. Each set corresponds to Zh-En translation, En-De translation, long form QA and topical summarization. For the reproducing purpose, we perform greedy decoding for the fine-grained feedback generation. We meta-evaluate the error pinpoint model by calculating Pearson correlation and pairwise accuracy between its score and ground-truth human ratings. We evaluate pinpointed error span using character-level precision/recall/F$_1$ scores (Blain et al., 2023).

Algorithm 1: SA for Iterative Refinement

```
Input: Input prompt $x$, Feedback model $F$, Base model $M$
Initialize: $y_0 \leftarrow greedy\_decode(M(x)), T_0, n$ # Initialize candidate, temperature, constant
for $i = 0..n$ do
    $f_i \leftarrow F(x, y_i)$ # generate feedback for the current candidate proposal
    $c_i \leftarrow Sampling(M(x, y_i, f_i))$ # Sample next candidate based on prior one and feedback
    $p_{acc} \leftarrow \min(1, e^{\frac{s(F(c_i))-s(F(y_i))}{n*T_i}})$
    if Accept then
        $y_{i+1} \leftarrow c_i$
    else
        $y_{i+1} \leftarrow y_i$
    $T_{i+1} = max(T_i - c * T_i, 0)$ # update temperature for the next iteration
Output: Sampled sequence $y_n$ with $n$ iterations
```

We meta-evaluate the error pinpoint model by calculating the correlation between its scores and ground-truth human MQM scores on the WMT'22 English-German and Chinese-English datasets, two benchmark datasets for meta-evaluating metrics. We calculate a segment score by summing the scores corresponding to the MQM error severity weights that are predicted by our error pinpoint model: 5 for major errors and 1 for minor errors. We report Pearson and pairwise accuracy with tie calibration (Deutsch et al., 2023) at the segment-level and compare to two state-of-the-art reference-free evaluation metrics, COMETKiwi-QE (Rei et al., 2022) and BLEURT-QE, a reference-free version of BLEURT (Sellam et al., 2020) that we trained ourselves on the same data used by COMETKiwi-QE.

To evaluate the actual spans produced by our feedback model, we adopt the character-level precision/recall/F_1 that was used by the WMT'23 QE Shared Task.[1] The evaluation treats each translation character as a classification problem and micro-averages the results. We compare our model to AutoMQM (Fernandes et al., 2023) and XCOMET (Guerreiro et al., 2023) on the news subset of the WMT'22 MQM dataset because XCOMET uses the remainder of WMT'22 for training (the results on the full dataset are available in Appendix B.

5.2 Refinement Implementation and Evaluation

Datasets & Evaluation Metrics. We evaluate the quality of the text generation produced by our refinement model and search algorithms on the WMT 22 and 23 English-German, Chinese-English (Kocmi et al., 2022), ASQA (Stelmakh et al., 2022) and topic summarization (Saunders et al., 2022) testing set. Each consists of 2037, 557, 1875, 1976, 948 and 284 samples respectively. The translations are automatically evaluated using MetricX (Freitag et al., 2022b), a state-of-the-art reference-based evaluation metric for MT. ASQA and summarization are evaluated by ROUGE-L (Lin, 2004).

Baseline Feedback Models. We experiment with different baseline forms of feedback for the generated output: 1) IMPROVE: The refinement model is always prompted to improve the translation without being provided any feedback. 2) SCORE-QE: The refinement model is provided the score from our error pinpoint model and prompted to improve the output. 3) BINARY-QE: The refinement model is prompted to improve the output given that if our error pinpoint model spots errors. 4) BLEURT-SCORE-QE: The refinement model is provided the score from the BLEURT-QE metric and prompted to improve the output. 5) BLEURT-BINARY-QE: The refinement model is prompted to improve the output given that the BLEURT-QE score for the output is below a hyperparameter threshold. The BLEURT feedback models are only available for the MT task. The prompt used for the refinement model varies based on the type of feedback. See Appendix Table 9 for the specific prompts that were used.

Generation and Refinement Models. The majority of our experimentation uses the PaLM-2 (Bison) LLM (Anil et al., 2023) for both initial translation generation as well as the refinement model. In each case, the LLM was 0-shot prompted for the task. We also experimented with alternative generation models to understand whether the feedback and refinement models could improve their translations, too. In particular, we used translations from the systems submitted to the WMT'22 General Machine Translation Task (Kocmi et al., 2022).

Baseline Generation Model. We compare the outputs from our proposed refinement models to that of 0-shot prompted PaLM-2. This model serves as a comparable baseline and allows us to understand how incorporating feedback via the refinement model can improve the original generation quality.

Implementation Details. The threshold for determining whether or not an error exists for the BLEURT-BINARY-QE model was set to be 0.95 and 1 for Zh-En and En-De, respectively.[2] They were chosen using the held-out WMT'21 test set (Akhbardeh et al., 2021).

For the reproducing purpose, we conduct all single step refinement using greedy decoding. For iterative refinement, we use top-k sampling, with k=40. For the uphill and always accept algorithms, temperature was set to default value 0.8. For the SA search algorithm, the initial temperature was set to 0.8 and is reduced by 10% on each iteration. We experiment different normalization constants from 1 to 10 on our development set WMT21 and choose the best performed constant 4 during simulated annealing. For iterative improvement, we set the maximum number of iterations n to be 10.

6 Results

We explore several research questions in our experiments: 1) How well does our error pinpoint model align with human annotations of translation quality? 2) Does fine-grained feedback result in

---

[1] `https://wmt-qe-task.github.io/`

[2] The BLEURT-QE scores are mostly between 0 and 1, but high-quality translations often receive a score > 1.

Metric	Zh-En		En-De	
	Acc.	r	**Acc.**	r
COMETKiwi-QE	0.516	0.509	0.583	**0.432**
BLEURT-QE	0.523	0.385	0.591	0.392
Error Pinpoint Model	**0.535**	**0.516**	**0.601**	0.394

Table 1: Segment-level accuracy (after performing tie calibration) and Pearson's r of our error span detection model compared to other reference-free evaluation metrics on the WMT'22 zh-en and en-de datasets.

Metric	En-De			Zh-En		
	P	**R**	**F$_1$**	**P**	**R**	**F$_1$**
AutoMQM (Bison)	0.05	0.58	0.09	0.10	0.17	0.13
XCOMET-XXL	0.24	0.38	0.29	0.15	0.57	0.24
Error Pinpoint Model	**0.28**	0.21	0.24	**0.30**	0.31	**0.30**

Table 2: Character-level precision/recall/F$_1$ of different error span tagging models (XCOMET-XXL is a reference-based metric and AutoMQM and error pinpoint are reference-free metrics). Our error pinpoint model has the highest precision compared to others, even with reference-based XCOMET. This implies that our predicted error spans are most reliable.

better downstream translations than more coarse feedback? 3) Can the feedback and refinement models be used to improve translations generated by unrelated text generation models? 4) Does the iterative refinement improve the generated translation quality?

6.1 Meta-Evaluating the Pinpoint Model

Table 1 contains the segment-level meta-evaluation results for our error pinpoint model, BLEURT-QE, and COMET-QE. In all but one evaluation setting, our feedback model has the best results compared to the strong baseline metrics. Therefore, we conclude that the feedback model is a state-of-the-art evaluation metric and is a high-enough quality to be used in the rest of our experiments.

Table 2 contains the automatic evaluation of the predicted spans. Among the metrics, our feedback model achieves the highest Character-level precision on both language pairs and the best Character-level F$_1$ on Chinese-English, making it a suitable candidate for identifying errors that should be corrected during the refinement step of our pipeline.

We meta-evaluate our error pinpoint model by comparing the gap in downstream translation quality when human-annotated error spans are used. This is to measure the effectiveness of our feedback model in guiding the refinement. We can compare the performance improvements achieved in this way (i.e., with a professional annotator's guidance) to those achieved with our feedback model's guidance (see Human vs. Inst-QE). What we find is that the performance of refinement with the feedback model is competitive, achieving an average improvement of 2.2 MetricX in En-De and 2.8 MetricX in Zh-En, with the scores on average a mere 0.2 and 0.3 behind those achieved with oracle human feedback for En-De and Zh-En, respectively. This discovery validates the effectiveness of our automatic feedback in improving the quality of the base translation. You can find input output examples of error pinpoint model for each task at Appendix Table 10,11 and 12

6.2 Fine- vs. Coarse-grained Feedback

Table 3 compares the quality of the refined translations when different forms of a feedback are used plus the PaLM-2 0-shot baseline quality.

Inadequate feedback could deteriorate the generation. While always prompting the refinement model to improve (IMPROVE) exhibits better translation performance for WMT'22 and WMT'23 when focusing on Zh−En, it results in a significant decline in translation quality for En-De. This highlights the instability of the direct prompting approach. Similar patterns are observed when examining using only scalar feedback scores from BLEURT-SCORE-QE and only refining translations when the metric predicts there is an error (BLEURT-BINARY-QE). We observe steady performance improvements by adding more detailed feedback at translation, long form question answering and Topical summarization. We argue that the lack of detailed error analysis increases the task difficulty and can't fully elicit LLM's refinement ability.

By contrast, fine-grained feedback from our error pinpoint model delivers significant and consistent improvements: Using our fine-grained feedback model with a single iteration consistently enhances the quality of the base translation in both Zh−En and En−De across all four testing sets and achieves the highest performance at ASQA and topic summarization.

Examining Generations with Errors Many of the original outputs from our PaLM-2 generation model are already error free according to our error pinpoint model. In such cases, no refinement is done and the result does not change, so

	MT22 Zh−En	MT23 Zh−En	MT22 En−De	MT23 En−De	ASQA	Topical Summ
Baseline	Metric-X	Metric-X	Metric-X	Metric-X	ROUGE-L	ROUGE-L
PALM-2 0-SHOT	75.3	73.8	83.1	78.3	17.6	28.7
Feedback Models						
IMPROVE	75.6	74.0	78.9	77.8	19.2	28.8
BLEURT-SCORE-QE	75.6	74.1	80.0	77.8	-	-
BLEURT-BINARY-QE	**75.9**	74.1	82.3	78.9	-	-
SCORE-QE	75.6	74.0	83.2	79.0	21.9	29.4
BINARY-QE	75.7	74.0	83.3	79.1	21.6	29.1
LLMREFINE	**75.9**	**74.2**	**83.5**	**79.3**	**26.1**	**30.5**

Table 3: We include three baseline models using coarse feedback: IMPROVE, BINARY-QE, SCORE-QE, BLEURT-BINARY-QE, BLEURT-SCORE-QE and LLMRefine, which is guided by our fine-grained error pinpoint model. All results are obtained through greedy decoding. In Appendix Table 14 and 15, we report additional results on open sourced LLMs and results of COMET scores to demonstrate the effectiveness of our method on open sourced models.

Model	WMT'22		WMT'23		ASQA	Summ
	Zh-En	En-De	Zh-En	En-De	QA	Summ
PaLM-2 0-shot	66.1	77.0	65.7	75.1	17.6	25.2
IMPROVE	67.7	77.1	67.5	75.9	19.2	25.5
SCORE-QE	67.5	77.2	67.2	76.3	21.9	26.4
BINARY-QE	67.6	77.9	67.3	76.5	21.6	26.0
LLMREFINE	**68.8**	**78.6**	**68.2**	**76.9**	**26.1**	**28.1**

Table 4: Fine-grained feedback vs coarse feedback on the examples that are marked as "errors" by our error pinpoint model. MetricX is used for all translation results and ROUGE-L is used for ASQA and summ.

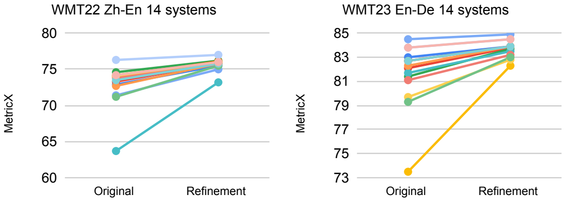

Figure 2: MetricX score improvement after one-step refinement of external systems' translations, evaluated on WMT22 Zh-En and En-De.

the magnitude of the MetricX or ROUGE-L improvement made by the refinement model is not well represented. Therefore, we additionally report results on the subset of the WMT'22, '23, ASQA and topical summarization datasets for which our feedback model detected an error [3].

From Table 4, we observe the improvements are much larger than on the entire dataset as a whole. For example, on WMT'22 zh-en, the improvement using our error pinpoint model is 2.7 MetricX points compared to 0.6 on the full dataset. This further demonstrates the effectiveness of our method. When the feedback model detects an error, the refinement model can make significant quality improvements.

6.3 Improving Other Source of Generation

We study the possibility of improving initial translations that come from systems other than PaLM-2, or even improving human translations. We conduct experiments on Zh-En and En-De for 14 submission systems and one set of human translations from WMT22. We performed one step refinement based on fine-grained feedback.

In Figure 2, our refinement pipeline consistently improves all of the WMT22 systems, with an average improvement of 2.2 MetricX in En−De and 2.8 MetricX in Zh−En. Notably, it is effective in improving the translation quality of systems that already demonstrated better performance than the PaLM 2 zero-shot translation.

Although the human translations are high-quality, they still contain errors as marked by MQM raters (Freitag et al., 2022b), therefore, there is room for improvement. Indeed, we find that our single-step refinement manages to improve even those by as much as 0.8 MetricX in the Zh-En task, and 0.7 MetricX in En-De.

To further analyze the granularity of fine-grained feedback, we conducted an ablation study on 10647 system outputs for WMT22 Zh−En and 6441 system outputs for WMT22 En−De, all of which were flagged as containing errors by our feedback model. Specifically, we examined the additive effects of each component (error location, severity, error type) and their contribution to the overall performance. Figure 3 shows that fine-grained feedback significantly improves error correction rate compared to coarse feedback,

---

[3] This consists of 407/1875, 329/1976, 465/2037, 334/557, 937/948 and 166/284 on the WMT'22 Zh-En, WMT'23 Zh-En, WMT'22 En-De, WMT'23 En-De, ASQA and topical summarization respectively

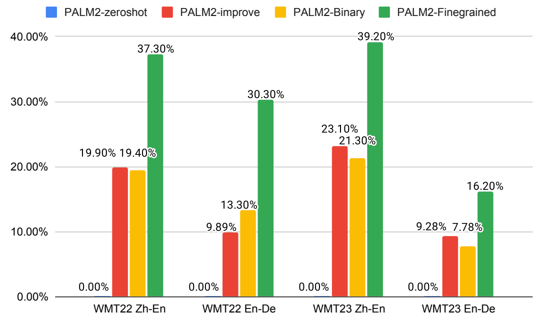

Figure 3: Fine-grained feedback improves the percentage of the corrections.

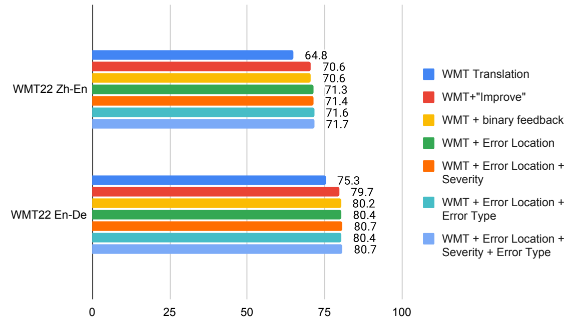

Figure 4: Fine-grained feedback improves the refinement performance

with a 17% increase for Zh-En and 13% for En-De translations, as measured by our error pinpoint model. In Figure 4, we observed that providing prompt with error location information significantly improved performance for WMT22 Zh−En, resulting in a MetricX improvement of 0.7 compared to only mentioning sentences containing errors. Additionally, severity labels and error types each had their own unique additive effects on the final performance. Finally, when all fine-grained feedback, including error type, location, and severity label, were combined, the joint feedback approach achieved the highest improvements.

6.4 Iterative Refinement

Figure 5 contains the results from running the various proposed refinement algorithms for up to 10 iterations. We demonstrate that Always Accept and Greedy Uphill each outperforms another in different test sets due to a trade-off between search space and error feedback. Overall, Simulated Annealing performs best in multi-step refinements. The figure shows that all three algorithms can result in further performance improvements on top of the initial output. Notably, we observe that always accepting the output (AA) demonstrates rapid convergence to the maximum, typically requiring only around 1 or 2 iterations. However, it can demonstrate instability of performance (See the fluctuation of the performance in the right figure) as they are lack of a quality selection process. In contrast, the uphill and simulated annealing techniques yield additional performance improvements over more iterations. We also include detailed iterative results with all tasks for first and fifth iteration at Appendix Table B.

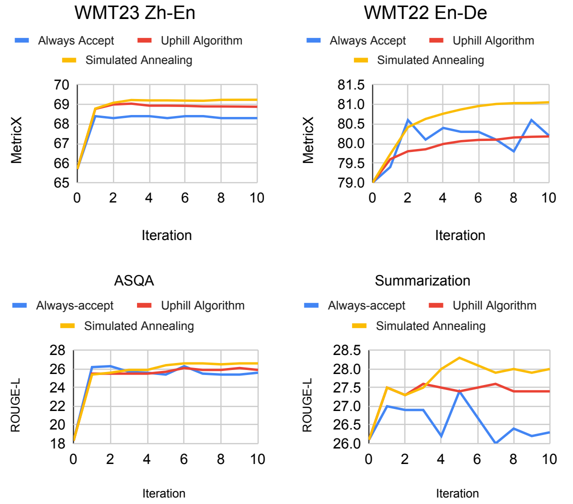

Figure 5: We conducted iterative experiments on WMT23 Zh-En and WMT22 for En-De, ASQA and topical summarization with always accept, greedy uphill and simulated annealing algorithms and report MetricX and ROUGE-L score.

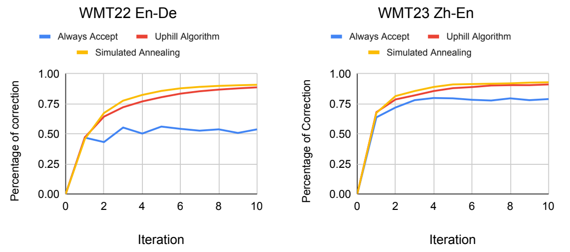

Figure 6: We conducted iterative experiments on WMT22 En-De and WMT23 Zh-En with Always Accept, Uphill and Simulated annealing algorithms and report correction rate of error pinpoint.

Simulated Annealing finds better candidates. In Figure 5 and 6, we present a comparison of three search algorithms on WMT22 En−De and WMT23 Zh−En, focusing on their performance in terms of MetricX/ROUGE-L and correction rate improvements (identified by our error pinpoint

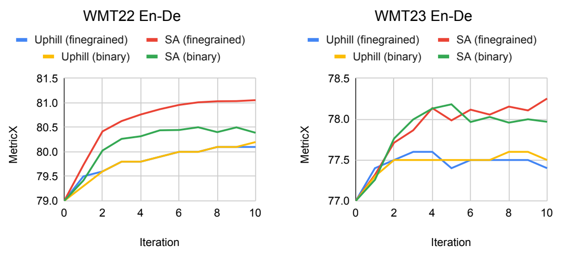

Figure 7: We study whether finegrained feedback can find better candidate generation compared to binary feedback. We conducted experiment on WMT22 and WMT23 at En-De with uphill and simulated annealing and report MetricX.

model). Our observations indicate that during the first iteration, simulated annealing may identify samples that achieve lower MetricX scores and corrects a smaller number of examples compared to uphill algorithm. However, owing to the diverse candidate proposals generated by SA under the measure of performance improvements, by the second to forth iteration, it already identifies samples that achieve higher MetricX scores. The performance gap between the three algorithms widens over the subsequent four or five iterations, ultimately resulting in a superior candidate proposal at the end of the iterations. We provide a concrete case study example in Appendix Table 7. In contrast to always accept, although with full search space, it could occasionally optimize MetricX on WMT22 En−De or ASQA. It can not fully optimize error correction rate without a quality selection process. On average, simulated annealing improves the uphill algorithm by 0.5 MetricX on Zh−En, 0.9 on En−De and by 0.7 ROUGE-L on ASQA and 0.9 ROUGE-L on topical summarization.

In Figure 7, we empirically show that simulated annealing can boost the performance for different types of feedback (binary and fine-grained). Specifically, we show that simulated annealing with both feedback can significantly improve the proposal quality for their counterparts under uphill algorithm. Furthermore, we demonstrate that simulated annealing with fine-grained feedback can achieve the best MetricX score in additional iterations.

6.5 Human Evaluation Results

We conduct head-to-head human evaluation on WMT22 En-De with the samples that marked as errors by our feedback model (465/2037). Professional bilingual annotators were shown the source sentence and asked to rate the quality of test translation against base translation with either win, lose or neutral options. We use the win/lose ratio of test translation against base translation as the final metric. If win/lose ratio is greater than 1, then test translation outperforms base translation. In Table 5, we compared single step fine-grained refinement against all coarse feedback baselines. We found that fine-grained feedback outperforms all other source of feedback, as win/lose are all above 1. Moreover, we compare simulated annealing (SA) baseline against always-accept (AA) and greedy baseline at 5th iteration. In Table 6, we find win/lose ratios are 1.56 and 1.38 respectively, indicating SA has superior performance against AA and greedy.

LLMRefine vs	**Win**	**Neutral**	**Lose**	Win lose ratio
0-SHOT	38%	46%	16%	2.34
IMPROVE	39%	45%	16%	2.44
BLEURT-SCORE-QE	41%	44%	15%	2.79
BLEURT-BINARY-QE	33%	48%	19%	1.76
SCORE-QE	33%	40%	27%	1.23
BINARY-QE	34%	48%	18%	1.84

Table 5: We conduct head-to-head human evaluation on LLMRefine against all baselines for single step refinement at WMT22 En-De. We report percentages of win, neutral and lose and win/lose ratio in the table.

Simulated Annealing vs	**Win**	**Neutral**	**Lose**	Win lose ratio
ALWAYS-ACCEPT	38%	38%	24%	1.56
GREEDY UPHILL	31%	47%	22%	1.38

Table 6: We conduct head-to-head human evaluation on our simulated annealing based algorithm against greedy at WMT22 En-De. We report percentages of win, neutral and lose and win/lose ratio in the table.

7 Conclusion

In this work, we proposed LLMRefine for incorporating a fine-grained error pinpoint into a text generation pipeline via refinement-feedback model loop. We empirically demonstrated that our fine-grained error pinpoint model with simulated annealing achieves superior performance compared to baseline feedback models and other search algorithms across three text generation tasks. Lastly, our experimental findings are further solidified by the human evaluation study. Humans demonstrate a significant preference for the output of LLMRefine over the baseline outputs.

8 Limitations

In this work, we demonstrate that our error pinpoint can achieve comparable Pearson correlation and segment-level accuracy to source based SOTA metrics in Machine translation at WMT22 En-De and Zh-En. Despite the great performance, we also demonstrate the trade-off between precision and recall at Table 2. Although achieving higher precision score compared to baseline metrics, our error pinpoint has lower recall. Future work can consider a better pipeline to boost the recall of our error pinpoint while maintaining a reasonably high precision score. Ultimately, this may significantly improve the quality of corrections after iterative refinement.

While LLMRefine in theory can be applied to landscape of instruction-fine-tuned large language models, it would be noteworthy to mention that the efficiency may differ when applied with models that lack instruction following capability. Training a large language model with instruction, feedback following ability can be great a future direction to mitigate this issue.

9 Ethical Statement

All the training data of our error pinpoint model is publicly available. We ascertain that the feedback data that is annotated by human labors do not contain risk or toxic content. We used an internal, proprietary tool to collect human evaluation data. The annotators were compensated fairly and did not have to disclose any personal information during the annotation process. All of the test sets used in this study are publicly available, and annotators were allowed to label sensitive information if necessary. The annotators are fully aware that the data which is collected from them will be used for research purposes. Each pair of translations is annotated by one rater. There are six annotators participated for each test vs base system comparisons.

A Feedback Scoring Scheme

We adopted the same setting as human evaluation respect to each task. For machine translation and long form question answering, we adopt MQM human scoring scheme (Freitag et al., 2021a) by counting the total number of errors and assigning the weight penalties to the individual error. We use the same severity level (major and minor) and weight penalty as MQM, assigning major error as penalty 5 and minor error as penalty 1. For the sentence without errors, we assign a score of 0. Similar to MQM scheme (Freitag et al., 2021a), for sentence contains more than five major errors, they all assigned to -25. The score range is between 0 to -25. For topical summarization, we adopt the same severity levels as Saunders et al. (2022)'s annotations. In particular, they contain four levels of severity: critical, major, medium and minor. Each response will only be assigned with one error type. Therefore, we score each sentence with 1 to 5 rating, with 5 corresponds to no-error and 1 corresponds to one critical error. We use those scores and human ratings to compute Pearson correlation and pairwise accuracy for meta-evaluating the feedback model. To ensure fair comparisons at our SCORE-QE baseline, we normalize different score ranges into 0 to 100. We include scoring examples of error pinpoint model at Table 10, 11 and 12.

B Additional Results

Table 13 contains the character-level evaluation of the span tagging models, AutoMQM and our error detection feedback model, on the full WMT'22 dataset. XCOMET is omitted because the non-news sections of the dataset were used for training and is thus not a fair comparison.

Source: 一个餐等了一个半小时。
Reference: I've waited one and a half hours for one meal.
Output: A meal had been waiting for an hour and a half.

1st candidate generation: A meal had been waiting for an hour and a half.
Feedback: Error type: mistranslation Major/minor: major Error location: A meal had been waiting.
Our Error Pinpoint Model: -5
BLEURT: 0.738

2nd candidate generation: "A meal had been waiting for an hour and a half." is a major mistranslation error.The correct translation should be: "The meal had been waiting an hour and a half."
Feedback: Error type: mistranslation Major/minor: major Error location: A meal had been waiting for an hour and a half.
Our Error Pinpoint Model: -5
BLEURT: 0.692

3rd candidate generation: The meal had been waiting for an hour and a half
Feedback: Error type: mistranslation Major/minor: major Error location: The meal had been waiting
Our Error Pinpoint Model: -5
BLEURT: 0.781

4th candidate generation: A meal waited an hour and a half.
Feedback: Error type: mistranslation Major/minor: major Error location: A meal waited
Our Error Pinpoint Model: -5
BLEURT: 0.703

5th candidate generation: A meal took an hour and a half to arrive.
Feedback: Error type: no-error Major/minor: no-error Error location: None
Our Error Pinpoint Model: 0
BLEURT: 0.876

Table 7: For uphill algorithm, pipeline is stuck at generating "A meal had been waiting for an hour and a half." with BLEURT score 0.738 for five iterations. For the simulated annealing, despite the model's ability at generating candidates with slightly worse BLEURT score. The pipeline yield global optimum solution at the fifth iteration.

"You are evaluating answer based on the passage. Passage: Drag Me to Hell Her boss advises her to demonstrate that she can make tough decisions. An elderly woman, Sylvia Ganush, asks for a third extension on her mortgage payment, and despite Ganushs financial and medical problems, Christine denies her an extension to prove herself. Ganush begs Christine not to repossess her house. Ganush is taken away, accusing Christine of shaming her and swears revenge. In the parking garage Christine is ambushed by Ganush, who is hiding in the back seat. Ganush rips a button from Christines coat and intones words in another language. Later, Christine and her boyfriend Clay meet fortune teller Rham Jas, who tells Christine that she is being haunted by a dark spirit, likely the result of a curse. At home, Christine is attacked by the entity and has nightmares about Ganush. At work the next day, she hallucinates and bleeds profusely from her nose. She leaves the office, and, amid the general panic, Stu steals a file from Christines desk. Christine goes to beg Ganush for forgiveness but discovers that Ganush has died. Christine returns to Jas, who explains that as long as Christine is the owner of an accursed object (the button), she will be haunted by a powerful demon called the Lamia. Drag Me to Hell Drag Me to HellDrag Me to Hell is a 2009 American supernatural horror film co-written and directed by Sam Raimi. The plot, written with his older brother Ivan, focuses on a loan officer, who, because she has to prove to her boss that she can make the hard decisions, chooses not to extend an elderly womans mortgage. In retaliation, the woman places a curse on the loan officer that, after three days of escalating torment, will plunge her into the depths of Hell to burn for eternity. Raimi wrote Drag Me to Hell with his brother, Ivan, before working on the Spider-Man trilogy. The film premiered at the Cannes Film Festival and was released to critical acclaim. It was also a box office success, grossing over $90 million worldwide. Drag Me to Hell won the award for Best Horror Film at the 2009 Scream Awards and the 2010 Saturn Awards. In 1969, in Pasadena, a couple seeks the aid of the medium Shaun San Dena, saying their son has been hearing evil spirits voices after stealing a silver necklace from a gypsy wagon. San Dena aids the family by carrying out a séance, but they are attacked by an unseen force that drags the boy to Hell. In present-day Los Angeles, bank loan officer Christine is in competition for a promotion with Stu Rubin. Pasadena, California Pasadena, CaliforniaPasadena is a city in Los Angeles County, California, United States, located 10 miles (16 kilometers) northeast of Downtown Los Angeles. The estimated population of Pasadena was 142,647, in 2017, making it the 183rd-largest city in the United States. Pasadena is the ninth-largest city in Los Angeles County. Pasadena was incorporated on June 19, 1886, becoming one of the first cities to be incorporated in what is now Los Angeles County, following the city of Los Angeles (April 4, 1850). It is one of the primary cultural centers of the San Gabriel Valley. The city is known for hosting the annual Rose Bowl football game and Tournament of Roses Parade. In addition, Pasadena is also home to many scientific and cultural institutions, including Caltech, Pasadena City College, Fuller Theological Seminary, ArtCenter College of Design, the Pasadena Playhouse, the Ambassador Auditorium, the Norton Simon Museum, and the USC Pacific Asia Museum. The original inhabitants of Pasadena (a Chippewa word meaning Crown of the Valley) and surrounding areas were members of the Native American Hahamog-na tribe, a branch of the Tongva Nation. They spoke the Tongva language (part of the Uto-Aztecan languages group) and had lived in the Los Angeles Basin for thousands of years. "You are evaluating a summarization based on question and passage. Passage: It was a cold, dark night…I lay in the corner of the street, my head in a puddle, a smell of what can only be described as death circling my very presence. I had lost count of how many days it had been, of how many faces I've seen pass me, of how many feet I've watched shuffle aside, trying their hardest to avoid my very existence. Of how many eyes had looked at me, and burnt hatred so deep it became almost intolerable. Sheer disgust, seeping out of the breath of everyone who passed. That is what my life had become. Ever since that one day. When everything I thought I knew was ripped apart in front of me.It was the youngest who took me in. He seemed kind, welcomed me. One of those people that deep down you can tell had a good heart even if they hid it beneath a rough, silent exterior. I lived in his room free to do what I felt, unless the others were around, the older ones. When their voices carried through the door, I was hidden under the bed, its so our friendship will be ours alone I would convince myself, that he wanted me to be all his. But I suppose that should have been the first warning sign. Can a place truly be called your home if you have to hide from its very inhabitants? But sadly, I was naive… no, I chose to ignore it, I was too obsessed, too caught up by this newfound friendship to ever even consider the truth. I thought everything was perfect. Then it happened. It was late at night, the door slammed behind him as the boy tumbled in. Raised voices instantly burnt through the very walls that surrounded me, through the doors, through everything. I had heard anger in those voices before, the times when I hid, but nothing like this, this was… new. The door crashed open, the boy collapsing to the ground. Eyes bloodshot, his mouth lined with dry, cracked vomit, his shirt, blooded, torn and stained. A sight that I wished I would never see again. As he hit the ground, he looked up at me, but there was no affection any more, just pure emptiness. I heard the voices come closer. There was no time to hide, no time to be hidden. Voices entered the room; eyes were cast down the decrepit shell lying on the floor, then to me. Hatred. Rough hands were placed on me, words crying out that I was to blame, that somehow, this was my entire fault. My protests, my cries of defense, all fell on deaf ears. No matter how much I pleaded, no matter how many times I cried out to them that there was more to me, more I could give to them, it was all to no avail. I was tossed out on the street, my once home fading in my eyesight as I tumbled, seemingly forever, sinking in to my own personal abyss. An icy wind blew threw me, bringing me back from the horrid memory. I rolled onto my side, no longer sure if it was by my own personal doing or if I simply lacked the strength to offer any resistance. This is it, I thought to myself. This is how it is going to end. All the things I could have done, the places I could have seen, and now this will become my final resting place, a blotch in the street, surrounded by the ear wrecking sound of traffic and drunks. Some rest indeed. Through all the noise, I heard footsteps walking towards me. No doubt to impose some form of abuse towards me in my final moments I had thought. But no, a hand rested on my body. Warmth that I had not felt since… the boy? I turned around and stared up, locking eyes with an unfamiliar face. It was irrelevant. This man has picked me up in my time of need. He had saved me. took me to some form of haven for my kind. After I adjusted to the contrast of light, I looked around and saw countless amounts of those in the same position as me. It was amazing. I was no longer a freak. No longer an outcast, I was amongst my own kind at last. The time I spent there was the happiest of my life. On occasions, members of our private little community would be taken away by strangers from the outside, I had lost a few good friends through that, but even then the kind man would always bring in new members, new friends to be made, stories to be heard, connections to be formed. I should have learnt. All good things must come to a pass. The horrendous noise sounded, the noise that sounded the arrival of a stranger. As usual, our host welcomed the man with open arms, allowing him to take his pick of who he wanted. The stranger cast his eyes along the crowd, passing by everyone I knew, his gaze nonchalant to all. All that is, except me. He looked straight at me, and stopped. Eyes bloodshot, his mouth lined with dry, cracked vomit, his shirt, blooded, torn and stained. The memory flooded through me. It was then I realized just how blind I had been. The night that changed it all, it had not been emptiness in the boy's eyes. It had been lust! And it was lust again the bore its way inside my soul. The stranger had chosen. I wouldn't be saying goodbye to a friend this time. I would be saying goodbye to everything. The door opened to his building. And a building it would always be, never a home. No place with so much vile hatred seeping out of every crack in the wall, so much murk and gloom pouring out of every shadow, could ever be called a home. He sat in front of me, breathing his horrid breath over my neck, running his fingers down my body, inhaling my breath. I knew straight away, this was never going to end well. He lifted me, I felt weightless and powerless under his grasp. He put his lips around me, and it felt like he drank the very life force from my body. His brown, crusted teeth scraping against me, as his course tongue brought him to the satisfaction he had desired for so long. After what felt like an eternity in the lowest ring of hell, he was done. The door was opened, and for the second time in my life, I was cast out. This time however, there was no remorse. There was nothing. I was resound to my fate.And that's how I arrived here, lying once again in a gutter. This time, I know there will be no retribution. I can see my life flowing from my body. It's coming to an end. If only things had been different. If only we really did have medicinal qualities, then maybe, just maybe, this wouldn't be the end of just one more bottle of Buckfast. Question: Answer the following question based on the above passage:Summarize what, according to the narrator, led to their being in a gutter. Answer: The narrator was deeply connected to the host, a boy who took the narrator in. After one night out, the narrator came back with dried bloody vomit trailing down his shirt, covered in blood, and the next day the host launched into a tirade of words against the narrator and tore the narrator out of its home. Reduced to a vague memory now, the narrator would recall the chilling last moment they had together. It was a night of deep lust that stained their friendship through the lasting and eternal pains of betrayal and lust. Your Feedback:"

Output for error pinpoint model:
This response contains a major coherence error. The sentence is written in a confusing way. The narrator realizes the lust in the boy's eyes, and their last night is horrendous for it. Then, the narrator is cast out again.

Table 12: A topical summarization example prompt and output we used for our error pinpoint trained from from PALM2, where a summarization example is based on a particular question. According to our scoring scheme, one major error corresponds to 2, at 1 to 5 scale. The normalized score is 40 out of 100.

Noisy Multi-Label Text Classification via Instance-Label Pair Correction

Abstract

In noisy label learning, instance selection based on small-loss criteria has been proven to be highly effective. However, in the case of noisy multi-label text classification (NMLTC), the presence of noise is not limited to the *instance-level* but extends to the (instance-label) *pair-level*. This gives rise to two main challenges. (1) The loss information at the pair-level fails to capture the variations between instances. (2) There are two types of noise at the pair-level: false positives and false negatives. Identifying false negatives from a large pool of negative pairs presents an exceedingly difficult task. To tackle these issues, we propose a novel approach called instance-label pair correction (iLaCo), which aims to address the problem of noisy pair selection and correction in NMLTC tasks. Specifically, we first introduce a holistic selection metric that identifies noisy pairs by simultaneously considering global loss information and instance-specific ranking information. Secondly, we employ a filter guided by label correlation to focus exclusively on negative pairs with label relevance. This filter significantly reduces the difficulty of identifying false negatives. Experimental analysis indicates that our iLaCo framework effectively corrects noisy pairs in NMLTC datasets, leading to a significant improvement in model performance.

1 Introduction

Multi-label text classification (MLTC) aims to predict the most relevant labels for each text from a label set. In real applications, noise is inevitably present in the data of MLTC (Snow et al., 2008; Chen et al., 2023). It poses a significant challenge for machine learning models, particularly deep learning models (Frénay and Verleysen, 2014; Arazo et al., 2019). When dealing with learning from noisy labels (LNL), one effective approach to mitigate the impact of noisy data is to identify a clean subset through sample (instance) selection (Hu et al., 2023; Li et al., 2023). By removing data with noisy labels, we can reduce the influence of mislabeled data and improve the learning process. The small-loss criteria is a popular method (Han et al., 2018; Wei et al., 2020; Xia et al., 2022), assuming that samples with lower loss values are likely to be clean. This is based on the observation that deep networks initially learn simple patterns and later tend to overfit to the noisy patterns (Wei et al., 2022; Han et al., 2018; Northcutt et al., 2021).

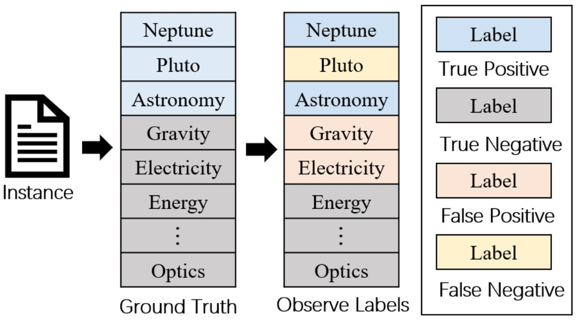

Figure 1: An example of noise in multi-label text classification.

However, what distinguishes noisy multi-label text classification (NMLTC) from typical LNL is that in NMLTC, noise occurs not at the *instance-level* but at the (instance-label) *pair-level*, as depicted in Figure 1. In this scenario, using the small-loss criterion for selection encounters two challenges. (1) The pair-level loss information is global and instance-independent, meaning it does not capture the distinctions between each individual instance. (2) NMLTC exhibits two types of noise: false positives (FP) and false negatives (FN). Specifically, due to the abundance of true negative (TN) pairs in NMLTC, it becomes challenging to identify the FN noise from the large pool of negative pairs.

To address these challenges, we propose a novel **i**nstance-**La**bel pa**i**r **Co**rrection (iLaCo) framework,

June 16-21, 2024

aiming to achieve pair selection and correction for noisy multi-label text classification tasks. The framework introduces three key components: holistic selection metric, negative pair filter, and co-correction.

We first designed a holistic selection metric (HSM) to assess the learning difficulty of instance-label pairs. Our HSM consists of both a loss-based metric and a rank-based metric. The loss-based metric captures the global learning difficulty of instance-label pair by considering the associated loss values. A lower loss indicates a lower learning difficulty for the corresponding instance-label pair. On the other hand, the rank-based metric reflects the instance-specific learning difficulty of instance-label pair. In MLTC, predictions rely heavily on the label rank, with lower ranks indicating better memorization of the instance-label pair by the model (Xiao et al., 2021). By incorporating the rank-based metric, we can prevent some instance-label pairs with high loss values but correctly predicted pairs from being classified as corrupted pairs. To ensure stability and consistency, we adopt a time-consistent approach (historical average) (Zhou et al., 2020; Xia et al., 2022), to reflect the learning difficulty of each instance-label pair throughout the entire training process.

To address the challenge posed by the abundance of negative pairs, as depicted in Figure 1, we first observe a strong label correlation between FN labels (i.e., Pluto) and true positive (TP) labels (i.e., Astronomy and Neptune) for the same instance. As a result, we adopt a filter guided by instance-specific label correlation, focusing on negative pairs that exhibit a certain level of label correlation with the positive pairs of each instance. By doing so, we significantly reduce the number of candidate negative pairs for each instance, thereby reducing the difficulty of identifying FN pairs within the negative pairs.

In the final stage, we perform noise estimation and label correction simultaneously for both positive and negative pairs. After obtaining the HSM for positive and negative pairs, we utilize a Gaussian mixture model (GMM) to estimate the noise rates. We then employ a pseudo-labeling approach that combines both soft and hard correction strategies for label correction. It is important to note that in multi-class tasks, after identifying noisy labels, the common practice is to utilize sample selection or sample weighting methods (Li et al., 2023; Hu et al., 2023). However, in the case of instance-label pairs being a binary classification problem, we can directly flip the labels to correct them.

Our contributions can be summarized into four key aspects: (1) We propose the instance-label pair correction (iLaCo) approach, which successfully applies the memorization effect to multi-label text classification for noise reduction. (2) We introduce a holistic selection metric (HSM) that combines the global information of the training process (loss) with the instance-specific information (rank). HSM provides a better reflection of the difficulty in memorizing instance-label pairs. (3) We devise a label correlation-based negative pair filter, which enhances the recognition of false negative pairs by removing most irrelevant true negative pairs through label correlation. (4) The superior performance of iLaCo is validated through extensive experiments on three benchmark datasets.

2 Method

The overall architecture of our model is illustrated in Figure 2. We first employ the standard architecture for multi-label text classification to train the model on the noisy dataset. Subsequently, based on the historical information obtained during the training process, we utilize our proposed iLaCo method to correct the labels and generate pseudo labels. Finally, we retrain the multi-label text classification model using the corrected pseudo labels to obtain the final model. The iLaCo framework consists of three components: the holistic selection metric (HSM), negative pair filter, and co-correction. We present more details of these components in the following sections.

2.1 Noisy Multi-Label Text Classification

In what follows, sets are in calligraphic letters (e.g., $\mathcal{A}$), matrices are in capital bold letters(e.g., $\mathbf{A}$), vectors are in lower-case bold letters (e.g., $\mathbf{a}$), and scalars are in capital or lower-case letters (e.g. A, a). For simplicity, let $[L] = \{1, ..., L\}$. Considering a noisy multi-label text classification (NMLTC) problem, the input of training stage includes N instances $\mathcal{P} = \{(\mathbf{x}_i, \tilde{\mathbf{y}}_i)\}_{i=1}^{N}$, each of which consists of an input vector $\mathbf{x}_i$ and several observed noisy labels $\tilde{\mathbf{y}}_i = (\tilde{Y}_{i,1}, \tilde{Y}_{i,2}, ..., \tilde{Y}_{i,L}) \in \{0,1\}^L$ related to the input. Here L is the total number of candidate labels. The goal of NMLTC is to learn a function f that maps the input instance $\mathbf{x}_i$ and a label l to a relevance score $\hat{Y}_{i,j} = f(\mathbf{x}_i, j)$. In the testing

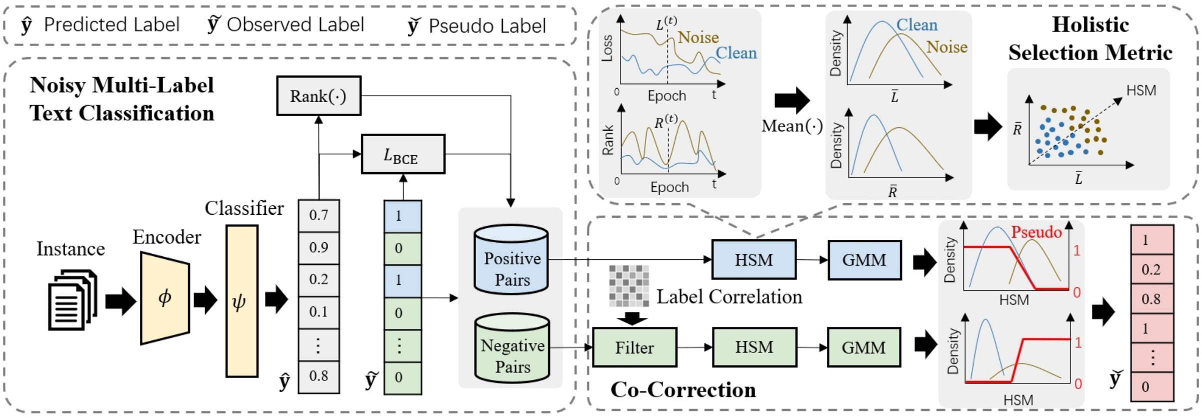

Figure 2: The overall framework of iLaCo.

stage, we aim to recommend the top-k labels with the highest relevance scores for a new instance.

We constructed the scoring function f by combining a text encoder ϕ and a multi-label classifier ψ. Following the approach of previous works (Ma et al., 2021; Xu et al., 2023b), we employed BiLSTM-based text encoders ϕ and adopted a multi-layer MLP as our multi-label classifier ψ. We then employed binary cross entropy (BCE) $L_{\text{BCE}} = \sum_{i=1}^{N}\sum_{l=1}^{L} L_{i,j}$ as the loss function, where

$$L_{i,j} = -(\tilde{Y}_{i,j}\log(\hat{Y}_{i,j}) + (1-\tilde{Y}_{i,j})\log(1-\hat{Y}_{i,j})). \tag{1}$$

The notation $L_{i,j}$ represents the loss value associated with the j-th label for the i-th instance. It can also be interpreted as the loss value corresponding to the instance-label pair with the index $\{i, j\}$.

2.2 Holistic Selection Metric Design

2.2.1 Beyond Small Loss Criteria

When learning with noisy labels (LNL), it is commonly observed that instances with clean labels typically have smaller loss values than those with noisy labels (Han et al., 2018; Northcutt et al., 2021). Such small-loss criteria have been widely adopted for selecting confident examples (Arazo et al., 2019; Wei et al., 2020; Xia et al., 2022). As illustrated in Figure 3 (a), this pattern is also evident in NMLTC. Hence, we can use the loss value $L_{i,j}$ in Equation 1 as a metric for identifying noise in instance-label pair.

However, relying solely on the loss value to reflect whether instance-label pair is well-memorized by the model is not comprehensive enough. This is because the loss and the optimization goal of MLTC are not entirely consistent (You et al., 2019). The final prediction in MLTC depends mainly on the ranking of the label $\hat{Y}_{i,j}$ within $\hat{\mathbf{y}}_i$. Therefore, even if the loss value $L_{i,j}$ is large, $\hat{Y}_{i,j}$ might still be a correct prediction. By introducing instance-specific label rank information, we can better distinguish between hard and noisy pairs For each instance $\mathbf{x}_i$ and its predicted label $\hat{\mathbf{y}}_i$, we can obtain the rank of each label using the rank function Rank(·):

$$\mathbf{r}_i = \text{Rank}(\hat{\mathbf{y}}_i), \tag{2}$$

where $\mathbf{r}_i = (R_{i,1}, R_{i,2}, ..., R_{i,L})$, and $R_{i,j}$ is the rank metric for $\hat{Y}_{i,j}$. As shown in Figure 3 (b), it is evident that rank-based metrics also possess noise identification capabilities. A smaller rank indicates that the label is more likely to be clean. Simultaneously, rank-based metrics that capture instance-specific information complement loss-based metrics that reflect global information, resulting in improved identification performance, as depicted in Figure 2 and Figure 3 (c).

2.2.2 Time Consistency

Let $L_{i,j}^{(t)}, i \in [N], j \in [L], t \in [T]$ denote the loss value corresponding to the j-th label of the i-th instance at the t-th epoch. $R_{i,j}^{(t)}$ represents the instance-specific rank value for the j-th label of the i-th instance at the t-th epoch. Calculating the selection metric directly based on the t-th epoch might lead to unstable results because both the loss values and ranking values exhibit large amplitudes during the optimization process(Zhou et al., 2020; Xia et al., 2022; Hu et al., 2022), as illustrated in Figure 2. Therefore, we mitigate the impact of large amplitudes by averaging over all epochs during the training process, yielding more stable selection metrics:

$$\bar{L}_{i,j} = \sum_{t=1}^{T} L_{i,j}^{(t)}, \bar{R}_{i,j} = \sum_{t=1}^{T} R_{i,j}^{(t)}. \tag{3}$$

To facilitate the integration of these two metrics, we perform min-max normalization on them (Hu et al., 2022), obtaining normalized results $\hat{L}_{i,j}$ and $\hat{R}_{i,j}$ respectively. The linear combination of both metrics results in a new holistic selection metric (HSM):

$$M_{i,j} = \alpha \cdot \hat{L}_{i,j} + (1-\alpha)\hat{R}_{i,j}. \tag{4}$$

The combination coefficient α plays a crucial role in determining the balance between the two metrics. By combining the advantages of both metrics, HSM not only provides a more comprehensive understanding of the model's behavior but also exhibits consistency in its performance. This consistency contributes to HSM's superior ability to identify noisy labels effectively (see Figure 3 (d)).

2.3 Co-Correction

Due to the characteristics of multi-label learning, there are two types of noise associated with each instance-label pair, namely false positive and false negative. Next, we will employ HSM to perform pair correction for both positive and negative noise.

2.3.1 Positive Pair Correction

Positive instance-label pair refers to the instance-label pair associated with labels for which the observed label is positive. First, we obtain the HSM set $\mathcal{M}^+$ corresponding to all positive instance-label pairs, i.e.,

$$\mathcal{M}^+ = \{M_{i,j} | \tilde{Y}_{i,j} = 1\}, \tag{5}$$

As illustrated in Figure 3 (d), its distribution roughly resembles a bimodal Gaussian mixture. Therefore, we adopt a two-component Gaussian mixture model (GMM) to model the bi-modal distribution (Arazo et al., 2019; Li et al., 2020) of true positive (TP) and false positive (FP) pairs. After training, we could obtain the probability of a pair being corrupted through the posterior probability of HSM distributions. Accordingly, the noise rate σ^+ is estimated as:

$$\sigma^+ = \mathbb{E}_{M_{i,j} \in \mathcal{M}^+}[p(\mu^+ | M_{i,j})], \tag{6}$$

where μ^+ is the Gaussian component with a larger mean, since noisy pairs have typically larger HSM values.

After obtaining the noise rate, we can proceed with pair correction based on the noise rate and the quantiles of $\mathcal{M}^+$. It is worth noting that, in multi-class tasks, after identifying a corrupted label, the usual approach involves sample selection or sample reweighting (Li et al., 2023; Hu et al., 2023). However, for each instance-label pair, as it is a binary classification problem, if the probability of being a TP pair is very low, it is highly likely to be a FP pair. Therefore, we can implement label correction by applying label flipping to obtain pseudo-labels:

$$\check{Y}_{i,j} = \begin{cases} 0 & M_{i,j} > Q_1, M_{i,j} \in \mathcal{M}^+ \\ \tilde{Y}_{i,j} & M_{i,j} \leq Q_1, M_{i,j} \in \mathcal{M}^+ \end{cases}, \tag{7}$$

where $Q_1 = \text{Quantile}(\mathcal{M}^+, 1-\sigma^+)$ denotes the $1-\sigma^+$ quantile of the set $\mathcal{M}^+$. However, since noisy labels and clean labels are challenging to distinguish near the decision boundary (as shown in Figure 2 and Figure 3 (d)), compared to hard pseudo-labels, we have employed a soft-hard combined pseudo-label strategy for label correction. For high-confidence noisy pairs (strong discrimination by HSM), we use a hard pseudo-label for correction. However, for low-confidence noisy pairs, as they are prone to confusion with clean pairs, we adopt a soft pseudo-label for correction. The specific approach is as follows:

$$\check{Y}_{i,j} = \begin{cases} 0 & M_{i,j} > Q_2, M_{i,j} \in \mathcal{M}^+ \\ \frac{M_{i,j}-Q_1}{Q_1-Q_2} & Q_1 < M_{i,j} \leq Q_2, M_{i,j} \in \mathcal{M}^+ \\ \tilde{Y}_{i,j} & M_{i,j} \leq Q_1, M_{i,j} \in \mathcal{M}^+ \end{cases} \tag{8}$$

where, $Q_1 = \text{Quantile}(\mathcal{M}^+, 1-\sigma^+), Q_2 = \text{Quantile}(\mathcal{M}^+, 1-\frac{1}{2}\sigma^+)$. The corrected pseudo-label $\check{Y}_{i,j}$ under positive pairs is obtained. The piecewise function is shown in Figure 2.

2.3.2 Negative Pair Filter and Correction

We also need to collect the corresponding HSM for negative pairs in the observed labels, i.e.,

$$\mathcal{M}^- = \{M_{i,j} | \tilde{Y}_{i,j} = 0\}. \tag{9}$$

However, in practice, this step is intractable. Firstly, there is an excessive number of negative pairs in multi-label learning, significantly increasing the storage burden. More importantly, due to the abundance of TN pairs, the occurrence of FN pairs within them is relatively rare. In such cases, the TN pairs tend to excessively dominate the negative pairs, making it nearly impossible to identify the

FN pairs, as illustrated in Figure 4 (a). Fortunately, as depicted in Figure 1, it is observed that the FN labels are correlated with the positive labels of the current instance. Meanwhile, TN labels mostly lack this kind of label dependency.

Therefore, we adopt a method based on label correlation to filter the massive amount of negative pairs, retaining only those negative labels that have a certain level of label correlation with the current positive labels as our candidate set. i.e.,

$$\mathcal{M}^{-} = \{M_{i,j} | \tilde{Y}_{i,j} = 0, D_{i,j} > \beta\}, \tag{10}$$

$$D_{i,j} = \sum_{k=1}^{L} \tilde{Y}_{i,k} \cdot C_{k,j}, \tag{11}$$

where $D_{i,j}$ represents the correlation coefficient between the j-th label of the i-th sample and all positive labels of the i-th sample, and β is the threshold. Meanwhile, $C_{k,j}$ denotes the label correlation between the k-th and j-th labels. The label correlation $C_{k,j}$ can be obtained using various methods such as label semantic similarity (Zhang et al., 2021) or the label co-occurrence matrix (Su et al., 2022). In our approach, to better align semantics with the characteristics of the dataset, we opt for the latter method to compute the label correlation matrix $\mathbf{C}$. Each element $C_{k,j}$ of $\mathbf{C}$ is defined as:

$$C_{k,j} = \frac{c_{k,j}}{\sum_{b=1}^{L} c_{k,b}}, k, j \in [L]. \tag{12}$$

$$c_{k,j} = \begin{cases} 0, k = j \\ \sum_{i=1}^{N} \tilde{Y}_{i,k} \cdot \tilde{Y}_{i,j}, k \neq j \end{cases} \tag{13}$$

Therefore, we have obtained a set $\mathcal{M}^{-}$ composed of high-quality negative pairs. Subsequently, based on the HSM set $\mathcal{M}^{-}$ corresponding to negative pairs, we also estimate the noise rate σ^{-} using GMM (similar to Equation 6). After obtaining the noise rate σ^{-}, we also apply the pseudo-labeling strategy:

$$\check{Y}_{i,j} = \begin{cases} 1 & M_{i,j} > Q_4, M_{i,j} \in \mathcal{M}^{-} \\ \frac{M_{i,j} - Q_3}{Q_4 - Q_3} & Q_3 < M_{i,j} \leq Q_4, M_{i,j} \in \mathcal{M}^{-} \\ \tilde{Y}_{i,j} & M_{i,j} \leq Q_3, M_{i,j} \in \mathcal{M}^{-} \end{cases} \tag{14}$$

where, $Q_3 = \text{Quantile}(\mathcal{M}^{-}, 1 - \sigma^{-}), Q_4 = \text{Quantile}(\mathcal{M}^{-}, 1 - \frac{1}{2}\sigma^{-})$. The piecewise function is also can be found in Figure 2.

3 Experiment

3.1 Experimental Setup

Datasets We verify the effectiveness of the proposed method on three synthetic noisy MLTC datasets, i.e. AAPD (Yang et al., 2018), RCV1 (Lewis et al., 2004) and EUR-Lex (Mencía and Fürnkranz, 2008). These datasets are well-known benchmark datasets in the MLTC (Xu et al., 2023b; Ma et al., 2021; Xiao et al., 2019) and NMLTC (Chen et al., 2023) fields. Table 1 contains the statistics of these three benchmark datasets.

Noisy-Label Generation Following previous works (Li et al., 2022; Chen et al., 2023), we randomly flip an element $Y_{i,j}$ in the label vector $\mathbf{y}_i$ from 0 to 1 or 1 to 0 by the probability $\rho_{-}$and ρ_{+} respectively. In some works (Chen et al., 2023; Ghiassi et al., 2022), it was assumed that $\rho_{-} = \rho_{+}$. However, we argue against this approach because in MLTC, the label dimension L is usually much larger than the average number of labels per instance L_{avg}. Therefore, if $\rho_{-} = \rho_{+}$, the number of FP labels would be much greater than the number of FN labels. This situation does not accurately reflect the challenges of NMLTC problems. Hence, we adopt the approach proposed in Multi-T (Li et al., 2022), setting $\rho_{+} = \rho$ and $\rho_{-} = \frac{L_{\text{avg}}}{L - L_{\text{avg}}}\rho$. This configuration is designed to ensure that the difference between the number of FP labels and FN labels is relatively small. The noise rate ρ is set to 0.2, 0.4, and 0.6.

Evaluation Metrics For a comprehensive and reliable evaluation, we follow conventional settings and report the following metrics: precision at 5 (P@5) and normalized discounted cumulative gain at 5 (N@5). These metrics have been widely used in literature to evaluate MLTC (Ma et al., 2021; Xiao et al., 2021). Note that only the training set is affected by noise, whereas the evaluation metrics are computed on the clean testing set. The best results are in bold, and the second-best results are in underscore.

Baselines To verify the effectiveness of iLaCo, we selected the nine most representative baseline models in three groups. (1) MLTC Methods: AttentionXML (You et al., 2019), HTTN (Xiao et al., 2021) and LSFA (Xu et al., 2023b). (2) Noisy multi-label learning (NMLL) methods: GCE (Zhang and Sabuncu, 2018), WSIC (Hu et al., 2019), Reweight-T (Patrini et al., 2017), Multi-T (Li et al., 2022),

Datasets	N_{trn}	N_{tst}	D_{vocab}	L	L_{avg}	N_{avg}	W_{trn}	W_{tst}

and MLLSC (Ghiassi et al., 2022). (3) NMLTC method: nEM (Chen et al., 2023). More details about the implementation setting can be found in Appendix A.3.

3.2 Main Results

As depicted in Tables 2-4, we have observed the following phenomena: (1) In most cases, existing MLTC methods tend to perform worse compared to NMLL methods. This is primarily due to the lack of ability to distinguish noisy labels exhibited by these methods. Moreover, these methods often overly prioritize learning head-to-tail knowledge transfer, resulting in overfitting to the noisy labels and subsequently reducing the overall generalization ability of the model. (2) The advantages of NMLL methods are not significant. Methods based on noise transition matrix estimation, such as Reweight-T and Multi-T, are mainly limited by the large number of labels in the MLTC scenario, making it more challenging to model noise transition in high-dimensional spaces. The nEM method, based on probabilistic graphical models, lacks explicit differentiation between positive and negative noise. The MLLSC method explicitly models both positive and negative noise. However, it solely relies on instantaneous DNN output probabilities as a metric, disregarding the potential instability during the training process of MLTC models. (3) In all cases, our method shows significant improvements compared to other methods. Particularly, as the label dimension L of the dataset increases, our method exhibits even greater enhancement. This is mainly due to the fact that as the label dimension increases, the influence of negative pairs becomes more pronounced. However, our method effectively addresses this issue by employing a negative pair filtering approach. Moreover, as the noise ratio increases, our method demonstrates a lower decrease in accuracy compared to other methods. This validates the effectiveness of our approach in accurately recognizing noise within NMLTC scenarios.

3.3 Ablation Study

In the following experiments, we aim to analyze the effectiveness of each component of the proposed iLaCo method on three datasets. To construct the synthetic noise datasets, we use a noise ratio of 0.4. We compare the complete iLaCo method with the

Noise Rate	$\rho = 0.2$		$\rho = 0.4$		$\rho = 0.6$	
Methods	P@5	N@5	P@5	N@5	P@5	N@5

following variants: (a) HSM (loss): This variant utilizes the instantaneous loss value as the selection metric. (b) HSM (rank): This variant employs the instantaneous rank value as the selection metric. (c) HSM (cons.): This variant transforms the instantaneous selection metric into a time consistency metric. (d) Filter: This variant applies a Filter based on label correlations to filter out a large number of negative pairs. Through these comparisons, we aim to assess the impact and effectiveness of each component in improving the performance of iLaCo on the given datasets.

Component analysis According to Table 5, we observe the following: (1) The Filter component significantly improves the model's performance. This improvement is attributed to the effective removal of a substantial number of irrelevant labels from the negative pair set through the Filter component. As a result, the identification of noisy labels within the negative pair set becomes more manageable for us. (2) The different components of the HSM metric collectively contribute to enhancing the quality of noise identification. By incorporating instance-specific rank information, the model gains the ability to differentiate between different instances, enabling a more accurate distinction between clean and corrupted labels. Additionally, the aggregation of information from multiple epochs allows the model to obtain a more consistent selection metric, further enhancing its capability to identify noise.

Effectiveness of HSM. In Figure 3, we present the distributions of positive pairs using HSM(loss), HSM(rank) and HSM. Firstly, as shown in (a) and (b), both the loss and rank metrics demonstrate certain capabilities in identifying noise. From (c),

				AAPD		RCV1		EUR-Lex

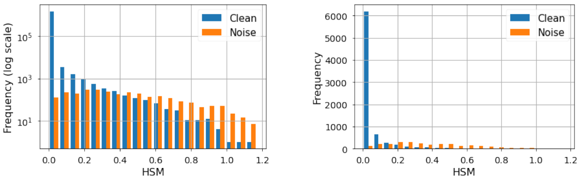
Figure 3: The visualization of metric distribution on EUR-Lex with 40% noise.



(a) Before Filter (b) After Filter

Figure 4: Comparison of the HSM distributions under negative pairs before and after Filter on EUR-Lex with 40% noise. Note that the presence of noise is only visible in (a) when using a logarithmic scale.

we can observe the complementary nature of the loss and rank metrics, which motivated us to combine them into a more comprehensive metric for improved accuracy in noise identification. Finally, in (d), it is evident that the combination of both metrics in HSM leads to a significantly enhanced noise identification capability.

Effectiveness of Filter. Figure 4 showcases the histograms of HSM for TN labels and FN labels, both before and after applying our proposed Filter. It can be observed that with the implementation of the Filter, FN labels can be effectively separated. However, without the use of the Filter, it is almost impossible to distinguish between these two types of labels. This demonstrates the effectiveness of our proposed Filter in improving the separation and identification of clean and noisy pairs under negative pairs.

4 Related Work

Multi-Label Text Classification The most common approach for addressing multi-label text classification (MLTC) is to use the identical document representation to train classification models (Liu et al., 2017). Consequently, label-specific feature learning (You et al., 2019; Xiao et al., 2019; Ma et al., 2021), which focuses on capturing the unique characteristics of each label, has shown promise in enhancing label discrimination. Some works (Xiao et al., 2021; Xu et al., 2023b) have also explored transfer learning from head labels to tail labels to mitigate the adverse effects of label long-tail distribution. Recently, there has been growing interest in MLTC under noisy settings (Chen et al., 2019, 2023). The nEM method (Chen et al., 2023) models the transition process of noisy labels using latent variable models to achieve robust MLTC. In this paper, we extend the memorization effect (Arpit et al., 2017) to noisy MLTC for the first time, and propose an instance-label pair correction method.

Learning from Noisy Labels In order to mitigate the influence of data noise, sample selection is an effective approach. The small-loss criterion (Arpit et al., 2017) is the most widely used criterion. MentorNet (Jiang et al., 2018) and MILD (Hu et al., 2023) propose new metrics based on information throughout the training process to distinguish between clean and corrupted data. Approaches such as GCE (Zhang and Sabuncu, 2018), WISC (Hu et al., 2019), and MLLSC (Ghiassi et al.,

2022) tackle multi-label noise learning by introducing robust loss functions or regularization methods. Reweight-T (Patrini et al., 2017) corrects models by estimating the noise transition matrix, while Multi-T (Li et al., 2022) leverages label correlations in multi-label learning to identify label noise, leading to better estimation of the noise transition matrix. Motivated by MILD, we propose a holistic selection metric for noisy MLTC that integrates global training information with instance-specific training information.

5 Conclusions

In this paper, we propose a method for instance-label pair correction that combines the historical loss information and rank information from the training process to identify and correct positive and negative noise in noisy multi-label text classification tasks. Our experiments yield compelling results, highlighting the superiority of our model compared to existing state-of-the-art (SOTA) baselines for multi-label text classification and noisy multi-label classification.

6 Limitations

There are still some limitations to our work. 1) This work utilizes the memorization effect (Arpit et al., 2017) in deep learning for sample selection and correction, which has not been observed in other traditional machine learning methods. Therefore, the proposed method is not applicable to such learning methods. 2) Since our method models the training process at the instance-label pair level, it possesses the ability to recognize instance-dependent noise (Chen et al., 2021). However, our work has not been validated on instance-dependent noise yet, which could be an area for future exploration.
