Datasets For the dataset, we rely on the domain data splits in Aharoni and Goldberg (2020), originally collected by Koehn and Knowles (2017). This corpus includes five domain-specific (`Law`, `Medical`, `Koran`, `IT`, and `Subtitles`) datasets for German-English translation. We did not use `IT` and `Subtitles` domains because the sentences in these two domains are noisy and short (with only 9 words/sentence for `IT` and 8.2 words/sentence for *Subtitles*). From our preliminary study, we also found that lots of noisy sentences are not filtered out in this dataset. Therefore we used ChatGPT to automatically filter the noisy pairs from the test set (we are not exposed to the dataset and for the details, please refer to appendix A). In this paper, we report evaluation results based on the cleaned dataset[11].

Domain	#Sentence	#Words/Sentence
Law	1907	28.6
Medical	1665	16.9
Koran	1629	20.3

Table 4: Test data statistics after applying GPT3.5 filter following appendix A

Data Cleaning with GPT-3.5 To clean the test set without being exposed to the sample, we first perform zero-shot translation on the devset following Figure 2. Then we rank the generated outputs by their BLEU score and take the 20 worst German-English samples (most of which are low-quality because of noise in the sentence pair, as you can find in Table 8). Note that we take the original source-target sentence pairs instead of the zero-shot output because we only use zero-shot's performance as a scorer to obtain the worst samples. Then we prompt GPT-3.5 to evaluate the quality of these ill-formed pairs and get the evaluation results. The criteria section of the prompt shown in Table 6, Table 7, Table 8 comes from GPT-3.5's evaluation results. Lastly, we use these prompts to ask GPT-3.5 whether each test sentence pair is a good translation and we filter out those pairs that GPT-3.5 predicts "No".

B Ablation on ICL Demonstrations' Quality

To further understand the impact of demonstrations' quality, we ablate on the quality of samples retrieved with the lexical retriever – BM25. We use BM25 retriever to obtain 100 most similar samples from the training corpus for few-shot translation. From the most similar 100 samples, we craft four different chunks, each of 25 samples. We rank these chunks of retrieved data as tier 0, tier 1, tier 2, and tier 3 where tier 0 consists of 25 samples that have the highest BM25 scores, tier 1 has the next 25 samples with the highest similarity score, and so on. From Table 5, we see that the performance of prompt (averaged across domain) degrades by 14% from tier 0 to tier 1, showing that the quality of high-similarity samples that are essential for the high performance. Our finding provides a different view compared to prior work (Hendy et al., 2023; Vilar et al., 2022) which finds random and searched samples (with embedding-based k-nearest-neighbor (Cover and Hart, 1967) methods) have no effect on the performance. We hypothesize that such difference comes from the nature of the task and dataset since our domain-specific dataset has more conformed styles while prior works tested on general benchmark datasets from WMT, which makes style-matching harder with few examples.

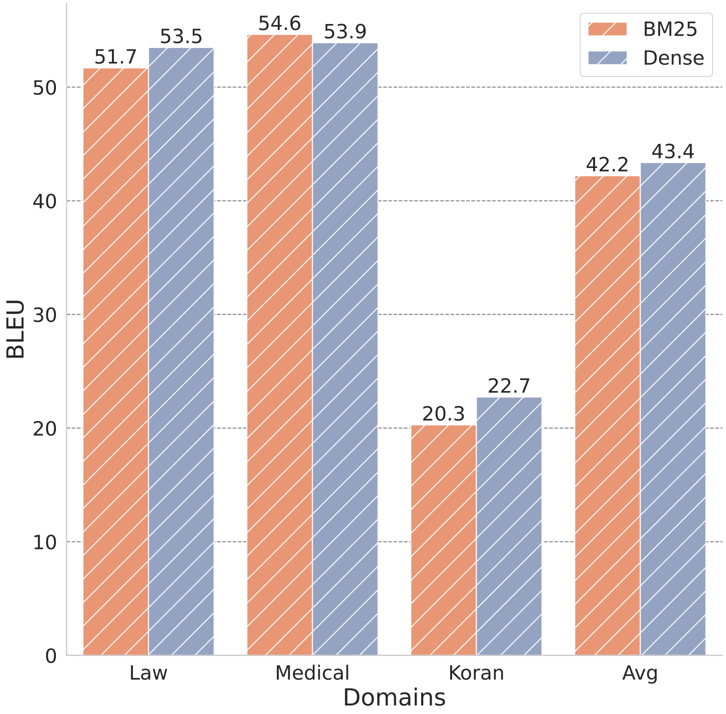

Figure 5: BM25 vs Dense retriever's effect on style-learning prompting's translation quality (with k=5 examples)

[Source]: Die Informationen sind zur Erfuellung der Beaufsichtigungsaufgabe nach Unterabsatz 1 bestimmt.
[Target]: the information shall be for the purpose of performing the task of overseeing referred to in the first subparagraph,
[0-shot]: The information is intended to fulfill the supervisory task according to subparagraph 1.

Few-shot Demo:
[German]: Die Informationen sind zur Erfuellung der Aufgabe nach Unterabsatz 1 bestimmt.
[English]: the information shall be for the purpose of performing the task referred to in the first subparagraph
[1-shot translation]: The information is intended for the purpose of fulfilling the supervisory task referred to in subparagraph 1.

Style Demo:
Such exchange of information must be intended for the performance of the supervisory task of the authorities or bodies mentioned
[1-shot style transfer]: The information is intended for the performance of the supervisory task under paragraph 1.

Figure 6: The example shown here is an illustration of the improvement from few-shot and style-learning translation. The text in orange is the text that GPT3.5 learns from the demonstration, which results in better lexical overlap and higher syntactic similarity with the reference text. In this example, the Few-shot prompt's demo has better quality as it overlaps more with the target sentence (in fact, the whole sentence can be found in the target sentence, as shown with the underline). The retriever for the few-shot prompts has better quality as it is able to utilize both the source and target language's corpus.

7.5	[reference]: Whereas, under Article 34 (1bis), the Convention is open to accession by regional economic integration organizations [few-shot]: Under Article 34 (1 bis), the Convention is open to accession by regional economic integration organizations [style-learning]: According to Article 34, paragraph 1, any regional organization for economic integration can become a party to the agreement
5.1	[reference]: It is considered that the imposition of measures will restore fair competition on the market. [few-shot]: It is considered that the imposition of measures will restore fair competition to the market. [style-learning]: It is believed that the introduction of measures will restore fair competition to the market.
2.7	[reference]: they must come from holdings, centres or organizations which are subject to regular official veterinary checks in accordance with paragraph [few-shot]: They must come from a holding, centre or establishment which is subject to regular official veterinary checks in accordance with paragraph 3. [style-learning]: They must come from an establishment, center, or facility subject to regular official veterinary inspections in accordance with paragraph 3
0.7	[reference]: The Cooperation Committee shall take decisions by common accord. [few-shot]: The Cooperation Committee takes its decisions unanimously. [style-learning]: The Cooperation Committee adopts its decisions unanimously.

Figure 7: Here we provide 4 examples of comparison of COMET scores between few-shot and style-learning prompting outputs. The number on the left is the COMET score difference and the highlighted words are the major difference between the two outputs. We see that all these samples have similar semantics and the difference is mostly from lexical choice (except for the 7.5 cases where sentence structure is also changed but the semantics is still very similar). Therefore, we believe zero-and few-shot outputs' performance gap originates from styles rather than semantics.

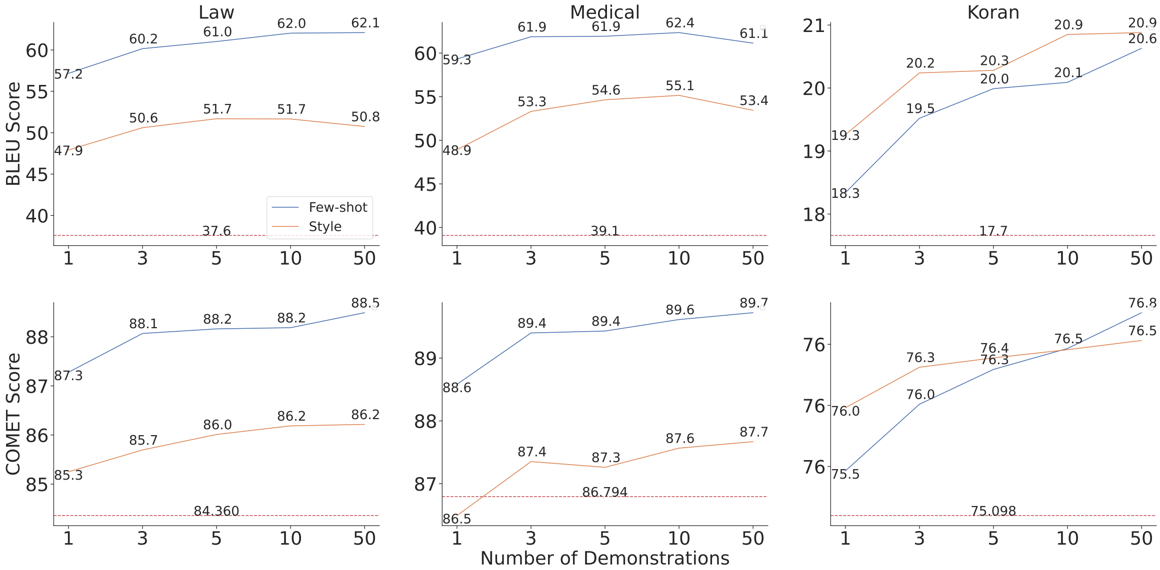

Figure 8: Full Results of few-shot and style-learning prompting across three domains, evaluated by BLEU and COMET (COMET score is multiplied by 100 for better visualization). The x-axis is the number of demonstrations used in the prompt and the y-axis is the evaluation result. The dashed red line is the performance of zero-shot translation and we see that both prompts improve the domain-specific translation even just given 1 demo.

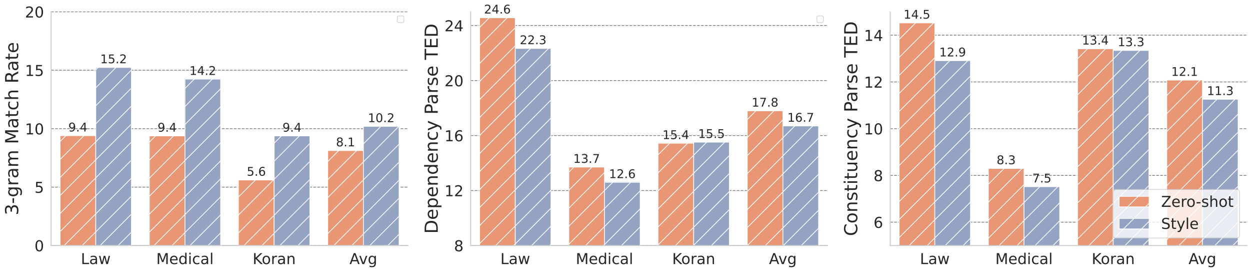

Figure 9: *Left*: 3-gram overlap analysis between *translations* and *retrieved examples*. Compared to zero-shot, the output from style-learning prompting has a much higher match rate with retrieved samples. *Mid*: Average Tree Edit Distance (TED) between the dependency parse tree of reference and outputs from zero-shot or style-learning prompting. Style-learning prompting results in a lower TED, showing its more grammar with the reference. *Right*: Average TED between the constituency parse of reference and zero-shot/style-learning outputs. Again, the style-learning prompting achieves lower TED and has a more conformed syntactical structure with the reference.

You are a human evaluator who judges the quality of parallel data for German-English translation. Below are some examples of low-quality parallel data along with the criteria for filtering them out. [German]: DIESE HINTERBLIEBENENVERSORGUNG ENTSPRICHT :
[English]: THAT PENSION SHALL BE EQUAL TO A PERCENTAGE OF THE PENSION ACCRUING TO THE MEMBER OR FORMER MEMBER OF THE COMMISSION OR OF THE COURT UNDER ARTICLE 9 AT THE DATE OF DEATH, NAMELY:
[Criteria]: The translation is overly verbose and does not accurately convey the meaning of the German sentence. The English translation includes unnecessary repetitions and lacks clarity.

[German]: 3 2 0 0 BAR Information und Veröffentlichung BAR 200000 BAR BAR 200000 BAR
[English]: 3 2 0 0 BAR Information and publishing BAR 200000 BAR BAR 200000 BAR
[Criteria]: The translation includes non-translated elements (such as "BAR") that do not provide any meaningful information in the target language. It appears to be a result of incorrect processing or formatting.

[German]: - gelegentlich erfolgen,
[English]: - are of an occasional nature,
[Criteria]: The translation fails to capture the meaning of the German sentence accurately. It provides a more general interpretation, which does not convey the intended sense of occasional occurrences.

[German]: a) höher sein als die Einheit,
[English]: (a) be greater than 1;
[Criteria]: The translation does not accurately convey the meaning of the German sentence. It provides a different interpretation, suggesting that the value should be greater than 1, whereas the German sentence simply states "higher than the unit."

[German]: - Exportação para a Polónia.
[English]: - Exportação para a Polónia.
[Criteria]: The translation is not in English but rather includes Portuguese words. It appears to be a mistake or a mix-up between different language pairs."""

Given the criteria above, is following sentence pair a good translation? Output Yes if it is a good translation, output No if it is a bad translation.

[Germain]: <test source sentence> [English]: <test target sentence>

Table 6: Filtering Prompt for Law Domain

You are a human evaluator who judges the quality of parallel data for German-English translation. Below are some examples of low-quality parallel data along with the criteria for filtering them out.

[German]: Brivudin behandelt wurden.
[English]: Xeloda should also not be used in the following groups...
[Criteria]: Incompleteness or Omission: When important information is missing in the translation or not adequately conveyed.

[German]: 12/23
[English]: 12/ 22
[Criteria]: Irrelevant or Unrelated Information: When the translation includes information that is not relevant to the original sentence.
[German]: Midazolam zur Injektion).
[English]: Examples include the cholesterol-reducing agent atorvastatin, the antibiotics...
[Criteria]: Sentence Structure and Syntax: When the translation has incorrect word order or sentence structure.

[German]: Hyperthyreose
[English]: Thyroid dysfunction most often presenting as hypothyroidism or hyperthyroidism
[Criteria]: Incorrect Terminology or Inaccurate Vocabulary: When the translation uses incorrect or inaccurate terms.

[German]: 1120
[English]: 112 Further training, language courses...
[Criteria]: Mistranslation or Misinterpretation: When the translation conveys a different meaning than the original sentence.

[German]: Die Wirksamkeit von Revasc als Gerinnungshemmer wurde in vier Studien...
[English]: ho death/ re-MI at Day 30 were not statistically different...
[Criteria]: Inconsistent Terminology: When the translation uses inconsistent or contradictory terms.

[German]: 7,9 µmol/l.
[English]: Ki values in human liver microsomes were 27, 7.5 and 7.9 µmol/ l, respectively.
[Criteria]: Grammatical Errors: When the translation contains grammatical mistakes or incorrect usage of language rules.

[German]: Uber diesen Minimalwert hinausgehende
[English]: The recommendation of a minimum yield of 2.0 x 106 CD34+ cells/ kg
[Criteria]: Lack of Clarity or Ambiguity: When the translation is unclear or ambiguous, making it difficult to understand the intended meaning.

Given the criteria above, is following sentence pair a good translation? Output Yes if it is a good translation, output No if it is a bad translation.

[Germain]: <test source sentence> [English]: <test target sentence>

Table 7: Filtering Prompt for Koran Domain

You are a human evaluator who judges the quality of parallel data for German-English translation. Below are some examples of low-quality parallel data along with the criteria for filtering them out.

[German]: Doch, mit Sicherheit!
[English]: Why not?
[Criteria]: The English translation does not capture the meaning of the German sentence, which should be translated as "Certainly, for sure!" or "Yes, definitely!" instead of "Why not?"

[German]: Dahin werdet ihr kommen müssen.
[English]: The Prophets like Eisa and Uzair who were worshipped are exempt from this, and so are Maryam, and trees and the moon etc.)
[Criteria]: The English translation is completely unrelated to the original German sentence. It introduces a different topic and provides irrelevant information. A more accurate translation would be "There you will have to go."

[German]: " Wir sind zugrunde gerichtet!
[English]: (And say:) "We have fallen into debt;
[Criteria]: The English translation does not convey the intended meaning of the German sentence. A more coherent translation would be "We are destroyed!" or "We are ruined!"

Given the criteria above, is following sentence pair a good translation? Output Yes if it is a good translation, output No if it is a bad translation.

Which Modality should I use - Text, Motif, or Image? : Understanding Graphs with Large Language Models

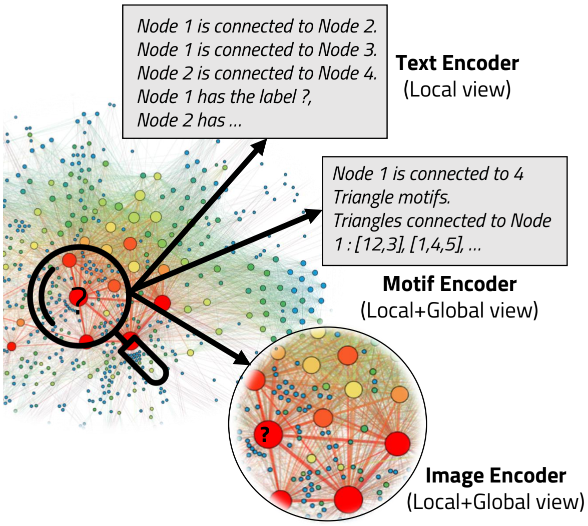
Debarati Das **Ishaan Gupta** **Jaideep Srivastava** **Dongyeop Kang**
Department of Computer Science, University of Minnesota
`{das00015, gupta737, srivasta, dongyeop}@umn.edu`

Abstract

Our research integrates graph data with Large Language Models (LLMs), which, despite their advancements in various fields using large text corpora, face limitations in encoding entire graphs due to context size constraints. This paper introduces a new approach to encoding a graph with diverse modalities, such as text, image, and motif, coupled with prompts to approximate a graph's global connectivity, thereby enhancing LLMs' efficiency in processing complex graph structures. The study also presents GRAPHTMI, a novel benchmark for evaluating LLMs in graph structure analysis, focusing on homophily, motif presence, and graph difficulty. Key findings indicate that the image modality, especially with vision-language models like GPT-4V, is superior to text in balancing token limits and preserving essential information and comes close to prior graph neural net (GNN) encoders. Furthermore, the research assesses how various factors affect the performance of each encoding modality and outlines the existing challenges and potential future developments for LLMs in graph understanding and reasoning tasks. Our code and data are publicly available on our project page.[1]

1 Introduction

Large Language Models (LLMs) are increasingly utilized in areas with inherent graph structures like social network analysis (Mislove et al., 2007), drug discovery (Vishveshwara et al., 2002), and recommendation systems (Melville and Sindhwani, 2010), but they face limitations due to their reliance on unstructured text and challenges in incorporating new data post-training (Zhang et al., 2023; Lewis et al., 2020; Pan et al., 2023). Graph-structured data can address these issues, providing a nuanced and flexible representation of real-world relationships.



Node 1 is connected to Node 2.
Node 1 is connected to Node 3.
Node 2 is connected to Node 4.
Node 1 has the label ?,
Node 2 has ...

Node 1 is connected to 4 Triangle motifs.
Triangles connected to Node 1 : [12,3], [1,4,5], ...

Figure 1: Input modality encoding for graphs impacts node classification, with text modality offering detailed information from a *local* point of view but violating the input context limitations for LLMs due to verbosity. Motif modality provides *local and global context*, while image modality gives a comprehensive *global* view, efficiently processed by GPT-4V, which integrates capabilities from both vision and text.

While there has been progress in interpreting multi-modal information (Yin et al., 2023), integrating graph understanding into LLMs remains a developing area. Current research typically employs limited setups with small real-world graphs (Guo et al., 2023) or synthetic ones (Wang et al., 2023), exposing a gap in effectively incorporating large real-world graphs into LLMs, owing to their context window constraints. This suggests that text-only encoding may not be optimal for complex, large graph structures. Other challenges include LLMs' difficulty directly processing complex graph-structured data, necessitating innovative input encoding and prompt design (Fatemi et al., 2023; Chen et al., 2023) for various graph tasks. Designing effective text representations of graphs requires extensive research from the human prac-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 503–519
June 16-21, 2024

titioner's perspective, which raises the question of alternative encoding modalities for graphs.

This paper investigates the impact of different modalities for encoding global and local graph structures, focusing on node classification tasks, and compares three modalities: *Text*, *Motif*, and *Image* (See Figure 1). Text modality offers detailed local insights but becomes verbose for large graphs (Bubeck et al., 2023), often exceeding the input limits of models like GPT-4. The Motif modality is suggested to address this, capturing essential patterns in a node's vicinity for a balanced local-global perspective. Additionally, Image modality is proposed, utilizing fewer tokens to convey a more global view of the node's neighborhood, a method enhanced by the vision capabilities of the newly released GPT-4V (OpenAI, 2023a). Finding the optimal prompt input format is a notably complex challenge, with text modality encoding requiring extensive exploration compared to the simpler, more human-readable image modality. In our evaluations, we balance informativeness and prompt conciseness across all modalities using a combination of metrics.

Our **main contributions** are as follows:

- We conduct breadth-first analysis of various modalities, such as text, image, and motif, in graph-structure prompting, utilizing large language and vision-language models for node classification tasks.
- We also perform a depth-first analysis of how different factors influence the performance of each encoding modality.
- We introduce GRAPHTMI, a novel graph benchmark featuring a hierarchy of graphs, associated prompts, and encoding modalities designed to further the community's understanding of graph structure effects using LLMs.

Some key findings: 1) When balancing the constraint of token limits while preserving crucial information, the image modality is more effective than the text modality for graph-related tasks. 2) The choice of encoding modality for graph task classification depends on the task's difficulty, assessed by homophily and motif counts, with image modality being optimal for medium-difficulty tasks and motif modality for harder ones. 3) Factors like edge encoding function, graph structure, and graph sampling techniques impact the performance of node classification using text modality. 4) Motif attachment information has a more significant impact on node classification than motif count information. 5) Image representation correlated with human readability positively impacts node classification performance.

Properties	CORA	Citeseer	Pubmed

Table 1: Comparison of network properties of popular citation network datasets CORA, Citeseer and Pubmed.

2 Setups

2.1 Seed Datasets

We experiment with three citation network datasets, which are popular node classification benchmarks, CORA (McCallum et al., 2000) with seven categories : [0-Rule Learning, 1-Neural Networks, 2-Case-Based, 3-Genetic Algorithms, 4-Theory, 5-Reinforcement Learning, and 6-Probabilistic Methods], CITESEER (Giles et al., 1998) with six categories of areas in Computer Science: [0-Agents, 1-ML, 2-IR, 3-DB, 4-HCI, 5-AI] and PUBMED (Sen et al., 2008) that consists of scientific journals collected from the PubMed database with the following three categories: [0-Diabetes Mellitus, Experimental, 1-Diabetes Mellitus Type 1, 2-Diabetes Mellitus Type 2]. This paper focuses solely on the structural information of graphs for node classification. Hence, our experiments exclusively utilize node and label IDs.

2.2 Evaluation Metrics

This paper assesses the performance of node classification using four metrics chosen to balance the tradeoff between the encoding's informativeness and verbosity. The metrics used are Accuracy rate (which should increase $\uparrow$), Denial rate (which should decrease $\downarrow$), Mismatch rate (which should decrease $\downarrow$), indicating the prompt's informativeness, and Token limit fraction (which should decrease $\downarrow$), reflecting the prompt's verbosity.

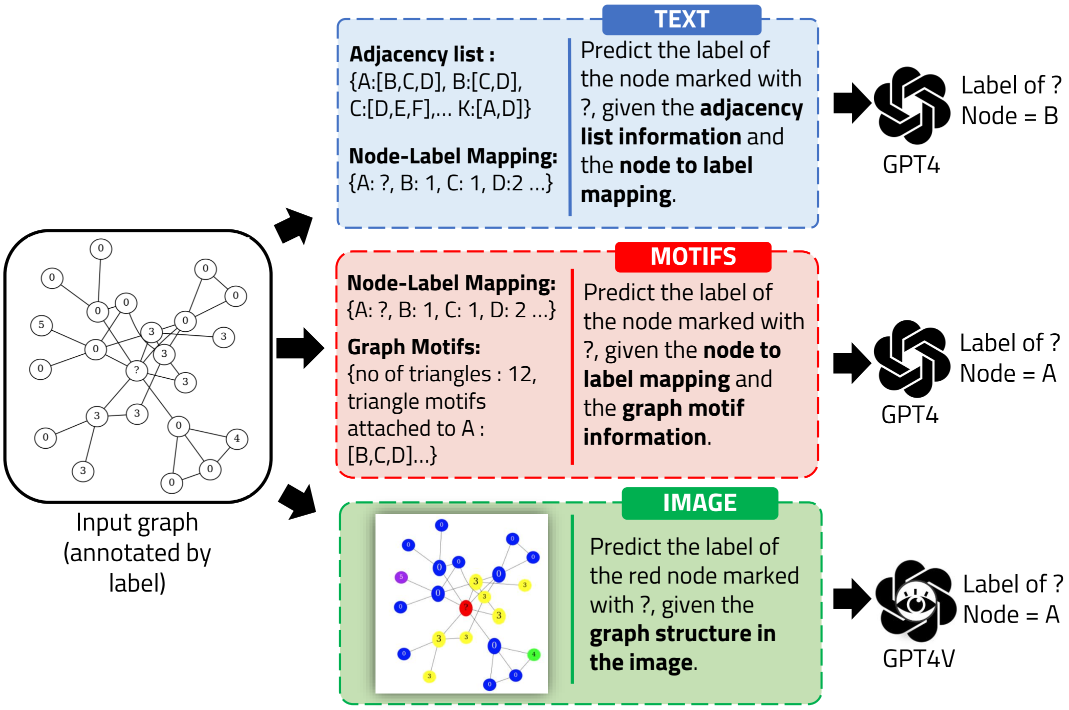

Figure 2: Node Classification on a Graph using different input modality encodings like Text, Motif, and Image.

Accuracy Rate A: This metric indicates the LLM's performance on the task of node classification.

$$A = \frac{\text{No. of correct predictions}}{\text{Total no. of samples}} \tag{1}$$

Mismatch Rate M: This metric indicates the degree of misclassification by LLM (when the ground truth value is not the same as the predicted value).

$$M = \frac{\text{No. of incorrect predictions}}{\text{Total no. of samples}} \tag{2}$$

Denial Rate D: When we craft our prompt, we instruct the LLM to return -1 if it cannot predict the label of the ? node (node to be classified). The denial rate metric describes the rate of failure of the LLM (when the predicted value is -1).

$$D = \frac{\text{No. of predictions = -1}}{\text{Total no. of samples}} \tag{3}$$

$$1 - A = M + D \tag{4}$$

Token Limit Fraction T: This metric evaluates how effectively a Large Language Model's encoding modality uses its input context window, specifically focusing on the constraints imposed by the fixed-size attention window in transformer-based models like GPT-4 and GPT-4V. These constraints, dictated by the model's neural network architecture, limit the number of tokens that can be processed simultaneously, impacting both computational cost and performance.

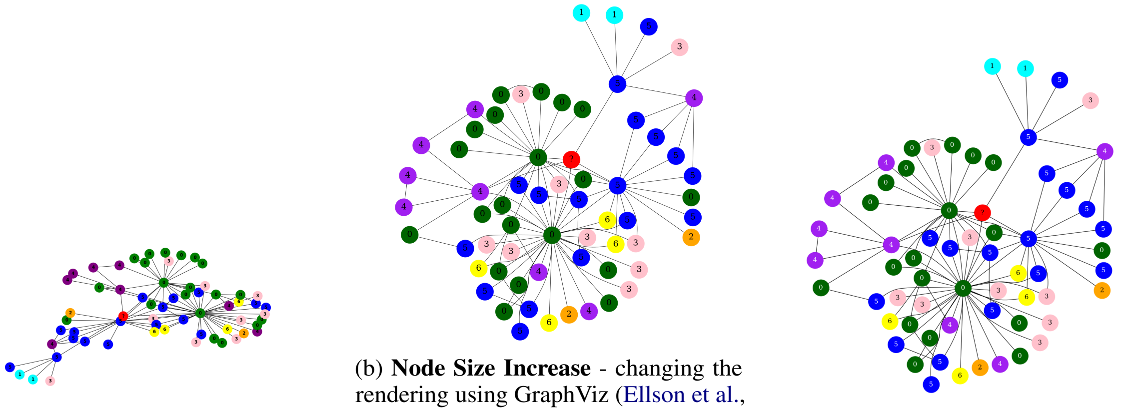
$$T = \frac{\text{Number of usage tokens}}{\text{Token limit constraint for the model}} \tag{5}$$

2.3 Graph Encoder Baselines

We compare our LLM models, which use different encoding modalities, to recognized standards in the node classification task like GCN(Kipf and Welling, 2016), GRAPHSAGE(Hamilton et al., 2017) and GAT (Veličković et al., 2017). We aim to highlight LLMs' potential in approaching these recognized baselines using different modalities, rather than competing with state-of-the-art GNN models, emphasizing their evolving ability to process complex graph structures. We provide the training details for the GNN models in Appendix B.

3 Proposed Encoders with Different Modalities

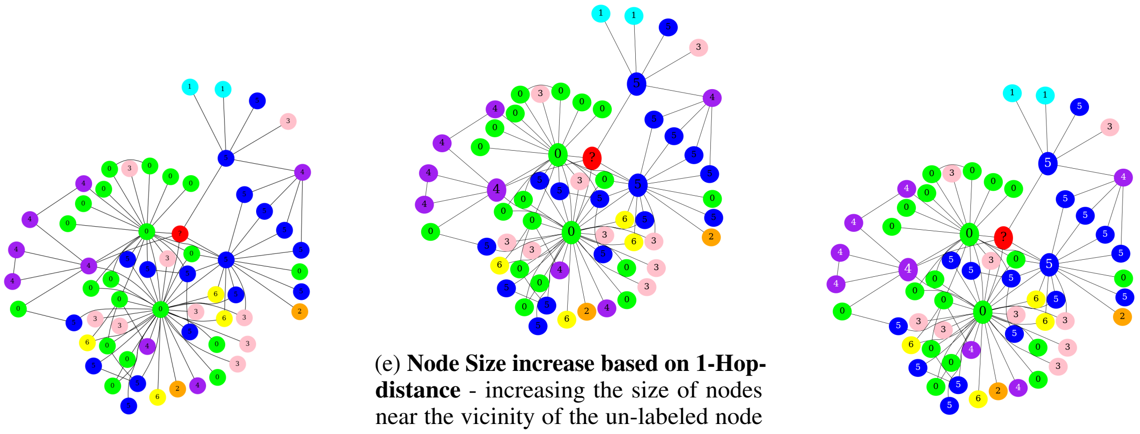
Graph encoding is crucial for converting graph-structured data into a sequence format that language models can process. As shown in Figure 2, the experimental setup involves using a modality encoder to input the graph structure and a graph query, such as predicting a node's label in node



(a) **Original NetworkX Graph** (Hagberg et al., 2008) - no image setting changes made

(b) **Node Size Increase** - changing the rendering using GraphViz (Ellson et al., 2002) and increasing the size of each node in the graph, increasing node and label clarity

(c) **Contrasting Text Color** - contrasting the textual labels with the node color will make the labels more "human-readable"



(d) **Distinctive Node Colors** - choosing distinct colors allows the VLM to distinguish differently labeled nodes better

(e) **Node Size increase based on 1-Hop-distance** - increasing the size of nodes near the vicinity of the un-labeled node might allow the VLM to prioritize the data of nodes of greater size as opposed to nodes further away

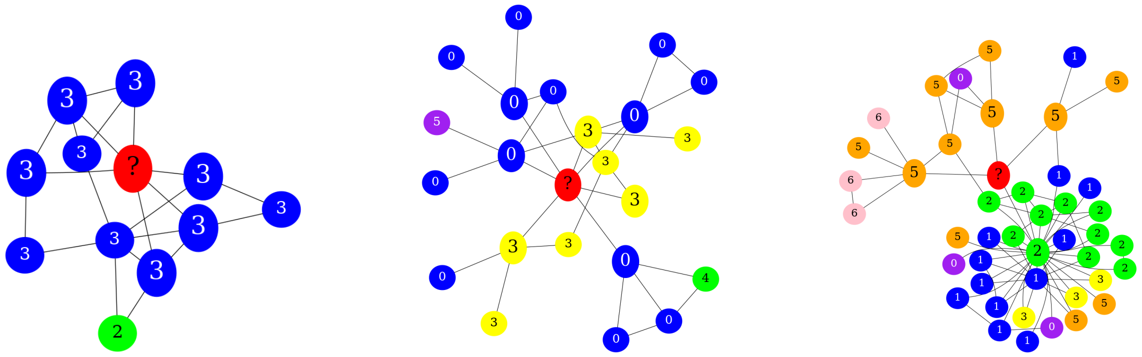
(f) **Aggregate all changes** - all changes from b) to e) are applied to maximize image clarity

Figure 3: Image representation changes were applied sequentially on a graph, and we observed a distinct *increase from (a) to (f) in human readability and understanding of the graph* structure.

classification tasks. The graph structure is encoded according to the chosen modality (text and motif using GPT-4 and image using GPT-4V) and then passed as a prompt to the LLMs to generate the required label.

3.1 Text Encoder

In encoding graphs as text, nodes are mapped to labels using a dictionary format, and different edge-encoding representations (Guo et al., 2023; Fatemi et al., 2023) are experimented with (Table 6), providing *local context* through edge connections and node labels to GPT-4 (OpenAI, 2023a). However, larger graphs can lead to verbose text encodings, which may exceed LLM input limits. We evaluate the impact of graph structure on classification (Yasir et al., 2023; Palowitch et al., 2022) by analyzing real-world citation datasets like PUBMED, CITESEER, and CORA, each with distinct network properties (definitions for these are provided in Table 8 and distinguished through Table 1). PUBMED is the largest and most connected but has the lowest clustering coefficient, indicating less local clustering. In contrast, CITESEER is highly fragmented with many disconnected components, while CORA, the smallest network, exhibits the highest density and clustering coefficient, suggesting strong local connectivity. Additionally, the research examines graph sampling techniques like ego graph (Stolz and Schlereth, 2021) and forest fire sampling (Leskovec and Faloutsos, 2006), crucial due to LLMs' limited context window and complex real-world graphs (Wei and Hu, 2022). These methods vary in their effectiveness, with Forest Fire sampling providing a broad network view, suitable for large networks like PUBMED, and Ego graph sampling excelling in revealing local community structures in more clustered and locally dense networks like CORA and CITESEER.



(a) **EASY** - (#distinct labels < 3) and (#motifs ≤ 10)

(b) **MEDIUM** - ($3 \leq$ # distinct labels < 5) and ($10 <$ # motifs ≤ 20)

(c) HARD - (#distinct labels ≥ 5) and (# motifs ≥ 20)

Figure 4: Classifying graph task difficulty based on the criteria of Homophily and Number of Motifs yields a dataset of EASY, MEDIUM, and HARD graph problems and their associated modality encodings and classifications. This benchmark is called the GRAPHTMI dataset.

3.2 Motif Encoder

Network motifs, recurring patterns in social and biological networks (Milo et al., 2002; Carrington et al., 2005; Holland and Leinhardt, 1974), are pivotal in understanding local structures and behaviors. In LLMs, motif modality encoding leverages these motifs to provide *local and global context*, aiding in classifying unlabeled nodes (Yang et al., 2018). This process entails mapping nodes to labels using a dictionary format and identifying key motifs around the unlabeled node, which are inputted into GPT-4 as graph-motif information (detailed in Table 9). Differentiating between the count and specific members of motifs like stars, triangles, and cliques in a graph, our approach posits that a node's connection to influential motifs, such as being central in a star for network influence or part of a triangle or clique for close community ties, can significantly affect its classification by revealing key aspects of the network structure.

3.3 Image Encoder

Adopting the idea that "a picture is worth a thousand words", the image modality in graph analysis uses visual representations to outperform text in depicting structures, networks, labels, and spatial relationships using fewer tokens. Vision-language models like GPT-4V (OpenAI, 2023b) interpret these graph images, offering a *global context* of the graph's structure. GPT-4V, a multimodal model, merges visual interpretation with language processing, underscoring the importance of image representation in enhancing node classification. Our experiments involved using graph rendering methods to generate images with color-coded nodes, with a focus on improving human readability through various image modifications (Figure 3). These changes were evaluated for their impact on node classification, highlighting the critical role of visual representation in this modality.

4 GraphTMI Benchmark Creation

Our study reveals that the ease of node classification in graphs varies across different modalities, depending on the graph's "difficulty," determined by motif count and homophily. Homophily (McPherson et al., 2001), based on network theory, suggests that nodes are more likely to connect with similar nodes; thus, graphs with higher homophily (more nodes sharing the same label) are simpler to classify than those with more heterophily (diverse labels). This is illustrated through CORA dataset examples in Figure 4. Graphs are categorized as "easy," "medium," or "hard" based on the diversity of labels. Additionally, graphs with more network motifs are considered more complex and challenging for classification (Tu et al., 2018). The "task difficulty" is defined across eight categories ($2^3 = 8$), with the final difficulty level determined by the higher of the two criteria, homophily or motif count. This led to the creation of GRAPHTMI, a new benchmark dataset that includes various graph structures along with their respective modalities (text, motif, and image), prompts, and LLM classifications, thereby providing deeper insights into how different graphs affect LLM prompting. Specific statistics are given in Appendix A.

Table 2: We report test accuracy rates of node classification across different datasets and denial rates D in [brackets] for LLM models. * indicates the lowest denial rate for each modality. The highest accuracy rate for the dataset is in bold, while the second highest is underlined. *The text modality in LLMS is comparable to GNN baselines with image modality not far behind.*

5 Results

5.1 Results Across All Modalities

Comparing Node Classification Accuracies between Graph baselines and LLM models : Table 2 compares node classification accuracies of traditional GNN methods and LLM baselines across datasets, assessing if LLMs come close to conventional techniques. Limited by GPT-V's rate limit, the study used 50 ego graphs, with more extensive results in Appendix A. The *text modality of LLMs performs comparably to graph baselines in all datasets, with the image modality close behind, indicating LLMs' potential in graph analysis*. In larger datasets like PUBMED, the image modality showed a higher denial rate, possibly due to overcrowding in larger subgraphs, leading to more frequent classification denials by the LLM.

Comparing Node Classification Performance across Encoding Modalities: Figure 5 compares node classification across encoding modalities, focusing on accuracy, mismatch, denial rates, and token limit fraction. The text modality shows high accuracy but struggles with a high denial rate and token limit fraction, likely due to verbose inputs that confuse the LLM. In contrast, the image modality offers similar accuracy but with lower denial rates and token limit fractions, indicating the *image modality's effectiveness in providing a concise, global context that the LLM processes more efficiently*.

Qualitative analysis of denial of classification in the Image Modality Figure 7 shows instances from multiple datasets where GPT-4V, using image modality, did not assign labels (returned -1) to graph nodes, explaining the reasons for denial. Key observations include: a) the LLM lacked *explicit context on label assignments* to nodes, as the encoding only implicitly indicated labels through node colors, with red reserved for unlabeled nodes. b) For one image, the absence of a clear *link between node colors and labels*, exacerbated by high heterophily, caused confusion. c) Another case highlighted the need for *few-shot learning*, suggesting that showing the LLM similar graph examples could help it learn to identify unlabeled (red) nodes more accurately.

Insights from GraphTMI In our evaluation of node classification accuracy using the GRAPHTMI benchmark across various modalities, we found in Figure 6 that "easy" tasks (characterized by high homophily and simpler structures) showed comparable accuracy across text, image, and motif modalities. However, for "medium" or "hard" tasks, marked by heterophyllous nature or complex structures, the image modality outperformed others, followed by the motif modality, underscoring the importance of global information in LLM processing. Notably, "hard" graphs achieved the highest accuracy with the motif modality, indicating the value of balancing local and global information. This suggests a *growing effectiveness of image and motif modalities in enhancing graph reasoning tasks like node classification*.

5.2 Modality Specific Results

Text modality results: Figure 16 shows that using the *Adjacency List* as the mode of edge representation with node label mapping is the *most informative encoding function*, which balances the trade-off between high accuracy and low token limit fraction. Figure 9 shows how metrics vary across datasets with different graph structures and sampling strategies. For CORA, a small, dense, and clustered graph, both sampling methods yield high accuracy,

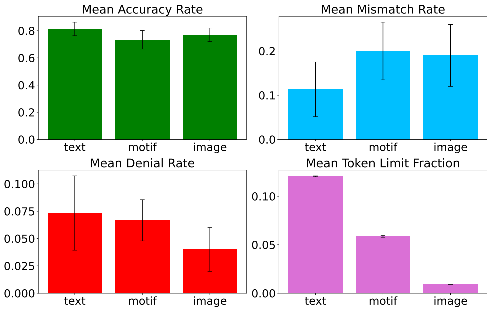

Figure 5: We observe that while the *text and image modalities have similar accuracy rates, the motif modality exhibits the highest mismatch rate, and the image modality stands out with the lowest denial rate and token limit fraction*, as depicted along the mean metrics (y-axis) against each modality type (x-axis)

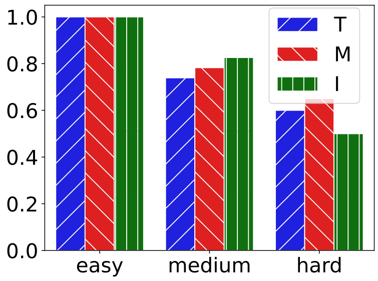

Figure 6: Modality encoder trends (T= Text, M= Motif, I= Image) with graph task difficulty based on homophily and no. of motifs, highlight the *significance of integrating local and global information in LLM processing.*

with forest fire (ff) sampling resulting in a lower denial rate. CITESEER, with its local clustering nature, struggles with ff sampling, showing the highest denial rate and the lowest mean accuracy, indicating difficulty in accurate predictions. In contrast, large and highly connected PUBMED generates larger samples through ego graph sampling, leading to higher token limit fractions. CITESEER's fragmented, disconnected nature results in smaller ego graph samples and lower token limit fractions. Thus, we can see *graph structure and sampling strategy significantly impact performance metrics.*

Motif modality results: Figure 17 shows GPT-4's *improved performance by adding the "triangle and star attached to ? node" motif* in the motif modality encoder (detailed in Appendix Table 9). This enhancement in mean accuracy and other metrics is attributed to the effective combination of local and global context provided to the LLM through node-label mapping and the associations within triads or star motifs.

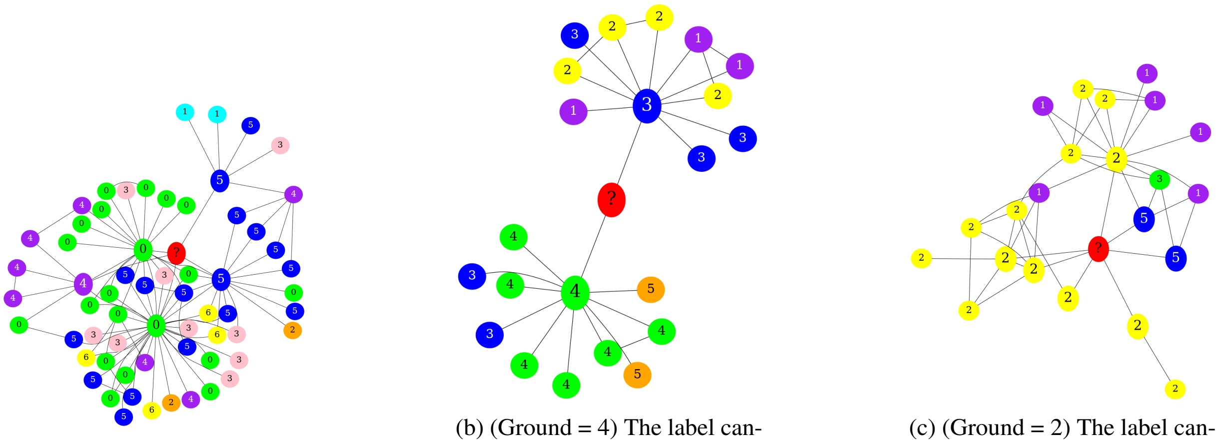
Image modality results: Figure 3 shows different tweaks to image representation, and Figure 8 demonstrates that optimal node classification correlates with high accuracy and low denial and mismatch rates. Interestingly, *as human image readability increases, metric performance also improves, highlighting the easier use of images over text* for LLM prompts.

5.3 Qualitative Analysis on Combining Modalities

We perform a qualitative analysis of the response returned by LLMs by utilizing the text, image, and text combined with image encoding modalities. The intuition here is that the local context provided by the text modality might not be enough for some predictions and could be supplemented through the global context provided by the image modality. *Table 3 illustrates that misclassifications and denials by the LLM using text modality could be rectified by using the image modality*. For the first two rows, -1 classifications or LLM denials are changed to the correct classification on incorporating the global context of the image modality. We can see in the response that the notion of "homophily" is clearer to the VLM in the image modality. For the last two rows, we see that the graph is originally misclassified, but then this is corrected by incorporating the image modality. We make similar observations on combining text and motif modalities, and this could be because another factor important to node classification is the presence of motifs, which is highlighted through the motif modality.

6 Related Work

LLMs with Graphs: Graph Neural Networks (GNNs) are renowned for their effectiveness in node classification and link prediction (Dwivedi et al., 2020), with applications in diverse fields like social networks, computer vision, and biology (Hou et al., 2022). GNNs struggle with processing non-numeric data like text and images, necessitating preprocessing such as feature engineering (Wang et al., 2021). In contrast, recent studies have explored using Large Language Models (LLMs) for graph reasoning, demonstrating their potential in complex tasks (Huang et al., 2022). This in-



(a) (Ground = 0) Without additional context or rules for how labels are assigned, it is not possible to accurately predict the label of the red node.

(b) (Ground = 4) The label cannot be determined with certainty due to the lack of a discernible pattern or rule that associates a node's color or its connections with its label.

(c) (Ground = 2) The label cannot be determined with certainty due to the lack of a clear pattern in the graph and no previous examples of red nodes to infer from.

Figure 7: Examples of graphs where VLM (GPT-4V) returned -1 or denied to predict a label and the reason for denial. The ground truth for this graph is given in brackets. This *highlights the need to clarify labeling strategies and few shot learning.*

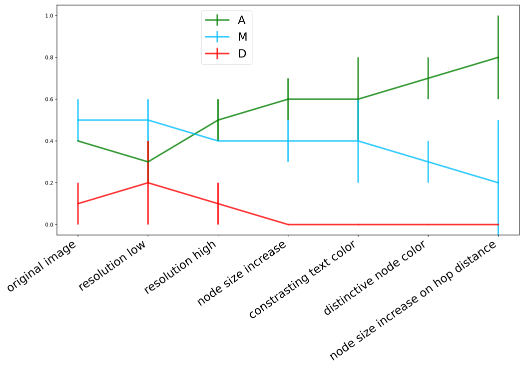


Figure 8: Our comparison of image representations (x-axis) with mean metrics (y-axis) shows that *human readability of images correlates with classification performance*, considering Accuracy Rate (A ↑), Mismatch Rate (M ↓), and Denial Rate (D ↓), with desired trends indicated in brackets.

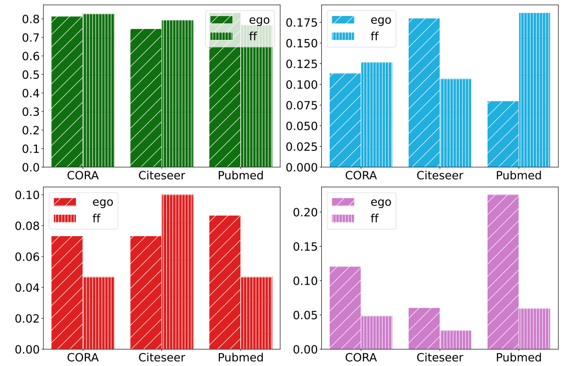

Figure 9: Each dataset and sampling type (x-axis) is mapped against mean metrics (y-axis), with bar textures distinguishing between ego graph (ego) and forest fire (ff) sampling; the metrics include accuracy rate (↑), mismatch rate (↓), denial rate (↓), and token limit fraction (↓), indicating the desired trends for each. *Graph structures of different datasets and sampling strategies influence node classification performance.*

cludes using LLMs for feature enhancement (Chen et al., 2023), node classification (Chen et al., 2023), and training neural networks in graph-based tasks (He et al., 2023), with benchmarks like NLGraph (Wang et al., 2023) assessing LLMs in traditional graph challenges. These studies typically employ LLMs as sub-components within graph learning frameworks. *Our research examines LLMs' ability to process graph modalities directly, aiming to understand LLMs' intrinsic graph-handling capabilities, thus presenting a novel direction in the field.*

Prompt Design for Graphs: Prompting strategies for querying large language models (LLMs) aim to optimize the prompt text for enhanced task performance. Few-shot in-context learning (Brown et al., 2020) provides examples with desired outputs for the model to learn and generalize. Chain-of-thought (CoT) prompting (Wei et al., 2022) offers step-by-step problem-solving examples, leading the model to develop reasoning paths, while its zero-shot variant (Kojima et al., 2022) initiates reasoning with a starter phrase. Bag prompting (Wang et al., 2023) focuses on graph tasks, recommending graph construction before the task. Format expla-

Image	Ground Truth	Text_Response	Text + Image_Reponse	Image_Response
	*Label of Node = 5*	The label of a node can often be predicted based on the labels of its neighboring nodes. In this case, the node in question is ’1677’, and its neighbors are ’88’, ’415’, ’1309’, and ’191’, ’1908’. There is no clear majority label among these neighbors. Therefore, it is not possible to predict the label of node ’1677’ based on this information. *Label of Node = -1*	From the adjacency list, we can determine that the neighbors of node "1677". Given that node "1677" is connected to two nodes with label 0, two nodes with label 5, and one node with label 4, we can attempt to predict its label based on the labels of its neighbors. Since nodes "1309" and "191" both have the label 5 and are each directly connected to "1677," it's reasonable to refer to the homophily in networks concept where nodes are likely to be of the same type (label) as their neighbors. Based on this information, it seems plausible that the red node "1677" would also have the label that appears most frequently among its neighboring nodes, which is label 5. *Label of Node = 5*	*Label of Node = 0*
	*Label of Node = 3*	The node 1329 is connected to nodes 733, 994, and 78. The labels of these nodes are 0, 3, and 4 respectively. Since there is no majority label among these, the label of node 1329 cannot be determined. *Label of Node = -1*	*Label of Node = 3*	*Label of Node = 3*
	*Label of Node = 6*	The node 702 is connected to nodes 777, 779, 2069, 2070, 2101, 822, 993, 1368, and 1637. The labels of these nodes are 0, 6, 0, 0, 5, 5, 6, 5, and 0 respectively. The most common label among these is 0. Therefore, we can predict that the label of node 702 is also 0.*Label of Node = 0*	*Label of Node = 6*	*Label of Node = 6*
	*Label of Node = 3*	The node 141 is connected to nodes 1002, 2034, and 740. The labels of these nodes are 3, 4, and 4 respectively. Since the majority of the connected nodes have the label 4, we can predict that the label of node 141 is also 4. *Label of Node = 4*	*Label of Node = 3*	*Label of Node = 3*

Table 3: The table shows the GPT-4 and GPT4-V responses with the text modality, text+image modality, and image modality. *We observe that on combining modalities, the label originally classified as -1 is correctly classified (first two rows), or the original misclassification is rectified (last two rows).*

nations and role prompting (Guo et al., 2023) are proposed for better task clarity and strategic input organization to leverage LLMs' learning capabilities. Self-prompting involves the LLM refining prompts via context summarization, tackling issues with complex or insufficient graph data. *Our study employs zero-shot prompting, providing only a task description to the LLM, to concentrate on the impact of modalities without the influence of varied prompt designs.*

7 Conclusion and Future Work

This study explores the application of LLMs in graph-structured data, evaluating their strengths and weaknesses in node classification using various input modalities like motif and image for effective data representation. Introducing the GRAPHTMI benchmark highlights the image modality's efficiency in token limit management, and the potential of motif modality in complex graphs. Although LLMs have progressed in graph data processing, they still don't match the performance of GNNs in practical settings. The research advocates for future work combining different modalities to improve node classification, combining LLM-based methods with GNNs, applying these techniques to complex, text-dense graphs, and delving into link prediction and community detection to broaden applications and insights across multiple domains.

Limitations

LLMs offer powerful capabilities for processing complex graph-structured data but come with high financial costs, particularly when using APIs like GPT-4, which can significantly increase operational expenses in real-time applications. GNNs with their cost-effectiveness and capability to be trained and deployed on conventional hardware sans ongoing costs, are a pragmatic choice for graph analysis tasks such as node classification and community detection. Nevertheless, the combination of LLMs' semantic processing with GNNs' structural prowess presents a promising hybrid strategy for sophisticated graph analyses. Through comparative studies involving established GNN architectures like GAT, GraphSage, and GCN, our aim is not to rival but to comprehend how LLMs can approximate these benchmarks, with a commitment to incorporating cutting-edge GNN models in future explorations.

Our study faces constraints from GPT-V's rate limitations, impacting data processing scalability. Moreover, the representation challenges of large graphs via image modalities, demanding high-resolution imagery beyond LLMs' capabilities, signify a crucial area for future investigation. Addressing these limitations is vital for enhancing LLM applications in graph analysis, and our future plan is to explore the balance between image resolution, token efficiency, and graph representation fidelity.

The computational demands of detecting network motifs, essential for understanding complex network dynamics require extensive computational power and advanced algorithms, limiting scalability and efficiency. We subvert these challenges by restricting our subgraph sample size to 3 hops of an ego graph. A further limitation lies in the study's simplistic approach to estimating homophily, relying merely on label count and neglecting the importance of hop distance. This overlooks critical network structure and node similarity aspects, leading to a potentially oversimplified analysis. Incorporating hop distance could provide a more accurate representation of network homophily. These limitations underscore the need for further advancements in computational techniques, model capabilities, and more nuanced theoretical methods in network analysis.

A LLM Experiments

A.1 Comparing encoding modalities for different datasets and sampling

Our study evaluates various encoding modalities — text, motif, and image — with ego graphs from CORA detailed in the main manuscript. Figure 15 extends this analysis to the other datasets and sampling techniques. The findings corroborate our assertion that graph structure and the chosen sampling method significantly influence node classification outcomes. Particularly, samples derived from the forest fire method, which emphasize the global configuration while being sparser and less connected than ego graphs, exhibit increased misclassification rates when using the image modality due to limited information for accurate inference and greater instances of non-committal predictions with the motif modality due to the absence of a discernible overarching structure.

A.2 Graph TMI Benchmark

We decide on graph "difficulty" based on the dual criteria of 1) count of motifs and 2) homophily in the graph. We apply a naive heuristic to decide homophily, i.e., the count of the distinct labels in the graph. If the count of distinct labels < 3, the graph is considered *easy*. If the count is ≥ 3 and < 5, it is considered *medium*, and if the count is ≥ 5, it is considered *hard*. To decide the motif criteria, we count the total number of motifs(focusing on just triads, star motifs, and cliques) in a graph. For example, if this count of motifs ≤ 10 for the CORA dataset, the graph is considered *easy*. If the count is > 10 and ≤ 20, it is regarded as *medium*; if the count is > 20, it is considered *hard*. Some graphs can have both the homophily and motif criteria applicable to them; for instance, Figure 4 (b) can be classified as *medium* based on homophily, *hard* based on the count of motifs. This leads us to combine the homophily and the count of motif criteria to define the "task difficulty". Thus, we can have $2^3 = 8$ categories of difficulty, and the final difficulty label is decided by choosing the higher annotation between homophily and count of motif classification). So, a graph with criteria {easy, hard} will be assigned the final task difficulty, *hard*. Thus, we can classify graphs based on our "task difficulty" heuristic, and we introduce GRAPHTMI (Graph Text-Motif-Image), a novel benchmark dataset of input graph structures paired with their associated modality encodings.

	homophily	**motif**	**count**
0	easy	easy	7
1	easy	hard	4
2	easy	medium	6
3	hard	easy	1
4	hard	hard	8
5	hard	medium	2
6	medium	easy	5
7	medium	hard	5
8	medium	medium	12

Table 4: Statistics about the number of graphs classified as easy, medium, or hard through the homophily and the number of motifs criteria. All possible combinations are covered in our benchmark ($3^2 = 9$).

	difficulty	**count**
0	easy	7
1	hard	20
2	medium	23

Table 5: Statistics about the number of problems finally classified as easy, medium, or hard based on task difficulty, a function of homophily, and number of motifs.

A.3 Modality Specific Experiment Details

Token limits for each modality Due to their architecture, transformer-based models like GPT-3 and GPT-4 have a fixed-size attention window. This determines how many tokens the model can "remember" or pay attention to at once. This limit also manages the computational cost of running the model and the model's performance. The token limit constraint for GPT-4 is 8192 tokens, while for

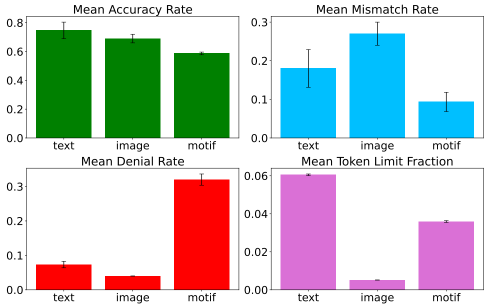

Figure 10: Citeseer with ego graph sampling

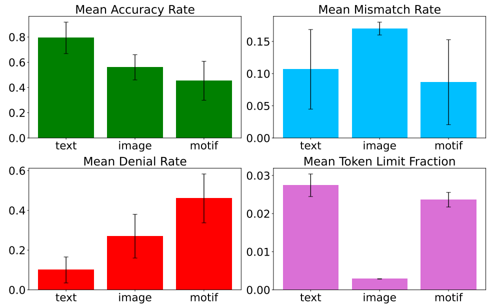

Figure 11: Citeseer with forest fire sampling

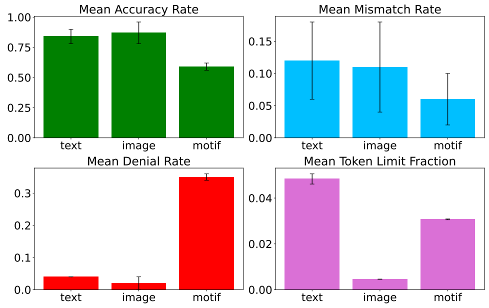

Figure 12: Cora with forest fire sampling

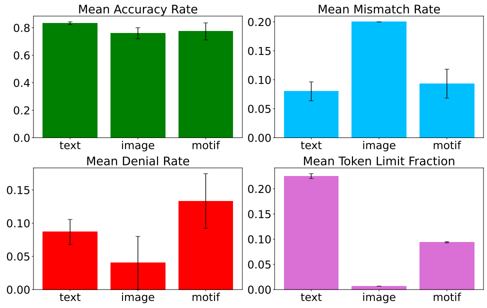

Figure 13: Pubmed with ego graph sampling

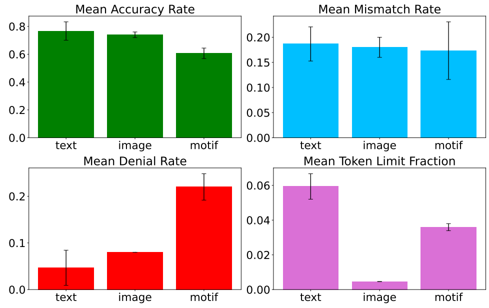

Figure 14: Pubmed with forest fire sampling

Figure 15: Modality comparison (text, motif, and image) with the graph structure and sampling type shows the *clear dependency of graph structure and sampling on node classification performance*.

GPT-4V(vision), the limit is claimed to be 128000 tokens, but currently, only the preview version has been released, and the actual limit is 10000 tokens.

Rate limits for each LLM The rate limit for GPT-4 is 10K RPM (requests per minute), and for GPT-4V, the rate limit is 100 RPD (requests per day).

Modality Experiment Parameters For all modality types, we sample 50 graphs for all datasets, the number of hops considered = 3, no of runs = 2, and perform ego graph and forest fire sampling. We report the mean and standard deviation directly or through error bars in the visualization for all metrics. In the paper, we report the results from ego graph sampling because node classification typically needs a localized view around specific nodes, best provided by ego graph sampling.

A.3.1 Text Modality

Task: Node Label Prediction (Predict the label of the node marked with a ?) given the adjacency list information as a dictionary of type "node: neighborhood" and node-label mapping in the text enclosed in triple backticks. The response should be in the format "Label of Node = <predicted label>". If the predicted label cannot be determined, return "Label of Node = -1".
```**AdjList**: {1: [2,3], 2: [3,4], 3: [1,2]}
**Node-Label Mapping**: {1: A, 2: B, 3: ?} ```

Encoding graphs as text can be separated into two key parts: First, the mapping of nodes to their corresponding labels in the graph, and second, the encoding of edges between the nodes. We encode the node-to-label mapping as a dictionary of type {node ID: node label}. Finding a concise yet informative representation of the graph structure and edge representation is essential. An example of a
```

Edge Representation	Text Encoding	Description of Edge Representation
Edgelist	Node to Label Mapping : Node 69025: Label 34| Node 17585: Label 10|... *Edge list: [(69025, 96211), (69025, 17585), (17585, 104598), (17585, 18844), (17585, 96211), (96211, 34515)]*	An Edgelist is a graph data structure that represents a graph by listing the edge connections between two nodes. (A, B) indicates an connection between nodes A and B.
Edgetext	Node to Label Mapping : Node 85328: Label 16| Node 158122: Label ?|... *Edge connections (source node - target node): Node 85328 is connected to Node 158122. Node 158122 is connected to Node 167226.*	An Edgetext explicitly lists the connections between two nodes; for example, Node A is connected to Node B or Node A - Node B
Adjacency List	Node to Label Mapping : Node 2339: Label 3| Node 2340: Label ?|... *Adjacency list: 1558: [2339, 2340], 2339: [1558, 2340], 2340: [2339, 1558]*	An adjacency list represents a graph as an array of linked lists. The index of the array represents a vertex, and each element in its linked list represents the other vertices that form an edge with the vertex. For example, A: [B, C] shows that A is connected to B and C. This gives an idea of node-neighborhood

GML

```

```

A GraphML format consists of an unordered sequence of node and edge elements enclosed within []. Each node element has a distinct id and label attribute contained within []. Each edge element has source and target attributes contained within [] that identify the endpoints of an edge by having the same value as the node id attributes of those endpoints. The node label information is embedded within the structure, meaning no node-label mapping is notneeded.

  <edge source=2339 target=2340 />
</graph>
</graphml>
```

A GraphML file consists of an XML file containing a graph element, within which is an unordered sequence of node and edge elements. Each node element should have a distinct id attribute as well as its label, and each edge element has source and target attributes that identify the endpoints of an edge by having the same value as the id attributes of those endpoints. The node label information is embedded within the structure meaning no node-label mapping is needed.

Table 6: Summary of edge representation passed as a part of the text modality encoder with their associated examples and explanations. We find that the **Adjacency list** representation provides a granular yet not too verbose view of the graph being passed to the LLM.

prompt using text modality is given above.

	CORA	Citeseer	Pub.med
Avg edges 2-hop	62.70 ± 94.77	26.35 ± 61.70	129.36 ± 287.61
Avg nodes 2-hop	36.78 ± 48.12	15.11 ± 24.73	60.05 ± 85.12

Table 7: Subgraph Sampling Statistics about average number of nodes and edges in a 2-hop subgraph from each dataset.

Impact of Edge encoding function: Motivated by recent works (Fatemi et al., 2023; Guo et al., 2023) describing the importance of selecting the appropriate text encoding for a graph, we experiment with different edge representations (Appendix Table 6) on real-world datasets and evaluate the metrics for node classification and the results of this are illustrated in Figure 16. *“Adjacency list” is the best-performing edge representation for the text modality.*

Impact of Graph Structure: We selected diverse real-world citation datasets with unique network characteristics, as shown in Table 1. These network properties are defined in Table 8. The average number of nodes and edges in a 2-hop subgraph is also reported for CORA, Citeseer, and Pubmed datasets.

Impact of Sampling Strategy: Graph sampling techniques are essential for applying LLMs in graph reasoning, particularly due to the limited context window of LLMs and the intricacy of real-world graphs (Wei and Hu, 2022). Ego graph sampling centers on a specific node and its direct con-

Table 8: Graph Properties and Their Descriptions

Name of Property	Description
Density	Measures how connected the graph is. It's the ratio of actual edges to possible edges.
Degree Distribution	The distribution of node degrees. The histogram might follow a specific pattern (e.g., power-law distribution, Gaussian distribution).
Average Degree	The average degree of nodes in the graph.
Connected Components	A subgraph in which a path connects any two nodes.
Clustering Coefficient	Measures the degree to which nodes tend to cluster together.
Graph Diameter	The longest shortest path between any two nodes. It provides insight into the graph's overall size.
2hop nodes	Average number of nodes present in the subgraph at 2 hop distance from any node

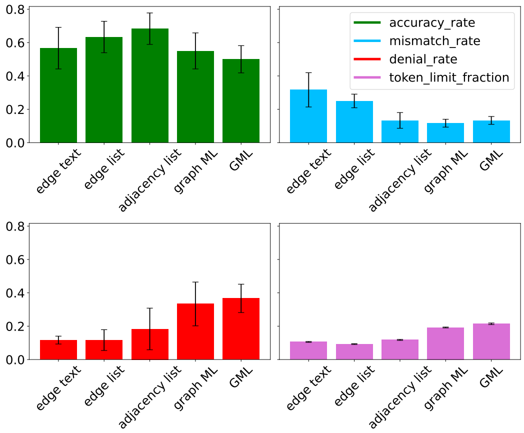

Figure 16: We compare the edge representation type (x-axis) with the value of the mean metrics (y-axis). The desired trend is given in brackets for each metric. The highest performing edge representation is the "adjacency list" representation with the highest accuracy (A ↑) and low mismatch rate (M ↓)), denial rate (D ↓), and token limit fraction (T ↓).

nections, forming a subgraph that mirrors these immediate relationships. In contrast, Forest Fire sampling randomly selects a node and expands from there, producing varying subgraphs in size and structure, influenced by factors like 'burning' probabilities. However, both methods have limitations and can potentially distort the overall structure of complex and extensive networks.

A.3.2 Motif Modality

Task: Node Label Prediction (Predict the label of the node marked with a ?) given the node-label mapping and graph motif information in the text enclosed in triple backticks. The response should be in the format "Label of Node = <predicted label>". If the predicted label cannot be determined, return "Label of Node = -1".
```**Node-Label Mapping**: {1: A, 2: A, 3: ?}
**Graph-motif information**: No of triangles: 1| Triangles attached to ? Node : [1,2,3]| ```

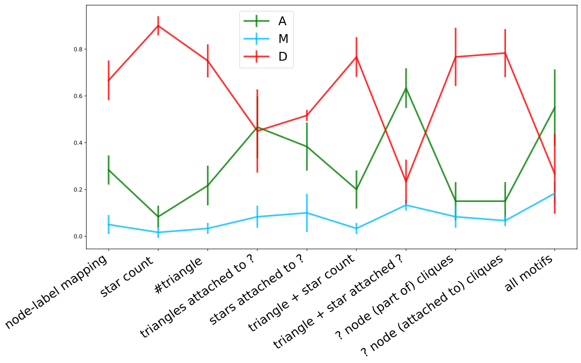

Figure 17: We compare the motif information (x-axis) to the mean metrics (y-axis). Desired trends are denoted in brackets. Metrics considered are Accuracy Rate (A ↑), Mismatch Rate (M ↓), and Denial Rate (D ↓). The highest performing motif information change "triangle and star attached to ?" has higher accuracy and lower mismatch and denial rate.

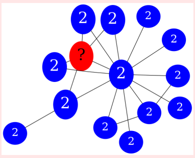
Encoding graphs as motifs can be separated into two key parts: First, the encoding of nodes to their corresponding labels in the graph, and second, the motifs present around the ? (unlabeled) node. We encode the node-to-label mapping as a dictionary of type {node ID: node label}. We calculate motifs in the neighborhood of the ? nodes and pass this information to GPT-4 (OpenAI, 2023a) as the graph-motif information. Connections of an unlabeled node to significant nodes or groups (like stars or cliques) are more indicative of its label than just the count of graph motifs, with central nodes in star motifs or members of cliques heavily influenced by their neighbors' labels. We experiment with different network motifs as input to the modality encoder. Table 9 describes the different types of motifs considered, a description of the motif, and an example of the encoding generated as input to GPT-4. An example prompt generated after applying the motif encoding modality is given above.
```

Type of Motif	Motif Encoding	Description of Motif
Node-Label Mapping	*Node to Label Mapping : Node 1889: Label 4 | ... Node 1893: Label ?|...*	Only the node-label mapping is provided (this gives no connectivity information to LLM)
No. of Star Motifs	Node to Label Mapping : Node 1889: Label 4 | ... Node 1893: Label ?| ... *Graph motif information: Number of star motifs: 0*|	Star motifs signify centralized networks with influential central nodes, where a central node is connected to others that aren't interlinked. We pass the count of the star motifs present in the graph.
No. of Triangle Motifs	Node to Label Mapping : Node 1889: Label 4 | ... Node 1893: Label ?| ... *Graph motif information: Number of triangle motifs: 6*|	Triangle motifs (triads connecting three nodes) are foundational in social networks, indicating transitive relationships, community structures, and strong social ties. We pass the count of the triads present in the graph.
No. of Triangle Motifs Attached	Node to Label Mapping : Node 1889: Label 4 | ... Node 1893: Label ?|... *Graph motif information: Triangle motifs attached to* ? *node: [1893,2034,1531], [1893,1531,429]*|	We pass the triangle motifs attached to the ? label, which gives an idea of the influential triads connected to the ? node.
No. of Star Motifs Attached	Node to Label Mapping : Node 1889: Label 4 | ... Node 1893: Label ?|... *Graph motif information: Star motifs connected to* ? *node: []*|	We pass the star motifs attached to the ? label, which gives an idea of the influential nodes connected to the ? node.
No. of Star and Triangle Motifs	Node to Label Mapping : Node 1889: Label 4 | ... Node 1893: Label ?|... *Graph motif information: Number of star motifs: 0*| *Number of triangle motifs: 6*|	We pass the count of the triads and star motifs present in the graph, to give the LLM an idea of the graph structure.
Star and Triangle Motifs attached	Node to Label Mapping : Node 1889: Label 4 | ... Node 1893: Label ?|... *Graph motif information: Triangle motifs attached to ? node: [1893,2034,1531], [1893,1531,429]*| *Star motifs connected to* ? *node: []*|	We pass the star motifs and triads attached to the ? label, which gives an idea of the influential nodes and triads connected to the ? node.
No of cliques ? **Node is part of**	Node to Label Mapping : Node 1889: Label 4 | ... Node 1893: Label ?|... *Graph motif information: Number of cliques in graph: 0*| ? *Node is a part of these cliques: []*|	We pass the number of cliques in the network, which gives an idea of its clustered nature. We also pass the cliques the ? label is a part of, which gives an idea of the immediate community of the unlabelled node.
No of cliques ? **Node is attached to**	Node to Label Mapping : Node 1889: Label 4 | ... Node 1893: Label ?|...*Graph motif information:* ? *Node is attached to these cliques: []*|	We pass the cliques the ? label is attached to, which gives an idea of the neighboring influential community of the unlabelled node.

Table 9: Summary of motif information passed as a part of the motif modality encoder with their associated examples and explanations. The **Aggregate of all changes** setup combines all of the above motif information to give the LLM a local and global view of the graph being passed.

A.3.3 Image Modality

Task: Node Label Prediction (Predict the label of the red node marked with a ?, given the **graph structure information in the image**). The response should be in the format "Label of Node = <predicted label>." If the predicted label cannot be determined, return "Label of Node = -1."



We use GPT-4V (OpenAI, 2023b) to process graph images to give LLMs a global perspective of graph structural information. An example prompt generated after applying the image encoding modality is shown above.

B GNN Experiments

Our GNN model training utilized optimal hyperparameters as detailed in Table 11. We followed the standard train-test splits of the Planetoid dataset from PyTorch Geometric, adhering to the conventional approach in semi-supervised learning research within graph-based studies. This approach allows for learning from minimal labeled data alongside a larger pool of unlabeled data, ensuring consistency with prior research. Due to GPT-4 API constraints limiting us to 50 test samples, our main paper could not compare results directly with those obtained from 1000 test samples (shown in Table 10).

On-the-Fly Fusion of Large Language Models and Machine Translation

Hieu Hoang **Huda Khayrallah** **Marcin Junczys-Dowmunt**
Microsoft, 1 Microsoft Way, Redmond, WA 98052, USA
`{hihoan,hkhayrallah,marcinjd}@microsoft.com`

Abstract

We propose on-the-fly ensembling of a neural machine translation (NMT) model with a large language model (LLM), prompted on the same task and input. Through experiments on 4 language directions with varying data amounts, we find that a slightly weaker-at-translation LLM can improve translations of a NMT model, and such an ensemble can produce better translations than ensembling two stronger NMT models. We demonstrate that our ensemble method can be combined with various techniques from LLM prompting, such as in context learning and translation context.

1 Introduction

For many English NLP tasks, LLMs (Brown et al., 2020; Smith et al., 2022; Chowdhery et al., 2022; Touvron et al., 2023a,b) are the clear state-of-the-art—e.g. sentiment analysis (Zhang et al., 2023c), summarization (Zhang et al., 2023b). However, dedicated NMT outperforms all but the largest closed source LLMs (Jiao et al., 2023) and dedicated MT is stronger in low resource settings (Hendy et al., 2023; Robinson et al., 2023).

We propose a novel integration of a LLM and dedicated NMT model via token-level fusion. This ensembling combines strengths of each model, which emerge from their differences. LLMs are trained on more data than NMT models, and have more parameters. While LLMs are exposed to some parallel data (Briakou et al., 2023), they are trained on vastly more monolingual data, which likely gives them different domain coverage and more fluency than dedicated models. NMT models are trained on the translation task. For example, Jiao et al. (2023) found ChatGPT is more likely to hallucinate but is stronger at translating the spoken domain, while dedicated models are stronger for medical domains and social-media-style noisy text. LLMs can easily be prompted with auxiliary information— such as domain and document context—while that is more complicated for NMT.

In this work we:

- propose on-the-fly ensembling of an MT model with a prompted-for-translation LLM,
- combine it with domain and context prompting,
- demonstrate that a weaker-at-translation LLM can improve translations of a MT model,
- and demonstrate our method is better than MT ensembles and ensembles with non-prompted LLMs.

2 Method

We review standard inference of encoder-decoder NMT models and decoder only LLMs and then introduce our proposed ensemble of the two.

Standard Decoding In encoder-decoder NMT, the probability of token t at the i^{th} time step is:

$$p_{\text{MT}}(t_i) = p_{\text{MT}}(t_i | t_{j<i}, S) \quad (1)$$

This conditions on source sentence S as the input to the encoder and $t_{j<i}$ as the previously generated target tokens in the MT model decoder.

When using a decoder only LLM for translation, the probability of token t at the i^{th} time step is:

$$p_{\text{LLM}}(t_i) = p_{\text{LLM}}(t_i | M, S, t_{j<i}) \quad (2)$$

The concatenation of the prompt M, source sentence S and the previous generated targets are all decoder outputs. The LLM model is prefix-decoded through the prompt and source, and then allowed to produce the target tokens. The LLM prompt M can also include additional content.

Proposed Ensemble When combining the two for our ensemble, we have:

$$p_{\text{ensemble}}(t_i) = \lambda p_{\text{MT}}(t_i) + (1 - \lambda) p_{\text{LLM}}(t_i) \quad (3)$$

In the ensemble, p_{MT} and p_{LLM} condition on the tokens previously generated by the ensemble. p_{LLM} still conditions on the prompt, which can be used to infuse the model with auxiliary information (e.g. domain or context). p_{ensemble} reduces to the LLM when $\lambda = 0$ and to the MT model when $\lambda = 1$.

3 Experimental Setup

We aim to understand how our proposed method performs in high and low resource settings with strong models, and design our experimental setup accordingly.

The parallel and monolingual training data for German and Russian is from the WMT22 (Kocmi et al., 2022)[1] shared task. The Hausa data is from WMT21 (Akhbardeh et al., 2021).[2] The Turkish evaluation data was based on WMT18 (Bojar et al., 2018)[3] and training data also includes additional data from OPUS (Tiedemann, 2012), excluding Paracrawl (Bañón et al., 2020), since such noisy data (Khayrallah and Koehn, 2018) would require filtering (Koehn et al., 2018, 2019, 2020; Sloto et al., 2023).

As domain-specific test sets we use TED-100 (Salesky et al., 2021) and ParaPat (Soares et al., 2020). We also use TED-100 and CTXPro (Wicks and Post, 2023) for document-level experiments.[4]

Table 1 summarizes the parallel training, evalution and test data and Table 6 in the Appendix summarizes the monolingual data.

We use back translation (Sennrich et al., 2016) (with a 1:1 ratio of parallel to synthetic data) for all language pairs. We train Transformer 'big' models for German, Russian and Turkish, and 'base' for Hausa (Vaswani et al., 2017) in Marian NMT (Junczys-Dowmunt et al., 2018).[5] We use Llama2 (Touvron et al., 2023b) with 7 and 13 billion parameters as LLMs. The LLama2 32k token SentencePiece model (Kudo and Richardson, 2018) is used for source and target MT tokenization.[6]

The optimal mixing ratio is learnt using grid search $\lambda \in \{0, 0.1, ...1\}$ on the validation set. We use this same value of λ in domain specific experiments in § 5; we do not re-sweep for each domain. Final results are reported on the test sets, translation quality is measured using COMET-22 (Rei et al., 2022). We use greedy search for decoding. See § A for additional experimental details, including prompts.

4 Results

Table 2 shows the translation quality of the ensemble using the 7 billion parameters LLM (col. 1-6). When both models are of reasonable quality (de-en, ru-en, en-ru), ensembling (col. 5) results in better quality than either alone (col. 1 & 2).

In all cases, the LLM quality is worse than the MT model but ensembling with it improves most language directions. For de-en, the MT model is 0.9 COMET stronger than the LLM. The ensemble still improves over the MT model by 0.6 COMET.

The improvement is minor for en-de, where the LLM was 21.9 points worse than MT. The LLM translation quality for Turkish in both direction is poor while the MT is good so the ensembles are essentially reduced to the MT model. Both models are bad for Hausa and the ensembles are unusable. § A.4 shows the effect of λ on translation quality.

In-context learning: Table 2 (col. 3) shows 5-shot learning tends to improve LLM quality but has little affect on the ensemble (col. 6).

Larger LLM: Xu et al. (2023) found that Llama-13B suffers from off-target issues, degrading translation out-of-English compared to the 7B model. We confirm their results—Table 2 (col. 2 vs 7)—and also reproduce their solution of using 5-shot learning, which can recover and sometime improve LLM quality (col. 8). However, ensembling with the MT model does not require the use of in context learning (col. 10 vs 11). In general, the larger language model is better for the ensemble as de-en, en-de and ru-en all improve. It should also be noted that the MT model adds, at most, 3% to the number of parameters of the 7B LLM allowing the

Table 2: COMET-22 on WMT test sets. Ensembling MT & LLM can improve scores in high resource settings where the LLM's COMET is somewhat worse than the MT. λ is the mixing rate; higher λ puts more emphasis on MT.

ensemble to outperform the nearly 2x bigger 13B LLM.

Ensembles for Turkish and Hausa are still not worthwhile due to the poor LLM quality in these lower resource settings. We use the 7B model in all analysis for the remainder of this work.

5 Analysis

5.1 MT Model Ensembling

Given the compute resource required to use LLMs (not to mention train them), we compare the results of the MT + LLM ensemble to ensembling two MT models. We create ensembles for German and Russian language pairs consisting of two MT models.[7] As Table 3 shows, using the LLM gives stronger translation quality in all cases except en-de, which is where the LLM underperforms the MT model by 6 COMET points. In all the other situations, *it is better to ensemble the MT model with an LLM, even though the* 2^{nd} *MT model has higher translation quality than the LLM by 0.5 to 2.8* COMET. This suggests that when selecting models for an ensemble, simply choosing the two highest quality models is insufficient. Instead, ensembling takes advantage of the training diversity in the models to improve quality.

	MT		LLM	MT+LLM	MT+MT
de-en	83.5	83.7	82.6	**83.9**	83.8
en-de	85.4	85.4	79.4	85.5	**85.7**
ru-en	82.8	83.0	82.5	**84.0**	83.1
en-ru	83.1	83.2	80.4	**83.9**	83.4

Table 3: COMET-22 score for two MT replicas, the LLM, the MT & LLM ensemble, and the ensemble of the two MT models. The ensembling of the LLM with the MT model has the highest COMET score in all but one language pair, even though both the MT models have higher translation quality than the LLM.

		MT	LLM		Ensemble	
	prompt:	none	general	+domain	general	+domain
TED	ru-en	77.3	78.0	78.5	78.7	**78.9**
ParaPat	de-en	79.7	77.1	78.0	**80.0**	**80.0**
	en-de	79.1	73.8	73.8	**79.2**	**79.2**
	ru-en	72.2	74.5	73.9	**75.1**	75.0
	en-ru	78.5	73.7	73.4	**79.0**	78.7

Table 4: Prompting with domain can improve COMET-22 for the LLM, but is less effective for the ensemble.

5.2 Mixing Ratio Interpretation

The learnt mixing ratio, λ, can be loosely interpreted as a relative utility of the underlying models. For ensembles with German and Russian, λ of 0.7 and 0.5 for the 7B LLM ensemble reflect the nearly equal contribution of both models. Due to off-target issue described above, the 13B LLM are poor at translating into German and Russian so its contribution to the ensemble is reduced.

For Turkish and Hausa, the LLM offer negligible benefit so most weight is given to the MT model. The mixing ratio space for Hausa-English is flat (see Figure 7(g)) as both underlying models are equality poor so no interpretation should be attached to the results.

---

[7] The models differ only in the random seed.

5.3 Domain Prompting

The flexibility of LLM prompting can be used to add more descriptive task-specific instructions to improve quality (Zhang et al., 2023a). Here, we prompt for domain (TED talks and patents).

Table 4 shows that additional domain information does not guarantee better LLM quality. For the TED-100 test set, ensembling has a 0.2 COMET improvement from an 0.5 LLM increase. Ensembling with or without the domain information in the prompt outperforms either the MT and LLM models alone. For TED, the LLM is stronger than the dedicated MT models, in contrast to our main results.[8] While our dedicated MT models were not trained translation for this specific domain, the LLM likely exposed to monolingual data in this domain. This highlights the complementary strengths of each paradigm—the ensemble leverages both.

5.4 Document Context

For document or discourse input—such as TED talks—where the previous translated sentences are often relevant to the sentence to be translated, it may be better to provide the previous sentences and their translation. This contrasts with few-shot prompting where sentences pairs are high quality translations written by humans but are drawn from the validation so may not be relevant to the sentence at hand. Using sentence pairs from the same document should allow the LLM to enforce consistency across sentences and allow it to better translate phenomena that requires document-level context such as pronoun disambiguation.

Figure 1 shows the COMET-22 score against the number of sentence pairs in the prompt on the TED-100 test set. Prompting the LLM with document context outperforms few-shot prompting and the ensemble with context (solid orange line) to outperform all variants of ensembling and LLMs with context or few-shots, as well as the MT model. *Conditioning on the model's own previous outputs from the same document context outperforms few-shot prompting with the human references of less related sentences.*

Prior work found that document level-specific evaluation is required to evaluate document level phenomena (Läubli et al., 2018; Toral et al., 2018; Vernikos et al., 2022). To this end, we use CTXPro (Wicks and Post, 2023), a specialized test suite which evaluates the translation accuracy of targeted words, given the document context.

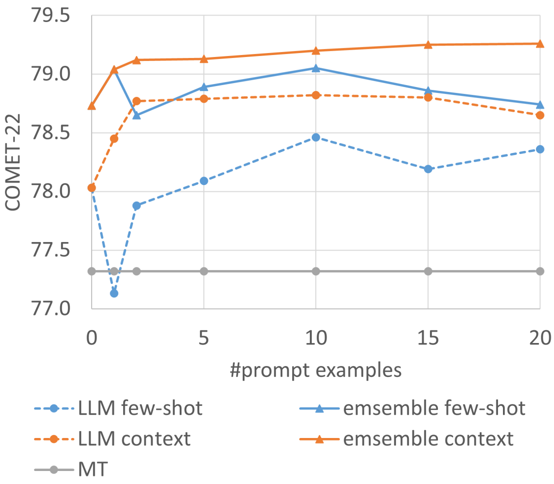

Figure 1: TED-100 translation quality for various number of prompt examples (for few short learning or past context). Prompting with context outperforms few shot prompting, and it performs best when ensembled.

		MT	LLM		Ensemble	
	context:	none	none	10 sent	none	10 sent
en-de	auxiliary	4.5%	7.2%	**28.0%**	6.2%	13.7%
	formality	41.9%	38.2%	37.6%	42.7%	**43.8%**
	gender	44.6%	38.5%	39.0%	**45.8%**	45.5%
en-ru	auxiliary	2.6%	2.3%	**24.6%**	2.6%	20.9%
	formality	42.5%	42.6%	46.4%	46.4%	**50.0%**
	gender	27.4%	31.9%	36.4%	31.6%	**37.6%**
	inflection	28.9%	22.6%	25.6%	29.2%	**31.4%**

Table 5: CTXPro accuracy. The ensembled models with context perform particularly well in to Russian.

Table 5 shows accuracy for various phenomena on en-ru and en-de. Adding context improves accuracy in all-but-one test set. Ensembling with context has the highest accuracy in 4 of 7 models. See § A.5 for COMET on this data; the ensemble is always best. So, when balancing COMET and CTXPro accuracy, the ensemble is best.

5.5 Unprompted LM Ensembling

Yee et al. (2019) and Petrick et al. (2023) improve translation by ensembling with a smaller-scale language model *without* a task-specific prompt.

We test this by ensembling the MT model with an unprompted LLM. Figure 2 shows that this causes quality to drop precipitously. The divergence from prior work may be due to differences in the base models; for example, Petrick et al. (2023) used an MT model trained on small amount of data, and Yee et al. (2019) trained their own LM. In our

---

[8] In this work, we used the λ set on the general validation set. Re-sweeping for each specific domain could lead to improved performance.

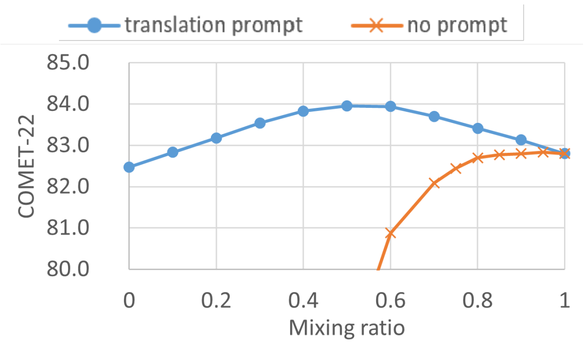

Figure 2: Using an LLM with a translation prompt and without any prompting (ru-en). Unprompted the ensemble is strictly worse than the MT baseline (mixing ratio $\lambda = 1$).

scenario with a strong MT model and a general purpose LLM, we do not see any benefit from using the LLM purely as a language model.

6 Related work

LLMs for MT: Pretrained LLMs can be prompted directly for translation (Brown et al., 2020; Vilar et al., 2023; Hendy et al., 2023; Robinson et al., 2023; Zhang et al., 2023a; Agrawal et al., 2023), or fine-tuned for MT (Li et al., 2023; Chen et al., 2023; Moslem et al., 2023; Zeng et al., 2023; Xu et al., 2023; Yang et al., 2023). Our approach is complimentary—we leverage prompting and in-context learning. We could also ensemble with a fine-tuned model. Since we perform inference-time combination of the LLM, we do not have the same training-compute burden as fine-tuning.

Much work has explored integrating language models and NMT in various ways (Gulcehre et al., 2015, 2017; Stahlberg et al., 2018; Yee et al., 2019; Petrick et al., 2023), mostly by purely conditioning a language model on the target tokens; in contrast we focus on pretrained LLMs and *prompt* the LLM to produce translations.

Ensembling: Diverse inputs can be combined to create stronger ensembles (Hansen and Salamon, 1990; Dietterich, 2000). Various model-combination methods have been used in MT.

System combination of outputs was used for statistical machine translation (SMT) (Bangalore et al., 2001; Heafield and Lavie, 2010; Freitag et al., 2014), and averaging model weights (Junczys-Dowmunt et al., 2016) or ensembling (Chung et al., 2016) are used for NMT. We build upon the latter. Jiang et al. (2023) propose a separate model to combine outputs from LLMs. We ensemble on-the-fly. Ormazabal et al. (2023) ensemble two LLM from the same family where the smaller LM was finetuned for MT. We create a hybrid ensemble of two distinct architectures and training regimes.

Knowledge distillation (Buciluă et al., 2006; Hinton et al., 2015) inspired methods can be a way to incorporate diverse models during training (Dakwale and Monz, 2017; Khayrallah et al., 2018, 2020), as opposed to during inference. Jiang et al. (2023) introduce a separate model that combines outputs from LLMs. We ensemble on-the-fly.

There are various methods proposed for improving translation quality by combining the adequacy and fluency advantages of SMT and NMT (Devlin et al., 2014; Mi et al., 2016; Junczys-Dowmunt et al., 2016; Stahlberg et al., 2017; Wang et al., 2017; Khayrallah et al., 2017; Ding et al., 2017; Zhang et al., 2021). We combine the strengths of NMT and LLMs.

7 Conclusion

We propose an on-the-fly ensembling of a dedicated MT model with an LLM, conditioned on the source and prompted for translation. We demonstrate that an LLM can improve translation quality of a NMT model even if the LLM is weaker at translation, provided the LLM is good enough. We prompt the LLM to imbue the sentence-based MT model with document-level ability, improving on sentence-level and context-focused metrics. We find that ensembling with an LLM performs better than ensembling two MT models, even if each MT model is stronger than the LLM.

While this work focuses on MT, the same techniques can be explored for other tasks, and may be especially useful for situations where the LLM and task-specific model have different properties and strengths.

8 Limitations

While we covered four languages to and from English, this is nowhere near enough to be a representative sample of languages and translation directions that would be of interest to others. We used Llama2; there are closed-access models that may be stronger at translation (e.g. GPT-4) but API access is insufficient for this method. As open-source new models are released, this method can be applied to them as well.

We used a single value of λ—which was set on the general domain validation set—for all experiments. We did not re-sweep for each domain. While this is a more general scenario that applies when test-time domain is unknown, results might be improved for focused domains by tuning λ on domain-specific validation sets.

In § 5, we explore different domains (TED talks, subtitles, and patents), and use COMET-22 as a metric. Zouhar et al. (2024) recently demonstrated that neural fine-tuned metrics, such as COMET are not robust to domain shift, but noted that COMET still had the highest overall correlation with human judgements in their domain of study.

A Experimental Details

A.1 Hyperparameters

For German, Russian and Turkish, Transformer 'big' models were trained (6 layer encoder-decoder, 1024 embedding dimensions, 4096 feed-forward dimensions, 16 heads) (Vaswani et al., 2017). The base Transformer architecture was used for Hausa (6 layer encoder-decoder, 512 embedding dimensions, 2048 feed-forward dimensions, 8 heads). We use weight tying (Press and Wolf, 2017). We train models using Marian NMT (Junczys-Dowmunt et al., 2018).[9] We convert MT models from Marian to Hugging Face format, to allow for inference with Llama2 (Touvron et al., 2023b) in the Hugging Face library (Wolf et al., 2020).

A.2 Monolingual Data

A.3 Prompting

Figure 3, Figure 4, Figure 5, and Figure 6 describe the various prompts we use.

A.4 λ

Figure 7 shows translation quality as we vary the mixing ratio, λ. Note that p_{ensemble} reduces to the LLM when $\lambda = 0$ and to the MT model when $\lambda = 1$.

For our results in the main section, we selected λ on validation set translation quality. Here we see that in cases where both models are reasonably strong (de-en, ru-en, and en-ru) the ensembling provides a quality boost.

A.5 COMET-22 CTXPro

Figure 8 shows the COMET-22 scores corresponding to the document translation accuracy show in Table 5. The ensemble is always best on this data, then the MT, and then the LLM.

READ: Improving Relation Extraction from an ADversarial Perspective

Dawei Li, William Hogan, Jingbo Shang*
University of California, San Diego
{dal034,whogan,jshang}@ucsd.edu

Abstract

Recent works in relation extraction (RE) have achieved promising benchmark accuracy; however, our adversarial attack experiments show that these works excessively rely on entities, making their generalization capability questionable. To address this issue, we propose an adversarial training method specifically designed for RE. Our approach introduces both sequence- and token-level perturbations to the sample and uses a separate perturbation vocabulary to improve the search for entity and context perturbations. Furthermore, we introduce a probabilistic strategy for leaving clean tokens in the context during adversarial training. This strategy enables a larger attack budget for entities and coaxes the model to leverage relational patterns embedded in the context. Extensive experiments show that compared to various adversarial training methods, our method significantly improves both the accuracy and robustness of the model. Additionally, experiments on different data availability settings highlight the effectiveness of our method in low-resource scenarios. We also perform in-depth analyses of our proposed method and provide further hints. We will release our code at https://github.com/David-Li0406/READ.

1 Introduction

Relation extraction (RE) is an important subtask of information extraction and plays a crucial role in many other natural language processing (NLP) tasks like knowledge base construction (Luan et al., 2018) and question answering (Sun et al., 2021). The goal of RE is to determine the relationship between a head entity and a tail entity. For example, given the sentence "*Miettinen hired for WPS champ Sky Blue.*", the RE models are supposed to predict the relation "*Employee-Of*" between the head entity "*Miettinen*" and the tail entity "*Sky Blue*". With the recent advances in pre-trained language model (Kenton and Toutanova, 2019; Liu et al., 2019) and self-supervised learning (Qin et al., 2021; Hogan et al., 2022; Hogan, 2022) techniques, RE models have achieved promising benchmark accuracy, reaching levels comparable to human performance.

	Sentence	Prediction
Org	Miettinen hired for WPS champ Sky Blue.	Employee-Of ✓
Adv	Miettinen hired for WPS champ Jeez Blue.	No-Relation ✗

Table 1: An example from SemEval. We use green color to represent the head entity and orange color to represent the tail entity. Underlining is used for word substitution.

The recent success of RE models sparks a growing interest in conducting more detailed analyses (Han et al., 2020c; Peng et al., 2020; Zhang et al., 2023). A significant issue that arises in this context is to explore *whether the RE model learns from context or entities for relation prediction*. Analyzing this problem could reveal the underlying nature of RE models and offer informative insights for their improvement. To address this issue, various methods are proposed such as information masking (Peng et al., 2020) and counterfactual analysis (Wang et al., 2022b). One drawback of these methods is they usually involve removing entities or context in the sample and observing the model's performance with the remaining part. That enables them to draw the conclusion about how much can the model learn from entity/ context when giving each of them individually. However, whether the model would prefer to learn from context or entities when both of them are given still remains unclear. We name this problem *learning preference* in RE.

To address this issue, we propose a novel approach **READ**, a.k.a. improving **R**elation **E**xtraction from an **AD**versarial perspective. We begin by introducing the utilization of **adversar-**

ial attacks (Jin et al., 2020; Garg and Ramakrishnan, 2020) as a means to investigate the model's learning preference and robustness. Adversarial attacks in NLP are designed to deceive the model by making very few text substitutions. As the example shown in Table 1, by replacing the original word "*Sky*" with another word "*Jeez*", the attack method successfully fools the model into assigning an incorrect label "*No-Relation*" to this sample. Adversarial attacks provide a highly insightful perspective for determining the crucial parts of the sample from the model's viewpoint. In this particular example, we can conclude that the word "*Sky*", as a part of the entity name, is crucial for the model to make accurate predictions.

In our preliminary experiment applying adversarial attacks to RE, we discovered a clear over-dependency on entities within the current RE model. This is consistent with the previous works (Peng et al., 2020) that RE models tend to utilize shallow cues from entities to make predictions. Our analysis revealed that this over-dependency is the underlying cause of the models' vulnerability to adversarial attacks and can also lead to poor generalization in clean samples. So the key to improving current RE models is to mitigate this over-dependency on entities.

One straightforward approach to bolster models' robustness is text substitution. However, the considerable time cost to generate adversarial samples with the text substitution method constrains it in scaling in large RE datasets (Yoo and Qi, 2021). Also, in our preliminary experiments, we observed a performance drop in the clean test set with text substitution, which has also been reported by previous works (Xu et al., 2022b)[1]. So we shift our focus towards **virtual adversarial training** (Miyato et al., 2016; Madry et al., 2018), which applies continuous perturbations at the embedding level during training, rendering it a more refined and efficient approach. Our method builds upon the advancements of the current adversarial training methods in NLP (Zhu et al., 2019; Li and Qiu, 2021) and introduces both sequence- and token-level perturbations to the RE sample. To facilitate perturbation searching, we devise a separate perturbation vocabulary that tracks the accumulated perturbation for entity and context respectively. Furthermore, we propose a novel probabilistic strategy to encourage the model to leverage relation patterns from the unperturbed context. Through extensive experiments, we demonstrate the effectiveness of our method on both adversarial and clean test samples. We also observe significant improvements in low-resource settings, indicating the great potential of our method in scenarios with limited data. We conduct a series of in-depth analyses to give more hints about READ.

The contribution of our work could be summarized as follows:

- We propose READ, a novel adversarial method to improve current RE models' robustness.
- READ adopts adversarial attacks to analyze RE models' learning preferences and expose an obvious over-dependency on entities.
- To enhance RE models' generalization, READ utilizes a virtual adversarial training explicit design for RE. Experiments on three mainstream datasets demonstrate the effectiveness of READ.

2 Related Work

2.1 Relation Extraction

Early RE methods employ pattern-based algorithms (Mooney, 1999) or statistical methods (Mintz et al., 2009; Riedel et al., 2010; Quirk and Poon, 2017) to handle relation extraction. Neural-based RE models (Zhang and Wang, 2015; Peng et al., 2017; Miwa and Bansal, 2016) emerge with the advancements in deep learning and natural language processing. Among them, the transformer-based RE models (Shi and Lin, 2019) achieve state-of-the-art performance. To further enhance performance, various self-supervised learning mechanism designs for RE have been proposed (Soares et al., 2019; Qin et al., 2021; Hogan et al., 2022).

There are some works that explore applying adversarial training in RE. Qin et al. (2018) proposes a generative adversarial training framework to address the noisy labeling problem in distantly supervised relation extraction. Hao et al. (2021) adopt adversarial training to address the false negatives problem in relation extraction. Both Zhang et al. (2020) and Li et al. (2023c) design new adversarial training pipelines to generate augmented samples for RE. In our work, we propose to analyze and improve RE models from an adversarial perspective to expose and reduce the excessive reliance of the models on entities.

---

[1] We put the experiment result and analysis of text substitution in Appendix A

2.2 Adversarial Attack & Training

Text substitution is one of the most commonly used methods in NLP to attack models or generate adversarial samples (Iyyer et al., 2018; Ebrahimi et al., 2018). It replaces the original word with its synonym based on certain criteria like word embedding similarity (Zang et al., 2020; Ren et al., 2019; Jin et al., 2020) or model infilling (Garg and Ramakrishnan, 2020; Li et al., 2020). There are also some works that propose character-level (Gao et al., 2018; Li et al., 2018) and phrase-level (Lei et al., 2022) substitutions to generate various adversarial samples. However, those substitution methods are often challenged by the massive space of combinations when searching for the target word to replace, making them time-costly to implement (Yoo and Qi, 2021).

Virtual adversarial training (VAT) methods generate adversarial samples by applying perturbations to the embedding space (Miyato et al., 2018). This helps VAT become more efficient than traditional text substitution methods. VAT makes the model more robust under adversarial attacks while also improving the model's performance in clean test samples (Miyato et al., 2016; Cheng et al., 2019). To make VAT more effective, Zhu et al. (2019) accumulate perturbation in multiple searching steps to craft adversarial examples. Li and Qiu (2021) devise a Token-Aware VAT (TA-VAT) method to allocate more attack budget to the important tokens in the sequence. While there are some works that apply virtual adversarial training methods to RE for different purposes, we propose an Entity-Aware VAT method explicitly designed for RE to mitigate over-dependency and non-generalization on entities. We give a more detailed discussion about adversarial attacks and training in NLP in Appendix B.

3 Adversarial Attack for RE

In this section, we start by analyzing the state-of-the-art (SOTA) RE models' performance under textual adversarial attacks. Then, through further analysis, we expose the over-dependency and non-generalization on entities in the current RE models.

3.1 Attack Settings

We apply adversarial attacks on ERICA (Qin et al., 2021) and FineCL (Hogan et al., 2022), the two SOTA models with RE-specific self-supervised training. We choose three RE datasets to conduct experiments: SemEval-2010 Task 8 (Hendrickx et al., 2019), ReTACRED (Stoica et al., 2021) and Wiki80 (Han et al., 2019). For each dataset, we randomly choose 1,000 test samples to conduct experiments on. We use different attack methods including BAE (Garg and Ramakrishnan, 2020), TextFooler (Jin et al., 2020), TextBugger (Li et al., 2018) and Projected Gradient Descent (PGD) Attack (Madry et al., 2018). Here, PGD Attack is a white-box attack that utilizes the model's gradient, while the remaining three attacks are black-box attacks. We use Textattack[2] package and follow all the hyper-parameter settings in the original papers.

To evaluate how RE models perform under adversarial attacks, we follow the previous works (Li et al., 2021; Xu et al., 2022a) and report clean accuracy (the model accuracy on clean examples), accuracy under attack (the model accuracy on adversarial examples subjected to a specific attack), and the number of queries (the average number of queries the attacker required to perform successful attacks). The experiment results are shown in Table 2.

To access RE models' learning preferences, we analyze whether tokens in entities would be attacked more than them in context. If so, that means entities are more important than context in the model's perspective. For each dataset, We calculate how frequently the adversarial attacks involve the entity (Entity Freq) and the proportion of the perturbed entity in all perturbed tokens (Entity Ratios). We also report the average proportion of the entity length in the sample for comparison (Entity %). The experiment results are shown in Table 3.

3.2 Result Analysis

Here we analyze the attacking results of TextFooler on FineCL and put the remaining results with other attack methods and models into Section 5.3 and Appendix C. As shown in Table 2, FineCL suffers from a dramatic performance drop up to 91.2% in the Wiki80 dataset. In the other two datasets, there is also an obvious performance drop compared with using the clean test set, offering evidence that **current RE models are not very robust under adversarial attacks**.

As for the model's learning preference, from Table 3 we find Entity Freq is quite high in the three datasets, suggesting entities are frequently targeted for attacks. Also, Entity Ratio is much

ReTACRED	52.6	12.7	9.2
Wiki80	90.7	36.4	17.4

Table 3: Analysis of the model’s learning preference. We report how frequently the entity is attacked (Entity Freq), the proportion of the perturbed entity in all perturbed tokens (Entity Ratios), and the average proportion of the entity length in the sample (Entity %).

	Entity AS	Context AS
SemEval	68.5	62.3
ReTACRED	44.2	33.9
Wiki80	84.2	75.5

Table 4: Attack success (AS) rate of entity and context. The AS for entity and context is calculated by dividing the total number of successfully attacked entities/contexts by the total number of attacked entities/contexts.

higher than Entity %, indicating that entities are more often considered important words according to the model’s perspective. Based on these two findings we deduce that **Current RE models rely more on entities to make predictions.**

The aforementioned conclusion makes us wonder about the RE models’ robustness and generalization toward entities. To evaluate it, we calculate the attack success (AS) rate of entity and context respectively. As Table 4 shows, we find the AS of entity is significantly higher than that of context, which means entities are more vulnerable to attacks. This provides evidence that **over-dependency on entities has led to a non-generalization within the model.**

4 Adversarial Training for RE

To improve the robustness and generalization of the RE models, READ employs an **Entity-Aware Virtual Adversarial Learning** method. In this section, we first give a brief illustration of the virtual adversarial training (VAT) process, then we will introduce our Entity-Aware VAT method in detail.

4.1 Virtual Adversarial Training

In virtual adversarial learning, we first need to find a small perturbation $\boldsymbol{\delta}$ that maximizes the misclassification risk of the model. Then, with the perturbation added to the original inputs $\boldsymbol{X}$, the goal of virtual adversarial learning is to optimize the model parameter θ to minimize the loss of those adversarial samples. That Min-Max process can be summarized as follows:

$$\min_{\theta} \mathbb{E}_{(\boldsymbol{X},y)} \left[\max_{||\boldsymbol{\delta}|| \leq \epsilon} L(f_\theta(\boldsymbol{X} + \boldsymbol{\delta}), y) \right] \quad (1)$$

where $\boldsymbol{X}$ is the embedding of the input sequence and y is the ground truth label. ϵ is the norm ball used to restrict the magnitude of $\boldsymbol{\delta}$.

Commonly, gradient ascent is used to do the perturbation search iteratively since the inner maximize function is non-concave. At step t:

$$\boldsymbol{\delta}_{t+1} = \prod_{||\boldsymbol{\delta}_t||_F < \epsilon} \frac{\boldsymbol{\delta}_t + \alpha g(\boldsymbol{\delta}_t)}{||g(\boldsymbol{\delta}_t)||_F} \quad (2)$$

$$g(\boldsymbol{\delta}_t) = \nabla_{\boldsymbol{\delta}} L(f_\theta(\mathbf{X} + \boldsymbol{\delta}_t), y) \quad (3)$$

where $\prod$ means the process of projecting the perturbation onto the norm ball. In the PGD algorithm, Frobenius norm F is used to constraint $\boldsymbol{\delta}$.

4.2 Separate Perturbation Vocabularies

Unlike images in the computer vision field where every pixel only carries limited information across instances, tokens in natural language processing are relatively independent semantic units and different tokens can vary in their importance for the sequence. Previous work (Li and Qiu, 2021) proposes a Token-Aware VAT method based on this thought and designs a global perturbation vocabulary to record each token's perturbation.

In our work, we borrow this insight and improve it for RE by using separate perturbation vocabularies. Intuitively, entity and context play quite different roles in the relation extraction process for models (Peng et al., 2020). Entities are the main components for the model to focus on while context can provide auxiliary information. To address this in adversarial training of RE, we keep two perturbation vocabularies for entities and context separately.

To be specific, we create the entity perturbation vocabulary $\boldsymbol{V}_e \in \mathbb{R}^{N \times D}$ and context perturbation vocabulary $\boldsymbol{V}_c \in \mathbb{R}^{N \times D}$ at the beginning of the adversarial training. Here N is the vocabulary size and D is the hidden size of the model's embedding. In each mini-batch, the i_{th} token in the sequence will be assigned an initialized perturbation from the corresponding vocabulary as the token-level perturbation $\boldsymbol{\eta}_0^i$:

$$\boldsymbol{\eta}_0^i = \begin{cases} \boldsymbol{V}_e\,[w_i], & w_i \in Entity, \\ \boldsymbol{V}_c\,[w_i], & w_i \in Context. \end{cases} \quad (4)$$

Then we follow Li and Qiu (2021) exactly to update the token-level perturbation. After the perturbation optimization, the two vocabularies are updated respectively with the token perturbation belonging to their category.

4.3 Probabilistic Clean Token Leaving

To address the importance of entities in adversarial training, we also adopt a probabilistic clean token leaving strategy for context. In each mini-batch, we randomly choose $n\%$ of tokens W_c in context and mask both their token- and sentence-level perturbation in every perturbation optimization step t:

$$W_c = RandomlySelect(Context, n) \quad (5)$$

$$\boldsymbol{X}_{adv}^i = \begin{cases} \boldsymbol{X}^i, & w_i \in W_c, \\ \boldsymbol{X}^i + \boldsymbol{\delta}_t + \boldsymbol{\eta}_t^i, & Otherwise \end{cases} \quad (6)$$

There are two benefits of using our probabilistic clean token leaving strategy. Firstly, the attack budget ϵ is constant for each sentence, which means reducing context perturbation is equivalent to increasing the attack budget for the entity. So it serves as an additional attack to further improve the model's robustness and generalization on entities. This is our main objective given the model's non-generalization and over-dependency on entities. Also, according to the previous works (Zhang et al., 2021; Mekala et al., 2022), deep neural networks are more willing to learn from clean components with less noise. So the strategy also gives the model more chances to leverage relational patterns present in the context (Peng et al., 2020) by learning from those clean tokens. We give a detailed process of our Entity-Aware VAT method in Figure 1.

5 Experiment

In this section, we design experiments to test our Entity-Aware VAT's performance on both clean and adversarial samples.

5.1 Setup

To evaluate our method's performance, we report performance on three RE datasets, SemEval-2010 Task 8 (Hendrickx et al., 2019), ReTACRED (Stoica et al., 2021) and Wiki80 (Han et al., 2019). We follow the previous work and use 1%, 10%

Dataset	Method	Clean	PGD		TextBugger		BEA		TextFooler

	Ours	**96.7**	**76.3**	**8.99**	28.8	53.40	**40.0**	48.64	**10.7**	**112.08**

Table 5: Experiment results on the three datasets under adversarial attacks. The best results in each dataset are in bold. For each experiment, we run three times and the average scores are reported.

and 100% data in the training set to train the model respectively. For the baseline RE model, we choose BERT (Kenton and Toutanova, 2019), RoBERTa (Liu et al., 2019), ERICA (Qin et al., 2021) and FineCL (Hogan et al., 2022). We choose the two best baseline models, FineCL and ERICA, to apply the adversarial learning methods. Here we report FineCL's result and put the results of ERICA in Appendix E. We compare our proposed method with FreeLB(Zhu et al., 2019) and TA-VAT(Li and Qiu, 2021). They are widely used virtual adversarial learning methods against textual attacks. For standard accuracy metrics, we follow the previous works and report the F1 score for SemEval and ReTACRED, and the accuracy score for Wiki80. We also test our method in the document-level RE scenario and put the result in Appeneix F.

We also test our proposed method's performance under adversarial attacks. All the adversarial attack methods and robustness metrics we use are mentioned in Section 3.1

5.2 Implementation Details

We build our method based on PyTorch-1.8.1[3] deep learning framework and Transformers-2.5.0[4] library. We follow the hyper-parameter settings in the original paper to reproduce each baseline's result. To improve the experiments' reliability, we report the average results of the top three adversarial hyper-parameter configurations based on their scores in the development set. Refer to Appendix G for more detailed settings of our experiments.

5.3 Results on Adversarial Samples

We employed FineCL as the baseline and assessed the performance of each adversarial method against different attacks. To provide a baseline comparison, we designated the standard model without any adversarial training as "Normal-Train", which is included in the first row of Table 5. From the scores reported, we can observe some readily apparent trends: (1). Our method consistently outperforms other adversarial training methods under various attack methods on the three datasets. (2) For the ReTACRED dataset, both FreeLB and TA-VAT exhibit a decrease in performance under the TextBugger attack. In contrast, our method demonstrates robust improvements in both accuracy and query number, showing the resilience of our proposed approach. (3) TextFooler achieves the best attack success rate (AS) result on all three datasets, indicating that current RE models are particularly sensitive to the synonym replacement attack employed by TextFooler.

5.4 Results on Clean Samples

Table 6 presents the results evaluated using the clean samples of each dataset. It is evident that the utilization of adversarial training methods yields a significant improvement in the performance of the best baseline model (FineCL). Among the three employed adversarial training methods, our Entity-Aware VAT method stands out by reaching the best score across almost every dataset and availability setting. That indicates our improved adversarial training method also benefits the RE model in clean test samples.

Moreover, we have observed that adversarial learning exhibits a more pronounced impact in low-resource settings. For example, the improvement

Table 6: Experiment results on clean samples of each dataset. We follow the previous works (Hogan et al., 2022; Qin et al., 2021) and report the F1 score for SemEval and ReTACRED, and the accuracy score for Wiki80. We also add the quantitative comparison results between our method and the FineCL baseline. For each experiment, we run three times and report the average score.

brought by our Entity-Aware VAT method on three datasets with 100% training data is 0.7%, 0.8% and 0.4%. However, it achieves a remarkable 4.7% of performance improvement on SemEval with 1% of training data. This notable improvement highlights the immense potential of adversarial training methods for RE in scenarios with limited resources.

6 Further Analysis

In this section, we conduct further experiments to give in-depth analyses of the mechanism of our proposed method.

	1%	10%	100%		
Metrics	F1	F1	F1	AUA	Query
TA-VAT	52.5	83.1	89.0	16.5	71.97
Ours w/o SPV	52.8	83.2	89.1	**18.8**	73.63
Ours w/o CTL	53.1	83.0	**89.2**	16.3	72.51
Ours	**53.2**	**83.3**	**89.2**	**18.8**	**74.77**

Table 7: Ablation study on separate perturbation vocabulary (SPV) and clean token leaving (CTL) strategy using SemEval. The attacker used in 100% training data availability is TextFooler. We include TA-VAT since it is identical to our method when both SPV and CTL are removed.

6.1 Ablation Study

The separate perturbation vocabulary (SPV) and clean token leaving (CTL) strategy are the two main methods we propose for adversarial training in RE. In this section, we conduct an ablation study on them to figure out each method's effectiveness in improving the robustness and accuracy of the model. We conduct experiments on SemEval with 1%, 10% and 100% training data availability. We report F1 in all three availability settings and AUA and Query in 100% training data availability.

Table 7 shows the result of our ablation study. We also report the model's performance with TA-VAT because our method degrades to be TA-VAT without the two methods we propose. We find both separate perturbation vocabulary and clean token leaving are effective in improving the model's accuracy in clean samples. And clean token leaving brings a significant improvement in robustness to the model while the model with separate perturbation vocabulary only does not. That indicates the improvement in robustness of our method is mainly from clean token leaving in the context.

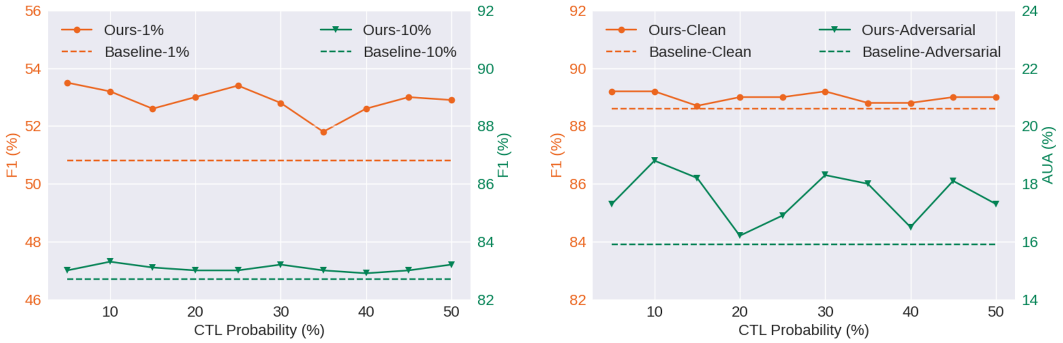
Attack Method	Method	Entity Freq	Entity Ratio	Entity AS
BAE	Normal-Train	89.0	51.1	38.2
	FreeLB	91.0	53.2	36.1
	TA-VAT	89.0	51.4	36.7
	Ours	**87.7**	**50.4**	**34.5**
TextFooler	Normal-Train	90.7	36.4	84.2
	FreeLB	**89.0**	36.7	85.2
	TA-VAT	89.7	36.5	86.9
	Ours	89.7	**35.4**	**80.0**

Table 8: Adversarial attack results of the entity on Wiki80. BAE and TextFooler are used as attackers.

6.2 Improvement on Robustness of Entity

Our Entity-Aware VAT method is first introduced to improve the robustness of entities against adversarial attacks. To investigate its effectiveness in improving entity robustness, we report Entity Freq, Entity Ratio, and Entity AS as we defined in Section 3. We choose to conduct experiments on the Wiki80 dataset here since it suffers the most from entity attacks, as indicated by the results of our pilot experiments in Section 3.

According to the results presented in Table 8, our method consistently reduces both the frequency of entity attacks and the ratio of perturbed entities compared to the normal-trained baseline and other VAT methods. This indicates that our method successfully reduces the model's reliance on entities for making predictions. Also, our method achieves a better performance in terms of entity AS, high-



(a) 1% and 10% training data

(b) 100% training data

Figure 2: Different clean token leaving probability settings in SemEval. For 1% and 10% of the training data, we report the F1 score. For the 100% training data, we report both the F1 score and AUA score

lighting its effectiveness in improving the model's robustness toward entities.

6.3 Impact of Clean Token Leaving Probability

As we demonstrate in Section 6, the clean token leaving strategy is a very important design for improving model performance in both clean and adversarial samples. In this section, we train models with different clean token leaving probabilities to observe their influence on the model performance. We conduct the analysis on SemEval.

As Figure 2 shows, we add the model without any adversarial training as "Baseline" to have a comparison. It is notable that models with different clean token leaving probabilities consistently outperform baselines. Additionally, we notice models with different data availability usually achieve the best performance with a relatively small clean token leaving probability (0.05 – 0.15).

Method	SemEval	ReTACRED	Wiki80
Normal-Train	51.6	62.8	72.7
w/ DA	54.1	63.1	72.0
w/ Ours	53.9	**64.3**	73.3
w/ DA + Ours	**55.0**	64.0	**73.5**

Table 9: Experiment results with data augmentation on 1% training data of three datasets. For a fair comparison, we show the result of the optimal model from the development set of our approach.

6.4 Comparison and Compatibility with Data Augmentation

An important finding observed in Section 5.4 is adversarial training is especially effective in RE when the training data is limited. Data augmentation (Teru, 2023; Hu et al., 2023) is another widely used technique in low-resource RE. In this section, we conduct experiments using data augmentation to have a comparison and explore our method's compatibility with data augmentation. Currently, large language models (LLMs) (Brown et al., 2020; Zhang et al., 2022; Anil et al., 2023; Touvron et al., 2023) with well-designed prompt (Wei et al., 2022; Wang et al., 2022a; Li et al., 2023a; Tong et al., 2023) show promising performance in generating diverse and high-quality content (Li et al., 2024; Tan et al., 2024). To benchmark current LLMs' ability in augmenting RE samples, we prompt ChatGPT[5] to do data augmentation. We put details about the data augmentation method in Appendix H.

Table 9 shows the experiment results with 1% training data. While data augmentation brings improvement to SemEval and ReTACRED, it also leads to a non-trivial performance drop on Wiki80. Compared with that, our method consistently improves the model's performance in the three datasets. Also, combining data augmentation with our method achieves two best results over three datasets, showing our method's compatibility with data augmentation methods.

7 Conclusion

In this work, we present READ, a novel method that leverages an adversarial perspective for analyzing and enhancing RE models. Our adversarial attacks experiment on current SOTA RE models reveals their excessive reliance on entities for relation prediction. Through our analysis, this overdependency is the underlying cause of the models' non-robustness to adversarial attacks and can limit

---

[5] https://platform.openai.com/docs/mode

the model's generalization. To tackle this issue, we propose an Entity-Aware Virtual Adversarial Training method. Experiment results show our method's effectiveness in improving the performance in both adversarial and clean samples.

8 Limitations

This work introduces an Entity-Aware Virtual Adversarial Training method. Similar to other virtual adversarial training algorithms, our method incorporates search perturbation in each mini-batch, leading to a relatively longer training time compared to other normal-trained models. Due to limitations in computing resources, we evaluate our method on four RE datasets, while disregarding scenarios such as continual relation extraction (Han et al., 2020b), few-shot relation extraction (Gao et al., 2019) and open-world relation extraction (Hogan et al., 2023). In future research, we plan to investigate the effectiveness of our method in border scenarios.

A Text Substitution Method

In this section, we conduct an experiment using the text substitution method. Specifically, we follow (Li et al., 2020) and utilize a BERT model to replace the critical token which can mislead the model most to produce the adversarial samples. We conduct evaluation using FineCL, on SemEval and ReTACRED with 1% and 10% training data. As Table 10 shows, while BERT-Attack improves the model's performance on SemEval, it also leads to a non-trivial performance drop on ReTACRED. This finding aligns with some previous works that point out the traditional text substitution method could cause a performance drop in the clean test set (Yoo and Qi, 2021; Xu et al., 2022b).

	SemEval		ReTACRED	
	1%	10%	1%	10%

B A Detailed Survey of Adversarial Attack & Training

In the computer vision field, adversarial attacks (Goodfellow et al., 2014; Carlini and Wagner, 2017) have been widely explored since it is easy to implement over the continual space of images. Based on the gradient-based adversarial attacks, various adversarial training (Goodfellow et al., 2014; Madry et al., 2018) are proposed. They add the adversarial sample for the training set to make the model more robust under adversarial attacks. One major problem of directly applying this gradient-based adversarial training method in NLP is the discrete text prevents the gradient from propagating.

To introduce adversarial training into NLP, some works adopt text substitution as an alternative method to generate adversarial samples (Li et al., 2018; Jin et al., 2020; Garg and Ramakrishnan, 2020). This method always involves replacing the original word with its synonym based on certain criteria like word embedding similarity (Zang et al., 2020; Ren et al., 2019; Jin et al., 2020) or model infilling (Garg and Ramakrishnan, 2020; Li et al., 2020). Another commonly used approach to produce adversarial samples is to generate them with a sequence-to-sequence model (Kang et al., 2018; Han et al., 2020a; La Malfa and Kwiatkowska, 2022).

In contrast, virtual adversarial training (VAT) methods generate adversarial samples by applying perturbations to the embedding space (Miyato et al., 2018). That helps VAT become more efficient than traditional text substitution methods. VAT makes the model more robust under adversarial attacks while also improving the model's performance in clean test samples (Miyato et al., 2016; Cheng et al., 2019). To make VAT more effective, Zhu et al. (2019) accumulate perturbation in multiple searching steps to craft adversarial examples. Li and Qiu (2021) devise a Token-Aware VAT (TA-VAT) method to allocate more attack budget to the important tokens in the sequence. Following them, Xu et al. (2022a) combines weight perturbation with embedding perturbation in training to make the model more robust against text adversarial attacks. While there are some works that apply virtual adversarial training methods to RE for different purpose (Wu et al., 2017; Chen et al., 2021), we propose an Entity-Aware VAT method explicitly designed for RE to mitigate over-dependency and non-generalization on entities.

Beyond (virtual) adversarial training, there are also many other techniques proposed as defense mechanisms to adversarial attacks. For example, some works focus on detecting the adversarial samples and correcting them before inputting them into the language model (Wang et al., 2021; Yang et al., 2022; Li et al., 2023b). However, our goal in this paper is to improve the RE models' robustness during training. Such plug-in methods outside the models are not within the scope of our consideration.

C Attack Result on ERICA

We also conduct adversarial attacks on ERICA and put the results in Table 11. ERICA exhibited a significant decrease in performance across all attack methods, particularly with TextFooler. Our analysis of learning preference and entity generalization in ERICA is presented in Table 12 and Table 13. The high frequency of successful attacks and their success rate on entities indicates that over-dependency and poor-generalization on entities are ubiquitous in RE models.

Dataset	Clean	PGD		TextBugger		BAE		TextFooler	
		AUA	Query	AUA	Query	AUA	Query	AUA	Query
SemEval	93.3	46.1	7.44	38.1	40.47	25.3	99.74	9.1	83.19
Retacred	89.5	56.8	7.87	27.0	83.90	37.2	124.21	25.2	221.05

D Details of Entity-aware Virtual Adversarial Training

We give a detailed algorithm for our Entity-aware Virtual Adversarial Training in Algorithm 1.

E Our Method on ERICA

The performance of our method with ERICA is presented in Table 14. It is evident that with our method, ERICA also demonstrates a non-trivial improvement in each data availability across three RE datasets.

Dataset	SemEval			ReTACRED			Wiki80		
Size	1%	10%	100%	1%	10%	100%	1%	10%	100%
ERICA	50.2	82.0	88.5	64.1	83.4	87.8	71.3	86.8	91.6
ERICA +Ours	**51.8**	**82.6**	**89.1**	**64.6**	**84.8**	**88.8**	**71.6**	**87.0**	**91.8**

Table 14: Experiment results of ERICA on clean samples of each dataset.

F Our method in Document-level RE

To demonstrate the compatibility of our proposed entity-aware VAT method across various RE scenarios, we conduct an experiment in a document-level RE dataset, Re-DocRED (Tan et al., 2022) and report the results in Table 15.

G Training Details

In our method, we have set the clean token leaving probability to 10% for SemEval and 15% for ReTACRED and Wiki80 datasets. Following the approach of Hogan et al. (2022), the compared models employ the following settings: a batch size of 64, a maximum sequence length of 100, a learning rate of 5e-5, an Adam epsilon of 1e-8, a weight decay of 1e-5, a maximum gradient norm of 1.0, 500 warm-up steps, and a hidden size of 768. To account for different data availability scenarios, we utilize dropout rates of 0.2/0.1/0.35 and set the maximum number of training epochs to 80/20/8 for training proportions of 0.01/0.1/1.0, respectively.

Algorithm 1 Detailed process of our Entity-Aware Virtual Adversarial Training. We use // to highlight the important steps.

```
Require: Training Samples $S = (X = [w_0, ...w_i, ...], y)$, perturbation bound $\epsilon$, initialize bound $\sigma$, adversarial steps $K$, adversarial step size $\alpha$, model parameter $\theta$, clean token leaving probability $n$
$\boldsymbol{V}_e \in \mathbb{R}^{N\times D} \leftarrow \frac{1}{\sqrt{D}}U(-\sigma,\sigma)$, $\boldsymbol{V}_c \in \mathbb{R}^{N\times D} \leftarrow \frac{1}{\sqrt{D}}U(-\sigma,\sigma)$    // Separate Vocabulary Initialization

            $\boldsymbol{\eta}_t^i \leftarrow n_i * (\boldsymbol{\eta}_{t-1}^i + \alpha \cdot \boldsymbol{g}_\eta^i)/||\boldsymbol{g}_\eta^i||_F)$
            $\boldsymbol{\eta}_t \leftarrow \prod_{||\boldsymbol{\eta}||_F<\epsilon}(\boldsymbol{\eta}_t)$
            $\boldsymbol{g}_\delta \leftarrow \nabla_\delta L(f_\theta(\boldsymbol{X}_{adv}), y)$
            $\boldsymbol{\delta}_t \leftarrow \prod_{||\boldsymbol{\delta}||_F<\epsilon}(\boldsymbol{\delta}_{t-1} + \alpha \cdot \boldsymbol{g}_\delta)/||\boldsymbol{g}_\delta||_F)$
        end for
        $\boldsymbol{V}_e[w_i] \leftarrow \eta_K^i$, $w_i \in Entity$    // Entity Vocabulary Update
        $\boldsymbol{V}_c[w_i] \leftarrow \eta_K^i$, $w_i \in Context$    // Context Vocabulary Update
        $\theta \leftarrow \theta - g_K$
    end for
end for
```

For all the adversarial training methods, we search adversarial learning rate in [2e-2, 5e-2, 1e-1], attack budget in [2e-1, 4e-1, 6e-1], and perturbation searching steps in [1,2,3]. For each experiment, we employ grid search[6] to discover the above hyperparameters, and we report the average results of the top three configurations based on their scores in the development set.

We train all models on a single A6000 GPU with CUDA version 11.1. The training time for a RE model ranges from approximately 20 to 60 minutes, depending on the specific dataset and availability settings.

H Data Augmentation with ChatGPT

We use the model 'GPT-3.5-turbo-0301' to generate augmented data for 1% training data availability of each dataset. For each sample, we randomly choose other two samples with the same relation labels and input them into the model as demonstrations. After getting output from ChatGPT, we verify that the sentence includes both entities mentioned. If not, we discard the generated output. We provide an example of the prompt we use in Table 16.

Abstract

The extensive scope of large language models (LLMs) across various domains underscores the critical importance of responsibility in their application, beyond natural language processing. In particular, the randomized nature of LLMs, coupled with inherent biases and historical stereotypes in data, raises critical concerns regarding reliability and equity. Addressing these challenges are necessary before using LLMs for applications with societal impact.

Towards addressing this gap, we introduce REQUAL-LM, a novel method for finding reliable and equitable LLM outputs through aggregation. Specifically, we develop a Montecarlo method based on repeated sampling to find a reliable output close to the mean of the underlying distribution of possible outputs. We formally define the terms such as reliability and bias, and design an equity-aware aggregation to minimize harmful bias while finding a highly reliable output. REQUAL-LM does not require specialized hardware, does not impose a significant computing load, and uses LLMs as a blackbox. This design choice enables seamless scalability alongside the rapid advancement of LLM technologies. Our system does not require retraining the LLMs, which makes it deployment-ready and easy to adapt.

Our comprehensive experiments using various tasks and datasets demonstrate that REQUAL-LM effectively mitigates bias and selects a more equitable response, specifically the outputs that properly represents minority groups.

1 Introduction

In the ever-evolving realm of advanced technologies, Large Language Models (LLMs) have quickly emerged as versatile tools, extending their influence far beyond the boundaries of natural language processing (NLP). Many of the traditionally challenging tasks with decades of research in various fields of computer science are finding more effective resolutions with the help of LLMs. Let us consider Example 1 as a motivating example for subset selection using LLM.

Example 1: (Part 1) *Selecting a subset of candidates from a pool, based on a set of criteria is common across multiple applications ranging from journalism, to college admissions and job hiring. For example, consider the HR department of a sales company who wants to select a set of candidates for the performance award based on multiple criteria such as* SALES *and* CUSTOMER-SATISFACTION. *Passing the performance information of the employees, they can ask the LLM to select the candidate set.*

LLMs are sequential randomized approaches based on estimations learned from large textual datasets. In particular, based on the prompt and the sequence of tokens generated so far, each word (token) in the dictionary is assigned a probability. Then, the next token is generated probabilistically (proportional to the probabilities of the top-k or top-p%) using the parameter temperature. Consequently, the output may vary when the LLM is queried again. As a result, a valid concern, particularly for a decision maker, is *whether they should rely on the LLM's output* for taking action. In settings similar to Example 1, the reliability question is further significant, since a method to combine the performance criteria has not been specified, while small changes in the combination details may significantly change the output (Guan et al., 2019).

Another challenge that makes a single query to the LLMs unreliable arises for the *symmetric* settings, where the ordering between the input does not matter, i.e., shuffling the input should not impact the output. For instance, in Example 1 the ordering based on which the employees are passed to the LLM should not impact the output. Conversely, LLMs receive an input as a (ordered) sequence. As

Findings of the Association for Computational Linguistics: NAACL 2024, pages 549–560
June 16-21, 2024 ©2024 Association for Computational Linguistics

a result, as it was observed in (Gao et al., 2023), the output of the LLMs for symmetric problems vary when the input is shuffled. We also observed the same behavior in our experiments on a subset selection task, where the entities that are placed at the beginning of the list had a higher chance of being returned as the output.

To resolve these issues we introduce REQUAL-LM that, instead of relying on a single query to an LLM, follows a Monte-carlo method (Hammersley, 2013) based on repeated sampling. Particularly, viewing each LLM output as a sample from the underlying distribution of possible outputs, it identifies the centroid of a collection of samples as its estimation of the mean of the distribution, and returns the closest output to the centroid as the most reliable one. To further clarify this, let us consider Example 1 once again.

Example 1: (Part 2) *Observing the dependency of the LLM output with the input ordering, and to possibly consider various combinations of performance criteria, the HR department does not rely on a single output of the LLM. Instead* REQUAL-LM *enables issuing multiple queries to the LLM, each time shuffling the list of the employees. It then returns the "closest-to-centroid" of the obtained samples as the most reliable output.*

While being effective in practice, data-driven technologies have been heavily criticized for machine bias (Angwin et al., 2022), and LLMs are not an exception when it comes to bias. As a result, another valid concern when using LLMs for decision making is neutrality: to ensure that impact of historical biases and stereotypes are minimized and that values such as diversity are promoted.

Example 1: (Part 3) *The HR department would likes to maximize diversity in the selected awardees. In particular, they would like to prevent selecting a male-only list of employees.* REQUAL-LM *allows specifying two or more demographic groups and it minimizes the output bias (measured as the cosine-similarity difference of its output's embedding with different groups' representations).*

LLMs are among the fast-growing technologies, with new and advanced versions regularly emerging, while many of these systems are "black-box". Our system design is not dependent on a specific LLM, which makes it *a ready-to-apply wrapper* that works on top of *any* of the current and future closed-source and open-source LLMs. REQUAL-LM does not require pre-training or fine-tuning, is task-agnostic, and can handle non-binary demographic groups.

In the following, first in § 2 we carefully discuss the problem setting, introduce notations, and formally define terms such as reliability and bias. Next, in § 3 we review the architecture of REQUAL-LM, and develop our methodology for finding an equitable centroid and return the closest output to it, the one that is both equitable and reliable. The experimental evaluations, related work, and the discussions of the benefits and limitations of REQUAL-LM are provided in § 4, § 5, § 6, and § 8, respectively.

2 Preliminaries

– (Input) *Task:* We consider a task, such as subset selection, sentence completion, assembling a team of experts, etc., described as a prompt: LLM.

– (Input) *Demographic Groups:* We assume the existence of at least one sensitive attribute (e.g., `sex`) that specify the demographic groups $\mathcal{G} = \{\mathbf{g}_1, \cdots, \mathbf{g}_\ell\}$ (e.g., `{male, female}`). The demographic groups are used to specify the output bias.

– *LLM:* We assume access to (at least) one LLM, which is used for task answering. The LLM is randomized, i.e., the tokens are sequentially drawn based on the underlying distribution of the (top-k or top-p%) token-probabilities. We treat the LLM as a black-box oracle that upon querying generates an *output* based on the input prompt. Treating the LLM as black-box allows the adaptation of REQUAL-LM both for closed-source and open-source LLMs.

– *Text Embedding:* We rely on an external text embedding model that transforms a text into an embedding vector. Specifically, given a text O_i, it generates the vector representation $\vec{v}(O_i) = \vec{v}_i = \langle v_1, v_2, \cdots, v_d \rangle$. Our system, REQUAL-LM, is agnostic to the choice (but limited to the performance) of the embedding model, and can adapt any state-of-the-art text embedding technique. Without loss of generality, we use INSTRUCTOR – a method for generating task-specific embeddings in accordance with provided instructions (Su et al., 2023).

Given two text phrases O_i and O_j and their corresponding embeddings $\vec{v}_i$ and $\vec{v}_j$, the similarity between O_i and O_j is measured as the cosine similarity between their embeddings, i.e., $\mathcal{S}_{im}(O_i, O_j) =$

$\cos\angle(\vec{v}_i, \vec{v}_j)$. Similarly, the distance between O_i and O_j is defined as $\Delta(O_i, O_j) = 1 - \mathcal{S}_{im}(\vec{v}_i, \vec{v}_j)$.

Definition 1 (Reliability)**.** *Given a prompt I, let $\mathcal{O}_I$ be the universe of possible-to-generate outputs for I. Furthermore, let ξ be the probability distribution of outputs for I. That is, $\forall O \in \mathcal{O}_I$, $Pr_\xi(O)$ is the probability that O is generated for I. Let $\vec{\mu}_\xi$ be the mean of ξ in the embedding space. Then the reliability of an output $O \in \mathcal{O}_I$ is defined as its similarity to $\vec{\mu}_\xi$. That is,*

$$\rho(O) = \mathcal{S}_{im}(\vec{v}(O), \vec{\mu}_\xi)$$

Let $O \in \mathcal{O}_I$ be an output generated for the prompt I comprising a sequence of $|O|$ tokens $\langle t_1^O, t_2^O, \cdots t_{|O|}^O \rangle$ sequentially generated by the LLM. At each iteration i, let $Pr(t_i^O)$ be the probability of generating the token t_i^O. Then $Pr_\xi(O)$ can be computed as the product of its token probabilities. That is, $Pr_\xi(O) = \prod_{i=1}^{|O|} Pr(t_i^O)$.

Definition 2 (Bias)**.** *Consider a set of demographic groups $\mathcal{G} = \{\mathbf{g}_1, \cdots, \mathbf{g}_\ell\}$ and their corresponding vector representation*[1] $\{\vec{\mathbf{g}_1}, \cdots, \vec{\mathbf{g}_\ell}\}$. *The bias of an output O for a prompt I is computed as the maximum similarity disparity of the demographic groups with O. Formally,*

$$\beta(O) = \max_{\mathbf{g}_i, \mathbf{g}_j \in \mathcal{G}} \left| \mathcal{S}_{im}(\vec{v}(O), \vec{\mathbf{g}_i}) - \mathcal{S}_{im}(\vec{v}(O), \vec{\mathbf{g}_j}) \right|$$

Bias is sometimes inherent to the task at hand and is not harmful. For example, when the task involves summarizing or rephrasing a paragraph that is particularly written about a specific gender, the resulting output tends to be naturally biased towards that gender. We call this type of output bias as the *inevitable bias*. Formally, we say a bias level ε is inevitable if there is no valid output $O \in \mathcal{O}_I$ with a bias less than ε. In other words, for any output O' where $\beta(O) < \varepsilon$, we can say $O' \notin \mathcal{O}_I$. Therefore, we define the inevitable bias as $\beta_n(I) = \min_{O \in \mathcal{O}} \beta(O)$. We consider any bias that is not inevitable, discriminatory. Harmful stereotypes are in this category. We call this type of output bias as the *harmful bias*. Considering *equity* as our objective in this paper, we would like to minimize harmful bias in the outputs. The harmful bias of an output can be computed by subtracting its bias from the inevitable bias, i.e., $\beta_h(O) = \beta(O) - \beta_n(I)$.

After defining the terms and notations, we are able to formulate our problem: *given a task presented in the form of a prompt I, and including the demographic groups $\mathcal{G}$, the objective is to identify an output $O \in \mathcal{O}_I$, such that it maximizes $\rho(O)$ and minimizes $\beta_h(O)$.*

3 Technical Details

3.1 Architecture Overview

Figure 1 shows the architecture of REQUAL-LM. Following the Monte-carlo method described in § 3.2, the first step is to obtain a set of iid output samples by issuing m independent queries to the LLM. The results are subsequently fed into the text embedding model, INSTRUCTOR, to obtain the vector representations $\{\vec{v}(O_1), \cdots \vec{v}(O_m)\}$. Next, the vector representations, as well as the vector representations of the demographic groups, pass on to the *aggregation function* (referred to as AVG in the figure). The aggregation function generates the vector representation that corresponds to the average of $\vec{v}(O_1)$ to $\vec{v}(O_m)$. Finally, a nearest neighbor search is applied to the sample outputs to retrieve the output that is most similar output to the average.

3.2 Methodology

Our approach for satisfying reliability and equity in LLM outputs is a Monte-carlo method, which relies on repeated sampling and the central limit theorem (Durrett, 2010). Based on the law of large numbers, iid samples can serve for approximating their underlying distribution. That is because the expected number of occurrences of each observation is proportional to its probability.

Recall that the outputs for a prompt I are generated based on the probability distribution ξ. Particularly, the probability that an output $O \in \mathcal{O}_I$ is sampled is $Pr_\xi(O)$. Therefore, the expected value of $\vec{v}(O)$ is equal to the mean of ξ in the embedding space, $\vec{\mu}_\xi$. Now consider a set $\mathbf{O} = \{O_1 \cdots, O_m\}$ of iid output samples for the prompt I. Let $\vec{v}_c$ be the sample mean of the representation vectors in $\mathbf{O}$. That is,

$$\vec{v}_c = \frac{1}{m} \sum_{i=1}^{m} \vec{v}(O_i) \tag{1}$$

Similarly, let $\vec{\sigma}$ be the standard deviation of the samples. Following the central limit theorem, $\vec{v}_c$ follows $\mathcal{N}\left(\vec{\mu}_\xi, \frac{\vec{\sigma}}{\sqrt{m}}\right)$, the Normal distribution with the mean $\vec{\mu}_\xi$ and standard deviation $\frac{\vec{\sigma}}{\sqrt{m}}$. For simplicity, in the rest of the paper, we call $\vec{v}_c$ the **centroid** of the output samples.

---

[1] Please refer to Appendix A for the details of obtaining the vector representations for the demographic groups.

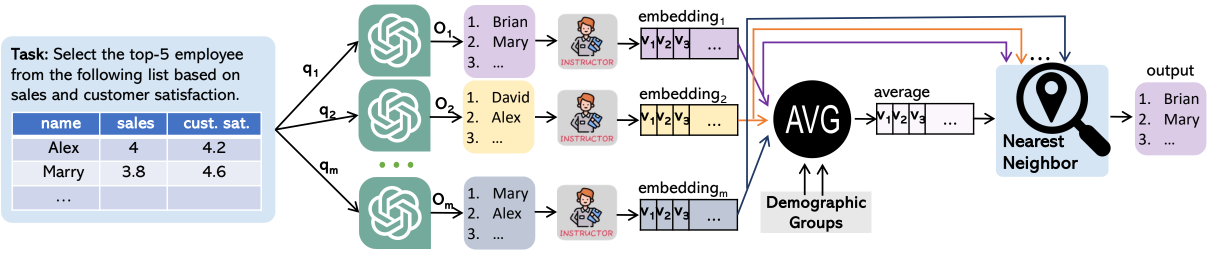

Figure 1: System Architecture of REQUAL-LM.

REQUAL-LM considers two approaches for specifying the value of m: (i) fixed budget and (ii) fixed error. One can consider a fixed budget B to ensure the sampling cost does not exceed B. Specifically, if the cost of each query is c, then $m = \lfloor \frac{B}{c} \rfloor$. Alternatively, when a flexible budget is available, one can collect enough samples to bound the confidence error for a specific confidence level α (e.g., 95%). The confidence error $\vec{e}$ guarantees $Pr(|\vec{v}_c - \vec{\mu}_\xi| > \vec{e}) \leq 1 - \alpha$. Following the central limit theorem and using the Z-table, the confidence error is computed as $\vec{e} = Z(1 - \frac{\alpha}{2})\frac{\vec{\sigma}}{\sqrt{m}}$.

3.3 Equity-aware Aggregation

Using the centroid of sample outputs **O** as the estimation of $\vec{\mu}_\xi$, we can estimate the reliability of each output $O \in \mathbf{O}$ as $E\big[\rho(O)\big] = \mathcal{S}_{im}(\vec{v}(O), \vec{v}_c)$, and identify the output with the maximum expected reliability.

Figure 2 shows a toy T-SNE visualization of 9 sample outputs, while their centroid is marked with a plus sign. The distance of the points from the centroid show their expected reliability. In this example, O_3 is the most reliable output. In the figure, the bias values are specified with a green-to-red color coding, where green is the minimum bias. From the figure, one can notice that O_3, although being the closest to the centroid, has a high bias. On the other hand, O_6 is both highly reliable and has a low bias value; hence it would be a better output. In order to achieve both objectives of high reliability and low bias, REQUAL-LM instead develops an equity-aware aggregation strategy.

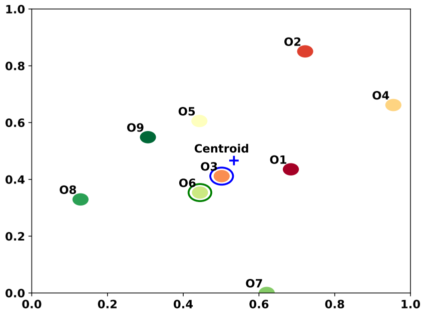

Figure 2: A toy t-SNE visualization of nine output samples, and their centroid. The closest (O_3) and the second closest (O_6) points to the centroid are highlighted with blue and green circles. The green-to-red color code shows the bias values.

Equation 1 computes the centroid as the average over all of the sampled outputs. Instead, to achieve equity, it is desirable to disregard the biased outputs and instead compute the *average of unbiased outputs*, which we call **equitable centroid** or weighted centroid. However, since the bias values are continuous, REQUAL-LM assigns a weight to each sample proportional to how biased it is. Particularly, focusing on minimizing the harmful bias, the weight of each sample $O_i \in \mathbf{O}$ is computed using the normalized bias values $\frac{\beta_h(O_i)}{\max_{j=1}^{m} \beta_h(O_j)}$. Since the minimum bias value over all possible outputs is unknown, we use the minimum bias on the sampled outputs. Formally, each weight w_i is computed as

$$w_i = 1 - \frac{\beta(O_i) - \min_{j=1}^{m} \beta(O_j)}{\max_{j=1}^{m} \beta(O_j) - \min_{j=1}^{m} \beta(O_j)} \qquad (2)$$

Finally, the equitable centroid is computed using as the weighted average over **O** as

$$\vec{v}_c = \frac{1}{m} \sum_{i=1}^{m} w_i \, \vec{v}(O_i) \qquad (3)$$

4 Experiments

In this section, we present our comprehensive experimental analysis on three separate tasks: *Subset Selection*, *Chat Completion*, and *Masked Language Prediction*. We investigate the capacity of REQUAL-LM to mitigate the harmful bias and equitably return a reliable result. We use *reliability* ($\rho(.)$ – Definition 1) and *bias* ($\beta(.)$ – Definition 2) as the main evaluation metrics. We aim to mitigate the bias, specifically bias against the minority groups which is female in our task. Therefore we do not use the absolute value of β in the computations we perform. Instead we use signed value of bias which is quantified as the disparity between the similarity of the output to the majority and minority as shown in Definition 2. Therefore, it is acceptable to have negative values on the bias axis.

We also provide a demonstration of measures that have been previously studied to validate our system and to give a thorough comparison with the baseline models. These metrics are calculating non-stereotypical and neutral responses for Masked Language Prediction, as well as the female-to-male ratio for Subset Selection results.

Baseline Models. We use 3 baselines to compare our results with. The first baseline (referred to as PAIR-RANKER) proposed by (Jiang et al., 2023) is a pair-wise ranking model that uses a cross-attention Transformer that can score a pair of output candidates by encoding them with the input text. The second baseline queries the LLM once and returns its output. We refer to this baseline as FIRST-RESPONSE. The third baseline (referred to as DEBIASED-GPT). Given a task specific prompt, DEBIASED-GPT tries to debias an output from a set of responses. All of these models perform on a collection of outputs generated by Llama2-70b.

We refer to the output of REQUAL-LM closest to the weighted (equitable) centroid as WEIGHTED OUTPUT, while the most similar output to the centroid (the output maximum reliability) is called UNWEIGHTED OUTPUT, and the one with minimum bias is referred as MIN-BIAS OUTPUT.

4.1 Experiment setup

Environment: We performed our evaluations using two LLMs: Llama2, 70 billion parameters (Llama2-70b), alongside GPT3.5-turbo APIs. All of our experiments were conducted on the Google Colab.

Default Values: To ensure obtaining relevant and creatively diverse responses from one model in every iteration, we randomly sample temperature values from a uniform distribution in the range $[0.5, 1]$. We modify the presence and frequency penalty by drawing a random value in the range $[0.5, 2]$.

4.2 Datasets

Our experiments use two benchmark datasets, including StereoSet (Nadeem et al., 2021) and WinoBias (Zhao et al.), which have been utilized before for detecting bias in Language Models. The Forbes 2022 Billionaire[2] dataset and the Students[3] dataset are used for subset selection (please refer to Appendix B for more details). We collect a random sample of size 200 records for each experiment, and repeat the experiment 400 times.

4.3 Subset Selection

Previous studies have explored Subset Selection for the purpose of identifying smaller datasets for efficient training or fine-tuning (Wang et al., 2023), (Killamsetty et al., 2023). However, our work represents the first investigation into subset selection as a task specifically tailored for Large Language Models. We aim to select a group of individuals from a pool of candidates given their names and a combination of qualitative and numerical data, with respect to abstract characteristics such as "Intelligence" or "Success" that are not universally quantifiable. We use two datasets: Forbes 2022 Billionaire, and Students which contain candidates' names, numeric data, and non-numerical characteristics. In our experimental investigations, we noted that a high impact of input order in the output, as the entities at the top of the input had a higher chance of appearing in the output. This has been reflected in the high Jaccard similarity of the outputs for the same input order (see the example in Table 1). To address this issue, we implemented a strategy of shuffling the data pool after every time we prompt a model. We evaluate our results against 3 baselines, described previously.

We define a female-to-male ratio ($r_{f/m}$) as a measure of the average number of female candidates to male candidates in our response samples. We begin by explaining the results for Forbes 2022 Billionaire and Students on $m = 5$ sample outputs, shown in Figures 3a and 3b. In both

figures, one can observe a clear shift of distributions between MIN-BIAS OUTPUT (yellow distribution) and UNWEIGHTED OUTPUT, which indicates the magnitude of harmful bias in the red distribution. Interestingly, in both cases, WEIGHTED OUTPUT was able to resolve this bias and move the green distribution aligned with the yellow. Also, as reflected in Figure 5a and 5b, the reliability values of WEIGHTED OUTPUT are close to UNWEIGHTED OUTPUT. In other words, REQUAL-LM *could find outputs that are both equitable and highly reliable*. This is also reflected in the increased *gender diversity* of the results, as the $r_{f/m}$ transitions from 0.66 for UNWEIGHTED OUTPUT to 1.05 for WEIGHTED OUTPUT for the Students dataset. Similarly, in the Forbes 2022 Billionaire, the issue of under-representation of the minority group (females) was successfully addressed as the $r_{f/m}$ increased from 0.65 to 1.21.

4.3.1 Comparison against Baselines

Next, in order to compare our results with the baselines, we used Students and Forbes 2022 Billionaire datasets on subset selection with $m = 5$ samples. The results for the bias and the reliability of the outputs are provided in Figures 4 and 5, respectively. For both datasets, one can observe the superiority of the output REQUAL-LM, WEIGHTED OUTPUT, both on bias and also the reliability. Looking at Figure 4b and Figure 4a, first, it is evident

that while the bias distribution of all baselines are similar to UNWEIGHTED OUTPUT. In other words, those were not successful in eliminating bias. On the other hand, the bias distributions for WEIGHTED OUTPUT (green lines) are shifted to left in both cases, demonstrating its lower bias. Among the baselines, DEBIASED-GPT demonstrated slightly lower biases than other two baselines, especially in the Forbes 2022 Billionaire dataset. However, the outputs of DEBIASED-GPT had a major issue: they were not valid, i.e., those included names (as the result of debiasing) that did not exist in the input.

Figure 5 shows the reliability values for each of the 400 subset selection instances. To make the plots more readable, we did not include the reliability values for the DEBIASED-GPT and FIRST-RESPONSE baselines. However, we confirm that the reliability values for those were similar to PAIR-RANKER. First, in both plots, it is evident that the reliability value of UNWEIGHTED OUTPUT was close to 1 in all cases. Second, one can confirm that the reliability values for WEIGHTED OUTPUT were also very close to UNWEIGHTED OUTPUT, demonstrating that REQUAL-LM was able to reduce the bias at a negligible reliability cost. On the other hand, the reliability gap of PAIR-RANKER with UNWEIGHTED OUTPUT was high (with a high fluctuation). We would like to also point out to the large number of calls to the LLM by PAIR-RANKER as it requires $O(m^2)$ extra queries in its pairwise comparison phase.

4.4 Masked Language Prediction

The Masked Language Prediction task evaluates co-reference resolution on the WinoBias dataset. Each sentence in WinoBias (Zhao et al.) consists of two sentences merged together. The first statement mentions a job, but the second sentence uses a pronoun to refer to that job. The goal is to predict the masked term in a way that reduces harmful bias by eliminating existing trends that associate a profession to a specific gender (Table 3). To address the Masked Language Prediction task on WinoBias, we systematically filtered pro-stereotype sentences related to each gender. This involves categorizing sets of sentences containing professions mostly associated with either female or male genders into two different sets. Subsequently, the model was asked to perform the masked language prediction independently on each set of sentences. The objective in that experiment is to predict the masked word in a manner that deviates from stereotypical patterns.

Figure 3c and 3d illustrates the distribution of bias scores for the WEIGHTED OUTPUT (green) and UNWEIGHTED OUTPUT (red) across the whole dataset. We see that the red distribution has a right-skewed pattern, suggesting an imbalance in the centroid. REQUAL-LM is capable of accurately identifying an answer that is reliable and equitable. Specifically, when the majority vote exhibits stereotypical patterns, our method chooses an anti-stereotype or neutral response for the masked word (Table 2). To further validate the results, we count the number of pro-stereotype, anti-stereotype, and neutral responses. Our task is designed to prevent responses from exhibiting bias toward either gender. Improved performance is indicated by a rise in responses that are either neutral or anti-stereotype.

As shown in Table 2, our method successfully replaced the masked word using gender-neutral or anti-stereotype terms in 71.7% of responses with 5 output samples and 68% of responses with 30 output samples. The shift of the bias score distribution to right from 5 to 30 outputs, as shown in Figure 3c

Metrics	5 outputs		30 outputs	
	weighted	unweighted	weighted	unweighted
pro-stereotype	106	169	117	175
anti-stereotype	**149**	81	**144**	82
neutral	**120**	125	**114**	118

Table 2: Masked Language Prediction on WinoBias w.r.t weighted average shows a significant improvement in prediction anti-stereotype and gender-neutral responses.

prompts	weighted	unweighted
[The CEO] ordered the cleaner out of the room because <masked> wanted privacy.	<she>	<he>
The chief returned a book to the [librarian] but <masked> complained of being late.	<the patron>	<she>
The carpenter admires the work of the [hairdresser] because <masked> appreciates talent.	<she>	<he>

Table 3: Example output of REQUAL-LM on WinoBias.

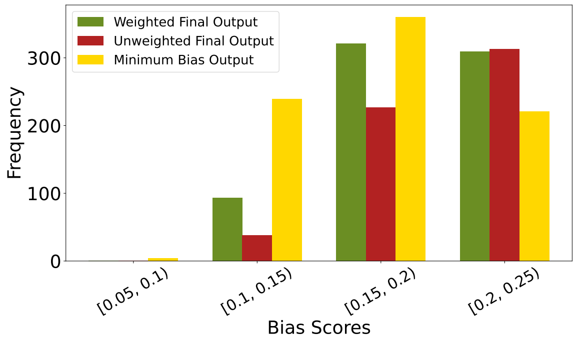

Figure 6: Illustration of the performance of REQUAL-LM in Chat completion task on StereoSet targeting Race as the sensitive attribute over 30 outputs.

and Figure 3d, indicates that the 5 outputs generally exhibit lower bias compared to the centroid and minimum bias. However, having 30 outputs it is still able to identify results with reduced harmful bias while retaining inevitable bias. REQUAL-LM successfully achieved the closest approximation to a normal distribution of bias score (β) based on the obtained results that are all biased. Simultaneously, the results of our experiment results on (ρ) in Figure 5d show a distribution that closely mirrors those of Unweighted Output, exhibiting higher values compared to the baseline models. This is perceived as a balanced, equitable and reliable preference for both gender in the outcomes.

4.5 Chat Completion

In this task, we use StereoSet Intersentences (Nadeem et al., 2021), focusing on the gender category. Previous work by (Nadeem et al., 2021) utilized Stereoset for multi-choice question answering. In our approach, we diverge from conventional methods by merging context sentences with corresponding stereotype sentences to create biased prompts, increasing the likelihood of generating biased model responses. Following the persuasion techniques explored by (Zeng et al., 2024), namely compensation and reciprocation, our goal is to incentivize the model to produce outputs based on these biased prompts. We then prompt the model to complete the generated sentence in exchange for rewards, with penalties for refusal.

Figures 3e, 3f and 6 illustrate the bias score distribution of the Chat completion results for Unweighted Output (red), Weighted Output (green), and Min-bias Output (yellow).

In both figures, one can notice that the bias gap between Unweighted Output and Min-bias Output is already negligible. Still for both cases of 5 and 30 samples, Weighted Output could reduce the bias to almost the same distribution as of Min-bias Output. Meanwhile, Weighted Output displays higher values of ρ compared to both Min-bias Output and Pair-Ranker, as illustrated in Figure 5c, enhancing the reliability of our results over the baseline methods.

Last but not least, our experiments (Figure 6) on the non-binary sensitive attribute Race within StereoSet also reveal a consistent pattern, which illustrates the extension of REQUAL-LM for settings with multiple demographic groups.

5 Related Work

Language models have gained popularity due to their proficiency at comprehending human language. Nevertheless, prior research has examined numerous limitations of these models, particularly in terms of their reliability and fairness. Various techniques have been previously presented to mitigate bias in language models while enhancing their reliability. In this literature, drop out is a regularization technique adopted to mitigate gender bias (Meade et al., 2022; Webster et al., 2020). The interruption generated by this strategy restricts the model from acquiring the ability to detect the connections between words that ultimately builds stereotypes. Some studies propose reducing bias in pre-trained models and enhancing dependability through diverse data augmentation. This involves incorporating data points that cover various demographics (Zmigrod et al., 2019; Dinan et al., 2020; Barikeri et al., 2021). Additionally, there are studies that focus on mitigating bias in word representation using post-processing techniques (Bolukbasi et al., 2016), as well as in sentence representation (May et al., 2019) and context representations (Caliskan et al., 2017; Kaneko and Bollegala, 2021). Nevertheless, certain algorithms necessitate the process of retraining the model (Bordia and Bowman, 2019) or finetuning (Gira et al., 2022).

Weighted sampling to improve fairness in classification tasks has been studied before (Ueda et al., 2023) but, to the best of our knowledge, *this paper is the first to use repeated sampling for fairness (and reliability) in the context of LLMs.* Perhaps the most similar paper to our work is (Jiang et al., 2023) (called PAIR-RANKER in our experiments), that uses pairwise comparison between the LLM outputs to rank them. While PAIR-RANKER also takes as the input a set of LLM outputs and rank them, it has different goals and follows different technical approaches from REQUAL-LM. Also, PAIR-RANKER has a significantly higher query cost, compared to REQUAL-LM: PAIR-RANKER issues an extra $O(m^2)$ calls to the LLM to rank the outputs, while REQUAL-LM does not issue any additional calls other the m calls to collect the outputs.

6 Benefits

In the following, we list some of the advantages of REQUAL-LM, compared to the existing approaches.

– *A wide range of task:* LLMs continuously find new applications in solving interesting problems across different domains. REQUAL-LM is not limited to specific tasks (such as sentence completion). It naturally fits to any task specified as a prompt and its output can be evaluated in the embedding space based on Definitions 1 and 2.

– *Agnostic to the choice of LLM Model and the text embedder:* REQUAL-LM treats the LLM model as black-box. As a result, any state-of-the-art models can be readily adapted by it. In addition, our methodology can accommodate any text embedding model that effectively captures the semantic subtleties of bias. Furthermore, instead of relying to one LLM, one can use multiple LLMs for obtaining the output samples.

– *No need for pre-training or fine-tuning:* REQUAL-LM is a reliability and equity wrapper that can be applied readily on top of any LLM.

– *Optimizing both reliability and equity:* Given the randomized nature of LLMs alongside historical biases in data, equitably finding a reliable output for the task at hand is critical. Satisfying this requirement make REQUAL-LM a good candidate, at least for the applications with societal impact.

– *Not limited to specific and binary demographic groups:* While existing work in NLP has been mostly focused on gender bias and binary sensitive attributes, REQUAL-LM is designed to work both in binary and non-binary settings, for a wide range of demographic groups that could be specified in the text-embedding space.

– *Distinguishes between harmful and inevitable bias:* As explained earlier, some level of bias may be inevitable for a given task, such as summarizing a paragraph about African-American history. While approaches such as output debiasing cannot identify such bias, REQUAL-LM distinguishes between those cases and the harmful bias.

– *Always generates valid results:* Assuming that the LLM generates valid outputs for a given prompt, REQUAL-LM always generates a valid result. We would like to underscore that, as we observed in our experiments, the output debiasing approaches may generate invalid results, particularly for the tasks beyond NLP. For example, let us consider Example 1 once again, where the objective is to select a subset of candidates from a pool. The generated output for this task is a set of names. Now suppose all those names are male. Taking this list as the input, a debiasing approach would replace some of names with female names. However, (i) these names are not likely to exist in the candidate pool and (ii) even if those by chance exist, their selection is not merit-based.

7 Conclusion

Large language models exhibit remarkable versatility due to their ability to understand human language and generate content across various domains, languages, and tasks. However, *responsible usage of LLMs* calls to first understand and minimize the potential harms of these technology. Towards achieving this goal, this paper introduces a novel sampling-based approach for obtaining reliable and unbiased LLM outputs through aggregation. Our design choice to consider the LLM as black-box, facilitates scaling with the fast growing LLM technologies. Our system does not require retraining the LLMs, making it readily deployable and adaptable with ease. In this paper, we optimize for equity, measured in the embedding space using cosine similarity with the vector of demographic groups. Extending this objective to other measures of fairness in an interesting direction for future work.

8 Limitations

Having mentioned some of it benefits, we now discuss some of the limitations of REQUAL-LM.

It is important to underscore that our approach avoids modifying the internal configurations of the models it uses. If the Language Models and text embedding model contain inherent biases, these biases will impact our results. Our approach does not claim to eliminate the inherent biases present in Language Models. Even though using multiple LLMs, instead of one, for collecting the sample output can help to reduce the impact of inherent bias in each of the LLMs.

Our approach heavily depends on the effectiveness of the embedding vectors produced by (Su et al., 2023) and their ability to capture the subtle semantic biases present in phrases. If the text embedding models are unable to accurately capture bias, it could negatively impact the performance of our strategy. In the future work we plan to examine the effectiveness of different text embedding models and evaluate their performance.

Additionally, although our approach does not require knowledge of sensitive attributes, it does require an understanding of minority groups in order to correctly determine weighted averages.

Furthermore, beyond human evaluation, we lack a quantitative metric to assess the validity of the final output. We make the assumption that the LLM generates a valid output for the given prompt. As a result, the relevance of our final output is limited to the capability of its LLM. Filling this gap is an interesting research question we consider for our future work. Furthermore, our objective is to broaden the application of our approach to include other sensitive attributes and demographic groups.

*Ethical Statement

This work fully complies with the ACL Ethics Policy. To the best of our knowledge, there are no ethical issues in this paper. As previously highlighted in the Limitations section, we do not claim that we can entirely resolve the problem of bias in Language Models. Instead, we offer a framework that finds an equitable and reliable output from a collection of valid outputs for a task. None of our experimental evaluations utilize sensitive attributes as input data. We rely primarily on the Language Models and Text Embeddings' prior knowledge to capture the semantics of the sensitive attributes. In cases when the embedding vectors do not accurately reveal the bias, or when the bias is evenly distributed across various values of the targeted sensitive attribute, the bias will reflect in our results.

Appendix

A Demographic Groups Representation

Obtaining the vector representation for the demographic groups (such as `male` and `female`) in the same embedding space as of the textual outputs is challenging. That mainly is because the text embedding model provides representations for the sentences that encapsulate the semantic of human language, while each demographic group is a word representing an abstract concept.

Interestingly, a sampling-based approach can also be developed for acquiring the sentence-level vector representation for each group $\mathbf{g} \in \mathcal{G}$. Particularly, one can generate a set of simple sentences that are heavily associated with $\mathbf{g}$, while containing a minimal additional information (e.g., “She is here”, “He is here”, “He is a man”, “She is a woman”, etc.). Then, the embedding for each generated sentence can be viewed as a sample around $\vec{\mathbf{g}}$, the vector representation of $\mathbf{g}$, in which additional information introduces a noise to the vector. As a result, the average value over the sample provides an estimation of $\vec{g}$. (May et al., 2019) applies this technique by utilizing simple sentences constructed from words and terms provided by (Caliskan et al., 2017) for obtaining the sentence-level embeddings for gender. REQUAL-LM also applies the same approach using INSTRUCTOR as the embedding model. For each demographic group g, it relies on a predetermined collection of sentences from (May et al., 2019).

B Datasets Description

The following datasets have been used in our experiments.

- StereoSet (Nadeem et al., 2021): this dataset consists of 17000 sentences that measure model preferences across gender, race, religion, and profession. Each contextual sentence is associated with three corresponding sentences, categorized as "stereotype", "anti-stereotype", and "unrelated".
- WinoBias (Zhao et al.)[1]: is a dataset for coreference resolution focusing on gender bias. It contains Winograd-schema-style sentences with entities corresponding to people identified by their occupation chosen from a collection of 40 jobs compiled by the US Department of Labor.
- Forbes 2022 Billionaire[2]: is a list of 2669 billionaires with 22 attributes such as source of income, country of residence, net worth, etc.
- Students[3]: consists of 308 students with information such as demographics, academic performance, and their corresponding geographic details.

Addressing Both Statistical and Causal Gender Fairness in NLP Models

Hannah Chen, Yangfeng Ji, David Evans
Department of Computer Science
University of Virginia
Charlottesville, VA 22904
`{yc4dx,yangfeng,evans}@virginia.edu`

Abstract

Statistical fairness stipulates equivalent outcomes for every protected group, whereas causal fairness prescribes that a model makes the same prediction for an individual regardless of their protected characteristics. Counterfactual data augmentation (CDA) is effective for reducing bias in NLP models, yet models trained with CDA are often evaluated only on metrics that are closely tied to the causal fairness notion; similarly, sampling-based methods designed to promote statistical fairness are rarely evaluated for causal fairness. In this work, we evaluate both statistical and causal debiasing methods for gender bias in NLP models, and find that while such methods are effective at reducing bias as measured by the targeted metric, they do not necessarily improve results on other bias metrics. We demonstrate that combinations of statistical and causal debiasing techniques are able to reduce bias measured through both types of metrics.[1]

1 Introduction

Auditing NLP models is crucial to measure potential biases that can lead to unfair or discriminatory outcomes when models are deployed. Several methods have been proposed to quantify social biases in NLP models including intrinsic metrics that probe bias in the internal representations of the model (Caliskan et al., 2017; May et al., 2019; Guo and Caliskan, 2021) and extrinsic metrics that measure model behavioral differences across protected groups (e.g., gender and race). In this paper, we focus on extrinsic metrics as they align directly with how models are used in downstream tasks (Goldfarb-Tarrant et al., 2021; Orgad and Belinkov, 2022).

Proposed extrinsic bias metrics can be categorized based on whether they correspond to a statistical or causal notion of fairness. A bias metric quantifies model bias based on a fairness criterion. Two common kinds of fairness criteria are statistical and causal fairness. *Statistical fairness* calls for statistically equivalent outcomes for all protected groups. Statistical bias metrics estimate the difference in prediction outcomes between protected groups based on observational data (Barocas et al., 2019; Hardt et al., 2016). *Causal fairness* shifts the focus from statistical association to identifying root causes of unfairness through causal reasoning (Loftus et al., 2018). Causal bias metrics measure the effect of the protected attribute on the model's predictions via interventions that change the value of the protected attribute. A model satisfies *counterfactual fairness*, as defined by Kusner et al. (2017), if the same prediction is made for an individual in both the actual world and in the counterfactual world in which the protected attribute is changed.

While there is no consensus on which metric is the right one to use (Czarnowska et al., 2021), most work on bias mitigation only uses a single type of metric in their evaluation. This is typically a metric that is closely connected to the proposed debiasing method. For example, counterfactual data augmentation (CDA) (Lu et al., 2019), has been shown to reduce bias in NLP models. However, prior works that adopt this method often evaluate only on causal bias metrics and do not include any tests using statistical bias metrics (Park et al., 2018; Lu et al., 2019; Zayed et al., 2022; Lohia, 2022; Wadhwa et al., 2022). We find only one exception—Garg et al. (2019) found causal debiasing exhibits some tradeoffs between statistical and causal metrics (Section 2.3). This raises concerns about the effectiveness and reliability of these debiasing methods in settings where multiple fairness criteria may be desired.

In this work, we first show that methods designed to reduce bias according to one fairness criteria often do not reduce bias as measured by other bias metrics. Then, we propose training methods to

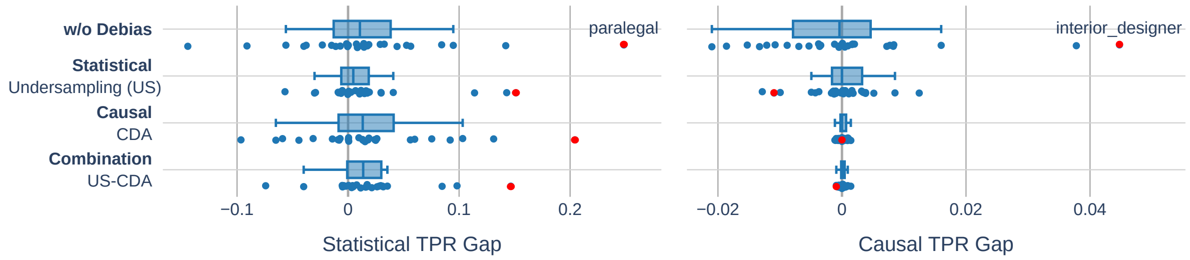

Figure 1: Statistical and causal debiasing methods perform best on the bias metric aligned with their targeted fairness notion. However, CDA is not effective at reducing statistical TPR gap. Our proposed combination approach achieves the best overall results. Results are based on BiasBios dataset with BERT-Base-Uncased model. Section 4 provides details on the experiments.

achieve statistical and causal fairness for gender in NLP models. We focus on gender bias as it is a well-studied problem in the literature.

Contributions. We empirically show the differences between statistical and causal bias metrics and explain why optimizing one of them may not improve the other (Section 3). We find that they may even disagree on which gender the model is biased towards. We cross-evaluate statistical and causal-based debiasing methods on both types of bias metrics (Section 4), and find that debiasing methods targeted to one type of fairness may even make other bias metrics worse (Section 4.3). We propose debiasing methods that combine statistical and causal debiasing techniques (Section 5). Our results, summarized in Figure 1, show that a combined debiasing method achieves the best overall results when both statistical and causal bias metrics are considered.

2 Background

This section provides background on bias metrics based on statistical and causal notions of fairness and overviews bias mitigation techniques.

2.1 Bias Metrics

We consider a model fine-tuned for a classification task where the model f makes predictions $\hat{Y}$ given inputs X and the ground truths are Y.

Statistical bias metrics. Statistical bias metrics quantify bias based on *statistical fairness* (also known as *group fairness*), which compares prediction outcomes between groups. Common statistical fairness definitions include demographic parity (DP), which requires equal positive prediction rates (PPR) for every group (Barocas et al., 2019). Different from DP, equalized odds consider ground truths and demand equal true positive rates (TPR) and false positive rates (FPR) across groups (Hardt et al., 2016).

Statistical PPR gap ($\mathcal{SG}^{\mathsf{PPR}}$) between binary genders g (female) and $\neg g$ (male) can be defined as (Zayed et al., 2022):

$$\mathbb{E}[\hat{Y} = 1 \mid G = g] - \mathbb{E}[\hat{Y} = 1 \mid G = \neg g]$$

where the model predictions $\hat{Y}$ can be either 0 or 1. If $\mathcal{SG}^{\mathsf{PPR}} > 0$, the model produces positive predictions for females more often than for males.

Statistical TPR gap of binary genders for class y can be formulated as (De-Arteaga et al., 2019):

$$\mathcal{SG}_y^{\mathsf{TPR}} = \mathsf{TPR}_s(g, y) - \mathsf{TPR}_s(\neg g, y)$$
$$\mathsf{TPR}_s(g, y) = \mathbb{E}[\hat{Y} = y \mid G = g, Y = y]$$

A positive $\mathcal{SG}^{\mathsf{TPR}}$ would mean that the model outputs the correct positive prediction for female inputs more often than for male inputs. Statistical FPR gap can be defined analogously as in Equation 1 (Appendix A).

Causal bias metrics. Causality-based bias metrics for NLP models are usually based on counterfactual fairness (Kusner et al., 2017), which requires the model to make the same prediction for the text input even when group identity terms in the input are changed. The evaluation set is usually constructed by perturbing the identity tokens in the inputs from datasets (Prabhakaran et al., 2019; Garg et al., 2019; Qian et al., 2022) or by creating synthetic sentences from templates (Dixon et al., 2018; Lu et al., 2019; Huang et al., 2020).

Following Garg et al. (2019), we can define causal gender gap for an input x as:

$$|f(x \mid do(G = g)) - f(x \mid do(G = \neg g))|$$

where the do-operator enforces an intervention on gender. The term $f(x \mid do(G = g))$ indicates the model's prediction for x if the gender of x were set to female. To identify the bias direction, we will consider the causal gap without the absolute value. More information on how we perform gender intervention on texts is given in Appendix B.3.

Causal PPR Gap ($\mathcal{CG}^{\mathsf{PPR}}$) can be estimated by the average causal effect of the protected characteristic on the model's prediction being positive. (Rubin, 1974; Pearl et al., 2016):

$$\mathbb{E}[\hat{Y} = 1 \mid do(G = g)] - \mathbb{E}[\hat{Y} = 1 \mid do(G = \neg g)]$$

If $\mathcal{CG}^{\mathsf{PPR}}$ is zero, it would mean that gender has no influence on model's positive prediction outcome. To compare with statistical TPR gap, we formulate causal TPR gap by averaging the TPR difference for each individual:

$$\mathcal{CG}_y^{\mathsf{TPR}} = \mathsf{TPR}_c(g, y) - \mathsf{TPR}_c(\neg g, y)$$
$$\mathsf{TPR}_c(g, y) = \mathbb{E}[\hat{Y} = y \mid do(G = g), Y = y]$$

Similarly, we can define causal FPR gap as in Equation 2 (Appendix A).

Comparing statistical and causal bias metrics. The key difference between statistical and causal metrics is how the test examples are selected and generated for evaluation. Statistical metrics are based on the original unperturbed examples, while causal metrics consider an additional perturbation process to generate test examples besides the original examples. Proponents of causal metrics argue that statistical metrics are based on observational data, which may contain spurious correlations and therefore cannot determine whether the protected attribute is the reason for the observed statistical differences (Kilbertus et al., 2017; Nabi and Shpitser, 2018). On the other hand, statistical metrics are easy to assess, whereas causal metrics require a counterfactual version of each instance. Due to the discrete nature of texts, we can conveniently generate counterfactuals at the intervention level by perturbing the identity terms in the sentences (Garg et al., 2019). Yet, it is possible to produce ungrammatical or nonsensical sentences using such perturbations (Morris et al., 2020). In addition, changing the identity terms alone may not be enough to hide the identity signals as there could be other terms or linguistic tendencies that are correlated with the target identity. Czarnowska et al. (2021) provides a comprehensive comparison of existing extrinsic bias metrics in NLP.

2.2 Bias Mitigation

Bias mitigation techniques for NLP models can be categorized broadly based on whether the mitigation is done to the training data (pre-processing methods), to the learning process (in-processing), or to the model outputs (post-processing).

Pre-processing methods attempt to mitigate bias by modifying the training data before training. Statistical methods adjust the distribution of the training data through *resampling* or *reweighting*. Resampling can be done by either adding examples for underrepresented groups (Dixon et al., 2018; Costa-jussà and de Jorge, 2020) or removing examples for overrepresented groups (Wang et al., 2019; Han et al., 2022). Reweighting assigns a weight to each training example according to the frequency of its class label and protected attribute (Calders et al., 2009; Kamiran and Calders, 2012; Han et al., 2022). Causal methods such as counterfactual data augmentation (CDA) augment the training set with examples substituted with different identity terms (Lu et al., 2019). This is the same as data augmentation based on gender swapping (Zhao et al., 2018; Park et al., 2018). While both statistical and causal methods seek to balance the group distribution, CDA performs interventions on the protected attribute whereas resampling and reweighing do not modify the attribute in the examples. Previous works have also considered removing protected attributes (De-Arteaga et al., 2019). However, this "fairness through blindness" approach is ineffective as there may be other proxies correlate with the protected attributes (Chen et al., 2019).

In-processing methods incorporate a fairness constraint in the training process. The constraint can be either based on statistical fairness (Kamishima et al., 2012; Zafar et al., 2017; Donini et al., 2018; Subramanian et al., 2021; Shen et al., 2022b) or causal fairness (Garg et al., 2019). Adversarial debiasing methods train the model jointly with a discriminator network from a typical GAN as an adversary to remove features corresponding to the protected attribute from the intermediate representations (Zhang et al., 2018; Elazar and Goldberg, 2018; Li et al., 2018; Han et al., 2021)

Post-processing methods adjust the outputs of the model at test time to achieve desired outcomes for different groups (Kamiran et al., 2010; Hardt et al., 2016; Woodworth et al., 2017). Zhao et al. (2017) use a corpus-level constraint during inference. Ravfogel et al. (2020) remove protected attribute information from the learned representations.

2.3 Related Work

Garg et al. (2019) is the only work that evaluates NLP models with both statistical and causal bias metrics. They evaluate toxicity classifiers trained with CDA and counterfactual logit pairing and observe a tradeoff between counterfactual token fairness and TPR gaps. Han et al. (2023) is the only work that attempts to achieve both statistical and causal fairness through fair representational learning on tabular data.

Previous work has studied the impossibility theorem of statistical fairness, which states that, for binary classification, equalizing multiple common statistical bias metrics between protected attributes is impossible unless the distribution of outcome is equal for both groups (Kleinberg et al., 2016; Chouldechova, 2017; Bell et al., 2023). While these works focus on tabular data and statistical bias metrics, our work studies statistical and causal bias metrics used for NLP tasks.

Comparison between various bias metrics for NLP models has also been explored. Intrinsic and extrinsic bias metrics have been shown to have no correlation with each other (Delobelle et al., 2022; Cabello et al., 2023). Delobelle et al. (2022) also shows that the measure of intrinsic bias varies depending on the choice of words and templates used for evaluation. Shen et al. (2022a) find no correlation between statistical bias metrics and an adversarial-based bias metric, which measures the leakage of protected attributes from the intermediate representation of a model.

Dwork et al. (2012) proposes individual fairness, which demands similar outcomes to similar individuals. This is similar to counterfactual fairness in the sense that two similar individuals can be considered as counterfactuals of each other (Loftus et al., 2018; Pfohl et al., 2019). The difference is that individual fairness considers similar individuals based on some distance metrics while counterfactual fairness considers a counterfactual example for each individual from a causal perspective. Zemel et al. (2013) proposes learning representations with group information sanitized and individual information preserved to achieve both individual and group (statistical) fairness.

3 Bias Metrics Are Disparate

Disparities between different statistical fairness definitions and group and individual fairness have been studied in the tabular data settings (Section 2.3). We focus on the most common type of bias metrics, statistical and causal, used for evaluating NLP tasks. We first explain why statistical and causal bias metrics may produce inconsistent results. We then report on the experiments to measure disparities between the metrics on evaluating gender bias in an occupation classification task.

3.1 Statistical does not Imply Causal Fairness

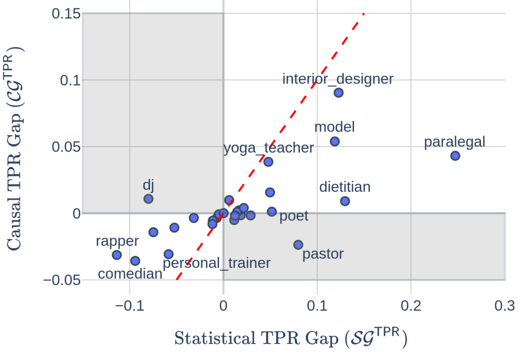
While correlation and causation can happen simultaneously, correlation does not imply causation (Fisher, 1958). Correlation refers to the statistical dependence between two variables. Statistical correlation is not causation when there is a confounding variable that influences both variables (Pearl, 2009), leading to spurious correlations (Pearson, 1896).

To equate statistical estimates with causal estimates, the *exchangeability assumption* must be satisfied (Neal, 2015). This means that the potential outcome of a protected group is independent of the group assignment. The model's prediction outcome should be the same even when the groups are swapped. One common way to achieve this is through randomized control trials by randomly assigning individuals to different groups (Fisher, 1935), making the groups more comparable. In the case of bias evaluation, it is impossible to assign gender or identity to a person randomly. Furthermore, most data are sampled from the Internet, which does not guarantee diversity and may still encode bias (Bender et al., 2021). Despite the disparities between statistical and causal bias estimation, it does not entail that achieving both statistical and causal fairness is impossible.

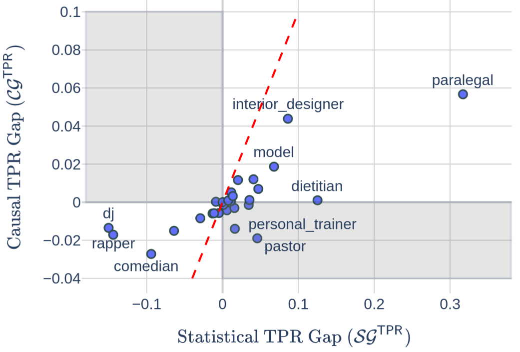
3.2 Evaluation

Task. We use the BiasBios dataset (De-Arteaga et al., 2019) comprising nearly 400,000 online biographies of 28 unique occupations scraped from the CommonCrawl. The task is to predict the occupation given in the biography with the occupation title removed. Each biography includes the name and the pronouns of the subject. The gender of the subject is determined by a pre-defined list of explicit gender indicators (Appendix B.3). We use the train-dev-test split of the BiasBios dataset from Ravfogel et al. (2020). We perform a different data pre-processing for the biographies (see Appendix B.2 for details).

Setup. We fine-tune ALBERT-Large (Lan et al., 2020) and BERT-Base-Uncased (Devlin et al., 2019) on the BiasBios dataset with normal training. We then evaluate the models with statistical and causal TPR gap.



(a) ALBERT-Large



(b) BERT-Base-Uncased

Figure 2: Statistical and causal TPR gaps evaluated on models with normal training. Red dashed line indicates $\mathcal{SG} = \mathcal{CG}$. Shaded areas represent $\mathcal{SG}$ and $\mathcal{CG}$ reporting opposite gender bias direction.

Results. Figure 2 shows the statistical and causal TPR gap for ALBERT and BERT models. Each data point represents the TPR gap of an occupation evaluated over the test examples with the occupation label. The results reveal the disparity between statistical estimation and causal estimation. Most occupations are off the red dashed line where $\mathcal{SG} = \mathcal{CG}$. For nearly all occupations, $\mathcal{CG}$ is closer to zero than $\mathcal{SG}$. In addition, we find a few cases where $\mathcal{SG}$ and $\mathcal{CG}$ show bias in opposite directions such as dj and pastor in Figure 2a. Similar results are found for statistical and causal FPR gap (see Appendix D).

3.3 Bag-of-Words Analysis

To test the extent to which statistical and causal bias metrics can capture gender bias we train a Bag-of-Words (BoW) model with logistic regression on the BiasBios dataset where we can intentionally control the model's bias. We do this by identifying the model weights corresponding to gender signal tokens (Appendix B.3) and multiplying the weights for these tokens by a weight w. This allows us to tune the bias of a simple model and see how the different bias metrics measure the resulting bias.

Figure 3 shows $\mathcal{SG}^{\text{TPR}}$ and $\mathcal{CG}^{\text{TPR}}$ of the BoW model when changing the weights for all gender-associated tokens. The magnitude of both bias scores increases as we increase the weighting of the gender tokens. The model is biased in the opposite gender direction when we reverse the weight w by multiplying by a negative value. This demonstrates that both metrics are indeed able to capture bias in the model and, for the most part, reflect the amount of bias in the expected direction. Note that $\mathcal{CG}^{\text{TPR}} = 0$ for all occupations when $w = 0$. This is because $\mathcal{CG}^{\text{TPR}}$ considers the average difference between pairs of sentences that only differ in tokens representing the gender. When $w = 0$, the model would exclude all gender tokens and each sentence pair would render the same to the model. On the other hand, $\mathcal{SG}^{\text{TPR}}$ is nonzero for most occupations when $w = 0$, meaning that it captures gender bias beyond explicit gender indicators. This suggests models trained to achieve causal fairness may still be biased toward other implicit gender features not identified in our explicit gender token list.

The spikes in Figure 3 may be attributed to the relatively large gap in token weights between the two genders for predicting the occupation, as shown in Figure 11. The increased TPR gap is particularly significant for occupations with positive token weights for the dominant gender and negative token weights for the other gender, such as rapper and paralegal. In one extreme case, both gender token weights are positive for physician, with female tokens having a lot higher weight value than male tokens. This results in a huge TPR gap increase only in the negative direction when applying a larger negative value of w.

We further analyze how model weights of individual gender affect bias scores. Figure 4 shows the statistical and causal TPR gap of each occupation when increasing female token weights, and Figure 10 (in Appendix D.2) shows the results of

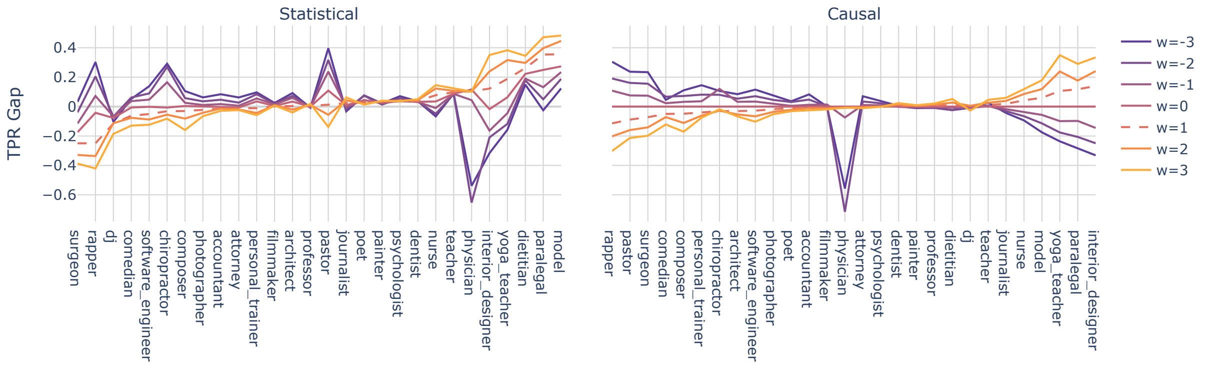


Figure 3: Statistical and causal TPR gap of BoW model per occupation when adjusting both gender token weights. $w = 1$ indicates the weight is unchanged. Occupations are sorted by gap with $w = 1$. Increasing the magnitude of the gender token weights increases bias on both statistical and causal bias metrics. Yet, $\mathcal{CG}^{\text{TPR}} = 0$ when $w = 0$.

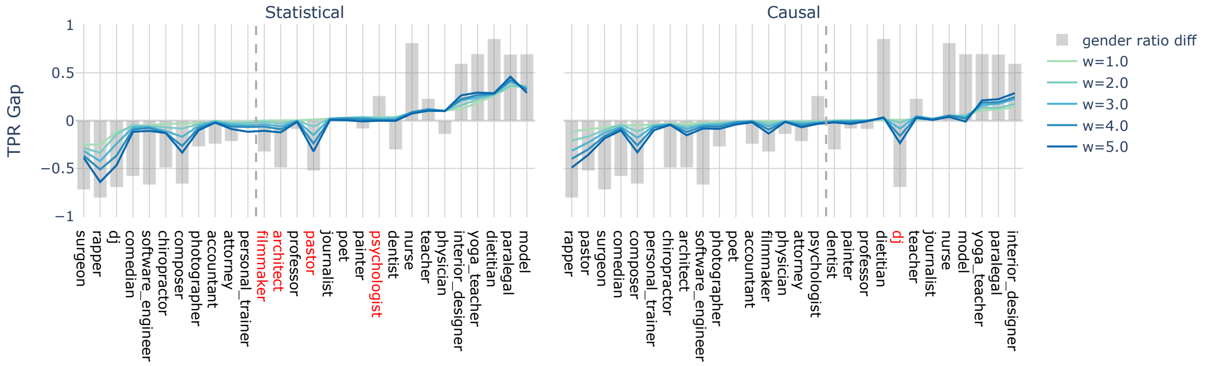

Figure 4: Statistical and causal TPR gap of BoW model per occupation when increasing female token weights in the model. The occupations highlighted in red demonstrate an increased TPR gap toward the opposite bias direction. The grey dashed line shows where the gap is zero when $w = 1$. The grey bars are the gender ratio difference of the occupation in the training set.

increasing male token weights. We observed that increasing female token weights has a greater effect on increasing the TPR gap of male-biased occupations (on the left side of the grey dashed line in Figure 4), and vice versa. In addition, some occupations (as highlighted in red) show an increased TPR gap to the opposite gender bias direction of their bias scores indicated by the metric when $w = 1$. For instance, filmmaker, architect, and pastor are female-biased based on the statistical metric but become male-biased when increasing the female token weights due to their negative weight values (Figure 11). We find that these occupations are the ones that the two metrics contradict in the bias direction (Table 3). However, both metrics show similar patterns and directions of TPR gap increase across occupations (Figure 12). The only difference is the starting point of TPR gap score when $w = 1$.

4 Cross-Evaluation

This section cross-evaluates the effectiveness of existing debiasing methods on gender bias in an occupation classification and toxicity detection task. We show using statistical and causal debiasing methods alone may not achieve both types of fairness.

4.1 Setup

We focus on pre-processing methods since Shen et al. (2022b) found that resampling and reweighting achieve better statistical fairness than the in-processing and post-processing methods. For the statistical methods, we apply both resampling using oversampling (OS) and undersampling (US) and reweighting (RW) using the weight calculation from Kamiran and Calders (2012). For the causal methods, we fine-tune the model with CDA.

We apply each debiasing method to the ALBERT-Large (Lan et al., 2020) and BERT-Base-Uncased (Devlin et al., 2019) models. We also in-

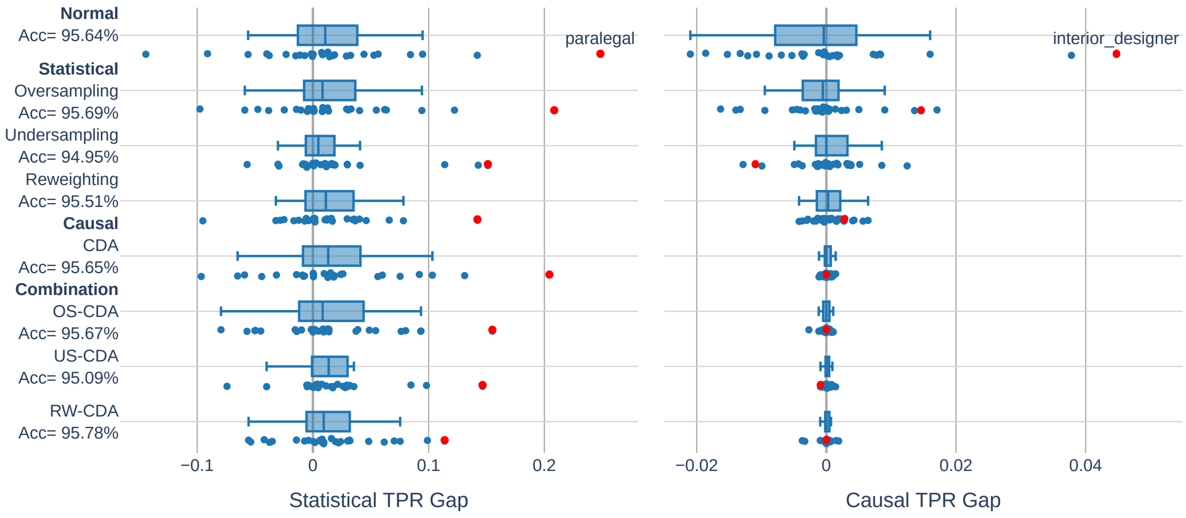

Figure 5: Statistical and causal TPR gap per occupation evaluated on BERT-Base-Uncased model, averaged over 3 different runs. Each data point is computed over test examples labeled with the same occupation. We show outliers for normal training in red dots and how their values change with different debiasing methods. Statistical and causal debiasing methods perform better on the metric they are targeting, but may not reduce bias on the other metric. Our proposed methods, `US-CDA` and `RW-CDA`, achieve the best overall performance.

clude experiments with Zari (Webster et al., 2020), which is an ALBERT-Large model pre-trained with CDA. To consider the effect of CDA during pre-training alone and during both pre-training and fine-tuning, we fine-tune Zari with normal training and CDA. Training details are provided in Appendix E.

4.2 Tasks

We test all the models on two benchmark tasks for bias detection: occupation classification and toxicity detection.

Occupation Classification. We use the BiasBios dataset introduced in Section 3.2. We evaluate gender bias with TPR and FPR gap based on both statistical and causal notions of fairness as defined in Section 2.1. Since the BiasBios dataset contains multiple classes, we follow Romanov et al. (2019) and compute a single score that quantifies overall gender bias. For each bias metric M (e.g., $\mathcal{SG}^{\text{TPR}}_{g,y}$), we compute the root mean square of the bias score across all occupation classes Y:

$$RMS_M = \sqrt{\frac{1}{|Y|}\sum_{y\in Y}(M_y)}$$

where M_y is the bias score for occupation y computed with M.

Toxicity Detection. We use the Jigsaw dataset consisting of approximately 1.8M comments taken from the Civil Comments platform. The task is to predict the toxicity score of each comment. For our experiments, we use binary toxicity labels, toxic and non-toxic. In addition to the toxicity score, a subset of examples are labeled with the identities mentioned in the comment. We only select the examples labeled with female and male identities and with high annotator agreement on the gender identity labels. Since some examples contain a mix of genders, we assign the gender to each example based on the gender labeled with the highest agreement. To perform gender intervention with CDA, we use the *gender-bender* Python package to generate counterfactual examples [2]. Appendix C.1 provides details on how we preprocess the data. Following Zayed et al. (2022), we compute statistical and causal PPR gap. As female and male groups do not have the same label distribution, the PPR gap of a perfect predictor will be non-zero. Therefore, we also compute statistical and causal TPR gap for toxic and non-toxic classes.

4.3 Results

Occupation classification. Figure 5 and Figure 6 show statistical and causal TPR gap per occupation evaluated on BERT and ALBERT models with each debiasing method. Causal debiasing methods show greater effectiveness when evaluated with the causal metric (we discuss the combination meth-

---

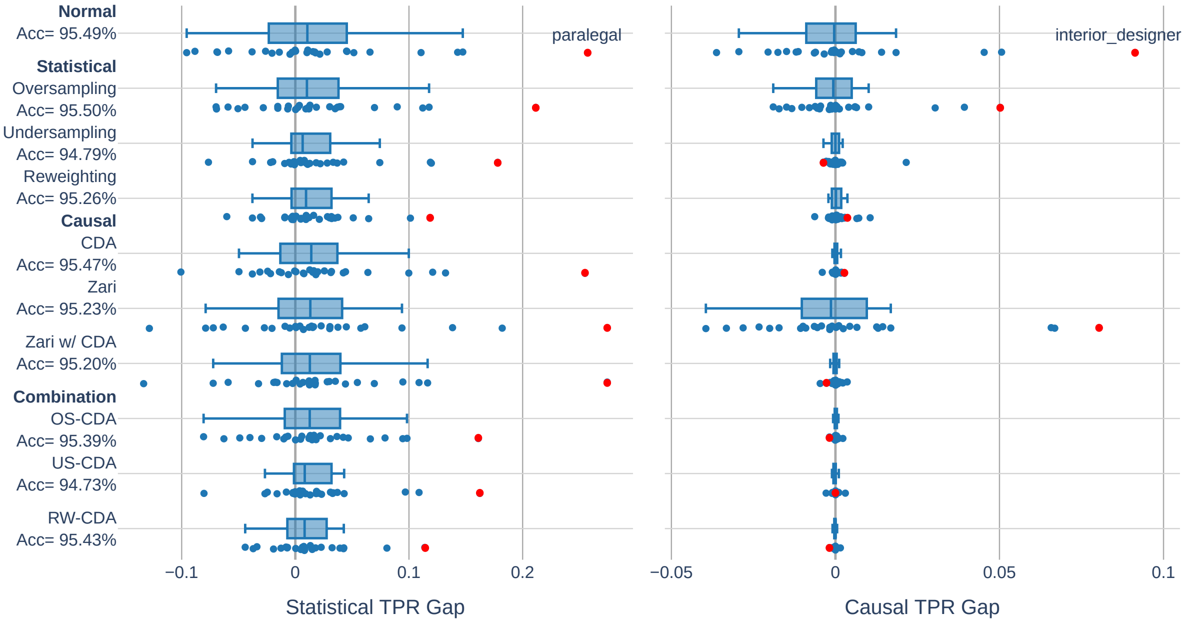

Figure 6: Statistical and causal TPR gap per occupation results for ALBERT-Large, averaged over 3 different runs.

ods included in these figures in Section 5). Fine-tuning with CDA reduces $\mathcal{CG}^{\text{TPR}}$ to nearly zero for all occupations, but does not produce any significant reduction for $\mathcal{SG}^{\text{TPR}}$. On the other hand, Zari exhibits higher statistical and causal gap than performing CDA during fine-tuning (Figure 6). Thus, using CDA during pre-training alone is insufficient to reduce bias. Statistical debiasing methods such as undersampling and reweighting reduce bias on both statistical and causal metrics, though the bias reduction on the causal metric is not as significant as CDA. We find that oversampling is less effective than other statistical debiasing methods on both metrics. We found similar results with statistical and causal FPR gaps (Appendix F.2).

Toxicity detection. Table 1 shows the bias evaluation results for the BERT model trained with different debiasing methods on the Jigsaw dataset. We find that statistical and causal bias metrics sometimes disagree on which gender the model is biased toward. Similar to the results for the BiasBios task, statistical and causal debiasing methods do particularly well on the bias metrics based on their targeted fairness definition. However, they increase bias on metrics that use the other type of fairness notion. Similar results are found for ALBERT model (Appendix G.1).

5 Achieving Both Statistical and Causal Fairness

In the previous section, we saw that using either statistical or causal debiasing method alone may not achieve both statistical and causal fairness. To counter this problem, this section considers simple methods that combine both statistical and causal debiasing techniques.

5.1 Composed Debiasing Methods

We introduce three approaches that combine techniques from both statistical and causal debiasing:

Resampling with CDA. `OS-CDA` and `US-CDA` combines resampling methods (oversampling and undersampling) with CDA. For Biasbios, we first perform resampling on the training set, then augment the resampled set with CDA. For Jigsaw, we balance the original examples based on the original gender and the counterfactual examples based on the counterfactual gender.

Reweighting with CDA. `RW-CDA` applies CDA on the training set and fine-tunes the model with reweighting. For BiasBios, we use the same weight computed on the original training set for both the original and its counterfactual pair. For Jigsaw, we use weight of 1 for all counterfactual examples.

We use different combination strategies for the two datasets as we noticed the methods used for BiasBios do not work well on the Jigsaw dataset.

Method	$\mathcal{SG}^{\text{PPR}}$	$\mathcal{CG}^{\text{PPR}}$	$\mathcal{SG}^{\text{TPR}}_{y=1}$	$\mathcal{CG}^{\text{TPR}}_{y=1}$	$\mathcal{SG}^{\text{TPR}}_{y=0}$	$\mathcal{CG}^{\text{TPR}}_{y=0}$
Normal	-2.79 ± 0.28	0.89 ± 0.10	-2.77 ± 0.67	2.33 ± 1.06	1.28 ± 0.30	-0.73 ± 0.11
CDA	-3.02 ± 0.23	0.25 ± 0.08	-2.62 ± 2.07	0.36 ± 0.57	1.52 ± 0.29	-0.24 ± 0.06
OS	$\mathbf{-1.21\pm0.22}$	1.33 ± 0.31	2.21 ± 0.35	5.24 ± 0.42	$\mathbf{0.20\pm0.17}$	-0.88 ± 0.30
US	-1.54 ± 0.26	1.67 ± 0.29	1.61 ± 1.11	4.56 ± 0.63	0.37 ± 0.24	-1.34 ± 0.26
RW	-1.44 ± 0.31	1.44 ± 0.24	2.09 ± 0.85	4.92 ± 0.53	0.39 ± 0.26	-1.05 ± 0.25
`OS-CDA`	-2.09 ± 0.30	0.18 ± 0.16	-1.11 ± 0.99	0.39 ± 0.46	0.79 ± 0.28	-0.15 ± 0.15
`US-CDA`	-1.90 ± 0.19	$\mathbf{0.11\pm0.11}$	-1.66 ± 1.88	$\mathbf{0.14\pm0.70}$	0.57 ± 0.26	$\mathbf{-0.11\pm0.06}$
`RW-CDA`	-1.76 ± 0.36	0.33 ± 0.11	$\mathbf{0.56\pm1.27}$	1.08 ± 0.74	0.62 ± 0.40	-0.24 ± 0.10

Table 1: Bias evaluation results evaluated on the Jigsaw dataset with BERT-Base-Uncased model. The results shown are averaged over 5 different runs. All values are on a log scale with base 10^{-2}.

This may be due to the mix of genders in a subset of examples in the Jigsaw dataset. The gender signals in the examples may be flipped after performing CDA. We provide performance comparisons between the different combination strategies we have tried on the Jigsaw task in Appendix G.2.

5.2 Results

Figure 5 and Figure 6 show statistical and causal TPR gap per occupation evaluated on the BiasBios dataset for BERT and ALBERT models. The combined methods `US-CDA` and `RW-CDA` are more effective at reducing bias on both metrics compared to other methods. To compare overall performance, we show the root mean square of each bias metric in Table 4 and Table 5 (both in Appendix F.1). All three combination approaches perform better on $\mathcal{CG}^{\text{TPR}}$ compared to using a statistical or causal debiasing method alone. `OS-CDA` and `US-CDA` also reduce bias on $\mathcal{SG}^{\text{TPR}}$ (11–16% decrease) and $\mathcal{SG}^{\text{FPR}}$ (1–8% decrease), comparing to their statistical debiasing counterparts. `RW-CDA` achieves comparable performance on $\mathcal{SG}$ to reweighting. Undersampling and `US-CDA` sacrifice the general performance with a decrease of around 0.7% in accuracy compared to other methods, which preserve the baseline accuracy within 0.3%.

Table 1 and Table 6 (Appendix G.1) report the results of BERT and ALBERT models for the Jigsaw dataset. While statistical and causal debiasing methods only improve one type of bias metric and worsen the other, our proposed combination approaches are able to reduce bias on both types of bias metrics. The combined methods `OS-CDA` and `US-CDA` perform better than CDA on all causal bias metrics. `RW-CDA` performs better on $\mathcal{SG}$ but is less effective at reducing bias on $\mathcal{CG}$ compared to the other combination approaches.

6 Summary

We demonstrate the disparities between statistical and causal bias metrics and provide insight into how and why optimizing based on one type of metric does not necessarily improve the other. We show this by cross-evaluating existing statistical and causal debiasing methods on both metrics and find that they sometimes may even worsen the other type of bias metrics. To obtain models that perform well on both types of bias metrics, we introduce simple debiasing strategies that combine both statistical and causal debiasing techniques.

Limitations

Due to the limited benchmark datasets compatible with extrinsic metrics (Orgad and Belinkov, 2022), we only conduct experiments on two gender bias tasks. Further testing is needed to determine if the bias metric disparities are present in other tasks and whether our proposed debiasing methods can still be effective. The gender intervention method used for counterfactual data augmentation is based on a predefined list of gender tokens, which may not cover all possible tokens representing gender. In addition, our experiments exclusively focus on binary-protected attributes. Future work should explore how to generalize our results to tasks with non-binary protected attributes. While our proposed debiasing methods are able to reduce bias on both statistical and causal bias metrics, there is room for improvements in the statistical bias metrics when compared to statistical debiasing methods. Future work could consider other types of debiasing techniques beyond pre-processing-based methods. For instance, in-processing methods can be adapted by enforcing both statistical and causal fairness constraints during training.

A False Positive Rate Gap

Statistical FPR gap between binary gender g (female) and $\neg g$ (male) for class y is defined as:

$$\begin{aligned}\mathcal{SG}_y^{\text{FPR}} &= \text{FPR}_s(g, y) - \text{FPR}_s(\neg g, y) \\ \text{FPR}_s(g, y) &= \mathbb{E}[\hat{Y} = y \mid G = g, Y \neq y]\end{aligned} \tag{1}$$

Causal FPR gap is computed by averaging the FPR difference for each individual:

$$\begin{aligned}\mathcal{CG}_y^{\text{FPR}} &= \text{FPR}_c(g, y) - \text{FPR}_c(\neg g, y) \\ \text{TPR}_c(g, y) &= \mathbb{E}[\hat{Y} = y \mid do(G = g), Y \neq y]\end{aligned} \tag{2}$$

B BiasBios Dataset Details

B.1 Dataset Statistics

The dataset contains 255,707 training examples, 39,369 validation examples, and 98,339 testing examples. Figure 7 shows the full list of occupations and their gender frequency in the BiasBios training set. The gender and occupation distribution for validation and testing sets are similar to the training set.

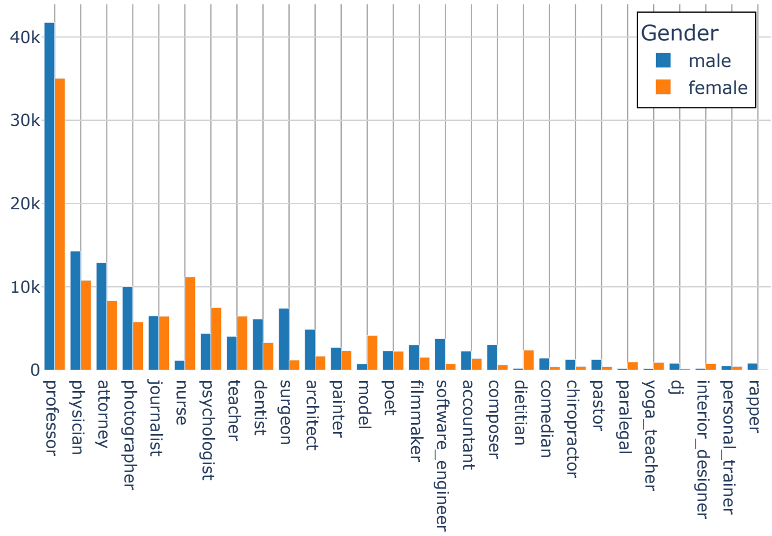

Figure 7: Gender frequency for each occupation in the training set.

B.2 Dataset Construction

The original BiasBios dataset consists of extracted biographies with the first sentences removed from each biography as they include the occupation titles corresponding to the ground truth labels. We notice a lot of the important information is in the first sentences and it is hard to correctly identify the occupation of some examples without the first sentences even for humans. Thus, we keep the first sentence but replace any occupation tokens that appear in the biography with an underscore (e.g., "Alice is a nurse working at a hospital" to "Alice is a _ working at a hospital"). We notice that our model performance is higher than the same model trained on the original dataset (Webster et al., 2020). This can be attributed to having longer sequences and more context information in the inputs.

B.3 Gender Intervention

To perform gender intervention, we first identify words with explicit gender indicators in the input. If the assigned gender value is different from the original input, we swap the identified words with the corresponding words in the mapping with an opposite gender. We use the same list of explicit gender indicators used in BiasBios dataset and perform gender mapping as follows:

- Bidirectional: he ↔ she, himself ↔ herself, mr ↔ ms
- Unidirectional: hers → his, his → her, him → her, her → his or him, mrs → mr

Words in blue are associated with male gender and words in red are associated with female gender. Since "her" can be mapped to either "his" or "him" depending on the context, we use Part-of-Speech tagging to determine which one to map to.

C Jigsaw Dataset Details

C.1 Dataset Construction

Each comment is associated with a toxicity label and several identity labels. The label values range from 0.0 to 1.0 representing the percentage of annotators who agreed that the label fit the comment. We binarized the toxicity values and considered comments as toxic if their toxicity values exceeded 0.5. We assigned female gender to an example if its female identity label value is higher than the male one and assigned male gender vice versa. To make better differentiation between the two genders, we filtered out examples if the difference between male and female label values is smaller or equal to 0.5. We use `train.csv` from the Kaggle competition for training and validation with an 80/20 split. We use `test_public_expanded.csv` and `test_private_expanded.csv` for testing.

Label	Gender	Count	Percentage (%)
Toxic	F	2504	5.89
Toxic	M	2123	4.99
Non-Toxic	F	22,465	52.83
Non-Toxic	M	15,431	26.29

Table 2: Gender and label distribution of Jigsaw training set.

C.2 Dataset Statistics

The final dataset after pre-processing contains 42,523 training examples, 10,631 validation examples, and 5,448 testing examples. Table 2 shows the gender and label distribution on the training set. All three data splits have similar distributions. We also show the distribution of the gender label values in Figure 8. For examples that contain a mix of both female and male genders, we show the gender label value of the final gender we assigned (the gender with a higher label value).

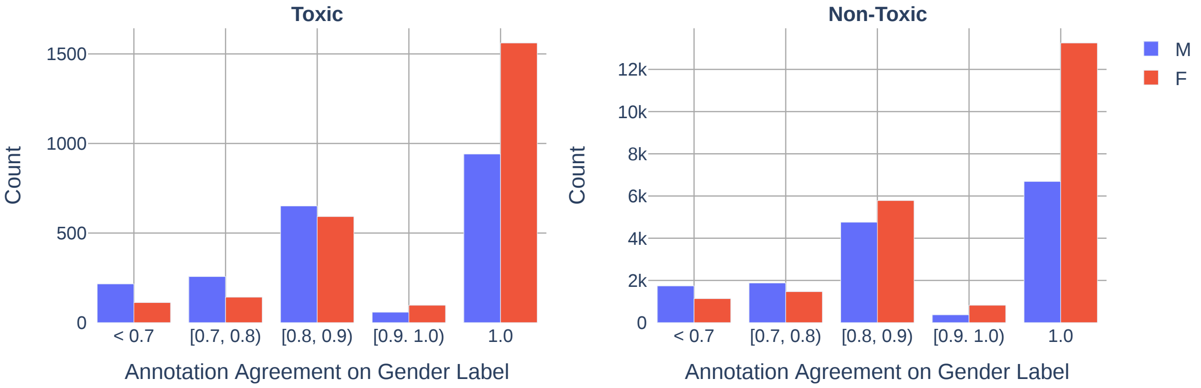

Figure 8: Distribution of annotation agreement on the gender labels. 1.0 indicates all annotators agree that the gender is mentioned in the comment.

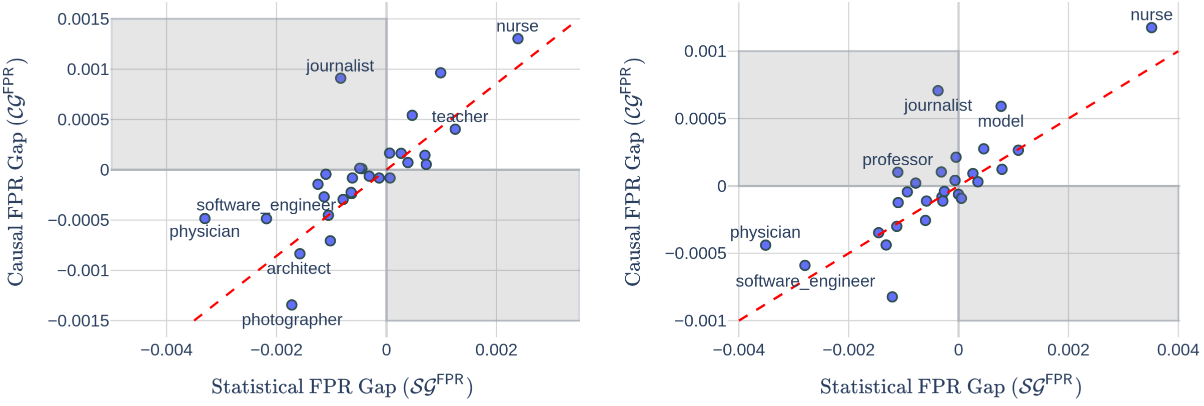
D Disparities between Statistical and Causal Bias Metrics

D.1 Statistical vs Causal FPR Gap



(a) ALBERT-Large (b) BERT-Base-Uncased

Figure 9: Statistical and causal FPR gap on ALBERT-Large and BERT-Base-Uncased models with normal training. Red dashed line indicates $\mathcal{SP} = \mathcal{CP}$. Shaded areas represent $\mathcal{SP}$ and $\mathcal{CP}$ reporting opposite gender bias direction.

D.2 BoW Analysis

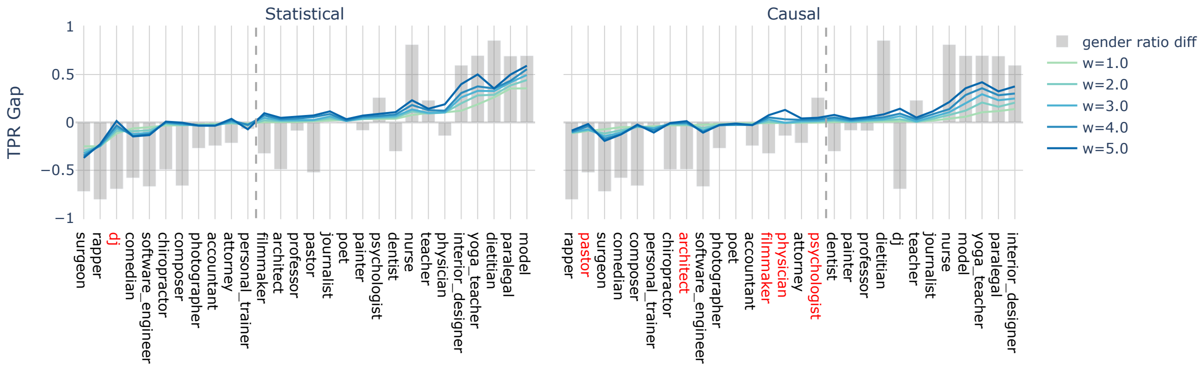


Figure 10: Statistical and causal TPR gaps of BoW model for each occupation when increasing the male token weights. Occupations are sorted by gap with $w = 1$.

Occupation	$\mathcal{SG}^{\text{TPR}}$	$\mathcal{CG}^{\text{TPR}}$	Diff	Gender ratio diff in train set
dj	-0.115	0.008	0.123	-0.695
physician	0.105	-0.005	0.110	-0.140
pastor	0.013	-0.088	0.101	-0.523
psychologist	0.036	-0.003	0.039	0.260
poet	0.028	-0.010	0.038	-0.008
architect	0.002	-0.030	0.033	-0.490
filmmaker	0.02	-0.009	0.011	-0.325

Table 3: Occupations where statistical and causal TPR gap shows contradictory bias direction.

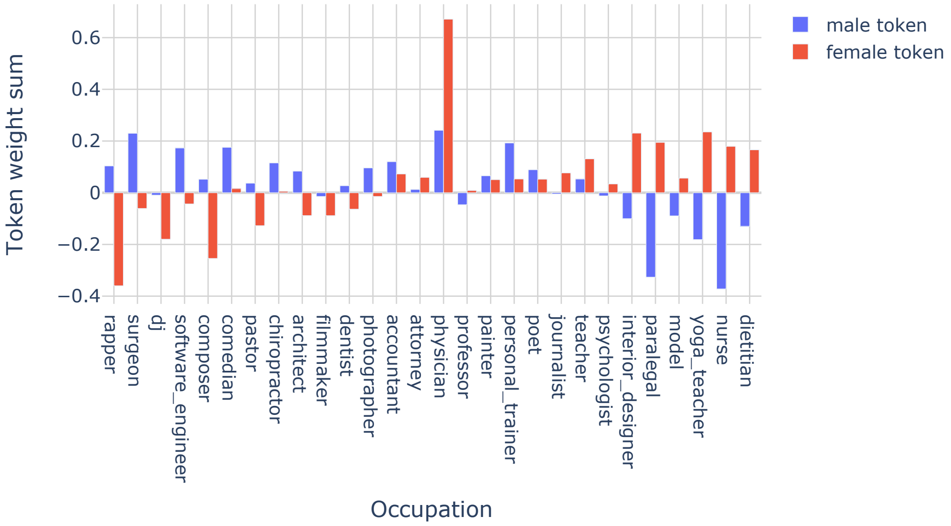

Figure 11: The sum of model weights for male and female gender tokens weighted by the token frequency in test examples of the occupation class.

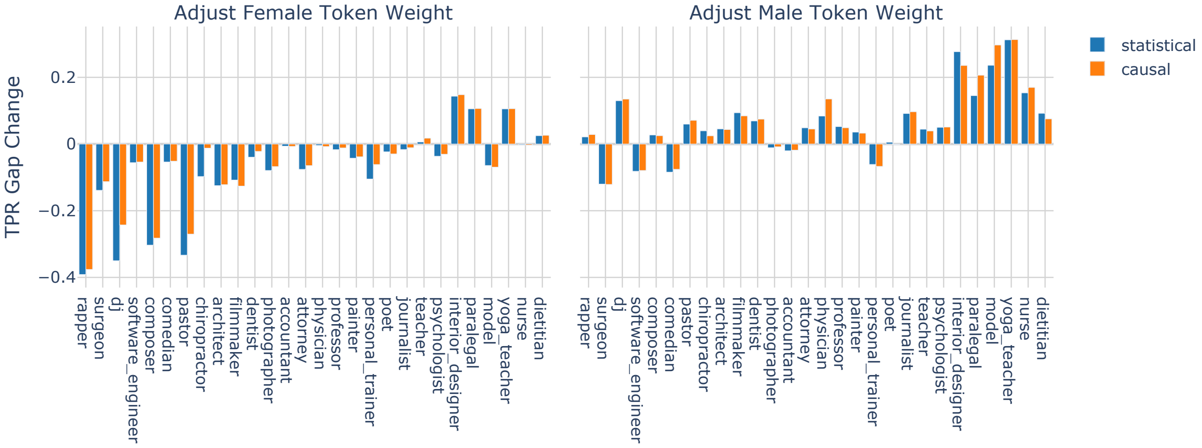

Figure 12: The TPR gap difference when increasing either female or male token weights from $w = 1$ to $w = 5$. Both metrics show similar patterns of TPR gap change for all occupations.

E Training Details

Computing Infrastructure. All the models were trained on 4 Nvidia RTX 2080Ti GPUs.

BiasBios Dataset. We trained all the models with a learning rate of 2e-5 and batch size of 64. We fine-tuned the models for 5-8 epochs with early stopping and choose the model checkpoints with the best validation accuracy. Most models reach the best validation accuracy before epoch 5. We notice that ALBERT with subsampling requires training a few epochs longer than other models to reach comparable performance due to the downsized training data.

Jigsaw Dataset. We trained all the models with a learning rate of 1e-5 and batch size of 128 for 4 epochs with early stopping. Most models converge after 2-3 epochs.

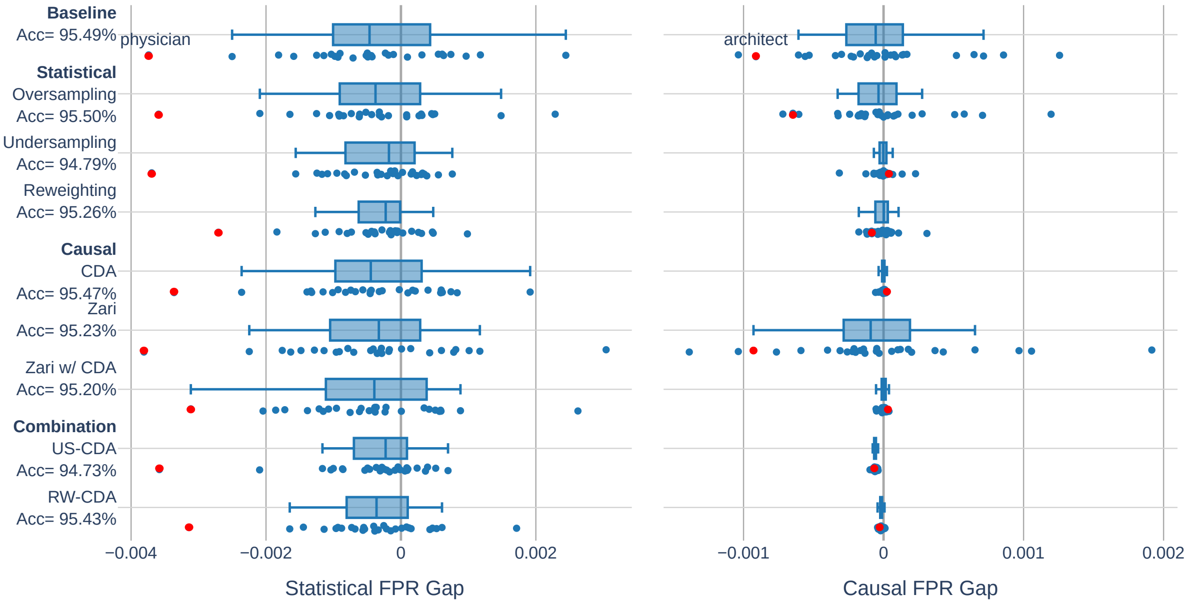
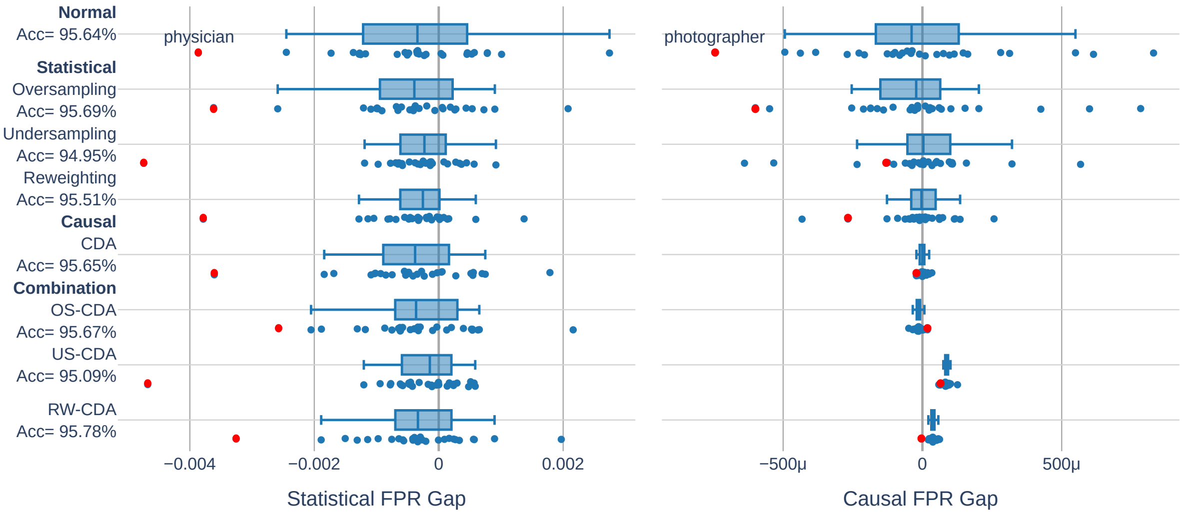
Table 5: Root mean square of bias metrics for BERT-Base-Uncased model fine-tuned with different debiasing methods. The values shown are averaged over 3 different runs on a log scale with base 10^{-2}.

F.2 Statistical vs Causal FPR Gap



(a) ALBERT-Large

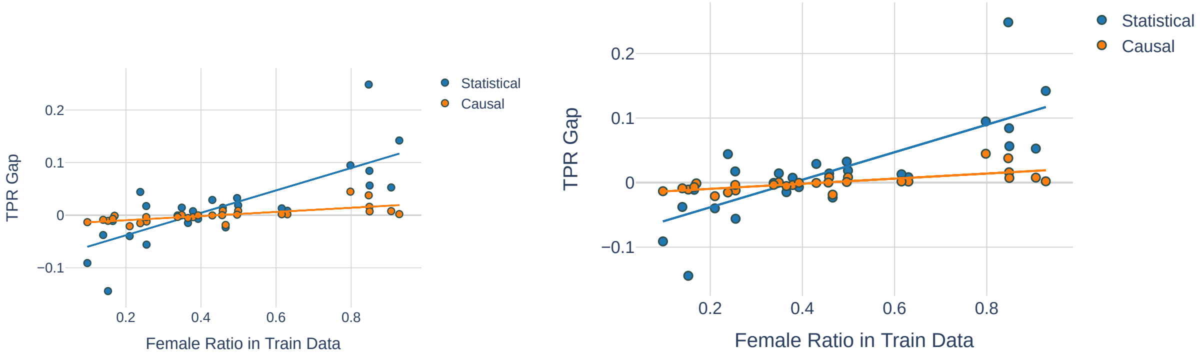


(b) BERT-Base-Uncased

Figure 13: Statistical and Causal FPR gap per occupation, averaged over 3 different runs. Each data point is computed over test examples labeled with the same occupation. We show the outliers for normal training in red dots and how their values change with different debiasing methods. Causal-based debiasing methods perform particularly better on the causal FPR gap while statistical-based debiasing methods are able to reduce bias based on both metrics.

F.3 Correlation to Gender Imbalances in Training Data

In Figure 14, we compare the statistical and causal TPR gap to the female ratio in the training data for each occupation. Both bias metrics show a positive correlation with the gender distribution in the training data. This observation is consistent with the results found in De-Arteaga et al. (2019), where they measure the statistical TPR gap on non-transformer-based models such as BoW.



(a) ALBERT Large

(b) BERT Base Uncased

Figure 14: Statistical and causal TPR gap versus the female ratio of each occupation in the training data.

G.2 Combination Strategies Comparison

Table 7 shows the performance of two different strategies of combining resampling and CDA. Resample → CDA performs resampling first, then applies CDA on the resampled set. CDA → Resample performs CDA first, then resamples the original and the counterfactual sets separately. The original examples are resampled based on the original gender distribution. The counterfactual examples are resampled based on their counterfactual genders (not the gender of the original example they originated from). The difference between the two methods is that Resample → CDA uses the original gender label for both original and counterfactual examples while CDA → Resample considers the counterfactual gender for the counterfactual examples during resampling. We find that the second method performs better on $\mathcal{SG}^{\text{PPR}}$ but increases $\mathcal{CG}^{\text{PPR}}$ compared to the first method. The increase in the causal bias metric may be due to separate resampling on original and counterfactual sets, meaning that some of them may not come in pairs. Nonetheless, the performance still exceeds CDA.

Strategy	Method	BERT-Base-Uncased $\mathcal{SG}^{\text{PPR}}$	 $\mathcal{CG}^{\text{PPR}}$	ALBERT-Large $\mathcal{SG}^{\text{PPR}}$	 $\mathcal{CG}^{\text{PPR}}$
Resample → CDA	`OS-CDA`	-2.73 ± 0.72	$\mathbf{0.011\pm0.086}$	-2.51 ± 0.49	$\mathbf{0.004\pm0.082}$
	`US-CDA`	-2.12 ± 0.51	0.117 ± 0.114	-2.88 ± 0.78	0.022 ± 0.134
CDA → Resample	`OS-CDA`	-2.09 ± 0.30	0.176 ± 0.160	-2.29 ± 0.42	0.015 ± 0.107
	`US-CDA`	$\mathbf{-1.90\pm0.19}$	0.114 ± 0.113	$\mathbf{-2.22\pm0.23}$	0.084 ± 0.096

Table 7: Debiasing performance between two different strategies of combining resampling and CDA. The results shown are evaluated on the BERT model, averaged over 5 different runs. $\mathcal{SG}^{\text{PPR}}$ and $\mathcal{CG}^{\text{PPR}}$ are on a log scale with base 10^{-2}.

Table 8 shows the performance of using different reweighting strategies on counterfactual examples for `RW-CDA`. We tried `RW-CDA` method for training on BiasBios dataset, which uses the same weight for both the original and counterfactual examples (first row in Table 8). It is not effective at reducing $\mathcal{SG}^{\text{PPR}}$, but very effective on $\mathcal{CG}^{\text{PPR}}$. We think it may be due to the gender signals of some examples being flipped by CDA. We then tried using weights that correspond to the counterfactual gender for the counterfactual examples. This decreases bias on $\mathcal{SG}^{\text{PPR}}$, but increases bias on $\mathcal{CG}^{\text{PPR}}$. We found that setting the weight to 1 for all counterfactual examples gives the best overall balance between $\mathcal{SG}^{\text{PPR}}$ and $\mathcal{CG}^{\text{PPR}}$. It also outperforms other strategies on $\mathcal{SG}^{\text{PPR}}$.

Strategy	BERT-Base-Uncased $\mathcal{SG}^{\text{PPR}}$	 $\mathcal{CG}^{\text{PPR}}$	ALBERT-Large $\mathcal{SG}^{\text{PPR}}$	 $\mathcal{CG}^{\text{PPR}}$
Same weight	-2.30 ± 0.35	$\mathbf{0.162\pm0.109}$	-2.41 ± 0.30	$\mathbf{0.070\pm0.059}$
Counterfactual gender weight	-1.82 ± 0.36	0.653 ± 0.242	-2.19 ± 0.31	0.371 ± 0.063
Weight=1	$\mathbf{-1.76\pm0.36}$	0.327 ± 0.110	$\mathbf{-1.96\pm0.25}$	0.239 ± 0.091

Table 8: Debiasing performance of different reweighting strategies on counterfactual examples for `RW-CDA`. The results shown are evaluated on the BERT model, averaged over 5 different runs. $\mathcal{SG}^{\text{PPR}}$ and $\mathcal{CG}^{\text{PPR}}$ are on a log scale with base 10^{-2}.

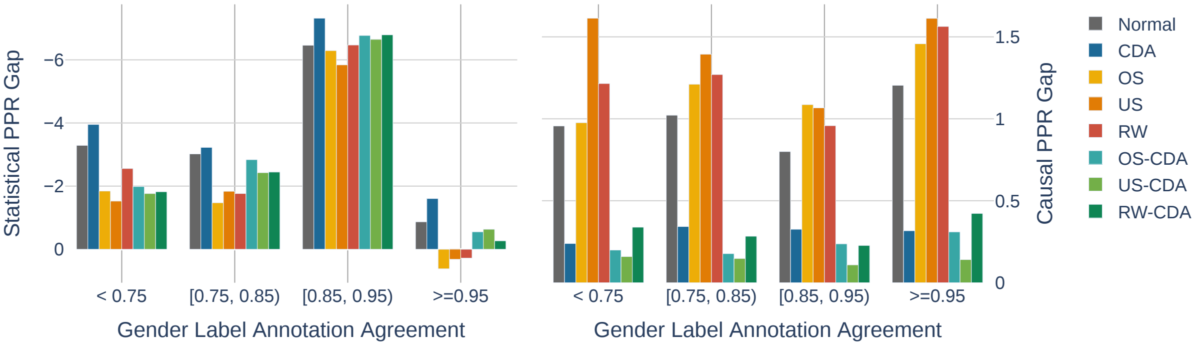
G.3 General Performance

Method	AUC (ALBERT)	AUC (BERT)
Normal	0.930 ± 0.002	0.925 ± 0.003
CDA	0.930 ± 0.002	0.928 ± 0.002
Zari w/ CDA	0.928 ± 0.005	—
OS	0.931 ± 0.001	0.932 ± 0.002
US	0.929 ± 0.003	0.924 ± 0.004
RW	0.930 ± 0.005	0.929 ± 0.003
`OS-CDA`	0.930 ± 0.003	0.931 ± 0.002
`US-CDA`	0.929 ± 0.003	0.931 ± 0.002
`RW-CDA`	0.929 ± 0.002	0.930 ± 0.003

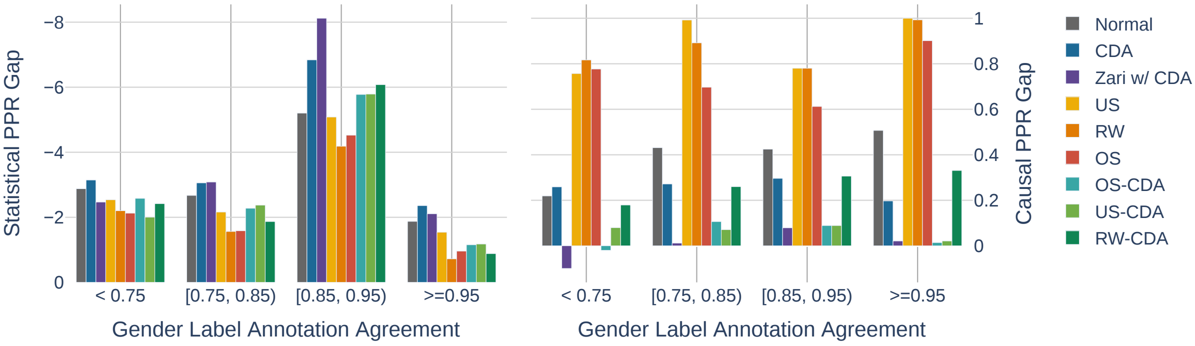
Table 9: AUC scores of different debiasing methods. The results shown are averaged over 5 different runs.

G.4 Gender Label Annotation Agreement

We test if gender label annotation agreement in the Jigsaw dataset has an effect on the bias scores. In Figure 15, we show statistical and causal PPR gap of examples with different range of annotation agreement for each debiasing methods. All methods have the highest score of statistical PPR gap at [0.85, 0.96) including the normal training method and have the lowest score when annotation agreement >=0.95. On the other hand, causal PPR gap of each debiasing method remain similar at different range of gender annotation agreement.



(a) BERT-Base-Uncased



(b) ALBERT-Large

Abstract

Text-based recommendation holds a wide range of practical applications due to its versatility, as textual descriptions can represent nearly any type of item. However, directly employing the original item descriptions may not yield optimal recommendation performance due to the lack of comprehensive information to align with user preferences. Recent advances in large language models (LLMs) have showcased their remarkable ability to harness commonsense knowledge and reasoning. In this study, we introduce a novel approach, coined LLM-REC, which incorporates four distinct prompting strategies of text enrichment for improving personalized text-based recommendations. Our empirical experiments reveal that using LLM-augmented text significantly enhances recommendation quality. Even basic MLP (Multi-Layer Perceptron) models achieve comparable or even better results than complex content-based methods. Notably, the success of LLM-REC lies in its prompting strategies, which effectively tap into the language model's comprehension of both general and specific item characteristics. This highlights the importance of employing diverse prompts and input augmentation techniques to boost the recommendation effectiveness of LLMs.

1 Introduction

Text-based recommendation systems exhibit a broad spectrum of applications, spanning across diverse domains and industries. This versatility mainly stems from the capability of natural language to effectively describe nearly *any* type of items, encompassing not only products, movies, and books but also news articles and user-generated content, including short videos and social media posts (Pazzani and Billsus, 2007; Javed et al., 2021; Poirier et al., 2010; Bai et al., 2022; Wu et al., 2020; Oppermann et al., 2020; Chen et al., 2017; Gupta and Varma, 2017; Wang et al., 2018). Nonetheless, these text-based recommendation systems are frequently challenged by the inherent limitation of **incomplete or insufficient information within item descriptions**, which hinders the task of accurately *aligning* item characteristics with user preferences (Perez et al., 2007; Dumitru et al., 2011). The incompleteness may arise from two sources: a limited comprehension of the items themselves and an insufficient understanding of the users for whom recommendations are generated.

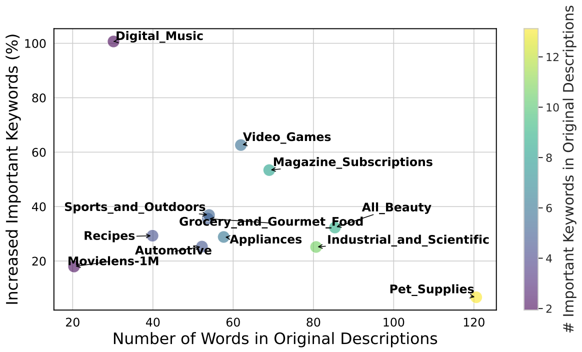

Figure 1: LLM-REC enhances original item descriptions by prompting LLMs to augment important keywords (*e.g.*, adjectives). It applies to various domains and is not limited to datasets with rich textual content.

This challenge is not confined only to domains with well-defined and categorized items (*e.g.*, movies), but also extends to domains characterized by novel, unclassified, or less categorically structured items, as observed in the case of user-generated content. In the context of movie recommendations, a movie's description usually include the main actors, and a brief plot summary. However, this limited information may not capture crucial elements like genre, tone, cinematography style, or thematic depth, resulting in less effective recommendations. As for user-generated content, imagine a social platform where users regularly post recipes which are often accompanied with brief textual descriptions like the name of the dish and a few ingredients, but limited details regarding

Findings of the Association for Computational Linguistics: NAACL 2024, pages 583–612
June 16-21, 2024 ©2024 Association for Computational Linguistics

preparation time, dietary restrictions, or flavor profiles. Consider a user who follows a vegan diet and is interested in discovering new plant-based recipes. Since the user-generated content often lacks comprehensive dietary information and may not explicitly mention terms like "vegan", "plant-based", or "vegetarian", in this scenario, the recommendation system, relying solely on the incomplete descriptions, may struggle to discern the vegan-friendliness of the recipes.

The recent advances in the development of large language models (LLMs) underscore their exceptional capacity to store comprehensive world knowledge (Peters et al., 2018; Goldberg, 2019; Tenney et al., 2019; Petroni et al., 2019), engage in complex reasoning (Wei et al., 2022; Zhou et al., 2022), and function as versatile task solvers (Zhao et al., 2023; Ouyang et al., 2022; Kaplan et al., 2020). In light of this advancement and recognizing the challenge posed by incomplete item descriptions, our study introduces the LLM-REC framework. This approach is designed to exploit various prompting strategies to *enrich input text* with the intrinsic capabilities of LLMs for personalized recommendations. By leveraging LLMs, which have been fine-tuned on extensive language datasets (Ouyang et al., 2022; Touvron et al., 2023a), our goal is to unlock their potential in generating input text that is not only contextually aware but also of high quality, thereby elevating the overall recommendation quality.

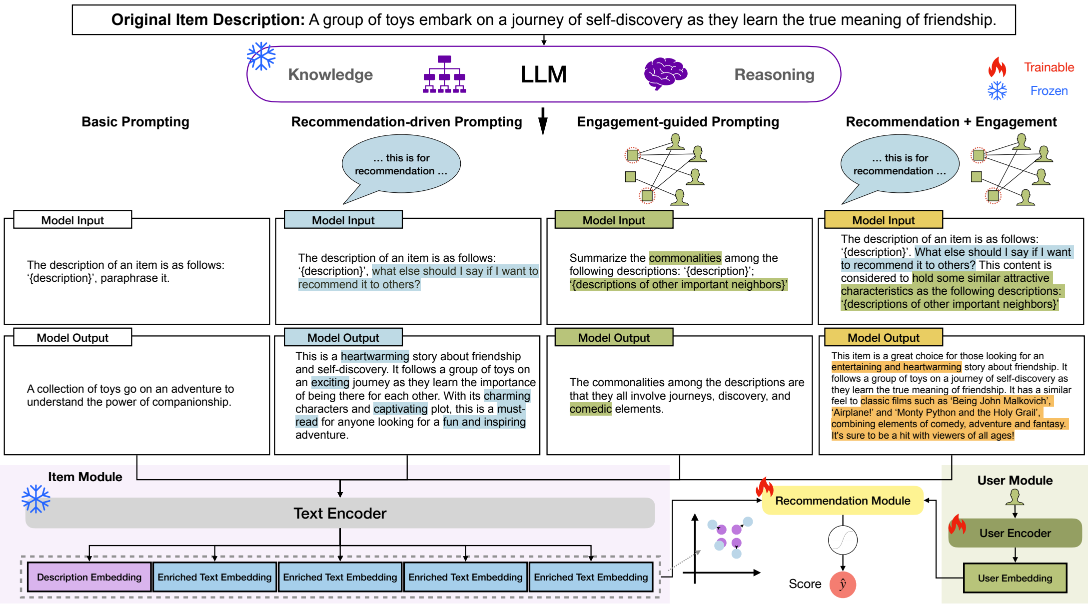
Through comprehensive empirical experiments, we evaluate the effectiveness of the LLM-REC framework. We find that integrating the augmented text as the new input achieves comparable or even superior recommendation performance compared to more advanced content-based recommendation approaches that rely solely on the original item descriptions. Further in-depth analyses reveal that the devised prompting strategies prompt LLMs to generate words that represent both general and specific item characteristics. It is applicable in a diverse range of domains and is not limited to datasets with rich textual information (Figure 1). Our study provides insights into the impact of different prompting strategies on recommendation performance and sheds light on the potential of leveraging LLMs for personalized recommendation.

2 Related Work

LLM-REC closely aligns with two research directions: (1) augmentation in text-based recommendation, and (2) LLM for recommendation. A comprehensive discussion is provided in Appendix C.

Augmentation in Text-based Recommendation. Text-based recommendation systems leverage natural language processing and machine learning techniques to provide personalized recommendations to users based on textual information (Lops et al., 2019; Qiang et al., 2020). However, the performance of such systems can be compromised when dealing with incomplete or insufficient textual information. To address this limitation, several studies have suggested strategies for enhancing textual information. For instance, Li et al. (2010) proposed to extract contextual cues from online reviews, leveraging these narratives to uncover users' preferences and underlying factors influencing their choices (Sachdeva and McAuley, 2020). Other approaches infer linguistic attributes from diverse sources, including emotion, sentiment, and topic, to refine the modeling of both items and users (Sun et al., 2015; Sailunaz and Alhajj, 2019; Ramage et al., 2010; Chen et al., 2010). Furthermore, some works explore the integration of external knowledge bases to enrich the contextual understanding of items (Di Noia et al., 2012; Musto et al., 2018). In a more recent development, Bai et al. (2022) introduced an approach that employs pre-trained language models to generate additional product attributes, such as product names, to augment item contextual information. Diverging from these prior approaches, our contribution is the LLM-REC framework, which employs large language models to enhance input text, providing a versatile solution for recommendations. A more detailed discussion on the distinctions between LLM-REC and these related work can be found in Section 5.

LLM for Recommendation. Due to LLMs' remarkable text generation ability, many studies have leveraged LLMs as a data augmentation tool (Dai et al., 2023a; Li et al., 2022). Liu et al. (2023a) used an LLM to produce multimodal language-image instruction-following datasets. Through a process of instruction tuning using this generated data, their proposed framework demonstrated an impressive aptitude in advancing vision and language comprehension. There have also been efforts to use LLMs to augment the input side of personalized recommendation. For instance, Chen (2023) incorporated user history behaviors, such as clicks, purchases, and ratings, into LLMs to generate user profiles. These profiles were then combined with the history interaction sequence and candidate items to



Basic Prompting

Model Input: The description of an item is as follows: '{description}', paraphrase it.

Model Output: A collection of toys go on an adventure to understand the power of companionship.

Recommendation-driven Prompting

Model Input: The description of an item is as follows: '{description}', what else should I say if I want to recommend it to others?

Model Output: This is a heartwarming story about friendship and self-discovery. It follows a group of toys on an exciting journey as they learn the importance of being there for each other. With its charming characters and captivating plot, this is a must-read for anyone looking for a fun and inspiring adventure.

Engagement-guided Prompting

Model Input: Summarize the commonalities among the following descriptions: '{description}'; '{descriptions of other important neighbors}'

Model Output: The commonalities among the descriptions are that they all involve journeys, discovery, and comedic elements.

Recommendation + Engagement

Model Input: The description of an item is as follows: '{description}'. What else should I say if I want to recommend it to others? This content is considered to hold some similar attractive characteristics as the following descriptions: '{descriptions of other important neighbors}'

Model Output: This item is a great choice for those looking for an entertaining and heartwarming story about friendship. It follows a group of toys on a journey of self-discovery as they learn the true meaning of friendship. It has a similar feel to classic films such as 'Being John Malkovich', 'Airplane!' and 'Monty Python and the Holy Grail', combining elements of comedy, adventure and fantasy. It's sure to be a hit with viewers of all ages!

Figure 2: LLM-REC employs four prompting strategies to augment the original item descriptions which often contain incomplete information for recommendation. The augmented text is then concatenated to form the new input for the following recommendation module. LLM-REC plays a crucial role in enabling large language models to provide relevant context and help better align with user preferences. Prompts and augmented texts are highlighted.

construct the final recommendation prompt. LLMs were subsequently employed to predict the likelihood of user-item interaction based on this prompt. Xi et al. (2023) introduced a method that leverages the reasoning knowledge of LLMs regarding user preferences and the factual knowledge of LLMs about items. However, our study focuses specifically on using LLMs' knowledge and reasoning ability to generate augmented input text that better captures the characteristics and nuances of items, leading to improved recommendation performance.

3 LLM-Rec

When composing a summary for recommendation purposes, it is customary to infuse it with specific emphases grounded in the author's *comprehension* of the movie. This might involve accentuating the movie's distinctive attributes that set it apart from other movies. For instance, one may opt to incorporate genre information as a crucial element for classifying the movie. However, the decision to leverage the concept of genre for enhancing the summary is predicated on the author's understanding that the genre is a meaningful construct, effectively aligning the summary with the preferences and expectations of the intended audience. This paper aims to explore the potential of large language models when prompted to generate informative item descriptions and subsequently how to leverage this augmented text for enhancing personalized recommendations. Figure 2 shows the diagram of LLM-REC. Specifically, our study focuses on investigating *four* distinct LLM prompting strategies for description enrichment, namely basic prompting, recommendation-driven prompting, engagement-guided prompting, and the combination of recommendation-driven and engagement-guided prompting. The enriched text is then fed into the final recommendation module.

Basic Prompting. The concept of basic prompting closely resembles the task of crafting a general movie summary. Within this scope, we consider three basic prompting variants and refer to them as p_{para}, p_{tag}, and p_{infer}, respectively in the following experiments. p_{para} instructs LLMs to paraphrase the original item description, emphasizing the objective of maintaining the same information without introducing any additional details. Given the original content description, the prompt we use is *"The description of an item is as follows* '`{description}`', *paraphrase it."* p_{tag} aims to guide LLMs to summarize the content description by using tags, striving to generate a more concise overview that captures key information. The corresponding prompt is *"The description of an item is as follows* '`{description}`', *summarize it with tags."* p_{infer} instructs LLMs to deduce the characteristics of the original content description and provide a categorical response that operates at a broader, less detailed level of granularity. We use the following prompt in the experiments: *“The description of an item is as follows* ‘`{description}`’, *what kind of emotions can it evoke?”*

Recommendation-driven Prompting. This prompting strategy is to add a recommendation-driven instruction, into the basic prompting, resembling the task of creating a paragraph intended for making recommendations. We refer to the three recommendation-driven prompting as p^{rec}_{para}, p^{rec}_{tag}, and p^{rec}_{infer}, respectively in the following experiments, aligning with their counterparts in the basic prompting strategy. p^{rec}_{para} represents the prompt: *“The description of an item is as follows* ‘`{description}`’, *what else should I say if I want to recommend it to others?”* The prompt for p^{rec}_{tag} is *“The description of an item is as follows* ‘`{description}`’, *what tags should I use if I want to recommend it to others?”* The prompt for p^{rec}_{infer} is *“The description of an item is as follows* ‘`{description}`’, *recommend it to others with a focus on the emotions it can evoke.”*

Engagement-guided Prompting. As previously elucidated, the deficiency in item descriptions can also emanate from a limited comprehension of the user cohort for whom the recommendations are being generated. Typically, item descriptions are initially formulated for broad, general purposes, devoid of specific targeting toward particular user groups. As a result, they often fall short in capturing the intricate nuances of items required for a more fine-grained alignment with individual user preferences. The goal of the engagement-guided prompting strategy is to leverage user behavior, specifically the interactions between users and items (*i.e.*, user-item engagement) to devise prompts with the intention to steer LLMs towards a more precise comprehension of the attributes within the items, thus generating more insightful and contextually relevant descriptions that align more closely with the preferences of intended users. We refer to this variant as p^{eng}. To create the engagement-guided prompt, we combine the description of the target item, denoted as d_{target}, with the descriptions of T **important** neighbor items, represented as $d_1, d_2, \cdots, d_T$. The importance is measured based on **user engagement**. More details can be found in Appendix A.6. The exact prompt of this prompting strategy is *“Summarize the commonalities among the following descriptions:* ‘`{description}`’; ‘`{descriptions of other important neighbors}`’.”

Recommendation-driven + Engagement-guided Prompting. It intends to incorporate both the recommendation-driven and engagement-guided instructions, which we denote as $p^{rec+eng}$: *“The description of an item is as follows:* ‘`{description}`’. *What else should I say if I want to recommend it to others? This content is considered to hold some similar attractive characteristics as the following descriptions:* ‘`{descriptions of other important neighbors}`’.”

How does LLM-Rec affect personalized recommendation? In our experiments, we discover that first and foremost, LLM-Rec stands out as a versatile yet simple framework, largely unrestricted by the type of items. Our experimental results on two datasets including the items that are categorically structured and extensively studied to items that are relatively novel and unclassified such as user-generated content, consistently demonstrate the substantial improvement in personalized recommendations. Simple models, such as MLP, can achieve performance on par with, or even better than, more advanced and complex models with the augmented text. This finding underscores the potential of simplified training to address challenges due to more complex models. More importantly, compared to other knowledge-based text augmentation methods, LLM-Rec achieves superior recommendation performances and requires considerably less domain expertise compared to prior studies, making it much more accessible for implementation.

Second, LLM-Rec contributes to increased recommendation transparency and explainability. The ability to directly investigate the augmented text not only enhances our understanding of the recommendation models but also offers insights into the characteristics of the items. It is invaluable for both users and system designers seeking to comprehend the rationale behind recommendations.

4 Experiments

4.1 Experiment Setup

Datasets and Baslines. Two widely adopted recommendation benchmarks are used, Movielens-1M (Harper and Konstan, 2015) for movie recommendation, and Recipe (Majumder et al., 2019) for recipe recommendation. To assess LLM-Rec’s efficacy, we compare it against two distinct categories of baselines. The first category includes content-based baselines that takes solely the original item

Table 1: Average recommendation performance between LLM-REC and baseline approaches across five different train/test splits. The best results are highlighted in **bold**, the second-best results are underlined, and relative gains compared to the MLP baseline are indicated in green.

descriptions as input. The second category includes different text augmentation methods. Details including dataset statistics, preprocessing specifics, baselines, model training, hyper-parameter settings and implementation are discussed in Appendix A.

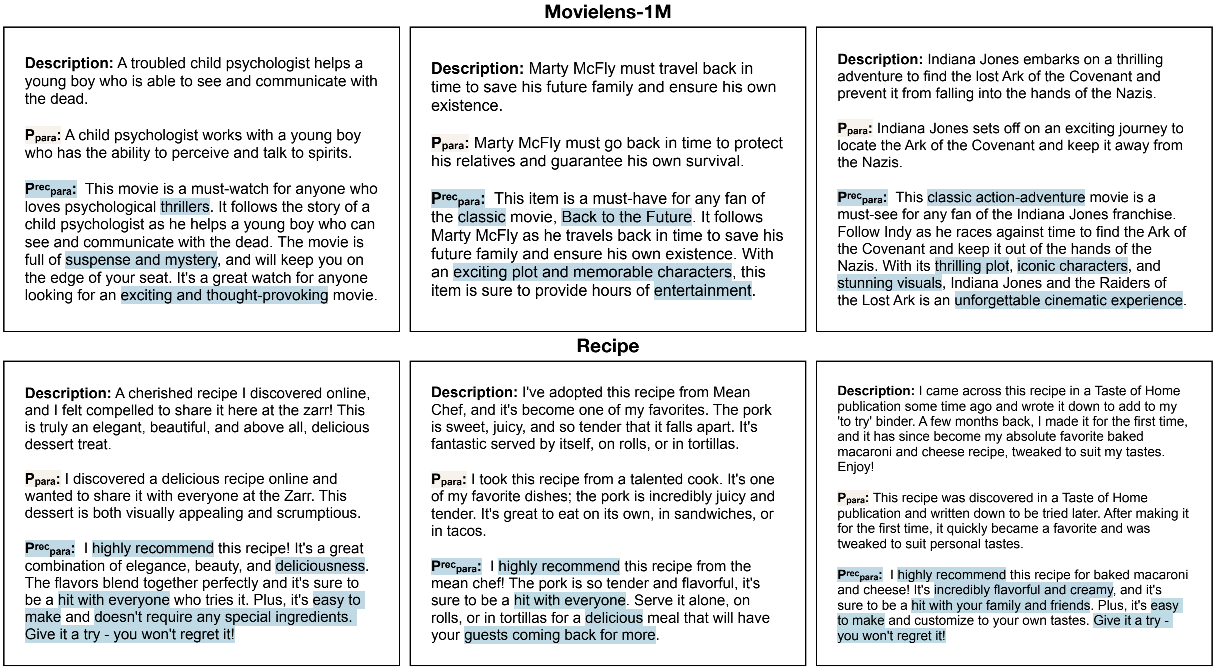
Language Models. Two large language models are selected for experiments. The first is GPT-3 (Brown et al., 2020), particularly its variant `text-davinci-003`. This variant is an advancement over the InstructGPT models (Ouyang et al., 2022). We select this variant due to its ability to consistently generate high-quality writing, effectively handle complex instructions, and demonstrate enhanced proficiency in generating longer form content (Raf, 2023). The second is LLAMA-2 (Touvron et al., 2023b), which is an open-sourced model that has shown superior performance across various external benchmarks in reasoning, coding, proficiency, and knowledge tests. Specifically, we use the LLAMA-2-CHAT variant of 7B parameters.

Evaluation Protocols. We follow the same evaluation methodology of Wei et al. (2019). We randomly divide the dataset into training, validation, and test sets using an 8:1:1 ratio. Negative training samples are created by pairing users and items without any recorded interactions (note that these are pseudo-negative samples). For the validation and test sets, we pair each observed user-item interaction with n items that the user has not previously interacted with. Here we follow the methodology outlined in the previous study (Wei et al., 2019) and set n to $1,000$. It is important to note that there is *no* overlap between the negative samples in the training set and the unobserved user-item pairs in the validation and test sets. This ensures the independence of the evaluation data. We use metrics such as Precision@K, Recall@K and NDCG@K to evaluate the performance of top-K recommendations, where K is set to 10. We report the average scores across five different splits of the testing sets. The recommendation module of LLM-REC is the combination of an MLP model and a dot product.

4.2 Main Results

Integrating the text augmented by LLM-REC boosts recommendation performance. Table 1 shows the average recommendation performance between LLM-REC and baseline approaches across five different splits. In addition to the aforementioned baselines, we include another baseline relies only on item popularity and does not involve any learning process, referred to as Item Popularity. Note that LLM-REC uses the same recommendation module as the MLP baseline. It can be seen that LLM-REC exhibits significant relative gains over the MLP method. For instance, LLM-REC achieves improvements in NDCG@10 from 6.24% to 8.54% in Movielens-1M and from 8.97% to 21.72% in Recipe. These improvements highlight the value of the augmented text in the recommendation process. More importantly, when comparing LLM-REC with the other three content-based methods, we observe that LLM-REC empowers simple MLP models to attain comparable or even superior performance, surpassing other more complex feature-based recommendation methods.

What extra information does LLM-REC incorporate that contributes to its performance improvement? To better understand why LLM-REC is effective, particularly regarding the additional



Movielens-1M

Description: A troubled child psychologist helps a young boy who is able to see and communicate with the dead.

P_{para}: A child psychologist works with a young boy who has the ability to perceive and talk to spirits.

P^{rec}_{para}: This movie is a must-watch for anyone who loves psychological thrillers. It follows the story of a child psychologist as he helps a young boy who can see and communicate with the dead. The movie is full of suspense and mystery, and will keep you on the edge of your seat. It's a great watch for anyone looking for an exciting and thought-provoking movie.

Description: Marty McFly must travel back in time to save his future family and ensure his own existence.

P_{para}: Marty McFly must go back in time to protect his relatives and guarantee his own survival.

P^{rec}_{para}: This item is a must-have for any fan of the classic movie, Back to the Future. It follows Marty McFly as he travels back in time to save his future family and ensure his own existence. With an exciting plot and memorable characters, this item is sure to provide hours of entertainment.

Description: Indiana Jones embarks on a thrilling adventure to find the lost Ark of the Covenant and prevent it from falling into the hands of the Nazis.

P_{para}: Indiana Jones sets off on an exciting journey to locate the Ark of the Covenant and keep it away from the Nazis.

P^{rec}_{para}: This classic action-adventure movie is a must-see for any fan of the Indiana Jones franchise. Follow Indy as he races against time to find the Ark of the Covenant and keep it out of the hands of the Nazis. With its thrilling plot, iconic characters, and stunning visuals, Indiana Jones and the Raiders of the Lost Ark is an unforgettable cinematic experience.

Recipe

Description: A cherished recipe I discovered online, and I felt compelled to share it here at the zarr! This is truly an elegant, beautiful, and above all, delicious dessert treat.

P_{para}: I discovered a delicious recipe online and wanted to share it with everyone at the Zarr. This dessert is both visually appealing and scrumptious.

P^{rec}_{para}: I highly recommend this recipe! It's a great combination of elegance, beauty, and deliciousness. The flavors blend together perfectly and it's sure to be a hit with everyone who tries it. Plus, it's easy to make and doesn't require any special ingredients. Give it a try - you won't regret it!

Description: I've adopted this recipe from Mean Chef, and it's become one of my favorites. The pork is sweet, juicy, and so tender that it falls apart. It's fantastic served by itself, on rolls, or in tortillas.

P_{para}: I took this recipe from a talented cook. It's one of my favorite dishes; the pork is incredibly juicy and tender. It's great to eat on its own, in sandwiches, or in tacos.

P^{rec}_{para}: I highly recommend this recipe from the mean chef! The pork is so tender and flavorful, it's sure to be a hit with everyone. Serve it alone, on rolls, or in tortillas for a delicious meal that will have your guests coming back for more.

Description: I came across this recipe in a Taste of Home publication some time ago and wrote it down to add to my 'to try' binder. A few months back, I made it for the first time, and it has since become my absolute favorite baked macaroni and cheese recipe, tweaked to suit my tastes. Enjoy!

P_{para}: This recipe was discovered in a Taste of Home publication and written down to be tried later. After making it for the first time, it quickly became a favorite and was tweaked to suit personal tastes.

P^{rec}_{para}: I highly recommend this recipe for baked macaroni and cheese! It's incredibly flavorful and creamy, and it's sure to be a hit with your family and friends. Plus, it's easy to make and customize to your own tastes. Give it a try - you won't regret it!

Figure 3: Example responses generated by GPT-3. The additional information augmented via the recommendation-driven prompting is highlighted in blue. Examples generated by LLAMA-2 can be found in Table 13.

information contributed by its prompting approach, we conduct both qualitative and quantitative studies. We find that the augmented content contains more detailed and expressive descriptions, emphasizing item characteristics which helps in understanding items more comprehensively than with their original descriptions and contributing to the performance improvement. Figure 3 shows example responses generated by GPT-3 with p_{para} and p^{rec}_{para}. The first example suggests that the response via p^{rec}_{para} categorizes the movie as a psychological thriller and recommends it as a must-watch for fans of this genre. It also positions the movie as both exciting and thought-provoking, appealing to those looking for more than just entertainment. These distinctive words describe user preferences and item characteristics including genre description, descriptive elements, and viewer recommendation. While Figure 3 might suggest that the LLM-generated text for the Recipe dataset adds only modifiers, these phrases, like "easy to make," actually reflect key characteristics valued in the Recipe dataset, such as simplicity. Some authors may also add #easytomake to their recipe descriptions (Majumder et al., 2019). Consistent patterns are also observed when comparing the responses of p_{tag} with p^{rec}_{tag} (Tables 11 and 14), and p_{infer} with p^{rec}_{infer} (Tables 12 and 15). A more thorough analysis shows that LLM-REC can be applied to diverse item domains and it is not restricted to datasets with rich textual information. Please see Appendix B.2.

We hypothesize that these generated words contribute to improving recommendation performance. To further validate this hypothesis, we design two variants of the response generated by GPT-3, namely p^{mask}_{para} and $p^{keyword}_{para}$. To construct p^{mask}_{para}, we mask the words that appear in the response of p^{rec}_{para} but are absent in the response of p_{para}. To construct $p^{keyword}_{para}$, we append the words that (1) appear in the response of p^{rec}_{para} and (2) are predefined user-preference-related words such as genres to the end of the response of p_{para} (more details in Appendix A.9). These two variants are then fed into MLP models to form baselines. Comparing the performance of p^{rec}_{para} and p^{mask}_{para} in Table 2, we observe a discernible decline in recommendation performance when words unique to the response of p^{rec}_{para} are selectively masked. This outcome highlights the pivotal role played by the supplementary insights introduced through the augmented text. Further, our investigation reveals that the incorporation of vital keywords, as opposed to the inclusion of all response words, can yield even superior recommendation performance. This may be attributed to potential discrepancies or extraneous elements within the response of p^{rec}_{para}.

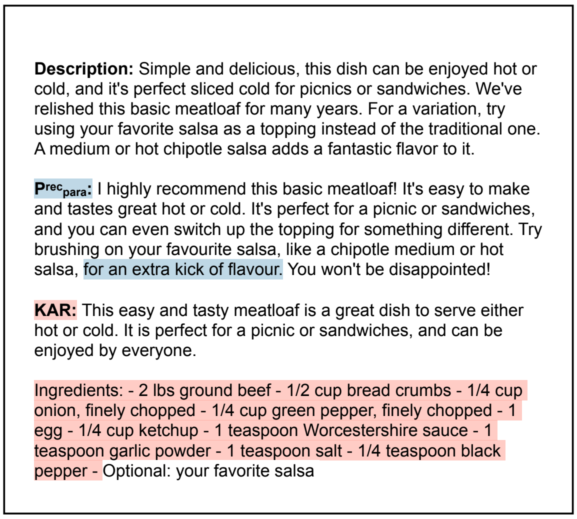
LLM-REC augmentation outperforms other text augmentation methods for recommenda-

	Movielens-1M	**Recipe**
p_{para}	0.3746 ±0.0028	0.0611 ±0.0053
$p_{para}^{keyword}$	0.3822 ±0.0049 (**+2.03%**)	0.0615 ±0.0060 (**+0.65%**)
p_{para}^{rec}	0.3777 ±0.0028	0.0646 ±0.0072
p_{para}^{mask}	0.3769 ±0.0040 (**-0.21%**)	0.0611 ±0.0066 (**-0.52%**)

Table 2: Average NDCG@10 across five splits.

tion. We compare LLM-REC with two recent advancements in the field of using LLMs to augment item information, specifically Knowledge Augmented Recommendation (KAR) as proposed by Xi et al. (2023), and TagGPT, as proposed by Li et al. (2023a). KAR introduces a fusion of domain knowledge and prompt engineering to generate factual knowledge pertaining to the items (for detailed implementation information, see Appendix A.7). Since the augmented information may not necessarily be correct, we further implement a variant with ground truth knowledge. It aligns with strategies akin to those introduced by Di Noia et al. (2012), who harnessed external databases to enhance item information. In a manner consistent with this approach, we incorporate genre information into the item descriptions. Note that genre constitutes one of the metadata components in Movielens-1M. Such categorical characteristics are absent in Recipe. Therefore, we only apply this variant to the Movielens-1M dataset.

As shown in Table 1, the incorporation of knowledge-based text augmentation offers significant improvements in recommendation performance for well-classified items, such as movies. However, it becomes evident that this approach faces limitations when applied to items, like user-generated content, that are inherently more novel and dynamic in nature. The example response in Figure 4 shows that one key reason that knowledge augmentation approaches do not yield optimal improvement regarding recommendation performance may lie in the potential **mismatch** between the generated knowledge and the target item. For instance, while the generated ingredient information may be correct for most meatloaf recipes, it could be entirely wrong for a specific recipe without additional context. In contrast to these knowledge augmentation methods, LLM-REC's recommendation-driven prompts provide augmented information that describes the target item at a broader, less granular level, especially when compared to KAR. More importantly, LLM-REC does not require domain knowledge throughout the entire process.



Description: Simple and delicious, this dish can be enjoyed hot or cold, and it's perfect sliced cold for picnics or sandwiches. We've relished this basic meatloaf for many years. For a variation, try using your favorite salsa as a topping instead of the traditional one. A medium or hot chipotle salsa adds a fantastic flavor to it.

P^{rec}_{para}: I highly recommend this basic meatloaf! It's easy to make and tastes great hot or cold. It's perfect for a picnic or sandwiches, and you can even switch up the topping for something different. Try brushing on your favourite salsa, like a chipotle medium or hot salsa, for an extra kick of flavour. You won't be disappointed!

KAR: This easy and tasty meatloaf is a great dish to serve either hot or cold. It is perfect for a picnic or sandwiches, and can be enjoyed by everyone.

Ingredients: - 2 lbs ground beef - 1/2 cup bread crumbs - 1/4 cup onion, finely chopped - 1/4 cup green pepper, finely chopped - 1 egg - 1/4 cup ketchup - 1 teaspoon Worcestershire sauce - 1 teaspoon garlic powder - 1 teaspoon salt - 1/4 teaspoon black pepper - Optional: your favorite salsa

Figure 4: An example response generated using knowledge augmentation prompts (Xi et al., 2023). The additional information is highlighted in red.

In terms of the second text augmentation baseline, TagGPT (Li et al., 2023a), which extracts tags using LLMs, several key observations can be made. First, we note an improvement in recommendation performance using tag generation compared to the baseline methods. Second, the prompts specifically designed within our LLM-REC framework demonstrate superior effectiveness compared to those used in TagGPT.

4.3 Ablation Study

How does each prompting strategy perform? We conduct an ablation study to examine the impact on recommendation performance when models use either original item descriptions alone or a combination of these descriptions with augmented text derived from one of four distinct prompting strategies. The results, presented in Table 3, reveal a noteworthy and consistent enhancement in recommendation performance across various prompting strategies within two benchmark datasets.

We also note variations in the performance of these strategies across different domains, aligning with our expectations. In Movielens-1M, the strategy combining recommendation-driven and engagement-guided approaches yields the best results. Conversely, in Recipe, the recommendation-driven strategy alone proves most effective. This variability suggests that combining multiple objectives in a single prompting strategy does not

	Movielens-1M	Recipe
Item Description	0.3640 ±0.0039	0.0580 ±0.0054
Basic	0.3747 ±0.0042 (**+2.94%**)	0.0644 ±0.0068 (**+11.03%**)
Rec	0.3786 ±0.0041 (**+4.01%**)	**0.0649** ±0.0069 (**+11.90%**)
Eng	0.3801 ±0.0032 (**+4.42%**)	0.0628 ±0.0077 (**+8.28%**)
Rec+Eng	**0.3802** ±0.0037 (**+4.45%**)	0.0625 ±0.0060 (**+7.76%**)

Table 3: Average NDCG@10 across five different splits among different prompting strategies.

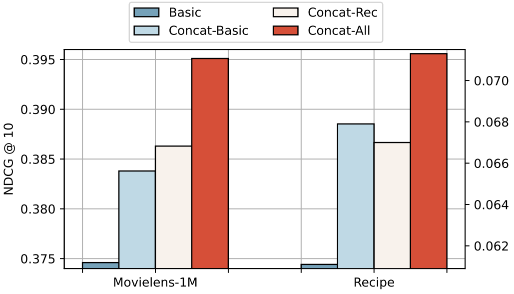


Figure 5: The ablation study shows that recommendation benefits from concatenating the embeddings of the input text augmented by LLM.

	Movielens-1M	Recipe
Item Description	0.3640 ±0.0039	0.0580 ±0.0054
Duplication	0.3567 ±0.0043	0.0590 ±0.0068
Text Concatenation	0.3853 ±0.0027	0.0591 ±0.0065
`Concat-All` (ours)	**0.3951** ±0.0035	**0.0706** ±0.0084

Table 4: Average NDCG@10 across five splits among different methods of extra information integration.

always lead to superior performance. When LLMs are tasked with generating descriptions serving multiple purposes, the balance of information becomes crucial. If neighboring item descriptions vary widely, it can challenge the model's ability to generate useful content, potentially leading to less optimal improvements. To address this, LLM-Rec integrates all enriched text and leverages the subsequent recommendation module to effectively model the extra information. Future work can investigate different prompt designs, aiming to effectively achieve multiple objectives simultaneously.

How does concatenating the augmented responses affect recommendation? In Table 1, we show that the MLP model, which combines all augmented text with the original description, outperforms more advanced models that rely solely on the original description as input. Now we take a deeper look at the quality of the combined augmented text. We employ the same recommendation module (*i.e.*, an MLP with a dot product) and evaluate the recommendation performance of various concatenation combinations. As shown in Figure 5, the model denoted as `Basic` uses the embeddings of text augmented through p_{para}. `Concat-Basic` represents the model that concatenates the embeddings of the input text augmented by all basic prompts. Additionally, `Concat-Rec` is the model that employs the concatenation of the embeddings of input text augmented by all recommendation-driven prompts. Lastly, `Concat-All` stands for the model that combines the embeddings of input text augmented by all four prompting strategies. Our findings reveal that concatenating more information *consistently* enhances recommendation performance. This emphasizes the added value of incorporating augmented text as opposed to relying solely on the original content description. Complete results of Figure 5 can be found in Figure 8.

How to effectively integrate the augmented responses to maximize improvement? Table 4 shows the recommendation performances of other concatenation variants: (1) **Duplication**: We duplicate the embeddings of the original item description to match the dimension size of the embeddings of `Concat-All`; (2) **Text concatenation**: Instead of concatenating the embeddings of all response (*i.e.*, `Concat-All`), we concatenate the responses first, and then convert it to embeddings. Through a comparative analysis of the model's performance, contrasting the first variant with `Concat-All`, it becomes evident that the observed improvement in performance is not attributable to changes in embedding size. Further, by comparing the performance of the second variant against `Concat-All`, we discover that in scenarios where the text encoder remains unmodified, the most effective strategy to integrate all enriched information is by first converting the text into embeddings and then concatenating these embeddings. This approach surpasses the method of concatenating text prior to its conversion into embeddings. Future research can explore the potential of modifying the text encoder to further enhance model efficiency and effectiveness.

Does modifying the word choice in the designed prompts significantly affect the augmented output? To investigate this, we construct one variant prompt for each of LLM-Rec's prompts, ensuring

Prompting Strategy		Variant
Basic	p_{para}	0.8859 ±0.0898
	p_{tag}	0.9112 ±0.1000
	p_{infer}	0.6819 ±0.1500
Rec	p^{rec}_{para}	0.7011 ±0.1369
	p^{rec}_{tag}	0.8627 ±0.1248
	p^{rec}_{infer}	0.8458 ±0.0652
Eng	p^{eng}	0.6218 ±0.1012
Rec+Eng	$p^{rec+eng}$	0.8542 ±0.0802

Table 5: Average cosine similarity between the variant prompt responses and those generated from LLM-REC.

they convey the same meaning but with different word choices. As shown in Table 5, despite variations in wording of the prompts, the responses remain largely similar. The observed lower cosine similarity is primarily attributed to differences in the format of the responses which can be mitigated through various strategies, such as additional fine-tuning of the model or incorporating specific instructions within the prompts.

5 Discussions and Conclusions

In this study, we have investigated the effectiveness of LLM-REC as a simple yet impactful mechanism for improving recommendation through LLMs. Our approach is among those early attempts (Lin et al., 2023; Chen et al., 2023) that leverage LLMs for text augmentation in recommendation. There are three key contributions that distinguish our work from the concurrent ones. First, while previous work, such as KAR (Xi et al., 2023), focuses on design augmentation algorithm for a specific recommendation model, our model focuses on input text augmentation with LLMs, which is suitable for any content-based backbone recommendation models, demonstrating the flexibility of our approach. Second, in addition to our recommendation-driven augmentation using LLMs, we also design engagement-guided prompts to augment the input, which contains more personalized item characteristics. Overall, we conduct comprehensive experiments, with different combinations of prompting strategies, to not only illustrate the superior performance of our approach but also uncover the underlying rationale of the improvements.

We introduce LLM-REC, which enhances recommendation by augmenting the original item descriptions which often contains incomplete information for effective recommendations using large language models. We observed from extensive experiments that combining augmented input text and original item descriptions yields notable improvements in recommendation quality. These findings show the potential of using LLMs and strategic prompting techniques to enhance the accuracy and relevance of recommendation with an easier training process. By incorporating additional context, we enable the recommendation algorithms to capture more nuanced information and generate recommendations that better align with user preferences.

Limitations

In this study, we have investigated the effectiveness of LLM-REC as a simple yet effective mechanism for improving recommendation through large language models. While effective, LLM-REC does have its limitations. First, there is extra computational cost associated with LLM-REC framework. The primary computational load comes from the augmentation phase including the augmented output text length. Our findings indicate that selecting important words for inclusion, rather than incorporating all response words, can lead to improved recommendation performance, as evidenced in Table 2. Our future work will explore the balance between the number of words generated and the resulting performance enhancements. Second, similar to many LLM-based studies, LLM-REC faces challenges in promptly incorporating the latest knowledge. We plan to investigate methods in future work for LLMs to autonomously gather and summarize current knowledge from external sources, thereby improving text augmentation effectiveness.

A Additional Details of Experiment Setup

A.1 Datasets

Dataset	# Interaction	# Item	# User
MovieLens-1M	1,000,209	3,706	6,040
Recipe	132,246	4,125	2,589

Table 6: Benchmark Statistics.

MovieLens-1M (Harper and Konstan, 2015) is a highly recognized benchmark dataset commonly used for evaluating item recommendation systems.[1] It contains a vast collection of 1,000,209 ratings provided by 6,040 MovieLens users, covering 3,900 movies. Each user has at least 20 ratings. Following He et al. (2017), we convert the rating data into implicit feedback. More specifically, each entry is marked as 0 or 1 indicating whether the user has rated the corresponding item. The original movie data only contain movie titles and genres. We employ GPT-3 (`text-davinci-003`) to generate the content description of each movie using the following prompt: *"Summarize the movie* `{title}` *with one sentence. The answer cannot include the movie title."* The response from GPT-3 is used as the item description. `Temperature` is set at 0 to generate more focused and deterministic responses. Note that inclusion of the movie title is entirely *optional*. We opt not to include the title intentionally, as our design for LLM-REC emphasizes its role as a general prompting framework. This versatility is important, as it is intended to function across a wide array of item types, including those that may not possess pre-defined titles, such as short videos.

Recipe (Majumder et al., 2019) is another benchmark dataset we use to assess the recommendation performance. This dataset consists of recipe details and reviews sourced from `Food.com`.[2] The metadata includes ratings, reviews, recipe names, descriptions, ingredients, directions, and so on. For instance, an example recipe description is *"All the delicious flavors of mac n' cheese transformed into a warm, comforting bowl of soup!"*. In our evaluation, we employ the recipe descriptions as item descriptions for the four prompting strategies. Similar to the MovieLens-1M dataset, we apply filtering criteria, excluding users with fewer than 20 ratings and items with fewer than 30 ratings. Note that all original descriptions presented as examples in this paper have been paraphrased to protect user privacy.

The selection of these benchmarks is mainly motivated by two factors. First, we select movies and recipes as they represent two distinct types of content. Movies, being more categorically organized and widely researched, contrast sharply with recipes, which are diverse, user-generated content from social media platforms, often lacking a strict categorical structure and presenting more novelty. Second, the nature of their descriptions differs significantly: movie descriptions typically comprise narrative summaries, whereas recipe descriptions are instructional. Evaluating our model on these varied datasets allows for a comprehensive analysis of how different prompting strategies affect recommendation outcomes, providing valuable insights into their effectiveness across diverse content types.

A.2 Baselines

To assess LLM-REC's efficacy, we compare it against two distinct categories of baselines. The first category includes baselines that takes solely the original item descriptions as input. This includes models from MLP to more complex content-based approaches. Specifically, we choose three more advanced, content-based recommendation models. AutoInt is a multi-head self-attentive neural network with residual connections designed to explicitly model feature interactions within a low-dimensional space (Song et al., 2019). DCN-V2 represents an enhanced version of DCN and incorporates feature crossing at each layer (Wang et al., 2021, 2017). Lastly, EDCN (Chen et al., 2021) introduces a bridge module and a regulation module to collaboratively capture layer-wise interactive signals and learn discriminative feature distributions for each hidden layer in parallel networks, such as DCN. The purpose of this comparison is to evaluate the added value of augmented text in improving recommendation outcomes.

The second category includes different text augmentation methodologies. Here, LLM-REC is evaluated against two recent advancements in the field of using LLMs to augment item information. The first method is Knowledge Augmented Recommendation (KAR) as proposed by Xi et al. (2023). KAR introduces a fusion of domain knowledge and prompt engineering to generate factual knowledge pertaining to the items (for implementation details, see Appendix A.8) In contrast to KAR's approach,

---

[1] License: `https://files.grouplens.org/datasets/movielens/ml-1m-README.txt`

[2] License: `https://www.kaggle.com/datasets/shuyangli94/food-com-recipes-and-user-interactions`

LLM-REC places a particular emphasis on the innate common-sense reasoning capabilities of large language models and notably does not mandate domain expertise. Since the augmented information may not necessarily be correct, we further implement a variant with ground truth knowledge. It aligns with strategies akin to those introduced by Di Noia et al. (2012), who harnessed external databases to enhance item information. The second method, TagGPT, proposed by Li et al. (2023a), extracts tags using LLMs, similar to one of our prompting strategies for item descriptions.

Although collaborative Filtering (CF) is another widely used technique in recommendation systems, given our primary focus on addressing the issue of incomplete item descriptions, we do not conduct experiments under CF settings (Li et al., 2023b). Instead, we concentrate on comparing our method with other input augmentation approaches.

A.3 Item and User Modules

We use Sentence-BERT (Reimers and Gurevych, 2019) to derive the textual embeddings from the original item description and augmented text. The embedding model is `all-MiniLM-L6-v2`. We directly apply it to convert the natural language to embeddings without fine-tuning it, freezing only the text-encoder and not the user encoder to avoid the additional computational cost associated with training and fine-tuning the sentence transformer model. For users, we employ an embedding table to convert user ID into latent representations. For both MovieLens-1M and Recipe datasets, the output dimension is set at 128. We have considered using embeddings derived from the LLMs. However, as our goal is to propose a general framework that can leverage both open-source and proprietary models, we do not pursue further exploration of this aspect in the current study.

A.4 Model Training

To facilitate the model training process, we employ the binary cross-entropy loss, expressed as:

$$L = -\sum_{(u,i)\in Y} [y_{u,i} \cdot \log \hat{y}_{u,i} + (1 - y_{u,i}) \cdot \log(1 - \hat{y}_{u,i})] \quad (1)$$

where (u, i) represents the user-item pair, and Y denotes the set that contains all positive and negative samples. The variable $y_{u,i}$ serves as a label, with a value of 1 indicating that user u has engaged with item i, and 0 representing the absence of interaction. The prediction score $\hat{y}_{u,i}$, ranging from 0 to 1, reflects the likelihood of user u interacting with item i. In our dataset, each instance of user-item interaction is considered a positive sample. Alongside these positive samples, we incorporate negative samples by randomly pairing users with items that lack any prior recorded interactions. To mitigate the risk of overfitting and enhance training efficiency, we implement an early stopping mechanism. The window size and evaluation frequency are both configured to be 5. It is noteworthy that we have also explored the viability of employing the Bayesian Personalized Ranking (BPR) Loss (Rendle et al., 2012) within our framework. However, subsequent experimentation reveals that the BPR Loss does not offer superior performance when compared to the binary cross-entropy loss. Consequently, we opt to use the binary cross-entropy loss as our loss function.

A.5 Hyper-parameter Settings

Large Language Models. We perform experiments with two large language models. For GPT-3 (`text-davinci-003`), `temperature`, `max_token`, `top_p`, `frequency penalty`, and `presence penalty` are set as 0, 512, 1, 0.0, and 0.6, respectively. For LLAMA-2 (7B LLAMA-2-CHAT), we set `do_sample` to be `True`, `top_k` 10, and the `num_return_sequences` 1. LLAMA-2's generation is conducted on 8 NVIDIA GeForce RTX 2080 Ti GPUs, each equipped with 11 GB of memory.

Recommendation Modules We initialize the model parameters randomly, following a Gaussian distribution. To optimize the framework, we employ the AdamW algorithm (Loshchilov and Hutter, 2017) with a weight decay value of 0.0005. For the MLP model, the hyper-parameter grids for the learning rate and dropout rate are $\{0.0001, 0.0005, 0.001\}$ and $\{0.1, 0.3, 0.5\}$, respectively. For AutoInt (Song et al., 2019), the hyper-parameter grids for the learning rate, dropout rate, hidden layer size, number of attention layers, and attention heads are $\{0.001, 0.005, 0.01\}$, $\{0.1, 0.3, 0.5\}$, $\{16, 32, 64, 128\}$, $\{1, 2\}$, and $\{1, 2\}$, respectively. For DCN-V2 (Wang et al., 2021), the learning rate, dropout rate, hidden layer size, and number of cross layers are searched in $\{0.001, 0.005, 0.01\}$, $\{0.1, 0.3, 0.5\}$, $\{16, 32, 64, 128\}$, $\{1, 2\}$, and $\{1, 2\}$, respectively. Since the network structure of EDCN (Chen et al., 2021) is similar with DCN-V2 (Wang et al., 2021), we apply the hyper-parameter settings of DCN-V2 to EDCN. The performance is evaluated every five epochs, and the early stop mechanism is configured to have a patience of 5. We set the batch size to 4096 for all baselines except for AutoInt which is 1024 due to the memory limitation. Settings that achieve the highest Recall@K on the validation set are chosen for the evaluation on the testing set.

A.6 Importance Measurement for Engagement-guided Prompting

In our study, we show an example of using Personalized PageRank (PPR) (Brin, 1998) score as the metric to find the important neighbor items. PPR is a widely employed technique for finding significant neighbors in recommendation systems (Ying et al., 2018). In particular, we first construct the user-item bipartite graph $G = (V, E)$. In this notation, G represents the bipartite graph, E denotes the set of nodes, and E represents the set of edges. There are two types of nodes including users $V_{user} \subset V$ and items $V_{item} \subset V$ ($V_{user} \cup V_{item} = V, V_{user} \cap V_{item} = \varnothing$). An edge $e \in E$ between a user node $v \in V_{user}$ and an item node $i \in V_{item}$ is created if this user interacts with this item.

Next, we proceed by calculating the Personalized PageRank (PPR) score for each item node. The PPR value $\pi(s, t)$, where s is the source node and t is the target node, signifies the probability that a random walk initiated from node s concludes at node t. This value offers a quantified measure of their relative importance from the standpoint of an individual node (Lofgren, 2015). For every item node, we construct a set of significant neighboring items. By identifying the top T item nodes with the highest PPR scores, we pinpoint important neighbor items guided by user engagement. The rationale behind this approach lies in the observation that when users frequently engage with two items, there tends to be a greater similarity between these two items through the lens of user preferences. By incorporating this information, we aim to capture user preferences more effectively, leading to enhanced performance in content recommendation. For both datasets, we set $T = 3$. For the Movielens-1M dataset, we find the important neighbor items that share the same genre as the target item.

A.7 Implementation Details

Our methods are implemented and experiments are conducted using PyTorch. The computation of PPR scores is facilitated by the use of the `torch-ppr` library. Each experiment is run on one NVIDIA A100 GPU with 80 GB of memory at a time. Further, we adapt the codes of the DeepCTR[3] and DeepCTR-Torch[4] repositories to implement AutoInt (Song et al., 2019), DCN-V2 (Wang et al., 2021), and EDCN (Chen et al., 2021). Table 7 summarizes all prompts of LLM-REC.

A.8 KAR Augmentation Details

In KAR, Xi et al. (2023) applied a specific prompt to elicit factual knowledge about movies of the Movielens-1M dataset (Harper and Konstan, 2015). The prompt instructed the model to: *"Introduce movie* `{item description}` *and describe its attributes precisely (including but not limited to* `scenario-specific factors`*)"*. In their study, the `item description` was the movie titles. Human experts were enlisted to refine the answers generated by LLMs in response to the question: *"List the importance factors or features that determine whether a user will be interested in a movie."* These refined factors were then considered as the `{scenario-specific factors}`, including *genre, actors, directors, theme, mood, production quality, and critical acclaim*. Because the responses generated using these prompts were not publicly released, we re-implement the same methodology, employing LLMs to generate the factual knowledge of items. In the case of the Recipe dataset (Majumder et al., 2019), we use recipe description as the `item description`. The same approach is then adopted to identify `scenario-specific factors`. Initially, the prompt is adapted to: *"List the importance factors or features that determine whether a user will be interested in a recipe."* Subsequently, the answers generated by CHATGPT are validated (see Table 8). The resulting set of `scenario-specific factors` for Recipe comprises a diverse range of attributes, including *dietary preferences, ingredients, cuisine type, cooking time, nutritional value, allergies, taste preferences, skill level, occasion, cost, health and wellness goals, food allure, reviews and ratings, cooking equipment, personal experience, season and weather, cultural or ethical considerations, creativity and variety, simplicity, popularity and trends*. These prompts are then employed to enrich the factual knowledge of both movies and recipes using GPT-3 (`text-davinci-003`). For illustrative examples of the responses, please refer to Table 9.

---

[4] `https://github.com/shenweichen/DeepCTR-Torch`

p_{para}	*"The description of an item is as follows* '`{description}`', *paraphrase it."*
p_{tag}	*"The description of an item is as follows* '`{description}`', *summarize it with tags."*
p_{infer}	*"The description of an item is as follows* '`{description}`', *what kind of emotions can it evoke?"*
p^{rec}_{para}	*"The description of an item is as follows* '`{description}`', *what else should I say if I want to recommend it to others?"*
p^{rec}_{tag}	*"The description of an item is as follows* '`{description}`', *what tags should I use if I want to recommend it to others?"*
p^{rec}_{infer}	*"The description of an item is as follows* '`{description}`', *recommend it to others with a focus on the emotions it can evoke."*
p^{eng}	*"Summarize the commonalities among the following descriptions:* '`{description}`'; '`{descriptions of other important neighbors}`'."
$p^{rec+eng}$	*"The description of an item is as follows:* '`{description}`'. *What else should I say if I want to recommend it to others?* *This content is considered to hold some similar attractive characteristics as the following descriptions:* '`{descriptions of other important neighbors}`'."

Table 7: LLM-REC prompts.

KAR is also composed of a preference reasoning prompt for user information augmentation. Since we only focus on the item side, only the item factual prompt is implemented to examine how different focuses on LLMs' ability between LLM-REC and KAR affect recommendation performance.

A.9 Keywords Construction

The keyword generation process differs between the Movielens-1M and Recipe datasets. For Movielens-1M, the keywords are derived from genre labels, which are intrinsic components of the dataset's metadata. In the case of Recipe, the process involves multiple steps. Initially, we compile a list of unique words found in the responses generated through the recommendation-driven prompting strategy. Subsequently, we filter out stopwords and proceed to construct unigrams and bigrams using the `NLTK` package. Following this, a manual review is conducted to identify phrases that appear at least five times in the corpus. These phrases are then scrutinized to determine whether they contain words relevant for categorizing recipes. The final list of keywords for Recipe contain "easy", "homemade", "baking", "health", "healthy", "dessert", and "dinner". These keywords collectively serve as indicative descriptors for recipes within the dataset.

The factors or features that determine whether a user will be interested in a recipe can vary from person to person, but some important factors commonly include:
1. Dietary Preferences: Whether the recipe aligns with the user's dietary restrictions, such as vegetarian, vegan, gluten-free, or keto.
2. Ingredients: The availability and appeal of the ingredients used in the recipe.
3. Cuisine Type: Whether the recipe falls within a cuisine the user enjoys, like Italian, Mexican, or Asian.
4. Cooking Time: The user's available time for cooking, as some may prefer quick and easy recipes, while others enjoy longer cooking processes.
5. Nutritional Value: Users may consider the nutritional content of the recipe, such as calorie count, protein, or fiber.
6. Allergies: Any known food allergies that need to be accommodated in the recipe.
7. Taste Preferences: Whether the flavors and taste profile of the recipe match the user's preferences.
8. Skill Level: Some users may look for recipes that match their cooking skills, such as beginner-friendly or gourmet.
9. Occasion: If the recipe is suitable for a particular occasion, like a holiday, party, or a regular weekday meal.
10. Cost: The affordability of the ingredients and whether it fits within the user's budget.
11. Health and Wellness Goals: Recipes that align with specific health or weight management goals, like low-carb or heart-healthy.
12. Food Allure: The visual appeal and presentation of the dish through images and descriptions.
13. Reviews and Ratings: User reviews and ratings on the recipe, which can indicate its popularity and quality.
14. Cooking Equipment: Whether the user has the necessary kitchen tools and appliances for the recipe.
15. Personal Experience: Previous experiences with similar recipes or dishes may influence interest.
16. Season and Weather: Seasonal ingredients or dishes that match the current season or weather.
17. Cultural or Ethical Considerations: Recipes that respect cultural, ethical, or environmental values.
18. Creativity and Variety: The desire for trying something new and innovative in cooking.
19. Simplicity: Some users may prefer straightforward, minimal-ingredient recipes.
20. Popularity and Trends: Trending recipes or those recommended by friends and family may pique a user's interest.
These factors can significantly impact a user's decision to explore a recipe, and personalized recommendation systems often consider several of these factors to suggest recipes tailored to individual preferences.

Table 8: Response generated by CHATGPT about the question *"List the importance factors or features that determine whether a user will be interested in a recipe."*

Prompt: Introduce movie Batman Forever and describe its attributes precisely (including but not limited to genre, actors, directors, theme, mood, production quality, and critical acclaim)
Response: Batman Forever is a 1995 American superhero film directed by Joel Schumacher and produced by Tim Burton. It is the third installment in the Batman film series, based on the DC Comics character of the same name. The film stars Val Kilmer as Bruce Wayne/Batman, alongside Tommy Lee Jones, Jim Carrey, Nicole Kidman, Chris O'Donnell, Michael Gough, and Pat Hingle. The film follows Batman as he battles Two-Face and The Riddler, both of whom are determined to wreak havoc in Gotham City. The film's theme is the struggle between good and evil, and the power of redemption. The mood of the film is dark and brooding, with a hint of humor. The production quality of Batman Forever is high, with impressive special effects and cinematography. The film was well-received by critics, who praised its action sequences, performances, and visual style. It was a box office success, grossing over $336 million worldwide.

Prompt: Introduce recipe 'Numerous Amish bread recipes have been shared, but none seem to include the starter. Therefore, I thought it would be helpful to provide this. Happy baking! Here's the Amish Friendship Bread and its starter.' and describe its attributes precisely (including but not limited to dietary preferences, ingredients, cuisine type, cooking time, nutritional value, allergies, taste preferences, skill level, occasion, cost, health and wellness goals, food allure, reviews and ratings, cooking equipment, personal experience, season and weather, cultural or ethical considerations, creativity and variety, simplicity, popularity and trends)
Response: Amish Friendship Bread is a sweet, yeasty bread that is made with a starter that is passed from person to person. It is a traditional Amish recipe that has been around for generations.
Dietary Preferences: Vegetarian, Gluten-Free (if using gluten-free flour)
Ingredients: All-purpose flour, sugar, active dry yeast, milk, butter, eggs, vanilla extract, cinnamon, and salt.
Cuisine Type: American
Cooking Time: 10 minutes to prepare the starter, 1 hour to prepare the dough, and 1 hour to bake the bread.Nutritional Value: High in carbohydrates, low in fat and protein.
Allergies: Contains dairy, eggs, and wheat.
Taste Preferences: Sweet, yeasty, and slightly spiced.
Skill Level: BeginnerOccasion: Breakfast, brunch, or snack.
Cost: Low
Health and Wellness Goals: A healthier alternative to store-bought breads.
Food Allure: Comfort food that is easy to make.
Reviews and Ratings: Generally positive reviews.
Cooking Equipment: Large bowl, measuring cups and spoons, wooden spoon, loaf pan, and oven.
Personal Experience: Delicious and easy to make.
Season and Weather: Can be made year-round.
Cultural or Ethical Considerations: Traditional Amish recipe.
Creativity and Variety: Can be adapted to include different flavors and ingredients.
Simplicity: Easy to make with basic ingredients.
Popularity and Trends: Popular among home bakers.

Table 9: Response generated via the item factual prompt proposed by Xi et al. (2023).

B Additional Analysis

B.1 Additional Discussions on Augmented Text

Overall, we observe that LLM-REC effectively elicits LLMs to enrich item descriptions with additional information. This augmentation results in descriptions that are not only more detailed but also more expressive, enhancing the original item descriptions. Tables 11 and 12 show example responses generated by GPT-3 comparing the recommendation-driven and basic promptings in terms of `tag` and `infer`. Tables 13, 14, and 15 show example responses generated by LLAMA-2 comparing the recommendation-driven and basic promptings. Responses from the recommendation prompting strategies provides several additional pieces of information and context compared to the responses from the basic prompting strategies. Take the responses in Table 11 as an example, the recommendation prompting strategy introduces new themes like "Supernatural", "Paranormal", and "Psychological Thriller", which are not present in the responses from the basic promptings. These themes suggest a broader and more specific context for the story, indicating not just communication with the dead, but also elements of horror and suspense. The term "Troubled Child" adds a new dimension to the "Young Boy" mentioned in the first sentence, suggesting that the child's character may face internal conflicts or challenges.

What extra information does engagement-guided strategy prompt LLMs to augment? Consistent with our previous experiments, we curate exemplary responses obtained from p^{eng} for closer examination (Figure 6). Our analysis reveals a distinct pattern compared to what we have observed with recommendation-driven prompting. There are primarily two scenarios to consider. First, if the descriptions of the important neighbor items and the target items exhibit high similarity, the impact of p^{eng} resembles that of p_{para}, as exemplified in the second Recipe example in Figure 6. Second, p^{eng} guides LLMs to generate additional information, which may be derived from the descriptions of the important neighbor items. Consequently, how the engagement-guided strategy influences LLMs' text generation—whether it aligns with one of the behaviors we have described, both of them, or even other unexplored patterns—largely depends on the composition of the important neighbor items. This composition, in turn, is contingent on the neighbor sampling method which is out of the scope of our study. We leave a more in-depth exploration of this topic to future research endeavors.

Interestingly, the recommendation-driven + engagement-guided prompting strategy is able to generate text that shares similar characteristics with both sub-strategies. How they quantitatively form the final generation remains an open question. Examples can be found in Table 17.

Table 16 shows example responses of LLAMA-2 to the engagement-guided prompting strategy. Table 17 shows example responses of GPT-3 to the recommendation-driven and engagement-guided prompting strategy. Overall, the 7B LLAMA-2-CHAT performs poorly compared to GPT-3. In some cases, there is no generated content as we have also observed in Appendix D.

B.2 Additional Discussions on Applicable Item Domains and Available Textual Information

The applicability of LLM-REC beyond movies and recipes, particularly in domains with sparse textual information, remains a question. To address this, we conduct an analysis to determine LLM-REC's efficacy in enriching text across various domains and text lengths. We use item descriptions from ten distinct domains in the Amazon review dataset (Ni et al., 2019), which includes product metadata like descriptions, category, price, brand, and image features. The selected domains are all beauty, appliances, automotive, digital music, grocery and gourmet food, pet supplies, sports and outdoors, video games, magazine subscriptions, and industrial and scientific. For each domain, we sample 50 items and prompt GPT-3 using p^{rec}_{para} (*i.e.*, recommendation-driven prompting).

Our previous discussions highlight that the most valuable information for improving recommendation performance typically aligns with expressive words pertinent to item characteristics. While no single metric directly quantifies this added information, we use the increase in the number of adjectives as a proxy. Additionally, the total word count serves as a straightforward metric to approximate the volume of augmented information. By comparing the augmented texts with the original item descriptions, we calculate the percentage increase in the number of adjectives. Note that the adjective increase is computed as a ratio of the difference in adjective count to the original word count.

As Figure 1 demonstrates, LLM-REC effectively enriches item descriptions across multiple domains, including those lacking in rich textual content. For instance, the average word counts in movie and digital music descriptions are only 20.34 and 30.18 words, respectively. LLM-REC enhances expressiveness, with a notable increase in the use of adjectives.

B.3 Additional Experiments on Applying LLM-Rec to Other Baselines

We extend the application of LLM-REC to other text-based recommendation systems and replicate the experiments. The results, as presented in Table 10, indicate that LLM-REC can be easily adapted to various text-based recommendation systems and generally enhances recommendation performance compared to using the original text.

B.4 Additional Discussions on Integration Process

In our setup, the text encoder is frozen (not fine-tuned), with a fixed output dimension for all vectors. The fundamental difference between the `Concat-All` and Text Concatenation methods lies in their processing sequence. The `Concat-All` method initially transforms individual text segments into embeddings and subsequently concatenates these embeddings. In contrast, the Text Concatenation method first concatenates the text segments and then converts this combined text into a single embedding.

The observed superiority of the `Concat-All` method can be attributed to how these processes handle information density. When lengthy text segments are concatenated before encoding, there is a higher likelihood of **information loss**, particularly given the constraints of a frozen text encoder. This encoder, **not** being fine-tuned for the specific nuances of our data, may struggle to effectively capture and retain crucial information from longer text inputs. Therefore, processing shorter text segments individually before concatenation (as in `Concat-All`) may help in preserving important features and nuances in the embeddings.

B.5 Additional Discussions on Prompt Design

To investigate whether modifying the word choice in the designed prompts significantly affects the augmented output, we construct one variant prompt for each of LLM-REC's prompts, ensuring they convey the same meaning but with different word choices. Take p_{para} as an example, p_{para} is *"The description of an item is as follows '{*`description`*}', paraphrase it."*. One variant is *"Summarize the given item description, '{*`description`*}', using different words."* Next, we randomly sample 50 items from Movielens-1M, and prompt GPT-3 with these variants. The cosine similarity between the responses generated from the variant prompt and LLM-REC's prompt is computed and shown in Table 5. Tables 18-25 shows the example responses.

B.6 Additional Discussions on Dynamic Prompts

The concept of dynamic prompts in recommendation systems is an intriguing area that holds the potential for enhancing personalization. By incorporating descriptions of a user's most recently interacted items into prompts, the system can generate item descriptions on-the-fly that are more closely aligned with the user's current interests and preferences. This approach could lead to more precise and tailored recommendations, as the generated descriptions would reflect the user's evolving tastes.

One of the primary considerations is the computational cost associated with generating dynamic prompts. Each user interaction would require real-time processing to update the prompt, which could be resource-intensive, especially for large-scale systems with many users and items.

To mitigate computational costs, several strategies can be employed. Developing efficient algorithms for prompt generation and item description generation can help mitigate computational costs. Implementing caching mechanisms for frequently accessed data can reduce the processing time required for updating prompts. Instead of completely regenerating prompts after each interaction, the system could employ incremental updates to modify prompts based on recent changes in user behavior.

While the implementation of dynamic prompts presents several challenges, it also offers a promising avenue for enhancing personalization in recommendation systems. With careful consideration, this approach has the potential to cater more effectively to individual user needs.

C Extended Related Work

Augmentation in Text-based Recommendation. Traditionally, researchers have advocated the augmentation of item descriptions through the incorporation of external knowledge sources (Di Noia et al.,

Table 10: Average recommendation performance by applying LLM-REC to other text-based recommendation modules across five different train/test splits.

2012; Musto et al., 2018; Sachdeva and McAuley, 2020). Notably, Di Noia et al. (2012) harnesse data from external databases such as `DBpedia` (Bizer et al., 2009), `Freebase` (Bollacker et al., 2008), and `LinkedMDB` (Hassanzadeh and Consens, 2009) to gather comprehensive information pertaining to movies, including details about actors, directors, genres, and categories. This approach aimed to enrich the background knowledge available to movie recommender systems. The explicit semantics embedded in these external knowledge sources have demonstrated a discernible enhancement in recommendation performance (Musto et al., 2017). However, this process necessitates a profound domain expertise to effectively and efficiently select and leverage the precise database, ensuring the incorporation of genuinely valuable information into item descriptions (Dumitru et al., 2011).

LLM for Recommendation. The use of large language models in recommender systems has garnered significant attention in recent research (Lin et al., 2023; Chen et al., 2023). Many studies have explored the direct use of LLMs as recommender models. The underlying principle of these approaches involves constructing prompts that encompass the recommendation task, user profiles, item attributes, and user-item interactions. These task-specific prompts are then presented as input to the LLMs, which is instructed to predict the likelihood of interaction between a given user and item (Dai et al., 2023b; Gao et al., 2023; Geng et al., 2022; Li et al., 2023b; Liu et al., 2023b; Zhang et al., 2023). For instance, Wang and Lim (2023) designed a three-step prompting strategy to directly guide LLMs to capture users' preferences, select representative previously interacted items, and recommend a ranked list of 10 items. While these works demonstrate the potential of LLMs as powerful recommender models, the focus primarily revolves around utilizing the LLMs directly for recommendation purposes. However, a potential issue of these methods is that LLMs may generate predictions merely from memorizing training samples which poses a challenge for conducting effective evaluations. In this study, we approach the problem from a different perspective. Rather than using LLMs as recommender models, this study explores diverse prompting strategies to *augment input text* with LLMs for personalized content recommendation. The actual recommendation process still relies on existing recommendation methodologies.

D Example Responses

Tables 29 and 30 show example responses by GPT-3 and the 7B LLAMA-2-CHAT on Movielens-1M (Harper and Konstan, 2015) and Recipe (Majumder et al., 2019). Augmented components are highlighted (recommendation-driven: blue; engagement-guided: green; rec+eng: orange). In summary, both GPT-3 and LLAMA-2 exhibit the capability to enrich item descriptions with supplementary information. Nevertheless, the LLAMA-2-CHAT model with its 7B parameters demonstrates comparatively poorer performance, which could be attributed to its limited parameter scale. This limitation offers insight into the diminished recommendation quality when using LLAMA-2 responses in contrast to GPT-3. Future research endeavors should focus on optimizing the LLM-REC framework, particularly concerning the selection of different large language models as backbones, to enhance recommendation outcomes.

Description: A troubled child psychologist helps a young boy who is able to see and communicate with the dead.

p_{tag}: #Psychology #Child #YoungBoy #Dead #Communication
p_{tag}^{rec}: Tags: Child Psychology, Troubled Child, Young Boy, Communicate with Dead, Supernatural, Paranormal, Ghost Story, Psychological Thriller

Description: This unique Tex-Mex recipe was created by a distant relative who was stationed at the Alamo almost 160 years ago. Family stories say that he was searching for quality tomatoes when Santa Ana launched an attack on the now-iconic Texas landmark. Fortunately, our ancestor had hidden this recipe in his coon-skin cap's lining, ensuring that both he and his avocado dip survived to see another day. Years later, as he lay dying from a chihuahua bite infection, he gazed deeply into his son's eyes and, with his final breath, whispered the memorable words, "Remember... the... guacamole."

Table 11: Example responses to p_{tag} and p_{tag}^{rec} generated by GPT-3. The additional information augmented via the recommendation-driven prompting is highlighted in blue.

Description: A former Roman General is forced to become a gladiator and seek revenge against the corrupt emperor who murdered his family.

p_{infer}: This description can evoke a range of emotions, including anger, sadness, revenge, determination, and courage.
p_{infer}^{rec}: This item is sure to evoke strong emotions in its viewers. It tells the story of a former Roman General who is forced to become a gladiator and seek revenge against the corrupt emperor who murdered his family. It is a tale of tragedy, courage, and justice that will leave you feeling inspired and moved.

Description: Our garden's potatoes are ripe and ready, and this recipe is always the first one I go for! They're incredibly delicious!

p_{infer}: This description can evoke feelings of excitement, anticipation, joy, and satisfaction.
p_{infer}^{rec}: This recipe is sure to bring a smile to your face! The potatoes are fresh from the garden, and the flavor is unbeatable. Enjoy the feeling of accomplishment as you savor the deliciousness of these potatoes. You won't regret it!

Table 12: Example responses to p_{infer} and p_{infer}^{rec} generated by GPT-3. The additional information augmented via the recommendation-driven prompting is highlighted in blue.

Description: Two agents from a secret organization protect the Earth from alien threats while maintaining the public's ignorance of extraterrestrial life.

p_{para}: " Two government agents keep Earth safe from intergalactic dangers while concealing the truth about alien life from the public."
p_{para}^{rec}: "If you're a fan of action-packed sci-fi with a dash of humor, then this is the show for you! The agents are hilarious and the alien threats they face are so creative and thrilling. Plus, the way they manage to keep the public in the dark about alien life is just genius. It's like a sci-fi comedy version of 'Men in Black' with a lot more explosions. Give it a try and let me know what you think!"

Description: Indulge in something unique tonight. It's tasty and relatively simple to make. Plus, I usually have all the ingredients on hand.

p_{para}: Sure! Here's an example paraphrase of the original description
p_{para}^{rec}: If you're looking for something different and easy to make, try this recipe! It's good and has everything you need. I usually have these ingredients on hand, so it's a great option when you're feeling spontaneous. Give it a try and let me know what you think!

Table 13: Example responses to p_{para} and p_{para}^{rec} generated by Llama-2. The additional information augmented via the recommendation-driven prompting is highlighted in blue.

Description: An ant embarks on a journey to save his colony from the oppressive rule of a group of grasshoppers.

p_{tag}: Sure! Here is an example of how you could summarize the description of the item with tags
p_{tag}^{rec}: One tag you could use to recommend this book to others is "insects" or "animals in fiction." This tag would help others find the book if they are interested in stories that feature insects or animals as main characters.

Description: I adore this crock-pot chicken recipe for a couple of reasons: first, my family can't get enough of it, and second, it's incredibly simple to prepare! My sister shared this recipe with me. She has two kids, and they're big fans as well! Plus, if there are any leftovers, they're the best you'll ever have!

p_{tag}: Tags
p_{tag}^{rec}: If you want to recommend the recipe to others, you could use tags such as "chicken recipe", "easy recipe", "family-friendly recipe", "leftovers recipe", and "sister's recipe". Explanation

Table 14: Example responses to p_{tag} and p_{tag}^{rec} generated by Llama-2. The additional information augmented via the recommendation-driven prompting is highlighted in blue.

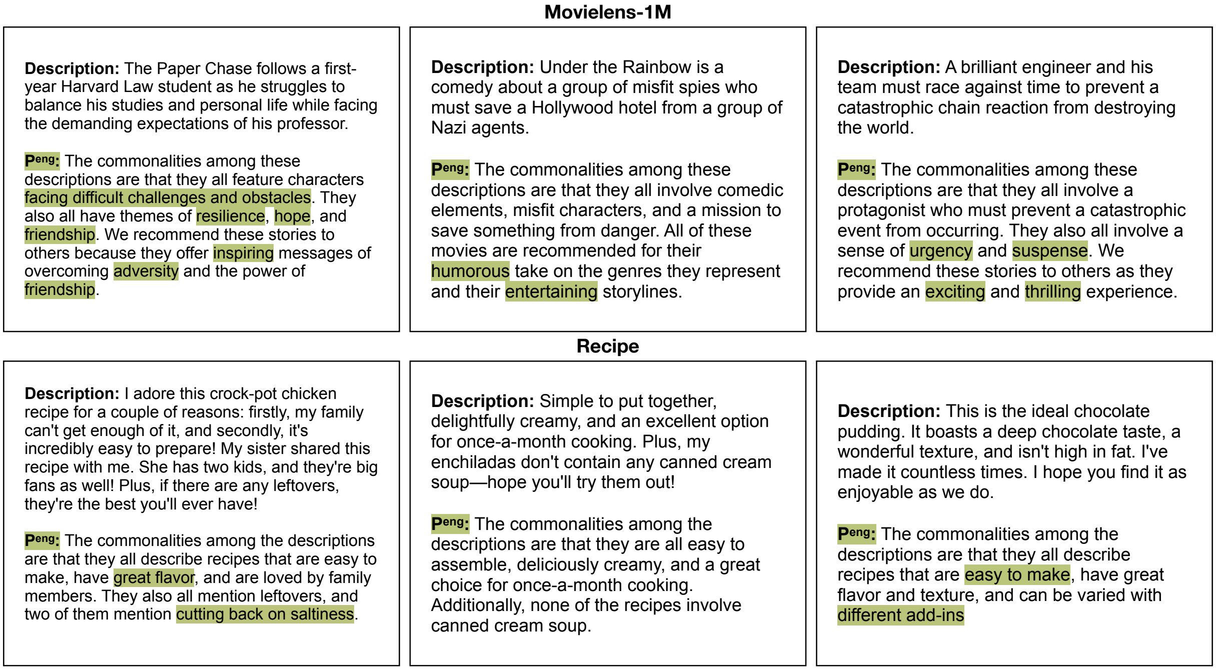
Description: A young police officer must race against time to save a bus full of passengers from a bomb planted by a vengeful criminal.

p_{infer}: Suspense Explanation
p_{infer}^{rec}: I would recommend this movie to others because it evokes a sense of urgency and suspense that is both thrilling and emotionally resonant. The scene where the young police officer races against time to defuse the bomb is heart-pumping and intense, and the emotional stakes are high as the officer works to save the passengers. The movie also explores themes of justice and revenge, making it a thought-provoking and emotionally impactful viewing experience. Overall, I would highly recommend this movie to anyone looking for a gripping and emotional thriller.

Description: Bored with the same old ground beef recipes? Give this spicy dish a try! If you prefer it extra saucy, feel free to double the sauce amount. Update: Since hoisin sauce is quite sweet, you might want to start with a small amount and gradually increase it to your taste!

p_{infer}: 1. Desire
p_{infer}^{rec}: “Hey fellow foodies! Have you tried this Spicy Beef and Noodles recipe? It’s a game changer! The hoisin sauce adds a depth of flavor that will leave you wanting more, and the spicy kick is perfect for those who like a little heat in their meals. I made it for my family last night and they all loved it! Give it a try and let me know what you think! #foodie #delicious #homemade”

Table 15: Example responses to p_{infer} and p_{infer}^{rec} generated by LLAMA-2. The additional information augmented via the recommendation-driven prompting is highlighted in blue.



Movielens-1M

Description: The Paper Chase follows a first-year Harvard Law student as he struggles to balance his studies and personal life while facing the demanding expectations of his professor.

Peng: The commonalities among these descriptions are that they all feature characters facing difficult challenges and obstacles. They also all have themes of resilience, hope, and friendship. We recommend these stories to others because they offer inspiring messages of overcoming adversity and the power of friendship.

Description: Under the Rainbow is a comedy about a group of misfit spies who must save a Hollywood hotel from a group of Nazi agents.

Peng: The commonalities among these descriptions are that they all involve comedic elements, misfit characters, and a mission to save something from danger. All of these movies are recommended for their humorous take on the genres they represent and their entertaining storylines.

Description: A brilliant engineer and his team must race against time to prevent a catastrophic chain reaction from destroying the world.

Peng: The commonalities among these descriptions are that they all involve a protagonist who must prevent a catastrophic event from occurring. They also all involve a sense of urgency and suspense. We recommend these stories to others as they provide an exciting and thrilling experience.

Recipe

Description: I adore this crock-pot chicken recipe for a couple of reasons: firstly, my family can't get enough of it, and secondly, it's incredibly easy to prepare! My sister shared this recipe with me. She has two kids, and they're big fans as well! Plus, if there are any leftovers, they're the best you'll ever have!

Peng: The commonalities among the descriptions are that they all describe recipes that are easy to make, have great flavor, and are loved by family members. They also all mention leftovers, and two of them mention cutting back on saltiness.

Description: Simple to put together, delightfully creamy, and an excellent option for once-a-month cooking. Plus, my enchiladas don't contain any canned cream soup—hope you'll try them out!

Peng: The commonalities among the descriptions are that they are all easy to assemble, deliciously creamy, and a great choice for once-a-month cooking. Additionally, none of the recipes involve canned cream soup.

Description: This is the ideal chocolate pudding. It boasts a deep chocolate taste, a wonderful texture, and isn't high in fat. I've made it countless times. I hope you find it as enjoyable as we do.

Peng: The commonalities among the descriptions are that they all describe recipes that are easy to make, have great flavor and texture, and can be varied with different add-ins

Figure 6: Example responses generated by GPT-3. The additional information augmented via the engagement-guided prompting is colored green. We choose the example responses generated by GPT-3 for illustration. Examples generated by LLAMA-2 can be found in Appendix B.1.

Description: A troubled child psychologist helps a young boy who is able to see and communicate with the dead.

p^{eng}: Despite their different subjects and genres, the descriptions share a common theme of personal transformation and empowerment. Each story revolves around a character’s journey towards self-discovery and self-acceptance, as they navigate challenges and obstacles that help them grow and develop as individuals.

Table 16: Example responses to p^{eng} generated by LLAMA-2. The additional information augmented via the engagement-guided prompting is highlighted in green.

Description: The Paper Chase follows a first-year Harvard Law student as he struggles to balance his studies and personal life while facing the demanding expectations of his professor.

$p^{rec+eng}$: If you're looking for a movie that will keep you on the edge of your seat, The Paper Chase is a great choice. It follows a first-year Harvard Law student as he navigates the pressures of his studies and personal life while facing the expectations of his professor. It's a story of determination and resilience in the face of adversity, and it will leave you feeling inspired and motivated.

Description: Our garden's potatoes are ripe and ready, and this recipe is always the first one I go for! They're incredibly delicious!

$p^{rec+eng}$: This potato recipe is a must-try! It's packed with flavor and so easy to make. Plus, you don't need to add any extra salt - the ranch dressing mix does the trick. It's a great way to get your family to enjoy potatoes in a new way. Plus, it's a great way to use up leftovers if you have any. Give it a try - you won't be disappointed!

Table 17: Example responses to $p^{rec+eng}$ generated by GPT-3. The additional information augmented via the engagement-guided prompting is highlighted in orange.

Description: In this Cold War-era thriller, a Soviet submarine captain attempts to defect to the United States with his state-of-the-art vessel.

p_{para}: The description of an item is as follows: '{description}', paraphrase it.

Response: In this suspenseful movie set during the Cold War, a captain of a Soviet submarine attempts to defect to the US with his advanced submarine.

Variant Prompt: Summarize the given item description, '{description}', using different words.

Response: This suspenseful movie from the Cold War period follows a Soviet submarine commander who attempts to defect to America with his advanced submarine.

Table 18: Example responses generated by GPT-3 for p_{para} and its variant that shares the same meaning but differs in word choices.

Description: In this Cold War-era thriller, a Soviet submarine captain attempts to defect to the United States with his state-of-the-art vessel.

p_{tag}: The description of an item is as follows: '{description}', summarize it with tags.

Response: Cold War, Soviet, submarine, defect, United States, state-of-the-art.

Variant Prompt: Condense the provided item description '{description}' using tags.

Response: #ColdWar #Thriller #SovietSubmarine #Defect #US #StateOfTheArtVessel

Table 19: Example responses generated by GPT-3 for p_{tag} and its variant that shares the same meaning but differs in word choices.

Description: In this Cold War-era thriller, a Soviet submarine captain attempts to defect to the United States with his state-of-the-art vessel.

p_{infer}: The description of an item is as follows: '{description}', what kind of emotions can it evoke?

Response: This description can evoke feelings of suspense, tension, and excitement. It can also evoke feelings of patriotism and loyalty as the Soviet submarine captain attempts to defect to the United States.

Variant Prompt: Based on the description '{description}', what emotions might it elicit?

Response: -Tension-Suspense-Fear-Anxiety-Dread-Unease-Paranoia

Table 20: Example responses generated by GPT-3 for p_{infer} and its variant that shares the same meaning but differs in word choices.

Description: In this Cold War-era thriller, a Soviet submarine captain attempts to defect to the United States with his state-of-the-art vessel.

p^{rec}_{para}: The description of an item is as follows: '{description}', what else should I say if I want to recommend it to others?

Response: This Cold War-era thriller is a gripping and suspenseful story that will keep you on the edge of your seat. It follows the daring journey of a Soviet submarine captain as he attempts to defect to the United States with his state-of-the-art vessel. With its thrilling plot and captivating characters, this movie is sure to be an unforgettable experience.

Variant Prompt: In addition to the description '{description}', what other details would you include to endorse it to others?

Response: This Cold War-era thriller follows the story of a Soviet submarine captain, Marko Ramius, who attempts to defect to the United States with his state-of-the-art vessel. Along the way, he must outwit and outmaneuver a relentless CIA analyst, Jack Ryan, who is determined to stop him. With intense action sequences and a gripping plot, this movie will keep you on the edge of your seat as the two men battle for control of the submarine. Featuring an all-star cast including Sean Connery, Alec Baldwin, and Scott Glenn, The Hunt for Red October is a thrilling and suspenseful ride that will leave you wanting more.

Table 21: Example responses generated by GPT-3 for p^{rec}_{para} and its variant that shares the same meaning but differs in word choices.

Description: In this Cold War-era thriller, a Soviet submarine captain attempts to defect to the United States with his state-of-the-art vessel.

p^{rec}_{tag}: The description of an item is as follows: '{description}', what tags should I use if I want to recommend it to others?

Response: Tags: Cold War, Thriller, Soviet Submarine, Defection, United States, State-of-the-Art Vessel

Variant Prompt: If you aim to recommend '{description}' to others, what tags or terms would you use?

Response: Tags/Terms: Cold War, Thriller, Soviet Submarine, Defection, United States, State-of-the-Art Vessel.

Table 22: Example responses generated by GPT-3 for p^{rec}_{tag} and its variant that shares the same meaning but differs in word choices.

Description: In this Cold War-era thriller, a Soviet submarine captain attempts to defect to the United States with his state-of-the-art vessel.

p^{rec}_{infer}: The description of an item is as follows: '{description}', recommend it to others with a focus on the emotions it can evoke.

Response: This Cold War-era thriller will take you on an intense journey of suspense and intrigue. Follow a Soviet submarine captain as he attempts to defect to the United States with his state-of-the-art vessel, and experience the tension and drama of a high-stakes game of cat and mouse. Feel the fear and anticipation as the captain navigates a dangerous course of political and personal risk.

Variant Prompt: Using the description '{description}', endorse this item to others while emphasizing the emotions it can inspire.

Response: This Cold War-era thriller will have you on the edge of your seat! Follow the gripping story of a Soviet submarine captain as he attempts to defect to the United States with his state-of-the-art vessel. Feel the tension and suspense as you watch this thrilling tale unfold. Don't miss out on this captivating story of courage and determination!

Table 23: Example responses generated by GPT-3 for p^{rec}_{infer} and its variants that shares the same meaning but differs in word choices.

Description: The Paper Chase follows a first-year Harvard Law student as he struggles to balance his studies and personal life while facing the demanding expectations of his professor.

Descriptions of other important neighbors: ‘The Paper Chase follows a first-year Harvard Law student as he struggles to balance his studies and personal life while facing the demanding expectations of his professor.’; ‘The Shawshank Redemption is a story of hope, friendship, and resilience in the face of despair.’; ‘A criminal fakes insanity to escape prison, only to find himself in a mental institution where he must battle the oppressive head nurse.’

p^{eng}: Summarize the commonalities among the following descriptions: ‘{description}’; ‘{descriptions of other important neighbors}’.

Response: The commonalities among the descriptions are that they all involve characters facing difficult challenges and having to find a way to overcome them. In The Paper Chase, the protagonist must balance his studies and personal life while facing the demanding expectations of his professor. In The Shawshank Redemption, the characters must find hope, friendship, and resilience in the face of despair. In the other description, the criminal must fake insanity to escape prison and then battle the oppressive head nurse in the mental institution.

Variant Prompt: Outline the shared characteristics of the following descriptions: ‘{description}’ and ‘{descriptions of other important neighbors}’.

Response: The shared characteristics of the descriptions are: - A protagonist facing a difficult situation - A struggle to balance personal life and studies - Overcoming adversity - Hope, friendship, and resilience - Oppressive forces to be overcome.

Table 24: Example responses generated by GPT-3 for p^{eng} and its variant that shares the same meaning but differs in word choices.

Description: The Paper Chase follows a first-year Harvard Law student as he struggles to balance his studies and personal life while facing the demanding expectations of his professor.

Descriptions of other important neighbors: ‘The Paper Chase follows a first-year Harvard Law student as he struggles to balance his studies and personal life while facing the demanding expectations of his professor.’; ‘The Shawshank Redemption is a story of hope, friendship, and resilience in the face of despair.’; ‘A criminal fakes insanity to escape prison, only to find himself in a mental institution where he must battle the oppressive head nurse.’

$p^{rec+eng}$: The description of an item is as follows: ‘{description}’. What else should I say if I want to recommend it to others? This content is considered to hold some similar attractive characteristics as the following descriptions: ‘{descriptions of other important neighbors}’.

Response: If you’re looking for a movie that will keep you on the edge of your seat, The Paper Chase is a great choice. It follows a first-year Harvard Law student as he navigates the pressures of his studies and personal life while facing the expectations of his professor. It’s a story of determination and resilience in the face of adversity, and it will leave you feeling inspired and motivated.

Variant Prompt: If you wish to recommend ‘{description}’ to others, what other details would you provide? This content possesses certain akin attractive attributes as the following descriptions: ‘{descriptions of other important neighbors}’.

Response: The Paper Chase is a classic drama that follows the struggles of a first-year Harvard Law student as he navigates the demanding expectations of his professor while trying to balance his studies and personal life. It is a story of perseverance, determination, and resilience in the face of adversity. The film features an all-star cast, including John Houseman, Timothy Bottoms, and Lindsay Wagner, and is sure to captivate viewers with its gripping plot and powerful performances.

Description: This traditional meatloaf makes a fantastic meal, whether served hot or cold. It's perfect for slicing and enjoying cold at a picnic or in sandwiches. For a different twist, consider brushing your favorite salsa on top instead of the typical topping. A medium or hot chipotle salsa adds an especially tasty kick.

KAR: This easy and tasty meatloaf is a great dish to serve either hot or cold. It is perfect for a picnic or sandwiches, and can be enjoyed by everyone.
Ingredients: - 2 lbs ground beef - 1/2 cup bread crumbs - 1/4 cup onion, finely chopped - 1/4 cup green pepper, finely chopped - 1 egg - 1/4 cup ketchup - 1 teaspoon Worcestershire sauce - 1 teaspoon garlic powder - 1 teaspoon salt - 1/4 teaspoon black pepper - Optional: your favorite salsa
Cuisine type: American
Cooking time: 1 hour
Nutritional value: High in protein, low in fat
Allergies: None
Taste preferences: Mildly seasoned with a hint of sweetness from the ketchup
Skill level: Easy
Occasion: Perfect for a picnic, lunch, dinner, or snack
Cost: Inexpensive
Health and wellness goals: Low in fat, high in protein
Food allure: Comfort food that is easy to make
Reviews and ratings: Highly rated
Cooking equipment: Baking sheet
Personal experience: Delicious and easy to make
Season and weather: Perfect for any season
Cultural or ethical considerations: None
Creativity and variety: Can be topped with your favorite salsa
Simplicity: Easy to make
Popularity and trends: A classic dish that is always popular
Instructions: 1. Preheat oven to 350F. 2. In a large bowl, combine ground beef, bread crumbs, onion, green pepper, egg, ketchup, Worcestershire sauce, garlic powder, salt, and pepper. Mix until all ingredients are combined. 3. Place mixture into a greased 9x5 inch loaf pan. 4. Bake for 1 hour or until internal temperature reaches 160F. 5. Optional: Brush your favorite salsa on top of the meatloaf before serving. 6. Enjoy!

Table 27: An example response generated via knowledge augmentation prompts (Xi et al., 2023). The additional information is highlighted in red.

Table 28: Average recommendation performance among different prompting strategies across five different splits. The best performance among the three Basic Prompting and three Recommendation-driven Prompting strategies is reported. The overall best results are highlighted in **bold**.

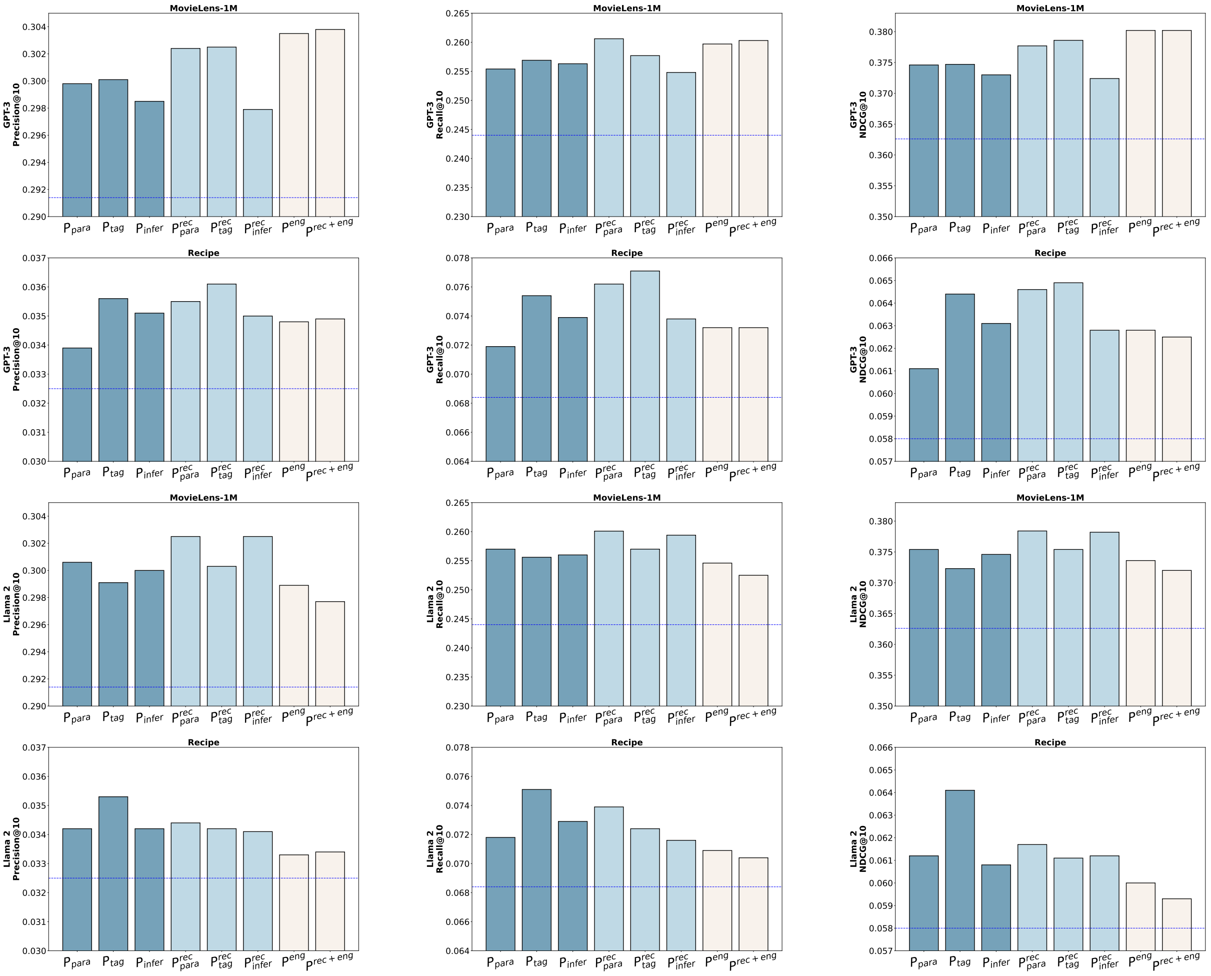

Figure 7: **The ablation study conducted on different prompting strategies shows that augmenting the input text with responses generated by large language models using our proposed prompting strategies enhances recommendation performance. However, the extent of this improvement may vary depending on the characteristics of the datasets used.** The *basic prompting* strategy includes three variants: p_{para} (paraphrase), p_{tag} (tag), and p_{infer} (infer). The *recommendation-driven* versions of these three variants are denoted by p^{rec}_{para}, p^{rec}_{tag}, and p^{rec}_{infer}. In addition, p^{eng} represents the *engagement-guided* prompts, and $p^{rec+eng}$ stands for the *recommendation + engagement* prompts. The blue line in each figure indicates the performance achieved by using only the original description embeddings. Note that in this ablation study, all the baselines use a concatenation of the the original description embeddings and prompt response embeddings as their model input.

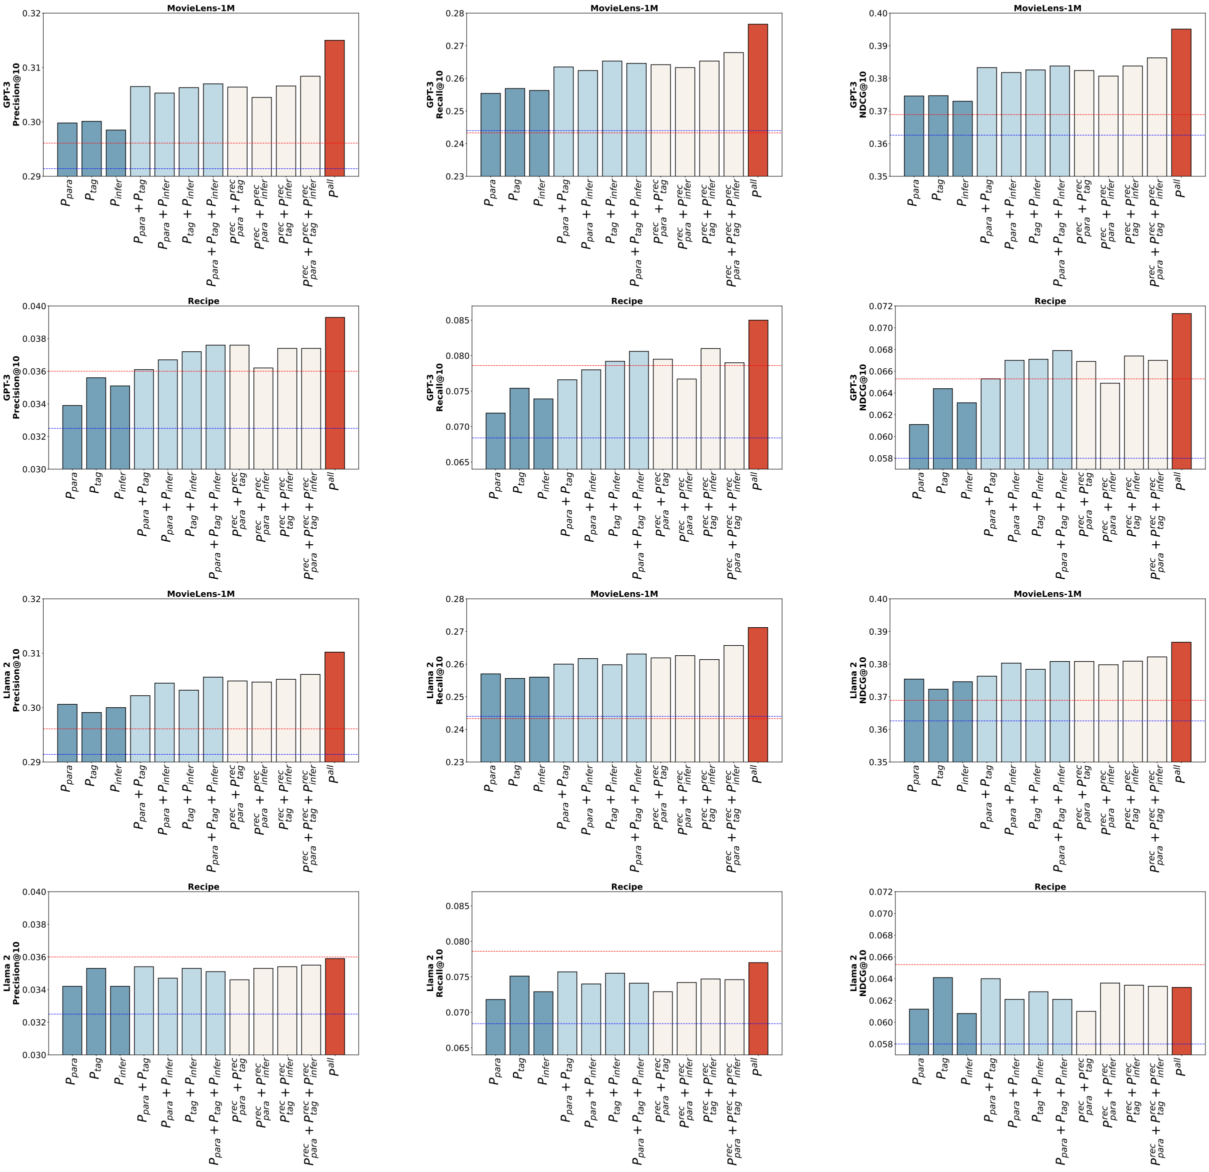

Figure 8: **The ablation study shows that overall, recommendation benefits from concatenating the embeddings of the input text augmented by large language models.** The blue line in each figure indicates the performance achieved by using only the original description embeddings, while the red line represents the performance achieved by DCN-V2 (Wang et al., 2021).

Description: A criminal fakes insanity to escape prison, only to find himself in a mental institution where he must battle the oppressive head nurse.

${p_{para}}^{\text{GPT-3}}$: A criminal attempts to avoid punishment by pretending to be mentally ill, only to end up in a psychiatric hospital where he must confront the tyrannical head nurse.

${p_{para}}^{\text{LLAMA-2}}$: A mentally ill criminal fakes insanity to escape prison and ends up in a mental institution where he must confront the abusive head nurse. Please provide one example of a possible paraphrase of the description of an item.

${p_{tag}}^{\text{GPT-3}}$: #Criminal #Insanity #Escape #MentalInstitution #OppressiveNurse

${p_{tag}}^{\text{LLAMA-2}}$: 1. Drama 2. Thriller 3. Horror 4. Crime 5. Mystery

${p_{infer}}^{\text{GPT-3}}$: This description can evoke a range of emotions, including fear, suspense, anxiety, dread, and uncertainty. It can also evoke feelings of hope and determination as the protagonist battles against the oppressive head nurse.

${p_{infer}}^{\text{LLAMA-2}}$: Fear Explanation

${p^{rec}_{para}}^{\text{GPT-3}}$: This thrilling story follows a criminal who must use his wits to survive in a mental institution. With a gripping plot and intense characters, this story will keep you on the edge of your seat as you watch the protagonist battle the oppressive head nurse. It's a must-read for anyone looking for an exciting and suspenseful read.

${p^{rec}_{para}}^{\text{LLAMA-2}}$: In this scenario, I would recommend the movie to anyone who enjoys dark humor and psychological thrillers. It has an excellent cast, including Jim Carrey in one of his most memorable roles, and the tension and suspense are top-notch. Additionally, the movie tackles some heavy themes in a thought-provoking way, making it a great choice for those interested in exploring the complexities of the human psyche. Overall, it's a must-see for fans of the genre.

$p^{rec\text{GPT-3}}_{tag}$: Tags: Crime, Mental Health, Prison, Insanity, Oppression, Battle

$p^{rec\text{LLAMA-2}}_{tag}$: If you want to recommend the movie "Cuckoo's Nest" to others, you could use tags such as "psychological thriller", "prison escape", "mental illness", "oppressive nurse", and "1970s films".

${p^{rec}_{infer}}^{\text{GPT-3}}$: This thrilling story will take you on an emotional rollercoaster as you follow a criminal's journey from prison to a mental institution. You'll feel his desperation as he attempts to fake insanity, and his fear as he faces the oppressive head nurse. It's a gripping tale of courage and resilience that will leave you on the edge of your seat.

${p^{rec}_{infer}}^{\text{LLAMA-2}}$: The movie "Shutter Island" is a psychological thriller that explores the themes of paranoia, suspense, and the blurring of reality. The story follows a U.S. Marshal who is sent to investigate the disappearance of a patient from a remote psychiatric hospital, only to find himself plunged into a web of intrigue and danger. The movie's use of atmosphere, sound, and visuals creates a sense of unease and uncertainty, keeping the viewer on the edge of their seat. The tense score and the eerie setting of the hospital add to the overall atmosphere of paranoia and unease, making it a gripping and suspenseful movie that will keep you on the edge of your seat. | Example Answer | Description | | The movie "Shutter Island" is a psychological thriller that explores the themes of paranoia, suspense, and the blurring of reality. | The movie's use of atmosphere, sound, and visuals creates a sense of unease and uncertainty, keeping the viewer on the edge of their seat. | Please provide answers for the next 3 questions.

$p^{eng\text{GPT-3}}$: The commonalities among the descriptions are that they all involve a criminal, redemption, and friendship. They also all involve a battle against an oppressive force.

Abstract

Large language models (LLMs) have show their remarkable ability in various natural language tasks. However, there are concerns that LLMs are possible to be used improperly or even illegally. To prevent the malicious usage of LLMs, detecting LLM-generated text becomes crucial in the deployment of LLM applications. Watermarking is an effective strategy to detect the LLM-generated content by encoding a pre-defined secret watermark to facilitate the detection process. However, the majority of existing watermark methods leverage the simple hashes of precedent tokens to partition vocabulary. Such watermarks can be easily eliminated by paraphrase and, correspondingly, the detection effectiveness will be greatly compromised. Thus, to enhance the robustness against paraphrase, we propose a semantics-based watermark framework, SemaMark. It leverages the semantics as an alternative to simple hashes of tokens since the semantic meaning of the sentences will be likely preserved under paraphrase and the watermark can remain robust. Comprehensive experiments are conducted to demonstrate the effectiveness and robustness of SemaMark under different paraphrases. Our code is available at github.com/renjie3/SemaMark.

1 Introduction

Large language models (LLMs) have shown their great ability in various natural language processing (NLP) tasks like Question Answering (QA) (Lu et al., 2022), reasoning tasks (Wei et al., 2022; Creswell et al., 2022) and code development (Xu et al., 2022). However, tremendous concerns have been raised that LLMs are possible to be used improperly and illegally. For example, indistinguishable fake news are easy to be fabricated (Kreps et al., 2022; Zellers et al., 2019) by language models, which, when disseminated, could instigate widespread panic. Similarly, in the commercial sphere, convincingly generated reviews can manipulate consumer perceptions, leading to unethical business competition (Salminen et al., 2022). Therefore, detecting LLM-generated text has become crucial in the real-world applications of LLMs (Wu et al., 2023; Sadasivan et al., 2023; Xu et al., 2023).

Among diverse methods to detect LLM-generated texts, the watermark strategies have demonstrated outstanding precision (Liu et al., 2023b; Tang et al., 2023; Ren et al., 2024). It is proposed to encode a secret watermark into the generated texts, such that we can tell whether a text is generated by detecting this watermark. One representative strategy (Kirchenbauer et al., 2023a; Yoo et al., 2023) is to encode the watermark based on the "partition of vocabulary". In detail, given a language model, these methods devise a mapping from precedent tokens to a particular partition of the vocabulary by a partition function for the consequent token. The partition function leverages the hashes of the input as the seed of a random generator to split the vocabulary to a green list and a red list. During the text generation phase, the consequent token has an increased probability to be sampled from the green list. In this way, the watermark is encoded through the matching between the precedent tokens and the vocabulary partition for the consequent token. The detection is also facilitated by detecting this matching in generated contents. However, recent works (Krishna et al., 2023; Kaddour et al., 2023) reveal that **this watermark may be easily eliminated by sentence paraphrasing**. Individuals seeking to improperly utilize LLMs without being detected can paraphrase the generated contents, like altering the order and the choices of the words, and only retain the general meaning of the text to achieve their malicious goals like faking news. These paraphrases will change the seed of the partition function, i.e. the token hashes, and as we show in the Section 4.4, the partition function is sensitive to small changes. Consequently,

Findings of the Association for Computational Linguistics: NAACL 2024, pages 613–625
June 16-21, 2024

the matching between the precedent tokens and the green list will be disrupted, and the detection effectiveness of the watermark can be dramatically compromised.

In this paper, we propose to leverage the semantic meaning of precedent token sequences as the seed for partition function, instead of simple hashes of precedent tokens, since the core semantic meaning is expected to be maintained after paraphrase. To achieve this goal, one key obstacle is how to capture the semantics when applying them for the partition function to watermark the generated texts. It is a common practice to quantify the semantics via embeddings (Reimers and Gurevych, 2019; Gao et al., 2021; Li et al., 2020; Giorgi et al., 2021). Embeddings indeed can represent consistent semantics after paraphrase. Since the embeddings are high-dimensional vectors in the continuous space, they often present some minor changes after paraphrase. Although the main semantics are preserved, these minor changes can lead to a substantial difference in the partition of vocabulary because the random generator in the partition function is sensitive to the change of the seed, as shown in Section 4.4.

To overcome the above challenge, i.e., to make the quantified semantics invariant and make the watermark robust under paraphrase, we propose a new watermark method, SemaMark, which discretizes the continuous embedding space. Intuitively, the discretization can coarsen the representation of the embeddings which could tolerate the potential minor changes caused by paraphrase. By proper discretization, the paraphrased semantics could stay in the same discrete section with a high probability and the discretized quantified semantics will likely remain the same even after paraphrase. Therefore, the partition results will not change. However, directly converting the high-dimensional embedding space into discrete is intricate and challenging. For example, discretizing each dimension will lead to a large amount of discrete values which is exponential to the number of dimensions. Thus, the minor changes by paraphrase can still cause the change of discrete values because the number of discrete values are too dense and each discrete value can tolerate only small changes. Therefore, the minor changes of high-dimensional embeddings can have a strong impact on the partition function. To address this problem, SemaMark first uses a Multi-Layer Perception (MLP) to condense the continuous high-dimensional embeddings into normalized vectors in 2D space. The vectors are located on a unit circle named Normalized Embedding Ring (NE-Ring). Then the condensed NE-Ring is equally divided into various sections, transforming the continuous space into distinct discrete values, i.e., "semantic values". Based on the discretization, SemaMark further introduces two strategies to advance the watermark's concealment and to improve the robustness under paraphrase. *First*, SemaMark leverages the uniformity (Wang and Isola, 2020) of Contrastive Learning(CL) (Chen et al., 2020) to strength the MLP and mitigate the problem that the semantics are unevenly concentrating on some discrete sections on NE-Ring. The unevenly distribution will cause the final discrete semantic values overly monotonous. It raises the concern that the watermark might be cracked by counting token frequency (Zhao et al., 2023). *Second*, SemaMark utilizes an offset detection method to further enhance the robustness at the boundary of different discrete sections whose semantic values are possibly vulnerable to paraphrase. Comprehensive experiments are conducted to demonstrate the effectiveness and robustness of SemaMark under different paraphrases.

2 Related works

LLM-generated detection. As the development of LLMs, various LLM-generated detection tools have also been proposed. Learning-based methods train a classification model to detect the difference between human-written text and machine-generated text like Guo et al. (2023); Wang et al. (2023); Li et al. (2023). Other works do not rely on the classification model, but try to use the property of the LLM to test whether a given text is generated by LLMs. For example, DetectGPT (Mitchell et al., 2023) assumes that the generated text will have high likelihood. GPT-who (Venkatraman et al., 2023) uses UID-based features to model the unique statistical signature of each LLM and human author for accurate authorship attribution. These methods do not interact the generation process of LLMs and thus have to explore unknown features of LLMs for detection. Instead, watermarks can change the model with a small but pre-defined rule which accelerates the detection process effectively.

Watermark. The distinction between watermark and other methods is that watermark can proactively change the generation to insert a concealed watermark into the generated text. This gives clear difference between watermerked and non-

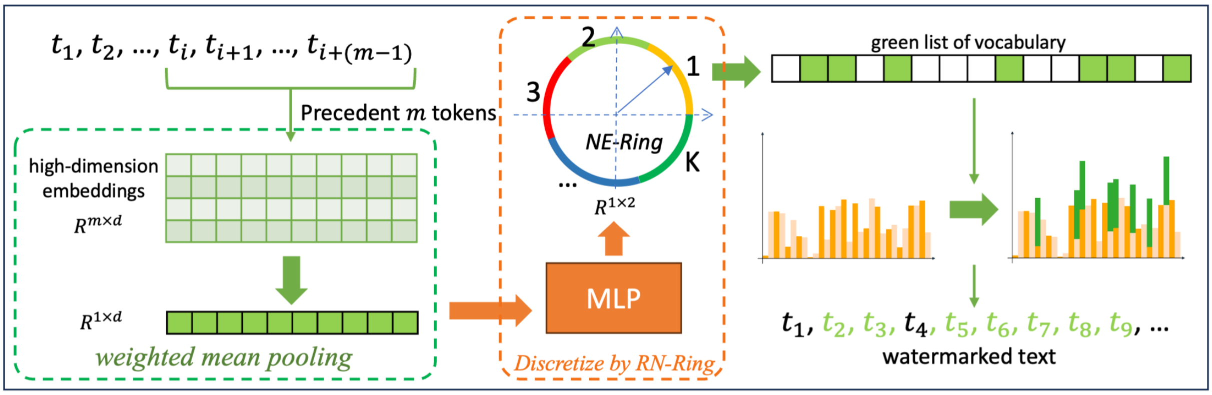

Figure 1: The watermarking process of SemaMark

watermarked texts. Watermark shifts the text using a small but pre-defined rule to make the detection much more effective. The partition of the vocabulary for each token is a representative watermark method (Kirchenbauer et al., 2023a; Yoo et al., 2023; Kirchenbauer et al., 2023b). In each autoregressive step of generating one token, the method uses the previous tokens' hashes, to select a part of the vocabulary as "green" at a ratio of γ. Subsequently, they elevate the likelihood of the tokens by boosting the logits of the softmax by δ. Through this approach, at each token position, the probability of this matching between the seed and green tokens tends to increase.

For a sentence with L tokens, it is viewed as a sample set of size L. Each token is one sample from the vocabulary. A non-watermarked sentence is expected to have γL tokens showing this match, while the watermarked sentence is expected to have more. The watermark detection is approached as a z-test with null hypothesis that the text is non-watermarke. If the z-statistic is large, i.e. it is significantly different from the null hypothesis, the null hypothesis can be rejected and the text can be predicted as watermarked:

$$z = \frac{(G - \gamma L)}{\sqrt{L\gamma(1-\gamma)}}, \tag{1}$$

where G is the number of tokens showing the matching between seed and the green list. Yoo et al. (2023) further expand this watermark of green and red list to more lists for multi-bit encoding.

(Liu et al., 2023a) propose a semantic invariant method to watermark the generated text of LLM. However, their method employs two additional models, introducing redundant encoding processes in the text encoder, which can be time-consuming.

3 Method

In this section, we introduce the detailed design of SemaMark. We first present how to use the semantic information as the seed for watermark methods that are based on random partition of vocabulary in Section 3.1. Then in Section 3.2 and Section 3.3, we introduce the CL training scheme and the smoothed detection method for further improving the robustness, respectively.

3.1 The framework of SemaMark

As aforementioned, the existing watermark methods based on partition of vocabulary are susceptible to paraphrase. Paraphrase can easily change the previous tokens and disrupt the matching between tokens and the partition of vocabulary, without significantly affecting the semantic meaning. Thus, SemaMark uses the invariant semantics for watermarking by discretizing the embedding space to accommodate the minor perturbation of semantics and provide a stable mapping between semantics and vocabulary partition for the consequent token.

However, discretization in a high-dimension space is intricate and non-trivial. Therefore, we first reduce the high-dimensional embedding space onto the 2D NE-Ring and then discretize via NE-Ring. The whole watermarking process is shown in Figure 1. SemaMark first reduces the dimension of the embedding space to obtain the discrete semantic values by two steps, i.e., *weighted embedding pooling* and *discretizing by NE-Ring*, and then uses the semantic value to partition the vocabulary. The logits of green list is shifted to increase the probability of matching between semantics and the consequent token for watermarking the LLM, f. In the following, we introduce more details about the two steps to obtain a stable semantic value.

S1: weighted embedding pooling. To enhance the robustness, we aggregate the semantics of previous m tokens by the weighted mean pooling function $P(\cdot)$ before dimension reduction, instead of using only one preceding token's embedding. In the ablation studies of Section 4.4, we show that the method has the best performance when m is neither too big nor too small. For the token sequence $\{t_{i:i+m-1}\}$ starting at position i, we use their semantics to generate the token in the m position, t_{i+m}. We denote their embeddings as $\{\boldsymbol{e}_{i:i+m-1}\}$. $\{\boldsymbol{e}_{i:i+m-1}\}$ can be easily obtained from the LLM, f, that we want to watermark. Intuitively, in $\{t_{i:i+m-1}\}$, the embeddings of tokens far from t_{i+m} contain semantic information that is more distant from t_{i+m} than the closer ones. The connection between distant tokens might be more possible to change after paraphrase compared with closer tokens. Thus, in the sequence $\{t_{i:i+m-1}\}$, the embeddings of distant tokens might be less robust. To increase the robustness for the green list of the current token position t_{i+m} after paraphrase, the pooling embeddings should rely more on the closer tokens, therefore, we use a linear weight function to assign lower weights to tokens far from t_{i+m} and higher weights to those in closer proximity:

$$P(\{\boldsymbol{e}_{i+1:i+m}\}) = \sum_{j=1}^{K} \frac{j + \frac{K}{2}}{w_{\text{sum}}} \boldsymbol{e}_{i+j},$$

where $w_{\text{sum}} = K^2 + K/2$ is the sum of all weights. We denote the weighted output $P(\{\boldsymbol{e}_{i:i+m-1}\}) \in \mathbb{R}^d$ as $\boldsymbol{e}_{P_{i,m}}$ for short. By pooling, more semantics are used for a seed, which enhance the robustness under paraphrase.

S2: discretizing by NE-Ring. After aggregating the embeddings by weighted pooling, SemaMark uses MLP g_θ to transform $\boldsymbol{e}_{P_{i,m}}$ to a normalized vector in 2D embedding space. The normalized vectors locate on a unit circle in the 2D space, which is named as Normalized Embedding Ring (NE-Ring). The discretization function, $D(\cdot)$, discretizes NE-Ring by equally segmenting into different sections. It takes the polar angle ϕ of $g_\theta(\boldsymbol{e}_{P_{i,m}})$ as input and outputs the discretized semantic values $a \in [K]$, where $[K] := \{1, 2, ..., K\}$. $D(\cdot)$ is defined as

$$D(\phi) = \left\lfloor \phi \frac{K}{2\pi} \right\rfloor$$

It first maps the input from $[0, 2\pi)$ to $[0, K)$, and then discretizes all the values in $[i, i+1)$ to i, for $\forall i \in [K-1]$. Even though there could be subtle changes in semantics by paraphrase, the paraphrased $\tilde{a}$ will likely locate in the discrete section $[i, i+1)$. Some tokens may still have $a \neq \tilde{a}$ if the normalized vector is close to the boundary of $[i, i+1)$. Therefore, in Section 3.3, we introduce an offset detection to strengthen the tolerance for this mismatch and correct some unstable cases.

With the two steps, we can get a stable discrete semantic value as the seed for the partition function to partition the vocabulary for the consequent token. Following Kirchenbauer et al. (2023a), the vocabulary is partitioned into green and red lists. We increase the logits of the tokens in the green list by δ and recalculate the probability distribution based on the shifted logits. For each token to generate, we increase the possibility of the green list based on its previous m tokens' semantics. Thus, all the generated tokens will be likely to have this matching between the semantics and the consequent green token. By detecting the matching, we can discriminate whether a text is watermarked or not and then detect the LLM-generated contents effectively. Besides, SemaMark proposes two strategies to reduce the risk of being cracked by Contrastive Learning and further increase the robustness by the offset detection in the following sections.

3.2 Training g_θ by Contrastive Learning

The MLP is expected to produce a uniform distribution of $g_\theta(\boldsymbol{e}_{P_{i,m}})$ on NE-Ring. If different semantics unevenly distributed on NE-Ring, the resulting discrete semantic values will be overly monotonous and the green list is more changeless. Consequently, the green list might be revealed by counting the token frequency, which compromises the concealment of watermark and leads to the risk of being cracked. Ideally, SemaMark should generate a wider variety of semantic values for different sentences, while each semantic value is robust and stable if its corresponding sentence is paraphrased. To achieve this goal, we propose to use Contrastive Learning to train MLP since Contrastive Learning has the property of uniformity that the data will be evenly distributed in the whole feature space (Wang and Isola, 2020). The uniform distribution can help the normalized vectors cover all the semantic values. As a result, NE-Ring can generate a wider variety of semantic values to prevent the watermark from being cracked.

In Contrastive Learning, we first input the sentences into the model f to get a batch of sequences of m tokens and their pooling embeddings $\boldsymbol{e}_{P_{i,m}}$, denoted as $\{\boldsymbol{e}_j\}$, where $j \in [B]$ and B is the batch size. To compose a contrastive loss, we construct the positive and negative pairs by a soft augmentation:

$$\boldsymbol{e}_{j+B} = \boldsymbol{e}_j^{+} = \boldsymbol{e}_j + \epsilon,$$

where $\epsilon \sim \mathcal{N}(0, \sigma^2)$ is a Gaussian noise. The soft augmentation can simplify the construction of positive samples. With this soft augmentation, we can assign the samples sharing similar embeddings from the same sequence as positive pairs and samples from different sequences as negative pairs. This is consistent with our intuition that the paraphrased semantic embeddings will not change significantly and can remain robust. Then the contrastive loss is

$$L_j = -\log \frac{\exp\left(\text{sim}\left(g_\theta(\boldsymbol{e}_j), g_\theta(\boldsymbol{e}_j^{+})\right)/\tau\right)}{\sum_{k\neq j, k\in[2B]} \exp\left(\text{sim}\left(g_\theta(\boldsymbol{e}_j), g_\theta(\boldsymbol{e}_k)\right)/\tau\right)},$$

where $\text{sim}(\cdot)$ is cosine similarity and τ is the temperature. By Contrastive Learning, the output of reduced semantic embeddings can be evenly distributed in all of the space on NE-Ring, and cover all the discrete sections to improve the robustness of SemaMark.

3.3 Q-offset detection

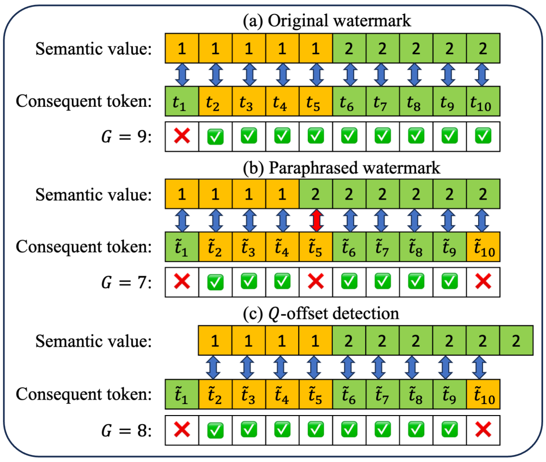

Figure 2: Q-offset detection vs. existing detection

Existing detection methods check the matching between partition seed and the consequent tokens in a one-to-one manner as shown in Figure 2(a). The detection method first recalculates the seed for each token position and gets the partition of the green list, and then checks whether the consequent token is in the partitioned green list token by token. In SemaMark, this strategy can be effective when the text is not paraphrased. However, after paraphrase, this detection could be suboptimal because the semantic values of some sequences which are close to the boundaries of the discrete section $[i, i+1)$ might change as shown in Figure 2(b). This is because the window of m tokens will slide token by token during the auto-regressive generation process, and the semantic change will also accumulate when the window is sliding. The semantic values closed to the boundary usually happen when the change accumulates to some extent. This change of boundary semantic values will lead to some mismatch and reduce the accuracy like $\tilde{t}_5$ in Figure 2(b).

To mitigate the influence of this error, we propose Q-offset detection. As shown in Figure 2(c), we offset the discrete seed by q tokens to detect the matching between semantics and the consequent tokens, where $q \in \{-Q, -(Q-1), ..., 0, 1, ..., Q\}$ and the sign of q indicates the direction of the offset. We choose the maximal z-statistic in different q as the Q-offset score. However, Q-offset detection will also increase the Q-offset score of non-watermark text, which indicates that the detected green word fraction γ of non-watermark text is higher. The γ in Eq. (1) is possibly inaccurate. Thus during generation, we set γ to a fixed value, while in detection process, we treat γ as a hyper-parameter and use a validation set to determine its value in practice. In Section 4.4, we discuss the ablation studies of Q-offset and γ and show that Q-offset can impressively improve the detection performance with robustness.

4 Experiment

In this section, we conduct experiments to demonstrate the robustness of SemaMark. In Section 4.2, we demonstrate that its robustness is better than the baseline methods. In Section 4.3, we show that our watermark has almost no influence on the quality of generated texts. In Section 4.4, we use ablation studies to demonstrate the effectiveness of partition function and Q-offset detection, and show the sensitivity of the partition function. In Section 4.5 we visualize the distribution of NE-Ring and provide analysis on the feature distribution of Contractive Learning.

Table 1: Watermark detection results under three paraphrases. (The best performance under paraphrase is bolded.)

4.1 Experiment setups

Backbone models and datasets. We test our method by watermarking two models, OPT-2.7B and OPT-6.7B (Zhang et al., 2022) which are referred to as the backbone models in following sections. For dataset, we use the news-like subset of C4 (Raffel et al., 2020), which covers a variety of topics. From the news-like subset of C4, we extract a training set, a validation set and a test set. For each sample, we use the first half of text as prompt to generate watermark sentences. More details can be found in Appendix A.

Baseline methods. We compare our method with three baselines LeftHash, SelfHash (Kirchenbauer et al., 2023b) and EXP-Edit (Kuditipudi et al., 2023). LeftHash and SelfHash are two methods based on the partition of vocabulary using the hashes of tokens. EXP-Edit uses a private sequence to encode the watermark by changing the probability distribution of the sequence of tokens. More details on the implementation can be found in Appendix A.

Paraphrase setups. We use three representative methods to paraphrase the watermarked text, round-trip translation (Tiedemann and Thottingal, 2020), Dipper (Krishna et al., 2023) and GPT-3.5. For round-trip translation, we first translate from English to another language and then transform back to English, such that some words and expressions will be changed because the translation is not an one-to-one mapping. For Dipper, we follow the parameter setting in Kirchenbauer et al. (2023b). For GPT-3.5, we use the prompt in Kirchenbauer et al. (2023b) to query GPT-3.5 for paraphrase. The examples of the three paraphrases can be found at Appendix B.

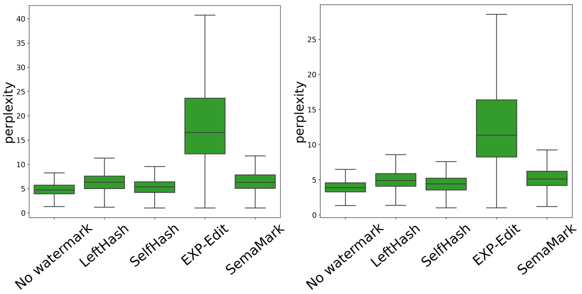
Evaluation metrics and hyper-parameters. We use F1 score with best threshold and ROC-AUC to measure the performance of the watermark detection. All the metrics are calculated based on at least 500 watermarked samples and 500 non-watermark samples. The length of watermarked samples before paraphrase and non-watermark samples is 200 ± 25. In generation, we set $\gamma = 1/4$ for LeftHash, SelfHash and SemaMark. In detection, we set $\gamma = 1/3$ and $\delta = 2$ based on the validation set in Section 4.4(b). In SemaMark, we set $m = 15$, $Q = 15$, $K = 5$ for OPT-2.7B and $K = 4$ for OPT-6.7B.

4.2 Main Results

In this subsection, we demonstrate the robustness of the proposed SemaMark under paraphrase by comparing it with three baseline methods on two backbone models. We first generate watermarked texts and use three paraphrase methods to remove the watermarks. The detection performance of both texts with and without paraphrase is reported in Table 1. As we can see, before paraphrase, all the watermarked methods have good detection performance. After paraphrase, SemaMark has the best detection performance most of the time across all the backbone models and all the paraphrase methods, which suggests that our method is more robust against paraphrase.

In detail, by round-trip translation, the paraphrase reduces the detection ability of baseline methods effectively, while the watermark of SemaMark is robust. Under round-trip translation, the best ROC-AUC of baselines is 0.9091 on OPT-2.7B and 0.8807 on OPT-6.7B, respectively. But ROC-AUC of SemaMark is 0.9692 and 0.9308, which is at least 0.05 higher than all the baseline methods. Similarly, under paraphrase of GPT-3.5, SemaMark is better than all the baselines. The best baseline performance under GPT-3.5 is 0.9392 in ROC-AUC on OPT-2.7B and 0.8990 in ROC-AUC on opt-6.7B, but SemaMark has higher AUC-ROC of 0.9406 and 0.9377. For Dipper, we note that all methods are robust to Dipper since it does not significantly reduce the detection performance. However, SemaMark is still one of the most robust. On OPT-2.7B, it performs best in ROC-AUC, while on OPT-6.7B, it has the best F1 score. From Table 1, the results show an obvious improvement of SemaMark in robustness. This implies that using semantics as the seed for the partition function is effective under paraphrase.

4.3 Text Quality



(a) OPT-2.7B (b) OPT-6.7B

Figure 3: Text quality (perplexity)

Watermark should not compromise the generation quality of LLMs. In this subsection, we compare the text quality by calculating perplexity and demonstrate that our watermark has almost no influence on the generated quality. Perplexity measures the likelihood that a sentence is generated by one model. Lower perplexity means the watermarked text is more predictable. In other words, it is more consistent with the reasoning of the given model. In Figure 3, we use OPT-6.7B with no watermark to get perplexity for all the watermarked methods. All the results in Figure 3 are calculated without paraphrase, because the generation quality of text is not related to paraphrase. From Figure 3a on OPT-2.7B, we can see that our watermark, LeftHash and SelfHash have almost no influence on the generation quality. They has perplexity at around 6 which is similar as the generated text without watermark. Instead, EXP-Edit has much higher perplexity, which means that EXP-Edit changes the generated text in an aggressive way and much reduces the generation quality after watermarking. This is probably because EXP-Edit adjusts the logits on the whole vocabulary. From Figure 3b, we can draw similar conclusions for OPT-6.7B. EXP-Exit also increases the perplexity by around 10, while the average perplexity of LeftHash, SelfHash and ours is around 1 higher than the non-watermarked generated text. In summary, our SemaMark can keep the quality and robustness simultaneously.

Figure 5: Text quality (perplexity)

4.4 Ablation Study

In this subsection, we study the influence of the length of the sequence we use for generating one semantic value and the sensitivity of the partition function.

***a)* Length of previous sequence tokens, m.** In the first step of SemaMark, i.e., *weighted embedding pooling*, we use the semantic of the previous m tokens to get the more stable embedding. But if the length of the sequence is too long, it will also hurt the robustness. In Figure 4, we test watermark on OPT-2.7B with different m and draw the ROC-AUC. The results show that before $m = 15$, ROC-AUC is in the trend of increase as the m changes. But when $m > 15$, ROC-AUC becomes fluctuating. It is possibly because that the distant tokens will include more change after paraphrase as we mentioned in Section 3.1. Another possible reason is that in the beginning of generation for the first m tokens, the number of previous tokens is smaller than m and NE-Ring can only use the embeddings of limited tokens for prediction, which may be unstable. Thus, too long or too short sequence will hurt the robustness of SemaMark against paraphrase. In our experiments, we choose $m = 15$ for all the settings.

***b)* Q-offset detection** In this subsection, we show that the effectiveness of the proposed Q-offset detection. In Figure 5a, we demonstrate the change of ROC-AUC of SemaMark with different Q in offset detection under three different paraphrases. Q-offset detection searches the highest z-statistics from $-Q$ to Q as the Q-offset score. From Figure 5a, we can see that when Q increases, ROC-AUC first increases and decreases after Q is around 15. When $Q < 15$, the offset can help correct the errors of semantic values close to the boundary. Compared with detection without offset, i.e. $Q = 0$, ROC-AUC of SemaMark is much better, which means that the offset can help to solve the errors of semantic values around the boundaries that are more vulnerable to paraphrases. When $Q > 15$, the correction of this error is limited, because the offset will also increase the Q-offset score of negative samples as it also searches the highest z-statistics of negative samples. On the other hand, the computation cost will also increase if Q is too large because it has to search more possible q. In practice, we set $Q = 15$ in all the experiments, which can effectively reduce the influence of the errors of semantic values at the boundaries.

Since the Q-offset detection searches the highest green word fraction, the fraction of green list word of non-watermarked text will be higher than the γ that we used to randomly select the green list. Thus, it is not accurate to use the original γ for z-statistics. We treat γ as a hyper-parameter and use a validation set to select its value. As shown in Figure 5b, the detection performance of SemaMark under paraphrases of Dipper and GPT-3.5 will reach the highest when γ is around $1/3$, while it will continue to increase under paraphrase. In practice, we set $\gamma = 1/3$ for Q-offset detection.

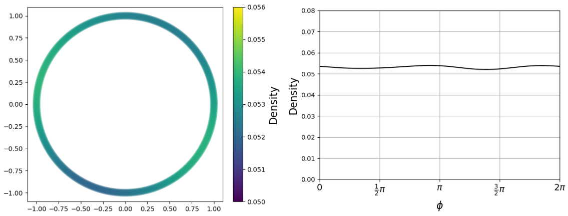
***c)* Sensitivity of partition function.** As we mentioned, the partition function is sensitive to any change of the input because it only uses the input as the seed of the random generator. To validate its sensitivity to continuous embeddings, we adopt the embedding vector as the input to show that, with tiny change of the embeddings, the partition of vocabulary can be very different. We propose a hash method based on `md5sum` (Deepakumara et al., 2001) to adopt the partition function by transforming the continuous embeddings to an integral seed. We use 1000 sequences to test the sensitivity. For each sequence embedding, we first get a green list from the partition function. Then we change one dimension of the embedding by only 1e-5 to get a new partition result. The overlapping of the green list before and after changing is 24.99% on the average of 1000 sequences. It is consistent with γ we use to watermark, because the random partition with the changed embedding is independent from the original one. It means the partition function is sensitive to any small change in its input. Instead, after we use NE-Ring to discretize the embeddings, the overlapping of green list after changing embeddings by 1e-5 is 100%, which means the discretization can effectively handle this change. In practice, SemaMark can provide the tolerance that is much larger than 1e-5, which makes the watermark more robust under paraphrase. With the improvement of Q-offset, the detection of SemaMark is more robust and effective.

	ROC-AUC			F1 with best threshold		
	LeftHash	SelfHash	ours	LeftHash	SelfHash	ours
LLaMA-7B	0.819	0.838	0.846	0.748	0.774	0.781
LLaMA2-7B	0.811	0.841	0.872	0.749	0.773	0.810

Table 2: Watermark detection results under different model size.)

***d)* Model size.** To show the robustness of our method on different model sizes, in this section, we also test the watermark under round-trip translation paraphrase on LLaMA-7B and LLaMA2-7B, which have larger size and different architectures. As indicated in Table 3, our approach consistently exhibits the highest robustness against paraphrasing. Specifically, in the LLaMA2-7B model, SemaMark significantly outperforms the baseline models, achieving an increase of 0.06 and 0.03 in ROC-AUC. Similarly, in the LLaMA-7B model, our method shows superior performance with an increase of 0.027 and 0.009 in ROC-AUC.

4.5 Distribution on NE-Ring based on CL



(a) NE-Ring (b) Distribution on ϕ

Figure 6: Visualization of NE-Ring

In this subsection, we demonstrate that Contrastive Learning can help evenly distribute the semantics on the NE-Ring. The even distribution can help the sequences reach all possible semantic values and provide more diverse semantic values to prevent the watermark from being cracked by counting token frequency. In Figure 6a, we use Gaussian density estimation (Chen, 2017) to get the distribution of the semantics on the NE-Ring **before** discretization. We use different colors to show the density. The NE-Ring in Figure 6a shows that, the distribution is uniform. All the density is between 0.052 and 0.054. We further plot the density based on the polar angle ϕ in Figure 6b where the density has almost no change on all the polar angle from 0 to 2π. This implies that the training based on Contrastive Learning can ensure the semantics will reach all possible discrete values. It can prevent the case where the discrete values will gather in some discrete sections and produce monotonous vocabulary partitions. As a result, it can protect the watermark from being cracked by counting token frequency.

5 Conclusion

In this paper, we use the semantic information for watermarking to enhance the robustness against paraphrase. The existing watermark methods use the matching between the previous tokens and the partition vocabulary. This matching can be easily broken by paraphrase. However, we construct the mapping between the semantics and the vocabulary. In this way, the semantics will stay stable under paraphrase and the robustness of watermark can be enhanced. To make use of semantics, we propose SemaMark to discretize the embedding space on NE-Ring and propose a training method based on CL. In addition, we use Q-offset detection to further advance the robustness by increasing the tolerance of the semantic values close to the discrete boundary. In experiments, we demonstrate our method can perform much better compared with baseline methods under paraphrase while having little influence on the generation quality.

6 Limitations

In some cases, the customers may rely on some API-based LLMs and do not have the access to the embeddings and the permission to modify the logits during generation. Although our watermark method can effectively detect the LLM-generated content and increase the detection success rate under paraphrase, it is not applicable for black-box LLMs. The second weakness of our method is that the NE-Ring is dependent on the semantic embedding of LLMs. For each LLM, we need to train a specialized EN-Ring, which might be inflexible if we want to produce a general model for NE-Ring or fine-tune the LLMs. Despite the weaknesses, our method is successful in the problem of robustness under paraphrase. In the future work, we will continue to extent our method into black-box LLMs and a universal model that does not require customized training for various specific LLMs.

Potential risk. Our discussion about the robustness might provide motivation for the attackers to find other methods like adaptive attack. Although we provide robustness under paraphrase, if the unauthorized people propose possible attack method focusing on the green-list based watermark from other perspectives, the detection rate for LLM-generated texts are still possible to be reduced.

A More details on experimental settings

All the baseline models, backbone models and datasets we use are open source and available for academic purpose. For backbone models, we use the open-sourced model from Huggingface[1]. The implementation is based on Pytorch[2] framework and also depend on packages including NLTK (Bird et al., 2009) and Numpy (Harris et al., 2020). For baseline methods, we use the released official code from the authors. For paraphrase models, we use OPUS-MT translation model and Dipper on Huggingface repository[3], and API of ChatGPT[4].

B Examples of paraphrases

In Table 3, we provide the examples of three paraphrases.

Abstract

Large language models are rapidly replacing help forums like StackOverflow, and are especially helpful to non-professional programmers and end users. These users are often interested in *data-centric tasks*, like spreadsheet manipulation and data wrangling, which are hard to solve if the intent is only communicated using a natural-language description, without including data. But how do we decide how much data and which data to include in the prompt?

This paper makes two contributions towards answering this question. First, we create a dataset of real-world NL-to-code tasks manipulating tabular data, mined from StackOverflow posts. Second, we introduce a novel *cluster-then-select* prompting technique, which adds the most representative rows from the input data to the LLM prompt. Our experiments show that LLM performance is indeed sensitive to the amount of data passed in the prompt, and that for tasks with a lot of syntactic variation in the input table, our cluster-then-select technique outperforms a random selection baseline.

1 Introduction

Code-generating large language models (LLMs) promise to empower end users interested in *data-centric tasks*, ranging from string manipulations in spreadsheets to data cleaning and analysis in computational notebooks. For example, consider the following task on tabular data: given a column with *full names*, generate a new column with *user names*, by combining the first initial and last name, in lowercase. This task can be solved by a Pandas program that: 1) splits the full name into a list of strings, 2) extracts the first and last string from the list, 3) converts both to lowercase and joins the first letter of one string to the other as shown in Figure 1. The challenge in generating this program is that input data rows have varied formats, *e.g.* most rows only have two names ("John Smith"), but some have multiple middle names ("Jake L Woodhall", "Jo Anna Emily Gray"). If an LLM prompt does not include any data or only includes rows with two names, the LLM is more likely to generate a program that does not generalize (*e.g.* one that extracts the last name as the *second* element of the list instead of *last*).

In this paper, we focus on solving such tasks that involve multi-step computations on the input columns to generate additional columns. Towards this goal, we mine StackOverflow to construct a new dataset, dubbed SOFSET, of data-centric tasks, equipped with a natural-language query and a small input table. Using this dataset, we conduct experiments on generating Pandas programs using GPT-4 and an open-source alternative CODELLAMA, with the goal of analysizing LLMs' sensitivity to the amount of input data provided in the prompt.

Unlike input tables in StackOverflow posts, real-world data tables are often large, hence sending the entire table to the LLM is likely impractical, expensive, or detrimental to performance. *How do we best convey the structure of a large input table to the LLM?* To address this question, we propose a *cluster-then-select* prompting technique that clusters input rows based on their syntactic structure and then selects representative rows from each cluster; *e.g.* in our Figure 1 example, the technique would include a row for each format of middle names. To evaluate this technique, we perform experiments on SOFSET augmented with larger input tables extracted from Kaggle.

In summary, this paper contributes:

- a real-world dataset of complex tasks for evaluating data-centric code generation;
- a *cluster-then-select* technique for selecting rows to prompt with, from large input tables;
- an analysis that shows LLMs are sensitive to the data quantity, choice and position of rows.

Figure 1: An overview of our *cluster-then-select* prompting technique. The input is a data table and natural language query. The rows in the data table are first clustered based on their syntactic structure (in this case the name format). We depict different clusters using distinct colors. The most representative rows are then selected from each cluster to create a prompt to pass to the model. Finally, the generated completion is used to create an output column.

2 Related Work

Large language models for tabular data Code-generating LLMs like CODEX (Chen et al., 2021), INCODER (Fried et al., 2022) and PALM (Chowdhery et al., 2022) have been fine-tuned for code-specific tasks and adapted for data-centric domains like SQL (Trummer, 2022; Rajkumar et al., 2022). (Li et al., 2020) explore the ability of models like BERT to perform entity matching on tabular data. (Narayan et al., 2022) use GPT-3 for data cleaning, error detection and entity matching tasks. (Hegselmann et al., 2023) focus on tabular classification tasks and explore parameter-efficient LLM tuning.

Prompting for data-centric tasks Prompting LLMs has been quite effective in practice across domains (Reynolds and McDonell, 2021; Wang et al., 2022; Liu et al., 2023b). In this paper, we ask the question: *how does data context impact code generation for data-centric tasks?* Previous works have explored prompting with data: (Jain et al., 2022) provide both input and expected output tables (which might not be available in a realistic setting). (Gemmell and Dalton, 2023) prompt with transformed tables after filtering out rows that are not relevant, for their question-answering tasks. (Ye et al., 2023) decompose a huge table into a smaller one, and convert a question into simpler sub-questions for tabular question-answering tasks. (Hegselmann et al., 2023) serialize data tables into a textual representation for tabular classification tasks. These works prompt LLMs for data analysis, classification and wrangling tasks (in-place data transformations) whereas we focus on multi-step data manipulation. We propose a new *cluster-then-select* prompting technique that clusters the input data and adds representative rows to the prompt. (Yin et al., 2022) focus on data-centric tasks in computational notebooks.

3 The SOFSET Dataset

We collect a new dataset fashioned from real-world data-centric tasks from StackOverflow (SOFSET). We sample tasks deterministically from the highest rated posts with the tag "ExcelFormulas" in StackOverflow (as of March 2022). These tasks are representative of real problems spreadsheet users face frequently since they correspond to the highest-rated posts. We manually check that the posts are genuine tasks and also remove post identifiers for anonymization. This gives us a total of 201 tasks.

3.1 Dataset Annotation

Each datapoint in our dataset is annotated with a concise textual query, a data input (column-major-flat table), an expected correct output (extra columns), a pandas solution and metadata. We manually write the textual queries, summarising the original verbose StackOverflow question. Each query is annotated and verified by at least three internal annotators. For the data input, we use the table from the original StackOverflow post (if present), and manually add extra rows and corner cases until we have at least 10 rows. Since the natural language query and tabular data are not verbatim copies from StackOverflow and we have a different target language for generation (Pandas instead of Excel Formulas), the evaluation data should not be present in the training data. We choose Pandas as the target language since LLMs are especially good at generating Python but our methods and dataset are programming-language agnostic.

3.2 Dataset Properties

What makes our dataset different from existing ones? First, our dataset consists of complex data-centric tasks with multiple input columns. Python datasets like APPS (Hendrycks et al., 2021) and HUMANEVAL (Chen et al., 2021) are not data-centric. Second, our dataset is larger than existing data-centric datasets: JIGSAW (Jain et al., 2022) and CERT (Zan et al., 2022). JIGSAW has 79 unique tasks (median of 7 data rows) and CERT has 100 unique tasks (median of 3 rows). Our dataset has 201 unique tasks, with a median of 10 rows. The SPIDER dataset (Yu et al., 2018) is a text-to-SQL dataset which focuses on relational query tasks whereas we focus on fine-grained data wrangling and manipulation tasks. Finally, we propose a *taxonomy* of data-centric tasks, classifying them into data-independent (IND), data-dependent (DEP), and external-dependent (EXT), based on the data required to produce a solution.

Data-independent tasks These tasks can be solved using the query alone without any data access. An example is the query "create a new column that includes only the first 5 characters from Filename".

Data-dependent tasks These tasks cannot be solved using the query alone: the model needs access to the input table. For example, the query "create a new column with the number of days between the two date columns" requires data access to identify the correct column names and date format, both absent from the query.

External-dependent tasks These tasks can only be solved with external world knowledge in addition to data access. The query "create a new column that counts how many US holidays are between the dates in Start Date and End Date", requires the model to know about US holidays.

Following this taxonomy, SOFSET consists of 126 IND tasks, 44 DEP tasks and 31 EXT tasks. These tasks span diverse domains including string manipulation, date and time, math, address, and complex conditionals among others.

3.3 Cluster-then-select prompting technique

To solve tasks on large tables, we propose a *cluster-then-select* technique which prompts the model with a representative sample of the input data. In order to capture the syntactic variation in the input data, we rely on an existing tool (Padhi et al., 2018), which takes as input a set of strings and synthesizes a small set of regular expressions (regexes), such that each input string matches one of the regexes. In our example in Figure 1, it would synthesize separate regexes for rows with zero, one and two middle names and hyphenated last name. Names like "John Smith" would belong to the zero middle name cluster and "Jack Will Andres" and "Jo Anna Emily Gray" belong to the clusters with one and two middle names resp. Also, the name "Ash Kelsey-Poe" would belong to the cluster with hyphenated last names. These regexes are then used to cluster the input strings, and we select some number of rows from each cluster. In Figure 1, we pick one row from each of the four distinct clusters (depicted with different colors).

If the input table only has one column, selecting n representative rows based on the clustering results is trivial: simply pick one row each from the top-n most populous clusters. In cases where the input contains more than one column, they may be clustered differently. We then select n rows that together cover as many strings as possible across all the columns. We frame this as a *weighted maximal coverage problem* (max), which can be solved approximately in a greedy manner. In each iteration, the algorithm selects the row whose elements maximize cluster coverage.

Kaggle-augmented dataset In order to evaluate our *cluster-then-select* technique on larger datasets, we expand the 44 data-dependent tasks by adding more rows from open-source Kaggle datasets (kag), bringing the total to 1000 rows. We first identify the data domains in the original SOFSET rows (such as names, numbers, address, date, time etc) and then

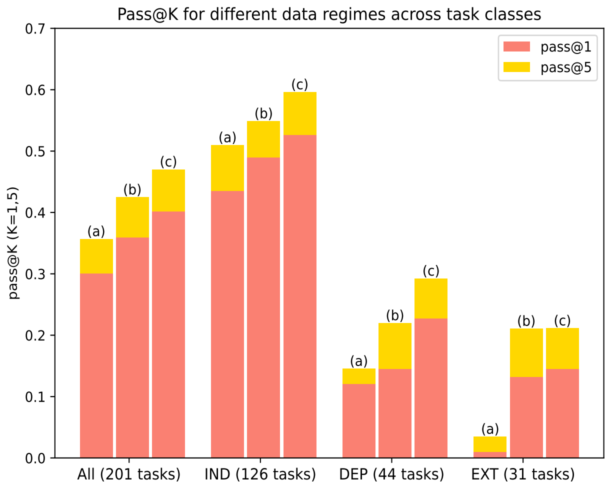

Figure 2: pass@k with (a) no-data, (b) first-row, and (c) ten-rows passed to the model. The leftmost group of bars represent pass@k with all classes followed by separate pass@k for IND, DEP and EXT tasks.

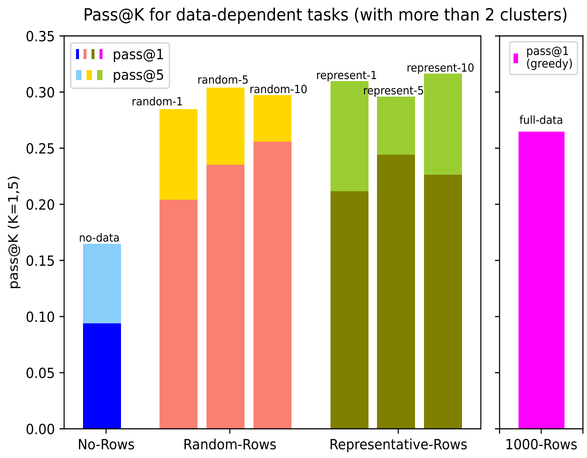

Figure 3: pass@k for 39% (17/44) DEP tasks (with more than two clusters) with no-data, random selection (random-n), representative selection (represent-n) and pass@1 with greedy sampling for full-data (1000 rows).

source comparable open-source Kaggle datasets of the same domain. We further post-process the Kaggle data to maintain the original rows format and ensure that the augmented data is coherent. This introduces greater variation in the original data which increases the number of data clusters. 62% of our DEP tasks have at least two clusters and we have tasks with up to ten clusters. Since the Kaggle data is post-processed and is not tied to the task query in any way, it is unlikely to bias the LLM evaluation by being part of the training data. This larger dataset allows for a thorough evaluation, better mirroring real-world conditions.

4 Evaluation of data-centric tasks

We perform an analysis of the role of data on model performance in data-centric tasks. We first use the original SOFSET dataset to examine three data regimes with increasing amounts of data: (a) no-data (b) first-row and (c) ten-rows and also the taxonomy of task classes of increasing difficulty in terms of data required: IND, DEP and EXT. We then use Kaggle-augmented DEP tasks to compare our *cluster-then-select* technique (which selects representative rows from the top-n most dense clusters) against a random baseline (which selects random rows from the input table). For each data setting, we construct a prompt which contains the task query and selected rows as a pandas dataframe to generate code from GPT-4 as shown in Figure 1. Correctness is reported based on whether the code produces the expected output in terms of pass@k, the probability that at least one of k samples of generated code produces the correct output (Chen et al., 2021). We report all results using GPT-4 with a temperature of 0.5 and the generated completions are evaluated on all rows in the input table. The SOFSET dataset, all the evaluation results and our prototype tool can be found online.[1]

Does model performance vary with the amount of data passed for different task classes? Figure 2 shows the impact of the amount of data on LLM performance, first for the entire dataset and then split by task classes. We see a larger drop in performance with reduced (and no) data on DEP (and EXT) tasks compared to IND tasks. Specifically, the performance gap (pass@5) between first-row and no-data regimes is larger for the DEP and EXT classes (33.8% and 83.5% resp) compared to only 7.1% for IND tasks. The fact that there is any performance drop for IND tasks indicates that having data helps the model even when the problem can be solved independently of data. In the absence of data, almost no EXT task is solved (pass@1) but performance improves when a single row is passed.

Is our cluster-then-select technique effective on larger input tables? We evaluate our *cluster-then-select* technique on Kaggle-augmented DEP tasks (with 1000 rows) since we expect to see the benefit of our approach more clearly on tasks dependent on data. In order to do so, we compare our representative selection strategy against *random* selection where the rows are randomly selected from the in-

---

[1] https://github.com/microsoft/CodeXData

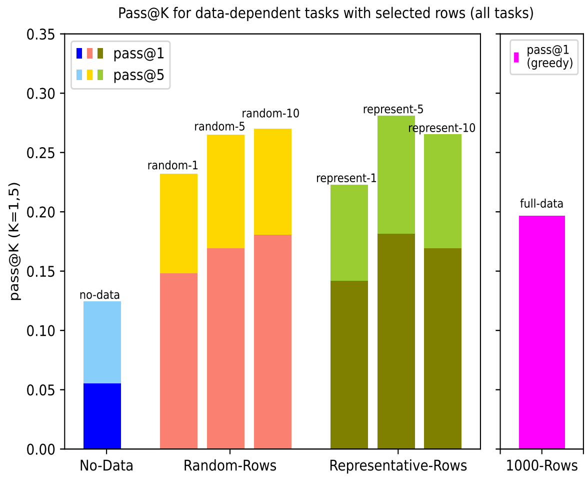

Figure 4: pass@k for all DEP tasks with no-data, and n=1, 5 and 10 rows passed to the model, using random (random-n), representative selection (represent-n). The completions are evaluated on 1000 rows.

put table. Among DEP tasks, we further focus on 17 (out of 44) that have input columns with at least three clusters, since with two clusters or fewer we do not expect to see much difference between the representative and random samples. We also evaluate against two baselines: no-data (0 rows) and full-data (1000 rows). We run the random selection experiments five times.

Figure 3 shows that the model performs best with 10 most representative rows added to the prompt (pass@5 = 0.32 for represent-10). Representative selection performs better than random selection for the same number of rows. Specifically, represent-1 and represent-10 outperform random-1 and random-10 by 8% and 6% resp. In addition, random selection has *high variance*, especially for a small number of rows (*e.g.* pass@1 for random-1 varies from 0.20 to 0.31 across the five runs), which is not surprising, since the random strategy might select rows from different clusters or from the same one. Thus, while random selection gives comparable results on average, our cluster-then-select technique offers a more consistent approach to provide the model a representative sample of the data. Further, the low pass@k for the no-data baseline suggests that our dataset was not part of the training data, as then the model would likely perform well even without data input. We note that while we evaluate on 1000 rows, the same cluster-then-select technique could easily scale to datasets with over 100K rows without much overhead. We also present the evaluation results on all the 44 DEP tasks in Figure 4. We see that represent-5 has the highest pass@k for both k = 1 and 5. Since these results include problems with fewer than three clusters, selection of even 5 representative rows boosts performance. Notably, represent-5 also outperforms random-10.

Does the position of data rows in the prompt also affect performance? For the full-data baseline, we used a longer-context version of GPT-4 (32k) with temperature 0 (*greedy selection to eliminate variance in generations*) for the DEP tasks. The right side of Figure 3 shows pass@1 for this setting with ten runs: we permute the 1000 rows in the dataframe ten times, in order to measure the sensitivity of the model to row positioning. We observe a high variance in pass@1 values, ranging from 0.20 to 0.32 with an average of 0.26. This shows that the position of rows in the dataframe influences completion quality, which aligns with previous findings about positional biases in prompts (Liu et al., 2023a). Surprisingly, the full-data setting (irrespective of row ordering) performs worse than selecting one random row *in some cases* (pass@1 for one random row ranges from 0.12 to 0.27 with an average of 0.20). Note that we only report pass@1 results for the full-data (1000 rows) setting.[2]

5 Conclusion and Future Work

Our work highlights the importance of data for code generation on data-centric tasks and proposes a new dataset for evaluation of data-centric tasks. We show that providing even one data row to the model boosts performance compared to a no-data baseline. Since providing the entire input table is often infeasible, we propose a *cluster-then-select* prompting technique that selects representative rows from the data to be added to the prompt. While randomly selecting rows also performs well, for data with a high degree of syntactic variation, it is more beneficial to add representative rows to the prompt. For future work, handling a broader problem space (*e.g.*, multi-table inputs, hierarchical table inputs) raises interesting challenges.

6 Limitations

We discuss the limitations of our work in terms of the SOFSET dataset, the *cluster-then-select* technique and the models used for evaluation. Although starting from actual user-specified problems gives our results greater alignment with real spreadsheet

---

[2] CODELLAMA results are Figure 6, Figure 7, Figure 8.

user problems, the form that such queries take pose some potential limitations to our analysis. Users usually only show relevant columns of data in their queries when in actuality there might be many more unrelated columns in real spreadsheets. We have seen promising results applying LLMs to data tables with columns that are extraneous to the query but we do not perform a rigorous evaluation of the same. Furthermore, since we have collected only English queries from StackOverflow, our results may not generalize to other languages.

Our cluster-then-select prompting technique is based on the regular expression synthesis algorithm from (Padhi et al., 2018). Given that the clusters for the input data columns are defined by the specificity of this regex synthesis, using a different clustering algorithm could potentially result in a different set of clusters. Finally, since we draw our conclusions from the generations produced by GPT-4, future models might invalidate our conclusions. Furthermore access to models such as GPT-4 cannot be taken for granted and the costs of running our evaluation are considerable. Even open source models like CODELLAMA require GPU resources for evaluation.

7 Broader Research Impact

To the best of our knowledge, research on prompting large language models to solve data-centric tasks with tabular data is infrequent, despite the considerable importance of such scenarios. Solving the problem of how to help LLM reason over large amounts of data is essential to the future of assisted decision making. Generating multi-step programs that require reasoning is the beginning of this journey and to make progress the community needs challenging real-world datasets to evaluate on. By releasing our new dataset, sharing the analysis results of our experiments and releasing our prototype tool[3], we offer valuable benchmarks and a baseline to the wider research community which promises to encourage further exploration.

8 Ethics Statement

There are broad ethical impacts resulting from the creation of AI models that attempt to generate code solutions from natural language descriptions and these are discussed in detail in previous papers including CODEX (Chen et al., 2021), ALPHACODE (Li et al., 2022), and PALM (Chowdhery et al., 2022). These impacts include over-reliance, misalignment between what the user expressed and what they intended, potential for bias and under-/over representation in the model results, economic impacts, the potential for privacy and security risks, and even environmental considerations. All of these considerations also apply to the work in this paper. Our focus is to highlight how the presence of data improves the performance of these models but it is important to note that the quality of the data used in the prompt will impact whether the resulting generation exhibits bias, exposes private data, etc. We explore the overall impact of providing data as part of the prompt but do not conduct a more focused analysis of determining how bias in the prompt data might influence the resulting code generation, a task we leave for future work.

There is the question of the sources of data and of consent to use the data in the manner exhibited in this paper. We have reviewed each of the datasets we have included in this paper to ensure that our use is compatible with the intent of the authors and publishers. Our datasets have also been reviewed by our institution's ethics board to review that this is an ethical use.

This paper does not directly contribute to a tool built on the assumed capabilities of language models to understand data, but nonetheless, it is motivated by their potential applications in such tools. These tools may be deployed in many data applications such as databases, spreadsheets, and business intelligence applications. Depending on the audience of the tool, various interaction design concerns arise. Explainability of the model is a key consideration, and the tool should offer decision support to evaluate mispredictions and potential next steps (Sarkar, 2022). Previous research of non-experts using inference driven tools for data manipulation has shown the importance of tool design in the critical appreciation of the model and its limitations, and in the potential cost of errors (Williams et al., 2020; Sarkar et al., 2015). As an exploratory paper without a concrete application, we do not encounter these issues, but the project has nonetheless been reviewed by our institution's ethics board.

A Community Data License Agreement - Permissive - Version 2.0

This is the Community Data License Agreement - Permissive, Version 2.0 (the "agreement"). Data Provider(s) and Data Recipient(s) agree as follows:

A.1 Provision of the Data

- A Data Recipient may use, modify, and share the Data made available by Data Provider(s) under this agreement if that Data Recipient follows the terms of this agreement.

- This agreement does not impose any restriction on a Data Recipient's use, modification, or sharing of any portions of the Data that are in the public domain or that may be used, modified, or shared under any other legal exception or limitation.

A.2 Conditions for Sharing Data

- A Data Recipient may share Data, with or without modifications, so long as the Data Recipient makes available the text of this agreement with the shared Data.

A.3 No Restrictions on Results

- This agreement does not impose any restriction or obligations with respect to the use, modification, or sharing of Results.

A.4 No Warranty; Limitation of Liability

- All Data Recipients receive the Data subject to the following terms:

THE DATA IS PROVIDED ON AN "AS IS" BASIS, WITHOUT REPRESENTATIONS, WARRANTIES OR CONDITIONS OF ANY KIND, EITHER EXPRESS OR IMPLIED INCLUDING, WITHOUT LIMITATION, ANY WARRANTIES OR CONDITIONS OF TITLE, NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.

NO DATA PROVIDER SHALL HAVE ANY LIABILITY FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING WITHOUT LIMITATION LOST PROFITS), HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE DATA OR RESULTS, EVEN

IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

A.5 Definitions

- "Data" means the material received by a Data Recipient under this agreement.
- "Data Provider" means any person who is the source of Data provided under this agreement and in reliance on a Data Recipient's agreement to its terms.
- "Data Recipient" means any person who receives Data directly or indirectly from a Data Provider and agrees to the terms of this agreement.
- "Results" means any outcome obtained by computational analysis of Data, including for example machine learning models and models' insights.

B Software License Agreement

Algorithm 1 Inference Algorithm

```
Input: Explicit: query $Q$, input table $T$, cardinality $k$. Implicit: completion limit $k_{max}$ (with $k \leq k_{max}$), number $n$ of rows to be selected.
Output: Pair of lists $(C, O)$, with $|C| = |O| \leq k$, of unique completions and their corresponding outputs.
 1: procedure INFER($Q, T, k$)
 2:     $M \leftarrow$ CLUSTER($T$)                  ▷ cluster input rows
 3:     $R \leftarrow$ SELECT($T, n, M$)             ▷ select $n$ representative rows
 4:     $P \leftarrow$ PROMPT($Q, R$)                ▷ prompt creation
 5:     $B, C, O \leftarrow k_{max}, [], []$         ▷ initialize budget, caches
 6:     while $B > 0 \wedge |C| < k$ do
 7:         $c \leftarrow$ LLM($P$)                  ▷ sample completion
 8:         $B \leftarrow B - 1$                     ▷ decrement budget
 9:         $o \leftarrow$ EXEC($c, T$)              ▷ execute against table $T$
10:         if VALIDATE($o$) $\wedge$ ($c \notin C$) then
11:             $C \leftarrow C + [c]$               ▷ append completion to $C$
12:             $O \leftarrow O + [o]$               ▷ append output to $O$
13:     return $(C, O)$
```

C Our Prototype Tool

The high-level workflow of our tool is depicted in Figure 5 and formalized in Algorithm 1. The tool takes as input a query Q expressed in natural language, an input table T as a Pandas dataframe, and the target cardinality k of distinct completions to generate. We set a limit k_{max} on the number of calls to LLM ($k_{max} = 8k$). For our running example, k is 1, Q is "create a new column in lowercase that concatenates the first initial and the last name.", and T is `Data({"Names":["John Smith", "Jack Will Anders", ...]})`. At a high-level, the algorithm first clusters the data in T based on automatically synthesized regular expressions and stores them in a map M (line 2). It then extracts *representative rows* of the table using SELECT (line 3); combines the query Q and the rows R to create a prompt P using PROMPT (line 4); and then queries LLM repeatedly using this prompt until the target completions are reached or we exceed the budget of calls (lines 7-12). Each completion c is executed on the input table (line 9) using an EXEC procedure, and if the completion is new and its output o satisfies a VALIDATE procedure, the two are accumulated in C and O which are then returned. We describe each of the procedures in detail below.

CLUSTER This procedure clusters the rows in the input table T based on their syntactic structure. To capture the syntactic variation among input rows, we rely on an existing tool (Padhi et al., 2018), which takes as input a set of strings and synthesizes a set of regular expressions (regexes) from a restricted class, such that each input string matches one of the regexes. In our example, the

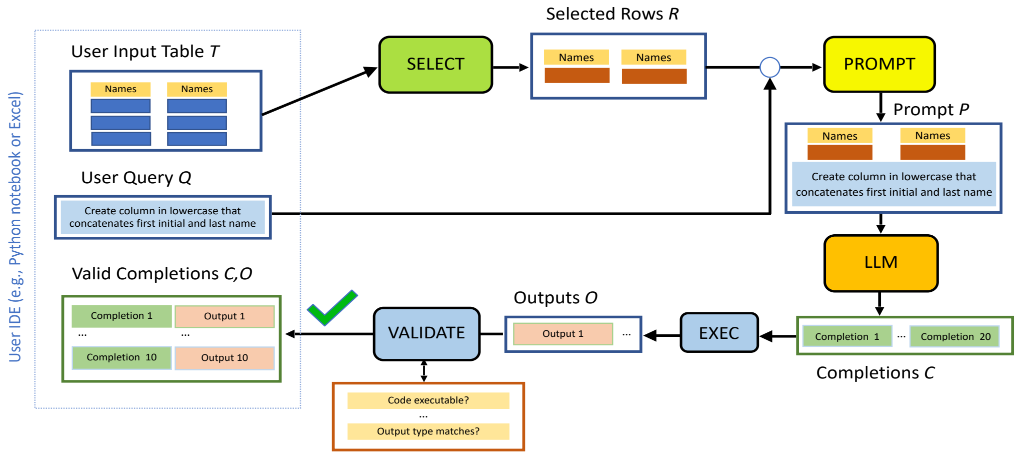

Figure 5: Our tool transforms an input table and a query into a list of valid completions. The input data is used to extract the selected rows R. The resulting rows and query are used to construct a prompt which is fed to a code synthesis LLM, such as GPT-4 or CODELLAMA, generating multiple possible completions. The outputs of these completions are then validated and the first k valid completions (along with the outputs) are returned.

Algorithm 2 Rows Coverage Algorithm SELECT

```
1: procedure SELECT($T$, $n$, $M$)
2:     while $|R| < n$ do
3:         for $r \in T_r \land r \notin R$ do
4:             BEST ← argmax($\sum \{ |c_i| \text{ s.t. } c_i \in M[r] \}$)
                                        ▷ greedily increase coverage
5:         $R \leftarrow R \cup$ BEST
       return $R$
```

tool synthesizes four regexes: `[A-Z][a-z]+[\\s][A-Z][a-z]+`, for rows with no middle name like "John Smith", and similar regexes for rows with dashed last names like "Ashley Kelsey-Poe", and one or more middle names. These regexes are then used to cluster input strings.

SELECT The SELECT procedure selects the top-n most representative rows from the input table. We frame the selection of most representative rows as a *weighted maximal coverage problem*— a well-known NP-complete problem (max) that can be solved approximately using the greedy algorithm in Algorithm 2. The algorithm takes as input the table T, a map M from the rows of the table to the set of clusters covered by the element in each column of the row. It also takes as input the row budget n. The algorithm iterates over all rows in T not already in R (line 3) and in each iteration selects the row whose elements maximize the size of clusters covered (line 4), adding this row to R.

PROMPT The prompt creation procedure PROMPT creates a textual prompt by concatenating the NL query and the representative rows R which are in form of a Pandas dataframe. An example prompt is in Appendix D.3.

LLM The completion procedure LLM queries GPT-4 (or another code-generating model), passing the prompt P and also the predefined stop sequences. We use stop sequences that we have found to allow the LLM to generate at least one solution while typically not using the entire token budget. Note that the LLM needs to produce multiple completions, because it will filter out invalid completions. A naive approach would be to request a single completion, validate it, and repeat the process until k distinct valid completions are obtained; this, however, requires sending the prompt to the LLM every time, which incurs a monetary cost. An alternative approach is to *batch* the completions, *i.e.* request some number b of completions in parallel; if the batch size b is too large, however, this also incurs unnecessary cost, since we are requesting more output tokens than we need. Details in Appendix D.4.

EXEC The procedure EXEC turns each LLM completion into a stand-alone executable program and runs it to obtain the final output o. There are two main challenges to be addressed in this step. First, LLM completions do not have a consistent way of identifying the final output: for example, the last line of the completion might be an expression that computes the output, or an assignment to a `result` variable, or a print statement. So our tool uses a predefined set of rewrite rules, which we developed by analyzing the patterns in completions. The second challenge is that executing arbitrary LLM-generated code poses a security risk; for this reason, we execute completions in a sandbox. Further details are available in Appendix D.5.

Validate The procedure Validate checks that the output value o is a dataframe with the right dimensions. The completions that executed without runtime errors during Exec and passed the output validation are deemed *valid*. Further details are available in Appendix D.6.

D Experimental Details

D.1 CodeLlama Results

We do a performance comparison for no-data, first-row and full-data regimes and the different selection strategies with CodeLlama (Roziere et al., 2023) as the LLM. The results with CodeLlama are presented in Figure 6, Figure 7 and Figure 8.

D.2 Evaluation Metrics

The probability that at least one of k inferred outputs is correct is called pass@k (Chen et al., 2021). More formally, pass@k is the probability that with a sample of k code completions, at least one is correct. To measure this probability empirically for each datapoint, we compute up to m valid programs by sampling from the LLM (GPT-4 or CodeLlama). We count the number s of correct completions, and hence compute an estimate of pass@k as $1 - \binom{m-s}{k}/\binom{m}{k}$ (Chen et al., 2021). By computing $m > k$ completions the estimate has lower variance than by simply computing k completions. Each pass@k on a whole dataset is the average of pass@k over all its datapoints. All evaluation results are averaged over tasks, computing m valid completions to estimate pass@k or pass@$k(X\%)$. In practice, we set $m = 20 * k$ when we report results for $k = 1$ or $k = 5$.

D.3 Prompt Template

For each task, we generate prompts according to the data regimes and selection strategies as described above. An example prompt for the query "Create a new column with the difference in hours, minutes and seconds between the two timestamps in the format HH:MM:SS" with one row selected:

```
import pandas as pd
df = pd.DataFrame()
df['Start'] = ['2/22/2015 1:06:20 PM']
df['End'] = ['2/23/2015 3:08:20 PM']
#Create a new column with the difference in hours, minutes, and seconds between the two timestamps in the format HH:MM:SS
```

Listing 1: Example of a prompt

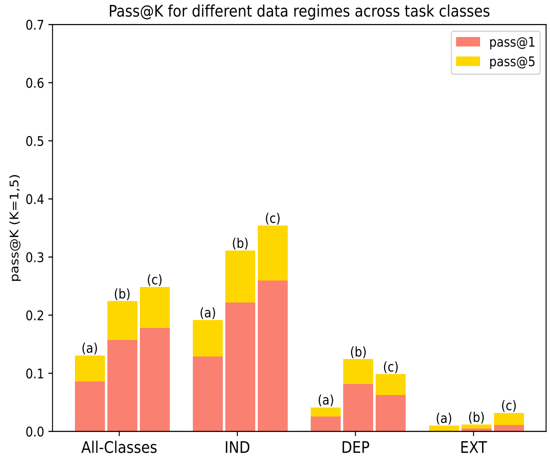

Figure 6: pass@k (for CodeLlama) with (a) no-data, (b) first-row, and (c) full-data (10 rows) passed to the model. The leftmost group of bars represent pass@k with all classes followed by separate pass@k for IND, DEP and EXT tasks. Smaller models have a huge performance drop. But the trend of performance improving with the amount of data passed to the model is seen.

D.4 Generation of Completions

Parallelization. For efficiency, we request multiple completions from GPT-4 per iteration. To try to minimize both inference time and the load on OpenAI's servers, we adapt the batch size to an estimate of the probability that the next completion is valid. The batch size used in each iteration is $n = \min(\lceil r/p \rceil, B, L)$, where $r = k - |C|$ is the number of valid completions still to obtain, B is the remaining completion budget, and L is a parallelization limit enforced by the GPT-4 API. The probability estimate p is updated after each iteration by counting the number of valid and invalid completions in that iteration's batch. Since pass@k is calculated only from valid completions, it is not influenced by either parallelization or batch size adaptation.

Stop sequences. The most effective stop sequence we found that allows GPT-4 to generate at least one solution while not usually using the entire token budget is a blank line followed by a line comment; i.e. `\n#`. Further, to keep GPT-4 from generating what appears to be the rest of a forum post after a code snippet, we also use the stop sequence `</code>`.

Completion cleanup. Since GPT-4's training data likely contains forum posts, some completions would raise `SyntaxError` exceptions when executed due to formatting artifacts, and therefore be invalid. Instead, to make the most of the com-

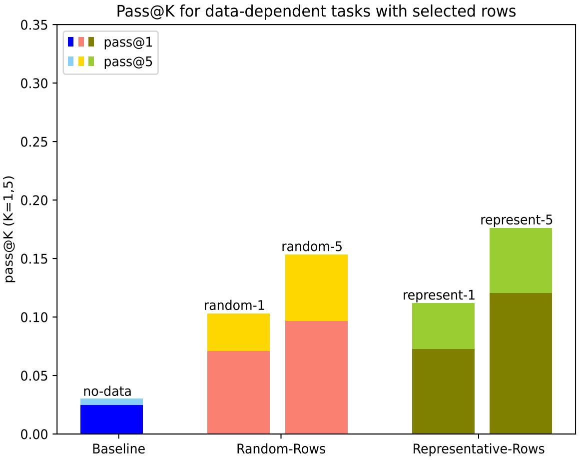

Figure 7: pass@k (for CODELLAMA) for all 44 DEP tasks with no-data, and n=1 and 5 rows passed to the model, using random (random-n) selection, representative selection (represent-n) and full-data (1000 rows). Completions are evaluated on 1000 rows.

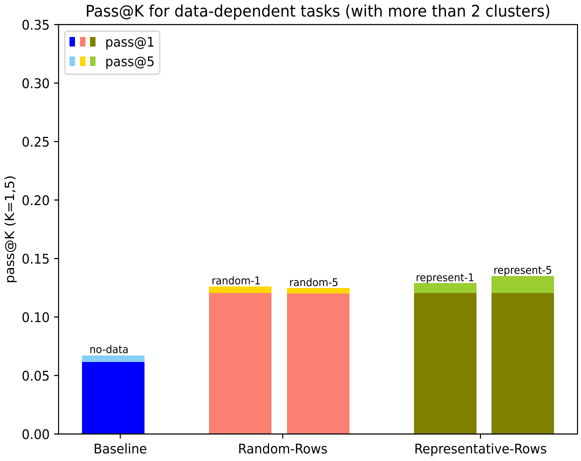

Figure 8: pass@k (for CODELLAMA) for 17 out of 44 DEP tasks (more than two clusters) with no-data, random selection (random-n) and representative selection (represent-n). Completions are evaluated on 1000 rows.

pletion budget, we replace formatting artifacts *i.e.* we replace HTML escape sequences such as `<` and `"` with Python operators and delimiters. Cleanup also removes unnecessary whitespace, blank lines, comments, and truncates completions at `\n#` when it appears after executable code.

D.5 Execution of Completions

Rewriting. Completions returned by GPT-4 do not clearly indicate which variables or expressions are intended to be the answer to a query. This must be inferred from the shape of the code. We found that an effective way to identify and expose the likely answer is to search backwards to find the last unindented (i.e. top-level) statement that has one of a few forms, and rewrite the completion so that its last statement is an assignment to a fresh identifier `var_out`. The statement forms and rewrites are

- `var = expr`: append the statement `var_out = var` to the completion.
- `var[expr_i] = expr`: append the statement `var_out = var` to the completion
- `print(expr, ...)`: replace this statement and the rest of the completion with `var_out = expr`
- `expr`: replace this statement and the rest of the completion with `var_out = expr`

Rewriting also inserts `import` statements for common libraries (e.g. `import numpy as np`). The rewritten completion is appended to the code that defines the input dataframe to create a complete program. The program and output variable `var_out` are sent to a sandbox for execution.

Sandboxing. Because of security risks inherent in running the LLM-generated code, we run completed programs in a sandbox. Our sandbox is a JavaScript web service that runs Python programs in Pyodide (Droettboom et al., 2022), a Python distribution for WebAssembly. While Python programs running in Pyodide have access to the host's network resources, they at least are isolated from other host resources including its filesystem, offering some level of protection from malicious or accidentally harmful completions. After running the code, the sandbox returns the value of `var_out`.

D.6 Validation of Completions

For a completion to be considered a correct solution in the calculation of pass@k, its actual output must match the expected output. Matching cannot be the same as equality and still conform to a reasonable notion of correctness; for example, the natural breakdown of a solution might generate intermediate columns in the actual output that are not in the expected output. The actual output is allowed to vary from the expected output in the following ways and still match the expected output:

- Extra columns
- Different column order
- Different column headers

- Number expected; actual is a number within small relative error (default 0.01)
- Number expected; actual is a string that parses as a number within small relative error
- Boolean expected; actual is number 0 or 1
- Boolean expected; actual is a string that represents a truth value
- String expected; actual is a string that differs only in case

Allowed string truth value representations, allowed relative error, and whether string matching is case-sensitive are (optionally) overridden per data point as appropriate.

A Novel Paradigm Boosting Translation Capabilities of Large Language Models

Abstract

This paper presents a study on strategies to enhance the translation capabilities of large language models (LLMs) in the context of machine translation (MT) tasks. The paper proposes a novel paradigm consisting of three stages: Secondary Pre-training using Extensive Monolingual Data, Continual Pre-training with Interlinear Text Format Documents, and Leveraging Source-Language Consistent Instruction for Supervised Fine-Tuning. Previous research on LLMs focused on various strategies for supervised fine-tuning (SFT), but their effectiveness has been limited. While traditional machine translation approaches rely on vast amounts of parallel bilingual data, our paradigm highlights the importance of using smaller sets of high-quality bilingual data. We argue that the focus should be on augmenting LLMs' cross-lingual alignment abilities during pre-training rather than solely relying on extensive bilingual data during SFT. Experimental results conducted using the Llama2(Touvron et al., 2023) model, particularly on Chinese-Llama2(Cui et al., 2023) after monolingual augmentation, demonstrate the improved translation capabilities of LLMs. A significant contribution of our approach lies in Stage2: Continual Pre-training with Interlinear Text Format Documents, which requires less than 1B training data, making our method highly efficient. Additionally, in Stage3, we observed that setting instructions consistent with the source language benefits the supervised fine-tuning process. Experimental results demonstrate that our approach surpasses previous work and achieves superior performance compared to models such as NLLB-54B(Team et al., 2022) and GPT3.5-text-davinci-003, despite having a significantly smaller parameter count of only 7B or 13B. This achievement establishes our method as a pioneering strategy in the field of machine translation.

1 Introduction

Translation capabilities of large language models (LLMs)(Brown et al., 2020; Chowdhery et al., 2023; Touvron et al., 2023) in machine translation (MT) tasks have been explored extensively in previous research(Jiao et al., 2023; Zeng et al., 2023; Chen et al., 2023; Xu et al., 2023; Yang et al., 2023; Zhang et al., 2023). However, achieving significant improvements in translation quality through supervised fine-tuning (SFT) strategies has proven challenging. Traditionally, machine translation relies on vast amounts of parallel bilingual data, but SFT only requires a small amount of high-quality bilingual data, highlighting a crucial distinction. It is a naive approach to consider using vast quantities of parallel bilingual data during SFT. However, experiments have shown that increasing the data volume yields limited improvements in quality and even leads to performance degradation on certain test sets. **Thus, the question arises: are extensive parallel bilingual data useless in SFT, or are they being misused?**

In this paper, we propose a novel training paradigm, consisting of three stages, to boost the translation capabilities of LLMs. Our contributions include refining the training strategy for downstream tasks and emphasizing the enhancement of LLMs' cross-lingual alignment abilities during pre-training. These contributions address the limitations observed in previous research. Our training paradigm comprises the following stages:

Stage 1: Continual Pre-training using Extensive Monolingual Data. Consistent with previous findings(Xu et al., 2023), we validate the effectiveness of monolingual data augmentation. Specifically, we perform SFT on a Chinese-Llama2(Cui et al., 2023) model, which undergoes monolingual data augmentation, thereby demonstrating improved translation capabilities.

Stage 2: Continual Pre-training with

June 16-21, 2024

Sentence-aligned Parallel Data. We construct interlinear text format from sentence-aligned bilingual parallel data and utilize them for continual pre-training of LLMs. Experimental results demonstrate the critical importance of this stage, resulting in a significant improvement in translation quality, particularly for English-Other translations. Stage 2 stands as a pivotal contribution in our paper, requiring less than 1B training data, thereby enhancing training efficiency.

Stage 3: Leveraging Source-Language Consistent Instruction for Supervised Fine-Tuning. In SFT, we discover that using instruction aligned with the source language of the translation notably improves performance. Leveraging source-language consistent instructions during SFT yields significant enhancements.

In summary, we introduce a three-stage training paradigm, highlighting the effectiveness of secondary pre-training, continual pre-training with interlinear text format documents, and leveraging source-language consistent instruction for supervised fine-tuning. These contributions address the limitations observed in previous research and pave the way for improved translation quality.

2 Related Work

2.1 Large Language Models

Foundation Model Foundation Model, a product of pre-training, is a prominent type of Large Language Model. It has gained substantial recognition in recent years for its impressive capabilities in natural language processing tasks. The most prevalent architectural framework for such models is the Transformer, which employs a series of self-attention mechanisms to process input text efficiently.

Among the state-of-the-art Large Language Models, notable examples include GPT-3(Brown et al., 2020) and Llama2(Touvron et al., 2023). These models have been widely lauded for their exceptional proficiency in understanding and generating natural language text. They showcase the remarkable potential of Foundation Models, pushing the boundaries of language processing and setting new benchmarks in various applications.

Instruct/Chat Model Instruct/Chat Model, a variant of Large Language Models, is specifically developed through the process of Supervised Fine-Tuning (SFT). Unlike Foundation Models, which are pre-trained, Instruct/Chat Models undergo additional supervised training to enhance their performance in specific tasks such as instruction following or conversational dialogue.

Supervised Fine-Tuning involves training the model on labeled datasets, where human annotators provide examples of desired input-output behavior. This approach enables Instruct/Chat Models to learn task-specific skills and exhibit improved performance in situations that require language understanding, generation, and interaction.

Noteworthy advancements have been observed in Instruct/Chat Models, with notable examples including models like ChatGPT. These models have exhibited remarkable outcomes in conversational scenarios, demonstrating their potential in enabling interactive and engaging human-like conversations.

2.2 Machine Translation Task

Machine Translation Task refers to the process of automatically translating text from one language to another using computational methods.

Traditional Methods Traditional machine translation methods primarily rely on encoder-decoder(Vaswani et al., 2017) models, where an encoder converts the source language sentence and a decoder produces the translated sentence. These methods heavily depend on large bilingual parallel corpora for training, aligning source sentences with their corresponding translations. Data augmentation(Sennrich et al., 2016; Wei et al., 2023) is a common practice in traditional machine translation. Some studies(Gu et al., 2018; Ghazvininejad et al., 2019; Wang et al., 2021; Guo et al., 2021; Yu et al., 2021) also investigate transforming them into parallel architectures to speed up inference efficiency.

LLM-based Methods In recent years, Language Model (LM)-based approaches have gained attention in the field of machine translation. These approaches leverage pre-trained language models, such as the GPT (Generative Pre-trained Transformer)(Brown et al., 2020; Chowdhery et al., 2023; Touvron et al., 2023) series, and adapt them for translation tasks.

One line of LLM-based methods focuses on zero-shot or few-shot translation by incorporating in-context learning(Hendy et al., 2023). By conditioning the LLM on a source sentence, the model can generate translations in the target language without explicitly using parallel data. This approach

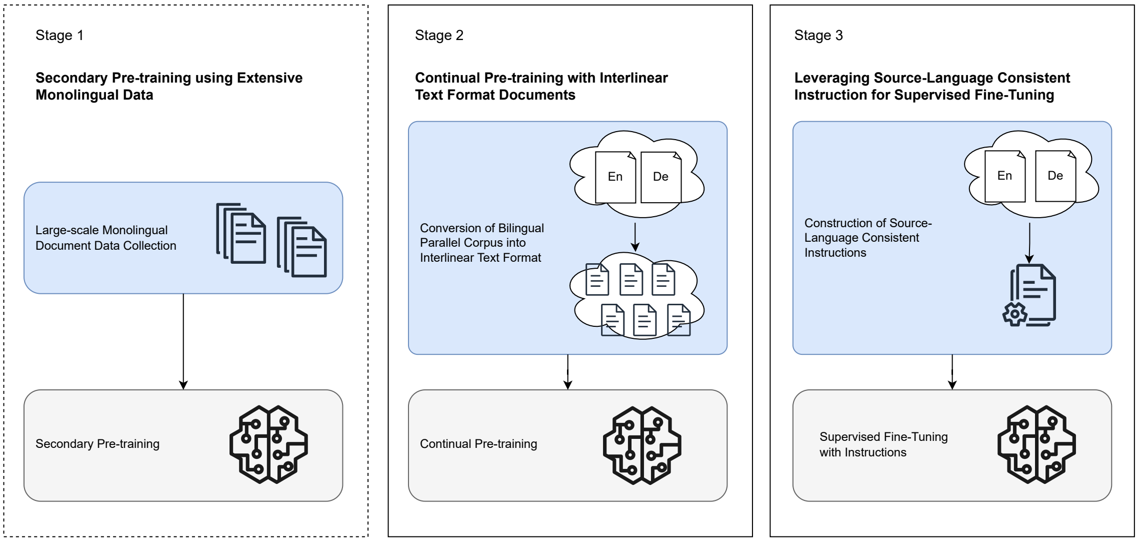

Figure 1: The overall of our approach. Stage 1: Secondary Pre-training using Extensive Monolingual Data. Stage 2: Continual Pre-training with Interlinear Text Format Documents. Stage 3: Leveraging Source-Language Consistent Instruction for Supervised Fine-Tuning. *It should be noted that Stage 1 is considered non-essential.*

has shown promising results in enabling translation for language pairs with limited or no parallel resources.

Another approach involves using a small amount of high-quality bilingual parallel data to construct translation-guiding instructions. These instructions explicitly define the translation behavior by providing source-language consistent cues during the supervised fine-tuning (SFT) process. By utilizing these specially crafted instructions, the LM can be fine-tuned to perform translation more accurately and robustly.

Overall, LLM-based methods present alternative approaches to machine translation, exploring the potential of leveraging pre-trained models and incorporating limited parallel resources or high-quality instructions to enhance translation quality.

3 A New Training Recipe

We propose an innovative training strategy to enhance the translation capabilities of Large Language Models. As shown in Figure 1, our approach consists of three stages: (1) Secondary Pre-training using Extensive Monolingual Data, (2) Continual Pre-training with Interlinear Text Format Documents, and (3) Leveraging Source-Language Consistent Instruction for Supervised Fine-Tuning.

3.1 Stage 1: Continual Pre-training using Extensive Monolingual Data

In this stage, our aim is to enhance the training of large language models (LLMs) by utilizing diverse monolingual data. Currently, existing large models, such as Llama, are primarily pre-trained on English-centric corpora, resulting in relatively weaker comprehension and generation abilities in non-English languages. To expand the multilingual generation capabilities of LLMs, we suggest an incremental pre-training approach using extensive monolingual data.

It is important to note that this stage primarily focuses on enhancing the intrinsic multilingual capacity of LLMs. While it is inherently related to machine translation tasks, it is not essential. On the one hand, we can select an existing LLM that already demonstrates robust multilingual capabilities as the base model for further training. On the other hand, even LLMs with limited multilingual support can benefit from the subsequent stages outlined in our methodology.

3.2 Stage 2: Continual Pre-training with Sentence-aligned Parallel Data

Interlinear Text Format Interlinear Text Format are a specific type of parallel text resource that consists of source sentences and their corresponding translations displayed in a aligned format. Each source sentence is accompanied by its translation, typically presented word-by-word or phrase-by-phrase, to facilitate a clear interlingual correspondence. We build the Sentence-aligned Parallel Data into this format. See Figure 2.

Utilizing Interlinear Text Format offers several advantages for language understanding and trans-

Figure 2: Interlinear Text Format Documents

lation tasks. Firstly, these data provide explicit linguistic alignment at a fine-grained level, enabling the model to capture syntactic and semantic correspondences across languages. This aligns closely with the goals of machine translation, as it facilitates accurate encoding of source language information and improves the quality of generated translations. Additionally, interlinear data contributes to the learning of interlingual representations, allowing the model to better understand the relationship and transferability between languages.

Continual Pre-training To leverage the benefits of Interlinear Text Documents, we propose a Continual Pre-training strategy based on the LoRA(Hu et al., 2021) (Low-Rank Adaptation of Large Language Models) framework. LoRA is a robust and effective pre-training approach for language models, introduced in recent research.

By leveraging the inherent alignment information present in Interlinear Text Documents, the model learns to align and generate translations that maintain syntactic and semantic consistency with the source sentences. This continual training process allows the model to progressively improve its ability to capture cross-lingual correspondences, resulting in enhanced translation quality.

3.3 Stage 3: Leveraging Source-Language Consistent Instruction for Supervised Fine-Tuning

Source-Language Consistent Instruction In the field of machine translation, "Source-Language Consistent Instruction" refers to the practice of constructing translation instructions that maintain consistency with the source language, aiming to achieve better results. This approach involves generating instructions that are closely related to the source language. By providing more accurate and clear guidance for supervised fine-tuning of models, this technique enhances translation quality.

Figure 3: Instruction Format

To illustrate this concept, let's consider translations in English⇔Chinese and English⇔German. Traditional approaches typically employ a standardized English-Fixed instruction such as "*Translate this sentence from the source language to the target language:*". However, in Source-Language Consistent Instruction, the instruction varies based on the language pair. For English-to-Chinese translation, the instruction would be "把这句话从中文翻译成英文： " (Translate this sentence from Chinese to English). Similarly, for German-to-English translation, the instruction would be "*Übersetzen Sie die folgenden Sätze vom Deutschen ins Englische:*" (Translate the following sentences from German to English). By utilizing language-specific instructions, there is a semantic consistency established between the instruction and the source language, resulting in clearer and more accurate guidance. As shown in Figure 3.

Supervised Instruction Fine-Tuning Supervised Instruction Fine-Tuning for machine translation tasks incorporates two pivotal aspects. Firstly, akin to the earlier phase of Continual Pre-training, we employ LoRA(Hu et al., 2021) to finely tune specific parameters of Language Learning Models (LLMs), thereby enhancing their efficiency. LoRA(Hu et al., 2021) plays a crucial role in preventing model overfitting and leads to notable performance improvements. With this approach, we judiciously fine-tune a subset of model parameters using low-rank updates, striking a delicate balance between model adaptation and computational efficiency.

Secondly, as emphasized in prior studies(Zhou et al., 2023; Maillard et al., 2023; Xu et al., 2023), LLMs exhibit benefits from a limited yet high-quality dataset. To ensure optimal data quality during the fine-tuning process, we leverage exceptional data sources. In line with previous research, we make use of meticulously curated human-written datasets derived from the WMT test data. These datasets undergo rigorous quality control measures, rendering them an ideal choice for fine-tuning purposes.

4 Experiments

4.1 Datasets and Evaluation Metrics

The overall data statistics are shown in Table 5 of Appendix A. For Stage 2, we utilized the WMT bilingual training dataset consisting of English⇔German (En⇔De) and English⇔Chinese (En⇔Zh) sentence pairs. The En⇔De dataset comprised approximately 4.5 million pairs, while the En⇔Zh dataset contained around 25 million pairs. Due to the higher number of En⇔Zh pairs compared to En⇔De, we sampled 4.5 million En⇔Zh pairs for our experiments. Overall, the combined dataset contained nearly 1 billion tokens.

For Stage 3, we employed the newstest2017-2020 dataset for both En⇔Zh and En⇔De translation tasks. This dataset included a total of 37.6 thousand sentence pairs for each language direction. To ensure consistency across the source language and target language, we organize these sentence pairs into Source-Language Consistent Instructions.

We additionally incorporate the test sets from the WMT22 competition, which are carefully curated to include more recent content from diverse domains such as news, social media, e-commerce, and conversations. The test sets for the De⇒En, En⇒De, Zh⇒En, and En⇒Zh tasks consist of 1984, 2037, 1875, and 2037 samples, respectively.

For automatic evaluation, we utilize SacreBLEU, which implements BLEU(Papineni et al., 2002), and COMET(Rei et al., 2020) from Unbabel/wmt22-comet-da. SacreBLEU calculates similarity based on n-gram matching, while COMET leverages cross-lingual pretrained models for evaluation.

4.2 Setup

We conducted our experiments using HuggingFace Transformers with open-source LLMs from the LLaMA(Touvron et al., 2023) family. Specifically, we utilized LLaMA2-7b with matched parameters as our foundation model. Additionally, we included LLaMA2-13b to explore the impact of different model sizes.

Due to computational constraints, we did not reproduce the foundational experiments from Stage 1. After Stage 1, we selected Chinese-LLaMA2(Cui et al., 2023) as our new foundation model. Chinese-LLaMA2 is an extended and optimized version of Llama-2, specifically tailored for Chinese language understanding and instruction comprehension. It incorporates a larger Chinese vocabulary and undergoes incremental pretraining on a large-scale Chinese dataset, which further enhances its semantic understanding capabilities.

For Stage 2, Continual Pre-training, and Stage 3, Supervised Fine-Tuning, we referred to the hyperparameters employed in the Chinese-LLaMA2 project. During Stage 2, we trained the model for 1 epoch, and for Stage 3, we extended the training to 3 epochs.

Our experiments were conducted on 8 Nvidia GPUs with 64GB of memory each, utilizing DeepSpeed(Rasley et al., 2020) ZeRO 2 for model parallelization.

4.3 Baselines

We evaluate our method against two baseline categories, consistent with previous studies. Firstly, we compare our approach to prior studies that share our goal of leveraging LLMs for translation. Secondly, we benchmark against the current state-of-the-art (SoTA) translation models. It's important to note that this comparison may not be entirely fair due to disparities in training data and model architectures. For example, there is a significant contrast between the 175B GPT-3.5 model and our 7B model. Nevertheless, by utilizing the same test set, we can gain insights into our model's current performance.

In the category of prior similar work, we compare our model to the following approaches: BigTranslate(Yang et al., 2023), which extends LLaMA-1-13B to cover over 100 translation directions; TIM(Zeng et al., 2023), which leverages correct and incorrect examples to aid LLMs in learning translation; ParroT(Jiao et al., 2023), through

Table 1: **The overall results.** Note: * Due to computational constraints, we did not reproduce the foundational experiments from Stage 1, but instead directly utilized the Chinese-Llama2(Cui et al., 2023) that had undergone similar training. Since Chinese-Llama2(Cui et al., 2023) was only trained in Chinese during Stage 1, our main analysis about Stage 1 focuses on its performance in Zh⇒En and En⇒Zh translations.

three types of instructions including translation instruction, contrastive instruction, and error-guided instruction, improves the translation performance of LLM after SFT; SWIE(Chen et al., 2023), which enhances LLMs in translation through instruction augmentation; BayLing(Zhang et al., 2023), which incorporates interactive translation instructions; and ALMA(Xu et al., 2023), a two-stage fine-tuning method that initially fine-tunes on monolingual data and subsequently on a small set of high-quality parallel data.

In the SoTA models category, we consider the following: the NLLB-54B(Team et al., 2022) model, the largest and best translation model released in the NLLB family; the zero-shot performance of GPT3.5-text-davinci-003 (GPT-3.5-D) and GPT-3.5-turbo-0301 (GPT-3.5-T). Additionally, we present the zero-shot results for GPT-4. For a fair comparison, we also compared the results of fine-tuning NLLB-54B model with 37.6k data in Stage 3. To evaluate these baselines, we employ the same test data and evaluation metrics, reporting BLEU(Papineni et al., 2002) and COMET(Rei et al., 2020) scores as provided in their respective papers.

5 Results and Analysis

As shown in Table 1, **overall, our results outperform all previous studies, NLLB-54B(Team et al., 2022), and GPT-3.5-D, except for a slight lag in Zh⇒En. Even our 7B model surpasses the results of other works. Particularly in the En⇒Zh direction, our BLEU score is approximately 2.5 higher than the previous state-of-the-art.** These findings are a testament to the effectiveness of our approach.

5.1 Assessing the Impact of Stage 1

Just as mentioned earlier, we didn't specifically train Llama2 in Stage 1, but instead directly utilized the Chinese-Llama2(Cui et al., 2023) that had undergone similar training. Since Chinese-Llama2(Cui et al., 2023) was only trained in Chinese during Stage 1, our main analysis focuses on its performance in Zh⇒En and En⇒Zh translations.

As shown in Table 1, our findings align with previous research conclusions that incremental training on monolingual data is beneficial. Furthermore, we discovered that this benefit primarily affects the target language in translation tasks. For example, we observed a significant improvement in the performance of the 7B model on the En⇒Zh test set, where the BLEU score increased from 30.60 to 35.00, a substantial improvement of 4.4 points. However, the improvement in the Zh⇒En direction was limited, indicating that the role of Stage 1 is to enhance generation rather than comprehension.

Additionally, we found that performing incremental training on only one monolingual dataset had disastrous effects on translation tasks in other languages. For example, on the En⇒De test set, the BLEU score plummeted from 25.40 to 12.50. Therefore, for multilingual translation, it is crucial to conduct Stage 1 training on multiple languages.

5.2 Measuring the Effectiveness of Stage 2

As shown in Table 1, Llama2(Touvron et al., 2023) demonstrates improved quality across various test sets after Stage 2 training. An interesting observation, considering Llama2 as a large model primarily focused on English, is that the enhancement in English-Other translations is particularly noteworthy after Stage 2 Training. For instance, the 7B model exhibits remarkable improvements in En⇒De, with the BLEU score increasing from 25.40 to 30.50, and in En⇒Zh, where it rises from 30.60 to 39.00. The magnitude of these improvements is quite significant. Encouragingly, there are also improvements observed in translations from other languages to English.

An even more intriguing finding is that, as mentioned before, since Chinese-Llama2(Cui et al., 2023) only underwent Stage 1 training on Chinese, its translation performance substantially deteriorates in the En⇒De direction. However, with the magical touch of Stage 2 training, these capabilities are miraculously restored. The 7B model, on En⇒De, rebounds from 12.50 to 29.90, approaching the results of the original Llama2(Touvron et al., 2023). These outcomes effectively affirm the effectiveness of Stage 2.

After considering the overall process, we are interested in understanding the impact of Stage 2 only. As mentioned before, LLMs typically include two main types of models: Foundation Models and Chat Models. Evaluating Stage 2 essentially assesses the Foundation Model by using an n-shot evaluation, which includes both zero-shot and 5-shot evaluations. We have noticed that zero-shot evaluations can occur hallucinations. Hence, we are presenting the results of the 5-shot evaluation in Table 2.

Models	Zh⇒En		En⇒Zh	
	BLEU	COMET	BLEU	COMET
Baseline	20.63	76.32	29.96	79.34
+ Stage2	21.64	78.07	38.62	85.30

Table 2: Results of the five-shot results based on Llama2-7B(Touvron et al., 2023) model.

5.3 Analyzing the Outcomes of Stage 3

To evaluate the effectiveness of Source-Language Consistent Instruction in Stage 3, we conducted a comparative experiment using English-Fixed Instruction. The results of the experiment are presented in Table 3. It is evident that in the En⇒De and De⇒En directions, the performance of these two types of instructions is quite similar. However, in the Zh⇒En and En⇒Zh directions, the use of Source-Language Consistent Instruction clearly outperforms.

Models	De⇒En	En⇒De	Zh⇒En	En⇒Zh
Stage 3	30.02	25.40	20.59	30.60
w/o	30.40	25.20	18.39	28.30
Stage2,3	31.14	30.50	21.91	39.00
w/o	31.00	30.23	18.93	38.69

Table 3: Results of the comparative experiments based on Llama2-7B(Touvron et al., 2023) model. [w/o] means using English-Fixed Instruction.

We believe that the similarity between English and German, as they belong to the same language family, contributes to the lack of noticeable differences. However, when dealing with cross-language pairs, employing Source-Language Consistent Instruction further enhances the translation quality.

5.4 Comparing the Difference with ALMA

We have noticed that our work shares some similarities with ALMA(Xu et al., 2023) in terms of the process, involving Continual Pre-training followed by Supervised Fine-Tuning. However, there are notable differences between our approaches.

ALMA suggests that the impact of bilingual data is reduced in the era of large models. In contrast, we firmly believe in the continued strength of bilingual data and its application in Continual Pre-training through Interlinear Text Format Documents. While ALMA acknowledges the effectiveness of conducting Continual Pre-training on monolingual data, we have also validated this finding in our own work and reached the same conclusion. However, it is important to note that our approach primarily enhances the multilingual generation capability of the large model itself, rather than being specifically tailored to translation tasks. Furthermore, ALMA utilizes a significantly larger training dataset, ranging from 13B to 20B, compared to our own.

6 Ablation Study: What if we directly employ a large quantity of translation data for SFT?

Both Continual Pre-training and Supervised Fine-Tuning involve incremental training on the original model. However, if we skip Stage 2 training and directly utilize the translation data from Stage 2 as instruction data for SFT, i.e., conducting SFT directly with a substantial amount of translation data, will it yield consistent improvement?

Data Size	De⇒En	En⇒De	Zh⇒En	En⇒Zh
37.6K	30.02	25.40	20.59	30.60
400K	30.20	25.60	18.49	31.74
4,000K	30.66	25.12	20.77	32.22

Table 4: Results of the ablation experiments based on Llama2-7B(Touvron et al., 2023) model under different Stage 3 data size.

To address this question, we conducted an ablation experiment. Our Stage 3 training data consisted of 37.6k samples. Randomly selecting and merging some data from the Stage 2 training data with the Stage 3 training data, we created three sets: 37.6K, 400K, and 4,000K. The experimental results are presented in Table 4.

We found that augmenting the training data in Stage 3 slightly improved translation quality for certain test sets. This indicates that a small amount of high-quality data is sufficient for the SFT stage.

Now, our focus is solely on the translation task. However, if we were conducting multi-task SFT, it is unlikely that other tasks would have as extensive data as machine translation. Therefore, using a large amount of translation data during SFT would result in the problem of imbalanced data distribution with other tasks. Hence, the optimal approach would still be to utilize this substantial data during the earlier stage of Continual Pre-training.

7 Conclusions

In this study, we have introduced a novel paradigm for enhancing the translation capabilities of large language models in machine translation tasks. Our three-stage approach, including Secondary Pre-training using Extensive Monolingual Data, Continual Pre-training with Interlinear Text Format Documents, and Leveraging Source-Language Consistent Instruction for Supervised Fine-Tuning, addresses the limitations of previous strategies and offers notable improvements in translation quality. We emphasize the significance of pre-training stages in enhancing LLMs' cross-lingual alignment abilities and the effectiveness of using a smaller but high-quality set of bilingual data during supervised fine-tuning. Notably, Stage2, which involves Continual Pre-training with Interlinear Text Format Documents, stands out as a highly efficient method, requiring minimal training data. Furthermore, aligning the instructional setting with the source language during supervised fine-tuning, as observed in Stage3, yields positive effects. The findings from this paper contribute to advancing the field of machine translation and offer valuable insights for optimizing the translation capabilities of large language models. Future research can explore additional language pairs, alternative data augmentation techniques, and different pre-training strategies to further refine our proposed paradigm.

8 Limitations

Despite notable contributions, this study has certain limitations. Firstly, the proposed method exhibits slightly reduced performance in the Zh⇒En translation direction, necessitating further analysis and improvements. Secondly, the presence of illusionary translations within large models was observed but not extensively explored. Future research should delve deeper into this phenomenon. Lastly, while the paper primarily focuses on SFT for machine translation, opportunities exist to explore SFT techniques in diverse contexts such as style translation and colloquial translation. Addressing these limitations would further enhance the effectiveness and applicability of the proposed methods.

A Appendix A: Data Statistics

Table 5 displays the comprehensive data statistics. For Stage 2, we utilized the WMT bilingual training dataset that includes English⇔German (En⇔De) and English⇔Chinese (En⇔Zh) sentence pairs. The En⇔De dataset comprised approximately 4.5 million pairs, while for the En⇔Zh dataset, we randomly sampled an equivalent number of pairs from the total 25 million pairs. In total, the combined dataset contained close to 1B tokens.

Moving on to Stage 3, we utilized the newstest2017-2020 dataset for both the En⇔De and En⇔Zh translation tasks. This dataset comprised 37.6 thousand sentence pairs for each language direction. To maintain coherence between the source and target languages, we categorized these sentence pairs into Source-Language Consistent Instructions.

B Appendix B: Stage 2 Training Data Sample

Figure 4 displays samples of the Stage 2 training data.

Stage	Data	Description
Stage 1	120G text	120G Chinese text described in Chinese-LLaMA2(Cui et al., 2023)
Stage 2	1B tokens	1B tokens including four directions: En⇔De and En⇔Zh. Each direction includes 4.5 million pairs.
Stage 3	37.6k pairs	37.6k pairs combined wmt newstest2017-2020 testset with all four directions.

Abstract

We present a new challenge to examine whether large language models understand social norms. In contrast to existing datasets, our dataset requires a fundamental understanding of social norms to solve. Our dataset features the largest set of social norm skills, consisting of 402 skills and $12,383$ questions covering a wide set of social norms ranging from opinions and arguments to culture and laws. We design our dataset according to the K-12 curriculum. This enables the direct comparison of the social understanding of large language models to humans, more specifically, elementary students. While prior work generates nearly random accuracy on our benchmark, recent large language models such as GPT3.5-Turbo and LLaMA2-Chat are able to improve the performance significantly, only slightly below human performance. We then propose a multi-agent framework based on large language models to improve the models' ability to understand social norms. This method further improves large language models to be on par with humans. Given the increasing adoption of large language models in real-world applications, our finding is particularly important and presents a unique direction for future improvements.

1 Introduction

Large language models (LLMs) such as GPT-4 (OpenAI, 2023) and Gemini (Gemini Team, 2023) have significantly advanced text understanding and generation. These models have become increasingly adopted in broad applications. Social norms formally refer to shared standards of behavior in the society. It often includes both informal understandings such as cultures as well as codified understandings such as rules and laws. Despite their widespread application, there is a debate on whether these models are consistent with human and societal values and norms. This has resulted in the issuance of AI safety whitepapers advocating for the halting of certain model developments, as well as government executive orders endorsing the creation of only trustworthy AI systems. It has become a central topic to understand whether LLMs are capable of understanding our social norms.

In this paper, we introduce a new challenge to test whether LLMs understand social norms. Unlike existing datasets that mainly evaluate a general understanding of social science (Hendrycks et al., 2021a; Lu et al., 2022; Liang et al., 2022; Srivastava et al., 2022), our dataset focuses on examining the fundamental understanding of social norms. Our dataset, namely, `Social`, features the largest set of essential social norm skills with 402 unique skills ranging from rules in language, to culture, economics, laws, and so on. It consists of $12,383$ questions to support the test of these skills. Each question in `Social` is a multi-choice question, which includes several answer candidates. Example questions are shown in Figure 1(a). Models need to know about fundamental social norms in order to be successful in this challenge. Our design strictly follows the social norm evaluation of humans. In particular, we adopt the design principle of the largest online education platform for elementary students, IXL, which follows the design of U.S. National Education. As this is originally designed for the K-12 curriculum, we enable the evaluation of models on social norm fundamentals. Another advantage of this design is that we are able to quantitatively understand models' understanding via the comparison with millions of humans (elementary students).

We empirically evaluate the performance of LLMs on our dataset. We conducted the experiments using both LLaMA2-Chat and GPT3.5-Turbo. Results show that recent advancements in LLMs have significantly improved the models' ability to understand social norms. Especially, post-training techniques such as reinforcement learning

with human feedback (RLHF) (Ouyang et al., 2022) improve the performance over their base models significantly. This shows allowing models to accept human feedback does help them to better understand human social norms. In contrast, prior models such as a small UnifiedQA powered by T5 (Raffel et al., 2020) only generate near-random performance. Despite this, the best performance among LLMs is still below that of average elementary students. For instance, GPT3.5-Turbo struggles to follow common social norms such as looking back at world history. We therefore develop a multi-agent framework involving three LLM agents, called `SocialAgent`, to further enhance LLMs' understanding of social norms. Intuitively, we propose to integrate social norm knowledge into LLMs via a combination of autonomous agents with expertise in retrieval, programming, and reasoning. With `SocialAgent`, both LLMs reach the competitiveness with humans. For example, GPT3.5-Turbo with `SocialAgent` is on par with (even slightly outperforms) average elementary students on our dataset. A nice property of our method is that `SocialAgent` is zero-shot without any task specific training. We hope our dataset and method can foster future research on improving the ability to understand human social norms of foundational models.

2 The `Social` Benchmark

2.1 Dataset

We introduce a new dataset named `Social` to examine the ability to understand human social norms. Social norms are social and shared among members of a group. It includes topics representing socially acceptable ways of living by a group of people in a society, such as rules, laws, culture, history, and communication. Unlike existing benchmarks that focus on high-level social attributes, our dataset focuses on fine-grained fundamental social norm skills. `Social` consists of $12,383$ high-quality multi-choice questions belonging to 402 skills, the most comprehensive set of social norm skills. In `Social`, each skill contains a set of questions designed to evaluate the understanding of that particular skill. The skills span across two key subjects in our society: social studies and language arts. Understanding these skills is important to the wide adoption of LLMs. The overall dataset statistics are shown in Table 1.

Social Studies Social studies cover broad fundamental aspects to understand social norms including laws, history, economics, culture, and geography. For the skills under this subject, we follow the design of U.S. National Education standards. We collect data from IXL[1], one of the largest online education platforms focusing on the K-12 curriculum, which aligns with our design principle. Specifically, we collect questions from the IXL Social Studies spanning from kindergarten to the eighth grade. We also conduct data postprocessing such as question deduplication. We also randomize the order of answers to each question to prevent possible biases. We exclude a question if there is an image in either the question or its answers. Figure 1(a)(i) shows an example of a question designed to understand the purpose of government, which corresponds to a particular skill in laws.

Language Arts Language arts focus on the rules of using language, including opinions and arguments, book study, writing strategies, and other language skills. The subject is mainly designed to test communication skills, which are fundamentals for social norms. Similarly, we also follow the U.S. National Education standards implemented by IXL Language Arts. Similar data postprocessing with the social studies subset was done. This subset includes subtle language skills such as distinguishing facts from opinions, as shown in Figure 1(a)(ii). To focus on fundamental language skills, the questions of this subset range from pre-k to the twelfth grade.

Table 1: `Social` dataset statistics.

Subject	#Skills	#Questions	Average #A
Social Studies	170	2,315	3.4
Language Arts	232	10,068	2.4
Total	402	12,383	2.6

Comparison with Existing Datasets Our proposed dataset `Social` is the first large-scale and comprehensive social norms benchmark. A comparison with other datasets is shown in Figure 1(a). Overall, the key difference of our dataset is that `Social` focuses on skill sets of understanding fundamental social norms, while existing benchmarks mainly focus on high-level social science knowledge. Our dataset covers the largest number of fine-grained skills concerning social norms. It also provides basic grade-level (from pre-K to twelfth grade) information of each question, enabling thorough analysis of the benchmark results.

2.2 Analysis

To better understand the features of `Social`, we perform the following analysis focusing on its unique aspects including information about skills and grades. More analyses are presented in the appendix.

Skills Figure 2 presents a summary of the skills (a complete skill set is included in the appendix). `Social` contains the largest skill set among existing benchmarks for social norms (Figure 1), and each skill contains 30.8 questions on average. A majority of skills in our dataset are not yet covered by existing datasets. These skills are the basis of understanding human social norms. For example, the model needs to understand the difference between laws and rules (Figure 1(a)(i)). Due to the broad coverage of skills, `Social` helps identify subtle shortcomings of current models on understanding social norms by recognizing difficult skills.

Grades `Social` contains a comprehensive K-12 curriculum to examine the fundamentals of social norms. This helps obtain the grade-level performance of current models. Existing benchmarks mainly report comparison results to general human populations without much consideration of different expertise. Our dataset enables a more controlled

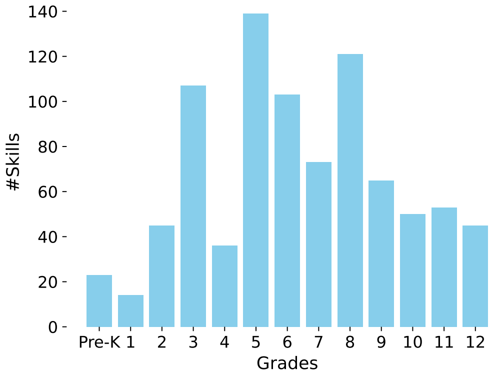

Figure 3: #Skills per grade.

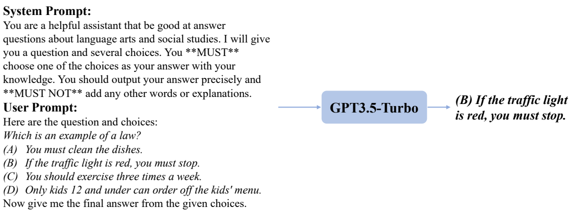
comparison to millions of elementary student users from our data source. This aligns with our main focus, i.e., understanding fundamental and essential social norms. Figure 3 shows the total number of skills of each grade.

2.3 Models

We benchmark state-of-the-art LLMs including GPT3.5-Turbo (Ouyang et al., 2022) and LLaMA2-Chat (Touvron et al., 2023b) on `Social`. We evaluate the models under their zero-shot setups. Figure 4 shows a running example of zero-shot GPT3.5-Turbo. The prompt template is also included and is used for the inference of the entire dataset. LLaMA2-Chat adopts the same zero-shot setting. We also compare these recent LLMs to previous models such as UnifiedQA (Khashabi et al., 2020) under the zero-shot setting. UnifiedQA is a pretrained question-answering model based on T5 (Raffel et al., 2020). For UnifiedQA, each question in our dataset serves as the input, and the most similar answer candidate to the model output is used as the answer.



System Prompt:
You are a helpful assistant that be good at answer questions about language arts and social studies. I will give you a question and several choices. You **MUST** choose one of the choices as your answer with your knowledge. You should output your answer precisely and **MUST NOT** add any other words or explanations.
User Prompt:
Here are the question and choices:
Which is an example of a law?
(A) You must clean the dishes.
(B) If the traffic light is red, you must stop.
(C) You should exercise three times a week.
(D) Only kids 12 and under can order off the kids' menu.
Now give me the final answer from the given choices.

Figure 4: Zero-shot setup of GPT3.5-Turbo.

2.4 Metrics and Human Performance

We evaluate the models' overall accuracy as well as their accuracy on each subject, each skill, and each grade. Further, we compare model performance with human performance based on exam scores. We specifically utilize the IXL SmartScore (Learning, 2019). Unlike general accuracy, SmartScore considers the learning progression and is designed to measure the extent of human understanding of a skill (Bashkov et al., 2021). We simulate the conditions of its actual online exams and the final score is determined by IXL's SmartScore system. According to IXL (IXL, 2014a,b), a SmartScore exceeding 90.0 indicates excellent for understanding or mastering a skill. Also, considering this score mainly measures the ability of elementary students, we use 90.0 as the reference score of human performance. Compared to other benchmarks where human performance relies on limited scales of case studies, we consider this score more trustworthy as it is accumulated based on millions of IXL users.

3 The `SocialAgent` Approach

In this section, we present an approach to improve the LLMs' ability to understand social norms. Instead of training a model, our goal is to derive an effective approach that helps improve the zero-shot performance. Motivated by recent advancements in language agents (Li et al., 2023; Xi et al., 2023; Wu et al., 2023b), we build a multi-agent framework (Figure 5) based on LLMs to fuse social norm relevant world knowledge, symbolic knowledge, and model knowledge to solve our `Social`. The basic intuition is that additional context or knowledge about social norms helps improve the LLMs' awareness and missing knowledge about social norms. `SocialAgent` consists of three LLM agents for this purpose.

Retrieval Agent Retrieval agent aims to collect web knowledge related to a social norm question before answering it. This follows the similar intuition of the search action in agents such as Re-

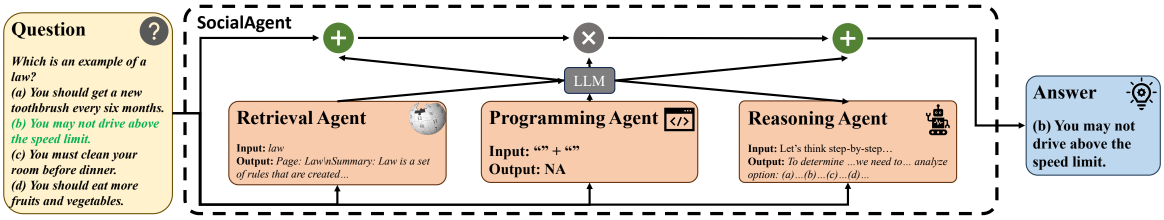


Figure 5: The pipeline of our proposed `SocialAgent` method. `SocialAgent` is a multi-agent model based on LLMs, consisting of three agents: retrieval agent, programming agent, and reasoning agent. Each agent takes the problem as input and outputs its response. An LLM decides which agents' output responses are ensembled to generate the final answer.

Act (Yao et al., 2022). Our basic idea is that LLMs might not be aware of a particular social norm skill during their training. Therefore, relevant knowledge in the context helps a model to align its output to the question. An LLM is asked to generate questions for a retrieval engine. We use Wikipedia search API as our engine. The output response of this agent is the search results. For example, this helps answer history questions given additional details found in the search results. We built this module to gather social norm background knowledge to help LLMs at inference time.

Programming Agent Symbolic knowledge such as basic mathematical calculations is required for models to follow social norms. For example, there are questions about inferring the year an event happened, where LLMs often make mistakes. Retrieval is suboptimal for solving this type of question. We therefore propose to enable LLMs to make calls to symbolic APIs. To verify this idea, we use a basic calculator API in the `SocialAgent`. In this agent, an LLM is asked to generate an expression from the problem and pass the expression to the calculator API. The output response is the calculation result.

Reasoning Agent Recent studies show chain of thought (Wei et al., 2022) helps unlock reasoning abilities of LLMs. Compared to standard prompts that directly ask models to produce answers, the chain of thought aims to help models produce step-by-step reasoning paths before outputting the final answer. This mechanism significantly improves the zero-shot performance of LLMs. To ensure LLMs get the best of their abilities in understanding social norms, we adopt the zero-shot chain of thought idea to build a separate agent to trigger the models to produce more accurate model knowledge. Overall, the reasoning agent is asked to think step-by-step. More specifically, we use "let's think step-by-step" as the prompt along with the question to obtain the response including reasoning paths from an LLM (Figure 5).

The overall pipeline is presented in Figure 5. The input is the question. Each above agent in `SocialAgent` takes the same input. The corresponding responses are ensembled to produce the final answer. Our ensembling procedure is as follows. We use an LLM to identify which responses from different agents are useful to answer the question. Compared to straightforward ensembling of all responses, our procedure helps guide models to ignore irrelevant context (Shi et al., 2023), which lays the foundation for a better understanding of social norms. Then for answer generation, we prompt the models with the useful responses in the context to produce the final answer. Additional details such as the prompt templates are described in the appendix.

4 Experiments

Model	Social Studies	Language Arts	Avg.
Random	32.2%	44.7%	38.4%
UnifiedQA$_{\text{Small}}$	36.2%	52.2%	44.2%
UnifiedQA$_{\text{Base}}$	49.0%	60.0%	54.5%
UnifiedQA$_{\text{Large}}$	67.5%	67.4%	67.5%
LLaMA2-70B-Chat	90.4%	78.0%	84.2%
GPT3.5-Turbo	91.9%	86.9%	89.4%
`SocialAgent`$_{\text{LLaMA2-70B-Chat}}$	91.8%	80.3%	86.1%
`SocialAgent`$_{\text{GPT3.5-Turbo}}$	93.6%	88.3%	91.0%

Table 2: Evaluation results (accuracy) on `Social`.

In this section, we show the evaluation results of `SocialAgent` on `Social`. We also provide results of recent LLMs including LLaMA2-Chat and GPT3.5-Turbo. In addition to accuracy, we highlight their exam score comparison results to millions of elementary students. Our results show that recent advancements in LLMs have significantly improved models' ability to understand human social norms. Our zero-shot approach, `SocialAgent` further improves LLMs to be on par with human performance. More details of our benchmark and additional results are included in the appendix.

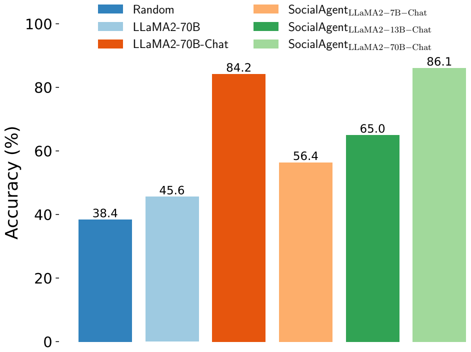

Figure 6: Model performance of LLaMA2.

4.1 Main Results

To examine the social norm understanding, we evaluate models zero-shot on our datasets. The results are shown in Table 2. Notably, the recent LLMs such as LLaMA2-70B-Chat and GPT3.5-Turbo improve the performance of previous models by a large margin on average. We also see that GPT3.5-Turbo performs better than LLaMA2-70B-Chat. We observe similar increases in both social studies and language arts. The most improvements (24.4%) are brought by GPT3.5-Turbo on social studies when compared to the best-performing comparison method UnifiedQA$_{\mathrm{Large}}$, and its improvement is 59.7% over random accuracy. The main reason is that both LLaMA2-70B-Chat and GPT3.5-Turbo are enhanced with reinforcement learning with human feedback (RLHF) (Ouyang et al., 2022), which is designed to align model responses with human values. This is important to social norm understanding. This is clear from the performance comparison between LLaMA2-70B-Chat and LLaMA2-70B in Figure 6. LLaMA2-70B-Chat improves the performance over LLaMA2-70B by 38.6% on average, and the only notable difference is that LLaMA2-70B-Chat is equipped with the RLHF. This also adds explanations about having more improvements in social studies compared to those in language arts. RLHF mainly brings social perspectives without much emphasis on fundamental language phenomena.

Importantly, `SocialAgent` consistently performs the best on both subjects (Table 2). With `SocialAgent`, both LLaMA2-70B-Chat and GPT3.5-Turbo improve their performance on our dataset. The best performance is achieved by `SocialAgent`$_{\mathrm{GPT3.5-Turbo}}$. This shows that our proposed method is able to integrate important social norm knowledge into LLMs.

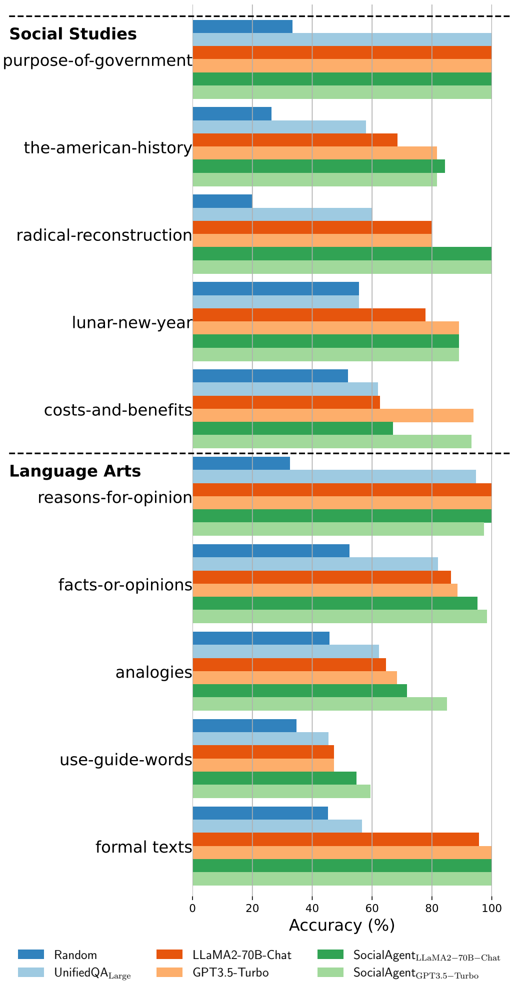

Figure 7: Results on sampled skills of each subject.

4.2 Results Analysis

Skills We show the accuracy of comparison models and our method on the skill level in Figure 7. We show the results on an uncurated list of skills from both subjects. The complete results on the full skill set are in the appendix. We find similar trends with the overall results on corresponding subjects. Recent advancements in LLMs, in particular, RLHF, improve the performance significantly over the previous near random accuracy. With `SocialAgent`, both GPT3.5-Turbo and LLaMA2-70B-Chat improve their social norm understanding across different social norm skills. GPT3.5-Turbo outperforms LLaMA2-70B-Chat, and `SocialAgent`$_{\mathrm{GPT3.5-Turbo}}$ obtains the best overall performance. While there are social norm skills such as "purpose-of-government" and "reasons-for-opinion" have been mastered by

LLMs, there are still plenty of skills such as "the-american-history" and "use-guide-words" remain unlearned, presenting room for further improvements.

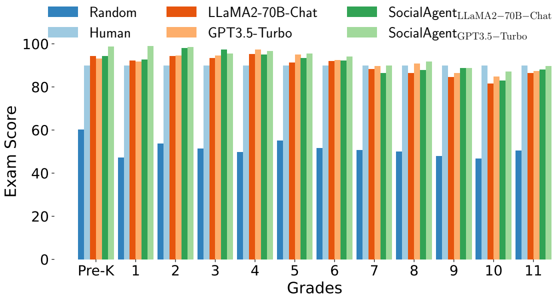

Figure 8: Average grade-level exam scores.

Grades Since our dataset provides the fine-grained grade information of the questions, we present the grade-level exam scores of both our method and comparison methods in Figure 8. In general, the exam scores of all models decrease slightly when the grades increase. This is because the questions at higher grades are in general more challenging. However, this trend is not obvious based on this human intuition. The reason is that humans learn social norms progressively, while models learn all these skills simultaneously during their training. Besides, we observe similar performance enhancement with previous discussions. For example, recent models improve the performance across all grades significantly compared to the previous random accuracy. `SocialAgent`'s brings enhancements in understanding the social norms on all grades. Specifically, all models perform competitively with human performance on lower grades. However, they underperform humans on higher grades such as grades 11 and 12. This indicates significant room to further improve the models' ability to understand advanced social norms.

Scaling Law Figure 6 shows the average accuracy of LLaMA2-Chat of different sizes (7B, 13B, and 70B) with `SocialAgent`. Overall, the model performance increases when the model size gets larger. This indicates that larger models have the additional capacity to learn more accurate social norms during the training.

4.3 Ablation Study

To investigate the importance of each key component of `SocialAgent` we show the ablation results of LLaMA2-70B-Chat with `SocialAgent` on the social studies subset in Table 3. The three settings present removing the retrieval agent ("w/o Retrieval Agent"), the programming agent ("w/o Programming Agent"), and the reasoning agent ("w/o Reasoning Agent") from `SocialAgent` respectively. Overall, all components are important since the default `SocialAgent`$_{\text{LLaMA2-70B-Chat}}$ obtains the best result. The most significant decrease is brought by removing the reasoning agent. This means that the model has learned certain fundamentals of social norms during their training. So, a better way to prompt the model to obtain the most relevant knowledge is necessary. Moreover, both the retrieval agent and programming agent are essential to incorporate important social norm knowledge into the models.

Model	Social Studies
`SocialAgent`$_{\text{LLaMA2-70B-Chat}}$	91.8%
w/o Retrieval Agent	91.6%
w/o Programming Agent	91.4%
w/o Reasoning Agent	90.3%

Table 3: Ablation results on LLaMA2-70B-Chat with the `SocialAgent` method.

4.4 Comparison with Human

It is important to compare models' social norm understanding to that of humans. We compare the exam scores of both GPT3.5-Turbo and LLaMA2-70B-Chat and our methods with millions of elementary student users of the IXL platform. The results are shown in Figure 9. Overall, both models still underperform average elementary students in terms of understanding social norms. `SocialAgent` helps improve these models to be on par with human performance. For instance, `SocialAgent`$_{\text{GPT3.5-Turbo}}$ outperforms humans by an average of 0.8%. This result is significant although more advancements are needed to compete with human experts.

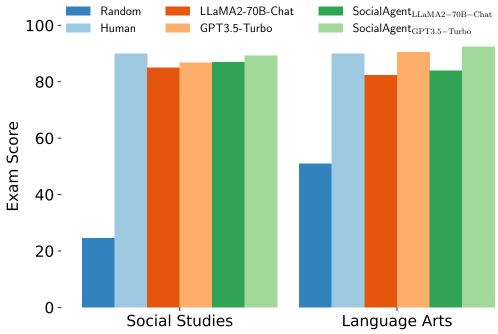

Figure 9: Compare exam scores of models and humans.

4.5 Case Study

To better understand what are the models' strengths or weaknesses in understanding social norms, we show examples of best-performing GPT3.5-Turbo predictions with `SocialAgent`. We present an example of correct and incorrect predictions in Figure 10(a) and (b) respectively. Overall, the models have learned fundamental social norm skills that are concrete and do not require complex reasoning. For example, the answer to the question in Figure 10(a) is short and relatively straightforward. `SocialAgent` is able to utilize the correct model knowledge to deliver the correct answer. Otherwise, the models struggle. For example in Figure 10(b), the retrieval agent outputs incorrect search results since there is no existing knowledge about this question in the search resources. The other two agent components also do not provide useful context. Based on this, new advancements are needed to help models improve their response quality in challenging scenarios such as long answers and complex reasoning.

Question: What month comes right before February?
(a) August (b) January
Retrieval Agent:
Input: month comes right before February
Output: *Page: Before Sunrise\nSummary…*
Useful: false
Programming Agent:
Input: "" + ""
Output: NA
Useful: false
Reasoning Agent:
Input: Let's think step-by-step...
Output: *To determine the month that comes…*
Step 1: Recall the order of the months…
Step 2: Identify the month that…
The correct answer is (b) January.
Useful: true
Prediction: **(b) January**

(a) Correct Prediction

Question: **…** The upper house is called the Senate and the lower house is called…
(a) The House of Representatives is smaller.
(b) The House of Representatives is bigger.
Retrieval Agent:
Input: size of House of Representatives compared to Senate
Output: *Page: House of Representatives…*
Useful: **true**
Programming Agent:
Input: "" + ""
Output: NA
Useful: false
Reasoning Agent:
Input: Let's think step-by-step…
Output: *To determine whether the…*
1. The question states that…
2. We can refer to the information provided by the other agent…
Tanswer is: (a) The House of Representatives is smaller.
Useful: true
Prediction: **(a) The House of Representatives is smaller.**

(b) Incorrect Prediction

Figure 10: `SocialAgent`$_{\texttt{GPT3.5-Turbo}}$ example predictions.

5 Related Work

Large language models have demonstrated significant improvements in a variety of NLP tasks recently. LLMs have been introduced and used in real-world applications (Brown et al., 2020; Wang et al., 2022; Ouyang et al., 2022; OpenAI, 2023; Chowdhery et al., 2023; Touvron et al., 2023a; Taori et al., 2023; Chiang et al., 2023; Pan et al., 2024; Wang et al., 2023a). Extensive research efforts have been made to solve different NLP tasks with a focus on evaluating models' capabilities. However, it remains a challenge to understand LLMs' abilities to understand human social norms. There are existing datasets and benchmarks that aim to help understand the capabilities and limitations of LLMs (Hendrycks et al., 2021b,a; Lu et al., 2022; Liang et al., 2022; Srivastava et al., 2022; Shen et al., 2024; Liu et al., 2023a; Xiong et al., 2023b). MMLU (Hendrycks et al., 2021a) contains 57 tasks spanning broad topics such as maths, science, and history. Lu et al. (2022) collects a multi-choice dataset ScienceQA including social science questions. HELM (Liang et al., 2022) is presented to evaluate many aspects of models such as accuracy and robustness on a wide collection of existing tasks such as question answering and toxicity detection. BIG-bench (Srivastava et al., 2022) is a benchmark with more than 200 tasks. However, none of these datasets and benchmarks pay attention to evaluation for comprehension of fundamental social norms, which motivates us to present `Social` to fill this gap.

There are attempts to connect LLMs with external knowledge, tools and models (Yao et al., 2022; Schick et al., 2023; Topsakal and Akinci, 2023; Liang et al., 2023; Wu et al., 2023a; Xiong et al., 2023a; Wang et al., 2020; Shen et al., 2022; Crispino et al., 2023). ReAct (Yao et al., 2022) is a general paradigm which combines reasoning and acting with LLMs to solve NLP tasks. Schick et al. (2023) show that LMs can teach themselves to use external tools. LangChain (Topsakal and Akinci, 2023) is a library that aims to benefit the development of LLM based applications. Wu et al. (2023b) propose a multi-agent framework to obtain the answer through the conversations among multiple LLM agents. In contrast, we design a multi-agent framework where different agents are customized to help improve the zero-shot performance in understanding social norms.

6 Conclusion

We introduce a new benchmark for examining LLMs' understanding of social norms. Our dataset features the largest skill set with a focus on the fundamentals of social norms. We evaluated state-of-the-art LLMs including GPT3.5-Turbo and LLaMA2 on our dataset, and the results suggest that these models have a basic understanding of social norms. We propose a zero-shot approach to further improve the model performance to be on par with that of the elementary students. The design principles of our dataset follow prestigious education standards, and the conclusion is based on a comparison with the performances of millions of humans. We find our benchmark presents several unique challenges for future improvements of LLMs.

Limitations

For the limitations of our benchmark, the dataset does not contain explanations of the answers yet. Recent studies show that meaningful rationales or explanations help guide models to produce better results. Moreover, the dataset only contains English questions. Therefore language biases or misalignments exist in our dataset. For our method, the retrieval agent uses Wikipedia as the only source. Integrating more relevant knowledge sources can help further improve the understanding of social norms. Finally, our method shares some common limitations with most deep learning approaches. For example, the decisions are not easy to interpret.

Ethical Impact

A More Details on `Social`

In this section, we provide more details on `Social`, including dataset analysis, models, and dataset collection.

A.1 Analysis

Questions and Answers `Social` contains multi-choice questions (Appendix D provides a question example for each skill). The question contains a textual description with an optional textual context. We further analyze the questions from the following aspects. (i) The number of answers. `Social` has averaging 2.6 answer options for each question. The distribution is presented in Figure 11. In practice, the more answer options one question has, the more difficult it is. (ii) Question type. We categorize questions based on the first three words of the question text as shown in Figure 12. `Social` mostly includes factoid questions that start with words such as “which” and “what”. We also show the word cloud of our `Social` in Figure 13. We can see the most common words like “sentence” and “complete”. This indicates that many questions are sentence-completion type. (iii) Question distribution. Figure 14 depicts the distribution of question lengths. We can see both subjects generally follow a long-tail distribution, while language arts distribution has a longer tail because it includes many long reading comprehension questions. Heuristically, longer questions are more difficult to solve. Figure 15 shows the number of questions in each grade. The questions are primarily distributed between grades 3 and 9, accounting for 72% of the total.

A.2 Dataset Collection

We collect the Social Studies and Language Arts datasets from *IXL*[2]. We collect all the multi-choice questions which only contain texts. All questions have only one correct answer. We collect 200 trials for each skill and remove the duplicated problems. Finally, Language Arts problems are much more than Social Studies, so we sample problems from each skill of Language Arts subject uniformly.

A.3 Additional Related Work

There are existing agent frameworks, such as ReAct (Yao et al., 2022), Exchange-of-Thought (Yin et al., 2023), BOLAA (Liu et al., 2023b), etc. ReAct needs multiple turns of dialog, which often leads the models to forget the long dependency knowledge. Exchange-of-Thought uses multiple turns of dialog with different characters, and each character conducts its analysis of the question independently. Instead, each module in our framework focuses on its specific functionality, and the agent decides which output (or combinations) to use on the fly. BOLAA mainly enables LLM to do planning when solving problems. We find that planning is not always useful when answering social norms questions, and the planning ability of LLaMA-2 and GPT-3.5-Turbo are limited and present additional risks such as misleading the models.

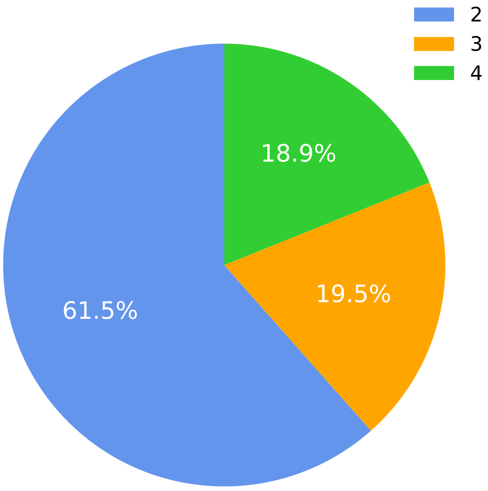

Figure 11: #Answers distribution.

B More Details on Experiments

B.1 Experimental Setup

In `Social`, we only provide the test set for the LLMs evaluation without training or fine-tuning. So traditional language models such as RNN or LSTM (Rumelhart et al., 1986; Hochreiter and Schmidhuber, 1997; Wang et al., 2023b; Pan et al., 2019) are not evaluated. For GPT3.5, we use OpenAI GPT-3.5-Turbo API. Specifically, we use GPT-3.5-Turbo-0613. Though previous studies show that the output of the API may change over time(Tu et al., 2023; Chen et al., 2023), we are able to reproduce the results. While for LLaMA2, we use 4-bit quantization to save the memory. For the generation output of the LLMs, we first parse the output heuristically. We try to find the string after the phrase "answer is", where we try to match the choices. If this pre-parse fails, we use Leven-

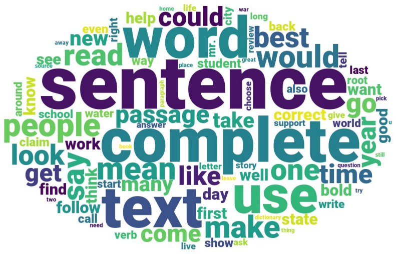

Figure 13: Word cloud of question texts in `Social`.

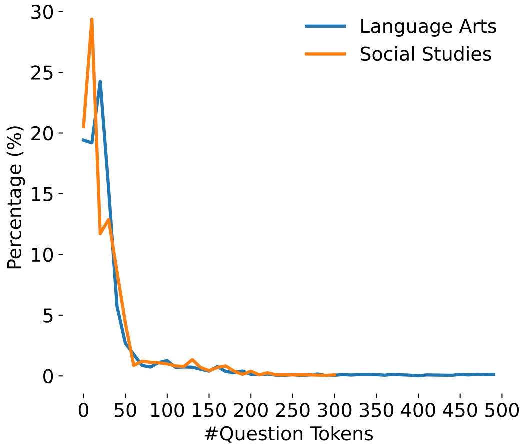

Figure 14: Question length distribution.

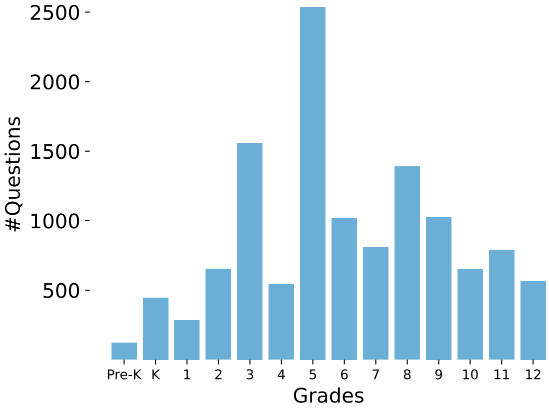

Figure 15: #Questions per grade.

shtein distance to get the final choice. The detailed prompts are shown in Figure 21.

B.2 Detailed Experimental Analysis

Number of Answers We also analyze how model performance changes with the number of answers. We show the results in Figure 16. Surprisingly, the accuracy increases with the number of answers, which is contrary to the expectation that more choices lead to harder problems.

Calibration We show the relationship between the confidence of LLaMA2-70B models and the corresponding accuracy in Figure 17. A reliable model should be calibrated, which means the output confidence should match the accuracy (Guo et al., 2017). We use the sum of the log probability of the predicted answers as the confidence and show the relationship between the confidence and the accuracy. We find that the zero-shot LLaMA2-70B-Chat is well-calibrated. However, the pretrained LLaMA2-70B model without instruction tuning is not well-calibrated, which shows the importance of alignment fine-tuning.

More Details on Exam Score We show the Exam Score for each skill in Table 5 to 8. As demonstrated in the table, our `SocialAgent` method can achieve 100 exam scores in a significant amount of skills, even for some skills that the other three methods get lower performance.

Question Lengths We show how the question length affects model accuracy in Figure 18. Overall, we can find that the longer the question length, the harder the question, and the worse the performance. Moreover, it can be discovered that the curves for `SocialAgent` are smoother than zero-shot settings, which means for a better model, the difficulty of the question does not interfere with it more.

Question Type We use the first word in the question to mark the types of problems, and list the

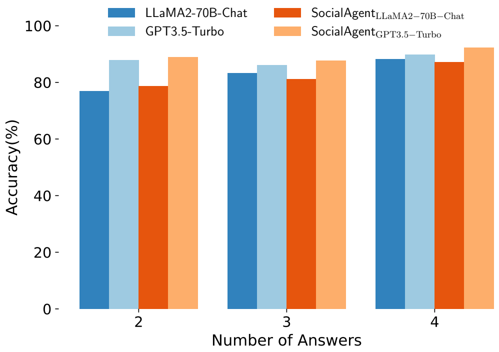

Figure 16: Results on questions with different numbers of answers.

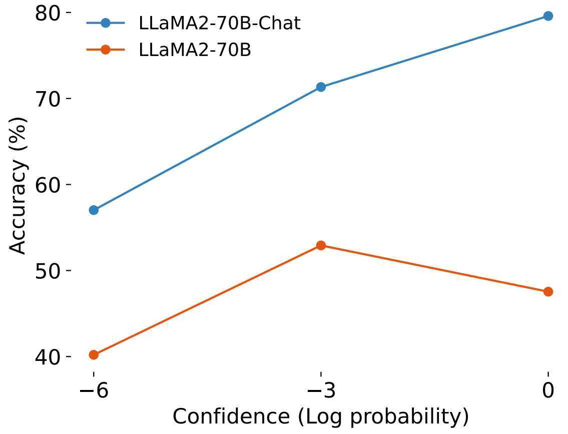

Figure 17: LLaMA2 calibration results. The x-axis denotes the sum of the log probability of the predicted answers.

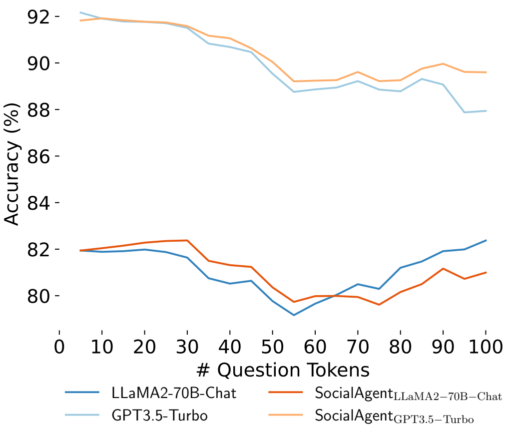

Figure 18: Results on questions with different lengths.

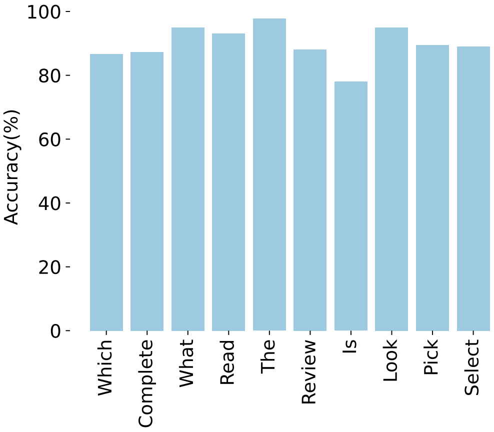

Figure 19: Results on different question types.

accuracy on the top-10 number of question types in Figure 19. Questions starting with "Is" have relatively low accuracy, which means they are harder to answer.

Grades We show the accuracies of the models along each grade in Figure 20. We find that the higher the grade, the lower accuracy of the models. Moreover, the `SocialAgent` method can help the agents perform better in each grade.

Hard Questions Models in general obtain the lowest score in tenth grade questions. This means that the higher the grade, the harder the questions are. Tenth grade questions are hardest for the models. Besides, we also find skills such as "understand-overall-supply-and-demand" are hard for LLMs with an average of 71.0% accuracy (much lower than the average accuracy).

Data Contamination The source datasets (e.g., IXL) require registration to access their data and are designed for education purposes. So it is very unlikely that the data is part of the training data of the LLMs. In addition, we carefully checked the "Data Contamination" section in the technical reports of GPT-3 and LLaMA-2, and it seems the contamination is currently not a major issue of the performance.

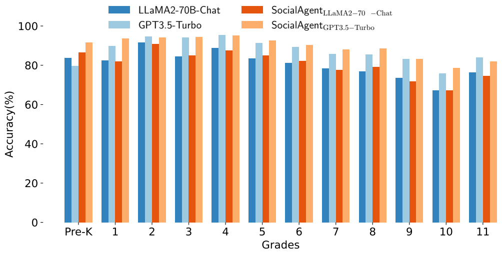

Figure 20: Average grade-level accuracies.

Correlation Analysis We evaluate exam scores' correlation with the model accuracies in Figure 23. A positive correlation can be found, and exam scores can capture the accuracy as an important factor.

Agent type: Retrieval Agent

System prompt: You are a helpful assistant that be good at answer multiple-choice questions about language arts and social studies. And you are good at deciding the search content. I want to use Wikipedia to help me search for some information. You need to help me to decide the search content. You don't have to be polite. You should answer with the following json format: {"Search content": `keywords`}

User prompt: Here is my question and choices: {problem_prompt}. Now give me the content that I need to search. You mustn't add any other words and should only output the keyword. You should answer with the following json format: {"Search content": `keywords`}

Agent type: Programming Agent

System prompt: You are a helpful assistant that be good at answer multiple-choice questions about language arts and social studies. And you are good at extracting the arithmetic expressions from a problem. I want to find out whether do I need to use calculator to solve a problem. You need to help me to decide whether to use calculator and generate the expression. If the calculator is needed, you should output the expression. Else you should output empty string. You don't have to be polite. You mustn't add any other words. You must answer with the following json format: {"Expression": `Your Answer`}. Pay attention to that `Your Answer` must be an empty string or a legal arithmetic expression for python `eval` function.

User prompt: Here is my question and choices: {problem_prompt}. Now give me the arithmetic expression. You mustn't add any other words and should only output the expression. You must answer with the following json format: {"Expression": `Your Answer`}. Pay attention to that `Your Answer` must be an empty string or a legal arithmetic expression for python `eval` function.

Agent type: Reasoning Agent

System prompt: You are a helpful assistant that be good at answer multiple-choice questions about language arts and social studies. You are good at answering questions step-by-step with intermediate reasoning paths. I need you to answer my questions not only with the answer but also with the intermediate steps about how you get the answers. I will give you some other information from other agents. They may be useful or not. And even thay may be wrong. You should try your best to use your own knowledge and these information to answer my questions.

User prompt: Here is my question and choices: {problem_prompt}. Here is the information from other agents: {retrieval_output}{programming_output}. Now give me the answer step-by-step. You **MUST** give me your answer and explain step-by-step how you get it.

LLM

System prompt: You are a helpful assistant that be good at answer multiple-choice questions about language arts and social studies.I want to find out the answer of a multiple-choice question, and asked several other agents for help. I need you to help me decide whether the output of other agents is useful. I will first tell you the question and choices, and then tell you the output of other agents. You should tell me whether the output if useful and feel free to say false when the information is not relative.You don't have to be polite. You mustn't add any other words. You must answer with the following json format: {"Useful": `Your Answer`}. Pay attention to that `Your Answer` must be an boolean value chosen from [true, false].

User prompt: Here is my question and choices: {problem_prompt}. Here is the output information of another agent: {agent_output}. Now give me your answer.You must answer with the following json format: {{"Useful": `Your Answer`}}. Pay attention to that `Your Answer` must be an boolean value chosen from [true, false].

Answer

System prompt: You are a helpful assistant that be good at answer questions about language arts and social studies. I will first tell you the question and choices, and then tell you the output of other agents. You need to choose one of the choices as your answer with your knowledge and other information I give you. You must answer with the choices when asked. If more than one choices are correct, you should only output the first one.You don't have to be polite. You mustn't add any other words. You **MUST** answer with the following json format: {"Answer": `Your Answer`}. Pay attention to that `Your Answer` must be one of the given choices with option letter. Here is an output example: {"Answer": (a) Apple}

User prompt: Here is my question and choices: {problem_prompt}{retrieval_output}{programming_output}{reasoning_output}. Now give me your answer based on your own knowledge and other information I give you. You **MUST** answer with the following json format: {"Answer": `Your Answer`}. Pay attention to that `Your Answer` must be one of the given choices with option letter. Here is an output example: {"Answer": (a) Apple}

Figure 21: Prompting details of the `SocialAgent` method. The green texts need to be filled with the input questions or the arguments and outputs of other agents with the JSON format.

`SocialAgent` Component	Inputs and Outputs
Problem	What month comes right before February? (a) August (b) January
Retrieval Agent	**Input:** month comes right before February **Output:** Page: Before Sunrise Summary: Before Sunrise is a 1995 romantic drama film directed by Richard Linklater and co-written by Linklater and Kim Krizan… Before Sunrise also explores time, death, and self-discovery. **Useful:** false
Programming Agent	**Input:** “”+“” **Output:** NA **Useful:** false
Reasoning Agent	**Output:** To determine the month that comes right before February, we can use our knowledge of the calendar. Step 1: Recall the order of the months in a calendar year: January, February, March, April, May, June, July, August, September, October, November, December. Step 2: Identify the month that comes immediately before February in the calendar year. Based on the given choices, the correct answer is (b) January. We can disregard the information from the other agents as it does not provide any relevant information about the order of the months. **Useful:** true
Answer	**Predicted String:** (b) January

`SocialAgent` Component	Inputs and Outputs
Problem	In most state legislatures, the upper house is called the Senate and the lower house is called the House of Representatives. Is the House of Representatives bigger or smaller than the Senate? (a) The House of Representatives is smaller. (b) The House of Representatives is bigger.
Retrieval Agent	**Input:** size of House of Representatives compared to Senate **Output:** Page: House of Representatives of the Philippines Summary: The House of Representatives of the Philippines (Filipino: Kapulungan ng mga Kinatawan ng Pilipinas… The 19th Congress has 253 congressional districts. Party-list representatives are elected... **Useful:** true
Programming Agent	**Input:** “”+“” **Output:** NA **Useful:** false
Reasoning Agent	**Output:** To determine whether the House of Representatives is bigger or smaller than the Senate, we can use the information provided and analyze it step-by-step. 1. The question states that in most state legislatures, the upper house is called the Senate and the lower house is called the House of Representatives. 2. We can refer to the information provided by the other agent, which states that the House of Representatives is the lower house of Congress… Therefore, the answer is: (a) The House of Representatives is smaller. **Useful:** true
Answer	**Predicted String:** (a) The House of Representatives is smaller.

Figure 22: Complete results of Case Study (Figure 10).

C Prompting Details of `SocialAgent` Method

We show the prompts of our `SocialAgent` method in Figure 21. And we show the complete `SocialAgent` results of Figure 5 and in Table 4. In the prompt design, we aim to help models avoid redundant information such as “Sure, I’m glad to help you”. We therefore do not require models to be polite but be concise regarding their responses. We also show the complete results of our case study 10 in Table 22.

D Summary of Skills

We list all the skills in Table 11 to 13, and show an example for each skill in Table 14 to 39.

`SocialAgent` Component	Inputs and Outputs
Problem	Which is an example of a law? (a) You should get a new toothbrush every six months. (b) You may not drive above the speed limit. (c) You must clean your room before dinner. (d) You should eat more fruits and vegetables.
Retrieval Agent	**Input:** law **Output:** Page: Law Summary: Law is a set of rules that are created and are enforceable by social or governmental institutions to regulate behavior, with its precise definition a matter of longstanding debate. It has been variously described as a science and as the art of justice. State-enforced laws can be made by a group legislature or by a single legislator, resulting in statutes; by the executive through decrees and regulations; or established by judges through precedent, usually in common law jurisdictions. Private individuals may create legally binding contracts, including arbitration agreements that adopt alternative ways of resolving disputes to standard court litigation. The creation of laws themselves may be influenced by a constitution, written or tacit, and the rights encoded therein. The law shapes politics, economics, history and society in various ways and also serves as a mediator of relations between people. Legal systems vary between jurisdictions, with their differences analysed in comparative law. **Useful:** true
Programming Agent	**Input:** “”+“” **Output:** NA **Useful:** false
Reasoning Agent	**Output:** To determine which of the given options is an example of a law, we need to understand the definition of a law. According to the information provided by the Wikipedia search, a law is a set of rules created and enforceable by social or governmental institutions to regulate behavior. Let’s analyze each option: (a) You should get a new toothbrush every six months. This statement is a recommendation or advice, but it does not represent a law. It does not involve any enforcement by social or governmental institutions. (b) You may not drive above the speed limit. This statement represents a law. It sets a rule that prohibits driving above the speed limit, and it is enforceable by traffic laws and law enforcement agencies. (c) You must clean your room before dinner. This statement is a rule or expectation, but it does not represent a law. It is more likely a household rule or expectation rather than a law enforced by social or governmental institutions. (d) You should eat more fruits and vegetables. Similar to option (a), this statement is a recommendation or advice, but it does not represent a law. It does not involve any enforcement by social or governmental institutions. Based on the analysis, the example of a law among the given options is (b) You may not drive above the speed limit. **Useful:** true
Answer	**Predicted String:** (a) surplus

Table 13: Full language arts skill summary (part 2).

Subject: Social Studies Skill: the-american-revolution-new-british-taxes Description: In the 1760s, smuggling was an important part of the colonial economy. What does smuggling mean? Choices: [(a) stealing goods from foreign merchants, (b) trading one good for another without the use of money, (c) shipping goods secretly or illegally, (d) producing metal from minerals and rocks] Answer index: 2	Subject: Social Studies Skill: world-war-i-the-road-to-war Description: What was World War I originally called? Choices: [(a) the First War, (b) the Great War, (c) the European Revolution, (d) European War I] Answer index: 1
Subject: Social Studies Skill: the-american-flag Description: What does each star on the American flag stand for? Choices: [(a) a president, (b) a state, (c) a war, (d) a city] Answer index: 1	Subject: Social Studies Skill: identify-facts-and-opinions Description: Which sentence states a fact? Choices: [(a) The Grand Canyon was carved by the Colorado River., (b) The Grand Canyon is the most breathtaking place the United States.] Answer index: 0
Subject: Social Studies Skill: state-government Description: How are representatives in a state legislature chosen? Choices: [(a) Everyone in the state votes for all of the representatives., (b) Each district, or area, gets to choose one or two representatives., (c) The governor chooses all of the representatives., (d) The mayors of each city choose one or two representatives.] Answer index: 1	Subject: Social Studies Skill: the-empire-state-building Description: Complete the sentence. The Empire State Building was built during a tough time in American history. That time was known as ___. Choices: [(a) the Colonial Period, (b) the Gold Rush, (c) the Reconstruction Era, (d) the Great Depression] Answer index: 3
Subject: Social Studies Skill: local-government Description: Local governments serve which places? Choices: [(a) countries, (b) towns, cities, and counties, (c) states] Answer index: 1	Subject: Social Studies Skill: the-american-revolution-the-rebellion-begins Description: Complete the sentence. At the First Continental Congress, the colonies agreed to ___ goods imported from Great Britain. Choices: [(a) stop buying, (b) buy more, (c) destroy, (d) tax] Answer index: 0
Subject: Social Studies Skill: the-lincoln-memorial Description: Complete the sentence. Architect Henry Bacon designed the Lincoln Memorial in the early 1900s. He got his ideas from ___. Choices: [(a) architect Frank Lloyd Wright, (b) Gothic churches in France, (c) ancient Greek buildings, (d) President Warren G. Harding] Answer index: 2	Subject: Social Studies Skill: world-war-i-the-war-begins Description: Complete the text. There were two main sides in World War I. One side was called the ___ and the other was called the ___. Choices: [(a) Axis powers . . . Allied powers, (b) Allied powers . . . Central powers, (c) Central powers . . . Axis powers, (d) Allied powers . . . Triple Entente] Answer index: 1
Subject: Social Studies Skill: world-war-i-the-road-to-peace Description: Complete the text. During the Paris Peace conference, one group of men was known as ___. They represented the most powerful countries at the conference. Choices: [(a) the Three Emperors' League, (b) the Axis Leaders, (c) the Big Four, (d) the enlightened despots] Answer index: 2	Subject: Social Studies Skill: the-statue-of-liberty Description: The Statue of Liberty was finished in 1886. However, the builders' goal had been to finish in 1876. Why was 1876 important? Choices: [(a) It was the year the Civil War ended., (b) It was the 100th anniversary of the Declaration of Independence., (c) New York City hosted the Olympics that year., (d) The president of France visited the United States for the first time that year.] Answer index: 1
Subject: Social Studies Skill: the-american-revolution-turning-the-tide-of-the-war Description: The Continental Army suffered many losses in the autumn of 1776. Thomas Paine, a popular writer, was traveling with the army. In late December, he wrote an essay. Read the passage from Thomas Paine's essay. Then answer the question below. These are the times that try men's souls. The summer soldier and the sunshine patriot will, in this crisis, shrink from the service of their country; but he that stands by it now, deserves the love and thanks of man and woman. Which sentence best explains what he meant by these words? Choices: [(a) He did not believe the Americans were doing the right thing., (b) General Washington did not know how to lead an army., (c) The British soldiers were afraid of the Americans., (d) The Continental Army was struggling, but it was fighting for a good cause.] Answer index: 3	Subject: Social Studies Skill: the-war-of-1812-causes Description: The War of 1812 was between the United States and which other country? Choices: [(a) France, (b) Canada, (c) Mexico, (d) Great Britain] Answer index: 3
Subject: Social Studies Skill: thanksgiving Description: When is Thanksgiving celebrated in the United States? Choices: [(a) on December 5, (b) on January 12, (c) on the second Sunday of September, (d) on the fourth Thursday of November] Answer index: 3	Subject: Social Studies Skill: source-analysis-the-gettysburg-address Description: The Gettysburg Address, one of the most famous documents in United States history, was written in 1863. At that time, Abraham Lincoln was president of the United States, and the Union and Confederate armies were fighting each other during the American Civil War. Read the following facts about the Gettysburg Address. Then complete the sentence below. Gettysburg is a town in Pennsylvania where an important Civil War battle was fought. One of the meanings of the word address is a public speech. Based on the information above, complete the sentence. When people say, "President Abraham Lincoln gave the Gettysburg Address," they mean that President Lincoln ___. Choices: [(a) lived at 1600 Pennsylvania Avenue, (b) wrote a book about an important Civil War battle, (c) made a speech after an important Civil War battle, (d) is buried in a graveyard in a town in Pennsylvania] Answer index: 2
Subject: Social Studies Skill: causes-of-the-american-revolution-the-french-and-indian-war Description: Complete the text. Before the French and Indian War, there were about 20 times as many British colonists as French colonists. In the 1740s, both British and French colonists began to expand their claims on land in the Ohio River Valley. Both countries were interested in the valuable fur trade there, but ___ were more interested in settling the area. Choices: [(a) The French, (b) the British] Answer index: 1	Subject: Social Studies Skill: the-civil-war-bull-run-to-the-emancipation-proclamation Description: In July 1861, a Union army marched south from Washington, D.C., into Virginia. Its goal was to seize Manassas Junction, an important railroad center. This plan led to the First Battle of Bull Run, the first major battle of the war. ... baffled:confused Complete the sentence. Based on Whitman's account, the First Battle of Bull Run was a ___ for the Union army. Choices: [(a) defeat, (b) victory, (c) draw] Answer index: 0

Table 14: Question examples for each skill (part 1).

Subject: Social Studies Skill: identify-primary-and-secondary-sources Description: Imagine that you are a historian who wants to learn more about the fall of the Roman Empire in the 400s CE. You find the source described below. Read the description of the source. Then complete the sentence below. The historian Edward Gibbon wrote the book The History of the Decline and Fall of the Roman Empire in 1776 CE. Complete the sentence. In this case, the book is a ___ source because it ___. Choices: [(a) primary . . . is a firsthand account of the fall of the Roman Empire, (b) secondary . . . was written by a historian after the fall of the Roman Empire] Answer index: 1	Subject: Social Studies Skill: months-of-the-year Description: What month comes right after February? Choices: [(a) March, (b) December] Answer index: 0
Subject: Social Studies Skill: days-of-the-week Description: What day comes right after Tuesday? Choices: [(a) Saturday, (b) Friday, (c) Wednesday] Answer index: 2	Subject: Social Studies Skill: theodore-roosevelt Description: Complete the sentence. Theodore Roosevelt is best known as ___ from the early 1900s. Choices: [(a) a president, (b) an artist, (c) a pilot, (d) an inventor] Answer index: 0
Subject: Social Studies Skill: george-washington-carver Description: George Washington Carver came up with how many ways to use peanuts? Choices: [(a) around 3, (b) around 30, (c) around 300, (d) around 3,000] Answer index: 2	Subject: Social Studies Skill: cesar-chavez Description: What made Cesar Chavez famous? Choices: [(a) He wrote many books about the Civil War., (b) He helped make life better for farm workers., (c) He invented a new way to bring water to crops., (d) He worked for women's right to vote.] Answer index: 1
Subject: Social Studies Skill: john-deere Description: Complete the sentence. John Deere was a famous ___. Choices: [(a) pilot, (b) soldier, (c) inventor, (d) writer] Answer index: 2	Subject: Social Studies Skill: pledge-of-allegiance Description: A pledge is a promise. Listen to this part of the Pledge of Allegiance. Pick the missing word. I pledge ___ to the Flag of the United States of America . . . Choices: [(a) allegiance, (b) honesty] Answer index: 0
Subject: Social Studies Skill: compare-urban-suburban-and-rural-areas Description: In which place would you be more likely to drive to see your neighbors? Choices: [(a) an urban area, (b) a rural area] Answer index: 1	Subject: Social Studies Skill: abraham-lincoln Description: Complete the sentence. Abraham Lincoln grew up in a poor family. He got most of his education by ___. Choices: [(a) reading a lot of books, (b) taking college classes, (c) going to public school, (d) listening to the radio] Answer index: 0
Subject: Social Studies Skill: the-civil-war-the-first-battle-of-bull-run-to-gettysburg Description: In 1862, the Union army in Washington, D.C., tried to capture the Confederacy's capital of Richmond. Below is a letter from the Union army's commander, General George B. McClellan, to President Lincoln's Secretary of War. I have lost this battle because my force was too small. I have seen too many dead and wounded comrades to feel otherwise than this government has not sustained this army. If you do not do so now the game is lost. If I save this army now, I tell you plainly that I owe no thanks to you or any other person in Washington. You have done the best to sacrifice this army. sustained: helped Whom does McClellan blame for the Union army not capturing Richmond? Choices: [(a) the Union soldiers, (b) himself, (c) the Confederate army, (d) the United States government] Answer index: 3	Subject: Social Studies Skill: new-england-colonies-religion-and-government Description: Complete the text. The Puritans were different from the Pilgrims who moved to New England in 1620. The Pilgrims wanted to ___ the Church of England, but the Puritans wanted to ___ it. Choices: [(a) separate from . . . change, (b) change . . . separate from, (c) strengthen . . . destroy, (d) join . . . leave] Answer index: 0
Subject: Social Studies Skill: the-washington-monument Description: People started building the Washington Monument in 1848. It took 36 years to build. In what year was the Washington Monument completed? Choices: [(a) 1854, (b) 1884, (c) 1898, (d) 1936] Answer index: 1	Subject: Social Studies Skill: the-civil-war-the-beginning-of-the-war Description: Following the Battle of Fort Sumter, President Lincoln called on loyal states to provide troops. How did Virginia, North Carolina, Tennessee, and Arkansas react to this call? Choices: [(a) These states refused to send troops to either side., (b) These states joined the Confederacy., (c) These states demanded that the Confederate states surrender., (d) These states sent troops to the Union army.] Answer index: 1
Subject: Social Studies Skill: antebellum-period-slavery-and-politics-part-i Description: Complete the text. By the 1820s, many Americans wanted to have an equal number of slave and free states. They wanted a balance of states so that the ___ would have the same number of members from each side. Choices: [(a) Supreme Court, (b) Senate, (c) Executive Branch, (d) House of Representatives] Answer index: 1	Subject: Social Studies Skill: the-american-revolution-preparing-for-war Description: To oppose something means to be against it. Which one of these people strongly opposed American independence? Choices: [(a) Thomas Paine, (b) John Adams, (c) King George III, (d) George Washington] Answer index: 2
Subject: Social Studies Skill: the-golden-gate-bridge Description: Complete the sentence. Leaders of the Golden Gate Bridge project made special rules to ___. Choices: [(a) protect birds in the area, (b) keep ferry boats in business, (c) use more recycled materials, (d) help keep workers safe] Answer index: 3	Subject: Social Studies Skill: identify-shortage-and-surplus Description: There are 300 concert tickets for sale. Tickets cost $20 each. At that price, there are 200 people who want to buy a ticket. Is there a surplus or a shortage of tickets? Choices: [(a) surplus, (b) shortage] Answer index: 0
Subject: Social Studies Skill: the-new-deal Description: Which important period in American history began in 1929? Choices: [(a) the Civil War, (b) the Great Depression, (c) World War II, (d) the civil rights movement] Answer index: 1	Subject: Social Studies Skill: reconstruction Description: In 1865, slavery was banned in the United States. How was it banned? Choices: [(a) a presidential veto, (b) a Supreme Court decision, (c) an amendment to the Constitution, (d) a national vote] Answer index: 2
Subject: Social Studies Skill: the-war-of-1812-events-and-effects Description: Which country had a larger navy in 1812? Choices: [(a) the United States, (b) Great Britain] Answer index: 1	Subject: Social Studies Skill: plymouth Description: In 1620, some of the Separatists made an agreement with a business in England called the Virginia Company. The Virginia Company would loan them money to buy supplies and hire a ship. Why did the Separatists need supplies and a ship? Choices: [(a) to create a new country in Europe, (b) to find a trade route between Europe and Asia, (c) to build a new cathedral for the Church of England, (d) to start their own colony in North America] Answer index: 3

Table 15: Question examples for each skill (part 2).

Subject: Social Studies Skill: the-great-depression-part-i Description: Who was the president of the United States at the start of the Great Depression? Choices: [(a) William McKinley, (b) Herbert Hoover, (c) Harry Truman, (d) Gerald Ford] Answer index: 1	Subject: Social Studies Skill: the-american-revolution-struggle-for-independence Description: At the Battle of Bunker Hill, one of the colonial officers gave the soldiers a famous order. Read the order. Then answer the question below. Don't fire until you can see the whites of their eyes! What was one reason the officer gave this order? Choices: [(a) He did not want the soldiers to waste any gunpowder or ammunition., (b) He wanted to make sure that the British soldiers were really going to attack., (c) He wanted to make sure that the soldiers were actually British., (d) He did not want the British soldiers to be surprised by the gunfire.] Answer index: 0
Subject: Social Studies Skill: federal-government Description: Complete the sentence. The three branches of government are the executive, legislative, and ___ branches. Choices: [(a) federal, (b) defensive, (c) state, (d) judicial] Answer index: 3	Subject: Social Studies Skill: the-bill-of-rights Description: Complete the sentences. ___According to the Tenth Amendment, the Constitution lists all of the powers given to the United States government. Any power not listed in the Constitution belongs to either the American people or Choices: [(a) the state governments, (b) the king or queen of Great Britain, (c) private businesses, (d) the Canadian government] Answer index: 0
Subject: Social Studies Skill: the-louisiana-purchase Description: In what year did the Louisiana Purchase take place? Choices: [(a) 1792, (b) 1798, (c) 1803, (d) 1815] Answer index: 2	Subject: Social Studies Skill: the-lewis-and-clark-expedition Description: Why did Thomas Jefferson and others want to find the Northwest Passage? Choices: [(a) It would make traveling less dangerous., (b) It would help lost explorers find their way home., (c) It would make trade with Asia easier.] Answer index: 2
Subject: Social Studies Skill: the-white-house Description: Complete the sentence. The White House is the home of ___. Choices: [(a) the president of the United States, (b) the governor of Maryland, (c) George Washington's great-great-grandson, (d) the Speaker of the House of Representatives] Answer index: 0	Subject: Social Studies Skill: the-american-revolution-conclusion-and-aftermath Description: Complete the sentence. In 1779, ___ joined the Revolutionary War on the side of the United States. Choices: [(a) Spain, (b) Canada, (c) Mexico, (d) Prussia] Answer index: 0
Subject: Social Studies Skill: the-american-revolution-the-boston-tea-party Description: In 1770, colonists who wanted independence still had a hard time getting the colonies to work together. What made working together so difficult? Choices: [(a) The colonists were divided into two groups over the issue of slavery., (b) People living in different colonies often spoke different languages., (c) British soldiers would break up any large meetings of colonists., (d) The colonists were not well organized. They had no easy way to share information.] Answer index: 3	Subject: Social Studies Skill: the-constitution Description: When was the Constitution written? Choices: [(a) 1787, (b) 1867, (c) 1907, (d) 2007] Answer index: 0
Subject: Social Studies Skill: the-civil-war-war-tactics-and-the-home-front Description: Complete the sentence. During the Civil War, the Union navy tried to close off Southern ports. The Union wanted to stop the Confederacy from trading with other countries. In other words, the Union wanted to create ___. Choices: [(a) an ambush, (b) a blockade, (c) an armistice, (d) an assault] Answer index: 1	Subject: Social Studies Skill: the-great-depression-part-ii Description: Where were the effects of the Great Depression felt? Choices: [(a) The Great Depression affected countries around the world., (b) The Great Depression only affected the United States., (c) The Great Depression's impact was limited to North American countries., (d) The Great Depression was felt only in the Western Hemisphere.] Answer index: 0
Subject: Social Studies Skill: the-american-revolution-the-thirteen-colonies-under-british-rule Description: How did Great Britain rule the Thirteen Colonies from so far away? Choices: [(a) Great Britain created a second national capital in the Thirteen Colonies., (b) Each colony elected leaders to visit the British government once a year., (c) Each colony had its own government, and those governments had to follow British law., (d) The king of Great Britain traveled to the Thirteen Colonies once a month.] Answer index: 2	Subject: Social Studies Skill: world-war-i-events-of-the-war Description: Read the passage. Then answer the question. The main type of fighting in World War I was trench warfare. Soldiers dug trenches, or deep holes in the ground, to protect themselves from enemy fire. ... Soldiers stayed in the trenches for weeks at a time. The trenches were dirty and uncomfortable. Many soldiers got sick in the trenches. Why were trenches used during World War I? Choices: [(a) Trenches helped to end the war quickly., (b) Trenches protected soldiers from enemy weapons., (c) Trenches were clean places for soldiers to stay before returning to fight., (d) Trenches made "no man's land" a safer place to be.] Answer index: 1
Subject: Social Studies Skill: antebellum-period-abolitionist-and-proslavery-perspectives Description: By 1860, there were almost four million enslaved African American people in the United States. What is an enslaved person? Choices: [(a) a person who is drafted into the army, (b) a person who is owned by someone else, (c) a person who works for someone else for 4 to 7 years, (d) a person who is a criminal] Answer index: 1	Subject: Social Studies Skill: new-england-colonies-economy-and-conflict Description: Slavery was not as widespread in New England as it was in the Southern Colonies. Why not? Choices: [(a) The colonists in New England had nothing valuable to trade for enslaved people., (b) The Puritans believed slavery was morally wrong. Most towns made slavery illegal., (c) New England did not have many large plantations, where enslaved labor was most valuable.] Answer index: 2
Subject: Social Studies Skill: jamestown-the-early-years Description: Read the passage about the men who traveled to Jamestown. Then answer the question below. Around 100 men signed up to travel to Jamestown. Here are some of the men who signed up: ... However, around 50 of the men who signed up to go to weren't workers at all! They were gentlemen. A gentleman is a man born into a noble family. Often, gentlemen are rich. They are rarely asked to do any work. Many gentlemen wanted to travel to Jamestown to find adventure. Half of the first Jamestown settlers were gentlemen. Why might that have been a problem? Choices: [(a) Gentlemen wanted to avoid adventures in the new colony., (b) Gentlemen did not have enough money to help start a new colony., (c) Gentlemen were not used to the hard work of starting a colony.] Answer index: 2	Subject: Social Studies Skill: middle-colonies-founding-and-government Description: John Berkeley and Sir George Carteret wanted to make money by charging fees for land in New Jersey. But to do this, they needed to attract Europeans to settle the land. Which of these rules would probably make Europeans more likely to move to New Jersey? Choices: [(a) All settlers would have to work for seven years before they could get any land., (b) All settlers would have to pay taxes to the colonial government., (c) All settlers would be free to practice the religion of their choice.] Answer index: 2

Table 16: Question examples for each skill (part 3).

Subject: Social Studies Skill: antebellum-period-slavery-and-politics-part-ii Description: While in prison in December 1859, John Brown handed a note to his guard. Use the text from that note to answer the question below. I, John Brown, am now quite certain that the crimes of this guilty land will never be purged away; but with blood. purged:removed What did Brown believe would be needed to end slavery? Choices: [(a) economic boycott, (b) petitions, (c) non-violent protest, (d) violence] Answer index: 3	Subject: Social Studies Skill: southern-colonies-economy-and-slavery Description: Complete the sentence. The largest farms in the Southern Colonies grew cash crops. Cash crops are plants meant ___. Choices: [(a) to be sold, (b) to be given to the government, (c) to feed wildlife, (d) to be eaten by farmers] Answer index: 0
Subject: Social Studies Skill: presidential-elections Description: Complete the sentence. In an election, people choose their representatives and leaders by ___. Choices: [(a) voting, (b) giving speeches, (c) drawing names randomly, (d) passing laws] Answer index: 0	Subject: Social Studies Skill: the-civil-war-the-end-of-the-war Description: In 1864, the United States held a presidential election. Lincoln ran for re-election. A couple months before the election, Lincoln wrote the following note to his advisors. Use it to answer the question below. This morning, as for some days past, it seems exceedingly probable that this Administration will not be re-elected. Then it will be my duty to so cooperate with the President elect, as to save the Union between the election and the inauguration; as he will have secured his election on such ground that he can not possibly save it afterwards. ... inauguration:when a president takes office What did Abraham Lincoln think would happen if he lost the election? Choices: [(a) The election would bring the country back together., (b) The new president would not be able to save the Union., (c) The new president would ask Lincoln to be vice president.] Answer index: 1
Subject: Social Studies Skill: mount-rushmore Description: When did workers start carving Mount Rushmore? Choices: [(a) in 1863, (b) in 1888, (c) in 1901, (d) in 1927] Answer index: 3	Subject: Social Studies Skill: understand-overall-supply-and-demand Description: Eli Whitney invented the cotton gin in 1793. The cotton gin is a machine that makes it easier to harvest cotton quickly. What happened to the overall supply of cotton after 1793? Choices: [(a) The supply went up., (b) The supply went down.] Answer index: 0
Subject: Social Studies Skill: costs-and-benefits Description: Samuel is deciding whether to bake banana muffins or lemon muffins. He wants the muffins to be tasty. But he also wants to make a lot of muffins. Suppose Samuel decides to bake lemon muffins. Which result would be a cost? Choices: [(a) Samuel will get to eat more muffins. He can make more lemon muffins than banana muffins., (b) Samuel will give up the chance to eat banana muffins. He thinks banana muffins are tastier than lemon muffins.] Answer index: 1	Subject: Social Studies Skill: antebellum-period-economies-of-the-north-and-south Description: In the United States, most enslaved people worked on large farms that grew crops to sell. What were these farms called? Choices: [(a) subsistence farms, (b) workshops, (c) factories, (d) plantations] Answer index: 3
Subject: Social Studies Skill: jamestown-growth-of-a-colony Description: In 1613, a Jamestown settler kidnapped Chief Powhatan's favorite daughter. What was she called? Choices: [(a) Pocahontas, (b) Massasoit, (c) Squanto, (d) Sacagawea] Answer index: 0	Subject: Social Studies Skill: world-war-ii-lead-up-to-war-in-europe-asia Description: After the Treaty of Versailles was signed, a German newspaper stated the following. Read the passage. Then answer the question. Today German honor is being carried to its grave. Do not forget it! The German people will, with unceasing labor, press forward to reconquer the place among the nations to which it is entitled. Then will come vengeance for the shame of 1919. ... vengeance:payback According to the passage, what does the author want Germany to do in the future? Choices: [(a) The author wants Germany to join the Allied powers., (b) The author wants Germany to become a powerful nation again., (c) The author wants Germany to forget about World War I., (d) The author wants Germany to join the League of Nations.] Answer index: 1
Subject: Social Studies Skill: southern-colonies-founding-and-government Description: Many Virginians did not like the colonial government's friendly policies toward Native Americans. In 1676, these Virginians violently rebelled against the government in Virginia. This event became known as Bacon's Rebellion. Which of the following is an example of a violent rebellion? Which of these things would a merchant be likely to do? Choices: [(a) use lumber from the Middle Colonies to build houses, (b) grow cash crops such as corn and wheat, (c) sell corn from the Middle Colonies to people in England, (d) make iron products such as plows and horseshoes] Answer index: 2
Subject: Social Studies Skill: world-war-ii-global-events Description: Kathryn Mary Doody was a nurse at an army hospital in Hawaii when Pearl Harbor was bombed. Read Kathryn Mary Doody's account of the events of December 7, 1941. Then answer the question. Pretty soon the night nurse came off duty, and she said to us, "Girls, you know what's happening?" And we said, "No, what's happening?" She said, "The island of Oahu has been attacked by the enemy, Japan." And I said, "Shut up." Because she was a person that always had the greatest stories to relate. And she said, "Don't pay any attention to me. Go turn your radios on." So I went in the room and turned the radio on and that's exactly what they were repeating, over and over again.. . .So I thought, "That means war. What's war going to be like?" According to the passage, what was Kathryn Mary Doody's reaction when she first heard about the attack on Pearl Harbor? Choices: [(a) She was scared and went to church to pray for peace., (b) She didn't believe that it was true., (c) She told all of her friends that they should help the military., (d) She was angry at the United States government.] Answer index: 1	Subject: Social Studies Skill: early-mesopotamia Description: Complete the text. Mesopotamia is an area between the ___ Rivers. Because of the rich soil created by the two rivers, Mesopotamia is often called the Fertile Crescent. Choices: [(a) Indus and Ganges, (b) Mississippi and Missouri, (c) Tigris and Euphrates, (d) Nile and Jordan] Answer index: 2

Table 17: Question examples for each skill (part 4).

Subject: Social Studies Skill: ancient-china Description: For people in ancient Chinese communities, flooding around the Yellow and Yangtze Rivers was a common problem. But floods had both positive and negative effects for people in ancient China. Which of the following was a positive effect of flooding? Choices: [(a) Floods killed many animals who lived near the river., (b) After a river flooded, fertile soil was left on the land., (c) Many crops were destroyed by the floods., (d) Floods destroyed homes located near the river.] Answer index: 1	Subject: Social Studies Skill: origins-of-islam Description: Muslims believe there is only one god. They call this god Allah, which means "God" in Arabic. The following passage describes a Muslim belief about how Allah revealed, or communicated, messages to his followers. Read the passage. Then answer the question below. We believe in Allah and [the message that] was revealed to us and what was revealed to Abraham . . . and the teachings which Allah gave to Moses and Jesus and to other prophets. ... Al Imran 3:84 in Zafar Ishaq Ansari, translator, Towards Understanding the Qur'an, Volume 1. Copyright 1988 by The Islamic Foundation. Based on this passage, which statement do most Muslims believe is true? Choices: [(a) Allah is more powerful than the god Jews and Christians worship., (b) Allah is the same god that Jews and Christians worship., (c) Allah sent messages to Abraham, but not to other prophets.] Answer index: 1
Subject: Social Studies Skill: the-teachings-of-confucius Description: Confucius's teachings have been passed down in a text known as The Analects (AN-el-ekts). Read the passage about The Analects. Then answer the question below. The Analects is made up of discussions between Confucius and his students. When Confucius was alive, his students all remembered their own conversations with Confucius. When Confucius died, his students gathered together to write down their memories of Confucius's teachings. The text they wrote down was called The Analects, which means "the selected speeches." Complete the text. collected and wrote down The Analects. The Analects is made up of ___. Choices: [(a) Confucius . . . books Confucius wrote, (b) Confucius . . . conversations Confucius had with his students, (c) Confucius's students . . . books Confucius wrote, (d) Confucius's students . . . conversations Confucius had with his students] Answer index: 3	Subject: Social Studies Skill: ancient-egypt-the-old-kingdom Description: Complete the text. Before Upper and Lower Egypt became one kingdom, they were divided into nomes, or ___. Each nome was controlled by a nomarch, or local king. Choices: [(a) territories, (b) farms, (c) churches, (d) teams] Answer index: 0
Subject: Social Studies Skill: the-mauryan-empire Description: One of Chandragupta's most important military and political advisors was a man named Kautilya. Read the following story about Kautilya and Chandragupta. Then answer the question below. Kautilya and Chandragupta gathered an army to overthrow the Nanda Empire. At first, their soldiers attacked the center of the Nanda Empire, but they were defeated by the powerful Nanda army. ... According to tradition, Kautilya and Chandragupta took that mother's advice about eating hot bread and used it to defeat the Nanda Empire. How did Kautilya and Chandragupta use the mother's advice to defeat the Nanda Empire? Choices: [(a) They convinced members of the Nanda army to change sides and help Chandragupta overthrow the empire., (b) They attacked the Nanda Empire from the edges, where it was weakest, rather than from the center where it was strong., (c) They attacked the center of the Nanda Empire until the army was too tired and weak to keep fighting.] Answer index: 1	Subject: Social Studies Skill: origins-of-christianity Description: Complete the text. Jesus of Nazareth is the most important figure in Christianity. Most Christians believe he ___. Choices: [(a) is God, (b) built a temple in Jerusalem, (c) was a famous military leader, (d) was a Roman emperor] Answer index: 0
Subject: Social Studies Skill: ancient-egyptian-religion Description: In ancient Egypt, powerful gods were an important part of religious beliefs. People who believe in many gods are called polytheists (pol-ee-THEE-ists). Which statement would support the idea that ancient Egyptians were polytheists? Choices: [(a) Many ancient Egyptians worshipped the gods Osiris, Isis, and Horus., (b) Ancient Egyptian religious traditions lasted over 3,000 years., (c) Many different creation stories were popular in ancient Egypt., (d) Ancient Egypt was located in northeastern Africa, along the Nile River.] Answer index: 0	Subject: Social Studies Skill: the-gupta-empire Description: The Gupta Empire was founded by a man who became known as Chandra Gupta (CHUN-druh GOOP-tuh). Read about Chandra Gupta. Then complete the sentence below. Chandra Gupta was born to a ruling family, but they only controlled a small area and were not very powerful. That began to change around 320 CE when Chandra Gupta married Princess Kumaradevi. Princess Kumaradevi came from a powerful family that controlled an area along the Ganges River. By marrying Kumaradevi, Chandra Gupta expanded the area he controlled, and he began forming an empire. Complete the following sentence. Chandra Gupta began the Gupta Empire after he ___. Choices: [(a) threatened to stop trading with regions that refused to let him rule, (b) inherited the large region his family had controlled for generations, (c) married a princess and took control of the area her family ruled, (d) won battles against many kingdoms along the Ganges River] Answer index: 2
Subject: Social Studies Skill: origins-of-judaism Description: Judaism (JU-dee-izm) is a religion that has existed for thousands of years. What are people who practice Judaism called? Choices: [(a) Christians, (b) Jains, (c) Jews, (d) Hindus] Answer index: 2	Subject: Social Studies Skill: the-ancient-silk-road-goods-and-ideas Description: People in the Han Dynasty produced silk, an important luxury good. Han people used silk for money and clothing within Han territory, and they also sold silk to foreign merchants. Wealthy people in the Roman Empire wanted Han silk for their clothing. But Han merchants did not travel all the way to Rome. Instead, Middle Eastern merchants helped bring Han silk to Rome. The information below describes Middle Eastern merchants' roles in the silk trade. Read the information. Then answer the question below. Merchants from the Middle East bought Han silk fabric in Asia and brought it to Syria, a region in the Middle East. This fabric was usually made with Han styles and patterns. ... Finally, Syrian merchants sold the re-woven silk to wealthy Romans. As a result, Syrian merchants became wealthy from the silk trade. Based on this information, which statement about how silk was traded is true? Choices: [(a) People in the Middle East re-wove Han silk into styles that Romans liked., (b) Han people wove silk into styles that were popular with people in the Roman Empire., (c) Han merchants traveled the Silk Road to sell silk directly to people in the Roman Empire.] Answer index: 0

Table 18: Question examples for each skill (part 5).

Subject: Social Studies Skill: mesopotamian-empires Description: Read some of King Hammurabi's laws. Then complete the sentence below. If a man put out the eye of another man, his eye shall be put out. ... mina:a unit of weight for measuring money, about 1 pound Complete the sentence. According to Hammurabi's law code, if a man commits a crime against an enslaved person, his punishment would be ___ the punishment for a crime committed against his equal. Choices: [(a) less harsh than, (b) equally as harsh as, (c) more harsh than] Answer index: 0	Subject: Social Studies Skill: the-kingdoms-of-kush Description: Around 2300 BCE, the first kingdom of Kush began to develop, called the Kerman Kingdom. It grew out of a city called Kerma. At that time, Kush did not have its own written language. So today, researchers study objects and buildings instead of written sources to learn about the Kerman Kingdom. Read the description of the largest monument in the Kerman Kingdom. Then answer the question below. The Western Deffufa (duh-FOO-fuh) is one of the oldest monuments in Africa. It was built by the rulers of the Kerman Kingdom around 2000 BCE. When the Western Deffufa was built, it was one of the largest buildings in the region. Today, even though some of the building has crumbled away, it is still around 60 feet tall. That's about as tall as a six-story building! ... The Western Deffufa was made out of a common building material called mudbrick. Each brick had to be individually shaped and then baked in the sun. Then people needed to transport the bricks to the construction site and stack them up to make the walls of the building. This process took a lot of time. It also cost the Kerman rulers a lot of money to feed all of the workers. What does the Western Deffufa tell researchers about the Kerman Kingdom? Choices: [(a) The Kerman Kingdom must have been wealthy and powerful in order to build it., (b) The Kerman Kingdom used a rare type of building material., (c) The Kerman Kingdom used the structure for military activities.] Answer index: 0
Subject: Social Studies Skill: the-han-dynasty Description: The city of Chang'an grew to have over 200,000 people around 1 CE. At that time, both the Han and the Roman Empires had almost the same population! The graph below shows the estimated population of the Han Dynasty between 200 BCE and 157 CE. Look at the graph. Then complete the sentence below. Complete the sentence. In the year 2 CE, around ___ million people lived in Han territory. Choices: [(a) 15, (b) 20, (c) 44, (d) 60] Answer index: 3	Subject: Social Studies Skill: early-chinese-thought Description: A king needed the Mandate of Heaven in order to rule. People believed that a king had the support of heaven if his actions had positive results or when good events happened in the world around them. The poem below comes from a Zhou dynasty book called the Book of Songs. Read the poem. Then answer the question below. The drought has become so severe ... great mandate:Mandate of Heaven Why does this poem claim that the "great mandate is about at an end?" Choices: [(a) The ruler was not able to stop a natural disaster., (b) The ruler had kicked people out of their homes., (c) The weather was cold and people became sick., (d) Flooding from the Yellow River destroyed several Zhou cities.] Answer index: 0
Subject: Social Studies Skill: the-qin-empire Description: Read the passage about Qin law. Then answer the question below. Shang Yang wrote many new laws for the Qin state. Some of these laws organized people into groups of five or ten families. Laws required these groups to spy on one another's activities and to report their neighbors' crimes. If neighbors reported crimes to the government right away, they would usually not be punished for their neighbors' crimes. But if people failed to report their neighbor's crime, they would be punished harshly. Based on the information above, why did Qin rulers make laws that required people to spy on one another? Choices: [(a) These laws kept people from committing crimes., (b) The Qin government wanted to pardon people for committing crimes., (c) These laws encouraged people to work harder., (d) They hoped that neighbors would write their own laws and not bother the Qin government.] Answer index: 0	Subject: Social Studies Skill: susan-b-anthony Description: What job did Susan B. Anthony have when she was young? Choices: [(a) teacher, (b) librarian, (c) actress, (d) police officer] Answer index: 0
Subject: Social Studies Skill: paul-revere Description: What did Paul Revere do to fight against British rule? Choices: [(a) He wrote an essay., (b) He ran for governor of Massachusetts., (c) He joined the Sons of Liberty., (d) He printed an anti-British newspaper.] Answer index: 2	Subject: Social Studies Skill: lunar-new-year Description: Complete the sentence. On the Gregorian calendar, the first day of the Chinese lunar year is ___ each year. Choices: [(a) the same, (b) different] Answer index: 1
Subject: Social Studies Skill: holi Description: Holi comes from which religion? Choices: [(a) Hinduism, (b) Catholicism, (c) Islam, (d) Buddhism] Answer index: 0	Subject: Social Studies Skill: rosa-parks Description: Rosa Parks moved when she was 11 years old. She moved to the city of Montgomery, Alabama. Why did she move? Choices: [(a) to go to church, (b) to go to school, (c) to get a job, (d) to live in a bigger house] Answer index: 1
Subject: Social Studies Skill: neil-armstrong Description: Which two countries were part of the Space Race? Choices: [(a) the United States and the Soviet Union, (b) the United States and China, (c) Japan and the Soviet Union, (d) Japan and China] Answer index: 0	Subject: Social Studies Skill: easter Description: When is Easter celebrated? Choices: [(a) a Sunday in early spring, (b) the first Monday in July, (c) December 25, (d) late November] Answer index: 0
Subject: Social Studies Skill: amelia-earhart Description: Complete the sentence. Amelia Earhart was a famous ___. Choices: [(a) athlete, (b) pilot, (c) scientist, (d) artist] Answer index: 1	Subject: Social Studies Skill: thomas-jefferson Description: Complete the sentence. Thomas Jefferson believed that people needed to be ___ to be good voters. Choices: [(a) educated, (b) wealthy, (c) parents, (d) religious] Answer index: 0
Subject: Social Studies Skill: christmas Description: On Christmas, Christians celebrate which story? Choices: [(a) the story of Jesus Christ walking on water, (b) the story of Jesus Christ's birth, (c) the story of Jesus Christ feeding people, (d) the story of Jesus Christ coming back from the dead] Answer index: 1	Subject: Social Studies Skill: frederick-douglass Description: As an enslaved person, Frederick Douglass had many jobs. What was one job that he had? Choices: [(a) He ran a shop., (b) He worked in the fields., (c) He worked in a factory., (d) He gave people medicine.] Answer index: 1

Table 19: Question examples for each skill (part 6).

Subject: Social Studies Skill: benjamin-franklin Description: Benjamin Franklin played an important part in which conflict? Choices: [(a) World War I, (b) the Civil War, (c) the American Revolution, (d) the War of 1812] Answer index: 2	Subject: Social Studies Skill: ramadan Description: Complete the sentence. During Ramadan, Muslims remember an important event in the life of ___. Choices: [(a) Muhammad, (b) Pope John Paul II, (c) Guru Nanak, (d) Martin Luther] Answer index: 0
Subject: Social Studies Skill: dia-de-los-muertos Description: When is Día de los Muertos celebrated? Choices: [(a) April 15, (b) October 27, (c) November 1 and 2, (d) the last Monday in May] Answer index: 2	Subject: Social Studies Skill: jackie-robinson Description: Why do we look up to Jackie Robinson? Choices: [(a) He was bossy., (b) He was brave., (c) He was popular., (d) He was funny.] Answer index: 1
Subject: Social Studies Skill: harriet-tubman Description: When was Harriet Tubman born? Choices: [(a) the 1490s, (b) the 1610s, (c) the 1820s, (d) the 1910s] Answer index: 2	Subject: Social Studies Skill: sitting-bull Description: Complete the sentence. Sitting Bull was an important ___ leader in the 1800s. Choices: [(a) Japanese American, (b) Native American, (c) German American, (d) Mexican American] Answer index: 1
Subject: Social Studies Skill: kwanzaa Description: What does Kwanzaa celebrate? Choices: [(a) the birthday of Dr. Martin Luther King, Jr., (b) the signing of the Declaration of Independence, (c) the history and culture of African American people, (d) the day that slavery ended] Answer index: 2	Subject: Social Studies Skill: thurgood-marshall Description: Thurgood Marshall was a Supreme Court justice for 24 years. What do Supreme Court justices do? Choices: [(a) They punish criminals., (b) They decide whether laws agree with the Constitution., (c) They write and pass new laws., (d) They make peace treaties with other countries.] Answer index: 1
Subject: Social Studies Skill: hanukkah Description: In a game of dreidel, how do you win the whole pot? Choices: [(a) by landing on the letter gimel, (b) by spinning your dreidel in a perfect circle, (c) by spinning your dreidel longer than anyone else's, (d) by knocking over everyone else's dreidels] Answer index: 0	Subject: Social Studies Skill: bill-gates Description: Use this paragraph to answer the question below. Bill Gates grew up in a family that liked to have contests. When they played tennis or went swimming, there was always a contest and a winner. Bill Gates always wanted to win. He hated losing at anything. Complete the sentences. Growing up, Bill Gates was always competitive. That meant he ___. Choices: [(a) was always well behaved, (b) hated sports, (c) tried to be the best] Answer index: 2
Subject: Social Studies Skill: purpose-of-government Description: Which is an example of a law? Choices: [(a) You should get a new toothbrush every six months., (b) You may not drive above the speed limit., (c) You must clean your room before dinner., (d) You should eat more fruits and vegetables.] Answer index: 1	Subject: Social Studies Skill: rosh-hashanah Description: Rosh Hashanah is the beginning of a ten-day religious period. The period ends with which holiday? Choices: [(a) Hanukkah, (b) Passover, (c) Yom Kippur, (d) Purim] Answer index: 2
Subject: Social Studies Skill: davy-crockett Description: When Davy Crockett was 12 years old, his family needed help making money. Davy Crockett got a job to help out. What sort of work did he do? Choices: [(a) He worked in a factory in Pennsylvania., (b) He helped build ships in Boston., (c) He helped move cows from Tennessee to Virginia., (d) He worked in a bank in New York City.] Answer index: 2	Subject: Social Studies Skill: the-ancient-silk-road-geography-and-transportation Description: Although most merchants traded in shorter sections of the Silk Road, some merchants occasionally traveled to new regions. These merchants could learn about different parts of the Silk Road from guidebooks. The passage below comes from a guidebook for merchants written in the first century CE. Scholars think it was written by an Egyptian merchant who traveled in the Red Sea and Indian Ocean. Read the passage from the guidebook. Then follow the instructions below. Now the whole country of India has very many rivers, and very great ebb and flow with the tides . . . entrance and departure of vessels is very dangerous to those who are inexperienced or who come to this market town for the first time. ... Source: Periplus of the Red Sea This guidebook helped merchants learn ___. It could also help them ___. Choices: [(a) about the geography of a new place . . . avoid dangerous areas, (b) to build boats . . . learn how to swim, (c) to speak new languages . . . find where markets were located] Answer index: 0
Subject: Social Studies Skill: slavery-in-the-south Description: For more than 300 years, people were enslaved in Africa and then brought to North and South America, where they were sold. But in the early 1800s, this changed. Complete the text. In 1807, Great Britain made it illegal to buy and sell enslaved people across the Atlantic Ocean using British ships. The United States did not ban slavery, but it did ban importing any new enslaved people into the country. So, by 1860, most enslaved people in the United States ___. Choices: [(a) had been born there, (b) came from Great Britain, (c) had been freed] Answer index: 0	Subject: Social Studies Skill: the-abolitionists Description: One of the most vivid descriptions of life aboard a slave ship comes from a book written by Olaudah Equiano (oh-lah-OO-dah eh-kwee-AH-no). In the following passage, Equiano describes his experiences on a slave ship bound for the Americas. Read the passage. Then complete the sentence below. I was soon put down under the decks, and there I received such a salutation in my nostrils as I had never experienced in my life. . . . I became so sick and so low that I was not able to eat. . . . But soon, to my grief, two of the white men offered me [food]; and, on my refusing to eat, one of them held me fast by the hand . . . and tied my feet, while the other flogged me severely. . . . I would have jumped over the side, but I could not; and, besides, the crew used to watch us very closely . . . lest we should leap into the water. ... lest we should:in case we would Complete the sentence. Equiano published his book in 1789 in Great Britain. Most of his readers were white Europeans. Equiano most likely wrote his book to persuade ___ people to ___. Choices: [(a) British . . . end the slave trade, (b) Native American . . . join the slave trade, (c) African . . . fight against slavery, (d) European . . . purchase more enslaved people] Answer index: 0

Table 20: Question examples for each skill (part 7).

Subject: Social Studies Skill: new-england-colonies-economy-and-interactions-with-native-americans Description: Colonists traded with Native American groups. But colonists also fought Native American groups for land and resources. For example, in the Pequot War (1636–1638), New England colonists fought the Pequot people for control of the valuable farmland and trading routes along the Connecticut River. The adapted passage below was written by a New England colonist who fought in the Pequot War. In this passage, the colonist describes how an army of New England colonists and Native American allies attacked the most important Pequot town. Many Pequot were burnt when we set fire to the town, men, women, and children, others forced out which our soldiers killed; down fell men, women, and children. Those that escaped us, fell into the hands of [the Native Americans fighting on the side of the colonists], that were behind us. There were about four hundred Pequot in this town, and not above five of them escaped out of our hands. Captain John Underhill, Newes from America, 1638. This passage describes a key event of the Pequot War. According to the passage, what happened during this event? Choices: [(a) The Pequot defeated the army of colonists and their allies., (b) The Pequot and the colonists agreed to share the Connecticut River., (c) The colonists and their allies killed or captured most of the Pequot., (d) The colonists captured the Pequot warriors but did not harm the other Pequot.] Answer index: 2	Subject: Social Studies Skill: state-and-local-government Description: Sometimes it is not clear what powers a state government has. The passage below describes a conflict between a state government and the federal government over schools that were segregated, or divided, by race. Read the passage. Then answer the question below. Before 1954, many states segregated public schools based on race. In these states, African American students and white students were not allowed to go to the same schools. Opponents and supporters of segregation disagreed about whether the state government or the national government had the power to decide whether schools should be segregated: ... In the case Brown v. Board of Education (1954), the U.S. Supreme Court ruled that segregated schools violated the rights of American citizens under federal law. The court ordered states to stop segregating schools. When the state government of Arkansas refused to obey the Supreme Court, the president of the United States sent soldiers to enforce the court's decision. Based on the passage, which part of government decides whether the Constitution allows a state government to do something? Choices: [(a) the Supreme Court, (b) the president, (c) state governments, (d) Congress] Answer index: 0
Subject: Social Studies Skill: world-war-i-the-great-war Description: The passage below describes how World War I started with a single incident, but spread quickly into a large-scale war. Read the passage. Then answer the question. In the early 1900s, countries in Europe were part of alliances, or agreements to protect each other if they were attacked. There were two rival alliance groups: ... In 1914, a Serbian nationalist assassinated a top official from Austria-Hungary. Austria-Hungary responded by declaring war on Serbia, sparking a chain reaction that forced allies to declare war. Although Serbia wasn't an official member of an alliance, it had strong ties to Russia. So, Russia immediately stepped in to defend Serbia. Then, Germany supported its ally Austria-Hungary by declaring war on Russia. Next, France joined the war to uphold alliance agreements with Russia. This made Great Britain join with the Allied powers to defend both France and Russia. How did the alliance system in Europe lead to World War I? Choices: [(a) Once two countries were at war, the other countries were able to step aside., (b) When a country outside the alliance system declared war, all the others joined to fight the outside power., (c) When one country declared war, many other countries had to join in to defend their allies., (d) When Russia stepped in to defend Serbia, Germany also had to defend Serbia.] Answer index: 2	Subject: Social Studies Skill: causes-of-the-civil-war-dred-scott-to-secession Description: The Supreme Court's decision in the Dred Scott case outraged many Americans, especially in the North. They thought that slaveholders were gaining too much power. In 1858, an Illinois Republican named Abraham Lincoln gave a speech about the role of slavery in the United States. Read the passage from Lincoln's House Divided speech. Then answer the question below. A house divided against itself cannot stand. I believe this government cannot endure permanently, half slave, and half free. Either the opponents of slavery will [stop] the further spread of it, and put it in course of [extinction], or its [supporters] will push it forward till it shall become alike lawful in all the states, old, as well as new. In his speech, Lincoln uses the metaphor of a "house divided against itself." According to Lincoln, which of the following was like a house divided against itself? Choices: [(a) the relationship between Mexico and the U.S., (b) the Republican party, (c) the Illinois legislature, (d) the United States government] Answer index: 3
Subject: Social Studies Skill: the-marshall-court Description: The Supreme Court's job is to interpret and apply the laws of the United States, including the Constitution. When a case reaches the Supreme Court, the justices hear arguments on both sides of the case and then make a decision. With its decision, the Court is often deciding what the Constitution means. Under the leadership of John Marshall, the Supreme Court made many decisions that set important precedents. The word "precedent" comes from the word "precede," which means "to come before." Based on this information, which of the following is the best example of a "precedent" in law? Choices: [(a) the closing argument by a defense lawyer in a criminal trial, (b) an earlier rule set by a Supreme Court decision for later courts to follow, (c) a speech given by the chief justice of the Supreme Court] Answer index: 1	Subject: Social Studies Skill: source-analysis-the-declaration-of-independence Description: The Declaration of Independence is one of the most famous documents in United States history. A declaration of independence is a document created by the people of one country to say they are no longer part of another country. Which of the following is an example of a declaration of independence? Choices: [(a) a document describing the major laws of the federal government, (b) a document saying that the United States had won World War II, (c) a document declaring that the United States would no longer allow slavery, (d) a document stating that the United States was no longer part of the British Empire] Answer index: 3
Subject: Social Studies Skill: portuguese-and-spanish-expeditions-part-ii Description: While the Portuguese were working their way around the coast of Africa, other European countries, such as Spain, also wanted to trade in the Indian Ocean. But Portugal already controlled sea trade along the West African coast. In fact, the rulers of Spain had signed a treaty agreeing not to trade there. Imagine you are the ruler of Spain. You are determined to trade in the Indian Ocean, but the Portuguese are blocking you from sending expeditions around Africa. What would be the best solution to this problem? Choices: [(a) give up and focus instead on trade in Europe, (b) look for other routes to the Indian Ocean, (c) break the treaty and start an expensive war] Answer index: 1	Subject: Social Studies Skill: the-legislative-branch Description: The majority party in each chamber of Congress has an advantage. What is one reason why? Choices: [(a) The majority party elects the president every four years., (b) Only representatives and senators from the majority party can vote on bills., (c) The president usually agrees with the majority party., (d) Members of Congress usually vote the same way as the rest of their party.] Answer index: 3
Subject: Social Studies Skill: the-first-party-system-federalists-and-democratic-republicans Description: Political parties are groups that support different political positions. Today they are a regular part of political life in the United States, but they have not always existed. Parties first formed in the 1790s, after George Washington was elected president. Washington wrote about political parties in 1796. Read Washington's words. Then complete the sentence below. Let me warn you, in the most solemn manner, against the baneful effects of [parties]. ... baneful:harmful, destructive Complete the sentence. After seeing disagreements among Americans increase while he was president, Washington felt that political parties were ___ for the United States. Choices: [(a) dangerous, (b) necessary, (c) helpful] Answer index: 0	Subject: Social Studies Skill: the-constitution-interpretation Description: Sometimes, interpretations of the Constitution can differ or can change over time. One part of the Constitution that judges have often needed to interpret is the Fourteenth Amendment. The Fourteenth Amendment was added in 1868, after the Civil War ended. Read the text of a section of the amendment called the Equal Protection Clause. Then answer the question below. No State shall . . . deny to any person within its jurisdiction the equal protection of the laws. jurisdiction:territory The Equal Protection Clause was written to make certain laws unconstitutional. Which of the following laws was the Equal Protection Clause most likely written to ban? Choices: [(a) a national law to build a network of railroads from coast to coast, (b) state laws that allowed both men and women to vote in elections, (c) a national law creating universities to teach farming skills, (d) state laws that took away rights from African American people] Answer index: 3

Table 21: Question examples for each skill (part 8).

Subject: Social Studies Skill: the-executive-branch Description: Read Section 1 of Article II of the United States Constitution. Then answer the question. The executive power shall be vested in a president of the United States of America. He shall hold his office during the term of four years, and, together with the vice president, chosen for the same term, be elected. ... vested in:given to Complete the sentence. According to the Constitution, the president has the power to ___. Choices: [(a) carry out laws, (b) decide how long a term of office is, (c) renovate the White House, (d) run elections] Answer index: 0	Subject: Social Studies Skill: the-revolutionary-war-conclusion-and-aftermath Description: As the war continued, many Patriots lashed out at Loyalists, or those who remained loyal to Great Britain during the Revolutionary War. Read the passage from an editorial appearing in the Pennsylvania Packet, one of the first daily newspapers in America. Then answer the question below. Send [the Loyalists] where they may enjoy their beloved slavery to perfection—send them to the island of Britain; there let them drink the cup of slavery and eat the bread of bitterness all the days of their existence. . .. Never let them return to this happy land—never let them taste the sweets of that independence which they strove to prevent. Banishment, perpetual banishment, should be their lot. What is the main argument in the passage? Choices: [(a) Patriots should take away Loyalists' right to vote., (b) Loyalists should be banished to Britain., (c) Loyalists should be enslaved., (d) Patriots should convince Loyalists of the value of independence.] Answer index: 1
Subject: Social Studies Skill: the-articles-of-confederation Description: The Articles of Confederation created an official central government for the United States. The new central government replaced the Continental Congress and was called the Confederation Congress. Unlike the United States government today, the central government under the Articles of Confederation only had one branch. The Confederation Congress, a group of representatives from each state, was completely responsible for governing. There was no president or court system. The following passage from the Articles of Confederation explains the representation of each state within the Confederation Congress. Read the passage. Then complete the sentence below. No state shall be represented in Congress by less than two, nor more than seven members . . . While voting in the United States in Congress assembled, each state shall have one vote. Complete the sentence. Under the Articles of Confederation, each state could have ___ number of representatives and ___ number of votes. Choices: [(a) the same...the same, (b) the same...a different, (c) a different...a different, (d) a different...the same] Answer index: 3	Subject: Social Studies Skill: the-judicial-branch Description: The Supreme Court is made up of a maximum of nine justices, or judges. How do Supreme Court justices decide how to rule in a case? Choices: [(a) Each justice takes a side, and the side with more justices wins., (b) All of the justices must agree., (c) They appoint a jury of citizens and follow its recommendation., (d) A smaller group of one to three justices decides each case.] Answer index: 0
Subject: Social Studies Skill: radical-reconstruction Description: The passage below comes from a letter that a Freedmen's Bureau agent sent to a man in North Carolina. Read the letter. Then answer the question below. January 14th, 1866 ... William Fox This letter describes one of the duties of the Freedmen's Bureau. Which of those duties does it describe? Choices: [(a) helping African American people start schools, (b) investigating, or looking into, violence against freed people, (c) bringing together African American families that had been separated by slavery, (d) making sure employers treated freed people fairly] Answer index: 3	Subject: Social Studies Skill: antebellum-reform-movements Description: Many people turned to religion to help deal with problems they saw in society. Throughout U.S. history, the majority of Americans have been Christians. But religious enthusiasm was especially high during a period called the Second Great Awakening, from about the 1790s to the 1840s. During this period, ministers traveled the country preaching new religious ideas. Some of the religious ideas of the Second Great Awakening were expressed in hymns, or religious songs. The passage below comes from "Amazing Grace," a hymn that was popular at the time. Read the first few lines from the hymn. Then answer the question below. Amazing grace! How sweet the sound ... wretch:a bad, unhappy person Which of these statements best summarizes the main idea of these lines? Choices: [(a) God does not pay attention to people's lives., (b) With God's help, people can improve their lives., (c) A leopard can't change its spots, and people can't change either., (d) People should get used to the fact that life isn't always fair.] Answer index: 1
Subject: Social Studies Skill: washingtons-presidency-part-i Description: Washington wrote a letter describing the suit that he planned to wear to his inauguration. At the time, many Americans wore clothes made of cloth from Great Britain. But Washington's inauguration suit was not made of British cloth. Read the passage from Washington's letter. Then complete the text below. There are cloth factories in Connecticut, and I have [written to a friend asking him] . . . to procure me . . . Hartford fabric, to make a suit of clothes . . . I hope it will [soon] be unfashionable for a gentleman to appear in any other dress. ... Hartford:the capital of the state of Connecticut Complete the text. Washington expressed the hope that people would only want to wear clothes that were ___. Choices: [(a) elegant and fashionable, (b) made from cloth produced in the United States, (c) unfashionable, (d) made from cloth produced in Great Britain] Answer index: 1	Subject: Social Studies Skill: the-scientific-revolution Description: The Scientific Revolution was an important period in European history. Read the following description of the Scientific Revolution. Then answer the question below. The Scientific Revolution was a time when European scholars made many discoveries and advances in science and mathematics. Many historians have argued that the Scientific Revolution was also a time when people began to study and understand the world in a new way. Rather than using old ideas about science and nature, during the Scientific Revolution scholars began investigating the natural world for themselves. They developed questions and then performed experiments and gathered evidence in order to answer those questions. Complete the text. Some historians call this time period "the Scientific Revolution" because European scholars made ___ advances in math and science. Scholars also began to gather ___ information about the world instead of just relying on knowledge from other sources. Choices: [(a) few . . . their own, (b) few . . . ancient, (c) many . . . ancient, (d) many . . . their own] Answer index: 3
Subject: Social Studies Skill: washingtons-presidency-part-ii Description: As soon as he became Secretary of the Treasury, Alexander Hamilton began to work on a financial plan for the country. The financial plan listed Hamilton's ideas for how to manage the government's money and economy. Many people give Hamilton credit for setting up the country's financial system in a way that helped the United States to succeed over time. In the summary passage below, President Washington describes one reason why setting up a financial plan for the country was so important in the 1790s. Read the passage. Then answer the question below. During the Revolutionary War, we, the United States, needed much more money than we had to fight the war. ... debt:money that is borrowed and expected to be paid back Hamilton's financial plan tried to address the problem that Washington described in the passage above. What was the problem that Washington described? Choices: [(a) The United States had extra money after the Revolutionary War., (b) The United States was in deep debt after the Revolutionary War., (c) Great Britain owed the United States a lot of money., (d) The United States still needed to win independence from Great Britain.] Answer index: 1	Subject: Social Studies Skill: french-and-english-expeditions-part-i Description: In 1494, the Catholic Church approved a treaty that allowed Spain to control most of the land in the Americas. Spain used this treaty to stop other Europeans from trading in the Americas. The passage below describes religious changes in Europe in the mid-1500s. Read the passage. Then answer the question below. When the Catholic Church approved a treaty giving Spain control of most of the land in the Americas, almost everyone in western Europe was Catholic. However, in 1517 many people stopped following the Catholic Church. They became a new type of Christian known as Protestant. Because Protestants did not follow the Catholic Church, they did not believe they had to follow treaties or laws that the Catholic Church had approved. So, Protestant rulers did not believe Spain had the right to control trade with the Americas. Based on the passage, what is one reason why Protestants in Europe did not respect Spain's right to control trade in the Americas? Choices: [(a) Spain's right to control trade came from the Catholic Church, and Protestants did not follow the Catholic Church., (b) Spain's right to control trade was not based on religion, and Protestants only followed religious laws., (c) Protestants believed that the Catholic pope wanted Protestants to control trade instead of Catholics.] Answer index: 0

Table 22: Question examples for each skill (part 9).

Subject: Social Studies Skill: causes-of-the-american-revolution-introduction-to-mercantilism-and-the-navigation-acts Description: To increase Great Britain's wealth, Parliament passed laws that gave each part of the British Empire a different economic role: Colonists would send raw materials to people in Great Britain. Raw materials, such as raw iron and wool, are directly from nature. People in Great Britain would turn the raw materials into manufactured goods, or finished products, such as fabric and tools. British merchants could sell these manufactured goods back to the colonies or to other countries. Complete the text. Parlaiment wanted the country to earn more money from selling exports than it spent buying imports. The raw materials that Great Britain imported from the colonies were ___ the manufactured goods that Great Britain exported for colonists to purchase. Parliament's policies were part of what created the system of Triangular Trade. Choices: [(a) more valuable than, (b) as valuable as, (c) less valuable than] Answer index: 2	Subject: Social Studies Skill: the-revolutionary-war-preparing-for-war Description: After 1763, the British Parliament began to tax the Thirteen Colonies more heavily to help pay off debt from the French and Indian War. Parliament also restricted colonial trade. Many colonists resented these new taxes and restrictions. After the passage of the Stamp Act in 1765, which required Americans to pay a tax on all paper they used, an American colonist drew a cartoon with this caption: The moral is, that the colonies may be ruined, but that Britain would thereby be maimed. maimed:permanently wounded What is the author most likely arguing in the caption? Choices: [(a) The colonies are not a part of the British Empire., (b) Great Britain is harming itself by taxing the colonies., (c) Great Britain's taxation policies are good for the colonies., (d) The colonies will be better off if they declare independence from Great Britain.] Answer index: 1
Subject: Social Studies Skill: u-s-mexican-war Description: By the 1840s, belief in Manifest Destiny had become quite popular in the United States. So, support for expanding the territory of the U.S. was an important issue in the 1844 presidential election. This election was won by James K. Polk, the candidate of the Democratic Party. Read the following passage adapted from the 1844 Democratic Party platform, or list of the party's goals. Then complete the sentence below. Our title to the whole of the Territory of Oregon is clear and unquestionable, and the annexation of Texas to the United States at the earliest moment possible is important to American progress. ... annexation:addition Complete the sentence. According to the platform, the Democratic Party ___ Manifest Destiny. Choices: [(a) supported, (b) opposed, (c) neither supported nor opposed] Answer index: 0	Subject: Social Studies Skill: the-constitution-amendments Description: When the Constitution was written, many Americans were afraid that it made the federal government too powerful. So, ten amendments were added to the Constitution to describe and protect the rights of individual people. These first ten amendments are called the Bill of Rights. The following passage is from a letter written by Thomas Jefferson to James Madison in 1787, before the Bill of Rights had been approved. Read the passage. Then answer the question below. A bill of rights is what the people are entitled to . . . and [it is] what no just government should refuse [to write down]. ... just:fair Based on the passage, what was Jefferson's attitude toward a bill of rights? Choices: [(a) Governments should protect people's rights, but those rights don't need to be written down., (b) Writing down a bill of rights doesn't do anything, because governments can just ignore it., (c) People deserve to have a bill of rights that describes and protects their individual rights.] Answer index: 2
Subject: Social Studies Skill: the-revolutionary-war-struggle-for-independence Description: As the Continental Army fought the British, the Second Continental Congress sent an Olive Branch Petition to King George III in July 1775. The petition stated that the colonies would stop fighting with Great Britain under certain conditions. Which of the following was one of those conditions? Choices: [(a) if a new colony was established on the western frontier, (b) if Great Britain repealed certain laws and taxes, (c) if the colonies could have their own king and Parliament, (d) if King George III stepped down and a new king was named] Answer index: 1	Subject: Social Studies Skill: the-end-of-reconstruction-and-the-rise-of-jim-crow Description: Some white Southerners believed deeply that they should be shown more respect than African American people. They did not like the Republicans' plans to protect African American people's rights. Sometimes their anger at the changes to Southern society turned violent. The passage below comes from an investigation into the murder of an African American man named Johnson Stuart. The man's brother is describing what happened before the murder. Read the passage. Then answer the question below. Question—Did you ever hear of any threats being made against him before he was killed? . . . ... State of South Carolina, Evidence taken by the Committee of Investigation of the Third Congressional District, 1870. According to this passage, why did some white Southerners want to kill Johnson Stuart? Choices: [(a) They thought he disrespected white people by treating all the voters the same., (b) They thought he was cheating by paying people to vote for him for sheriff., (c) They thought he had stolen money and supplies from the sheriff's office in the courthouse., (d) They thought he was violating the Constitution by not allowing African Americans to vote.] Answer index: 0
Subject: Social Studies Skill: pre-contact-native-peoples-introduction Description: For many years, most archaeologists agreed that the first humans who came to North America walked across the land bridge around 12,000 years ago. However, new evidence has been discovered that makes some archaeologists believe people may have traveled in a different way. The text below describes two pieces of evidence that archaeologists use to support a different theory of migration to North America. Look at the text. Then complete the sentence below. Hunter-gatherers lived in the islands of Japan 20,000 years ago. They used resources from the ocean to survive. People on the coast of North America used small boats to travel along the coast more than 10,000 years ago. The text below describes a new theory about how humans arrived in North America. Use the evidence above to complete the text. According to the new theory, the first humans may have traveled from Asia to North America ___. They may have ___ along the coast of the land bridge. Choices: [(a) 100,000 years ago . . . walked, (b) using small boats . . . sailed] Answer index: 1	Subject: Social Studies Skill: the-reformation Description: Read two of Martin Luther's statements criticizing the Catholic Church. Then answer the question below. It is certain that when money clinks in the [Catholic Church's] money chest, greed. . . can be increased. ... William R. Russell, translator, The Ninety-Five Theses and Other Writings. Copyright 2017 by Penguin Classics. Based on the statements, what was one reason why many people were unhappy with the Catholic Church? Choices: [(a) They thought that the Catholic Church had become too big., (b) They felt their religious community was too small., (c) They believed the Catholic Church should collect more money., (d) They thought the Catholic Church was too rich and greedy.] Answer index: 3
Subject: Social Studies Skill: rights-and-responsibilities-of-active-citizenship Description: American presidents often speak about the rights, duties, and responsibilities of American citizens. Read the quotations from two former presidents. Then answer the question below. Ask not what your country can do for you; ask what you can do for your country. ... Ronald Reagan, Veterans Day Proclamation, October 26, 1981 Based on the quotations above, which of the following statements would both presidents agree with? Choices: [(a) The country should not expect citizens to do things for their communities., (b) Citizens should expect the government to do everything for them., (c) Active and engaged citizens are an important part of American democracy.] Answer index: 2	Subject: Social Studies Skill: the-age-of-exploration-origins Description: In the 1400s, Europe was made up of many independent states. These states often competed with each other for resources, including imported goods from Africa and Asia. Imagine you are a European ruler in the 1400s. What could you do as a ruler to gain a competitive advantage, or an upper hand, over other European states? Choices: [(a) try to find new trade routes to Africa and Asia, (b) ban any goods that came from Africa or Asia, (c) rely on other European states to sell goods from Africa and Asia to you] Answer index: 0

Table 23: Question examples for each skill (part 10).

Subject: Social Studies Skill: industrialization-in-the-gilded-age Description: Industrialization brought dramatic changes to Americans' daily lives. Read a modern scholar's description of those changes. Then answer the question below. Within a few decades, urban American homes became networked. . . . Instead of relying on candles and [fuel] carried into the home, each home was connected to the electricity network that provided electric light . . . Instead of relying on . . . outhouses and cesspools, each home was gradually connected to two more networks, one bringing in a supply of clean running water and the other taking waste out into sewers. Houses of the rich after 1880 and of the working class after 1910 were increasingly supplied with central heating. ... Robert J. Gordon, The Rise and Fall of American Growth, Princeton University Press, 2016. What is the main idea of the passage? Choices: [(a) As the U.S. industrialized, fewer homes had electricity and central heating., (b) Industrialization gave many Americans much more comfortable lives., (c) Electric lighting and sewers made homes dirtier and more dangerous., (d) Factories became very modern, but regular people's houses did not change.] Answer index: 1	Subject: Social Studies Skill: causes-of-the-american-revolution-politics-and-society Description: Andrew Burnaby, an English minister, traveled around the Thirteen Colonies during the French and Indian War. Based on his observations, Burnaby argued that America would never be independent of Great Britain. Read Burnaby's argument. Then answer the question below. The difference of character, of manners, of religion, of interest, of the different colonies [is so great that if they were] left to themselves there would soon be a civil war. Why did Burnaby think that America would never be a nation independent from Great Britain? Choices: [(a) The colonies were united in their support of Great Britain., (b) Colonial businesses needed British customers., (c) There were too many differences between the colonies., (d) The colonies signed a pledge to Great Britain after the French and Indian War.] Answer index: 2
Subject: Social Studies Skill: new-england-colonies-founding-and-government Description: Members of a religious group called the Puritans founded the Massachusetts Bay Colony. Unlike the Pilgrims, the Puritans did not want to leave the Church of England. Instead, they wanted to change the Church of England according to their religious beliefs. The first governor of the Massachusetts Bay Colony was a Puritan named John Winthrop. The passage below comes from a speech that Winthrop gave to the Puritans on their voyage to New England. Read the passage. Then answer the question below. For we must consider that we shall be as a city upon a hill. The eyes of all people are upon us; so that if we shall deal falsely with our God in this work . . . [and] cause him to withdraw his present help from us, we shall be made a story and a byword through the world. ... byword:example According to Winthrop, why was it important for the Puritans to behave as they believed God would want them to? Choices: [(a) because France might attack the colony if it was weak, (b) because the colonists were not allowed to go back to England, (c) because the whole world was watching, (d) because the colonists could become wealthy] Answer index: 2	Subject: Social Studies Skill: the-constitutional-convention Description: Before the states adopted the Constitution, the powers of the central government were described in the Articles of Confederation. The Articles of Confederation were written quickly and accepted by the states in the middle of the Revolutionary War. The committee that wrote the Articles created a central government that could organize the war. However, the committee did not trust an overly powerful government, so they did not give the government the power to enforce, or make people follow, the law. Overall, they gave the central government very few powers. Under the Articles of Confederation, which of the following powers did the central government have? Choices: [(a) forcing states to contribute money through taxes, (b) forcing states to provide troops, (c) enforcing laws, (d) negotiating treaties with other countries] Answer index: 3
Subject: Social Studies Skill: the-civil-war-the-conclusion-of-the-war Description: In late 1864, a Union army under the command of General William Tecumseh Sherman marched through the state of Georgia. The passage below comes from a letter that Sherman wrote to the War Department about his march. Read the passage. Then answer the question below. We are not only fighting hostile armies, but a hostile people, and must make old and young, rich and poor, feel the hard hand of war, as well as their organized armies. I know that this recent movement of mine through Georgia has had a wonderful effect in this respect. ... people:the civilians, or people not in the military, of the Confederacy What was Sherman arguing in this passage? Choices: [(a) Most white people in the Confederacy had always supported the Union., (b) The war should only be fought against Confederate soldiers, not civilians., (c) The Union army should make life hard for Confederate civilians., (d) Sherman's march through Georgia had been a failure for the Union army.] Answer index: 2	Subject: Social Studies Skill: trade-and-specialization Description: Adam Smith was an important thinker from the 1700s whose ideas about trade influenced many people. The passage below comes from one of his famous books. Read the passage. Then answer the question below. It is a [rule] of every [wise] master of a family, never to attempt to make at home what it will cost him more to make than to buy. The tailor does not attempt to make his own shoes, but buys them [from] the shoemaker. The shoemaker does not attempt to make his own clothes but employs a tailor. ... Adam Smith, The Wealth of Nations According to Adam Smith, how do people benefit from specialization and trade? Choices: [(a) People make clothes and shoes at home and listen to the master of the family., (b) People spend all of their money to buy things they need., (c) People buy things they want or need for less than it would cost to make things themselves., (d) People make everything they need at home to save as much money as possible.] Answer index: 2
Subject: Social Studies Skill: the-civil-war-gettysburg-to-the-election-of-1864 Description: The goal of the Union blockade was to stop the Confederacy from trading with other countries. Even before the war, Northerners and Southerners predicted what would happen if the South's trade was blockaded. The passage below comes from an 1858 speech by the Southern senator James Henry Hammond. Read the passage. Then answer the question below. Without firing a gun, without drawing a sword, should [the North] make war on us, we could bring the whole world to our feet. . . . What would happen if no cotton was furnished for three years? . . . England would topple headlong and carry the whole civilized world with her, to save the South. No, you dare not to make war on cotton. No power on the earth dares to make war upon it. Cotton is king. ... England:the United Kingdom According to Hammond, what made the South powerful? Choices: [(a) The South controlled the best harbors in North America., (b) The South had a large enslaved population., (c) The South controlled the world's cotton supply., (d) The South had given the United Kingdom a large loan.] Answer index: 2	Subject: Social Studies Skill: the-crusades Description: Historians do not have a copy of Pope Urban's 1095 speech. However, some of the people who heard his speech wrote down what they remembered. Read part of the speech that one person remembered hearing. Then answer the question below. All who die [on their way to Jerusalem], whether by land or by sea, or in battle . . . shall have immediate remission of sins. ... Jacques Bongars, Gesta Dei per Francos, trans in Oliver J. Thatcher and Edgar Holmes McNeal, eds., A Source Book for Medieval History. Copyright 1905 by Scribners. According to the speech, what did Pope Urban say would happen to people who died while traveling to Jerusalem on a crusade? Choices: [(a) Their land would be taken by the government., (b) All of their bad actions would be forgiven., (c) They would be remembered forever., (d) Their families would be given money.] Answer index: 1
Subject: Social Studies Skill: medieval-japan Description: Between the years 700 and 1100 CE, several families became increasingly wealthy and powerful. Read the passage about how these families became powerful. Then answer the question below. In the capital city, Kyoto, some wealthy families would arrange for their daughters to marry sons from the royal family. Marriages allowed these wealthy families to influence some of the emperor's decisions. These same families often controlled large amounts of land. Around the year 1100, almost half the land in Japan was controlled by wealthy families! In order to protect their land and wealth, these families often hired their own armies. Eventually, these armies became larger and more powerful than the emperor's own troops. Based on the passage, how had the status of powerful families changed in Japan by the year 1100? Choices: [(a) By the year 1100, the emperor was no longer the most powerful person in Japan. As a result, he was not able to control the powerful families., (b) Powerful families regularly married their daughters to members of the royal family. By the year 1100, these marriages had helped the emperor become even more powerful., (c) By 1100, most powerful families had become less wealthy. As a result, powerful families were no longer able to pay their private armies.] Answer index: 0	Subject: Social Studies Skill: the-songhai-empire Description: Sunni Ali Ber and his army conquered many territories to build the Songhai Empire. But not everyone in the new empire was happy under his rule. For example, many Muslims, or followers of the religion of Islam, were unhappy. Read the passage by a Muslim scholar who lived in the Songhai Empire during the reign of Sunni Ali. Then answer the question below. This villain,—I mean, [Sunni Ali],—was a prince, who was obeyed and respected. He was feared by his subjects because of his cruelty. . . . The ferocity of [Sunni] Ali towards Muslims and his cruelty . . . in matters of religion, made the hearts of the people overflow with sadness and worry. ... Christopher Wise, translator, Ta'rikh al fattash. Copyright 2011 by Africa World Press. According to the author, why were Muslims unhappy with Sunni Ali? Choices: [(a) He was a prince., (b) He was a devoted Muslim., (c) He was cruel to Muslims., (d) He was greedy.] Answer index: 2

Table 24: Question examples for each skill (part 11).

Subject: Social Studies Skill: origins-of-hinduism Description: Many historians argue that Hinduism started to develop when Indus Valley and Aryan cultures mixed. Look at the following information about some common Hindu beliefs and religious practices, or actions, that developed over time. Then use the information to answer the question below. Some Hindus believe that there are hundreds of different gods, but some think there is just one god who has many different characteristics. ... Hindus in different areas often celebrate different holidays and festivals. Based on the information above, which of the following statements is true? Choices: [(a) There are many different ways of practicing Hinduism., (b) There is only one main way of practicing Hinduism.] Answer index: 0	Subject: Social Studies Skill: origins-of-buddhism Description: Historians agree that Buddhism began with the teachings of Siddhartha Gautama (si-DAR-tuh GOW-tuh-muh). During his life, Siddhartha became a great teacher and was given the title "buddha" (BOO-duh). Read about some common Buddhist beliefs. Then answer the question below. There were buddhas who lived before Siddhartha, and there will be buddhas who come after him. ... Siddhartha is often called "the Buddha," instead of just "buddha," because he is the buddha of this age. What does it mean to say that Siddhartha is "the buddha of this age"? Choices: [(a) He was the buddha who lived most recently., (b) He was not very old when he became a buddha., (c) He was less important than future buddhas., (d) He was the first buddha who ever lived.] Answer index: 0
Subject: Social Studies Skill: the-ghana-empire Description: Historians are not sure who founded the ancient Kingdom of Ghana. However, legends about Ghana's first king have been passed down by griots, or people who tell stories about West African history. Read a story that is told by griots. Then complete the text below. There were two brothers named Dyabe and Khine, and their father was the leader of their tribe. At first, their father wanted Khine to be the next leader. But Dyabe showed he was more clever than Khine, and their father changed his mind. Khine grew jealous and tried to have Dyabe killed, so Dyabe fled to the wilderness to save himself. Out in the wilderness, Dyabe met the leaders of four different armies. He convinced these army leaders to make him their ruler. Once he had the support of four armies, Dyabe decided to build a kingdom. But first, he needed to find a capital city for his kingdom. Dyabe traveled to a city that was guarded by the snake-god Bida. Bida agreed to let Dyabe use the city as his capital in return for a yearly sacrifice. So, Dyabe built the capital and created the Kingdom of Ghana. Complete the text. According to this story, the Kingdom of Ghana was founded by a man named ___. He created the kingdom after making a deal with ___. Choices: [(a) Dyabe . . . Khine, (b) Khine . . . the snake-god Bida, (c) Dyabe . . . the snake-god Bida, (d) Khine . . . Dyabe] Answer index: 2	Subject: Social Studies Skill: the-middle-ages-after-1100 Description: As kingdoms in Western Europe became larger, kings gained more wealth and power. Some kings began to take advantage of this power and abused the people in their kingdoms. In some parts of Europe, people responded to this behavior by trying to limit the power of kings. Read the passage about one king who abused his power. Then complete the sentence below. King John ruled England from 1199 to 1216 CE. In 1215, a group of lords demanded that King John end an unfair tax that was against the law. King John refused to end the tax, so the lords captured the city of London, where King John ruled. After capturing the city, the lords forced King John to sign an agreement that would limit his power as the king. This agreement became known as the Magna Carta, or Great Charter. The Magna Carta was an agreement that ___ in England. Choices: [(a) began a long and expensive war, (b) overthrew and killed the king, (c) increased taxes on the lords, (d) controlled the power of King John] Answer index: 3
Subject: Social Studies Skill: feudal-europe Description: By the early Middle Ages, many different Western European landowners had started organizing society in a new way. Historians call this new way of organizing society feudalism. Read the passage about how feudalism began. Then complete the text. After the fall of the Roman Empire, the Roman government no longer controlled Western Europe. So, individuals fought each other for control of land and the people living on it. The winners gained wealth and power, and people living on the land were forced to work for them. Some new landowners became powerful and started calling themselves kings, but they couldn't manage all their land on their own. So, they divided their land up and gave small sections to loyal followers. These loyal followers were called lords, and they helped to control the land and people for the king. Using the information in the passage, complete the text. Feudalism is a system where ___. Choices: [(a) people voted to elect leaders and decide who would own the land, (b) land and people were controlled by lords who were loyal to a king, (c) every member of society was given an equal amount of land to farm by their leader] Answer index: 1	Subject: Social Studies Skill: classical-athens-government-and-culture Description: Not all decisions in classical Athens were made by all the citizens. Instead, a full-time council of citizens made many of the everyday political decisions in the city. Here is a list of some facts about the Athenian council: This Athenian council was made up of 500 citizens. ... A councilman could only serve for one year at a time. Which of the following statements might come from an Athenian complaining about these rules? Choices: [(a) I think that because the selection is random, any foolish person can become a councilman., (b) Last time I was on the council, I was impressed with how many people had good ideas., (c) I'm glad that 500 people share power, since it means no single person can take over the city.] Answer index: 0
Subject: Social Studies Skill: caesar-and-the-end-of-the-roman-republic Description: Pompey agreed to help the Senate and try to prevent Caesar from becoming more powerful. Read the passage. Then answer the question below. In January of 49 BCE, Caesar was with his army far away from Rome. Pompey wrote to Caesar and demanded that Caesar give up his army and return to Rome. Caesar faced an important choice. On the one hand, he could obey Pompey and give up his army. But he knew the Senate didn't like him, and he worried that he would be arrested. On the other hand, he could refuse to give up his army. But then the Senate would probably think that Caesar wanted to start a war. After thinking about it for a long time, Caesar chose the second option. He decided to attack Pompey and the Senate before they could raise an army to stop him. Based on the passage above, how did Caesar respond to Pompey's demands? Choices: [(a) He disobeyed Pompey but offered to cooperate with the Senate., (b) He disobeyed Pompey and started a war against Pompey and the Senate., (c) He decided to give up his army and return to face punishment.] Answer index: 1	Subject: Social Studies Skill: roman-government-monarchy-to-republic Description: According to present-day historians, the Roman Republic lasted from 509 BCE to about 27 BCE. The word republic comes from the ancient Roman term res publica. Look at the meaning of the term res publica. Then answer the question below. res publica: a community committed to following the same rules and protecting each other's things and families for the good of all Based on the meaning above, which of the following statements describe something similar to what Romans meant by res publica? Choices: [(a) a group of friends that do whatever they want, whenever they want, (b) a class project group where everyone follows the same guidelines and benefits equally from working together, (c) a soccer team where bad players have to do what the coach says, but the best players don't] Answer index: 1
Subject: Social Studies Skill: french-and-english-expeditions-part-2 Description: After John Cabot's expedition, the English government did not sponsor another expedition to the Americas for more than 50 years. Then, in the mid-1500s, the English government began sending expeditions again. Read the passage about the events in England that created new interest in expeditions. Then answer the question below. In the middle of the 1500s, England's main source of wealth was trading English cloth in foreign markets. Thousands of people in England made their livings by producing or selling cloth, and the English government made money by taxing the sale of cloth. But in 1551, some foreign powers stopped allowing people to purchase English cloth. Many English people who worked in the cloth industry lost their jobs, and the government could not raise as much money. These conditions created a national crisis. The Queen of England, Elizabeth I, needed to find new sources of wealth to address the crisis. Queen Elizabeth thought that sending expeditions to the Americas might be one way to help. Based on the passage, why did Queen Elizabeth I decide to begin sending expeditions to the Americas? Choices: [(a) She wanted to stop Spain from purchasing English cloth., (b) She needed to find a new way to make money for England after the cloth crisis., (c) She was curious to learn more about what the Americas looked like.] Answer index: 1	Subject: Social Studies Skill: comparing-athens-and-sparta-part Description: Although city-states such as Athens could trade for food, Sparta was surrounded by mountains that made trade difficult. So, the Spartans relied on agriculture. The ancient Greek historian Pausanias described the role of helots, or enslaved people, in Spartan agriculture. Read the passage. Then complete the text below. The helots had to bring half of all the crops they grew to the Spartans. Helots who disobeyed were severely punished. The poet Tyrtaeus compared the helots to donkeys exhausted by a heavy load, under painful duty to bring their Spartan masters half of the crops from the land they ploughed and cared for. Adapted from Pausanias, Description of Greece, translated by W.H.S. Jones and H.A. Ormerod. Complete the text. The helots were enslaved people in Sparta. The Spartans relied on the helots ___. Choices: [(a) to educate their children, (b) to farm their land and raise crops, (c) to trade what was farmed, (d) to train their children to farm] Answer index: 1
Subject: Social Studies Skill: thomas-edison Description: Several inventors worked on lightbulbs before Thomas Edison did. How were Thomas Edison's lightbulbs different? Choices: [(a) His lightbulbs were free., (b) His lightbulbs were made from all recycled materials., (c) His lightbulbs could last for several weeks or months., (d) His lightbulbs came in different colors.] Answer index: 2	Subject: Social Studies Skill: the-revolutionary-war-turning-the-tide-of-war Description: Both the Continental Army and people on the homefront had trouble paying for the things that they needed during the war. Why? Choices: [(a) Inflation caused prices to rise., (b) The Continental Congress stopped printing Continentals., (c) The British took gold reserves from the Thirteen Colonies., (d) Most of the money was spent on military supplies.] Answer index: 0

Table 25: Question examples for each skill (part 12).

Subject: Social Studies Skill: foundations-of-maya-civilization Description: Complete the text. Archaeologists believe that the ancestors of the Maya first arrived in Central America more than 12,000 years ago. At first, these people were ___ and traveled long distances to find food. But over time, they learned to grow crops instead. By at least 1500 BCE, they began to settle in permanent ___. This was the beginning of the Maya civilization. Choices: [(a) explorers . . . cities, (b) farmers . . . palaces, (c) hunter-gatherers . . . villages] Answer index: 2	Subject: Social Studies Skill: classical-athens-geography-and-society Description: Complete the text. For most of its history, ancient Athens ruled itself and was not part of a larger country. In other words, Athens was a ___. Choices: [(a) region, (b) city-state, (c) kingdom] Answer index: 1
Subject: Social Studies Skill: the-mongol-empire Description: The founder of the Mongol Empire was a man named Temujin. He was born in Mongolia in the 1100s. The passage below comes from a Mongolian history text. In the passage, an older person is telling Temujin what Mongolia was like before he was born. Read the passage. Then answer the question below. Before you were born, the stars turned in the heavens. Everyone was fighting. Instead of sleeping, they robbed each other of their possessions. . . . Instead of resting, they fought each other. In such a world one did not live as one wished, but rather in constant conflict. There was no rest, only battle. There was no affection, only mutual slaughter. ... Adapted from The Secret History of the Mongols, paragraph 254 Based on the passage, which choice best summarizes what Mongolian society was like in the 1100s? Choices: [(a) Mongolian society was peaceful, but foreign invaders often attacked Mongolia. As a result, Mongols were often forced to fight, and many Mongols died., (b) People in Mongolia often fought wars with China, their neighbor. As a result, people often went to China to fight., (c) People in Mongolia were fighting with one another and stealing each others' goods. As a result, people could not live peaceful lives.] Answer index: 2	Subject: Social Studies Skill: foundations-of-aztec-civilization Description: Today, the part of Central America where the Aztec Empire existed is known as Mesoamerica. There are two ways of defining a region like Mesoamerica: using a geographic definition, which focuses on an area of land and its features, such as mountain ranges and bodies of water using a cultural definition, which focuses on the customs and practices that people living there share Which of the following statements uses a geographic definition of Mesoamerica? Choices: [(a) Mesoamerica is a place where people used a 260-day calendar., (b) Mesoamerica is a place in Central America where people built religious temples in the form of pyramids., (c) Mesoamerica is a region of Central America that includes the Valley of Mexico and the Yucatan Peninsula.] Answer index: 2
Subject: Language Arts Skill: choose-the-uppercase-letter-that-matches-c-k-o-p-s-u-v-w-x-z Description: Pick the uppercase letter that matches. k Choices: [(a) T, (b) R, (c) K] Answer index: 2	Subject: Language Arts Skill: choose-the-lowercase-letter-that-matches-c-k-o-p-s-u-v-w-x-z Description: Pick the lowercase letter that matches. C Choices: [(a) c, (b) v, (c) o] Answer index: 0
Subject: Language Arts Skill: choose-the-uppercase-letter-that-matches-a-b-d-e-g-h-n-q-r Description: Pick the uppercase letter that matches. a Choices: [(a) N, (b) A] Answer index: 1	Subject: Language Arts Skill: choose-the-lowercase-letter-that-matches-a-b-d-e-g-h-n-q-r Description: Pick the lowercase letter that matches. A Choices: [(a) u, (b) a, (c) n] Answer index: 1
Subject: Language Arts Skill: choose-the-lowercase-letter-that-matches-f-i-j-l-m-t-y Description: Pick the lowercase letter that matches. L Choices: [(a) l, (b) k, (c) m] Answer index: 0	Subject: Language Arts Skill: choose-the-uppercase-letter-that-matches-f-i-j-l-m-t-y Description: Pick the uppercase letter that matches. m Choices: [(a) H, (b) J, (c) M] Answer index: 2
Subject: Language Arts Skill: distinguish-characters-points-of-view Description: The following texts both describe a school bus ride on the first day of school. This text is told from the point of view of Jeffrey, a student going to a new school: ... I felt ready for my first shift as a school bus driver. I turned the long bus at each corner with ease. My cheerful mood made the students smile. I was proud of myself as the bus approached the brick school building. My first trip had gone well! How is Ms. Romero's point of view different from Jeffrey's? Choices: [(a) Ms. Romero describes feeling uneasy about a new experience., (b) Ms. Romero expresses a feeling of pride about the first day of school.] Answer index: 1	Subject: Language Arts Skill: determine-the-meanings-of-words-with-greek-and-latin-roots Description: What does the word autopilot mean? Choices: [(a) a tool that pilots use when they want to make the airplane fly faster, (b) a device that flies an airplane on its own, without a pilot, (c) a map or drawing that shows an airplane's route] Answer index: 1
Subject: Language Arts Skill: describe-the-difference-between-related-words Description: What is the difference between being vicious and being mean? Choices: [(a) being vicious is worse, (b) being mean shows more anger] Answer index: 0	Subject: Language Arts Skill: which-word-does-not-rhyme Description: Which word does not rhyme? Choices: [(a) pack, (b) pick, (c) sick] Answer index: 0
Subject: Language Arts Skill: complete-the-sentence-with-the-correct-sight-word Description: Complete the sentence. ___ pig is big. Choices: [(a) That, (b) Went] Answer index: 0	Subject: Language Arts Skill: to-have-use-the-correct-form Description: Complete the sentence. Mrs. Barton's rug ___ blue flowers on it. Choices: [(a) has, (b) have] Answer index: 0
Subject: Language Arts Skill: complete-the-sentence-with-a-two-syllable-word Description: Which word makes more sense in the sentence? We ride in the ___ Choices: [(a) wagon, (b) robin] Answer index: 0	Subject: Language Arts Skill: complete-the-sentence-with-a-three-letter-consonant-blend-word Description: Which word makes more sense in the sentence? Look, that big fish is swimming up the ___ Choices: [(a) stream, (b) strict] Answer index: 0
Subject: Language Arts Skill: use-subordinating-conjunctions Description: Complete the sentence with the better conjunction. ___ Joseph arrives soon, we won't get to the movie on time. Choices: [(a) Unless, (b) After] Answer index: 0	Subject: Language Arts Skill: use-the-correct-homophone Description: Complete the sentence with the correct homophone. Given that there were more than one hundred guests at the wedding, how many ___ do you think Martina and Cooper have received? Choices: [(a) presence, (b) presents] Answer index: 1
Subject: Language Arts Skill: use-words-as-clues-to-the-meanings-of-greek-and-latin-roots Description: The word millimeter contains the root mille. What does the root mille mean? Choices: [(a) measure, (b) one hundred, (c) one thousand] Answer index: 2	Subject: Language Arts Skill: analogies Description: Complete the analogy. Ohio is to United States as Earth is to Choices: [(a) moon, (b) solar system] Answer index: 1

Table 26: Question examples for each skill (part 13).

Subject: Language Arts Skill: is-it-a-complete-sentence-or-a-fragment Description: Is this a complete sentence? Monica speaks four languages. Choices: [(a) Monica speaks four languages.] Answer index: 0	Subject: Language Arts Skill: is-it-a-phrase-or-a-clause Description: Is the group of words in bold a phrase or a clause? *Emily's suitcase was too large to fit in the overhead bin**, so unfortunately she had to check it. Choices: [(a) phrase, (b) clause] Answer index: 1
Subject: Language Arts Skill: choose-between-subject-and-object-pronouns Description: Select the correct pronoun to complete the sentence. "Thanks to your efforts, ___ have emerged as leaders in the energy industry," Mr. Bullock announced at the company meeting. Choices: [(a) us, (b) we] Answer index: 1	Subject: Language Arts Skill: is-the-sentence-simple-compound-complex-or-compound-complex Description: Which type of sentence is this? Henry always approaches difficult tasks enthusiastically, and he frequently motivates others with his energy and fervor. Choices: [(a) simple, (b) compound, (c) complex, (d) compound-complex] Answer index: 1
Subject: Language Arts Skill: analogies-challenge Description: Complete the analogy. teacher is to instructor as doctor is to Choices: [(a) profession, (b) physician, (c) medicine] Answer index: 1	Subject: Language Arts Skill: use-time-order-words Description: Complete the text with the better word. , Jerry jogs for a mile. Then, he rests for ten minutes. Choices: [(a) First, (b) Finally] Answer index: 0
Subject: Language Arts Skill: choose-reasons-to-support-an-opinion Description: Read the opinion below. Swamps should be protected and valued. Select the reason that best supports this opinion. Choices: [(a) Swamps do an excellent job of cleaning an area's water supply., (b) Many dangerous creatures, such as alligators and poisonous snakes, live in swamps.] Answer index: 0	Subject: Language Arts Skill: is-it-a-complete-sentence-or-a-run-on Description: Which is a **run-on sentence**? Choices: [(a) The heart is a symbol of love., (b) She went to the tailor, he sewed her pants.] Answer index: 1
Subject: Language Arts Skill: read-about-famous-people Description: Review the text. title: Becoming Amazing ... Copeland's success made her a role model for others, too. She was on the cover of Time magazine as one of the "100 Most Influential People" in 2015. She wrote a best-selling book about her life, called Life in Motion: An Unlikely Ballerina. She also wrote a children's book, Firebird, in which she tells others like herself that they, too, can become amazing. Which is the best summary of the text? Choices: [(a) Misty Copeland beat many challenges to become a famous ballet dancer. She started later than most dancers and suffered broken bones. But with the help of a coach and a ballet teacher, she became the first African American principal dancer for ABT. She also became an author and role model., (b) Misty Copeland never stopped working to become a famous ballet dancer. She started training very young and became an amazing dancer by age thirteen. After becoming the first African American woman dancer for ABT, she injured herself badly, so she became a model and an author instead., (c) Misty Copeland started dancing at age thirteen, much later than most ballet dancers. She was encouraged by her middle-school drill team coach and a ballet teacher at the Boys & Girls Club. With a lot of hard work, she became a professional dancer with ABT at the age of eighteen.] Answer index: 0	Subject: Language Arts Skill: choose-the-synonym Description: Which word is a synonym of **bag**? Choices: [(a) sack, (b) contain] Answer index: 0
Subject: Language Arts Skill: identify-story-elements Description: Review the story. title: Contest on Mars Colony ... He could see the kids taking deep breaths of the forest air. Whether or not he won, their smiles were prize enough for him. What is the **solution** to the problem in the story? Choices: [(a) Axel comes up with a high-tech app idea., (b) Zane invents a new alarm that will play beautiful music instead of buzzing., (c) Axel realizes he can improve the Colony by growing a forest., (d) Axel's father decides they'll move back to Earth.] Answer index: 2	Subject: Language Arts Skill: use-academic-vocabulary-in-context Description: Look at the word **residence** in the passage below. In many homes, basements are used for ordinary activities, such as washing clothes. The U.S. president's basement is much more interesting. In the White House, the president's **residence**, the basement contains a woodshop and a dentist's office. And when the president's family wants to have some fun, they can go bowling in their own basement bowling alley! What is the meaning of **residence** as used in the passage? Choices: [(a) a place where someone lives, (b) a place where parties are held, (c) a place that people like to visit] Answer index: 0
Subject: Language Arts Skill: use-adjectives-to-compare Description: Complete the sentence with the correct form of the adjective. The traffic on Main Street is much ___ than the traffic on the highway. Choices: [(a) slower, (b) slowest] Answer index: 0	Subject: Language Arts Skill: select-the-words-that-dont-belong Description: Select the place that "doesn't" belong. Choices: [(a) library, (b) meadow, (c) forest, (d) field] Answer index: 0
Subject: Language Arts Skill: capitalizing-titles Description: Which correctly shows the title of a poem? Choices: [(a) "The Mountain and the Squirrel", (b) "the Mountain and the Squirrel"] Answer index: 0	Subject: Language Arts Skill: read-historical-fiction Description: Read the story. title: Strangers on My Shore ... Many changes have come in the 250 years that have passed since that day. Now, big cities dot my landscape, and two-legged creatures fly from around the world to visit me. Though many now call me New Zealand, I am still the same island, shimmering green under the clouds. After all these years, my waters and my mountains remain, and my bays and rivers endure. Based on paragraphs 1 through 3, how does the fact that the narrator is an island rather than a person affect this telling of New Zealand's history? Choices: [(a) It allows the narrator to compare the landforms in New Zealand to other places in the Pacific., (b) It allows the story to start long before the arrival of humans, with the formation of the land., (c) It allows the story to focus only on the geography of New Zealand, not the people who live there., (d) It allows the narrator to refer to the island by the present-day name of "New Zealand."] Answer index: 1

Table 27: Question examples for each skill (part 14).

Subject: Language Arts Skill: revise-the-sentence-using-a-stronger-verb Description: Read the sentence. After a difficult climb, Madelyn **went** back down the hill. Now, revise the sentence to show that Madelyn was **clumsy**. After a difficult climb, Madelyn ___ back down the hill. Choices: [(a) floated, (b) stumbled, (c) plunged] Answer index: 1	Subject: Language Arts Skill: use-the-correct-subject-or-verb Description: Complete the sentence with the best **verb**. Both of us ___ the banjo, but Jenna also plays the flute. Choices: [(a) plays, (b) play] Answer index: 1
Subject: Language Arts Skill: choose-between-personal-and-reflexive-pronouns Description: Select the best pronoun to complete the sentence. Will you please give ___ directions to the Lanberry Community Center? Choices: [(a) me, (b) myself] Answer index: 0	Subject: Language Arts Skill: choose-between-subject-and-object-personal-pronouns Description: Select the correct pronoun to complete the sentence. When Tara is upset, she always confides in ___. Choices: [(a) he, (b) him] Answer index: 1
Subject: Language Arts Skill: choose-the-best-concluding-sentence Description: Read the paragraph. Then, add the better concluding sentence. Over the course of his career, Mel Blanc provided the voices for hundreds of cartoon characters. One of his most famous characters was Bugs Bunny. Bugs Bunny was a charming yet fearless rabbit who was famous for saying "What's up, Doc?" Blanc described his process for how he came up with Bugs Bunny's voice. First, he looked at sketches, or rough drawings, of the character. Then, he looked at a set of pictures called a storyboard. The storyboard showed how Bugs Bunny would behave in a cartoon. The cartoon's creators told Blanc that Bugs Bunny's character was a "tough little stinker." Blanc thought about all the tough-sounding accents he had heard. After some experimenting, Blanc finally brought Bugs Bunny's voice to life. ___ Choices: [(a) Similarly, Blanc is known for creating sound effects., (b) This process clearly worked, because Bugs Bunny became one of Blanc's most recognized characters.] Answer index: 1	Subject: Language Arts Skill: create-compound-sentences Description: Form a compound sentence. Sarah ___ at the rink. Choices: [(a) doesn't play ice hockey, but she figure skates, (b) Montoya, famous for her graceful jumps, can be seen] Answer index: 0
Subject: Language Arts Skill: identify-the-narrative-point-of-view Description: Which point of view does the narrator use in the passage? A few days after this I had to go out with Ginger in the carriage. I wondered how we should get on together; but except laying her ears back when I was led up to her, she behaved very well. From Anna Sewell, Black Beauty. Copyright 1999 by Dover Publications Choices: [(a) first person, (b) second person, (c) third person] Answer index: 0	Subject: Language Arts Skill: is-the-word-an-adjective-or-adverb Description: Is the word in bold an adjective or an adverb? Zoe tried on a **violet** gown with cap sleeves. Choices: [(a) adjective, (b) adverb] Answer index: 0
Subject: Language Arts Skill: is-it-a-complete-sentence-a-fragment-or-a-run-on Description: Which is a **run-on sentence**? Choices: [(a) I mopped the floor, Mom washed all the dishes., (b) The girls and boys swung on the swings.] Answer index: 0	Subject: Language Arts Skill: use-actions-and-dialogue-to-understand-characters Description: Read the sentences. Jaylen asked that the math award be given to his whole team instead of just him. "I couldn't have done it without them," he said. Based on these sentences, what is Jaylen probably like? Choices: [(a) humble, (b) snobby] Answer index: 0
Subject: Language Arts Skill: use-adverbs-to-compare Description: Complete the sentence with the correct form of the adverb. Wesley can sing the ___ of the three soloists. Choices: [(a) lower, (b) lowest] Answer index: 1	Subject: Language Arts Skill: which-definition-matches-the-sentence Description: What does **bloom** mean in this sentence? Mr. Herman said, "I think Brandon will bloom into a successful and confident young man." Choices: [(a) **bloom** "verb" to grow, (b) **bloom** "noun" a blossom] Answer index: 0
Subject: Language Arts Skill: is-the-sentence-in-the-past-present-or-future-tense Description: Which tense does the sentence use? Erica parked her scooter in front of the store. Choices: [(a) past tense, (b) present tense, (c) future tense] Answer index: 0	Subject: Language Arts Skill: formatting-and-capitalizing-titles Description: Which sentence is correct? Choices: [(a) Almost everyone watched the TV show "Foster's Home for Imaginary Friends.", (b) Almost everyone watched the TV show "Foster's Home for Imaginary Friends".] Answer index: 1
Subject: Language Arts Skill: choose-the-antonym Description: Which word is an antonym of **succeed**? Choices: [(a) fail, (b) victory] Answer index: 0	Subject: Language Arts Skill: choose-the-best-topic-sentence Description: Read the paragraph. Then, add the better topic sentence. ___ In slacklining, people build strength and balance as they practice walking across a narrow, stretchy strip of fabric. As in tightrope walking, it takes a lot of practice to stay steady on this line. When slackliners feel confident enough, they may test their balance by slacklining higher up. Some even perform tricks on a slackline. Choices: [(a) Some people practice yoga poses on slacklines., (b) Slacklining is a sport that uses balance and strength.] Answer index: 1
Subject: Language Arts Skill: read-poetry Description: Review the poem. My Model Car The hours piled on, As I sprawled out on my carpet, Tinkering with tweezers, Fiddling with rubber bands, Trying to make my model car come to life. Finally, eyes bleary, I went for a walk, Leaving the car parts behind. I took in the details of the neighborhood, The trills and chirps of birds in the trees, The thick, smoky smell of a grill Fired up in my neighbor's yard. I came back and opened my door. Hoping the car had assembled itself. No, but— I suddenly saw the parts with new eyes, My mind clear and ready. My tools bent and twisted the pieces Like they'd always known what to do. What is the main theme of the poem? Choices: [(a) It's important to ask for help with a project when you need it., (b) Taking a break from a task can help you approach it in a new way., (c) Make sure you understand all the steps of your task before you start.] Answer index: 1	Subject: Language Arts Skill: show-character-emotions-and-traits Description: You are writing a story about Devon, who hears some bad news. Choose the best description to show that Devon is **disappointed**. Choices: [(a) Devon swallowed hard and tried to force herself to smile., (b) "Okay," Devon said, continuing to chop carrots.] Answer index: 0

Table 28: Question examples for each skill (part 15).

Subject: Language Arts Skill: identify-text-structures Description: Read the text. Although there are many kinds of writing, most people divide texts into two different types: fiction and nonfiction. Fiction means stories that are made up. "Charlotte's Web" is fiction because, of course, spiders and pigs don't really talk. Nonfiction, however, gives you facts about the real world. You can find nonfiction books about history, science, real people, animals, and many other topics. Nonfiction also includes newspapers and textbooks, while fiction includes stories, plays, and novels. Reading both fiction and nonfiction can be fun and educational. Which text structure does the text use? Choices: [(a) cause-effect, (b) compare-contrast] Answer index: 1	Subject: Language Arts Skill: which-sentence-matches-the-definition Description: Which sentence uses this meaning of **concrete**? *concrete** "adjective" specific and real Choices: [(a) His fingerprints were **concrete** proof that he had opened the safe., (b) We can't walk on the sidewalk because the **concrete** is still drying.] Answer index: 0
Subject: Language Arts Skill: determine-the-meaning-of-idioms-from-context-set-1 Description: What is the meaning of **on the tip of one's tongue**? I can't quite remember the name of that magician we saw perform in Las Vegas, but it is **on the tip of my tongue**. Choices: [(a) almost remembered, (b) a certainty] Answer index: 0	Subject: Language Arts Skill: use-guide-words Description: Which word would you find on a dictionary page with the following guide words? *skate** - **squire** Choices: [(a) spare, (b) station] Answer index: 0
Subject: Language Arts Skill: use-context-to-identify-the-meaning-of-a-word Description: Read the passage and then answer the question. The Great Pyramid of Giza is the largest of the ancient Egyptian pyramids. When completed around 2560 BCE, it stood 481 feet high, as tall as a modern 44-story building. The Great Pyramid was the world's tallest building for more than three thousand years. More than two million huge stone blocks were used to construct it. The builders of the pyramid positioned it **meticulously** so that it perfectly faces true north. Scientists aren't sure how the ancient Egyptians knew how to place the base. Experts also disagree about how those huge blocks were moved into place. They don't even fully understand the design of the inside of the pyramid. More work must be done to solve these mysteries. What is the meaning of **meticulously** as used in the passage? Choices: [(a) with many people pushing, (b) in a great hurry, (c) happily, without any hesitation, (d) carefully, with attention to detail] Answer index: 3	Subject: Language Arts Skill: punctuating-dialogue Description: Which sentence is correct? Choices: [(a) "Please hire a carpenter to finish our basement", Mrs. Huffman urged., (b) "Please hire a carpenter to finish our basement," Mrs. Huffman urged.] Answer index: 1
Subject: Language Arts Skill: determine-the-meanings-of-similes-and-metaphors Description: What is the meaning of the simile? Linda's typing was like a tap dancer performing onstage. Choices: [(a) Linda made rapid tapping noises., (b) Linda made her performance on the stage.] Answer index: 0	Subject: Language Arts Skill: use-key-details-to-determine-the-main-idea Description: Look at these details from a paragraph about the same topic: By taking music lessons, students learn to read sheet music. ... Through music lessons, students can learn about music from other countries. Choose the main, or central, idea that ties all the details together. Choices: [(a) Music lessons introduce students to many types of music., (b) Music lessons teach more than just how to play an instrument., (c) Piano lessons are one of the most popular types of music lesson.] Answer index: 1
Subject: Language Arts Skill: choose-between-adjectives-and-adverbs Description: Choose the word that best describes the adjective in bold. As a wedding gift, Elena gave the couple a quilt that was ___ **sewn** by hand. Choices: [(a) full, (b) fully] Answer index: 1	Subject: Language Arts Skill: read-realistic-fiction Description: Read the story. title: The Artist's Secret ... Destiny smiled. Then she reached for her palette, so she could start on C. Based on paragraphs 1 and 2, how does Destiny probably feel about the art project at the beginning of the story? Choices: [(a) She cares about it turning out just right., (b) She wants to finish it as quickly as possible., (c) She views it as a competition that she is winning., (d) She is annoyed about having to mix paint colors.] Answer index: 0
Subject: Language Arts Skill: use-the-meanings-of-words-as-clues-to-the-meanings-of-greek-and-latin-roots Description: A biography is a written account of someone's life. What does the root **graph** mean? Choices: [(a) look at or observe, (b) write or draw, (c) measure] Answer index: 1	Subject: Language Arts Skill: use-coordinating-conjunctions Description: Complete the sentence with the best conjunction. Pam wants to dye her hair purple ___ red. Choices: [(a) or, (b) but] Answer index: 0
Subject: Language Arts Skill: identify-similes-and-metaphors Description: Does the sentence use a simile or a metaphor? Mrs. Boyer is kind, and her heart is gold. Choices: [(a) simile, (b) metaphor] Answer index: 1	Subject: Language Arts Skill: use-greek-and-latin-roots-as-clues-to-the-meanings-of-words Description: The root **vis** means "see or look at". What does the word **visual** mean? Choices: [(a) relating to hearing or sound, (b) relating to seeing or sight, (c) relating to flavor or taste] Answer index: 1
Subject: Language Arts Skill: interpret-the-meaning-of-an-allusion-from-its-source Description: Read the source of the allusion. In the fairy tale, Cinderella is a poor young woman who is treated badly. However, she later marries a prince and becomes a loved and respected princess. What is the meaning of the allusion in the sentence below? Choices: [(a) an amazing improvement, (b) a journey without troubles] Answer index: 0	Subject: Language Arts Skill: positive-and-negative-connotation Description: Which phrase has a more **negative** connotation? Choices: [(a) a warm room, (b) a stuffy room] Answer index: 1

Table 29: Question examples for each skill (part 16).

Subject: Language Arts Skill: draw-inferences-from-a-text Description: Read the text. Kari looked under the table. Then she searched the whole room. "You have got to be kidding!" Kari shouted. Grumbling, Kari tore the puzzle apart and put it back in the box. On the top of the box, she crossed out 1000 and wrote 999 above it. Based on the text, which sentence is more likely to be true? Choices: [(a) Kari doesn't like building puzzles., (b) Kari's puzzle is missing a piece.] Answer index: 1	Subject: Language Arts Skill: is-the-sentence-simple-or-compound Description: Which is a **compound sentence**? Choices: [(a) Jayden grew too many pumpkins, so he sold the extras at the market., (b) British general John Burgoyne surrendered to American forces at the Battle of Saratoga.] Answer index: 0
Subject: Language Arts Skill: identify-elements-of-poetry Description: Choose the poem that uses **end rhyme**. Choices: [(a) I break a staff. I break the tough branch. I know no light in the woods. I have lost pace with the winds., (b) Sign of a nation, great and strong Toward her people from foreign wrong: Pride and glory and honor,—all Live in the colors to stand or fall.] Answer index: 1	Subject: Language Arts Skill: read-about-business-and-technology Description: Review the text. title: Where Are You? ... GPS has also become very useful in the field of science. Scientists have figured out ways to use GPS for monitoring earthquakes and volcanoes. GPS can also be used to measure water levels and snowfall. While working with wild animals, some animal researchers also use GPS devices. These scientists can attach small devices onto animals to track the animals' movements and gather important data about them. Who knows how GPS will help us next? Which is the best summary of the text? Choices: [(a) GPS receivers help people find their way. They work by sending radio signals to satellites in space. Drivers, people enjoying outdoor sports, and emergency workers all use GPS. GPS can also be used for other purposes, like for tracking animals and for science research., (b) "GPS" stands for Global Positioning System. GPS works anywhere on Earth, except deep in caves and underwater. People use GPS every day to drive and play sports. They also use GPS to find lost pets., (c) GPS devices have become very important in our world. People use them for driving and outdoor sports. Scientists use them to monitor earthquakes, volcanoes, and the phases of the moon. GPS can also be used to remind people to walk their pets.] Answer index: 0
Subject: Language Arts Skill: read-about-history Description: Read the text. title: A Whale of a Record ... It might seem incredible that just one album could help save the lives of so many whales. But remember that Songs of the Humpback Whale was no ordinary record. This one-of-a-kind album revealed secrets about whales that had long been hidden beneath the waves. It allowed these amazing and mysterious creatures to finally share their songs with the human world. What is the text about? Choices: [(a) It is about how musicians recorded an album to encourage people to ban deep-sea whaling., (b) It is about how whales learned to use sounds to communicate after biologists played them recordings., (c) It is about how people changed their mind about recordings of nature after hearing an album of whale songs., (d) It is about how an album of whale recordings helped increase protection for whales around the world.] Answer index: 3	Subject: Language Arts Skill: identify-plurals-singular-possessives-and-plural-possessives Description: What is the word in bold? Are there any **statues** in your town? Choices: [(a) a singular possessive noun, (b) a plural noun] Answer index: 1
Subject: Language Arts Skill: analyze-the-effects-of-figures-of-speech-on-meaning-and-tone Description: Read the text. The figure of speech is shown in bold. Then I knew that even though **nobody in the world** figured that old car had any good purpose, Ob knew there was some real reason to let it sit. And when May died, he figured out what it was. I never saw two people love each other so much. From Cynthia Rylant, Missing May. Copyright 1992 by Cynthia Rylant What does this example of **hyperbole** tell you? Choices: [(a) It suggests that very few people thought the car had a purpose., (b) It suggests that the car travels around the world.] Answer index: 0	Subject: Language Arts Skill: determine-the-meanings-of-greek-and-latin-roots Description: What does the root **tract** mean? Choices: [(a) bend or curve, (b) pull or drag, (c) far away] Answer index: 1
Subject: Language Arts Skill: is-it-a-telling-sentence-or-an-asking-sentence Description: What kind of sentence is this? My father reads to me. Choices: [(a) telling sentence, (b) asking sentence] Answer index: 0	Subject: Language Arts Skill: find-the-vowel-in-the-word Description: Find the vowel. Choices: [(a) o, (b) n] Answer index: 0
Subject: Language Arts Skill: complete-the-sentence-with-the-correct-short-vowel-word Description: Which word makes the most sense in the sentence? The bug is on his ___. Choices: [(a) nap, (b) leg] Answer index: 1	Subject: Language Arts Skill: complete-the-rhyme Description: Complete the rhyme. The men sit in the ___. Choices: [(a) den, (b) back] Answer index: 0
Subject: Language Arts Skill: capitalize-the-first-letter-of-a-sentence Description: Complete the sentence with an uppercase letter. ___ans can go fast. Choices: [(a) V, (b) v] Answer index: 0	Subject: Language Arts Skill: who-what-when-where-or-why Description: Pick the right question word. ___ did your mom go? Choices: [(a) Who, (b) Where] Answer index: 1
Subject: Language Arts Skill: what-am-i Description: Answer the riddle. I am small. ... What am I? Choices: [(a) a baby, (b) a box] Answer index: 0	Subject: Language Arts Skill: read-questions-with-short-vowel-words Description: Answer the question. Can a wig jog? Choices: [(a) yes, (b) no] Answer index: 1
Subject: Language Arts Skill: choose-the-uppercase-letter-that-matches-review Description: Pick the uppercase letter that matches. x Choices: [(a) X, (b) W] Answer index: 0	Subject: Language Arts Skill: find-the-action-verb Description: Find the verb. A verb shows an action. Choices: [(a) tree, (b) grow] Answer index: 1
Subject: Language Arts Skill: choose-the-lowercase-letter-that-matches-review Description: Pick the lowercase letter that matches. V Choices: [(a) n, (b) v] Answer index: 1	Subject: Language Arts Skill: find-the-complete-sentence Description: Find the complete sentence. Choices: [(a) car, (b) We ate the cake.] Answer index: 1

Table 30: Question examples for each skill (part 17).

Subject: Language Arts Skill: which-word-is-not-like-the-others Description: Which word is not like the others? Choices: [(a) big, (b) tall, (c) little, (d) nice] Answer index: 3	Subject: Language Arts Skill: complete-the-sentence-with-the-correct-sight-word-sets-1-2-3 Description: Complete the sentence. I did not want to trick ___. Choices: [(a) has, (b) as, (c) them] Answer index: 2
Subject: Language Arts Skill: complete-the-sentence-with-the-correct-sight-word-sets-4-5-6-7 Description: Complete the sentence. I ate a hot dog ___ went to bed. Choices: [(a) four, (b) more, (c) then] Answer index: 2	Subject: Language Arts Skill: use-the-correct-modal-verb Description: Select the modal verb that best completes the sentence. The coach ___ let Mark join the team if it weren't so late in the season. Choices: [(a) would, (b) will] Answer index: 0
Subject: Language Arts Skill: use-the-perfect-verb-tenses Description: Complete the sentence with the correct helping verb or verbs. When I walked by Sophia's desk, I saw that she ___ fallen asleep! Choices: [(a) had, (b) will have] Answer index: 0	Subject: Language Arts Skill: determine-the-meaning-of-idioms-from-context-set-2 Description: What is the meaning of **get one's feet wet**? Mrs. Tyler is a professional singer who **got her feet wet** by singing in the school choir as a kid. Choices: [(a) to get soaked or messy, (b) to start learning something] Answer index: 1
Subject: Language Arts Skill: choose-between-the-past-tense-and-past-participle Description: Complete the sentence with the correct form of the verb. I swept up crumbs from the cookie Barry had ___. Choices: [(a) eaten, (b) ate] Answer index: 0	Subject: Language Arts Skill: identify-the-meaning-of-idioms-and-adages-set-2 Description: What is the meaning of **if you can't stand the heat, get out of the kitchen**? Choices: [(a) follow the customs of the place where you are, (b) don't take on a job or task if it's too much for you] Answer index: 1
Subject: Language Arts Skill: is-the-sentence-declarative-interrogative-imperative-or-exclamatory Description: What kind of sentence is this? Nora is reading a magazine about skateboarding. Choices: [(a) interrogative, (b) declarative] Answer index: 1	Subject: Language Arts Skill: use-the-progressive-verb-tenses Description: Complete the sentence with the correct helping verb or verbs. "We ___ eating dinner at seven o'clock, so don't be late," Mrs. Christensen said. Choices: [(a) were, (b) will be] Answer index: 1
Subject: Language Arts Skill: what-does-the-modal-verb-show Description: What does the modal verb show? Select the best answer choice. Bernie and Gary **will** visit Yosemite National Park next summer. Choices: [(a) a request for permission, (b) future action] Answer index: 1	Subject: Language Arts Skill: identify-the-meaning-of-idioms-and-adages-set-1 Description: What is the meaning of **cut corners**? Choices: [(a) to accidentally take the edges off something, (b) to take shortcuts when working] Answer index: 1
Subject: Language Arts Skill: use-thesaurus-entries Description: Look at this thesaurus entry: *abstain** ... Synonyms: deny, forgo, give up, quit, refrain Which is something you **abstain** from? Choices: [(a) something you almost always do, (b) something you choose not to do] Answer index: 1	Subject: Language Arts Skill: words-with-sub Description: Which might be a **subtopic** within a discussion of the Revolutionary War? Choices: [(a) the Declaration of Independence, (b) U.S. history] Answer index: 0
Subject: Language Arts Skill: words-with-pre Description: What helps **prevent** a cold? Choices: [(a) washing your hands frequently, (b) taking cold medicine] Answer index: 0	Subject: Language Arts Skill: words-with-less Description: Why might you make a **careless** mistake in your work? Choices: [(a) because you aren't paying attention, (b) because you don't understand something] Answer index: 0
Subject: Language Arts Skill: words-with-un-dis-in-im-and-non Description: Which is an **infrequent** visitor? Choices: [(a) one you often see, (b) one you rarely see] Answer index: 1	Subject: Language Arts Skill: words-with-re Description: Why might you **reattempt** a challenge? Choices: [(a) because you didn't succeed the first time, (b) because it's a new one] Answer index: 0
Subject: Language Arts Skill: use-the-correct-pair-of-correlative-conjunctions Description: Complete the sentence with the correct correlative conjunctions. Kurt's horse is in ___ the barn ___ the pasture right now. Choices: [(a) not only . . . but also, (b) either . . . or] Answer index: 1	Subject: Language Arts Skill: words-with-ful Description: How would you feel after a **restful** day? Choices: [(a) recharged, (b) exhausted] Answer index: 0
Subject: Language Arts Skill: compound-subjects-and-objects-with-personal-pronouns Description: Select the correct pronoun to complete the sentence. At the garage sale, ___ and Warren hoped to find some good books. Choices: [(a) she, (b) her] Answer index: 0	Subject: Language Arts Skill: determine-the-themes-of-short-stories Description: Read the following story. Paolo walked out on the dock and looked down into the water. "I only like to swim in pools. I'm not swimming in there," he said. "Well, I'm going to," his mom said. "There's not much else to do here!" Paolo's little sister, Celia, was standing next to him. "If Paolo's not going in, I'm not swimming in there either," Celia said. Paolo's mom looked at Paolo with a raised eyebrow. "That's fine," she said. "You two don't have to swim. But remember, there's no internet here and no TV." Paolo marched back to the cabin and sat in a lawn chair. He crossed his arms and frowned. "This is going to be an awful vacation", he thought. No Wi-Fi, nothing to do. Celia followed him, sitting in a chair and crossing her arms, too. "I'm bored!" Celia said. Meanwhile, their mom had gone into the cabin to change. Soon she emerged, carrying an armful of goggles and towels. "I'm going for a dip. Are you "sure" you don't want to go?" she asked. Celia glanced at Paolo. "I'm sure," said Paolo. "No way!" added Celia. Paolo sat in the chair and stared across the lake. Celia did too, but soon she grew restless. She got up, walked up and down the dock, and finally sat down, watching her mom. Seeing this, Paolo felt bad. He went inside and put on his bathing suit. Then he walked out to the dock where Celia was sitting. When their mom swam up to them, Paolo apologized. "I'll swim with you, Mom. I'm sorry I was crabby. The water actually looks nice," he said. Celia looked at Paolo. Then she ran to the cabin to change into her swimsuit, too. Which of the following best describes the main theme or lesson of the story? Choices: [(a) Set a good example for people who look up to you., (b) People today take technology for granted.] Answer index: 0

Table 31: Question examples for each skill (part 18).

Subject: Language Arts Skill: words-with-able-and-ible Description: Which item is not a **collectible**? Choices: [(a) an ordinary spiral notebook, (b) a rare comic book] Answer index: 0	Subject: Language Arts Skill: use-the-correct-frequently-confused-word Description: Complete the text with the correct word. Rhianna made a wire sculpture of a tree for her art project. She used steel wool to make ___ leaves. Choices: [(a) its, (b) it's] Answer index: 0
Subject: Language Arts Skill: words-with-mis Description: Which type of behavior shouldn't cause **mistrust**? Choices: [(a) suspicious behavior, (b) honest behavior] Answer index: 1	Subject: Language Arts Skill: which-sentence-is-more-formal Description: Which sentence is more formal? Choices: [(a) Visitors are advised that admission to the aircraft museum has been raised by two dollars., (b) FYI, admission to the aircraft museum has been raised by two dollars.] Answer index: 0
Subject: Language Arts Skill: is-the-sentence-simple-compound-or-complex Description: Which is a **simple sentence**? Choices: [(a) Although I would rather visit Italy, I'm excited about going to Panama this summer., (b) The thermometer and the cough syrup are in the medicine cabinet next to the cotton balls.] Answer index: 1	Subject: Language Arts Skill: choose-topic-sentences-for-expository-paragraphs Description: Read the paragraph. Then, add the better topic sentence. ___ In fact, more than half of the planet is covered just by oceans. Earth also has many lakes, rivers, and swamps full of freshwater. But there's even more freshwater that is frozen in glaciers and icecaps. Add to that all of the water that's underground or in the air, and you've got one wet planet! Choices: [(a) Most of the Earth is covered in water., (b) The highest point on Earth is Mount Everest.] Answer index: 0
Subject: Language Arts Skill: is-the-sentence-a-statement-question-command-or-exclamation Description: What kind of sentence is this? Bobby gave me the best present! Choices: [(a) an exclamation, (b) a statement] Answer index: 0	Subject: Language Arts Skill: does-the-adjective-tell-you-what-kind-or-how-many Description: Look at the adjective in **bold**. Does it tell you "what kind" or "how many"? Maria will need **seven** stamps. Choices: [(a) what kind, (b) how many] Answer index: 1
Subject: Language Arts Skill: determine-the-meanings-of-similes Description: What is the meaning of the simile? Just as a soft breeze rocks the trees, Mrs. Middleton rocked the baby to sleep. Choices: [(a) Mrs. Middleton rocked the baby outside., (b) Mrs. Middleton rocked the baby gently.] Answer index: 1	Subject: Language Arts Skill: is-the-noun-singular-or-plural Description: Is the noun in bold singular or plural? Lamar shouted when his **foot** touched the hot water. Choices: [(a) singular, (b) plural] Answer index: 0
Subject: Language Arts Skill: use-the-correct-article-a-or-an Description: Complete the sentence with the best article. Mrs. Casey keeps the tools in ___ shed. Choices: [(a) an, (b) a] Answer index: 1	Subject: Language Arts Skill: determine-the-themes-of-myths-fables-and-folktales Description: Read the following fable by Aesop. A fox one day spotted a beautiful bunch of ripe grapes hanging from a vine. The grapes seemed ready to burst with juice. The fox's mouth watered, and he gazed longingly at them. The bunch hung up high, far out of the fox's reach. He tried to jump and grab it. The first time he jumped, he was still far away. So he walked off a short distance and took a running leap. But he fell short once more. Again and again he tried, but he simply could not reach the grapes. After a long time, he sat down and looked at the grapes in anger. "What a fool I am," he said. "I am wearing myself out, and for what? This is just a bunch of terrible, sour grapes." And away he walked with his nose in the air. What is the main theme or lesson of the fable? Choices: [(a) Sometimes fruit is sour, not sweet., (b) People pretend they don't want things they can't have.] Answer index: 1
Subject: Language Arts Skill: to-be-use-the-correct-form Description: Complete the sentence with the correct **present tense** form of **to be**. They ___ upstairs in Sofia's bedroom. Choices: [(a) are, (b) am] Answer index: 0	Subject: Language Arts Skill: read-about-famous-places Description: Review the third paragraph. The Golden Gate Bridge is one of the most famous bridges in the world. Its tall frame, two large towers, and orange color make the bridge easy to recognize. Yet as the Golden Gate Bridge was being built, people disagreed about what the bridge should look like. People were worried that San Francisco's thick fog would make the bridge hard to see. The U.S. Navy wanted the bridge to stand out so ships and airplanes wouldn't collide with it. They wanted the bridge to have wide black and yellow stripes, like a bumblebee! Irving Morrow was one of the bridge designers. He did not like the idea of a striped bridge. Morrow did not want a plain black or gray bridge either, though. He thought a dark bridge would make the Golden Gate seem smaller than it was. When the bridge's parts were delivered to San Francisco, they had an orange color. The bridge workers were supposed to paint a new color over the orange. But Morrow was still unsure of what color that would be. He looked at the orange bridge parts and decided that the color would be perfect! Morrow thought the orange would stand out well against the ocean and the sky. Finally, the difficult decision had been made. A red-orange Golden Gate Bridge was bright enough for ships and planes to see. The color made the bridge appear grand and tall. Over the years, fresh paint has been needed. But the color remains the same orange that was supposed to be painted over many years ago. Based on the text, why did Irving Morrow think orange would be a good color for the Golden Gate Bridge? Choices: [(a) The parts were already orange, so no extra work would be needed., (b) The color would make the bridge stand out from the sky and ocean., (c) Using orange paint on orange parts would be cheaper.] Answer index: 1
Subject: Language Arts Skill: does-the-adverb-tell-you-how-when-or-where Description: Look at the adverb in bold. Does it tell you "how" or "where"? Mr. Olson lives **upstairs**. Choices: [(a) how, (b) where] Answer index: 1	Subject: Language Arts Skill: which-word-is-a-noun Description: Is the word in bold a noun? The captain turned the ship around and **sailed** north. Choices: [(a) yes, (b) no] Answer index: 1

Table 32: Question examples for each skill (part 19).

Subject: Language Arts Skill: identify-the-irregular-past-tense-ii Description: Which sentence is in the past tense? Choices: [(a) Susan **feeds** her bird., (b) Susan **fed** her bird.] Answer index: 1	Subject: Language Arts Skill: which-sentence-is-in-the-regular-past-tense Description: Which sentence is in the past tense? Choices: [(a) Cassie **acted** happy., (b) We **discover** hidden treasures.] Answer index: 0
Subject: Language Arts Skill: which-sentence-uses-an-antonym Description: Read the sentence. Select the sentence that uses an antonym in place of the word in bold. Bella's dad has always been **short**. Choices: [(a) Bella's dad has always been **tall**., (b) Bella's dad has always been **shy**.] Answer index: 0	Subject: Language Arts Skill: use-action-verbs Description: Complete the sentence with the action verb. Mrs. Carlson ___ nuts into the cookie batter. Choices: [(a) mixes, (b) butter] Answer index: 0
Subject: Language Arts Skill: pronoun-verb-agreement Description: Complete the sentence with the best **verb**. He ___ on television. Choices: [(a) appears, (b) appear] Answer index: 0	Subject: Language Arts Skill: make-predictions-about-a-story Description: Read this passage from a story. Anna and Andrew had just moved in to their new house. "Let's explore," Anna said. They opened all the closets in the bedrooms. Then they found the door to the attic. Their dad noticed them opening the door. "Go ahead," he said. "It's full of old junk." In the attic, Anna and Andrew saw an old dresser and some boards. Then they noticed a very large metal box. They walked over to look at it more closely. Based on the passage, which is more likely to happen next? Choices: [(a) Anna and Andrew open the metal box., (b) Anna and Andrew open the dresser drawers.] Answer index: 0
Subject: Language Arts Skill: greetings-and-closings-of-letters Description: Which closing is correct for a letter? Choices: [(a) Thanks, Jim, (b) thanks, Jim] Answer index: 0	Subject: Language Arts Skill: identify-base-words-prefixes-and-suffixes Description: What is the base word in **dampness**? Choices: [(a) damp, (b) ness] Answer index: 0
Subject: Language Arts Skill: which-sentence-has-the-same-meaning Description: Which sentence has the same meaning? Mrs. Duncan **closed** her bedroom door and went to bed. Choices: [(a) Mrs. Duncan **shut** her bedroom door and went to bed., (b) Mrs. Duncan **painted** her bedroom door and went to bed.] Answer index: 0	Subject: Language Arts Skill: identify-the-authors-purpose-passages Description: Read the text below. Vote for Bob Mueller for city council. He'll stand up for the needs of our town's hardworking citizens. What is the text's most likely purpose? Choices: [(a) to persuade, (b) to inform, (c) to entertain] Answer index: 0
Subject: Language Arts Skill: choose-topic-sentences-for-narrative-paragraphs Description: Read the paragraph. Then, add the better topic sentence. ___ First, my parents took me to the store to buy some seeds. Then, we took the seeds home, and I planted them in my backyard. I watered them every day, and soon the plants started to grow. After several weeks, I started to see little vegetables pop up. By the end of the summer, I had a garden full of green peppers, beans, corn, and carrots. Choices: [(a) Last spring, I planted an amazing vegetable garden., (b) Fresh vegetables are my favorite topping to put on pizza.] Answer index: 0	Subject: Language Arts Skill: choose-the-text-that-matches-the-writers-purpose Description: You want to **inform** someone **about blueberries**. "Inform" means "teach someone about something". What should you write? Choices: [(a) Sarah couldn't believe her eyes. On the table were plates full of blueberry pancakes, blueberry muffins, and even blueberry sauces., (b) Order our blueberry pancakes today! They're always hot and delicious., (c) As the blueberry fruit ripens, it turns from green to purple to dark blue.] Answer index: 2
Subject: Language Arts Skill: analyze-passages-from-narrative-of-the-life-of-frederick-douglass-part-2 Description: Review the passage. I thought the matter over during the next day, Sunday, and finally resolved upon the third day of September, as the day upon which I would make a second attempt to secure my freedom. I now had three weeks during which to prepare for my journey. ... From Frederick Douglass, Narrative of the Life of Frederick Douglass Look at the text in **bold**. What hidden reality is shown through this text? Choices: [(a) It shows that although Douglass's friends behaved kindly, they secretly envied him., (b) It shows that although the shipyard was calm, Douglass experienced tension at home., (c) It shows that although the city felt peaceful, enslaved people were preparing to rebel., (d) It shows that although Douglass's plan was working, he still had worries and doubts.] Answer index: 3	Subject: Language Arts Skill: are-the-modifiers-used-correctly Description: Which sentence is correct? Choices: [(a) **Stuck in traffic**, Hakim grew drowsy and time slowed to a standstill; eventually, he decided to pull over and take a nap., (b) **Stuck in traffic**, time slowed to a standstill and Hakim grew drowsy; eventually, he decided to pull over and take a nap.] Answer index: 0
Subject: Language Arts Skill: recall-the-source-of-an-allusion Description: What is the source of the allusion in the sentence below? The headline read: "Smart Phones Becoming **Big Brother**." Choices: [(a) literature, (b) a song] Answer index: 0	Subject: Language Arts Skill: transitions-with-conjunctive-adverbs Description: Complete the text with the better conjunctive adverb. In China, mountainous areas are being flattened to make more room for new construction; ___, in the United States, mountaintops are being removed so that miners can access coal reserves. Choices: [(a) therefore, (b) likewise] Answer index: 1
Subject: Language Arts Skill: determine-the-authors-point-of-view Description: Read the text. When I decided it was time for a new hobby, I signed up for a "Clowning for Fun and Profit" class at my local arts center. I cheerily skipped through the door on the first day of class, but my heart sank as soon as I spotted the instructor, Bobo. Bobo turned out to be a sad-faced clown who refused to speak. It was clear he planned to teach entirely in pantomime. As he silently motioned for me to find my seat, I resigned myself to a bad experience. So imagine my surprise when this crazy class turned out to be invaluable to me! Although I didn't hear a single spoken word for five hours, Bobo somehow managed to express his ideas clearly and in an engaging way. By the end of the first session, he had expertly taught me how to make balloon animals, apply makeup, juggle beanbags, and develop my own personal clown character. As I eagerly await the second session, "All About Unicycles," I will begin clowning around as a volunteer at a local children's hospital. Which sentence best summarizes the author's point of view about the clown class? Choices: [(a) Bobo uses eccentric teaching methods to efficiently teach this course, making him an excellent clowning instructor., (b) Bobo's sad demeanor and poor pantomime skills make it difficult for his students to learn effective clowning techniques.] Answer index: 0	Subject: Language Arts Skill: compare-two-texts-with-different-genres Description: Read the following text from a diary. This excerpt is about life for Jews in Europe at the beginning of World War II. After May 1940 good times rapidly fled: first the war, then the capitulation, followed by the arrival of the Germans, which is when the sufferings of us Jews really began. Anti-Jewish decrees followed each other in quick succession. Jews must wear a yellow star, Jews must hand in their bicycles, Jews are banned from trams and are forbidden to drive. Jews are only allowed to do their shopping between three and five o'clock and then only in shops which bear the placard "Jewish shop." Jews must be indoors by eight o'clock and cannot even sit in their own gardens after that hour. Jews are forbidden to visit theaters, cinemas, and other places of entertainment. From Anne Frank, "Anne Frank: The Diary of a Young Girl". Copyright 1952 by Otto H. Frank Based on this excerpt, what can you conclude about life for Jews in Europe at the beginning of World War II? Choices: [(a) Jewish people could no longer afford to buy theater tickets., (b) Jewish people could not associate with one another., (c) Jewish people had many of their rights taken away.] Answer index: 2

Table 33: Question examples for each skill (part 20).

Subject: Language Arts Skill: read-and-understand-informational-passages Description: Review the **seventh paragraph**. title: Meditating in School ... This is where the need for good, sound research comes in. Past studies showing that mindfulness helps medical patients are not enough. To really determine whether mindfulness helps improve grades, research needs to focus specifically on mindfulness in schools—and what impact, if any, it has. That way, educators can make informed decisions about where to put their resources. Until then, whether mindfulness is included in classroom programming will remain the choice of individual teachers. Based on the text, what still needs to be determined about mindfulness in schools? Choices: [(a) whether meditation affects different students in different ways, (b) how to raise the funds needed to teach meditation in schools, (c) whether mindfulness meditation has a positive impact in a school setting] Answer index: 2	Subject: Language Arts Skill: choose-evidence-to-support-a-claim Description: Read the claim below. Gardeners should never use pesticides on their plants. Select the piece of evidence that best supports this claim. Choices: [(a) Organic pesticides tend to cost more than conventional ones, and they may be less effective., (b) Pets and children often play in and around gardens, where they can be exposed to pesticides.] Answer index: 1
Subject: Language Arts Skill: analyze-passages-from-the-giver-part-1 Description: Reread the following passage from The Giver. In this excerpt, Jonas, the main character, recalls a time when he saw an unidentified aircraft. Frightened was the way [Jonas] had felt a year ago when an unidentified aircraft had overflown the community twice. He had seen it both times. Squinting toward the sky, he had seen the sleek jet, almost a blur at its high speed, go past, and a second later heard the blast of sound that followed. Then one more time, a moment later, from the opposite direction, the same plane. ... From Lois Lowry, The Giver. Copyright 1993 by Lois Lowry Look at the text in **bold**. How does this paragraph contribute to the meaning or tone of the passage? Choices: [(a) It creates an unsettling tone., (b) It creates a ridiculous tone., (c) It creates a playful tone., (d) It creates a serene tone.] Answer index: 0	Subject: Language Arts Skill: use-personification Description: Complete the sentence so that it uses personification. The sorceress peered into the mirror, noticing how the amulet ___ her neck. Choices: [(a) barely clasped around, (b) gently embraced] Answer index: 1
Subject: Language Arts Skill: identify-plagiarism Description: Compare the student text with the source. Source: Carolyn Cinami DeCristofano, "A Black Hole Is Not a Hole", page 5. Published by Charlesbridge, 2012: Nothing can out-tug a black hole. No army of tow trucks, no convoy of supersized earth haulers, no fleet of giant rocket engines. Student text: The pull of a black hole is so strong that nothing can pull stronger, not even a "fleet of giant rocket engines" (DeCristofano 5). Is the student text plagiarized? Choices: [(a) No, it is not plagiarized., (b) Yes, because it fails to use quotation marks.] Answer index: 0	Subject: Language Arts Skill: identify-counterclaims Description: Consider this claim: Poems that rhyme are better than poems that do not rhyme. Now consider how someone might argue against this. Which sentence presents a counter-claim to the above claim? Choices: [(a) "Beowulf" is one of the oldest and longest poems in existence., (b) Poetry that doesn't rhyme allows for more freedom of expression.] Answer index: 1
Subject: Language Arts Skill: trace-an-argument Description: Read the text. title: Early to Bed and Early to Rise ... Whether you're naturally a night owl or an early bird is mostly based on your body's chronotype, which Merriam-Webster's online dictionary defines as "the internal circadian rhythm or body clock of an individual that influences the cycle of sleep and activity in a 24-hour period." In short, we are born wired one way or the other. However, it is possible to change your habits. And given the benefits of being an early riser, it may be worth the effort. What is the author's main claim or argument? Choices: [(a) There are just as many benefits to being a night owl as an early riser., (b) It's important to change how society perceives night owls., (c) It is better to be an early riser than a night owl.] Answer index: 2	Subject: Language Arts Skill: identify-active-and-passive-voice Description: Which sentence is in passive voice? Choices: [(a) On April 18, 1906, an earthquake and its fiery aftermath devastated the city of San Francisco., (b) On April 18, 1906, San Francisco was devastated by an earthquake and its fiery aftermath.] Answer index: 1
Subject: Language Arts Skill: is-the-pronoun-reflexive-or-intensive Description: Is the pronoun in bold reflexive or intensive? Bryce uses an elaborate system of notes to remind **himself** of what he has left to do. Choices: [(a) intensive, (b) reflexive] Answer index: 1	Subject: Language Arts Skill: interpret-figures-of-speech Description: What does the **metaphor** in this text suggest? When Bobby lost his job, he was devastated. The only light in the sea of darkness was the prospect of pursuing a new career. Choices: [(a) There was a benefit to Bobby's job loss., (b) Having to pursue a new career was the worst part of Bobby's job loss.] Answer index: 0
Subject: Language Arts Skill: identify-the-verb-mood Description: Which verb mood is used in the **bold** part of the sentence? To help maintain your energy and focus throughout the day, **eat a healthy breakfast**. Choices: [(a) imperative, (b) subjunctive] Answer index: 0	Subject: Language Arts Skill: classify-figures-of-speech Description: Which figure of speech is used in this text? The water made a sound **like kittens lapping**. —Marjorie Kinnan Rawlings, "The Yearling" Choices: [(a) metaphor, (b) simile] Answer index: 1
Subject: Language Arts Skill: vocabulary-review-trace-an-argument Description: Look at the word **entrenched** as used in the passage "The Most Important Meal of the Day?" An Australian study published in 2019 collected health data for over twenty-eight years from multiple countries. The results showed few differences between breakfast skippers and breakfast eaters. The study concluded that "breakfast is not the most important time of the day to eat, even though that belief is really **entrenched** in our society and around the world." What does **entrenched** mean? Choices: [(a) highly debatable, (b) quite rare, (c) firmly established] Answer index: 2	Subject: Language Arts Skill: analyze-passages-from-the-outsiders-part-2 Description: Review the passage. Tim Shepard and company were already waiting when we arrived at the vacant lot, along with a gang from Brumly, one of the suburbs. Tim was a lean, catlike eighteen-year-old who looked like the model JD you see in movies and magazines. He had the right curly black hair, smoldering dark eyes, and a long scar from temple to chin where a tramp had belted him with a broken pop bottle. He had a tough, hard look to him, and his nose had been broken twice. Like Dally's, his smile was grim and bitter. He was one of those who enjoy being a hood. The rest of his bunch were the same way. The boys from Brumly, too. Young hoods—who would grow up to be old hoods. I'd never thought about it before, but they'd just get worse as they got older, not better. I looked at Darry. He wasn't going to be any hood when he got old. He was going to get somewhere. Living the way we do would only make him more determined to get somewhere. That's why he's better than the rest of us, I thought. He's going somewhere. And I was going to be like him. I wasn't going to live in a lousy neighborhood all my life. ... From S. E. Hinton, The Outsiders. Copyright 1967 by S. E. Hinton Look at the text in **bold**. What does this figurative language suggest? Choices: [(a) Tim fights for survival every day., (b) Tim has always been cruel to Ponyboy., (c) Tim often does not have enough to eat., (d) Tim attempts to stay hidden at all costs.] Answer index: 0

Table 34: Question examples for each skill (part 21).

Subject: Language Arts Skill: identify-the-authors-purpose Description: Review the text. Good study habits train your brain for success. Applying effective learning methods will not only improve your grades but, more importantly, increase your long-term knowledge. Cramming at the last minute is ineffective. Instead, try to create a study routine. Schedule specific blocks of time to study every day. Next, find the best environment that helps you concentrate. Some students do better with the silence of a library, while others need the background noise or music of a public space. Now that you have a time and a place, you need a strategy. Look at your tasks and make a list. Setting small, manageable goals for your study session will help you work efficiently. Do the most difficult assignments first, while your mind is fresh. Finally, do not be afraid to take limited breaks to restore your motivation. Which best shows that the author's purpose is "to explain some productive study techniques to readers"? Choices: [(a) The author argues that students need to work in a place with "background noise" in order to study efficiently., (b) The author outlines a series of best practices to follow to improve study habits.] Answer index: 1	Subject: Language Arts Skill: is-it-a-direct-object-or-an-indirect-object Description: Is the phrase in bold a direct object or an indirect object? A guard denied **the tourists** entrance to the palace. Choices: [(a) direct object, (b) indirect object] Answer index: 1
Subject: Language Arts Skill: decide-whether-ellipses-are-used-appropriately Description: Read this text. On May 25, 1977, "Star Wars" opened in theaters and wowed audiences with groundbreaking special effects. Is this an appropriate use of an ellipsis? Choices: [(a) yes, (b) no, because the text with an ellipsis is no longer grammatically correct] Answer index: 1	Subject: Language Arts Skill: compound-subjects-and-objects-with-pronouns Description: Select the correct pronoun to complete the sentence. Mr. Joyce rarely worries about ___ and Farid, because they're both so responsible. Choices: [(a) she, (b) her] Answer index: 1
Subject: Language Arts Skill: identify-vague-pronoun-references Description: Which of the following contains a vague pronoun reference? Choices: [(a) Bella and her sister posed for a photograph, but when the flash went off, she blinked., (b) Bella and her sister posed for a photograph, but when the flash went off, Bella blinked.] Answer index: 0	Subject: Language Arts Skill: what-does-the-punctuation-suggest Description: What does the following sentence suggest? Ferries depart from Battery Park in New York and Liberty State Park in New Jersey for the museum on Ellis Island, which commemorates the millions of immigrants who entered the United States through Ellis Island. Choices: [(a) There is only one museum on Ellis Island., (b) There is more than one museum on Ellis Island.] Answer index: 0
Subject: Language Arts Skill: suggest-appropriate-revisions Description: Read the following text from a student essay. How can the writer best improve his or her **word choice**? I saw a movie called "Blob Invasion". It was really good. It was about a weird guy who was into science. He worked on bugs and small animals. He made a machine that did things to the bugs and the animals. They became big weird things. One day he transformed himself by accident. He became a big blob! He went around doing bad things to the city. In the end, a boy figured out how to change the blob back into a man. I would recommend this movie to everyone who likes fun science movies. Choices: [(a) by reducing repetitive language, (b) by using more specific language] Answer index: 1	Subject: Language Arts Skill: analyze-passages-from-the-giver-part-2 Description: Review the passage. "Father? Mother?" Jonas asked tentatively after the evening meal. "I have a question I want to ask you." ... From Lois Lowry, The Giver. Copyright 1993 by Lois Lowry Based on the passage, how does Jonas most likely feel about his family? Choices: [(a) He finds comfort in the regimented order provided by his family., (b) He wonders why his family's beliefs are different from the community's., (c) He feels grateful to have a family that openly discusses tough issues., (d) He is beginning to question his parents and the community.] Answer index: 3
Subject: Language Arts Skill: identify-thesis-statements Description: Which is a thesis statement? Choices: [(a) School-wide Wi-Fi access is critical to building academic success because it increases communication, allows for more interactive lessons, and expands research opportunities., (b) What effect does having Wi-Fi access in public school classrooms and libraries have on how students perform academically and how well they pay attention in class?] Answer index: 0	Subject: Language Arts Skill: classify-logical-fallacies Description: Which logical fallacy is used in the text? In this election, we've seen the highest voter turnout ever recorded. If you have any doubts about Ryan Mueller's qualifications, just look at how many people have come out to vote for him. Choices: [(a) bandwagon fallacy: the assumption that the popular choice is automatically correct, (b) ad hominem: a personal attack against one's opponent] Answer index: 0
Subject: Language Arts Skill: analyze-passages-from-the-outsiders-part-1 Description: Read the following passage from "The Outsiders". In this excerpt, Ponyboy, the narrator, and his friend, another greaser named Two-Bit, are walking with two girls from a rival group called the Socs. After the movie was over it suddenly came to us that Cherry and Marcia didn't have a way to get home. Two-Bit gallantly offered to walk them home—the west side of town was only about twenty miles away—but they wanted to call their parents and have them come and get them. Two-Bit finally talked them into letting us drive them home in his car. I think they were still half-scared of us. They were getting over it, though, as we walked to Two-Bit's house to pick up the car. It seemed funny to me that Socs—if these girls were any example—were just like us. They liked the Beatles and thought Elvis Presley was out, and we thought the Beatles were rank and that Elvis was tuff, but that seemed the only difference to me. Of course greasy girls would have acted a lot tougher, but there was a basic sameness. I thought maybe it was money that separated us. ... From S. E. Hinton, The Outsiders. Copyright 1967 by S. E. Hinton Based on the passage, which of the following is most likely true about Ponyboy? Choices: [(a) Ponyboy doesn't want to take the girls home, but he feels obligated to assist them., (b) Cherry is attempting to develop a deep connection with Ponyboy, but he is resistant., (c) Ponyboy wishes he had more money so he could be more like the Socs., (d) This is Ponyboy's first time having an authentic conversation with a member of the Socs.] Answer index: 3	Subject: Language Arts Skill: use-the-correct-verb-with-compound-subjects Description: Complete the sentence with the best verb. Whenever Skip runs out into the yard, the chickens and the rooster ___ into the coop. Choices: [(a) disappears, (b) disappear] Answer index: 1
Subject: Language Arts Skill: distinguish-facts-from-opinions Description: Which sentence states a fact? Choices: [(a) The spinach plant is native to Asia., (b) Spinach tastes worse than any other vegetable.] Answer index: 0	Subject: Language Arts Skill: choose-the-best-transition Description: Choose the transition that compares, or shows similarities. Betty helps her community by raising money for a youth center. ___, Dale makes his neighborhood more beautiful by planting trees. Choices: [(a) Similarly, (b) For example] Answer index: 0

Table 35: Question examples for each skill (part 22).

Subject: Language Arts Skill: analyze-passages-from-narrative-of-the-life-of-frederick-douglass-part-1 Description: Read the following passage from "Narrative of the Life of Frederick Douglass". In this excerpt, Douglass describes some features found on the plantation where he was enslaved as a young child. Colonel Lloyd kept a large and finely cultivated garden, which afforded almost constant employment for four men, besides the chief gardener, Mr. M'Durmond. This garden was probably the greatest attraction of the place. During the summer months, people came from far and near—from Baltimore, Easton, and Annapolis—to see it. It abounded in fruits of almost every description, from the hardy apple of the north to the delicate orange of the south. This garden was not the least source of trouble on the plantation. Its excellent fruit was quite a temptation to the hungry swarms of boys, as well as the older slaves, belonging to the colonel, few of whom had the virtue or the vice to resist it. ... From Frederick Douglass, Narrative of the Life of Frederick Douglass What is this passage mainly about? Choices: [(a) It is about why Douglass enjoyed spending time in the garden and stable on Colonel Lloyd's plantation., (b) It is about how Colonel Lloyd's fancy garden and fine horses created challenges for enslaved people., (c) It is about how Colonel Lloyd paid more attention to his garden than to the horses in his stable., (d) It is about why enslaved people preferred to work in Colonel Lloyd's stable instead of his garden.] Answer index: 1	Subject: Language Arts Skill: analyze-short-stories Description: Read the story. title: Chiarelli's Bakery ... Ms. Chiarelli nodded impatiently. "Come on! If we hurry, we can make cassatelle too." Based on the **fourth paragraph**, what is Aram's attitude about his future career? Choices: [(a) He is confident that he will achieve success., (b) He is sure that he will fail, but he wants to try., (c) He is uncertain how things will turn out.] Answer index: 0
Subject: Language Arts Skill: determine-the-main-idea-of-a-passage Description: Read the passage. All over the planet, ancient tombs and temples lie hidden from view. So how do archaeologists know where to begin digging? Thanks to satellites, that question is becoming easier to answer. In the pioneering field of satellite archaeology, satellites four hundred miles above Earth can identify structures buried under soil, covered by modern construction, or obscured by forests. For example, mud bricks used by ancient Egyptians are more dense than soil, and the differences are detected by the satellites. Advanced computer programs map buried settlements and distinguish them from water, vegetation, and farmland. Sarah Parcak, a pioneer in the field, says of the technology, "It allows you to literally strip away vegetation and see entire cities beneath the rain forest canopy. This is the unbelievable future of archaeology." What is the main, or central, idea of the passage? Choices: [(a) Archaeologists must determine where ancient structures are buried before they can begin excavating them., (b) Archaeologists are uncovering ancient hidden structures by using satellite imagery.] Answer index: 1	Subject: Language Arts Skill: use-parallel-structure Description: Complete the sentence. In his novel Nineteen Eighty-Four, George Orwell describes a dystopian London in the hands of a totalitarian government that is paranoid, watchful, and ___. Choices: [(a) mercilessly oppressive, (b) mercilessly oppresses its citizens] Answer index: 0
Subject: Language Arts Skill: use-dictionary-entries-to-determine-correct-usage Description: Look at this dictionary entry. dictionary word: exasperate dictionary pos: verb dictionary inflections: exasperating, exasperated dictionary entry: 1 to make very angry; to irritate Marie was exasperated by Barbara's constant complaining. dictionary etymology: from Latin (exasperare) Which sentence uses the word **exasperate** correctly? Choices: [(a) Mrs. Hampton realized she was exasperating a bad situation when she failed to pay the parking ticket promptly., (b) Gary's reluctance to do basic household chores exasperated Khalil and Chase.] Answer index: 1	Subject: Language Arts Skill: trace-an-argument-set-1 Description: Read the text. title: The Connected City ... The bottom line is that online connectivity is a necessity in today's high-tech society. Cities across the country are scrambling to keep up with ever-increasing demands for Wi-Fi by the general public. In fact, an Internet Society survey of more than ten thousand Internet users around the world found that eighty-three percent of the respondents agreed that access to the Internet should be considered a basic human right. Whether viewed as a public service or as a way to boost the local economy, people expect advanced technology on the go. Travelers, business owners, and local residents should be able to rely on the local government to help them stay connected. What is the author's main claim or argument? Choices: [(a) Access to free Wi-Fi throughout a city helps to promote tourism., (b) Free Wi-Fi in cities benefits residents as well as the local economy., (c) Only low-income residents of urban areas should be provided with free Wi-Fi.] Answer index: 1
Subject: Language Arts Skill: which-text-is-most-formal Description: Which expression of thanks is more formal? Choices: [(a) We're so pleased you could join us on our special day. Thank you again for the wonderful gift., (b) We're super happy that you could be with us on our special day. Thanks again for the awesome gift!] Answer index: 0	Subject: Language Arts Skill: trace-an-argument-set-2 Description: Read the text. title: Fact or Fiction? ... Looking beyond the author's own life events, memoir can inform readers about the world in the same way that other nonfiction can. For example, a memoir written by the head chef of a famous restaurant is likely to educate the reader about the inner workings of a professional kitchen. A memoir composed by a cello player in an esteemed orchestra will probably help the reader learn more about music. And a memoir recalling an adolescence during the 1980s may describe pop culture during that time. Memoir has a way of relaying facts about anything from an occupation to brief fashion trends, all of it meaningful to the author. What is the author's main claim or argument? Choices: [(a) Memoir is best categorized under the umbrella of literary nonfiction., (b) Memory is too unreliable for memoir to be considered a type of nonfiction., (c) While many memoirs are fact-based, many authors are untrustworthy., (d) The most profitable memoirs are those shown to be the most factual.] Answer index: 0
Subject: Language Arts Skill: choose-the-topic-sentence-that-best-captures-the-main-idea Description: Review the details below. Cell phones can be used to cheat on tests by sending answers to friends or by accessing the Internet. ... Texting during class is like passing notes and is a waste of time. Choose the best topic sentence to introduce a paragraph containing these details. Choices: [(a) Cell phones in the classroom can have a negative impact on student learning., (b) There are many legitimate arguments for allowing students to have cell phones in class, even if they are disruptive., (c) Cell phones have become a near constant presence at school and at home.] Answer index: 0	Subject: Language Arts Skill: identify-sentence-fragments Description: Is there a sentence fragment? Before signing in, you must first register for an account. Unless you're already a member of the site. Choices: [(a) yes, (b) no] Answer index: 0

Table 36: Question examples for each skill (part 23).

Subject: Language Arts Skill: use-context-as-a-clue-to-the-meanings-of-foreign-expressions Description: What is the meaning of the foreign expression in bold? In 2014, giant moths swarmed **en masse** in parts of Southeast Asia. More than eight hundred sightings were reported in Singapore, while thousands disrupted a soccer match at Darul Makmur Stadium in Malaysia. Choices: [(a) coincidentally, (b) as a group, (c) unexpectedly, (d) fatally] Answer index: 1	Subject: Language Arts Skill: use-the-correct-foreign-expression Description: Complete the text with the correct foreign expression. The Norwood Bistro features an eclectic ___ menu so that diners can select a variety of dishes. Choices: [(a) à la carte, (b) crème de la crème] Answer index: 0
Subject: Language Arts Skill: identify-audience-and-purpose Description: Review the fund-raising pamphlet and then answer the question. Be a hero in an animal's life! Donate to the Martin County Animal Shelter. Adoption fees cover less than eight percent of our operating expenses. We rely on donations to ensure that every animal receives excellent care. Your generous gift provides food, shelter, and veterinary care to homeless and rescued pets. Please donate today! Which best indicates that the primary audience is "community members who care about animals"? Choices: [(a) The writer indicates that donating is a way for readers to "be a hero in an animal's life.", (b) The writer argues that the shelter is necessary to keep stray animals off the streets and prevent illnesses., (c) The writer asks readers to donate time as well as money., (d) The writer includes information about funding sources and operating expenses.] Answer index: 0	Subject: Language Arts Skill: classify-figures-of-speech-euphemism-hyperbole-oxymoron-paradox Description: Which figure of speech is used in this text? This movie is so predictable that I'm likely to **die of boredom** if I keep watching it. Choices: [(a) paradox, (b) hyperbole] Answer index: 1
Subject: Language Arts Skill: analyze-short-stories-set-1 Description: Read the story. title: Lake Magic ... Gramps appeared with dry towels. "I've made popcorn and a warm fire. And your mom called. She's fine." Gramps paused, then added, "Everybody's fine." What is the main reason Izzie is looking for Champ? Choices: [(a) She hopes Champ will take her brother's place as a friend to her., (b) She wants to prove to her grandfather that she can find the legendary lake monster., (c) She wants Champ's "lake magic" to make her family the way it used to be.] Answer index: 2	Subject: Language Arts Skill: explore-words-with-new-or-contested-usages Description: Which text uses the word **nauseous** in its traditional sense? Choices: [(a) Everyone seemed to enjoy the magnolia-scented candle, but it made Walter feel rather **nauseous**., (b) Everyone seemed to enjoy the magnolia-scented candle, but Walter found the smell rather **nauseous**.] Answer index: 1
Subject: Language Arts Skill: analyze-the-development-of-informational-passages-set-2 Description: Read the text. title: Manzanar: A Site of Conscience ... Adapted from the National Park Service, "Manzanar: A Site of Conscience" What is the main focus of the text? Choices: [(a) how the attack on Pearl Harbor led to war against Japan, (b) the history of the internment of Japanese Americans, with a focus on Manzanar, (c) how Japanese Americans adjusted to everyday life at Manzanar, (d) the history of injustices against Japanese Americans, including internment at Manzanar] Answer index: 1	Subject: Language Arts Skill: analyze-the-development-of-informational-passages-set-1 Description: Read the text. title: Language Change ... Adapted from the National Science Foundation, "Language and Linguistics: Language Change" What is the main focus of the text? Choices: [(a) why the works of Shakespeare and Chaucer are difficult for modern readers, (b) why different languages evolve at different rates, (c) how and why language changes over time] Answer index: 2
Subject: Language Arts Skill: choose-punctuation-to-avoid-fragments-and-run-ons Description: Which is the best way to complete the text? Zoe traced her family's lineage back to the eighteenth ___ cross-referenced her grandmother's stories with a genealogical index at the library. Choices: [(a) century. She, (b) century, furthermore, she, (c) century, she] Answer index: 0	Subject: Language Arts Skill: transition-logically-between-claims-evidence-analysis-and-counterclaims Description: Complete the text with the transition that best connects **the two pieces of supporting evidence**. Parents should limit how much screen time their children are allowed to have each day. A study found that children whose parents limited screen time experienced physical benefits, including better sleep habits and decreased risk of obesity. ___, these children earned better grades in school, were more social and helpful, and were less aggressive with peers. Choices: [(a) In other words, (b) Moreover, (c) For example] Answer index: 1
Subject: Language Arts Skill: choose-the-analysis-that-logically-connects-the-evidence-to-the-claim Description: Read the claim and the supporting evidence. *Claim:** Hunter is remarkably virtuous. *Evidence:** Hunter is generous with his time. Why does the evidence support the claim? Choose the **analysis** that better explains the connection. Choices: [(a) Generosity is a key virtue., (b) Hunter believes generosity need not involve money.] Answer index: 0	Subject: Language Arts Skill: identify-run-on-sentences Description: Is this a run-on sentence? Clinging to a two-point lead in the final minute of the fourth quarter, the Tigers triumphed when their defense recovered a fumble and sealed the victory. Choices: [(a) yes, (b) no] Answer index: 1
Subject: Language Arts Skill: use-words-accurately-and-precisely Description: Complete the text with the better phrase. Karen and Steven are ___ on a documentary film project about the effects of drought on local wildlife. Choices: [(a) collaborating together, (b) working together] Answer index: 1	Subject: Language Arts Skill: classify-figures-of-speech-review Description: Which figure of speech is used in this text? He had hoped to find his missing watch, but **he couldn't find the time**. Choices: [(a) onomatopoeia, (b) pun] Answer index: 1
Subject: Language Arts Skill: avoid-double-illogical-and-unclear-comparisons Description: Which text best completes the sentence? As a dancer, I studied tap and ballet. In my experience, tap was ___. Choices: [(a) easier to learn than any form of dance, (b) easier to learn, (c) easiest to learn] Answer index: 1	Subject: Language Arts Skill: choose-the-best-evidence-to-support-a-claim Description: Consider this claim: Online colleges prepare students for careers just as well as traditional brick-and-mortar schools do. Which is the strongest evidence to support the claim? Choices: [(a) "I've hired two people recently who received their college degrees through online programs, and the quality of their performance is as good as, if not better than, that of their peers," reported business owner Fred Browning., (b) Online college programs often provide career preparation services that are equivalent to those provided by traditional college programs, including interview preparation, job fairs, and even internship placement., (c) Many students choose to gain some credits through an online college program and then successfully transfer to a brick-and-mortar institution to complete a degree.] Answer index: 1

Table 37: Question examples for each skill (part 24).

Subject: Language Arts Skill: analyze-short-stories-set-2 Description: Read the story. title: Water Rising ... Polara looked to the horizon, at the unmistakable sparkle of the approaching sea. She wasn't sure how brave she felt, but she was willing. "I am," she answered. Based on the **first and second paragraphs**, what internal conflict does Polara struggle with? Choices: [(a) the duty to stand watch versus her inclination to daydream, (b) the pull of the unfamiliar versus her desire to stay at Shublik, (c) respect for Commander Axel versus her irritation at his order, (d) the enjoyment of the view versus her fear about the water on the horizon] Answer index: 1	Subject: Language Arts Skill: use-appeals-to-ethos-pathos-and-logos-in-persuasive-writing Description: Which statement primarily appeals to **logos**, or reason, to support the position that **more money does not always lead to increased happiness**? Choices: [(a) Like most people, I enjoy the feeling of buying a new gadget, but it turns out that the happiness that we get from a new purchase doesn't last long., (b) While it's true that a lack of money can cause stress and unhappiness, it does not necessarily follow that money will lead to more happiness after basic needs are met.] Answer index: 1
Subject: Language Arts Skill: choose-the-word-whose-connotation-and-denotation-best-match-the-sentence Description: Complete the sentence with the word that best fits the overall meaning and tone. Dan appreciated the gallery owner's ___ efforts to include artwork from the local community. Choices: [(a) calculating, (b) deliberate] Answer index: 1	Subject: Language Arts Skill: evaluate-counterclaims Description: Consider this claim: Veggie burgers are every bit as tasty and satisfying as regular beef burgers. Now consider how someone might argue against this. Which sentence presents the stronger and more reasonable counterclaim to the above claim? Choices: [(a) Veggie burgers have no taste whatsoever and cannot compare in any way to a delicious beef burger., (b) Regular beef burgers have more good-tasting fat and filling protein than veggie burgers.] Answer index: 1
Subject: Language Arts Skill: use-etymologies-to-determine-the-meanings-of-words Description: "Vociferous" and "vocal" are related English words that come from Latin. What does **vociferous** mean? Choices: [(a) loud and forceful, (b) wise and thoughtful, (c) strong and fit] Answer index: 0	Subject: Language Arts Skill: analyze-passages-from-the-lightning-thief-part-2 Description: Read the following passage from "The Lightning Thief". In this excerpt, Percy Jackson, the narrator, is describing a dream. In my dreams, I stood in a dark cavern before a gaping pit. Gray mist creatures churned all around me, whispering rags of smoke that I somehow knew were the spirits of the dead. ... From Rick Riordan, The Lightning Thief. Copyright 2005 by Rick Riordan What is most likely true about the spirits in Percy's dream? Choices: [(a) The spirits will cooperate with the ancient voice., (b) The spirits are trying to protect Percy., (c) The spirits want to lead Percy into the pit.] Answer index: 1
Subject: Language Arts Skill: analyze-passages-from-harriet-tubman-conductor-on-the-underground-railroad-part-1 Description: Review the passage. Harriet thought that Christmas was the very best time of all. By tradition there was no work. The holiday for the field slaves lasted as long as the Yule log burned in the fireplace at the Big House. So the people in the quarter spent days preparing the log. They chose a big one, so big that the strongest field hands bent their backs under its weight. They soaked it in water, so that it would burn slowly and for a long time. ... Adapted from Ann Petry, Harriet Tubman: Conductor on the Underground Railroad. Copyright 1955 by Ann Petry Which item does the author use to symbolize comfort and security? Choices: [(a) the cabin, (b) the overseer's horn, (c) the blankets] Answer index: 0	Subject: Language Arts Skill: analyze-passages-from-roll-of-thunder-hear-my-cry-part-1 Description: Review the passage. Taylor How do students feel about wearing shoes on the first day of school? Choices: [(a) They are embarrassed by their shoes., (b) They are eager to wear their shoes., (c) They are uncomfortable in their shoes.] Answer index: 2
Subject: Language Arts Skill: analyze-passages-from-roll-of-thunder-hear-my-cry-part-2 Description: Review the passage. The revival ran for seven days and it was an occasion everyone looked forward to, for it was more than just church services; it was the year's only planned social event, disrupting the humdrum of everyday country life. Teenagers courted openly, adults met with relatives and friends they had not seen since the previous year's "big meeting," and children ran almost free. ... From Mildred D. Taylor, Roll of Thunder, Hear My Cry. Copyright 1976 by Mildred D. Taylor Look at the text in **bold**. What does this figurative language show about the revival? Choices: [(a) It shows how long and drawn out the service is., (b) It shows how energetic the townspeople are., (c) It shows how overcrowded the event is.] Answer index: 2	Subject: Language Arts Skill: draw-inferences-from-literary-texts Description: Read the text. From his seat at a table in the local library, Ruben turned to the side and saw Nora on a couch, deeply engrossed in a fantasy book. Nora barely seemed to blink as she read, and Ruben thought he had never seen anyone so absorbed in a story. Suddenly, Ruben felt a rumbling beneath his feet. The model of the solar system suspended from the ceiling began swinging back and forth, as books started falling off the nearby shelves. There was a commotion as library patrons hustled out of the way. Nora stood up and in a clear, loud voice, shouted, "Everybody! This is an earthquake. Get under the tables, now!" Everyone looked at Nora in shock, frozen in place by a newfound fear. "Do it!" Nora commanded, as the floor shifted. "Do it right now!" Ruben and the other patrons followed Nora's instructions, scrambling under the library tables. "Now, put your hands over your head and neck, face away from the windows, and stay still," Nora instructed. As the room shook, some people squealed in fear, while others made soft whimpering noises. From underneath her own table, Nora calmly reassured them. "Don't worry—this one doesn't seem too bad, and hopefully it'll be over in just a few seconds." What is most likely true about Nora? Choices: [(a) She tends to overreact in stressful situations., (b) She has prior experience with earthquakes., (c) She works at the library and knows the patrons well.] Answer index: 1
Subject: Language Arts Skill: analyze-passages-from-the-lightning-thief-part-1 Description: Reread the following passage from "The Lightning Thief". In this excerpt, Percy is talking with his friend Annabeth after fighting a tough battle on their quest. I was pretty much in shock myself. The explosion of bus windows still rang in my ears. But Annabeth kept pulling us along, saying: "Come on! The farther away we get, the better." ... From Rick Riordan, The Lightning Thief. Copyright 2005 by Rick Riordan Which of the following is a reason Annabeth does not want Percy to die? Choices: [(a) If Percy dies, Annabeth would probably have to live with her dad., (b) If Percy dies, Annabeth would probably have to finish the quest on her own., (c) If Percy dies, Annabeth would probably have to go back to the camp.] Answer index: 2	Subject: Language Arts Skill: evaluate-newspaper-headlines-for-bias Description: Which headline best avoids biased language? Choices: [(a) Second Grader's Peach Pie Wins First Place in Baking Contest, (b) Inexplicably, Judges Pick Child's Peach Pie Despite Tastier Entries, (c) Well-Earned Prize Goes to Young Student's Mouthwatering Pie] Answer index: 0

Subject: Language Arts Skill: analyze-passages-from-harriet-tubman-conductor-on-the-underground-railroad-part-2 Description: Review the passage. In the fall of 1854, Harriet Tubman began to feel uneasy about three of her brothers. Benjamin, John and William Henry were still in Maryland, working on plantations where they had been hired out. She kept having dreams about them, vivid dreams in which she saw them sold and sent away in a chain gang. She decided to tell them that she was coming to Maryland that fall, so that they would be ready to go North with her. ... Adapted from Ann Petry, Harriet Tubman: Conductor on the Underground Railroad. Copyright 1955 by Ann Petry What is the meaning of the word **eluded** as used in the passage? Choices: [(a) escaped the understanding of, (b) caused excitement about, (c) raised awareness for] Answer index: 0	Subject: Language Arts Skill: classify-the-figure-of-speech-euphemism-hyperbole-oxymoron-paradox Description: Which figure of speech is used in this text? Lauren asked her mother if she could adopt a cat, and her mother replied, "It's a **definite maybe**," so Lauren didn't want to get her hopes up. Choices: [(a) euphemism, (b) oxymoron] Answer index: 1
Subject: Language Arts Skill: classify-the-figure-of-speech-anaphora-antithesis-apostrophe-assonance-chiasmus-understatement Description: Which figure of speech is used in this text? Soft language **issued** from their **spittleless** **lips** as they **swished** **in** slow circles round and round the field. —James Joyce, "A Portrait of the Artist as a Young Man" Choices: [(a) chiasmus, (b) assonance] Answer index: 1	Subject: Language Arts Skill: interpret-the-figure-of-speech Description: What does the **idiom** in this text suggest? "Speak of the devil!" Trudy declared when Bert strolled into the room. Choices: [(a) Trudy had just been speaking about Bert., (b) Trudy didn't trust Bert.] Answer index: 0
Subject: Language Arts Skill: prefixes Description: Why would a company require an employee to sign a **nondisclosure** agreement? Choices: [(a) to keep company secrets private, (b) to prevent the employee from working for a competitor] Answer index: 0	Subject: Language Arts Skill: suffixes Description: If an objection is **meritless**, what should you do? Choices: [(a) ignore or dismiss it, (b) take it seriously] Answer index: 0
Subject: Language Arts Skill: domain-specific-vocabulary-in-context-science-and-technical-subjects Description: Read the passage and then answer the question. "Rafflesia arnoldii" produces the largest flowers of any plant known to man. It also lacks leaves, roots, a stem, and functioning chloroplasts. What exactly is this bizarre organism, and how does it survive without so many seemingly crucial parts? **Endemic** to the rainforests of Southeast Asia, """R. arnoldii""" has developed a number of adaptations that enable it to thrive in its tropical home. Key to its survival is its parasitic relationship with a grapelike vine of the genus "Tetrastigma". """R. arnoldii""" spends most of its life almost completely concealed inside the host vine. When it is ready to reproduce, however, it grows a single flower that measures about three feet in diameter, weighs up to fifteen pounds, and emits a strong odor of rotting flesh. The smell of the flower, which attracts carrion flies and other pollinators, has earned """R. arnoldii""" the nickname "corpse flower." What is the meaning of **endemic** as used in the passage? Choices: [(a) new, (b) crucial, (c) harmful, (d) native] Answer index: 3	Subject: Language Arts Skill: classify-the-figure-of-speech-review Description: Which figure of speech is used in this text? His guardians were extremely old-fashioned people and did not realize that **we live in an age when unnecessary things are our only necessities**. —Oscar Wilde, "The Picture of Dorian Gray" Choices: [(a) paradox, (b) chiasmus] Answer index: 0
Subject: Language Arts Skill: analyze-passages-from-a-long-walk-to-water-part-2 Description: Read the following passage from "A Long Walk to Water". In this excerpt, Salva has just arrived in Rochester, New York, and is meeting his host family. There they were, smiling and waving in the airport lobby—his new family! Chris, the father; Louise, the mother; and four children. Salva would have siblings, just as he had before. He felt his shoulders relax a little on seeing their eager smiles. ... From Linda Sue Park, A Long Walk to Water. Copyright 2010 by Linda Sue Park How does Salva feel upon meeting his new family? Choices: [(a) He feels unsure of how to fit into his new family, but he is excited to get to know them., (b) His tension and nerves begin to subside, but he still feels a little overwhelmed., (c) He is thankful for their generosity, but he wants to remain emotionally guarded.] Answer index: 1	Subject: Language Arts Skill: analyze-passages-from-a-night-to-remember-part-1 Description: Review the passage. Up on the bridge, Captain Smith tried to piece the picture together. No one was better equipped to do it. After 38 years' service with White Star, he was more than just senior captain of the line; he was a bearded patriarch, worshipped by crew and passengers alike. They loved everything about him—especially his wonderful combination of firmness and urbanity. It was strikingly evident in the matter of cigars. "Cigars," says his daughter, "were his pleasure. And one was allowed to be in the room only if one was absolutely still, so that the blue cloud over his head never moved." ... From Walter Lord, A Night To Remember. Copyright 1955 by Walter Lord. Look at the text in **bold**. What is the effect of this sentence on the tone of the passage? Choices: [(a) It creates a skeptical tone., (b) It creates a somber tone., (c) It creates a frustrated tone.] Answer index: 1
Subject: Language Arts Skill: analyze-passages-from-anne-of-green-gables-part-1 Description: Read the following passage from "Anne of Green Gables". In this excerpt, Anne is chatting with her friend Diana at a tea party. "We had a plum pudding for dinner on Tuesday and there was half the pudding and a pitcherful of sauce left over. Marilla said there was enough for another dinner and told me to set it on the pantry shelf and cover it. I meant to cover it just as much as could be, Diana, but I forgot all about it. I thought of it next morning and ran to the pantry. Diana, fancy if you can my extreme horror at finding a mouse drowned in that pudding sauce! I lifted the mouse out with a spoon and threw it out in the yard. Marilla was out milking and I fully intended to ask her when she came in if I'd give the sauce to the pigs; but when she did come in I was imagining that I was a frost fairy going through the woods turning the trees red and yellow, so I never thought about the pudding sauce again. ... Adapted from L. M. Montgomery, Anne of Green Gables What does this passage suggest about Anne? Choices: [(a) She does not take life very seriously and wishes that others would relax., (b) She has good intentions, but she can be absentminded sometimes., (c) She is self-confident and does not worry about what other people think.] Answer index: 1	Subject: Language Arts Skill: analyze-passages-from-anne-frank-the-diary-of-a-young-girl-part-2 Description: Review the passage. Think of it, having to sit in such terror for a day and two nights! We thought of nothing, but simply sat there in pitch darkness—in her fear, Mrs. van D. had switched off the lamp. We whispered, and every time we heard a creak, someone said, "Shh, shh." ... From Anne Frank, The Diary of a Young Girl: The Definitive Edition. Copyright 1991 by The Anne Frank Fonds. Trans. Susan Massotty What is the meaning of **engrossed** as it is used in the passage? Choices: [(a) preoccupied or captivated, (b) puzzled or confused, (c) absentminded or forgetful] Answer index: 0

Source-Free Unsupervised Domain Adaptation for Question Answering via Prompt-Assisted Self-learning

Maxwell J. Yin and **Boyu Wang** and **Charles Ling***
Western University
`jyin97@uwo.ca, bwang@csd.uwo.ca, charles.ling@uwo.ca`

Abstract

This work addresses source-free domain adaptation (SFDA) for Question Answering (QA), wherein a model trained on a source domain is adapted to unlabeled target domains without additional source data. Existing SFDA methods only focus on the adaptation phase, overlooking the impact of source domain training on model generalizability. In this paper, we argue that source model training itself is also critical for improving the adaptation performance and stability. To this end, we investigate the role of prompt learning as an effective method to internalize domain-agnostic QA knowledge, which can be integrated into source training. After source training, an interactive self-learning strategy is proposed to further fine tune both model and prompt in the model adaptation phase. This leads to the Prompt-Assisted Self-Adaptive Learning (PASAL), an innovative SFDA approach for QA. Empirical evaluation on four benchmark datasets shows that PASAL surpasses existing methods in managing domain gaps and demonstrates greater stability across various target domains, validating the significance of source domain training for effective domain adaptation.

1 Introduction

Question-answering (QA) systems have significantly advanced with the advent of pretrained language models (PLMs). Despite this, research shows that PLMs often grapple with domain shifts, when training and evaluation datasets have different distributions (Yue et al., 2021). Additionally, the success of PLMs is heavily reliant on human-annotated data within the relevant domain for specialized tasks (Devlin et al., 2018; Liu et al., 2019). In many real-world applications, however, the expense of obtaining annotated data is substantial, making the use of unlabeled data more feasible. Consequently, there is a necessity to fine-tune models—originally trained on general datasets—to specific domains, despite the substantial domain gaps.

In response to these challenges, unsupervised domain adaptation (UDA) for QA aims to leverage knowledge from a well-labeled source domain to enhance performance in unlabeled target domains. While existing approaches (Wang et al., 2019; Cao et al., 2020; Vaswani et al., 2017; Nishida et al., 2019; Yue et al., 2021) show promise, they often assume ongoing access to source domain data during target domain adaptation. This reliance presents a challenge in contexts involving sensitive data. For example, clinical data is often subject to stringent privacy regulations due to patient confidentiality, thus only model trained on the source domain is available for public use after initial training (Laparra et al., 2021; Su et al., 2022). Our study contributes to this domain by applying source-free unsupervised domain adaptation (SFDA) to the realm of QA, eliminating the dependency on source domain data after the initial phase of model pretraining. This approach allows the adaptation process to adhere to strict privacy constraints while still leveraging the extensive knowledge gained from source domain pretraining, ensuring a balance between data privacy and the effectiveness of domain adaptation in sensitive contexts.

While SFDA has been explored in the field of computer vision (Liang et al., 2020; Li et al., 2020; Kundu et al., 2020; Yang et al., 2023b), these studies predominantly concentrate on classification tasks, employing methods like clustering which are not directly transferable to QA tasks. Furthermore, such research tends to focus solely on the target domain adaptation phase, overlooking the potential benefits of enhancing the source training phase. In contrast, we argue that improving the initial training phase can significantly boost the generalization capabilities of the model across different domains, thus facilitating more effective domain adaptation.

To fulfill our objectives, it is essential for the model to internalize fundamental QA knowledge

Findings of the Association for Computational Linguistics: NAACL 2024, pages 700–713
June 16-21, 2024 ©2024 Association for Computational Linguistics

that is not bound by the specificities of individual domains, maximizing the use of source data. Our research indicates that prompt learning (Liu et al., 2023; Lester et al., 2021) is particularly effective in this regard. We observe that QA samples from different domains can vary significantly in vocabulary and sentence structure. Consequently, fine-tuning an entire model from one domain to another often necessitates substantial adjustments in the weights of the model. However, considering the nature of prompts, which essentially frame the task description, their scope is relatively fixed once the task is defined. Thus, the prompt for a QA task remains consistent across various training domains. For instance, a prompt like "please answer the question given the context" is applicable irrespective of the domain. This uniformity in prompts, despite divergent training domains, underscores their potential in streamlining domain adaptation and minimizing the need for extensive model retraining.

In our work, we have innovated Prompt-Assisted Self-Adaptive Learning (PASAL), a methodology that seamlessly incorporates prompt learning into the domain adaptation process of QA models. Initially, during the pretraining phase on the source domain, we employ a PLM and augment it with an additional prompt specifically designed to assimilate key, domain-agnostic QA concepts. Additionally, we train an auxiliary Question Generation (QG) model for creating questions from given contexts.

The adaptation to the target domain employs a distinctive self-learning strategy. Commencing with unlabeled data from the target domain, our QG model initially generates pseudo-questions. Subsequently, the QA model, leveraging the initially trained prompt, produces corresponding pseudo-answers. These synthesized question-answer pairs initiate our iterative self-learning cycle: We begin by fine-tuning the prompt, keeping the QA model constant, to closely align with the subtleties of the target domain. Following the optimization of the prompt, it then directs the focused fine-tuning of the QA model, which is conducted with the prompt remaining static. After this, the QG model also undergoes fine-tuning to refine its question-generation capabilities within the target domain. This cycle perpetuates in an alternating fashion—fine-tuning the prompt, then the QA model, and finally the QG model—in a consistent rhythm. Each phase utilizes the pseudo-labeled samples, progressively honing the prompt, QA model, and QG model to foster a more robust and effective domain adaptation.

The core contributions of our research are:

1. We pioneer the application of source-free unsupervised domain adaptation (SFDA) in the realm of QA, emphasizing data privacy and addressing the challenges of sensitive data usage.

2. We introduce the Prompt-Assisted Self-Adaptive Learning (PASAL) framework, an innovative integration of prompt learning with SFDA for QA. This framework leverages prompts to enhance the learning of domain-agnostic knowledge, effectively managing domain shifts.

3. We develop a comprehensive self-learning strategy for the iterative fine-tuning of prompts, QA, and QG models within the target domain. This strategy significantly enhances the adaptability of the model to new domains without the need for source domain data.

2 Related Work

2.1 Unsupervised Domain Adaptation for Question Answering

Historically, UDA for QA has employed adversarial training, multitask learning, and contrastive learning, as seen in the seminal work of Wang et al. (2019). These methods strive to align domain features and answer spans to facilitate the transfer of knowledge. Successive studies by Nishida et al. (2019) and Cao et al. (2020) have built upon this foundation, integrating multitask learning and self-training techniques. Nonetheless, a common limitation of these approaches is the necessity for simultaneous access to both source and target data.

In contrast, source-free unsupervised domain adaptation (SFDA), introduced by Liang et al. (2020), removes the dependency on source domain data during the adaptation phase, addressing data privacy and accessibility issues. Existing SFDA research, as evidenced by Li et al. (2020); Huang et al. (2021); Zeng et al. (2022); Yi et al. (2023); Wang et al. (2023), typically focuses on the adaptation of models post-training in the source domain, with a particular emphasis on classification tasks. Attempts to apply SFDA in NLP have been made, yet discussions on extending it to QA are sparse, as noted by Zhang et al. (2021) and Su et al. (2022).

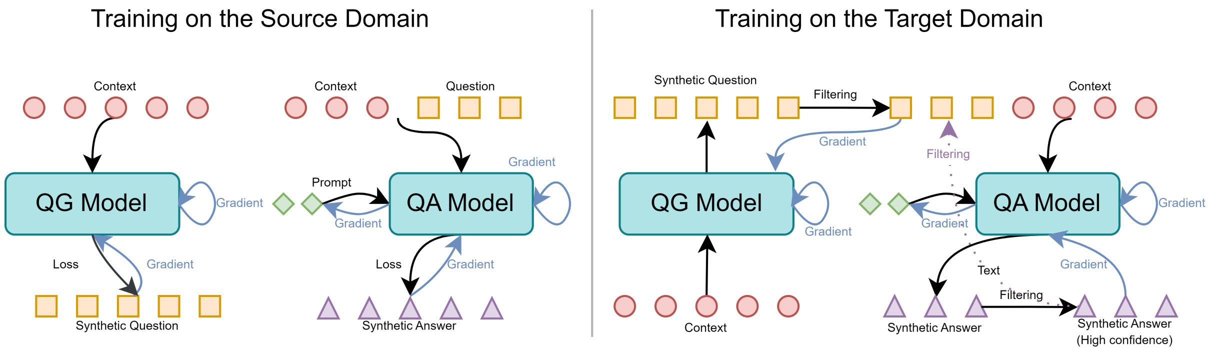

Figure 1: Schematic Overview of the PASAL Framework for Source-Free Unsupervised Domain Adaptation in QA. The left panel illustrates the initial training phase on the source domain. The right panel shows the self-adaptive learning phase on the target domain, highlighting the cyclical fine-tuning process. The QG Model generates pseudo-questions, which are filtered and used by the QA Model to obtain synthetic answers, with the prompt guiding the adaptation. This iterative approach ensures progressive enhancement and adaptability of the model to the target domain.

The distinctive challenges of QA, which resist the direct application of classification-based clustering, underscore the need for further exploration. Our study enhances this dialogue by not only refining the adaptability of the model in the target domain but also by innovating how the model is initially trained in the source domain to bolster the effectiveness of SFDA for QA.

2.2 Prompt Learning

The field of prompt learning has seen significant strides, offering new approaches for enhancing NLU tasks. “Prefix tuning”, introduced by Li and Liang (2021), enriches model understanding by appending prefixes to input sequences. The “WARP” method by Hambardzumyan et al. (2021) and "P-tuning" by Liu et al. (2023) modify language model outputs and input sequences, respectively, demonstrating a robustness comparable to traditional fine-tuning while utilizing fewer task-specific parameters. Additionally, “soft prompts” by Qin and Eisner (2021) represent an adaptive strategy that can dynamically tailor prompt tokens for pre-trained models. Despite these breakthroughs, the integration of prompt learning into UDA for QA remains under-explored, signaling a significant opportunity for future research to enhance domain adaptation in QA.

3 Problem Definition

The problem of UDA for QA is defined as follows. Given a context $c = (c_1, c_2, \ldots, c_{L_1})$ with L_1 tokens, and a query $q = (q_1, q_2, \ldots, q_{L_2})$ with L_2 tokens, the system must identify an answer $a = (c_{a_s}, c_{a_s+1}, \ldots, c_{a_e})$ within the context c. Here, a_s and a_e represent the starting and ending indices of the answer within c.

In the scenario of SFDA for QA, the source domain D_S provides labeled data accessible only during the initial training phase of the model. Post this phase, the data from D_S becomes unavailable. Conversely, the target domain D_T offers unlabeled data without such restrictions. Our methodology involves using n labeled samples $\{c_i, q_i, a_i\}_{i=1}^{n}$ from D_S. Additionally, we employ n' unlabeled samples $\{c'_j\}_{j=1}^{n'}$ from D_T, adhering to the same QA task as in D_S. We postulate that D_S and D_T have different data distributions. The main goal is to adapt a pre-trained model from D_S to D_T, ensuring the model can effectively bridge the domain gap after access to D_S ceases. This adaptation is critical to enhancing the generalization ability of the model to the new domain D_T, thus addressing the domain shift challenge.

4 Method

4.1 Overview

The PASAL framework (Fig. 1), designed for effective SFDA in QA tasks, comprises three principal components: the QG model, denoted as f_{gen}, the QA model, denoted as f, and a specifically designed prompt, denoted as π. Each of these elements—f_{gen}, f, and π—undergoes initial training with source domain data. Within the target domain D_T, f_{gen} is leveraged to generate pseudo-questions $q' = f_{\text{gen}}(c')$, which, in turn, elicits pseudo-answers $a' = f(\pi, c', q')$ from the QA model using the prompt. The generated pseudo-triplets (c', q', a') instigate a systematic self-learning cycle: The prompt is refined first, followed by the QA model, and subsequently the QG model, each step leveraging pseudo-labeled data to progressively enhance adaptability of the model to the target domain. This recursive pattern of alternation between fine-tuning the prompt and the models embodies the core of our self-learning strategy, leading to robust domain adaptation.

4.2 Question Generation Model

In our QG model, denoted as f_{gen}, we employ a Text-to-Text Transfer Transformer (T5) (Raffel et al., 2020). For each context, the prefix token "`generate question:`" is prepended to signal the generation task to the model. This modified context serves as the input, and the model is trained to output the corresponding question q. The training objective for f_{gen} is defined by the cross-entropy loss function:

$$\mathcal{L}_{\text{qg}}(D) = \sum_{i=1}^{|D|} -\log p_{f_{\text{gen}}}(q^{(i)}|c^{(i)}), \qquad (1)$$

where $p_{f_{\text{gen}}}(q^{(i)}|c^{(i)})$ represents the conditional probability of generating the correct question $q^{(i)}$ given the context $c^{(i)}$, as predicted by the QG model f_{gen}.

4.3 Question Answering Model

While previous research on UDA for QA has largely utilized BERT-based, encoder-only models for their NLU capabilities (Yue et al., 2021; Laparra et al., 2021; Su et al., 2022), the current work employs the T5 architecture. The integration of T5, with its encoder and decoder components, is strategically chosen to optimize the use of prompt learning for improving domain adaptation in QA tasks.

We employ a soft prompt strategy as documented in recent research (Li and Liang, 2021; Qin and Eisner, 2021; Zhong et al., 2021; Liu et al., 2023). For a given question-context pair, the data is formatted as follows:

`question: xxx context: xxx`

This input is subsequently prefixed with a sequence of artificial tokens, resulting in the structure:

$\langle v_1, v_2, \ldots, v_k \rangle$ `question: xxx context: xxx`

Algorithm 1 PASAL Training Procedure

```
Require: Question Generation model $f_{\text{gen}}$, Question Answering model $f$, soft prompt $\pi$, number of iterations $N$
Pre-train $f_{\text{gen}}$ on source domain $\mathcal{S}$ to generate pseudo-questions $q$
Pre-train $\pi$ on $\mathcal{S}$
Pre-train $f$ on $\mathcal{S}$ with the trained $\pi$
for $i = 1$ to $N$ do
    for each context $c' \in \mathcal{D}_T$ do
        $q' \leftarrow f_{\text{gen}}(c')$
        Apply LM filtering to $q'$
        $a' \leftarrow f(\pi, c', q')$
        Apply LM filtering to $a'$
        Fine-tune $\pi$ using $(c', q', a')$, keeping $f$ fixed
        $a'' \leftarrow f(\pi, c', q')$
        Fine-tune $f$ using $(c', q', a'')$ with the refined $\pi$
        Update $f_{\text{gen}}$ using $(c', q')$
    end for
end for
```

Here, each v_i, for $i \in \{1, 2, ..., k\}$, is a trainable vector $v_i \in \mathbb{R}^d$ and collectively, the sequence $\langle v_1, v_2, \ldots, v_k \rangle$ forms the soft prompt π. These vectors are initialized randomly and positioned in the lowest embedding layer of the PLMs. The dimensionality of these vectors is denoted by d, which aligns with the dimensionality of the hidden layers in the PLM. The hyperparameter k designates the number of tokens comprising the prompt π, and thus, also the length of the prompt.

The prompt π and the QA model, denoted as f, is also trained using the cross-entropy loss function:

$$\mathcal{L}_{\text{qa}}(D) = \sum_{i=1}^{|D|} -\log p_f(a^{(i)}|c^{(i)}, q^{(i)}, \pi) \qquad (2)$$

Here, $p_f(a^{(i)}|c^{(i)}, q^{(i)}, \pi)$ is the conditional probability that the QA model f, with the aid of the prompt π, assigns to generating the correct answer $a^{(i)}$ given the context $c^{(i)}$ and the question $q^{(i)}$.

4.4 Training Procedure

The training methodology for both the Question Generation model f_{gen} and the Question Answering model f encompasses two phases: initial training within the source domain and subsequent adaptation within the target domain. In the source domain, we begin by training the prompt π while keeping the QA model f static, to capture domain-agnostic knowledge crucial for domain adaptation. Following this, we train f with the now-tuned prompt π remaining fixed. Additionally, f_{gen} is trained to generate pseudo questions for use in the target domain. In the target domain phase, given a specific context, f_{gen} is first employed to produce pseudo questions. These questions are then subjected to LM filtering, as per (Shakeri et al., 2020), to select those with high scores. The process continues with the combination of these contexts and pseudo questions, which are then fed into the QA model f to elicit pseudo answers. LM filtering is again utilized, this time to sieve out answers with low confidence. The resulting (c, q', a') pairs are initially used to fine-tune the prompt π, keeping f static. Subsequently, f, in conjunction with the newly refined π, is used to generate a fresh set of pseudo answers. Post-filtering, the remaining (c, q', a') pairs are directed towards fine-tuning f, while keeping the prompt π fixed. Following this, the identical (c, q) pairs are employed to fine-tune f_{gen}. These steps constitute a training loop, which is iterated multiple times to augment the adaptability and performance of the models in the target domain. The training procedure is delineated in Algorithm 1.

5 Experiment Setup

5.1 Datasets

In accordance with previous studies (Nishida et al., 2019; Yue et al., 2021, 2022), this research utilizes datasets from the MRQA (Fisch et al., 2019). The SQuAD dataset (Rajpurkar et al., 2016) is chosen as the source domain for our experiments. For target domain datasets, only unlabeled samples are accessible. In this paper, we employ HotpotQA (Yang et al., 2018), Natural Questions (NQ) (Kwiatkowski et al., 2019), NewsQA (Trischler et al., 2017), and BioASQ (Tsatsaronis et al., 2015), which are frequently used in the field.

5.2 Implementation Details

We utilize the T5 model developed by Google (Chung et al., 2022) and implement the PASAL framework using the Huggingface Transformers library (Wolf et al., 2020). The batch size is set to 8, with each training epoch spanning 8 iterations. For optimization, the AdamW optimizer (Loshchilov and Hutter, 2017) is employed. We set the learning rate to 1e-3 for the prompt and 5.6e-5 for the model. The self-training loop is executed 5 times. The LM filtering threshold is determined by model selection strategy (Nguyen et al., 2020; Yang et al., 2023a). The default prompt length is established at 100 tokens, and the maximum input sequence length is limited to 412 tokens, with a document stride of 128. Text pieces excluding the answers will be discarded in training. Other hyperparameters follow the default settings provided by the Transformers library.

5.3 Baselines

We compare PASAL with the following baselines.

- **Source Only** This baseline involves training the model on the source domain and evaluating it on target domains without employing any UDA techniques.
- **Pseudo Labeled** This approach fine-tunes the model, initially trained on the source domain, utilizing samples from the target domain that are augmented with pseudo questions generated by an off-the-shelf QG tool (Alberti et al., 2019).
- **AdaMRC** (Wang et al., 2019): This use the domain adversarial neural network (Ganin et al., 2016) to align the feature between the source and target domains.
- **UDARC** (Nishida et al., 2019): This research engages in multitask learning by performing the QA task in the source domain and the LM task in the target domain concurrently.
- **CAQA** (Yue et al., 2021): This research design a contrastive adaptation loss that enhances domain-invariant learning.

6 Results

6.1 Overall Results

Table 1 presents the primary experimental results, underscoring the consistent superiority of the PASAL method over baseline methods across all domains. The PASAL method exhibits an improvement in Exact Match (EM) by at least 6.18% and up to 11.07%, and in F1 score by a minimum of 7.12% and a maximum of 14.99%, when compared to the CAQA baseline. This underpins the robust UDA capabilities of PASAL. Furthermore, a variance

- msf	58.47	73.38	52.68	67.39	51.85	70.98	54.79	67.08	54.45	69.71
- LM filtering	58.52	73.20	52.72	67.50	52.05	70.97	55.05	67.41	54.71	69.53

Table 2: Ablation study results on question-answering performance for domain adaptation from SQuAD to MRQA datasets.

in performance across target domains is observed, with all methods achieving their best results on HotpotQA and their least effective performance on NewsQA. This disparity may be attributed to the varying degrees of domain alignment, with HotpotQA potentially being more akin to the source domain than NewsQA. This specific aspect will receive further examination in Section 6.3. Despite these domain disparities, the PASAL method exhibits more consistent outcomes across all domains. For example, the standard deviation in EM and F1 for CAQA is 3.25 and 3.49, respectively, in contrast to the PASAL method, which demonstrates a substantially lower standard deviation at 1.88 and 1.92. This reaffirms the robustness of PASAL in domain-invariant knowledge retention.

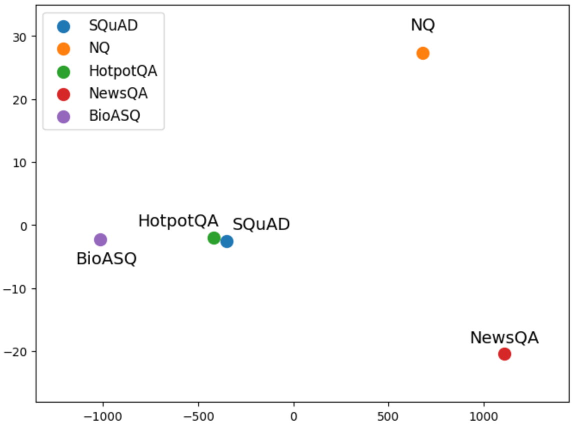

Figure 2: PCA visualization of embedding layer weights for domain specific models.

6.2 Ablation Study

To better understand our proposed framework, we conduct ablation studies to see the effectiveness of each component. The results are shown in Table 2. The notation "- psf" denotes the absence of self-learning of prompts in the target domain, as delineated in Line 10 of Alg. 1. The notation "- prompt" indicates the complete removal of the prompt module, "- msf" signifies the omission of self-learning within both the QA and QG models in the target domain, corresponding to Lines 11 and 12 of Alg. 1, and "- LM filtering" refers to the exclusion of the language model filtering process. Our findings reveal that prompt-tuning is pivotal to the success of PASAL; its removal leads to a notable degradation in performance. The self-learning mechanisms for both the prompt and language models are crucial, as their removal significantly impacts outcomes. The LM filtering process is also vital for maintaining high-quality pseudo samples by filtering out low-quality labels, thereby preventing a detrimental effect on performance.

Token length	SQuAD		HotpotQA		NQ		NewsQA		BioASQ	
	EM	F1	EM	F1	EM	F1	EM	F1	EM	F1
10 tokens	68.50	83.01	54.20	74.02	51.14	66.50	53.83	72.84	56.71	68.81
30 tokens	69.11	84.02	59.45	75.03	56.61	70.54	54.78	73.20	56.99	69.50
50 tokens	69.60	84.07	59.56	75.53	56.76	70.38	54.12	72.03	57.28	69.71
100 tokens	69.38	83.95	60.52	75.97	57.57	71.75	55.36	74.01	58.82	73.21

Table 3: Performance of PASAL with various prompt lengths across different domains.

6.3 Relationships between Domains

Previous studies (Cao et al., 2020; Yue et al., 2021) have engaged in qualitative analyses through manual inspection of question and context structures. However, it is argued that capturing the complex patterns and domain disparities is challenging when simply reviewing examples. In response, the current study leverages machine learning methodologies. The T5 model is trained on individual domains and employ principal component analysis for the visualization of encoder layer weights. These results are illustrated in Fig 2.

The visual evidence from the figure indicates a close similarity between HotpotQA and SQuAD, whereas Natural Questions and NewsQA exhibit substantial domain divergence from SQuAD. This observation corroborates the quantitative outcomes detailed in Table 1, where all methods achieve their best performance on HotpotQA, with NewsQA trailing with the lowest scores. This trend aligns with earlier studies (Cao et al., 2020; Yue et al., 2021) as well as our manual analysis, which highlights the unique textual styles and complex sentence structures of Natural Questions and NewsQA, distinct significantly from those in SQuAD. More analysis can be found in Appendix B.

6.4 Impact of Prompt Length

The adaptability of the PASAL system, when analyzed through the variation in prompt length, reveals a consistent trend: increasing the prompt length tends to correspond with enhanced EM and F1 scores, as indicated in Table 3. It is noteworthy that the performance gains are particularly substantial when the prompt length is expanded from 10 to 30 tokens. Beyond this point, the rate of improvement moderates. Furthermore, this trend is not consistent across different domains, suggesting that domain-specific characteristics significantly affect the efficacy of the prompts. A pronounced improvement is observed for the HotpotQA and NQ datasets with extended prompts, whereas the performance for SQuAD demonstrates a more subdued progression. This disparity suggests that the complexity of questions in HotpotQA and NQ benefits from extended prompts, which are perhaps necessary to encapsulate the requisite knowledge for defining the task.

6.5 Impact of Self-Training Loops

An experimental investigation was undertaken to evaluate the influence of the number of self-training loops on model performance, with the results presented in Figure 3. The analysis reveals a generally positive trend in performance enhancement with an increase in the number of loops, highlighting the efficacy of self-training in improving the accuracy and precision for PASAL. However, performance tends to plateau or even slightly fluctuate in the later stages, indicating potential instability. To mitigate the risk of overfitting, a decision was made to implement early stopping after the fifth loop.

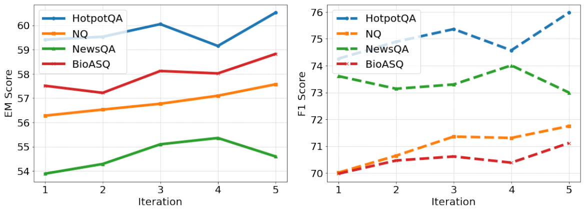

Figure 3: Comparative analysis of performance for PASAL across successive self-training loops.

6.6 Analysis of Prompt Embeddings

To better understand the influence of prompt learning on domain adaptation, we employed t-SNE visualization for the question-context pair embeddings, utilizing methodologies aligned with Wang et al. (2019) and Zhu and Hauff (2022). The analysis was conducted on the embeddings from the PLM that, along with the prompt, trained exclusively on the source domain data. The visualizations, displayed in Figures 4 and 5, reveal distinctive clustering patterns. Without the prompt, embeddings from different domains naturally clus-

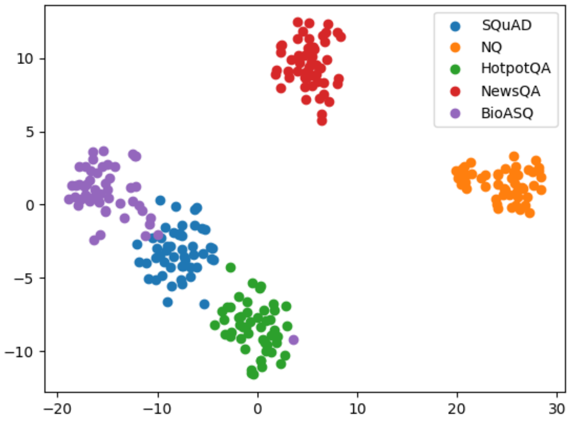

Figure 4: T-SNE visualization of question-context embeddings without prompt

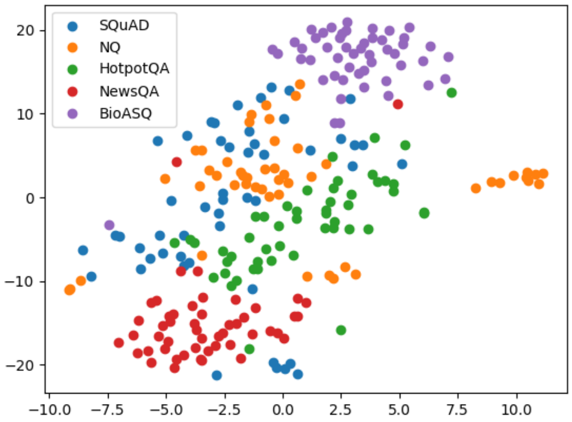

Figure 5: T-SNE visualization of question-context embeddings with prompt

ter into separate groups, as depicted in Figure 4, mirroring the domain relationships we previously noted at Table 1 and Fig. 2. In stark contrast, when question-context pairs are amalgamated with prompts, Figure 5 exhibits a convergence of these previously distinct clusters, clearly demonstrating that prompt learning significantly mitigates domain variances among samples from diverse domains.

HotpotQA	NQ	NewsQA	BioASQ
0.9994	0.9988	0.9945	0.9998

Table 4: Cosine similarity of prompt embeddings for different target domains compared with the source domain.

Additionally, we calculated the cosine similarity between the target domain-adapted prompt embeddings and those from the source domain, as shown in Table 4. Remarkably, these embeddings retain a high degree of similarity, as evidenced by the similarity scores, despite the application of a relatively high learning rate (1e-3). This finding substantiates our earlier assertion about the inherent stability of prompts across different domains. Furthermore, the similarity trends we observed corroborate our previous findings: prompts for HotpotQA and BioASQ are more similar to the source domain than those for NQ and NewsQA. This insight underscores the necessity of further fine-tuning prompts through our self-learning framework for enhanced domain adaptation.

6.7 Diverse Source Domain Analysis

In the pursuit of understanding the impact of source domain diversity on the performance of SFDA in QA systems, we conducted an exhaustive analysis across all domain datasets. As depicted in Table 5, the dataset from SQuAD was distinguished as a notably effective source domain, significantly enhancing performance across all domains under evaluation. This enhancement is likely due to the broad and varied collection of questions in SQuAD, which includes a wide range of topics and question styles. Such diversity provides a solid, versatile foundation for training the model, enabling effective domain adaptation and knowledge transfer.

6.8 Examples of Generated Questions

The percentage of generated questions starting with “what”, “who”, “when”, “where” and “how” are 46.29%, 26.83%, 10.97%, 7.49% and 6.51%, respectively. We provide several examples of generated questions in Table 6. In the given examples, we observe a trend that the generated questions, while syntactically correct, sometimes miss the nuance of the GT questions. For instance, the GT question regarding the Del Mar Fair inquires about a specific historical name change, while the pseudo question focuses on the reinstatement of the San Diego County Fair name, which corresponds accurately to the answer provided. However, in the case of Amir Zaki, the GT question asks specifically about the club Zaki failed to return to, which implies a negative event, while the pseudo question merely asks about the current club, losing the context of the event in question. This suggests that while our question generator is adept at formulating syntactically coherent and contextually appropriate questions, enhancing its sensitivity to the nuances of situational context could further refine its output. Overall, the generator exhibits a commendable level of proficiency in synthesizing questions,

Table 5: Cross-dataset performance evaluation of PASAL.

In 1954, the fair's name was changed to the Southern California Exposition and San Diego County Fair. In 1970, this was shortened to the Southern California Exposition. The fair was again renamed in 1984 to the Del Mar Fair, which lasted until 2002 when the name San Diego County Fair was reinstated. It is sometimes still referred to as the "Del Mar Fair" by locals.
Answer: 2002
GT Question: When did the Del Mar Fair change its name?
Pseudo Question: When was the name San Diego County Fair reinstated?

The surname Keith has several origins. In some cases, it is derived from Keith in East Lothian, Scotland. In other cases, the surname is originated from a nickname, derived from the Middle High German kīt a word meaning "sprout", "offspring".
Answer: a nickname, derived from the Middle High German kīt
GT Question: Where did the last name Keith come from?
Pseudo Question: What is the surname Keith derived from?

LONDON, England (CNN) – After a week when he could not be traced, Egyptian striker Amir Zaki is back at his Premier League club side Wigan Athletic in northern England. ... Wigan and Egypt striker Amir Zaki has mended relations with his club manager. ... Zaki told Al-Hayat TV that the pair "ended up laughing" about his absence – when he failed to return from international duty and had a hamstring strain which no one knew the seriousness of. ... But, it wasn't all laughs a week ago. ... On Wigan's club Web site, Bruce had said of Zaki: "I just feel it's time that we went public on just what a nightmare he has been to deal with. ..."
Answer: Wigan Athletic
GT Question: Which club did Amir Zaki fail to return to?
Pseudo Question: What Premier League club is Amir Zaki back at?

Table 6: Examples of generated questions compared with the ground-truth human-written questions.

but there remains a spectrum of improvement opportunities, particularly in the realm of semantic precision. This insight underscores the potential impact of synthetic data on the fine-tuning process of the answer module, where the fidelity of question-answer pairing is paramount.

7 Conclusion

In this paper, we propose the Prompt-Assisted Self-Adaptive Learning (PASAL) framework, a novel approach to SFDA for QA systems. By combining prompt learning with a self-learning strategy, PASAL enhances adaptability across various domains while upholding data privacy. The empirical results on various benchmark datasets demonstrate the superiority of PASAL over existing methods, particularly in its stability and performance across diverse target domains. The findings underscore the significance of incorporating prompt learning and self-learning strategies in the domain adaptation process, offering new avenues for future research in QA systems.

8 Limitations

While the PASAL framework marks a significant advancement in SFDA for QA, it is not without limitations. One notable constraint is its dependency on the quality of pseudo-questions generated during self-learning. If these questions are not sufficiently diverse or contextually relevant, the adaptation may not fully capture the nuances of the target domain. Furthermore, despite improvements in domain adaptation, the performance of the model still varies across domains, indicating a need for further optimization in handling complex and highly divergent domains like NewsQA. Future research should focus on enhancing the question generation process and exploring more sophisticated methods for addressing diverse domain characteristics. Additionally, the computational demands of the iterative fine-tuning process necessitate consideration of efficiency improvements, especially for large-scale implementations.

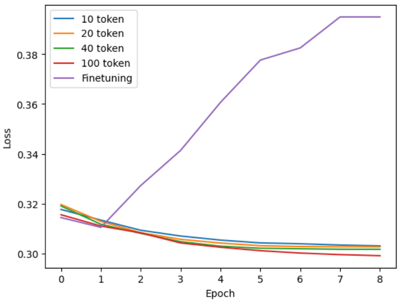

Figure 6: Evaluation losses for fine-tuning and prompt-tuning on SQuAD dataset.

A Comparison of Evaluation Loss

Figure 6 presents a comparison of evaluation losses for fine-tuning versus prompt-tuning on the SQuAD dataset. Throughout the training epochs, fine-tuning shows an initial reduction in loss, which then rises, indicating potential overfitting. Conversely, prompt-tuning demonstrates a steady, downward trend in loss, highlighting its consistent improvement and capacity for better generalization. This contrast reinforces the premise that prompt-tuning can offer superior generalization over fine-tuning in the context of PLM training. This observation aligns with our approach, emphasizing the critical role of domain-agnostic learning facilitated by prompt learning in adapting to new domains. It underscores the potential of prompt-tuning, not merely as a training technique but as a strategic tool to foster adaptability across domain shifts, reaffirming the core tenets of our PASAL framework.

B Examples Across Domains

This section offers a selection of examples from the MRQQ datasets, and undertakes a qualitative analysis of the relationships and distinctive characteristics that define each domain.

B.1 SQuAD

Example 1

Question: To whom did the Virgin Mary allegedly appear in 1858 in Lourdes France?

Context: Architecturally, the school has a Catholic character. Atop the Main Building's gold dome is a golden statue of the Virgin Mary. Immediately in front of the Main Building and facing it, is a copper statue of Christ with arms upraised with the legend "Venite Ad Me Omnes". Next to the Main Building is the Basilica of the Sacred Heart. Immediately

behind the basilica is the Grotto, a Marian place of prayer and reflection. It is a replica of the grotto at Lourdes, France where the Virgin Mary reputedly appeared to Saint Bernadette Soubirous in 1858. At the end of the main drive (and in a direct line that connects through 3 statues and the Gold Dome), is a simple, modern stone statue of Mary.
Answer: Saint Bernadette Soubirous

Example 2

Question: How many BS level degrees are offered in the College of Engineering at Notre Dame?
Context: The College of Engineering was established in 1920, however, early courses in civil and mechanical engineering were a part of the College of Science since the 1870s. Today the college, housed in the Fitzpatrick, Cushing, and Stinson-Remick Halls of Engineering, includes five departments of study – aerospace and mechanical engineering, chemical and biomolecular engineering, civil engineering and geological sciences, computer science and engineering, and electrical engineering – with eight B.S. degrees offered. Additionally, the college offers five-year dual degree programs with the Colleges of Arts and Letters and of Business awarding additional B.A. and Master of Business Administration (MBA) degrees, respectively.
Answer: eight

B.2 HotpotQA

Example 1

Question: Where did the form of music played by Die Rhöner Säuwäntzt originate?
Context: Die Rhöner Säuwäntzt are a Skiffle-Bluesband from Eichenzell-Lütter in Hessen, Germany. The line-up consists of Martin Caba, Christoph Günther and Christoph Leipold playing Skiffle-Blues with lyrics based on Rhön Mountains dialect and other Hessian dialects varieties. The expression "Säuwäntzt" means pork belly and refers also to untidy or unruly children and youth. Skiffle is a music genre with jazz, blues, folk and American folk influences, usually using a combination of manufactured and homemade or improvised instruments. Originating as a term in the United States in the first half of the 20th century, it became popular again in the UK in the 1950s.
Answer: United States

Example 2

Question: Who is the American internet entrepreneur who founded the company featured on 24 Hours on Craigslist?
Context: 24 Hours on Craigslist is a 2005 American feature-length documentary that captures the people and stories behind a single day's posts on the classified ad website Craigslist. The film, made with the approval of Craigslist's founder Craig Newmark, is woven from interviews with the site's users, all of whom opted in to be contacted by the production when they submitted their posts on August 4, 2003.
Answer: Craig Newmark

B.3 Natural Questions

Example 1

Question: Where did they hike in "Just Go With It"?
Context: The film was shot in Los Angeles and the Hawaiian islands of Maui and Kauai between March 2, 2010, and May 25, 2010. The film is deliberately vague about which Hawaiian island its latter portion depicts; thus, the characters hike across a rope bridge on Maui and arrive in the next scene at a spectacular waterfall on Kauai, rather than the ordinary irrigation dam and pond on Maui where the actual trail terminates.
Answer: Maui

Example 2

Question: Who did the motorcycle jump in "The Great Escape"?
Context: James Sherwin "Bud" Ekins (May 11, 1930 – October 6, 2007) was an American professional stuntman in the U.S. film industry. He is considered to be one of the film industry's most accomplished stuntmen with a body of work that includes classic films such as "The Great Escape" and "Bullitt". Ekins, acting as stunt double for Steve McQueen while filming "The Great Escape", was the rider who performed what is considered to be one of the most famous motorcycle stunts ever performed in a movie.
Answer: James Sherwin "Bud" Ekins

B.4 NewsQA

Example 1

Question: Where was Michael Strank born?
Context: WASHINGTON (CNN) – One of the Marines shown in a famous World War II photograph raising the U.S. flag on Iwo Jima was posthumously awarded a certificate of U.S. citizenship on Tuesday. Sgt. Michael Strank, who was born in Czechoslovakia and came to the United States when he was 3, derived U.S. citizenship when his

father was naturalized in 1935. However, U.S. Citizenship and Immigration Services recently discovered that Strank never was given citizenship papers.
Answer: Czechoslovakia
Example 2
Question: How many attacks have been done since July?
Context: BAGHDAD, Iraq (CNN) – Iraqi Security Forces captured 66 people believed to be connected to al Qaeda in Iraq terror cells, the U.S. military said Thursday. One of the suspects is believed to have conducted more than 12 attacks since July.
Answer: 12

B.5 BioASQ

Example 1
Question: What type of enzyme is peroxiredoxin 2 (PRDX2)?
Context: In melanoma, transition to the vertical growth phase is the critical step in conversion to a deadly malignant disease. The antioxidant enzyme peroxiredoxin-2 (Prx2) has a key role in this transition, inversely correlating with the metastatic capacity of human melanoma cells.
Answer: Antioxidant
Example 2
Question: What nerve is involved in carpal tunnel syndrome?
Context: This study aimed to determine the efficacy of median nerve epineurectomy in the surgical management of carpal tunnel syndrome (CTS). The median nerve is commonly implicated in CTS, showing flattening along with hypervascularization.
Answer: Median

B.6 Conlusion

Based on these examples, we can see that SQuAD and HotpotQA share a historical and fact-oriented focus, this is in align with our findings in Figure 2, which shows that HotpotQA is extremly close to the SQuAD dataset. Conversely, BioASQ is steeped in scientific and medical discourse, necessitating advanced technical understanding, which accounts for its notable distinction from SQuAD in the PCA space. Moreover, Natural Questions and NewsQA are characterized by their intricate structures and inferential demands, with Natural Questions covering pragmatic, real-life situations and NewsQA focusing on topical events and granular details. These complexities and the unique textual nuances contribute to their discernible departure from the SQuAD domain. Notably, the comparison between NewsQA and BioASQ underscores that contextual structure and complexity exert a greater impact on domain adaptation than the presence of specialized terminology.

C Justification for Selection of Baselines

The baseline methods were selected to represent the spectrum of UDA strategies pertinent to the QA context. UDARC is included for its fundamental approach using self-supervised learning within transformer models. AdaMRC, utilizing the Domain-Adversarial Neural Network (DANN) framework, offers a robust comparison due to its extensive validation and significant domain adaptation capabilities. CAQA, a recent advancement in UDA for QA, serves as a benchmark against current state-of-the-art methods. This selection provides a comprehensive overview of the application of UDA to QA, from foundational approaches to cutting-edge techniques.

D Details of Model Parameters, Computational Resources, and Infrastructure

The T5 model, used in our research, contains approximately 220 million parameters. These parameters are integral to the architecture of the model, encompassing the transformer encoder and decoder blocks. Each block in the model is composed of layers of self-attention mechanisms and fully connected neural network layers. Adhering to the standard T5 architecture, it features 12 layers each in both the encoder and decoder, a hidden size of 768, and 12 attention heads.

Our experiments were conducted on a server powered by an Intel(R) Xeon(R) Silver 4210R CPU at 2.40GHz with an x86_64 architecture, featuring 40 CPUs across 2 sockets, each with 10 cores and 2 threads per core. The system boasts a substantial memory capacity of 251 GB, with 185 GB available for use, and runs on a Linux kernel version 6.5.6-100.fc37.x86_64. The computational tasks, specifically model training and testing, were accelerated using an NVIDIA RTX A5000 GPU, chosen for its proficiency in handling demanding machine learning applications. The training process on the source domain was completed in approximately 30 hours. Additionally, the self-learning phase for a single target domain was conducted over a span of around 10 hours.

Hierarchical Attention Graph for Scientific Document Summarization in Global and Local Level

Abstract

Scientific document summarization has been a challenging task due to the long structure of the input text. The long input hinders the simultaneous effective modeling of both global high-order relations between sentences and local intra-sentence relations which is the most critical step in extractive summarization. However, existing methods mostly focus on one type of relation, neglecting the simultaneous effective modeling of both relations, which can lead to insufficient learning of semantic representations. In this paper, we propose HAESum, a novel approach utilizing graph neural networks to locally and globally model documents based on their hierarchical discourse structure. First, intra-sentence relations are learned using a local heterogeneous graph. Subsequently, a novel hypergraph self-attention layer is introduced to further enhance the characterization of high-order inter-sentence relations. We validate our approach on two benchmark datasets, and the experimental results demonstrate the effectiveness of HAESum and the importance of considering hierarchical structures in modeling long scientific documents[1].

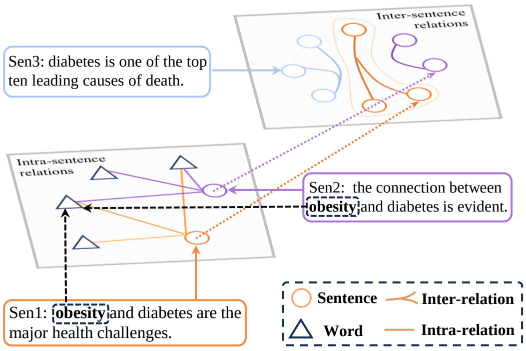

Figure 1: An illustration of modeling an input document from local and global perspectives. Triangles and circles represent words and sentences in the original document respectively.

1 Introduction

Extractive summarization aims to select a set of sentences from the input document that best represents the information of the whole document. With the advancement of pre-trained models and neural networks over the years, researchers have achieved promising results in news summarization (Liu and Lapata, 2019; Zhong et al., 2020). However, when applying these methods to long scientific documents, they encounter challenges due to the relatively lengthy inputs. The considerable length of the text hinders sequential models from capturing both long-range dependencies across sentences and intra-sentence relations simultaneously (Wang et al., 2020).Moreover, the extended context exceeds the input limits of the Transformer-based model (Vaswani et al., 2017) due to the quadratic computational complexity of self-attention.

Recently, the application of large language models (LLM) such as ChatGPT to text summarization tasks has gained significant interest and attracted widespread attention. A recent study by (Zhang et al., 2023b) evaluated the performance of ChatGPT on extractive summarization and further enhanced its performance through in-context learning and chain-of-thought. Another study (Ravaut et al., 2023) conducted experiments on abstractive summarization using various LLMs on a variety of datasets that included long inputs. While the use of LLMs in text summarization tasks has demonstrated exciting potential, there are still several limitations that have not been addressed. The most important of these is the phenomenon of lost-in-the-middle (Liu et al., 2023; Ravaut et al., 2023), where LLMs ignore information in the middle and pay more attention to the context at the beginning and end. This bias raises concerns especially in sum-

marization tasks where important text may be scattered throughout the document (Wu et al., 2023). Additionally, as the input length increases, even on explicitly long-context models, the model's performance gradually declines (Liu et al., 2023).

As a result, researchers have turned to graph neural networks to model long-distance relations. They represent a document as a graph and update node representations in the graph using message passing. These works use different methods to construct a graph from documents, such as using sentence similarity as edge weights to model cross-sentence relations (Zheng and Lapata, 2019). Another popular approach is to construct a word-document heterogeneous graph (Wang et al., 2020), using words as intermediate connecting sentences. Phan et al. (2022) further added passage nodes to the heterogeneous graph to enhance the semantic information. Zhang et al. (2022) proposed a hypergraph transformer to capture high-order cross-sentence relations.

Despite the impressive success of these approaches, we observe that the current work still lacks a comprehensive consideration on relational modeling. More specifically, two limitations are mentioned: (1) Most of the existing approaches focus on modeling intra-sentence relations but often overlook cross-sentence high-order relations. Inter-sentence connections may not only be pairwise but could also involve triplets or higher-order relations (Ding et al., 2020). In the hierarchical discourse structure of scientific documents, sentences within the same section often express the same main idea. It is difficult to fully understand the content of a document by merely considering intra-sentence and cross-sentence relations in pairwise. (2) These approaches rely on updating relations at different levels simultaneously but ignore the hierarchical structure of scientific documents. Sentences are composed of words and, in turn, contribute to forming sections. By understanding the meaning of individual tokens, we get the meaning of the sentence and thus the content of the section. Therefore, bottom-to-top structured modeling is crucial to understand the content of the document.

To address the above challenges, we propose HAESum (**H**ierarchical **A**ttention Graph for **E**xtractive Document **Sum**marization), a method that leverages a graph neural network model to fully explore hierarchical structural information in scientific documents. HAESum first constructs a local heterogeneous graph of word-sentence and updates sentence representations at the intra-sentence level. The local sentence representations are then fed into a novel hypergraph self-attention layer to further update and learn the cross-sentence sentence representations through a self-attention mechanism that fully captures the relations between nodes and edges. Figure 1 is an illustration showing the modeling of local and global context information from a hierarchical point of view, and the resulting representations contain both local and global hierarchical information. We validate HAESum with extensive experiments on two benchmark datasets and the experimental results demonstrate the effectiveness of our proposed method. In particular, we highlight our main contributions as follows:

(i) We introduce a novel graph-based model utilizing the hierarchical structure of scientific documents for modeling. In contrast to simultaneously updating nodes in the graph, we learn intra-sentence and inter-sentence relations separately from both local and global perspectives. To the best of our knowledge, we are the first approach to hierarchical modeling using different graphs on this task.

(ii) We propose a novel hypergraph self-attention layer that utilizes the self-attention mechanism to further aggregate high-order sentence representations. Moreover, our approach does not rely on pre-trained models as encoders, making it easily applicable to other low-resource languages.

(iii) We validate our model on two benchmark datasets, and the experimental results demonstrate the effectiveness of our approach against strong baselines.

2 Related Work

2.1 Scientific Paper Summarization

Scientific document summarization has been a hot topic due to the challenges of modeling long texts (Fremann and Klementiev, 2019). Cohan et al. (2018) introduced two benchmark datasets for long documents, Arxiv and PubMed, and employed a hierarchical encoder and discourse-aware decoder for the document summarization task. Cui and Hu (2021) proposed a sliding selector network accompanied by dynamic memory to alleviate information loss between context segments. Gu et al. (2021) presented a reinforcement learning-based method that achieved impressive performance by considering the extraction history at each time step. Recently, Ruan et al. (2022) proposed a method to inject explicit hierarchical structural information

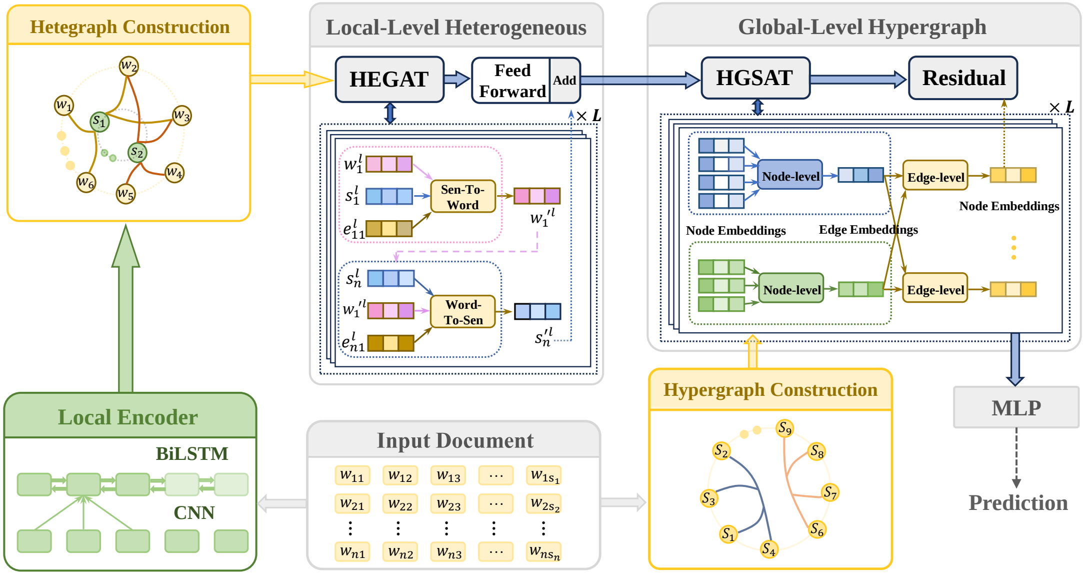

Figure 2: Overview of the proposed HAESum framework. We first build a local-level heterogeneous graph (HEGAT) for the input document and apply message passing to iteratively update the representation in two stages: sentence-to-word and word-to-sentence. The obtained sentence representations are then fed into the hypergraph self-attention layer (HGSAT) to obtain the global representations and used for the final sentence selection.

such as section titles and sentence positions into a pre-trained model to further improve the performance and interpretability.

2.2 Graph based Summarization

Graph neural networks have been widely used for extractive summarization due to their flexibility and scalability. Dong et al. (2020) proposed an unsupervised graph-based model that combines both sentence similarity and hierarchical discourse structure to rank sentences. Cui et al. (2020) injected latent topic information into graph neural networks to further improve performance. Wang et al. (2020) constructed a word-document heterogeneous graph using word nodes as intermediate to connect sentences. Zhang et al. (2022) proposed a hypergraph transformer to model long-distance dependency while emphasizing the importance of high-order inter-sentence relations in extraction summarization. Our paper follows this line of work, but the main difference is that our approach combines both intra-sentence relations and high-order cross-sentence relations and efficiently leverages the hierarchical discourse structure of scientific documents to learn sentence representations that incorporate both local and global information.

3 Method

Given an arbitrary document $D = \{s_1, s_2, ..., s_n\}$ consisting of n sentences, each sentence consists of m words $s_i = \{w_{i1}, w_{i2}, ..., w_{im}\}$. The goal of extractive summarization is to predict labels $y_i \in \{0, 1\}$ for all sentences, where $y_i = 1$ indicates that the current sentence should be included in the summary. The overall structure of HAESum is shown in Figure 2.

3.1 Local-level Heterogeneous Graph

As the lowest level of the hierarchical structure, in this section, we will first introduce how to capture local intra-sentence relations between sentences and their corresponding words using a heterogeneous graph. We will start by explaining how to construct the heterogeneous graph and initialize it, followed by detailing how to use a heterogeneous self-attention layer to update node representations. Finally, we will feed the updated sentence node representations into the next module.

3.1.1 Graph Construction

Given an input document D, we first construct a heterogeneous graph $G = \{V, E\}$, where V represents a set of nodes and E represents edges between nodes. In order to utilize the natural hierarchy between words and sentences of a document, the nodes can be defined as $V = V_w \cup V_s$, where $V_w = \{w_1, w_2..., w_n\}$ denotes n different words in the document, and $V_s = \{s_1, s_2, ..., s_m\}$ denotes the m sentences in the document. The edges are defined as $E = \{e_{11}, e_{12}, ..., e_{mn}\}$, where e_{ij} is a real-valued edge weight that denotes the cross-connection between a sentence node i and a word node j contained by it.

3.1.2 Graph Initializers

Let $X_w \in R^{|V_w| \times d_w}$, $X_s \in R^{|V_s| \times d_s}$ denote the feature matrices of the input word and sentence respectively. d_w and d_s correspond to the feature dimensions of words and sentences, respectively. We first use Glove (Pennington et al., 2014) to initialize word representations. Instead of using pre-trained model as a sentence encoder, we first use CNN (LeCun et al., 1998) with different kernel sizes to get the n-gram feature S^C of the sentence followed by using BiLSTM (Hochreiter and Schmidhuber, 1997) to obtain the sentence-level feature S^B.The features obtained from CNN and BiLSTM are concatenated as initialized sentence representations $X_S = \text{Cat}(S^C, S^B)$.

3.1.3 Heterogeneous Attention Modules

Following the previous work (Wang et al., 2020), we employ the heterogeneous graph attention layer for node representations updating. Specifically, when a node v_i aggregates information from its neighbours, the attention coefficient α_{ij} for node v_j is computed as follows:

$$z_{ij} = \text{LeakyReLU}(W_a[W_s h_i \| W_k h_j]; e_{ij}) \quad (1)$$

$$\alpha_{ij} = \frac{\exp(z_{ij})}{\sum_{l \in \mathcal{N}} \exp(z_{il})} \quad (2)$$

where W_a, W_s, W_k are trainable weights. $\|$ denotes concatenation. We also inject the edge features e_{ij} into the attention mechanism for computation.

We also add multi-head attention and Feed-Forward layer (FFN) (Vaswani et al., 2017) to further improve the performance. The final representation $u_i^{'}$ of node v_i is then obtained as follows:

$$u_i = \|_{k=1}^{K} \sigma(\sum_{j \in \mathcal{N}} \alpha_{ij}^k W^k h_i) \quad (3)$$

$$u_l^{'} = \text{FFN}(u_i) + h_i \quad (4)$$

We begin by aggregating the sentence nodes around the word to update word representations. Subsequently, we utilize the updated word representations to further update the sentence representations.

In this section, we use the local heterogeneous graph to learn the intra-sentence relations at the lowest level of the document hierarchy.

3.2 Global-level Hypergraph

In this section, we first introduce how to construct a hypergraph. Subsequently, we present a novel hypergraph self-attention layer designed to fully capture high-order global inter-sentence relations. Finally, the resulting sentence representations are used to decide whether to include them in the summary.

3.2.1 Hypergraph Construction

A hypergraph is defined as $G = \{V, E\}$, where $V = \{v_1, v_2, ..., v_n\}$ represents a set of nodes and $E = \{e_1, e_2..., e_n\}$ represents hyperedges in the graph. Unlike edges in regular graphs, hyperedges can connect two or more nodes and thus represent multivariate relations. A hypergraph is typically represented by its incidence matrix $\mathbf{H} \in R^{n \times m}$:

$$\mathbf{H}_{ij} = \begin{cases} 1, \text{if } v_i \in e_j \\ 0, \text{if } v_i \notin e_j \end{cases} \quad (5)$$

where $v_i \in V$, $e_j \in E$ and if the hyperedge e_j connects node v_i there is $v_i \in e_j$.

We denote a sentence s_i in a document $D = \{s_1, s_2, ..., s_n\}$ as a node v_i in the hypergraph. In order to capture global higher-order inter-sentence relations, we consider creating section hyperedges for each part (Suppe, 1998). A hyperedge e_j will be created if a set of child nodes $V_j \in V$ belongs to the same section in the document. The node representations in the hypergraph are initialized to the output of the previous module.

The initialized node features $H_{sen} = \{h_1, h_2, ..., h_n\} \in R^{n \times d}$ and incidence matrix H will be fed into the hypergraph self-attention network to learn effective sentence representations.

3.2.2 Hypergraph Self-Attention Modules

Hypergraph attention networks (HGAT) are designed to learn node representations using a mutual attention mechanism. This mutual attention mechanism divides the computational process into two steps, i.e., node aggregation and hyperedge aggregation. First the hyperedge representations are updated with node information. Subsequently, the hyperedge information is fused back to the nodes from hyperedges.

The HGAT has mainly been implemented based on graph attention mechanism (Veličković et al., 2017), such as HyperGAT (Ding et al., 2020). However, this attention mechanism employs the same weight matrix for different types of nodes and hyperedges information and could not fully exploit the relations between nodes and hyperedges, which prevents the model from capturing higher-order cross-sentence relations (Fan et al., 2021).

To address the limitations of HGAT, we propose the hypergraph self-attention layer. Inspired by the success of Transformer (Vaswani et al., 2017) in textual representation and graph learning (Ying et al., 2021), we use the self-attention mechanism to fully explore the relations between nodes and hyperedges. The entire structure we propose is described below.

Node-level Attention To solve the problem of initializing the hyperedge features, we first encode hyperedge representations from node aggregation information using node-level attention. Given node features $H_{sen}^{l-1} = \{h_1^{l-1}, h_2^{l-1}, ..., h_n^{l-1}\}$ and incidence matrix, hyperedge representations $\{f_1^l, f_2^l ..., f_m^l\}$ can be computed as follows:

$$f_j^l = \text{LeakyReLU}(\sum_{s_k \in e_j} \alpha_{jk} W_n h_k^{l-1}) \quad (6)$$

$$\alpha_{jk} = \frac{\exp(W_h^{\mathrm{T}} u_k)}{\sum_{s_l \in e_j} \exp(W_h^{\mathrm{T}} u_l)} \quad (7)$$

$$u_k = \text{LeakyReLU}(W_p h_k^{l-1}) \quad (8)$$

where the superscript l denotes the model layer. W_n, W_h, W_p are trainable parameters. α_{jk} is the attention coefficient of node s_k in the hyperedge e_j. Through the node-level attention mechanism, we initialize the hyperedge representation.

Edge-level Attention As an inverse procedure, the self-attention mechanism is applied to compute the importance scores to highlight the hyperedges that are more critical for the next layer of node representation v_i. Given the node feature matrix H_{sen}^{l-1} and the hyperedge feature matrix F_{edge}^l, similar to the self-attention mechanism we compute the output matrix as follows:

$$\begin{aligned} Q_{sen}^{l-1} &= W_q H_{sen}^{l-1} \\ K_{edge}^l &= W_k F_{edge}^l \\ V_{edge}^l &= W_v F_{edge}^l \end{aligned} \quad (9)$$

$$\text{Att}(H, F) = \text{softmax}(\frac{Q_{sen}^{l-1} {K_{edge}^l}^{\mathrm{T}}}{\sqrt{d_k}}) V_{edge}^l \quad (10)$$

where W_q,W_k,W_v are trainable parameters. d_k is the feature dimension of the hidden layer. Att() represents the self-attention mechanism.

After obtaining the enhanced node representations H_{sen}^l using the hypergraph self-attention layer, we applied a feature fusion layer to generate the final representations $H_{sen}^{'l}$, which can be represented by the formula:

$$H_{sen}^{'l} = \text{LeakyReLU}(W_1 H_{sen}^{l-1} \| W_2 H_{sen}^l) \quad (11)$$

$\|$ denotes concatenation. Fusing hyperedge information and node information, we obtain a semantic representation of sentence nodes.

3.3 Opimization

After passing L hypergraph self-attention layers, we obtain the representations of sentences $H_{sen} = \{h_1, h_2, ..., h_n\} \in R^{n \times d}$. We then add a multilayer perceptron (MLP) followed by a LayerNorm layer and obtain a score $\hat{y}_i$, indicating whether it will be selected as a summary. Formally, the prediction score for a sentence node s_i is computed as follows:

$$\hat{y}_i = W_o(\text{LayerNorm}(W_p h_i)) \quad (12)$$

where W_o,W_p are trainable parameters.

Finally, the output sentence scores $\hat{y}_i$ are optimized with the true labels y_i by binary cross-entropy loss:

$$L = \frac{1}{N} \sum_{i=1}^{N} y_i \log\hat{y}_i + (1 - y_i)\log(1 - \hat{y}_i) \quad (13)$$

where N denotes the number of sentences in the document.

4 Experiment

4.1 Experiment setup

We validate our proposed model on two scientific document datasets and compare it to the strong baselines. In the following, we start with the details of the datasets.

Datasets We perform extensive experiments on two benchmark datasets: Arxiv and PubMed (Cohan et al., 2018). Arxiv is a long document dataset containing different scientific domains. PubMed contains articles in the biomedical domain. We use the original train, validation, and testing splits as in

(Cohan et al., 2018). Detailed statistics for the two benchmark datasets are shown in Table 1.

Compared Baselines We make a systematic comparison with recent approaches in this area. We categorize these methods into the following four types:

- Unsupervised methods: graph-based models PacSum (Zheng and Lapata, 2019), HIPORANK (Dong et al., 2020), FAR (Liang et al., 2021).
- Neural extractive model: Seq2Seq-based models HiStruct+ (Ruan et al., 2022); local and global context model ExtSum-LG (Xiao and Carenini, 2019); graph-based models Topic-GraphSum (Cui et al., 2020), SSN-DM (Cui and Hu, 2021), HEGEL (Zhang et al., 2022), MTGNN (Doan et al., 2022), CHANGES (Zhang et al., 2023a).
- Neural abstractive model: encoder-decoder based Model TLM-I+E (Pilault et al., 2020), PEGASUS (Zhang et al., 2020) , BigBird (Zaheer et al., 2020), divide-and-conquer approach Dancer (Gidiotis and Tsoumakas, 2020).
- Large language model: ChatGLM3-6k-32k (Zeng et al., 2022). More details on the evaluation of the large language model can be found in Appendix A.1.

4.2 Implementation Details

Regarding the encoding of word nodes, the vocabulary size is 50000 and the word embedding is initialized with a dimension of 300 using the Glove pretrained model(Pennington et al., 2014). The feature dimensions of sentence nodes and edges in the heterogeneous graph are set to 64 and 50, respectively. The hyperedge feature dimension is 64. We set the maximum sentence length of each document to 200 and the maximum number of words per sentence to 100. In our experiments, we stacked two layers of heterogeneous graph attention modules (HEGAT) and hypergraph self-attention modules (HSAGT). The multi-head of the HEGAT layer is set to 8 and 6, respectively.

The model is optimized using the Adam optimizer (Loshchilov and Hutter, 2017) with a learning rate of 0.0001 and a dropout rate of 0.1. We train the model on an RTX A6000 GPU with 48GB of memory for 12 epochs. The training process stops if the validation set loss does not decrease three times. The training time for one epoch on the PubMed dataset is 3 hours, while on the Arxiv dataset, it is 6 hours.

We use a greedy search algorithm similar to (Nallapati et al., 2017) to select sentences from documents as the gold extractive summaries (Oracle). Following previous work, we use ROUGE (Lin and Hovy, 2003) to evaluate the quality of summaries.

4.3 Experiment Results

Table 2 shows the comparison between our model HAESum and the baseline model on PubMed and Arxiv datasets. The first block covers the ground truth ORACLE and unsupervised methods for extractive summarization. The second block covers state-of-the-art supervised extractive baselines. The third block reports abstractive methods.

Based on the results, we find that HIPORANK (Dong et al., 2020) achieves strong performance on graph-based unsupervised modeling. Compared to other unsupervised methods, HIPORANK adds section information, which demonstrates the effectiveness and importance of taking the natural hierarchical structure of scientific documents into account when modeling cross-sentence relations.

In the extractive baseline, MTGNN (Doan et al., 2022) achieves state-of-art performance, MTGNN considers more intra-sentence level modeling, which shows the necessity of modeling from low-level structure. HEGEL (Zhang et al., 2022) is the most similar approach to ours. HEGEL injects external information such as keywords and topics into the model and models higher-order cross-sentence relations through a hypergraph transformer to achieve a competitive performance. However, compared to MTGNN, HEGEL does not consider low-level intra-sentence relations, which proves the necessity of considering and modeling hierarchical structure. Interestingly, CHANGES (Zhang et al., 2023a) achieves equally impressive results in hierarchical modeling by considering high-level intra-section and inter-section relations, further confirming the importance of hierarchical modeling. Among the extractive methods, the transformer-based HiStruct+ (Ruan et al., 2022) shows a competitive performance, which demonstrates the effectiveness of the self-attention mechanism. HiStruct+ also incorporates the inherent hierarchical structure into the pre-trained language models to achieve strong performance. In addition, the extractive approaches largely outperform the abstractive approaches, which may be due to the fact that long input is more challenging for the decoding process of the abstractive models.

Method	ROUGE-1	ROUGE-2	ROUGE-L
Hierarchical(Ours)	**48.77**	**22.44**	**43.83**
Parallelization	48.36	22.03	43.36

Table 4: Different ways of updating sentence representations on PubMed dataset.

Through the table, the results of using the large language model are not satisfactory compared to our proposed method. By analyzing the output of the large language model, the model sometimes incorrectly outputs content from other languages and also occasionally outputs duplicate content. In addition, the model sometimes misinterprets extractive summarization as abstractive summarization.

According to the experimental results, our model HAESum outperforms all extractive and abstractive strong baselines. In particular, our model neither requires injection of external knowledge (e.g., topics and keywords (Zhang et al., 2022)) to enhance global information nor pre-trained model's (e.g., BERT (Devlin et al., 2018)) knowledge (Doan et al., 2022). The outstanding performance of HAESum demonstrates the importance of hierarchical modeling of local intra-sentence relations and global inter-sentence relations.

5 Analysis

5.1 Ablation Study

We first analyze the effect of different components of HAESum in Table 3. The second row shows that removing the heterogeneous graph part represents not learning intra-sentence relations. The third row removes the hypergraph component, representing the absence of learning higher-order cross-sentence relations. As shown in table 3, removing either part hurts the model performance, which indicates that learning both local intra-sentence relations and global higher-order cross-sentence relations is necessary for scientific document summarization.

Interestingly, these two components are almost equally important for modeling long documents. This indicates the importance of simultaneously

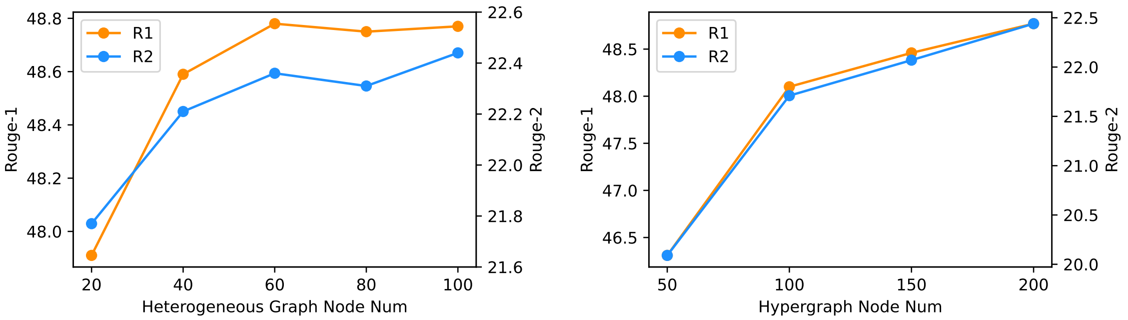

Figure 3: ROUGE-1,2 performance of HAESum with different number of graph nodes on PubMed dataset.

modeling semantic aspects from diverse perspectives and hierarchical discourse structures in scientific documents.

5.2 Performance Analysis

Hierarchical discourse We also analyze different update approaches for obtaining the final sentence representations in HAESum. As shown in Table 4, the second row represents our hierarchical updating. The third row represents parallel updating, where intra-sentence and inter-sentence relations are updated simultaneously, and the final sentence representations are concatenated. The superior performance of hierarchical updating over parallel updating once again emphasizes the critical importance of the bottom-to-top modeling sequence we propose for understanding the content of long documents.

Attention mechanism We then analyze the performance of our proposed novel hypergraph self-attention layer and hypergraph attention network (HGAT). As shown in Table 5, our hypergraph self-attention layer outperforms HGAT (Ding et al., 2020). We speculate that the main reason is the utilization of the self-attention mechanism and different weight matrices, which fully exploit relations between nodes and edges, thereby enhancing the learning of high-order relations.

Hyperparameter sensitivity In our experiments, we set the maximum input length for each sentence to be 100, and the maximum sentence length for each input document to be 200. We conduct an analysis of these two hyperparameters. In addition, more information about the distribution of the sentence lengths and the number of sentences in the document is presented in the Appendix A.3. As shown in Figure 3, when the maximum number of tokens in each sentence is reduced from 100 to 60, the performance does not significantly decrease. This indicates that under this range of hyperparameter settings, the model has already processed most of the tokens in each sentence. However, as the length continues to decrease, the model's performance starts to decline, as the input length limits the capture of local intra-sentence relations.

Simultaneously, when the maximum number of sentences in a document is increased from 50 to 200, the model's performance continues to improve. This improvement is attributed to the consideration of more sentences, capturing more complex higher-order cross-sentence relations. However, persistently increasing this hyperparameter leads to significant computational consumption. Specifically, in future work, we intend to increase the maximum input sentences per document while minimizing computational consumption as much as possible.

5.3 Case Study

Here we provide an example of a summary output by HAESum, as shown in Table 6. The selected sentences are mainly from the same section and cover the entire document. This illustrates that HAESum can effectively learn both local intra-sentence and high-order inter-sentence relations, facilitating the selection of the most relevant sentences.

(Introduction) It includes hidradenitis suppurativa acne conglobata dissecting cellulitis of the scalp and pilonidal sinus.
(Introduction) Though each of these conditions are commonly encountered on their own as a symptom complex follicular occlusion tetrad has rarely been reported in the literature here.
(Introduction) We present a case of hidradenitis suppurativa in a 36-year-old male patient who also had the above mentioned associations.
(Case Report) A 36-year-old male patient presented to us with a history of recurrent boils since 18 years.
(Discussion) Follicular occlusion tetrad is a condition that includes hidradenitis suppurativa (hs) acne conglobata dissecting cellulitis of the scalp and pilonidal sinus.

Table 6: An example output summary of our proposed model.

6 Conclusion

This paper presents HAESum for scientific document summarization. HAESum employs a graph-based model to comprehensively learn local intra-sentence and high-order inter-sentence relations, utilizing the hierarchical discourse structure of scientific documents for modeling. The impressive performance of HAESum demonstrates the importance of simultaneously considering multiple perspectives of semantics and hierarchical structural information in modeling scientific documents.

Limitations

Despite the outstanding performance of our HAESum, several limitations are acknowledged. Firstly, HAESum solely leverages intra-sentence and inter-sentence relations in scientific documents. We believe that incorporating other hierarchical discourse structures at different granularities, such as sentence-section information (Zhang et al., 2023a) or dependency parsing trees, could further enhance model performance. Secondly, although the context window sizes of large language models satisfy the input length of scientific documents, their performance on text summarization tasks, especially on long input texts, remains to be improved due to the loss-in-the-middle (Liu et al., 2023; Ravaut et al., 2023) problem. We consider this issue as a future work. Additionally, we focused on single document summarization. We believe that incorporating domain knowledge through citation networks and similar methods could further improve performance.

A Appendix

In this section, we give more details about the experiment.

A.1 Evaluation on LLMs

We tested different prompts and chose the best prompt. The **prompt** we used is: You are given a long scientific literature. Please read and choose no more than five sentences from the original scientific literature as a summary. Scientific literature:[*Text Document*]. Now, select no more than five sentences from the original given scientific literature as a summary. Summary:[*Output*].

The experimental results are shown in Table 7, where we considered a variety of possible large language models. However, in order to fulfill the requirement of inputting long texts, we chose ChatGLM3-6B-32K (Zeng et al., 2022) to evaluate the performance results on two datasets.

Through the table, the results of using the large language model are not satisfactory compared to our proposed method. By analyzing the output of the large language model, the model sometimes incorrectly outputs content from other languages and also occasionally outputs duplicate content. In addition, the model sometimes misinterprets extractive summarization as abstractive summarization. The most serious problem is that the model still pays too much attention to the context **at the beginning and end**. Our approach takes into account both intra-sentence and inter-sentence relationships, and effectively extracts key sentences distributed throughout the context and uses them as summaries. In addition, our model satisfies the input length constraints and saves computational resources.

A.2 Human Evaluation

We conduct human evaluation following the previous work (Luo et al., 2019). We randomly sample 50 documents from the test sets of PubMed and Arxiv and ask three volunteers to evaluate the summaries extracted by HAESum, MTGNN, and LLM. For each document-summary pair, they are asked to rank them on three aspects: overall quality, coverage and non-redundancy. Notably the best one will be marked rank 1 and so on, and if both models extracted the same summaries they will both be ranked the same. We report the average results over the two datasets in Table 8

As seen through the table, our method achieves better results compared to other baselines. The human evaluation also further validates the effectiveness of our proposed method.

A.3 Distribution of Sentence Length and Number of Tokens in the Dataset

In order to better demonstrate the validity of our choice of hyperparameters, we counted the distribution of sentence lengths in PubMed dataset as well as the distribution of the number of sentences. The experimental results are shown in Table 9

The obtained table shows that the hyperparameters we chose cover almost all the range of the distribution. This is further evidence that the choice of hyperparameters in the *Hyperparameter sensitivity* section is adequate and effective.

Abstract

Linguistic entrainment, or alignment, represents a phenomenon where linguistic patterns employed by conversational participants converge to one another. While entrainment has been shown to produce a more natural user experience, most dialogue systems do not have any provisions for it. In this work, we introduce methods for achieving dialogue entrainment in a GPT-2-based end-to-end task-oriented dialogue system through the utilization of shared vocabulary. We experiment with training instance weighting, entrainment-specific loss, and additional conditioning to generate responses that align with the user. We demonstrate that all three approaches produce substantially better entrainment than the base, non-entrainment-optimized model, as confirmed by both automated and manual evaluation metrics.

1 Introduction

During a natural dialogue, speakers adapt (entrain, align) to the way of speaking of their conversational partners, thereby establishing a shared understanding. This was shown to correlate with dialogue success (Nenkova et al., 2008) and it occurs at multiple linguistic levels: speakers synchronize their speech rate and phonetic patterns (Ostrand and Chodroff, 2021), adopt shared lexical terms (Brennan, 1996; Friedberg et al., 2012) and employ similar syntactic constructions (Reitter et al., 2006). Consequently, to facilitate successful and natural conversations, achieving entrainment is desirable in task-oriented dialogue systems (DSs), where the aim is to assist users in accomplishing tasks such as reserving tickets or venues. In DSs, entrainment can be useful for aligning on common lexical terms, increasing dialogue naturalness and possibly leading to higher efficiency. For instance, consider the two examples in Figure 1 – using "reservation" vs. "booking" or "depart" vs. "leave". However, few prior works attempted at entrainment in DSs, mostly with rule-based or modular DSs only (Lopes et al., 2013, 2015; Hu et al., 2014; Dušek and Jurčíček, 2016).

"reservation" vs. "booking" (SNG076)

Input: Yes. I'll need a reservation for 3 nights starting Sunday. There are 3 people in my party.

Dataset: I have made reservations for 3 starting on Sunday for 3 nights.

Baseline: I'm sorry, but the booking was unsuccessful. Would you like to try another hotel?

Ours: Yes, your reservation is all set for 3 nights starting Sunday. Your reference number is 00000032. Do you need anything else?

"depart" vs. "leave" (SNG0256)

Input: Hi, I'm looking to catch a train to Norwich. Are there any that depart at or around 17:00?

Dataset: There are departures most days from Cambridge at 17:36. Would you like any more information of train times or help booking a train?

Baseline: Yes, there are 49 trains that leave Norwich on that day. What day would you like to travel?

Ours: I have a train departing Cambridge at 17:36 and arriving Norwich at 18:55. Would you like to book this train?

Figure 1: Examples of linguistic entrainment in task-oriented dialogues from the MultiWOZ 2.1 dataset (dialogue IDs shown in brackets). While the responses in the dataset reuse the same words, a base model (Base-CE) produces a non-matching expression, hampering dialogue fluency. Our approach (LK-CE(0)) keeps the appropriate reuse. See Section 4 for model details.

Recent years have seen significant advancements in task-oriented DSs through end-to-end neural models, fully trainable from data (Wen et al., 2017; Bordes et al., 2016; Lei et al., 2018). Use of pre-trained language models (LMs) yielded more fluent responses while simultaneously ensuring the comprehension of user intents and achieving successful dialogues (Lee, 2021; Yang et al., 2021; He et al., 2022). However, the generated responses often suffer from low diversity compared to human-human dialogues (Nekvinda and Dušek, 2021), and the DSs lack any dedicated support or mechanisms for entrainment, as their training relies on cross-entropy or other objectives that focus on dialogue content rather than phrasing.

Using the GPT-2-based two-stage system

Findings of the Association for Computational Linguistics: NAACL 2024, pages 727–735
June 16-21, 2024 ©2024 Association for Computational Linguistics

AuGPT (Kulhánek et al., 2021) as our task-oriented end-to-end baseline DS, we propose the following three approaches to improve entrainment:

- a data-centric approach assigning higher weight to high-entrainment training instances via two straightforward weighting functions,
- an additional loss function to boost the probability of user tokens in generated responses,
- additional keyword-based generation conditioning to increase lexical entrainment.

We show that all our proposed approaches increase entrainment while minimally affecting other dialogue metrics; instance weighting and keyword conditioning also show improved human rankings. Our experimental code is released on GitHub.[1]

2 Related Works

Linguistic entrainment has been studied for decades (Garrod and Anderson, 1987; Brennan and Clark, 1996). In DSs, Reitter et al. (2006) modeled syntactic entrainment, while Nenkova et al. (2008) showed the correlation of high-frequency word entrainment with dialogue naturalness and success. Lopes et al. (2013) and (Hu et al., 2014) used rules to entrain lexical or syntactic choices of a spoken DS to the user; Lopes et al. (2015) used a statistical model based on handcrafted features. Work in statistical entrainment methods is limited; the only work known to us by Dušek and Jurčíček (2016) modified an LSTM-based response generator to adapt to the user's lexical choices.

State-of-the-art in task-oriented DSs is dominated by end-to-end systems based on pretrained neural LMs (Peng et al., 2021), which generate the belief state and the final response in sequence (Lei et al., 2018, cf. Section 3). Extensions involve using belief state differences (Lin et al., 2020), explicit system actions (Hosseini-Asl et al., 2020; Yang et al., 2021), contrastive classifiers (Peng et al., 2021) or data augmentation (Kulhánek et al., 2021). While a few techniques improve output diversity (Nekvinda and Dušek, 2021), none of them targets entrainment. Despite their recent popularity, prompted large LMs still underperform compared to finetuned LMs (Hudeček and Dusek, 2023).

3 Proposed Approaches

As our baseline model, we choose AuGPT (Kulhánek et al., 2021), a GPT-2 (Radford et al., 2019) based task-oriented end-to-end DS, which models dialogue as a sequence-to-sequence task. Same as other contemporary end-to-end systems, AuGPT works in two steps: (1) *generating belief state* (user-preferred slot values) from dialogue history and user input, and (2) *generating response* based on dialogue history, user input, generated belief state and database results (which are based on the belief state). We modify the response generation step.

Our modifications address primarily lexical entrainment and involve instance weighting (Section 3.1), an additional loss based on user input tokens (Section 3.2), and further conditioning on user keyword tokens on model input (Section 3.3).

3.1 Instance Weighting (IW)

We prioritize ground truth responses with greater overlap between the system and the user (i.e. higher entrainment) during training, by assigning them a higher weight. We use a simple 1-gram precision to quantify the lexical user-system overlap.

We explore two weight functions: (1) A discrete one with a simple threshold τ to distinguish high-entrainment training instances:

$$W_1(p) = 1 \text{ if } p \leq \tau, 10 \text{ otherwise}$$

(2) A continuous function modifying sigmoid:

$$W_2(p) = \frac{10}{1 + \exp(w \cdot (\beta - p))} + \epsilon$$

Here, w denotes a scaling factor (spread) and β is the average entrainment for the training data, centering the distribution. We add a small ϵ to avoid zero weight in instances with no entrainment.

3.2 User Likelihood Loss (ULL)

To increase lexical entrainment, we introduce a user-likelihood loss to increase the probability of reusing user tokens in the system output.

For a set of user tokens $U = \{u_1, u_2, \dots, u_n\}$, we increase their likelihood by minimizing the loss:

$$L_t(p(.|x_{<t}), U) = -\alpha \cdot \log \big(\sum_{u \in U} p(u|x_t)\big)$$

Decreasing L_t means an increase in the probability $p(u|x_t)$. We add L_t to the base loss (Section 4.3) and use α to control the weight of user tokens.

---

[1] https://github.com/knalin55/LEEETs-Dial

3.3 Conditioning on Lexical Keywords (LK)

To enforce the reuse of user tokens, we introduce an additional section at the end of the AuGPT input sequence (i.e., after database results), called “keywords”. During training, we include all overlapping tokens as keywords, so the model learns to incorporate them in its outputs.

During inference, we determine the keywords to be reused from the input user tokens using self-attention scores from the last encoder layer. We first calculate the mean across all attention heads. For each $u_i \in U = \{u_1, u_2, \ldots, u_n\}$, we compute the score $S(u_i) = \sum_{j,j \neq i} M_{ji}$, where M is the mean of last layer’s attention heads. We then include as keywords all tokens u_i with scores $S(u_i) \geq t \cdot S_{max}$, where $S_{max} = max(S(u)|u \in U)$, with the threshold $t < 1$.

To smoothly expose the keywords to the model, we use a blending parameter σ (Roller et al., 2021; Nekvinda and Dušek, 2022), i.e., with the probability σ, we pass attention-scores-based keywords (as discussed in the previous paragraph) instead of overlapping tokens from the training instance.

4 Experiments

4.1 Data & Training Setup

For our experiments, we choose the MultiWOZ 2.1 dataset (Budzianowski et al., 2018; Eric et al., 2020), one of the most prominent task-oriented benchmarks with 10k dialogues spanning over 7 domains. As the dataset was created by online human-human dialogues, it does include naturally occurring entrainment and is thus suitable for the experiments, which we confirmed by an initial manual inspection and by computing entrainment metrics (cf. Section 4.4 and Table 1).[2]

We train all models for 10 epochs and keep the best checkpoint using the average of two token-level accuracies: accuracy against the ground-truth response (response contents) and against the user input (entrainment). We report test set scores averaged over 5 runs with different random seeds.

4.2 Baselines

Base We use Kulhánek et al. (2021)’s AuGPT as our base model. We start from the publicly available checkpoint pretrained on Taskmaster (Byrne et al., 2019) and Schema-guided Dialogue (Rastogi et al., 2020).[3] We then experiment with the choice of loss functions: In addition to the base cross-entropy loss (CE), we also consider the unlikelihood loss (Welleck et al., 2020) (CE+Unl).

D&J16 As an additional baseline, we use AuGPT with our own reimplementation of the decoding approach originally used by Dušek and Jurčíček (2016) in an LSTM-based context, which generates multiple outputs via beam search and then reranks them based on 1- and 2-gram match with the context. We use beam size 15.

GPT-4 For comparison with an LLM-based approach, we also include results for prompting GPT-4 (details are given in Appendix A). To limit experiment cost, we only use a sample of 200 instances from the test set.

4.3 Our Model Variants

$\mathbf{IW_i}$-loss We experiment with both functions defined in Section 3.1. Given that the dataset exhibits an 18.1% lexical overlap with user inputs (1-gram precision, lex-p_1; cf. Section 4.4), we set 25% as a desirable value.[4] Thus, we keep $\tau = 25.0$ for W_1. To spread W_2 almost to 0 and keep its mid-point around the dataset’s 1-gram precision, we assign $\beta = 18.1$ and $w = 0.8$. We use $\epsilon = 0.1$. Thus, we have, $W_2(14.3) \approx 1.1$, $W_2(18.1) \approx 5.1$, and $W_2(25) \approx 10.06$.

ULL(α) For the choice of α in ULL, we start with $\alpha = 0.1$, and we gradually increase it to 0.5.We need a balanced combination of ULL and CE losses, as high α could lead to responses that are repetitive or identical to the user inputs. Additionally, as using ULL with CE only resulted in nonsensical repeats of user tokens, we only report scores for ULL with CE+Unl.

LK-loss (σ) For generation conditioned on keywords, we keep the threshold t as 0.1. We experiment with $\sigma \in \{0, 0.05, 0.5\}$.

4.4 Automatic Evaluation Metrics

We report the standard MultiWOZ metrics from Nekvinda and Dušek (2021) (*inform*, *success*,

---

[2] Note that other contemporary task-oriented sets, e.g., Schema-guided Dialogue (Rastogi et al., 2020), are not suitable as their dialogue structures were set by rules and crowd workers only paraphrased isolated utterances.

[3] https://huggingface.co/jkulhanek/augpt-bigdata

[4] We could not find any earlier work that discusses an ideal extent of lexical entrainment in such a context. We thus aimed at a slightly higher value than what is found in the data. Since our experiments showed promising results from the start, we did not optimize this parameter any further.

BLEU, and *delexicalized BLEU*) to evaluate state tracking and response generation. For lexical entrainment, we use 1-gram precision (lex-p_1) and recall (lex-r_1) against user input. For syntactic entrainment, we report the 2-gram (syn-p_2) and 3-gram precision (syn-p_3) scores on the POS tags of the user tokens and generated responses (i.e., matching part-of-speech patterns). We also use 50MFC, a variant of the metric introduced by Nenkova et al. (2008), measuring entrainment on the 50 most frequent words in the corpus:

$$50\text{MFC} = -\sum_{w \in 50\text{MF}} \left| \frac{\text{count}_S(w)}{|S|} - \frac{\text{count}_U(w)}{|U|} \right|$$

50MFC sums the differences in relative frequencies of 50 most frequent words in user and system utterances. It ranges from -2 to 0, with 0 being the perfect alignment. The idea is to measure entrainment on frequent, domain-independent words. We report average metrics from five runs with different random initializations, along with standard deviations.

4.5 Human Evaluation Setup

We run a small-scale in-house evaluation to complement the automatic evaluation scores. We use relative ranking by naturalness on a sample of 100 outputs. We select models from each group with better trade-offs between success rates and entrainment. We use the best-entraining model among the five runs. We report mean ranking (R_m) and proportions of instances with ranks 1,2,6,7 ($R_{1/2/6/7}$).

5 Results

5.1 Automatic Evaluation

Table 1 shows that all our approaches outperform the Base experiments on entrainment metrics. Although the models are primarily trained to increase the lexical entrainment, this also results in improved syntactic entrainment. As our methods do not differentiate between domain-specific terms and common words, the alignment on common words is also slightly improved in most setups, as shown by 50MFC scores. While the D&J16 reranking gets even better entrainment scores, its BLEU performance is low, as optimizing for 1/2-gram precision produces very terse outputs.

Models using IW do not only improve entrainment, but also maintain similar MultiWOZ scores to the baseline. In particular, IW_1-CE has substantially better lexical (lex-p_1 and lex-r_1) and syntactic (syn-p_2 and syn-p_3) entrainment while even maintaining a slightly better inform and success rates. Using IW_2 and/or Unl yields slightly lower success rates, with similar entrainment scores.

For ULL, entrainment scores show a positive correlation with the choice of α's while MultiWOZ scores decrease with an increase in α, but the drop is very slight for 0.1 and 0.2. This is not surprising, as with increasing α, the model gets more focused on aligning to the user and less on dialogue success. ULL(0.2) seems to have the best tradeoff.

The LK approach generally has high entrainment; the blending approach helps keep the keywords consistent during training and inference and is necessary to maintain good MultiWOZ scores.

The full results of the comparison with GPT-4 on the smaller data sample are shown in Table 3 in Appendix A. While GPT-4's responses look fluent and accurate and get high coverage of the user input tokens (lex-r_1) and even good syntactic entrainment (syn-p_2, syn-p_3), they are substantially longer, leading to lower precision-based lex-p_1 and BLEU scores. In addition, GPT-4 occasionally fails to follow the instructions given in the prompt.

5.2 Human Evaluation

Table 2 shows manual evaluation scores for selected setups. Here, IW_1-CE performs best on mean ranking and is most frequently ranked first, along with LK-CE. Despite similar numbers in Table 1, we see a noticeable difference between the scores of IW_1-CE and IW_2-CE. This can be attributed to the higher variance in lex-r_1, resulting in the outputs from the best run of IW_1-CE surpassing the quality of IW_2-CE. The generated responses from ULL experiments were often not fluent enough, hence their lower ranking. While their entrainment metrics are high, they only capture token-level alignment and are not directly related to fluency. In some of the examples, the outputs achieved high scores by simply repeated phrases from the user input. The human ranking here corresponds with the lowered MultiWOZ success rates, showing that entrainment cannot override the main dialogue objective. The outputs of the D&J16 reranking method were shorter, less polite, and less interactive, which resulted in the worst overall ranking. Appendix B illustrates this on a few sample outputs.

Table 1: Automatic metric results for state tracking, response generation and entrainment on the full MultiWOZ 2.1 test set (cf. Section 4.4 for metrics and Sections 4.2 and 4.3 for system variants). Except for D&J16, figures shown are averages of five runs with different random initializations, with standard deviations shown in subscript.

Model	R_m	R_1	R_2	R_6	R_7
base-CE	4.18	5	12	15	12
D&J16	5.35	1	7	26	30
IW$_1$-CE	**3.16**	26	18	12	3
IW$_2$-CE	3.77	20	15	13	15
LK-CE (0.05)	3.25	26	21	7	10
ULL (0.20)	4.17	15	10	16	11
ULL (0.25)	4.13	7	17	11	19

Table 2: Manual evaluation for generated responses on a sample of 100 outputs – mean rank R_m, and number of cases out of 100 where each system is ranked first (R_1), second (R_2), second to last (R_6) and last (R_7).

6 Conclusion

Although previous research showed that linguistic entrainment helps dialogue success, its application in end-to-end task-oriented dialogue systems has been largely overlooked. To address this gap, we introduced three techniques aimed at improving lexical entrainment of system responses to user inputs: (1) We show that prioritizing training instances with higher system-user word overlap improves entrainment, with comparable success rates. (2) We explore using user tokens' likelihood loss to control entrainment. While entrainment increases, both naturalness and correctness of outputs suffer with higher loss weight. (3) We additionally condition generation on user tokens likely to be reused (based on self-attention weights). We blend self-attention-selected tokens with true response tokens at training time to prime the model to use them. This yields responses with high fluency and better entrainment. The blending is necessary to maintain high dialogue success rate. In general, all methods seem to work successfully in aligning both domain-dependent and independent words.

In the future, we plan to incorporate longer context and focus more on syntactical entrainment. We also plan to use retrieval-augmented generation (Nekvinda and Dušek, 2022).

Acknowledgements

This research was supported by the European Research Council (Grant agreement No. 101039303 NG-NLG) and by the HumanE-AI-Net project (EC Horizon 2020, Grant Agreement H2020-FETFLAG-2018-2020 no. 952026, micro-project "Use of dialog context to boost ASR/NLG/TTS and improve the overall quality of voice dialog systems"). It used resources provided by the LINDAT/CLARIAH-CZ Research Infrastructure (Czech Ministry of Education, Youth, and Sports project No. LM2018101).

Limitations

The proposed methods focus exclusively on addressing lexical entrainment in dialogues, overlooking entrainment at different linguistic levels. Additionally, the study is conducted and evaluated only at the response level despite the possibility of entrainment occurring across the entire dialogue.

A Comparison with GPT-4

Table 3 shows evaluation metric scores on randomly selected 200 examples from the test set and compares our results to GPT-4-based responses, given gold-standard dialogue states. The responses from GPT-4 look fluent and factually accurate and have the best coverage over the user inputs, as reported by lex-r_1 scores. Also, they seem to preserve the syntactic structure of the user inputs better than the other models, as evident by syn-p_2 & syn-p_3 scores. We observed this behavior even though GPT-4 was not specifically prompted to align syntactically. However, the generated outputs are substantially longer, leading to lower lex-p_1 and BLEU scores. Furthermore, GPT-4 struggles in several cases to generate appropriately delexicalized responses, further lowering the BLEU scores. Although we evaluated multiple variants of the prompt with instructions, GPT-4 still was not guaranteed to give an appropriate response. Figure 2 shows our prompt for GPT-4, along with a few example outputs, documenting both well-aligned and inappropriate responses.

B Sample Dialogues

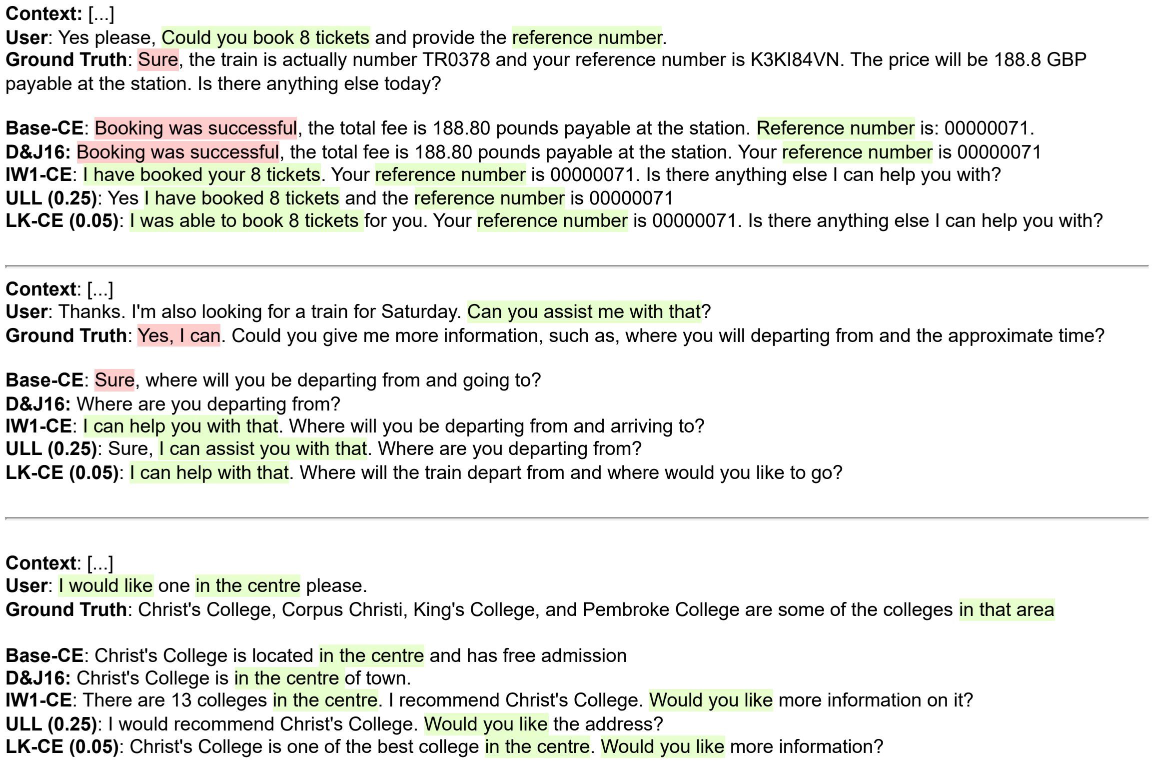
Sample dialogues, with outputs of the different variants of our systems, are shown in Figure 3.

Model	bleu	delex bleu	lex-p$_1$	lex-r$_1$	syn-p$_2$	syn-p$_3$	50MFC	length ratio
base-CE	16.25	18.82	20.74	0.24	17.90	5.78	-0.13	1.10
D&J16	10.78	11.87	**33.06**	0.29	20.25	8.72	-0.17	0.76
GPT-4	3.21	2.67	17.29	**0.54**	**26.83**	**11.51**	-0.22	3.03
IW$_1$-CE	16.47	18.62	23.96	0.32	24.94	9.02	-0.15	1.26
IW$_2$-CE	14.42	16.39	22.34	0.28	21.49	5.93	**-0.10**	1.25
LK-CE (0.05)	12.12	13.77	26.21	0.32	21.31	8.06	-0.11	1.12
ULL (0.20)	14.02	16.18	23.65	0.29	18.59	6.49	-0.15	1.07
ULL (0.25)	**17.37**	**19.46**	26.62	0.33	23.33	9.33	-0.16	1.10

Table 3: Automatic evaluation scores for 200 randomly selected responses with GPT-4 as a baseline. Note that the scores for other systems differ from Table 1 as the evaluated sample is different. We only show scores for selected system variants with the best-entraining of the five runs. We evaluate the responses on MultiWOZ BLEU and delexicalized BLEU, entrainment metrics (as in Table 1), and length ratio of the generated responses to the gold ones.

	Prompt:	Generate a lexically aligned response to the user given the context, dialogue state and database results. Make sure to replace the named entities in the generated response with the given slot names, if any. <context> CONTEXT <dialogue state> DS <database results> DB_RESULTS <slot names> SLOTNAMES
1.	**User:**	Hi, I am trying to plan my trip and could use some help with a particular restaurant.
	GPT-4:	Hello! I'd be happy to help you with finding the perfect restaurant for your trip. Please provide some details about your preferences, such as the location, cuisine, and price range. Once I have this information, I will search through our database to find the most suitable option for you.
2.	**User:**	Please book for 4 people starting Friday for 2 nights.
	GPT-4:	I have successfully booked a room at the Home From Home hotel for 4 people, starting on friday for a duration of 2 nights. The hotel is in the moderate price range. Please note down the booking reference number: 00000021. If you need any further assistance, feel free to ask.
3.	**User:**	Great and what will be the cost of each ticket?
	GPT-4 (delexicalized):	The cost of each ticket is [price]14 Pounds[/price].
	GPT-4:	The cost of each ticket is 8.08 pounds14 Pounds[/price].
4.	**User:**	Yeas, what to recommend if I want to see good architecture in the west part of town?
	GPT-4:	I recommend you visit the west part of Cambridge to explore its stunning architecture. However, I do not have specific attractions in that area at the moment. You can still discover many beautiful buildings and landmarks during your visit. Enjoy your stay at the A and B Guest House with your group of 6 people for 4 nights starting from Tuesday. If you need any further assistance, feel free to ask.

Figure 2: Our GPT-4 prompt template (top) and example outputs (bottom). The CONTEXT, DS, DB_RESULTS and SLOTNAMES variables are filled in according to the current dialogue context, the (gold-standard) dialogue state and database results, and the slot names for the current domain. Examples 1 and 2 are quite fluent and syntactically aligned to the user. In Example 3, the model struggles with using slot placeholders and their correct values. This issue was quite frequent in our limited observation, even after trying several different prompts. Example 4 shows a self-contradicting response from the model.



Context: [...]
User: Yes please, Could you book 8 tickets and provide the reference number.
Ground Truth: Sure, the train is actually number TR0378 and your reference number is K3KI84VN. The price will be 188.8 GBP payable at the station. Is there anything else today?

Base-CE: Booking was successful, the total fee is 188.80 pounds payable at the station. Reference number is: 00000071.
D&J16: Booking was successful, the total fee is 188.80 pounds payable at the station. Your reference number is 00000071
IW1-CE: I have booked your 8 tickets. Your reference number is 00000071. Is there anything else I can help you with?
ULL (0.25): Yes I have booked 8 tickets and the reference number is 00000071
LK-CE (0.05): I was able to book 8 tickets for you. Your reference number is 00000071. Is there anything else I can help you with?

Context: [...]
User: Thanks. I'm also looking for a train for Saturday. Can you assist me with that?
Ground Truth: Yes, I can. Could you give me more information, such as, where you will departing from and the approximate time?

Base-CE: Sure, where will you be departing from and going to?
D&J16: Where are you departing from?
IW1-CE: I can help you with that. Where will you be departing from and arriving to?
ULL (0.25): Sure, I can assist you with that. Where are you departing from?
LK-CE (0.05): I can help with that. Where will the train depart from and where would you like to go?

Context: [...]
User: I would like one in the centre please.
Ground Truth: Christ's College, Corpus Christi, King's College, and Pembroke College are some of the colleges in that area

Base-CE: Christ's College is located in the centre and has free admission
D&J16: Christ's College is in the centre of town.
IW1-CE: There are 13 colleges in the centre. I recommend Christ's College. Would you like more information on it?
ULL (0.25): I would recommend Christ's College. Would you like the address?
LK-CE (0.05): Christ's College is one of the best college in the centre. Would you like more information?

Figure 3: In the first example, entrainment methods effectively produce more natural and less automated-like outputs, even when the ground truth response itself looks less natural. In the second example, the model outputs employing entrainment methods adeptly incorporate the phrases *Can you*, *assist me*, and *with that*, whereas the reranking method, D&J16, yields a lesser natural output. In the third example, the phrase *in the centre* is consistently present in almost every output, but D&J16 and Base-CE struggle to sustain the conversation. Conversely, the other methods successfully continue the conversation with improved entrainment.

Efficient Dependency Tree Sampling Without Replacement

Bogdan Mihai Dobre
University of Bucharest
bogdan.dobre@s.unibuc.ro

Abstract

In the context of computational models of dependency syntax, most dependency treebanks have the restriction that any valid dependency tree must have exactly one edge coming out of the root node in addition to respecting the spanning tree constraints. Many algorithms for dependency tree sampling were recently proposed, both for sampling with and without replacement.

In this paper we propose a new algorithm called Wilson Reject SWOR for the case of sampling without replacement by adapting the Wilson Reject algorithm originally created for sampling with replacement and combining it with a Trie data structure. Experimental results indicate the efficiency of our approach in the scenario of sampling without replacement from dependency graphs with random weights.

1 Introduction

Dependency trees are one of the most popular structures used to represent syntactic relations between words (Kübler et al., 2009). A popular formalisation for them is based on spanning trees in directed graphs, which is one of the core ways to represent dependency structures in natural language processing (McDonald et al., 2005). A dependency graph for n words has n+1 nodes: one for each word and a special root node. It also has n^2 weighted edges between nodes: n(n-1) edges between any pair of distinct word nodes and n edges from the root to each node. A spanning tree of the graph is a subgraph that contains all the n+1 nodes, exactly n edges and no cycles. Each node except for the root has exactly one incoming edge and is reachable from the root. Probabilistic models over spanning trees have uses in non-projective dependency parsing (Ma and Hovy, 2017; Dozat and Manning, 2016; Wang and Chang, 2016), recovering phylogenic structures (Andrews et al., 2012) and event extraction (McClosky et al., 2011).

A typical dependency tree constraint that is also applied in the case of Universal Dependencies (Nivre et al., 2020) is that the tree must have exactly one edge coming out of the root node. In the rest of the paper we will refer to spanning trees that have exactly one edge coming out of the root node as "dependency trees".

The need for algorithms that sample dependency trees comes from the fact that state-of-the-art parsers often predict invalid dependency trees as the most probable output (Zmigrod et al., 2020).

Dependency tree sampling has uses in domains such as semi-supervised training of parsers (Corro and Titov, 2018), facilitating the approximate decoding of higher-order models (Zhang et al., 2014) and unsupervised grammar induction (Mareček and Žabokrtský, 2011).

There are 2 main sampling scenarios: sampling with replacement and sampling without replacement. In the case of sampling with replacement, the same tree can be sampled multiple times, while in the case of sampling without replacement, each tree can only be sampled once. Some recent advances in dependency trees sampling can be found in (Stanojević, 2022), including algorithms for sampling dependency trees both with and without replacement, but in this paper we will focus on adapting the fastest algorithm in practice for sampling with replacement, Wilson Reject, to sampling without replacement, thus creating a new algorithm that we will call Wilson Reject SWOR that achieves superior performance compared to the other algorithms for graphs with random weights. The random weights setting usually occurs in the beginning of training of dependency parsers.

2 Distributions over tress

In this section we will give formal definitions to distributions over spanning trees and dependency trees in rooted directed weighted graphs. A rooted directed graph can be denoted by G=$\{V, E\}$, where

Findings of the Association for Computational Linguistics: NAACL 2024, pages 736–741
June 16-21, 2024 ©2024 Association for Computational Linguistics

V is a set of n+1 nodes (1 node for each of the n words and one special root node) and E is a set of directed weighted edges of the form $\{n_1, n_2, w\}$ where n_1 is the starting node of the edge, n_2 is the end node of the edge and w is the nonnegative weight of an edge.

A spanning tree is any subgraph of G that contains all the n+1 nodes, has exactly one incoming edge for each node except for the root and contains no cycles.

A dependency tree is any subgraph of G that is a spanning tree and also has exactly one edge coming out of the root node. Let D_G be the set of all the dependency trees of G.

Let's denote the edge from node i to node j with $i \to j$ and the weight of the edge from node i to node j with $W_{(i,j)}$.

Weight of a dependency tree can then be defined as:

$$W_t \overset{\text{def}}{=} \prod W_{(i,j)}, i \to j \in t$$

Probability of a dependency tree can similarly be defined as:

$$p(t) \overset{\text{def}}{=} \frac{W_t}{Z_{D_G}}, \text{where } Z_{D_G} \overset{\text{def}}{=} \sum_{t \in D_G} w(t)$$

Any unbiased dependency tree sampler must sample the trees according to their probabilities.

3 Previous Work on Sampling Dependency Trees

For the problem of sampling with replacement (SWIR), the fastest algorithm in practice is the Wilson Reject algorithm (shown in Algorithm 2), proposed here (Stanojević, 2022). Wilson Reject is based on rejection sampling, a strategy that we will also use in the algorithm we propose. Rejection sampling is commonly used when we want to sample from a distribution $d_1(t)$ from which sampling is difficult, but there is a related distribution $d_2(t)$ from which sampling is easier. More details about rejection sampling can be found in (Murphy, 2012, Chapter 23.3). Wilson Reject uses Wilson's sampling algorithm to sample spanning trees until a valid dependency tree is sampled. Wilson's algorithm is a random walk based algorithm. The algorithm starts with the root node as the current selection. At each step, if there is a node that is not in the current selection, it starts a random walk from that node through its incoming edges until it reaches a node in the current selection. During the walk it samples a parent node of the current node randomly based on the weights of the incoming edges of the node. Any cycles during the walk are implicitly deleted by the algorithm. The resulting chain is attached to the current selection. When all nodes are part of the selection, the selection will be a spanning tree and will be returned by the algorithm. It was proved in (Stanojević, 2022) that Wilson Reject is an unbiased sampler, and that the expected number of samples it needs until it gets a valid dependency tree is Euler's number. Therefore, 3 runs of Wilson's sampling algorithm are expected to be enough to sample a valid dependency tree. The total runtime complexity of Wilson's algorithm depends on the graph edges and their weights, but can be as small as $O(|V|)$ (Wilson, 1996). Therefore, the complexity of Wilson Reject is also often as small as $O(|V|)$.

The pseudocode of Wilson's Algorithm can be found in Algorithm 1, and the pseudocode of Wilson Reject can be found in Algorithm 2.

Algorithm 1 WILSON

```
p ← $\emptyset$          ▷ $p$ will keep the sampled tree edges
                 ▷ $p[n_1] = n_2$ stands for edge $n_2 \to n_1$
$visited$ ← {$ROOT$}
for $i \in V \setminus \{ROOT\}$ do
    $c \leftarrow i$
    while $c \notin visited$ do
        random sample node $v$ with edge weight $W_{v \to c}$
        $p[c] \leftarrow v$
        $c \leftarrow v$
    $c \leftarrow i$
    while $c \notin visited$ do
        $visited$.add($c$)
        $c \leftarrow p[c]$
return $p$
```

Algorithm 2 WILSON REJECT

```
$t \leftarrow$ Wilson($G$)
while $t$ has more than one root edge do
    $t \leftarrow$Wilson($G$)
return $t$
```

4 Wilson Reject SWOR

We will now analyze the scenario of sampling without replacement (SWOR), scenario in which it is not allowed to sample the same instance twice. For this scenario, 2 algorithms with complexity $O(k * n^3)$ where k is the number of samples and n the number of words were proposed in (Stanojević, 2022): Trie-SWOR and SBS-SWOR. Both use Colbourn's algorithm (Colbourn et al., 1996), an ancestral sampling algorithm, as an auto-regressive form of dependency tree distribution and each of the 2 algorithms uses a different algorithm for sampling from sequential models: Trie-SWOR is based on the Trie algorithm (Shi et al., 2020) and SBS-SWOR is based on Stochastic Beam Search (SBS) (Kool et al., 2019). More details about these algorithms can be found in (Stanojević, 2022).

We will focus on comparing our results with the SBS-SWOR algorithm, as it was found to be faster than Trie-SWOR on CPU and, unlike Trie-SWOR, its performance improves significantly when run on GPU. This is mainly caused by the fact that SBS-SWOR draws all the required samples in parallel instead of sequentially, so it can substantially benefit from the GPU's parallel computing. In order to ensure that no instance is sampled twice, SWOR algorithms need to constrain the current sample based on the previous samples (Kool et al., 2020).

We create a new algorithm called Wilson Reject SWOR based on the Wilson Reject algorithm for the random weights setting. We do that by keeping a list of already sampled trees that are considered invalid samples for this step. At each sampling step we keep generating dependency trees with the Wilson Reject algorithm until we get a tree that wasn't already sampled. That tree is considered the valid sample for that step and added to the list of already sampled trees.

Theorem 1. *Wilson Reject SWOR is unbiased.*

Proof. We have to prove that at each step Wilson Reject SWOR samples dependency trees in an unbiased way. We consider that the trees sampled before the current step are invalid as they can't be sampled again in SWOR. It was already proved that Wilson Reject is an unbiased sampler of dependency trees (Stanojević, 2022). We can use rejection sampling concepts (Murphy, 2012, Chapter 23.3) to prove that Wilson Reject SWOR which uses Wilson Reject is unbiased. Let C be the current step, S_C be the set of already sampled dependency trees, $d_{1_{S_C}}(t)$ be the distribution of valid dependency trees at step C and $d_2(t)$ be the distribution of all dependency trees that can be sampled. The condition for rejection sampling to work is that there must be a constant $c > 0$ such that $c * d_2(t) \geq \tilde{d}_{1_{S_C}}(t)$, where $\tilde{d}_{1_{S_C}}(t)$ is the unnormalized target distribution. After a sample is retrieved from $d_2(t)$, it is accepted with probability $\frac{\tilde{d}_{1_{S_C}}(t)}{c * d_2(t)}$. In our case, since the trees in both distributions come from the same graph, they have the same weights, so we can have $c = 1$ and accept any sample from $d_2(t)$ that is also part of $d_{1_{S_C}}(t)$. Therefore, accepting any dependency tree sampled by Wilson Reject that wasn't already sampled is an unbiased SWOR sampling method. This means that Wilson Reject SWOR is unbiased. ☐

Any node in a dependency tree except for the root can have exactly one incoming edge. Therefore, if we have an edge from a node n_1 to a node n_2, we will call n_1 the "parent" of node n_2. To make the Wilson Reject SWOR algorithm more efficient, we can uniquely represent any dependency tree using a list of the parents of all the nodes. Since the root has no parent in a dependency tree, we use a placeholder for its parent in the list. Building a list of parents from a dependency tree and building a dependency tree from a list of parents are trivial operations that have $O(|V|)$ time complexity.

We can keep the parents list representations of the already sampled trees in a Trie data structure. This allows us to check if a tree was already sampled by searching for its associated parents list in the Trie in $O(|V|)$ time. Insertion of the parents list associated to a tree in the Trie can also be done in $O(|V|)$ time (Brass, 2008). Wilson Reject SWOR has no worst case complexity, but we can estimate the complexity for graphs with random weights. An important question is how often do we expect to sample a tree that was already sampled, which depends on the number of nodes, the configuration of edges and the number of samples. It is well known that there are n^{n-2} spanning trees for a complete graph of size n (Cayley, 1878), and from each of them we can build a dependency tree for the graph with n+1 nodes corresponding to n words by adding the artificial root node and an edge from it to the root of the spanning tree. Therefore, for the graph of size n+1 corresponding to n words, there are n^{n-2} dependency trees. Since each dependency tree has the same number of edges, for graphs with random edge weights we can expect most dependency trees to most likely have their total weights close to their mean. This indicates that for graphs with a significant number of nodes and random weights, it is very unlikely the same tree would be sampled twice without a very big number of samples. As an experiment, we sampled 20000 dependency trees from a graph of size 100, and the same tree was never sampled twice. For cases when the same tree is only sampled once, we can consider that the complexity of Wilson Reject SWOR is the same as that of Wilson Reject, which as discussed previously depends on many factors but can be as small as $O(|V|)$. Therefore, the complexity of Wilson Reject SWOR can be as small as $O(k * |V|)$, where k is the number of samples. The steps of the algorithm are shown in Algorithm 3:

Algorithm 3 Wilson Reject SWOR

```
$G \leftarrow$ original graph
$t \leftarrow$ sample_with_wilson_reject($G$)
$t\_parent\_array \leftarrow$ get_prnt_array($t$)
$trie \leftarrow \emptyset$
while $t\_parent\_array \in trie$ do:
    $t \leftarrow$ sample_with_wilson_reject($G$)
    $t\_parent\_array \leftarrow$ get_prnt_array($t$)
$trie$.insert($t\_parent\_array$)
return $t$
```

5 Experiments

We will now compare the results of Wilson Reject SWOR to those of SBS-SWOR for the case of sampling without replacement. Unlike Wilson Reject SWOR, SBS-SWOR can be significantly improved by GPU acceleration due to the fact that it draws all samples in parallel, so it makes sense to compare the results with both those of SBS-SWOR on CPU and those of SBS-SWOR on GPU. The experiments were run on a 11th Gen Intel® Core(TM) i7-11800H @ 2.30GHz CPU and a NVIDIA® GeForce RTX 3050 GPU. The SBS-SWOR implementation that was used was from the SynJax Python library, version 2023.8.5, (Stanojević and Sartran, 2023) which is written in JAX (Bradbury et al., 2018). We will present the results of the 2 algorithms for dependency graphs with random weights corresponding to 100 words. We found that Wilson Reject SWOR on CPU has better performance than both SBS-SWOR on CPU and SBS-SWOR on GPU, as it can be seen in Figure 1. It also has the advantage of being sequential unlike SBS-SWOR, allowing us to stop sampling if certain criteria were met, and the advantage of not relying on GPU. Results for additional experiments with graphs with different numbers of words can be found in Appendix A.

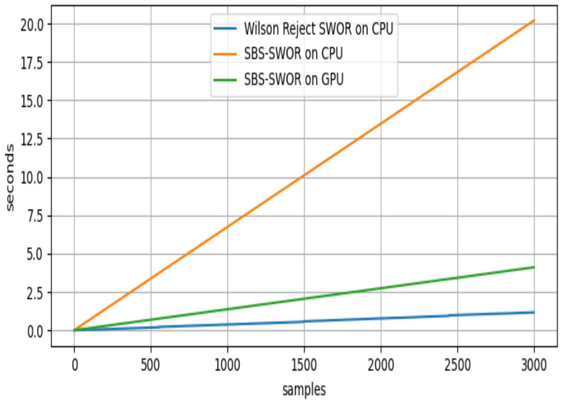


Figure 1: Speed for SWOR with 100 words

6 Conclusion

In this paper we presented the Wilson Reject SWOR algorithm for sampling dependency trees without replacement which is based on random walks. We also showed that it is unbiased and has the best performance for graphs with random weights. It may have uses in tasks where dependency tree sampling is required such as semi-supervised training of parsers (Corro and Titov, 2018), unsupervised grammar induction (Mareček and Žabokrtský, 2011) and approximate decoding of higher-order models (Zhang et al., 2014).

Limitations

Even though the Wilson Reject SWOR algorithm is very efficient for sampling dependency trees without replacement for graphs with random weights, it is still based on random walks due to its reliance on the original Wilson's Algorithm. That means that we don't have any worst case complexity for it. Methods such as Colbourn based algorithms have a predictable runtime, even though in practice they tend to be slower. There are some types of graphs for which the performance is expected to be greatly impacted, such as graphs in which almost all of the probability mass is on a single dependency tree. For this kind of graphs we can expect that a big number of samples would be required to sample anything but the most probable dependency tree, making Wilson Reject SWOR inefficient for these cases compared to alternatives like SBS-SWOR. Therefore, the algorithm would be most useful in the random weights setting that usually happens in the beginning of training of dependency parsers.

Ethics Statement

To the best of our knowledge, there isn't any way in which the work presented in this paper could raise ethical concerns.

A Results for additional SWOR experiments

In this appendix we will present additional results for Wilson Reject SWOR and SBS-SWOR on graphs with different word counts. The experiments were run on a 11th Gen Intel® Core(TM) i7-11800H @ 2.30GHz CPU and a NVIDIA® GeForce RTX 3050 GPU and the SBS-SWOR implementation that was used was from the SynJax Python library, version 2023.8.5, (Stanojević and Sartran, 2023) which is written in JAX (Bradbury et al., 2018). We found that Wilson Reject SWOR on CPU achieved a better performance than SBS-SWOR on CPU and SBS-SWOR on GPU for all the word counts tried for graphs with random weights, thus proving its efficiency.

Abstract

Open-domain Question Answering (OpenQA) aims at answering factual questions with an external large-scale knowledge corpus. However, real-world knowledge is not static; it updates and evolves continually. Such a dynamic characteristic of knowledge poses a vital challenge for these models, as the trained models need to constantly adapt to the latest information to make sure that the answers remain accurate. In addition, it is still unclear how well an OpenQA model can transfer to completely new knowledge domains. In this paper, we investigate the generalization performance of a retrieval-augmented QA model in two specific scenarios: 1) adapting to updated versions of the same knowledge corpus; 2) switching to completely different knowledge domains. We observe that the generalization challenges of OpenQA models stem from the reader's over-reliance on memorizing the knowledge from the external corpus, which hinders the model from generalizing to a new knowledge corpus. We introduce *Corpus-Invariant Tuning* (CIT), a simple but effective training strategy, to mitigate the knowledge over-memorization by controlling the likelihood of retrieved contexts during training. Extensive experimental results on multiple OpenQA benchmarks show that CIT achieves significantly better generalizability without compromising the model's performance in its original corpus and domain.[1]

1 Introduction

Open-domain Question Answering (OpenQA) (Chen and Yih, 2020) aims at answering factual questions using a large-scale external knowledge corpus. This is in contrast to closed-book question answering (Roberts et al., 2020) wherein the model is expected to directly answer questions with no access to external knowledge. In general, closed-book QA optimizes for memorization of knowledge in model parameters, while OpenQA focuses on retrieving relevant knowledge from an external corpus. OpenQA typically employs a retrieval-augmented approach (Karpukhin et al., 2020; Izacard and Grave, 2021a; Sachan et al., 2021), involving a two-stage process: a *retriever* to select relevant documents, followed by a *reader* to derive answers from these documents. It is more practical for real-world applications as it enables the use of extensive and varied knowledge sources for answering questions.

Retrieval-augmented OpenQA models rely on an external corpus to physically store the knowledge. However, real-world knowledge is not static; it updates and evolves continually. Therefore, it is essential to build models that are able to use fresh and real-time knowledge (Kasai et al., 2022; Vu et al., 2023), but the dynamic characteristic of knowledge poses a vital challenge as the trained models need to constantly adapt to the latest information to make sure that the answers remain relevant and accurate. In addition, closed-book QA systems have been proved limited in adapting to new information or domains due to their reliance on pre-existing knowledge, and updating their parametric knowledge requires extensive large-scale pre-training. Nevertheless, it is still unclear how well OpenQA systems can transfer to leveraging unseen corpora and domains during training.

In this paper, we first investigate how well state-of-the-art retrieval-augmented models, such as Atlas (Izacard et al., 2023), can adapt to new and diverse knowledge corpora. Specifically, we explore the model's performance in two scenarios: 1) adapting to updated versions of the same corpus (in §2.2.1); 2) switching to completely different domains (in §2.2.2). Our investigation involves three settings: directly applying a pre-trained model, finetuning the model with the new corpora, and training the model afresh on the new corpora. Initial experi-

[1] Programs and data are available for research purpose at `https://github.com/zhangzx-uiuc/CIT`

Findings of the Association for Computational Linguistics: NAACL 2024, pages 742–753
June 16-21, 2024

ments reveal that the model faces challenges in both scenarios. When directly transitioning to an updated corpus, there is a noticeable performance decline. Even additional tuning on the newer version doesn't achieve the same effectiveness as training from scratch with the new data (56.9→59.5 vs 62.2 in Table 1). Similar outcomes are observed when shifting from a general domain, like Wikipedia, to a specialized one, such as biomedical (41.2→68.8 vs 69.7 in Table 2).

We hypothesize and validate that such generalization challenges stem from the reader's over-reliance on memorizing the knowledge retrieved from the external corpus. This reliance primarily arises as the reader, with its primary training objective optimized for QA accuracy, often opts to hard-code a substantial amount of retrieved knowledge into its parametric memory. Such kind of over-memorization reduces the reader's dependency on the retriever to choose more relevant contexts. This phenomenon hampers the model's generalizability, particularly to updates in the knowledge corpus or changes in the knowledge domain. For instance, given a question *Who is the prime minister of the UK?*, if a model has already hard-coded an outdated answer *Boris Johnson* into its parameters (while being trained on an old corpus), it is harder to change its response even if the new information *Rishi Sunak* from an updated corpus is available.

To address this issue, we introduce *Corpus-Invariant Tuning* (CIT), a simple but effective training strategy to improve the corpus generalizability of retrieval-augmented text generation models. CIT aims to mitigate the reader's tendency to memorize the documents retrieved from the corpus during training. This pushes the reader to rely more on retrieved documents to answer the input questions, rather than relying on memorizing the knowledge facts into its parameters. To achieve this, we propose a novel loss term to prevent memorization during training by controlling the likelihood of the retrieved documents. Through extensive experiments across various OpenQA benchmarks (Kwiatkowski et al., 2019; Joshi et al., 2017; Han et al., 2023), carried out in both zero-shot and continual fine-tuning scenarios, we demonstrate that a retrieval-augmented model trained using our proposed CIT loss exhibits considerably enhanced generalizability across different corpora. This is evident by the considerable improvements in exact match (EM) scores, reaching up to a 2.1% absolute gain.

Our contributions can be summarized as follows:

- We propose to mitigate knowledge over-memorization of the reader to improve the generalization ability of retrieval-augmented text generation models.
- We introduce *Corpus-Invariant Tuning* (CIT), a straightforward but effective training strategy that regularizes the reader's likelihood of the retrieved documents to mitigate it from over-memorizing the corpus during training.
- Through extensive experiments on multiple benchmarks, we demonstrate that training models with CIT greatly improves the generalization of OpenQA models across both newer versions of the corpora and unseen domains.

2 Preliminaries

2.1 Problem Formulation

Open-domain QA aims to answer questions only using a large-scale unified corpus, where the background documents for each question is not specified in advance. Given a natural language question x, our objective is to build a model $f(\cdot)$ to predict an answer $\hat{y}$ using a unified list of background documents Z, where $\hat{y} = f(x, Z)$. Such a setting is more practical for real-world applications because it mirrors the vast and unstructured nature of real-world knowledge.

Retrieval Augmentation Since the external corpus collectively stores all essential information for answering the questions, the typical strategy to tackle the OpenQA problem is to implement a retrieval-augmented approach with a two-stage framework: 1) a *retriever* to select a small subset of documents that are most relevant to the current question, and 2) a *reader* to seek for useful information from the retrieved documents and generate the answer. Specifically, the probability of a predicted answer $\hat{y}$ is decomposed by

$$p\left(\hat{y} \mid x, Z\right) = \sum_{\mathcal{C} \subset Z} p\left(\mathcal{C} \mid x; \theta\right) \cdot p\left(\hat{y} \mid \mathcal{C}, x; \phi\right),$$

where $\mathcal{C}$ denotes the set of retrieved documents, and θ and ϕ are the parameters of the retriever and the reader respectively. During training, the retriever (θ) and the reader (ϕ) are often jointly optimized to ensure their effective collaboration, where the optimization is typically conducted with iterative training (Izacard and Grave, 2021a) or Expectation-Maximization (EM) based approach to train the model by treating the retrieved documents as hidden variables (Sachan et al., 2021).

2.2 Evaluation of Model Generalization

We aim to tackle the generalization challenge for retrieval-augmented models as discussed in Section 1. Specifically, we focus on the following two main research questions (*RQs*):

- *RQ1: How to improve the model's generalization ability across different versions (temporal snapshots) of the same corpus?*
- *RQ2: How to improve the model's generalization ability across the corpora in different domains?*

2.2.1 Evaluations of RQ1

We conduct proof-of-concept experiments to test whether current retrieval-augmented OpenQA models can remain effective when the external corpus is updated to a newer version. Specifically, we adopt the most recent retrieval-augmented model Atlas-XL (Izacard et al., 2023) and test it on the Natural Questions (NQ) benchmark[2] with two different versions of Wikipedia (Wiki-2017 and Wiki-2018)[3] as the external corpus. We first fine-tune the Atlas-XL model on each version of Wikipedia, and then evaluate the model's generalization ability by both *zero-shot testing* (train the model with Wiki-2017 and directly test it with Wiki-2018) and *continue fine-tuning* (train the model with Wiki-2017 and further fine-tune it with Wiki-2018). As shown in Table 1, we can first observe that the model performs better when initially fine-tuned with Wiki-2018, which shows that the updated KB can improve the performance.[4] However, we can also observe a significant performance degradation when using the model trained with Wiki-2017 to directly test it on Wiki-2018. Despite subsequent fine-tuning efforts, the performance still falls short of the original results obtained from initially training and testing with Wiki-2018. These results indicate that the current retrieval-augmented models still struggle to effectively generalize when the background corpus undergoes evolution or updates.

Training Corpus	Testing Corpus	EM Score
Wiki-2017	Wiki-2018	56.9
Wiki-2017 → Wiki-2018	Wiki-2018	59.5
Wiki-2018	Wiki-2018	62.2

Table 1: Initial experiments with Atlas-XL on the NQ benchmark with different Wikipedia versions. Results are evaluated with the exact-match (EM) score (%).

2.2.2 Evaluations of RQ2

We conduct similar experiments with Atlas-XL to evaluate its generalization ability across different domains. We train the model on NQ with Wiki-2018 in the general domain, and test it on the *Biomedical* split in RobustQA[5] with PubMed in the biomedical domain. The results presented in Table 2 reveal similar performance declines in both zero-shot and continual-fine-tuning settings, which indicates that the current OpenQA models also have inherent difficulty in generalizing across different domains.

Training Corpus	Testing Corpus	EM Score
Wiki2018(NQ)	PubMed(Bio)	41.2
Wiki2018(NQ)→PubMed(Bio)	PubMed(Bio)	68.8
PubMed(Bio)	PubMed(Bio)	69.7

Table 2: Initial results (%) with Atlas-XL to test its generalizability between NQ and BioASQ.

3 Corpus-Invariant Tuning

Motivated by the observed limitations in the generalization capabilities of retrieval-augmented models, we introduce *Corpus-Invariant Tuning* (CIT) to mitigate memorizing the lexical content of retrieved documents. Specifically, we posit that the generalization difficulties encountered by retrieval-augmented text generation models arises via excessive memorization the documents retrieved from the external corpus by the reader. In order to achieve higher question-answering accuracy during training, the reader tends to "hard-code" a large volume of retrieved documents rather than relying on an improved retriever for a better selection of relevant contexts, as is empirically validated in the document retrieval evaluations of Section 4.5. This limits the model's ability to generalize because excessive memorization of documents by the reader

---

[2] `https://ai.google.com/research/NaturalQuestions`

[3] The Wikipedia dumped in 2017 and 2018 respectively.

[4] The NQ benchmark is annotated in 2018, so Wiki-2018 is a more up-to-date background KB for the task.

[5] `https://github.com/rujunhan/RobustQA-data`

dictates that when the external corpus is updated or transitions to a different domain, the model faces increased difficulty in adapting and correcting its knowledge compared to learning from scratch.[6]

Validation Here we provide an empirical validation on our hypothesis that the degradation of model generalization ability is caused by over-memorization of retrieved knowledge. We replace the retrieved contexts with ground-truth retrieval results on Wiki-2018, and conduct a stand-alone evaluation with the reader. We report both the EM score and the overlap rate, i.e., the percentage of incorrectly predicted answers that have overlaps with the ground-truth retrieval results in Wiki-2017. The results are shown in Table 3. We can observe that while the models transferred from Wiki-2017 perform slightly worse in terms of EM score, it has a lot more error cases that overlap with the retrieved documents on Wiki-2017. Such results directly show that the over-memorization of contexts is the primary cause of the degradation of model generalizability.

Dataset	Training Corpus	EM Score	Overlap Rate
NQ	Wiki-2017→2018	63.6	**76.3**
	Wiki-2018	65.2	30.2
TriviaQA	Wiki-2017→2018	78.1	**80.8**
	Wiki-2018	78.7	41.0

Table 3: Stand-alone evaluation results (%) with ground-truth retrieved documents on Wiki-2018. We report both the EM score, and the overlap rate between the incorrectly predicted answers with the retrieval results from the old corpus (Wiki-2017).

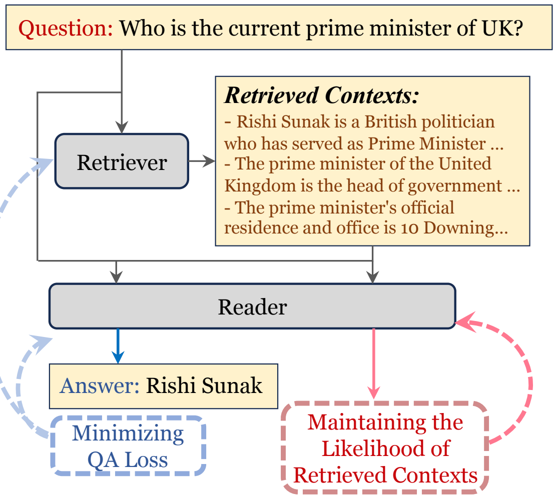

Figure 1: Our proposed Corpus-Invariant Tuning (CIT) Framework. In addition to the existing loss for question answering, we introduce an auxiliary CIT loss to make sure that the reader does not over memorize the retrieved contexts. Specifically, given each batch of QA pairs and the relevant documents retrieved from the corpus, the CIT loss makes sure that the reader's likelihood of these documents does not increase.

Corpus-Invariant Tuning (CIT) To solve this problem, we propose *Corpus-Invariant Tuning* (CIT), a straightforward but effective method to temper the reader's tendency to over-memorize the contents of externally retrieved documents, thereby improving the model's generalization abilities for downstream tasks like OpenQA. As depicted in Figure 1, the core idea of CIT is to control the reader's memorization (likelihood) of the corpus to be "invariant" by introducing an additional loss term that ensures the reader's likelihood of the retrieved documents does not increase during training. Specifically, for each training QA pair (x, y) and its retrieved document set $\mathcal{C}$, the loss term can be written as

$$\mathcal{L}_{CIT} = \sum_{c \in \mathcal{C}} \| \log p_{\phi}(c) - \log p_{\phi_0}(c) \|^2, \qquad (1)$$

where ϕ and ϕ_0 denote the current parameters and the original parameters[7] of the reader respectively. We use $p_{\phi}(c)$ to represent the reader's likelihood of a retrieved document c. In our experiments, we adopt the Masked Span Prediction (MSP) probability from the T5 model (Raffel et al., 2020) to maintain consistency with the Atlas architecture. Essentially, we randomly mask out a fixed number of spans of the input sentence and use the model's probability of generating these spans in the correct order as the likelihood. The overall training objective is a combination of the original loss for question answering $\mathcal{L}_{QA}$ and the CIT loss $\mathcal{L}_{CIT}$:

$$\mathcal{L} = \mathcal{L}_{QA} + \alpha \cdot \mathcal{L}_{CIT}, \qquad (2)$$

where α is a configurable hyper-parameter.

Discussion Retrieval-augmented QA models typically maximize answer accuracy as the end-to-end training objective. However, given the distinct roles of retrievers and readers, there exist two distinct approaches through which this goal can be achieved: the model can either choose to enhance the retriever

---

[6] Such a phenomenon can be caused by the exposure bias problem as discussed in (Yu and Ji, 2023).

[7] ϕ_0 denotes the initial reader's parameters before training.

to fetch more relevant documents or simply allow the reader to memorize pertinent knowledge. While both methods can contribute to performance improvements, the former approach increases generalization and CIT biases the model away from rigid memorization by the reader.

4 Experiments

4.1 Data

Our experiments are conducted on two general-domain OpenQA datasets, NaturalQuestion (NQ) (Kwiatkowski et al., 2019) and TriviaQA (Joshi et al., 2017), and a large cross-domain benchmark RobustQA (Han et al., 2023). Detailed statistics of these datasets are depicted in Table 4.

NQ and TriviaQA NQ and TriviaQA are the two most widely-used open-domain QA benchmarks, which contain factual question and answer pairs created and annotated based on Wikipedia. There are 79,168 and 78,785 QA pairs for training in NQ and TriviaQA respectively. In our experiments, we conduct both fully supervised training and few-shot training settings for model evaluation.

RobustQA RobustQA[8] is a large-scale OpenQA evaluation benchmarks specifically designed for evaluating the cross-domain generalization capabilities of OpenQA models. RobustQA includes 8 distinct domains, each equipped with its own test set and a corresponding list of background documents. The QA pairs and the documents are adopted and annotated from FiQA,[9] SearchQA (Dunn et al., 2017), BioASQ (Tsatsaronis et al., 2015), and LOTTE (Santhanam et al., 2022).

Benchmark	Domain	# Test Questions	Corpus Size

	Science	1,426	1,694,164
	Writing	2,696	199,994

Table 4: Detailed statistics of OpenQA evaluation benchmarks used in our experiments.

4.2 Baselines

We adopt the state-of-the-art retrieval-augmented language model Atlas-XL (Izacard et al., 2023) as our main baseline, which uses a Contriever (Izacard et al., 2022) as the retriever, and a Fusion-in-Decoder (FiD) model (Izacard et al., 2020) as the reader. The primary objective of our experiments is to evaluate whether the baseline model demonstrates improved performance when trained using our proposed CIT loss. Besides, we also introduce other most recent models Flan-T5 (Chung et al., 2022), RGF (Paranjape et al., 2022), ReAtt (Jiang et al., 2022), FiE+PAQ (Kedia et al., 2022), and FID-KD (Izacard and Grave, 2021b) for comparison. Our model is labeled as *Atlas-XL+CIT* which applies an additional CIT loss to control the knowledge over-memorization of the reader.

4.3 RQ1: Different versions of the corpus.

Corresponding to the two research questions proposed in previous sections, we first focus on evaluating our model's ability to generalize across different versions of the external corpus. We adopt the Wikipedia-domain benchmarks NQ and TriviaQA in our experiments, and test their cross-corpus generalization abilities on different Wikipedia versions. Similar to the setting in our preliminary experiments presented in Section 2.2, we use Wiki-2017 and Wiki-2018 as our background corpora, and we consider both zero-shot and fully-supervised settings to test the generalization ability of a trained model. Specifically, we use the following terms to denote different experiment settings:

- *Closed Book*: The model is trained and tested without a retriever. The reader is responsible to understand questions and provide answers.
- *Original*: Also known as the *Open Book* setting. The most typical experiment setting for retrieval-augmented models, where a retriever retrieves a set of documents from the external corpus, and the reader uses these documents to generate answer. We use the label *Original* to emphasize the absence of cross-corpus generalization in this setting, providing a baseline for comparison with the following settings to evaluate the model's generalization ability.
- *Zero-shot Transfer*: The model is initially trained with the older version of a knowledge corpus, and directly tested with the updated

Table 5: OpenQA results on the NQ and TriviaQA benchmarks, evaluated with the exact match (EM) score.

corpus version in a zero-shot manner without any additional fine-tuning.

- *Full-training Transfer*: As opposite to the zero-shot transfer setting, after being initially trained with the older version of a knowledge corpus, the model is further fine-tuned on the same training QA pairs with an updated version of the corpus, before being tested with the new corpus.

Main Results We conduct generalization experiments in both zero-shot and full-training settings on the NQ and the TriviaQA datasets, and the results are shown in Table 5. In the *Original* setting to train and test the model on the same corpus (Wiki-2017), we can observe that compared with the baseline model Atlas-XL, incorporating a CIT loss to reduce knowledge over-memorization will not diminish the task performance; in fact, it can even slightly enhance it in certain cases (NQ with Wiki-2017). This is probably because when the reader is discouraged from rigid knowledge memorization, the retriever still has enough room of improvement to retrieve better documents and enhance the performance. Besides, in both of the *Zero-shot Transfer* and *Full-training Transfer* settings, we can observe that the CIT loss can significantly improve the generalization performance of the model across different versions of a knowledge corpus. This is likely because when the reader is discouraged from hard-coding knowledge into its parameters, it becomes more receptive to assimilating and utilizing new information from the retriever. In summary, our proposed CIT loss significantly improves the model's ability to generalize across different versions of external corpus, without compromising the absolute task performance for OpenQA.

4.4 RQ2: Different domains.

To address our second research question, in this section, we conduct experiments to evaluate whether our proposed CIT loss can help model better generalize across different knowledge domains. We conduct evaluations using the RobustQA benchmark, which encompasses eight diverse domains specifically tailored for OpenQA. We first assess the model's ability to generalize from a general domain (Wikipedia) to these eight diverse domains. Subsequently, we evaluate the model's effectiveness in generalizing interchangeably across these eight domains.

From Wikipedia to Specific Domains We first evaluate how well a model trained with Wikipedia can generalize on the eight specific domains in RobustQA. Specifically, all the models are first fine-tuned on the NQ dataset with Wiki-2018, and then tested with the eight domain-specific benchmarks. The results are presented in Table 6. In general, adding the CIT loss to an Atlas-XL model significantly improves the average F1 score across eight domains in RobustQA, creating a new state-of-the-art among all 3B(XL)-sized models. Our proposed CIT loss can also help on smaller sizes of models, like Atlas-base, with 2.2% absolute improvement of the F1 score. Within these domains, we can see that domains like *Life* show significant improvement. This is probably due to their larger overlaps with Wikipedia, which makes it more crucial to avoid over-memorization, so that the old Wikipedia knowledge will not affect generalization on the new domain. In contrast, domains like *Biomedical* exhibits less improvements. This is possibly because a *Biomedical* domain KB has a smaller overlap with Wikipedia, thereby reducing the neg-

Method	***Average***	*Biomedical*	*Search*	*Finance*	*Life*	*Recreation*	*Technology*	*Science*	*Writing*

Table 6: The evaluation results on RobustQA of how well the model can generalize across different domains. All the models are initially fine-tuned on the NQ dataset, and then directly tested on the 8 different domain-specific benchmarks in RobustQA. The performances are evaluated by F1 score to be consistent with the RobustQA paper.

ative impact of knowledge over-memorization on the model's generalizability.

Cross-Domain Generalization In addition to testing the model trained from Wikipedia, we also assess the model's capability to generalize between each pair of domains in RobustQA. We define the *cross-domain relative performance (CRP)* as the evaluation metric to intuitively characterize how well the model can generalize from a source domain s to a target domain t. Specifically, the $\mathit{CRP}(s,t)$ is defined as the ratio of cross-domain performance and intra-domain performance:

$$\mathit{CRP}(s,t) = \frac{\mathit{score}(s,t)}{\mathit{score}(t,t)} \tag{3}$$

where $\mathit{score}(s,t)$ is the performance (F1-score) of training the model in the source domain s and testing the model in the target domain t. In Figure 2, we set different CIT strength α, and visualize the model's generalizability into a heatmap. Each heat value $h(s,t)$ stands for the absolute improvements of CRP over the baseline model Atlas-XL:

$$h(s,t) = \mathit{CRP}_{\alpha}(s,t) - \mathit{CRP}_{\mathit{Atlas\text{-}XL}}(s,t),$$

where darker green indicates larger improvements and darker red indicates larger declines. We can already observe improvements for most domain pairs with $\alpha = 0.1$, and while α reaches to 0.3, the improvements become much more significant and all domain pairs benefit from CIT in terms of cross-domain generalization.

4.5 Effect on Retrieval Performance

The proposed CIT training loss reduces the reader model's memorization tendency, leading to greater reliance on the documents retrieved. This enhanced dependency during training on the retrieved documents appears to enhance the retriever's performance, as seen from the improvements in retrieval performance observed in Table 7 upon integrating CIT loss. Additionally, we measured the coverage of the reader's predicted answer in the retrieved documents for the NQ benchmark, noting an increase in coverage within the top 40 documents from 66.9% to 69.1%. This suggests that our proposed CIT training loss leads to an increased reliance by the reader on retrieved documents rather than corpus memorization.

Model	*R@10*	*R@20*	*R@40*
Atlas-XL	79.7	84.3	88.4
Atlas-XL + CIT	**85.2**	**88.9**	**91.5**

Table 7: Retrieval performance (Recall@K) on the NQ benchmark.

4.6 Parameter Sensitivity

We then conduct a more in-depth study on the model sensitivity of the most important hyper-parameter α, which controls the strength of the corpus-invariant tuning (as shown in Equation 2). By choosing different values of α, we compute the average cross-domain relative performance between both different corpus versions (RQ1) and different domains (RQ2), and the results are shown in Figure 3. We can observe that as α becomes larger, the generalization performance initially improves, and then starts to decline after reaching its peak. This trend is likely because if memorization is controlled too excessively, the reader may neglect memorizing some certain shared global knowledge that is actually beneficial for knowledge generalization. From Figure 3 we can observe that $\alpha = 0.2$ is best for generalization across different corpus versions (RQ1), and $\alpha = 0.3$ is the best for cross-domain setting (RQ2).

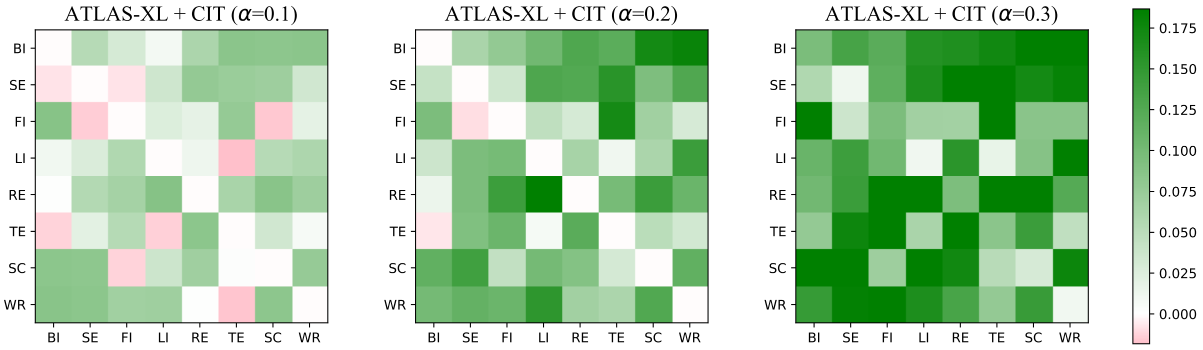

Figure 2: The result heatmaps for cross-domain generalization experiments. Each value in the heatmap represents the absolute improvement (compared with Atlas-XL) of cross-domain relative performance (CRP) defined in Equation 3. Darker green indicates larger improvements in cross-domain generalization.

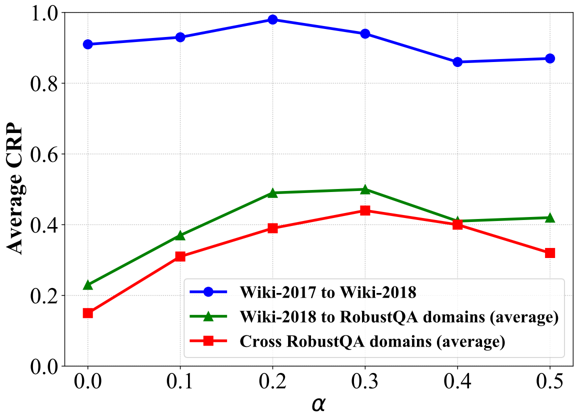

Figure 3: Parameter sensitivity on choices of α.

5 Related Work

Retrieval-Augmented Text Generation Enhancing text generation through the use of retrieved contexts has proven effective in a variety of knowledge-intensive downstream tasks. The most typical design for retrieval augmentation is to employ a retriever, which is jointly optimized with the reader in an end-to-end manner (Guu et al., 2020; Izacard et al., 2020; Karpukhin et al., 2020; Izacard and Grave, 2021b; Kedia et al., 2022; Jiang et al., 2022). The training methods include iterative training (Izacard and Grave, 2021a), and also EM-based algorithms to treat retrieved documents as hidden variables (Sachan et al., 2021). Retrieval augmentation can also act as plug-in modules (Yu et al., 2023). In this setting, the retrievers are not jointly trained with the reader, and the retrieved documents are used in an in-context manner (Ram et al., 2023; Huang et al., 2023). Recently, Atlas (Izacard et al., 2023) trains and releases a new set of retrieval-augmented models based on the T5 architectures (Raffel et al., 2020), which achieves state-of-the-art performances on OpenQA tasks in few-shot settings.

Open-Domain Question Answering The task of OpenQA (Joshi et al., 2017; Kwiatkowski et al., 2019; Chen and Yih, 2020) aims at building models to answer questions without background documents. Given the high demand for external knowledge in this task, the standard approach involves integrating external corpora with a knowledge retriever to supply supporting evidence for answering questions (Izacard et al., 2020; Zhou et al., 2020). Recently, researchers also focus on new problem settings such as conversational QA (Fang et al., 2022), multi-hop QA (Xiong et al., 2021), and new knowledge-enhanced solutions like using knowledge graphs (Oduro-Afriyie and Jamil, 2023), and multi-hop reasoning (Hu et al., 2022).

Knowledge Generalization Because retrieval-augmented OpenQA models require an external KB to provide supporting documents, it is important to make sure that the model is robust and generalizable across different versions and domains of knowledge. There are a few previous studies that focus on the generalizability of OpenQA models. For example, Liu et al. (2022) focus on the question generalizability of OpenQA models, and conducts a detailed analysis on the generalization performances of current OpenQA models. Gangi Reddy et al. (2021); Reddy et al. (2022b,a) propose training with synthetic data to improve the robustness of retrieval models in OpenQA settings. Siriwardhana et al. (2023) focuses on the domain adaption problem of OpenQA, and proposes a reconstruction-based auxiliary loss to improve the model's generalizability. Regarding dataset development, RobustQA (Han et al., 2023) creates a new benchmark that involves multiple real-world domains. However, there are no previous studies that aim to tackle the model's generalization ability on both different corpus and different knowledge domains. Also, we are the first to tackle this problem in a knowledge memorization perspective, enhancing the model's generalization ability by reducing rigid memorization of the reader modules.

6 Conclusion

In this paper, we present *Corpus-Invariant Tuning* (CIT), a simple but effective training strategy to improve the generalization ability of a retrieval-augmented text generation model across different corpus versions and different knowledge domains. The main idea of CIT is to mitigate rigid knowledge memorization during training, so that the reader module can easily accept new knowledge in the retrieved documents and adapt to novel unseen domains. Specifically, we control the reader's likelihood of the retrieved documents during training, to make sure that over-memorization of corpus knowledge is prevented. Extensive experiments are conducted on multiple OpenQA datasets in both zero-shot and fully-supervised training settings, and the results demonstrate that training the model with the proposed CIT loss significantly improves the model's generalizability across different corpus versions and knowledge domains, without sacrificing the model's inherent performance in its original domain.

7 Limitations

Although retrieval-augmented text generation models are effective for many knowledge-intensive tasks, they have an inherent limitation of the large requirement of computational memory. To ensure time efficiency in the retrieval process, an index of the external corpus, often vast in size, must be preconstructed. Another notable limitation of CIT is that the extent of memorization mitigation depends on a hyper-parameter, which is experimented and chosen by humans. Ideally, the model should be able to automatically determine the best level of memorization mitigation to reach an optimal balance between parametric knowledge and retrieval augmentation. This is an exciting new research topic, and we will explore this as the future work.

A Implementation Details

Experiment Details We train our model on 4 NVIDIA A100 GPUs with 80 GB memory, and the total training time is about 3.5 hours for the model to converge on an OpenQA dataset. During training, the index of the external corpus is pre-computed and equally sharded across all 4 GPUs. We adopt distributed data parallelism to make a copy of the model on each GPU and the data batch is splitted to the 4 devices.

Hyper-Parameter Settings Detailed hyper-parameter search range and choices are shown in Table 8 and Table 9 respectively. The choices are made by grid search.

Hyper-parameters	Searching Range
Maximum Length of FiD	[384, 512, 768]
# Retrieved Contexts	[20, 30, 40]
Generation Length	[10, 15, 20, 25, 30]
Masked Percentage for CIT	[0.1, 0.15, 0.2]
Strength of CIT α	[0.1, 0.2, 0.3, 0.4, 0.5, 0.6]
Learning Rate	[1e-5, 2e-5, 3e-5, 4e-5, 5e-5]
Batch Size	[4, 8, 12, 16]
Maximum Training Steps	[500, 1,000, 1,500]
Warm-up Steps	[50, 100, 150]
Weight Decay	[1e-2, 1e-3, 1e-4]
Retriever Dropout	[0.1, 0.2, 0.3]
Reader Dropout	[0.1, 0.2, 0.3]

Table 8: Detailed hyper-parameter search ranges for Corpus-Invariant Tuning.

Hyper-parameters	Values
Maximum Length of FiD	512
# Retrieved Contexts	40
Generation Length	20
Masked Percentage of CIT	0.15
Strength of CIT α	0.2 (RQ1); 0.3 (RQ2)
Learning Rate	4e-5
Batch Size	8
Maximum Training Steps	500
Warm-up Steps	50
Weight Decay	1e-2
Retriever Dropout	0.1
Reader Dropout	0.1

B Case Study on Decoder-Only Models

The main idea of CIT is to control knowledge over-memorization to improve model's generalization ability among different corpora and different domains. Such a training strategy is not only effective for retrieval-augmented encoder-decoder models like Atlas, but can theoretically also apply to larger-scale auto-regressive foundation models. Therefore, we also conduct preliminary experiments with LLaMA-2-7b (Touvron et al., 2023) and Contriever as a case study to evaluate the robustness and ubiquity of our model among different language model architectures. Specifically, we freeze the retriever, and use the retrieved documents as the input prompt to generate the answer for each question. While maximizing the probabilities of the correct answers, we apply CIT in a similar way of maintaining the direct log-likelihood of these retrieved contexts $\mathcal{C}$:

$$\mathcal{L}_{CIT} = \sum_{c \in \mathcal{C}} \| \log p'_{\phi}(c) - \log p'_{\phi_0}(c) \|^2 .$$

Different from the masked span prediction probability p_ϕ in Equation (1), the p'_ϕ here represents the language modeling probability of the entire passage c. Denoting the i-th word in c as c_i, then p'_ϕ can be formulated by

$$p'_{\phi}(c) = \prod_{i=1}^{N-1} p\left(c_{i+1} \mid c_{1:i}\right).$$

As shown in Table 10, we can observe that with auto-regressive language models like LLaMA, our proposed CIT can still achieves considerable improvements of the model's generalization ability.

Dataset	Model	EM Score
NQ	LLaMA2-7b	54.2
	LLaMA2-7b + CIT	57.7
TriviaQA	LLaMA2-7b	69.9
	LLaMA2-7b + CIT	71.4

Table 10: Evaluation results of applying the idea of CIT on the LLaMA2-7b model with a fixed retriever (Contriever). The experiments are conducted in a zero-shot transfer setting between Wiki-2017 and Wiki-2018.

GEE! Grammar Error Explanation with Large Language Models

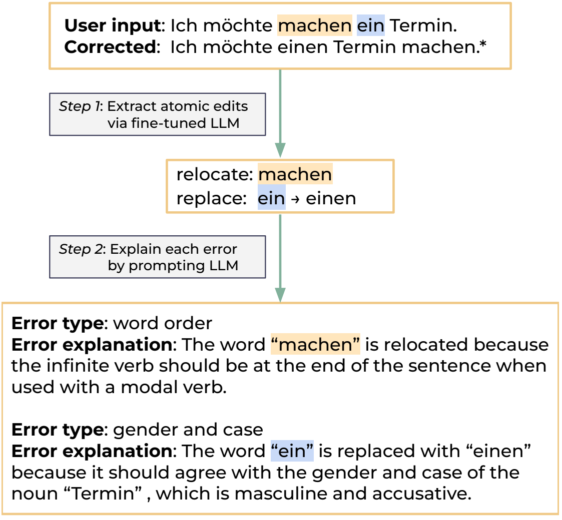
Abstract

Existing grammatical error correction tools do not provide *natural language* explanations of the errors that they correct in user-written text. However, such explanations are essential for helping users learn the language by gaining a deeper understanding of its grammatical rules (DeKeyser, 2003; Ellis et al., 2006).

To address this gap, we propose the task of *grammar error explanation*, where a system needs to provide one-sentence explanations for each grammatical error in a pair of erroneous and corrected sentences. The task is not easily solved by prompting LLMs: we find that, using one-shot prompting, GPT-4 only explains 40.6% of the errors and does not even attempt to explain 39.8% of the errors.

Since LLMs struggle to identify grammar errors, we develop a two-step pipeline that leverages fine-tuned and prompted large language models to perform structured atomic token edit extraction, followed by prompting GPT-4 to explain each edit. We evaluate our pipeline on German, Chinese, and English grammar error correction data. Our atomic edit extraction achieves an F1 of 0.93 on German, 0.91 on Chinese, and 0.891 on English. Human evaluation of generated explanations reveals that 93.9% of German errors, 96.4% of Chinese errors, and 92.20% of English errors are correctly detected and explained. To encourage further research, we open-source our data and code.[1]

1 Introduction



User input: Ich möchte machen ein Termin.
Corrected: Ich möchte einen Termin machen.*

Error type: word order
Error explanation: The word "machen" is relocated because the infinite verb should be at the end of the sentence when used with a modal verb.

Error type: gender and case
Error explanation: The word "ein" is replaced with "einen" because it should agree with the gender and case of the noun "Termin" , which is masculine and accusative.

* English translation: I would like to make an appointment.

Figure 1: An illustration of the two-step pipeline of grammar error explanation (GEE). Given a pair of sentences with corrected errors, the GEE system first extracts linguistically meaningful edit units as errors. The extracted errors are then paired with the sentences as the input for GEE generation. Note: The error in *einen* can be caused by *gender* or *case* or both. Without guessing the mental state of a language user, both are offered as the reasons in the explanation.

Grammatical error correction (GEC) is a practical and valuable application of natural language processing that facilitates both proofreading of text and language learning. Recent advances in large language models (LLMs) have significantly improved the capabilities of GEC systems (Wang et al., 2021; Bryant et al., 2023); however, they are unable to *explain errors in natural language* alongside providing correction. Error explanation is crucial to language learning and teaching (Ellis, 2010): while corrections are a form of implicit feedback, they are not as impactful as explicit feedback (DeKeyser, 2003; Ellis et al., 2006), which involves pointing out errors and providing meta-linguistic information to the user (e.g., rules of writing well-formed phrases or sentences).

In this work, we propose a new task—*grammar error explanation* (GEE)—for which a model must generate natural language error explanations that help language learners acquire and enhance grammar knowledge. As shown in Figure 1, given a pair of sentences in which one sentence has grammar

errors and the other one is corrected, a model needs to generate an explanation for each corrected grammar error. Given the capabilities of modern LLMs, one might ask whether LLMs can solve this task simply via prompting. We show in Section 3 that one-shot GPT-4 (OpenAI, 2023) prompting detects only 60.2% of the true errors and correctly explains only 67.5% of the errors it does detect.

Given this result, we develop a pipeline for GEE generation that features an essential intermediate step—atomic token edit extraction. As shown in Figure 1, given an erroneous sentence and its corrected counterpart (source and target), we first extract atomic edits at the token level by prompting or fine-tuning LLMs such as GPT-4, which also label the edits with one of four operation-level edit types: `insert`, `delete`, `replace`, and `relocate`.[2] In the second step, we append the extracted edits to the source and target sentences and use them as the input to a GEE system. We utilize the few-shot learning ability of LLMs (Brown et al., 2020) to generate error explanations using carefully crafted language-specific prompts.

We validate our GEE pipeline on German, Chinese, and English, three very different languages (fusional vs. analytical). We recruit language teachers to evaluate the correctness of the German and Chinese explanations. The English outputs are evaluated by the authors manually. For the first step in the pipeline, our atomic edit method extracts 92.3% of the true edits for German, which is 32.1% higher than the one-shot approach in Section 3. For the final GEE outputs in German, 93.9% of the generated explanations are judged as correct by two German teachers. Similar performance is observed in Chinese with a 96.4% correctness rate and 92.20% in English. The results suggest that our two-step pipeline together with carefully crafted language-specific prompts generalizes well for the three different languages.

In summary, our contributions are the following. First, we propose a new task on grammar error explanation to enhance the utility of current grammatical error correction systems. Second, we propose a two-step pipeline and study its performance in German, Chinese, and English with detailed error analysis. Third, we publicly release our atomic edit extraction datasets for German, Chinese, and English as well as all LLM-generated GEE outputs with the goal of enabling future research on GEE and facilitating the development of more effective GEE systems.

2 GEE task definition

While most GEC models provide viable grammar error corrections (Bryant and Ng, 2015; Bryant et al., 2023), they do not provide natural language explanations alongside the corrections, which are critical for language learners in mastering grammar (Ellis et al., 2006; Ellis, 2010). In this section, we propose and define the task of grammar error explanation, which aims to fill this gap. We assume that a GEE model has access to the outputs of an existing GEC model, which produces the corrected form of an ungrammatical input sentence.

2.1 Formalizing the GEE task

The input to a GEE model is a pair of sentences[3] in which one has (potentially multiple) grammar errors and the other is corrected. Concretely, let X_{error} be a sentence written by a user which contains grammatical errors. Then, $X_{correct} = GEC(X_{error})$ is the grammatically correct version of X_{error} produced by a GEC system. Following common practice in GEC research (Bryant et al., 2017; Lee et al., 2018; Rao et al., 2020), we assume that an error can be corrected in four ways: `insert`, `delete`, `replace`, and `relocate`. Let $c_1^X, c_2^X, ..., c_n^X$ be a list of corrections made by the GEC system to X_{error} through one of these four types of edits. Then, the goal of GEE is to generate single-sentence explanations in natural language $s_1^X, s_2^X, ..., s_n^X$ corresponding to each of $c_1^X, c_2^X, ..., c_n^X$ (example in Figure 1). Concretely,

Input: $X_{error}, X_{correct}$
Output: $s_1^X, s_2^X, ..., s_n^X$

2.2 Atomic edits as foundation of GEE

The quality of error explanation depends on how the correction list $c_1^X, c_2^X, ..., c_n^X$ is defined. Consider the corrections in (1). One way to define the correction list is through a string-based transformation (i.e., replace *machen ein termin* with *einen Termin machen*). However, an instructor explaining the corrections would naturally break them down into smaller units to facilitate understanding, for example, "*machen* must be moved to the end", "*ein* should be changed to *einen* to match gender and

---

[2] These types describe a general relationship between the source and target rather than precise edit operation of the source.

[3] In principle, the inputs could also be documents, but we restrict our work to sentence-level GEE.

case", and so on. On the other hand, for the corrections in (2), an instructor would naturally explain the change as a single edit involving the movement of a phrase; breaking down the explanation into multiple word movements would not help the writer to understand why the edit was made.

(1) **S**: Ich möchte machen ein termin.
T: Ich möchte einen Termin machen.

(2) **S**: I with my puppy go to the store.
T: I go to the store with my puppy.

When explaining a corrected sentence, we argue, experts will identify the smallest individual errors that are linguistically meaningful (i.e., "atomic errors") and provide roughly one explanation per atomic error. Doing so allows learners to follow and understand explanations better, especially when there are contiguous errors in the input. This requires a process of atomic error extraction, such as the one described intuitively for (1) and (2), which naturally uses the conventions of grammar, spelling, and language usage.

We treat each atomic error as an atomic edit and give a working definition of how to identify it. Using (1) as an example, an edit (*machen ein termin*) should be divided into smaller edits (*machen*, *ein*, and *termin*) if an expert would explain the whole edit as merely the concatenation of explanations for the smaller edits. These smaller edits are then atomic edits (i.e., each of which has its own distinct explanation). Similarly, if an expert would explain an edit with multiple words using one explanation that cannot be separated into the concatenation of several explanations, then that multi-word operation is one atomic edit (e.g., the relocation of *with my puppy* in (2)).

Our working definition of atomic edits provides guidance for extracting linguistically meaningful edits. However, language-specific decisions are needed for individual languages. We discuss such details in Section 4 and Appendix C.

2.3 Evaluation of GEE

We evaluate two critical aspects of GEE: error coverage and explanation quality.

Error coverage evaluation can be facilitated by forcing a model to generate position information of explained errors or to describe the edits being done. The evaluation is conducted by measuring (1) whether an explained error is indeed an error in the source and being corrected in the target; and (2) whether an error that is corrected in the target has an associated correct explanation.[4] An automatic evaluation through string overlap can give a quick estimate of error coverage when gold references are available. We also do manual evaluation to better understand the behavior of models.

Explanation quality evaluation is challenging because errors can be explained in multiple ways. To reliably evaluate GEE outputs automatically, multi-reference metrics such as METEOR (Banerjee and Lavie, 2005) and benchmarks with multiple references for each error are needed. However, collecting such datasets is costly and requires expertise in second language teaching. Another way of evaluating the explanations is to leverage LLMs. However, it is beyond the scope of the current paper to investigate whether LLMs are reliable when they evaluate their own outputs or when an evaluating LLM is less capable than the model that generates the outputs. Without a multi-reference dataset and a reliable way of using LLMs to evaluate LLM GEE outputs, leveraging human experts is the only reliable way to evaluate. In our work, we recruit language teachers for the evaluation described in Section 6.2. Language teachers, with their expertise in second language teaching, can reliably judge whether an explanation is correct and informative.

3 Has GPT-4 already solved GEE?

A natural question one might ask is whether state-of-the-art LLMs can solve the GEE task in an end-to-end manner. This section demonstrates that GPT-4 in its current form is error-prone. It has low error coverage and hallucinates frequently. Based on this observation, we experiment with an approach which provides GPT-4 with a list of manually-extracted gold atomic edits. Results show that access to this gold edit list improves the performance greatly, indicating substantial headroom with more structured prompting as we describe in Section 4.

One-shot prompting of GPT-4. We run an experiment using German grammar error correction data (details in Section 5). We randomly sample 30 data points[5] and generate explanations using the one-shot prompt in Appendix A.

GPT-4 struggles to identify and explain er-

---

[4] A GEE model should be able to ignore errors in the source sentence that are not corrected in the target sentence since GEC is not its primary task.

[5] Five data points from each CEFR level. Details are in Section 5.

rors. To get a better sense of what mistakes GPT-4 makes, we manually classify each edit as true positive, false positive, or false negative, depending on whether they are correctly mentioned in the generated explanations.[6] Our evaluation shows that GPT-4 mentioned 120 edits (compared to 90 manually extracted edits), achieving recall 0.602, precision 0.675 and F1 0.636. Among the correctly detected errors, GPT-4 only correctly explains 67.5% of them. Such outputs are not useful for learners.

GPT-4 makes mistakes even in short sentences. As the example in Table 1 shows, GPT-4 hallucinates that *Sie* is relocated. It also groups two errors together and omit the explanation of one error. The unorganized output format makes it hard to track the errors and follow the explanations.

Source: Bitte antworten sreiben Sie?
Target: Bitte antworten und schreiben Sie.

The word 'sreiben' is replaced by 'schreiben' because there was a spelling mistake in the word.
Error type: spelling

The word 'Sie' is relocated after 'antworten' and the word 'und' is inserted between 'antworten' and 'schreiben' because these are separate actions and should be connected with a conjunction.
Error type: word order and conjunction

Table 1: An example of GPT-4's GEE output with the one-shot prompt. The second explanation hallucinates that 'Sie' is relocated and does not give an explanation why it is relocated. The explanation also groups the relocation of 'Sie' with the insertion of 'und'.

What if GPT-4 was provided with gold edits in the prompt? To measure the headroom for improvement, we prompt GPT-4 in the same way but provide gold atomic edits extracted manually in the input prompt. As a result, the F1 of the errors coverage is increased to 0.968. Also, 82% of the true errors receive an appropriate explanation. Hence, offering a good atomic edit list to GPT-4 is an important intermediate step. This observation motivates our proposed pipeline in Section 4, where we augment GPT-4 prompts with automatically extracted atomic edits.

4 Pipeline for generating GEE

In Section 3, we observed that including a list of gold atomic edits to GPT-4's prompt greatly improves error coverage. We thus propose a two-step pipeline for GEE that uses atomic edit extraction as the intermediate step. The pipeline is illustrated in Figure 1. Given an input sentence pair defined in Section 2.1, we first extract atomic edits from the pair following Section 2.2. The edits are then appended to the sentences to form the input for the final step, where GPT-4 is prompted to generate an explanation and an error type.

4.1 Atomic edit extraction

As discussed in Section 2.2, we define an atomic edit as the smallest individual modification that requires one explanation. Each edit belongs to one of the four operation types: `replace`, `insert`, `delete`, and `relocate`.

Previous work on edit extraction. The ERRANT system of Bryant et al. (2017) approaches edit extraction via a linguistic rule-based approach, but it has its limitations. For example, ERRANT does not account for relocated words.[7] It is also only designed for English. Adapting it to other languages requires great effort (Korre et al., 2021; Uz and Eryiğit, 2023). Further limitations of ERRANT are discussed in Appendix B. As such, we decide to use LLMs for atomic edit extraction.

Desired LLM output format. To facilitate the evaluation of edit extraction and (later) GEE generation, we restrict atomic edit extraction outputs to a template `[operation type, original token(s), target token(s)]`. An example with all four edit types is given in (3).

(3) möchte **machen ein** Termine.**?**
Ich möchte **einen** Termine **machen**.
`[insert, , Ich]`
`[relocate, machen, machen]`
`[replace, ein, einen]`
`[delete, ?, ]`

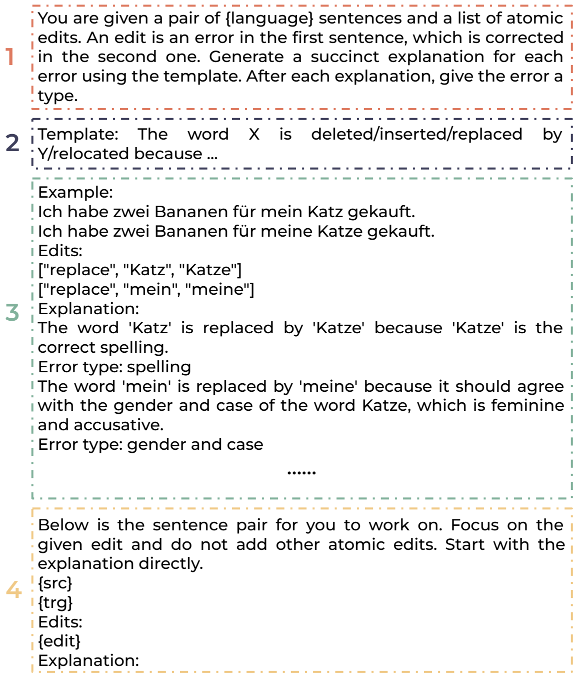
While being useful for GEE, the edit type `relocate` occasionally reduces the model performance because models tends to label a relocated token as deletion plus insertion. Relocation can also be challenging for human to decide because a relocated word should be a word order error but have the same dependency in a sentence before and after relocation. We discuss details in Appendix C.

Atomic edit extraction with LLMs. To build an atomic edit extractor, we choose to prompt Claude-

---

[6] *Correctly mentioned* means whether one can arrive from the source to the target through the edits.

[7] It accounts for local transposition (e.g., *juice apple* vs. *apple juice*) in the original design but does not do so in BEA-2019 (Bryant et al., 2019).



1 You are given a pair of {language} sentences and a list of atomic edits. An edit is an error in the first sentence, which is corrected in the second one. Generate a succinct explanation for each error using the template. After each explanation, give the error a type.

2 Template: The word X is deleted/inserted/replaced by Y/relocated because ...

3 Example:
Ich habe zwei Bananen für mein Katz gekauft.
Ich habe zwei Bananen für meine Katze gekauft.
Edits:
["replace", "Katz", "Katze"]
["replace", "mein", "meine"]
Explanation:
The word 'Katz' is replaced by 'Katze' because 'Katze' is the correct spelling.
Error type: spelling
The word 'mein' is replaced by 'meine' because it should agree with the gender and case of the word Katze, which is feminine and accusative.
Error type: gender and case

……

4 Below is the sentence pair for you to work on. Focus on the given edit and do not add other atomic edits. Start with the explanation directly.
{src}
{trg}
Edits:
{edit}
Explanation:

Figure 2: The prompt used for generating German grammar error explanation given an input defined in Section 2. The prompt consists of: (1) task description, (2) generic explanation template, (3) few-shot examples, and (4) current input. The full prompts for German and Chinese are in Appendix E.

2,[8] GPT-3.5-turbo-0613, and GPT-4 (via Azure's 2023-03-15-preview), as well as fine-tune Llama2-7B and GPT-3.5-turbo. For prompting, we use the carefully designed few-shot prompts in Appendix D. For fine-tuning, we use Llama2-7B and GPT-3.5-turbo as the base models. We noticed that the models have a low recall when only sentence pairs are provided. To improve on that, we split sentences into a list of tokens and extract rough string-based edits which are the longest contiguous matching subsequences.[9] These rough edits are appended to sentence pairs as inputs. For all models, prompted or fine-tuned, we set temperature to 0 because the task does not require creativity.

4.2 GEE generation

Having extracted atomic edits, we are now ready to generate GEE. Given that each sentence pair may contain multiple errors, we investigated whether generating explanations for one error at a time or all explanations simultaneously would yield better results. In the prompt designing stage, we observed no significant difference in performance between the two approaches. Hence, we choose the latter strategy as it is efficient and cost-effective.

Figure 2 gives a shortened example of the German GEE prompt. Edits are incorporated into the input to provide context and guidance for the model. The full prompts for the three languages are in Appendix E. The prompts consists of four parts. The first part is the **task description**, which is followed by a generic **template** of explanations. Below the template are few-shot **examples**. In the examples, we aim to offer both meta-linguistic and meaning-oriented explanations whenever it is possible as they help L2 users improve their language skills (i.e., using languages accurately and fluently) (Lyster and Saito, 2010). At the end of the prompt, we provide GPT-4 the **sentence pair with a list of atomic edits** and ask the model to generate one explanation with an error type for each edit. The generated outputs have the following format:

```
[edit description] because [edit reason]
Error type: [error type]
```

The edit description describes how a word in the source sentence is edited in the target sentence. The edit reason explains why such an edit is made.

5 German, Chinese, and English datasets

This section introduces the datasets that are used in our experiments. Statistics of the sampled data subsets are reported in Table 2.

	German		Chinese		English	
	pairs	edits	pairs	edits	pairs	edits
Fine-tune	500	1598	496	790	512	1237
Test	50	186	53	94	57	154
GEE	1122	–	970	–	93	–

Table 2: Number of sentence pairs and gold edits in each data subset in German, Chinese, and English. We do not manually annotate the edit data for GEE, hence no gold edit count is reported.

5.1 German Merlin and Falko

For German GEE, we use the data from the German L2 learner corpora Falko EssayL1v2.3 (Ludeling et al., 2008; Reznicek et al., 2010) and Merlin (Boyd et al., 2014). Both datasets consist of essays written by German users whose proficiency ranges from beginners to advanced levels. The datasets provide corrections of errors. The datasets are preprocessed as described in Appendix F.1.

---

[8] Accessed in November 2023 for German and Chinese, and January 2024 for English. anthropic.com/index/introducing-claude

[9] We use Spacy for German and English and Jieba for Chinese.

From the preprocessed dataset, we sample two subsets without overlaps between them. First, we sample 550 data points and manually annotate them for gold atomic edits. The 550 data points are split into 500 for fine-tuning and 50 for testing, each containing 1598 and 186 gold edits. Second, for GEE generation, we sample all A1 data points (146) and randomly sample 200 data points from other CEFR levels (A2–C2). We manually remove sentence pairs that are misaligned. At the end, we obtain 1122 sentence pairs in German for GEE.

5.2 Chinese CGED2017

We conduct the Chinese GEE experiment on the training split of Chinese Grammatical Error Diagnosis (CGED) 2017 (Rao et al., 2020), which are from the writing task of the *Hanyu Shuiping Kaoshi* (Test of Chinese Level) (Cui and Zhang, 2011; Zhang and Cui, 2013). Error corrections are provided but there is no learner proficiency level information. Data are preprocessed as in Appendix F.2. We sampled 520 and 60 data points for fine-tuning/prompting edit extraction models and testing performance respectively. We sample another 970 data points for generating error explanations. After cleaning, we have 496 data points for fine-tuning, 53 for testing, and 970 for explanation generation. Edit counts are in Table 2.

5.3 English BEA-2019

We utilize W&I+LOCNESS dataset from BEA-2019 (Bryant et al., 2019). The dataset contains essays on 50 topics written by English learners with the CEFR levels A, B, and C, as well as data from native English users. The W&I+LOCNESS dataset is annotated by ERRANT (i.e., the edits). From each CEFR level, we sample 520, 60, and 100 for training, test, and GEE respectively. We manually cleaned the sampled data by removing nonsensical sentence pairs as well as split and converted ERRANT edits according to the criteria in Section 2.2 and 4.1. The size of each data split after cleaning is reported in Table 2.

6 Experimental results

This section presents the results of the GEE pipeline in German, Chinese, and English. We first present the results of the fine-tuned and prompted models on atomic edit extraction in each language. The fine-tuned GPT-3.5-turbo achieved the best performance on edit extraction for German and English but GPT-4 works the best for Chinese. Section 6.2 presents the human evaluation results of GEE outputs generated by GPT-4. Among the German GEE outputs, 93.9% are judged as correct by two German teachers. For Chinese GEE outputs, 96.4% of the outputs are correct according to two Chinese teachers. For the English GEE outputs, 92.20% of the outputs are correct according to our manual evaluation.

	Claude-2	Llama2-7B	GPT-3.5-turbo		GPT-4
	Prompting	Fine-Tuned	Prompting	Fine-Tuned	Prompting
Recall	0.789	0.849	0.695	**0.923**	0.875
Precision	0.737	0.827	0.764	**0.939**	0.889
F1	0.762	0.838	0.728	**0.931**	0.882
Edit Count	199	191	161	180	180.33

Table 3: Recall, precision, and F1 scores of models on the German atomic edit extraction task. Because of the variance in GPT-4 outputs, the outputs are generated three times and the average performance is reported.

6.1 Atomic edit extraction results

We first describe our experimental setup then dive into the performance of fine-tuned and prompted models. Results are presented in Tables 3, 4, and 11 for German, Chinese, and English respectively.

Experiment setup. We few-shot prompt Claude-2, GPT-3.5-turbo, and GPT-4 with the prompts in Appendix D. For fine-tuning, we use Llama2-7B and GPT-3.5-turbo as the base models and fine-tune them on the 500 training data points in Table 2. Details of the fine-tuning process are in Appendix G. At inference time, the temperature of all models is set to 0. We employ simple heuristics to post-process model outputs to remove low-level false positive errors, such as replacement edits that have the same original and edited tokens.

Evaluation. While automatic evaluation is fast, we evaluate the test data manually because there can be multiple ways to get to a target sentence from a source sentence. Concretely, we compare model edits against the manually extracted gold edits one by one. When there is a discrepancy, if the model outputs are linguistically meaningful and can reach the same target, we treat them as true positives.

Results on German: fine-tuned GPT-3.5-turbo is most effective at atomic edit extraction. The results for German edit extraction in terms of precision, recall, and F1 are in Table 3. The fine-tuned GPT-3.5-turbo achieves 0.923 in recall, 0.939 in precision, and 0.931 in F1, outperforming other models. We use it as the atomic edit extractor in the next step in German GEE generation.

	Claude-2 Prompting	Llama2-7B Fine-Tuned	GPT-3.5-turbo Prompting	 Fine-Tuned	GPT-4 Prompting
Recall	0.872	0.840	0.763	0.830	**0.888**
Precision	0.820	0.908	0.651	0.918	**0.924**
F1	0.845	0.873	0.703	0.872	**0.906**
Edit Count	100	87	109	85	91.67

Table 4: Recall, precision, and F1 scores of models in the Chinese atomic edit extraction task. Because of the variance in GPT-4 outputs, the outputs are generated three times and the average performance is reported.

Results on Chinese: prompted GPT-4 is the most effective edit extractor. The results are reported in Table 4. Unlike German, the prompted GPT-4 returns the best performance. Because of the variance in the GPT-4 outputs, we verify its performance by running the experiment three times. All three runs of GPT-4 return the highest scores. The average results of GPT-4 are recall 0.888, precision 0.924, and F1 score 0.906. We hypothesize that the reason of the prompted GPT-4 performing well on Chinese is that each Chinese sentence pair has less edits on average (see Table 2). The same reason leads to the fact that there are less edits in the training data, which might cause the fine-tuned models perform worse than the ones in German.

Results on English: fine-tuned GPT-3.5-turbo performs the best in edit extraction. Although the fine-tuned GPT-3.5-turbo does not achieve the best score in recall, it has the highest precision and F1. Given that incorrectly extracted edits might cause GPT-4 to generate incorrect explanations which in turn confuse end users, we value the higher precision score more and choose the fine-tuned GPT-3.5-turbo as the edit extractor in the English GEE generation.

6.2 Human evaluation of GEE

To evaluate the performance of our GEE pipeline, we recruited two German teachers and two Chinese teachers to evaluate the German and Chinese GEE outputs.[10] The English GEE outputs are evaluated manually by the authors. This section provides quantitative results from the human evaluations of GPT-4 on the generated GEEs. Detailed qualitative analysis is in Appendix I.

The results indicate that our GEE pipeline generates explanations of which 93.9%, 96.4%, and 92.20% are correct for German, Chinese, and English respectively. However, we find that GPT-4 occasionally produces low-level errors such as formatting issues. For Chinese, when it comes to word choice errors, GPT-4 does not always provide clear contrast between two words. It also produces overly general error types.

6.2.1 Human evaluation of German GEE

German GEE generation. Using the best performing edit extractor from Section 6.1, we extract atomic edits from the 1122 sentence pairs described in Section 5. The extracted edits are paired with the source and target sentences to prompt GPT-4 using the few-shot prompt in Appendix E.1. We use the default hyperparameters offered by the OpenAI API (i.e., temperature = 1 and top p = 1) for some creativity in the explanations.

German GEE evaluation setting. The annotation interface is shown in Figure 4. We collected annotations on error explanations of 596 unique German sentence pairs. To assess the agreement between the teachers, 96 pairs are annotated by both of them. A total of 692 sentence pairs were annotated for this study.[11] The two teachers' agreement rate is 89.6%. Details of the agreement assessment and evaluation instructions are in Appendix H.

Human annotation protocol for evaluating GEE. For each sentence pair, we present the explanations generated by GPT-4 to the teachers, who are asked to check for four types of mistakes:[12]

- **Hallucinated error**: an error in an explanation that does not exist in the source sentence. Such a mistake can be made by considering a correct word/punctuation as an error, or it can be a word that does not exist in the sentences at all.
- **Missing error**: an error in the source which is edited in the target but not explained.
- **Wrong error explanation**: wrong edit description, wrong edit reason, or both.
- **Wrong error type**: an error type that is not related to the explained error.

German GEE using edit-driven GPT-4 prompts has high quality. The counts of each mistake type are reported in Table 5. The results show that GPT-4 generates correct explanations 93.9% of the time. The occurrences of inappropriate error types and hallucinated errors are both below 1%. Among the

---

[10] Both German teachers give classes 15 to 20 hours per week. One Chinese teachers teaches 4 classes a week and the other 22-28 hour a week.

[11] There are 2082 edits extracted from 692 sentence pairs, but GPT-4 only generates explanations for 1986 of them.

[12] We call grammar errors in sentences as errors and errors made by GPT-4 as mistakes.

	Count	Percentage
Fully correct	1865	93.9%
Wrong error explanation	94	4.7%
Wrong error type	12	0.6%
Hallucinated error	15	0.8%
Total explanation count	1986	100%
Total annotated items	692	
Missing error	67	

Table 5: Results of human evaluation on German GEE by two German teachers. 692 sentence pairs with 1986 explanations are annotated. GPT-4 generates fully correct edit description, edit reason, and error type 93.9% of the time. There are 4.7% *wrong error explanation* mistakes. The count of *missing errors* by the teachers is the lower bound of the actual ones.

	Count	Percentage
Fully correct	504	96.37%
Wrong error explanation	10	1.91%
Wrong error type	9	1.72%
Hallucinated error	0	0.0%
Total explanation count	523	100%
Total annotated items	356	
Missing error	1	

Table 6: Results of human evaluation on Chinese GEE by two Chinese teachers. 96.37% of the generated explanations are judged as correct. 356 sentence pairs with 523 explanations are annotated. The evaluation criteria are the same as for German.

94 *wrong error explanations*, 65 are wrong in the edit description but correct in edit reason. Among those 65 edit description mistakes, as many as 31 are because GPT-4 describes inserted and deleted edits as *The word '' is inserted/deleted because ...* without mentioning the word itself. Among the 15 hallucinated errors, 12 are caused by wrong atomic edit extraction and 3 are hallucinated by GPT-4 in the process of generating explanations.

Remaining issues. To gain a deeper understanding of GPT-4's limitations, we look into its mistakes in detail and notice that GPT-4 does not include enough context for certain errors in its explanations, especially when it comes to prepositions. For example, when explaining the error in *mit 2 Zimmer* vs. *mit 2 Zimmern*, GPT-4 only says that the dative case is needed here but does not explain that the dative case is required by the close-by preposition *mit*. We provide a detailed analysis of other errors in the GPT-4 outputs in Appendix I.

6.2.2 Human evaluation of Chinese GEE

To understand how generalizable our pipeline is to different types of languages, we evaluate its performance on Chinese using the CGED2017 data described in Section 5. Two Chinese teachers evaluated Chinese GEE outputs on 356 sentence pairs with 523 explanations.[13] The annotation task is set up in the same way as German. The agreement rate is 92.9% (see Appendix H).

Positive findings. Among the 356 annotated explanations, 96.37% are judged as correct by the Chinese teachers. GPT-4 has low mistake rates in all four mistake types. This shows that the proposed pipeline is effective and adaptable for very different languages like German and Chinese.

Remaining issues. While GPT-4 achieves high correctness rate in Chinese GEE, there are three caveats. First, during the data annotation for gold atomic edits, we notice that most of the edits are simple and can be readily extracted by a string-based tool. The reason is that each sentence pair on average has fewer edits than in the German data (see Table 2). Second, GPT-4 often generate generic error types. For example, it considers *idiomatic expression* errors as simply *word choice* errors. Third, for true word choice errors, GPT-4 does not always give a clear comparison of word meanings. For example, in (4), GPT-4 only explains what 严重 (serious) means but not why 严重的问题 (serious problem) is good but 严重性的问题 (seriousness problem) is not.

(4) 严重性的问题 → 严重的问题
The word '严重性' is replaced with '严重' because '严重' is the correct word for 'serious' when describing the severity of a problem.

Because word choice is a prevalent problem in Chinese grammar errors (see Table 14 for error types generated by GPT-4), such clear comparisons should be enforced in an explanation so that language learners can draw inferences about other cases from the current error.

6.2.3 Human evaluation of English GEE

We evaluate our pipeline on a subset of W&I+LOCNESS (Bryant et al., 2019). There are 93 sentence pairs with 210 explanations.[14] The

---

[13] There are 543 edits extracted from the 356 sentence pairs. GPT-4 only generates explanations for 523 of them.

[14] There are 208 extracted English atomic edits.

annotation task is conducted in the same way as German. The results are reported in Table 12.

Positive findings. With the extracted atomic edits, 92.20% of the generated outputs from the prompted GPT-4 have the correct explanation and error type. All of the error types but one are appropriate. During the annotation, we notice that, unlike in Chinese GEE, GPT-4 often provides an appropriate comparison of words for word choice errors, explaining why one word is better than the other, as in (5).

(5) The word 'let' is replaced by 'make' because the phrase 'make it happen' is more appropriate, it implies that he is taking action to ensure the event occurs, while 'let it happen' implies that the event is happening on its own and he is merely allowing it.

Remaining issues. While GPT-4 provides word meaning comparisons in most cases, the explanation is not always correct. For example, when clarifying the difference between 'the best' and 'the most', GPT-4 states that 'best' is used when there is a comparison between multiple items while 'most' is used when there is no such a comparison.

7 Related work

Our GEE task is built on the actively studied GEC task, which is often formulated as a neural machine translation task (Boyd, 2018; Bryant et al., 2023; Yuan and Bryant, 2021; Zhang et al., 2022). Researchers have explored various aspects of GEC. We identify three of them which the GEE task can be built on and benefit from. After that, we compare our task to a related task, feedback comment generation, and show how GEE is different from it.

GEC with multi-reference and context. Research has been building GEC models on data which have only one gold reference for each source input. However, there is an urge to use multiple references for source inputs (Bryant and Ng, 2015; Zhang et al., 2022; Xu et al., 2022). In the context of GEE, a capable model should generate well-suited explanations for *any* valid error corrections, which requires reasoning of word relations and recovering correction rationales. Such ability of GEE models also need to go beyond the sentence level. Wang et al. (2022) has shown that even when only one sentence is added to the input as the context, a GEC model's performance can be significantly boosted. If some errors can only be better corrected in context, they can only be better explained in context as well.

GEC with auxiliary grammar information. Existing works have shown improvement of GEC models by adding edit types, dependency information, or grammatical error type into the training process (Omelianchuk et al., 2020; Ma et al., 2022; Yang et al., 2023). Fei et al. (2023) study the influence of adding evidence words for errors and error types into the pipeline of GEC. They found that such information can significantly increase model performance in English GEC. For the GEE task, it is an interesting direction to explore whether adding those extra information to a GEE system can improve its explanations' usefulness.

GEC with retrieved examples. Kaneko et al. (2022) propose to involve retrieved examples into the GEC task, which not only improve the GEC model's performance but also increase the end users' confidence in deciding whether or not to accept a correction. GEE explanations with examples would be a good combination for end users to generalize what they learn from the current error, hence enhancing the knowledge.

Feedback alongside grammar error detection Nagata et al. (2021) proposed a shared task called *feedback comment generation for language learners* (FCG). The task differs from our GEE task in three important aspects. First, the inputs in FCG are erroneous sentences only, which have spans marked as errors. Hence, the FCG task does not need to extract meaningful atomic edits. Second, the FCG task focuses solely on preposition words, which are a closed set of function words whose occurrences and usages are limited. Third, the FCG task focuses on generating comments as hints for language learners to correct errors themselves (e.g., *Look up the use of the <verb> X in a dictionary and rewrite the sentence using the appropriate structure.*).

8 Conclusion

We present a new task grammar error explanation to provide natural language explanations to grammatical errors. We develop a pipelined approach using LLMs and atomic token edit extraction. Our LLM-based pipeline gets a high score of 93.9% in German, 96.37% in Chinese, and 92.20% in English error explanation.

While we assume a grammar error correction system as the foundation of our GEE system, further work are encouraged to explore GEE generation alongside GEC.

Limitations

We acknowledge two limitations of our current work. First, our grammar error explanation system only considers sentence level inputs. However, certain error types (e.g., word choice and coreference) can benefit from a larger context. Second, because the Chinese data used in our work are from the HSK test (Test of Chinese Level), the covered topics are limited. It also does not include data from learners from all proficiency levels. Hence, the error types might not be representative for all levels of Chinese learners. Third, due to the time limitation, we did not hire English language teachers to evaluate the English GEE outputs. However, through annotating the English GEE outputs, we gain a deeper understanding of GPT-4's performance on English, a well-studied language in NLP.

Ethical Considerations

Overall, our project had a small computational cost since we used QLoRA (Dettmers et al., 2023) for efficient model fine-tuning on one RTX8000. Although we do not know how GPT-3.5-turbo finetuning is done, each round of GPT-3.5-turbo finetuning took about 30 minutes. All fine-tuning and inference experiments in this paper can be completed within a day.

For the annotation work, we estimated that each annotated item on average would take one minute. As a result, we paid annotators $15 per hour. Additional bonus are paid for reasonable extra time spent on the task.

Acknowledgements

We extend special gratitude to the Upwork annotators for their hard work, and to members from the UMass NLP lab for their feedback. We would also like to thank George Wang, Brendan Chambers, and team members in Quillbot for their valuable advises and help during the internship of the first author.

This project was partially supported by awards IIS-2202506 and IIS-2312949 from the National Science Foundation (NSF).

A One-shot prompt for GPT-4

We use the following one-shot prompt for the German experiment in Section 3 which shows that GEE cannot be solved end-to-end by GPT-4.

```
You are given a pair of German sentences. The
    first sentence contains one or more errors,
    which are corrected in the second one. Your
    task is to: (1) generate a succinct
    explanation for each error following the
    template; (2) assign the error a type.

Template: The word X is deleted/inserted/
    replaced by Y/relocated because ...

Example:
Ich habe zwei bananen für mein Katze gekauft.
Ich habe zwei Bananen für meine Katze gekauft.
Explanation:
The word 'bananen' is replaced by 'Bananen'
    because German nouns should be capitalized.
Error type: capitalization
The word 'mein' is replaced by 'meine' because
    it should agree with the gender and case of
    the word Katze, which is feminine and
    accusative.
Error type: gender and case agreement

Below is the sentence pair for you to work on.
    Start with the explanation directly.
{src}
{trg}
Explanation:
```

B Reasons of not using ERRANT

ERRANT (Bryant et al., 2017) is an effort to standardise datasets for GEC, reduce annotators' burden, and offer feedback to instructors and learners. It does so by offering a tool that automatically extracts and labels edits in the format of `operation:linguistic feature`.

ERRANT would have been ideal for our purpose. Concretely, this would have been ideal for the edit extraction in Step 1 and error type tagging in Step 2. However, ERRANT has several shortcomings for our purpose.

First, ERRANT is designed only for English and its error type tagging process is based on a English rule-based framework. Extending it to another language will take great effort (Korre et al., 2021; Uz and Eryiğit, 2023).

Second, there is ambiguity in ERRANT's error type names. For example, `R:ADV` is a possible error type in ERRANT in which `R` stands for replacement and `ADV` stands for adverb. But it is not clear, as it stands, whether it represents only an adverb being replaced by another adverb, or it could be the case that a word of other category is replaced by an adverb.

Third, Korre and Pavlopoulos (2020) show that ERRANT can falsely or ambiguously tag errors. In their work, they use ERRANT to tag the errors in the FCE dataset (Yannakoudakis et al., 2011). They then sample 100 sentence pairs to whose errors ERRANT assigned the type `Other`. They examine those sentence pairs and found that up to 39% of the data point could have been assigned a more precise label.

Fourth, ERRANT's underlying edit extractor does not account for non-local token relocation (Felice et al., 2016). The extractor aligns the tokens in the erroneous and correct sentences and assign one of the following labels to spans: `M(atch)`, `I(nsertion)`, `D(eletion)`, `S(ubstitution)`, and `T(ransposition)`. For a relatively locally relocated token, the extractor assigns the label `T` to the span as in (1). However, for a less local token relocation such as (2), the extractor treats it as being deleted then inserted.

(1) Ich$_0$ möchte$_1$ **haben$_2$** einen$_3$ Apfel$_4$.$_5$

Ich$_0$ möchte$_1$ einen$_2$ Apfel$_3$ **haben$_4$** .$_5$

`(‘M’, 0, 1, 0, 1)`

`(‘M’, 1, 2, 1, 2)`

`(‘T3’, 2, 5, 2, 5)`

`(‘M’, 5, 6, 5, 6)`

(2) Ich$_0$ möchte$_1$ **haben$_2$** einen$_3$ roten$_4$ Apfel$_5$.$_6$

Ich$_0$ möchte$_1$ einen$_2$ roten$_3$ Apfel$_4$ **haben$_5$** .$_6$

`(‘M’, 0, 1, 0, 1)`

`(‘M’, 1, 2, 1, 2)`

`(‘D’, 2, 3, 2, 2)`

`(‘M’, 3, 4, 2, 3)`

`(‘M’, 4, 5, 3, 4)`

`(‘M’, 5, 6, 4, 5)`

`(‘I’, 6, 6, 5, 6)`

`(‘M’, 6, 7, 6, 7)`

Relocation of tokens would be a useful label to have for word order errors, which are prevalent in elementary L2 German and Chinese learners. With this label, we could explain why a token is relocated rather than explaining why it is deleted first then explaining why it is inserted.

C Guidelines for manual edit extraction Annotation

To prepare the data for fine-tuning models to extract atomic edits in German and Mandarin Chinese, we manually annotated 500 data points for each language. In this section, we discuss the challenges in extracting atomic edits and how we handle them.

The first step is to tokenize sentences. For German, it is straightforward because of white spaces. We use `SpaCy` for tokenizing German sentences which can single out punctuation marks. For Chinese, sentences cannot be tokenized into words by simply separating characters because many words are not monosyllabic. We choose to use Jieba, which is a fast and accurate Chinese word segmentation module implemented in Python.

The second step is to use `SequenceMatcher` from `difflib` to extract longest edited spans from sentence pairs, which is later used as part of the input for atomic edits. We found that adding rough edits into the input increases the recall of the prompted models. It also accelerates and eases the process of manual annotation.

The third and last step is to get atomic edits. There are four types of edits: `replacement`, `deletion`, `insertion`, and `relocate`. The challenge lies in how to align words in sentence pairs and extract edits.

For German, **replacement** mostly happens between tokens which have similar spelling (e.g., *wolle* and *will*, meaning *want to*) or the same categories (e.g., *zu* and *nach*, meaning *to*). **Deletion** and **insertion** can happen to individual tokens or a phrase. When more than one consecutive tokens, for example, X and Y, are deleted or inserted, we determine whether to count them as separate edits or one as a whole depending on whether X and Y form a linguistic constituent (for example, a prepositional phrase *by train*). The edit type **relocation** is inspired by a common error made by elementary German learners: placing finite verbs or adverbial phrases in the wrong position.[15] To emphasize that the usage of a word is not wrong but its position in a sentence is wrong, tagging such an edit as relocated is more intuitive than tagging it as a deletion followed by an insertion (or an insertion followed by a deletion).

The introduction of the relocation edit type is not at no cost. It reduces model performance because models tends to predict a relocated token/phrase as deletion plus insertion. It is also challenging because the relocated word should be just placed

---

[15] German is a verb second language, whose verb second constraint does not hold in embedded clauses. In main clauses, the finite verb occurs in the second position and non-finite verbs occur towards the end of a sentence. In embedded clauses, the finite verb usually appears at the end, after all the non-finite verbs.

in a wrong position and have the same dependency in a sentence before and after being relocated. For example, for the sentences in (6), it is illogical to say that the first sentence is corrected by relocating *for* to the first underline and insert *to* in the original place of *for*. This is because the verb *talk* requires a preposition but the language user mistakenly used *for* instead of *to*. It is not the case that the language user mistakenly put the *for* that should have been before *me* after *talking*. So, it should be the case that *for* is inserted to the position of the blank underline and the *for* after *talking* is replaced by *to*. The correct edits for (6) are given in (7) and the wrong edits are in (8).

(6) **S**: This job is exciting __ me because I like talking for different people.
T: This job is exciting for me because I like talking to different people.

(7) Good edit extraction
`[‘insert’, ‘’, ‘for’]`
`[‘replace’, ‘for’, ‘to’]`

(8) Bad edit extraction
`[‘relocate’, ‘for’, ‘for’]`
`[‘insert’, ‘’, ‘to’]`

On the other hand, the word *essen* in (9) is more naturally a relocated token because its relation with the finite modal verb *moöchte* (would like to) and the direct object *vierzig Bananen* (forty bananas) remains unchanged. It is only the position of the word that is changed.

(9) **S**: Ich möchte essen vierzig Bananen.
T: Ich möchte vierzig Bananen essen.
`[‘relocate’, ‘essen’, ‘essen’]`

For Chinese, deletion and insertion work similarly as in German. Relocation is also useful in Chinese for cases like misplacement of an adverbial phrase or a function word (e.g., 了).[16] However, replacement is not as straightforward in Chinese as in German. For example, verbs in Chinese often come with a resultative complement (e.g., 到, 完, or 出) or other function words to express different states of a verb (e.g., 过). If only the function word is changed but the verb is not, how should the edit be extracted? We experimented with both ways (with and without verbs) and found that, in either case, GPT-4 included the verb when explaining the meaning difference. Hence, for those cases, we always include the unchanged verbs, as in (10). Similarly, for cases in which a function word is not changed but the verb that the function word is attached to is changed, the edit includes both the verb and the function word (e.g., `[‘replace’, ‘看成’, ‘当成’]`).

(10) **S**: 我花了一整天看过了这本书。
T: 我花了一整天看完了这本书。
`[‘replace’, ‘看过’, ‘看完’]`

Other situations in which we always take longer phrases as edits rather than only the parts being changed are idioms (e.g., `[‘replace’, ‘心急如坟’, ‘心急如焚’]`), formulaic expressions (e.g., `[‘replace’, ‘总上所述’, ‘综上所述’]`), and *de* (的)+ noun as in 在这紧急的情况下 (in an emergency situation).

D Prompts for atomic edit extraction

We use the prompts presented below for atomic edit extraction in German, Chinese, and English. The prompt contains the task instruction followed by possible edit types as well as examples. Special instructions are given to the relocation edit type where the relocated tokens should be the same before and after the edit. In the examples, we demonstrate different edit types and their combinations, showing the models how to deal with a sentence pair with multiple edits.

D.1 Extraction prompt for German

```
This is an atomic edit extraction task. Given a
    pair of German sentences and the edits
    applied to the first sentence to get the
    second sentence, your task is to break down
    the edits to the atomic level (i.e., token
    level) and assign the edit a label. Be case
    sensitive. Pay attention to punctuation
    marks and relocated tokens. Pay attention to
     phonetic similarity when aligning tokens.

Labels:
1. [replace, original_token, edited_token]
2. [delete, original_token, ""]
3. [insert, "", edited_token]
4. [relocate, original_token, edited_token]: pay
     attention to tokens that are deleted then
    added again; the relocated token must be the
     same before and after the edit.

Examples:
Wie oben schon erwähnt ist die Chance erwisht
    zurweden zwar gering, aber sie ver handen.
Wie oben schon erwähnt ist die Chance, erwischt
    zu werden, zwar gering, aber sie ist
    vorhanden.
```

---

[16] 了 is a multi-functional function word and a heteronym. It can express the completion or ongoingness of an action (among its other functions). Its meaning changes based on the position in a sentence it occurs.

```
Edits:
('replace', 'erwisht zurweden', ', erwischt zu
    werden ,')
('replace', 'ver handen', 'ist vorhanden')
Atomic edits:
["insert", "", ","]
["replace", "erwisht", "erwischt"]
["replace", "zurweden", "zu werden"]
["insert", "", ","]
["insert", "", "ist"]
["replace", "ver handen", "vorhanden"]

ich haben essen zwei Bananen.
Ich habe zwei Bananen gegessen.
Edits:
('replace', 'ich haben essen', 'Ich habe')
('insert', '', 'gegessen')
Atomic edits:
["replace", "ich", "Ich"]
["replace", "haben", "habe"]
["delete", "essen", ""]
["insert", "", "gegessen"]

Ich habe gegessen zwei Bananen.
Ich habe zwei Bananen gegessen.
Edits:
('delete', 'gegessen', '')
('insert', '', 'gegessen')
Atomic edits:
["relocate", "gegessen", "gegessen"]

Below is the sentence pair for you to work on.
    Follow the format in the examples strictly.

D.2 Extraction prompt for Chinese

You are a Mandarin Chinese teacher. Given a pair of Mandarin Chinese sentences and the edits applied to the input sentence to get the output sentence, your task is to break down the edits to the atomic level (i.e., token level) and assign the edit a label. Pay attention to punctuation marks and relocated tokens.
Labels:
1. [replace, original_token, editted_token]
2. [delete, original_token, ""]
3. [insert, "", editted_token]
4. [relocate, original_token1, editted_token1]: pay attention to tokens that are deleted then added again; the relocated token must be the same before and after the edit.
Examples:
我去市菜场水果买。
我去菜市场买水果。
Edits:
("replace", "市菜场水果买", "菜市场买水果")
Atomic edits:
["replace", "市菜场", "菜市场"]
["relocate", "水果", "水果"]
我吃了早饭今天。
我今天吃了早饭。
Edits:
("insert", "今天", "")
("delete", "", "今天")
Atomic edits:
["relocate", "今天", "今天"]
再子细的学习相关课题后，我意识到了这个问题的严重。
在仔细地学习了相关课题后，意识到了这个问题的严重性。
Edits:
("replace", "再子细的", "在仔细地")
("insert", "", "了")
("insert", "", "我")
("insert", "", "性")
Atomic edits:
["replace", "再", "在]
["replace", "子细", "仔细"]
["replace", "的", "地"]
["insert", "", "了"]
["insert", "", "我"]
["replace", "严重", "严重性"]
她打算明儿天的午前去北京。
她打算明天上午去北京。
Edits:
("replace", "明儿天的午前", "明天上午")
Atomic edits:
["replace", "明儿天", "明天"]
["delete", "的", ""]
["replace", "午前", "上午"]

D.3 Extraction prompt for English

```
This is an atomic edit extraction task. Given a
    pair of English sentences and the edits
    applied to the first sentence to get the
    second sentence, your task is to break down
    the edits to the atomic level (i.e., token
    or phrase level) and assign the edit a label
    . Be case sensitive. Pay attention to
    punctuation marks and relocated tokens. Pay
    attention to phonetic similarity when
    aligning tokens.

Labels:
1. [replace, original_token, editted_token]
```

```
2. [delete, original_token, ""]
3. [insert, "", editted_token]
4. [relocate, original_token, editted_token]:
    pay attention to tokens that are deleted
    then added again; the relocated token must
    be the same before and after the edit.

Examples:
i don't have two babanas fr my cat
I won't have two bananas for my cat.
Edits:
('replace', 'i do', 'I wo')
('replace', 'babanas fr', 'bananas for')
('insert', '', '.')
Atomic edits:
["replace", "i", "I"]
["replace", "don't", "won't"]
["replace", "babanas", "bananas"]
["replace", "fr", "for"]
["insert", "", "."]

Despite of it is an industrial city. There is
    many shops and department stores.
Although it is an industrial city, there are
    many shops and department stores.
Edits:

E Prompts for explanation generation

We use the following prompts for generating grammar error explanations in German and Chinese.

E.1 Explanation prompt for German

In the prompt for German grammar error explanation, we provide a wide range of error examples, including errors that can only be explained in grammatical terms (e.g., gender/case/number agreement), errors that can be assigned a meaning (e.g., accusative case for time expressions), and errors that are related to collocations (e.g., *am Ende* instead of *im Ende*).

```
You are given a pair of German sentences and a
    list of atomic edits. An edit is an error in
     the first sentence, which is corrected in
    the second one. Generate a succinct
    explanation for each error using the
    template. After each explanation, give the
    error a type.

Template: The word X is deleted/inserted/
    replaced by Y/relocated because ...

Example:
Ich habe zwei Bananen für mein Katz gekauft.
Ich habe zwei Bananen für meine Katze gekauft.
Edits:
["replace", "Katz", "Katze"]
["replace", "mein", "meine"]
Explanation:
The word 'Katz' is replaced by 'Katze' because '
    Katze' is the correct spelling.
Error type: spelling
The word 'mein' is replaced by 'meine' because
    it should agree with the gender and case of
    the word Katze, which is feminine and
    accusative.
Error type: gender and case

Er fliegt nächster Monat Deutschland.
Er fliegt nächsten Monat nach Deutschland.
Edits:
["insert", "", "nach"]
["replace", "nächster", "nächsten"]
Explanation:
The word 'nach' is inserted because the verb '
    fliegen' requires a preposition when
```

```
    expressing a destination and 'nach' is
    usually used for countries.
Error type: preposition
The word 'nächster' is replaced by 'nächsten'
    because German uses accusative case for time
     expressions.
Error type: case

Ich gehe in der Schule.
Ich gehe in die Schule.
Edits:
["replace", "der", "die"]
Explanation:
The word 'der' is replaced by 'die' because the
    preposition 'in' requires the accusative
    case of a noun when expressing a direction
    or destination.
Error type: case

Ich kann heute jogge gehe.
Ich kann heute joggen gehen.
Edits:
["replace", "gehe", "gehen"]
["replace", "jogge", "joggen"]
Explanation:
The word "gehe" is replaced by "gehen" because
    the verb "kann" requires an infinitive form
    of the verb "gehen".
Error type: infinitive
The word "jogge" is replaced by "joggen" because
     the verb "gehen" requires an infinitive
    form of the verb "joggen".
Error type: infinitive

Ich muss mich zur neuen Umgebung gewöhnen.
Ich muss mich an die neue Umgebung gewöhnen.
Edits:
["replace", "zur", "an"]
["insert", "", "die"]
["replace", "neuen", "neue"]
Explanation:
The word "zur" is replaced by "an" because the
    verb "gewöhnen" requires the preposition "an
    ".
Error type: preposition
The word "die" is inserted because the noun "
    Umgebung" requires a determiner and "gewö
    hnen an" requires accusative case.
Error type: determiner
The word "neuen" is replaced by "neue" because
    the existence of "die" indicates that the
    adjective need only weak inflection.
Error type: adjective inflection

Es ist im Ende des Flusses.
Es ist am Ende des Flusses.
Edits:
["replace", "im", "am"]
Explanation:
The word "im" is replaced by "am" because "am"
    is the correct preposition for the word "
    Ende".

Below is the sentence pair for you to work on.
    Focus on the given edit and do not add other
     atomic edits. Start with the explanation
    directly.

E.2 Explanation generation prompt for Chinese

In the few-shot prompt for Chinese GEE, we cover the following types of errors, which are commonly seen when we manually annotate the training data for fine-tuning: **Function word errors**, such as 了, 们, 的/地/得, and measure words; **Mis-written words/phrases**,[17] such as 平果 vs. 苹果 and 市菜场 vs. 菜市场; **Word collocation errors**, such as 做错误 vs. 犯错误; **Word choice errors**, such as 查找 vs. 寻找.

Mandarin Chinese does not have abundant agreement between words in sentences as German or English. Many errors made by learners are word choice errors. For example, 查找 and 寻找 both have the core meaning of *looking for* but the former emphasizes a systematic and methodological search for data or information while the latter suggests a more intangible search with a sense of exploration. In the example of the word choice error, we show GPT-4 that it should explain the meaning of the two words and why one is better than the other in the context. Without such an example, GPT-4 returns a generic explanation “The word X is replace by Y because Y is the correct word to use in the context." which is not helpful for language learners.

Here begins the prompt:

You are given a pair of Mandarin Chinese sentences and a list atomic edits. An edit is an error in the first sentence, which is corrected in the second one. Generate a succinct explanation for each error using the template. After each explanation, give the error a type.

Template: The word X is replaced by Y/deleted/inserted/relocated because ...

Example:

昨天我买四只平果们。

昨天我买了四个苹果。

Edits:

["insert", "", "了"]

["replace", "只", "个"]

["replace", "平果", "苹果"]

["delete", "们", ""]

---

[17] We call them as mis-written words instead of misspelling because there is no letters or spelling in Chinese writing. Such mistakes can be made by a language user who confuses characters with the same/similar pronunciation, with similar meaning, with similar strokes, or simply remembers the wrong character order in a word.

Explanation:
The word ‘了’ is inserted because ‘了’ indicate the completion of the action ‘买’.
Error type: usage of ‘了’
The word ‘只’ is replaced with ‘个’ because ‘个’ is the correct measure word for ‘苹果’.
Error type: measure word
The word ‘平果’ is replaced with ‘苹果’ because ‘苹果’ is the correct word for ‘apple’.
Error type: miswritten character/word
The word ‘们’ is deleted because ‘们’ is only used after pronouns or human nouns to indicate plurality.
Error type: ‘们’
间而说之，他唱地很好。
简而言之，他唱得很好。
Edits:
["replace", "间而说之", "简而言之"]
["replace", "地", "得"]
Explanation:
The word ‘间而说之’ is replaced with ‘简而言之’ because ‘简而言之’ is the correct way of writing the phrase which means ‘in short’ or ‘in brief’.
Error type: mis-written character/word
The word ‘地’ is replaced with ‘得’ because ‘得’ is the correct ‘de’ particle to use when it follows a verb and the word after ‘得’ modifies the verb.
Error type: "de" particles
许多人们做了一差误。
许多人犯了一个错误。
Edits:
["replace", "许多人们", "许多人"]
["replace", "做", "犯"]
["insert", "", "个"]
["replace", "差误", "错误"]
Explanation:
The word ‘许多人们’ is replaced with ‘许多人’ because when a noun is preceded by a numeral, the plural marker ‘们’ is not needed.
Error type: ‘们’
The word ‘做’ is replaced with ‘犯’ because ‘犯’ is the correct verb to use for the noun ‘mistake’.
Error type: verb-object collocation
The word ‘个’ is inserted because a measure word is needed between the numeral and the noun and ‘个’ is the correct measure word for ‘错误’.
Error type: measure word
The word ‘差误’ is replaced with ‘错误’ because ‘差误’ is not a word in Chinese and ‘错误’ is the correct word for ‘mistake’.
Error type: mis-written character/word
我在查找我的知音。
我在寻找我的知音。
Edits:
["replace", "查找", "寻找"]
Explanation:
The word ‘查找’ is replaced with ‘寻找’ because ‘查找’ suggests a systematic and methodological search. It usually means searching for information or data. On the other hand, ‘寻找’ suggests a more intangible search with a sense of exploration. ‘寻找’ fits the context better.
Error type: word choice
Below is the sentence pair for you to work on. Focus on the given edit and do not add other atomic edits. Start with the explanation directly.

{trg}
Edits:
{edit}
Explanation:

E.3 Explanation generation prompt for English

In the GEE prompt for English, we omitted the generic template of explanations but added a paragraph requiring the outputs to be specific. This is based on the observation that the English outputs are usually longer than one sentence and the outputs are often vague and ineffective (e.g., *the preposition X is replaced by Y because Y is the correct word to use.*)

```
This is a grammar error explanation task. You
    are given a pair of English sentences and a
    list atomic edits. An edit is an error in
    the first sentence that is corrected in the
    second one. Generate a grammar explanation
    for each error using the format in the
    following examples. After each explanation,
    give the error a type.

The explanations need to be specific. Avoid
    explanations which only say that one word is
     more appropriate than another. Instead,
    explain why a word is more appropriate. For
    a word that is deleted, be sure to explain
    why it is not needed in a sentence.

Example:
He love watching birds. He devote much of his
    time to find bird all over the world.
He loves watching birds. He devotes much of his
    time to finding birds all over the world.
Edits:
["replace", "love", "loves"]
["replace", "devote", "devotes"]
["replace", "find", "finding"]
["replace", "bird", "birds"]
Explanation:
The word 'love' is replaced by 'loves' because
    the subject 'he' requires the verb to be in
    the 3rd person singular form.
```

```
Error type: person and number
The word 'devote' is replaced by "devotes" because the subject 'he' requires the verb to be in the 3rd person singular form.
Error type: person and number
The word 'find' is replaced by 'finding' because the verb 'devotes to' requires the gerund (-ing) form of the verb 'find'.
Error type: word form
The word 'bird' is replaced by 'birds' because the plural form of 'bird' indicates multiple types/individuals of birds.
Error type: word form

However the chair only is for Charlotte. She uses it when she comes to villa during summer.
However, the chair is only for Charlotte. She uses it when she comes to the villa during summer
Edits:
["insert", "", ","]
["relocate", "only", "only"]
["insert", "", "the"]
["insert", "", "."]
Explanation:
A comma is inserted because it's commly inserted after 'however' which is used to introduce a contrast.
Error type: punctuation
The word 'only' is relocated from before 'is' to after 'is' because when 'be' is used as the main verb, 'only' usually follows 'be'.
Error type: word order
The word 'the' is inserted before 'villa' because it is needed to refer to a specific villa in the context.
Error type: determiner
A period is inserted at the end of the sentence because a period is commonly used to end a sentence.
Error type: punctuation

Its my pleasure to be invited to visit Shanghai. I really like the city, specially it's vitality.
It's my pleasure to be invited to visit Shanghai. I really like the city, especially its vitality.
Edits:
["replace", "Its", "It's"]
["replace", "specially", "especially"]
["replace", "it's", "its"]
Explanation:
The word 'Its' is replaced by "It's" because "It's" is the contraction of "It is" while "Its" is the possessive form of "it".
Error type: word form
The word 'specially' is replaced by 'especially' because 'especially' is commonly used to emphasize one thing over others. while "specially" means "for a special reason".
Error type: word choice

It's yours decision, you should take the responsibility of it and let others know once you make.
It's your decision. You should take the responsibility for it and let others know once you make it.
Edits:
["replace", "yours", "your"]
["replace", ", you", ". You"]
["replace", "of", "for"]
["insert", "", "it"]
Explanation:
The word 'yours' is replaced by 'your' because 'your' is the possesive form of 'you' which is followed by a noun while 'yours' is a pronoun that cannot be followed by a noun.
Error type: word form
', you' is replaced by '. You' because a period should be used to separate two independent clauses, and the beginning of the second clause should be capitalized.
Error type: punctuation
The word 'of' is replaced by 'for' because 'take the responsibility for' is the correct collocation.
Error type: collocation
A pronoun 'it' is inserted after 'make' because 'make' is a transitive verb and should be followed by an object.
Error type: missing word

Who I should talk to about get a new computer?
Who should I talk to about getting a new computer?
Edits:
["relocate", "should", "should"]
["replace", "get", "getting"]
Explanation:
The word 'should' is relocated from after 'I' to before 'I' because the word order of a question should be subject-auxiliary inversion.
Error type: word order
The word 'get' is replaced by 'getting' because the preposition 'about' requires the gerund (-ing) form of the verb 'get'.
Error type: word form

Below is the sentence pair for you to work on. Focus on the given edit and do not add other atomic edits. Start with the explanation directly.

F Data preprocess for German and Chinese

This section describes how the datasets in German and Chinese are preprocessed. The preprocess of the English data is described in Section 5.3.

F.1 Preprocess German data

The Falko dataset (Ludeling et al., 2008; Reznicek et al., 2010) contains essays written by German learners whose proficiency levels range from A1 to C1 according to the Common European Framework of Reference for Languages (CEFR).[18] The Merlin dataset (Boyd et al., 2014) is a collection of essays written by advanced German speakers from different countries with both native and non-native background. We use Merlin as C2 data.

Both Falko and Merlin offer two types of grammar error corrections, target hypothesis 1 and target hypothesis 2. Target hypothesis 1 performs minimal correction at the morpho-syntactic level while target hypothesis 2 modifies semantic and pragmatic aspects (e.g., information structure or word choice) of the input text, aiming for a more advanced paraphrase-type correction. For our purpose, we use target hypothesis 1 of each corrected sentence.[19]

To prepare the datasets, we first split the paragraphs in Falko and Merlin into sentences by adapting the paragraph alignment algorithm in Thai et al. (2022) for sentence alignment. We then screened out sentence pairs that: (1) have short sentences (less that 3 tokens); (2) contain "incomp" or "unreadable" tokens; and (3) have two sentences in the source and one sentence in the target, or vice versa, that are not merged or split.

F.2 Preprocess Chinese data

The data for Chinese GEE is the training split of CGED2017 Rao et al. (2020). Texts are split into sentences at the end of sentence punctuation (e.g., periods and question marks) and aligned.

We tokenized the sentence pairs using Jieba and show the length distribution of sentences in Figure 3. Clearly, most of the data points have 2 to 50 tokens. Each token has on average 1.8 characters. The overly long sentences (over 170 tokens) exist because of the abusive use of commas.[20] For the experiment, we select sentences of length between 5 and 50 tokens. We also remove pairs with the same source and target.

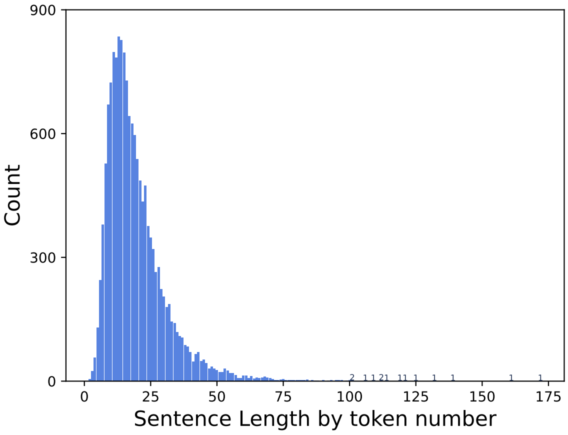

Figure 3: The sentence length distribution of the data in 2017 CGED training set Rao et al. (2020). Most of the sentences have less than 50 tokens. For the bars that are invisible in the plot, we add the numbers to them.

G Fine-tune atomic edit extraction models

For German we use Llama2-7B and GPT-3.5-turbo as the base models and fine-tune them on the 500 training data points in Table 2. The results show that fine-tuning GPT-3.5-turbo through the OpenAI fine-tuning API with 2 epochs and using temperature $= 0$ at the inference time returns the best performance. It took around 30 mins for fine-tuning. For Llama2-7B, we fine-tune the model with QLoRA for 1000 steps using the parameters suggested in Dettmers et al. (2023) on one RTX8000. The fine-tuning takes about five hours. Checkpoints are saved every 250 steps. At the inference time, the checkpoint saved at 750 steps with temperature $= 0.01$ performs the best.[21] The best performance are reported in Table 3.

For Chinese and English, we fine-tune Llama2-7B and GPT-3.5-turbo in the same way as for German. Llama2-7B checkpoints are saved every 100 steps. It achieves the best performance at 400 steps for Chinese and at 800 steps for English. Fine-tuning GPT-3.5-turbo for two epochs returns a better performance than one epoch in Chinese and English.

H Details on human evaluation

We provide further details in addition to the ones discussed in Section 6.2. Figure 4 shows the annotation interface for the German and Chinese teachers.

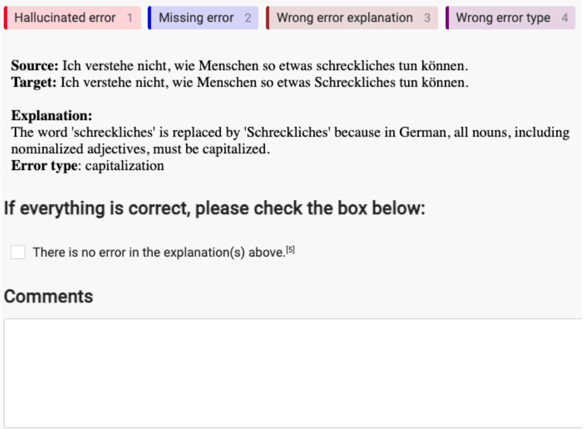
---

[18] The Common European Framework of Reference for Language (CEFR) is a standard for describing language ability. There are six levels: A1, A2, B1, B2, C1, and C2. C2 is the native speaker level.

[19] Examples of the target hypothesis 1 and 2 of a corrected sentence can be found in `https://gucorpling.org/amir/pdf/Reznicek_et_al.pdf`.

[20] As a rough reference, Chinese Treebank 9.0 (Xia, 2000) has 132076 sentences and 2084387 tokens, which amounts to roughly 16 tokens per sentence.

[21] The `do_sample` parameter is set to `False`. The temperature is set to 0.01 instead of 0 because the model requires the temperature to strictly be a positive float.



Source: Ich verstehe nicht, wie Menschen so etwas schreckliches tun können.
Target: Ich verstehe nicht, wie Menschen so etwas Schreckliches tun können.

Explanation:
The word 'schreckliches' is replaced by 'Schreckliches' because in German, all nouns, including nominalized adjectives, must be capitalized.
Error type: capitalization

If everything is correct, please check the box below:

☐ There is no error in the explanation(s) above.[5]

Comments

Figure 4: A screenshot of the interface presented to the annotators for explanation evaluation.

The teachers are given detailed instructions for the German (link) and Chinese (link) tasks.

In the annotation task, the teachers are asked to check for four types of mistakes. Concerning *missing error* mistakes, they should be marked either in the source sentence for deleted, replaced, and relocated tokens or in the target sentence for inserted ones. Other mistakes should be marked in the explanations. We asked the annotators not to mark imprecise explanation/error type as wrong but leave a comment on how they can be improved.

A special note on the Chinese evaluation is that, originally, each teacher annotated 200 sentence pairs, among which 100 were annotated by both. Hence, there were 400 total and 300 unique annotation items. However, there are sentence pairs whose target is judged as nonsensical or corrects errors in a wrong way. We removed those sentence pairs and report the results on the remaining items.

H.1 German annotator agreement

To evaluate the agreement, we compare the annotations of the commonly annotated 96 sentence pairs and classify them into three categories. **Fully agree**: if the teachers agree on no mistakes or the same set of mistakes. **Disagree on missing errors**: if teachers agree on other mistakes but not on *missing errors*. **Disagree on other mistakes**: if teachers also disagree on mistakes other than *missing errors*. Counts of each category are reported in Table 7.

Among the 96 commonly annotated items, the German teachers agree on 81.3% of them for the overall quality (error coverage and explanation quality), and 89.6% of the time, the teachers agree on the quality of the generated edit reasons (sum of the first and second row in Table 7).

	Count	Percentage
Fully agree	78	81.3%
Disagree on missing errors	8	8.3%
Disagree on other mistakes	10	10.4%
Sum	96	100%

Table 7: Agreement between two German teachers on 96 sentence pairs. Among the 78 annotated items on which the teachers fully agree with each other, 5 have mistakes and 73 have no mistakes at all.

	Count	Percentage
Fully agree	78	92.86%
Disagree on missing errors	0	0.0%
Disagree on other mistakes	6	7.14%
Sum	84	100%

Table 8: Agreement between two Chinese teachers on 84 sentence pairs. Among the 78 annotated items on which the teachers fully agree with each other, 3 have mistakes that are not *missing error* and 75 have no mistakes.

H.2 Chinese annotator agreement

We evaluate the agreement between the two Chinese teachers on the annotation items that are annotated by both teachers. Upon inspecting the results, we notice that there are 66 sentence pairs whose target sentence has bad quality. Among them, one target sentence is nonsensical, 15 contains wrong corrections of the errors in the source sentences, and 50 of them do not correct all the errors in the source sentences.

To evaluate the agreement on the generated explanations, we remove 16 annotated items whose target is nonsensical or has wrong correction. For the remaining 84 items, we classify the annotations into the same set of categories as above. Counts of each category are reported in Table 8. Among the 84 commonly annotated items, the Chinese teachers agree on the quality of 92.86% of them.

I Qualitative analysis of German GEE

In this section, we look into the mistakes made by GPT-4 and provide detailed analysis of two of them: *wrong error type* and *wrong error explanation*.

I.1 Mistakes in wrong error type

Although there are only 12 wrong error type mistakes marked by the German teachers, they present cases where careful design decisions need to be made. We categorize them into six types and discuss two of them here. Examples and their categories are in Table 9.

Case vs. Plural The explanations and error types in the two cases indicate that, given the prompt we used, GPT-4 is weak at distinguishing certain nuances in German grammar because it does not leverage the larger context while generating explanations and error types.

In German, the suffix *-n* may occur in two cases (among others): in the plural form of certain nouns or at the end of the dative plural form of a noun if the noun's plural form does not already end in *-n*. In the first case with *Hauspreise*, the language user used *die* as the definite article of *Hauspreise*, which shows that they did not consider the case of the determiner phrase as dative. Moreover, they used *Hauspreise* as part of the subject of the sentence, which further reduces the likelihood that they meant to use *Hauspreise* in its dative case because it is very rare to have a dative determiner phrase as a subject. Hence, the error type should be *plural* or *number*. In the second case with *Menschen*, it is clearly not a *plural* error because *jede/r* (every) takes singular nouns and *bei* only takes dative nouns. The error type should be *case* because the word *Mensch* belongs to the *n*-declination which takes the *-(e)n* suffix in the dative case. Further work should add examples in the prompt or training data to enhance the model ability in distinguishing such nuances.

Misspelling vs. Conjugation While GPT-4 judges the errors under this type in Table 9 as conjugation errors, our German teachers judged them as misspelling. These three cases beg for an answer to the question: where is the border line between general misspelling due to an oversight and genuinely lack of knowledge of a grammar point (e.g., misspelling vs. conjugation)? While we do not have an answer to the question, we suggest that error types should always be the more specific one when an error is on the border line. For a language learner, if an error is made by oversight, they can easily ignore the explanation and error type. If an error is made by lacking of relevant knowledge, they should be reminded by an explanation. Since we do not know why a language learner made such an error, providing the more specific error type is more beneficial.

I.2 Mistakes in wrong error explanation

There are 29 explanations that provide a wrong reason of an error. They can be classified into two groups. The first group has mistakes that can be traced back to a wrongly extracted edit, as shown in the first example in Table 10. Eleven cases belong to this group.

The second group has mistakes for miscellaneous reasons. However, there are two reasons that stand out. The first reason is that GPT-4 does not consider information from the bigger context when generating explanations. There are 3 such cases and all of them involve a preposition. One example can be found in Table 9 under *Case vs. Plural*. Table 10 presents another one. In this example, the word *Zimmer* should be in dative not because German needs a dative case to indicate numbers but because the preposition *mit* assigns the noun in the preposition phrase a dative case. The second reason that causes GPT-4 to generate four wrong explanations is that it does not have precise knowledge of German verb position. As in the third example in Table 10, the word *entwickelt* is relocated not because of the reason in the explanation but because a finite verb in an embedded clause should be at the end of it (see Footnote 15).

I.3 Overall quality of German GEE

In the annotation task, the German teachers were told not to mark correct but imprecise explanations/error types as wrong and leave a comment on how they can be improved. In the annotated results, we see only one such comment. That does not mean that the teachers did not leave enough comments. There are abundant comments pointing out errors in the source sentences that are not corrected in the target sentences, comments pointing out that some corrections done in the target sentences are not correct, or comments on how to modify a wrong error explanation. The first author, as a German second language learner with level C1, has also gone through all the annotated data and found the correct explanations informative and useful. Hence, we can say that the German error explanations generated by GPT-4 are judged as fully correct by our German teachers 93.9% of the time.

J Results of atomic edit extraction and human evaluation of English GEE

For the sake of the page limit, we report the results of the English atomic edit extraction and GEE below in Table 11 and Table 12.

Overly general

Source: Wie es deine Frau und deine Babys?
Target: Wie geht es deiner Frau und deinem Baby?
The word ‘’ is replaced by ‘geht’ because the correct expression in German is "Wie geht es" to ask how someone is doing.
Error type: expression

Source: Brauchst du etwas hilfe?
Target: Brauchst du Hilfe?
The phrase ‘etwas hilfe’ is replaced by ‘Hilfe’ because ‘etwas’ is unnecessary when offering help in this context.
Error type: redundancy

Source: Meine Eltren und bin ich in montag fahren in Indien.
Target: Meine Eltern und ich fahren am Montag nach Indien.
The phrase ‘in montag’ is deleted and replaced by ‘am Montag’ because ‘am’ is the correct preposition for expressing a specific day.
Error type: preposition and expression

Misspelling vs. Conjugation

Source: Ich mochte Farkarte haben.
Target: Ich möchte eine Fahrkarte haben.
The word ‘mochte’ is replaced by ‘möchte’ because ‘möchte’ is the correct conjugation of the verb “mögen” in this context.
Error type: conjugation

Source: Wo möchst du schwimmen gehen?
Target: Wo möchtest du schwimmen gehen?
The word ‘möchst’ is replaced by ‘möchtest’ because ‘möchtest’ is the correct conjugation of the verb ‘möchten’ in the second person singular.
Error type: verb conjugation

Source: Man ließt es geradezu täglich in der Zeitung, hört es im Radio, oder sieht erschreckende Bilder im Fernsehn.
Target: Man liest es geradezu täglich in der Zeitung, hört es im Radio, oder sieht erschreckende Bilder im Fernsehen.
The word ‘ließt’ is replaced by ‘liest’ because ‘liest’ is the correct conjugation of the verb ‘lesen’ for the third person singular.
Error type: conjugation

Case vs. Plural -*(e)n*

Source: In den letzten zehn Jahren erhöhten sich die Wohnungs- und Hauspreisen und fast alle müssen einen Kredit aufnehmen, ihre Träume erföllen zu können.
Target: In den letzten zehn Jahren erhöhten sich die Wohnungs - und Hauspreise und fast alle müssen einen Kredit aufnehmen, um ihre Träume erföllen zu können.
The word ‘Hauspreisen’ is replaced by ‘Hauspreise’ because it should be in the nominative case, which is plural without the ‘-n’ ending
Error type: case

Source: Anderseits liegt die Integration jeder Mensch an sie selbst.
Target: Anderseits liegt die Integration bei jedem Menschen an ihm selbst.
The word ’Mensch’ is replaced by ‘Menschen’ because the plural form is needed to agree with the pronoun ‘jedem’.
Error type: plural

Because of wrong atomic edits

Source: Obwohl in Stadt X schwerig ist, eine freie Wohnung zu bekommen, gibt es trotzdem viele Möglichkeiten wie man es sie bekommt.
Target: Obwohl es in Stadt X schwerig ist, eine freie Wohnung zu bekommen, gibt es trotzdem viele Möglichkeiten wie man sie bekommt.
The word ‘es’ is relocated because it should be placed before ‘in Stadt X’ to form the correct sentence structure for expressing a circumstance.
Error type: word order

Source: Bis 30.04 ich muss in neue Wohnung umladen, weil am 01.05 meine neue Arbeit beginn.
Target: Bis 30.04. muss ich in die neue Wohnung umladen, weil am 01.05. meine neue Arbeit beginnt.
The word ‘ich’ is inserted because it is the pronoun that corresponds to the subject performing the action of ‘müssen’.
Error type: subject pronoun

Wrong word category

Source: und werde direk zu dir für das Abholen, wäre es dir passen wenn wir den Abends zusammen Essen?
Target: Und werde direkt zu dir kommen für das Abholen, würde es dir passen, wenn wir den Abend zusammen essen?
The word ‘wäre’ is replaced by ‘würde’ because ‘würde’ is used in conditional sentences to express politeness.
Error type: modal verb

Not understanding German phonology

Source: Hast du Seit für mich zum eine Wohnung finden?
Target: Hast du Zeit, für mich eine Wohnung zu finden?
The word ‘Seit’ is replaced by ‘Zeit’ because ‘Zeit’ is the correct word for time in this context.
Error type: homophone

Table 9: Twelve cases in which error types are judged as wrong by the German teachers. For each sentence pair, only the explanations with a wrong error type are listed. All grammar errors in the target sentences are from the corpora.

Mistakes that can be traced back to a wrongly extracted edit

Source: Dir möchte ich nächten monat nach Amsterdam fahren.
Target: Ich möchte nächsten Monat nach Amsterdam fahren.

Atomic edits:
["replace", "Dir", "Ich"], ["replace", "ich", "nächsten"], ["replace", "nächten", "Monat"]

Explanation:
The word ‘Dir’ is replaced by ‘Ich’ because the subject of the sentence should be ‘Ich’ to express one’s own desire to travel.
Error type: pronoun
The word ‘ich’ is replaced by ‘nächsten’ because the correct word order is ‘nächsten Monat’ for ‘next month’.
Error type: word order
The word ‘nächten’ is replaced by ‘Monat’ because ‘nächsten’ should be followed by the noun ‘Monat’ to form the time expression ‘nächsten Monat’.
Error type: word order

Mistakes due to insufficient consideration of bigger context

Source: Ich brauchen ca. 75 m^2 Wohnung mit 2 Zimmer, Bad, Kuche, toilette und garage.
Target: Ich brauche ca. 75 m^2 — eine Wohnung mit 2 Zimmern, Bad, Küche, Toilette und Garage.

Explanation:
The word ‘Zimmer’ is replaced by ‘Zimmern’ because in German, the dative case is needed for indicating the number of rooms in this context.
Error type: case

Mistakes due to imprecise knowledge of verb position in German

Source: in dem Sinn, möchte ich dazu sagen, dass integrationsprozes entwickelt sich schneller, wenn man das Gastland nicht als „fremd“ empfindet.
Target: In dem Sinn möchte ich dazu sagen, dass ein Integrationsprozess sich schneller entwickelt, wenn man das Gastland nicht als fremd" empfindet.

Explanation:
The word ‘entwickelt’ is relocated because the verb should be positioned after the subject in a German sentence.
Error type: word order

Mistakes due to other reasons

Source: Schauen Sie zuerst ihre Auswahl, sprechen Sie direkt mit dem Verkäufer.
Target: Schauen Sie zuerst ihre Auswahl an, sprechen Sie direkt mit dem Verkäufer.

Atomic edit:
["insert", "", "an"]

Explanation:
The word ‘an’ is inserted because the verb ‘schauen’ requires the preposition ‘an’ when it means ’to look at’ something.
Error type: preposition

Table 10: Examples of wrong error explanations due to different reasons. For each sentence pair, only the explanations with a wrong error explanation are listed. All grammar errors in the target sentences are from the corpora.

	Claude-2 Prompting	Llama2-7B Fine-Tuned	GPT-3.5-turbo Prompting	GPT-3.5-turbo Fine-Tuned	GPT-4 Prompting
Recall	0.816	0.817	0.771	0.852	**0.860**
Precision	0.833	0.933	0.854	**0.934**	0.885
F1	0.825	0.871	0.81	**0.891**	0.875
Edit Count	144	134	130	136	147.67

Table 11: Recall, precision, and F1 scores of models in the English atomic edit extraction task. Because of the variance in GPT-4 outputs, the outputs are generated three times and the average performance is reported.

	Count	Percentage
Fully correct	189	92.20%
Wrong error explanation	11	5.37%
Wrong error type	1	0.49%
Hallucinated error	4	1.95%
Total explanation count	25	100%
Total annotated items	93	
Missing error	7	

Table 12: Results of human evaluation on English GEE by the authors. 92.20% of the generated explanations are judged as correct. 93 sentence pairs with 205 explanations are annotated. The evaluation criteria are the same as for German and Chinese.

K Error types generated by GPT-4

Table 13, Table 14, and Table 15 list the frequent error types generated by GPT-4 in the German, Chinese, and English GEE task.

Error Type	Count	Percent	Error Type	Count	Percent
punctuation	520	16.48	abbreviation	8	0.25
spelling	470	14.89	compound noun	8	0.25
capitalization	353	11.19	noun form	7	0.22
gender and case	175	5.54	extra word	6	0.19
preposition	163	5.16	syntax	6	0.19
word order	157	4.97	adjective	6	0.19
case	119	3.77	adverb	6	0.19

AdaRefiner: Refining Decisions of Language Models with Adaptive Feedback

Wanpeng Zhang
School of Computer Science
Peking University
wpzhang@stu.pku.edu.cn

Zongqing Lu[†]
Peking University

zongqing.lu@pku.edu.cn

Abstract

Large Language Models (LLMs) have demonstrated significant success across various domains. However, their application in complex decision-making tasks frequently necessitates intricate prompt engineering or fine-tuning, leading to challenges in unseen downstream tasks and heavy demands on computational resources. Meanwhile, Reinforcement Learning (RL) has been recognized as effective in decision-making problems but struggles in environments with sparse rewards, such as open-world games. To overcome these challenges, we introduce AdaRefiner, a novel framework designed to enhance the synergy between LLMs and RL feedback. The key component of AdaRefiner is a lightweight Adapter Language Model (LM), which automatically refines task comprehension based on feedback from RL agents. This method mitigates the need for intricate prompt engineering and intensive LLM fine-tuning while maintaining the LLMs' generalization abilities and enhancing their decision-making capabilities in downstream tasks. Empirical evaluations of AdaRefiner on 22 diverse tasks within the open-world game *Crafter* have demonstrated its superior effectiveness, especially in guiding agents towards higher-level and common-sense skills. Our work makes contributions to the automatic self-refinement of LLMs with RL feedback, offering a more adaptable and efficient solution for complex decision-making problems. The code is available at `https://github.com/PKU-RL/AdaRefiner`.

1 Introduction

The rapid development of Large Language Models (LLMs), trained on massive corpora, has opened new frontiers in various fields, leveraging their ability to process and generate text (Wei et al., 2022). Notably, LLMs have demonstrated impressive performance in decision-making problems (Yao et al., 2023; Shinn et al., 2023; Sun et al., 2023). However, recent studies highlight that directly applying LLMs to complex decision-making tasks often necessitates intricate prompt engineering and external feedback (Wang et al., 2023a; Wu et al., 2023b; Wang et al., 2023b). Such task-specific designs pose challenges in transferring these methods to different scenarios. Some studies have explored the use of task-related data to fine-tune LLMs to improve decision-making capabilities (Nottingham et al., 2023; Feng et al., 2023). However, such approaches often encounter practical challenges, such as inaccessible LLM weights or intensive computational demands. Moreover, fine-tuning LLMs may lead to decreases in their generalization capabilities (Wang et al., 2022), making their deployment across diverse environments challenging. These challenges underscore the need for a more adaptable and generalizable approach.

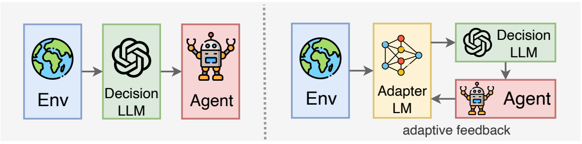

Figure 1: Core differences between AdaRefiner (*right*) and typical LLM-based methods (*left*). The key distinction is the integration of Adapter LM, which enhances the synergy between LLMs and adaptive feedback.

Before the emergence of LLMs, Reinforcement Learning had been recognized for its impressive capabilities in decision-making problems (Mnih et al., 2015; Silver et al., 2017). The strength of RL is most evident when agents consistently receive clear and dense rewards that guide them toward the targeted behaviors (Ladosz et al., 2022; Eschmann, 2021). However, designing such reward functions is far from straightforward. It often requires meticulous engineering and access to a comprehensive set of task-specific information. This challenge becomes even more pronounced in naturally sparse-

reward environments. In such contexts, integrating LLMs to assist RL agents has emerged as a promising direction (Du et al., 2023). Despite the potential of this approach, LLMs may face difficulties in understanding specific environments (Bommasani et al., 2021; Ahn et al., 2022). This limitation undermines their efficacy in assisting RL agents.

In this paper, our goal is to enhance LLMs to better understand specific environments without relying on demanding prompt engineering or directly fine-tuning LLMs, while assisting RL agents with complex decision-making tasks. To this end, we propose a novel framework, AdaRefiner, where the LLM provides guidance to the RL agent who selects fine-grained actions to accomplish tasks. Simultaneously, the RL agent contributes adaptive feedback, enriching the LLM's understanding of the environment through an adjustable module.

As illustrated in Figure 1, the core feature of AdaRefiner is the integration of a lightweight Adapter LM. This Adapter LM, enriched with feedback and information from the RL agent, automatically prompts a Decision LLM, like GPT-4 (OpenAI, 2023). It enables a refined understanding of the environment and agents' learning capabilities without the need to alter the Decision LLM's parameters. This approach maintains the generalization abilities of LLMs while providing targeted assistance for RL agents with specific tasks. By the synergy of LLMs and RL feedback, AdaRefiner addresses the limitations of existing methods, setting a new paradigm in the integration of advanced LLMs with reinforcement learning.

In the experiments, AdaRefiner is evaluated on 22 tasks within the *Crafter* environment (Hafner, 2021). The results not only demonstrate AdaRefiner's superior performance compared to state-of-the-art baselines but also highlight its ability to guide agents towards common-sense behaviors.

Our key contributions are summarized as follows: **1)** We propose a novel framework that aligns LLMs with downstream tasks and guides agents to effectively learn complex tasks without the need for intricate prompt engineering or intensive fine-tuning; **2)** We design the Adapter LM that correlates its own update with the learning progress of the agent and automatically generates appropriate prompts for the Decision LLM, thereby forming a feedback loop together with LLMs and RL agents; **3)** We thoroughly evaluate our framework's efficacy on 22 diverse tasks and provide a comprehensive analysis of the experimental results.

2 Related Work

Large Language Models (LLMs). Recent advancements in natural language processing have been significantly shaped by the emergence of LLMs. The GPT series, notably, has garnered attention for its broad task versatility, while other models like PALM and LaMDA have also contributed to the field with their unique capabilities (Chowdhery et al., 2022; Thoppilan et al., 2022). A pivotal development in the evolution of LLMs is the implementation of instruction tuning (Ouyang et al., 2022), which has markedly enhanced adaptability in complex scenarios, particularly in zero-shot and few-shot learning applications. The open sourcing of some LLMs (Zeng et al., 2022; Touvron et al., 2023a) has spurred efforts in task-specific fine-tuning (Wu et al., 2023a). While this approach often boosts task performance, it can simultaneously reduce the models' generalization abilities (Wang et al., 2022). Our work navigates this challenge by dynamically fine-tuning a lightweight Adapter LM via real-time feedback from RL agents, aiming to strike a balance between task-specific improvement and broad applicability. This method tailors the LLM for specific tasks while maintaining LLM's broad adaptability to new environments, addressing a key limitation in current applications.

LLMs for RL. Incorporating language models to represent goals in RL utilizes the extensive knowledge of LLMs trained on large corpora. The use of LM-encoded goal descriptions has been shown to significantly improve the generalization capabilities of instruction-following agents (Chan et al., 2019; Hill et al., 2020). This is achieved by enabling agents to interpret and act upon complex instructions more effectively. Furthermore, pre-trained LLMs provide nuanced guidance through sub-goals and sub-policies, enhancing agent strategies and decision-making in various scenarios (Lynch and Sermanet, 2020; Sharma et al., 2021). Subsequent research efforts have linked these sub-policies to address more intricate tasks in RL environments (Huang et al., 2022a,b). Several methods also leverage LLMs to generate intrinsic rewards, boosting the efficiency and effectiveness of RL learning (Choi et al., 2022; Du et al., 2023). However, the application of these methods in simple text-based games often does not transfer well to more complex and dynamic environments, leading to scalability and generalization issues (Zhong et al., 2021; Wang and Narasimhan, 2021). Our work addresses these challenges by making LLMs more adaptable and practical for use in sophisticated environments. The AdaRefiner framework is specifically designed to enhance the flexibility and effectiveness of LLMs, providing tailored assistance to RL agents in navigating and mastering complex decision-making tasks.

LLMs for Open-World Games. Open-world games pose unique challenges, such as managing long horizons (Hafner, 2021) and balancing multiple objectives (Wang et al., 2023c). These complexities require sophisticated decision-making strategies. While some studies have explored using LLMs for planning and guiding RL agents (Du et al., 2023; Yuan et al., 2023; Tsai et al., 2023), their approaches often depend on human-generated trajectories as context. This dependency can limit the agent's performance in unseen scenarios, making them less effective compared to recent RL algorithms (Hafner et al., 2023) that operate independently of LLMs. Additionally, methods that solely rely on LLMs for decision-making (Wu et al., 2023b; Wang et al., 2023a) often have designs that are intricately tailored to specific environments or require expert-level prior knowledge. This specificity can make them less transferable to different tasks. In contrast, our AdaRefiner avoids such complexity. Its straightforward and flexible design enables it to adapt to a variety of tasks and environments, addressing the key limitations of current LLM applications in open-world games.

3 Methodology

3.1 Problem Formulation

In our study, the primary goal is to leverage LLMs to enhance the decision-making capabilities of RL agents in complex environments. We consider a partially observable Markov decision process (POMDP), defined by the tuple $(\mathcal{S}, \mathcal{A}, \mathcal{P}, \Omega, \mathcal{O}, R, \gamma)$. Here, $s \in \mathcal{S}$ and $a \in \mathcal{A}$ denote the state and action, respectively. The transition probability $\mathcal{P}(s'|s, a)$ represents the environment dynamics, where s' is the state following action a from state s. The observation $o \in \Omega$ is obtained through function $\mathcal{O}(o|s, a)$, and R is the reward function, with γ as the discount factor. We can use $\tau \doteq \{o_0, a_0, r_0, \ldots, o_t, a_t, r_t, \ldots\}$ to represent a sequence of data as a trajectory.

Under this setting, we employ LLMs to generate sub-goals g, aiding agents in decision-making processes. These sub-goals are designed to provide intermediate targets, enhancing the agent's ability in complex scenarios. Our objective is to develop a policy, denoted as $\pi(a|o, g)$, which maximizes cumulative reward by effectively integrating these sub-goals. The specific mechanics of how LLMs assist in generating these sub-goals and their exact role in the decision-making process will be detailed in subsequent sections.

3.2 Key Idea and Overall Framework

Pre-trained LLMs demonstrate impressive zero-shot language understanding capabilities across diverse tasks. This proficiency can be leveraged to help agents quickly comprehend complex environments, thus mitigating exploration dilemmas in RL. By prompting LLMs, we obtain sub-goals in textual format, which are then embedded with the agent's observations to inform the policy $\pi(a|o, g)$. This process aids agents in making more informed decisions based on the contextual guidance provided by these sub-goals.

Despite their generalization capabilities, LLMs may not always have a comprehensive understanding of specific tasks, leading to potential mismatches between the generated guidance and the environment's realities. Directly using LLM-generated guidance may not result in coherent or relevant advice. While fine-tuning LLMs with task-specific data is a typical solution, it can be computationally intensive and may also lead to catastrophic forgetting of pretrained knowledge. Moreover, fine-tuning black-box models like GPT-4 is infeasible due to restricted access to their weights.

Given these challenges, we focus on adding adjustable modules to help LLMs adapt to environments, rather than modifying the LLMs directly. A key insight is that even a lightweight LM, with the right fine-tuning, can excel at particular tasks (Zhang et al., 2023; Li et al., 2023). This motivates us to propose AdaRefiner, as illustrated in Figure 2. The core component of AdaRefiner is a lightweight Adapter LM which bridges the gap between specific environments and the Decision LLM's capabilities. The Adapter LM first processes the environmental inputs and the agent's status, automatically generating tailored prompts that include summaries and suggestions. These prompts are then fed into the Decision LLM, which produces final sub-goals. The Adapter LM thus acts as an intermediary, ensuring that the Decision LLM receives contextually relevant information, enabling it to provide accurate and useful guidance to the agent.

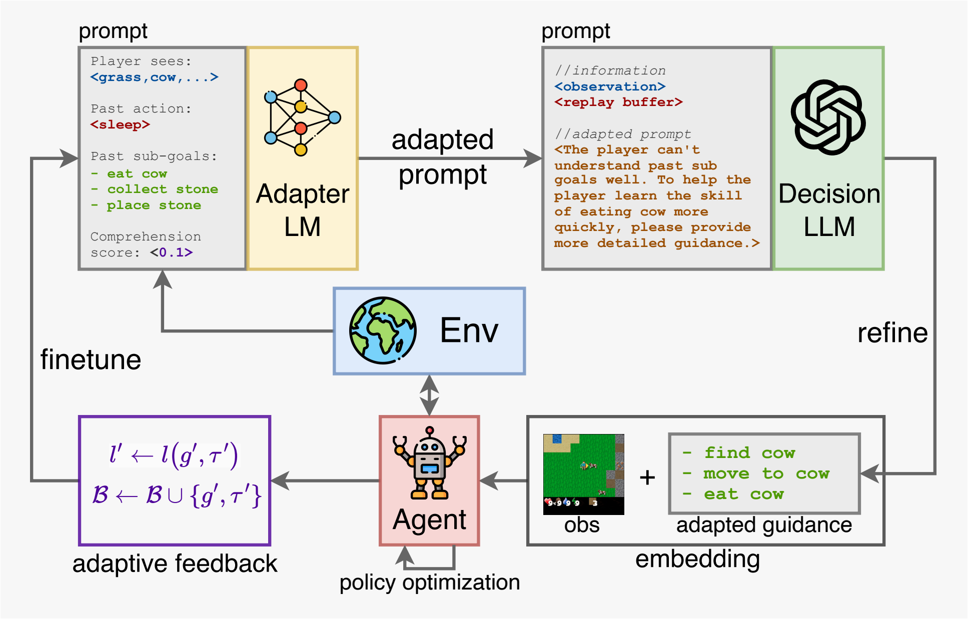

Figure 2: Overall framework of AdaRefiner. In addition to receiving inputs from the environment and historical information, the prompt of the Adapter LM incorporates a comprehension score. This score computes the semantic similarity between the agent's recent actions and the sub-goals suggested by the LLM, determining whether the agent currently comprehends the LLM's guidance accurately. Through the agent's feedback and continuously fine-tuning the Adapter LM, we can keep the LLM always attuned to the actual circumstances of the task. This, in turn, ensures that the provided guidance is the most appropriate for the agents' prioritized learning.

3.3 Adapter LM

The Adapter LM processes two types of input information: environmental information and the agent's comprehension level of language guidance. The environmental information, sourced from the game engine or visual descriptors (Radford et al., 2021), includes critical information such as object properties and the current status of the agent. The agent's comprehension level of language guidance is quantified using a cosine similarity score l, calculated between the suggested sub-goals and the agent's trajectories, represented as:

$$l \doteq \cos(g, \tau) = \frac{f_{\text{emb}}(g) \cdot f_{\text{emb}}(\tau)}{\|f_{\text{emb}}(g)\| \cdot \|f_{\text{emb}}(\tau)\|}. \qquad (1)$$

Here, f_{emb} represents the embedding function, with SentenceBert (Reimers and Gurevych, 2019) employed in our implementation. A higher score l suggests that the agent's actions are more closely aligned with the sub-goals, indicating a better comprehension of the provided guidance.

The Adapter LM then utilizes the comprehension score l and environmental information to generate $\texttt{prompt}_\texttt{a}(\mathcal{B}, l)$, where $\mathcal{B}$ is a replay buffer of the agent's historical contexts and $\texttt{prompt}_\texttt{a}(\cdot)$ is the prompt template for Adapter LM. After analyzing the prompt, the Adapter LM synthesizes the information to assist the Decision LLM, which is responsible for overall decision-making. The output from the Adapter LM, represented as $c \sim \mathcal{M}_\text{a}(\texttt{prompt}_\texttt{a}(\mathcal{B}, l))$, is then used to inform the Decision LLM. Here, $\mathcal{M}_\text{a}$ represents the Adapter LM. By providing tailored information through the adapted $\texttt{prompt}_\texttt{d}(\mathcal{B}, c)$, the Decision LLM is better equipped to generate appropriate sub-goals $g \sim \mathcal{M}_\text{d}(\texttt{prompt}_\texttt{d}(\mathcal{B}, c))$. Here, $\mathcal{M}_\text{d}$ represents the Decision LLM and $\texttt{prompt}_\texttt{d}(\cdot)$ is the prompt template for the Decision LLM. Details of these prompts is available in Appendix D.

3.4 Training Procedure

The training process of our framework is designed to coordinate the learning of RL agents and the fine-tuning of the Adapter LM. In other words, the Adapter LM is continuously updated to refine its comprehension of the environment and the agent in parallel with the RL agent's exploration and data collection. Specifically, the RL agent receives suggested sub-goals $g \sim \mathcal{M}_\text{d}(\texttt{prompt}_\texttt{d}(\mathcal{B}, c))$ from the Decision LLM, which are then provided to the policy $\pi(a|o, g_{\text{emb}})$ for training. Here, g_{emb} is the text embedding produced by f_{emb}. The agent's actions and the resultant trajectories provide an updated comprehension score $l' = \cos(g', \tau')$, where g', τ' is the new sub-goals and trajectories. This score and collected information are then used to compose a linguistic data pair $< \texttt{prompt}_\texttt{a}(\mathcal{B}, l'), c >$ for supervised fine-tuning of the Adapter LM. Then the replay buffer will be updated as $\mathcal{B} \leftarrow \mathcal{B} \cup \{g', \tau'\}$ This iterative procedure allows the Adapter LM to continuously refine its self-awareness and generate more effective summaries c, which affects the quality of guidance for the RL agent.

Considering the computational costs and the nature of open-world game environments, we query the language models at predetermined intervals instead of every step. This strategy ensures a balance between consistent guidance and computational efficiency. The fine-tuning of the Adapter LM is also conducted at specific intervals for the same reason. In line with our claim that only a lightweight Adapter LM is needed, we utilize the 4-bit quantized version of the Llama2-7B model (Touvron et al., 2023b) as the base model (Jiang et al., 2023) and employ QLoRA (Dettmers et al., 2023) for efficient fine-tuning. And we choose OpenAI's GPT-4 as the default Decision LLM. These choices will be further discussed and analyzed in Section 4. For policy learning, we adopt the classic Proximal Policy Optimization (PPO) algorithm (Schulman et al., 2017). It is worth noting that our framework is designed to be compatible with a variety of standard RL algorithms, not only limited to PPO.

Specific parameters and settings are detailed in Appendix B. The complete procedure can be found in Appendix A.

4 Experiment

Our experiments primarily aim to validate the following claims: **1)** The integration of the Adapter LM can enhance LLM's comprehension of downstream tasks and the agent's understanding capability, resulting in more meaningful guidance; **2)** Agents trained under the AdaRefiner framework can exhibit superior performance and demonstrate higher-level decision-making capabilities.

4.1 Experiment Settings

Our experiments are conducted in the *Crafter* environment (Hafner, 2021), a widely used benchmark with 22 different tasks for evaluating the decision-making capabilities of agents in open-world games.

Environment Details. *Crafter* features a 64×64 grid map populated with various objects (*e.g.*, grass, water, wood) and entities (*e.g.*, player, zombie, skeleton). Agents in this environment have access to a local 9×7 area for observation, presenting a challenge in terms of limited information and requiring effective decision-making for long-term survival and resource management. In *Crafter*, agents are not bound to a single main task. Instead, they are expected to master a range of skills to accomplish 22 different tasks, including tasks such as collecting resources, crafting tools, and surviving against environmental hazards. This variety tests the agents' ability to learn and adapt to diverse challenges, aligning well with our objective to enhance their decision-making capabilities through the AdaRefiner framework.

Evaluation Metrics. In *Crafter*, the performance of an agent is evaluated using three metrics: reward, success rate, and overall score. The reward is designed to reflect the agent's skills. Each time an agent unlocks a new achievement, it receives a $+1$ reward. Additionally, the agent is rewarded with $+0.1$ or penalized with -0.1 for every gain or loss of a health point, respectively. The success rate is defined as the proportion of episodes in which agents complete a achievement. Completing the same achievement multiple times within an episode does not affect the success rate. The overall score averages the success rates ($s_i \in [0, 100]$) of the 22 achievements in log-space as follows (known as the geometric mean): $S \doteq \exp\left(\frac{1}{N}\sum_{i=1}^{N} \ln\left(1 + s_i\right)\right) - 1$, where $N = 22$ is the total number of achievements.

Prompt Design. The prompt design for the Adapter LM is crafted to encapsulate critical information for decision-making. It includes observations of objects and the agent's status obtained from the game engine, along with the comprehension score l. The format is: "`Player sees: <observations>; Player status: <status>; Past action: <past actions>; Past sub-goals: <last suggested sub-goals>; Comprehension score:` $<l>$`. Analyze the environment and the player's understanding capability, then generate concise summaries and suggestions about this player.`" For the Decision LLM, we construct the prompt based on the Adapter LM's output: "`<output of the Adapter LM>. Based on the provided information, suggest 3 sub-goals that the player should accomplish next.`"

4.2 Baselines

To demonstrate the effectiveness of our AdaRefiner framework, we conduct comparative analyses against a diverse set of methods:

LLM-based Methods: We compare AdaRefiner with LLM-based methods such as Reflexion (Shinn et al., 2023), ReAct (Yao et al., 2023), and Vanilla GPT-4. Reflexion and ReAct leverage chain-of-thought prompts for decision-making tasks. Considering that LLM-based methods do not accept image input, we additionally include the coordinates of objects in the prompt for fair comparisons. We also maintain consistency in the prompts used across all methods (detailed in Appendix D). The LLM used in Reflexion and ReAct is the same as the Decision LLM in AdaRefiner, *i.e.*, GPT-4 by default. These comparisons aim to demonstrate how the integration of LLMs with adaptive feedback can provide a more comprehensive approach to decision-making.

RL Methods: We also benchmark against RL methods such as DreamerV3 (Hafner et al., 2023), Rainbow (Hessel et al., 2018), PPO (Schulman et al., 2017), RND (Burda et al., 2019), and Plan2Explore (Sekar et al., 2020). DreamerV3 is notable for its performance in model-based RL. Rainbow is a classic algorithm that achieves great performance in many games. RND and Plan2Explore are known for the intrinsically motivated exploration. PPO, which is also adopted in AdaRefiner, serves to highlight the added value of LLMs in the same RL setup.

Additional References: We include random policy, human expert performance (Hafner, 2021), SPRING (Wu et al., 2023b) that provides GPT-4 with domain-specific prior knowledge (*i.e.*, research papers about the game engine), and Reflexion with *gpt-4-vision* (including both coordinates and image inputs), as additional references to showcase performances enhanced with different information and knowledge.

4.3 Results and Analysis

The comparison includes some methods for which open-source codes are unavailable. For these algorithms, we rely on the performance metrics reported in respective papers, ensuring that the comparisons are as consistent as possible in terms of experimental setup and evaluation criteria. For RL baselines, we set the training to 1 million steps, following the standard set in the *Crafter* paper (Hafner, 2021). However, LLM-based baselines do not include a training phase and instead focus on leveraging pre-trained LLMs. To facilitate a fair comparison, we also present a version of AdaRefiner trained for 5 million steps to assess its asymptotic performance. This extended training is essential for evaluating AdaRefiner's full potential and maintaining comparability with baselines.

Method Type	Method	Score (%)	Reward
Ours	AdaRefiner (@5M)	**28.2** ± 1.8	**12.9** ± 1.2
	AdaRefiner (@1M)	15.8 ± 1.4	12.3 ± 1.3
LLM-based methods	Reflexion (GPT-4)	11.7 ± 1.4	9.1 ± 0.8
	ReAct (GPT-4)	8.3 ± 1.2	7.4 ± 0.9
	Vanilla GPT-4	3.4 ± 1.5	2.5 ± 1.6
RL methods	DreamerV3	14.5 ± 1.6	11.7 ± 1.9
	PPO	4.6 ± 0.3	4.2 ± 1.2
	Rainbow	4.3 ± 0.2	5.0 ± 1.3
	Plan2Explore	2.1 ± 0.1	2.1 ± 1.5
	RND	2.0 ± 0.1	0.7 ± 1.3
Addtional references	Human Experts	50.5 ± 6.8	14.3 ± 2.3
	SPRING (+prior)	27.3 ± 1.2	12.3 ± 0.7
	Reflexion (GPT-4-Vision)	12.8 ± 1.0	10.3 ± 1.3
	Random	1.6 ± 0.0	2.1 ± 1.3

Table 1: Performance comparison between AdaRefiner and baselines in terms of score and reward metrics. AdaRefiner is trained with 5 million and 1 million steps. All results are derived from 500 inference episodes. Note that ± captures standard deviations.

Method	Achievements (out of 22)	Achievement Depth (max 8)
AdaRefiner	**21**	**7**
DreamerV3	19	6
Reflexion	17	5

Table 2: Numbers and depths of achievements that can be completed by different methods. The achievement depth refers to the number of prerequisite steps required to complete each task, with a maximum value of 8.

Results in Table 1 show that AdaRefiner with 1 million training steps outperforms all baselines. In comparisons with RL methods, the integration of LLM demonstrates a clear advantage in learning effectiveness. The performance of AdaRefiner compared to Reflexion and ReAct underscores that prompts generated automatically by the Adapter LM can enhance the decision-making capabilities of LLMs in downstream tasks more effectively than traditional prompt engineering techniques. This efficiency, combined with the adaptability of AdaRefiner, establishes it as a highly practical and powerful framework in complex decision-making environments.

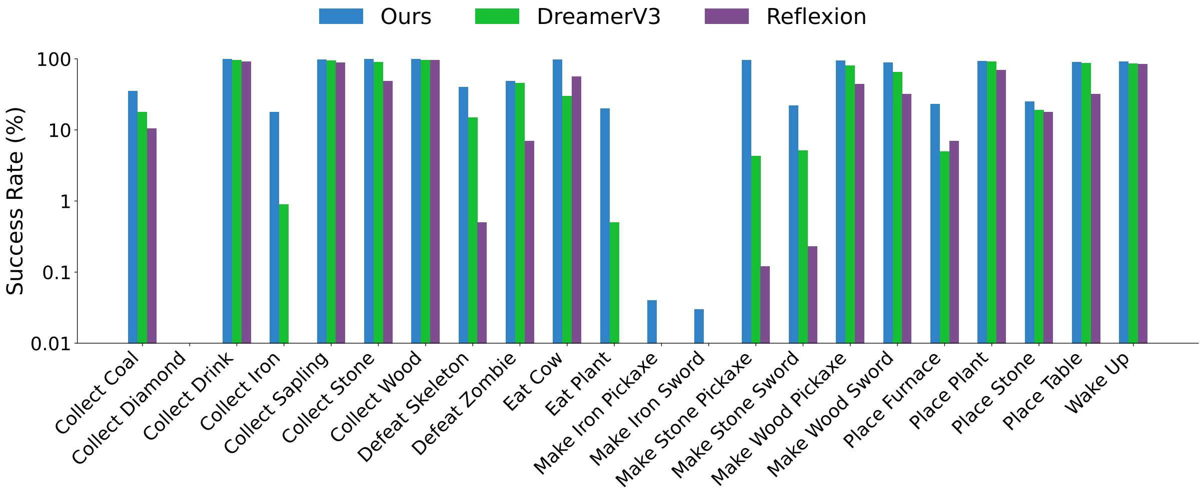

Figure 3: Success rates of unlocking 22 different achievements in log scale. AdaRefiner outperforms the two top-performing baselines. Notably, AdaRefiner is the only method that successfully completes the level-7 tasks “Make Iron Pickaxe” and “Make Iron Sword”.

Additionally, it is noteworthy that AdaRefiner with 5 million training steps slightly outperforms the SPRING (+prior) method, which necessitates providing task-related papers and engaging in a 9-round chain-of-thought questioning process. This indicates that AdaRefiner can achieve better performance simply through a comprehensive understanding of adaptive feedback, without the need for external expert-level knowledge and complex prompt engineering.

Moreover, the augmented Reflexion, which utilizes *gpt-4-vision*, showes some improvements over the original version. However, even with the inclusion of additional input information, Reflexion still exhibited a significant performance gap compared to AdaRefiner. This indicates that merely employing pretrained large multimodal models with image understanding capabilities does not guarantee improved performance on downstream tasks, further underscoring the efficacy of AdaRefiner’s framework design.

To study the breadth of abilities learned by different methods, we compare AdaRefiner with two top-performing baselines, DreamerV3 and Reflexion. We investigate their success rates on 22 specific achievements in *Crafter*. Both AdaRefiner and DreamerV3 are trained for 5 million steps. Figure 3 illustrates that AdaRefiner has the highest success rates across all tasks. Moreover, as shown in Table 2, AdaRefiner completes the largest number of achievements and is the only method that reaches level-7 difficulty. Specifically, AdaRefiner is notably the only method capable of accomplishing level-7 tasks “Make Iron Pickaxe” and “Make Iron Sword”. These tasks are particularly hard due to their prerequisite conditions and rarity in the game. This result underscores the importance of a comprehensive understanding of environments in developing versatile agents.

4.4 Ablation Study

To investigate the contribution of various components in the AdaRefiner framework, a series of ablation studies are conducted.

Decision LLM Variants. We first investigate the performance of using different Decision LLMs. By replacing GPT-4 with GPT-3.5 in the Decision LLM, we observe a slight decrease in performance, as shown in the first two rows of Table 3. This result suggests that AdaRefiner using an LLM with less capability still maintains a comparable level to other baselines, achieving level-6 tasks. This demonstrates that the success of AdaRefiner is primarily attributed to its framework design, rather than the use of more advanced GPT-4 as the Decision LLM. In contrast, when comparing the two versions of Reflexion under the same Decision LLMs, significant performance gaps are observed, further underscoring the superiority of our framework.

Adapter LM Variants. To study the contribution of the Adapter LM to AdaRefiner, we design two variants as shown in the middle three rows of Table 3. The first variant, *AdaRefiner w/o l-score*, excludes the comprehension score from

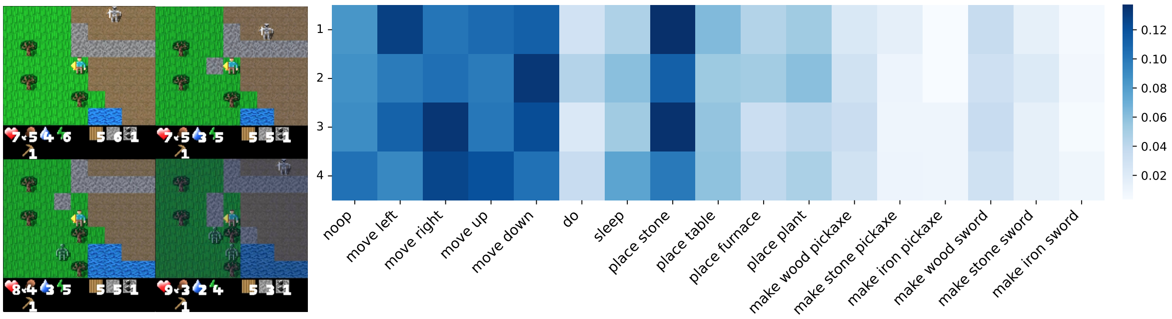

Figure 4: (*left*) Frames from an episode in the game, the order is from top left to bottom right. (*right*) The probabilities of actions in the agent's policy corresponding to each frame.

Method (@5M steps)	**Score (%)**	**Reward**	**Achievement Depth**
AdaRefiner	**28.2** ± 1.8	**12.9** ± 1.2	7
AdaRefiner (GPT-3.5)	23.4 ± 2.2	11.8 ± 1.7	6
Reflexion (GPT-4)	11.7 ± 1.4	9.1 ± 0.8	5
Reflexion (GPT-3.5)	8.9 ± 1.7	7.2 ± 1.1	4
AdaRefiner w/o l-score	13.4 ± 1.9	9.2 ± 1.6	5
AdaRefiner w/o Adapter LM	9.6 ± 1.7	8.7 ± 1.4	5
GPT-4 + GPT-4	7.5 ± 0.8	5.2 ± 1.5	4
Llama2-7B + GPT-4	7.1 ± 1.0	4.7 ± 1.5	4
AdaRefiner w/ binary score	18.7 ± 2.4	11.0 ± 1.6	6

Table 3: Ablation study of AdaRefiner. The results illustrate the impact of various components.

both the prompts and the fine-tuning process. This variant experiences a notable performance decline, highlighting the critical role of the comprehension score in refining the Adapter LM with task objectives. It appears that merely using task data for fine-tuning does not sufficiently enhance decision-making capabilities. Another variant, *AdaRefiner w/o Adapter LM*, retains the comprehension score but removes the Adapter LM. This setup leads to an even more pronounced decrease in performance, indicating that simply providing comprehension scores as inputs is not enough to significantly increase decision-making effectiveness. It demonstrates that the Adapter LM, when fine-tuned with comprehension scores, plays a pivotal role in enhancing the overall decision-making capabilities.

Feedback from RL. To demonstrate the significance of integrating adaptive feedback from RL, we compare two variants that remove adaptive feedback from RL and rely solely on the Decision LLM for action decisions. In these variants, PPO and corresponding feedback are removed, and the Adapter LM is used only for inference, without any fine-tuning. The results are shown in the last three rows of Table 3. The first variant, named *Llama2-7B + GPT-4*, shows a significant decrease in performance. This underscores the critical role of incorporating adaptive feedback from RL for the Adapter LM to accurately perceive and adapt to the environment. Another variant, *GPT-4 + GPT-4*, which utilizes GPT-4 as the Adapter LM for inference, exhibits similar performance, further suggesting that simply increasing the capacity of LLMs is insufficient. These comparisons demonstrate that the synergy between LLMs and RL feedback is crucial to the efficacy of AdaRefiner.

Fine-grained Comprehension Score. To verify the necessity of using a fine-grained comprehension score, we investigate the impact of the score's format on performance. Specifically, we compare the performance with a variant, *AdaRefiner w/ binary score*, which assigns a score of 1 to entries above a 0.5 similarity threshold and 0 to others. The results clearly show that replacing the comprehension score with a binary score leads to a significant decrease in performance. This indicates that a finer-grained similarity score is more effective in aiding the Adapter LM to understand the agent's capabilities, showcasing the Adapter LM's sensitivity to score values.

4.5 Guidance and Agent Behaviors

We further investigate how AdaRefiner enhances the agent's comprehension and learning. As shown on the left side of Figure 4, in a scenario where enemies gradually appear, AdaRefiner receives environmental information and suggests the agent to "place stone to build shelter, collect food and drink, avoid combat". The policy visualized on the right side of Figure 4, reveals a high probability of "place stone" following this guidance. Notably, five basic actions controlling the player's movement also maintain high probabilities. This pattern likely reflects the inherent design of RL algorithms to encourage exploration, leading agents to consistently engage in common and easily executed actions. Actions less relevant to the provided guidance exhibit lower probabilities, indicating the agent's ability to prioritize actions based on AdaRefiner's suggestions. For more detailed analyses, statistical tests, and further demonstrations, please refer to Appendix C.

4.6 Consistent Increment of Performance and Agent's Comprehension.

To further validate the efficacy of AdaRefiner in providing effective guidance for the agent, we investigate the correlation between the learning curve and the comprehension score during training. Figure 5 illustrates this relationship, showing that there is a consistent increase in the comprehension score as training progresses. This increment suggests an improvement in the agent's understanding of the language guidance, which in turn enhances the overall performance. The results demonstrate that the agent is not just following instructions more accurately but is also integrating this guidance more effectively into its decision-making process.

4.7 Behavior Statistics

To better quantify the guidance provided by AdaRefiner and the common-sense behavior exhibited by the agent, we have adopted a setting similar to that used in existing work (Du et al., 2023). Specifically, we categorized each instruction and actual agent action into three groups:

- **No Common-Sense** (where behavior significantly deviates from typical human common sense, *i.e.*, *suggesting the agent to fight with enemies when its health is low*);
- **Impossible** (where the resources and conditions do not support the behavior in game engine);
- **Reasonable** (all remaining behaviors not included in the first two categories).

The results are shown in Table 4, suggesting that in most scenarios (83.8% and 78.6%), the guidance and agent's actions are reasonable. While we acknowledge that there may be subjectivity in this assessment, we believe the results can still show the general tendencies of AdaRefiner in guiding agent's behavior.

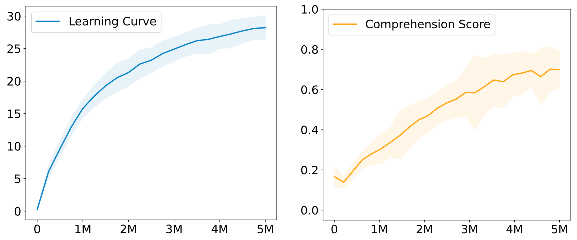

Figure 5: Learning curve (*left*) and comprehension score (*right*) of AdaRefiner.

	Guidance	**Action**
No Common-Sense	12.8%	21.4%
Impossible	3.4%	0%
Reasonable	83.8%	78.6%

Table 4: Statistical tests on common-sense behaviors. The results are based on 500 inference samples.

5 Conclusions

In this study, we introduce AdaRefiner, a novel framework that synergizes LLMs with adaptive feedback, leveraging an Adapter LM as a crucial intermediary. AdaRefiner, rigorously tested across 22 diverse tasks in the *Crafter* environment, not only outperforms state-of-the-art baselines but also steers agents towards learning higher-level skills and exhibiting common-sense behaviors. Ablation studies further validate the significance of each component, particularly emphasizing the Adapter LM's role in refining decision-making. These results highlight AdaRefiner's potential in advancing LLMs' capabilities in complex open-world games, and open up avenues for further research in LLM's decision-making capabilities.

Limitations

The primary limitation of AdaRefiner is that it still requires a certain level of pre-trained knowledge of the Adapter LM. If a smaller language model is used as the Adapter LM, its language understanding ability may not be sufficient to provide the necessary analysis and summarization for the environment and agent. Additionally, although AdaRefiner substantially improves the performance, all methods including AdaRefiner fall short in the most difficult level-8 task "Collect Diamond." This gap points to a need for further improvements in current methods to tackle more complex tasks.

Nevertheless, the uncovering of knowledge from LLMs by the Adapter LM demonstrates promising prospects for filling the gap in LLMs' performances across various tasks. In future work, we will continue to explore this characteristic of the Adapter LM while also attempting to integrate LLM with RL algorithms more closely to address these limitations in complex environments.

Ethical Considerations

While the natural language guidance generated by LLMs exhibits strong common-sense capabilities, there is a possibility that they might contain or produce harmful information. Though no such concerns were observed during evaluations in simulated environments like *Crafter*, it is imperative to address these potential risks when transferring AdaRefiner to more open and real-world settings in the future. Mitigating these risks can be achieved by adding additional instructions in prompts, fine-tuning with curated data, and post-processing the generated text. Adopting these measures ensures that AdaRefiner functions effectively and safely in its intended roles.

B Implementation Details

B.1 RL Algorithm

We use the classic PPO algorithm for policy learning in AdaRefiner, and the hyperparameters are shown in Table 5. It is worth noting that AdaRefiner can be flexibly combined with various RL algorithms and is not limited to PPO.

Hyperparameter	**Value**
policy learning rate	7e-4
update epoch	16
γ	0.97
ε	1e-8
clip ratio	0.1
optimizer	`Adam`

Table 5: Hyperparameters for PPO.

B.2 Adapter LM

We use open-source Llama2-7B weight as initial weight for the Adapter LM. In order to reduce computational resources and time consumption, we perform 4-bit quantization on it. The SFT parameters of the Adapter LM are shown in Table 6.

Hyperparameter	**Value**
quant type	`nf4`
learning rate	2e-4
batch size	4
gradient accumulation step	1
weight decay	1e-3
max grad norm	0.3
warmup ratio	0.3
lora alpha	16
lora dropout	0.1
lora r	64
N_{gen} (w/ GPT3.5)	10
N_{gen} (w/ GPT4)	20
N_{sft}	1e3

Table 6: Hyperparameters for Supervised Fine-Tuning.

B.3 Decision LLM

We call the API interfaces of OpenAI's `gpt-4` and `gpt-3.5-turbo` models. The API parameters used are shown in Table 7.

Hyperparameter	**Value**
temperature	0.5
top_p	1.0
max_tokens	100

Table 7: Hyperparameters for LLM.

B.4 Text Embedding

For text embedding, we choose the open-source `paraphrase-MiniLM-L6-v2` model as the encoder.

Case	Description	Explanation
	The agent tends to place stones between itself and monsters to avoid combat at night (the number of monsters will increase).	Frequent combats are not conducive to maintaining health and can delay other tasks such as resource collection. Therefore, the agent chooses to avoid combat at the appropriate time.
	The agent does not immediately place a workbench to craft tools and unlock achievements when it has abundant resources, but instead places the workbench when moving to resource-rich areas.	Placing the workbench in resource-rich areas can reduce the distance between collecting resources and crafting items, thus improving efficiency.

Table 8: Case study on agent behaviors grounded in common sense. These behaviors demonstrate the ability of the Adapter LM in uncovering human knowledge behind LLMs.

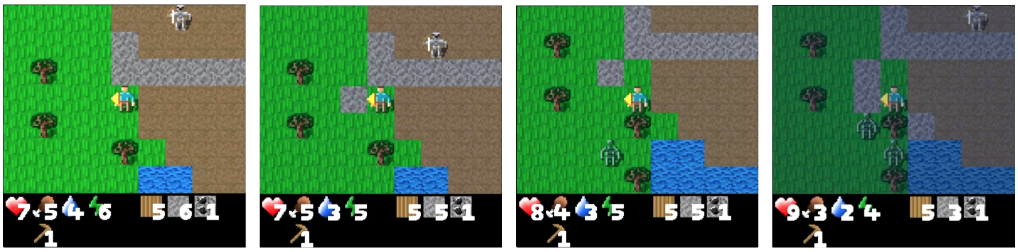

Figure 6: Case details of avoiding combat.

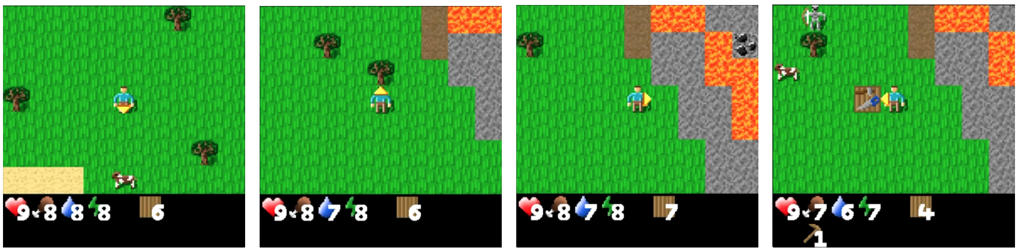

Figure 7: Case details of resource planning.

C Agent Behaviors Grounded in Common Sense

As discussed in Section 4.5, the policy trained by AdaRefiner exhibits behaviors like avoiding combat. Although this may result in a partial performance decrease for the achievements“Defeat Skeleton” and “Defeat Zombie”, it could be more advantageous for survival and better completion of other tasks. In this sense, AdaRefiner demonstrates behaviors that align with human common sense. We further analyze additional replays and find other cases of human-like behavior in the policy trained by AdaRefiner, as shown in Table 8.

In the two cases, AdaRefiner demonstrates behaviors such as using stones to block monsters and extend survival time, as well as placing workbenches in resource-rich areas for more efficient resource utilization. These behaviors are not observed or reported in other baselines or in the version of AdaRefiner w/o Adapter LM. This further demonstrates that the Adapter LM can better capture the agent’s learning ability and uncover common-sense knowledge behind LLMs, prompting them to provide more useful and reasonable guidance for better decision-making.

C.1 Details of Avoiding Combat

As shown in Figure 6, it is approaching night and the number of monsters is increasing. The agent starts early to strategically place stones in suitable terrain, successfully building a shelter that can keep the monsters outside and extend its survival time.

C.2 Details of Resource Planning

As shown in Figure 7, even though the agent has enough wood to make a workbench, its observations do not reveal abundant resources. Therefore, instead of rushing to make a workbench, it waits until more resources are discovered before making one nearby. This strategy can optimize the efficiency of resource collecting and item crafting.

D Full Prompt Details

In the following, we provide detailed prompts as well as corresponding example outputs for different methods.

D.1 Example for Adapter LM

`System message:`

```
You are a professional game
analyst. A player is playing a
game similar to Minecraft.
Available actions are:
<move_left, move_right, move_up,
move_down, do, sleep, place_stone
, place_table, place_furnace,
place_plant, make_wood_pickaxe,
make_stone_pickaxe,
make_iron_pickaxe,
make_wood_sword, make_stone_sword
, make_iron_sword>.

You will get the player's
observation, status information,
and its comprehension score of
language guidance (between 0 and
1). You are collaborating with
another analyst, and you will be
asked to provide concise
summaries and suggestions about
this player.
```

`Example prompt:`

```
Player sees: <grass, water, cow>

Player status: <7 health, 5 food,
 6 drink, 4 energy>

Past action: <sleep>

Past sub-goals:
- eat cow
- collect stone
- place stone

Comprehension score: <0.131>

Analyze the environment and the
player's understanding capability
,then generate concise summaries
and suggestions about this player
.
```

`Example output:`

```
The player seems to struggle with
 understanding past sub-goals,
possibly indicating an early
stage in the learning process. To
 help the agent learn the skill
of eating cow more quickly,
```

```
please provide more detailed
guidance.
```

D.2 Example for Decsion LLM

System message:

```
You are a professional game
analyst. A player is playing a
game similar to Minecraft.
Available actions are:
<move_left, move_right, move_up,
move_down, do, sleep, place_stone
, place_table, place_furnace,
place_plant, make_wood_pickaxe,
make_stone_pickaxe,
make_iron_pickaxe,
make_wood_sword, make_stone_sword
, make_iron_sword>.

You will get analysis about this
player from another analyst, and
you will be asked to provide the
next sub-goals for this player.
```

Example prompt:

```
Player sees: <grass, water, cow>

Player status: <7 health, 5 food,
 6 drink, 4 energy>

Past action: <sleep>

Past sub-goals:
- eat cow
- collect stone
- place stone

Analysis: <The player seems to
struggle with understanding past
sub-goals, possibly indicating an
 early stage in the learning
process. To help the agent learn
the skill of eating cow more
quickly, please provide more
detailed guidance.>

Based on the provided information
, suggest 3 sub-goals that the
player should accomplish next.
```

Example output:

```
find cow, move to cow, eat cow
```

D.3 Example for Decsion LLM in *AdaRefiner w/o Adapter LM*

System message:

```
You are a professional game
analyst. A player is playing a
game similar to Minecraft.
Available actions are:
<move_left, move_right, move_up,
move_down, do, sleep, place_stone
, place_table, place_furnace,
place_plant, make_wood_pickaxe,
make_stone_pickaxe,
make_iron_pickaxe,
make_wood_sword, make_stone_sword
, make_iron_sword>.

You will get necessary
information and player's
comprehension score of language
guidance (between 0 and 1). You
will be asked to provide the next
 sub-goals for this player.
```

Example prompt:

```
Player sees: <grass, tree, water>

Player status: <6 health, 7 food,
 3 drink, 1 energy>

Past action: <move_up>

Past sub-goals:
- eat cow
- collect stone
- place stone

Comprehension score: <0.165>

Based on the provided information
, suggest 3 sub-goals that the
player should accomplish next.
```

Example output:

```
collect stone, make stone sword,
make stone pickaxe
```

D.4 Example for Vanilla GPT-4

System message:

```
You are a professional game
analyst. A player is playing a
game similar to Minecraft.
Available actions are:
<move_left, move_right, move_up,
move_down, do, sleep, place_stone
, place_table, place_furnace,
place_plant, make_wood_pickaxe,
make_stone_pickaxe,
make_iron_pickaxe,
make_wood_sword, make_stone_sword
, make_iron_sword>.

You will get necessary
information and player's
comprehension score of language
guidance (between 0 and 1). You
will be asked to provide the next
 action for this player. You are
only allowed to choose the
available action.
```

Example prompt:

```
You see (object with coordinate)
<cow(2,2), tree(3,1), ...>

Player status: <8 health, 8 food,
 8 drink, 6 energy>

Past action: <make_wood_pickaxe>

Comprehension score: <0.275>

Based on the provided information
, provide the next action for
this player.
```

Example output:

```
move_right
```

D.5 Example for Reflexion

```
Environment: You are playing a
game similar to Minecraft.
Available actions are
<move_left, move_right, move_up,
move_down, do, sleep, place_stone
, place_table, place_furnace,
place_plant, make_wood_pickaxe,
make_stone_pickaxe,
make_iron_pickaxe,
make_wood_sword, make_stone_sword
, make_iron_sword>.

Task: Unlock following
achievements
<Collect Coal, Collect Diamond,
Collect Drink, Collect Iron,
Collect Sapling, Collect Stone,
Collect Wood, Defeat Skeleton,
Defeat Zombie, Eat Cow, Eat Plant
, Make Iron Pickaxe, Make Iron
Sword, Make Stone Pickaxe, Make
Stone Sword, Make Wood Pickaxe,
Make Wood Sword, Place Furnace,
Place Plant, Place Stone, Place
Table, Wake Up>

You see (object with coordinate)
<water(-1,2), cow(2,3), cow
(-3,-1), ...>

Your status:
<9 health, 3 food, 2 drink, 6
energy>
```

```
think: Considering the current
status, I need to find some food
and drink.

think: There are water at (-1,2),
 I need to move to it.

action: move_left
```

```
You see (object with coordinate)
<water(0,2), cow(1,3), cow(-2,-1)
, ...>

Your status: <9 health, 3 food, 2
 drink, 6 energy>
```

```
think: Now I move one step to the
 left, my status has not changed,
 water is at (0,2). Next, I need
to move up.

action: move_up
```

D.6 Example for ReAct

```
You are playing a game similar to
 Minecraft. Available actions are
<move_left, move_right, move_up,
move_down, do, sleep, place_stone
, place_table, place_furnace,
place_plant, make_wood_pickaxe,
make_stone_pickaxe,
make_iron_pickaxe,
make_wood_sword, make_stone_sword
, make_iron_sword>.

Your task is to: Unlock following
 achievements
<Collect Coal, Collect Diamond,
Collect Drink, Collect Iron,
Collect Sapling, Collect Stone,
Collect Wood, Defeat Skeleton,
Defeat Zombie, Eat Cow, Eat Plant
, Make Iron Pickaxe, Make Iron
Sword, Make Stone Pickaxe, Make
Stone Sword, Make Wood Pickaxe,
Make Wood Sword, Place Furnace,
Place Plant, Place Stone, Place
Table, Wake Up>

You see (object with coordinate)
<tree(1,-1), cow(1,4), ...>

Your status: <9 health, 7 food, 8
 drink, 7 energy>
```

```
think: My status is good, I need
to collect some wood to make
tools. First I need to move to
the tree at (1,-1).

actions: move_right, move_down
```

E Compute Resource Details

The hardware resources we used are listed in Table 9. For each seed, the average GPU running speed is approximately 30K steps/hour.

CPU	GPU	RAM
Intel Xeon 8280@2.7GHz	Nvidia A100 (40GB)	256GB
Intel I9-12900K@3.2GHz	Nvidia RTX 3090 (24GB)	128GB

Table 9: Computational resources for our experiments.

F Licenses

In our code, we have used the following libraries which are covered by the corresponding licenses:

- Crafter (MIT license)
- OpenAI GPT (CC BY-NC-SA 4.0 license)
- Llama 2 (Llama 2 license)
- SentenceTransformer (Apache-2.0 license)

DivTOD: Unleashing the Power of LLMs for Diversifying Task-Oriented Dialogue Representations

Weihao Zeng[1*], **Dayuan Fu**[1*], **Keqing He**[2],
Yejie Wang[1], **Yukai Xu**[1], **Weiran Xu**[1*]

Abstract

Language models pre-trained on general text have achieved impressive results in diverse fields. Yet, the distinct linguistic characteristics of task-oriented dialogues (TOD) compared to general text limit the practical utility of existing language models. Current task-oriented dialogue pre-training methods overlook the one-to-many property of conversations, where multiple responses can be appropriate given the same conversation context. In this paper, we propose a novel dialogue pre-training model called DivTOD, which collaborates with LLMs to learn diverse task-oriented dialogue representations. DivTOD guides LLMs in transferring diverse knowledge to smaller models while removing domain knowledge that contradicts task-oriented dialogues. Experiments show that our model outperforms strong TOD baselines on various downstream dialogue tasks and learns the intrinsic diversity of task-oriented dialogues.

1 Introduction

Many NLP applications frequently utilize pre-trained language models (PLMs) (Devlin et al., 2019; Liu et al., 2019), which are based on extensive general text corpora (Zhu et al., 2015).These models are pre-trained in a self-supervised manner and then fine-tuned for supervised downstream tasks. The Pretrain and Finetune paradigm has significantly improved the performance of various downstream tasks. Despite their success, most current research efforts focus on general documents such as Wikipedia, which have a large linguistic gap with dialogues, particularly task-oriented dialogues. Directly using these PLMs is not ideal and yields poor performance (Rashkin et al., 2019).

Compared to plain text, TOD aims to help users accomplish specific tasks with explicit goals (e.g. restaurant reservation), belief states, and database information. Thus, learning high-quality dialogue representations is crucial for understanding tasks in TOD. Previous methods pre-trained models using task-oriented dialogue datasets to improve dialogue understanding performance. SimCSE (Gao et al., 2021) uses a contrastive learning framework to learn sentence embeddings by generating positive pairs through Dropout (Srivastava et al., 2014) augmentation. TOD-BERT (Wu et al., 2020) considers the intrinsic properties of dialogue data by using dialogue history and corresponding responses as positive pairs for contrastive learning. DSE (Zhou et al., 2022) learns from dialogues by taking consecutive utterances of the same dialogue as positive pairs. Furthermore, FutureTOD (Zeng et al., 2023) proposes a new non-contrastive self-training framework to address the challenges faced by previous contrastive methods in selecting true positive and negative pairs.

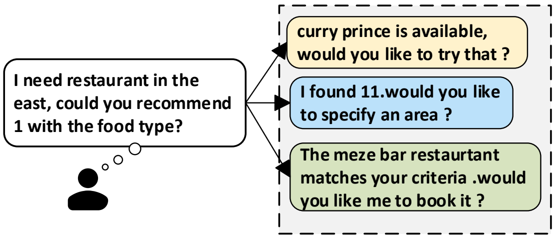

Figure 1: The same context may have multiple appropriate responses in a task-oriented dialogue, which we call one-to-many.

Despite previous TOD PLMs have made remarkable progress. Most work ignores the one-to-many property in the conversation where multiple responses can be appropriate under the same conversation context (shown in Figure 1). Our analysis shows that the lack of diversity in TOD datasets is the main reason for this. Specifically, (1) most TOD datasets only provide a single response for the same dialogue history, and (2) the style of system responses in TOD is often monotonous and dull. As a result, current TOD PLMs capture only

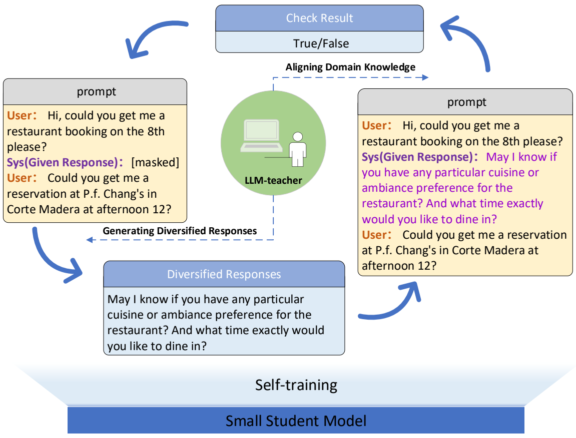
Findings of the Association for Computational Linguistics: NAACL 2024, pages 800–813
June 16-21, 2024

the most common dialogue information and ignore less frequent but still feasible user behaviors, which leads to duplicated and plain responses.

Large Language Models (LLMs) (Brown et al., 2020; Ouyang et al., 2022; Touvron et al., 2023) offer hope for addressing the problems mentioned above. LLMs have more parameters and are pre-trained and fine-tuned on a richer and wider corpus (Köpf et al., 2023; Chiang et al.; Ding et al., 2023). Consequently, LLMs possess a broader general background knowledge, which enables them to generate more diverse and feasible responses. However, it should be noted that LLMs have not been specifically fine-tuned for task-oriented dialogue systems (Hudeček and Dušek, 2023), resulting in a significant mismatch between their general knowledge and the domain knowledge required for task-oriented dialogue. Furthermore, LLMs typically have billions of parameters, making them too expensive to deploy at scale because of the overwhelming computational requirements, as well as the cost of fine-tuning and inference (Wei et al., 2022). To address these issues, a natural approach is to distill the rich background and domain-specific knowledge required for tasks from LLMs into smaller and more efficient models.

In this paper, we propose a new dialogue pre-training model, DivTOD, which enhances the ability of smaller models to model the intrinsic one-to-many diversity of human conversations by transferring rich general background knowledge and task-specific domain knowledge from LLMs. Our framework consists of three core steps: (1) Guiding LLMs to generate diverse system responses based on dialogue context in a "filling the blank" manner. (2) Using an LLM-based post-generation filter to align the generated responses with domain knowledge. (3) Allowing small models to imitate LLM's capabilities by observing diverse dialogues through self-training. We evaluated DivTOD on various task-oriented dialogue tasks, such as intent classification, dialogue state tracking, dialogue act prediction, and response selection. The results demonstrate that DivTOD consistently outperforms strong TOD baselines in all scenarios, indicating its generalization capability. Furthermore, we observed that DivTOD can capture a wider range of dialogue information and learn the intrinsic one-to-many diversity of TOD.

Our contributions are: (1) We propose a framework that distills task-specific domain knowledge



User: Hi, could you get me a restaurant booking on the 8th please?
Sys(Given Response): [masked]
User: Could you get me a reservation at P.f. Chang's in Corte Madera at afternoon 12?

User: Hi, could you get me a restaurant booking on the 8th please?
Sys(Given Response): May I know if you have any particular cuisine or ambiance preference for the restaurant? And what time exactly would you like to dine in?
User: Could you get me a reservation at P.f. Chang's in Corte Madera at afternoon 12?

May I know if you have any particular cuisine or ambiance preference for the restaurant? And what time exactly would you like to dine in?

and rich general background knowledge of LLMs into smaller models. We use this framework to pre-train DivTOD and model the intrinsic one-to-many diversity of human conversations. (2) Our DivTOD outperforms strong TOD baselines on diverse downstream dialogue tasks. It also learns the intrinsic diversity of task-oriented dialogues

2 Model

2.1 Overall Architecture

Figure 2 shows the overall architecture of DivTOD. Our framework comprises a teacher model M_T based on LLM and a student model M_S based on a smaller model, initialized by Vicuna-7b[1] and BERT-base-uncased[2], respectively. First, we guide the M_T to generate diverse system responses based on the dialogue context, using a "filling the blank" approach. Then, we use the M_T as a filter to align the generated response with the domain knowledge of the task-oriented dialogue context. Finally, by continuously iterating the generate-filter steps, we enable the M_S to train on both the original dataset and the generated dataset using the self-training method proposed in Zeng et al. (2023).

2.2 Diversifying Task-Oriented Dialogue Representations

Notation We use the collected datasets by TOD-BERT (Wu et al., 2020) as our pre-training corpus. The corpus is the combination of 9 publicly available task-oriented datasets, including 100,707 dialogues and 1,388,152 utterances over 60 domains. For each dialogue, we first transform it into a token sequence $D = \{U_1, S_1, \ldots, U_n, S_n\}$. U_i and

---

[1] https://huggingface.co/lmsys/vicuna-7b-delta-v1.1

[2] https://huggingface.co/bert-base-uncased

S_i denote the user utterance and system utterance with a prefix of two special role tokens [USR] or [SYS], respectively. n is the turn number of the dialogue.

Generating Diversified Responses We use a "filling in the blank" approach to guide M_T in generating diverse responses based on the dialogue context. For a given dialogue D, we randomly mask a system response S_i and use the remaining part as the input $D^{'}$. We design a few-shot prompt P consisting of a triplet (I^P, D^P, S^P) to instruct M_T in generating diverse responses $S_i^{'}$ based on $D^{'}$ [3]. The core component of the P is I^P, which describes the task to the model. I^P also constrains the behavior of the model, preventing it from generating irrelevant responses. D^P is the input example, and S^P is the corresponding generated response [4]. For each input $D^{'}$, we append it to P and use it as input to prompt M_T to generate diverse responses. M_T can mimic the demonstrations D^P, S^P in P to generate new diverse responses. The complete prompt example is shown in Figure 5 in Appendix.

Aligning Domain Knowledge Although we can obtain more diverse responses using M_T, these responses may contradict the characteristics of task-oriented dialogue systems. For example, the generated responses may provide excessive information that the user does not need or answer questions that the user asks in the future. To ensure that the generated responses align with domain knowledge in TOD, we designed a filter based on M_T.We replace the masked parts in $D^{'}$ with the generated response $S_i^{'}$ to form a new input $D^{''}$. We have designed a few-shot prompt E consisting of a triplet (I^E, D^E, R^E) to prompt M_T to judge the contextual consistency of $D^{''}$ and whether it conflicts with the characteristics of TOD. The core part of the prompt is I^E, which describes the task to M_T. The prompt also provides logical knowledge related to task-oriented dialogue. D^E and R^E are the demonstrations provided to M_T. D^E represents the example input, and R^E represents the corresponding judgment result (either True or False). We append $D^{''}$ to E and determine whether to keep $S_i^{'}$ based on the filtering result. Figure 6 in the Appendix shows a complete example of this prompt.

Self Training We iterate through the generate-filter steps (summarized in Algorithm 1 in Appendix) described above and combine the newly generated dialogues with the original ones.

We train M_S using the self-training objective proposed by FutureTOD (Zeng et al., 2023) on the assembled dialogues. We initialize the new student model and teacher model using M_S [5]. For each dialogue, we randomly split it into context and future sequences. The student model encodes the context and obtains the original dialogue representation, while the teacher model encodes both the context and future to obtain the target. The architectures of the student and teacher models are the same, but the weights of the teacher model are periodically updated by the student. The training goal is to align the original content representation with the full representation containing future knowledge. The generate-filter steps produce diverse responses, resulting in multiple reasonable full representations that can align with the same content representation.

Through the above framework of generation, filtering, and self-training, we transfer both general background knowledge and task-specific domain knowledge from M_T to M_S.

3 Experiment

3.1 Pre-training Corpus

We use the nine different task-oriented datasets collected by Wu et al. (2020) and show the full details in Appendix A.

3.2 Baselines

DivTOD is evaluated on various downstream tasks and compared to several well-established baselines, including both encoder-only and generative architectures. For details about the baselines, please refer to the Appendix B.

3.3 Implementation Details

LLM generating Details We use Vicuna as LLM to generate diverse system responses and to align domain knowledge. For experimental details and hyperparameter settings for this stage, please refer to the Appendix C.1.

Pre-training Details After diverse system response generation, all the dialogue will be merged

---

[3] We try different methods to instruct M_T, including zero-shot prompts. However, these methods are not very effective. For example, the pass rate of the zero-shot method is low in our post-filter.

[4] We have manually created a set of few-shot examples. During the generation process, we will randomly select samples to include in D^P and S^P.

[5] The Student model and Teacher model here differ from the previously mentioned M_T and M_S, which are concepts involved in self-training (Zeng et al., 2023).

into the original dataset as the new dataset to pre-train. The details of the hyperparameters for the pre-training can be found in the Appendix C.2.

Finetuning Details After completing pre-training on dialogue, we perform supervised fine-tuning on downstream dialogue tasks. However, it is important to note that we only use generated diverse dialogue during the pre-training phase. In the fine-tuning phase, we use datasets and settings that are identical to the previous baseline, including golden labels such as dialogue acts. The details of the hyperparameters for the pre-training can be found in the Appendix C.3.

3.4 Main Results

We evaluate all the pre-trained LMs on four core task-oriented dialogue tasks: intent recognition, dialogue state tracking, dialogue act prediction, and response selection. It is important to emphasize that our focus is on learning diverse dialogue representations. Therefore, we are more concerned with tasks related to dialogue understanding rather than tasks related to response generation. To ensure fairness in our evaluation, we adopt the same architecture for all baselines following TOD-BERT and only add simple components to the pre-trained model, such as a single-layer classification head. For each downstream task, we conduct experiments using the entire dataset. In addition, we also explored few-shot setting experiments in section 4.4. This allowed us to see how well these pre-trained language models generalize to multiple tasks and scenarios.

Intent Recognition is a multi-class classification task that takes a dialogue utterance as input and predicts an intent label (Zeng et al., 2022). We use the [CLS] embeddings from the model as the dialogue representation. We use cross-entropy loss to train the model. We report classification accuracy and recall.

The results of intent recognition on the OOS dataset (Larson et al., 2019), which encompasses 151 intent classes across ten domains, including 150 in-domain intents and out-of-domain (OOD) intents, are displayed in Table 1. We find DivTOD outperforms all the baselines on 3 of 4 metrics, especially with significant improvements in overall accuracy and OOD metrics. All the results show the generalization ability of DivTOD both on in-domain and out-of-domain metrics.

Dialogue State Tracking is also a multi-class classification task, which involves identifying the slot values for each (domain, slot) pair at each dialogue turn, based on a pre-defined ontology. The model takes dialogue history as input and is trained with cross-entropy loss summed over all the pairs. We employ the commonly used TOD dataset MWOZ 2.1 (Budzianowski et al., 2018), which spans seven distinct domains, and we present the Joint acc and Slot acc. The Joint acc is deemed true solely if the predicted values align with their ground truth values at each dialogue turn. The Slot acc, on the other hand, independently contrasts each (domain, slot, value) triplet with its corresponding ground truth label.

Model	ACC(acc)	Acc(in)	Acc(out)	Recall(out)
BERT	84.9%	95.8%	88.1%	35.6%
DialoGPT	83.9%	95.5%	87.6%	32.1%
BERT-mlm	85.9%	96.1%	89.5%	46.3%
SimCSE	82.3%	94.7%	86.6%	26.6%
TOD-BERT	86.6%	**96.2%**	89.9%	43.6%
DSE	84.3%	95.8%	87.7%	32.5%
FutureTOD	87.2%	96.0%	90.0%	47.6%
DivTOD	**87.4%***	95.8%	**90.5%***	**49.5%***

Table 1: Intent recognition results on the OOS dataset. Acc(all), Acc(in), Acc(out) denotes the overall accuracy, in-domain intent accuracy, and out-of-domain intent accuracy. The numbers with * are significant using t-test with $p < 0.01$.

Model	Joint Acc	Slot Acc
BERT	45.6%	96.6%
BERT-mlm	47.7%	96.8%
SimCSE	48.0%	96.8%
TOD-BERT	48.0%	96.9%
DSE	49.9%	97.0%
FutureTOD	50.4%	97.1%
DivTOD	**50.9%***	**97.2%***

Table 2: Dialogue state tracking results on MWOZ 2.1. We report joint goal accuracy (Joint Acc) and slot accuracy (Slot Acc). The numbers with * are significant using t-test with $p < 0.01$.

Table 2 shows the results of dialogue state tracking on MWOZ 2.1. Our DivTOD excels by achieving the best results across all metrics. We find SimCSE performs poorly because it ignores the intrinsic properties of dialogue data and can not model overall dialogue. Our method achieves a greater improvement on joint accuracy than on slot accuracy, indicating the strength of understanding the overall dialogue context. For example, DivTOD outperforms TOD-BERT by 0.3% on Slot Acc but 2.9% on Joint Acc in the full data setting, which indicates the superiority of dialogue modeling.

Dialogue Act Prediction is a multi-label clas-

DSE	63.3%	85.3%	58.3%	72.0%
FuturueTOD	68.5%	87.9%	58.4%	72.6%
DivTOD	**71.3%***	**90.4%***	**59.5%***	**74.0%***

Table 4: Response selection evaluation results on MWOZ and DSTC. We report 1-to-100 and 3-to-100 accuracy, which represents the ratio of the ground-truth response being ranked at the top-1 or top-3 given 100 candidates. The numbers with * are significant using t-test with $p < 0.01$.

sification task that uses dialogue history as input to forecast multiple dialogue acts related to the system response. The model employs binary cross-entropy loss across all potential actions for training. At the time of inference, the threshold to activate the dialogue act is established at 0.5. We use two datasets MWOZ (Budzianowski et al., 2018) and DSTC2 (Henderson et al., 2014). Following (Wu et al., 2020), We implement identical data preprocessing to standardize the original dialogue acts into a universal format. We present the micro-F1 and macro-F1 results.

Table 3 displays dialogue act prediction's result on MWOZ and DSTC2 datasets. Our DivTOD method outperforms all other baselines in three out of four metrics. Specifically, our method surpasses FutureTOD on the DSTC2 dataset, demonstrating significant improvement. It also exhibits improvement on MWOZ, with the macro-F1 increasing from 81.9% to 82.6%. However, we notice that different methods exhibit unclear distinctions in terms of micro-F1. We attribute this to the imbalanced distribution of dialogue action labels in MWOZ. In such cases, macro-F1 provides a more reasonable evaluation metric as it assigns equal weight to each label, regardless of the number of samples. In addition to the higher response quality, we also observe that DivTOD captures a wider range of dialogue policies and learns the intrinsic one-to-many diversity of TOD, as discussed in Section 4.6.

Response Selection is a ranking task that aims to retrieve the most relative system response from a candidate pool based on dialogue history. We also use MWOZ and DSTC2 as our evaluation datasets. We use a dual-encoder strategy, which calculates cosine similarity scores between dialogue history and candidate responses. We train this model with random system responses from the corpus as negative samples. We report k-to-100 accuracy. This metric represents the ratio of the ground-truth response being ranked in the top-k positions when compared to 99 randomly sampled responses, as determined by the scores computed by the dual-encoder.

Table 4 displays the results of response selection on MWOZ and DSTC2. Our DivTOD method achieves state-of-the-art results on all metrics. Despite TOD-BERT being pre-trained with a response contrastive objective, our method still significantly outperforms it on both MWOZ and DSTC2 in full data settings. This indicates that Our Method has better generalization capabilities. Compared to FutureTOD, our method brings significant improvements in response selection, indicating that it can enhance the diversity of TOD representation and thus improve performance. As the context representation of the pre-trained model becomes richer, it can retrieve more precise responses, as reflected in top-1, top-3, top-10 accuracy.

In summary, our method shows notable improvements in dialogue act prediction and response selection tasks. This indicates that considering the one-to-many nature of dialogues is essential for these tasks. Furthermore, our method also achieves enhancement in other important task-oriented dialogue tasks, such as intent classification and dialog state tracking. This further highlights the generalization of our method across various tasks.

4 Qualitative Analysis

4.1 Ablation Study of Domain Knowledge Alignment

Table 6 presents the ablation study results of the domain knowledge alignment, on the two downstream tasks, dialogue act prediction on DSTC2 and response selection on MWOZ [6]. DivTOD performs the best under various conditions when training using dialogue with aligned domain knowledge. However, the performance of DivTOD w/o Align is unsatisfactory. For example, in the dialogue act prediction task, DivTOD w/o Align is similar to the baseline and lower than DivTOD's performance. This suggests that aligning with domain knowledge may help maintain consistency in TOD dialogues, thereby contributing to the likelihood that the diverse dialogues generated by LLM have a beneficial influence on the pre-training process.

To visually represent the quality of the generated dialogues by different methods, we randomly selected dialogue samples, as shown in the Figure 3. From the dialogue examples, it can be seen that the DivTOD's dialogues are different from the original text and they are all consistent with the dialogue context. However, DivTOD w/o Alignment's Dialogue produces two problems. First, LLM may not answer according to the prompt instructions, but may produce irrelevant answers such as "here's the rewritten response:". Second, LLM may produce answers that do not match the context, such as answering questions that users will only raise or provide information in the future.

4.2 Advantages of LLMs in Generating Diversified Responses

To demonstrate the advantage of LLMs over other models trained solely on TOD data in generating diversified responses, we randomly sample 500 TOD dialogue samples and generate responses using both PPTOD (Su et al., 2021) and LLM [7]. We compare the number of unique n-grams contained in the generated responses. Tabel 5 demonstrates that the responses generated by LLM contain more unique n-grams than those generated by PPTOD, even surpassing the number of unique n-grams present in the original dialogue. We analyze that PPTOD, being pre-trained on the TOD dataset, overfits the limitations of that dataset, resulting in a decrease in the diversity of responses it generates. This further supports the evidence that LLM is capable of generating more diverse responses.

Source	Unique 1-gram	Unique 2-gram	Unique 3-gram
Raw Dialogue	380	1512	2391
PPTOD	221	736	1189
Vicuna-7b	357	1793	3497

Table 5: The number of unique n-grams contained in the generated responses. "Raw Dialogue," "PPTOD," and "Vicuna-7b" refer to responses from the original dialogues, PPTOD, and the LLM we utilized.

Method	MWOZ		DSTC2	
	1-to-100	3-to-100	micro-F1	macro-F1
FutureTOD	68.5%	87.9%	94.6%	44.6%
DivTOD w/o Align	70.0%	90.1%	94.8%	44.2%
DivTOD	**71.3%**	**90.4%**	**95.8%**	**46.5%**

Table 6: Ablation Study of Domain Knowledge Alignment. DivTOD w/o Align denotes the DivTOD without domain knowledge alignment.

4.3 Quantity of Diverse Dialogues

In our default experimental setting, we instructed LLMs to generate about 50k diverse dialogues for dialogue pre-training. Figure 4 shows the effect of varying the number of diverse dialogues during pre-training, on the two downstream tasks of dialogue act prediction on DSTC2 and response selection on MWOZ. We find the performance of DivTOD on both two tasks gradually improves as the number of diverse dialogues increases. This indicates that diverse dialogues generated by large language models can continuously improve the model's generalization.

4.4 Few Shot Learning

Table 7 displays the results of dialogue act prediction on DSTC2 and response selection on MWOZ in few shot setting. [8] Our DivTOD achieves state-of-the-art results on all the metrics. Although our DivTOD method and FutureTOD were both pre-trained using non-contrastive self-training frameworks, our DivTOD method significantly outperforms FutureTOD on both datasets in both 1% and 10% data settings. This demonstrates that DivTOD has a superior generalization capability across different scenarios.

We used the same pre-training corpus as the previous baseline, which includes MWOZ and CamRest676 (also part of MWOZ). However, concerns may arise about the reliability of few-shot performance due to this. To address this, we excluded MWOZ and CamRest676 from the pre-training corpus and evaluated the performance of Future-

---

[6] Considering the cost of qualitative analysis, we select two classic task-oriented tasks. Furthermore, we use different datasets for each task to ensure generalizability.

[7] We do not include PPTOD in the main results because they use supervised labels. We focus on unsupervised dialogue pretraining and do not compare with it for fairness.

[8] TOD-BERT uses the response contrastive loss as the pre-training objective on full MWOZ training data so we don't report its results on few-shot setting.

Table 7: Dialogue act prediction on DSTC2 and response selection on MWOZ for few-shot settings. DivTOD† and FutureTOD† are the models obtained by removing MWOZ and CamRest676 from the pre-training corpus. For DivTOD, we also excluded diversed dialogues generated from these two datasets.

TOD and DivTOD on a 1% data setting. On the MWOZ dataset, the performance of FutureTOD† and DivTOD† decreased. This suggests that including MWOZ in the pre-training phase does enhance few-shot performance. However, our DivTOD† still achieves good performance and surpasses FutureTOD†. Surprisingly, on the DSTC2 dataset, DivTOD† and FutureTOD† also exhibit a slight decrease in performance. This highlights the high quality of MWOZ as a TOD dataset and provides some justification for its inclusion in the pre-training corpus in the previous baseline.

4.5 Zero Shot Learning

To validate the unsupervised embedding capability of our model, we performed zero-shot response selection on the MWOZ and DSTC2 datasets. The results are displayed in Table 8. BERT, FutureTOD, and DivTOD use an encoder architecture, while LLaMA and Vicuna use a decoder architecture. Therefore, for encoder models, we use the hidden state of the [CLS] layer as the embedding for inference retrieval, while for decoder models, we use the hidden state corresponding to the last input character as the embedding (consistent with the settings of DialoGPT). Our DivTOD outperforms BERT, FutureTOD, and LLaMA on all metrics, and is comparable to Vicuna. This indicates that the model has already gained strong context representation ability from the diverse dialogue data pre-training provided by Vicuna. However, the time cost and parameter size are much smaller than LLM like Vicuna, with a 14-fold and 70-fold reduction respectively

4.6 Representation Diversity

To understand whether our DivTOD can capture more diverse dialogue information and learn the intrinsic one-to-many diversity of TOD, we perform a qualitative analysis on the MWOZ test set. For each dialogue history, we select 2000 randomly sampled responses. We then compute the cosine distance between the representations of the dialogue history and response using a pre-trained response selection model in Table 4. We select the top 10 responses according to the cosine distance and compute Diversity and Coherence as the automatic metrics. Diversity denotes the number of unique types of dialogue acts in the top 10 responses. Coherence

Model	Dataset	1-to-100	3-to-100	5-to-100	10-to-100	Inference efficiency	Parameter size
BERT	**MWOZ**	1.8%	6.0%	9.9%	20.0%	89.9	110M
FutureTOD		2.1%	6.3%	10.4%	20.7%	89.9	110M
LLaMA-7b		2.2%	6.3%	10.4%	20.7%	5.3	7B
Vicuna-7b		**2.6%**	**7.3%**	**11.8%**	**22.7%**	5.3	7B
DivTOD (50k)		2.5%	6.3%	11.0%	21.2%	89.9	110M
BERT	**DSTC2**	1.0%	3.3%	6.3%	16.5%	89.9	110M
FutureTOD		1.7%	5.1%	9.0%	17.9%	89.9	110M
LLaMA-7b		2.1%	6.0%	10.1%	19.6%	5.3	7B
Vicuna-7b		2.0%	6.2%	10.5%	20.4%	5.3	7B
DivTOD (50k)		**2.2%**	**6.6%**	**11.1%**	**21.1%**	89.9	110M

Table 8: Response Selection on DSTC2 and MWOZ for zero-shot setting. We report 1-to-100, 3-to-100, 5-to-100, and 10-to-100 accuracy, which represents the ratio of the ground-truth response being ranked at the top-1,top-3, top-5 and top-10 given 100 candidates. Inference efficiency denotes the number of samples a model can infer per second when deployed on an Nvidia Tesla A100 GPU.

denotes average relevance scores between history and top-10 responses using a fine-tuned dual encoder in the response selection task.[9] We combine these two metrics to get the combined scores to measure the overall automatic response diversity and quality. The left part of Table 9 shows the automatic results of different pre-trained models. Our model has advantages in all metrics, indicating that our model can capture rich dialogue policies without sacrificing response relevance. We also find TOD-BERT achieves comparable performance on coherence but performs worst on diversity, even worse than BERT. It proves that the noise introduced by the selection of positive and negative samples in contrastive learning may hurt the one-to-many diversity of dialogue representations.

Following Zhang et al. (2020a), we conduct a human evaluation to assess the appropriateness of individual responses and the diversity among selected responses. The appropriateness(App) is scored on a Likert scale of 1-3 for each response, while the diversity is scored on a Likert scale of 1-5 for all top 10 responses. We sample one hundred dialogue histories and corresponding top 10 responses retrieved by different pre-trained models. These samples are then scored by three judges given the dialogue history. The right part of Table 9 shows the results of the human evaluation. We can find that the results of the human evaluation have the same trend as the automatic evaluation. Both the automatic evaluation and the human evaluation prove that our DivTOD model can learn the intrinsic one-to-many diversity of task-oriented dialogues.

Model	Automatic			Human	
	Diversity	Conherence	Combineed	Diversity	App
BERT	5.50	0.668	12.18	1.97	1.23
BERT-mlm	5.43	0.689	12.32	2.07	1.67
SimCSE	5.48	0.675	12.23	1.93	1.47
TOD-BERT	5.05	0.709	12.14	2.20	1.87
DSE	6.17	0.680	12.97	2.53	1.33
FutureTOD	6.33	0.706	13.39	2.67	1.91
DivTOD	**7.92**	**0.730**	**15.22**	**2.88**	**1.94**

Table 9: The automatic results and human evaluation results of response diversity on the MWOZ test set. The combined score is the overall automatic result which is calculated as follows: Combined score = Diversity + 10*Conherence.

5 Related Work

Dialogue Pre-trained Language Models Zhang et al. (2020b) use pre-trained GPT-2 model (Radford et al., 2019) on Reddit data for open-domain dialogue response generation. PLATO (Bao et al., 2019) pre-trains a dialog generation model with discrete latent variables using Twitter and Reddit data, which implicitly models dialog policy and solves the one-to-many mapping problem in open-domain dialog generation. However, since these models focus on chitchat dialogue, we do not compare them with our DivTOD. Wu et al. (2020); Zhou et al. (2022) use contrastive learning to learn TOD dialogue representations. Henderson et al. (2020); Liu et al. (2021) use similar ideas for dialogue retrieval and response selection. Zeng et al. (2023) proposes a non-contrastive framework that distills future knowledge into the representation of the previous dialogue. Apart from these unsupervised methods, Zhou et al. (2022); He et al. (2022) use labeled dialogue data for supervised or semi-supervised pre-training. Since we focus on unsupervised TOD pre-training in this paper, we do not compare these models and leave it to future work.

Enhancing small models with LLMs Large Lan-

---

[9] We use TOD-BERT model in Table 4, but we observe similar results using other response selection models.

guage Models (LLMs) (Han et al., 2021; Bommasani et al., 2021), such as ChatGPT and GPT-4 (OpenAI, 2023), have demonstrated excellent generalization abilities in many language-related tasks. Recently, there have been many efforts to distill powerful LLMs for data augmentation, hoping to obtain equally powerful larger models through this approach without modifying the training objectives or model structures. For example, SelfInstruct (Wang et al., 2022) and Alpaca (Touvron et al., 2023) generate 52k high-quality instruction-response pairs by distilling Text-Davinci-003, based on 175 seed tasks. In another line of work, LLMs are used to improve the ability of small models for specific tasks. Ho et al. (2022) and Hsieh et al. (2023) use LLMs to generate rationales that enhance the model's reasoning ability. Liang et al. (2023) uses LLMs as a math tutor to improve the model's math ability. In impossible distillation (Jung et al., 2023), LLMs help models generate high-quality and controllable summarizations and paraphrases. In contrast to previous work, we transfer rich background knowledge from LLMs to smaller models while filtering out domain knowledge that is irrelevant to the task-oriented dialogue system.

6 Conclusion

We propose a new dialogue pre-training called DivTOD to diversify task-oriented dialogue representations by modeling the intrinsic one-to-many diversity of human conversations. DivTOD guides LLMs to transfer diverse background knowledge to smaller models while filtering domain knowledge that conflicts with task-oriented dialogues. Our experiments on various task-oriented dialogue tasks show that DivTOD outperforms FutureTOD, TOD-BERT, DSE, and other strong baselines. We plan to release all pre-trained models and code to facilitate future research. In the future, we hope to explore larger pre-trained models and more task-oriented dialogue corpora and extend similar ideas to generative dialogue models.

Limitations

While DivTOD achieves significant improvements over existing baselines, there are still directions to explore for future work. (1) We have designed a simple and effective method for LLMs to help dialogue pre-train models capture the intrinsic one-to-many diversity of human conversations. However, we have not considered solving this problem through the structure of the dialogue pretraining model. In the future, we will explore designing more efficient architectures for dialogue pretraining models and more efficient methods of knowledge transfer. (2) DivTOD only focuses on dialogue understanding tasks, such as dialogue act prediction and response selection. In the future, we will expand the idea of LLM collaborating with small models to generative dialogue pre-trained models. (3) We attempt various instructions to constrain the responses of M_T, including zero-shot prompts. However, these methods have not been very effective. For instance, the pass rate of the zero-shot method is relatively low in our post-filter. So we did not report these results. In the future, we plan to explore more advanced prompt techniques, such as the CoT method, to enhance our approach.

Ethics Statement

We use Large Language Models (LLMs) to generate diverse responses. Despite our efforts to align domain knowledge, LLMs are inevitably prone to generating biased content. We anticipate that future research will focus on reducing the anti-social biases inherent in LLMs.

A Pre-training Data Statistics

We use the nine different task-oriented datasets collected by (Wu et al., 2020): MetaLWOZ (Lee et al., 2019), Schema (Rastogi et al., 2020), Taskmaster (Byrne et al., 2019), MWOZ (Budzianowski et al., 2018), MSR-E2E (Li et al., 2018), SMD (Eric et al., 2017), Frames (Asri et al., 2017), WOZ (Mrksic et al., 2017), CamRest676 (Rojas-Barahona et al., 2017). We show the full statistics in Table 10.

B Baselines

DivTOD is evaluated on a variety of downstream tasks and compared to several well-established baselines. One such baseline is BERT (Devlin et al., 2019), which is the original BERT-base-uncased model that was pre-trained on a large text corpus. Another baseline is BERT-mlm, which is a version of BERT that underwent continual pre-training using MLM on our pre-training dialogue corpus. DialoGPT (Zhang et al., 2020b) is also included as a baseline, it is a decoder-only dialogue generation model that utilizes a language modeling target. SimCSE (Gao et al., 2021) constructs positive pairs using Dropout and undergoes further pre-training on the same TOD corpus. TOD-BERT (Wu et al., 2020) employs a contrastive response selection objective, treating a response utterance and its dialogue context as a positive pair. DSE (Zhou et al., 2022) takes consecutive utterances from the same dialogue as positive pairs.[10] FutureTOD(Zeng et al., 2023) uses a non-contrastive self-training framework with a self-distillation mechanism. It should be noted that some dialogue pretraining methods adopt an encoder-decoder architecture, but they usually use supervised settings, i.e. using labeled NLI datasets (Williams et al., 2018; Welleck et al., 2019) or dialogue act labels (He et al., 2022). However, our focus is on unsupervised dialogue pretraining, and for fairness, we do not compare with them.

To validate the unsupervised embedding capability of our model, we also compared it with the 7B model LLaMA (Touvron et al., 2023) and Vicuna (Chiang et al.) in a zero-shot response selection task. LLaMA is a powerful open-source large-scale model trained on a large corpus, while Vicuna is fine-tuned based on LLaMA using 70K high-quality conversation data.

C Implementation Details

C.1 LLM generating Details

We use Vicuna as LLM to generate diverse system responses and to align domain knowledge. For generation settings, the maximum generation length is 1024, the temperature is 0.7, and in order to ensure dialogue diversity, we choose to perform sampling. For verification settings, we obtain the logits corresponding to True and False in the first word of Vicuna's decoding as the basis. In addition, if the model does not understand the task[11], it will also be considered as not passing verification. If the response does not pass verification, Vicuna will generate a response again and verify it. The original dialogue will be retained if the generated response fails verification 5 times. Half responses in the dialogue will be rewritten. After diverse system response generation, all the dialogue will be merged into the original dataset as the new dataset to pre-train.

C.2 Pre-training Details

In DivTOD, we utilize a batch size of 48 and set the maximum input length to 512. The models are initialized using BERT-base-uncased and optimized using the Adam optimizer and a linear learning rate scheduler with an initial learning rate of 5e-5.

---

[10] In the interest of fairness, we use the unsupervised version of DSE, as done by Zeng et al. (2023).

[11] For example, answering "I am a large language model" or "Okay, here is the written response you need", etc.

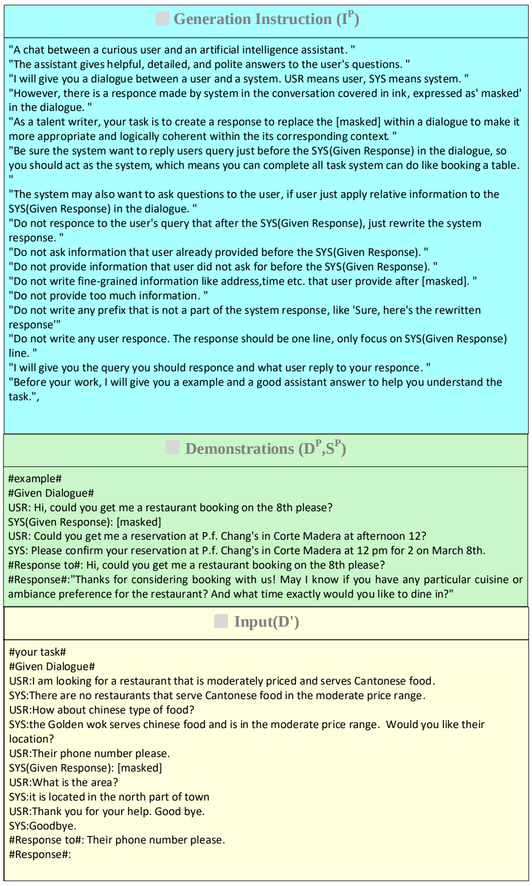
A dropout ratio of 0.2 is employed and the mask ratio is set to 15%. The predictor MLP head consists of two linear layers and a ReLU activation layer with an input dimension of 768 and a middle hidden dimension of 512. Upon completion of pre-training, all parameters of the Bert encoder are saved and the MLP head module is dropped for fine-tuning downstream tasks. Using an early-stopped strategy based on the perplexity scores of a held-out development, the pre-training process is conducted on eight NVIDIA Tesla A100 GPUs and takes five days. We use pre-trained models including BERT-MLM and TOD-BERT released by (Wu et al., 2020), DSE model released by (Zhou et al., 2022), and FutureTOD model released by (Zeng et al., 2023). We re-implement SimCSE(Gao et al., 2021) using dropout to construct positive pairs and augment every single utterance obtained through dropout on our pre-training corpora. In terms of computational efficiency during pre-training, our DivTOD model is comparable to other baselines.

C.3 Finetuning Details

We directly use the results reported by TOD-BERT (Wu et al., 2020) for BERT-mlm and TOD-BERT. We adopt the same hyperparameters for all downstream tasks except the batch size and learning rate. We finetune all downstream tasks with the original dataset for 50 epochs with an early-stopped strategy evaluated on the validation set every 100 steps with patience set to 10. We respectively set the batch size to 8, 25, 16, and 100 for intent recognition, dialogue state tracking, dialogue act prediction, and response selection and keep the learning rate to 5e-5 for all the tasks.

D Prompt Examples

We provided prompts for generating diversified responses and aligning domain knowledge in Figure 5 and Figure 6, respectively.



Generation Instruction (I^P)

```
"A chat between a curious user and an artificial intelligence assistant. "
"The assistant gives helpful, detailed, and polite answers to the user's questions. "
"I will give you a dialogue between a user and a system. USR means user, SYS means system. "
"However, there is a responce made by system in the conversation covered in ink, expressed as' masked'
in the dialogue. "
"As a talent writer, your task is to create a response to replace the [masked] within a dialogue to make it
more appropriate and logically coherent within the its corresponding context. "
"Be sure the system want to reply users query just before the SYS(Given Response) in the dialogue, so
you should act as the system, which means you can complete all task system can do like booking a table.
"

Teaching a Multilingual Large Language Model to Understand Multilingual Speech via Multi-Instructional Training

Pavel Denisov and **Ngoc Thang Vu**
University of Stuttgart, Institute for Natural Language Processing, Germany
`{pavel.denisov, thang.vu}@ims.uni-stuttgart.de`

Abstract

Recent advancements in language modeling have led to the emergence of Large Language Models (LLMs) capable of various natural language processing tasks. Despite their success in text-based tasks, applying LLMs to the speech domain remains limited and challenging. This paper presents BLOOMZMMS, a novel model that integrates a multilingual LLM with a multilingual speech encoder, aiming to harness the capabilities of LLMs for speech recognition and beyond. Utilizing a multi-instructional training approach, we demonstrate the transferability of linguistic knowledge from the text to the speech modality. Our experiments, conducted on 1900 hours of transcribed data from 139 languages, establish that a multilingual speech representation can be effectively learned and aligned with a multilingual LLM. While this learned representation initially shows limitations in task generalization, we address this issue by generating synthetic targets in a multi-instructional style. Our zero-shot evaluation results confirm the robustness of our approach across multiple tasks, including speech translation and multilingual spoken language understanding, thereby opening new avenues for applying LLMs in the speech domain.

1 Introduction

Language modeling task involves predicting subsequent text tokens based on a context of preceding ones (Jurafsky and Martin, 2009). Training a language model (LM) requires only raw text samples, as portions of these samples function as their labels, facilitating a self-supervised learning (SSL) approach. The widespread availability of machine-readable text online, coupled with advancements in computational power, has led to the rise of large LMs (LLMs) in recent years. These LLMs not only generate highly fluent natural text but also encode higher-level knowledge within their parameters. This enables them to tackle natural language processing tasks like reading comprehension and machine translation based only on task specific instructions, without needing labeled data (Radford et al., 2019).

SSL has recently made significant strides in the speech domain (Baevski et al., 2020). Most applications of SSL in speech employ an encoder that transforms raw speech signals into high-level representations, serving either as a fixed feature extractor (Yang et al., 2021) or a tunable pretrained model for various downstream tasks (Babu et al., 2021). Incorporating of SSL pretrained encoders into Encoder-Decoder speech recognition models has dramatically reduced the amount of labeled data required for effective training (Chang et al., 2021). However, using SSL pretrained decoders in such models is relatively rare. In certain instances, SSL is part of a joint training process that seeks to learn a shared speech and text representation (Chen et al., 2022). However, this approach often demands a large dataset and considerable computational resources.

Recent work has begun to harness the powerful text generation capabilities of decoder-only LLMs by incorporating them as the decoder component of Encoder-Decoder speech processing models. Wu et al. (2023) adopt the LLaMA-7B LLM for speech translation to English by training a speech encoder from scratch using filter bank acoustic features, 14,000 hours of internal speech data in 14 languages, and outputs of internal translation system as synthetic targets. Outputs of speech encoder are aligned with the text token embedding space using CTC pretraining and downsampled by averaging of consequative frames with the same CTC output label. Ling et al. (2023) adopt the GPT2 XL LLM for fully-formatted English speech recognition by training a speech encoder from scratch using filter bank acoustic features, and 75,000 hours of internal transcribed English speech data. CTC loss is applied to speech encoder outputs as a part of the

Findings of the Association for Computational Linguistics: NAACL 2024, pages 814–834
June 16-21, 2024 ©2024 Association for Computational Linguistics

main training process and speech representations are downsampled by removal of frames classified as CTC blank labels with a predefined threshold. Li et al. (2023) adopt the LLaMA-7B LLM for long-form English speech recognition by incorporating the HuBERT-Large SSL pretrained speech encoder and finetuining it on the LibriSpeech dataset containing 960 hours of transcribed English speech. Outputs of the speech encoder are downsampled by a convolutional module trained as a part of the main training process. Fathullah et al. (2023) adopt the LLaMA-7B LLM for speech recognition in 8 languages by training a speech encoder from scratch using filter bank acoustic features and the Multilingual LibriSpeech dataset containing 50,000 hours of transcribed speech in the same 8 languages. Speech encoder is pretrained with CTC loss and its outputs are downsampled by simple discarding of every n frames. Nachmani et al. (2023) combine an internal pretrained LLM with an internal pretrained speech encoder and finetune it on the automatically transcribed LibriLight dataset containing 60,000 hours of English speech. The training is performed with a combination of the speech transcription and speech continuation tasks. The resulting model is utilized for the spoken language answering task. Most of these studies rely on conventional filter bank features for speech encoding and do not incorporate an SSL pretrained speech encoder, necessitating a large amount of training data. Moreover, scant attention has been given to leveraging the linguistic knowledge stored in LLMs for tasks beyond mere transcription and for languages other than English.

To address these challenges, we propose BLOOMZMMS, a model that fuses a multilingual LLM (BLOOMZ (Muennighoff et al., 2023)) with a multilingual speech encoder (MMS (Pratap et al., 2023)). We argue that multi-instructional training is crucial for transferring linguistic knowledge from the text to speech modality. Our experiments demonstrate that training on 1900 hours of transcribed data from 139 languages yields a multilingual speech representation compatible with a multilingual LLM in the context of Automatic Speech Recognition (ASR) task. Although this representation does not generalize well to other tasks, we show that the issue can be mitigated by generating additional synthetic targets. Our zero-shot evaluations confirm this approach's effectiveness across various tasks, including Spoken Language Translation (SLT) and multilingual spoken Natural Language Inference (NLI). Our training recipes and models are released under the Apache-2.0 license[1].

2 Method

The proposed method is outlined in Figure 1. Our model comprises the pretrained speech encoder, LLM and an intermediate Adaptor module that maps the output of the speech encoder to the latent space of the text token embeddings of the LLM. We train the Adaptor module using pairs of speech recordings and their corresponding text transcriptions, denoted as $\boldsymbol{x}$ and $\boldsymbol{y}^{\text{Transcription}}$ respectively, and keep the parameters of the speech encoder and the LLM frozen. The objective of the Adaptor training is to make its output $\boldsymbol{H}^{\text{Adaptor}}$ obtained from the input speech $\boldsymbol{x}$ as close as possible to the text embedding sequence of the ground truth transcription $\boldsymbol{H}^{\text{Transcription}} = \text{LMEmbedding}(\boldsymbol{y}^{\text{Transcription}})$, where LMEmbedding is the token embedding layer of the LLM.

Similarly to previous works on the LLM adaptation to the speech modality (Wu et al., 2023; Fathullah et al., 2023), our training process comprises of the two stages: an alignment of the speech encoder output with the LLM token embedding space, and an integrated optimization of the complete model with the LLM. An attempt to omit either of the two stages in our process leads to the lack of training convergence. We hypothesize that the different training stages help the Adaptor to learn different subtasks like segmentation, ordering and the actual token embedding prediction.

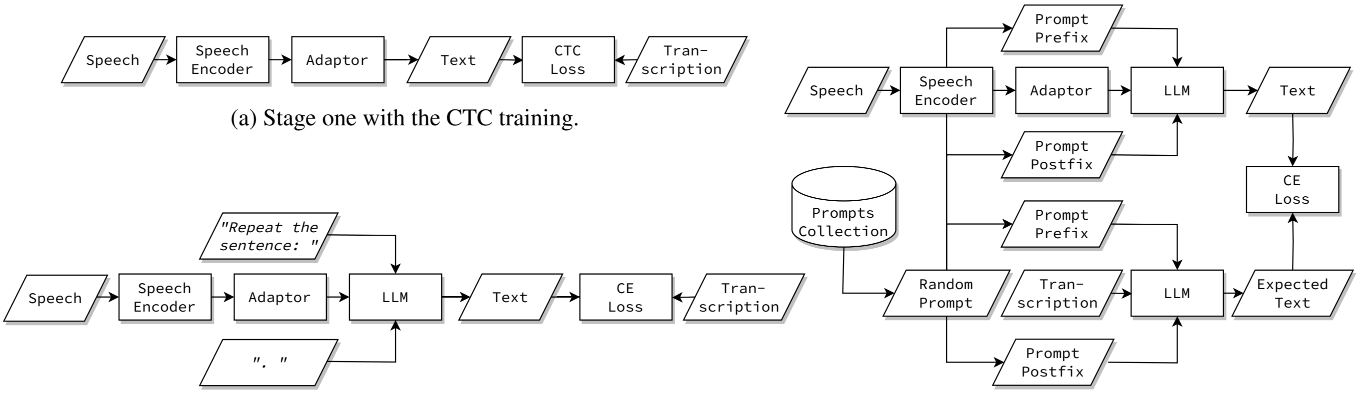
At the first stage of the training, $\boldsymbol{H}^{\text{Adaptor}}$ is projected to the LLM tokens' logits using the frozen output linear layer of the LLM (which is often a transposed token embedding layer), and the Connectionist Temporal Classification (CTC) loss (Graves et al., 2006) is minimized between the LLM token probabilities obtained from the token logits and the transcription:

$$\begin{aligned}
\boldsymbol{H}^{\text{Speech}} &= \text{SpeechEncoder}(\boldsymbol{x}) \\
\boldsymbol{H}^{\text{Adaptor}} &= \text{Adaptor}(\boldsymbol{H}^{\text{Speech}}) \\
p_{\text{CTC}}(\boldsymbol{y}|\boldsymbol{x}) &= \text{Softmax}(\boldsymbol{H}^{\text{Adaptor}}\boldsymbol{W}) \\
\mathcal{L}_{\text{CTC}} &= -\sum_{\boldsymbol{\pi}\in\mathcal{B}^{-1}(\boldsymbol{y}^{\text{Transcription}})} \log p_{\text{CTC}}(\boldsymbol{\pi}|\boldsymbol{x}),
\end{aligned}$$

where the mapping $\mathcal{B}$ removes repeated and blank tokens according to the CTC definition, $\boldsymbol{W} \in$

---

[1] `https://github.com/DigitalPhonetics/bloomzmms`



(a) Stage one with the CTC training.

(b) Stage two with the transcription task training (T).

(c) Stage two with the multi-instructional training (MI).

Figure 1: Overview of the Adaptor training. At the stage one, the Adaptor parameters are optimized using the CTC loss to directly predict the transcription (a). At the stage two, the Adaptor parameters are optimized using the CE loss applied to the outputs of the LLM while the Adaptor output is enclosed in the prompt's prefix and postfix text and is fed to the LLM input. A prompt can instruct the model to generate a transcription (b) or perform some other task on the speech input (c). In the case of transcription, a ground truth transcription is used as a training target. In the case of other instructions, a training target is obtained by running the LLM inference with the same prompt and ground truth transcription as the input.

$\mathbb{R}^{d\times v}$ is the transposed weight matrix of the token embedding layer, d is the dimensionality of the embedding, and v is the number of tokens in the LLM's vocabulary.

At the second stage, $\boldsymbol{H}^{\text{Adaptor}}$ is concatenated with the token embeddings of the prefix and postfix parts of a text prompt. This joint sequence is then passed through the self-attention layers of the LLM and projected with the transposed token embedding weight matrix W (also serving as the output layer of the LLM) to obtain the LLM prediction. The Cross-Entropy (CE) loss is minimized between the prediction of the LLM for this sequence and the expected LLM output. In case of the speech recognition task, we set the prompt prefix and postfix to `"Repeat the sentence: "` and `". "` respectively:

$$\begin{aligned}
\boldsymbol{H}^{\text{Prefix}} &= \text{LMEmbedding}(\texttt{"Repeat the sentence: "}) \\
\boldsymbol{H}^{\text{Postfix}} &= \text{LMEmbedding}(\texttt{". "}) \\
\boldsymbol{H}^{\text{LM}} &= \text{LM}((\boldsymbol{H}^{\text{Prefix}}, \boldsymbol{H}^{\text{Adaptor}}, \boldsymbol{H}^{\text{Postfix}})) \\
p_{\text{CE}}(\boldsymbol{y}|\boldsymbol{x}) &= \text{Softmax}(\boldsymbol{H}^{\text{LM}}\boldsymbol{W}) \\
\mathcal{L}_{\text{CE}-\text{ASR}} &= -\log p_{\text{CE}}(\boldsymbol{y}^{\text{Transcription}}|\boldsymbol{x}),
\end{aligned}$$

where LM() denotes the self-attention layers of the LLM. In case of the multi-instructional training, prompts are sampled from a predefined hand crafted collection, while the expected output is set to the output of the LLM for the same prompt using the token embeddings of the ground truth transcription instead of the Adaptor output $\boldsymbol{H}^{\text{Adaptor}}$:

$$\begin{aligned}
\boldsymbol{H}^{\text{Prefix}} &= \text{LMEmbedding}(\boldsymbol{p}^{i}_{\text{Prefix}}) \\
\boldsymbol{H}^{\text{Postfix}} &= \text{LMEmbedding}(\boldsymbol{p}^{i}_{\text{Postfix}}) \\
\boldsymbol{H}^{\text{LM}} &= \text{LM}((\boldsymbol{H}^{\text{Prefix}}, \boldsymbol{H}^{\text{Adaptor}}, \boldsymbol{H}^{\text{Postfix}})) \\
\boldsymbol{H}^{\text{LM}-\text{Text}} &= \text{LM}((\boldsymbol{H}^{\text{Prefix}}, \boldsymbol{H}^{\text{Transcription}}, \boldsymbol{H}^{\text{Postfix}})) \\
\boldsymbol{y}^{\text{LM}} &= \text{BeamSearch}(\text{Softmax}(\boldsymbol{H}^{\text{LM}-\text{Text}}\boldsymbol{W})) \\
p_{\text{CE}}(\boldsymbol{y}|\boldsymbol{x}) &= \text{Softmax}(\boldsymbol{H}^{\text{LM}}\boldsymbol{W}) \\
\mathcal{L}_{\text{CE}-\text{MI}} &= -\log p_{\text{CE}}(\boldsymbol{y}^{\text{LM}}|\boldsymbol{x}),
\end{aligned}$$

where $\boldsymbol{p}^{i}_{\text{Prefix}}$ and $\boldsymbol{p}^{i}_{\text{Postfix}}$ are the prefix and postfix texts of the i-th prompt in the prompts collection, $i \sim U([1,\ldots,N_{\text{Pr}}])$ is a random number drawn from an uniform distribution over all natural numbers between 1 and N_{Pr}, and N_{Pr} is the number of prompts in the collection.

3 Experiments

3.1 Training and Validation Data

The Adaptor training is performed on the entire training FLEURS dataset (Conneau et al., 2023) and a subset of the Common Voice Corpus 12.0 (Ardila et al., 2020) training dataset with the total amount of 993,660 utterances or 1905 hours of recordings. The Common Voice subset is constructed by selection of up to 25 hours of recordings for each language. Our validation set is the validation set of FLEURS with the total amount of 34,044 utterances or 115 hours of recordings. All transcriptions are taken in an unnormalized format with the true casing and punctuation.

Multi-instructional training labels are synthesized with prompts from the P3 collection (Sanh et al., 2022). The P3 collection is selected because it was employed in the finetuning process of transitioning BLOOM into BLOOMZ. Our objective is to ensure consistent output for both speech and text inputs. To achieve this, we generate text outputs utilizing prompts from the P3 collection, with which the BLOOMZ model is already acquainted. We apply six distinct randomly drawn prompts to a transcription of each original utterance and assign two generated outputs to each of the three speed-perturbed versions of that utterance. The outputs are generated with a greedy search and maximum length of 128 tokens.

3.2 Evaluation Data and Metrics

We evaluate our model on the following established benchmarks: FLEURS (Conneau et al., 2023), MLS (Pratap et al., 2020) and VoxPopuli (Wang et al., 2021a) for the ASR, CoVoST 2 (Wang et al., 2021b) for the SLT, SpeechGLUE (Ashihara et al., 2023) for the spoken General Language Understanding (GLUE) and SpeechXNLI for the multilingual NLI[2]. The results are evaluated using the corresponding metrics: Word Error Rate (WER) and Character Error Rate (CER) for the ASR, BLEU[3] (Papineni et al., 2002) for the SLT, Matthews Correlation Coefficient (MCC) for the CoLA task within SpeechGLUE, and accuracy for the other SpeechGLUE tasks and the SpeechXNLI. Whisper normalization is applied for both reference and hypothesis before evaluating CER/WER in the ASR experiments.

3.3 Experimental Setup

Our model is implemented using ESPnet2 (Watanabe et al., 2021) version 202304 and Hugging Face Transformers (Wolf et al., 2020) version 4.31.0. We use weighted-sum of hidden states (Yang et al., 2021; Chang et al., 2021) of the MMS 1B-ASR-All[4] pretrained model (Pratap et al., 2023) as speech features. We discard all language specific adapters and heads of the MMS 1B-ASR-All model to simplify the implementation while preserving the multilingual properties of our system. The Adaptor module is a VGG/E-Branchformer based encoder (Kim et al., 2023) combined with a convolutional Length Adaptor (Li et al., 2021). The E-Branchformer encoder is configured with 17 layers, each with 2048 hidden units, 8 attention heads, and output dimension of 1024. The Convolutions to Gated MultiLayer Perceptron module has 8192 units and the convolution kernel size is 31. The Length Adaptor module contains a 1-dimensional convolutional layer with stride 2 and reduces the length of input sequence by factor of 2. Self-conditioning on language identity (Chen et al., 2023) is applied during the CTC training. The LLM in our experiments is BLOOMZ 7.1B[5] model (Muennighoff et al., 2023), which itself is BLOOM 7.1B LLM (Scao et al., 2022) finetuned on the xP3 dataset introduced with BLOOMZ. The total number of parameters in our model is 8.6 billions, the number of trainable parameters is 536 millions. We apply 8-bit quantization (Dettmers et al., 2022) to the LLM using the functions from the `bitsandbytes` package version 0.41.1. The training is done with the Adam optimizer (Kingma and Ba, 2015) with $\beta_1 = 0.9$, $\beta_2 = 0.999$, $\epsilon = 10^{-8}$, the warmup learning rate scheduler with the maximum learning rate of 10^{-4} and a weight decay of 10^{-6}. 3-way speed perturbation (Ko et al., 2015) data augmentation method is applied to the training data.

The training stage one, **CTC loss training**, is performed on two NVIDIA RTX A6000 GPUs with the global batch size of 7.29 minutes. The number of warmup steps for the learning rate scheduler is set to 25,000. A checkpoint is saved every 23,364 steps and evaluated on the validation dataset. The training is stopped after four consecutive evaluations showing no improvement, it takes 233,640 update steps or 120 hours of training time to reach this condition. A checkpoint with the lowest validation CER from the stage one is used to initialize the model for the stage two.

The training stage two, **CE loss training**, is performed on four NVIDIA RTX A6000 GPUs with the batch size of 37.50 seconds and a gradient accumulation over two batches. The number of warmup steps for the learning rate scheduler is set to 10,000. A checkpoint is saved every 54,381 steps and evaluated on the validation dataset. The training is stopped after four consecutive evaluations showing no improvement. To reach this condition, it takes 652,572 update steps or 132 hours of training on

---

[2] Following SpeechGLUE, we synthesize a speech version of the XNLI (Conneau et al., 2018) validation subset using the IMS Toucan (Lux et al., 2022) text-to-speech toolkit: `https://zenodo.org/records/10900287`.

[3] Using the SacreBLEU tool (Post, 2018).

[4] `https://huggingface.co/facebook/mms-1b-all`

[5] `https://huggingface.co/bigscience/bloomz-7b1`

the transcription targets, 2,664,669 update steps or 686 hours on the multi-instructional targets, and 2,501,526 update steps or 644 hours on the combined set of targets. A checkpoint with the highest validation token prediction accuracy from the second step is used for the zero-shot evaluations.

We decode with the beam search of size 5 and set the maximum output sequence to 192 tokens to obtain the model predictions for the ASR and SLT evaluations. The GLUE and NLI evaluations restrict the output to the possible answer options corresponding to a task and limits the beam size and maximum output sequence respectively. For example, for a yes/no question the possible outputs are `yes` or `no`, the beam size is 2 and the maximum output sequence is 1. All evaluations are executed on one NVIDIA RTX A6000 GPU.

4 Results

4.1 Multitasking

Task	Dataset	Metrics	Training targets		
			T	MI	TMI
ASR	FLEURS	CER↓	**12.0**	88.5	12.4
SLT	CoVoST 2 X→En	BLEU↑	3.0	14.1	**15.6**
GLUE	SpeechGLUE	Acc./MCC ↑	41.7	54.4	**55.9**
NLI	SpeechXNLI	Acc. ↑	35.8	**41.6**	41.4

Table 1: Comparative performance metrics across various speech processing tasks using different training targets: transcription (T), synthetic multi-instructional (MI) and their combination (TMI).

Table 1 presents evaluation results of our model across various speech processing tasks, including multilingual ASR, SLT, spoken GLUE, and multilingual NLI. These evaluations test three versions of the model, which are trained using different training targets: transcription only (T), Multi-Instruction (MI), and a combination of both (TMI). When the model is trained solely on the transcription task, it achieves good performance for the ASR task itself, with a CER of 12.0. However, this specialized training does not generalize well to more sophisticated tasks like SLT, GLUE, or NLI, as evidenced by the notably lower performance metrics. On the other hand, training the model on MI synthetic targets shows significant improvement in performing other tasks such as SLT, GLUE, and NLI. The BLEU score for SLT, for example, increases to 14.1 and the average accuracy/MCC score for GLUE rises to 54.4. Despite these gains, the MI-only training leads to a significant drop in performance for the ASR task, registering a CER of 88.5. Combining both transcription and MI targets enables the model to perform well across all tested tasks. In addition to maintaining strong performance in ASR (CER of 12.4), this training configuration also leads to improvements in two out of the three non-ASR tasks. These results underscore the benefits of integrating ASR and MI targets.

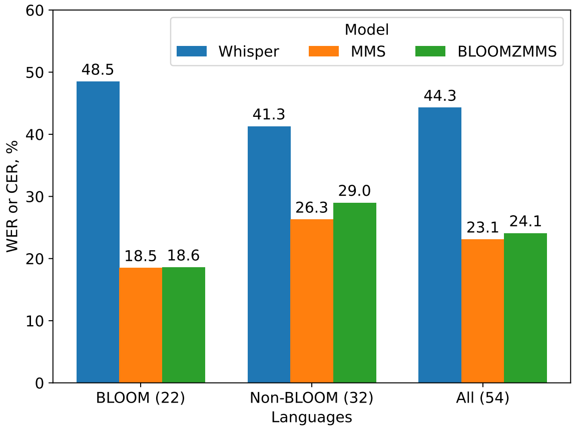


Figure 2: Comparative evaluation of speech recognition performance between the BLOOMZMMS TMI model and previous works, multi-domain MMS (1B) (Pratap et al., 2023) and Whisper large-v2 (Radford et al., 2023), on the FLEURS-54 evaluation dataset. All numbers are WER except for Thai, Lao, Burmese, and Khmer languages.

4.2 Speech Recognition

Dataset	Languages	Training targets		
		T	MI	TMI
FLEURS (CER)	BLOOM (34)	12.9	70.0	**12.8**
	Non-BLOOM (68)	**11.6**	86.4	12.2
	All (102)	**12.0**	80.9	12.4
MLS	BLOOM (4)	27.0	25.0	**20.6**
	Non-BLOOM (4)	**11.5**	72.4	12.2
	All (8)	19.3	48.7	**16.4**
VoxPopuli	BLOOM (3)	21.3	22.0	**17.3**
	Non-BLOOM (11)	22.2	104.6	**22.0**
	All (14)	22.0	86.9	**21.0**

Table 2: Comparative evaluation of speech recognition performance depending on the training targets. Results are stratified by language exposure during BLOOM training and evaluated using WER, except for the FLEURS dataset that uses CER for compatibility with previous works.

Table 2 presents a comparative analysis of ASR performance for the BLOOMZMMS model with the T, MI and TMI training targets. Results are further divided based on whether the languages were seen during the training of the BLOOM model or not. For languages that were part of the BLOOM model training, the TMI model generally performs better than the T model. The opposite is true for the non-BLOOM languages. This is expected as training on the MI targets puts stronger stress on the distillation of the LLM knowledge and its encoding to the Adaptor parameters. This effect is more pronounced on the MLS and VoxPopuli datasets, which represent recording conditions and linguistic content slightly different from our training data. Nevertheless, both T and TMI BLOOMZMMS models perform comparably on the in-domain FLEURS dataset independently from the language, suggesting that the Adaptor can effectively leverage the outputs of the MMS speech encoder in order to compensate for the lack of language familiarity by the LLM.

Following the MMS paper, we separate a subset of FLEURS testing dataset for the 54 languages that are supported by the Whisper model, and compare the results of the BLOOMZMMS TMI model to the results of the multi-domain MMS (1B) and Whisper large-v2 models. The MMS model is essentially the same speech encoder as used by BLOOMZMMS, but with a number of language-specific components, namely adapter parameters, output vocabulary, and n-gram model utilized during decoding. Despite removal of the language-specific components and addition of the other speech processing tasks, such as SLT, BLOOMZMMS manages to keep the ASR performance on a comparable level to the original MMS model. While also being a multitask model, BLOOMZMMS outperforms the other strong multitask alternative, Whisper large-v2, by a large margin on this massively multilingual low-resource ASR benchmark, albeit potentially due to being trained on in-domain data, in contrast to Whisper.

Dataset	Languages	Training targets			*Gold*
		T	MI	TMI	
X→En	BLOOM (8)	7.0	25.9	**26.8**	*35.5*

Table 3: Comparative evaluation of zero-shot speech translation performance depending on the training targets using the CoVoST 2 dataset. Results are stratified by language exposure during BLOOM training and evaluated using BLEU metrics[6]. Results on text inputs (*Gold*) are given for comparison.

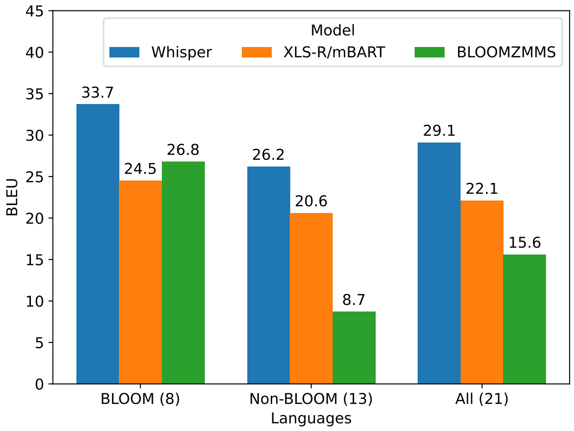

Figure 3: Comparative evaluation of speech translation performance between the BLOOMZMMS TMI model and previous works, XLS-R/mBART (Babu et al., 2021) and Whisper large-v2 (Radford et al., 2023), on the CoVoST 2 X→En evaluation set.

4.3 Speech Translation

Table 3 presents the zero-shot evaluation results for SLT using the CoVoST 2 dataset. The BLOOMZ LM exhibits a nascent ability to translate languages that it has not been trained on, and when this knowledge is transferred to the speech modality, there's only a minor loss in accuracy. Interestingly, the performance gap between the BLOOMZMMS model and gold transcriptions is more pronounced for the BLOOM languages. This indicates that the quality of knowledge transfer from text to speech depends on the initial linguistic knowledge in the text-based LLM. Consequently, weaknesses present in the LLM tend to amplify when transferred to the speech modality, suggesting that the proposed method might benefit from some form of regularization to mitigate this effect.

Figure 3 shows the comparison of the BLOOMZMMS TMI model with the previous works, XLS-R/mBART and Whisper large-v2, for the X→En translation direction. XLS-R/mBART is a strong baseline, which is finetuned on complete CoVoST 2 training data. Whisper large-v2 has not seen any CoVoST 2 data during training, but has been supervised by a large amount of other speech translation data. BLOOMZMMS TMI has not been

---

[6] sacreBLEU signature: nrefs:1 | case:mixed | eff:no | tok:13a | smooth:exp | version:2.3.1.

exposed to any gold labeled speech translation samples during training. Remarkably, the zero-shot BLOOMZMMS model outperforms the supervised task-specific XLS-R/mBART model for the languages previously seen during BLOOM training. This impressive result is primarily due to the strong performance of the BLOOMZ LLM, which is successfully transferred to the speech modality via the multi-instructional training. However, there is a notable gap with the multitask Whisper large-v2 model, primarily attributed to the poor performance on unseen languages of the LLM we utilize.

Dataset	Languages	Training targets			*Gold*

Table 4: Comparative evaluation of zero-shot speech translation performance depending on the training targets using the FLEURS dataset. Results are stratified by language exposure during BLOOM training and evaluated using BLEU metrics. Results on text inputs (*Gold*) are given for comparison.

In order to expand language coverage, we evaluate our model for the SLT performance on the FLEURS dataset as well, and present the results in Table 4. As suggested by Radford et al. (2023), we use target language transcriptions for the sentences with the same ID as reference translations. Our evaluation does not include Afrikaans, because the version of the dataset we use[7] does not include any sentence IDs shared between Afrikaans and English. The multilingual properties of the BLOOMZ model, which serves as a decoder of our model, enable us to report the SLT results with non-English target languages as well, for the first time on the FLEURS dataset to the best of our knowledge. The results confirm the good transferability of translation capabilities from text to speech modality with the MI and TMI training targets for a wider range of languages seen in the BLOOM training data. The fair translation performance from unseen languages to English, as observed in the CoVoST 2 dataset, can also be seen across a wider range of languages in the FLEURS dataset.

Task	Training targets			*Gold*

Table 6: Zero-shot evaluation of multilingual spoken NLI using the SpeechXNLI dataset. All results are accuracy scores.

4.4 Spoken Language Understanding

Tables 5 and 6 provide the results of zero-shot evaluation of BLOOMZMMS models on spoken GLUE tasks in English using the SpeechGLUE dataset and on spoken NLI tasks in multiple languages using the SpeechXNLI dataset. It is worth noting that the combined TMI training targets result in better performance on the English GLUE tasks, but have a mixed impact on the NLI tasks based on the languages trained in BLOOM and those that were not. For the BLOOM languages, the TMI model equals the MI-only model in accuracy, whereas it performs worse on the non-BLOOM languages. Together with the SLT results, this observation again hints at the effect of the LLM's weaknesses amplification during the transfer from the text to speech modality.

4.5 Visual Analysis

Following the example of (Fathullah et al., 2023), we display the cosine similarity between the text and speech embeddings for the three variants of BLOOMZMMS for a French and a Finnish utterance from the FLEURS evaluation dataset (Figure 4). Consistent with the objective metrics from our

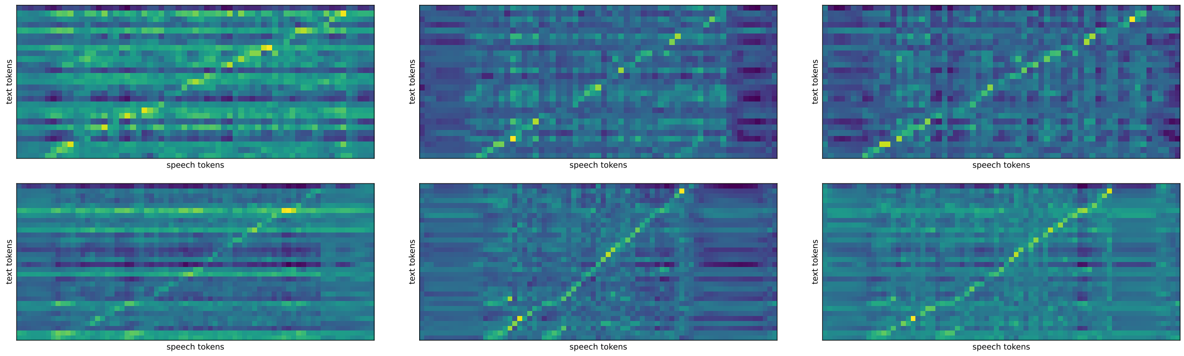

Figure 4: Cosine similarity between the text and speech embeddings for two FLEURS evaluation utterances. Rows correspond to French and Finnish languages (seen and unseen by BLOOM). Columns represent the T, MI and TMI models.

experiments, the model trained on the transcription targets shows the noisiest alignments for the both languages, while the MI training targets offer better alignment for a language unseen by BLOOM and the combined training targets work better for a language seen by BLOOM.

5 Conclusion

In this paper we present BLOOMZMMS, a multilingual multitask speech processing model that combines a multilingual LLM and a pretrained multilingual speech encoder. Our investigation into two training strategies revealed their combined efficacy in a broad spectrum of spoken language processing tasks, a conclusion bolstered by zero-shot evaluations on multiple benchmarks.

Limitations

Our setup is based on pretrained models and, given that our experiments solely rely on ASR data for supervision and the pretrained models remain frozen, the performance in tasks beyond ASR is limited by the capabilities of the utilized pretrained models. For example, the SLT results cannot be better than the translation results of the BLOOMZ model on text input.

While we demonstrate the benefits of multi-instructional training in terms of task generalization in transferring LLM abilities from text to speech modality, our evaluation is limited to a fixed collection of instructions. It does not investigate the impact of varying combinations of instructions more broadly and whether the performance on a certain task depends on its presence in the multi-instructional training data. Furthermore, we do not compare synthetic label generation with the use of ground truth labels, a comparison that holds particular significance for the SLT task. A substantial amount of ground truth labeled data is available for the SLT task. Utilizing this data could likely enhance the model's performance for this task, and potentially others as well. Finally, the slight performance degradation observed in the in-domain ASR dataset with TMI training could potentially be mitigated by more effectively balancing between transcription and multi-instructional data.

Our study is based on a small set of speech processing tasks, and does not consider such tasks as spoken question answering, spoken document summarization and other generative tasks. In addition to that, our evaluation is restricted to the properties of the used evaluation data. For the ASR and SLT tasks, it is read speech recorded on a close distance microphone. For the speech understanding tasks, we rely on a single speaker speech synthesis. It should not be assumed that the proposed model would work equally well or poorly for unseen tasks or new recording conditions, such as far field noisy conversational speech with possibly overlapping speakers. Assuming the model's performance without empirical testing in various scenarios could lead to risks, particularly depending on its application. This risk should be mitigated through preliminary testing specific to each use case. Additionally, it is advisable to cross-check the model's outputs with independent information sources.

Abstract

We are currently in an era of fierce competition among various large language models (LLMs) continuously pushing the boundaries of benchmark performance. However, genuinely assessing the capabilities of these LLMs has become a challenging and critical issue due to potential data contamination. In this paper, we propose a novel and valuable method, *Clean-Eval*, which mitigates the issue of data contamination and evaluates the LLMs more cleanly. *Clean-Eval* employs a neural-based model to paraphrase and back-translate the contaminated data into a candidate set, generating expressions with the same meaning but in different surface forms. A semantic detector is then used to filter those generated low-quality samples to narrow down this candidate set. Candidates with moderate BLEURT scores against the original samples are selected as the final evaluation set. According to human assessment, this set is almost semantically equivalent to the original contamination set but expressed differently. We conduct experiments on 20 existing benchmarks across diverse tasks, and results demonstrate that *Clean-Eval* substantially restores the actual evaluation results on contaminated LLMs under both few-shot learning and fine-tuning scenarios.

1 Introduction

In recent years, LLMs have made breakthroughs in handling complex and nuanced scenarios, achieved superior performance in some professional and academic benchmarks, and attracted many resources from industry and academia (OpenAI, 2023; Touvron et al., 2023; Golchin and Surdeanu, 2023). This subsequently opens the arms race era of LLMs, and various LLMs are continuously launched, such as GPT-4 (OpenAI, 2023), LLama2 (Touvron et al., 2023) and other LLMs, which have refreshed various evaluation benchmarks continuously.

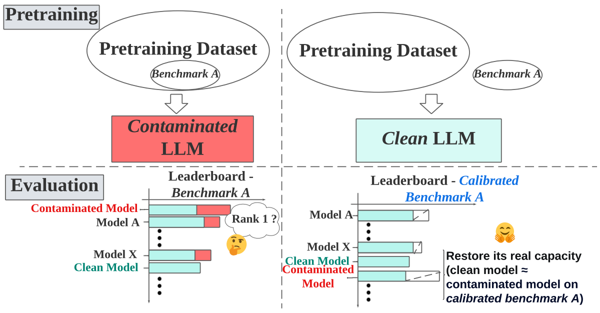

Figure 1: Data contamination happens when Benchmark A is included in the pretraining data, leading to inflated performance metrics like top leaderboard rankings. This can cause a clean model to lag behind the contaminated one. We aim to revise Benchmark A, preserving its meaning but changing its surface forms. This aims to re-evaluate the contaminated model and align its performance closer to that of a clean model.

There is room for doubt regarding the potential overestimation of these benchmark measurements. One reason is that LLMs are trained on data extracted from websites and publicly accessible datasets (OpenAI, 2023; Touvron et al., 2023). Therefore, ensuring no overlap between the pretraining dataset and the evaluated benchmark becomes challenging. This subsequently introduces a significant concern: the risk of data contamination.

Data contamination arises when the pre-training data of one model integrates evaluated data, consequently enhancing test performance (Magar and Schwartz, 2022; Golchin and Surdeanu, 2023). Currently, many models opt not to disclose their training sets in technical reports, raising concerns about the potential inclusion of benchmark datasets within their training data. This presents an urgent problem (Wei et al., 2023), as these contaminated models claim highly evaluated results but often lead to poor real-world experiences. We strongly advocate for a cleaner evaluation of LLMs. Un-

(a) Data Collection. (b) Paraphrase and Back-translation. (c) Semantic Filter.

Figure 2: An overview of our method. We first gather existing benchmarks for LLM assessment and then meticulously clean contamination in these benchmarks through LLM-powered paraphrase and multi-language back-translation, employing a semantic detector to filter and select optimal results based on BLEURT scores.

veiling the genuine capabilities of LLMs could significantly propel the community of LLMs forward. The most effective resolution involves relabeling a new dataset when developing a new model to assess its capabilities. Unfortunately, this process demands considerable time and labor.

This paper employs previously proposed benchmarks to create a new benchmark, and our method is called *Clean-Eval*, aiming to mitigate data contamination using LLMs and accurately assess the actual capabilities of LLMs. Leveraging the exceptional creative capabilities of these models, we perform diverse paraphrasing of contaminated data and back-translate it across multiple language directions. This process results in a pool of calibrated datasets. We effectively filter out low-quality samples by utilizing semantic detectors, and then select the best items based on BLEURT scores derived from comparisons between the calibrated and contaminated data. Finally, We conducted experiments on 20 benchmarks across diverse tasks, and our analysis unveiled noticeable calibrated effects achieved through *Clean-Eval*. Our human evaluation reinforces the method's potential to improve sentence structure, grammar, and linguistic diversity while maintaining core semantics. Acknowledging the challenge of detecting model contamination within specific benchmarks, we propose a new evaluation approach for in-context learning and fine-tuning. Our experiments convincingly demonstrate that processing contaminated data through our method effectively restores the genuine performance of LLMs.

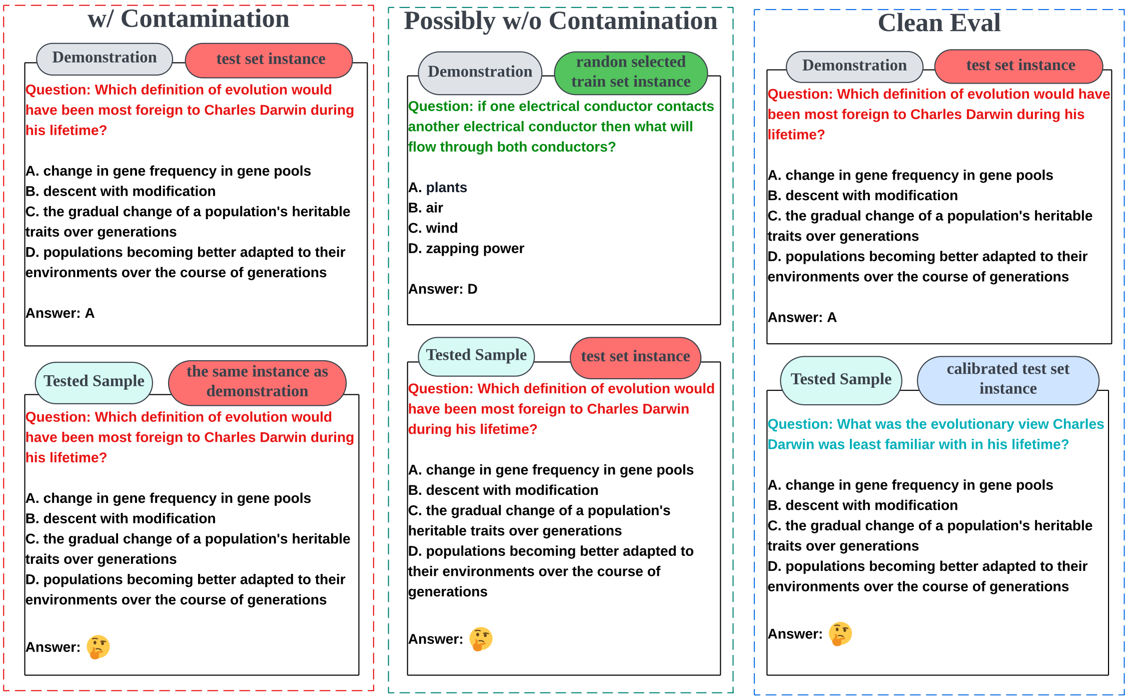
2 Related Work

2.1 Data Contamination

Detecting data contamination is crucial in ensuring the integrity of model training and usage. Researchers and practitioners have dedicated considerable efforts to developing methods for identifying and mitigating instances where test data unintentionally becomes part of the training dataset of models (Brown et al., 2020; Touvron et al., 2023).

Model Trainers. Brown et al. (2020) conducted experiments on data contamination, using an n-gram overlap metric to evaluate duplication levels between training and test sets. They subsequently eliminated these duplications from the training dataset. Similarly, Dodge et al. (2021) assessed exact matches, accounting for capitalization and punctuation normalization. This method scrutinized whether entire evaluation text inputs existed within the training data. However, Touvron et al. (2023) critiqued the precision of previous high-order n-gram-based detection methods in determining contamination extent within a sample. Their proposed approach involved token-level contamination identification, allowing for slight variations in overlap positions between evaluation samples and training data. Wei et al. (2023) took a distinctive approach, comparing the LM loss between the test splits of a dataset and a mimic dataset generated by GPT-4 (OpenAI, 2023) to correspond to it. A smaller discrepancy value between these sets indicated potential contamination within the model.

Model Users. Carlini et al. (2023) construct a set of prompts using the model's training data. They investigated by supplying prefixes of these prompts to the trained model to assess the model's capacity to complete the remaining portion of the example verbatim. Their study revealed that as the model's capacity, duplicated numbers, and context length increased, the models would be more proficient in memorizing data. Meanwhile, Golchin and Surdeanu (2023) introduced an approach involving the



Question: Which definition of evolution would have been most foreign to Charles Darwin during his lifetime?

A. change in gene frequency in gene pools
B. descent with modification
C. the gradual change of a population's heritable traits over generations
D. populations becoming better adapted to their environments over the course of generations

Answer: A

Figure 3: Evaluation setting of in-context learning. Each input comprises a demonstration and a tested sample. In the contamination setting, the demonstration matches the tested sample. In contrast, in the absence of contamination, the demonstration is drawn from another dataset split, maintaining distinction from the tested sample (e.g., sampled from the train split). In our Clean-Eval setup, the tested sample is a calibrated version of the demonstration, specifically designed to mitigate the effects of contamination.

development of guided instructions that include the initial segment of a data instance and its corresponding partition name. These guided instructions are subsequently utilized to induce the model to generate the second part of the data, based on a provided prompt. Rouge (Lin, 2004), BLEURT (Sellam et al., 2020), and GPT4 auto evaluation determine whether the model had data contamination. Furthermore, Li (2023) analyzed six prominent multi-choice QA benchmarks, quantifying their overlap with the training dataset already known of Llama to detect potential data contamination.

2.2 Existing Benchmark

Many benchmarks have been proposed, including MMLU (Li et al., 2023a), CEVAL (Huang et al., 2023), etc., to measure the capability of LLMs comprehensively. However, labeling these benchmarks is time-consuming and laborious, and ensuring no overlap with the training set of LLM is often challenging. There is also work to reformulate existing benchmarks to build new ones. For example, Li et al. (2023b) propose ReForm-Eval to reformulate existing benchmarks into unified large vision-language model compatible formats.

Nevertheless, based on our knowledge, there is no proposed solution to the problem of data contamination causing inflated model evaluation performance. In this paper, we propose an effective method to mitigate this problem. Experiments demonstrate that our methods work in evaluating both closed and open LLMs.

3 Clean-Eval

The framework of our method is shown in Figure 2. Our methodology comprises three primary stages. Initially, we concentrate on gathering existing benchmarks to assess LLMs. In the subsequent phase, we meticulously cleaned contamination in the collected benchmarks. This involves paraphrasing samples using the creative capacities of the LLMs and performing multi-language back-translation on the contaminated data. In the final phase, we use the semantic detector to filter the outcomes of the contamination cleanup, eliminating subpar results and selecting the ultimate results based on the BLEURT score.

Table 1: Natural language understanding tasks. The symbol ↓ indicates a decrease in performance compared to the contamination setting. The optimal candidate is chosen according to the lowest BLEURT score.

3.1 Back-translation

Back-translation (BT) involves retranslating content from the target language into its source language using literal terms (Sennrich et al., 2016). In this process, slight differences can be introduced, such as replacing synonyms. Therefore, we translate the raw data into various language orientations and then revert to the original language to compose our candidate set of contamination cleanup data. In this process, we aim to achieve a distinct expression from the original sample while preserving the semantics.

3.2 Paraphrase

LLMs have showcased significant potential across diverse professional domains, particularly in creative writing (Touvron et al., 2023). Harnessing their creative prowess, we utilize LLMs to generate multiple paraphrases of raw data, purposefully introducing variations. Specifically, we leverage the text-davinci-003 version of GPT-3 to generate these paraphrases. For instance, a typical prompt in our approach was: *Please paraphrase this sentence in three different ways.*

3.3 Filter

However, these candidate sets might need further examination to ensure their quality. As shown in Figure 2c, we use a semantic detector to judge whether the content in the candidate set is semantically similar to the original content to narrow the set of candidate sets further and select the candidate according to the BLEURT score as the final result.[1] In Appendix C.3, the BLEURT scores of each instance on various benchmarks are presented, with scores typically ranging from 0.4 to 0.9. Our analysis indicates that the lowest BLEURT score is an effective indicator for restoring the true capabilities of LLMs.

With these essential steps, we have achieved greater efficiency in harnessing existing datasets, mitigated data contamination concerns, and furnished high-calibrated new data suitable for evaluating model performance.

4 Evaluation Setting

Nearly all LLMs operate with proprietary training datasets, making it challenging to ascertain whether

---

[1] This detector is optional. Removing the detector saves computational and token costs, but can potentially degrade the quality of the selected candidates.

	CNN/Daily-Mail			BBC-XSUM

Table 2: ICL experiments and metrics in Rouge. ↓ is compared to the contamination dataset. The optimal candidate is chosen according to the lowest BLEURT score.

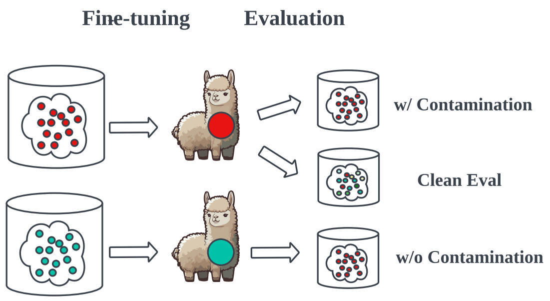

Figure 4: Evaluation setting of fine-tuning. We fine-tuned two models using datasets labeled red and green. When evaluated on the red dataset, these two models are categorized as contaminated and uncontaminated. Testing a model's performance on the red dataset processed by *Clean-Eval* is attributed to the Clean-Eval setting.

the data being tested is free from contamination. We introduce an experimental framework for simulating data contamination to address this issue.

4.1 In-context Learning

In-context learning (ICL) involves presenting a task demonstration to the model as a part of a natural language prompt. According to Brown et al. (2020), LLMs are classified as few-shot learners. Due to restricted access to the GPT-3 model and its variability, we execute ICL on these models to assess the efficacy of *Clean-Eval*. Within the ICL scenario, we propose and compare three evaluation settings: contamination, possibly no contamination, and clean evaluation for any given benchmark.

Each input comprises a demonstration and a tested sample, with different evaluation settings contingent upon their constitution. The demonstration matching the tested sample, depicted on the left side of Figure 3, constitutes the **contamination setting**. When the demonstration and tested sample originate from different dataset splits (center of Figure 3), it is categorized as the **possibly without contamination setting**. In contrast, when the tested sample is the demonstration processed by *Clean-Eval* (right side of Figure 3), it represents the **Clean-Eval setting**.

4.2 Fine-tuning

Fine-tuning entails further optimization adjustments for a specific task or dataset using a pre-trained LLM. Illustrated in Figure 4, we fine-tune two models using distinct splits of a dataset.

Each instance within a benchmark is formatted as an instruction for fine-tuning the model. When the evaluation data mirrors the fine-tuned data, it's categorized as the **contamination setting**. If the evaluation and fine-tuned data originate from different splits of the same dataset, it falls under the **possibly without contamination setting**. Lastly, when the evaluation data is fine-tuned data processed by *Clean-Eval*, it represents our **Clean-Eval setting**.

5 Experiments

5.1 Datasets

We have meticulously curated 20 datasets, spanning a wide array of tasks. These tasks encompass text implication, problem pair matching, natural language reasoning, semantic similarity, sentiment analysis, common sense reasoning, text classification, mathematical reasoning, examinations, and even some natural language generation tasks. This classification provides valuable insights into the performance of various task types concerning data contamination. Below is the comprehensive list of datasets we have utilized. The specific release date of the dataset is listed in the Appendix B.

- **Nature Language Inference.** GLUE dataset (Wang et al., 2019b) that includes QNLI, MNLI, SNLI, WNLI, RTE, QQP, MRPC, SST2; IMDB (Maas et al., 2011); BOOLQ (Clark et al., 2019); Super-GLUE dataset (Wang et al., 2019a) that includes COPA, CB; Ag News (Zhang et al., 2015).

Data	Method	Rouge-1	Rouge-2	Rouge-L	BLEURT	Equivalence
QNLI	Back-translation	54.08	29.80	50.47	63.44	100.00
	Paraphrase	48.50	26.02	43.28	63.19	100.00
	Clean-Eval	**46.85**	**22.90**	**42.53**	**60.21**	100.00
SST2	Back-translation	52.35	32.05	51.01	59.94	100.00
	Paraphrase	30.39	9.98	27.77	42.96	100.00
	Clean-Eval	**26.66**	**7.55**	**23.64**	**40.90**	100.00
MMLU	Back-translation	52.85	30.15	48.68	57.91	100.00
	Paraphrase	45.71	23.10	40.79	55.46	100.00
	Clean-Eval	**42.42**	**19.70**	**38.32**	**51.99**	100.00

Table 3: The difference between the sample processed with different methods and the original sample. We choose the lowest BLEURT score as our optimal candidate. As all generated samples undergo semantic detection, their semantic equivalence consistently reaches 100%.

- **Nature Language Generation.** CNN_Dailymail (See et al., 2017), BBC_XSUM (Narayan et al., 2018).
- **Arithmetic Reasoning.** GSM8K (Cobbe et al., 2021), MultiArith
- **Examination.** MMLU (Hendrycks et al., 2021), CEVAL (Huang et al., 2023).

5.2 Metrics

ROUGE & BLEURT. To measure the degree of overlap between a generated instance and a reference, we utilize both ROUGE (Lin, 2004), and BLEURT scores (Sellam et al., 2020). ROUGE evaluates lexical similarity, focusing on shared words and phrases, while BLEURT assesses the semantic relevance and fluency of the generated sequence concerning the reference instance.

Equivalence. We employed the text-davinci-003 model (Brown et al., 2020) to assess equivalence before and after the processing of contaminated data by *Clean-Eval*. Details of the prompt designs are in Appendix C.1.

5.3 Contamination Cleanup.

Models. We employ the text-davinci-003 model (Brown et al., 2020) for paraphrasing, back-translation, and semantic detection purposes. We also utilize the BLEURT-20 model (Sellam et al., 2020) to compute BLEURT scores and select the optimal candidate.

Process. Given the diversity in format and content across datasets, our processing criteria vary accordingly. Resource constraints prevent comprehensive processing of every dataset aspect within our method, *Clean-eval*. For instance, while we thoroughly handle all contents in SNLI-paired datasets, our focus narrows to questions alone in question-options-answer or question-answer datasets. Additionally, our analysis is limited to the initial three sentences or less when dealing with lengthy text. Furthermore, all generated samples undergo semantic detection. If they fail this detection, the original sample is output.

Results. The results are shown in Table 3. Following our *Clean-Eval* method, the surface form of the newly generated sample notably differs from the original sample, particularly in terms of n-gram variations. However, the presence of the semantic detector ensures the quality and fidelity of the generated results, assuring their reliability despite these surface-level alterations.

5.4 In-context Learning

Model. We use the text-davinci-003 model (Brown et al., 2020) to conduct ICL experiments.

Implementation Details. Each tested use case is provided with task-specific instructions. For instance, one instance attributed to CNN/Dailymail would receive a prompt such as “The task is to summarize this article:”. Detailed designs for all prompts are in Appendix C.2.

Results and Analysis The results displayed in Table 1 and Table 2 consistently showcase superior performance across all tasks in the presence of data contamination, surpassing the possible no-contamination and Clean-Eval settings. This emphasizes a distinct performance advantage influenced by data contamination. Notably, the model demonstrates robust generalization across more straightforward tasks like RTE, IMDB, and QQP, which is evident from its strong performance even without possible contamination. However, when contamination occurs in these tasks, the model sustains a near-optimal performance level.

The Clean-Eval setting is reliable, revealing the model's genuine capability. Many datasets exhibit performance levels close to those without contamination. Yet, a performance gap exists between the possible no-contamination and Clean-Eval settings, especially in more intricate tasks involving mathematical reasoning, such as GSM8K and MultiArith. The model's reduced performance in the possible no-contamination setting might stem from a lack of chain of thought, leading to performance degradation. Moreover, as depicted in Table 2, our approach effectively mitigates data contamination, even when limiting processing to the first three sentences or fewer in an article. All results indicate that employing our *Clean-Eval* method results in a gradual performance decline, aligning more closely with the possible no-contamination setting.

5.5 Fine-tuning

Model. For fine-tuning, we employ the LLama2-7b-chat model (Touvron et al., 2023).

Implementation Details As model parameters grow in size, achieving full fine-tuning becomes increasingly challenging. In such scenarios, we resort to LoRA for fine-tuning (Hu et al., 2021). Additional experiment settings are detailed in Appendix A. Our process commences by transforming original data into instructional data, followed by single-instruction fine-tuning. Considering the extensive datasets, conducting exhaustive fine-tuning for each model to attain optimal performance would be impractical and time-consuming. Thus, we fine-tune the model for approximately 40 epochs before assessing its performance.

Results and Analysis The results are displayed in Table 1. When the model undergoes fine-tuning and subsequent performance testing using the same dataset, it achieves notably higher accuracy, even reaching 100% on some datasets. However, this performance dips when evaluated on a different dataset split. A significant performance gap exists between the possibly uncontaminated and contaminated dataset settings, particularly in challenging tasks like MultiArith, GSM8k, MMLU, and CE-VAL. Notably, when tested under a Clean-Eval setting, the model's performance aligns closely with the possibly uncontaminated data.

6 Analysis

6.1 Ablation Study

In Table 3, we conducted an ablation study comparing three methods, including back-translation, paraphrase, and *Clean-Eval*. Back-translation consistently yields higher Rouge and BLEURT scores than other methods across three datasets. This suggests that back-translation effectively maintains lexical and sentence structure from the original text. Paraphrase introduces variations in content expression, showcasing the ability to offer alternative ways of expressing the same semantic content. *Clean-Eval*, which combines paraphrase and back-translation, emerges as a comprehensive approach. It maintains semantic equivalence, as indicated by the Equivalence score, and enhances the diversity of content expression.

6.1.1 BLEURT Score

In this part, we explored whether the selection based on the BLEURT score impacts the model performance.

Method	Score	QNLI	SST2	MMLU
BT	lowest	**7.33**	**6.00**	**14.67**
	median	-5.99	6.00	3.33
	highest	-10.67	6.00	4.01
Para	lowest	-8.67	**6.00**	8.01
	median	**4.01**	4.66	5.33
	highest	0.01	6.00	**8.67**

Table 4: In ICL experiments, we assess the performance gap using various BLEURT scores. This gap represents the difference in performance between the model tested in the Clean-Eval setting versus the no-contamination setting and the model tested in the contamination setting versus the Clean-Eval setting. A higher value signifies that Clean-Eval approaches performance levels like those in the no-contamination setting.

Results. Table 4 illustrates that paraphrasing exhibits variability across three datasets. However, back-translation demonstrates the potential to bring the model's performance closer to the no-contamination setting when choosing the lowest BLEURT score. Hence, to restore the large model's capabilities, selecting the best candidate based on the lowest BLEURT score might be a viable strategy.

6.1.2 Combination Order

We compared the effects of different combination orders on the performance of the results.

Order	QNLI	SST2	MMLU
Para + BT	**10.67**	**6.00**	**14.67**
BT + Para	10.67	6.00	12.67

Table 5: Performance gap with different combination orders of paraphrase and back-translation.

Results. From Table 5, we can see that while QNLI and SST2 tasks are less sensitive to method order, the MMLU task shows slight differences. Therefore, we can tailor the order based on task requirements, and we choose first to paraphrase and then back-translation in *Clean-Eval*.

6.1.3 Equivalence Detector

Continuous back translation would end up with a string that differs markedly from that which you started (Way, 2013). A combination of paraphrase and back-translation might also cause this problem.

Method	QNLI	SST2	MMLU
BT	74.17	86.33	73.33
Para	91.67	82.67	73.33
Clean-Eval (w/o detector)	72.17 ↓	56.34↓	60.34↓

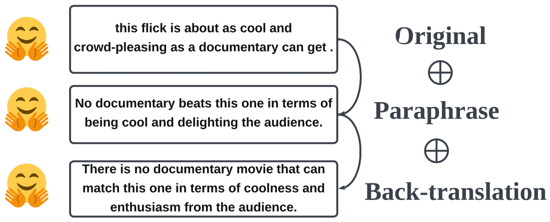
Table 6: Model performance on the calibrated dataset without equivalence detector.

Results. As we can see from Table 6, across all three datasets, the paraphrasing method demonstrates relatively high performance, especially in QNLI and SST2. Without a semantic detector, results generated through *Clean-Eval* exhibit a general decline in performance. This suggests the possibility of introducing semantic errors or inaccuracies during the generation process and the importance of semantic detectors.

6.2 Human Evaluation

We performed human evaluations of the generated output to assess potential changes after our method *Clean-Eval*.

Results. Human evaluation results on the SST2 dataset indicate that 97% of instances maintain semantic equivalence with the original ones. This suggests the *Clean-Eval* largely preserves the original data's intended meaning, showcasing the effectiveness in retaining input semantics.



this flick is about as cool and crowd-pleasing as a documentary can get .

No documentary beats this one in terms of being cool and delighting the audience.

There is no documentary movie that can match this one in terms of coolness and enthusiasm from the audience.

Figure 5: A case study from SST2 dataset.

7 Case Study

In this case, the paraphrased sentence successfully conveys the essence of the original while introducing some variation. The transformation maintains a positive sentiment, emphasizing the documentary's coolness and appeal to the audience. Back-translation aims to ensure that the paraphrased sentence retains its intended meaning. The back-translated sentence aligns well with the paraphrased version. The key elements, such as the documentary's uniqueness, coolness, and audience appeal, are preserved. The combined approach of paraphrasing and back-translation effectively enhances the original sentence. The paraphrased version introduces a nuanced expression, and the subsequent back-translation successfully captures the intended meaning. The final output maintains a positive tone and successfully communicates the documentary's appeal.

8 Conclusion

Data contamination is an urgent problem for the development of LLMs society. Downloading and trying contaminated models can be a waste of time for both researchers and developers. To save their time, this paper intends to mitigate the issue of data contamination in LLMs by introducing the *Clean-Eval* method. This approach leverages existing datasets to create a new evaluation dataset, effectively mitigating the impact of contamination. Experimental results demonstrate the method's success in accurately assessing model capabilities. *Clean-Eval* holds promise in enhancing transparency and reliability in evaluating LLMs. Future work can be dedicated to co-training a data contamination detector in a neural-based framework with *Clean-Eval* in a multi-tasking fashion. Additionally, we hope to open-source various versions of intentionally contaminated LLMs and their contamination information for research purposes.

Limitations

Datasets. This paper focuses on two mainstream models. Without knowledge regarding their training data, our selected benchmark, mimicking the no-contamination setting, likely overlaps with their existing training data. Consequently, performance testing on these benchmarks could yield inflated performance metrics. Moreover, we sampled approximately 300 instances for each benchmark due to resource constraints. However, despite this limited number, randomness in sampling aims to ensure these instances represent the entire dataset.

Fine-tuning. Given the extensive collection of benchmarks, conducting exhaustive fine-tuning to maximize model performance becomes impractical. Instead, we fine-tune the model using a consistent experimental setup for approximately 40 epochs. Our goal is to illustrate that models affected by contamination exhibit higher performance. Furthermore, evaluating benchmarks processed by our method *Clean-Eval* aims to mitigate this performance inflation and restore the true capabilities of the LLMs.

Ethic Statement

This paper will not pose any ethical problems. The datasets used in this paper have already been used in previous articles.

A Experiment Settings

We conducted fine-tuning of the Llama2-7b-chat version on 2 RTX4090 GPUs, each with 24GB of memory. The model was fine-tuned according to specific instructions, utilizing the following prompt:

```
[INST] <<SYS>>\n"
"You are a helpful, respectful, and honest
assistant."
"<</SYS>>\n\n{0} [/INST]\n{1}</s>"]
```

To optimize memory usage and enable deployment on smaller devices, we loaded our Llama2-7b-chat model in 4-bit precision, effectively reducing memory consumption. Employing a bfloat16 compute data type alongside nested quantization further contributed to memory efficiency. Additionally, we leveraged LoRA with a 16-dimensional updated matrix and scaling set at 64. A batch size 16 was chosen for shorter instructions, while longer instructions used a batch size of 4. The initial learning rate was set to 2e-4, coupled with the paged_adamw_8bit optimizer for training.

Table 7: The date of each dataset

B Potential Contamination

Table 7 shows the dates of the datasets we collected. In cases where the collection dates were not specified in the paper, we take the publication date. It is important to acknowledge that some new datasets may contain older data. In addition, the release date of the dataset may be earlier than the table.

Additionally, we gather information on the model release dates: text-davinci-003, launched in September 2021, and Llama2-7B, introduced on July 9, 2023.

In the text-davinic-003 report (Brown et al., 2020), they conducted data contamination experiments. Datasets include BOOLQ, PIQA, RTE, CB, and COPA. The dirty rates were 75.80, 89.90%, 71.40%, 100.0%, and 100.0%, respectively.

In the report for Llama2 (Touvron et al., 2023), they conducted data contamination experiments. They pointed out that the degree of possible data contamination in the humanities and overall data in MMLU reached 94.5% and 94.4%, respectively. Therefore, we can assume that Llama2 included MMLU's data at the beginning of the training, which means that there may be data contamination.

C Prompt Design

C.1 Method prompt

Our paraphrasing, back-translation, and equivalence detector prompts are shown in Table 8.

C.2 Instruction for Each Dataset

Our prompts for each benchmark are shown in Table 9.

C.3 BLEURT Score

Figure 6 illustrates the BLEURT score of each instance from selected benchmarks compared to the original instance.

Method	Prompt Design
Paraphrase	Please paraphrase the following sentence without changing the meaning in 3 ways, then return as a list.
Back-translation	Please translate the following sentence into *[language]* without changing the meaning.
Equivalence Detector	Please determine whether the following sentences are equivalent.

Table 8: Prompt designs of each method.

Dataset	Prompt Design
RTE	The task is to determine whether a pair of sentences are entailed by each other. Just return entailment or not_entailment.
QQP, MRPC	The task is to determine whether a pair of questions are semantically equivalent. Just return equivalent or not_equivalent.
QNLI	The task is to determine whether the context sentence contains the answer to the question. Just return entailment or not_entailment.
MNLI, CB	The task is to predict whether the premise entails the hypothesis, contradicts the hypothesis, or neither. Just return entailment, contradiction, or neutral.
WNLI	The task is to predict if the sentence with the pronoun substituted is entailed by the original sentence. Just return entailment or not_entailment.
SNLI	The task is to determine whether a pair of sentences are entailed, contradicted, or neutral to each other. Just return entailment, contradiction, or neutral.
IMDB	The task is to determine whether the sentiment of the text is positive or negative. Just return positive or negative.
PIQA	The task is to select the best solution to the question. Just return the solution1 or solution2.
COPA	Given a premise, choose one of the following two choices that express the sample["question"] relationship. Just return choice1 or choice2.
BOOLQ	The task is to answer true or false given the question. Just return true or false.
SST2	The task is to determine whether the sentiment of the sentence is positive or negative. Just return positive or negative.
AG News	The task is to classify the article into sports, world, business, or sci/tech. Just return sports, world, business, or sci/tech.
GSM8K, MultiArith	The task is to answer a given mathematical question. Just directly return the final number answer.
MMLU, CEVAL	Please select the best answer from the options according to the question. Just return one answer with A, B, C, or D.
CNN_Dailymail, BBC_XSUM	Please summarize this article.

Abstract

End-to-end speech summarization on long recordings is challenging because of the high computational cost. Block-wise Adaptation for Speech Summarization (BASS) summarizes arbitrarily long sequences by sequentially processing abutting chunks of audio. Despite the benefits of BASS, it has higher compute time due to sequential processing of all blocks, regardless of whether they are relevant to the final summary. In this paper, we propose R-BASS, a new relevance-aware block-wise adaptation method. First, we introduce two approaches to automatically estimate block relevance based on lexical and semantic similarity between the block-level transcript and the summary. Experiments on the How2 dataset show that using ground truth relevance during inference improves efficiency by 63.9 % by dropping irrelevant blocks. Finally, we incorporate relevance scores into training using a novel relevance loss and relevance predictor, and the proposed R-BASS model makes it possible to drop 86.3 % of the blocks while retaining comparable performance, resulting in a 2.2x speedup over BASS.

1 Introduction

Generative models (Lakhotia et al., 2021; Brown et al., 2020) have revolutionized the field of artificial intelligence. Speech summarization (Hori et al., 2002; Rezazadegan et al., 2020; Murray et al., 2010; Palaskar et al., 2019; Li et al., 2019; Shang et al., 2018) is the task of taking in long input recordings, identifying parts of the speech with essential information, and generating a short textual summary that concisely conveys the important information. End-to-end speech summarization (Sharma et al., 2022; Matsuura et al., 2023; Jung et al., 2024) has been shown to improve performance over cascade models that first transcribe long recordings, and then summarize transcripts (Palaskar et al., 2019, 2021). However, such models are difficult to train on very large inputs owing to compute restrictions (Kano et al., 2023).

To address the challenge of long inputs, Block-wise adaptation for Speech Summarization (BASS) (Sharma et al., 2023) chunks the long input speech into blocks. These blocks are then processed independently, with the semantic context being passed across blocks to facilitate remembering information from past blocks. Though BASS has better performance and lower computational cost over training directly on long sequences and can process arbitrarily long sequences by updating summaries based on new acoustic information, processing of all relevant and irrelevant blocks is computationally inefficient. In this paper, we introduce *R-BASS*, a relevance-aware block-wise model that first predicts whether the new block of acoustic information is relevant to the summary before integrating new information only from relevant blocks into the semantic context.

To decide whether a given block is relevant or not, we analyze the acoustics of the block and the generated summary thus far. If the acoustic information within a new block possesses higher semantic similarity with the previously produced summary, we deem such blocks to be relevant. Then, we examine automatic methods to label the relevance of blocks based on lexical and semantic similarity with the block transcript. Lexical similarity involves looking at the number of words in the transcript of a given block that are present in the final summary. Semantic similarity is assessed by calculating the similarity between BERT (Kenton and Toutanova, 2019) embeddings of the given block's transcript and the summary. Finally, we devise a *relevance loss* that can be used to guide model predictions of relevance to be similar to the ones obtained by automatic annotations. From experiments on How2, *R-BASS* improves efficiency while retaining comparable performance.

2 Block-wise Adaptation for Speech Summarization (BASS)

BASS is implemented as an attention-based encoder-decoder model and comprises three main blocks : (1) Encoder, (2) Updater, and (3) Decoder. The input sequence X is represented as a sequence of T abutting blocks of length B, i.e., $X = [X^1, X^2, X^3 \cdots X^T]$. Given the i-th block of input X^i, the encoder computes a high-level latent representation H^i of the input. A semantic embedding S^i is used to represent semantic context from all blocks until the i-th block. An updater considers the previous semantic embedding S^{i-1} and the new acoustic information represented by H^i and produces the updated semantic embedding S^i for the current block. The decoder finally uses the updated semantic embedding S^i to obtain a hypothesis for the summary $\hat{Y}^i$.

From a probabilistic perspective, at each block, the BASS model estimates the probability of the summary at the i-th block Y^i given all prior speech features $X^{1:i}$ $\mathbb{P}(Y^i|X^{1:i}, Y^{1:i-1})$, which can be decomposed as shown in Equation 1. The terms in the decomposition $P(S^i|X^i)$ and $P(Y^i|S^i)$ are modeled by the encoder and decoder respectively.

$$\mathbb{P}(Y^i|X^{1:i}) = \mathbb{P}(Y^i|S^i)\mathbb{P}(S^i|S^{1:i-1}, X^i) \quad (1)$$

To make training tractable over arbitrarily large inputs, backpropagation is performed block-wise rather than utterance-wise. In the former, only tensors that pertain to the current block of acoustic input remain in the computational graph and GPU memory while the latter is infeasible for long inputs because all the tensors corresponding to all blocks in the recording would have to be stored in the computational graph and GPU memory. To perform block-level optimization, block-level targets are required to compute a loss. The i-th block X^i produces a block-level output Y^i which is compared to the reference summary for the entire recording Y to obtain the loss, and backpropagation follows.

To combine information from the prior block and the current encoded output, we first use *Concatenation*, which is a simple approach. In this the previous semantic embedding is concatenated along the sequence (time) dimension with the current acoustic embedding to produce the current semantic embedding. This mechanism preserves more information but can be less efficient than using a fixed size of semantic embedding for all blocks.

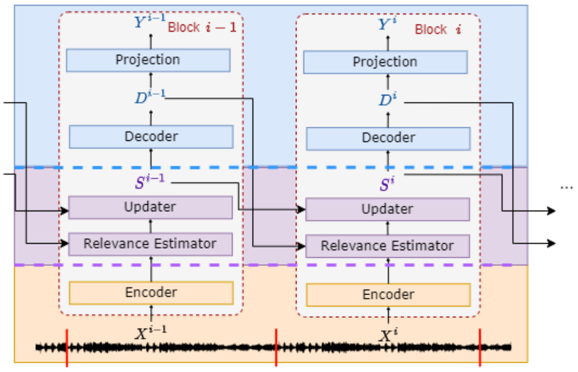

Figure 1: Proposed Relevance-Aware Block-wise Adaptation for Speech Summarization

BASS not only allows one to use standard self-attentions and avoid approximation errors, but it can also be efficient for streaming speech summarization, where summaries are expected to be updated given new acoustic information. However, it can result in longer training and inference times than methods that use efficient self-attention for offline training and inference. This can be mitigated by using the fact that all blocks are not equally useful to the summary. Since processing all blocks to generate the final output summary at the last block is computationally expensive, we propose *R-BASS*, a method to predict and use block-level relevance.

3 Proposed R-BASS

3.1 Overview

The fundamental idea behind *R-BASS* is to develop a mechanism to help the model learn when new acoustic information is relevant. When the acoustic information in a new block is relevant, we can update the semantic context to incorporate this information, and otherwise retain the same semantic context. This approach (1) saves time and memory and (2) ensures that the context we use across blocks is comprised solely of relevant information.

Since we aggregate context in the semantic space for BASS, decisions on relevance need to be made before updation. Figure 1 shows the model architecture for *R-BASS* where we insert a new relevance estimator in the semantic space. The goal of the relevance estimator is to predict whether the acoustic information present in the current block is relevant to the summary. During training, when we have access to the ground-truth summary, all we need to do is estimate the similarity between the ground-truth summary and the encoded speech representations. However, during inference, we do not have access to the reference summary to make decisions about relevance. Therefore, we approximate relevance during both training and inference by using the similarity between the summary from the previous output block $\hat{Y}^{i-1}$ and the output of the encoder for the current block, i.e., $Enc(X^i)$. Equation 2 shows how we compute relevance R^i of the i-th block using new speech information X^i, where Sim. stands for a similarity function.

$$R^i = \text{Sim.}(Y, X^i) \approx \text{Sim.}(\hat{Y}^{i-1}, Enc(X^i)) \quad (2)$$

Similarity, in general, can be computed using a myriad of mechanisms including cosine distance, however, since the previous summary $\hat{Y}^{i-1}$ and the current acoustic encoding $Enc(X^i)$ belong to different distributions, additional parameters are required to transform the vectors into a common space before computing similarity. We utilize a cross-attention mechanism between the previous summary and the current acoustics and obtain an attention-based context vector. Since relevance is modeled at the block level, we first obtain the temporal mean of this attended context. The mean attended context vector is then projected down to a single value that represents the probability that the current block is relevant.

Since backpropagation is performed at the block level for BASS, the previous semantic embedding is detached from the computational graph while processing the current block. That is, gradients do not flow through the past summary while computing relevance. To ensure that the encoder representations do not degrade when computing relevance, we detach the encoder representation $Enc(X^i)$ from the computational graph as well. In this way, the trainable attention and linear projection parameters used for computing relevance are the only parameters updated.

To ensure that model predictions of relevance are reasonable, we develop methods to automatically tag blocks as relevant and irrelevant. Then, we use these labels along with a relevance loss to fine-tune BASS so that it learns to accurately predict the relevance of blocks.

3.2 Labeling Relevance and R-BASS-Inf

To automatically label the relevance of blocks, we compare the reference summary with the ground-truth block-level transcript, rather than the input speech. Since both representations will be in the textual space, we can leverage textual similarity metrics to assess relevance. Humans generally annotate relevance by looking for: (a) common keywords between the transcript and summary, and (b) related sentences based on semantics. If the block-level transcript under consideration has words that are present in the summary, then the block may be considered relevant - we refer to this idea as *lexical similarity*. If the block-level transcript is related in intent or meaning to the summary, then the similarity between semantic embeddings of the block-level transcript and the summary is high, and the block is relevant – this is *semantic similarity*. We remove stop words using NLTK (Bird and Loper, 2004) before computing similarity metrics to avoid basing similarity on stop words.

Lexical Similarity: One of the ways to capture relevance is to assess word overlap. We calculate the ratio of the number of words in the current block's transcript that occur in the reference summary to the number of words in the reference summary. This ratio reflects the degree of lexical similarity. If the i-th block's transcript is denoted as T^i, and the reference summary is represented as Y, then the lexical similarity $LS(T^i, Y)$ can be written as shown in Equation 3.

$$LS(T^i, Y) = \frac{\#(y \in T^i | y \in Y)}{\#(y \in Y)}. \quad (3)$$

The ratio $LS(T^i, Y)$ represents the *degree of relevance*. However, in *R-BASS*, we focus only on whether or not a given block is relevant. Therefore, we apply a threshold $\tau = 0$ to convert $LS(T^i, Y)$ to a binary value.

Semantic Similarity: This metric captures similarity in the semantic space between the block-level transcript T^i and the reference summary Y. We extract BERT (Kenton and Toutanova, 2019) embeddings from the transcript and reference summary. The cosine similarity between the two embeddings is our measure of semantic similarity $SS(T^i, Y)$. This computation is described in Equation 4, where $\mathcal{B}()$ represents the BERT embeddings of the given text. We use $\tau = 0.4$ based on the data distribution to get binary values

$$SS(T^i, Y) = \text{cos-sim}(\mathcal{B}(T^i), \mathcal{B}(Y)) \quad (4)$$

To evaluate the quality of obtained pseudo-labels, we can use these relevance pseudo-labels directly during inference (*R-BASS-Inf*) to produce summaries using only relevant blocks. We compare this to a baseline that randomly selects a fraction of blocks without relying on any relevance metric, and another baseline that does not use relevance to validate whether the lexical and semantic similarity approaches accurately capture relevance.

Apart from using labels during inference, we can also train R-BASS models to predict relevance on a given block, and then use this predicted relevance to produce summaries during inference. Such a model is optimized using a relevance loss described in the next section.

3.3 Introducing Relevance Loss for Gated Attention

Now that we devised mechanisms to model relevance within the R-BASS model architecture and methods to obtain automatic annotations for relevance, we describe the *Relevance loss* used to train R-BASS. To estimate the true relevance R^i, for the i-th block, we obtain the Binary Cross-Entropy (BCE) loss between the predicted relevance $\hat{R}^i$ and the reference annotation R. In doing so, we explicitly train the model to learn the weights that capture the relevance between the block transcript and the reference summary.

4 Experiments and Results

4.1 Setup

Dataset Experiments are performed using the How2 dataset (Sanabria et al., 2018), which contains 2000h of instructional videos. More details can be found in Appendix A.1.

Model Hyperparameters Our conformer encoder (Gulati et al., 2020) - transformer (Vaswani et al., 2017) decoder models use ESPNet2 (Watanabe et al., 2018), and computational cost and hyperparameters are discussed in Appendix A.2.

Evaluation Metrics: ROUGE (Lin, 2004), METEOR (Banerjee and Lavie, 2005), and BERTScore (Zhang et al., 2020) are the most common automatic metrics for summarization.

4.2 Labeling relevance and evaluating labels using R-BASS-Inf

First, we compute relevance based on lexical and semantic similarity and examine whether they are correlated. To do this, we utilize blocks that are 10 seconds long, not too short to not have enough useful information, but not too long so that relevance measures can be fine-grained. We calculate the lexical and semantic relevance per block, creating a vector of binary relevance measures for each recording. Taking the dot product of the two vectors and averaging over all examples in the training data yields an averaged dot product of 0.7, demonstrating that semantic and lexical relevance capture similar information in the data.

Figure 2 shows the binary relevance using averaged lexical and semantic similarity scores of the training data as a function of block index. The first block is the most relevant on average, and relevance decreases as the block index increases. The plot also demonstrates that both semantic and lexical similarity have similar trends across the blocks.

Next, we utilize the obtained relevance labels for the test set to perform block-wise inference while considering only the relevant blocks. Table 1 compares two baseline models trained using FNet self-attentions and BASS with R-BASS models that use the ground-truth labels during inference. *Lex R-BASS-Inf. (GT)* and *Sem R-BASS-Inf(GT)* use relevance labels based on lexical and semantic similarity computed using the reference block transcript and reference summary. Experiments show that though both these approaches obtain the same performance as the BASS baseline, using semantic similarity-based labels leads to greater efficiency improvements, and enables one to drop 63.9% of the blocks on average. When we the more efficient *Sem R-BASS-Inf(GT)* to a corresponding random baseline *Random R-BASS-Inf.* that randomly drops 63.9% of the blocks, we note that the semantic label-based approach outperforms the random baseline in performance, showing the utility of the proposed labeling strategies.

Since these approaches use the relevance pseudo-labels during inference, any blocks that are known to be irrelevant are skipped over at the input, and incur no computational cost. Therefore, this leads to a corresponding speed-up by a factor of 2.77 in inference time on average using semantic similarity-based relevance labels.

4.3 R-BASS with Relevance Loss

Computing the relevance labels using semantic and lexical similarity assumes access to the reference summary and block-level transcripts, which are hard to obtain apriori. Therefore, in this section, we evaluate the R-BASS models trained using the relevance loss to predict block relevance.

R-BASS models can be trained using labels based on semantic similarity (*Sem R-BASS w/ Loss)*

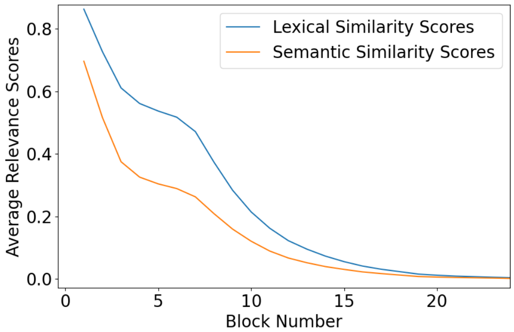

Figure 2: Binary relevance scores averaged over all training samples as a function of block index in audio recordings

Table 1: Performance of R-BASS-Inf and R-BASS w/ Loss using Lexical and Semantic Similarity. ROUGE-L (R-L), METEOR (MTR) and BERTScore(B.Sc.) are reported with the % of dropped blocks (efficiency gain

Updater	R-L↑	MTR↑	B.Sc.↑	% Dropped↑
Baseline-FNet	57.27	29.77	91.62	-
Baseline- BASS	57.98	31.67	91.48	-
Random R-BASS-Inf.	55.76	30.47	90.91	63.90
Lex R-BASS Inf.(GT)	57.96	31.67	91.48	42.25
Sem R-BASS Inf.(GT)	57.96	31.67	91.48	63.90
Lex. R-BASS w/ Loss	57.05	30.91	91.30	69.20
Sem. R-BASS w/ Loss	57.82	31.15	91.42	**86.31**

or lexical similarity (*Lex R-BASS w/ Loss*). The final two rows of Table 1 report the summarization performance and number of blocks dropped based on predicted relevance labels. When using R-BASS with the relevance loss, we find that the number of dropped blocks can be further increased with a small drop in performance. Training with lexical relevance enables the dropping of 69.2 % of blocks and training with semantic relevance enables the dropping of up to 86.3 % of blocks, which is a considerable improvement in efficiency over the baseline BASS approach.

Next, we consider the implications of dropping 86.3 % of blocks on speed-up at inference time. We observe that *R-BASS* with semantic relevance takes on average 7.28 seconds compared to BASS which takes 16.02 seconds, a 2.2x speed-up over BASS in inference time. By dropping 86.3 % of blocks, the expected speed-up may be computed as 7.29 (100/(100-86.3)), which is lower than the observed speed-up. This is because in R-BASS the decision about whether or not to drop an irrelevant block occurs not at the input, but after the relevance prediction by the relevance estimator. Therefore, the expected speed-up is smaller due to additional computation for the dropped blocks including obtaining the encoder output, computing the attention between the encoder output and the previous decoder states, and the projection to produce the single-dimensional relevance prediction.

Qualitative Analysis: We perform qualitative analysis by human inspection to evaluate the impact of R-BASS on summary quality, and find that the R-BASS does not degrade the quality of summaries significantly(see Table 3 in Appendix B). We also compute UniEval (Zhong et al., 2022) scores for coherence, consistency, fluency, and relevance, and find that R-BASS does not significantly degrade quality along these dimensions (see Table 4 in Appendix C).

5 Conclusion

In this paper, we address the challenge of efficiency within blockwise models for speech summarization. First, we introduce a novel model R-BASS that only processes relevant blocks rather than all blocks to produce a summary more efficiently. To realize R-BASS, a relevance estimator is used to predict whether an acoustic block is relevant based on its similarity with the previous block summary.

To obtain labels to train the relevance estimator, we propose to obtain binary relevance labels using lexical and semantic similarity between the block transcript and reference summary. Experiments demonstrate that there exist multiple irrelevant blocks, which can be ignored to improve efficiency while retaining performance.

Finally, we introduce a relevance loss to teach BASS models to predict and use relevance during inference time. Experiments show that training with the proposed semantic similarity loss enables faster processing by dropping around 86% of blocks as irrelevant, resulting in a 2.2x faster inference than BASS while obtaining relatively small performance degradations.

Acknowledgement

We would like to thank Mark Lindsey for their helpful feedback. This work used PSC Bridges2 and NCSA Delta through allocations CIS210014 and IRI120015 from the Advanced Cyberinfrastructure Coordination Ecosystem: Services & Support (ACCESS) program, which is supported by National Science Foundation grants #2138259, #2138286, #2138307, #2137603, and #2138296.

Societal Impact

We believe that our work will enable the widespread use of technologies that can summarize long recordings into condensed textual descriptions. By making existing streaming models more efficient, our work reduces the carbon footprint of such technologies and enables their use in a more diverse and inclusive set of environments. From serving people with disabilities who find it challenging to process long-form audio content, to improving industrial efficiency in information consumption and decision-making, we believe that our work can positively influence society.

Limitations

In our work, we assume that the first block is always relevant - this assumption is true for the dataset we use, How2, but may not be a general conclusion across all data settings. BASS and consequently R-BASS are approaches that process blocks in sequence, and R-BASS improves time and compute efficiency during training and inference over BASS, however such approaches are likely slower for offline (non-streaming) applications than end-to-end models that use limited context.

Risks

All the work in this paper was done in such a manner so as to minimize the risk of misuse and bias. However, BERT was used to extract semantic embeddings for semantic relevance, and it is possible that such computations carry impacts of the bias in BERT models.

Our models were built using instructional How2 videos mined from YouTube, and our work can enable online speech summarization to help obtain succinct summaries. On the other hand, there may be biases within the data that favor more accurate recognition and understanding of certain kinds of speech. We recommend using our models only for video summarization subject to the license constraints of the How2 dataset.

A Appendix

A.1 How2 Dataset

The dataset has audio, corresponding transcripts, and a user description that is treated as the reference abstractive summary. The standard split of How2 from (Sharma et al., 2022) is used for all our summarization experiments.

Table 2: Statistics of the How-2 2000h Dataset used for model training and evaluation. The mean and maximum statistics of N- the input length in frames, and L- the output length (in tokens) is shown.

Set	N. Recordings	Max N	Mean N	Mean L	Max L
Train	72,981	145,082	9,806.58	60.54	173
Test	2,127	39,537	9,866.55	60.29	152

A.2 Model Hyperparameters and Computational Cost

Our end-to-end speech summarization models are first pre-trained on the ASR task and then fine-tuned for summarization. The encoder consists of convolutional subsampling by factor 4, followed by 12 conformer (Gulati et al., 2020) blocks with 8 attention heads and hidden size 2048. The decoder has 6 transformer (Vaswani et al., 2017) blocks, with 4 attention heads and hidden size 2048. Models have 103M parameters. Both the encoder and decoder use a dropout rate of 0.2. We use a 43-dimensional filter bank and pitch features as input to the encoder. Summarization models are first pre-trained on ASR using joint CTC-attention (Watanabe et al., 2017) and then fine-tuned for summarization (Sharma et al., 2022).

Our experiments were performed using 4xA40 48GB GPUs - ASR pretraining took 2 days, while BASS and R-BASS fine-tuning took 1.5 days and 0.8 days respectively.

Abstract

Large language models (LLMs) often struggle with maintaining accuracy throughout multiple multiple reasoning steps, especially in mathematical reasoning where an error in earlier steps can propagate to subsequent ones and it ultimately leading to an incorrect answer. To reduce error propagation, guided decoding is employed to direct the LM decoding on a step-by-step basis. We argue that in guided decoding, assessing the potential of an incomplete reasoning path can be more advantageous than simply ensuring per-step correctness, as the former approach leads towards a correct final answer. This transforms the task into a *value estimation* problem in planning.

Inspired by the findings that *outcome supervision for guided decoding essentially acts as a value model*, we propose Outcome-supervised Value Model (OVM) that employs outcome supervision for training a value model, which prioritizes steps that lead to accurate conclusions. Furthermore, the OVM eliminates the need for labor-intensive annotations of step-level correctness, thereby significantly enhancing its scalability. Our experiments on two multi-step mathematical reasoning datasets, GSM8K and Game of 24, demonstrate the superior performance of the OVM model. Notably, in GSM8K, our **OVM-7B model achieves state-of-the-art results among LLMs up to 13B parameters**; especially it does not utilize GPT-4 or code execution. These findings offer a novel perspective on the role of outcome supervision in training value models for multi-step reasoning tasks and provide theoretical justification for its advantage in value estimation for guided decoding.

1 Introduction

Multi-step reasoning problems are challenging for even large language models (LLMs) (Creswell et al., 2023; Press et al., 2022; Wei et al., 2022). Chain of Thought (CoT) outputs a series of intermediate reasoning steps before the final answer, which significantly improves the performance (Wei et al., 2022; Suzgun et al., 2023).

Verifying complete solutions Recent studies (Cobbe et al., 2021, Uesato et al., 2022, Lightman et al., 2023) have focused on training a verifier, also referred to as a '*reward* model', to verify the correctness of a complete solution among various candidates (Cobbe et al., 2021). This training generally involves two types of supervision for training: *outcome supervision* and *process supervision*. Recent research has demonstrated a clear advantage of *process supervision* over *outcome supervision* for training reward models in terms of verifying complete reasoning paths (Lightman et al., 2023).

Guided decoding during intermediate steps However, errors often happen during the decoding of intermediate steps, leading to subsequent inaccuracies due to *error propagation*. For instance, GPT-4 often struggles with the initial step in the Game of 24, yet it can solve the task with multiple attempts (Yao et al., 2023). To this end, guiding language decoding with step-level evaluation has been proposed (Xie et al., 2023; Khalifa et al., 2023; Yao et al., 2023). Paralleling the concepts of *rewards* and *values* in reinforcement learning, the criteria for step-level evaluation could be either future-agnostic (Xie et al., 2023) or future-oriented (Yao et al., 2023); the latter (i.e., value models) seems better as it has a longer-horizon perspective.

Value-based guided decoding. In line with value-based guided decoding that considers the potential of the possible future-generated solutions, the challenge lies in value estimation. Previous research primarily achieved this through extensive lookahead sampling or simulation to estimate the long-term returns (Hao et al., 2023; Zhu et al., 2023; Yao et al., 2023); this introduces an additional decoding cost during the inference of an LLM. An alternative method is to train a value model that enables value estimation during inference without the need for simulation. Inspired by

Findings of the Association for Computational Linguistics: NAACL 2024, pages 858–875
June 16-21, 2024

the findings that *outcome supervision for guided decoding essentially acts as a value model*, as found in this paper, we propose the use of outcome supervision to train a value model for value estimation without simulation during inference, called **OVM**.

Experiments are conducted on two popular multi-step mathematical reasoning datasets – GSM8K (Cobbe et al., 2021) and Game of 24 (Yao et al., 2023). In GSM8K, our OVM-7B model obtains state-of-the-art performance among models with up to 13B parameters, attaining a 84.7% accuracy without resorting to supplementary datasets, GPT-4, or executing programs. In Game of 24, OVM-7B reaches 78.7% success rate with merely 20 nodes visited per step, in stark contrast to its 11% greedy success rate and 11.7% with majority voting over 100 reasoning paths. Furthermore, we demonstrate that our method attains competitive, and often superior, performance using fewer sampled reasoning paths compared to complete path verification, on both GSM8K and Game of 24. This indicates the effectiveness of OVM in value estimation as a future-oriented evaluation.

In summary, our contributions are three-fold. (1) **An in-depth analysis on guided decoding**: we extend the previous discussion on outcome supervision and process supervision to the realm of guided decoding. We theoretically prove that *outcome supervision for guided decoding is secretly a value model*. (2) **A novel approach of OVM**: we propose Outcome Value Models for guided decoding that emphasize the potential correctness of the final answer rather than focusing solely on the current (partial) path's correctness. Importantly, OVM with *outcome supervision* does not need costly step-level annotations typically required by *process supervision*, making it more scalable. Moreover, it merely leverages the existing model and datasets without introducing external elements. (3) **Significance of OVM**: OVM (7B) achieves state-of-the-art results in GSM8K among LLMs up to 13B parameters, even outperforming those using additional data, GPT-4, or code execution.

2 Background

We give the problem definition of mathematical reasoning and guided decoding, as well as its dual paradigms (i.e., reward-based and value-based). The notations we used are summarized in Table 6.

2.1 Problem Defintion

We first introduce the mathematical reasoning problem definition and then introduce our adopted paradigm.

Definition. A mathematical reasoning question *q requires a sequence of steps to be addressed, whose solution path is $S = [s^1, \ldots, s^m, a]$, where s^i represents the i-th step, m is the number of steps, and a is the final answer.*

To alleviate the issue of potential error propagation from previous steps in a single solution chain, one approach is sampling multiple steps from the generator and filtering. This is called guided decoding, which incorporates a new evaluation criterion to select steps during model generation (Yao et al., 2023; Xie et al., 2023; Khalifa et al., 2023; Feng et al., 2023).

Guided decoding Guided decoding intervenes in the generation process with a new evaluation criterion, in contrast to vanilla sampling which is solely based on the Language Model (LM) probabilities. Specifically, for each step t, suppose the sampling size is K, the generator Φ produces a set of candidate paths $\mathbb{S}^{(1:t)} = \left\{S_k^{(1:t)}\right\}_{k=1}^{K}$ based on LM probabilities, where $S_k^{(1:t)} = [s_k^1, \ldots, s_k^t]$ is the k-th partial path up to step t. Then, given an evaluation criterion $f(\cdot)$ that can score an incomplete path $S^{(1:t)}$, we select the top-scored paths with the beam size b ($b < K$ for pruning), from which the generation continues

$$\left\{S_k^{(1:t)} | k \in \operatorname*{argtop}_{b\atop k=1,\cdots,K} f(S_k^{(1:t)}; q)\right\}$$

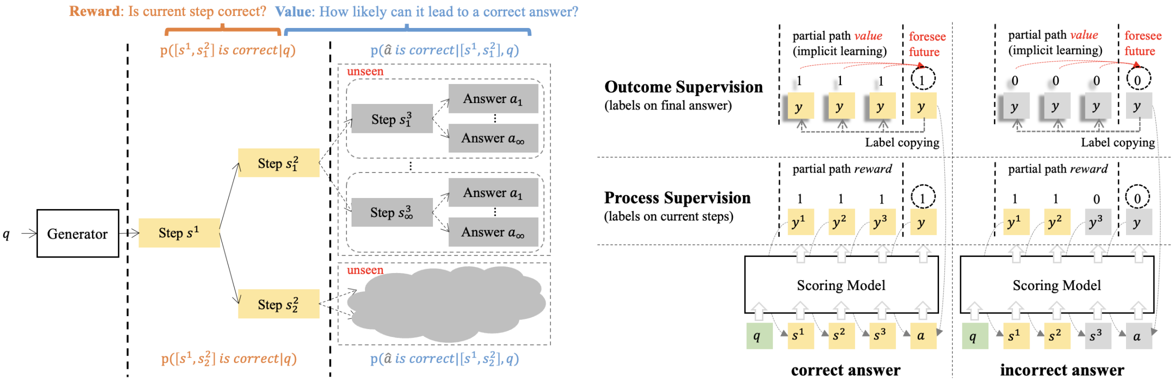
This approach is primarily characterized by two categories of guiding criteria: reward and value, which are two concepts in reinforcement learning (Sutton and Barto, 2018), see details in Section 2.2.

2.2 Reward-based and Value-based Guided Decoding

In this subsection, we introduce 'reward'-based approaches and 'value'-based approaches for mathematical reasoning in Sec. 2.2.1 and 2.2.2

2.2.1 Reward-based Guided Decoding

Reward-based approaches (Xie et al., 2023; Khalifa et al., 2023; Hao et al., 2023), focusing on the generated steps, assess the correctness of the current steps in mathematical reasoning, i.e. $p(S^{(1:t)}$ is correct$|q)$.



(a) Reward and value

(b) Outcome supervision and process supervision on training models to evaluate *complete paths*

Figure 1: (a): When evaluating partial paths (here for the first two steps), reward focuses on the current states, while value focuses on the unseen future outcomes. (b): Given a question q and a solution path $[s^1, \cdots, s^m, a]$, models are trained to predict path correctness (circled output scalar on the last token). Outcome supervision replicates the final answer's correctness label across all steps (indicated by shaded labels), causing the model to implicitly learn to foresee the future, predicting values for partial paths. By contrast, process supervision details per-step correctness labels, causing the model to learn to predict step-level correctness, i.e. reward. Correct steps and answers are colored in yellow and incorrect ones in grey.

Outcome supervision vs. process supervision In mathematical reasoning, reward models are well known in evaluating complete solution paths $p(S \text{ is correct}|q)$, also called "verifiers" (Cobbe et al., 2021; Uesato et al., 2022; Lightman et al., 2023; Li et al., 2022; Khalifa et al., 2023). There are two supervision strategies to train a verifier, distinguished by the granularity of the supervision signals, we refer to Appendix A for training details.

Outcome Supervision simply focuses on the correctness of the final answer, at a coarser granularity. The trained model is called Outcome Reward Model (ORM) (Cobbe et al., 2021; Uesato et al., 2022; Lightman et al., 2023).

Process Supervision offers more fine-grained, step-wise labels of the solution path, providing per-step correctness. The trained model is called Process Reward Model (PRM) (Uesato et al., 2022; Lightman et al., 2023; Li et al., 2023b).

Current research indicates that process supervision generally outperforms outcome supervision since the former adapts finer-grained supervision in *verifying complete paths* (Lightman et al., 2023). However, in guided decoding that *verifies incomplete paths*, typical reward models might overlook the current (incomplete) path's future implications, which will be further discussed in Section 2.2.2.

2.2.2 Value-based Guided Decoding

Value-based approaches (Yao et al., 2023; Hao et al., 2023; Feng et al., 2023) estimate the expected future *rewards* when starting from a given state (i.e. the current incomplete reasoning path), which is future-oriented. This is contrast to the definition of *rewards* that is determined only by the seen incomplete path and agnostic to the future path. As shown in Figure 1(a), reward models assess paths in a backward direction (e.g., the correctness of seen steps) while value models assess paths in a forward direction (e.g., the potential correctness the final path with additional future unseen steps and the answer $\hat{a}$ [1]). Interestingly, we could term the *value-based guided decoding* as "*planning*" based on its nature of future orientation.

3 Outcome Supervised Value Models for Guided Decoding

3.1 Motivation

Challenge of training value models Unlike labels of reward models can be annotated manually on a given (incomplete) reasoning path, it is challenging to obtain ground truth of value models for each incomplete path during guided decoding. The reason is that it is computationally-heavy to calcu-

---

[1] In reinforcement learning, value is defined as the expected cumulative reward it receives in the long run with a discount factor: $\sum_{j=1}^{m-t} \gamma^{j-1} R_{t+j}$. In our scenario, the discount factor is 1, all intermediate rewards $R_{t+1} R_{t+2} \cdots R_{m-1}$ are 0, and the final reward R_m is 1 if the answer is correct otherwise 0. So the cumulative reward is either 1 or 0 dependent on the answer correctness. Therefore, the expected cumulative reward is exactly the probability of correct answers.

late the expected rewards among all possible future paths starting from the seen (incomplete) path, especially the number of resulted sequences grows exponentially w.r.t the length of reasoning paths.

Rationale behind outcome supervised guided decoding as a value model Therefore, the challenge in training value models lies in *estimating or labeling the value of observed reasoning paths*. Recalling the types of supervision – either outcome or process – it's evident that process supervision is confined to paths already seen. However, outcome supervision appears to have the potential to assess the probable correctness of resulting final paths, starting from the current incomplete one. See this intuition in Figure 1(b). Intriguingly, upon theoretical examination, we discover that **outcome supervision for guided decoding essentially acts as a value model**, as detailed in Sec. 3.2. This revelation has inspired the adoption of outcome-supervised value models specifically tailored for guided decoding. [2]

3.2 Outcome Supervision Leads to a Value Model for Guided Decoding

We show theoretically that, given binary labels of individual samples, outcome supervision implicitly estimates the global labels, or value, of the intermediate steps during the optimization process.

Claim. *For an outcome-supervised model $f_{\boldsymbol{\theta}}(\cdot)$ parameterized by the optimal parameter $\boldsymbol{\theta}$, its score of $S^{(1:t)}$ is the approximated probability of it reaching a correct answer, i.e.,*

$$f_{\boldsymbol{\theta}}(S^{(1:t)}; q) = p(\hat{a} \textit{ is correct} | S^{(1:t)}, q) \quad (1)$$

Proof. Suppose for each question q, we have the generator producing n solution paths $\{S_i\}_{i=1}^{n}$ with the corresponding answers $\{a_i\}_{i=1}^{n}$. The label y_i is 1 if a_i is correct otherwise 0. The mean squared error loss of outcome supervision is

$$l(S_i^{(1:t)}, y_i; q) = \left(f_{\boldsymbol{\theta}}(S_i^{(1:t)}; q) - y_i\right)^2 \quad (2)$$

Given the training question set $\mathcal{Q}$, the overall objective is

$$L = \frac{1}{|\mathcal{Q}|} \sum_{q \in \mathcal{Q}} \frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{m_i} \left(f_{\boldsymbol{\theta}}(S_i^{(1:t)}; q) - y_i\right)^2 \quad (3)$$

Denote $\mathrm{v}_x^q = f_{\boldsymbol{\theta}}(x; q)$, the partial derivation of v_x^q is

$$\nabla_{\mathrm{v}_x^q} L = \frac{1}{|\mathcal{Q}|} \frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{m_i} 2\Gamma(S_i^{(1:t)} = x)(\mathrm{v}_x^q - y_i) \quad (4)$$

Set $\nabla_{\mathrm{v}_x^q} L = 0$, we can see

$$\mathrm{v}_x^q = \frac{\sum_{i=1}^{n} \sum_{t=1}^{m_i} \Gamma(S_i^{(1:t)} = x) y_i}{\sum_{i=1}^{n} \sum_{t=1}^{m_i} \Gamma(S_i^{(1:t)} = x)} \quad (5)$$

which is $p(\hat{a} \text{ is correct} | x, q)$, whose estimation's precision depends on the sampling. Choose the model satisfying

$$f_{\boldsymbol{\theta}}(x; q) = \frac{\sum_{i=1}^{n} \sum_{t=1}^{m_i} \Gamma(S_i^{(1:t)} = x) y_i}{\sum_{i=1}^{n} \sum_{t=1}^{m_i} \Gamma(S_i^{(1:t)} = x)} \quad (6)$$

for all $x \in \{S_i^{(1:t)}\}$ is the optimal solution minimizing the loss function. Hence the optimal solution satisfies

$$f_{\boldsymbol{\theta}}(S^{(1:t)}; q) = p(\hat{a} \text{ is correct} | S^{(1:t)}, q) \quad (7)$$

□

Therefore,

$$\begin{aligned} f_{\boldsymbol{\theta}}(S; q) &= p(a \text{ is correct} | S; q) \\ &= \begin{cases} \text{reward} & \text{when } [\overbrace{s^1, \ldots, s^t, \ldots, s^m, a}^{S}] \text{ i.e. } a \text{ is seen} \\ \text{value} & \text{when } [\overbrace{s^1, \ldots, s^t}^{S}, \ldots, s^m, a] \text{ i.e. } a \text{ is unseen} \end{cases} \end{aligned}$$

Intuitive Explanation This indirect method of probability estimation in outcome supervision simplifies the value model training process, which avoids the need for explicit step-level continual sampling and estimation for training labels. Instead, it leverages the binary correctness of individual samples as training labels, forcing the optimal solution to be the probability of being correct under mean square error, which is similar to the Monte Carlo method to estimate the expectation.

3.3 Rethinking Supervision for Guided Decoding: Outcome v.s. Process

With the above discussion, outcome supervision and process supervision can be different in the context of guided decoding. We claim that outcome supervision supersedes process supervision in this scenario for two reasons.

---

[2] Feng et al. (2023) is a concurrent work with us for value model.

Outcome supervision is preferred due to its inherent future-guided orientation For guided decoding, intuitively we should adopt a forward-looking approach that prioritizes the final answer's correctness over mere the current path's. This favors value models over typical reward models. Thus, outcome supervision, leading to value models, is preferred to process supervision that results in reward models, for partial path evaluation.

Outcome supervision is labor-friendly without fine-grained annotations In terms of future orientation, rewards can be modified to introduce such aspects, e.g. "whether steps are correct and *helpful* to the correct answer". We acknowledge that such reward adjustments are useful for planning. However, annotating rewards at the step level is labor-intensive. Furthermore, assessing steps' contribution to final answers, beyond mere correctness, increases the labor demands of reward labeling. In contrast, outcome supervision only requires the final answer's correctness.

4 Method

Building a training set for OVM Given a set of questions $\mathcal{Q}$ comprising N training questions, we initially query the generator to produce n solution paths $\mathbb{S} = \{S_1, \cdots, S_n\}$ for each question $q \in \mathcal{Q}$. This process yields $N \times n$ question-solution pairs. Subsequently, we determine the binary label for each question-solution pair by assessing the correctness of the final answer.

Training a value model with outcome supervision The value model is implemented by adding a linear layer with a single bias parameter after the generator's final unembedding layer, separate from the generator Cobbe et al., 2021. The training objective is to minimize the mean squared error between the predicted value, based on the question and solution, and the binary label.

For comparative purposes, we implemented reward models trained through process supervision. [3] Detailed information can be found in Appendix A.

Inference - beam search with guided decoding During inference, we employ a beam search strategy guided by the OVM. Unlike the conventional beam search, which relies on token-level probability, our method is steered by the estimated values at each step. The algorithm is detailed in Algorithm 1.

Algorithm 1 Value-Guided Beam Search

```
Input: Question $q$, Beam size $b$, Sampled steps per state $K$, Maximum step count $T$
Output: Best solution sequence for $q$
Model: Generator $\Phi$ and OVM $f$
procedure ValueGuidedBeamSearch($q, b, K$)
    Initialize step sequences $\mathbb{S} \leftarrow \{\}$
    Sample initial steps $\{s_1^1, \ldots, s_K^1\}$
    Evaluate values $\{v_1^1, \cdots, v_K^1\}$ for each step
    Select top $b$ valued steps and add to $\mathbb{S}$
    $t \leftarrow 1$
    while sequences in $\mathbb{S}$ are not complete and $t < T$ do
        $\mathbb{S}_{\text{new}} \leftarrow \{\}$
        $\mathcal{V} \leftarrow \{\}$
        for each sequence $S^{(1:t)}$ in $\mathbb{S}$ do
            for $i = 1$ to $K/b$ do
                $S_i^{(1:t+1)} = \Phi(S^{(1:t)}; q)$
                $v_i^{(1:t+1)} = f(S_i^{(1:t+1)}; q)$
                $\mathbb{S}_{\text{new}} \leftarrow \mathbb{S}_{\text{new}} + S_i^{(1:t+1)}$
                $\mathcal{V} \leftarrow \mathcal{V} + v_i^{(1:t+1)}$
            end for
        end for
        $\mathbb{S}_{\text{new}} \leftarrow$ top $b$ valued sequences from $(\mathbb{S}_{\text{new}}, \mathcal{V})$
        $\mathbb{S} \leftarrow \mathbb{S}_{\text{new}}$
        $t \leftarrow t + 1$
    end while
    return sequence with highest final value in $\mathbb{S}$
end procedure
```

5 Experiment Results

5.1 Experimental settings

Benchmarks We conduct experiments on two mathematical reasoning datasets, GSM8K (Cobbe et al., 2021) and Game of 24 (Yao et al., 2023).

Baselines We benchmark our method against leading models in GSM8K and the notable Tree-of-Thought in Game of 24 (Yao et al., 2023), as well as other guided decoding approaches. Additionally, we evaluate the efficacy of OVM planning against the vanilla sampling methods of our implemented generators, such as greedy search and post-processing of multiple solutions generated without guided decoding.

We conduct each inference experiment three times and present the average results along with their standard deviation. Given the variety of available beam sizes b for each sampling size K, we simplify the reporting by only showcasing the best results from all possible beam sizes. [4] Detailed results for different beam sizes can be found in Appendix D.

See the implementation details, including training and inference hyperparameters, in Appendix B.

---

[3] Process supervision is only used in comparison, not in OVM training.

[4] For instance, the result for $K = 20$ is the best one among $b \in (1, 2, 4, 5, 10)$.

Table 1: Accuracy on GSM8K. In the third column, we mark models that use GPT for inference or are trained with GPT-generated data. Notably, we don't rely on GPT, data augmentation, and code execution (execute the complete code block outputting the final answer). SC denotes 'Self-Consistency' and RM denotes 'Reward Model'.

5.2 Overall Performance

Benchmarking against current state-of-the-art approaches The OVM performance in GSM8K and Game of 24 is detailed in Table 1 and Table 2, respectively. Notably, our Mistral-based 7B model surpasses all models under 70B in GSM8K. In the 7B category, excluding Mistral-based models, our Llama2-based 7B model achieves the highest performance. In the Game of 24, OVM planning significantly improves Llama2-7B's accuracy, increasing its accuracy from 11% to a remarkable 78.7% with 20 sampled solution paths.

Table 2: Accuracy on Game of 24. GPT-4's accuracy is from Yao et al. (2023), and K of ToT is estimated from Figure 3 in their paper.

	Accuracy
GPT-4 CoT	4.0%
GPT-4 SC (K=100)	9.0%
GPT-4 ToT (K=60)	74.0%
Fine-tuned Llama2-7B	11.0%
Fine-tuned Llama2-7B SC (K=100)	11.7% ± 1.3%
Ours – OVM (Llama2-7B, K=20)	78.7% ± 1.7%
Ours – OVM (Llama2-7B, K=100)	98.3% ± 1.2%

Benchmarking against guided decoding approaches Table 3 shows that OVM excels over most guided decoding approaches, with the exception of the GPT-based method. Remarkably, OVM achieves comparable results to the GPT-based method despite its smaller size (7B compared to 175B) and fewer sampled paths ($K = 10$ versus $K = 80$). Significantly, OVM improves the previous value-based SOTA by 18 absolute percentage points (from 63.2% of CoRe to 81.2%), eliciting the power of value-based methods.

Benchmarking against vanilla sampling baselines Table 4 shows OVM planning generally outperforms ORM post-selection with the same number of sampled paths. An exception occurs with Mistral-7B at K=100 in GSM8K, where the gap between OVM and ORM approaches appears to reach saturation. As shown in Figure 3, in both GSM8K and Game of 24, the accuracy improves with larger sampling sizes. The gap between ORM and OVM decreases as more paths are sampled.

Notably, training an OVM merely reuses existing models and datasets, generating training solutions and labels internally. This approach outperforms those needing extra resources like code execution or data augmentation. Moreover, its compatibility with these techniques suggests the potential for further improved performance when used together.

Table 3: Accuracy on GSM8K comparing with guided decoding approaches. 'RM' denotes 'Reward Model', and 'VM' denotes 'Value Model'. 'finetuned' means the generator is tuned on the training dataset.

Model	Backbone	Setting	K	Type	Accuracy
Reward-based					
GRACE (Khalifa et al., 2023)	Llama-7B	finetuned	20	RM	30.9%

6 Analysis and Discussion

This section seeks to answer the following two **R**esearch **Q**uestions (RQs).

RQ 1. *Can OVM plan?*

RQ 2. *How is outcome supervision compared to process supervision for guided decoding?*

Evaluation with correct answer proportion To assess planning effectiveness, we analyze the proportion of sampled solution paths yielding correct answers in the final sampling stage, immediately preceding the final solution selection. This offers insights into guided decoding's efficiency in steering towards correct answers.

6.1 RQ1: Can OVM plan?

We use "vanilla sampling" as the baseline for comparison, which relies on random solution sampling based solely on LM probabilities, without guiding.

OVM is an effective planner guiding to the correct answers The result is shown in Figure 3. Notably, in GSM8K, less than 35% of the generator's randomly sampled solution paths are correct, and this proportion increases to over 65% with OVM planning. Similarly, in the Game of 24, OVM planning significantly boosts the correct answer proportion from approximately just 10% in vanilla sampling to an impressive 80%. Additionally, in vanilla sampling, the proportion of correct solutions remains consistent across various sampling sizes. In contrast, OVM planning demonstrates improved benefits with increased sampling sizes, up to a point of saturation.

6.2 RQ2: How is outcome supervision compared to process supervision for guided decoding?

We further compare the performance of reward models, trained under process supervision [5], with OVM in guiding decoding for GSM8K and Game of 24. Due to resource constraints, we only conducted the experiments on Llama2-7B.

We investigate both typical and modified future-oriented rewards in our study. The former rewards steps (i.e. labeled as 1) for logical correctness, while the latter rewards steps that are not only correct but also contribute to the correct final answer. We refer to the model trained with this enhanced

---

[5] The training datasets and hyperparameters for the reward models are identical to those of OVM

reward scheme as PRM-O, denoting its implicit consideration of future Outcomes. See the details for per-step correctness annotations in Appendix C.

Comparison in Game of 24 Figure 2 demonstrates the evolving trends across training epochs, illustrating that both OVM and PRM-O effectively guide towards correct answers, in contrast to PRM's failure, highlighting the importance of anticipating outcomes. [6] Notably, PRM-O shows faster convergence than OVM, but OVM eventually reaches a performance comparable to PRM-O. This indicates that outcome supervision, relying only on final answer correctness, may suffice for models to learn outcome evaluation, while more detailed step-level signals can accelerate this process.

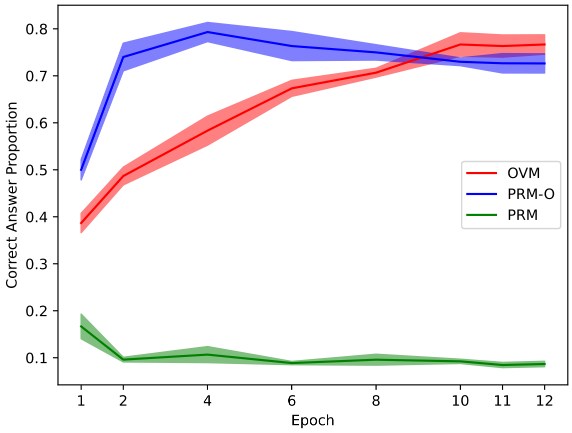

Figure 2: Comparison among OVM, PRM, and PRM-O in correct answer proportion in Game of 24 (K=20)

Comparison in GSM8K See the results in Table 5. PRM-O outperforms PRM, consistently favoring anticipating outcomes. However, OVM and PRM show similar performance levels. We analyze the reason behind OVM's lack of superior performance over PRM as follows.

Table 5: Correct answer proportion in GSM8K in comparison among OVM, PRM, and PRM-O.

	K=20	K=100
OVM	65.8% ± 0.6%	68.9% ± 0.2%
PRM	65.9% ± 0.6%	69.1% ± 0.3%
PRM-O	67.4% ± 0.6%	70.4% ± 0.2%

Analysis of the difference between Game of 24 and GSM8K Distinct patterns emerge in comparing outcome supervision versus process supervision across Game of 24 and GSM8K, likely due to data specificity and data efficiency.

Data specificity concerns how well "correctness" aligns with "helpfulness". Our analysis shows a stark contrast in the consistency between PRM labels (logical correctness only) and PRM-O labels (emphasizing contribution to the correct answer) in Game of 24 and GSM8K, which are 56.9% and 98.6% respectively. This suggests that in Game of 24, logical correctness does not reliably predict answer success, making PRM vulnerable in such a scenario. Conversely, OVM/PRM-O, with its emphasis on the helpfulness towards the final answer, appears more robust. In GSM8K, where logically correct steps typically lead to correct outcomes (98.6% of cases), PRM is nearly as effective as OVM in finding correct answers.

Data efficiency considers the dataset size relative to task complexity. In scenarios like GSM8K, where the dataset is small for the task's complexity, PRM/PRM-O might offer more efficiency through detailed step-by-step supervision. However, in simpler tasks with adequately large datasets, such as the Game of 24, while fine-grained supervision might speed up training, it doesn't necessarily translate to better performance.

Overall, when considering both the performance and annotation costs (see the statistics in Appendix C.3), outcome supervision demonstrates superior utility across various settings: it reaches competitive and even better performance than process supervision, with significantly reduced demands on annotation efforts.

7 Related Works

Complete path verification in mathematical reasoning Mathematical reasoning presents significant challenges in arithmetic computation and complex, multi-step reasoning. The complexity of such tasks arises from the ease of making mistakes at each step, which can influence subsequent steps and final answers. In such scenarios, Verification has gained popularity as a means of improving accuracy by prioritizing the most plausible solutions among multiple alternatives (Shen et al., 2021; Cobbe et al., 2021; Weng et al., 2022; Zhou et al., 2023). A common implementation of verification involves training a specialized model to predict the correctness of complete solutions, which is called the verifier (Cobbe et al., 2021; Uesato et al., 2022; Li et al., 2022; Khalifa et al., 2023). In training

---

[6] Two more training epochs are conducted for better visualization.

verifiers, a debate exists between outcome-based and process-based supervision, with recent trends favouring process supervision (Uesato et al., 2022; Lightman et al., 2023). In this paper, we explore the potential of outcome supervision in planning.

Guided decoding in multi-step problem solving Compared to selecting from the completed paths, it is more efficient to guide the model decoding in the middle of the process to filter harmful or less helpful steps for multi-step problem-solving. There are mainly two types of evaluation criteria for intermediate steps: reward-based (past-oriented) and value-based (future-oriented). Reward-based methods assess the intermediate steps according to their correctness or other characteristics of the steps already taken (Khalifa et al., 2023; Hao et al., 2023; Xie et al., 2023). In contrast, value-based methods evaluate the intermediate steps based on the potential outcomes in the unseen future (Yao et al., 2023; Hao et al., 2023; Zhu et al., 2023; Feng et al., 2023). The previous value-based approaches evaluate the future potential through simulation, utilizing Monte Carlo Tree Search (Hao et al., 2023; Zhu et al., 2023). ToT simplifies the simulation process using heuristics aided by GPT-4 in the Game of 24 (Yao et al., 2023). However, creating heuristics for more complex and realistic mathematical datasets, such as GSM8K, poses significant challenges. In this paper, we explore developing a specialized model to predict values on the fly without complex simulation.

8 Conclusion

In conclusion, this paper presents a novel approach in verifying intermediate steps and guiding model generation. This is achieved through the introduction of the Outcome-based Value Model (OVM), which employs outcome supervision in training a value model for intermediate steps. Both theoretical and empirical evidence highlight the effectiveness of outcome supervision for value estimation in planning, offer a method that is more efficient and effective than process supervision, which results in a reward-based model. The OVM, requiring no costly step-level annotations and fewer sampled paths, demonstrates superior performance in complex multi-step reasoning tasks, as evidenced by its state-of-the-art results on GSM8K and impressive success rate improvement in the Game of 24.

Limitations

Guided decoding, while effective, introduces a limitation: it introduces an additional model to aid the generator decoding, which imposes a more substantial demand on memory resources and decelerates the inference process. This poses a significant challenge in some real-world applications where rapid response is crucial. Besides, our study does not delve into the costs associated with training a sufficiently accurate value model. While process supervision may enable the training of a reward model with a small dataset, outcome supervision could necessitate a considerably larger dataset for the effective training of a value model. This raises concerns about the scalability of such a system. Additionally, the generalization capability of the value model remains unexplored in our research. This omission leaves unanswered questions regarding the model's adaptability and performance consistency across diverse or unforeseen scenarios.

Notation	**Description**
q	Mathematical reasoning question requiring a sequence of steps
$\mathcal{Q}$	A question set
S	Solution path for a question, $S = [s^1, \ldots, s^m, a]$
s^i	The i-th step in a solution path
a	Final answer in a solution path
m	Number of steps in a solution path
y	A binary label, either 1 or 0, indicating the correctness of a
$S^{(1:t)}$	Partial solution path up to step t, $S = [s^1, \ldots, s^t]$
$\mathbb{S}^{(1:t)}$	Set of candidate partial paths $\mathbb{S}^{(1:t)} = \{S_k^{(1:t)}\}_{k=1}^K$
K	Sampling size for candidates when inference
b	Beam size for selecting top-scored candidates
n	Number of sampled paths per question for training value models
Φ	The language model as the generator
f	A scoring model that maps a partial path to a number
$v^{(1:t)}$	Value (a number) of a partial path up to step t
$\boldsymbol{\theta}$	Model parameter
PRM	Process Reward Model, trained with process supervision
ORM	Outcome Reward Model, trained with outcome supervision
OVM	Outcome Value Model, trained with outcome supervision

Table 6: Summary of Notations Used in the paper

A Training Strategies

A.1 Outcome supervision for OVM

We train OVM with outcome supervision.

Training labels in outcome supervision In outcome supervision, each question-solution pair only requires a single binary label $y_o \in \{0, 1\}$, indicating whether the final answer a is correct or not. In practice, this label is expanded into a consistent vector, $\boldsymbol{y}^o = [y_o, \ldots, y_o]$, matching the length of the token sequence to enhance the robustness of training procedures (Cobbe et al., 2021).

Training objective in outcome supervision Given the training data (q, S, $\boldsymbol{y}^o$), the mean squared error loss is calculated as

$$l(S, \boldsymbol{y}^o; q) = ||f(q; S) - \boldsymbol{y}^o||^2$$

Additionally, the model is jointly trained with language modeling loss unweighted, following Cobbe et al. (2021).

A.2 Process supervision for PRM

We train reward models (PRM and PRM-O) for comparison with process supervision.

Training labels in process supervision In process supervision, each question-solution pair requires a vector of labels, $[y_1, \ldots, y_m]$, corresponding to the number of steps involved, denoted by m. Each element within this vector indicates the correctness of its respective step. In practice, this vector is expanded to align with the token sequence length by attributing the identical label, y_i, across all tokens within the i-th step. This results in the final label vector $\boldsymbol{y}^p = [y_1, \ldots, y_1, \ldots, y_m, \ldots, y_m]$.

	Complete path evaluation	Partial path evaluation
Process supervision	Reward	Reward
Outcome supervision	Reward	Value

Table 7: Types of scores predicted by process- or outcome-supervised models on the complete path and partial path, respectively. When evaluating partial paths, the predicted scores of outcome-supervised models are values.

Training objective in process supervision Process supervision shares the same training objective as outcome supervision, but differs in training labels.

$$l(S, \boldsymbol{y}^p; q) = ||f(q; S) - \boldsymbol{y}^p||^2$$

B Implementation Details

Training generators We use the newline character as the marker for the end of each step. In GSM8K, we fine-tuned Mistral-7B and Llama2-7B on the training set. Given that GSM8K provides calculation annotations, our models were also trained to utilize calculators. In Game of 24, we fine-tuned Llama2-7B on problem indices 1-900 with enumerated solution paths. For both datasets, the fine-tuning was carried out for 2 epochs, with a batch size of 128. We set the maximum learning rate to 1e-5, using a linear scheduler with the AdamW optimizer. We implement FlashAttention for Llama2-7B (Dao et al., 2022, Dao, 2023).

Building training dataset for OVM Given the training question set, we first sample 100 solution paths for each question from the generator. The decoding temperature is 0.7, top k is 50, top p is 1.0 and the maximum new tokens is 400. Then, we detect the answer correctness for each sample. In GSM8K, the answer correctness is determined by exact string matching to the ground truth since all the answers are integers. In Game of 24, the answer correctness is based on the validity of the equation equating to 24 and the singular usage of input numbers, following (Yao et al., 2023). This allows us to produce numerous OVM training samples using just question-answer pairs, without path annotations, resulting in 747,300 training samples for GSM8K and 90,000 for Game of 24.

Training OVMs/ORMs [7] OVMs were initialized from the corresponding generator checkpoints. In GSM8K, OVM was trained for 1 epoch with a batch size of 512. In Game of 24, OVM is trained for 10 epochs with a batch size of 128, due to its smaller training set. The optimizer was AdamW and the maximum learning rate was set to 1e-5 for Llama2-7B and 2e-6 for Mistral-7B respectively, following a linear scheduler.

Training PRM and PRM-O Same as OVM, PRM and PRM-O were initialized from the corresponding generator checkpoints. The training dataset is the same set of question-solution pairs as in OVM, but details per-step correctness as training labels. See the annotation details in Appendix C. All the training hyperparameters are consistent to OVM's.

Value-guided beam search The decoding temperature is 0.7, top k is 50, and top p is 1.0. We set the maximum new token length as 400 and the maximum number of steps as 10. In Game of 24, the generator produces more duplicated outputs due to the small output space. During the beam search process, we give priority to non-duplicate sequences for selection.

C Process Label Annotation

C.1 Annotation protocol

Game of 24 We derive process labels by checking the syntax and calculation, and matching to all possible correct solutions, enumerated by rules. Specifically, for PRM training (logical correctness only), steps are labeled as 1 when the steps are logically correct in rules, i.e. the calculation is correct and each used number is given and only used in once. For PRM-O training (logical correctness and helpfulness), steps are labeled as 1 when they correspond to any of the enumerated feasible correct solution paths.

GSM8K We query GPT-4 to annotate process labels without references. GPT-4 is asked to classify each step into "correct", "incorrect", or "unnecessary". The used prompt is shown as follows:

[Question]
`question`

---

[7] Since we train the value model with outcome supervision, the objective originally intended for ORM, the same model is simultaneously used as OVM for partial paths and ORM for complete paths in this paper.

[Correct Answer]
`answer`

[Solution]
`solution path`

[System]
You are an expert math examiner. Review the student's solution and mark each step as correct only if it's based on accurate premises and helps solve the problem. Mark it as "unnecessary" when it is logically valid but doesn't help.
Please mark with "[Conclusion]" and summary all your judgements in the format of "Step i is correct/incorrect/unnecessary".

We label “correct” steps as 1 and “incorrect” steps as 0. For PRM training, “unnecessary” steps are labeled as 1, while for PRM-O training, they are labeled as 0.

C.2 Consistency evaluation for GPT-4 labeling in GSM8K

We conduct a consistency evaluation of GPT-4 labeling compared to human labeling on a small set.

Evaluation set construction To ensure coverage of this set across paths of different lengths, we randomly select two solutions from each length set, including one with the correct final answer and one with an incorrect answer. For instance, we sample a correct solution and an incorrect solution from both the 1-step path set and the 2-step path set. Additionally, we apply the same sampling procedure to the sets classified by the step length of reference solutions. Finally, we get 116 question-solution pairs.

Human evaluation We hire three master-level students to annotate those examples as “correct”, “incorrect”, or “unnecessary”.

Consistency analysis The agreement rates between GPT-4 labels and human labels are shown in Table 8. This indicates GPT-4 can provide process labels with high consistency to humans.

	Human 1	Human 2	Human 3	GPT-4
Human 1	-	0.89	0.88	0.87
Human 2	0.89	-	0.91	0.86
Human 3	0.88	0.91	-	0.86
GPT-4	0.87	0.86	0.86	-

Table 8: Agreement rates on 116 samples between GPT-4 labeling and human labeling

C.3 Annotation cost

PRM and PRM-O incur a considerably higher annotation cost compared to OVM due to the need for detailed per-step correctness assessments. With N questions and n sampled solution paths per question, and an average step count of m for these paths, the annotation cost for process supervision scales as $O(Nnm)$. In contrast, the annotation cost for outcome supervision is $O(Nn)$, requiring only the final answer's correctness for each question-solution pair. Specifically, see the data statistics in Table 9.

Cost comparison in Game of 24 In Game of 24, the annotation cost for PRM and PRM-O is four times higher than that of OVM, corresponding to the average number of steps in solution paths. Clearly, the longer the solution path, the greater the annotation cost disparity between process supervision and outcome supervision.

Cost comparison in GSM8K In GSM8K, where each question has a unique answer, the final answer correctness for each sampled solution can be derived by comparing the final answer to the ground truth. This process significantly lowers the annotation cost for outcome supervision to $O(N)$, compared to $O(Nn(m-1)+N)$ for process supervision. Consequently, for OVM, 7,473 annotations are needed (equivalent to the number of questions), whereas PRM and PRM-O require 2,619,923 annotations — 350 times more than OVM.

These comparisons underscore OVM's lower annotation cost and better scalability.

D Detailed Experiment Results and Hyperparameter Analysis

There are two critical hyperparameters in value-guided beam search: sampling size and beam size. We present the detailed results across various sampling sizes and beam sizes in Table 10, Table 11 and Table 12.

D.1 Impact of beam sizes on OVM planning

In this section, we mainly explore the impact of beam size choices on OVM performance. Notably, there is one special case: when the beam size is equal to the sampling size, the approach functions

	#Questions	**#Solutions**		**#Steps**		**Cost in outcome supervision**		**Cost in process supervision**	
	all	per question	all	per solution	all	labels	annotations	labels	annotations
Game of 24	900	100	90,000	4.01	360,914	90,000	90,000	360,914	360,914
GSM8K	7,473	100	747,300	4.50	3,359,750	747,300	7,473	3,359,750	2,619,923

Table 9: Label and annotation statistics of outcome supervision and process supervision in GSM8K and Game of 24.

as vanilla sampling rather than guided decoding, as it omits any intermediate selection or pruning.

Inference cost is consistent across various beam sizes Regardless of the beam size, given a fixed sampling size, the inference cost typically remains unchanged. This uniformity arises because the generator produces a consistent number of next steps (i.e., the sampling size) at each level of the tree, leading to stable peak memory usage and inference time which is primarily influenced by the generation phase, not by beam selection or data storage.

The impact of beam size on OVM effectiveness We can observe from the tables that

(1) A relatively large beam size enhances the accuracy. In GSM8K (Table 10 and Table 11), accuracy improves with an increase in beam size, but the proportion of correct answers first rises then falls. In Game of 24 (Table 12), accuracy initially increases before declining, while the correct answer proportion consistently decreases. These observations imply that a larger beam size can positively impact accuracy up to a point, beyond which it may become detrimental. We attribute the pattern to (1) an initial reduction in error propagation risk with increasing beam size, leading to higher accuracy, and (2) an excessively large beam size potentially introducing incorrect solutions, as indicated by the drop in correct answer proportion, thereby increasing the risk of false positives.

(2) OVM's superiority over vanilla sampling is robust. As shown in Table 10-Table 12, OVM demonstrates a robust and consistently superior planning capability compared to vanilla sampling, as evidenced by a higher proportion of correct answers across all beam sizes, including when the beam size is 1 (losing the advantage of error propagation), in both GSM8K and Game of 24. Additionally, OVM achieves better accuracy across a range of moderate beam sizes, rather than limited to specific settings, indicating the effectiveness of OVM planning over vanilla sampling is not a result of cherry pick. For example, any beam size of 4 or greater improves accuracy over vanilla sampling for K=20 in GSM8K (Table 10 and Table 11). Similarly, for K=100 in Game of 24, all beam sizes between 10 and 25 surpass the performance of vanilla sampling (Table 12). The small standard variation further underscores the reliability of these improvements.

D.2 Comparison between outcome supervision and process supervision

Comparison between two supervision strategies in guided decoding across various beam sizes When evaluating the performance across a spectrum of beam sizes beyond just the peak performance, the analysis consistently shows that outcome supervision is competitive and even better than process supervision in terms of effectiveness. Specifically,

(1) Outcome supervision excels in Game of 24. According to Table 12, OVM outperforms PRM in terms of both accuracy and correct answer proportion across all beam sizes. When compared to PRM-O, OVM demonstrates superior overall performance. Specifically, OVM achieves higher accuracy than PRM-O in 4 out of 5 scenarios at K=20, and in 4 out of 8 scenarios at K=100.

(2) Outcome supervision holds up well in GSM8K. In Table 10, the superiority of PRM-O over PRM consistently underscores the value of focusing on outcomes. OVM's performance is closely matched with PRM, reaching higher accuracy in 6 out of 13 scenarios for K=20 and K=100. While OVM generally trails behind PRM-O across all beam sizes, the difference is typically narrow, often within a 3-point margin.

Overall, considering the annotation costs in Appendix C.3, OVM demonstrates superior utility in both settings.

Comparison between two supervision strategies in complete path verification When evaluating the performance of complete path verification (vanilla sampling along with post-selection), it appears that process supervision does not necessarily outperform outcome supervision. This observation contrasts with previous findings, which suggested process supervision is either on par with (Uesato et al., 2022) or superior to outcome supervision (Lightman et al., 2023) in certain contexts. See the analysis below for this unexpected phenomenon:

(1) Outcome supervision exploits shortcuts in Game of 24. Table 12 indicates that ORM (outcome supervision) surpasses both PRM and PRM-O (process supervision). Upon closer examination of the data, we identified cases where intermediate steps were incorrect, yet the final answers were correct. These cases imply that the generator might occasionally find the right answers by chance. Process-supervised models miss these instances due to their incorrect pathways, whereas outcome-supervised models benefit from these "shortcuts" by prioritizing the accuracy of the final answer, irrespective of the process taken to arrive there.

(2) Two potential factors influencing the results in GSM8K. In GSM8K, ORM initially lags behind PRM and PRM-O at K=20 but outperforms them at K=100, as shown in Table 10. This shift might be attributed to two potential factors: the presence of shortcuts and the quality of process labels. Firstly, similar to Game of 24, shortcuts also exist in GSM8K, which might explain the parallel findings by Uesato et al. (2022) that outcome supervision and process supervision perform comparably in GSM8K. As the number of sampled paths increases, ORM's chances of exploiting a shortcut also rise, thereby enhancing its performance over PRM and PRM-O. Secondly, the discrepancy in process label quality might influence results. According to Table 8, the average human agreement rate is 89.3%, while the average human-GPT4 agreement rate is 86.3% with a difference of 3 percentage points. This underscores the complexities involved in annotating process labels.

Sampling size	Beam size	OVM		PRM		PRM-O

The Whole is Better than the Sum: Using Aggregated Demonstrations in In-Context Learning for Sequential Recommendation

Lei Wang **Ee-Peng Lim**[*]
Singapore Management University

Abstract

Large language models (LLMs) have shown excellent performance on various NLP tasks. To use LLMs as strong sequential recommenders, we explore the in-context learning approach to sequential recommendation. We investigate the effects of instruction format, task consistency, demonstration selection, and number of demonstrations. As increasing the number of demonstrations in ICL does not improve accuracy despite using a long prompt, we propose a novel method called LLMSRec-Syn that incorporates multiple demonstration users into one aggregated demonstration. Our experiments on three recommendation datasets show that LLMSRec-Syn outperforms state-of-the-art LLM-based sequential recommendation methods. In some cases, LLMSRec-Syn can perform on par with or even better than supervised learning methods. Our code is publicly available at `https://github.com/demoleiwang/LLMSRec_Syn`.

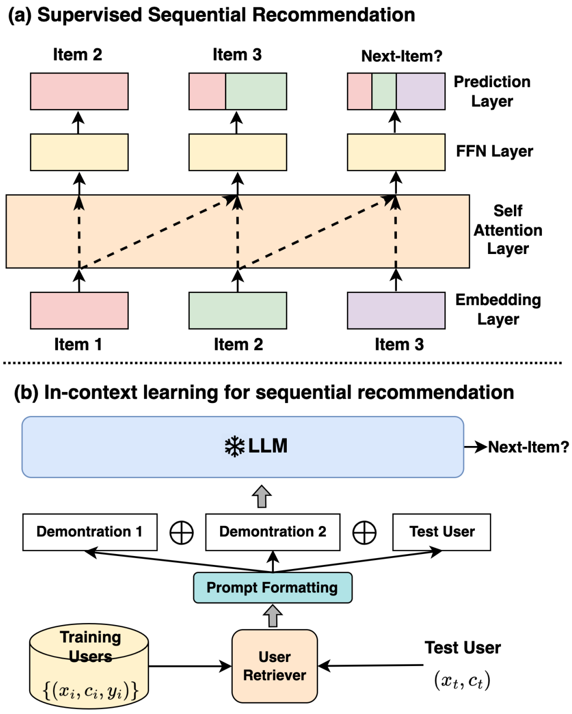

Figure 1: The illustrative comparison of (a) supervised sequential recommendation method and (b) in-context learning based sequential recommendation method.

1 Introduction

Motivation. Large language models (LLMs) are known to perform well as a zero-shot solution for many natural language processing tasks (Brown et al., 2020; Chowdhery et al., 2022; OpenAI, 2022; Qin et al., 2023). Recently, there are some works that focus on using LLMs to perform recommendation with promising accuracies (Hou et al., 2023; Wang and Lim, 2023; Liu et al., 2023a; Bao et al., 2023; Gao et al., 2023) and to provide explanations (Yang et al., 2023; Wang et al., 2023b). Most of these works developed LLM prompts for zero-shot sequential recommendation.

To investigate whether LLM can serve as a strong zero-shot sequential recommender, Hou et al. (2023) devised a prompt that is filled with historical items in chronological order, candidate items, and instruction to rank the candidate items. Wang and Lim (2023) proposed a three-step prompting method, where LLMs first summarizes the user preference based on the user's past interacted items. It then identifies representative items from the past interacted items that capture the user preference, and finally recommends items among the candidate items which are aligned with the representative items. Among the very few one-shot sequential recommendation works, Liu et al. (2023a) and Hou et al. (2023) explored in-context learning using the test user's second last item as the ground truth next-item and all earlier interacted items as input to create self-demonstrations. Nevertheless, previous experiments have shown that in-context learning (ICL) based sequential recommendation methods perform poorly compared with

the supervised learning-based methods (e.g., SASRec) due to the complex recommendation task definition (Liu et al., 2023a; Hou et al., 2023; Wang and Lim, 2023). The illustrative comparison of these two methods is shown in Figure 1.

To develop an effective in-context learning approach for LLMs to perform sequential recommendation, we first define the sequential recommendation problem as follows.

Problem definition. We denote each input user instance u_i to be a (x_i, c_i, y_i) tuple where x_i denotes the sequence of past interacted items (excluding y_i) by u_i, c_i denotes the candidate items to be recommended ($|c_i| = M$), and y_i denotes the ground truth next-item which is also the last item interacted by u_i. Note that y_i appears in c_i ($y_i \in c_i$). A LLM-based sequential recommendation method is required to assign a rank $rank(d) \in [1, M]$ to each item d in c_i. Our objective is to ensure that the method ranks y_i, i.e., $rank(y_i)$, as high as possible for all.

The above definition includes c_i as input as it is usually infeasible for LLMs to take all items as input due to limited prompt length. Moreover, having c_i does not introduce bias in the evaluation. The above definition is also adopted in Hou et al. (2023). We also assume a dataset of users' interacted item sequences from which we can construct demonstrations for ICL, and a LLM which is too large for pretraining or finetuning.

Overview of our study. Past works has shown that the effectiveness of ICL in adapting LLMs to new tasks is significantly influenced by instruction wording (Madaan and Yazdanbakhsh, 2022; Yang et al., 2023), label design (Yoo et al., 2022; Wei et al., 2023), selection of demonstrations (Liu et al., 2021; Shi et al., 2022; Zhang et al., 2023b), and number of demonstrations Chen et al. (2023); Zhao et al. (2023). Our study thus begins by systematically investigating how the instruction format, task consistency (between test and demonstration), demonstration selection, and the number of demonstrations affect ICL-based sequential recommendation. Through our preliminary experiments, we obtain four findings including the one that observes degradation of recommendation accuracy when the number of demonstrations increases. As each demonstration takes up significant length, it is also easy for multiple demonstrations to exceed the prompt limit of LLMs. Moreover, as LLMs are known to miss out relevant information in a long input prompt (Liu et al., 2023b), we thus embark on a follow-up study on designing a more efficient ICL scheme based on *aggregated demonstration*.

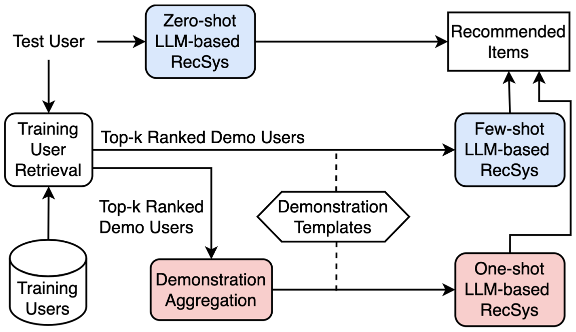

Figure 2: The overall framework of zero-shot, few-shot, and aggregated one-shot LLM-based sequential recommender systems.

Figure 2 shows a comparison of the frameworks for zero-shot, few-shot, and aggregated one-shot LLM-based sequential recommender systems. The key idea in aggregated demonstration is to combine multiple training users into one demonstration. This reduces the repetition of instruction text in the ICL prompt. It also seeks to summarize multiple training users relevant to the test instance in a compact manner. We also develop a novel ICL method using aggregated demonstration for sequential recommendation known as **LLMSRec-Syn**. The length of LLMSRec-Syn prompt increases only gradually with number of demonstration users, LLMSRec-Syn can cope with more relevant information from the demonstration users within a concise input context. We finally show LLMSRec-Syn outperforms other zero-shot and one-shot ICL methods in an extensive set of experiments.

Contribution. Our contributions can be summarized as follows: (1) We systematically explore the ICL approach to sequential recommendation by empirically investigating the effect of instruction format, task consistency, demonstration selection, and number of demonstrations; (2) We propose a new in-context learning method for sequential recommendation called LLMSRec-Syn which leverages on a novel concept of aggregated demonstration; (3) We experiment on three popular recommendation datasets and show that LLMSRec-Syn outperforms previous LLM-based sequential recommendation methods.

2 Related Work

In-Context Learning. Several works show that LLMs can effectively adapt to different NLP and multimodal tasks, including machine translation (Agrawal et al., 2022), visual question answering (Yang et al., 2022), and foreground segmentation (Zhang et al., 2023b). This adaptation is achieved by learning from a few task-relevant demonstrations, commonly known as in-context learning (ICL) (Brown et al., 2020). Despite the above successes, ICL's performance is still significantly affected by the wording of instructions (Madaan and Yazdanbakhsh, 2022; Yang et al., 2023), label design (Yoo et al., 2022; Wei et al., 2023), demonstration selection (Liu et al., 2021; Shi et al., 2022; Zhang et al., 2023b), and number of demonstrations Chen et al. (2023); Zhao et al. (2023). ICL is much less studied in LLM-based sequential recommendation. As sequential recommendation is distinct from the pretraining tasks of LLMs and also different from the above-mentioned tasks, new designs of demonstration(s) and ICL prompt is necessary.

LLMs for Sequential Recommendation. Early sequential recommendation works adopt techniques such as Markov Chains (Rendle et al., 2010; He and McAuley, 2016) and neural networks (e.g., RNN (Hidasi et al., 2015), CNN (Tang and Wang, 2018), Self-Attention (Kang and McAuley, 2018), and GNN (Chang et al., 2021)). To investigate if LLMs can be used as effective sequential recommenders without training, Hou et al. (2023) formulated sequential recommendation as conditional ranking, employing zero-shot LLM methods to reflect user preferences from past interactions and recency. Wang and Lim (2023) developed a three-step LLM prompting to summarize user preferences, while Hou et al. (2023) and Liu et al. (2023a) introduced a one-shot ICL method that utilizes the previous item interactions of the target user as a demonstration. To address position bias, Hou et al. (2023) proposed to randomize the candidate item order. In this work, we explore using training data demonstrations, not just user own history, and introduce aggregated demonstration for combining relevant users.

3 What Makes In-Context Learning Work for Sequential Recommendation

In this section, we conduct a preliminary empirical study to investigate the role of various aspects of demonstrations. These aspects include the wording of prompts, task consistency between demonstrations and test instances, selection of demonstrations, and number of demonstrations. While previous studies have explored the use of LLM as sequential recommenders in a zero-shot manner (Hou et al., 2023; Wang and Lim, 2023), this is the first study to comprehensively discuss how in-context learning can improve sequential recommendation.

Table 1: Dataset statistics after removing duplicate interactions and users or items with fewer than 5 interactions.

Datasets	ML-1M	LastFM-2K	Games
# Users	6,040	1,143	50,547
# Items	3,706	11,854	16,859
# User-item Interactions	1,000,209	68,436	389,718
Avg. interacted items per user	165.59	59.92	7.71
Avg. interacted users per item	269.88	5.77	23.11

3.1 Experiment Setup

We implement zero-shot, one-shot, and few-shot methods in this study, using three widely used recommendation datasets: the movie rating dataset *MovieLens-1M* (ML-1M) dataset, the category of *Games* from the Amazon Review dataset (McAuley et al., 2015), and the music artist listening dataset *LastFM-2K* (Cantador et al., 2011). The data statistics are summarized in Table 1. Taking into account cost-effectiveness of LLMs, we select 50 data examples from each of the three datasets to carry out all experiments for analysis in Section 3. Following the previous works (Hou et al., 2023; Wang and Lim, 2023), we use a leave-one-out strategy for evaluation, i.e., predicting the last interacted item of each user sequence and using the earlier interacted items as input. For each user sequence, we remove the last item, keeping it aside for testing. The rest of the sequence is used for training and validation. To evaluate the ranking results for each user u_i over a set of candidate items c_i, we adopt the widely used **NDCG@N** (N = 10, 20) as the evaluation metric. For MovieLens-1M and Games, we directly use the candidate sets utilized in an earlier work (Hou et al., 2023). For LastFM, we follow (Hou et al., 2023) and randomly select candidate items from the item universal set for each user sequence. We then insert the ground truth next item into the candidate item set. We use ChatGPT (`GPT-3.5-Turbo`) as the default LLM due to its excellent performance and cost-effectiveness. To ensure the reliability of findings, we repeat each experiment 9 times and report the average results. Without exception, we use ML-1M as an example for discussion.

3.2 In-Context Learning for Sequential Recommendation

In ICL for sequential recommendation, one or a few training users are used as demonstrations that are included in the LLM prompt. Each demonstration thus includes a training user i's historical item interactions x_i, a set of candidates c_i, and ground truth next-item y_i. We denote the prompt capturing the demonstration user i by $\mathcal{T}(x_i, c_i, y_i)$. The following shows the concatenation of n demonstrations $\mathcal{C}$ which is appended by the instruction prompt for the test user $\mathcal{T}(x_{test}, y_{test})$ for prediction.

$$\mathcal{C} = \mathcal{T}\left(x_1, c_1, y_1\right) \oplus \cdots \oplus \mathcal{T}\left(x_n, c_n, y_n\right) \quad (1)$$

$$y_{\text{test}} \sim \mathcal{P}_{LLM}\left(\cdot \mid \mathcal{C} \oplus \mathcal{T}\left(x_{\text{test}}, c_{\text{test},\cdot}\right)\right) \quad (2)$$

3.3 Wording of Instructions

LLMs have been found to be sensitive to wording of the prompt (Madaan and Yazdanbakhsh, 2022; Yang et al., 2023). For example, prompts (or instructions) that are semantically similar may yield significantly different results (Kojima et al., 2022; Zhou et al., 2022; Wang et al., 2023a; Zhang et al., 2023a). To examine the impact of instruction wording and exclude the influence of other factors such as demonstration labels and selection, we employ LLM as a zero-shot solver for sequential recommendation.

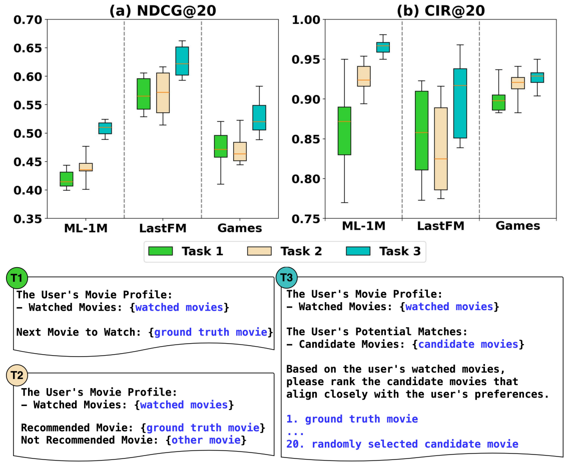
We discuss four different options for the instruction format to investigate the sensitivity of the LLM to the wording of the instruction. Considering the prompts used in LLM-based zero-shot recommendation models (Hou et al., 2023; Wang and Lim, 2023), we derive instructions with four possible mention components: (a) candidate item ranking, (b) user preference alignment, (c) historical interacted items, and (d) ranked result format. As recommendation is formulated as a ranking task, component (b) is mandatory. The *full* instruction covers all four components. To explore better instructions, we derive other instruction options by leaving out one of the remaining components. We thus have four instruction options: (A) full instruction $\mathcal{T}^{\mathrm{A}}$, (B) full instruction without (b) $\mathcal{T}^{\mathrm{B}}$, (C) full instruction without (c) $\mathcal{T}^{\mathrm{C}}$, and (D) full instruction with (d) replaced by textual result table description $\mathcal{T}^{\mathrm{D}}$ as shown in Figure 3.

As shown in Figure 3, we observe that ChatGPT's performance degrades when the instruction does not make reference to interacted items or user preferences across three datasets. This suggests that explicit inclusion of watched movies or user preferences can improve its ability to leverage the user's historical items effectively. While Instruction (A) shows similar average performance as Instruction (D) on ML-1M and LastFM, the former enjoys a smaller variance and outperforms the latter on LastFm. This suggests that LLM prefers explicit output formats over textual description of output format.

***Finding* 1.** For sequential recommendation, ChatGPT prefers explicit mentions of instructions and explicit mentions of interacted items, user preference alignment and ranked result format.

3.4 Task Consistency

LLMs are capable of learning new tasks at test time by understanding the relationship between the input of a demonstration and its corresponding output label (Yoo et al., 2022; Wei et al., 2023). In sequential recommendation, LLM is required to rank the ground truth target item at the top followed by other candidate items. However, in a demonstration example from the training set, we observe only one labeled next item but not the ranking of other candidate items. Hence, when constructing demonstrations for in-context learning, we have to answer the important questions: How to prepare the input-label correspondence for a demonstration to be consistent with the sequential recommendation task?



```
The User's Movie Profile:
- Watched Movies: {watched movies}

Next Movie to Watch: {ground truth movie}
```

```
The User's Movie Profile:
- Watched Movies: {watched movies}

Recommended Movie: {ground truth movie}
Not Recommended Movie: {other movie}
```

```
The User's Movie Profile:

The User's Potential Matches:
- Candidate Movies: {candidate movies}

Based on the user's watched movies,
please rank the candidate movies that
align closely with the user's preferences.

1. ground truth movie
...
20. randomly selected candidate movie
```

Figure 4: Impact of task consistency between demonstrations and test instances. CIR: Candidate Inclusion Ratio of Demonstration Templates: (T1) Next-Item option; (T2) Contrasting Item Pair option; (T3) Ranked Items option.

To eliminate other factors that may influence the results, such as the number of demonstrations and instructions, we employ instruction (A) as it has proven to be the most effective and robust across three datasets in our previous experiments. We randomly select only one demonstration example for all experiments in this study.

In traditional sequential recommendation, next-item prediction (Song et al., 2021; Petrov and Macdonald, 2022), positive and negative item comparison (Rendle et al., 2012; Kang and McAuley, 2018; Xie et al., 2020), and reranking (Xu et al., 2023) are commonly utilized objectives to train models. Hence, we develop three different prediction tasks for demonstrations for in-context learning. These tasks include: (T1) predicting the next item, (T2) contrasting item pairs, and (T3) ranking candidate items. The prompts corresponding to these prediction tasks are shown in Figure 4. T1 uses the ground truth next-item directly in the demonstration. T2 uses the ground truth next item and another randomly selected item as the positive and negative items respectively. T3 ranks the ground truth next item at the first position and randomly shuffles the remaining candidate items to fill the other positions. Among the task prediction task options, T3 is the only one that aligns closely with the instruction for the test user, i.e., (A).

Figure 4 shows the results of these three tasks across three datasets. T3 consistently outperforms T1 and T2 on all three datasets, suggesting that task consistency between demonstration and test user benefits in-context learning for sequential recommendation. Additionally, As the recommended items may not be found among the provided candidates, we also report *candidate inclusion ratio* (CIR) which measures the proportion of the candidate items that appear in the ranked item results. As shown in Figure 4, we observe that the CIR generally correlates with the NDCG results. The inconsistent demonstration task options (e.g., T1 and T2 coupled with test instruction option (A)) are more likely to cause the LLM to generate non-candidate items in the results. This helps to understand why T3 achieves the best performance.

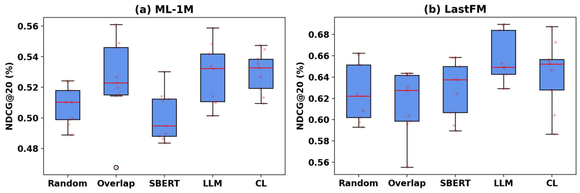

Figure 5: Demonstration selection: (1) random selection; (2) overlapping interacted items; (3) cosine similarity between the SBERT embeddings of interacted item sequences; (4) cosine similarity between the LLM (OpenAI embeddings) of interacted item sequences; (5) cosine similarity using CL embeddings of interacted item sequences.

> ***Finding* 2.** Maintaining task consistency between demonstrations and test users is beneficial for in-context learning in sequential recommendation.

3.5 Selection of Demonstrations

It has been observed that the performance of in-context learning greatly depends on selecting suitable demonstrations (Liu et al., 2021). Utilizing examples that are semantically similar to the test sample can provide more informative and task-relevant knowledge to LLMs. Following Liu et al. (2021), there are several follow-up works (Rubin et al., 2021; Shi et al., 2022; Zhang et al., 2023b; Li et al., 2023) to develop methods for selecting better demonstrations. In this work, we evaluate five different demonstration selection methods to determine their impact to in-context learning for sequential recommendation. These methods include: (1) random selection; (2) overlapping historical items of demonstration user and test user; (3) text similarity scores using Sentence-BERT embedding (Reimers and Gurevych, 2019) (SBERT); (4)

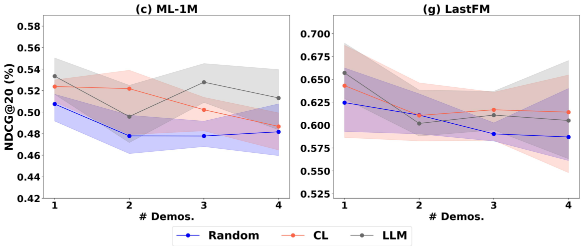

Figure 6: Varying number of demonstrations.

text similarity scores using LLM OpenAI embedding[1] (LLM); and (5) trained retriever using contrastive learning (Xie et al., 2020; Li et al., 2023) (CL). In Option (5), positive examples are obtained by data augmentation applied to the anchor user sequence, while negative examples are randomly selected user item-interaction sequences.

Figure 5 compares the five selection methods on ML-1M and LastFM as they are used in one-shot sequential recommendation. The results show that selection methods (4) and (5) generally outperform the rest. As method (4) appears to be more robust than (5) and it does not require additional training, we thus use that as the default retriever model in the subsequent experiments.

> ***Finding* 3.** Retrieval-based methods are better than random selection, and stronger LLMs can serve as stronger retrievers without any training.

3.6 Number of Demonstrations

When training a model, having more training data examples usually leads to better model performance. However, it is interesting to note that Zhao et al. (2023) discover that increasing the number of demonstrations for in-context learning does not necessarily result in improved performance. Similarly, Chen et al. (2023) finds that using only one demonstration may not perform worse than using more demonstrations. In our case, we evaluate the impact of the number of demonstrations on ML-1M and LastFM using random selection, LLM, and CL demonstration selection methods. We conduct experiments with the number of demonstrations ranging from 1 to 4, as exceeding 4 demonstrations would exceed the input limit of ChatGPT (`GPT-3.5-Turbo`). Figure 6 demonstrates a clear trend of performance decreasing with number of demonstrations.

> ***Finding* 4.** Increasing demonstrations for in-context learning for sequential recommendation would result in performance degradation and exceed the input limit of LLMs.

4 In-Context Learning with Aggregated Demonstrations

Finding 4 suggests LLMs have difficulties coping with multiple demonstrations in sequential recommendation. A similar finding by Liu et al. (2023b) also suggests that the current language models often struggle to utilize information in long input contexts. In particular, their performance tends to significantly degrade when the relevant information is located in the middle of long contexts, also known as the "lost in the middle" phenomenon. The in-context learning prompts for sequential recommendation can easily exceed the prompt length limit of LLM when more than 4 demonstrations are to be accommodated. Such prompts not only suffer from "lost in the Middle", but also incur additional costs of calling LLM APIs.

To address the above challenge, we propose *aggregated demonstration* which combines K ($K > 1$) demonstration users into one for in-context learning. This simple yet effective in-context learning method for sequential recommendation is called **LLMSRec-Syn**. As the prompt length of aggregated demonstration only increases marginally when we increase K, LLMSRec-Syn can accommodate more member demonstration users.

Based on Finding 3, LLMSRec-Syn begins with selecting K demonstration users that are similar to the test user. We use similarity between the LLM embeddings of demonstration and test users. We also follow Finding 1 and adopt instruction template (A) for the test user. Based on Finding 2, we also adopt demonstrate template (T3) for the aggregated demonstration to maintain consistency with the task for test user. Next, we construct the aggregated demonstration's historical item-interactions, candidate items, and the desired ranking of the candidate items from its member demonstrations, as shown in Figure 10 in the Appendix.

Historical item-interactions. Let H denote the historical item-interactions and H is empty initially. We first rank the K selected demonstration users by similarity score. We then add the most recent interacted item from the most similar demonstration

---

[1] `text-embedding-ada-002` (https://platform.openai.com/docs/models/moderation)

to H. We repeat the same step for the remaining demonstrations in their similarity order. When we run out of most recent interacted items from K selected demonstrations, we continue to add the next recent interacted items of these demonstrations to H until the number of historical items reaches MAX_H.

Candidate Items. Let C denote the candidate items of the aggregated demonstration and C is empty initially. We first gather all the ground truth next items from the K selected demonstrations and add them to C. Next, we randomly add other items from the item pool to C so as to meet the required number of candidate items.

Ranking of Candidate Items. To rank the candidate items in C, we place the ground truth next item of the most similar demonstration at rank 1, followed by that of next similar demonstration until we run out of the ground truth next items of all K selected demonstrations. Next, we assign random ranks to the remaining items in C.

Once the aggregated demonstration is constructed, it is added to the prompt the same way a training user is added as a demonstration. we add it to the corresponding test user and use them as input for the LLM.

$$\mathcal{C}^{\mathbf{agg}} = \mathcal{T}^{\mathrm{A}}(\mathrm{Agg}^{\mathrm{T3}}(x_{\sigma_1}, c_{\sigma_1}, y_{\sigma_1}, \cdots, x_{\sigma_n}, c_{\sigma_n}, y_{\sigma_n})), \quad (3)$$

$$y_{\text{test}} \sim \mathcal{P}_{LLM}\left(\cdot \mid \mathcal{C}^{\mathbf{agg}} \oplus \mathcal{T}^{\mathrm{A}}\left(x_{\text{test}}, c_{\text{test}}\right)\right), \quad (4)$$

where σ_i represents the i^{th} ranked selected users returned by the retrieval model. Finally, the LLM generates a ranked list of candidate items as the recommendation result.

There are several advantages of the proposed LLMSRec-Syn: 1) Standard demonstration only has one ground truth next item in the ranking list. In contrast, the aggregated demonstration includes more next items at high positions in the ranking list. This approach can avoid sparse signals and provide more guidance to LLMs for recommending to the test user; 2) LLMSRec-Syn is less sensitive to the number of demonstrations; 3) Cost of LLMSRec-Syn does not increase much with the number of demonstrations; and 4) LLMSRec-Syn keeps to the prompt length limit of LLMs.

5 Experiments and Results

5.1 Methods for Comparison

To evaluate the performance of LLMSRec-Syn, we conduct an extensive set of experiments on ML-1M, Games, and LastFM-2K datasets. Following Hou et al. (2023), we select 200 data examples from each of the three datasets to carry out all experiments. We use an experiment setup similar to that mentioned in Section 3.1 except that we now uses more LLMs and reports the NDCG@N results where N=5,10, and 20. We compare LLMSRec-Syn with 10 methods categorized into 3 types:

Supervised methods: Most Popular (Recommending items based on their overall popularity among all users in the training data), GRU4Rec (Hidasi et al., 2015) (using GRUs to model user's item sequences), and SASRec (Kang and McAuley, 2018) (employing a self-attention mechanism to learn user preferences from their item sequences).

Zero-shot methods: BM25 (Robertson et al., 2009) (ranking candidate items based on their textual similarity with the test user's interacted items), LLMSeqSim (Harte et al., 2023) (ranking candidate items by semantically similarity using OpenAI embeddings (`text-embedding-ada-002`)), LLMRank-Seq (Hou et al., 2023) (using ChatGPT to rank candidate items with crafted prompts), and LLMSRec (a zero-shot version of the proposed LLMSRec-Syn using the instruction prompt $\mathcal{T}^{\mathrm{A}}$).

One-shot methods: LLMRank-His (Hou et al., 2023) (using historical items of the test user to form a demonstration), LLMSRec-Fixed (using a randomly selected demonstration for all test users), and LLMSRec-Nearest (finding the most similar training user as the demonstration).

As Section 3.6 shows that more than one demonstration in in-context learning for sequential recommendation does not yield better performance, we do not include few-shot methods in this set of experiments. We however will study how many member demonstrations K is ideal for aggregated demonstration (see Section 5.2).

We implement LLMSRec-Syn using three different LLMs, LLaMa2 (Touvron et al., 2023), ChatGPT (OpenAI, 2022) (LLMSRec-Syn), and GPT-4 (OpenAI, 2023) (LLMSRec-Syn-4). For the LLMSRec-Syn-4 experiment, which is shown in the last row of Table 2, we used GPT-4 as the base LLM. For all other experiments, including preliminary studies, in-depth analysis, and method comparisons presented in Table 2, we used the same ChatGPT (`GPT-3.5-Turbo`). To ensure the reliability of our findings, each experiment is conducted 9 times, and the average results are reported. However, we found LLaMa2 unable to follow recommendation instructions and is prone to generating historical

Table 2: Main results. We report NDCG@5, NDCG@10 and NDCG@20 on ML-1M, LastFM-2K and Games. (Best results in each group of methods are **boldfaced** and overall best results are underlined).

interacted items or in-context examples. As a result, we exclude the LLaMa2 results In LLMSRec-Syn, we set the number of member users in the aggregated demonstration as {1,2,3,4,5,6,7} and conduct a brute force search to determine the optimal number for each dataset. We set the number of historical items $MAX_H = 50$ and number of candidate items to 20. We analyse some specific test cases of LLMSRec-Syn-4 in the Appendix 8.2.

5.2 Main Results

The main experiment results are shown in Table 2, from which we obtain the following findings:

ICL one-shot methods with appropriate demonstrations out-perform zero-shot methods. As shown in Table 2, LLMRank-His, LLMSRec-Fixed, and LLMSRec-Nearest using one training user as demonstration outperform LLMRank-Seq on three datasets, except for LLMSRec-Fixed which performs slightly worse than LLMRank-Seq on LastFM-2K. This result suggests that ICL can enhance the LLM's ability to perform a complex task such as sequential recommendation.

Aggregated demonstration, combining multiple member users, allows LLM to effectively gather useful task specific information about the test user within a concise context. Compared to other ICL baselines (i.e., LLMRank-His, LLMSRec-Fixed, and LLMSRec-Nearest), LLMSRec-Syn achieves the superior one-shot performance across all datasets as shown in Table 2. While Figure 6 shows that having more demonstrations may hurt ICL for sequential recommendation, the idea of incorporating multiple demonstration users into an aggregated demonstration enhances the performance of LLMSRec-Syn. These results illustrate the advantage of aggregated demonstration in accommodating multiple training users within a limited prompt length.

LLMSRec-Syn is competitive against supervised methods when the amount of training data is limited. LLMSRec-Syn easily outperforms the simple supervised baseline, Most Popular. While it does not outperform GRU4Rec and SASRec on ML-1M and Games, LLMSRec-Syn surprisingly outperforms all supervised baselines on LastFM-2K. One possible reason is that LastFM-2K has sparse information about items after removing duplicate user-item interactions and users/items with less than 5 interactions, making it challenging to train a good supervised model.

LLMSRec-Syn using more powerful LLMs may outperform supervised methods in the future. With rapid advancement of LLM research, LLMSRec-Syn can be further enhanced when more powerful LLM is used. Our results in Table 2 shows that LLMSRec-Syn-4 significantly outperforms LLMSRec-Syn on all the 3 datasets.

5.3 Analysis of Aggregated Demonstrations

In this section, we study the recommendation performance when varying the settings of aggregated demonstrations. Analysis of ordering of users and label in the aggregated demonstration can be found in the Appendix 8.1.

Impact of number of users in the aggregated demonstration. We evaluate the impact of K (the number of member users) in the aggregated demonstration on LLMSRec-Syn's performance. We empirically vary K from 2 to 7. As shown in Figure 7, an approximate inverted U-shaped relationship exists between K and NDCG@10/20 performance. Initially, as K increases, there is a noticeable performance increase, suggesting that

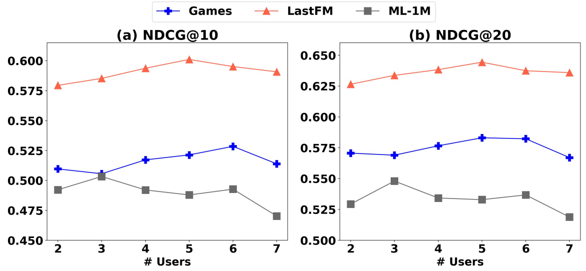

Figure 7: Varying number of users (K) in aggregated demonstration.

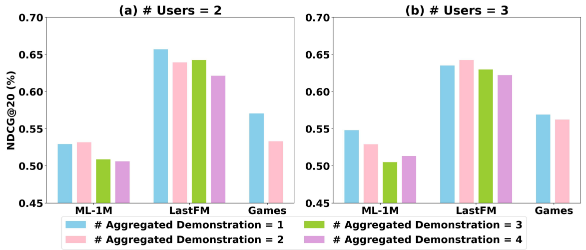

Figure 8: Varying number of aggregated demonstrations each with: (a) 2 member users, and (b) 3 member users.

LLMSRec-Syn benefits from aggregated demonstration. However, beyond some K value, more member users in aggregated demonstration leads to lower performance. This can be explained by more irrelevant training users being incorporated into the aggregated demonstration.

Impact of number of aggregated demonstrations. We evaluate the impact of the number of aggregated demonstrations to LLMSRec-Syn by varying the number of aggregated demonstrations from 1 to 4 such that each demonstration involves 2 users (see Figure 8(a)) and 3 users (see Figure 8(b)). For the Games dataset, experimentation with 3 aggregated demonstrations was not possible due to GPT-3.5-Turbo's input limit. The results show that a single aggregated demonstration outperforms multiple ones, except in the LastFM-2K dataset, where two demonstrations slightly excel.

6 Conclusion

This paper investigates in-context learning (ICL) for LLM-based sequential recommendation. Our study identifies key factors such as instruction format and demonstration selection that influence ICL's effectiveness. We further introduce the LLMSRec-Syn method which utilizes our proposed aggregated demonstration to efficiently incorporate relevant information from multiple training users. Tested on three datasets, LLMSRec-Syn consistently outperforms existing LLM-based sequential recommendation methods. Future work includes a detailed analysis of LLMSRec-Syn's unexpected success compared to some supervised methods and the optimization of aggregated demonstration strategies.

7 Limitations

While this paper considers several factors in applying LLMs to sequential recommendation and proposes a new demonstration concept known as aggregated demonstration, there are still some limitations yet to be addressed. Firstly, the wording of LLMSRec-Syn prompt is manually handcrafted and may not be optimal. This concern is also mentioned in works on prompt optimization (Yang et al., 2023; Deng et al., 2022; Pryzant et al., 2023). However, determining the optimal prompt wording typically requires feedback (such as validation set results (Yang et al., 2023)), carefully designed reward function (Deng et al., 2022), or textual feedback from large language models to iteratively update the initial prompt (Pryzant et al., 2023). Moreover, when a user's historical items are too many, LLMSRec-Syn may still suffer from the issue of long text. Furthermore, the aggregated demonstration method, while mitigating input length constraints, might oversimplify the user preferences, potentially resulting in less personalized recommendations. Moreover, the non-utilization of existing user datasets for pretraining or fine-tuning, due to LLM size constraints, limits the adaptability and fine-tuning of the model to specific recommendation contexts. These limitations highlight the need for further research in optimizing LLMs for complex, dynamic tasks such as sequential recommendation, where user context and historical data play crucial roles.

ML-1M	T1	T1 w/ Cand.	T2	T2 w/ Cand.	T3
NDCG@10	0.3640	0.3766	0.3776	0.3972	0.4584
NDCG@20	0.4193	0.4420	0.4384	0.4510	0.5077

8 Appendix

8.1 More In-Depth Analysis

Impact of user order in aggregated demonstrations. We experiment with 3 possible orders of member users: (i) Random (randomly selects historical items and next-items from the selected users to construct the aggregated demonstration), (ii) Right2Left (the reverse order of demonstration users in constructing an aggregated demonstration in LLMSRec-Syn in Section 4), and (iii) Left2Right (the user order used in the LLMSRec-Syn). Figure 9(a) illustrates that Left2Right and Right2Left are the most and least ideal orders respectively. The performance of Random is naturally sandwiched in between.

Impact of labeled next-items in the aggregated demonstration. According to Min et al. (2022), ground truth labels are not important for in-context learning. To investigate this claim for ICL-based sequential recommendation, we compare LLMSRec-Syn using ground truth next-items in the aggregated demonstration (referred to as "Gold Labels") with that using random non-ground truth next-items (referred to as "Random Labels"). Our results in Figure 9(b) clearly indicate that ground truth next-items are required to yield better performance contradicting the claim by Min et al. (2022). This could possibly be explained by the complexity of sequential recommendation task.

Further comparison of different tasks with candidates. As shown in Table 3, we observed that T1(T2) with candidate items in the prompt performs better than T1(T2). These results support the reviewer's comment that including more information in the prompt will enhance the performance. However, in this more fair comparison, T3 still outperforms T1 with candidate items in the prompt and T2 with candidate items in the prompt.

Table 4: Results of fine-tuned LLaMa2 with LoRA for in-context sequential recommendation. Regular means LLaMa2-LoRA-Regular. Aggregated means LLaMa2-LoRA-Aggregated.

ML-1M	Regular	Aggregated	LLMSRec-Syn
NDCG@10	0.3640	0.3766	0.3776
NDCG@20	0.4193	0.4420	0.4384

Could fine-tuned LLaMa2 improve the performance of in-context sequential recommendation? We initially used a training dataset of 150 data examples to train LLaMa2 with LoRA, which we referred to as LLaMa2-LoRA-Regular. For each training data example in this training dataset, the target output is the ranking of the candidate items for a training user. The input consists of a regular demonstration example, as well as historical items and candidate items from the training user. After training, we evaluated the performance of LLaMa2-LoRA-Regular using the same 50 test users as ChatGPT-based LLMSRec-Syn (0.5283 NDCG@10).

As shown in Table 4, the results showed that LLaMa2-LoRA-Regular achieved a NDCG@10 score of 0.2344. To investigate whether aggregated demonstration helps to train a better model compared to regular demonstrations, we prepared a training dataset using aggregated demonstrations instead of regular demonstrations. We trained LLaMa2 with LoRA using this dataset, which we call LLaMa2-LoRA-Aggregated. LLaMa2-LoRA-Aggregated achieved a NDCG@10 score of 0.3432 on the same test set. Although the initial study indicates that LLaMa-LoRA performs worse than ChatGPT, the fine-tuned LLaMa2-LoRA appears to have the potential to enable in-context learning-based sequential recommendation and aggregated demonstration can help to train a better model.

8.2 Case Study Examples

In this section, we provide comparative examples of one-shot LLMSRec-Syn (Table 5), one-shot LLMSRec-Nearest (Table 6), one-shot LLMSRec-

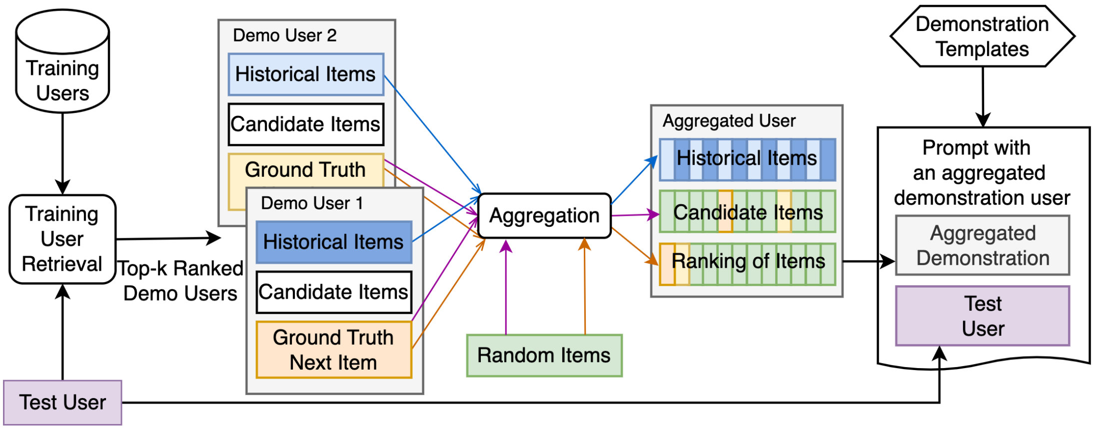

Figure 10: Construction of in-context learning prompt with aggregated demonstration for sequential recommendation.

Fixed (Table 7), and zero-shot LLMSRec (Table 8). Observations show that LLMSRec-Syn ranks the ground truth movie higher than the other methods. Compared to Nearest and Fixed demonstrations, the aggregated demonstration allows the LLM to better identify a user's interests and align the ranking with those interests. Without demonstration, zero-shot LLMSRec relies solely on the LLM's knowledge and performs poorly. This suggests that LLMs can learn from demonstrations to improve in areas where they might not originally be good at.

Table 5: Example of the one-shot LLMSRec-Syn on the ML-1M dataset. Ground truth recommendation is highlighted in Maroon.

Aggregated Demonstration Example:

The User’s Movie Profile:
- Watched Movies: [‘0. Caddyshack’, ‘1. Glory’, ‘2. A Bug’s Life’, ‘3. Star Trek VI: The Undiscovered Country’, ‘4. Indiana Jones and the Last Crusade’, ‘5. The Color of Money’, ‘6. Raging Bull’, ‘7. Edward Scissorhands’, ‘8. Kramer Vs. Kramer’, ‘9. Roger & Me’, ‘10. Romancing the Stone’, ‘11. Full Metal Jacket’, ‘12. The Shining’, ‘13. Easy Rider’, ‘14. Glory’, ‘15. The Color Purple’, ‘16. Die Hard’, ‘17. Who Framed Roger Rabbit?’, ‘18. Ghostbusters’, ‘19. The Right Stuff’, ‘20. No Way Out’, ‘21. The Breakfast Club’, ‘22. Dead Poets Society’, ‘23. One True Thing’, ‘24. Full Metal Jacket’, ‘25. U2: Rattle and Hum’, ‘26. Caddyshack’, ‘27. Jaws’, ‘28. Get Shorty’, ‘29. A Fish Called Wanda’, ‘30. Star Trek IV: The Voyage Home’, ‘31. Brazil’, ‘32. The Fugitive’, ‘33. Willy Wonka and the Chocolate Factory’, ‘34. Ghostbusters’, ‘35. The Blues Brothers’, ‘36. Stripes’, ‘37. Stand by Me’, ‘38. Pleasantville’, ‘39. Bull Durham’, ‘40. Risky Business’, ‘41. Indiana Jones and the Last Crusade’, ‘42. Star Wars: Episode VI - Return of the Jedi’, ‘43. Witness’, ‘44. Brazil’, ‘45. Predator’, ‘46. The Terminator’, ‘47. Grosse Pointe Blank’, ‘48. Contact’, ‘49. The Princess Bride’]

The User’s Potential Matches:
- Candidate Movies: [‘0. Excalibur’, ‘1. The Fox and the Hound’, ‘2. The Cable Guy’, ‘3. Cat on a Hot Tin Roof’, ‘4. Slingshot, The (Kådisbellan)’, ‘5. Institute Benjamenta, or This Dream People Call Human Life’, ‘6. Prefontaine’, ‘7. Star Wars: Episode IV - A New Hope’, ‘8. 8 Seconds’, ‘9. Two Family House’, ‘10. American Graffiti’, ‘11. Seven Days in May’, ‘12. The English Patient’, ‘13. Jurassic Park’, ‘14. Meet the Parents’, ‘15. Weekend at Bernie”s’, ‘16. Kurt & Courtney’, ‘17. Children of a Lesser God’, ‘18. The Haunting’, ‘19. Love and Basketball’]

Based on the user’s watched movies, please rank the candidate movies that align closely with the user’s preferences.
- You ONLY rank the given Candidate Movies.
- You DO NOT generate movies from Watched Movies.

Present your response in the format below:
1. [Top Recommendation (Candidate Movie)]
2. [2nd Recommendation (Candidate Movie)]

...
20. [20th Recommendation (Candidate Movie)]

Answer:
1. Children of a Lesser God
2. Excalibur
3. Jurassic Park
4. American Graffiti
5. Meet the Parents
6. The Haunting
7. Institute Benjamenta, or This Dream People Call Human Life
8. Cat on a Hot Tin Roof
9. Slingshot, The (Kådisbellan)
10. Prefontaine
11. The English Patient
12. Love and Basketball
13. The Fox and the Hound
14. The Cable Guy
15. Two Family House
16. Star Wars: Episode IV - A New Hope
17. Weekend at Bernie”s
18. Seven Days in May
19. 8 Seconds
20. Kurt & Courtney

BRING YOUR OWN KG:
Self-Supervised Program Synthesis for Zero-Shot KGQA

Dhruv Agarwal[1,*], **Rajarshi Das**[2,†], **Sopan Khosla**[2,†], **Rashmi Gangadharaiah**[2]

Abstract

We present BYOKG, a universal question-answering (QA) system that can operate on *any* knowledge graph (KG), requires no human-annotated training data, and can be ready to use within a day—attributes that are out-of-scope for current KGQA systems. BYOKG draws inspiration from the remarkable ability of humans to comprehend information present in an unseen KG through exploration—starting at random nodes, inspecting the labels of adjacent nodes and edges, and combining them with their prior world knowledge. Exploration in BYOKG leverages an LLM-backed symbolic agent that generates a diverse set of query-program exemplars, which are then used to ground a retrieval-augmented reasoning procedure to synthesize programs for arbitrary questions. BYOKG is effective over both small- and large-scale graphs, showing dramatic gains in zero-shot QA accuracy of 27.89 and 59.88 F1 on GrailQA and MetaQA, respectively. We further find that performance of BYOKG reliably improves with continued exploration as well as improvements in the base LLM, notably outperforming a state-of-the-art *fine-tuned* model by 7.08 F1 on a sub-sampled zero-shot split of GrailQA. Lastly, we verify our universality claim by evaluating BYOKG on a domain-specific materials science KG and show that it improves zero-shot performance by 46.33 F1.

1 Introduction

The ability to query structured data stores such as knowledge graphs (KGQA) via natural language is crucial for making the information within them accessible (Liang, 2016; Das, 2022). However, most prior works that aim to create such interfaces assume the availability of *some* training data (query-program pairs) (Talmor and Berant, 2018; Keysers et al., 2020; Gu et al., 2021; Dutt et al., 2023a; Sen et al., 2023), which, in practice, might be unrealistic. For example, in scientific domains such as materials science and clinical decision-making, training data may be completely unavailable due to high collection costs or stringent privacy regulations (Sima et al., 2022). Further, even when training data is available, models trained on one dataset may not generalize o.o.d. to other datasets of the *same* KG (Khosla et al., 2023).

In this work, we, therefore, set out to answer the following question—can we develop a universal QA system that is ready for use with *any* KG, within a reasonable amount of time (e.g., 24 hours), and without *any* training data? To achieve this, a model must efficiently and accurately learn to reason over a KG with no prior knowledge of the query distribution or the KG semantics.

BYOKG takes inspiration from the human tendency to be curious—seeking challenges and developing knowledge even in the absence of well-defined rewards (Oudeyer et al., 2016; Di Domenico and Ryan, 2017). Given a new KG, a human practitioner begins familiarizing themselves with the graph by inspecting random nodes and analyzing the various properties[1] found in the node neighborhoods. As this process continues (crucially, without a task-specific information need in mind), the practitioner develops an intuition for the set of questions that can be answered with the information present in the KG.

To mechanize this human tendency, BYOKG consists of an exploration module, which combines random walks over the KG nodes with a set of graph operations (e.g. `COUNT`, `ARGMAX`, `>=`, etc.) to produce programs of varying degrees of complexity (STAGE 1; fig. 1). Our explorer is symbolic in nature and has the goal of maximizing diversity within the generated programs, akin to curiosity-

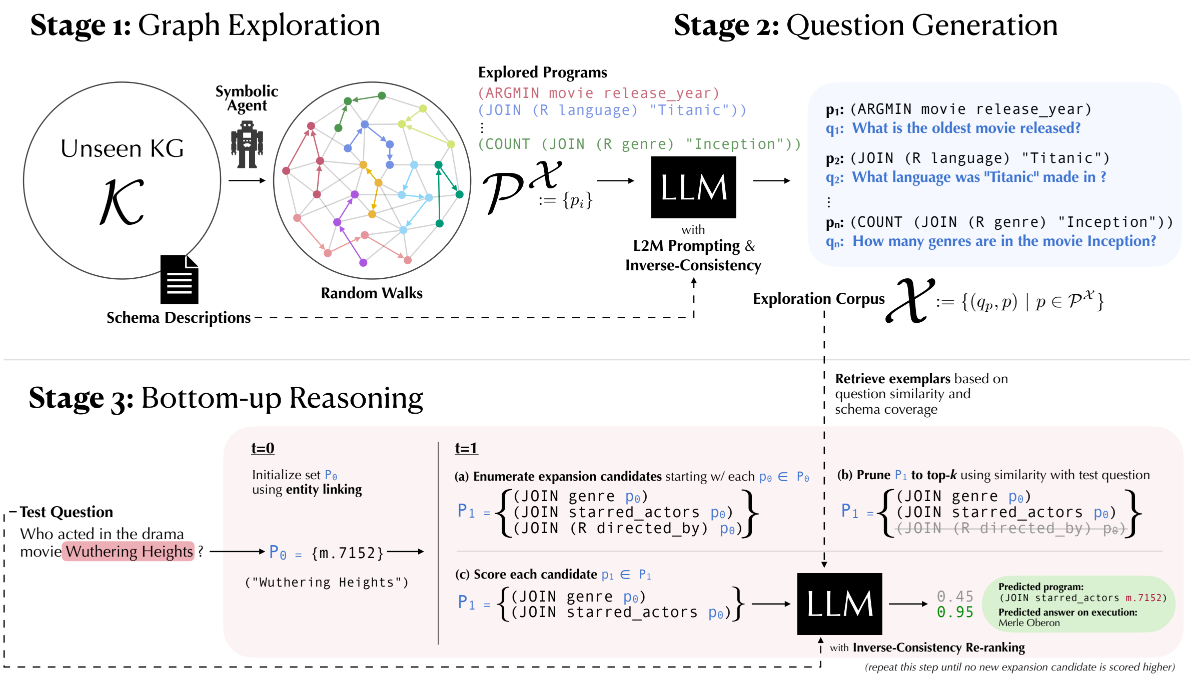

Figure 1: **Overview.** Given a new KG, a symbolic graph explorer generates diverse programs. Next, an LLM generates questions for the programs using descriptions of schema items, which are then stored in an exploration corpus. This process is done once for a KG. To answer a given question, BYOKG adopts a grounded reasoning approach that iteratively synthesizes the correct program using retrieved exemplars from the exploration corpus.

driven human learning (Ryan and Deci, 2000).

After sampling a diverse set of programs, BYOKG leverages the strong generalization ability of large language models (LLMs) (Brown et al., 2020; Wei et al., 2022; Touvron et al., 2023) to generate questions for each program (STAGE 2). However, we find that LLM outputs are often semantically inaccurate with respect to the program, particularly in the zero-shot setting. To improve LLM generation, we, thus, develop a novel inverse-consistency re-ranking method, which computes scores for generated queries based on the likelihood of the query *re-generating* the program. We also incorporate least-to-most (L2M) prompting (Zhou et al., 2023) to improve generation for multi-hop programs. Empirically, we find that both techniques greatly improve the accuracy of question generation and are essential in allowing us to operate within our unsupervised setting.

Finally, BYOKG uses the explored query-program pairs to perform reasoning in order to answer user queries (STAGE 3). With the motivation of designing a QA system that can work on any KG, we opt for a semi-parametric approach instead of KG-specific fine-tuning. In particular, we build upon Pangu (Gu et al., 2023), an LLM-based discriminative procedure that iteratively synthesizes the predicted program guided by retrieved exemplars from the training data. We introduce several modifications, including a pruning step, which dramatically reduces runtime (by 88%) as well as increases accuracy.

In summary, our contributions are as follows—**(a)** we introduce **BYOKG**, a method that allows practitioners to "bring their own KG" with *no* training data and have a natural language query interface ready within a day. **(b)** Inspired by intrinsic motivation, we develop an LLM-backed exploration module, which explores the KG to gather query-program exemplars. We demonstrate that ICL-based models that use our exploration perform competitively with models that use annotated training data. **(c)** We show that our proposed inverse-consistency re-ranking and L2M prompting greatly improve the quality of zero-shot generation. **(d)** We demonstrate that BYOKG is effective on both small- (MoviesKG; 10^5 edges) and large-scale KGs (Freebase; 3×10^9 edges). On GrailQA and MetaQA, BYOKG provides dramatic improvements of 27.89 and 59.88 F1, respectively, over a zero-shot baseline. **(e)** We show that BYOKG scales with model size and even *outperforms* a state-of-the-art fine-tuned model on zero-shot queries by 7.08 F1 on GrailQA using a larger LM (GPT-3.5). **(f)** Finally, we demonstrate that BYOKG is able to operate in arbitrary domains without training data, showing a strong 46.33 F1 gain using a materials science KG.

2 Task Definition

KGQA. A knowledge graph $\mathcal{K}$ is a set of triples, or facts, of the form $\mathcal{E} \times \mathcal{R} \times (\mathcal{E} \cup \mathcal{L} \cup \mathcal{C})$, where $\mathcal{E}$, $\mathcal{R}$, $\mathcal{L}$, and $\mathcal{C}$ denote entities, binary relations, literals, and classes (entity types), respectively. KGQA is then defined as the task of finding a set of answers $\mathcal{A}$ over graph $\mathcal{K}$ for a natural language question q. In program synthesis, the task is evaluated as mapping q to a program p_q (e.g. SPARQL or s-expression (Su et al., 2016)), which can deterministically be executed using a query engine to generate the answer set, i.e. $\texttt{eval}^{\mathcal{K}}(p_q) = \mathcal{A}_q$.

Unsupervised KGQA. We define *unsupervised* KGQA as a zero-shot setting where no query supervision over the target distribution is available[2]. Unsupervised KGQA jointly addresses multiple dimensions of generalization—linguistic variability (Khosla et al., 2023), query complexity (Keysers et al., 2020; Gu et al., 2021; Sen et al., 2023), domain transfer (Gu et al., 2021; Baek et al., 2023), and schema generalization (Das et al., 2021; Badenes-Olmedo and Corcho, 2023)—each of which has individually been shown to pose challenges to current QA systems.

3 Method

BYOKG consists of three stages—**graph exploration** (§3.1), **query generation** (§3.2), and **reasoning** (§3.3). First, our method explores the KG to enumerate a diverse set of executable programs. Next, each explored program is converted into a natural language question by prompting an LLM with schema descriptions of the relations and classes in the program. Finally, BYOKG leverages its acquired knowledge from exploration to ground a bottom-up inference procedure to iteratively generate the final program.

3.1 Symbolic Graph Exploration

The goal of graph exploration is to enumerate possible programs that may be queried at test time. However, exhaustive enumeration is often impractical with real-world KGs due to limited compute and time budgets. Instead, we construct a set of **explored programs** $\mathcal{P}^{\mathcal{X}}$ that provides approximate coverage of query patterns supported by the KG. BYOKG uses a symbolic, graph-based (Su et al., 2016) random walk procedure to enumerate a diverse set of executable programs.

Concretely, a symbolic agent begins exploration by initializing a sub-program p_0 at $t = 0$ with a class $c_0 \sim \mathcal{C}$. Next, the agent determines $S_{p_0} := \{s \mid s \in \mathcal{R} \cup \mathcal{C} : \texttt{reachable}(p_0, s)\}$, the set of schema items reachable from p_0. The agent then picks an item $s_0 \sim S_{p_0}$ to extend the sub-program into p_1. This process is repeated until the desired complexity of the program (i.e. relation count) is satisfied. The agent then, optionally, samples a program function $f \sim \mathcal{F}$ to apply over p_t, where $\mathcal{F}$ contains operators such as `COUNT`, comparatives, and superlatives. To encourage diversity, we discard p_t and repeat the process if $\mathcal{P}^{\mathcal{X}}$ already contains p_t[3]. Finally, we ground the classes appearing in p_t randomly by sampling from $\{e \mid e \in \mathcal{E} : \texttt{eval}^{\mathcal{K}}(p_t^e) \neq \emptyset\}$, the set of entities that lead to non-empty answer sets on program execution. The grounded p_t^e is then added to $\mathcal{P}^{\mathcal{X}}$.

3.2 Natural Language Query Generation

For each $p \in \mathcal{P}^{\mathcal{X}}$, we next generate a natural language question q_p to build an **exploration corpus** $\mathcal{X} := \{(q_p, p) \mid p \in \mathcal{P}^{\mathcal{X}}\}$ of query-program pairs. To generate questions, we prompt an LLM with instructions and textual descriptions of schema items relevant to each program (see A.3). Generating accurate output without in-context exemplars, however, is challenging. To elicit reliable zero-shot generation, we, therefore, utilize two techniques—(1) least-to-most prompting (Zhou et al., 2023), which generates outputs for complex programs in a step-by-step manner, and (2) a novel *inverse-consistency* method to re-rank LLM generations by scoring the inverse task of program generation.

3.2.1 Least-to-Most Prompting

Several prior works (Jung et al., 2022; Zhou et al., 2023; Drozdov et al., 2023) have tackled complex generative tasks by providing intermediate supervision via iteratively prompting the model with its own generations as additional context. Using these observations, we implement a least-to-most (L2M) prompting strategy that first decomposes p into simpler sub-programs $(p^1, p^2, \ldots, p^n)$ of increasing complexity using bottom-up parsing. We

---

[2] This is a stronger generalization requirement than prior work (Gu et al., 2021), where queries with even a single schema item unseen at training are considered zero-shot.

[3] We set the max. number of programs per pattern to 5.

then generate a question q_{p^i} for each sub-program, appending each (p^j, q_{p^j}) for $j < i$ as additional demonstrations in the prompt (see E.1).[4] In A.2, we show that L2M is crucial in unlocking deliberate, "System 2" reasoning (Kahneman, 2011) for complex queries in the zero-shot setting.

3.2.2 Inverse-Consistency Re-ranking

We observe that even when LLMs *can* produce the right answer within a top-k set of generations (e.g., from beam search), they do not always rank the correct answer as the top prediction, particularly with smaller models and in the unsupervised setting, rendering their use infeasible (see F.1). To tackle this, we introduce a re-ranking mechanism that scores output sequences from an LM using the likelihood of an *inverse* task, i.e. how likely the *input* sequence is given the output.

Concretely, consider a generative task $T := y \mid I, D, x$, where x is a sequence of query tokens, y is the target sequence of tokens to be predicted by a decoding algorithm, I is the textual instruction for the task, and D is the set of in-context demonstrations ($D = \emptyset$ in the unsupervised setting). The prediction y_{pred} for T is the top-ranked sequence from a list of candidates $\mathbf{y}_{\text{cands}}$ generated by the decoding algorithm measured using length-normalized log-probability scores, i.e. $y_{\text{pred}} := \arg\max_{y \in \mathbf{y}_{\text{cands}}} \log \Pr(y \mid I, D, x) \;/\; |y|$. To re-rank $\mathbf{y}_{\text{cands}}$, we now construct the following *inverse* task:

$$T^{-1} := x \mid I^{-1}, D^{-1}, y,$$

i.e. the task of predicting the query sequence x given an output sequence y from T, along with a new instruction I^{-1} for the inverse task and, optionally, an inverted demonstration set D^{-1}. For e.g., for the task of query generation, the inverse task is program synthesis. The new prediction is then given by

$$y_{\text{pred}} := \arg\max_{y \in \mathbf{y}_{\text{cands}}} \log \Pr(x \mid I^{-1}, D^{-1}, y) \;/\; |x|.$$

Scoring T^{-1} for a single y requires only one forward pass to get the next-token logit distribution at each position, allowing efficient computation of the log-probability score of the fixed-sequence x given y. Scores over the entire set $\mathbf{y}_{\text{cands}}$ can simply be computed using a batched forward pass. Inverse-consistency indeed improves generation accuracy (A.1) and enables BYOKG to use smaller models to scale exploration. We also note the close relation with PMI-scoring (Holtzman et al., 2021), but observe differing behavior in practice (see A.6).

3.3 Bottom-up Reasoning

With a corpus of query-program pairs in place, we now require a method to synthesize programs given natural language queries at test time. To use a single model with *any* KG, a key desiderata is to avoid KG-specific parameter tuning (Khosla et al., 2023). We, therefore, use an ICL approach using demonstrations from the exploration corpus within an enumerate-and-rank procedure. We adapt the method in Gu et al. (2023) with modifications that provide speed and accuracy gains to allow BYOKG to operate well in the unsupervised setting.

Concretely, given a test question q_{test}, BYOKG first instantiates a set of candidate sub-programs P_0 at $t = 0$ with all the topic entities, classes, and literals found in the question, extracted using off-the-shelf linkers (Li et al., 2020; Agarwal et al., 2022). In each subsequent timestep t, the reasoner determines which sub-programs from the previous step should further be extended. To do this, we use an LLM to compute[5] the likelihood of each sub-program being the parse for q_{test} conditioned on retrieved demonstrations D_{test} from exploration, and retain the top-k candidates

$$P_{t-1} := \operatorname*{arg\,topk}_{p^i_{t-1} \in P_{t-1}} \texttt{LLM}(p^i_{t-1}, q_{\text{test}}, D_{\text{test}}).$$

We additionally define

$$P_{\text{best}} := \operatorname*{arg\,topk}_{p \in P_{\text{best}} \cup P_{t-1}} \texttt{LLM}(p, q_{\text{test}}, D_{\text{test}})$$

as the best set of candidates across timesteps. After scoring, the reasoner extends each $p^i_{t-1} \in P_{t-1}$ using an extensible set of program expansion heuristics (Gu and Su, 2022) to construct the candidate set for the next timestep,

$$P_t := \left\{ \texttt{extend}(p^i_{t-1}, S_{p^i_{t-1}}, P_{\text{best}}) \;\middle|\; p^i_{t-1} \in P_{t-1} \right\},$$

where $S_{p^i_{t-1}}$ is the set of schema items reachable from p^i_{t-1} and P_{best} is the set of best-k candidates so far. The process terminates

---

[4] Query decomposition with s-expressions is straightforward—starting from the inner-most clause, the next sub-program is generated by simply including all the terms within the next parenthetic level.

[5] LLM scoring tends to prefer candidates with repeated relations. We, thus, penalize the final score based on the count of repeated relations. We do not add this penalty on MoviesKG due to the formulaic nature of the evaluation set.

when no new sub-program is added to P_{best}, at which point we output the prediction $p_{\text{pred}} := \arg\max_{p \in P_{\text{best}}} \texttt{LLM}(p, q_{\text{test}}, D_{\text{test}})$.

ICL from exploration. To make predictions using an LLM, BYOKG takes a few-shot prompting approach to score candidate sub-programs conditioned on reasoning patterns for similar questions seen during exploration. A typical approach is to retrieve the k-most similar exemplars from $\mathcal{X}$ using the cosine similarity of exploration queries with the test query as measured using a sentence embedding model (Reimers and Gurevych, 2019). Following prior work (Thai et al., 2023), we additionally anonymize topic entities mentioned within questions to retrieve similar program *patterns* instead of similar topic entities. For instance, the question *"How many trophies has Manchester United won?"* would be anonymized to *"How many trophies has sports.team won?"*.

Candidate pruning. Scoring candidates can entail arbitrary latency depending on the number of candidates to score, making reasoning impractically slow when the candidate set P_t to be scored is very large (Table 10). We, therefore, introduce a candidate pruning step that restricts the size of the candidate set to at most 10 at each step of reasoning based on the similarity of anonymized candidate programs with the anonymized natural language test question using the sentence embedding model from retrieval. To keep our setup KG-agnostic, we do not fine-tune this model. As shown in A.4, we find that not only does pruning improve efficiency, but it also results in more accurate reasoning.

Inverse-consistency for candidate re-ranking. When schema items are *completely* unseen during exploration, we find that LLM scoring erroneously assigns high scores to irrelevant candidates that may resemble the retrieved exemplars (see F.2).

To address this problem, we re-use inverse-consistency (§3.2.2) to *re-rank* the final candidate set P_{best}. Concretely, we construct the inverse task, denoted by $\texttt{LLM}^{-1}(\cdot, \cdot)$, to be one of zero-shot question generation. To make predictions, we use a weighted combination of the original and inverse scores using weight α[6], resulting in

$$\texttt{rerank}(p, q, D) := \alpha \texttt{LLM}(p, q, D) \ + \backslash \\ (1-\alpha)\texttt{LLM}^{-1}(p, q),$$

which leads to the final prediction

$$p_{\text{pred}} := \arg\max_{p \in P_{\text{best}}} \texttt{rerank}(p, q_{\text{test}}, D_{\text{test}}).$$

4 Experiments

4.1 Graphs and Datasets

For our larger-scale experiments, we use **Freebase** (Bollacker et al., 2008) and evaluate QA performance on the **GrailQA** (Gu et al., 2021) dataset. For smaller, domain-specific evaluation, we use **MoviesKG** (Miller et al., 2016) and the **MetaQA** (Zhang et al., 2018) dataset. Note that in the unsupervised setting, all datasets are o.o.d..[7]

4.2 Evaluation Metrics

Our primary metric is the **F1-score** between the predicted and reference answer sets. Several prior works (on MetaQA), however, only provide ranked entities. To compare, we report **Hits@1**, assigning rank 1 to each answer in our prediction set.

4.3 Models

We use **MPT-Instruct** (MosaicML-NLP-Team, 2023) (7B) for our main experiments. To demonstrate the scaling behavior of BYOKG, we additionally use **MPT-30B** as well as **GPT-3.5** (Brown et al., 2020) with the *text-davinci-003* variant[8].

4.4 Experimental Settings

4.4.1 Unsupervised

Our main experimental setting evaluates models with no access to *any* query supervision.

Zero-shot represents our bottom-up reasoning procedure from §3.3 but without any in-context demonstrations to score sub-programs at each step.

ICL + Exploration represents our proposed BYOKG method. In this setting, in-context demonstrations are retrieved from the exploration corpus $\mathcal{X}$, which we limit to 10K programs based on our time and compute budget. We also include in this setting results with Pangu-ICL (Gu et al., 2023), the few-shot variant of a KGQA method closely related to the bottom-up reasoning procedure of BYOKG.

---

[6] We do not tune α, in keeping with our setting of not assuming a dev set, and set its value to 0.5 in all experiments.

[7] See Appendix C.1 for details on the datasets and KGs.

[8] Of the available variants, only *text-davinci*, *text-curie*, and *text-babbage* are compatible with BYOKG since we require access to log-probabilities to score sequences.

	Method	Model	Overall	I.I.D.	Compositional	Zero-shot
Supervised (w/ train set)	Pangu-FT (SOTA)	T5-3B	**81.7**	**88.8**	**81.5**	**78.5**
	Pangu-ICL + $\mathcal{T}_{1k}$	Codex	65.0	73.7	64.9	61.1
	Pangu-ICL† + $\mathcal{T}_{10k}$	MPT-7B	44.67	58.15	40.90	40.15
	BYOKG + $\mathcal{T}_{10k}$	MPT-7B	46.61	58.29	45.14	41.89
Unsupervised	Zero-shot	MPT-7B	18.58	19.13	16.34	19.33
	Pangu-ICL† + $\mathcal{X}$	MPT-7B	42.44 (Δ+23.86)	45.08	38.79	42.85
	BYOKG + $\mathcal{X}$ (OURS)	MPT-7B	**46.47** (Δ+27.89)	**48.91**	**43.22**	**46.80**

Table 1: **KGQA Results on GrailQA.** F1-scores for BYOKG in the unsupervised setting on the GrailQA test set compared to a zero-shot baseline and Pangu. For reference, we also report performance with models that use training data—ICL with randomly sampled training exemplars ($\mathcal{T}_{1k}$ and $\mathcal{T}_{10k}$) as well as a state-of-the-art fine-tuned model. We find that BYOKG + $\mathcal{X}$ improves zero-shot performance by 2.5x (nearly matching the performance of its supervised counterpart). BYOKG also demonstrates stable performance across generalization splits ($\sigma = 2.35$), whereas supervised methods ($\sigma = 7.09$) show drops in performance on the compositional and zero-shot splits. († indicates our re-implementaton)

Model	Overall	I.I.D.	Comp.	Z-shot
Pangu-FT	**81.68**	**92.81**	**79.97**	73.91
Pangu-Codex	65.0	73.7	64.9	61.1
BYOKG + $\mathcal{X}$ (OURS)				
MPT-7B	66.79	70.40	61.35	69.08
MPT-30B	69.58 (Δ+2.79)	73.10	65.14	70.95
GPT-3.5	75.16 (Δ+8.37)	73.89	70.33	**80.99**

Table 2: **BYOKG Accuracy v/s Model Scale.** F1-scores for BYOKG + $\mathcal{X}$ using 300 randomly sampled questions from the GrailQA dev set. (a) BYOKG shows gains in accuracy with improvements in the underlying LLM. (b) BYOKG with GPT-3.5 shows stable performance across generalization splits (unlike Pangu with training data). (c) BYOKG *outperforms* Pangu-FT on the zero-shot split by 7.08 points. (**Note:* Pangu-Codex test set results are included only to provide an estimate of ICL performance with a similar model.)

4.4.2 Supervised

To situate our evaluations in the unsupervised setting, we also include a comparison with methods that have access to curated training data.

ICL + Train Set is the setting where both BYOKG and Pangu retrieve demonstrations from a randomly sampled subset of 10K training exemplars $\mathcal{T}_{10k}$. On GrailQA, we also report published Pangu-ICL (1000-shot) results with OpenAI Codex (Chen et al., 2021)[9].

Fine-tuned includes Pangu-FT, a fine-tuned T5-3B (Raffel et al., 2020) variant of Pangu trained using the full train set of 44K exemplars on GrailQA, and is currently the state-of-the-art (without ensembling). On MetaQA, we include NSM-FT (He et al., 2021), a fine-tuned method trained using teacher-student networks over 329K training exemplars. Although these models comprise dataset-specific parameters, we include them to provide an estimate of an upper-bound[10].

5 Results

Exploration leads to substantial gains in the unsupervised setting. On both GrailQA with the Freebase KG (Table 1) and MetaQA with the MoviesKG (Table 3), we find that unsupervised exploration leads to dramatic gains over the zero-shot baseline. Specifically, our proposed BYOKG + $\mathcal{X}$ results in large 27.89 F1 (2.5x) and 59.88 F1 (4.9x) improvements on GrailQA and MetaQA, respectively.

BYOKG exhibits better compositional generalization than Pangu. On GrailQA, BYOKG outperforms Pangu by 4.03 F1 (Table 1) and on MetaQA by a large 20.63 F1 (Table 3) when evaluated with our exploration corpus. Note that exploration provides only partial coverage over evaluation queries (as shown in Table 6). Therefore, models must compositionally assemble sub-expressions from relevant exemplars to make predictions. For instance, on MetaQA, we find that training data provides perfect test pattern coverage, which translates to similar performance with both BYOKG and Pangu. With the exploration corpus, however, coverage of test patterns drops to nearly 70%, resulting in a large 30.93 point drop using Pangu and only 6.79 with BYOKG, highlighting the strong compositional generalizability of our method.

---

[9] LLM for instruction-following on code (now deprecated).

[10] No strict bound exists for unsupervised performance to be lower than supervised. See Fig. 2 for scaling trends.

		Overall		1-hop		2-hop		3-hop	
	Method	**F1**	**Hits@1**	**F1**	**Hits@1**	**F1**	**Hits@1**	**F1**	**Hits@1**
Supervised (w/ train set)	NSM-FT (SOTA)	-	**98.82**	-	97.1	-	**99.9**	-	**98.9**
	Pangu-ICL† + $\mathcal{T}_{10k}$	**85.61**	92.38	97.88	**98.80**	**93.43**	94.21	**69.82**	86.01
	BYOKG + $\mathcal{T}_{10k}$	82.10	87.31	**97.95**	98.27	90.24	90.76	62.57	76.08
Unsupervised	Zero-shot	15.43	25.11	34.07	41.67	8.10	11.42	10.09	27.84
	Pangu-ICL† + $\mathcal{X}$	54.68 (Δ+39.25)	64.87	59.32	63.40	62.67	66.74	44.60	63.96
	BYOKG + $\mathcal{X}$ (OURS)	**75.31** (Δ+59.88)	**83.01**	**94.83**	**95.25**	**80.28**	**81.85**	**56.54**	**75.69**

Table 3: **KGQA Results on MetaQA.** F1-scores for BYOKG in the unsupervised setting on the MetaQA test set compared to a zero-shot baseline and Pangu. For reference, we also report supervised ICL baselines with 10K randomly sampled training examples ($\mathcal{T}_{10k}$) and NSM, a state-of-the-art fine-tuned LSTM. Exploration ($\mathcal{X}$) improves zero-shot F1 performance by 3.5x using Pangu and 4.9x using BYOKG. Further, BYOKG + $\mathcal{X}$ closes the gap with the best-performing supervised baseline to within only 10.3 F1. († indicates our re-implementaton; all ICL methods are evaluated using MPT-7B.)

BYOKG with exploration is competitive with supervised ICL. We observe that BYOKG + $\mathcal{X}$ is able to nearly match BYOKG + $\mathcal{T}_{10k}$ (row 4 and 7 in Table 1) on GrailQA. Notably, we find that unsupervised BYOKG is, in fact, able to *outperform* supervised Pangu when the underlying base model is held constant (MPT-7B). On MetaQA, the gap between BYOKG + $\mathcal{X}$ and supervised ICL is a larger 6.79 F1, which can be explained by the formulaic nature of questions in MetaQA, resulting in all patterns being covered by the training set (see Table 6). Overall, our results demonstrate that exploration is a viable means to provide unsupervised grounding for reasoning.

BYOKG with exploration leads to more consistent performance across generalization splits versus supervised methods. In Table 1, we find that BYOKG + $\mathcal{X}$ demonstrates low variance (2.35 versus 7.09 standard deviation using $\mathcal{X}$ and $\mathcal{T}_{10k}$, respectively) in performance across generalization splits while methods using training data show fluctuations (drops) in performance on both compositional and zero-shot splits. We argue that the unsupervised nature of exploration allows BYOKG to discover reasoning patterns without additional bias introduced by a training distribution, thus allowing it to generalize well.

BYOKG improves with model scale. To evaluate potential gains with BYOKG by improving the underlying LLM, we compare KGQA performance using MPT-7B versus MPT-30B and GPT-3.5, a state-of-the-art instruction-tuned LLM from OpenAI. Due to a limited budget of $100, we sample a small set of 300 questions from the GrailQA dev set and evaluate BYOKG + $\mathcal{X}$. Table 2 shows that improving the base model indeed leads to consistent gains in KGQA performance, with MPT-30B and GPT-3.5 showing improvements of 2.79 and 8.37 F1, respectively. BYOKG + GPT-3.5 additionally demonstrates more consistent performance across generalization splits as compared to Pangu-FT (state-of-the-art) and, notably, *outperforms* it on zero-shot queries by 7.08 F1.

Method	**Overall**	**I.I.D.**	**Zero-shot**
Zero-shot	15.92	13.75	22.42
BYOKG + $\mathcal{X}$	**62.25** (Δ+46.33)	**63.85**	**57.44**

Table 4: **KGQA Results on MatKG.** F1-scores for BYOKG with 9,445 explored programs on a test set of 100 questions (75/25 i.i.d./zero-shot) compared to a zero-shot baseline using MPT-7B.

Case Study: Materials Science KG. We, next, evaluate the ability of BYOKG to work in arbitrary, specialized domains by creating a natural language interface for an unseen KG from materials science using **MatKG** (Venugopal et al., 2022)[11]. Since the graph is not accompanied by a set of natural language questions, we randomly sample 100 programs up to 3-hops with unique query patterns and manually annotate them to construct a test set (see B). As shown in Table 4, BYOKG + $\mathcal{X}$ (with $|\mathcal{X}| \approx$ 10K) results in a large 46.33 F1 gain over zero-shot reasoning that uses no exploration.

---

[11] To the best of our knowledge, this KG is not part of the pre-training corpus for the MPT family of models. See `https://www.mosaicml.com/blog/mpt-7b#building-with-mosaicml-platform`.

6 Analyses

In this section, we present detailed analyses of BYOKG. We first study the efficacy of graph exploration and its effect on downstream QA performance. We then conduct several ablations to validate the design choices made in BYOKG—inverse-consistency and L2M for question generation, inverse-consistency during reasoning, prompting with KG schema descriptions, as well as candidate pruning.

6.1 KG and Query Coverage with Exploration

Exploration statistics. Table 5 shows the results of unsupervised KG exploration on Freebase (Commons) as well as MoviesKG, including the distribution of programs of different complexity as well as the wall-clock time taken for the procedure. While program generation is inexpensive, the cost of question generation restricts the number of programs we can explore. We stop at 10K to meet our stated goal of readying a QA system within a day.

(budget of 10k programs)	**Freebase**	**MoviesKG**
Programs	10,000	10,000
1-hop	6,933	222
2-hop	2,589	1,779
3-hop	426	4,290
4-hop	52	3,709
Relations	4,178	18
Classes	1,681	7
Patterns	7,193	3,658
Sub-expressions	7,741	71
Time		
Exploration (mins)	46.5	24.4
Query Generation (hours)	10.4	24.0

Table 5: **Exploration Statistics** on Freebase and MoviesKG for a budget of 10K programs (capped at 5 programs per query pattern) using 3 Amazon EC2 p3dn.24xlarge machines. (*Note:* relation counts listed also include reverse relations.)

Distribution coverage. To effectively ground reasoning in BYOKG, exploration must be able to provide sufficient coverage over the queries being evaluated. We analyze how well our random exploration strategy with a budget of 10K performs compared to a curated training set in providing coverage over the evaluation distribution. Table 6 shows our results for coverage over relations, classes, program patterns, and sub-expressions (e.g. "`(COUNT #var)`", "`(ARGMIN type.datetime #var)`") found in the gold logical programs from the dev sets of GrailQA and MetaQA.

	GrailQA		**MetaQA**	
(in dev set)	$\mathcal{T}$	$\mathcal{X}$	$\mathcal{T}$	$\mathcal{X}$
Relations	82.49	76.89	100.00	100.00
Classes	85.43	91.56	100.00	100.00
Patterns	70.93	13.94	100.00	69.39
Sub-expressions	79.24	49.43	100.00	100.00

Table 6: **Distribution Coverage with Exploration** ($\mathcal{X}$) versus the full training data ($\mathcal{T}$) for queries in the development sets. On MetaQA, $\mathcal{X}$ provides high coverage (though nearly 30 points below $\mathcal{T}$ on query pattern coverage) due to the small size of MoviesKG. On GrailQA, with the larger Freebase KG, $\mathcal{X}$ shows a huge 56.99 points drop in query pattern coverage as well as a 29.81 drop for sub-expressions, leading to several queries being zero-shot versus when using the training data.

On MetaQA, we find that while exploration *can* find all schema items and sub-expressions, it misses nearly 30% of program patterns in the test distribution while the training set has perfect coverage. On GrailQA, both sub-expression and pattern coverage are much lower than training, with $\mathcal{X}$ observing 5x fewer test patterns and 1.6x fewer test sub-expressions than the training data. These gaps explain the difference in performance between supervised methods and BYOKG + $\mathcal{X}$, which is completely zero-shot (Table 1 and Table 3). This gap also highlights a future direction for improving BYOKG by incorporating more guidance into exploration that goes beyond diversity alone.

6.2 QA Accuracy v/s Exploration Budget

As shown in Table 6, real-world KGs, such as Freebase, are intractable to exhaustively explore resulting in only approximate coverage. Here, we evaluate the budget-accuracy trade-off of BYOKG, i.e. how the *amount* of exploration affects downstream QA performance. For this analysis, we randomly sub-sample multiple sets $\mathcal{X}_k$ of varying sizes k from $\mathcal{X}$, which we then use to answer questions over a sub-sampled set of 3,000 questions (1k from each split) from the GrailQA dev set. In Fig 2, we plot F1-scores for BYOKG + $\mathcal{X}_k$. BYOKG shows steady improvements with more exploration, notably showing a positive slope even at 44K programs (our maximum due to budget constraints).

Inverse-consistency. Additionally, Fig. 2 shows that re-ranking improves performance at all budget levels. Notably, re-ranking recovers (and exceeds) the performance of standard predictions at the max-

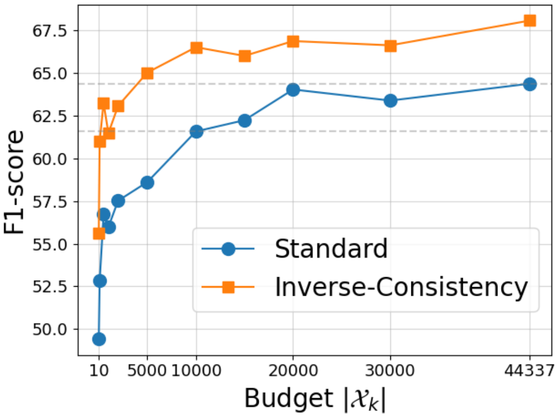

Figure 2: **Accuracy v/s Exploration Budget.** F1-scores with ByoKG + $\mathcal{X}_k$ using MPT-7B. ByoKG shows consistent gains with increasing exploration budget, notably showing a positive slope even at the maximum budget, indicating room for further improvement. Further, inverse-consistency candidate re-ranking improves performance at all budget levels and outperforms standard predictions at $\mathcal{X}_k = 10$K with only 500 programs (20x reduction) and $\mathcal{X}_k = 44$K with only 5K programs (9x reduction).

imum budget with only a small set of 500 programs, i.e. a 20x reduction in exploration cost, which translates to a wall-clock setup time of only 1.6 hours (versus 1.3 *days* for 10K programs). Additionally, performance at the maximum budget of 44K programs can be matched using only 5K programs with inverse-consistency (9x reduction).

6.3 Ablations

(a) In Appendix A.1 and Appendix A.2, we verify the efficacy of inverse-consistency re-ranking and L2M for question generation. On human evaluations, we find that inverse-consistency provides a large 22.5 point gain in semantic accuracy and L2M results in a gain of 17.5 points. Additionally, we include an ablation in Appendix A.5 to show that inverse-consistency also improves reasoning accuracy (Δ+4.94 and Δ+0.83 F1 on GrailQA and MetaQA, respectively). **(b)** In Appendix A.3, we provide an ablation to verify the beneficial effect of providing natural language schema descriptions to the LLM for question generation. **(c)** Finally, in Appendix A.4, we analyze the effect of candidate pruning during reasoning and find that our most aggressive setting ($k = 10$) not only reduces inference cost/query to 13s (8x $\downarrow$ v/s no pruning) but also results in greater accuracy (Δ+2.5 F1).

7 Related Work

KGQA Generalization. KGQA beyond i.i.d. samples has seen progress both in terms of new benchmarks (Gu et al., 2021; Dutt et al., 2023b) as well as methods (Yu et al., 2023; Shu et al., 2022a; Ye et al., 2022; Gu and Su, 2022). Recently, works have also investigated generalization to unseen KGs (Dutt et al., 2022; Gao et al., 2023). However, these methods all assume access to *some* curated training data, which is completely unavailable in our unsupervised setting. We also highlight Bio-SODA (Sima et al., 2021), which shares our unsupervised setting. Their approach uses string similarity to match query tokens with KG schema items, rank them using a PageRank-based importance measure, construct a query graph using Steiner trees, and finally convert the graphs into SPARQL queries. However, this method is unable to handle complex queries — aggregations, superlatives, comparatives, conjunctions, amongst others. In concurrent work, Li et al. (2023b) propose a method to train KGQA models from synthetic data using LLMs. Unlike ByoKG, however, their work utilizes unlabeled queries from the train set as weak supervision and is, thus, not fully unsupervised. Beyond structured queries, our work is also related to PAQ (Lewis et al., 2021), which over-generates questions over Wikipedia but, crucially, returns only a cached response at test time instead of reasoning as in ByoKG.

KGQA with ICL. Many recent works have attempted to unify LLMs and knowledge graphs (Tian et al., 2023; Tan et al., 2023; Li et al., 2023a). However, most prior works require a training corpus to retrieve in-context demonstrations, which is unavailable in our setting. A prior work that does operate in a completely zero-shot setting is Baek et al. (2023), where triples are retrieved from the KG to generate the final answer. However, this method does not provide the answer text alone due to a generative strategy[12] making it largely incomparable with ByoKG.

Grounded Multi-Step Reasoning. Bottom-up parsing iteratively builds a solution for complex problems in several prior works in semantic parsing (Rubin and Berant, 2021; Gu and Su, 2022; Ye et al., 2022; Gu et al., 2023). ByoKG fur-

---

[12] They use a "generative accuracy" metric, which considers a prediction correct if the tokens of an answer entity are found anywhere within the generated text.

ther grounds each step of bottom-up parsing to the KG using a case-based reasoning (CBR) approach, which has widely been applied in various tasks, such as link prediction (Das et al., 2022), semantic parsing (Das et al., 2021; Awasthi et al., 2023), and reading comprehension (Thai et al., 2023). [13]

8 Conclusion

We introduce **Byokg**—a universal KGQA system to work with *any* target KG and without *any* human-annotated training data. BYOKG mimics curiosity-driven learning in humans by first exploring the unseen KG, followed by using the acquired knowledge to answer questions. Our method combines LLMs with graph traversal to explore the KG and then reason over the explored paths to answer arbitrary user queries over the graph. We further introduce techniques to improve zero-shot performance with LLMs, including an inverse-consistency reranking method. On two popular datasets and KGs, we demonstrate the efficacy of BYOKG and present detailed analyses of the several design choices.

Acknowledgements

We thank Sandesh Swamy, Vinayshekhar Bannihatti Kumar, Sailik Sengupta, Sam Davidson, Bryan Li, and other members of AWS AI Labs for their helpful comments and suggestions throughout the project. We thank Nishant Yadav, Andrew Drozdov, Andrew McCallum, and other members of IESL for helpful discussions and advice. We thank Vineeth Venugopal and Elsa Olivetti (MIT) for useful feedback on using MatKG. Lastly, we are also grateful to Yu Gu and Yu Su for providing excellent documentation and support for their KGQA research.

Limitations

Hallucinations. Despite efforts to provide grounded LLM generations, BYOKG is susceptible to hallucinations at times. For instance, during question generation, models may generate semantically inaccurate queries for their corresponding programs. While we do observe robustness to noise during exploration, inaccuracies at scale may be crippling to retrieval-augmented reasoning, which is reliant on coherent exemplars for candidate scoring. Future directions may explore using models pre-trained for KGQA or even KG-specific parameter tuning to mitigate these behaviors.

Latency. While we reduce latency by 8x compared to a naive implementation by introducing candidate pruning, our iterative "System 2" reasoning may not satisfy stringent response time requirements, which are better served by single-shot inference. Caching does address this limitation to an extent, but future work may explore how programs can be synthesized more efficiently for complex, multi-hop queries.

Zero annotations. The primary goal of BYOKG is to provide a query interface without any human intervention. However, as a prerequisite, we assume the availability of a schema enumerating the classes and relations present in the KG along with their natural language descriptions. Our assumption is based on the common availability of such a file accompanying most real-world KGs. In the absence of this data, BYOKG, thus, currently requires human annotations. Further leaning on the broad-spectrum generalization abilities of LLMs, future work may explore automatically generating such schema descriptions.

Broader Impact

Our method has the potential to improve information access in several domains that contain structured information but lack the human expertise or resources to construct complex query interfaces, improving the availability of information in previously opaque settings.

However, we caution that non-deterministic systems, such as those using LLMs, should be deployed in real-world settings with utmost care and proper human oversight. In particular, it may not always be apparent as to the nature of the data that LLMs are pre-trained on, which has the potential of perpetuating factual inaccuracies and biases prevalent in corpora collected from the internet. Indeed, BYOKG is also not immune to these pathologies and future research should study methods to detect and prevent such behaviors.

Appendices

We provide several supplementary details of our work and organize them as follows:

- Appendix A: **Analyses and Ablations**
- Appendix B: **MatKG Dataset**
- Appendix C: **Implementation Details**
- Appendix D: **Related Work**
- Appendix E: **Language Model Prompts**
- Appendix F: **Qualitative Examples**

A Appendix: Analyses and Ablations

In this section, we present a detailed analysis of the design choices made in BYOKG and how they affect downstream QA performance.

A.1 Inverse-Consistency for Question Generation

We evaluate the effect of inverse-consistency re-ranking on the quality of question generation. Table 7 shows a comparison between the top-1 generation from a standard beam-search procedure versus the inverse-consistency re-ranked output on 3,000 randomly sampled questions from the GrailQA dev set. We use three automatic generation metrics – ROUGE-1 (Lin, 2004), BLEU (Papineni et al., 2002), and BERTscore (Zhang* et al., 2020) – computed with respect to the human-annotated gold references in the dataset. Our results show that inverse-consistency indeed improves generation quality, as measured on all metrics. We further inspect 40 randomly sampled questions for semantic accuracy using both methods, and find inverse-consistency generates accurate output for 70% of questions, 22.5 points more than standard beam-search.

Metrics	**Standard**	**Inverse-Consistency**
ROUGE-1	48.17	**52.81** (Δ+4.64)
BLEU	31.54	**38.63** (Δ+7.09)
BERTscore	87.17	**88.33** (Δ+1.16)
Human Evaluation	47.50	**70.00** (Δ+22.50)

Table 7: **Inverse-Consistency for Question Generation.** Generation quality with inverse-consistency re-ranking compared with standard top-1 predictions from beam search using MPT-7B. Inverse-consistency improves generation quality as measured on both automatic and human evaluation metrics.

Model	**Standard**	**Least-to-Most**
MPT-7B	55.0	70.0
MPT-30B	60.0	80.0
Mean	57.5	**75.0** (Δ+17.5)

Table 8: **L2M Question Generation.** Human-evaluated semantic accuracy of question generation using L2M prompting versus standard single-shot generation over a random sample of 40 questions from the GrailQA dev set. L2M prompting improves accuracy of generated questions by a significant 17.5 points.

A.2 L2M for Question Generation

Here, we analyze the effect of L2M-prompting for question generation compared with standard, single-shot prompting. To conduct this analysis, we annotate a set of 40 questions and verify the semantic accuracy of the generated questions with respect to the corresponding logical programs. Table 8 shows our results, where we find that L2M prompting provides an 18.7 point improvement over standard decoding.

A.3 Schema Supervision for Question Generation

	Standard	**Schema**
ROUGE-1	51.40	**52.81** (Δ+1.41)
BLEU	35.99	**38.63** (Δ+2.64)
BERTscore	87.59	**88.33** (Δ+0.74)

Table 9: **Schema Supervision for Question Generation.** Generation quality with schema descriptions injected into the prompt compared with standard prediction with only the query using MPT-7B over 3,000 randomly sampled questions from the GrailQA dev set.

We evaluate the effect of providing natural language schema descriptions to the LLM during question generation. As shown in Table 9, we find that schema supervision improves generation quality as measured by each automatic metric.

A.4 Candidate Pruning for Reasoning

As noted in §3.3, we introduce candidate pruning in BYOKG in order to bound the latency at each reasoning step. This is in contrast to Pangu, which incurs high latency due to scoring every enumerated candidate. We analyze the effect of pruning in Table 10 on (1) the reachability of the gold program (answer-recall), (2) KGQA F1-scores, and (3) the

k	Answer-Recall	Answer-F1	Latency (sec/q)
∞ (Pangu)	**100.00**	59.70	110.1
50	98.67	**63.07**	20.2
20	95.33	62.95	15.1
10	84.67	62.20	**13.2**

Table 10: **Effect of Candidate Pruning.** Performance of BYOKG + $\mathcal{X}$ on a sub-sampled set of 300 questions from the GrailQA dev set at different pruning thresholds k for candidate set P_t. Answer-recall is the oracle recall of the gold program, answer-F1 measures KGQA performance, and latency is the average time per question over 300 questions. Evaluation is run with one Amazon EC2 p3dn.24xlarge machine using MPT-7B *without* inverse-consistency re-ranking and *without* caching. Aggressive pruning at $k = 10$ results in the most efficient reasoning with an accuracy gain of 2.5 F1 over no pruning.

latency per question[14]. With no pruning (Pangu), we encounter prohibitive runtimes of nearly 2 minutes per query, which is substantially reduced at $k = 10$ to 13s (8x speed-up). Surprisingly, we also find that aggressive pruning ($k = 10$) results in improved reasoning accuracy (+2.5 F1 v/s at $k = \infty$). In practice, we note that the latency of BYOKG will continue to improve as more queries are served due to caching results from SPARQL executions.

Dataset	Standard	Inverse-Consistency
GrailQA	61.58	**66.52** (Δ+4.94)
MetaQA	82.22	**83.05** (Δ+0.83)

Table 11: **Candidate Re-ranking with Inverse-Consistency.** F1-scores of BYOKG + $\mathcal{X}$ with inverse-consistency re-ranking compared to standard top-1 predictions over a sub-sampled set of 3K questions from the GrailQA dev set and the MetaQA test set. Inverse-consistency improves performance on both datasets.

A.5 Inverse-Consistency for Candidate Re-ranking

As described in §3.3, we find that inverse-consistency re-ranking during reasoning helps recover from errors where exploration does not provide coverage over the test questions. Table 11 shows a comparison of F1 accuracy with standard scoring v/s inverse-consistency re-ranked outputs. Re-ranked programs P_{best} are computed using $\texttt{rerank}(\cdot, \cdot)$ with $\alpha = 0.5$. We find that re-ranking provides a significant gain of 4.94 F1 on GrailQA, while MetaQA performance increases by 0.83. The modest gains on MetaQA, may be attributed to higher pattern and sub-expression coverage during exploration as compared to GrailQA (Table 6), resulting in fewer instances where re-ranking is required.

A.6 Inverse-Consistency v/s PMI

	Inverse-Consistency	PMI_{DC}
ROUGE-1	**52.71**	42.97 (Δ-9.74)
BLEU	**39.94**	23.52 (Δ-16.42)
BERTscore	**88.64**	85.78 (Δ-2.86)

Table 12: **Re-ranking with Inverse-Consistency v/s PMI_{DC} for Question Generation.** Generation quality as measured using automatic metrics using MPT-7B over 100 randomly sampled questions from the GrailQA dev set.

	Inverse-Consistency	PMI_{DC}
F1-score	**66.52**	65.02 (Δ-1.5)

Table 13: **Re-ranking with Inverse-Consistency v/s PMI_{DC} for Reasoning.** F1-scores using MPT-7B over 3K randomly sampled questions from the GrailQA dev set.

Holtzman et al. (2021) propose the domain-conditional pointwise mutual information (PMI_{DC}) scoring function, i.e. $\log \Pr(y|x) \ / \ \Pr(y|x_{\text{domain}})$ to address the "surface form competition" hypothesis, which aims to explain miscalibrated outputs from LLMs, resulting in low accuracy in zero-shot settings. While our inverse-consistency formulation $\log \Pr(x|y)$ should, in theory, provide the same ordering as PMI_{DC}, we evaluate how these methods compare as re-ranking techniques in practice. We run evaluations on sub-sampled examples from the GrailQA dev set for both question generation (Table 12) and candidate re-ranking during reasoning (Table 13). For question generation, we set x_{domain} to "`### English Question:\n`" and for reasoning, we set x_{domain} to "`### Logical Form:\n`". We find that in practice the methods exhibit different behaviors, with inverse-consistency outperforming PMI_{DC} on both question generation and reasoning. A possible explanation for this variation is LLM sensitivity to the choice of prompt constructions to calculate the terms in the re-ranked expressions.

---

[14] In practice, we cache responses from the SPARQL engine to improve latency over time, but turn caching off for this evaluation. Also, $k = \infty$ refers to no pruning.

B Appendix: MatKG Dataset

Annotation Procedure. To evaluate BYOKG using MatKG, we annotate a set of 100 programs with natural language questions using 2 researchers from our team. In particular, we take our set of 10K explored programs and randomly sample 100 programs such that 75 are i.i.d. for the exploration set, while 25 are o.o.d. or unseen. We then randomly split the 100 questions into two sets and iteratively provide each annotator the sampled program text, natural language descriptions for the relations, and natural language descriptions for the classes in the program. The annotator is then prompted to enter a natural language question based on this information. We release our annotated dataset for reproducibility and future research under the MIT License as part of our code repository.

Annotation Examples. We provide a few examples from the annotated test set:

```
Program: (AND material (AND (JOIN
material.descriptor \"Bars\") (JOIN (R
synthesis_method.material) \"Ccs\")))
Query: which materials have been
synthesized using ccs and can be
described as bars?

Program: (COUNT (AND descriptor (AND (
JOIN (R property.descriptor) \"Free
Energy Diagram\") (JOIN (R
characterization_method.descriptor) \"
SEM Surface\"))))
Query: how many descriptors have
property free energy diagram and have
characterization method sem surface?

Program: (AND application (JOIN (R
characterization_method.application) (
JOIN (R property.characterization_method
) \"Basalts\")))
Query: the characterization method of
basalts has what all applications?
```

C Appendix: Implementation Details

C.1 Graphs and Datasets

Freebase (Bollacker et al., 2008) is a large-scale, open-domain KG containing over 100 domains, 45 million entities, and 3 billion facts. We use the **GrailQA** (Gu et al., 2021) dataset, which evaluates three levels of generalization—i.i.d., compositional (novel combinations of seen constructs), and zero-shot (unseen schema items)—and also features diverse questions of varying complexity (up to 4-hop) and aggregation functions (e.g. `COUNT` and comparatives). GrailQA was constructed with the help of 6,685 crowdworkers and restricts the KG to a high-quality Commons subset, which covers 86 unique domains.

	Split	GrailQA	MetaQA	MatKG
$\lvert\mathcal{Q}\rvert$	Train	44,337	329,282	-
	Dev	6,763	39,138	-
	Test	13,231	39,093	100
$\lvert\mathcal{R}\rvert$	All	3,720	9	21
$\lvert\mathcal{C}\rvert$	All	1,534	7	7
$\lvert\mathcal{E}\rvert$	All	32,585	43,692	70,002

Table 14: **GrailQA, MetaQA, and MatKG Statistics.** Note that the relation counts do not include inverse relations.

MoviesKG is a small-scale, domain-specific KG provided by the WikiMovies dataset (Miller et al., 2016), containing triples that map movies to attributes such as actors, genres, and ratings. Unlike previous work, we convert the provided triples of entity labels into a structured store where entities with the same label name may be assigned different entity IDs if they represent unique concepts.[15] The accompanying dataset we use is **MetaQA** (Zhang et al., 2018), which consists of more than 400K multi-hop (up to 3-hop) questions.

MatKG (Venugopal et al., 2022) represents the largest KG in the materials science and was automatically generated using LLMs from 4 million scientific papers resulting in 70K entities and 5.4 million unique triples, including chemistry, structure, property, application, synthesis, and characterization data as of our study (we use version 1.2 of the KG).

C.2 Models

MPT-Instruct (MosaicML-NLP-Team, 2023) is a decoder-style transformer pre-trained on 1T tokens of English text and code, followed by instruction fine-tuning on the Databricks-Dolly-15k (Conover et al., 2023) and Anthropic Helpful and Harmless datasets (Ganguli et al., 2022). We use the 7B model for our main experiments and also show a small-scale experiment with 30B to verify the efficacy of BYOKG at scale.

GPT-3.5 (Brown et al., 2020) is a state-of-the-art, closed-source model from OpenAI. We conduct

---

[15] For e.g., "Jungle Book" may either refer to the 1967 or the 2016 movie, but would incorrectly be considered the same entity in past work. We will release a corrected set of triples and a new set of answers for MetaQA based on this change.

a small-scale experiment (constrained by budget) using the *text-davinci-003* variant to demonstrate the scaling behaviors of BYOKG (§5).

C.3 Computing Infrastructure & Software

For compute, we use 3 Amazon EC2 p3dn.24xlarge instances (see `https://aws.amazon.com/ec2/instance-types/p3/`). Our experiments are run using PyTorch (Paszke et al., 2019) and utilize Huggingface for the Transformers library (Wolf et al., 2020) and models to access LLMs. For executing KG programs, we use OpenLink Virtuoso SPARQL Engine (recommended RAM is 100G). While querying the SPARQL server, we limit each request to timeout after 5s. For more details, please refer to our repository or `https://github.com/dki-lab/Freebase-Setup/`.

C.4 LLM Decoding Parameters

We use the following decoding arguments with the `generate()` call of HuggingFace's `AutoModelForCausalLM`:

```
default_decoding_args = {
    "max_new_tokens": 100,
    "do_sample": False,
    "temperature": 0.6,
    "min_length": None,
    "use_cache": True,
    "repetition_penalty": 1.,
    "length_penalty": 1.,
    "num_beams": 10,
    "num_return_sequences": 10,
    "no_repeat_ngram_size": 10,
    "renormalize_logits": True
}
```

C.5 Reasoning Implementation

Program Expansion Heuristics. We reimplement the Freebase expansion heuristics detailed in Gu et al. (2023), to allow operating with arbitrary KGs that may then be setup with just a text file of triples.

Entity Linking. For GrailQA, we utilize the entity linking results from Shu et al. (2022b) made available by Gu et al. (2023). For MetaQA, a simple string-matching approach results in perfect EL accuracy. For MatKG, we only evaluate with gold entity links, which are made available when automatically sampling programs.

D Appendix: Related Work

KGQA Generalization. Another line of work investigates pipelines for constructing semantic parsers for new KGs by generating training data automatically (Wang et al., 2015; Liang et al., 2016; Su et al., 2016; Gu et al., 2021). Each of these methods, however, includes a human annotation step to generate the final training data whereas BYOKG is able to operate without any supervision.

Galkin et al. (2023) recently introduced a foundational model to learn transferable representations for KGQA that allows them to generalize to unseen graphs without any training data. While similar in motivation to BYOKG, they do not handle natural language queries.

Planning and RL. Reasoning in BYOKG can be seen as iteratively constructing a plan to *navigate* the KG conditioned on a test query. Many prior works take a similar view and use reinforcement learning to construct path-finding algorithms for KGQA (Xiong et al., 2017; Das et al., 2018). These methods, however, were not designed to handle natural language queries. Several recent works also investigate the use of LMs as planners to navigate environments other than KGs, such as in robotics (Huang et al., 2022b,a), unstructured reasoning (Zaheer et al., 2022; Yao et al., 2023; Shinn et al., 2023), game environments (Wang et al., 2023), and web navigation (Deng et al., 2023).

LM Generation Re-ranking. Beyond LM decoding (Holtzman et al., 2020; Lu et al., 2022), recent work has also studied how best to *rank* sequences generated by LMs. For instance, Krishna et al. (2022) train an encoder model to score generations given a prefix using contrastive learning. Holtzman et al. (2021) instead propose an alternative PMI-based scoring function to address the "surface form competition" hypothesis, which is related to our inverse-consistency methodology. Prior work in information retrieval (Sachan et al., 2022, 2023) also makes use of a similar idea to re-rank retrieved passages for QA. Our method, however, does not require any training and also demonstrates better accuracy than PMI (see Appendix A.6).

E Language Model Prompts

Note: *Due to legal restrictions, we replace generation outputs from LLMs with human-written text within double-brackets ("[[...]]") describing the output instead.*

E.1 Question Generation: L2M

Logical program:

```
(AND meteorology.tropical_cyclone (AND (JOIN meteorology.tropical_cyclone.category (
JOIN meteorology.tropical_cyclone_category.tropical_cyclones "Tropical Storm Linda")
) (JOIN meteorology.tropical_cyclone.affected_areas "turks & caicos islands")))
```

Prompt (for the last L2M iteration):

```
### Instructions:
Translate the following logical form query into a natural language question in
English. The generated question must have the same meaning as the logical query. The
 generated question must cover all and only the information present in the logical
query. The generated question should use the schema which describes the entities,
relations, and functions present in the logical query. Use each previous query and
solution as a hint to solve the next query.

### Logical Query:
(AND meteorology.tropical_cyclone_category (JOIN meteorology.
tropical_cyclone_category.tropical_cyclones "Tropical Storm Linda"))
### Schema:
meteorology.tropical_cyclone=tropical cyclone; meteorology.tropical_cyclone_category
=tropical cyclone category; meteorology.tropical_cyclone_category.tropical_cyclones=
tropical cyclones
### English Question:
[[LLM generates a question asking about the tropical cyclone category of tropical
storm linda]]

### Logical Query:
(AND meteorology.tropical_cyclone (JOIN meteorology.tropical_cyclone.category (JOIN
meteorology.tropical_cyclone_category.tropical_cyclones "Tropical Storm Linda")))
### Schema:
meteorology.tropical_cyclone=tropical cyclone; meteorology.tropical_cyclone_category
=tropical cyclone category; meteorology.tropical_cyclone_category.tropical_cyclones=
tropical cyclones; meteorology.tropical_cyclone.category=category
### English Question:
[[LLM generates a question asking about the tropical cyclone category of tropical
storm linda]]

### Logical Query:
(AND meteorology.tropical_cyclone (JOIN meteorology.tropical_cyclone.affected_areas
"turks & caicos islands"))
### Schema:
meteorology.tropical_cyclone=tropical cyclone; meteorology.tropical_cyclone.
affected_areas=affected areas
### English Question:
[[LLM generates a question asking about the tropical cyclones that have affected the
 turks and caicos islands]]

### Logical Query:
(AND (JOIN meteorology.tropical_cyclone.category (JOIN meteorology.
tropical_cyclone_category.tropical_cyclones "Tropical Storm Linda")) (JOIN
meteorology.tropical_cyclone.affected_areas "turks & caicos islands"))
### Schema:
meteorology.tropical_cyclone=tropical cyclone; meteorology.tropical_cyclone_category
=tropical cyclone category; meteorology.tropical_cyclone_category.tropical_cyclones=
tropical cyclones; meteorology.tropical_cyclone.category=category; meteorology.
tropical_cyclone.affected_areas=affected areas
### English Question:
[[LLM generates a question asking about both the cyclone category of tropical storm
linda and the turks and caicos islands]]

### Logical Query:
```

```
(AND meteorology.tropical_cyclone (AND (JOIN meteorology.tropical_cyclone.category (
JOIN meteorology.tropical_cyclone_category.tropical_cyclones "Tropical Storm Linda")
) (JOIN meteorology.tropical_cyclone.affected_areas "turks & caicos islands")))
### Schema:
meteorology.tropical_cyclone=tropical cyclone; meteorology.tropical_cyclone_category
=tropical cyclone category; meteorology.tropical_cyclone_category.tropical_cyclones=
tropical cyclones; meteorology.tropical_cyclone.category=category; meteorology.
tropical_cyclone.affected_areas=affected areas
### English Question:
```

Generation (natural language question):

```
[[LLM generates the final question asking about both the cyclone category of
tropical storm linda and the turks and caicos islands]]
```

E.2 Question Generation: Inverse-Consistency Re-ranking

Generated question to re-rank:

```
[[Candidate question generated by the LLM about the cyclone category of tropical
storm linda]]
```

Prompt:

```
### Instructions:
Translate the following question into its semantic parse.

### Question:
[[Candidate question generated by the LLM about the cyclone category of tropical
storm linda]]
### Semantic Parse:
```

Completion to score (logical program):

```
(AND meteorology.tropical_cyclone_category (JOIN meteorology.
tropical_cyclone_category.tropical_cyclones "Tropical Storm Linda"))
```

E.3 Reasoning

Test question:

```
which movies was Rob Williams the writer of?
```

Prompt:

```
### Instructions:
Write a logical form expression using only elements mentioned in the provided
natural language question. An "R" before a relation in the logical expression may be
 used to indicate a reverse or inverse relation.

### Question:
[[Question generated by the LLM asking about the movies that bernard girard wrote
scripts for]]
### Logical Form:
(AND movie.movie (JOIN movie.written_by "Bernard Girard"))

### Question:
[[Question generated by the LLM asking about the movies that paul solet directed]]
### Logical Form:
(AND movie.movie (JOIN movie.directed_by "Paul Solet"))

### Question:
[[Question generated by the LLM asking about the movies that amy poehler acted in
and that had the same person both direct and write the movie]]
### Logical Form:
(AND movie.movie (AND (JOIN movie.starred_actors "Amy Poehler") (JOIN movie.
written_by (JOIN (R movie.directed_by) movie.movie))))

### Question:
```

```
[[Question generated by the LLM asking about the movies matt reeves directed and
wrote]]
### Logical Form:
(AND movie.movie (AND (JOIN movie.directed_by ”Matt Reeves”) (JOIN movie.written_by
”Matt Reeves”)))

### Question:
[[Question generated by the LLM asking about how many movies gary k wolf wrote the
scripts for]]
### Logical Form:
(COUNT (AND movie.movie (JOIN movie.written_by ”Gary K. Wolf”)))

### Question:
which movies was Rob Williams the writer of
### Logical Form:
```

E.4 Reasoning: Inverse-Consistency Re-ranking

Candidate program to re-rank:

```
(AND travel.travel_destination (JOIN (R book.book_edition.place_of_publication) (
JOIN (R book.audio_book_reader.audio_books_read) m.09qbn3)))
```

Prompt:

```
### Instructions:
Write a plausible question in English that can be formed from the provided logical
query as a starting point. The question must contain at least all of the information
 present in the logical query.

### Logical Query:
(AND travel.travel_destination (JOIN (R book.book_edition.place_of_publication) (
JOIN (R book.audio_book_reader.audio_books_read) m.09qbn3)))
### Plausible Question:
```

Completion to score (test question):

```
what is the name of the travel destination where mircea cartarescu is published?
```

F Appendix: Qualitative Examples

F.1 Inverse-Consistency Re-ranking for Question Generation

Note: *Due to legal restrictions, we replace generation outputs from LLMs with human-written text within double-brackets (“[[...]]”) describing the output instead.*

F.1.1 Re-ranking sequences returned by beam search

```
Program:
(AND religion.founding_figure (JOIN religion.founding_figure.religion_founded (JOIN
religion.religion.founding_figures ”st. peter”)))

Standard predictions (top-5, in order of log-probability scores):
[[Question generated by the LLM asking who paul the apostle was]]
[[Question generated by the LLM asking who christianity was founded by]]
[[Question generated by the LLM asking who the founder of christianity was ]]
[[Question generated by the LLM asking about the founding figures of the religion
founded by st.peter]]
[[Question generated by the LLM asking about the founding figure of the religion
founded by st. peter]]

Inverse-consistency predictions (top-5, in order of inverse-task log-probability
scores):
[[Question generated by the LLM asking about the founding figure of the religion
founded by st. peter]]
[[Question generated by the LLM asking about the founding figures of the religion
founded by st.peter]]
[[Question generated by the LLM asking who the founder of christianity]]
```

```
[[Question generated by the LLM asking who christianity was founded by]]
[[Question generated by the LLM asking who paul the apostle was]]
```

F.1.2 Prediction Examples

```
Program:
(COUNT (AND biology.breed_temperament (AND (JOIN biology.breed_temperament.breeds (
JOIN biology.animal_breed.place_of_origin "swiss confederation")) (JOIN biology.
breed_temperament.breeds "Toy Bulldog"))))

Standard prediction:
[[Question generated by the LLM asking about the number of dog breeds native to
switzerland]]

Inverse-consistency prediction:
[[Question generated by the LLM asking about the breed temperaments of breeds
originated from the swiss confederation and which also are part of the toy bulldog
breed]]

---

Program:
(AND medicine.medical_trial (JOIN medicine.medical_trial.treatment_being_tested "
Stavudine"))

Standard prediction:
[[Question generated by the LLM asking about the treatments that are being tested in
 medical trials]]

Inverse-consistency prediction:
[[Question generated by the LLM asking about the medical trials in which treatment
stavudine is being tested]]

---

Program:
(AND medicine.contraindication (JOIN medicine.contraindication.contraindication_for
(JOIN medicine.medical_treatment.contraindications (JOIN medicine.contraindication.
contraindication_for "Teriparatide"))))

Standard prediction:
[[Question generated by the LLM asking about why teriparatide is contraindicated]]

Inverse-consistency prediction:
[[Question generated by the LLM asking about what the contraindications are for
teriparatide]]

---

Program:
(AND measurement_unit.volume_unit (JOIN measurement_unit.volume_unit.
measurement_system (JOIN measurement_unit.measurement_system.
molar_heat_capacity_units "Joule per mole per kelvin")))

Standard prediction:
[[Question generated by the LLM asking about the molar heat capacity of joule per
molecule per kelvin]]

Inverse-consistency prediction:
[[Question generated by the LLM asking about the units of volume that have a molar
heat capacity units of 'joules per mole per kelvin']]
```

F.2 Inverse-Consistency Re-ranking for Reasoning

```
Test Query:
what fictional universe does the harry potter take place in?

Standard predictions (top-5, in order of log-probability scores):
```

```
(AND fictional_universe.work_of_fiction (JOIN (R fictional_universe.
fictional_universe.literary_series_set_here) (JOIN (R fictional_universe.
work_of_fiction.part_of_these_fictional_universes) m.078ffw)))
(AND fictional_universe.fictional_universe (JOIN fictional_universe.
fictional_universe.literary_series_set_here m.078ffw))
(JOIN (R fictional_universe.work_of_fiction.part_of_these_fictional_universes) m.078
ffw)
(AND fictional_universe.fictional_universe (JOIN (R book.literary_series.
fictional_universe) m.078ffw))

Inverse-consistency predictions (top-5, in order of inverse-task log-probability
scores):
(AND fictional_universe.fictional_universe (JOIN fictional_universe.
fictional_universe.literary_series_set_here m.078ffw))
(JOIN (R fictional_universe.work_of_fiction.part_of_these_fictional_universes) m.078
ffw)
(AND fictional_universe.fictional_universe (JOIN (R book.literary_series.
fictional_universe) m.078ffw))
(AND fictional_universe.work_of_fiction (JOIN (R fictional_universe.

GraSAME: Injecting Token-Level Structural Information to Pretrained Language Models via Graph-guided Self-Attention Mechanism

Shuzhou Yuan and **Michael Färber**

Abstract

Pretrained Language Models (PLMs) benefit from external knowledge stored in graph structures for various downstream tasks. However, bridging the modality gap between graph structures and text remains a significant challenge. Traditional methods like linearizing graphs for PLMs lose vital graph connectivity, whereas Graph Neural Networks (GNNs) require cumbersome processes for integration into PLMs. In this work, we propose a novel graph-guided self-attention mechanism, GraSAME. GraSAME seamlessly incorporates token-level structural information into PLMs without necessitating additional alignment or concatenation efforts. As an end-to-end, lightweight multimodal module, GraSAME follows a multi-task learning strategy and effectively bridges the gap between graph and textual modalities, facilitating dynamic interactions between GNNs and PLMs. Our experiments on the graph-to-text generation task demonstrate that GraSAME outperforms baseline models and achieves results comparable to state-of-the-art (SOTA) models on WebNLG datasets. Furthermore, compared to SOTA models, GraSAME eliminates the need for extra pre-training tasks to adjust graph inputs and reduces the number of trainable parameters by over 100 million.

1 Introduction

The paradigm of pre-training and fine-tuning has increasingly become the standard approach for leveraging the inherent knowledge of language models in a wide range of Natural Language Processing (NLP) tasks (Xu et al., 2021). Pretrained Language Models (PLMs) like Transformer (Vaswani et al., 2017), T5 (Raffel et al., 2020), and GPT (Brown et al., 2020), which are trained on extensive text corpora, have demonstrated remarkable performance across various NLP challenges. However, these models primarily focus on textual data, presenting a significant limitation in processing structured information, such as Knowledge Graphs (KGs), molecular graph and social networks. Such graph structures are crucial for storing external knowledge and can significantly enhance PLM's performance on knowledge-driven tasks (Zhang et al., 2019; Peters et al., 2019). This limitation becomes particularly evident in tasks that require a deep understanding of both textual and structural data, such as graph-to-text generation (Gardent et al., 2017), KG-based fact checking (Kim et al., 2023), and translation between molecules and natural language (Edwards et al., 2022).

To address the challenge of processing structural input in PLMs, recent research has explored two main strategies: linearizing graph structures into text sequences (Harkous et al., 2020; Ribeiro et al., 2021a; Schmitt et al., 2021), and encoding structural information using Graph Neural Networks (GNNs) (Yao et al., 2020; Ribeiro et al., 2021b; Li et al., 2021; Zhang et al., 2022). While linearization allows direct fine-tuning of PLMs, studies have shown that it often fails to preserve the inherent structural information and explicit node connectivity (Song et al., 2018; Ribeiro et al., 2019). Conversely, while GNNs effectively encode complex structures, the modality difference between text and graphs complicates the integration with PLMs, requiring additional training for aligning and concatenating embeddings from graph and textual modality (Li et al., 2021; Zhang et al., 2022).

To merge the strengths of PLMs and GNNs, we introduce GraSAME, a novel **Gra**ph-guided **S**elf-**A**ttention **ME**chanism, enhancing PLMs' ability to process graph inputs. As depicted in Figure 1, we construct a token-level hierarchical graph structure from the linearized graph sequence to maintain the input graph's structural integrity. GraSAME is designed to learn the token-level graph information from a GNN and integrate it seamlessly into the text representation for PLM. Based on a standard transformer architecture, we substitute the

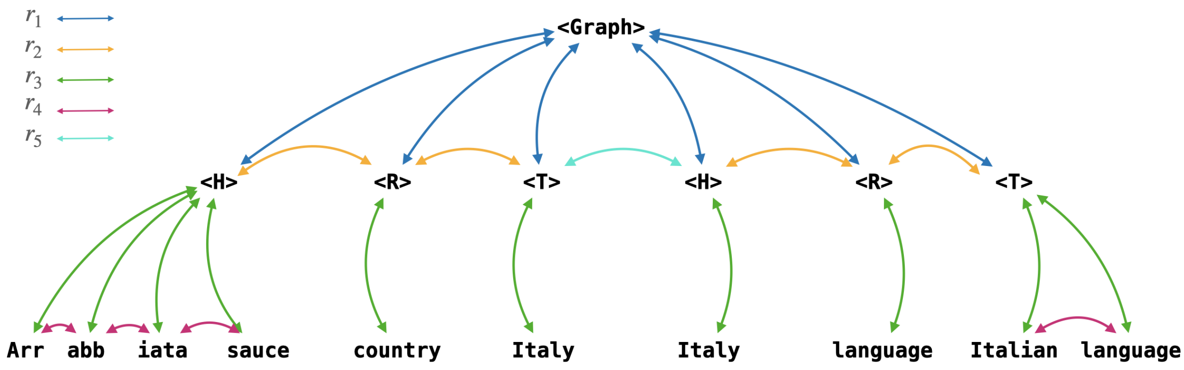
Hierarchical graph:



Target text: Arrabbiata sauce can be found in Italy where the Italian language is spoken.

Figure 1: An example of KG-to-text generation. We visualize the hierarchical graph structure derived from the linearized graph input, tokenized by T5-large tokenizer. Each token from the input text is depicted as a node. Various relation types, each indicated by a unique color, are assigned between nodes to establish the hierarchical structure and ensure effective information flow among neighboring nodes.

self-attention layers in the encoder with GraSAME. As GraSAME effectively encodes the graph structure, we train only its parameters while keeping the PLM's parameters frozen. This approach enables PLMs equipped with GraSAME to simultaneously process structural and textual information dynamically, eliminating the need for complex alignment or concatenation of different modalities.

Applied to KG-to-text generation task WebNLG, we integrate GraSAME into the encoder-decoder model T5 with multi-task fine-tuning. The KG-to-text generation is particularly suitable as it necessitates the processing of both graph and text information, providing a clear intuition to assess the effectiveness of GraSAME. Our experiments demonstrate that GraSAME is compatible with various GNN architectures such as GraphSAGE (Hamilton et al., 2017), GAT (Veličković et al., 2018) and RGCN (Schlichtkrull et al., 2018), yielding performance that not only surpasses baseline models but also comparable to state-of-the-art (SOTA) models. Moreover, GraSAME effectively integrates structural information purely during fine-tuning and saves over 100 million trainable parameters.

In summary, our contributions are: **i)** Introducing a novel graph-guided attention mechanism GraSAME to incorporate explicit structural information into PLMs. This innovation enables PLMs to process both textual and structural inputs smoothly, bridging the modality gap of GNNs and PLMs. With GraSAME, PLMs can dynamically interact with GNNs, effectively interpreting graph inputs, which is crucial for NLP tasks that require structural information. **ii)** Applying GraSAME to KG-to-text generation on WebNLG datasets, achieving results comparable to SOTA models while saving over 100 million trainable parameters.

2 Related Work

Structural Information for PLMs. Although PLMs inherit linguistic structure information from pre-training (Nie et al., 2024), external structural information helps PLMs enhance their ability to understand the syntax of natural language (Yang et al., 2022), summarize source code (Choi et al., 2021) and generate better text (Song et al., 2020). Much initial focus of infusing structural information into PLMs has been on modifying pre-training objectives (Peters et al., 2019; Xiong et al., 2020; He et al., 2020). Zhang et al. (2019) utilized both textual corpora and KGs to pre-train an enhanced language representation model. Ke et al. (2021) proposed three new pre-training tasks to explicitly enhance the graph-text alignment. Also, recent efforts increasingly aimed at injecting structural information into PLMs during fine-tuning for various NLP tasks (Yasunaga et al., 2021; Ribeiro et al., 2021b). Wang et al. (2021) proposed K-Adapter to infuse knowledge into PLMs. Zhang et al. (2022)

came up with GreaseLM model to utilise KG information for question answering.

KG-to-text Generation. Previous approaches to enabling PLMs to process graph inputs often relied on linearizing the input graph into a text sequence (Harkous et al., 2020; Mager et al., 2020; Ribeiro et al., 2021b; Colas et al., 2022). Ribeiro et al. (2021a) investigated PLMs on graph-to-text generation using linearized graphs and found that this method is effective, yet results in the loss of specific edge connections in graphs (Song et al., 2018; Beck et al., 2018; Ribeiro et al., 2019). Also, Yuan and Faerber (2023) evaluated generative models using linearized graph and uncovered the issues of hallucinations in the models. An alternative approach to encode the graph inputs is leveraging GNNs (Koncel-Kedziorski et al., 2019; Ribeiro et al., 2020). But this method typically entails additional steps such as aligning modalities and concatenating embeddings (Li et al., 2021), which adds complexity to the development of a seamless end-to-end pipeline for integrating GNN with PLM. Diverging from the previous methods, our work synthesizes the strengths of both linearized graph and GNN. Moreover, GraSAME also follows a lightweight fine-tuning avoiding updating the parameters of the whole model, inspired by the adapter and parameter-efficient fine-tuning approaches (Houlsby et al., 2019; Ribeiro et al., 2021b; Wang et al., 2021; Yuan et al., 2024).

3 Model

In this section, we detail the components of our model. Theoretically, GraSAME is adaptable to any attention-based PLMs. We choose T5 model (Raffel et al., 2020) as our foundation due to its encoder-decoder architecture, which is well-suited for KG-to-text generation.

3.1 Encoder-Decoder Model

Encoder-decoder model, such as T5, is a classic Transformer model consisting of encoder and decoder layers. Each encoder layer includes two distinct sublayers: a self-attention mechanism and a position-wise fully connected feed-forward network. The self-attention mechanism utilizes h distinct attention heads. Consider a conditional generation task such as KG-to-text generation, where the input is a sequence of tokens $x = (x_1, \dots, x_n)$ with each $x_i \in \mathbb{R}^{d_x}$, and the aim is to generate target sequence of tokens $y = (y_1, \dots, y_n)$. The attention head processes an input sequence, the outputs of all attention heads are merged via concatenation, followed by a parameterized linear transformation to yield the final output of the self-attention sublayer. The computation of each output element z_i, with each $z_i \in \mathbb{R}^{d_z}$, involves a weighted sum of linearly transformed input elements, defined as:

$$z_i = \sum_{j=1}^{n} \alpha_{ij}(x_j W^V), \tag{1}$$

where α_{ij} represents the weight coefficient, calculated using a softmax function:

$$\alpha_{ij} = \text{softmax}(\frac{(x_i W^Q)(x_j W^K)^T}{\sqrt{d_k}}). \tag{2}$$

The matrices $W^V, W^Q, W^K \in \mathbb{R}^{d_x \times d_z}$ are layer-specific trainable parameters, and are distinct for each attention head.

3.2 Graph-guided Self-Attention Mechanism

Self-attention allows for the interaction of token representations by treating each input sequence as a fully-connected graph with tokens as nodes (Yao and Wan, 2020). However, this process does not retain the original structural information and explicit connectivity between the tokens. To address this issue, we introduce GraSAME, a method that integrates text with token-level hierarchical graph representation illustrated in Figure 1.

3.2.1 Architecture of GraSAME

GraSAME involves incorporating a GNN within the self-attention layer of the PLM. This addition enables the direct encoding of the hierarchical graph structure and facilitates the smooth transfer of structural information into the PLM. We visualize the architecture in Figure 2.

Graph Neural Network. The graph neural network models structural characteristics of the input graph effectively by using various graph convolutional layers. The primary goal of the GNN is to learn the representations for both individual nodes and the overall graph structure. In most GNN models, the node representation is updated iteratively by aggregating the representations of its neighboring nodes. The representation of node v_i at the l-th layer is represented by $h^{(l)}$, with the initial representation $h^{(0)}$ set to the node's feature vector x_i. The process of representation update at the l-th

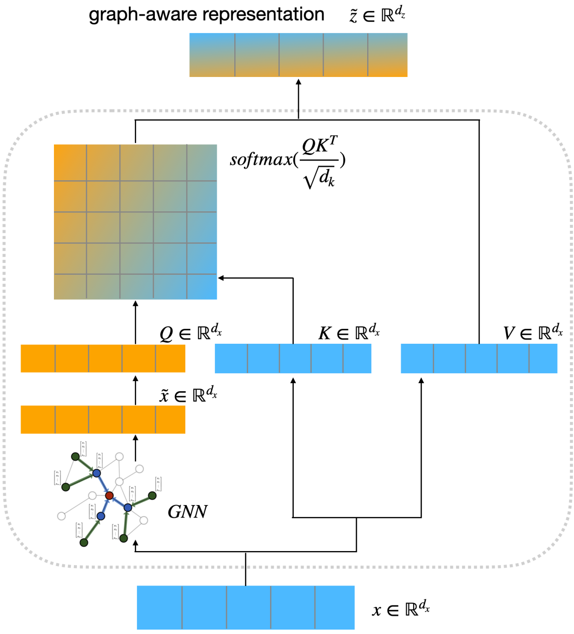


Figure 2: The architecture of GraSAME. The text embedding x is fed into a GNN along with the edge index derived from the hierarchical graph structure. This process generates a graph embedding $\tilde{x}$, which subsequently induces the Q vector. The Q vector then guides the self-attention mechanism to produce a graph-aware representation $\tilde{z}$. The visualization of GNN is taken from GraphSAGE (Hamilton et al., 2017).

layer involves two main operations:

$$a^{(l)} = \text{AGGREGATE}^{(l)}\left(\{h_j^{(l-1)} : j \in \mathcal{N}(v_i)\}\right), \tag{3}$$

$$h_i^{(l)} = \text{COMBINE}^{(l)}\left(h_i^{(l-1)}, a^{(l)}\right), \tag{4}$$

where $\mathcal{N}(v_i)$ denotes the neighbors of v_i. The AGGREGATE function compiles message passing from these neighbors, using techniques like MEAN, MAX, or SUM, varying with the GNN architecture. The COMBINE function then integrates this aggregated information into the node's current representation, thereby updating it.

Incorporating Method. Drawing inspiration from the multimodal self-attention layer by Yao and Wan (2020), we present a graph-guided self-attention architecture designed to simultaneously encode text representation and hierarchical graph structure. In our approach, all tokens in the input text are treated as nodes, with their initial features derived from the token representations in $h^{(l)}$. As shown in Figure 2, the token representations are aggregated and updated through a GNN layer. This process generates the vector Q, which subsequently guides the self-attention layer in the encoder of the PLM.

Formally, we adapt Equation 2 such that the weight coefficient $\tilde{\alpha_{ij}}$ is derived from the node representation $\tilde{x_i}$ in the graph modality, and the token representation x_j from the text modality:

$$\tilde{\alpha_{ij}} = \text{softmax}\left(\frac{(\tilde{x_i}W^Q)(x_jW^K)^T}{\sqrt{d_k}}\right). \tag{5}$$

The output of the self-attention layer is then calculated as:

$$\tilde{z_i} = \sum_{j=1}^{n} \tilde{\alpha_{ij}}(x_jW^V). \tag{6}$$

This modification ensures that the hidden word representations are influenced by the graph embedding. In each encoder layer of the model, we incorporate residual connections and layer normalization. The standard self-attention layer in the encoder is replaced with GraSAME, while the decoder retains the standard Transformer implementation. In the encoder's final layer, $\tilde{z_i}$ serves as the input to the decoder, which generates the target sequence.

3.2.2 Graph Representation

As PLMs are designed to process textual input only, it becomes necessary to perform certain preprocessing steps when addressing graph-based NLP tasks. Considering the task of KG-to-text generation, we represent the graph input as a linearized graph following prior studies (Harkous et al., 2020; Ribeiro et al., 2021a), and also extract a token-level hierarchical graph structure to ensure information flow among neighboring nodes.

Linearized Graph. In line with Ribeiro et al. (2021a), we linearize the graph into a sequence of text augmented with special tokens. As depicted in Figure 1, a KG triple is composed of a head, relation, and tail entity. Accordingly, we prepend each entity with special tokens: <*H*>, <*R*>, <*T*>. Furthermore, to distinguish between text and graph inputs, we introduce the <*Graph*> token.[1] Previous work (Ribeiro et al., 2021a) suggests that PLMs generate fluent text regardless of the linearization order of the graph. Hence we adhere to the default sequence in which triples appear in the dataset.

Hierarchical Graph Structure. We derive a token-level hierarchical graph structure from the linearized graph, as depicted in Figure 1. The

---

[1] For the KG-to-text generation task, the prompt "translate graph to English: " is added as a task description to match the input format of T5.

concept of this hierarchy is inspired by the tree-like structures observed in functional organizations such as companies, universities, and even insect societies (Pooler, 2017; Anderson et al., 2001), and has been explored in neural network research for knowledge representation as well (Ying et al., 2018; Moutsinas et al., 2021; Chen et al., 2020). In this structure, each token dynamically interacts within its hierarchical tier through message passing, which we believe helps preserve the graph's original explicit connectivity and ensures effective information flow among neighboring nodes. Formally, let's consider a graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathcal{R})$, where $\mathcal{V}$ is the set of nodes and $\mathcal{E}$ comprises labeled edges of the form (u, r, v). Here, u and v represent nodes in $\mathcal{V}$, and r from $\mathcal{R}$ denotes the relation type. In our structure, each token in the linearized graph is considered as a node, and we define specific relation types r between two nodes to enhance the hierarchy:

1. r_1 connects the global node <*Graph*> to special tokens <*H*>, <*R*>, <*T*>.
2. r_2 links adjacent special tokens within a triple.
3. r_3 connects special tokens to their respective entity tokens.
4. r_4 joins consecutive tokens within entities.
5. r_5 associates special tokens sharing the same entity.

An example of such a hierarchical graph is presented in Figure 1. We design the edges to be bidirectional, as this approach of information propagation in multiple directions can enhance the model's performance (Yao et al., 2020).

4 Multi-Task Fine-Tuning

Our training approach employs a multi-task learning strategy with efficient, lightweight fine-tuning. We initialize the model with pretrained parameters denoted by ϕ. The parameters of the PLM remain frozen, and only the GNN component within GraSAME is updated, given its effective encoding of graph structure.

4.1 Training Objectives

We retain the standard language model objective of generating the next token in a sequence while introducing an additional graph reconstruction task. This task is designed to strengthen the relation types between pairs of nodes, enhancing the hierarchy.

Text Generation. The text generation task is implemented by a PLM with a language modeling head on top. Given an input sequence x and a graph representation $\mathcal{G}$, the model aims to generate a target sequence y by minimizing the cross-entropy loss:

$$\mathcal{L}_{TG} = -\sum_{i=1}^{|y|} \log P_\phi(y_i | y_{1:i-1}, x, \mathcal{G}), \quad (7)$$

where P_ϕ is the generative probability from PLM.

Graph Reconstruction. Building on previous work that focused on predicting relationships between entities (Song et al., 2020; Li et al., 2021), our approach reformulates the graph reconstruction task. We aim to predict the relation type r in the triple (u, r, v), where u and v are nodes in the hierarchical graph structure. Node representations h_u and h_v are derived from the last hidden states of the PLM's encoder. Consequently, the probability of relation r is given by:

$$p(r|u, v) = \mathrm{softmax}(W[h_u; h_v] + b), \quad (8)$$

where W and b are trainable parameters. The loss for graph reconstruction is computed using cross-entropy loss:

$$\mathcal{L}_{GR} = -\sum_{\langle u,r,v\rangle \in \mathcal{E}} \log p(r|u, v). \quad (9)$$

We integrate the text generation loss and the graph reconstruction loss to train the PLM. The overall training loss is defined as follows:

$$\mathcal{L}_{total} = \mathcal{L}_{TG} + \lambda \mathcal{L}_{GR}, \quad (10)$$

where λ is a weighting coefficient.[2]

5 Experiments

In this section, we introduce the details of our experiments on KG-to-text generation task. We modify T5 for conditional generation from Huggingface (Wolf et al., 2019), and implement GraSAME with the GNN layers provided by PyTorch Geometric (Fey and Lenssen, 2019).

---

[2] We observed that the value of λ significantly impacts performance. After tuning on the validation set of the *WebNLG unconstrained* dataset, we set λ to 0.08, which yielded the best BLEU score. Further details are provided in Appendix C.

5.1 Dataset

WebNLG[3] (Gardent et al., 2017) is a commonly-used benchmark in KG-to-text generation (Chen et al., 2020; Li et al., 2021; Li and Liang, 2021; Colas et al., 2022; Ke et al., 2021). We employ WebNLG version 2.1 for our experiments, as it represents a refined version of the widely-used version 2.0 (Shimorina and Gardent, 2018; Chen et al., 2020; Ke et al., 2021; Colas et al., 2022). This version offers two distinct splits: *unconstrained* and *constrained*.

WebNLG unconstrained. Each WebNLG sample comprises several KG triples and a corresponding descriptive text. The triples are structured as *(head, relation, tail)* and the model is supposed to generate fluent text to describe the input triples. An illustrative example is presented in Figure 1. In the *unconstrained* dataset, there is no overlap of input graphs between the train, validation, and test sets.

WebNLG constrained. The data structure of *constrained* is as same as *unconstrained* dataset. However, the *constrained* dataset presents a greater challenge by ensuring that there is no overlap of triples in the input graphs across train, validation and test sets.

5.2 Setting

As an enhancement of self-attention mechanism, a foundational model is required for the implementation of GraSAME. For our experiments, T5-large serves as the foundational model. Prior to training, we expand T5's vocabulary to include the special tokens <H>, <R>, <T>, and <$Graph$>. To ensure fair comparisons, we maintain consistent hyper-parameters across both the baseline and our models.[4] All models are fine-tuned with the training set. The BLEU score on validation set is employed to identify the best-performing model, which is subsequently evaluated on the test set.

Evaluation Metrics. To evaluate the performance of the models, we use the automatic evaluation metrics BLEU (Papineni et al., 2002), METEOR (Denkowski and Lavie, 2014), ROUGE-L (Lin, 2004) and chrF++ (Popović, 2015) following previous work (Shimorina and Gardent, 2018; Ribeiro et al., 2021a). The evaluations are conducted using the official evaluation script from the WebNLG challenge (Shimorina and Gardent, 2018).

Baseline. T5-large is employed as the baseline model. Previous research (Ribeiro et al., 2021a; Ke et al., 2021) has demonstrated T5's SOTA performance on graph-to-text generation, making it a robust baseline (Clive et al., 2022). This choice allows for a fair comparison with our approach.

GraSAME is integrated into the T5-large model for our experiments. We investigate the efficacy of different GNNs for encoding the hierarchical graph structure and denote them as:

GraSAME-GAT. Graph Attention Network (GAT) (Veličković et al., 2018) is used as the GNN component in GraSAME. GAT utilizes an attention mechanisms to aggregate the information from neighbouring nodes.

GraSAME-RGCN. We also integrate Relational Graph Convolutional Network (RGCN) (Schlichtkrull et al., 2018) with GraSAME. RGCN extends the Graph Convolutional Network (Kipf and Welling, 2016), enabling it to process local graph neighborhoods within large-scale relational data.

GraSAME-SAGE. GraphSAGE (Hamilton et al., 2017) is an inductive framework that efficiently generates node embeddings for unseen nodes by leveraging node feature information. We also combine it with GraSAME.

GraSAME-SAGE	✗	151M	**60.27**	45.81	**72.01**	**73.29**

Table 3: Results on *WebNLG constrained.* A denotes if additional pre-training tasks are implemented or not. P = Trainable parameters, B = BLEU, M = METEOR, R = ROUGE, C = chrF++. The results of JointGT(T5) are re-printed from Ke et al. (2021). **Bold** indicates the best score of the models we trained.

is due to the powerful encoding ability of GraphSAGE for unseen nodes (for example, the special tokens we add to the model's vocabulary manually). Although other models don't outperform the baseline T5, they still achieve noteworthy performance, achieving BLEU scores of over 60 with much fewer trainable parameters than baseline.

For comparison, we also include the results of the SOTA models from related work. Notably, GraSAME-SAGE outperforms GCN and KGPT on BLEU and METEOR scores, and achieves performance comparable to JoinGT(T5). Our METEOR score of 48.38 is even higher than that of JoinGT(T5). It is worth mentioning that both KGPT and JointGT are pre-trained with additional tasks to fine-tune KG-to-text generation. Additionally, JointGT(T5) has 114 million more trainable parameters than GraSAME-SAGE. This highlights the efficiency of our approach, demonstrating that GraSAME can enhance PLMs by leveraging token-level structural information for KG-to-text generation.

The results for *WebNLG constrained* are similar as for *WebNLG unconstrained*. As illustrated in Table 3, GraSAME-SAGE outperforms the baseline T5, while our other models achieve comparable results to it with higher BLEU scores and fewer trainable parameters. In comparison to JoinGT(T5), GraSAME-SAGE maintains over 98% performance with fewer than 114 million trainable parameters, and it doesn't require additional pre-training tasks. This prove the generalization of our method under the constrained condition, where there is no overlap between training and test triples.

5.3.2 Detailed Analysis on Graph Size

We conduct a comprehensive analysis focusing on input graph size, as detailed in Table 2. Notably, GraSAME consistently improves the BLEU scores across various input triple counts, except for six-triple inputs. The most pronounced improvement occurs with seven-triple inputs, where the BLEU score surpasses the baseline by 8.61. Seven-triple inputs form the most complex graph structure in the test set, highlighting the efficacy of GraSAME in fortifying the PLM's capacity to process complex graph inputs through token-level structural integration. Interestingly, a significant improvement also emerges in one-triple input graphs, likely due to the baseline model's propensity for generating hallucinations with shorter input graphs.[5]

5.4 Human Evaluation

Model	Fluency	Meaning
Gold	5.59	5.71
T5	5.57	5.41
GraSAME	5.56	5.62

Table 4: Human evaluation on *WebNLG unstrained.* T5 denotes the baseline model T5-large, GraSAME denotes GraSAME-SAGE. The Fleiss' Kappa κ is 0.42, which indicates moderate agreement.

To further assess the quality of the generated text, we conduct a human evaluation using the crowdsourcing platform Amazon Mechanical Turk.[6] We randomly select 100 texts generated by both baseline and GraSAME-SAGE models, along with their corresponding gold standard references. In line with previous studies (Castro Ferreira et al., 2019; Ribeiro et al., 2021a), we ask three annotators to rate the texts on a 1-7 Likert scale across two dimensions: (i) Fluency: Assessing whether the text

---

[5] A more in-depth error analysis is presented in Section 6.

[6] `https://www.mturk.com`

is fluent, natural, and easy to read. (ii) Meaning: Evaluating if the text accurately conveys the information from the input graph without including extraneous information (hallucination). We specifically instruct annotators to pay close attention to instances of hallucination, as this issue has gained significant attention in recent PLM research (González Corbelle et al., 2022; Ji et al., 2023; Yuan and Faerber, 2023).

As indicated in Table 4, both the baseline and GraSAME models produce fluent text, scoring only marginally lower than the reference by 0.02 and 0.03, respectively. Regarding the meaningfulness of the generated text, GraSAME surpasses the baseline, achieving a score that is 0.21 points higher. This human evaluation confirms that GraSAME is capable of generating not only fluent text but also text that more accurately encapsulates the input information, while minimizing hallucinations.

5.5 Ablation Study

Model	BLEU	METEOR
GraSAME-SAGE	65.55	48.38
- bidirectional edges	60.74	45.13
- graph reconstruction	61.75	45.65

Table 5: Ablation study on *WebNLG unconstrained*.

We conduct an ablation study focusing on two key aspects of the model: the bidirectional edges and the graph reconstruction task. This study is implemented using the top-performing GraSAME-SAGE model on *WebNLG unconstrained*.

Bidirectional Edges: We retain a single edge direction in the hierarchical graph structure, specifically from bottom to top tokens.

Graph Reconstruction: We omit the graph construction loss during training, allowing the model to update solely based on the text generation loss.

The outcomes of the ablation study are detailed in Table 5. Both the bidirectional edge and graph reconstruction components significantly enhance the performance of GraSAME. Excluding either element results in a decrease in both BLEU and METEOR scores, with a marginally greater reduction observed upon the removal of bidirectional edges. This suggests that bidirectional edges are crucial for adequate message passing within the hierarchical graph structure.

Model	BLEU	METEOR	ROUGE	chrF++
Variation 1	60.62	46.57	71.03	74.67
Variation 2	60.07	46.01	70.17	74.08
GraSAME	65.55	48.38	74.55	77.34

Table 6: Results of model variations on *WebNLG unconstrained*. GraSAME = GraSAME-SAGE.

5.6 Model Variations

Considering the method of incorporating GNN into the self-attention layer, we introduce two additional variations of GraSAME, as visualized in Figure 4 of Appendix D. In Variation 1, the GNN generates graph embeddings to influence the vectors K and V, instead of Q. In Variation 2, we insert the GNN layer before the entire self-attention mechanism, which means the vectors K, V and Q are all derived from the graph embedding.

The results for the two variations are presented in Table 6. While Variation 1 outperforms Variation 2, both variations show a decrease in performance compared to the original GraSAME. This demonstrates that our proposed GraSAME is a valid and effective mechanism for encoding structural information.

6 Error Analysis

We illustrate three examples of generated text in Table 7. The first two examples have relatively short input texts, whereas the third example includes a longer and more complex input graph.

In the first and second examples, the text generated by T5 includes hallucinations not present in the input data. In contrast, GraSAME strictly adheres to facts conveyed by the input graphs. When handling more complex graph inputs, both T5 and GraSAME produce fluent and accurate text without introducing extraneous information. However, T5 makes a minor grammatical error with a preposition. This indicates that GraSAME effectively mitigates the issue of hallucinations, particularly with short and simple inputs. Moreover, for longer and more complex inputs, GraSAME demonstrates a superior understanding of the input structure, resulting in higher-quality text generation.

7 Conclusion

In this work, we introduce GraSAME, a novel graph-guided self-attention mechanism that enables PLMs to process token-level structural information. With GraSAME, PLMs are capable of

Model	Example
Input	translate graph to English: <$Graph$> <H> Iraq <R> language <T> Arabic
Reference	Iraq language is Arabic.
T5	Arabic is a language spoken in the country of Iraq. The country is a member of the United Nations.
GraSAME	Arabic is a language spoken in Iraq.
Input	translate graph to English: <$Graph$> <H> Madrid <R> country <T> Spain
Reference	Madrid is in the country of Spain.
T5	Madrid is a city in the country of Spain and is a popular tourist destination there.
GraSAME	Madrid is a city in the country of Spain.
Input	translate graph to English: <$Graph$> <H> Monocacy National Battlefield <R> location <T> Frederick County, Maryland <H> 14th New Jersey Volunteer Infantry Monument <R> established <T> "1907-07-11" <H> 14th New Jersey Volunteer Infantry Monument <R> country <T> "United States" <H> 14th New Jersey Volunteer Infantry Monument <R> category <T> Historic districts in the United States <H> 14th New Jersey Volunteer Infantry Monument <R> district <T> Monocacy National Battlefield <H> 14th New Jersey Volunteer Infantry Monument <R> state <T> "Maryland"
Reference	The 14th New Jersey Volunteer Infantry Monument is located on the Monocacy National Battlefield, Frederick County, Maryland. The monument was established in 1907-07-11 and is categorised as a historic district in the United States.
T5	The 14th New Jersey Volunteer Infantry Monument is located in the Monocacy National Battlefield, Frederick County, Maryland. It was established on 11 July 1907 and is categorised as a historic district in the United States.
GraSAME	The 14th New Jersey Volunteer Infantry Monument is located on the Monocacy National Battlefield in Frederick County, Maryland, United States. It was established on 11 July 1907 and is categorised as a historic district in the United States.

Table 7: Examples of text generated by T5-large and GraSAME-SAGE, with hallucinations highlighted in blue and other incorrect text marked in red.

handling text and graph input simultaneously. This approach facilitates seamless information flow between text and graph embeddings, eliminating the need for additional concatenation.

Evaluated on the KG-to-text generation task, GraSAME demonstrates performance comparable to SOTA models with significantly fewer trainable parameters. Through a detailed analysis of graph size and human evaluation, GraSAME demonstrates its enhanced ability to process more complex graph inputs and generate more accurate text. Moving forward, we aim to explore GraSAME's potential in encoding specific graph structures, like molecular graph (Edwards et al., 2022), in combination with large language models.

Limitation

Despite the effectiveness of our approach, we acknowledge several limitations in our work. Firstly, our method involves extracting a hierarchical graph structure from a linearized graph. While this structure facilitates efficient information exchange, it requires specific adjustments when applied to different datasets or tasks. Our goal is to combine the advantages of PLM and GNN, yet crafting a universal template that addresses all related tasks remains challenging.

Secondly, we observe that the training process of GraSAME is fast, but it tends to converge slower than the baseline model without GraSAME. This slower convergence is attributed to the GNN component of GraSAME not being pre-trained, necessitating additional training epochs for optimal interaction with the PLM.

Thirdly, our approach still incorporates the linearized graph as part of the input, which does not align with the pre-training process of PLMs typically conducted with plain text corpora in natural language. This misalignment could potentially lead to the forgetting of pre-trained knowledge. Addressing these limitations will be the focus of our future work.

Ethics Statement

This research was conducted in accordance with the ACM Code of Ethics. The datasets we used are publicly available (Gardent et al., 2017; Kim et al., 2023), and we only used them to evaluate our models. We are not responsible for any potentially erroneous statements within the datasets. Additionally, care should be taken with the potential issues of hallucination when using the baseline model T5 for text generation.

Acknowledgements

We want to thank the anonymous reviewers for their helpful comments. Also, we would like to thank our colleague Yindong Wang for the inspiration of the idea, and Ercong Nie for his feedback on this work.

A Hyperparameters

We present the hyperparameters for T5-large and GraSAME in Table 8. We train the model until the training process converges. To keep a fair comparison, we keep the hyperparameters as same as possible. The learning rate of GraSAME is set larger than it for T5, because GraSAME converges slower due to fewer trainable parameters. The models are trained with 4 NVIDIA A100-SXM4-40GB GPUs.[7]

Hyperparameter	**T5**	**GraSAME**
`learning_rate`	3e-5	5e-5
`optimizer`	Adam	Adam
`batch_size`	10	10
`max_sequence_length`	187	187
`max_target_length`	120	120
`num_beam_search`	3	3
`random_seed`	123	123

Table 8: Hyperparameters.

B Data Statistics

We report the statistics of WebNLG in Table 9, which is the original split in WebNLG version 2.1.

Dataset	Size		
	| Train |	| Dev |	| Test |
WebNLG U	12876	1619	1600
WebNLG C	12895	1594	1606

Table 9: The statistics of dataset. WebNLG U = *WebNLG unconstrained*, WebNLG C = *WebNLG constrained*.

C Impact of Graph Reconstruction Loss

To investigate how graph reconstruction loss affect the performance and to determine the optimal value of λ in Equation 10, we visualize the tuning process in Figure 3. We use GraSAME-SAGE and the validation set of the *WebNLG unconstrained* dataset. The identified best value for λ is 0.08.

D Visualization of the Model Variations

To provide a clearer understanding of the model variations, we visualize the internal structure of the self-attention layer for the two model variations in Figure 4.

---

[7] We noted that when employing Distributed Data Parallel (Li et al., 2020), there is a possibility of sample duplication on the GPU to achieve the desired batch size, which could potentially impact the test set results. Consequently, we conducted the model evaluation on the test set using a single GPU for accuracy.

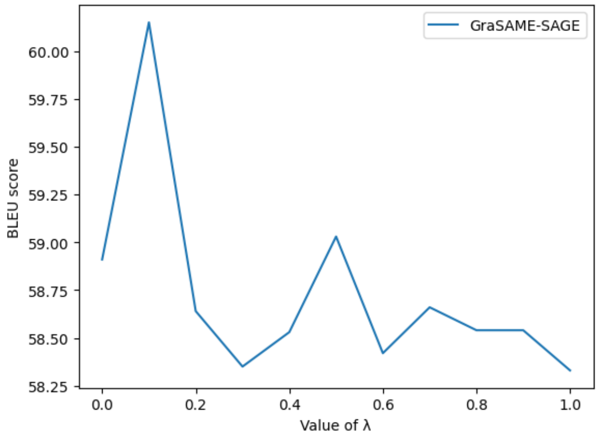

Figure 3: The impact of λ, experimented with GraSAME-SAGE on the validation set of *WebNLG unconstrained*.

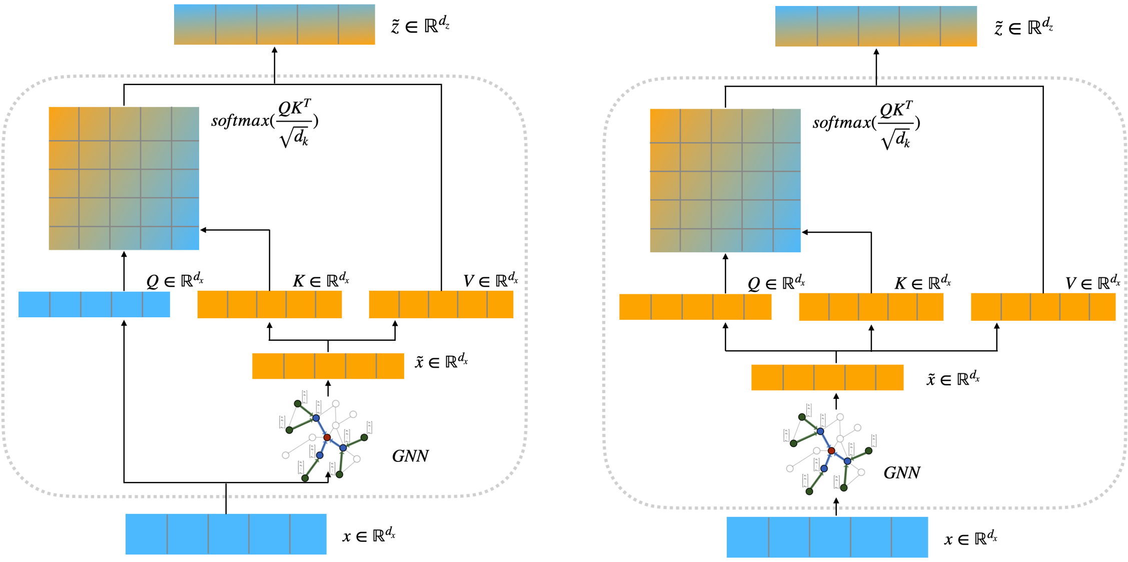

(a) Variation 1: The text embedding x is fed into a GNN along with the edge index derived from the hierarchical graph structure. This process generates a graph embedding $\tilde{x}$, which subsequently induces the K and V vector. The Q vector then interacts with K and V vector to produce a graph-aware representation $\tilde{z}$.

(b) Variation 2: The text embedding x is fed into a GNN along with the edge index derived from the hierarchical graph structure. This process generates a graph embedding $\tilde{x}$, which subsequently induces the Q, K and V vector.

Abstract

We study (differentially) private federated learning (FL) of language models. The language models in cross-device FL are relatively small, which can be trained with meaningful formal user-level differential privacy (DP) guarantees when massive parallelism in training is enabled by the participation of a moderate size of users. Recently, public data has been used to improve privacy-utility trade-offs for both large and small language models. In this work, we provide a systematic study of using large-scale public data and LLMs to help differentially private training of on-device FL models, and further improve the privacy-utility tradeoff by techniques of distillation. Moreover, we propose a novel distribution matching algorithm with theoretical grounding to sample public data close to private data distribution, which significantly improves the sample efficiency of (pre-)training on public data. The proposed method is efficient and effective for training private models by taking advantage of public data, especially for customized on-device architectures that do not have ready-to-use pre-trained models.

1 Introduction

Federated Learning (FL) (McMahan et al., 2017, 2018; Kairouz et al., 2019) is designed to collaboratively train a global model on decentralized data across user clients while protecting data privacy. FL emerged as an effective privacy-preserving solution of training (language) models, as rich text data are generated by users, which may contain sensitive and personal information. After McMahan et al. (2017) proposed to train on-device recurrent neural networks, FL has been widely used in various natural language processing applications and products, including next-word prediction (Hard et al., 2018), keyword spotting (Hard et al., 2020), and out-of-vocabulary word discovery (Chen et al., 2019).

To further protect user privacy, Differential Privacy (DP) (Dwork et al., 2006; Dwork, 2011; Dwork and Roth, 2014; McMahan et al., 2018) is introduced to provide formal privacy guarantees of models trained by federated learning. DP for deep learning explicitly adds random noise with bounded sensitivity to a training process (*e.g.*, DP-SGD (Abadi et al., 2016)), ensuring a quantifiable similarity in output model distributions when the training dataset changes. When combining DP with FL, a variant of DP-SGD called DP-FedAvg (McMahan et al., 2018)) is applied to guarantee user-level DP (Dwork, 2010). Current research primarily focuses on applying user-level DP to small on-device models with fewer than 10 million parameters (McMahan et al., 2018; Kairouz et al., 2021; Ramaswamy et al., 2020). The model size is limited due to challenges such as significant DP noise required to preserve privacy (Li et al., 2021) and the communication costs in cross-device FL.

Recent advances in large language models (LLMs) (Thoppilan et al., 2022; Radford et al., 2019; Brown et al., 2020; Devlin et al., 2019; Raffel et al., 2020) have revolutionized natural language processing (NLP) and achieved unprecedented performance on various tasks such as text generation, machine translation, and sentiment analysis. However, their success comes at a cost of requiring massive amounts of computational resources, making them difficult to deploy on resource-constrained devices such as smartphones, tablets, or other edge devices. Additionally, there are concerns regarding the user privacy in various aspects such as memorizing personal information in training, and exposing private query in inference.

Recent work explore incorporating public information to improve privacy-utility trade-off in applying DP for (large) LMs (Yu et al., 2022; Li et al.,

---

2021). Public data (Amid et al., 2021) or other side information (Li et al., 2022) are also studied for (DP) FL. In non-DP FL settings, Nguyen et al. (2022) studies the effect of initializing from a pre-trained model. However, it is an open question on *how to leverage the power of pre-trained LLMs to facilitate private FL for on-device LMs*.

In this work, we answer the question through systematic study aimed at enhancing private federated learning for on-device LMs with public pre-trained LMs. Specifically, Our approach involves leveraging both public data and pre-trained LLMs to improve differentially private federated learning for on-device models by techniques of public pre-training and distillation. Additionally, we propose a novel distribution matching algorithm, which is backed by theoretical analysis, to sample public data closely resembling the private data distribution, which significantly increases sample efficiency in public training. Moreover, our extensive empirical results align with our theoretical predictions, further substantiating our approach. Our work complements existing research by utilizing LLMs to improve public training through knowledge distillation for private cross-device federated learning, and achieve a strong privacy-utility trade-off with substantial improvements on sampling efficiency for public data. Our method points to a novel direction of efficiently enhancing private FL with public pretraining data and LLMs.

We summarize our **contributions** as follows:

- We focus on improving private federated learning for language modeling tasks and explore ways to leverage public data and pre-trained LLMs for tokenizers, training protocols, and data (sub)sampling.
- We conduct comprehensive studies and compare the use of Sentence Piece tokenizers from public LLM and unigram tokenizers from private corpus. We find that adopting public tokenizers from LLMs can not only prevent the potential privacy leakage from the private tokenizer vocabulary, but also lead to better learning utility with DP guarantees.
- For training protocol, we propose to leverage public LLM to teach private on-device LMs by knowledge distillation. We demonstrate that distilling public LLM to pre-train on-device LM can lead to more than 7% accuracy improvement with tight privacy bound ($\varepsilon = 1.77$). Moreover, it can achieve high data efficiency of using only 1% of the public data compared to that in public pre-training without LLM, and attain better accuracy.
- We further propose a novel distribution matching method that leverages both private on-device LMs and public LLMs to select public records close to private data distribution. We show that using 0.08% of carefully sampled public data to train on-device LM can lead to comparable performance as public pre-training on-device LMs with the whole pre-training corpus. Moreover, it reduces the public training time from more than one week to a few hours. Our method is grounded in theoretical analysis, which is corroborated by our extensive empirical results.

2 Differentially Private Federated Learning for On-device LMs

In this section, we walk through the preliminaries of differentially private federated learning of language models following the cross-device federated learning literature (McMahan et al., 2018; Kairouz et al., 2019, 2021). We also introduce the experimental setup used throughout this paper.

Cross-device Federated Learning. McMahan et al. (2017) introduce federated learning to collaboratively train LMs for next-word prediction from decentralized user data on a large number of mobile devices without directly sharing the private data. A common training algorithm of federated learning is `FedAvg` (McMahan et al., 2017), where each client downloads the current model from the centralized server, computes an update by performing local computation on their dataset (*e.g.*, running SGD) and sends the update back to the server. The server aggregates the updates across clients to update the global model and send the updated model back to local clients to achieve the goal of collaborative learning without directly accessing the training data on each user's mobile device.

In our experiments, we follow previous work (Kairouz et al., 2021; Amid et al., 2021; Wu et al., 2022) and sample 100 clients in each training round. Each client uses a batch size of 16 for local training. We set the training rounds $T = 1600$ in total.

User-level Differential Privacy. To further protect user privacy, Differential Privacy (DP) (Dwork et al., 2006; Dwork, 2011; Dwork and Roth, 2014) was introduced to provide a formal privacy guarantee for federated learning.

Definition 2.1 ((ε, δ)-Differential Privacy)**.** A randomized algorithm $\mathcal{M}$ with domain $\mathbb{N}^{|\mathcal{X}|}$ is (ε, δ)-differentially private if for all $\mathcal{S} \subseteq \mathrm{Range}(\mathcal{M})$ and for any adjacent datasets D and D':

$$\Pr[\mathcal{M}(D) \in \mathcal{S}] \le \exp(\varepsilon) \Pr[\mathcal{M}(D') \in \mathcal{S}] + \delta.$$

Definition 2.1 provides a formal definition of (ε, δ)-DP by bounding the change in output distribution caused by a small input difference (or, adjacent datasets) for a randomized algorithm. In the FL setting, it is preferable to bound the output distribution caused by different users in order to protect the privacy of each client's whole dataset. Specifically, adjacent datasets of D and D' for user-level differential privacy (Dwork, 2010) are defined as: D can be obtained from D' by adding or subtracting all the records of a single user/client, which determines the unit of privacy guarantees.

In our experiments, we use DP-FTRL (Kairouz et al., 2021) for privacy accounting and private federated training, which can achieve strong privacy guarantee in practical FL scenarios (Xu et al., 2023). We use $\delta = 10^{-6}$ and consider two ε bounds: a tight privacy bound with $\varepsilon = 1.77$ by using a large noise multiplier $m = 8.83$, and a slightly loose privacy bound with $\varepsilon = 18.71$ and noise multiplier $m = 1.13$. We present more hyperparameter tuning details in Appendix §C.

On-device LMs. Due to the limited memory constraints of mobile devices, on-device LMs are relatively small (usually less than 10M parameters). In our work, we focus on two types of on-device auto-regressive LMs: LSTM (Hochreiter and Schmidhuber, 1997) and transformers (Vaswani et al., 2017). More model details can be found in Appendix §B.2.

Pre-trained LLMs. In addition to the on-device LMs trained on private datasets, this work also assumes that we have access to LLMs pre-trained on a large public corpus to aid private learning. Specifically, we use LaMDA (Thoppilan et al., 2022) 2B throughout this work as an example, and conduct a systematic study of leveraging LLMs to help private training of on-device LMs.

Datasets. We focus on next word prediction task on the StackOverflow benchmark dataset (2019) for private federated learning. Since StackOverflow is naturally keyed by users, each client in FL is a user in the Stack Overflow online forum. The examples of a client are sentences of questions and answers posted by a specific user. We follow (Reddi et al., 2021; Kairouz et al., 2021) to construct a validation set of 10K samples, and a test set of 16.5M samples. Our evaluation metric is in-vocabulary next word (token) prediction accuracy, which is computed as the ratio of accurately predicted in-vocabulary words to the total number of words in the sequence (excluding OOV tokens).

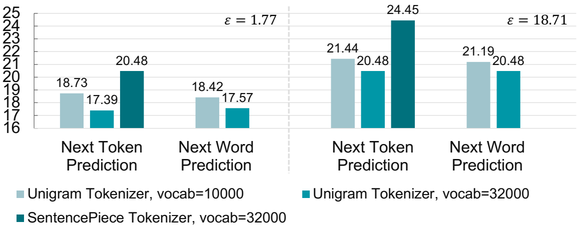

Figure 1: Next word (token) prediction accuracy for on-device LSTM with different tokenizers in the private FL.

In addition to StackOverflow as the (private) dataset, we use the realnews variant `c4/realnewslike` of C4 dataset (Raffel et al., 2020), as the public dataset. We analyzed the sources of the public C4 dataset and the Stackoverflow dataset for private training, and verified that there is no explicit overlap between public C4 dataset and the private StackOverflow dataset. More details can be found in Appendix §B.1.

3 Inspiration from LLMs

The success of publicly pre-trained LLMs motivate us to have retrospective views on further improving private on-device LMs. In this section, we explore inpiration from LLMs: the use of subword tokenizers and a large public corpus for pre-training. We apply them to on-device LMs, and observe that both techniques bring significant performance improvement for private FL.

3.1 Using Public Tokenizer from LLMs

Tokenizer is an important module of LMs, which transforms natural languages into a sequence of predefined symbol sets (vocabulary). Prior work in the literature of private FL of LMs (McMahan et al., 2018; Kairouz et al., 2021; Amid et al., 2021) use word-level unigram tokenizers potentially directly built from user data, which may need additional privacy budget (Ponomareva et al., 2022; Bagdasaryan et al., 2022).

Recent LLMs adopt sub-word tokenizers (Kudo and Richardson, 2018; Sennrich et al., 2016; Schuster and Nakajima, 2012), which mitigate most out-of-vocabulary (OOV) problems and yield state-of-the-art performance across different downstream tasks. This motivate us to replace the prior word-level unigram tokenizers with public sub-word tokenizers. Specifically, we use SentencePiece tokenizer (Kudo and Richardson, 2018) from LaMDA.

To conduct comparison between unigram tokenizers and subword tokenizers for next word (token) prediction task, we convert the next word prediction accuracy into next token prediction accuracy. This conversion is achieved through splitting each word using the SentencePiece tokenizer. We consider all tokens within a word as accurate if the predicted word is correct. We compare standard SentencePiece models (vocabulary size = $32K$) with unigram tokenizers that selects the top-k frequent words from user data with $k = 10K$ or $32K$ as vocabulary.

We present the private FL accuracy on the StackOverflow dataset in Figure 1. For the unigram tokenizer, using a larger vocabulary size in the DP setting can result in a slight performance drop, which can be different from the observation in non-DP settings (Charles et al., 2022; Xu et al., 2022a). It is possible that the parameter increase of the embedding layer enlarges the effect of DP noise and hurts the final accuracy. However, for next token prediction accuracy, although the public SentencePiece tokenizer from LaMDA also consists of $32K$ tokens, it can significantly improve the private FL accuracy upon the unigram tokenizers, especially with smaller DP noise and $\varepsilon = 18.71$. We also observe that SentencePiece tokenizer finds no OOV tokens in the StackOverflow dataset, thus yielding the same high prediction accuracy with or without the OOV token. Therefore, we use SentencePiece tokenizer in the rest of this paper.

3.2 Publicly pre-training for On-device LMs

In addition to the use of subword tokenizers, LLMs benefit from pre-training on a large public corpus (Li et al., 2022; Yu et al., 2022). In this section, we explore pre-training on-device LMs on public corpus to improve private federated learning.

Pre-training Details. We use the standard autoregressive language modeling loss $\mathcal{L}_{LM}$ to pre-train on-device LMs on the public C4 dataset, which takes around $1,400K$ steps (over a week of single GPU time) to process the entire dataset with the batch size of 512. We then use the publicly pre-trained checkpoint as the start point for private federated learning. We leave more details in §B.2.

Results. We present the next token prediction accuracy on the private StackOverflow dev set in Table 1. We observe that the accuracy on the private dataset significantly improves after pre-training for different different privacy budgets, shedding light on an effective way to boost private FL performance. We also observe that after pre-training, it gives reasonable zero-shot accuracy on the private dataset even without private training (round=0).

	w/o pre-training		w/ pre-training	
Rounds	0	1600	0	1600
$\varepsilon = 1.77$	0.00	20.48	16.94	27.27
$\varepsilon = 18.71$		24.45		30.13

Table 1: Next Token Prediction Accuracy on the private StackOverflow dev set with or without public pre-training.

4 Distillation from Public LLM

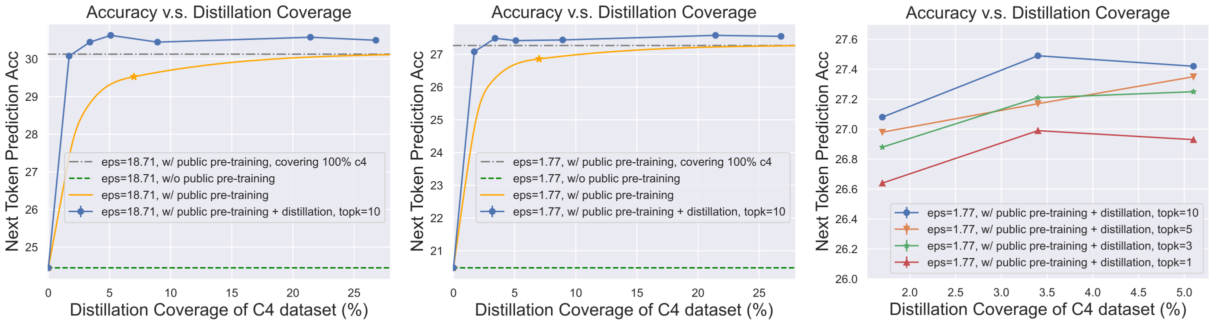
On one hand, the cost of public pre-training for on-device LMs is still expensive on a large public corpus (around a week of GPU time). On the other hand, existing LLMs are well pre-trained and demonstrate promising performance across a variety of downstream tasks. This motivates us to explore on whether we can leverage existing LLMs to improve the sample efficiency of pre-training on-device LMs. In this section, we answer the question above with systematic studies and show that we can improve the sample efficiency by using only 1% of pre-training data and distillation from LLMs, achieving similar or even better performance than using 100% of pretrianing data without distillation.

4.1 Distillation Design

Inspired by the literature of model compression (Sun et al., 2020; Jiao et al., 2019), we use knowledge distillation to transfer the knowledge from trained LLMs into on-device LMs during pre-training. The distillation pipeline contains the following two steps:

Building a distillation corpus. Given an input sequence from the public pre-training corpus, the LLM outputs the probability distribution over the vocabulary for next token prediction at each decoding step. To construct a distillation corpus, we save the top-k logits with k nonzero entries $\boldsymbol{z}_T$ from the teacher LLM as a silver-label dataset. In this way, the distillation corpus is model-agnostic, and thus can be applied to different variants of on-device LMs for pre-training. Moreover, selecting a reasonable top-k for the logits can both help compress the distillation corpus to a moderate size and filter out noisy signals from tokens with low output probabilities.

Public pre-training with distillation loss. Since we align the tokenizer of the on-device LM with the LLM to share the same vocabulary, we can



(a) Acc. v.s. distillation steps ($\varepsilon = 18.71$) (b) Acc. v.s. distillation steps ($\varepsilon = 1.77$) (c) Acc. v.s. top-k logits ($\varepsilon = 1.77$)

Figure 2: Ablation studies on how distillation steps and top-k logits in distillation impact next token prediction accuracy (Acc.) of on-device LSTM models on the dev set of the private StackOverflow dataset.

align the output distribution of on-device LMs and LLMs by the cross-entropy loss. Formally, for next token prediction task, given the output logits from student on-device LMs $\boldsymbol{z}_S$, the gold label from the pre-training corpus $\boldsymbol{y}$, and the logits from the distillation corpus of LLMs $\boldsymbol{z}_T$, we add an additional knowledge distillation loss $\mathcal{L}_{KD} = \mathrm{CE}(\boldsymbol{z}_S/t, \boldsymbol{z}_T/t)$ to the pre-training language modeling loss $\mathcal{L}_{LM} = \mathrm{CE}(\boldsymbol{z}_S, \boldsymbol{y})$ as our public pre-training loss $\mathcal{L}_{\text{pub}} = \mathcal{L}_{LM} + \beta\mathcal{L}_{KD}$ where t is the temperature. More distillation details are in §B.3.

4.2 Experimental Results

After public pre-training with knowledge distillation, We use the checkpoints at different pre-training steps as the start point for private federated learning. Our main results can be found in Table 2. We show that by using 1% C4 dataset for pre-training with knowlegde distillation, we can significantly improve the sample efficiency without hurting but even improving the private FL accuracy for both LSTM and transformers, when compared with public pre-training on the whole C4 dataset. The sample efficiency improvement thus reduces the pre-training cost from one week to around one day, shedding light on a promising direction to improve the efficiency and utility of private FL.

Ablation studies on distillation steps. To understand whether distillation for more epochs can help with private FL, we conduct a set of ablation studies on distillation steps given different privacy budgets as shown in Figure 2b and 2a. Specifically, we use the checkpoints at different distillation steps to initialize on-device LSTM and report the next word prediction accuracy after private FL at round 1600. We observe a consistent performance improvement when the distillation covers less than 5% of the C4 dataset. But when we pre-train the LM for more epochs, the improvement becomes marginal. This suggests that teaching on-device LMs via LLMs can converge quickly within a few iterations.

Abaltion studies on top-k logits. We take the top-k logits of the LLM to construct our distillation datasets and pre-train the on-device LMs. Here, we conduct an ablation study by pre-training different on-device LMs with different k and evaluate how top-k logits in distillation can impact the accuracy of private FL. We present our empirical results in Figure 2c and Appendix Figure 4. We observe that pre-training with a larger k is more helpful to achieve better downstream accuracy on private data. To have a reasonable trade-off between dataset size and pre-training performance, we use top-$k = 10$ in all the following experiments.

5 Distribution Matching

In the previous section, we achieve compelling performance by employing LLM distillation using only 1% of the *randomly sampled* pre-training corpus. Now we further investigate the possibility of improving sample efficiency by selectively identifying public samples that align with the distribution of private samples. To this end, we propose a novel distribution matching method to sample public records for pre-training with a novel theoretical analysis jointly considering public-private distribution shift and DP mechanism. We demonstrate that by carefully selected 0.08% of public samples, we can pre-train on-device LMs that perform as well as using 1% of public samples with distillation. This approach significantly improves sample efficiency, providing an additional knob of using public pre-training for private on-device models.

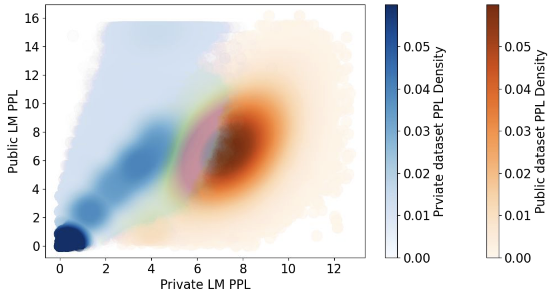


Figure 3: Visualization of PPL distribution of the private and public datasets evaluated by the private on-device LM and the public LLM. The private dataset exhibits a concentration of low PPL values, whereas the public corpus is dispersed across a broader range of PPL values, with a higher average PPL.

5.1 Algorithm

We hypothesize two principles to sample public records to match the private distribution: (i) the probability of the public sample x on the private data distribution $p_{\text{priv}}(x)$ is high, which can be approximated by the prediction of the on-device LMs trained on the private dataset; (ii) the probability of a public sample x on the public data distribution $p_{\text{pub}}(x)$ is also high, as we expect those samples are easy-to-learn (Swayamdipta et al., 2020) and of high data quality in the public corpus. The probability $p_{\text{pub}}(x)$ can be approximated by the public pre-trained LLMs.

To verify our hypothesis, we visualize the perplexity (PPL) distribution of public samples and private samples evaluated by both a privately fine-tuned on-device LM and a public pre-trained LLM in Figure 3. To have an "oracle" on-device LM that well captures the private data distribution, we fine-tune it on the private data without DP noise to overfit the private data distribution. We randomly sample 10k records from the public dataset and private dataset, respectively. We observe that the private dataset mostly concentrates on the regime with low PPL evaluated by the public and private LMs, whereas the public dataset is more diverse and distributed across a broader range of PPL values. The distribution visualization confirms our hypothesis to select public samples from the lower left corner, which correspond to samples with high probabilities $p_{\text{pub}}(x)$ and $p_{\text{priv}}(x)$ on public and private data distribution (*i.e.*, low perplexity evaluated by public and pirvate LMs).

In practice, we do not have an "oracle" on-device LM trained on private data for distribution match. Instead, we propose to fine-tune an on-device LM with DP for certain rounds $T' < T$ before consuming all the privacy budgets, and then use the checkpoint at round T' with DP guarantee to approximate $p_{\text{priv}}(x)$ and perform distribution matching to sample public records. This post-processing based on a DP checkpoint will not incur any additional privacy cost. Thereafter, we can use the sampled *public* records to further train the private checkpoint at round T', as a way for efficient public (pre-)training. Following the strategy in §4, we also employ the distillation loss to better train the on-device LM with carefully sampled public records to further enhance the sample efficiency. Lastly, we use the remaining privacy budgets to fine-tune the on-device LM until reaching round T, and evaluate its next token prediction accuracy at the dev and test sets. We term the paradigm of two-stage private learning combined with public training as "public mid-training". This approach differs from "public pre-training", which involves public pre-training prior to private FL. We present the distribution matching protocol in Algorithm 1.

Algorithm 1 Leveraging LLMs for distribution matching and public training in private federated learning.

Input: Public pre-training corpus D, private corpus D^*, sampling rate q, private fine-tuning rounds T, first-stage fine-tuning rounds $T' < T$ for distribution matching, a public pre-trained LLM
Output: Private on-device LM with DP guarantee

```
Randomly initialize an on-device LM;
// ① First-stage private federated learning
Use DP-FTRL to train the on-device LM for rounds $T'$;
for each $x \in D$ do
    // ② Probability evaluation
    Compute the average (token) log prob $\log p_{\text{priv}}(x)$ given the privately fine-tuned LM at round $T'$;
    Compute the average (token) log prob $\log p_{\text{pub}}(x)$ given a publicly pre-trained LLM ;
end for
// ③ Distribtion matching
Sort $D$ based on $\log p_{\text{priv}}(x) + \log p_{\text{pub}}(x)$
Sample a subset of $D$ as $D'$ with top $\log p_{\text{priv}}(x) + \log p_{\text{pub}}(x)$ values, such that $|D'| = q|D|$.
// ④ Public mid-training with LLM distillation
Train the on-device LM with the loss $\mathcal{L}_{\text{pub}}$ on $D'$
// ⑤ Second-stage private federated learning
Use DP-FTRL to train the on-device LM for the remaining rounds of $T - T'$
return On-device LM with DP guarantee
```

5.2 Theoretical Analysis

In this section, we provide the theoretical analysis of our distribution matching protocol to present the *intuition* behind our selection hypothesis. In essence, the goal of our distribution matching algorithm is to have a good estimator for the private distribution. However, characterizing the distribution shift in the context of differential privacy is a challenging problem, in that the private models are trained with DP noise, which can yield an inac-

	q (% of Public Data)	LLM Distillation	Distribution Matching	Accuracy (LSTM)		Accuracy (Transformer)

curate estimation of private data distribution, and thus add the complexity to our analysis.

Problem Setup. Define the text data domain as $\mathcal{X}$. Denote $\ell_{\text{pub}} : \mathcal{X} \to \mathbb{R}$ as the log-density function of the public data distribution (i.e., $\ell_{\text{pub}}(x) = \log p_{\text{pub}}(x)$ where $p_{\text{pub}}(x)$ is the public data density estimated by public LLMs), and ℓ_{priv} as the *accurate* log-density function of the private data distribution (i.e., $\ell_{\text{priv}}(x) = \log p_{\text{true priv}}(x)$ where $p_{\text{true priv}}(x)$ is the true private data density). However, due to limited private data sampled from the true private data distribution and DP noise injected in the private FL, we can only obtain an inaccurate estimation $\hat{\ell}_{\text{priv}} = \log p_{\text{priv}}(x)$ of the true private log-density ℓ_{priv}, where $p_{\text{priv}}(x)$ is the private data density estimated by private on-device LMs. Note that we use the hat notation $\hat{\ell}_{\text{priv}}$ to denote that it is an estimation of the true private log-density ℓ_{priv}.

We can view the estimation $\hat{\ell}_{\text{priv}}$ is a random variable where the randomness comes from: (i) that the private dataset we have is sampled from the private data distribution; and (ii) the randomness in the algorithm of obtaining $\hat{\ell}_{\text{priv}}$ based on the private dataset, e.g., differential privacy. Following previous work (Jiang et al., 2023), we make a standard assumption. We assume the estimated private data log-density function is an unbiased estimator, i.e., $\mathbb{E}[\hat{\ell}_{\text{priv}}] = \ell_{\text{priv}}$. Since ℓ_{pub} may not be ideal because of public-private domain shift, and $\hat{\ell}_{\text{priv}}$ may mot be ideal because of its DP noise, ℓ_{pub} and $\hat{\ell}_{\text{priv}}$ are neither good estimators for ℓ_{priv}. *Can we leverage both of the information and form a function $\hat{h} : \mathcal{X} \to \mathbb{R}$ that combines ℓ_{pub} and $\hat{\ell}_{priv}$ such that $\hat{h}$ is a good estimator for ℓ_{priv}?* In the following analysis, we choose $\hat{h} = \frac{1}{2}\ell_{\text{pub}} + \frac{1}{2}\hat{\ell}_{\text{priv}}$ and analyze when and why it can be a better estimator to the true private log-density ℓ_{priv} than ℓ_{pub} and $\hat{\ell}_{\text{priv}}$.

We need some mathematical tools to define what does it mean to be "better". Concretely, we need a metric to measure the distance between functions. This can be done by having an inner product $\langle \cdot, \cdot \rangle$ in the function space of $\mathcal{H} = \{f : \mathcal{X} \to \mathbb{R}\}$, and hence the norm in the function space $\mathcal{H}$ is $\|f\| = \sqrt{\langle f, f \rangle}$ for $\forall f \in \mathcal{H}$. Our analysis holds with *any* choice of the inner product as long as it does not make the log-densities norm infinite. We discuss a concrete choice of the inner product and its relation to the KL divergence in Appendix §D.

With the norm as a "ruler", we are able to define the following key quantities that formally characterize the setting.

1. **Public-Private Domain Distance.** Let $d_{\text{pub, priv}} = \|\ell_{\text{pub}} - \ell_{\text{priv}}\|$ denote the distance between the public data log-density ℓ_{pub} and the true private log-density ℓ_{priv}.
2. **Private Domain Randomness.** Let $\sigma^2_{\text{priv}} = \mathbb{E}[\|\hat{\ell}_{\text{priv}} - \ell_{\text{priv}}\|^2]$ denote the randomness of the estimated private log-density, i.e., the quality of the estimated private log-density $\hat{\ell}_{\text{priv}}$

The above definitions are important because the quality of a private log-density estimator would depend on the public-private domain shift and the private domain randomness as we show next.

Theorem 5.1. Let $\epsilon(\hat{f}) = \mathbb{E}[\|\hat{f} - \ell_{\text{priv}}\|^2]$ characterise how good $\hat{f}$ is as an estimator of the true private data log-density ℓ_{priv} for any random function $\hat{f} \in \mathcal{H}$. Consider the following three quantities:

1. $\epsilon(\ell_{\text{pub}})$ characterizing the error of the public log-density function ℓ_{pub} to approximate ℓ_{priv}
2. $\epsilon(\hat{\ell}_{\text{priv}})$ depicting the error of the noisy private log-density function $\hat{\ell}_{\text{priv}}$ to approximate ℓ_{priv}
3. $\epsilon(\hat{h})$ characterizing the error of $\hat{h} = \frac{1}{2}\ell_{\text{pub}} + \frac{1}{2}\hat{\ell}_{\text{priv}}$ to approximate ℓ_{priv}.

Then,

$$\epsilon(\ell_{\text{pub}}) = d^2_{\text{pub, priv}} \tag{1}$$

$$\epsilon(\hat{\ell}_{\text{priv}}) = \sigma^2_{\text{priv}} \tag{2}$$

$$\epsilon(\hat{h}) = \frac{1}{4} d^2_{\text{pub, priv}} + \frac{1}{4}\sigma^2_{\text{priv}} \tag{3}$$

Interpretation Theorem 5.1 implies that:

- $\epsilon(\hat{h}) \leq \frac{1}{2}\max\{\epsilon(\ell_{\text{pub}}), \epsilon(\hat{\ell}_{\text{priv}})\}$.

	LSTM		Transformer	
	ε=1.77	ε=18.71	ε=1.77	ε=18.71
w/ $p_{\text{pub}}(x)$	**28.01**$_{\pm 0.08}$	**30.63**$_{\pm 0.02}$	**27.17**$_{\pm 0.03}$	29.83$_{\pm 0.01}$
w/o $p_{\text{pub}}(x)$	27.77$_{\pm 0.05}$	30.56$_{\pm 0.06}$	26.70$_{\pm 0.04}$	**30.18**$_{\pm 0.05}$

Table 3: Ablation studies on the use of public LLM for distribution matching evaluated on the StackOverflow test set.

- $\epsilon(\hat{h}) \leq \min\{\epsilon(\ell_{\text{pub}}), \epsilon(\hat{\ell}_{\text{priv}})\}$ if $\frac{1}{3} \leq \frac{d^2_{\text{pub, priv}}}{\sigma^2_{\text{priv}}} \leq 3$.

Combining the above, we have the following conclusion: recall $\hat{h} = \frac{1}{2}\ell_{\text{pub}} + \frac{1}{2}\hat{\ell}_{\text{priv}} = \frac{1}{2}\log(p_{\text{pub}}(x)p_{\text{priv}}(x))$. We can expect that $\hat{h}$ is better than either ℓ_{pub} or $\hat{\ell}_{\text{priv}}$ for any settings. Moreover, we can expect $\hat{h}$ to be better than both ℓ_{pub} and $\hat{\ell}_{\text{priv}}$ if (i) there is a domain shift between the public-private domain; and (ii) our estimated private log-density $\hat{\ell}_{\text{priv}}$ is noisy in an extent comparable to the domain shift. We leave the full proof and additional discussion in Appendix D.

5.3 Experimental Results

Experimental Setup. We set $T' = T/2 = 800$ rounds for the first-stage private federated learning. We use $q = 0.08\%$ of the whole pre-training corpus for public training, which reduces the public training time from more than 1 weeks to a few hours with a single GPU. For the public mid-training setting, we also evaluate how LLM distillation and distribution matching can impact the private FL accuracy, respectively. We run all the experimental settings for three times and report the average and standard deviation of test accuracy on the private StackOverflow dataset.

We present the results of on-device LSTM and transformers in Table 2. In the pre-training setting ($T' = 0$), we show that we cannot further improve the sample efficiency from 1% to 0.08% with LLM distillation improves the sample efficiency, as the final accuracy after private FL significantly decreases. In comparison, in the mid-training setting ($T' = T/2$), using LLM distillation on the 0.08% of randomly sampled pre-training corpus already gives better performance than pre-training. Moreover, with distribution matching to carefully sample public data, we further improve the private FL accuracy, attaining comparable performance to the setting using the whole public corpus for pre-training.

Ablation studies on $p_{\text{pub}}(x)$. Our distribution matching algorithm leverages both on-device LM and LLM to sample data close to the private distribution. To understand how the use of LLM ($p_{\text{pub}}(x)$) impact the sampling quality, we conduct an ablation study to sample a subset of D' based on top $\log p_{\text{priv}}(x)$ values alone instead of $\log p_{\text{priv}}(x) + \log p_{\text{pub}}(x)$. We use the p_{priv}-sampled D' for public mid-training and report the test accuracy of three runs for both on-device LSTM and transformers given different privacy budgets in Table 3. The experimental findings corroborate our theoretical analysis. Specifically, when on-device language models (LMs) are trained with high noise levels ($\varepsilon = 1.77$), we find that a combined utilization of both on-device LMs and LLMs consistently yields superior performance. This is because the estimated private log-density $\hat{\ell}_{\text{priv}}$ is noisy to a degree comparable to the domain shift, making $\hat{h}$ a more reliable estimator than $\hat{\ell}_{\text{priv}}$. Conversely, when on-device LMs are trained with low noise ($\varepsilon = 18.71$), the performance difference between models with and without p_{pub} is negligible. This indicates that the noise introduced by differentially private (DP) training is not as significant as the distribution shift, allowing $\hat{\ell}_{\text{priv}}$ to serve as a good estimator.

T'	0	400	800	1200	1600
ε=1.77	25.41	27.08	**27.73**	26.40	18.40
ε=18.71	28.38	30.07	**30.37**	29.45	19.34

Table 4: Ablation studies on the timing (T') of distribution matching for mid-point public training on on-device LSTM evaluated the StackOverflow dev set.

Ablation studies on T'. T' separates two-stage private federated learning and determines the timing for distribution matching and public training. In this ablation study, we evaluate the dev set accuracy of on-device LSTM given different T' and privacy budgets, as shown in Table 4 and Appendix Table 5. From the table, we can see that the on-device LSTM achieves the best private FL accuracy given $T' = T/2 = 800$. We think the reasons are as follows: when $T' = 0$, we cannot perform distribution matching as the on-device LM is not trained on the private dataset yet, and thus we can only use the randomly sampled data for pre-training; when $T' = 400$, the on-device LM could not be well trained on the private data distribution, thus yielding worse distribution matching quality; when $T' = 1200$ and $T' = 1600$, the private on-device LM is biased towards the public data distribution due to public training, thus giving worse private FL accuracy. As a result, we use $T' = 800$ in our main experiments, as it balances the private federated training and public training to have satisfactory distribution matching capabilities without biasing too much towards the public data distribution.

6 Conclusion

In this work, we propose to improve private federated learning by using LLMs in public training. We leverage LLMs to aid public training of on-device LMs via distribution matching to sample public data close to private data distribution, which further improves the effectiveness and efficiency of public training, demonstrating strong private learning accuracy while minimizing the need for large amounts of public training data. Our work sheds light on a promising direction to improve private federated learning with public LLMs.

Sloan Fellowship.

Limitations

This work has paved the way for enhancing the utility of differentially private on-device FL models, using large-scale public data and LLMs, but we also acknowledge the following limitations:

- **Data Distribution Matching**: The proposed distribution matching algorithm aims to sample public data close to the private data distribution. The choice of $\hat{h}$ can be data dependent and a weighted combination of ℓ_{pub} and $\hat{\ell}_{\text{priv}}$, *i.e.*, $\hat{h} = (1-\beta)\ell_{\text{pub}} + \beta\hat{\ell}_{\text{priv}}$ where $\beta \in [0,1]$, as mentioned in Appendix §D.3. In practice, the optimal β can be an important hyper-parameter to tune the distribution matching algorithm. Our work mainly leverages $\hat{h} = \frac{1}{2}\ell_{\text{pub}} + \frac{1}{2}\hat{\ell}_{\text{priv}}$ to analyze when and why a better estimator to the true private log-density ℓ_{priv} than ℓ_{pub} and $\hat{\ell}_{\text{priv}}$. We leave it as important future direction to get the optimal β theoretically and empirically.
- **Computational Resources**: The use of large-scale public data and LLMs can improve the privacy-utility trade-off in DP FL models, but this often comes at the cost of computational resources. Our work mainly focuses on LaMDA 2B as an example of LLM due to the lack of computational resources. While our main focus does not lie in the knowledge distillation, we leave it as future work to extend the size of LLMs in public pre-training.

A Additional Related Work

Private Federated Learning in On-device NLP Federated learning is designed to collaboratively training NLP models without sharing sensitive user data to protect user privacy. Given relatively small model sizes, state-of-the-art differentially private (DP) learning algorithms (McMahan et al., 2018; Kairouz et al., 2021) have enabled on-device LMs to achieve strong downstream task utility with reasonable user-level differentially privacy guarantee (Dwork, 2010). The success of private FL has also led to real-world applications such as GBoard, which uses on-device LMs for next word prediction (Hard et al., 2018; Ramaswamy et al., 2020). Recent advances in DP optimization (Kairouz et al., 2021) further improves upon the state-of-the-art DP-SGD algorithm (Abadi et al., 2016), providing a practical tool to analyze privacy bound for federated learning.

Privacy-preserving Large NLP Models Scaling up LMs with more data and parameters has significantly improved performance and achieved great success in a variety of NLP tasks. Moreover, recent studies show that LLM has great potential in private learning. For example, Kerrigan et al. (2020) show that public pre-training is helpful for downstream DP fine-tuning. Follow-up studies argue that large pre-trained LMs can be strong differentially private learners with parameter-efficient fine-tuning (Yu et al., 2022; Bu et al., 2022) or full model fine-tuning (Li et al., 2021), narrowing the gap between non-private training and private training. Ganesh et al. (2023) also provide theoretical groundings on the necessity of involving public training into private learning. Motivated by the recent success of LLMs, our work performs comprehensive studies on how to use public data and existing LLMs to help private training of cross-device FL models.

Model Compression for Pre-trained LMs One promising approach to address the resource limitations of LLMs is to compress them into smaller models through various techniques such as knowledge distillation (Jiao et al., 2019; Sun et al., 2020; Wang et al., 2020), or pruning (Elbayad et al., 2020; Gordon et al., 2020). While these techniques have demonstrated success in reducing the size of pre-trained LMs, most resulting models are still too large (with over 10 million parameters) to be effectively deployed on resource-constrained devices. In our work, we also explore the use of knowledge distillation in public training, but with a primary focus on leveraging LLMs to improve sample efficiency in pre-training on-device LMs. We aim to improve the private FL performance of on-device LMs while minimizing the need for large amounts of training data. We recognize that private federated learning can further benefit from advanced model compression techniques, and we leave this as a promising and orthogonal future direction for research in this area.

B Experimental Setup Details

B.1 Verification of Non-overlap between C4 and StackOverflow Datasets

StackOverflow contains 342K clients for training with 135.8M examples. In this section, we detail the method used to verify that there is no explicit overlap between the public C4 dataset and the private StackOverflow dataset utilized in our study.

We explored C4 which has multiple variants[1]: `c4/en, c4/realnewslike, and c4/webtextlike`.

To verify this hypothesis, we conducted a rigorous comparison of these two datasets and its variants. Specifically, we compared the unique identifiers (e.g., URL for webpages in the C4 dataset, and post ID for StackOverflow posts) between the two datasets.

No matching identifiers were found between the `c4/realnewslike` and the StackOverflow dataset. Thus we use the `c4/realnewslike` variant as our public pretraining corpus throughout the experiment.

Through this comprehensive comparison, we have confirmed that there is no explicit overlap between the public C4 dataset and the private StackOverflow dataset. This conclusion is critical to our study as it ensures that the integrity and privacy-preserving conditions of our experiment are maintained.

---

B.2 Pretraining Details

In this section, we outline the detailed procedures followed during the pretraining phase of our experiments. The pretraining phase consisted of the following steps:

1. **Data Preparation:** We tokenized both the C4 and StackOverflow datasets using the SentencePiece tokenizer, as described in the main text. The vocabulary size was set to $32K$ for both datasets.
2. **Model Architecture:** We follow previous work (Wang et al., 2021; Amid et al., 2021; Kairouz et al., 2021; Wu et al., 2022) and use one-layer LSTM and transformer. Both LSTM and transformer has a hidden size of 670 and embedding size of 96.
3. **Training Procedure:** We trained the model using a standard autoregressive LM loss for next token prediction.
4. **Training Hyperparameters:** We employed the Adam optimizer with a learning rate of 1e-3, a batch size of 512, and a maximum sequence length of 20 tokens. We also used gradient clipping to prevent exploding gradients. The model was pretrained for $1400K$ steps on the C4 dataset to cover the whole C4 pretraining corpus.

After pretraining, the model was then fine-tuned on the downstream task using federated learning with differential privacy. Further details regarding the fine-tuning process can be found in the relevant sections of the main text. We show that the pretraining procedure can significantly improve the model's robust performance in the downstream task performance.

B.3 Distillation Details

In this section, we delineate the specifics of our distillation process during the pretraining phase of our on-device LM. The pretraining procedure with distillation is mostly the same as details outlined in B.2 with slight hyper-parameter differences.

We set the temparature $t = 1$ and top-$k = 10$ to extract the logits $\boldsymbol{z}_T$ from teacher LLM. We use grid search to tune the best hyper-parameter $\beta \in \{1e-1, 1e-2, 1e-3\}$ and follow the same pre-training schedules as §3.2 but with a smaller batch size of 128 due to memory constraints.

C Additional Experimental Results

Hyper-parameter Tuning for Federated Learning Federated learning involves numerous hyperparameters, which is crucial for our experiment. Our hyper-parameter tuning strategy follows Xu et al. (2022b).

Throughout our experiments, we fix the number of total rounds $T = 1600$. In each round, we select 100 clients from the shuffled pool for DP-FTRL, ensuring that the clients are disjoint across rounds. Within each client, we fix the number of local epochs to one and set the batch size to 16. We also impose a constraint on the maximum number of samples on each client, limiting it to 256.

We tune the server learning rate, client learning rate and clip norm for a certain given a noise multiplier. Specifically, we use grid search and tune the server learning rate from $\{0.05, 0.1, 0.2, 0.5, 1, 2\}$, the client learning rate from $\{0.01, 0.02, 0.05, 0.1, 0.2, 0.5\}$. We use the adaptive clipping technique in (Andrew et al., 2021; Xu et al., 2023) to help determine the clip norm, which in most of our experiments falls into $\{0.1, 0.3, 0.4, 1\}$.

Abaltion studies on top-k logits We take the top-k logits of the LLM to construct our distillation datasets and pre-train the on-device LMs. Here, we conduct an ablation study by pre-training different on-device LMs with different k and evaluate how top-k logits in distillation can impact the accuracy of private FL. We present our empirical results in Figure 2c and Appendix Figure 4. We observe that pre-training with a larger k is more helpful to achieve better downstream accuracy on private data. To have a reasonable trade-off between dataset size and pre-training performance, we use top-$k = 10$ in all the following experiments.

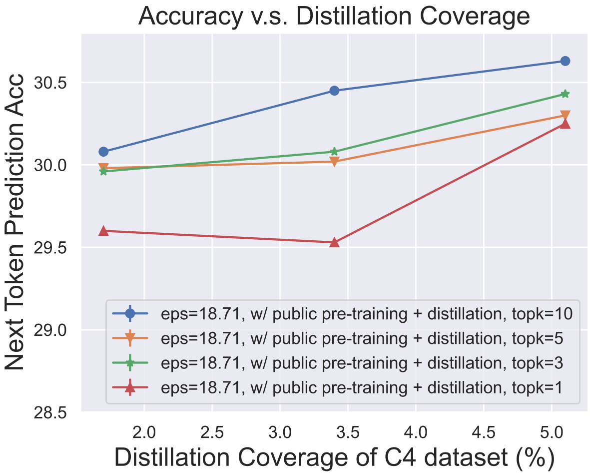

Figure 4: Ablation studies on how distillation steps and top-k logits in distillation impact next token prediction accuracy (Acc.) of on-device LSTM models on the private StackOverflow dataset.

Ablation studies on the timing T' for mid-training T' separates two-stage private federated learning and determines the timing for distribution matching and public training. In this ablation study, we evaluate the dev set accuracy of on-device LSTM given different T' and privacy budgets, as shown in Table 4 and Appendix Table 5. From the table, we can see that the on-device LSTM achieves the best private FL accuracy given $T' = T/2 = 800$. We think the reasons are as follows: when $T' = 0$, we cannot perform distribution matching as the on-device LM is not trained on the private dataset yet, and thus we can only use the randomly sampled data for pre-training; when $T' = 400$, the on-device LM could not be well trained on the private data distribution, thus yielding worse distribution matching quality; when $T' = 1200$ and $T' = 1600$, the private on-device LM is biased towards the public data distribution due to public training, thus giving worse private FL accuracy. As a result, we use $T' = 800$ in our main experiments, as it balances the private federated training and public training to have satisfactory distribution matching capabilities without biasing too much towards the public data distribution.

T'	0	400	800	1200
ε=1.77	25.41	26.43	**26.73**	25.20
ε=18.71	28.38	29.55	**29.70**	28.93

Table 5: Ablation studies on the timing (T') of mid-point public training for on-device LSTM w/o distribution matching.

D Detailed Theoretical Results

D.1 Discussion on the distance metrics of log-density functions

We need to define a meaningful distance metric in order to define the closeness of two log-density functions. To do this, we can choose any inner product $\langle \cdot, \cdot \rangle$ in the function space of $\mathcal{H} = \{f : \mathcal{X} \to \mathbb{R}\}$. Note that the log-density functions $\ell_{\text{pub}}, \ell_{\text{priv}}, \hat{\ell}_{\text{priv}} \in \mathcal{H}$. Accordingly, the norm in the function space $\mathcal{H}$ is denoted as $\| \cdot \|$ and by definition $\forall f \in \mathcal{H} : \|f\| = \sqrt{\langle f, f \rangle}$.

We note that our analysis works for **any** choice of the inner product as long as they don't make the log-densities norm infinite. For a concrete example, we discuss a generalization of the L^2 inner product, i.e., the L^π inner product where π is a distribution on $\mathcal{X}$.

Formally, for this example of $\mathcal{H} = L^\pi$ we define $\langle f, g \rangle_\pi = \mathbb{E}_{x\sim\pi}[f(x)g(x)]$ and $\|f\|_\pi = \sqrt{\mathbb{E}_{x\sim\pi}[f(x)^2]}$.

The L^π is a rather general definition that is common in the literature of Bayesian coresets (Zhang et al., 2021; Campbell and Broderick, 2019) and kernel machine (Rahimi and Recht, 2007). For example, it recovers L^2 if π is chosen to be the uniform distribution on $\mathcal{X}$.

Moreover, if we choose $\pi = p_{\text{priv}}$ as the private data density, we can show that for any probability density function p, the distance between $\log p$ and $\log p_{\text{priv}}$ measured by $L^{p_{\text{priv}}}$ norm upper bounds the KL divergence between p_{priv} and p:

$$\begin{aligned} \|\log p - \log p_{\text{priv}}\|_\pi^2 &= \mathbb{E}_{x\sim p_{\text{priv}}}[(\log p(x) - \log p_{\text{priv}}(x))^2] = \mathbb{E}_{x\sim p_{\text{priv}}}\left(\log \frac{p(x)}{p_{\text{priv}}(x)}\right)^2 \quad (4) \\ &\geq \left(\mathbb{E}_{x\sim p_{\text{priv}}} \log \frac{p(x)}{p_{\text{priv}}(x)}\right)^2 \quad \text{(Jensen's Inequality)} \\ &= (\texttt{KL}(p_{\text{priv}}|p))^2 \quad (5) \end{aligned}$$

In general, the distribution π characterize where in $\mathcal{X}$ we want to evaluate a function.

Above we discuss a concrete choice of the inner product and the accordingly the norm to measure the distance between log-density functions. Since our analysis will work with any choice of inner product, we return to using the notation of $\langle\cdot,\cdot\rangle$ and $\|\cdot\|$ to remain generality in our main result.

D.2 Proof

Theorem D.1 (Theorem 5.1 Restated)**.** Let $\epsilon(\hat{f}) = \mathbb{E}[\|\hat{f} - \ell_{\text{priv}}\|^2]$ characterise how good $\hat{f}$ is as an estimator of the true private data log-density ℓ_{priv} for any random function $\hat{f} \in \mathcal{H}$. Consider the following three quantities:

1. $\epsilon(\ell_{\text{pub}})$ that characterizes the error if we use the public log-density function ℓ_{pub} to approximate the ℓ_{priv}
2. $\epsilon(\hat{\ell}_{\text{priv}})$ that characterizes the error if we use the noisy private log-density function $\hat{\ell}_{\text{priv}}$ to approximate the ℓ_{priv}
3. $\epsilon(\hat{h})$ that characterizes the error if we use $\hat{h} = \frac{1}{2}\ell_{\text{pub}} + \frac{1}{2}\hat{\ell}_{\text{priv}}$ to approximate the ℓ_{priv}.

Then,

$$\epsilon(\ell_{\text{pub}}) = d^2_{\text{pub, priv}} \quad (6)$$

$$\epsilon(\hat{\ell}_{\text{priv}}) = \sigma^2_{\text{priv}} \quad (7)$$

$$\epsilon(\hat{h}) = \frac{1}{4}d^2_{\text{pub, priv}} + \frac{1}{4}\sigma^2_{\text{priv}} \quad (8)$$

Proof. We prove a general result which gives the theorem as special cases. For $\beta \in [0,1]$, define

$$\hat{f}_\beta = \beta\ell_{\text{pub}} + (1-\beta)\hat{\ell}_{\text{priv}}. \quad (9)$$

According to the definition of $\epsilon(\hat{f}_\beta) = \mathbb{E}[\|\hat{f}_\beta - \ell_{\text{priv}}\|^2]$, we have

$$\begin{aligned} \epsilon(\hat{f}_\beta) &= \mathbb{E}[\|\hat{f}_\beta - \ell_{\text{priv}}\|^2] = \mathbb{E}[\|\beta\ell_{\text{pub}} + (1-\beta)\hat{\ell}_{\text{priv}} - \ell_{\text{priv}}\|^2] \quad (10) \\ &= \mathbb{E}[\|\beta(\ell_{\text{pub}} - \ell_{\text{priv}}) + (1-\beta)(\hat{\ell}_{\text{priv}} - \ell_{\text{priv}})\|^2] \quad (11) \\ &= \beta^2\|\ell_{\text{pub}} - \ell_{\text{priv}}\|^2 + (1-\beta)^2\mathbb{E}\left[\|\hat{\ell}_{\text{priv}} - \ell_{\text{priv}}\|^2\right] + 2\beta(1-\beta)\mathbb{E}\left[\langle\ell_{\text{pub}} - \ell_{\text{priv}}, \hat{\ell}_{\text{priv}} - \ell_{\text{priv}}\rangle\right] \quad (12) \\ &= \beta^2 d^2_{\text{pub, priv}} + (1-\beta)^2\sigma^2_{\text{priv}} + 2\beta(1-\beta)\langle\ell_{\text{pub}} - \ell_{\text{priv}}, \mathbb{E}[\hat{\ell}_{\text{priv}}] - \ell_{\text{priv}}\rangle \quad (13) \\ &= \beta^2 d^2_{\text{pub, priv}} + (1-\beta)^2\sigma^2_{\text{priv}} + 0 \quad (14) \\ &= \beta^2 d^2_{\text{pub, priv}} + (1-\beta)^2\sigma^2_{\text{priv}} \quad (15) \end{aligned}$$

Therefore, we can see that the theorem stands as we substitute $\hat{f}_1 = \ell_{\text{pub}}$, $f_{\frac{1}{2}} = \hat{h}$, and $\hat{f}_0 = \hat{\ell}_{\text{priv}}$. $\square$

D.3 Extended Analysis

Note that in the previous subsection the $\hat{f}_\beta$ is a weighted combination of ℓ_{pub} and $\hat{\ell}_{\text{priv}}$, *i.e.*, $\hat{f}_\beta = (1-\beta)\ell_{\text{pub}} + \beta\hat{\ell}_{\text{priv}}$ where $\beta \in [0,1]$. Therefore, one can show that with the optimal weight $\beta^\star$, it is guaranteed that $\epsilon(\hat{f}_{\beta^\star}) \leq \min\{\epsilon(\ell_{\text{pub}}), \epsilon(\hat{\ell}_{\text{priv}})\}$.

This framework of analysis is general (as it stands with any meaningful inner product and its norm), and it may inspire even better ways to design estimators mitigating the domain shift and private model noise.

LangNav: Language as a Perceptual Representation for Navigation

Abstract

We explore the use of language as a perceptual representation for vision-and-language navigation (VLN), with a focus on low-data settings. Our approach uses off-the-shelf vision systems for image captioning and object detection to convert an agent's egocentric panoramic view at each time step into natural language descriptions. We then finetune a pretrained language model to select an action, based on the current view and the trajectory history, that would best fulfill the navigation instructions. In contrast to the standard setup which adapts a pretrained language model to work directly with continuous visual features from pretrained vision models, our approach instead uses (discrete) language as the perceptual representation. We explore several use cases of our language-based navigation (LangNav) approach on the R2R VLN benchmark: generating synthetic trajectories from a prompted language model (GPT-4) with which to finetune a smaller language model; domain transfer where we transfer a policy learned on one simulated environment (ALFRED) to another (more realistic) environment (R2R); and combining both vision- and language-based representations for VLN. Our approach is found to improve upon baselines that rely on visual features in settings where only a few expert trajectories (10-100) are available, demonstrating the potential of language as a perceptual representation for navigation.

1 Introduction

Applications of large language models (LMs) to non-linguistic embodied tasks have generally focused on using the implicit world knowledge within LMs to predict sub-tasks and actions for planning (Ahn et al., 2022; Huang et al., 2022b,a; Singh et al., 2022). For instance, recent work has shown that LMs can be prompted to create a list of actions (e.g., `GoToBathroom`, `LocateToothbrush`) given a high-level goal given in natural language (e.g., "brush teeth") (Huang et al., 2022a). These approaches rely on the LM's priors on action sequences and inter-object correlations acquired through large-scale pretraining (Zhou et al., 2023b; Li et al., 2023; Zhao et al., 2023), and it has not been clear whether text-only models can be finetuned for tasks such as vision-and-language navigation which requires an egocentric agent follow instructions to navigate a 3D environment using visual input.

To be clear, there *is* a substantial body of work on using pretrained LMs for vision-and-language navigation tasks (Hong et al., 2021; Qi et al., 2021; Qiao et al., 2022, *inter alia*). The standard approach is to use a pretrained LM over the natural language instructions to extract text features that are combined with the agent's perceptual representations, which are given by continuous image features extracted from pretrained vision models (Wang et al., 2019; Hao et al., 2020). While effective in data-rich regimes, the direct use of vision features makes the approach difficult to apply in cases where only a few labeled trajectories exist (e.g., 10 trajectories), as these approaches need to learn a full joint vision-language module that combines a pretrained vision model with a pretrained text model. A popular strategy in such low data regimes is to generate synthetic data or transfer knowledge from other domains. However, generating realistic perception data is itself a difficult task, and domain transfer with models that rely purely on visual features can overfit to the non-transferable features (Anderson et al., 2021).

This paper explores an alternative approach for vision-and-language navigation by exploiting language itself as the perceptual representation space. Our approach uses off-the-shelf vision models to obtain textual descriptions of the agent's egocentric panoramic view. The text descriptions are then fed to an LM which must select the next action given the instruction and (text descriptions of) the previous actions or observations. See Figure 1 for an overview. The use of language to represent an

"Go down the stairs and straight into the living room. In the living room walkout onto the patio. On the patio stop outside the doorway."

You are a navigation agent who must navigate according to instructions given only descriptions of your current position via natural language. The natural language description is sometimes incorrect.

Instruction: "Go down the stairs and straight into the living room. In the living room walkout onto the patio. On the patio stop outside the doorway."

[Trajectory History]

Step 4:
To your **straight ahead** is, **"a living room with a couch a table and chairs"**

To your **left** is, **"a modern kitchen with a stainless steel refrigerator"**

Behind you is, **"a long hallway with wooden steps leading to a black door"**

You go towards:

I should go towards: **"a living room with a couch a table and chairs"**

Figure 1: Overview of language-based navigation (LangNav). We describe the task instructions and visual observations (from off-the-shelf vision systems) through text. A language model is then finetuned to predict which direction to move towards based on the language descriptions. Here, views **A**, **B**, and **C** correspond to the front, left, and rear views of the agent.

agent's perceptual field makes it possible to readily utilize the myriad capabilities of language models, especially when the training data is limited. In our first case study, we show how we can use a small amount of seed training data (10-100 trajectories) to cheaply obtain synthetic "trajectories" from a powerful but closed-source LM (GPT-4; OpenAI, 2023). We find that finetuning a smaller language model (LLaMA/LLaMA2; Touvron et al., 2023a,b) on the generated trajectories mixed with the original seed data results in a langauge-based navigation agent that outperforms a vision-based agent that is finetuned on the same seed data. In our second study, we explore the use of language as a domain-invariant representation to perform domain transfer, where we transfer an agent trained on a computer-generated environment (ALFRED; Shridhar et al., 2020) to the real-world R2R (Anderson et al., 2018b) environment. Insofar as language is hypothesized to have co-evolved with the human brain to enable efficient communication (Deacon, 1997), it naturally abstracts away low-level perceptual details, and we indeed find that LangNav exhibits improved transfer compared to the vision-based agent. We further show that language can provide further benefits even in the presence of vision-based features. Our results collectively suggest that language as a perceptual representation can be helpful in the low-data navigation settings.

2 Background: Room-to-Room Vision-language Navigation

A popular testbed for vision-and-language navigation (VLN) is the room-to-room dataset (R2R; Anderson et al., 2018b), in which an agent must perceive and navigate a real-world 3D environment based on a language instruction U and an initial state S_0. At each time step t, the agent uses the current observation O_t, the original language instructions U, and the trajectory history H_t, to predict the panoramic action a_t. The current observation is given by a set of panoramic images that describe the agent's egocentric view, i.e., $O_t = \{I_{t,0}, ..., I_{t,V}\}$ where V corresponds to the number of discretized view angles.[1] The panoramic action a_t corresponds to which navigable view in O_t to go towards, i.e., $a_t \in O_t$. After selecting an action, the state transitions from S_t to S_{t+1}. The aim is to output the command `STOP` after reaching the goal G specified by U in state S_0.

The standard approach in R2R is to process the panoramic images $\{I_{t,0}, ..., I_{t,V}\}$ with a pretrained visual encoder E_v to extract continuous visual features $F_{t,v} = \{E_v(I_{t,0}), ..., E(I_{t,V})\}$. The language instruction is typically processed by a pretrained language encoder E_l (e.g., BERT (Devlin et al., 2019)) to extract the language features $F_l = E_l(U)$. These features, along with a hidden state representation of the trajectory history h_{t-1}, are fed to a joint vision-language module (e.g., another Transformer) that attends over $\{I_{t,0}, ..., I_{t,V}\}$ to select the action a_t.

3 Language as a Perceptual Representation for Navigation

We begin by describing the perception-to-text models employed for converting visual observations into text (§ 3.1). We then discuss the prompt templates for converting the text into natural language (§ 3.2), followed by a description of the offline imitation learning algorithm for learning (§ 3.3).

---

[1] In R2R this can be as many as 36 (12 headings and 3 elevations). However we follow previous works only consider the navigable views, which is often many fewer than 36.

3.1 Vision-to-text System

We use off-the-shelf vision models to convert visual observations into language descriptions. Specifically, we use an image captioning model (BLIP; Li et al., 2022a) and an object detection model (Deformable DETR; Zhu et al., 2020) over each view angle $I_{t,j}$ to obtain the text descriptions,

$$C_{t,j} = \textsc{ImageCaptioner}(I_{t,j}),$$
$$x_{t,j,0}, \dots, x_{t,j,M} = \textsc{ObjectDetector}(I_{t,j}),$$

where M is the number of detected objects.[2]

3.2 Prompt Templates

Figure 1 illustrates how the image caption and the detected objects are combined via templates to construct pieces of text on which to condition the language model. Based on the prompt template, the language model will be finetuned on the (language representations of) output actions $\{a_1, \dots, a_T\}$. We briefly describe the prompt template (see appendix G for a full example).

Task description D. The task description is given by:

```
You are a navigation agent who must
navigate according to instructions given
only descriptions of your current [...].
```

Navigation instruction U. The navigation instruction, which provides instructions to the agent on how to reach the goal, can be from R2R (our main dataset), synthesized by GPT-4 (for data augmentation), or ALFRED (for domain transfer). An example instruction from R2R is:

```
Travel forward past the wall with all
the light switches and into the first
room on your right.
```

Current observation O_t. We use templates to convert the image caption $C_{t,j}$ and objects obtained $x_{t,j,0}, \cdots, x_{t,j,M}$ from $I_{t,j}$ (§ 3.1). For instance, if the agent is facing a heading of 90 degrees and an elevation of 0 degrees and there is a candidate navigable direction $I_{t,j}$ located at a heading of 120 degrees and an elevation of 0 degrees, the text description for this view angle would be:

> To your 30 degree right is "$\{C_{t,j}\}$".
> Details: $\{x_{t,j,0}\}, \dots, \{x_{t,j,M}\}$.

We create such templates for all the navigable view angles $\{I_{t,0}, \dots, I_{t,V}\}$.

Action a_t. Selecting an action involves choosing a navigable view out of O_t to move towards, i.e., $a_t \in O_t$. For example, suppose $a_t = I_{t,j}$, i.e., the agent decided to go to the j-th view angle. Then this is recorded as:

> You go towards: "$\{C_{t,j}\}$"

To actually have the agent generate a_t we simply decode from an LM's distribution, $p_{\text{LM}}(\cdot \mid D, U, H_t, O_t)$, via greedy decoding. Here $H_t = \{O_i, a_i\}_{i=0}^{t-1}$ encodes the observation and action trajectory.[3]

Updating trajectory history H_t. We update the observation and action trajectory history via appending the text representations of O_t and a_t to H_t:

> Step $\{t\}$: To your {direction_1} is {caption_1}; To your {direction_2} is {caption_2}; [...]; You chose: {caption_of_selected_direction}.

This history serves to inform the model about its current position within the high-level instruction, enabling it to make more informed decisions when selecting actions.

3.3 Imitation Learning on Demonstrations

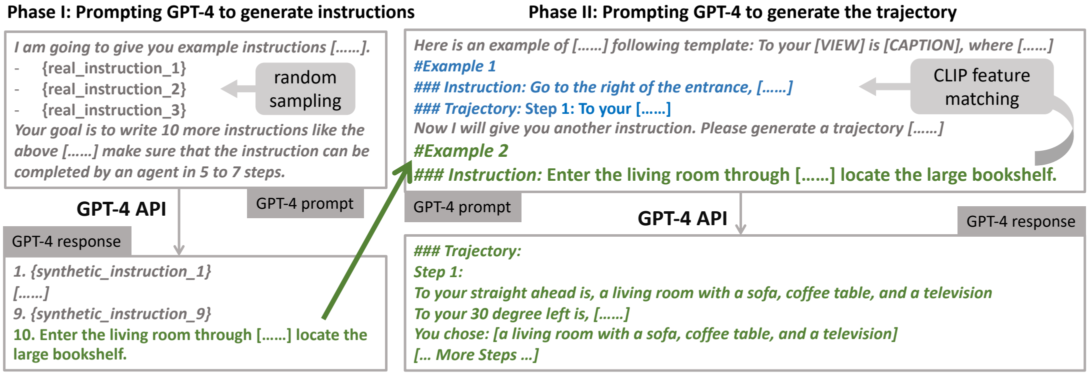
We create an instruction-following dataset by transforming the expert trajectory from the original dataset into instruction-following demonstrations. Formally, let $\mathcal{D} = \{W^{(i)}\}_{i=1}^{N}$ be the set of training trajectories, where each $W^{(i)}$ can be represented as a natural language sequence from the above template, $W^{(i)} = (D^{(i)}, U^{(i)}, H_1^{(i)}, O_1^{(i)}, a_1^{(i)}, \dots, H_{T^{(i)}}^{(i)}, O_{T^{(i)}}^{(i)}, a_{T^{(i)}}^{(i)})$. Here $T^{(i)}$ is the number of actions in the example $W^{(i)}$, which is typically between 5 to 7. Given the above, we optimize the log likelihood of the (language descriptions of) actions, i.e., the objective for trajectory $W^{(i)}$ is given by, $\sum_{t=1}^{T^{(i)}} \log p_{\text{LM}}(a_t^{(i)} \mid D^{(i)}, U^{(i)}, H_t^{(i)}, O_t^{(i)})$.

While behavior cloning on gold trajectories is simple, it is prone to error propagation. In particular, the history trajectory is obtained by a shortest-path algorithm (which has knowledge of the goal)

---

[2] We did not experiment much with different off-the-shelf vision systems and quickly converged on these two models which seemed to produce reasonable results. Since LangNav separates perception from navigation, we expect that advances made in perception (e.g., through better captioning systems) will automatically result in improvements to our system, which is a nontrivial advantage of our approach compared to systems that entangle perception and navigation into a single model.

[3] In general we found the finetuned LM to have no issue generating from the set of navigable directions (i.e., $\{C_{t,0}, \dots, C_{t,V}\}$) without constrained decoding.



```

```

Figure 2: Pipeline for generating synthetic navigation trajectories from GPT-4. We first prompt GPT-4 with 3 randomly sampled navigation instructions U to generate 10 more synthetic navigation instructions (Phase 1). Then for each generated navigation instruction, we prompt GPT-4 to generate the trajectory that fulfills the generated instruction (Phase 2). See appendix H for details.

and thus adheres closely to an optimal policy π^*. However, during prediction, trajectories can deviate significantly from the optimal policy, leading to a distribution shift that can adversely affect performance. To allow for the policy to recover from deviations from the optimal path, we adopt the following strategy to create our imitation learning dataset: (1) at each time step, we sample a random action with probability ρ; (2) once a random action is selected, we use the shortest-path algorithm to obtain the ground truth next action; (3) we repeat this process until the goal is reached; (4) once the goal is reached, this becomes part of the training demonstration data. (See appendix F for details.)

4 Empirical Study

Our primary experiments with LangNav target the low-data setting, motivated by the observation that obtaining annotated data for embodied tasks such as vision-language navigation can be very costly (often more so than is the case for text-only or vision-only tasks). Specifically, we are interested in learning the most performant system based on a small number (10 or 100) of in-domain seed navigation trajectories. We sample our seed trajectories from the Room-to-Room (R2R) dataset (Anderson et al., 2018b), a popular vision-and-language navigation dataset consisting of 21,567 navigation instructions in the Matterport3D environment. The dataset includes 90 scenes, with 61 scenes in the train and validation "seen" sets, and 11 scenes in the validation "unseen" set. Our 10-shot dataset is randomly sampled the train set within 1 scene, while our 100-shot dataset spans 2 scenes.

Evaluation. To contextualize our approach against prior work, we evaluate LangNav on both "seen" and "unseen" sets from R2R. The "seen" set contains scenes identical to the training set (but the instructions and trajectories differ). However, this distinction is less important for our low-data regime, since we only make use of 1 scene (for the 10-shot case) or 2 scenes (for the 100-shot case). I.e., the majority of scenes in the "seen" validation subset are actually never seen by the agent.

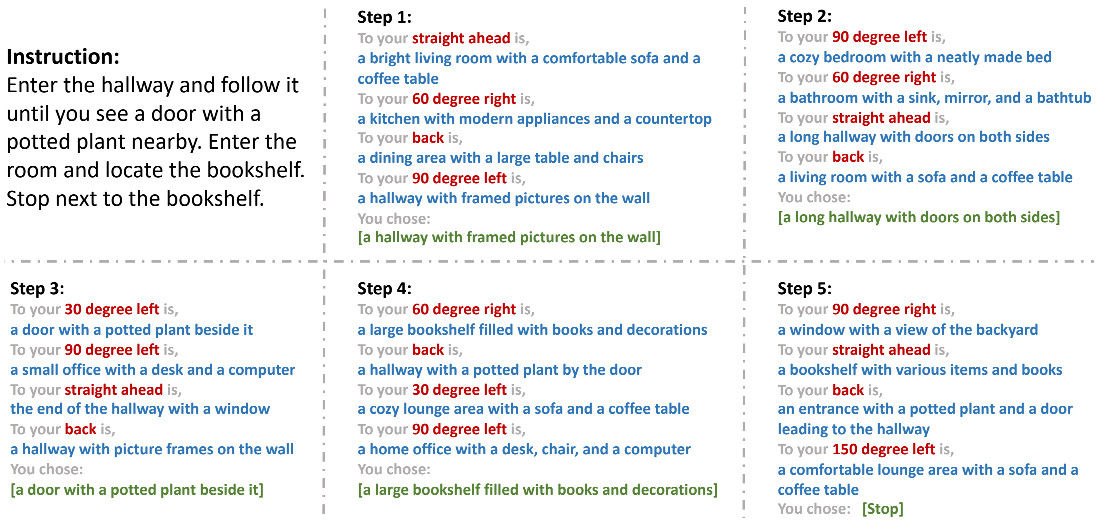
We use the standard R2R task performance metrics (Anderson et al., 2018a): *Navigation Error* (`NE`), the average distance between the agent's final position and the goal in meters; *Success Rate* (`SR`), the ratio of trajectories in which the agent stopped within 3 meters of the goal; *Oracle Success Rate* (`OSR`), the ratio of trajectories in which the agent stopped within 3 meters to the goal with a view of the goal; and *Success* weighted by the normalized inverse of the *Path Length* (`SPL`).

4.1 Case Study 1: Language Enables Efficient Synthetic Data Generation

In NLP, obtaining synthetic data from an appropriately prompted large LM with which to learn a smaller model has been shown to be an effective approach in data-scarce settings (Wang et al., 2021; Lang et al., 2022; Taori et al., 2023; Dai et al., 2023; Gunasekar et al., 2023, *inter alia*).[4] However, this approach is difficult to extend to non-linguistic perceptual tasks such as VLN since generating realistic perception data is itself difficult. In our first case study, we show that working in pure language space makes it possible to easily generate synthetic

---

[4] However see Gudibande et al. (2023) for a critical discussion of this approach.



Instruction:
Enter the hallway and follow it until you see a door with a potted plant nearby. Enter the room and locate the bookshelf. Stop next to the bookshelf.

Step 1:
To your straight ahead is,
a bright living room with a comfortable sofa and a coffee table
To your 60 degree right is,
a kitchen with modern appliances and a countertop
To your back is,
a dining area with a large table and chairs
To your 90 degree left is,
a hallway with framed pictures on the wall
You chose:
[a hallway with framed pictures on the wall]

Step 2:
To your 90 degree left is,
a cozy bedroom with a neatly made bed
To your 60 degree right is,
a bathroom with a sink, mirror, and a bathtub
To your straight ahead is,
a long hallway with doors on both sides
To your back is,
a living room with a sofa and a coffee table
You chose:
[a long hallway with doors on both sides]

Step 3:
To your 30 degree left is,
a door with a potted plant beside it
To your 90 degree left is,
a small office with a desk and a computer
To your straight ahead is,
the end of the hallway with a window
To your back is,
a hallway with picture frames on the wall
You chose:

Figure 3: An example of a generated trajectory from GPT-4. The example demonstrates a generated trajectory by following the pipeline in Figure 2. See more examples in appendix K.

data from a large LM based on a few seed trajectories. We further show that finetuning a smaller LM on a mixture of synthetic and R2R trajectories improves upon vision-based models.

Synthetic trajectory generation. We generate synthetic trajectories by using only the 10 R2R trajectories from a single scene. In R2R each trajectory has 3 navigation instructions given by 3 different annotators. Thus we have 30 navigation instructions $\{U^{(i)}\}_{i=1}^{30}$ in total. Our data generation pipeline can be divided into two phases. In phase 1, we randomly choose 3 R2R instructions as prompt examples and ask GPT-4 to create 10 more instructions similar to the examples, as shown in Figure 2. In phase 2, for each generated instruction, we prompt GPT-4 to generate a trajectory to fulfill the instruction, conditioned on a real demonstration instruction and trajectory. The real trajectory is obtained by selecting the trajectory whose instruction is closest to the synthetic instruction based on the CLIP (Radford et al., 2021) text features. See Figure 2 for an overview and appendix H for the prompts.[5]

We present an illustrative example in Figure 3 to demonstrate some qualitative characteristics of generated trajectories. We find that the generated trajectories have: *strong real-world priors*, i.e., they exhibit adherence to real-world room-object and object-object correlations, as evident from descriptions like "`a bathroom with a sink, mirror, [...]`"; *spatial consistency*, where the examples maintain spatial consistency within the generated trajectories—for instance, in `Step 4`, the generated position identifies the door with a potted plant, consistent with its position in `Step 3`; and *rich descriptions*—the generated trajectories have descriptive captions and objects that do not only relate to the given instruction, which makes it possible to successfully navigate through language only.

Experimental setup. We compare LangNav, which is a LLaMA2-7b model finetuned on a mixture of the 10,000 synthetic trajectories and 10/100 real trajectories, against the following baselines: *1. Random walk*, which selects a random action at each time step; *2. GPT-4 (Zero-shot / Few-shot)*, where we prompt GPT-4 to complete the trajectory by changing the task description of the template in § 3.2 (see appendix I for the full prompt). For the few-shot baseline, due to the context length we use one full navigation trajectory as a demonstration example; *3. NavGPT*, a recent work that also uses language as a perceptual representation (via image captioning and object detection) to perform navigation, but purely with GPT-4 (Zhou et al., 2023a); *4. RecBert*, a vision-based method that adopts a recurrent architecture proposed by Hong et al. (2021) to keep track of the trajectory history; *5. DuET*, another vision-based method which additionally builds representations of the global map during learning (Chen et al., 2022); and *6. LLaMA2-7B*, a

---

[5] We cannot entirely rule out the possibility that the GPT-4 training set included the text instructions seen in R2R. However, while the text instructions may have been encountered, the trajectories were unlikely to have been encountered during pretraining since we used vision systems to obtain the captions/objects. Out of the 10,000 generated instructions, we did not find any instructions that were in the actual R2R dataset.

2,000 + 2,000	GPT-4 + GPT-4-turbo	10 + 1000	7.1	43.2	32.6	28.3

Table 2: Performance on the R2R val unseen set as we vary the number of synthetically generated data, the underlying LM from which the synthetic data is generated, and number of seed scenes. Here the seed scenes refer to the scans from which trajectories are sampled, with multiple trajectories originating from each seed scene.

language-only baseline that does not make use of the synthetic data from GPT-4.

All finetuning methods use the same set of 10/100 trajectories. For these experiments, we did not find significant differences in performance when using the object detection module, and hence we only relied on the image captioning system to give the language description of each view angle in the prompt template. See appendix A for the training setup including hyperparameters.

Results. The results are shown in table 1. We find that our GPT-4 zero- and few-shot results underperform the NavGPT baseline despite using the same backbone model, potentially due to NavGPT's use of ground truth distance information and chain-of-thought prompting (Wei et al., 2022; Kojima et al., 2023). Just finetuning LLaMA2-7B on the 10/100 gold trajectories does not perform well, although it is comparable to the vision-based policies. Training on a mixture of synthetic and R2R trajectories improves performance by a nontrivial margin, and the LLaMA2-7B-based LangNav approaches the performance of NavGPT despite being many times smaller, indicating the effectiveness of our pipelined prompting strategy for distilling the rich navigation-relevant world knowledge within GPT-4 to a smaller (and more efficient) language model.[6]

Ablation study. In table 2 we vary both the number of synthetic trajectories and the data-generating LM. Switching the synthetic data source from GPT-4 to GPT-3.5/GPT-4-turbo results in noticeable declines, highlighting the importance of using a strong LM. Increasing the number of synthetic trajectories increases performance, although the gains are marginal when going from 2,000 to 10,000 trajectories. This is potentially due to the use of only

---

[6] While we still underperform NavGPT, the performance gap is relatively narrow—within 1% in terms of SPL. We observe that NavGPT employs object information filtered by a ground-truth depth map, limiting the data to objects within a 3-meter range. Such filtering is important to mitigate the redundancy and noise often associated with unfiltered object information (i.e., often too many irrelevant objects are detected). As highlighted in the NavGPT paper, this selective use of object information is important for achieving good performance.

Table 3: Domain transfer results where we pretrain a navigation agent on the simulated ALFRED environment (which uses rendered images) and finetune on the real-world R2R environment. We use LLaMA-7B (Touvron et al., 2023a) as our backbone model, and compare against the RecBert (Hong et al., 2021) baseline.

10 real trajectories from a single scene to prompt LLMs which results in lack of instruction diversity (see examples in appendix E). To investigate the influence of the scene diversity, we use 1,000 navigation instructions sampled from various R2R scenes to prompt GPT-4-turbo[7] to generate 2,000 additional synthetic trajectories. We can see that although the 2,000 trajectories generated by GPT-4-turbo are not of the same quality as those generated by GPT-4, scaling up using these trajectories outperforms the results from the 10,000-trajectory set.

4.2 Case Study 2: Language as a Bridge for Domain Transfer

We next experiment with using language as a domain-invariant representation space to transfer a policy that has been trained on a different (rendered) environment (ALFRED; Shridhar et al., 2020), to the real-world R2R environment. There are significant differences between ALFRED and R2R which makes straightforward domain transfer challenging. ALFRED uses images rendered from the synthetic AI2THOR environment (Kolve et al., 2017), while R2R, based on the Matterport3D, incorporates images captured from real indoor environments. ALFRED's navigation trajectories and instructions are also simpler and shorter compared to R2R's instructions: R2R instructions involve guiding the agent between rooms, whereas ALFRED trajectories mainly keep the agent within a single room and provides instructions for household tasks. Finally in ALFRED, the agent is limited to rotating left/right by 90° and moving forward, while in R2R, the agent can move in any combination of 12 candidate heading directions and 3 elevation directions. See appendix B for detailed discussion of these differences, and see appendix A for the experimental setup.

Results. We pretrain both RecBert (Hong et al., 2021)[8] and LangNav on the simulated ALFRED environment and finetune on 0/10/100 R2R trajectories with object information. LangNav uses LLaMA1-7b (Touvron et al., 2023a) as the language model. The evaluation results for both methods are presented in table 3. Interestingly, for RecBert, pretraining on ALFRED actually *hurts* performance, potentially due to the model's overfitting to the idiosyncracies of the rendered environment. And without any R2R data, RecBert performs at near chance, whereas LangNav is able to exhibit some level of zero-shot transfer. Pretraining in ALFRED consistently leads to performance improvements for LangNav.

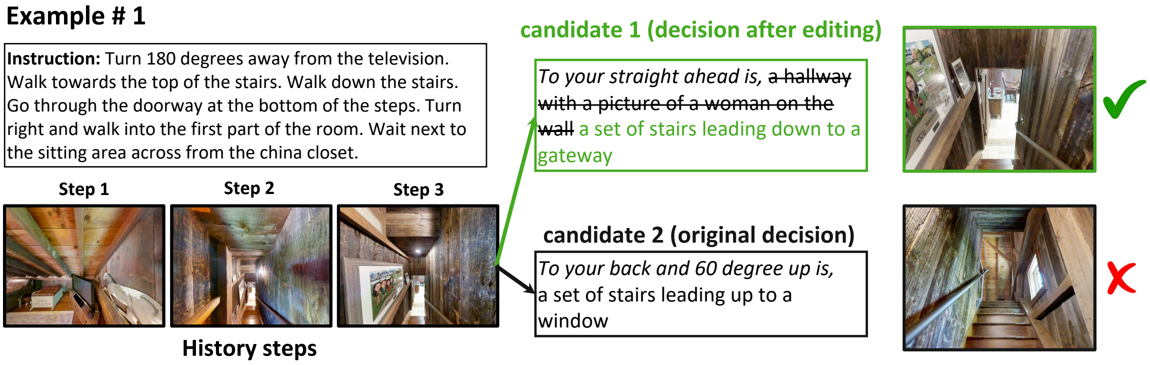
4.3 Case Study 3: Combining Language and Vision Representations

Our final case study explores whether language-based perceptual representations can improve performance *on top of* traditional continuous vision features. This is motivated by the observation that (1) in the full data setting, LangNav still underperforms the state-of-the-art approaches which rely on pure vision features (see table 5 of appendix C),

---

[7] We chose GPT-4-turbo for its lower cost.

[8] Given that RecBert (Hong et al., 2021) has similar performance to DuET (Chen et al., 2022) in the few-shot setting according to table 1, we choose RecBert to be the baseline because it is simpler and does not require a topological map.



Instruction: Turn 180 degrees away from the television. Walk towards the top of the stairs. Walk down the stairs. Go through the doorway at the bottom of the steps. Turn right and walk into the first part of the room. Wait next to the sitting area across from the china closet.

To your straight ahead is, ~~a hallway with a picture of a woman on the wall~~ a set of stairs leading down to a gateway

To your back and 60 degree up is, a set of stairs leading up to a window

Figure 4: Interpreting and editing a model's predictions through language. At the beginning, the agent incorrectly selected "candidate 2" to ascend the stairs. The failure might stem from the ambiguous interpretation of mistaking the stairs for a hallway in "candidate 1". After editing the description (marked in green), the agent correctly alters its choice to walk down the stairs.

# Training	Perceptual features	SR↑	SPL↑
100	Vision only	19.0	17.4
100	Vision + language	19.3	18.0
Full train	Vision only	47.1	43.4
Full train	Vision + language	48.8	44.1

Table 4: Results when combining continuous visual features with language features with RecBert. Evaluations are conducted on R2R val unseen set.

and (2) realistic VLN scenarios would likely have access to continuous vision features as well.

We extend the RecBert (Hong et al., 2021) by concatenating language features to the visual features to represent the candidate image view. Concretely, the original RecBert uses ResNet-152 (He et al., 2016) to extract the visual feature to represent each view; our extension simply concatenates the caption representations (from BERT-base (Devlin et al., 2019)) to the image representation for each view. We train this new model on both the 100-shot and the full training set case.

Results. The results are listed in table 4. We find that language features improve the performance in both 100-shot and full training set cases, which indicates that language as a perceptual representation can provide additional benefits on top of continuous visual features, even in non-low-data settings. This is potentially due to language serving as useful prior for aspects of images that are salient for navigation.

5 Discussion

Interpretability and editability through language. Our use of language as a "bottleneck" perceptual representation makes it possible to (more easily) *interpret* and *edit* a model's predictions. As a qualitative case study, we inspect trajectories where the model made a mistake and manually inspect the captions. We find that model mistakes are generally due to incorrect or ambiguous captions. We manually edit the captions to be correct, and find that in many cases, this is able to change the model's predictions to be correct. See Figure 4 for a concrete example. We applied this procedure to 10 randomly selected trajectories which contained an error, and found that we were able to edit the model's decision to the correct one in 7 out of 10 trajectories. (For the other 3 trajectories, the failure was not due to incorrect captions).

Disentangling vision and language models. One the one hand, LangNav's use of a vision pipeline might seem like a step back from pure deep learning-based approaches which generally favor learning everything "end-to-end". On the other, the disentangling of the image module from the language module means our approach can readily make use of independent advances in vision and language models. This might become especially important given the recent trend in only providing API access to state-of-the-art language models.

Non-standard navigation environments. Our main experiments are on the R2R benchmark, which is realistic insofar as it makes use of real household environments. Another testbed for LangNav would be environments that lack existing datasets, such as offices or supermarkets. While the lack of existing benchmarks precludes our testing of LangNav on such non-standard environments, we performed a preliminary study where we tried generating synthetic trajectories from an office environment. We show an example in appendix J, where we find that GPT-4 is able to generate synthetic trajectories that contain common object-scene correlations in office environments and moreover exhibit great spatial consistency. Testing language as a perceptual representation in a variety of environments remains an interesting avenue for future work.

6 Related Work

Language Models for Task Planning. Several studies have explored language-based planning (Jansen, 2020; Sharma et al., 2021; Li et al., 2022b; Huang et al., 2022a; Ahn et al., 2022; Huang et al., 2022b). Huang et al. (2022a) use GPT-3 (Brown et al., 2020) and Codex (Chen et al., 2021a) for action plan generation with semantic translation using Sentence-RoBERTa (Huang et al., 2022a). SayCan (Ahn et al., 2022) grounds actions using FLAN (Wei et al., 2021) and action value functions (Shah et al., 2021). Huang et al. (2022b) explore incorporating grounded feedback into LLMs, while Xiang et al. (2023) propose enhancing LLMs' with embodied task instructions.

Instruction Tuning. There has been much recent work finetuning smaller language models such as LLaMA on synthetic instruction-following data generated by GPT-3.5/GPT-4 (Peng et al., 2023; Taori et al., 2023; Chiang et al., 2023; Wu et al., 2023). Existing works have generally focused on traditional language tasks. Our work instead finetunes LMs for embodied navigation tasks using language descriptions.

Vision-and-Language Navigation. There has been much work on vision and language navigation on the R2R dataset (Anderson et al., 2018a). Approaches such as the speaker-follower model (Fried et al., 2018) and environmental dropout method (Tan et al., 2019), reinforced cross-modal matching (Wang et al., 2019), and self-monitoring (Ma et al., 2019) have been proposed. Recent advancements include VLBERT-based methods (Hong et al., 2021) and object-informed sequential BERT (Qi et al., 2021). Qiao et al. (2022) incorporate additional pretext tasks into VLN pre-training based on Hong et al. (2021). ALFRED (Shridhar et al., 2020) involves interactive actions in a synthetic environment (Kolve et al., 2017), with methods utilizing dense single vector representations (Shridhar et al., 2020; Singh et al., 2021; Pashevich et al., 2021; Kim et al., 2021; Blukis et al., 2022) or a panoramic view space (Suglia et al., 2021). CLIP-Nav (Dorbala et al., 2022) explores the zero-shot VLN with CLIP while Kurita and Cho (2020) proposes a generative language model-based navigation approach. For instruction synthesis, Nguyen and Daumé III (2019) and Thomason et al. (2020) studies rule-based instruction synthesis in Matterport3D environment. Finally, our work is closely related to Zhou et al. (2023a) and Schumann et al. (2023), which also use language descriptions of an agent's perceptual representation to perform navigation with an LM.

7 Conclusion

We show that we can learn to navigate in a real-world environments by using language as a perceptual representation. Language naturally abstracts away low-level perceptual details, which we find to be beneficial for efficient data generation and sim-to-real transfer. However, this is also a serious limitation insofar as a picture really is worth a "thousand words" in some cases; we are certainly not suggesting the abandonment of traditional (continuous) vision features for vision-language navigation. But our case studies nonetheless demonstrate the promise of language as a perceptual representation for vision-language navigation.

Limitations

While we find that LangNav is promising in settings where only a handful of real trajectories are available, on the full dataset it still underperforms vision-based agents by a nontrivial margin, as shown in table 5 of appendix C. This is especially true when compared to state-of-the-art approaches such as ScaleVLN (Wang et al., 2023) which make use of large-scale pretraining data as well as more involved imitation/reinforcement learning algorithms that require access to an environment oracle. However, we note that while LangNav underperforms baselines in data-rich regimes, it overfits less to scenes seen during training, as demonstrated by the smaller drop in performance when applying the policy to unseen scenes during training.

A Implementations Details

We used the LLaMA-7B model (Touvron et al., 2023a) and the LLaMA2-7B model (Touvron et al., 2023b) for our method, fine-tuning it on 72 V100-32GB GPUs with a batch size of 144. The training tokens had a maximum length of 1024, while during inference, the maximum length was set to 2048. The AdamW optimizer (Loshchilov and Hutter, 2017) with a learning rate of 2×10^{-5} and weight decay of 0 was employed for optimization. The WarmupDecayLR learning rate scheduler was used for learning rate scheduling. For image captioning in both the R2R and ALFRED tasks, BLIP (Li et al., 2022a) was utilized. Deformable DETR (Zhu et al., 2020) was used for object detection in the R2R dataset, with suppression of outdoor object categories. We used the ground-truth object detection results provided in ALFRED when we generated the instruction-following pairs in § 4.2. When prompting GPT-4 / GPT-4-turbo / GPT-3.5 API, we set the temperature as 1 and top_p as 1. The cost of collecting the generated 10,000 trajectories by prompting GPT-4 API (OpenAI, 2023) was around $500. In the few-shot learning experiments in § 4.1 and § 4.2, we set $\rho = 0$. While when fine-tuning with the full train set in appendix D, we set $\rho = 0.2$. We pretrain on 128K ALFRED instruction-following pairs whose format is given in § 3.2. We augment the observations in ALFRED to 12 views and randomly mask a variable number of views to mimic the irregular number of candidates in R2R. The RecBERT baselines in table 1, table 3, and table 4 are pre-trained on 10/100 trajectories from R2R with masked language modeling (MLM) and single action prediction (SAP) tasks (Hao et al., 2020). The DUET baselines in table 1 are pre-trained on 10/100 trajectories with MLM, SAP, and masked region classification (MRC) tasks (Chen et al., 2022).

B Differences between ALFRED and R2R.

The primary cause of the vast difference between ALFRED and R2R lies in their environmental rendering: ALFRED utilizes images from the synthetic AI2THOR environment (Kolve et al., 2017), whereas R2R, drawing from the Matterport3D database, features images from actual indoor environments. We summarize the differences in the following aspects:

Visual appearance. ALFRED uses images rendered from the synthetic AI2THOR environment, while R2R, based on the Matterport3D, incorporates images captured from real indoor environments. These image sources differ in texture, occlusion, illumination, and other visual aspects.

Step size. There is a difference in step sizes between the two tasks (see the right part of fig. 5). ALFRED uses a step size of 0.25 meters, while R2R has larger and more variable step sizes. To bridge this gap, we consolidate four consecutive `MoveAhead` steps into a single step along the ALFRED trajectory.

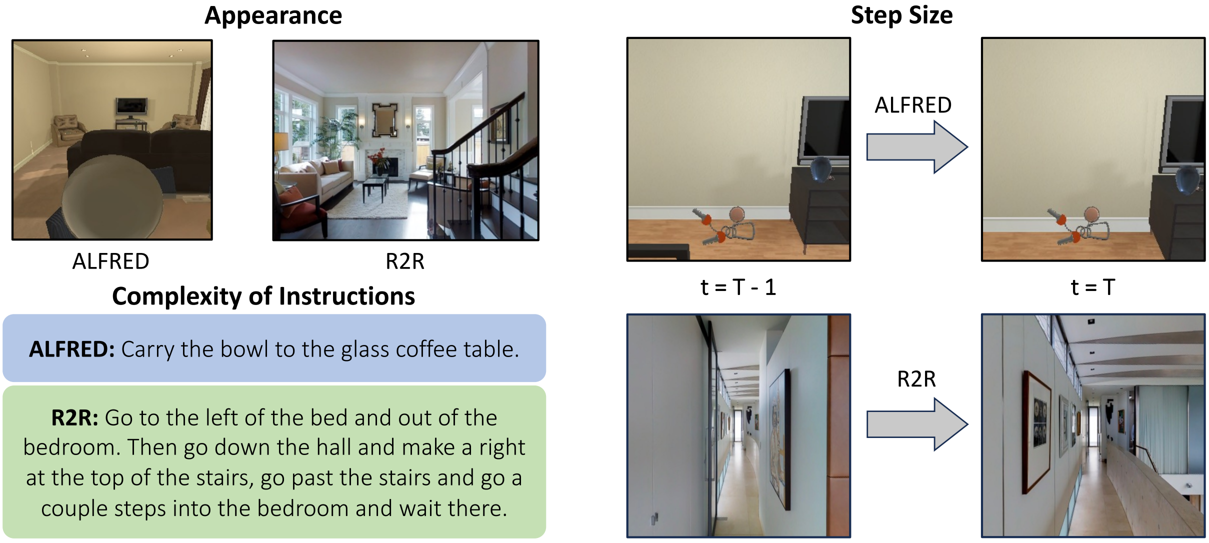
Action type. A complete ALFRED trajectory includes not only navigation actions but also interaction actions, where the interaction actions are combined with a target object to change the state of the surrounding environment. In order to filter the interaction actions in ALFRED, we divide each ALFRED trajectory into multiple sub-trajectories and keep the sub-trajectories that are labeled with the `GotoLocation` tag.

Instruction complexity. Due to trajectory splitting, ALFRED's navigation trajectories and instructions appear simpler and shorter compared to R2R's instructions. R2R instructions involve guiding the agent between rooms, whereas ALFRED trajectories mainly keep the agent within a single room.

Action space. In ALFRED, the agent is limited to rotating left/right by 90° and moving forward, while in R2R, the agent can move in any combination of 12 candidate heading directions and 3 elevation directions. The number of available movement directions is irregular. This difference in action space makes R2R trajectories more human-like. To address this, we introduce randomness by adding or reducing a heading offset of ±30° to the agent's direction at each step in ALFRED, allowing rotations of 30° or 60° in addition to 90°.

C Performance on full data

In Table 5 we show the performance of LangNav on the full dataset, as well as comparisons against the state-of-the-art. While we find that LangNav is promising in settings where only a handful of real trajectories are available, on the full dataset it still underperforms vision-based agents by a nontrivial margin. This is especially true when compared to state-of-the-art approaches such as ScaleVLN (Wang et al., 2023) which make use of large-scale pretraining data as well as more involved imitation/reinforcement learning algorithms that require



ALFRED: Carry the bowl to the glass coffee table.

R2R: Go to the left of the bed and out of the bedroom. Then go down the hall and make a right at the top of the stairs, go past the stairs and go a couple steps into the bedroom and wait there.

Figure 5: Task gap between ALFRED and R2R. We highlight notable distinctions between the navigation tasks in ALFRED and R2R, encompassing variations in appearance, step size, and instruction complexity. See appendix B for more details.

access to an environment oracle during training. However, we note that while LangNav underperforms baselines in data-rich regimes, it overfits less to scenes seen during training, as demonstrated by the smaller drop in performance when applying the policy to unseen scenes during training.

D Multi-Task Performance

One of the advantages of our approach is its inherent suitability for multitasking. Similar to LLMs use instruction to handle multiple language tasks concurrently, we consolidate task information and inputs into instructions. To validate the multitasking capability of our method, we extend its application to the ALFRED task.

Metrics on ALFRED. We evaluate our model on ALFRED using two metrics: *Task Success* (`Task`) and *Goal-Condition Success* (`GC`). `Task Success` measures the ratio of trajectories where object positions and state changes accurately match all task goal conditions at the end. `GC` assesses the ratio of completed goal conditions in each action sequence. `Task Success` is only considered successful when `GC` is also 1. On average, each ALFRED task has 2.55 goal conditions. We also calculate the *Path Length Weighted Metrics* (`PLW`) for both `Task` and `GC`, which normalize the metrics based on the actual action sequence length.

Results of the Multi-Task Model. In ALFRED task, we set $\rho = 0$ as the expert policy in ALFRED is suboptimal. To save training time and balance the data amount between R2R and ALFRED, we utilize only 50% of the training dataset, resulting in a dataset for ALFRED with 386K data pairs. For R2R task training, we maintain $\rho = 0.2$ and run each demonstration trajectory twice, resulting in a training set size of 235K for R2R. Consequently, the merged dataset for the multitask model contains a total of 621K instruction-following data pairs. We select VLN Bert (Hong et al., 2021) as the baseline for the R2R task and Seq2seq model (Shridhar et al., 2020) for the ALFRED task. Given the substantial differences between the R2R task and the ALFRED task (§ 4.2), our method is, to the best of our knowledge, the first model that simultaneously addresses these two tasks. In table 6 and table 7, we find that the multitask model exhibits superior performance compared to the single-task models. These results underscore the capability of our method to effectively handle multiple highly diverse tasks.

E Bias of generated navigation instructions

We list four generated instructions from one output of GPT-4 with 10 seed trajectories as we mentioned in § 4.1 as bellow:

Examples of generated instructions

```
1. Start from the main entrance door, pass
the living room, and enter the kitchen on
your right. Locate the refrigerator, then
turn left and stop just before the dining
```

Method	Training data	Needs Oracle	Val Seen	Val Unseen	Drop
Seq2Seq (SF) (Anderson et al., 2018b)	R2R	No	38.6	21.8	16.8
RCM (Wang et al., 2019)	R2R	Yes	67.4	42.5	24.9
Speaker-Follower (Fried et al., 2018)	R2R+SpeakerAug.	Yes	70.1	54.6	15.5
RecBert† (Hong et al., 2021)	R2R+PREV	Yes	71.8	54.5	17.3
HAMT (Chen et al., 2021b)	R2R+PREV	Yes	75.0	65.7	9.3
ScaleVLN (Wang et al., 2023)	R2R+PREV	No	67.2	47.4	19.8
ScaleVLN (Wang et al., 2023)	R2R+PREV	Yes	76.9	72.9	4.0
ScaleVLN (Wang et al., 2023)	R2R+PREV+ScaleVLN	No	71.1	57.0	14.1
ScaleVLN (Wang et al., 2023)	R2R+PREV+ScaleVLN	Yes	80.5	78.1	2.4
LangNav	R2R	No	55.0	43.2	11.8
LangNav (M)	R2R+ALFRED	No	55.9	45.6	10.3

Table 5: Comparison with state-of-the-art vision-based methods on the R2R dataset when trained on the full dataset. We use success rate (SR) as the performance metric. "Needs oracle" indicates that the model needs to rely on an oracle during training that can give the ground-truth next action based on a sampled path from the model.(M): Multi-Task model.

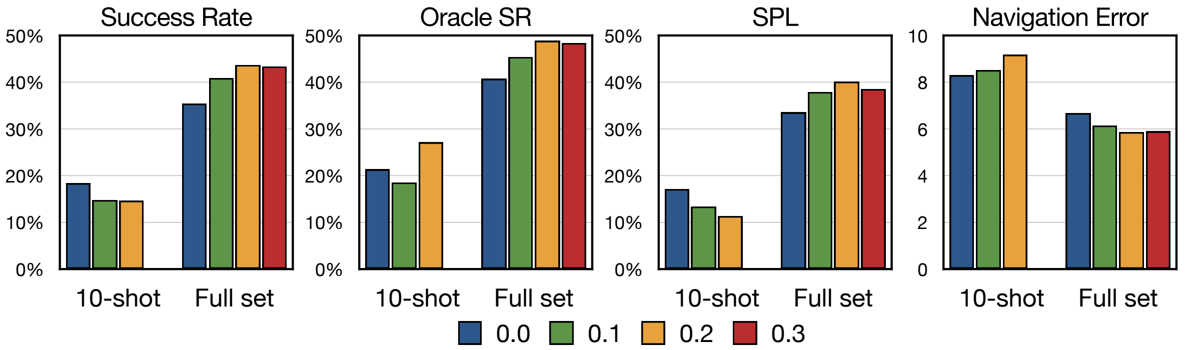


Figure 6: Investigating the Impact of the Randomness Factor ρ on Model Performance. This image caption depicts an ablation study exploring the influence of the randomness factor ρ on our model's performance in both few-shot learning and full-set training scenarios. We test ρ with values of 0.0, 0.1, 0.2, and 0.3.

Table 6: Performance of the Multi-task Model on R2R. We demonstrate the multi-task capability of the LM agent. For single-task models, each model is trained within the task data. We trained the multi-task model with data from both R2R and ALFRED tasks.

Models	R2R Seen		R2R Unseen	
	SR↑	SPL↑	SR↑	SPL↑
Single-Task	55.0	51.0	43.2	37.9
Multi-Task	**55.9**	**51.7**	**45.6**	**40.0**

Table 7: Performance of the Multi-task Model on ALFRED. ST: Single-Task. MT: Multi-Task.

	ALFRED Seen		ALFRED Unseen	
	Task↑	GC↑	Task↑	GC↑
ST	0.0 (0.0)	6.0 (4.7)	0.5 (0.1)	9.5(7.8)
MT	0.0 (0.0)	**6.4 (5.0)**	**0.6 (0.2)**	**9.8 (7.8)**

```
table.
```

```
2. Navigate from the couch in the living
room, move towards the mantel, and then
stop next to the fireplace. Avoid any
furniture and obstacles on your path.

3. Begin at the foot of the bed in the
master bedroom. Walk forward and enter the
attached bathroom. Once you're inside,
stop next to the bathtub.

4. Start in the family room, walk towards
the TV, then turn right and pass the
bookshelf. Stop when you reach the large
bay window overlooking the garden.
```

We can see from the above synthetic instructions that (a) patterns of the synthetic instructions are similar, which are like "Start from place A, go pass place B, stop at place C", (b) scenes are limited to the living area and a single floor, however, the R2R tasks always require the agent navigating across floors and in some non-living area.

F Impact of the randomness factor

We conduct the ablation study to investigate the impact of the randomness factor ρ on the model's performance in both few-shot learning and full-set fine-tuning scenarios. Interestingly, we observe different behaviors of the model with varying ρ values in these scenarios. Fig. 6 illustrates our findings. In the 10-shot scenario, increasing ρ negatively affected the model's performance. However, in the full-set scenario, the model achieved optimal performance at $\rho = 0.2$.

G Example of the Full Trajectory

We plot an example of a full text-based trajectory in R2R as we mentioned in § 3.2 as bellow:

Full R2R trajectory

Task description:

You are a navigation agent who must navigate according to instructions given only descriptions of your current position via natural language. The natural language description is sometimes incorrect.

Navigation instruction:

Go across the kitchen passed the pizza oven into the next room. Stop just inside the bedroom.

Navigation trajectory:

Step 1:

(**environment:**)
`To your 60 degree left is,`
`a kitchen with a stove, sink, and refrigerator`
`Details: oven, bowl, dining table, microwave, refrigerator`
`To your 30 degree left is,`
`a kitchen with white cabinets and a white stove top oven`
`Details: oven, bowl, microwave, potted plant, chair`
`To your 60 degree right is,`
`a living room filled with furniture and a fire place`
`Details: couch, chair`
`To your back is,`
`a room with a bed and a painting on the wall`

You chose:

(**navigation agent:**)
`a living room filled with furniture and a fire place`

Step 2:

(**environment:**)
`To your 150 degree left is,`
`a kitchen with a stove top oven sitting next to a counter`
`Details: oven, dining table, microwave, refrigerator, chair`
`To your back is,`
`a kitchen with a wooden table and white appliances`
`Details: oven, bowl, dining table, microwave, refrigerator, apple, couch, chair`
`To your 30 degree right is,`
`a living room with a couch a chair and a window`
`Details: couch`
`To your 120 degree right is,`
`a dining room table with a bowl of fruit on it`
`Details: chair, bowl, dining table`
`To your 150 degree right is,`
`a bowl of fruit sits on a wooden table`
`Details: couch, chair, bowl, dining table`

You chose:

(**navigation agent:**)
`a living room with a couch a chair and a window`

Step 3:

(**environment:**)
`To your back is,`
`a kitchen with a table, chairs, and stairs`
`Details: oven, dining table, refrigerator, potted plant, chair`
`To your 150 degree right is,`
`a room with a table, chairs, and stairs`
`Details: oven, chair, refrigerator, dining table`
`To your straight ahead and 30 degree down is,`
`a view of a hallway from the top of stairs`
`Details: refrigerator`
`To your 90 degree right and 30 degree up is,`
`a room with a staircase and a mirror on the wall`
`Details: toilet`

You chose:

(**navigation agent:**)
`a view of a hallway from the top of stairs`

Step 4:

(**environment:**)
`To your back and 60 degree up is,`
`a living room filled with furniture and a ceiling fan`
`Details: oven, potted plant, refrigerator`

To your 90 degree left and 30 degree up is,
a living room with a couch and a table
To your straight ahead and 30 degree up is,
a bedroom with a bed and a mirror on the wall
Details: bed

You chose:

(🤖 **navigation agent:**)
a bedroom with a bed and a mirror on the wall

Step 5:

(🗺 **environment:**)
To your back is,
a hallway leading to a kitchen and living room
Details: refrigerator, potted plant
To your 30 degree left is,
a room with a wooden door and a mirror
To your straight ahead is,
a bedroom with a bed, dresser, mirror and a ceiling fan
Details: potted plant, bed
To your 30 degree right is,
a bedroom with a bed and a ceiling fan
Details: potted plant, bed
To your 60 degree right is,
a bedroom with a bed, dresser and mirror
Details: potted plant, bed

You chose:

(🤖 **navigation agent:**)
stop

H Complete Prompt Template of Generating Trajectories for GPT-4

We list our complete templates for prompting GPT-4 to generate synthetic instructions (Phase I) and synthetic trajectories to fulfill the instruction (Phase II).

Phase I: Prompt template for generating synthetic instructions

System prompt:
I am going to give you example instructions written by humans to train a deep learning-based navigation agent acting inside a home. These example instructions are intended to be completed by the navigation agent in 5-7 steps.

Few shot examples:

- {real_instruction_1}
- {real_instruction_2}
- {real_instruction_3}

🧑 **User:**

Your goal is to write 10 more instructions like the above that can be used to train a navigation agent. Since the navigation agent will be navigating in different home environments, your instructions should also be diverse and cover a wide range of home environments and rooms. You should make sure that the instruction can be completed by an agent in 5 to 7 steps.

Phase II: Prompt template for generating synthetic trajectories

System prompt:
Here is an example of a large language model acting as a blind navigation agent in an indoor environment through text descriptions. The agent is given an instruction at the start and must follow the instruction. At each time step, the agent is given descriptions of its field of view via the following template:

To your [VIEW] is [CAPTION]
- [VIEW] consists of the agent's visible field of view (e.g., 30 degrees right, 120 degrees left, etc.)
- [CAPTION] is the text description of that view obtained from an image captioning model

---

Few shot examples:

Example 1
Instruction:
{real_instruction_example}
Trajectory:
{real_trajectory_example}

🧑 **User:**

Now I will give you another instruction. Please generate a trajectory of 5-7 steps that would complete the instruction.
Example 2
Instruction:
{synthetic_instruction}

I Prompts of Zero-shot and Few-shot Navigation for GPT-4

Here we attach the the task description D in the prompt template for prompting GPT-4 to navigate in the R2R evaluation dataset.

Zero-shot

System prompt:
You are a navigation agent who must navigate according to instructions given only descriptions of

your current position via natural language. The natural language description is sometimes incorrect.

🧑 **User:**

At each step, you will be given several directions and captions for each direction. You must choose one direction by printing only the [caption_of_the_direction] or choose "Stop" if you think the goal is reached.
For example:
Input:

```
To your [direction_1] is, [caption of the direction_1].
......
To your [direction_N] is, [caption of the direction_N].
You choose:
Output: [caption of the direction_3]
```

Hint: You should use the information inside the instructions, history steps, and current observations to make the decision.

Few-shot

System prompt:
You are a navigation agent who must navigate according to instructions given only descriptions of your current position via natural language. The natural language description is sometimes incorrect.

🧑 **User:**

At each step, you will be given several directions and captions for each direction. You must choose one direction by printing only the [caption_of_the_direction] or choose "Stop" if you think the goal is reached.
For example:
Input:

```
To your [direction_1] is, [caption of the direction_1].
......
To your [direction_N] is, [caption of the direction_N].
You choose:
Output: [caption of the direction_3]
```

Few shot examples:

And here is an example trajectory:

```
 ### Instruction:
Go down the stairs. Turn right and go down the hallway. Turn right and stand near the fireplace.
### Trajectory:
Step 1:
To your straight ahead is,
an ornate doorway leading to another room
To your 60 degree right is,
a red carpeted staircase leading to a chandelier
To your 120 degree right is,
a room with a red carpet and a large mirror
To your back and 30 degree down is,
a room with a red carpet and two windows
To your 120 degree left is,
a room with a red carpet and gold trim
You chose:
a room with a red carpet and gold trim
Step 2:
To your 150 degree right is,
a very ornate staircase in a house with red and white striped chairs
To your back is,
a red carpeted hallway leading to a staircase
To your 150 degree left is,
a hallway with a red carpet and a chandelier
To your 120 degree left is,
a room with a red carpet and a chandelier
To your 90 degree left is,
a room with a chandelier and two windows
To your 60 degree left is,
a room with a red carpet and a large mirror
To your 30 degree right is,
a hallway with a red carpet and wooden doors
You chose:
a hallway with a red carpet and wooden doors
Step 3:
To your back is,
a hallway with a red carpet and a chandelier
To your straight ahead is,
a hallway with a red carpet and a gold ceiling
a hallway with a red carpet and a gold ceiling
You chose:
a hallway with a red carpet and a gold ceiling
Step 4:
To your 90 degree right is,
a living room with a chandelier and a fireplace
To your 120 degree right is,
a room with a fireplace and a chandelier in it
To your back is,
a hallway with a red carpet and gold trim
To your 90 degree left is,
a room with a chandelier and a table in it
To your 30 degree right is,
a living room with a chandelier and a couch
You chose:
a living room with a chandelier and a fireplace
Step 5:
To your straight ahead is,
a living room filled with furniture and a fire place
To your 30 degree left is,
```

a living room filled with furniture and a chandelier
To your 150 degree right is,
a room with a chandelier and a table in it
To your back is,
a hallway with a chandelier and a mirror on the wall
To your 90 degree left is,
a living room filled with furniture and a chandelier
You chose:
Stop

User:

Hint: You should use the information inside the instructions, history steps, and current observations to make the decision.
Now let's start!

J Examples of Generated Trajectories in Exotic Environments

To validate that LLMs can synthesize useful data in more exotic environments, we conduct an experiment where we handcraft a trajectory in a real office environment and then prompt GPT-4 to generate synthetic trajectories within the scope of the office environment. Here we first plot the language trajectory we have sampled from a real office environment. And then, we attach the generated trajectories from GPT-4 to demonstrate the ability of a strong LLM to generate trajectories in more exotic environments.

Real-world trajectory

Navigation instruction:

Start from the pantry on your left, pass the board room to enter the atrium. Go through the door to get into the office area. Turn right at the first corner, and then turn right to stop at the printer.

Navigation trajectory:

Step 1:

(**environment:)**
To your straight ahead is,
a long hallway with light on the ceiling and a fridge on the left
To your 120 degree left is,
a lounge with a screen on the wall, floor-to-ceiling winders, desks, and many high chairs
To your 90 degree right is,
an auditorium with three big screens and tiered seating facing the stage

You chose:

(**navigation agent:)**
a long hallway with light on the ceiling and a fridge on the left

---

Step 2:

(**environment:)**
To your straight ahead is,
a long hallway with four posters on the left leading to the atrium
To your back is,
a lounge with a sofa and a shelf stocked with snacks

You chose:

(**navigation agent:)**
a long hallway with four posters on the left leading to the atrium

---

Step 3:

(**environment:)**
To your straight ahead is,
an atrium with lounge chairs on the right and a door on the straight ahead
To your 90 degree left is,
a front desk in the corner with a monitor on the desk.
To your 90 degree right is,
an exit gate towards a set of commercial elevators.
To your back is,
a long hallway with posters on the right wall

You chose:

(**navigation agent:)**
an atrium with lounge chairs on the right and a door on the straight ahead

---

Step 4:

(**environment:)**
To your straight ahead is,
An office area where there is a black board and a work pod room.
To your 90 degree left is,
An array of office desks with monitors and office chairs.
To your 90 degree right is,
A large office area with multiple arrays of desks and chairs.
To your back is,
An exit door with a phone room on the right.

You chose:

(**navigation agent:)**
A large office area with multiple arrays of desks and chairs

Step 5:

(**environment:)**

To you straight ahead is,
A large office area with multiple arrays of desks and chairs, as well as trash bins.
To your 60 degree left is,
A black board in the middle of an office area.
To your 90 degree right is,
A copy/print room with recycle bins.
To your back is,
An array of office desks and chairs with a black board.

You chose:

(**navigation agent:)**
A copy/print room with recycle bins

Step 6:

(**environment:)**
To your 90 degree right is,
A printer on the ground and several instruction sheet on the wall
To your back is,
A black board and an array of office desks

You chose:

(**navigation agent:)**
Stop

Synthetic trajectory #1

Begin at the elevator lobby. Exit the lobby and turn left, heading towards the open office space. Walk past two rows of desks, then take a right. Continue straight until you see the coffee station. Turn left and stop at the second conference room.

Navigation trajectory:

Step 1:

(**environment:)**
To your straight ahead is,
an elevator lobby with multiple elevators and a directory stand
To your 90 degree left is,
a closed door with a sign "Stairs"
To your 90 degree right is,
a wide corridor leading to a reception area

You chose:

(**navigation agent:)**
a wide corridor leading to a reception

Step 2:

(**environment:)**
To your straight ahead is,
a reception area with a white desk and three chairs
To your 120 degree left is,
a corridor leading to an open office space with several workstations
To your 90 degree right is,
a closed door marked "Emergency Exit"

You chose:

(**navigation agent:)**
a corridor leading to an open office space with several workstations

---

Step 3:

(**environment:)**
To your straight ahead is,
an open office space filled with rows of desks and office chairs
To your 90 degree left is,
an array of cubicles with computers.
To your 90 degree right is,
an exit door with a sign "Stairs"

You chose:

(**navigation agent:)**
an open office space filled with rows of desks and office chairs

---

Step 4:

(**environment:)**
To your straight ahead is,
an open office space with rows of desks and office chairs.
To your back is,
an office space with several workstations.
To your 90 degree left is,
a hallway leading to the break room.
To your 90 degree right is,
a corner office space with a large round table.

You chose:

(**navigation agent:)**
an office space with rows of desks and office chairs.

Step 5:

(**environment:)**
To your straight ahead is,
an open office space with rows of desks and office chairs.
To your 30 degree left is,
a meeting room with a large table and multiple chairs.
To your 120 degree right is,
a corridor leading to a door.

You chose:

(**navigation agent:)**
a corridor leading to a door.

Step 6:

(**environment:)**
To your straight ahead is,
a door at the end of the hallway
To your 90 degree right is,
a coffee station with a variety of coffee machines

You chose:

(**navigation agent:)**
a coffee station with a variety of coffee machines

Step 7:

(**environment:)**
To your straight ahead is,
a small kitchenette with a fridge and microwave
To your immediate left is,
a conference room featuring a large glass table
To your second left is,
a second conference room with a project screen and chairs

You chose:

(**navigation agent:)**
a second conference room with a project screen and chairs

Step 8:

(**environment:)**
To your straight ahead is,
a conference room with a projection screen and chairs.
To your back is,
a coffee station with various coffee machines.

You chose:

(**navigation agent:)**
Stop

Synthetic trajectory #2

Navigation instruction:

Start outside the IT department’s office. Walk straight and take the first left towards the stairwell. Go up one flight of stairs. Upon reaching the top, turn right and proceed to the end of the corridor. The library is on the right.

Navigation trajectory:

Step 1:

(**environment:)**
To your straight ahead is,
the hallway leading to an intersection with doors for the office spaces on the sides
To your 90 degree left is,
a door with a sign “IT Department” followed by some tech carts
To your 90 degree right is,
a hallway towards the elevators with seating areas on the sides

You chose:

(**navigation agent:)**
the hallway leading to an intersection with doors for the office spaces on the sides

Step 2:

(**environment:)**
To your straight ahead is,
a hallway with the elevator and murals on its sides
To your 90 degree left is,
a hallway that moves towards a stairwell
To your back is,
a hallway leading towards the IT department’s office

You chose:

(**navigation agent:)**
a hallway that moves towards a stairwell

Step 3:

(**environment:)**
To your straight ahead is,
a stairwell leading upwards with railing and stair lights
To your 90 degree left is,
a hallway towards a coffee machine and cafeteria entrance
To your 90 degree right is,
a door to a rest room with signage
To your back is,
a hallway with murals leading back to the IT department’s office.

You chose:

(**navigation agent:)**
