Evaluating Step-by-Step Reasoning through Symbolic Verification

Abstract

Pre-trained language models (LMs) have shown remarkable reasoning performance using explanations or chain-of-thoughts (CoT)) for in-context learning. On the other hand, these reasoning tasks are usually presumed to be more approachable for symbolic programming. To understand the mechanism of reasoning of LMs, we curate synthetic datasets containing equivalent (natural, symbolic) data pairs, where symbolic examples contain first-order logic rules and predicates from non-parametric knowledge bases (KBs), supporting automated verification of intermediate reasoning results. Then we revisit neuro-symbolic approaches and propose to learn from demonstrations containing logic rules and corresponding examples to iteratively reason over KBs, recovering Prolog's backward chaining algorithm and supporting automated verification of LMs' outputs. Comprehensive experiments are included to systematically compare LMLP with CoT in deductive reasoning settings, showing that LMLP enjoys more than 25% higher accuracy than CoT on length generalization benchmarks even with smaller model sizes.

1 Introduction

There are emerging interests in leveraging LMs to enable planning (Li et al., 2022; Huang et al., 2022), heuristic search (Dahlgren et al., 2021) and symbolic inference (Wei et al., 2022b; Zelikman et al., 2022; Zhang et al., 2022). Among them, *chain of thought* prompting or scratchpads (Wei et al., 2022b; Nye et al., 2021) shows that taking `(input, explanation, output)` as in-context examples for LMs can lead to significant performance gain in reasoning tasks. However, like many fine-tuning approaches, it can be difficult for these models to generalize compositionally (Zhou et al., 2022a), meaning they may struggle to apply their knowledge to solve new problems that involve novel combinations of information (Lake and Baroni, 2018; Bahdanau et al., 2018; Keysers et al., 2019). One notable case is that LMs would suffer from catastrophic performance degradation when tested on sequences longer than training ones (Figure 1). As a solution, *least-to-most prompting* (Zhou et al., 2022a) takes inspiration from symbolic programs and proposes to tackle the challenge by modularizing the prompt on the reduced problem. The divide-and-conquer strategy is useful to improve the reasoning ability of language models, but it also presents additional challenges: what are the appropriate representations for factual knowledge and in-context samples that can ensure the correctness of each individual reasoning step? How do natural language explanations compare to symbolic provenance, which is easily verifiable, when used as prompts for reasoning?

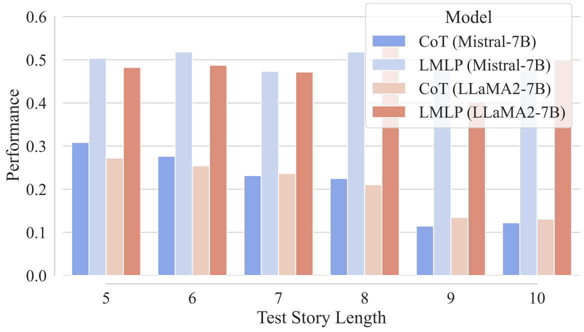

Figure 1: Deductive reasoning performance (human evaluation accuracy) comparisons on the CLUTRR-LP given training data with story length 2, 3, 4.

Our goal is to evaluate the natural and symbolic paradigms closely in order to answer these questions. To enable fine-grained comparison and gain insight into in-context learning for reasoning tasks, we study relational reasoning over both natural language and knowledge bases (KBs). KBs are particularly useful for this purpose because they are constructed using clear pipelines and strong su-

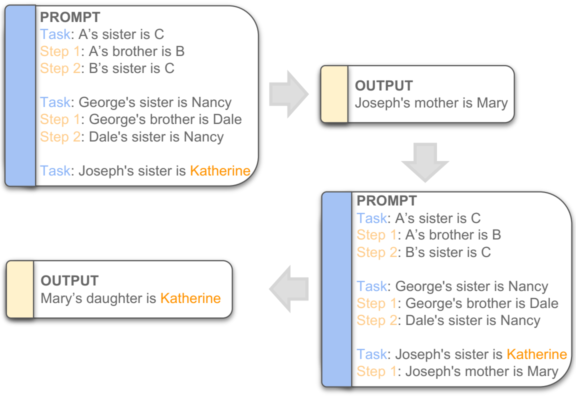
June 16-21, 2024

pervision, which makes them reliable and easy to control. This allows us to verify and evaluate reasoning paths and provenances without the need for human-provided rationales or explanations (Camburu et al., 2018; Zhou et al., 2020; Wei et al., 2022b; Nye et al., 2021; Zelikman et al., 2022). We study language models as logic programmers (LMLP) to enable few-shot learning from symbolic demonstrations and simultaneous planning in an explainable and scalable way. LMLP uses logic rule templates, examples, and pre-trained knowledge to iteratively perform in-context learning and answer relational queries.

Specifically, given a goal query as the in-context example that can be interpreted as a question answering (QA) task, LMLP searches or retrieves a related task example with a corresponding logic rule (Figure 2). Then the context and task description are concatenated as the input prompt for an autoregressive planning LM. At each step of generation, we use a masked translation LM to compare the similarity between the generated natural language sentences and encoded it into `(subject, relation, object)` predicates in the KB. In this way, each generated sentence is transformed into the most similar predicate and the reasoning path is confined within the KB. The process is iterated until a predefined maximum iteration or the target of interest is reached (Figure 2) and the generated reasoning path is evaluated manually.

To evaluate the reasoning capability of CoT and LMLP, we curate two datasets and design a series of experiments, aiming to compare two recent in-context learning paradigms and explore both symbolic and naturalistic scenarios. Specifically, we adopt synthetic datasets containing `(natural, symbolic)` data pairs. The symbolic part contains predicates and first-order logic (FOL) rules, which are well-suited for investigating the role of symbolic representations for few-shot reasoning. The natural part of our study includes a story written in natural language that describes a set of entities and relations, as well as the reasoning paths that connect them. These reasoning paths can be seen as explanations for the relationships and events described in the story. Moreover, we create experimental settings that are unfavorable for LMLP since (i) we use GPT-2 and SentenceBERT as its backbones, which is known to be of much smaller scale compared to CoT which is usually based on GPT-3 (Brown et al., 2020) or PaLM (Chowdhery et al., 2022a); (ii) LMs are pre-trained over natural language sentences as opposed to KBs, which creates substantial gaps in semantics and representations, thus posing a grounding challenge where LMs are known to be ineffective (Bisk et al., 2020).



Task: A's sister is C

Step 1: Joseph's mother is Mary

Mary's daughter is Katherine

Figure 2: Illustration of a deductive reasoning example and iterative prompting of LMLP. LMLP retrieves a first-order logic rule and an associated grounded example to answer the question. It stops when predefined maximum iterations or the target entity of interest is reached. The reasoning path explains the *sister* concept.

Controlled experiments on relational reasoning have shown that (i) CoT prompting struggles to solve the compositionality challenge (Sinha et al., 2019), while with explicit verification, LMLP can work more reliably as reasoning length increases by taking symbolic inputs that explicitly separate logic and control (Kowalski, 1979). (ii) While it is commonly believed that large pre-trained language models (LMs) are not grounded in contexts that require rich experiences, experimental results suggest that in-context learning, which maps the conceptual structure of a space learned from text onto a new structured space, is sufficient to solve some challenging reasoning tasks over knowledge bases (KBs). (iii) LMs struggle to effectively solve relational reasoning tasks without proper demonstrations containing the target relation and correct input-label mappings. This is supported by evidence in in-context examples, which are poorly understood and have many intricate design choices (Zhao et al., 2021; Liu et al., 2021; Min et al., 2022).

2 Related Works

In-context learning concerns feeding input texts describing a task with some examples to the black-box model for learning the task (Brown et al., 2020). Many works show that there are intricate design choices like prompt formats (Jiang et al., 2020; Liu et al., 2021; Zhao et al., 2021; Min et al., 2022), example choices and their ordering (Zhao et al., 2021; Lu et al., 2021b), pretraining data distribution (Xie et al., 2021; Shin et al., 2022; Chan et al., 2022) and model architectures (Chan et al., 2022) to improve the LMs' powerful and versatile in-context learning ability. Recent work focuses on bootstrapping LM with natural language explanations, intermediate steps, or rationales for reasoning (Camburu et al., 2018; Zhou et al., 2020; Nye et al., 2021; Wei et al., 2022b; Nye et al., 2021; Zelikman et al., 2022). Recent works showcase both some positive (Clark et al., 2021) and negative results (Kassner et al., 2020; Helwe et al., 2021; Talmor et al., 2020) in adapting LMs for symbolic or logical reasoning. The length generalization challenge is echoed in a few recent works (Zhang et al., 2022; Anil et al., 2022; Liu et al., 2022; Zhou et al., 2022b; Press et al., 2022). Though there are some encouraging progress (Clark et al., 2021; Wei et al., 2022b; Chowdhery et al., 2022a; Zelikman et al., 2022), they require a significant amount of computation for re-training and human annotations about reasoning paths or explanations (Wei et al., 2022b; Nye et al., 2021). Moreover, their entangled nature with natural language makes them hard to make robust inferences over symbolic factual knowledge. However, our goal is fundamentally different from theirs in investigating the role of symbolic representations on few-shot reasoning using in-context learning. LMLP that bootstraps the reasoning process from the LMs in a few-shot manner (Figure 2) is in contrast to popular methods that need expensive human annotations and retraining (Camburu et al., 2018; Zhou et al., 2020; Wei et al., 2022b; Zelikman et al., 2022) or uncontrollable using only pre-trained knowledge (Kojima et al., 2022). Moreover, related works typically *finetune* the model using rationales or explanations (Camburu et al., 2018; Zhou et al., 2020) or focus on natural language based reasoning such as commonsense reasoning, arithmetic reasoning, open domain question answering (Wei et al., 2022b), concept grounding (Patel and Pavlick, 2021) etc. Synthetic ontology datasets are constructed in (Saparov and He, 2022) to understand the failure modes of CoT reasoning, but they are in natural language forms instead of investigating the reasoning done over interpretable symbolic structures as we do. Huang et al. (2022) uses a mechanism for constraining the LLM output to feasible action sequences, which we adopt in this work. LMLP can be conceptually understood as a realization of recency biases (Press et al., 2021), which has been shown effective in scratchpad-based reasoning (Liu et al., 2022). Therefore, all the above works are different from our goal of exploring the representations of prompts in-context learning.

Retrieval-augmented Generation. Our study is also related to retrieval-augmented generation (Lewis et al., 2020) like kNN-LM (Khandelwal et al., 2019), DPR (Karpukhin et al., 2020), RALM (Guu et al., 2020), and RETRO (Borgeaud et al., 2022), which integrates parametric models with non-parametric KBs to address key LM challenges like knowledge staleness (Roberts et al., 2020) and hallucination (Shuster et al., 2021), reasoning (Shao et al., 2023). We explore more controllable environments where the evaluation of intermediate reasoning can be automated, demonstrating that this verification process helps filter out incorrect reasoning paths. This, in turn, enhances reasoning performance by assessing how effectively language models can reason when instances of hallucination are minimized.

3 Methodology Overview

We consider the reasoning task with an SRL query as the question and some background knowledge as the context. The relational information in the query and context can be expressed either using natural language or a `(subject, relation, object)` predicate/triplet. There is a KB with facts $\mathcal{F}$ and (FOL) rules $\mathcal{R}$ to support the above QA. There are two equivalent ways for representing the problem, symbolic or natural language, which leads to the designs below.

Datasets construction. To ensure that the natural and symbolic data are equivalent, we keep the ground truth facts the same in natural language stories and knowledge bases. We construct natural language story datasets following the method described in (Sinha et al., 2019). As shown in Table 1, we seek to curate new symbolic datasets from the original ones into (i) *A query subset* containing predicates needed for proving. (ii) *A set of facts* $\mathcal{F}$ containing all the available facts/predicates, which composes a KB, and (iii) *A set of rules* $\mathcal{R}$ containing examples (A task and its proofs) extracted from the training subset using backward chaining based neuro-symbolic reasoners (Rocktäschel and Riedel, 2017). See appendix B.1 for more details.

Dataset	Natural Language Samples	Query	Facts $\mathcal{F}$	Logic rules $\mathcal{R}$
CLUTRR	Task: What's the relationship between Ashley and Nicholas? Story: Ashley told her daughter Lillian to wash up. Dinner was ready. Lillian called her brother, Nicholas up to see how he was doing after surgery.	(Ashley, son, Nicholas)	(Ashley, daughter, Lillian) (Lillian, brother, Nicholas) ...	Task: Ashley's son is Nicholas Step 1: Ashley's daughter is Lillian Step 2: Lillian's brother is Nicholas
Countries	Task: Is palau located in oceania?	(palau, locatedIn, oceania)	(palau, locatedIn, micronesia) ...	Task: palau locatedIn oceania Step 1: palau locatedIn micronesia Step 2: micronesia locatedIn oceania

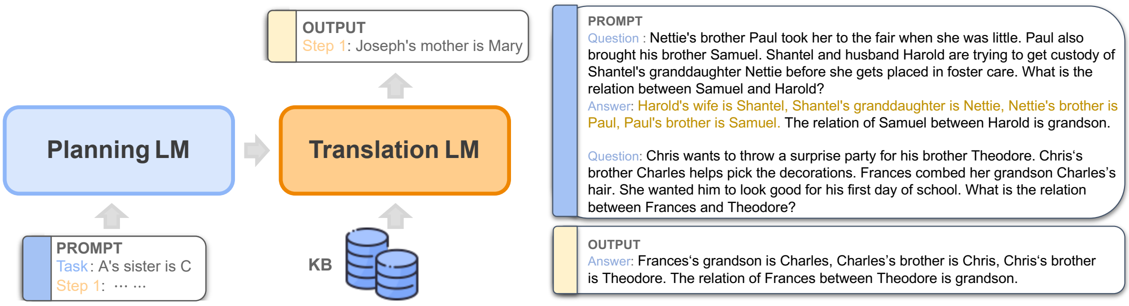
Table 1: Examples of data processing and curation.

Task. Given a query `Task: Joseph's sister is Katherine`, which consists of two entities `Joseph, Katherine` and a target relation `sisiter`. Our task is to find a proof path from `Joseph` to `Katherine` where the relationship `sisiter` can be correctly inferred. On a high level, we need to leverage an abstract logic rule `Sister(A,C) ← Brother(A,B) ∧ Sister(B,C)` and its grounded example `Sister(George, Nancy) ← Brother(George, Dale) ∧ Sister(Dale, Nancy)` to derive the answer for the query `Sister(Joseph, Katherine)` (Figure 3(a)).

Language Models as Logic Programmers achieves this goal using in-context learning. At first, examples and logic rules r in $\mathcal{R}$ are selected. For example, in Figure 2, LMLP samples one logic rule and its grounded example, which is concatenated with the query q `Task: Joseph's sister is Katherine` as a prompt $r' = [r, q]$. The prompt is fed into a **Planning LM** $\mathcal{P}_\theta$, which is an autoregressive LM such as GPT-3 for proof generation. Multiple sentences x are generated using temperature sampling from $\mathcal{P}_\theta(r')$. However, these sentences are in free-form language and often not in the `(subject, relation, object)` predicate format. In LMLP, the generated output is converted to the most similar fact in KB $\mathcal{F}$ using the cosine similarity of the embedding from a **Translation LM** $\mathcal{T}_\phi$, implemented as a sentence-specific Masked LM. Specifically, $\mathcal{T}_\phi$ embed the output sentence from $\mathcal{P}_\theta$: $\mathcal{T}_\phi(x)$ and all predicates f from $\mathcal{F}$: $\mathcal{T}_\phi(f)$, calculating their cosine similarity. The most similar f to x is chosen as the conversion results f'. By translating the output space of $\mathcal{P}_\theta$ into an external KB this way, LMLP is expected to produce a more plausible provenance to explain the reasoning process of a final prediction. Given frozen $\mathcal{P}_\theta$ and $\mathcal{T}_\phi$, we then repeatedly generate proofs by prompting $\mathcal{P}_\theta$ using $r' = [r', f']$, projecting the generated sentences to the KB by the $\mathcal{T}_\phi$, attaching the output to the prompt (Figure 2). The model terminates when the predefined maximum number of iterations or the target entity of interest is reached. To improve coherency, we enforce the chain rule transition constraints: the tail entity of the previous predicate should be the same as the head entity of the next predicate for each output step. Specifically, during the translation phase, we only select the predicates satisfying the requirement to compare similarity with $\mathcal{T}_\phi(x)$. The faithfulness of the reasoning path is governed by post-hoc human evaluations. The overall algorithm is described in Algorithm 1 in Appendix B. Using the prompt supported by the KBs, we bootstrap the reasoning process from the LMs in a few-shot manner (Figure 2).

Chain-of-Thought prompting. CoT (Wei et al., 2022b) solves complicated multi-step reasoning tasks by providing explanations, which is also intuitive for our multi-hop SRL tasks since we can take intermediate reasoning paths as explanations.

Figure 3(b) shows an example of applying CoT to solve an SRL task from the CLUTRR dataset (Sinha et al., 2019): given an in-context sample in the form of `(input, explanation, output)`. LMs are expected to imitate the reasoning process of the given explanation to generalize to a new query. The explanation of each question is generated just the same as the rule set $\mathcal{R}$, which is extracted from the training set using a neuro-symbolic reasoners and converted to natural language forms. Specifically, the in-context exemplar adapts LMs to another sample containing multiple relations and a query for the relation between two entities *"What is the relation between Theodore and Frances?"*, CoT first generates a reasoning path from *Frances* to *Theodore*, namely *"France's grandson is Charles, . . . , Chris's brother is Theodore."*, and finally answers the query: *"The relation of Frances between Theodore is grandson"*. With such a prompt, LMs are expected to generate both the reasoning paths and the resulting queried relation. For a fair comparison with LMLP, human judgments on the reasoning path are included to calculate the accuracy. Note that the explanation in CoT is extracted from the story in the question, which contains much clearer information than the logic rules for LMLP.



PROMPT

Question : Nettie's brother Paul took her to the fair when she was little. Paul also brought his brother Samuel. Shantel and husband Harold are trying to get custody of Shantel's granddaughter Nettie before she gets placed in foster care. What is the relation between Samuel and Harold?

Answer: Harold's wife is Shantel, Shantel's granddaughter is Nettie, Nettie's brother is Paul, Paul's brother is Samuel. The relation of Samuel between Harold is grandson.

Question: Chris wants to throw a surprise party for his brother Theodore. Chris's brother Charles helps pick the decorations. Frances combed her grandson Charles's hair. She wanted him to look good for his first day of school. What is the relation between Frances and Theodore?

OUTPUT

Answer: Frances's grandson is Charles, Charles's brother is Chris, Chris's brother is Theodore. The relation of Frances between Theodore is grandson.

(a) LMLP (b) CoT

Figure 3: Schematic overview of (a) LMLP and (b) CoT.

4 Experiments

We now describe the experimental setups, empirically evaluate LMLP and compare it with existing methods. See Appendix C for full details of data preprocessing and performance evaluation.

Settings. We curate two datasets for evaluating the in-context learning capability of LMs for reasoning: CLUTRR-LP and Countries-LP, which are based on CLUTRR (Sinha et al., 2019) and Countries (Bouchard et al., 2015) datasets respectively. CLUTRR (Sinha et al., 2019) contains a group of KBs, where each node denotes a family member and edges are family relations. The target of CLUTRR dataset is to infer a two-family members' relationship that is not explicitly mentioned. The training set of CLUTRR consists of graphs that the target relation can be inferred by traversing a limited number of edges while the relation in the test set needs more traversing steps for inference, which allows controlled studies on compositionality. Another intriguing property of CLUTRR is that there are ground truth **one-to-one correspondances** between KBs and natural language stories, which exactly suits our needs. Countries (Bouchard et al., 2015) concerns link prediction, where countries, regions, and sub-regions are entities and relations containing *LocatedIn* and *NeighborOf*. Countries has three tasks, *R1*,*R2*, and *R3*, each requiring reasoning skills of increasing complexity (Rocktäschel and Riedel, 2017).

Implementation details. For LMLP, we implement the planning LM $\mathcal{P}_\theta$ as GPT-2 (Radford et al., 2019), the translation LM $\mathcal{T}_\phi$ as Sentence BERT (Sent-BERT) (Reimers and Gurevych, 2019) based on Hugging Face Transformers (Wolf et al., 2019). The default model for Translation LM is Sentence-RoBERTa-Large and for Planning LM is GPT2-Large (Radford et al., 2019) pretrained on large corpora by default. For CoT, we follow the original paper (Wei et al., 2022b) to sample in-context samples. We conduct all the experiments on a machine with four Nvidia TITAN XP (10GB) GPU cards.

Since prompt formats lead to significant performance variations (Liu et al., 2021), we propose to explore two simple design choices for LMLP and find that they can further boost the reasoning capacity. (i) Multiple examples for prompting. Denote N the number of examples we used in one proof task. Table 9 shows two examples with $N = 1$ and $N = 2$ are supplied respectively. The intuition is that, getting more examples in the prompt can make LMs better recognize the proof task and thus produce more reliable reasoning paths. See the experimental section for empirical verification. (ii) Prompts Ensembling. Table 10 shows the results of different prompts for the same task. We can see the influence of prompts on the generated proof path. The first few proof steps are largely similar to the provided example. If the provided example supplies a wrong direction, the proof is likely to be wrong. To study and exploit the benefit brought by different prompts, during experiments, we propose to use K prompts alternatively for one task, where one task is marked to be successfully proved if any of these K prompts gets the right result. Namely, a larger K means that we have a higher probability of picking a good prompt. The default hyper-parameters N, K are set to one.

Evaluation metrics In Table 2 and Table 3, where LMLP is compared to various baselines, the correctness of the proven reasoning path is evaluated manually. For each reasoning path, we ask annotators to answer "Yes" or "No" to whether the generated proof path is plausible to human commonsense and the target relation can be induced from it. We include 5 participants to reduce randomness and observe that their answers are almost the same. Because of resource Limitations, for other simple ablation studies of LMLP, the metric is **proven accuracy or success rate**. For example, for query "Task: palau locatedIn oceania", we begin with entity "palau" and select facts from the $\mathcal{F}$. If the chosen triplet ends with entity "oceania", the proven path is correct, e.g., "micronesia locatedIn oceania" in Table 1. For LMLP, if there is no chosen triplet ends with entity "oceania", the prediction is incorrect.

4.1 Comparisons of LMLP and CoT

The goal of this part is to systematically compare LMLP with CoT both quantitatively and qualitatively on SRL tasks to better understand the reasoning of LMs using in-context learning.

In Figure 1 and Table. 4, we compare LMLP to CoT and the reported performances are all human evaluation results. Qualitatively, CoT can get positive results on some query examples, for example, in Table 12, we showcase two examples where CoT can generate a correct proof path and predict the target relation at the same time. However, compared to LMLP, CoT achieves inferior results in all query sets with test reasoning length $5, 6, 7, 8, 9, 10$ with different LLMs for text generation. In addition, as the reasoning length increases, the performance of CoT shows a clear downward trend. Table 12 shows two negative examples where the story contains sophisticated relations and the model cannot get the right reasoning path or just generate a wrong relation. In contrast, LMLP can consistently achieves a high human evaluation score (Table 2), which again verifies the systematic generalization capability of LMLP. Table 7 in the appendix shows examples with the same task but processed by the two methods respectively, where CoT cannot get deduce a right relation path from *Margaret* to *Charles* but LMLP can extract a simple yet right relation path. The reason why LMLP is better than CoT can be that, although CoT decomposes complex multi-hop relation reasoning tasks into a multi-step reasoning process and then predict the final results, the proof path is all generated by LMs at once. The decomposition of LMLP to multi-hop reasoning tasks is more thorough, where the generation of a proof path is divided into multi-steps and each step will be projected into the KB, which is a much stronger inductive bias. Therefore, the decomposed tasks in each step are easier to solve and the knowledge in the KB can be well exploited. See appendix for results on Countries-LP.

4.2 Analysis of LMLP

Given the above observations that LMLP outperforms CoT by a large margin, we systematically analyze LMLP with extensive experiments below.

Ablation Studies on prompting strategies. As illustrated in Table 2, **No Prompt** means that we only feed the target directly and generate each step, prompts in the **Only Rule** baseline is one proof example with entities replaced by some symbols. We also compare LMLP to Language Planner (Huang et al., 2022), which first finds the most similar target in the $\mathcal{R}$ and uses such an example as the prompt. **LMLP-reverse** swaps the position of the abstract logic rule and its grounded example in the prompt of LMLP. For example, in Figure 2, the in-context prompt of LMLP-reverse will place `Sister(George, Nancy) ← Brother(George, Dale) ∧ Sister(Dale, Nancy)` before its abstract logic rule `Sister(A,C) ← Brother(A,B) ∧ Sister(B,C)`. Examples for all baselines are shown in Appendix Table 9.

Table 2 shows that directly applying Language Planner for relational reasoning does not work and using only facts or no prompt attain inferior performance. The possible reason for the inferior performance of Planner can be that it finds the example from $\mathcal{R}$ with the most similar task as the prompt, which usually retrieves rules with the same entities of the goal task. However, for reasoning tasks over KBs, relation contains much more information of the task than the entity. As shown in Table 9, for the task "Patricia's uncle is Donald", Planner finds the example with task "David's nephew is Don", whose following proofs do not make sense for the relation "uncle". LMLP in contrast finds an example whose task has the same relation as the goal predicate, which is more informative.

LMLP can be robust to large search space. We may wonder if the superior results of LMLP are an artifact for datasets with a small search space. To control the confounding, we progressively inject $5,000$ random noisy facts/predicates into the facts set $\mathcal{F}$. With more noisy facts, at each decoding step, it will be more difficult for LMLP to choose the correct proof path as the search space is enlarged. Figure 4(b) shows the results when we vary the number of noisy facts, where the noisy rate is 0.5

Test Story Length	Baseline		Ablation				Ours	
	Planner	**CoT**	**No Prompt**	**Only Rule**	**Random**	**Entity-based**	**LMLP-reverse**	**LMLP**

means that we add $5000 * 0.5$ random facts to the $\mathcal{F}$ during evaluation and noisy rate 0 means $\mathcal{F}$ only contains query-relevant facts. We see that enlarging the search space generally decreases the performance. However, even though when all the noisy facts are injected into $\mathcal{F}$, i.e. more than 95% facts are noisy, the performance is still favorable (more than 38% success rate), showing that LMLP can produce robust reasoning performance.

Effects of model size. Figure 4(c) shows the impact of the size of the planning LM model: larger GPT models generally attain better performance; using GPT2-large and LlaMA2-7B (Touvron et al., 2023) can dramatically improve model performance, which aligns with the findings that reasoning performance can emerge in larger models (Wei et al., 2022a; Saparov and He, 2022).

Prompts ensembling boosts the reasoning capability. For each test example, we sample K in-context examples and count as correct if any one of them can solve the task. We show the evaluation results on CLUTRR-LP in Table 6 and the proposed method can generate realistic and correct proof paths. A large K can further boost performance, which also verifies the importance of prompt ensembling: Table 5 shows the performance on Countries-LP where almost all the query samples can be proved correctly with a large K. One interesting phenomenon is that LMLP can generate a much longer proof path even though the proof path length in the rule set $\mathcal{R}$ is less than 3. This manifests a potential improvement with respect to the significant weakness in systematic generalization of fine-tuning or re-training of LMs (Sinha et al., 2019). The $\mathcal{R}$ of CLUTRR-LP contains only examples whose proof paths are less than five. However, during testing, our model can produce proof paths much longer than five steps and perform well on all query sets.

Prompting using multiple examples boosts the

reasoning capability. N denotes the number of in-context examples used in one proof task. Results show that a larger N can generally produce performance gains (Figure 4(a)). However, longer prompts require larger GPU memories, so there is a trade-off between memory and performance.

4.3 Analysis of Demonstrations of ICL

Besides results in Appendix Table 7, we conduct qualitative analysis of demonstrations of in-context learning.

Failure cases analysis of baselines. Since the generated sentences are closely related to the prompt, Table 11 in Appendix shows that if we randomly choose prompts, the generated proof path has relations similar to the prompt, but is wrong for the given task. For entity-based prompts, since the task has the same start entity as the in-context exemplar, the generated steps 1 in this setting are very similar, leading to many wrong proof paths. Language Planner, without chain rule constraint, the generated triplets are chaos, e.g., in Example 1, the generated proof does even not contain the subject "Jon" and thus exactly wrong. Although the proposed LMLP attains a high success rate, there are also some failure cases. As shown in Appendix Table 10, an appropriate prompt needs to be chosen for the right proof paths.

Takeaways. Similar to previous work (Liu et al., 2021; Min et al., 2022), we find that in-context learning performance varies greatly with choices of exemplars (Table 6). One of the key findings in (Min et al., 2022) is that even without any labeled data, LMs can achieve k-shot performance by simply prompting with demonstrations containing unlabeled inputs. Our findings are generally in-line is in line with the importance of input-label formats highlighted in the work. However, we show in Table 8 and 9 that the correct mapping of rule-example pairs is important since giving only rules with symbols like X, Y, Z rather than concrete entities like $China$ makes LMLP fail catastrophically.

5 Concluding Remarks

In this study, we systematically examine in-context learning of language models (LMs) from a symbolic reasoning perspective, demonstrating that LMs can be prompted with logical demonstrations to generate plausible explanations for reasoning tasks over knowledge bases (KBs). Our evaluation results show that constraining outputs of LMs and ensuring intermediate reasoning correctness are important for reasoning performance, providing new insights into in-context learning and a mechanism to reduce incorrect reasoning through symbolic verification.

Limitations

Like previous works, we study reasoning empirically without theoretical justifications and focus specifically on synthetic data. Therefore, our results serve as a proof of concept on investigating how ensuring and reducing hallucination can improve overall reasoning, and might not transfer to more complex reasoning tasks. Moreover, due to access and computation restrictions, we are not able to conduct experiments with the latest LMs like PaLM (Chowdhery et al., 2022b).

Appendix

A Extended Related Work

Neuro-Symbolic Reasoning. ILP (Muggleton and De Raedt, 1994) and its neural version (Yang and Song, 2020) are unable to reason about disjoint relations in confront of missing links when KBs are noisy like in FreeBase, which means ILP only synthesizes rules based on existing relations. Methods like Neural-LP (Yang et al., 2017) and RNNLogic (Qu et al., 2020) require enumeration of all possible rules given a max rule length T. Thus the complexity of these models grows exponentially as maximum rule length increases, which is a significant disadvantage for systematicity problems. For deductive reasoning, NTP (Rocktäschel and Riedel, 2017) and its improved versions (Minervini et al., 2018, 2020) require hand-crafted templates to imitate backward chaining for deductive reasoning. This belies the considerable user burden of authoring the templates which then fundamentally biases the tool toward a specific subset of programs that the author has in mind. Moreover, the performance and efficiency of NTP is far from satisfactory: the performance usually lags far behind its neural counterparts like knowledge graph embedding methods (Lin et al., 2015); during both training and inference, NTPs need to compute all possible proof trees needed for proving a query, relying on the continuous unification of the query with all the rules and facts in the KB. The search space of existing works is exponentially large, which makes them hard to scale up in general (Minervini et al., 2018; Chaudhuri et al., 2021).

LMs for Theorem Proving. Most works focus on proving formal mathematical theorems: GPT-f (Polu and Sutskever, 2020) shows promising results by generative language modeling over mathematical formulas. Systematicity of LMs when training on proofs is evaluated in (Gontier et al., 2020) but shows negative results in generalizing to unseen proof steps in extrapolation and complex language. Three synthetic tasks inspired by three reasoning primitives of deduction, induction, and abduction are demonstrated in (Wu et al., 2021). The above works provide insights into understanding LMs' reasoning capabilities. Though they share similar problem structures like compositionality with ours, they fundamentally require large-scale pre-training and fine-tuning due to the mismatch between Wikipedia pre-training corpora and mathematical formulas. Such a re-training requirement not only results in computational inefficiency but lacking in compositional generalization to longer proof steps unseen during training (Gontier et al., 2020).

Symbolic Reasoning with LMs. Large LMs pre-trained on open-domain text corpora have achieved impressive advances in natural language generation and understanding tasks (Kenton and Toutanova, 2019; Brown et al., 2020). By self-supervised imitation on human-generated texts, LMs contain rich factual knowledge (Petroni et al., 2019; Bouraoui et al., 2020; Roberts et al., 2020) and linguistic structures (Manning et al., 2020), serving as a versatile inference regime for various downstream tasks (Brown et al., 2020; Lu et al., 2021a). Among them, GPT-3 stands out by its few-shot generalization to unseen cases without further fine-tuning given in-context samples as demonstrations (Brown et al., 2020). Constraint decoding is shown to be effective in incorporating logical constraints into natural language generation (Lu et al., 2022). However, it is a common belief that LMs have not yet enjoyed a comparable success in tasks that require extensive planning and grounding (Glenberg and Kaschak, 2002; Bender and Koller, 2020; Bisk et al., 2020) as well as symbolic reasoning (Kassner et al., 2020; Helwe et al., 2021; Razeghi et al., 2022).

B Algorithm Description

Algorithm 1 describes the procedure or LMLP. It can also be illustrated in Figure 3(a).

B.1 Data Generation.

CLUTRR-LP. CLUTRR has 9 subsets with difference story length, named $l_2, l_3, \ldots, l_{10}$. Following (Minervini et al., 2020), we convert l_2, l_3, l_4 to the $\mathcal{R}$ and use $l_5, \ldots, l_{10}$ to the **query sets**. As illustrated in Table. 1, data samples in CLUTRR consist of a story and a target, where the target contains two entities and the relation that is needed to be inferred, the story contains available triplets. Each sample in the l_2, l_3, l_4 will be converted to the format "Task: ..., Step i: ..." and added to the $\mathcal{R}$. Note that all examples in the $\mathcal{R}$ have a story

Algorithm 1 Generate proof path from Pre-Trained Language Models.

```
Require: Planning LM $\mathcal{P}_\theta$, Translation LM $\mathcal{T}_\phi$, Query set $\mathcal{Q}$ that contains all query triplets, $\mathcal{F}$ that
    contains all available facts, $\mathcal{R}$ that contains all the available logic rules or proof examples.
    for $q = (s, p, o) \in \mathcal{Q}$ do // $s, p, o$ denote subject entity, predicate (relation) and object entity respectively.
        Find $r \in \mathcal{R}$, whose task relation is $p$.
        Construct prompt $r' = [r, q]$.  // $[r, q]$ means the concatenation of two strings.
        while Max step is not reached do
            Sample 10 sentences $\{x_i\}_{i=1}^{10}$ from $\mathcal{P}_\theta(f')$.
            Set $\mathcal{F}' \in \mathcal{F}$ whose first entity are $s$.
            if $|\mathcal{F}'| == 0$ then
                Break  // No available facts in the $\mathcal{F}$ start with entity $s$.
            for $x \in \{x_i\}_{i=1}^{10}$ do
                $score_i = \max_{\forall r \in \mathcal{F}'} cosine(\mathcal{T}_\phi(x), \mathcal{T}_\phi(r))$;// Cosine similarities of $s$ to facts in $\mathcal{F}'$.
                $idx = \arg\max_{\forall r \in \mathcal{F}'} cosine(\mathcal{T}_\phi(x), \mathcal{T}_\phi(r))$;// Select $r \in \mathcal{F}'$ with the highest similarity to $x$.
                $x' = \mathcal{F}'[idx]$
            Choose the highest score rule $x^*$ as the next proof step and append it to the prompt $f' = [f', x^*]$.
            if $o' == o$ then
                Break  // The object entity converges to the target entity $o$.
```

length of less than five, which enables us to test the systematic generalization ability of LMLP. For CLUTRR, the story triplets in the $\mathcal{R}$ are not useful for test target proving, because they are all from different relation graphs. For example, story triplets in the l_2, l_3, l_4 contain "(William's brother is Steve)" while one test story on l_5 contains "(William's uncle is Steve)". During the evaluation, if the model chooses "(William's brother is Steve)", the proof path will be wrong. However, the similarity of these two triplets is high, the model is then easy to make errors and these noisy facts increase proof difficulties. We hence evaluate our methods in two settings considering the number of noisy facts. The simplest setting (**Test Facts Setting**) is that, when queries are from $l_i, i \in [5, \ldots, 10]$, the $\mathcal{F}$ only contains facts in l_i. In this case, the $\mathcal{F}_{5\sim10}$ have 251,222,275,279,285,304 facts respectively. The most difficult setting is termed **All Facts Setting**. We first extract facts in the $\mathcal{F}$ with length l_2, l_3, l_4 and get totally $5,210$ facts. When queries are from $l_i, i \in [5, \ldots, 10]$, the $\mathcal{F}$ contains triplets in l_i, l_2, l_3, l_4, where the additional $5,210$ facts are not useful for the proof path and are noisy facts. The All Facts Setting is set as our default setting and experimental results of the Test Facts Setting are mainly in the Appendix. For CoT, the $\mathcal{F}$ is needless and the construction of prompt examples is slightly different from the procedure above. Specifically, as shown in Figure 3(b), for each target in the training samples, we need to preserve the story and extract a proof path for the target.

Countries-LP. Training samples in Countries are triplets that describe the *neighbor of* relation or *located in* relation of two regions/subregions/countries and can thus be directly used as $\mathcal{F}$. Because the three tasks (*S1, S2, S3*) (Minervini et al., 2020) have different training sets and thus have different $\mathcal{F}$. Test samples in Countries are also triplets with specific entities and relations, hence the **query set** is just the test set of the original Countries dataset. One main difficulty in applying the proposed method to Countries is the lack of off-the-shelf proof paths ($\mathcal{R}$). The CTP (Minervini et al., 2020) model is trained and used for proving each triplet in the training set. CTP returns the scores of the possible proof path and the proof with the maximum score is iteratively searched as added into the $\mathcal{R}$. After that, $924, 906, 705$ available examples are found for *S1, S2, S3* tasks respectively.

C Additional Experimental Setups and Results

Human evaluation results on the Countries-LP benchmark. Because Countries-LPis a simple reasoning benchmark, which has only two predicates, namely `LocatedIN`, and `NeighborOf`. Table. 3 shows that simple baselines with entity-based prompts or no prompt can attain comparable or higher results than LMLPon the simplest task $S1$. However, LMLPattains better reasoning capability

CoT Prompting	**LMLP**
Question: Wilhelmina took her uncle Hugh to the grocery store. Francisco and his brother Wesley were wrestling. Wilhelmina, Francisco's daughter, was cheering on the competition. What is the relation between Hugh and Wesley? Answer: Wesley's brother is Francisco, Francisco's daughter is Wilhelmina, Wilhelmina's uncle is Hugh. The relation of Hugh between Wesley is brother. Question: Constance went shoe shopping with her sister Ellen. Elsie had a daughter named Constance. Elsie had picked her daughter Margaret out the cutest new dress to wear on her birthday. Charles and his sister Kathleen have been best friends ever since childhood. Nadia and her father, James, went to the marina. James's daughter, Mabel, had purchased a boat, and they were eager to see it. Mabel bought her mother, Ellen, a puppy for her birthday. James hung his son Charles's finger paintings on the refrigerator. The paintings were right next to the paintings of Nadia, Charles's sister. Kathleen wasn't old enough to make any paintings for her father, James. What is the relation between Margaret and Charles? Answer: charles' mother is nancy, nancy's daughter is elizabeth, elizabeth's husband is john, john's wife is mary, mary's brother is george, david's nephews are william, william's nephews are robert.✗	Task: A's aunt is B Step 1: A's sister is C Step 2: C's mother is D Step 3: D's sister is B Task: Carrie's aunt is Lynn Step 1: Carrie's sister is Natasha Step 2: Natasha's mother is Cindy Step 3: Cindy's sister is Lynn Task: Charles's aunt is Margaret Step 1: Charles's sister is Nadia Step 2: Nadia's aunt is Margaret ✓

Abstract

Grounded text generation, encompassing tasks such as long-form question-answering and summarization, necessitates both content selection and content consolidation. Current end-to-end methods are difficult to control and interpret due to their opaqueness. Accordingly, recent works have proposed a modular approach, with separate components for each step. Specifically, we focus on the second subtask, of generating coherent text given pre-selected content in a multi-document setting. Concretely, we formalize *Fusion-in-Context* (`FiC`) as a standalone task, whose input consists of source texts with highlighted spans of targeted content. A model then needs to generate a coherent passage that includes all and only the target information. Our work includes the development of a curated dataset of 1000 instances in the reviews domain, alongside a novel evaluation framework for assessing the faithfulness and coverage of highlights, which strongly correlate to human judgment. Several baseline models exhibit promising outcomes and provide insightful analyses. This study lays the groundwork for further exploration of modular text generation in the multi-document setting, offering potential improvements in the quality and reliability of generated content.[1]

1 Introduction

Grounded text generation is the task of producing a passage from source texts, where the output is anchored around use-case-dependent spans within the source texts. Although such a task involves two distinct subtasks – identifying relevant spans and fusing them – it is commonly handled in an end-to-end approach, recently by using Large Language Models (LLMs) (Shuster et al., 2022; Su et al., 2022; Zhang et al., 2023). While effective, this approach often lacks flexibility and control over the generation process, given its opaque nature.

Addressing this, Slobodkin et al. (2022) recently advocated splitting grounded generation tasks into their two subtasks, and particularly focused on the fusion step. They introduced *Controlled Text Reduction* (CTR), a task where pre-selected spans in a source document ('highlights') are fused into a coherent text that exclusively covers the spans. This approach enhances control and modularity in text generation, enabling a single CTR model to work with various content selection strategies and user preferences, applicable in different contexts like summarization or long-form question-answering. It could also support human-in-the-loop scenarios for tailored outputs based on user preferences, as explored in Slobodkin et al. (2023b). Further, the direct access to the highlights that contribute to the output facilitates attributed generation (Bohnet et al., 2023; Gao et al., 2023a,b), where models can cite source spans for generated text.

Despite its benefits, CTR's focus on single-input scenarios limits its applicability to the broader, and more complex, multi-document setting. In this paper, we bridge this gap and extend the task to the multi-document setting. For that, we introduce the task of *Fusion-in-Context* (`FiC`), a generalized version of the CTR task, which processes multiple documents with pre-selected highlights, and aims to fuse them into a coherent, non-redundant text covering all and only the highlighted content, as demonstrated in Figure 1. In addition to the challenges of the single-input CTR task, including coreference resolution and proper discourse for coherence, the multi-document setting also requires handling repetitive, and sometimes conflicting information (Ma et al., 2020). Specifically, our work focuses on the business reviews domain, where contradicting opinions are more prevalent than in other more fact-oriented domains, such as news.

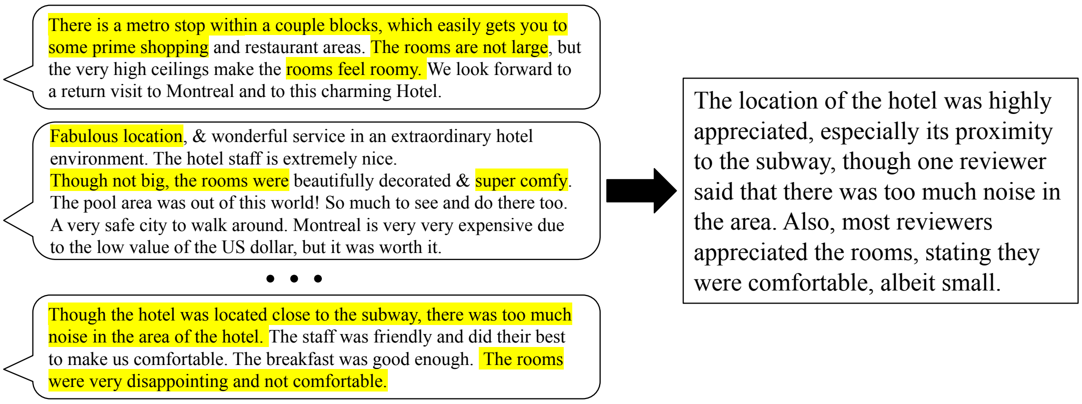
Findings of the Association for Computational Linguistics: NAACL 2024, pages 3003–3021
June 16-21, 2024



There is a metro stop within a couple blocks, which easily gets you to some prime shopping and restaurant areas. The rooms are not large, but the very high ceilings make the rooms feel roomy. We look forward to a return visit to Montreal and to this charming Hotel.

Fabulous location, & wonderful service in an extraordinary hotel environment. The hotel staff is extremely nice.
Though not big, the rooms were beautifully decorated & super comfy. The pool area was out of this world! So much to see and do there too. A very safe city to walk around. Montreal is very very expensive due to the low value of the US dollar, but it was worth it.

• • •

Though the hotel was located close to the subway, there was too much noise in the area of the hotel. The staff was friendly and did their best to make us comfortable. The breakfast was good enough. The rooms were very disappointing and not comfortable.

The location of the hotel was highly appreciated, especially its proximity to the subway, though one reviewer said that there was too much noise in the area. Also, most reviewers appreciated the rooms, stating they were comfortable, albeit small.

Figure 1: An example of an input, consisting of multiple reviews with highlights (left), and the generated text fusing the highlighted content while preserving coherence and non-redundancy (right). Such highlights in realistic use cases may be produced by different content-selection strategies.

To promote research on `FiC`, we start by formally defining the task (§3). We then introduce a dataset (§4), carefully constructed via controlled crowdsourcing (Roit et al., 2020). Each of its 1000 instances comprises a set of inputs with highlights, and a corresponding fused text. The dataset is created through an efficient procedure, adapted from Slobodkin et al. (2022), leveraging existing multi-document summarization datasets, specifically in the business reviews domain. We also develop an evaluation framework (§5) that assesses outputs' faithfulness and coverage of highlights. The dataset and evaluation framework are released as a benchmark, called FUSEREVIEWS. We explore various baseline models on the benchmark and report their performance (§6). Our findings reveal that while these models show promising results, there is still room for further improvement in future research.

2 Background

Grounded text generation, an area focusing on generating text from source documents, requires identifying relevant task-specific details within the inputs, such as salient content for summarization, as well as their coherent fusion. This field includes tasks like long-form question-answering (Fan et al., 2019; Stelmakh et al., 2023), summarization (Nallapati et al., 2016a,b; Shapira and Levy, 2020; Bražinskas et al., 2020b; Zhao et al., 2022), and dialogue systems (Yan et al., 2017; Xu et al., 2019; Thoppilan et al., 2022), with most related datasets aimed at end-to-end training (Fan et al., 2019; Bražinskas et al., 2020a; Liu et al., 2021; Iso et al., 2022a).

Despite the prevalence of end-to-end systems, there has been a growing trend towards decomposed pipeline approaches, particularly in summarization, with several recent studies focusing on content selection (Gehrmann et al., 2018; Lebanoff et al., 2020a; Ernst et al., 2021). Conversely, content fusion was largely explored at the full-sentence fusion level (Geva et al., 2019; Lebanoff et al., 2020b), with less emphasis on sub-sentence fusion.

Recently, Slobodkin et al. (2022, 2023a) have proposed a distinct separation of content selection from fusion, treating each as an independent task. They specifically concentrated on fusion, defining it as a standalone task termed *Controlled Text Reduction* (CTR). This task takes as input pre-selected spans, or 'highlights', within an input document, and requires a coherent merging of all the highlighted content, and nothing else. They also released a designated dataset and several CTR models showing strong adherence to these highlights.

While these studies acknowledged the benefits of decomposing grounded generation to subtasks, they mainly focused on single-document inputs. Our work builds on this decomposed approach, extending it to multi-document settings, which introduce new challenges such as managing longer inputs, handling redundant highlights (Suzuki and Nagata, 2017; Calvo et al., 2018), and dealing with potentially conflicting facts or opinions (Kim and Zhai, 2009; Ma et al., 2022).

Additionally, previous CTR studies assessed highlight adherence by comparing outputs with the concatenated highlights, using lexical metrics like ROUGE (Lin, 2004) and METEOR (Banerjee and Lavie, 2005), and semantic metrics like BERTScore (Zhang et al., 2020). These methods, while suitable for single-input scenarios, are less effective for multi-document contexts where redundant and conflicting highlights are more prevalent. Additionally, these approaches did not distinctly evaluate faithfulness and coverage of highlights, typically assessing them jointly, with only manual evaluation for separate evaluation.

Addressing this, we explore more suitable metrics focusing separately on faithfulness and coverage of fused texts, inspired by recent progress in this area. Several recent studies have used Natural Language Inference (NLI) models for faithfulness evaluation (Laban et al., 2022; Schuster et al., 2022). There have also been advances in utilizing LLMs to evaluate faithfulness in a zero-shot setting with NLI-style prompts (Chen et al., 2023; Kocmi and Federmann, 2023; Liu et al., 2023), or after fine-tuning on synthetic data for faithfulness evaluation (Kryscinski et al., 2020; Yin et al., 2021; Gekhman et al., 2023). Yet, these works mainly targeted overall source text faithfulness rather than to specific segments. Moreover, they have not been widely applied to assess coverage, which has traditionally been evaluated using lexical metrics (Grusky et al., 2018) or manual evaluation (Syed et al., 2021). In our work, we adapt these methods to our highlights-focused setting, both for faithfulness and coverage, and assess their effectiveness.

3 Task Definition

The *Fusion in Context* (`FiC`) task is defined as the process of synthesizing a coherent text from a given set of documents, specifically focusing on pre-selected spans within these documents, referred to as *highlights*. Formally, given a document set D with marked spans $H = \{h_1, h_2, ..., h_n\}$ (such that h_i may be non-contiguous), a coherent and non-redundant passage f is generated, adhering to the following two criteria: (1) *highlight faithfulness* – f must be collectively entailed by the content in H, adding only minimal non-highlighted content required for coherence; (2) *highlight coverage* – each $h_i \in H$ must be represented in f, either explicitly, or via a generalized reference. For instance, if a highlight states *"the place serves great sushi"*, the output should either directly mention *"great sushi"* or refer to it in more general terms, such as *"great food"*. Moreover, the task permits the abstraction and aggregation of multiple highlights into a single, synthesized statement. For example, separate highlights noting *"the beds were clean"*, *"the bathrooms were spotless"*, and *"the windows were clean"* could be collectively abstracted to a general statement like *"the rooms are clean"*. Overall, the goal is to produce a faithful, non-redundant and non-omissive, yet potentially abstractive and aggregated, fusion of the highlighted content.

Next, we describe a dataset (§4) and an evaluation framework (§5) that comply with the task definition. These are released as the FUSEREVIEWS✎ benchmark for the `FiC` task.

4 Dataset for `FiC`

To comply with the task definition, an instance in a `FiC` dataset is expected to be a document set D with marked spans $H = \{h_1, h_2, ..., h_n\}$, and a corresponding fused text f. To compile such data, we leverage existing multi-document summarization datasets and extract high-quality `FiC` instances via controlled crowdsourcing (Roit et al., 2020), by adapting the method from Slobodkin et al. (2022) to the multi-text setting, and the business reviews domain.

4.1 Dataset Collection

Given a document set D and corresponding reference summary $\widehat{f}$ from an existing multi-document summarization dataset, the annotation process aims to identify the spans in the source texts $\{h_1, h_2, ..., h_n\}$ that cover all the information within $\widehat{f}$. This approach simplifies the annotation process compared to annotating from scratch, i.e., reading documents, marking highlights according to some specifications, and writing a coherently-fused text, which is reminiscent of standard formation of multi-document summarization datasets. Conversely, our approach requires locating and aligning spans between the source text and the already available reference summary, essentially "reverse engineering" the original human summarization process.

Source data. For our dataset, we turn to the business reviews domain, and sample review-sets and corresponding summaries from the CocoTrip (Iso et al., 2022b) and the FewSum (Bražinskas et al., 2020a) datasets. CocoTrip is a dataset of comparative opinion summaries of hotel review-sets, and FewSum consists of summaries of review-sets on businesses. Each review-set in these datasets comprises 8 reviews and up to 6 (average 3.13) corresponding reference summaries.

Annotation interface. To facilitate the annotation of alignments between reviews and their corre-

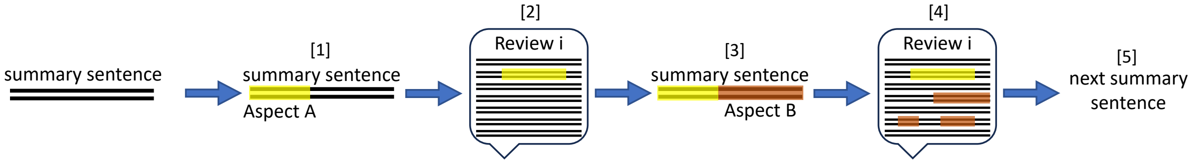


Figure 2: Illustration of the highlighting annotation process for a summary sentence, with reference to a specific review: [1] A *summary* aspect is identified and its statement highlighted; [2] Corresponding *review* spans are highlighted, and the alignment is saved; [3] Another *summary* aspect is identified and highlighted; [4] The matching *review* spans are highlighted, and the alignment is saved; [5] When all summary aspects that are alignable to the current review are highlighted, we proceed to the next sentence, and so on. In this example, the summary consists of two aspects, but steps 1 and 2 can be repeated as needed per sentence, until all alignable aspects are annotated. Borrowed and adapted from Slobodkin et al. (2022).

sponding summary, we adapt a web-based annotation tool from Slobodkin et al. (2022), and deploy it on Amazon Mechanical Turk[2] for crowdsourcing (§4.3 will explain the controlled crowdsourcing procedure). The application presents reviews and the respective summary side-by-side, and annotators are guided to highlight pairs of spans in the reviews and the summary that directly align. To reduce cognitive load, a summary is displayed alongside an individual review, and focus is placed on one summary sentence at a time. To further ease the process for annotators, lemmas in the review overlapping with lemmas in the currently focused summary sentence are emboldened.[3] This enables quick skimming through the review, however, workers are trained not to rely solely on exact matches for highlighting (as discussed in §4.2 and §4.3).

Annotation procedure. Annotators are guided to align statements dealing with a single aspect of a hotel or business (e.g., "room cleanliness") from the summary with the most relevant spans in the reviews, and to do so for all summary aspects in order to cover the whole summary text (see §4.2 for the detailed annotation guidelines).[4] This, in turn, creates instances of highlighted spans within reviews, with a corresponding coherent fusion of those highlights (the summary). Each review-summary pair is annotated by a single trained annotator. To enhance quality, submissions are randomly sampled and reviewed, with feedback provided as necessary.

Resulting dataset. In total, we sampled 1000 instances of review-set/summary pairs (700 instances from CocoTrip and 300 from FewSum). See Table 1 for full statistics.[5]

4.2 Annotation Guidelines and Data Traits

Figure 2 illustrates the annotation flow. When presented with a review of an entity (hotel or business) and a summary with a sentence in focus, an annotator first identifies aspects of the entity within the focused summary sentence. An aspect is not simply a facet of an entity, such as "rooms" or "staff", but more specifically it is a characteristic, such as "room cleanliness", "room style" or "staff helpfulness" (more on this in Appendix A.1).

Upon identifying an aspect in the summary sentence, annotators are tasked with locating corresponding spans in the review. These are the minimal spans that adequately cover the information as in the summary regarding the aspect, where omitting any content would miss out on some detail of that aspect in the summary. For example, omitting any mention of the room being 'small' from the review highlights in Figure 1, would overlook this characteristic of the room, which is mentioned in the second summary sentence.

As outlined in §3, alignments on aspects need to consider two entailment-related traits. Firstly, a summary may express a generalized phrasing of an aspect that is stated in the reviews. For instance, a review may say *"great sushi"* while the summary might just say *"great food"*. Annotators are hence directed to also mark review excerpts that are more specific than in the corresponding spans in the summary. Secondly, several spans in the reviews pertaining to the same aspect may yield an aggregated abstraction in the summary. Annotators must therefore also include review spans that exemplify the summary aspect. For example, aligning

[3] Lemmatizing with spaCy (Honnibal and Montani, 2017).

[4] We observed that instructing annotators to focus on one aspect at a time enhances the efficiency in locating the relevant review spans, particularly when a summary sentence includes content that is scattered across different parts of the review.

[5] See Appendix F for more details.

Table 1: Statistics of our dataset, including the number of unique review-sets, the average number of summaries per review-set, the number of summary/review-set pairs (a unique review-set creates a pair with each of its summaries), the mean review/summary size (in tokens and in sentences), the maximum review/review-set/summary size (in tokens), the percentage of summary sentences whose alignments span across more than one review, and the percentage of summary sentences whose alignments span across more than one review sentence within one of its reviews (namely, within a single review, the alignments come from more than one sentence).

a review statement such as *"the beds were clean"* with a summary phrase *"the rooms were clean"*.

Additionally, reviews often express varying opinions about the same aspect, such as *"the service was great"* as opposed to *"the staff was unprofessional"*. When summarizing, all these varying opinions should be considered to reflect the overall sentiment. As a result, summary segments may range from statements like *"the staff was overall liked"* to *"some people liked the staff"*, depending on the spectrum of opinions. Hence, to properly capture this consolidation of differing viewpoints, annotators are also guided to align review mentions that either sentimentally entail *or* contradict the summary aspect. For example, the two aforementioned conflicting *review* spans should be aligned to the summary span *"the service was mostly good"*.

Finally, annotators may mark multiple spans in reviews that redundantly represent the same statement. The guidelines also address paraphrasing, non-consecutive highlights, and unalignable summary spans. A detailed explanation of these guidelines can be found in Appendix A.2.

4.3 Annotator Training

The requirements of the aforementioned annotation process call for proficient-level annotations, which we achieved by means of controlled crowdsourcing (Roit et al., 2020). We identified qualified annotators through three open qualification rounds, followed by three closed rounds for selected annotators, focusing on further training and refinement. Each open round involved annotators reading a brief task description and accordingly aligning information between a single summary sentence and a short review, on a simplified interface. After each open round, we reviewed the alignment and provided feedback. We then checked whether the annotators implemented our feedback in the following round (with a different sentence-review instance). If the annotators satisfyingly cooperated throughout the open rounds, they moved on to the closed rounds. Before the closed rounds, the qualified workers were asked to watch a 25-minute tutorial on the full annotation tool and guidelines (§4.1 and §4.2). The closed rounds were conducted similarly to the open rounds, but with a whole summary and review, with all guidelines, and on the full interface. The qualification process was fully compensated with a customary wage, requiring up to 5 minutes per round. From this process, we were able to gather 8 trained annotators, who annotated the 1000 instances in our dataset.

4.4 Dataset Quality

To evaluate the quality of the compiled dataset, we compute the inter-annotator agreement. To this end, for every two annotators, we calculate intersection-over-union (*IoU*) of the tokens' indices (considering only content words) between the highlighted review spans that are aligned to the same summary sentence, similarly to Ernst et al. (2021). The *IoU* scores are gathered on the sentence level across three review-set/summary pairs, annotated by six crowdworkers. The resulting IoU score is 61.8.

To better understand the sources of disagreements, we analyzed all cases when $IoU < 90\%$. We found that the main cause of disagreement was related to our criteria for generalization and aggregation. Here, some annotators chose specific review spans they believed exemplified a summary characteristic, while others opted for different spans. This does not harm the quality of our data, as in all cases, the summary segment was indeed aligned with each of the corresponding review spans, according to our criteria. Another common source of disagreement involved annotators including additional phrases that provided only insignificant extra details on top of the summary. For detailed examples, refer to Appendix G.

Finally, an interesting aspect of our dataset is that 80% of the summary sentences align to spans from multiple reviews, and over 50% of the summary sentences align with non-consecutive spans from different sentences within a single review (see Table 1). We also find that on average, 25% of a review's tokens were highlighted. These properties reflect the real-world challenges faced by `FiC` models, expected to coherently fuse disparate, and at times redundant, details.

5 Evaluation Framework

Consistent with the task definition in §3, a passage produced by a model as a fusion of highlights within source documents must uphold several criteria. (1) *Faithfulness*: it must only contain information from the highlights; (2) *Coverage*: it must cover all the information in the highlights, be it in an explicit, generalized, or aggregated form; (3) *Coherence and Redundancy*: it must convey the information in a well-structured and non-redundant form. In this section, we suggest several automatic metrics for faithfulness and coverage, and assess their effectiveness by correlating to human scores that we collected. Coherence and redundancy are measured using manual evaluation.

5.1 Limitations of Lexical and Semantic Matching

Output's adherence to highlights was previously measured in Slobodkin et al. (2022, 2023a) by comparing the output passage and the concatenated highlights, using lexical metrics like **ROUGE** (n-gram matching) and **METEOR** (word matching with synonyms), and semantic metrics like **BERTScore** (probability of generating the output text). Our work, however, extends beyond the single-document scenario explored in these previous works, to also include multi-document contexts. This shift introduces additional complexities, such as managing redundancy and contradictions among highlights drawn from diverse sources, which may not be fully captured by standard lexical and semantic matching techniques. Further, our setting also enables highlights aggregation and generalization, which these metrics may not adequately address. Additionally, these automated approaches primarily measured overall adherence to the highlights without making a distinction between faithfulness and coverage. These latter aspects were evaluated manually, but only on a limited number of instances.

5.2 NLI-based Faithfulness Metric

Highlight-faithfulness requires the output passage to be entailed by the collective highlighted content. We employ the `flan-t5-xxl` model (Chung et al., 2022), shown to exhibit high performance on NLI tasks, for evaluating faithfulness to highlights in a zero-shot setting with a standard **NLI** prompt (see Appendix B). Previous research that used NLI models for faithfulness evaluation in summarization (Maynez et al., 2020; Laban et al., 2022; Honovich et al., 2022) typically set the grounding text as the premise, and the generated text as the hypothesis. Accordingly, we set the highlights concatenation to serve as the premise, since the outputs are expected to be entailed by all the highlighted content collectively (see §3). For the hypothesis, we segment the output passage into sentences, with each sentence serving as a separate hypothesis. The average of the sentence-level entailment scores is used as the overall entailment probability of the corresponding passage. This approach, inspired by (Laban et al., 2022), was found to be more effective than using the entire output as a single hypothesis.[6]

5.3 Trained Coverage Metric

Inspired by recent work that evaluates faithfulness and factuality using a dedicated **trained** model (Yin et al., 2021; Utama et al., 2022; Gekhman et al., 2023; Soleimani et al., 2023), we finetune an LLM that is tasked to assess whether the generated passage fully covers the highlights. In our methodology, each highlight is individually input along with the entire output, and the model outputs a binary answer for whether the highlight is contained in the passage.[7] We derive synthesized training data for this task from our `FiC` dataset, using highlights and their corresponding summaries. For negative samples, we remove the summary sentence that aligns with the highlight. For positive samples, a random non-aligning summary sentence is omitted (to avoid a potential bias caused by sentence exclusion in the negative samples). We finetune a `flan-t5-large` model (Chung et al., 2022) with the synthesized coverage data. The input to the model is the highlight and modified summary, and the output is 'yes' or 'no', for positive and negative samples, respectively. The final score is the average

---

[6] We also experimented with other methods for evaluating faithfulness and coverage, which exhibited lower correlation to human judgment. See Appendix E for more details.

[7] We also tried concatenating all the highlights together, and found it to be inferior.

Metric	Faithfulness		Coverage	
	τ	CI	τ	CI
ROUGE-1 (R)	0.2319	0.23-0.24	0.3467	0.34-0.35
ROUGE-1 (P)	0.5468	0.54-0.55	-0.0533	-0.06–0.05
ROUGE-2 (R)	0.3555	0.35-0.36	0.2731	0.27-0.28
ROUGE-2 (P)	0.5253	0.52-0.53	0.0071	0.00-0.01
ROUGE-L (R)	0.0958	0.09-0.10	0.3835	0.38-0.39

METEOR	0.4017	0.40-0.41	0.2736	0.27-0.28
BERTScore (R)	0.2380	0.23-0.24	0.4165	0.41-0.42
BERTScore (P)	0.6004	0.59-0.60	0.0529	0.05-0.06
NLI (Faithfulness)	**0.6745**	**0.67-0.68**	0.0929	0.09-0.10
Trained (Coverage)	0.1771	0.17-0.18	**0.4992**	**0.49-0.50**

Table 2: Average Kendall-Tau rank correlations (τ) and their 95% confidence intervals (CI) for tested evaluation metrics against human judgment. Recall-based metrics (R) are more effective for coverage, and precision-based metrics (P) for faithfulness. Best correlations for each axis are in bold.

probability of the token 'yes' across all highlights.[8]

5.4 Meta-Evaluation

Setup. To assess our evaluation metrics we follow the common practice (Fabbri et al., 2021) of correlating scores to human judgment. To that end, we gather faithfulness and coverage ratings for generated outputs from three co-authors of this paper. The outputs were produced by two models (see Flan-T5$_{\text{H}}$ and Flan-T5$_{\text{no-H}}$ in §6.1). A total of 50 review sets were randomly selected from our test set, leading to 100 scores for each of coverage and faithfulness. A 1-to-7 Likert scale was used to rate faithfulness and coverage separately for an output.

To ensure agreement among annotators, the three authors first evaluated a separate set of 10 outputs, and inter-annotator agreement was computed with Cohen's Kappa coefficient (Cohen, 1960). The average Kappa coefficients were 0.49 and 0.42 for faithfulness and coverage, respectively, indicating a moderate level of agreement (Viera et al., 2005). For more details, see Appendix E.3.

After collecting scores for the 100 instances, we computed their correlation with human judgment using Kendall-Tau rank correlation, as suggested in (Deutsch et al., 2022).[9] We also apply bootstrapping (Efron, 1987) by performing 1000 samplings of 70 instances (with repetition) and calculating correlation scores for each such subset. We report the average correlation and 95% confidence intervals for each metric.

Results. Table 2 shows the average correlations with their 95% confidence intervals for faithfulness and coverage. We find that while certain lexical- and semantic-based metrics yield decent results, notably BERTScore-precision for faithfulness and BERTScore-recall for coverage, our proposed metrics demonstrate significantly higher correlations, with average values of 0.6745 and 0.4992 for faithfulness and coverage, respectively. In light of these findings, we employ our NLI-based and trained metrics for assessing model performance in terms of faithfulness and coverage, respectively (in §6.2).

5.5 Human Evaluation of Coherence and Redundancy

We adopt the coherence assessment methodology from (Slobodkin et al., 2022). Crowdworkers judge the coherence of 100 randomly selected instances from the test set, for each examined model. A score between 1 and 5 is specified, and each passage is reviewed by three workers and averaged. Similarly, the redundancy of information in a passage is appraised. This approach follows standard practice, where coherence and redundancy are best evaluated manually (Fabbri et al., 2021; Steen and Markert, 2021). For more details see Appendix D.

6 Experiments

6.1 Experimental Setup

We examine several baseline models for solving the `FiC` task. The input to a model is a document set with spans marked within the documents (highlights), and the model is trained to generate a fused passage around the highlights.

Models with full input. Using the training set of our dataset, we finetune a large language model, marking the highlights in the input via designated mark-ups, following Slobodkin et al. (2022). Specifically, we finetune a `flan-t5-large` model (Chung et al., 2022), that exhibited enhanced performance in tasks requiring constrained generation (Sanh et al., 2022; Wei et al., 2022). We will refer to this model as **Flan-T5$_{\text{H}}$** ('H' for 'Highlights'). We develop an additional variant of Flan-T5$_{\text{H}}$, which we further finetune using Reinforcement Learning (**RL**), following the method in Slobodkin et al. (2023a). It applies the Quark algorithm (Lu et al.,

---

[8] We also explored an NLI-based coverage metric, where the passage serves as the premise and the highlights function as the hypothesis. We found it to achieve comparable results, however it requires substantially more computation time and memory. For more details, see Appendix E.

[9] Spearman correlations were also calculated, showing similar trends. See Appendix E.4.

Model	Faithfulness	Coverage	F-1	Coherence	Redundancy
Flan-T5$_{\text{H}}$	72.8	86.4	79.0	4.3	4.1
Flan-T5$_{\text{H}}$ (RL)	54.0	82.0	65.1	4.1	4.0
Flan-T5$_{\text{only-H}}$	**84.6**	**87.8**	**86.2**	3.6	3.8
Flan-T5$_{\text{no-H}}$	53.7	76.9	63.2	4.1	3.9
GPT-4	81.6	85.6	83.6	**4.7**	**4.5**

Table 3: Results for the proposed models on our `FiC` dataset. Faithfulness is measured with our NLI-based metric, and Coverage with our trained metric. The F-1 is a harmonic mean of the two latter scores. Coherence and Redundancy are measured through manual assessment. For each metric, the best score is in bold.

2022) combined with a dual-reward policy (Pasunuru and Bansal, 2018), alternating between our NLI-based faithfulness and trained coverage metrics (§5) as rewards. We also examine the performance of a one-shot **GPT-4** model (OpenAI, 2023), guided with an example of the task.[10]

Models with highlights only. To reveal the importance of the surrounding context, we also train a `flan-t5-large` model only with a concatenation of the highlights as the input (excluding surrounding context). We denote this variant **Flan-T5$_{\textbf{only-H}}$**.

Models without highlights. Finally, we examine `flan-t5-large` in a standard summarization setting, where it is finetuned with the input review-set without the highlighted spans, denoting this variant **Flan-T5$_{\textbf{no-H}}$**. It offers insights into the model's ability to pick up on signals that point to highlights.

6.2 Results

We apply our evaluation metrics on the proposed systems, with results presented in Table 3. We first observe that the exclusion of context from the input (Flan-T5$_{\text{only-H}}$) yields the strongest faithfulness and coverage scores, yet the lowest coherence and redundancy scores. This shows the importance of incorporating context for more seamless outputs. Meanwhile, the removal of highlights (Flan-T5$_{\text{no-H}}$) leads to a substantial degradation in faithfulness and coverage. This indicates that the Flan-T5$_{\text{H}}$ model indeed succeeds in learning to adjust the output according to the highlights, underlining the highlights' role in enhancing the model's performance.

Interestingly, even though the RL reward functions used in the RL-enriched model are the faithfulness and coverage metrics themselves, the outputs are eventually negatively affected when evaluating with these metrics. This result calls for a more in-depth investigation of enhanced reward functions that can leverage the benefits of RL training, as was shown to be helpful in Slobodkin et al. (2023a) for the single-input setup. We also find that single-shot GPT-4 yields the most coherent and least redundant texts. While it ranks highly in faithfulness and coverage, it is still overtaken by the finetuned Flan-T5$_{\text{only-H}}$. Overall, our findings invite for further research on the `FiC` task, to develop fusion strategies that ensure comprehensive coverage and faithfulness to highlighted content, with coherent and low-redundancy outputs.

7 Conclusion

In this paper, we further promote the decomposition of grounded text generation as presented in (Slobodkin et al., 2022), extending it to the multi-document setting. To that end, we introduce the Fusion-in-Context (`FiC`) task, an extension of the task from (Slobodkin et al., 2022) which focuses on the content fusion step, to the multi-document setting. The `FiC` setting facilitates employing a single general-purpose fusion model for diverse content selection needs, capturing the challenges of repetitiveness and contradictions in source documents. It also supports interactive, user-driven generation, by allowing users to choose personalized content for the `FiC` module to merge into a customized passage. Moreover, direct access to the pre-selected "highlights" can facilitate attributed generation, where the pre-selected segments also serve as supporting cited content for the fused text. To advance the task, we introduce the FUSEREVIEWS🖍 benchmark, which includes a high-quality dataset, an evaluation framework for faithfulness and coverage of selected spans, and several baseline models to stimulate further research and exploration.

Future work may include expanding the `FiC` task to other multi-input contexts, e.g., the news do-

---

[10] Preliminary experiments on a separate development set, with varying numbers of in-context examples, indicated that a single exemplar yields the best results. See Appendix C.

main. We also plan to investigate ways to leverage the built-in traceability of the output text's origin, namely the highlights, for facilitating attributed generation.

8 Limitations

In this work, we construct the first `FiC` dataset, developed by instructing crowdworkers to identify relevant spans within reviews that align with the content of corresponding summaries. To reduce cognitive load, each summary was displayed alongside individual reviews. While this approach streamlined the annotation process, there are instances where viewing the complete set of input reviews is advantageous, particularly for aggregative summary segments. In such segments, multiple review spans are combined into a single summary span, necessitating a broader understanding of the entire input set for accurate highlighting.

Moreover, the focus of our dataset on the business reviews domain may constrain its generalizability to other contexts with distinct textual structures, like news articles. This limitation extends to our trained evaluation metrics, which were developed using a derivative of our crowdsourced dataset and, therefore, are tailored to the specific characteristics of business reviews.

9 Ethics Statement

The proposed Fusion-in-Context (`FiC`) task, despite offering enhanced control over the content generated, is not expected to achieve complete resolution. Therefore, integrating `FiC` modules in modular generative systems should be done so with caution, since there is a possibility that these modules may overlook certain highlighted content or inadvertently include content that was not highlighted. This concern is particularly relevant for future endeavors that aim to use `FiC` for attributed generation. In such cases, there is a risk that some portions of the generated content may not be directly traceable to the pre-defined highlighted segments, leading to potential inaccuracies, or incompleteness, in attribution.

A Annotation Full Guidelines

In this section, we provide the full annotation guidelines, presented to our workers.

A.1 Summary-related Guidelines

As mentioned in §4.2, we guide annotators to segment summary sentences into the different aspects of hotels or businesses. The annotation guidelines distinguish between two classifications of aspects:

- DIFFERENT ASPECTS: This refers to independent facets of the business, e.g., location and room quality.
- DIFFERENT CHARACTERISTICS OF THE SAME ASPECT: This pertains to addressing varied characteristics within the same aspect, for example, the cleanliness and size of a room.

A.2 Review-related Guidelines

This section provides a detailed overview of the review-related guidelines presented to our crowdworkers during their training:

- ANY MENTION OF THE ASPECT: Annotators are trained to align all review mentions of a summary aspect, encompassing both similar and contrasting sentiments. For instance, if the summary aspect is *"The staff was friendly"*, both positive and negative mentions regarding staff friendliness are to be aligned.
- SPECIFICITY IN REVIEWS: Crowdworkers are advised to align review mentions that offer more specificity than the summary aspects. For example, a general summary statement like *"The staff was helpful"*, should be aligned with a more specific review comment, such as *"the concierge was very helpful"*. We also emphasize that the other way around, namely, that the summary is more specific than the reviews, should not be aligned.
- EXEMPLIFICATION IN REVIEWS: In line with the previous point, annotators are guided to focus on identifying review segments that provide examples of the summary statements. An example would be aligning the summary span *"The hotel is well-maintained"* with a review segment that exemplifies it, such as *"the pool area is very clean"*. As in the previous point, we discourage our crowdworkers from considering the reverse cases, when the summaries exemplify the reviews.
- PARAPHRASING: Annotators are instructed to align paraphrased mentions in reviews with the summary content, such as aligning *"the hotel is overpriced"* with *"you can stay at lovely B&B in the old town that is actually cheaper than this"*.
- CONSECUTIVENESS: We guide our workers to avoid highlighting unnecessary details, i.e., that did not appear in the summary span, and keep the highlights inconsecutive if needed.
- UNALIGNABLE SPANS: Recognizing that each summary is derived from multiple reviews, but reviewers assess only one review at a time, it is often the case that not all summary details will be present in the reviewed content. In such instances, annotators are instructed to leave such summary spans unhighlighted.

B NLI Zero-Shot Prompt

Figure 3 demonstrates the structure of the zero-shot prompt used for the nli-based evaluation frameworks of highlights coverage and faithfulness.

Number of Exemplars	Faithfulness	Coverage	F-1
1	**80.1**	85.0	**82.5**
2	72.1	**86.1**	78.5
3	73.6	84.0	78.5
4	72.8	82.2	77.2

Table 4: Faithfulness, coverage, and F-1 scores of the zero-shot GPT-4 model on 30 instances for the `FiC` development set, for varying numbers of in-context examples in the prompt. For each metric, the best scores are in bold.

C GPT-4 Prompting

Table 4 presents the faithfulness, coverage, and F-1 scores of the zero-shot GPT-4 model across 30 instances from the `FiC` development set, for varying numbers of in-context examples in the prompt. Based on these outcomes, we chose to proceed with a single in-context example.

D Fluency and Redundancy Human Annotation Protocol

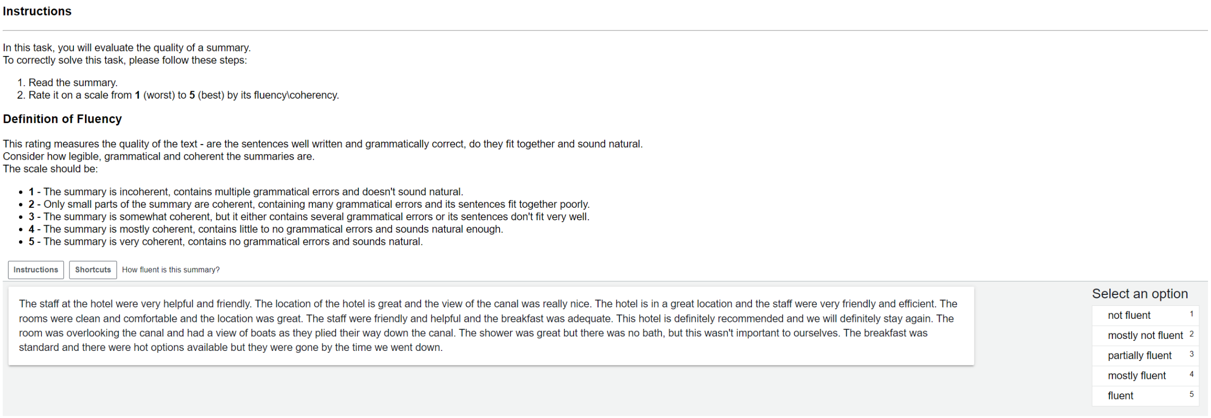
We ask crowd-workers to assess the fluency and redundancy of the texts produced by all models under examination. We employ annotators who have demonstrated proficiency in semantic tasks, including summarization, in previous experiments. For evaluation purposes, 100 instances are randomly selected from our test set, and the texts generated by each model for these instances are evaluated, resulting in 500 total samples. Each sample is reviewed by three different annotators, and their scores are averaged to obtain a final assessment. The evaluation is facilitated through two Amazon Mechanical Turk interfaces, specifically designed for this study. One interface focuses on evaluating coherence, while the other assesses redundancy, with each interface presenting the annotators with one of the 500 samples (as depicted in Figure 4). Consistent with the methodology of (Slobodkin et al., 2022), a 5-point Likert scale is employed to rate the fluency and redundancy of the generated summaries. To minimize ambiguity and promote consistent ratings, each score on the scale is accompanied by explicit criteria (also illustrated in Figure 4). Taking into account an average response time of 30 seconds for each evaluation, we set the compensation for each response at 10 ¢.

```
### Instruction: Read the following and determine if the hypothesis can be inferred from the premise.
Options: Entailment, Contradiction, or Neutral

### Input:
Premise:  {Premise}
Hypothesis: {Hypothesis}

### Response (choose only one of the options from above):
```

Figure 3: The prompt structure employed in zero-shot configurations as a basis for evaluating the frameworks of faithfulness and coverage.



Instructions

In this task, you will evaluate the quality of a summary.
To correctly solve this task, please follow these steps:

1. Read the summary.
2. Rate it on a scale from **1** (worst) to **5** (best) by its fluency\coherency.

Definition of Fluency

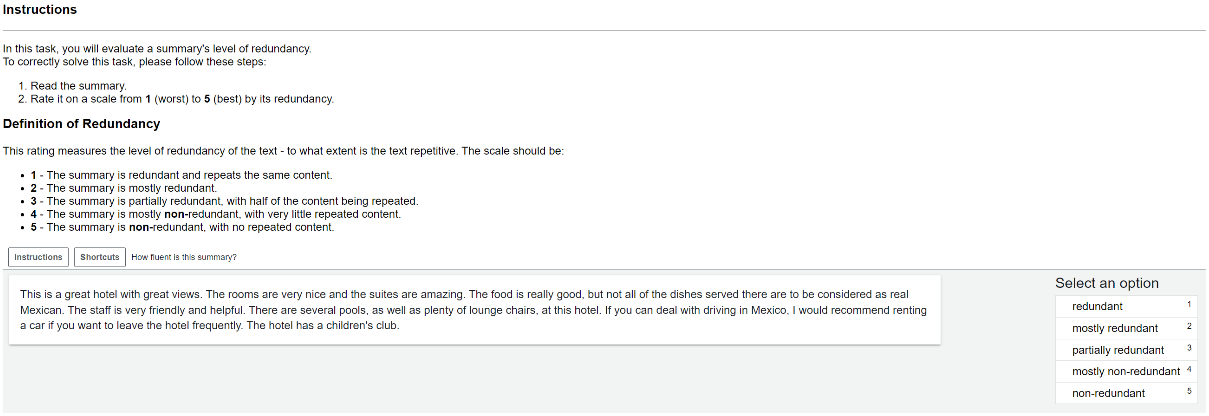
This rating measures the quality of the text - are the sentences well written and grammatically correct, do they fit together and sound natural.
Consider how legible, grammatical and coherent the summaries are.
The scale should be:

- **1** - The summary is incoherent, contains multiple grammatical errors and doesn't sound natural.
- **2** - Only small parts of the summary are coherent, containing many grammatical errors and its sentences fit together poorly.
- **3** - The summary is somewhat coherent, but it either contains several grammatical errors or its sentences don't fit very well.
- **4** - The summary is mostly coherent, contains little to no grammatical errors and sounds natural enough.
- **5** - The summary is very coherent, contains no grammatical errors and sounds natural.

How fluent is this summary?

The staff at the hotel were very helpful and friendly. The location of the hotel is great and the view of the canal was really nice. The hotel is in a great location and the staff were very friendly and efficient. The rooms were clean and comfortable and the location was great. The staff were friendly and helpful and the breakfast was adequate. This hotel is definitely recommended and we will definitely stay again. The room was overlooking the canal and had a view of boats as they plied their way down the canal. The shower was great but there was no bath, but this wasn't important to ourselves. The breakfast was standard and there were hot options available but they were gone by the time we went down.

(a) Fluency Evaluation Interface



Instructions

In this task, you will evaluate a summary's level of redundancy.
To correctly solve this task, please follow these steps:

1. Read the summary.
2. Rate it on a scale from **1** (worst) to **5** (best) by its redundancy.

Definition of Redundancy

This rating measures the level of redundancy of the text - to what extent is the text repetitive. The scale should be:

- **1** - The summary is redundant and repeats the same content.
- **2** - The summary is mostly redundant.
- **3** - The summary is partially redundant, with half of the content being repeated.
- **4** - The summary is mostly **non-**redundant, with very little repeated content.
- **5** - The summary is **non-**redundant, with no repeated content.

How fluent is this summary?

This is a great hotel with great views. The rooms are very nice and the suites are amazing. The food is really good, but not all of the dishes served there are to be considered as real Mexican. The staff is very friendly and helpful. There are several pools, as well as plenty of lounge chairs, at this hotel. If you can deal with driving in Mexico, I would recommend renting a car if you want to leave the hotel frequently. The hotel has a children's club.

(b) Redundancy Evaluation Interface

Figure 4: Example of the data collection interfaces used by the crowd-workers to evaluate the fluency (4a) and redundancy (4b) of summaries.

E Additional Evaluation Framework Details

E.1 Trained Faithfulness Metric

In a similar fashion to the trained coverage metric, we we use our crowdsourced dataset to generate training data for evaluating highlights faithfulness. This approach mirrors the NLI-based metric we proposed, wherein a model is trained to individually evaluate the faithfulness of each output sentence, subsequently averaging the scores across all sentences.

For the positive training instances, we separate each summary from our crowdsourced dataset into sentences, and pair each sentence with all the instance's highlights. In contrast, for the creation of negative instances, we remove all highlights that were aligned with any segment of the cor-

Judges	Faithfulness	Coverage
1-2	0.37	0.31
2-3	0.71	0.67
1-3	0.39	0.27

Table 5: The individual Cohen's Kappa coefficients for each pair of judges, on the faithfulness and coverage axes.

responding summary sentence. The training process involves fine-tuning a `flan-t5-large` model (Chung et al., 2022). In this setup, the input comprises the highlights and the summary sentence, while the output is either the token 'yes' for positive instances, or 'no' for negative ones. The final score is calculated based on the probability assigned to the token 'yes' by the model.

E.2 NLI-based Coverage Metric

For the evaluation of highlight-coverage using Natural Language Inference (NLI), our approach mirrors the one implemented for assessing faithfulness using NLI (see §5.2), albeit with a role reversal, where the output serves as the premise and the highlights function as the hypothesis. Rather than treating all highlights collectively as the hypothesis, we calculate the coverage of each highlight separately and then average across all highlights.[11]

E.3 Additional Meta Evaluation Setup Details

Pairwise Cohen Kappa Coefficients Table 5 shows the pairwise Cohen's Kappa coefficients for each pair of judges.

Reconciliation Process To achieve further agreement between the three authors, an additional reconciliation procedure was undertaken for the ten instances annotated by all three authors. This procedure entailed discussions for each instance where the annotations diverged by more than one point, separately for the faithfulness and coverage scores. During these discussions, each author explained the rationale behind their assigned score. Subsequently, the authors endeavored to reach a unanimous agreement on each instance, thereby further aligning their scoring criteria.

E.4 Additional Meta Evaluation Results

Tables 6 and 7 present the full correlations with human judgments using the Kendall-Tau rank correlations and Spearman's rank correlations, respectively, including the additional evaluation frameworks we explored (see Appendices E.1 and E.2), and the F-1 scores for the ROUGE and BERTScore metrics.

	Faithfulness		**Coverage**	
Metric	τ	**CI**	τ	**CI**
ROUGE-1 (R)	0.2319	0.23-0.24	0.3467	0.34-0.35

Table 8: Full statistics of our dataset, including the number of unique review-sets, the average number of summaries per review-set, the number of summary/review-set pairs (a unique review-set creates a pair with each of its summaries), the mean review/summary size (in tokens and in sentences), the maximum review/review-set/summary size (in tokens), the percentage of summary sentences whose alignments span across more than one review, and the percentage of summary sentences whose alignments span across more than one review sentence within one of its reviews (namely, within a single review, the alignments come from more than one sentence).

F Additional Dataset Details

F.1 Full `FiC` Dataset Statistics

Table 8 presents the full `FiC` dataset statistics, including specific statistics for each of the dataset's splits and instances origin, i.e., CocoTrip or FewSum.

F.2 Annotation Cost

Each annotation instance, averaging 4 minutes, is priced at 70¢. Annotators also receive compensation for training activities, including a 5$ bonus for taking the 25-minute tutorial and an additional 2$ for reviewing feedback. The total cost for the dataset amounted to approximately 5700$.

F.3 Additional Details about the Annotators Recruitment

For our crowdsourcing project, we hired annotators from English-speaking countries who had over 5000 approved HITs as well as an approval rate higher than 98% on Amazon Mechanical Turk. During the recruitment process, in addition to explaining the annotation guidelines, we also explained to the crowdworkers the purpose of the dataset, in order to rationalize different aspects of the annotation protocol.

G IAA disagreement Examples

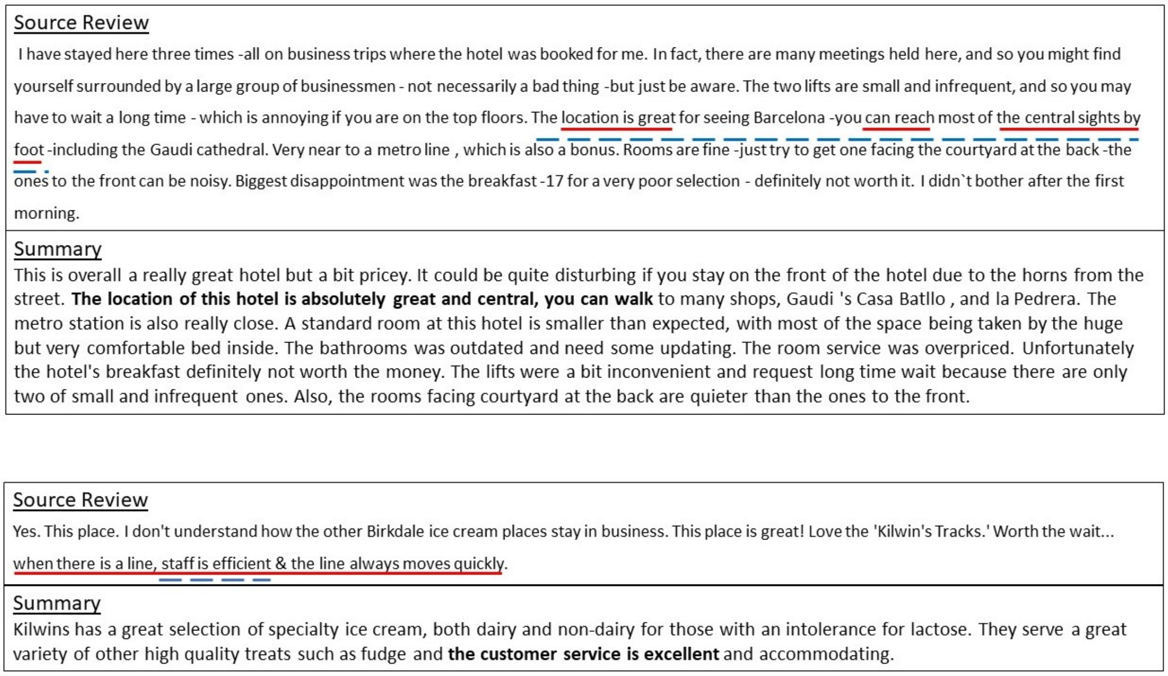
Figure 5 demonstrates two instances of disagreements between our annotators.

H Additional Experimental Details

To incorporate the highlighting signal in the baseline Flan-T5$_{\text{H}}$, <*extra_token_1*> and <*extra_token_2*> tokens were added to the input, before and after each highlight. For all trained models, we set the maximum input length to 2048, to accommodate the input length of the language model.

We also set the maximum target length to 200, which we found works best, as well as setting the batch size to 1. The other parameters are similar to Slobodkin et al. (2022, 2023a). The model is trained for 10k steps. Training is performed on two A100-SXM4-80GB GPUs, and costs about 12 GPU hours for the supervised models (Flan-T5$_{\text{H}}$, Flan-T5$_{\text{no-H}}$, and Flan-T5$_{\text{only-H}}$) and about 36 GPU hours for the RL-tuned variant of Flan-T5$_{\text{H}}$.

Additionally, to train the trained faithfulness and coverage evaluators, we concatenate the highlights concatenation and the output's sentence (for faithfulness) and the generated output with each of the highlights (for coverage), and use the special token <*extra_token_4*> as a delimiter. For both evaluators, we set the maximum input length to 1024, the maximum target length to 4 , and the batch size to 1. We train the models for 10 epochs. Training is



Source Review

I have stayed here three times -all on business trips where the hotel was booked for me. In fact, there are many meetings held here, and so you might find yourself surrounded by a large group of businessmen - not necessarily a bad thing -but just be aware. The two lifts are small and infrequent, and so you may have to wait a long time - which is annoying if you are on the top floors. The location is great for seeing Barcelona -you can reach most of the central sights by foot -including the Gaudi cathedral. Very near to a metro line , which is also a bonus. Rooms are fine -just try to get one facing the courtyard at the back -the ones to the front can be noisy. Biggest disappointment was the breakfast -17 for a very poor selection - definitely not worth it. I didn`t bother after the first morning.

Summary

This is overall a really great hotel but a bit pricey. It could be quite disturbing if you stay on the front of the hotel due to the horns from the street. **The location of this hotel is absolutely great and central, you can walk** to many shops, Gaudi 's Casa Batllo , and la Pedrera. The metro station is also really close. A standard room at this hotel is smaller than expected, with most of the space being taken by the huge but very comfortable bed inside. The bathrooms was outdated and need some updating. The room service was overpriced. Unfortunately the hotel's breakfast definitely not worth the money. The lifts were a bit inconvenient and request long time wait because there are only two of small and infrequent ones. Also, the rooms facing courtyard at the back are quieter than the ones to the front.

Source Review

Yes. This place. I don't understand how the other Birkdale ice cream places stay in business. This place is great! Love the 'Kilwin's Tracks.' Worth the wait... when there is a line, staff is efficient & the line always moves quickly.

Summary

Kilwins has a great selection of specialty ice cream, both dairy and non-dairy for those with an intolerance for lactose. They serve a great variety of other high quality treats such as fudge and **the customer service is excellent** and accommodating.

Figure 5: Two examples of disagreement between annotators. For each example, the bottom part is the summary (with the summary span over which there was disagreement in bold) and the top part is a review with both the annotators' highlights (marked with a red solid line and a blue dashed line to indicate each highlight).

Model	Faithfulness	Coverage	F-1
`flan-t5-small`	66.9	83.4	74.2
`flan-t5-base`	70.1	85.5	77.0
`flan-t5-large`	72.8	86.4	79.0

Table 9: Faithfulness, coverage, and F-1 results on the `FiC` testset, for different sizes of `flan-t5` (all finetuned on the `FiC` trainset).

performed on a single A100-SXM4-80GB GPU, and costs about 4 GPU hours.

Overall, our trained models, both for faithfulness and coverage evaluation and for the `FiC` task, use `flan-t5-large` as their backbone model, which consists of 780 million parameters, and our zero-shot NLI-based evaluation frameworks use `flan-t5-xxl` as the backbone model, consisting of 11 billion parameters.

I Generation Examples

Figure 6 and Figure 7 demonstrate two examples of highlighted reviews and the corresponding output generated by Flan-T5$_\mathrm{H}$.

J Impact of Model Size

Table 9 illustrates the performance on the test set of `flan-t5` with different model sizes, finetuned on the `FiC` trainset.

Review 1: I recently travelled to Singapore and ended up to the Grand Hall City Park as booking late on a busy weekend, the rest was either sold out or too expensive. I had a corporate rate, and must say it was good value for money, given the quite central location. The service was good and the hotel staff very friendly. On the negative side, the hotel is a bit outdated and lacking style. I got a room close to the elevator, which turned out to be very noisy, and got waken up in the middle of the night by people spekaing loud (isolation is really bad, and that is the main reason why i would not recommend this hotel). Also breakfast was disappointing with very limited choices and no fresh fruit apart from apples and bananas. There is a pool, which is ok, but very very small. Perhaps a better room would make me change my opinion, but still it was lacking style and personality.

Review 2: I am a first time traveller overseas with my husband, therefore we are comparing to 5 star accomodation in Australia. We read the reviews on all the hotels in Singapore and decided this was the hotel for us. The hotel was very clean, although the furnishings are getting old and need updating in the rooms and eating areas. We found the staff very accomodating and the buffet breakfast and dinner meals changed all the time. The hotel was central for all our travelling. The only bad comment, we were on a non smoking floor, yet the wardrobes smelt smoky. There was a cross section of travellers. When we go back to Singapore, we would stay again as good value for the price Over 50s from Adelaide

Review 3: We were very impressed by the standard of service we received from all the staff, especially Ms Kripa at the club floor. The staff were friendly and keen to ensure we enjoyed our stay at the hotel. The location is great, close to MRT, Clarke Quay, the National Museum etc - all walking distances. Our king size bed was very comfortable but the bathroom was a little small and only one person at a time can fit, but having a full size bath was very nice to relax in. We would stay at this Hotel again.

Review 4: for the last 3 years have been staying 3to 4times a year for periods of up to 2 weeks in this hotel. plusses: great location with short walk to mrt, staff very friendly and helpfull.minus is no wifi in rooms.rooms at floor which are not yet removated are run down.

Review 5: Went to Singapore for the Grand Prix and this hotel was just 2 minutes away from Gate 4. The hotel staff were very helpful and the whole hotel we found to be very pleasant and would definitely go back again to stay.

Review 6: This is my first time in the hotel. I found it conveniently located, very nice and friendly staff, excellend dining and a very nice fitness Center. I look forward to returning.

Review 7: This is a very central, large good value hotel in Singapore. Maybe the rooms are not as grand as the reception area, but overall I would recommend it to most travellers

Review 8: Great location, excellent service, beautiful view, nice staffs. The price is quite high but worth it.

Generated Summary : This hotel is in a great location and the staff is very friendly and helpful. Besides this the hotel is very pleasant and the view from the hotel was really good too. The Grand Prix of Singapore was only 2 minutes away from this hotel and it is very close to the MRT, Clarke Quay and the National Museum too. Overall this hotel is a very pleasant place to stay and the price is quite high but it is worth the money because it is in such a central location and there are lots of attractions nearby.

Figure 6: Example of generated output by Flan-T5$_H$.

Review 1: Very nice staff! It's always packed in here & I'm not surprised! Quality food! Lots of options! I absolutely love the vegan options as well as the GMO-free foods (all Trader Joe's brand is GMO-free). I have to say the prices are greats as well! Love TJ's!!

Review 2: I love getting my Pirate Booty from here (the puffs people) and the ready made pizzas, pretty much everything that they have ready made is really good. The store can get pretty crowded, especially during the dinner hour rush. Employees are friendly and I recommend you take advantage of the samples throughout the store. Come hungry!

Review 3: This store gives me a nice and warm feeling. The feeling that I didn't and won't have with Walmart Market. Trader Joe's has a lot of eye-catching snacks and healthy food. Therefore, I have no idea which items I should buy. If I can, I want to try everything. Absolutely, comeback

Review 4: Checked out this location. Smaller than the Albuquerque NM store that we frequently visit but found the items we were needing but noticed selection was different or maybe I just wasn't finding what I needed. I didn't find the selection of jelly and jams that I wanted but that is okay.

Review 5: Love this store... can't get enough of it. I have been going to Trader Joe's for years. This store always makes me happy. From great recepies idea to great selections of groceries. Staff is really friendly as well. Thumbs up Trader Joe on Camelback Rd!

Review 6: This is a big TJ's. What else is there to say? It's a Trader Joes. Awesome food, great employees. I don't know what I could complain about. Skip Fry's and shop here. The food is healthier and taste better.

Review 7: The parking for this location can be a madhouse because it's located in a very busy strip mall and largely due to the construction surrounding it. But in TJ fashion, it won't disappoint with all the usual goodies that make you feel so adult and domesticated shopping here. Staff is always awesomely happy and helpful.

Review 8: This is my favorite Joe's. From SF to SD to Scottsdale, the T & C location is the best. Everyone here genuinely knows me and my son. They interact with you like a friend. Products are always great and when they're not they exchange with no hassle. Thanks to the whole staff for always being so welcoming.

Generated Summary : This Trader Joe's is a great place to shop for groceries. The store is located in a busy strip mall, so it can get crowded, especially during the dinner hour rush. However, the store is well-stocked with healthy food options, as well as vegan and GMO-free options. The staff is friendly and helpful, and there are samples available to take advantage of. Overall, this store is highly recommended for its quality food, friendly staff, and warm, welcoming atmosphere.

Abstract

Retrieval-Augmented Neural Machine Translation (RAMT) architectures retrieve examples from memory to guide the generation process. While most works in this trend explore new ways to exploit the retrieved examples, the upstream retrieval step is mostly unexplored. In this paper, we study the effect of varying retrieval methods for several translation architectures, to better understand the interplay between these two processes. We conduct experiments in two language pairs in a multi-domain setting and consider several downstream architectures based on a standard autoregressive model, an edit-based model, and a large language model with in-context learning. Our experiments show that the choice of the retrieval technique impacts the translation scores, with variance across architectures. We also discuss the effects of increasing the number and diversity of examples, which are mostly positive across the board.

1 Introduction

Retrieval-Augmented Language Models and Translation Models are getting a lot of traction (see (Li et al., 2022a) for a recent review). For translation tasks, the use of retrieval-based techniques that identify the most relevant segment(s) in a Translation Memory (TM) has long been used in professional Computer Aided Translation environments (Bowker, 2002), where the retrieved segments provide translators with valuable suggestions. Segments closely resembling the source sentence to be translated can also be directly edited to speed up translation. Such ideas have also been used in Machine Translation (MT), first in the example-based tradition (Nagao, 1984; Somers, 1999; Carl et al., 2004), then in the statistical-based paradigm (Koehn and Senellart, 2010), more recently for neural machine translation (NMT).

There are several ways to take advantage of translation examples in NMT architectures: Farajian et al. (2017) use a small set of examples to perform on-the-fly, lightweight, fine-tuning (using both source and target sides); Bulte and Tezcan (2019) simply concatenate the (target side of) a handful of examples on the source side of the encoder, leaving the rest of their autoregressive decoder unchanged; Xu et al. (2023) repurpose the edit-based architecture of Gu et al. (2019) to compute new translations from existing ones with a non-auto-regressive (NAT) decoder; finally, in-context learning (ICL) in large language models (LLMs) provides yet another way to seamlessly combine TMs with text generation (see Moslem et al. (2023), *inter alia*).

These studies (and several others, fully discussed in §5) not only differ in the way they use examples but also in the way TMs are searched, retrieved, and filtered. This makes the direct comparison between these proposals sometimes difficult to reproduce and analyze. Furthermore, it also prevents precisely assessing the computational complexity of the complete translation pipeline.

In this paper, we perform experiments with several representative retrieval methods that we systematically combine with multiple RAMT architectures. In doing so, our main goal is not to compare these downstream architectures, but rather to better understand the interplay between the retrieval and generation tasks, to make the trade-offs between these steps explicit, and to formulate recommendations regarding future uses of TMs in NMT.

Specifically, we address the following questions:

- How much does the example selection impact translation performance? Is one retrieval technique always better than the others, irrespective of the MT architecture, or is it necessary to adapt the former to the latter?
- Do we need multiple examples? If so, what makes a good set of examples? Does the diversity of examples help?

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3022–3039
June 16-21, 2024

- By restricting retrieval to a restricted subset of examples based on the source domain, can we expect better performances, even though the quality of the best retrieved match is decreased?

We notably find that (a) retrieval actually matters for edit-based and in-context learning; (b) existing retrieval pipelines can be simplified at inference; (c) optimizing source coverage and/or instance diversity is helping, especially when the closest match is poor.

2 Retrieval in NMT architectures

2.1 Retrieval Pipeline

In the information retrieval (IR) framework, given a query q, a set of documents D is filtered and/or ranked according to a retrieval score. The challenge is to craft a score $s(q, d)$ that will retrieve documents d that are relevant for a downstream task. In MT, q is a source sentence, and D is a translation memory from which we can extract relevant (source, target) pairs ($d = (x, y)$). The retrieval process can be divided into three steps (Figure 1):

1. **Domain selection** selects the corpus to retrieve examples from, typically based on domain/genre similarity;

2. **Filtering** narrows down the set of relevant examples based on superficial comparison between the source query q and each example d.

    - Filtering can use a simple similarity score to filter TM candidates based on some minimal threshold: Bulte and Tezcan (2019) uses Jaccard similarity between bag-of-word representations; (Xu et al., 2020; Bouthors et al., 2023) use an n-gram match similarity;
    - Filtering can also be controlled by the specification of the indexing vocabulary, which typically excludes frequent words, thereby shortening the list of similar documents (see Appendix B.2).

3. **Ranking** uses a retrieval score such as n-gram overlap (Xu et al., 2020), BM25 score (Gu et al., 2018; Cheng et al., 2022), edit distance (ED) (Bulte and Tezcan, 2019; Xu et al., 2020; Bouthors et al., 2023), cosine similarity between q and x's embeddings (Xu et al., 2020; Pham et al., 2020; Vilar et al., 2023). *Incremental ranking* or *Weighted Coverage* can also be used to enforce diversity when retrieving multiple samples (Cheng et al., 2022; Agrawal et al., 2023; Sia and Duh, 2023a).

In a final **selection step**, only the top-k most similar candidates are eventually retained. Depending on the choice of the filtering parameters, the actual number of examples retrieved for a given query may be strictly smaller than k. For some domains, retrieval may even return an empty list.

2.2 Measuring Retrieval Quality

The effects of a retrieval strategy are only observed once a translation model is trained and evaluated. As this is an excessively costly process, we introduce several aspects that define *a priori* the quality of retrieved similar examples. For a single example d, this includes its semantic relatedness with q or the lexical overlap with the query; d's length also matters, as long examples may include irrelevant words that can hurt translation (Xu et al., 2020), and increase the computational processing cost. Now, looking at *sets of examples*, we would also like them to cover most query words, while remaining diverse and short on average.

To evaluate these facets, we compute the following scores for each set of similar examples:

- **Coverage** is the proportion of query tokens covered by the example tokens. It can be defined in several ways (bag-of-word recall, modified recall[1], n-way alignment score[2]).

- **Relevance** is the proportion of contributing tokens from the example tokens (with the same three underlying definitions as coverage). All other words are deemed lexically irrelevant; we report an average over examples.

- **Length** is the average number of tokens of retrieved examples.

In the next paragraphs, we describe how these quantities are controlled during retrieval.

2.3 Smoothed Longest Common Subsequence

The Levenshtein edit distance (LED) is widely used as the ranking function in RAMT (see §2.1).

---

[1] Each source token can only be covered at most once.

[2] Based on an alignment graph between examples and query that forbids swapping, as defined by Bouthors et al. (2023).

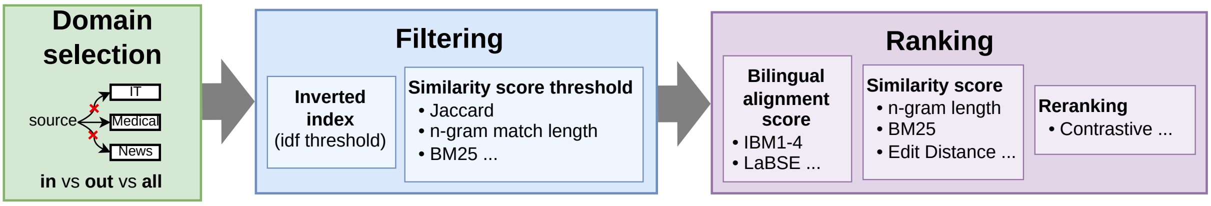

Figure 1: High-level overview of the retrieval pipeline in fuzzy-matching.

It counts the minimum number $\Delta(x, q)$ of word-level operations (deletion, insertion, replacement) required to edit x into q and then normalizes:

$$\text{LED}(x, q) = 1 - \frac{\Delta(x, q)}{\max(|x|, |q|)}, \qquad (1)$$

Using LED mainly selects examples that are lexically similar to the source. As it penalizes non-matching parts (in the normalizer), it may discard long examples containing good matches in a substring. Such examples can still be relevant if they yield a high coverage of the query.

As an alternative to LED, setting the deletion cost to zero in (1) computes the Longest Common Subsequence (LCS) between x and q, which maximizes the coverage at the expense of relevance. This also means that there is no penalization for length, which can lead to long and hard-to-exploit examples. We propose a smoothed version, namely δ-LCS, with a small non-zero deletion cost δ. δ-LCS thus performs a trade-off between coverage, relevance, and length. Details are in Appendix A.

2.4 Controlling Diversity: Contrastive Retrieval

As is well known in the IR literature, it is unproductive to retrieve multiple identical examples. Diversity can help increase coverage without hurting the relevance of individual examples. For RAMT, a small number of diversity preserving approaches have been proposed: Cheng et al. (2022) (Levenshtein distance), Agrawal et al. (2023) (n-gram overlap) and Sia and Duh (2023b) (BM25) rely on an iterative algorithm inspired by the Maximal Marginal Relevance (MMR) criterion of Goldstein and Carbonell (1998). In a nutshell, this means that the ranking scoring function is iteratively updated to downgrade candidate examples that are either too similar to already selected examples or that cover already covered words. In our experiments, we follow Cheng et al. (2022), and after selecting $|M|$ matches in M, we penalize the ranking scores of remaining candidates with the following term:

$$\frac{\alpha}{|M|} \sum_{x \in M} \text{LED}(\cdot, x), \qquad (2)$$

where $\alpha > 0$ controls the strength of the penalty.

2.5 Integrating TMs in Translation

In our comparisons, we consider three NMT architectures with variants. The first, called Neural Fuzzy Augmentation (NFA), implements the autoregressive approach of Bulte and Tezcan (2019), with minor variants. The second, `TM-LevT`, is edit-based and mostly follows Xu et al. (2023), as recently extended by Bouthors et al. (2023) to handle multiple matches. The third is based on in-context learning (ICL) with large LMs, using the causal BLOOM LM (BigScience et al., 2022) and the HuggingFace Transformer library[3] to run the experiments. We provide full details regarding these architectures in Appendix C. At a high level, the most important distinction is between the *autoregressive generative approaches* of NFA and ICL, which both use an enriched context comprising the source sentence and additional source and/or target matches, and `TM-LevT`, which tries to reuse, via an editing process, subparts of the retrieved matches. Another major difference is between ICL, which inputs the source side of matches for decoding, and the other two approaches, which do not need it during generation. This notably impacts the computational cost of encoding the context.

3 Data and Metrics

3.1 Data

We consider two translation directions, from English to French (en-fr) and from German to English (de-en), and experiment with multiple domains. This allows us to study a wide range of settings, with a varying density of matches: our datasets include ECB, EMEA, Europarl, GNOME, JRC-Acquis, KDE4, PHP, Ubuntu, OpenSubtitles,

---

[3] `https://github.com/huggingface/transformers`.

and Koran[4] (statistics in Tables 1 and 2). For en-fr, these datasets reproduce the setting of (Xu et al., 2020). [5] For de-en, we reuse the data prepared by Koehn and Knowles (2017) with the split of Aharoni and Goldberg (2020).[6] The most favorable situation is to translate in a narrow domain with large TMs, ensuring that multiple good matches can be found (e.g. JRC-Acquis and EMEA). However, in a narrow domain, the TM can sometimes be small (e.g., Ubuntu), and this is where other related domains can also help. On the other end of this spectrum, Europarl or News-Commentary are thematically very diverse and good matches much harder to find.

For each dataset $\mathcal{D}$, we compute a *density* score based on the number of connected components (NCC) in a similarity graph Γ. Two translation examples are linked in Γ if their similarity score (1) is greater than 0.4:

$$\text{density}(\mathcal{D}) = 1 - \frac{1 - \text{NCC}(\Gamma)}{1 - |\mathcal{D}|} \qquad (3)$$

In high-density domains, it is thus easier to retrieve relevant translation examples (see Tables 1 and 2).

Note that these data are not ideal. First, for some domains, the corresponding data may be included in the very large corpora used to train LLMs. In our experiments with BLOOM, which is trained on the ROOTS corpus (Laurençon et al., 2022), this is the case for JRC-Acquis, Wikipedia, Europarl, TEDTalks (en-fr).[7]

Furthermore, the en-fr test sets have been selected based on the existence of at least one close example in the same domain, using the standard LED to compute similarities. More precisely, the 1,000 instances in *test-0.6* always have at least one match with similarity greater than 0.6, for *test-0.4* the nearest match has a similarity comprised between 0.4 and 0.6 (details in (Xu et al., 2020)).[8]

This design allows us to focus on the effect of retrieval quality (medium vs high-scoring matches) on translation scores. It however yields absolute scores that do not compare with what would be obtained with a fully randomized selection process. For a more realistic evaluation, we use the de-en data, which, however, cover fewer domains. In general, our experiments are more thourough with en-fr data as this language pair was used to select a subset of interesting configurations to be then also tested for de-en.

As a last word of caution, we observe that some domains are much easier to translate than others: JRC-Acquis is very repetitive, which yields BLEU scores in the high 70's; NewsCommentary, on the other hand barely achieves BLEU scores higher than 20. Averaged results should be looked at with care - only per-domain scores can tell the full story (Appendix E).

3.2 Metrics

We report BLEU scores (Papineni et al., 2002) computed by SacreBLEU (Post, 2018),[9] as well as COMET-22[10] scores (Rei et al., 2022) using the official implementation. Additionally, we use the multi-reference sentence BLEU scores between the target side of examples, and the translation output[11], averaged over corpora, to evaluate the *copy rate* of systems, i.e. their ability to recopy subparts of the retrieved examples.

3.3 Implementation and Parameters

We use in-house, open-source[12] libraries that implement the various retrieval methods explored in this paper. Details regarding parameter settings are in Appendix B. For translation architectures, refer to Appendix C.

In our experiments, we contrast three strategies for domain selection: in-domain, out-of-domain, no-selection. Regarding filtering (step 2 in Figure 1), we compare n-gram matching (NGM), BM25, and no filter. NGM filters out examples unless they share a common n-gram g with the source q of relative length greater than a threshold τ (e.g. $\frac{|g|}{|q|} \geq \tau$). As for BM25, we only retain the L best BM25 candidates.

Finally, regarding ranking, we compare various definitions of the edit distance (ED) (see §2.3) with BM25.

Computational issues In our experiments below, we mostly analyze retrieval results. However, note that each retrieval pipeline yields specific training

and inference computational costs. Domain selection always speeds up the subsequent steps, with a very strong impact when the target domains are small. Regarding filtering, NGM has an algorithmic complexity $O(\bar{\ell}\log(n\bar{\ell}))$ for a single query using suffix array – with $\bar{\ell}$ the average sentence length and n the TM size – whereas BM25's complexity is $O(n|q|)$. Finally, regarding ranking, ED calculation takes ($O(n\bar{\ell}|q|)$), so again, linear w.r.t. n for one query.

4 Experiments

4.1 Comparing Retrieval Techniques

We first measure how much a change in the retrieval technique actually affects the instances that are eventually retrieved. For this, we compute bag-of-word coverage, relevance, and length (introduced in §2.2). We compare a baseline NGM filter using the LED ranker, as used in Bouthors et al. (2023), with filter-free pipelines. The corresponding results for all testsets are in Table 3. LED yields the highest relevance, while δ-LCS and contrastive ranking yield a higher coverage. Overall, changing the retrieval technique does impact the set of instances that are used in training and inference.

4.2 Interactions Between Retrieval and Translation

In this section, we look at the interactions between retrieval and translation and systematically vary the retrieval component for the three architectures of §2.5. Notably, we compare two filters (NGM and BM25) during training and also contrast with a filter-free version in inference. We also vary the edit costs and the number of retrieved examples.

4.2.1 Architectures Comparison

Neural fuzzy augmentation We observed, in preliminary results, that NFA is insensitive to the retrieval setting at training time. We only report results for a model trained on the baseline setting NGM+LED ($\tau = 0.3$), then used in inference in a filter-free setting.

ranker	*test-0.4*	*test-0.6*	*test-de*
NGM+LED 1-1	55.1	64.3	-
NGM+LED 3-1	54.8	63.9	-
NGM+LED 3-2	54.8	64.2	-
NGM+LED 3-3	54.9/44.6	64.3/45.7	41.6
BM25	54.7/44.6	64.2/45.6	-
BM25$_c$	54.7/44.6	64.2/45.6	-
LED	54.9/44.7	64.4/45.7	41.7
δ-LCS	54.8/44.6	64.3/45.7	41.9
δ-LCS$_c$	54.8/44.6	64.3/45.7	41.8

Table 4: Average BLEU (/COMET ($\times$100)) scores for en-fr (11 domains) and de-en (5 domains) using NFA models. k_t-k_i in NGM+LED denotes a model trained with k_t examples, while inference uses k_i; $_c$ denotes contrastive ranking.

Results in Table 4 are very consistent and hardly vary across domains (see Table 13 in Appendix E) and language pairs. This is a first important result that somehow consolidates observations already performed for this model, which seems to be robust with respect to variations in the retrieval strategy.

Edit-based techniques Regarding edit-based approaches, we train Multi-Levenshtein Transformer (`TM`^{3}`-LevT`) on the same dataset, comparing a set of retrieval settings and both NGM and BM25 filters. We report the following results in Table 5:

- The setting used in the original `TM`^{3}`-LevT` paper: NGM+LED ($\tau = 0.3$) both at training and inference time.
- The best-performing train and inference setting pairs, as identifiable in Appendix D, for NGM and BM25 filters separately.
- We evaluate our best overall training pipeline (BM25+LED) on a filter-free setup with varying ED costs (using $\delta = 0.1$).

filter	NGM ($\tau = 0.3$)	-	-	-	-	-	-
ranker	LED	LED	LED	δ-LCS	δ-LCS	BM25	BM25

BM25	3	48.1/35.0	51.8/34.8	-
BM25$_c$	3	48.1/34.8	51.4/35.2	-

Table 6: Average BLEU/COMET $(\times 100)$ scores averaged accross **7** en-fr domains (*test-0.4/6*) and 5 de-en domains (*test-de*) for ICL (k-shot) for several filter-free retrieval setups. $_c$ denotes contrast; $\delta = 0.1$.

We observe here a stronger impact of retrieval on the downstream scores, with a large gain over the baseline (for test-0.4 and en-de). 0.1-LCS slightly outperforms LED in most conditions and metrics, with a very small difference between the contrastive and non-contrastive versions of the ranking.

In-context learning We evaluate BLOOM in k-shot translation for $k = 1$ and 3 with two rankers: ED and BM25.[13] The retrieval scope is always "in-domain". We do not use any filter to ensure the retrieval of exactly k examples for each test instance.[14] Results in Table 6 show again small differences between retrieval techniques, with a positive effect of contrastive ranking policy, which yields the best results. For this architecture, we also note that retrieving at least very good match (e.g. *test-0.6*) does not necessarily imply very high BLEU scores, contrarily to NFA and `TM-LevT`.

4.3 Complementary Analyses

What makes a good set of examples? We use a linear model and try to predict BLEU scores using the retrieval metrics (coverage, relevance, and length) of §2.2 for `TM`^{3}`-LevT` and ICL w.r.t. coverage, relevance, and length. First, with `TM`^{3}`-LevT`, the linear model has an average squared residuals of 0.2 BLEU. On the other hand, a constant model, which supposes that the model-agnostic metrics are independent of BLEU, has an error of 1.2. Coverage, relevance, and length have respective coefficients of 0.13, 0.09, and 0.03. This highlights the importance of coverage and relevance measures in the explanation of BLEU performance. As for ICL, the constant model has the same average residual error (0.28 against 0.26), with respective coefficients of 0.04, 0.03, and 0.00. Thus, ICL seems more robust to changes in the retrieved examples.

Copying input tokens The *copy rate*, introduced in §3.2 measures how much the translation model exploits slices from the examples to produce its output. Pipelines with high covering examples systematically imply a higher *copy rate*. We find that *copy rate* is correlated with higher BLEU scores for `TM`^{3}`-LevT` and ICL; in contrast NFA fails to produce higher BLEU scores with increasing *copy rate*.

Also note that, even though it relies on explicit edits, `TM`^{3}`-LevT` always has a lower *copy rate* than NFA or ICL; the latter notably has the highest *copy rate* for *test-0.6* and also the worst translation scores, suggesting that too many irrelevant tokens are kept in the output.

Domain Filtering Relaxing the constraint that similar examples should be retrieved "in-domain" increases the retrieval rate. However, it turns out to be detrimental for all architectures: results are in Table 8, where we compare in-domain retrieval

---

[13] We also consider a "random" ranking policy for contrast, which yields comparatively very poor results that are about 15 BLEU points below the others for $k = 3$. This confirms the findings of Moslem et al. (2023, Table 1, p. 235) on the benefits of TM-based retrieval.

[14] In some situations however, we could not find 3 candidates with a score greater than 0.

Out	45.5 / 51.2	30.2 / 33.5	30.7 / 29.6

Table 8: Average BLEU scores (*test-0.4* / *test-0.6*, en-fr) according to the domain selection strategy, using filter-free LED as ranker.

The impact of the "all-domain" policy is genuine: when this policy is enforced, the most similar examples are found out-of-domain for 35.1% of our 22k test samples. The most impacted domains are Ubuntu (82.8% matches are out-of-domain) and NewsCommentary (79.7%). The per-domain analysis (Appendix E) however shows that this is detrimental for Ubuntu (-6.1/-6.7 BLEU for *test-0.4*/*test-0.6*), and neutral for NewsCommentary (-0.2/+0.2 BLEU). As expected, enforcing an "out-of-domain" selection constraint yields dramatic losses in BLEU (-15.4/-23.8 BLEU).

These results confirm the benefit of retrieving "in-domain", even for small domains: not only does it greatly speed up retrieval, but it also yields better examples and, ultimately, higher translation scores.

Simplifying the Retrieval Pipeline For large domains, removing the filtering step in the retrieval pipeline considerably increases the computational cost, especially during training.[15] Yet, it may prematurely discard useful examples, especially when using contrastive ranking. To evaluate this, we turn off filtering for test samples during inference. This simplification of the pipeline improves the scores for TM^3-LevT, while there is no effect for NFA (see lines for filtering free inference in Tables 4 and 5). Thus, for the former method at least, a trade-off can be made between latency and translation scores.

Increasing the number of examples We vary k, the number of TM examples retrieved, from 1 to 3. Overall, we observe a gain (BLEU/COMET) when k increases. For ICL, this is already clear from the results in Table 6 where 3-shots clearly outperforms 1-shot. We get a similar conclusion for TM^3-LevT based on the results in Table 5, where we vary the inference procedure for a model trained on (BM25+LED). The test retrieval is filter-free LED with either exactly $k = 1$, 2, or 3 retrieved examples.

As for NFA, a model trained on up to 3 instances slightly benefits from more examples but does not compete with a model using only the one-best match in training and inference. This seems to contradict Bulte and Tezcan (2019), who claim the superiority of using more examples.

Optimizing for coverage with δ-LCS By design, δ-LCS retrieves examples having a higher coverage of the source than LED, which turns into higher *copy rates* for all architectures. For ICL and TM^3-LevT, it yields similar BLEU gain (ICL: +0.3/+0.1/+0.4; TM^3-LevT: +0.3/+0.1/+0.5 on resp. *test-0.4*, *test-0.6*, *test-de*). The analysis in Appendix D shows a consistent benefit of δ-LCS for TM^3-LevT when coupled with filters at training (NGM) and inference time (NGM and BM25).

Enforcing diversity with contrastive ranking We observe that using a contrastive ranker is mostly beneficial for medium-scoring similar examples (*test-0.4*), regardless of the architecture. It can even be detrimental when at least one high-matching example is found. This is because contrastive ranking generates less similar examples that are not necessarily relevant. In comparison, for *test-0.4*, increasing the diversity in retrieval seems beneficial, as it increases the coverage of the source. This suggests that contrastive methods should adapt their strength parameter (α in (2)) to the retrieval scores, enforcing more diversity when matches are poor.

---

[15] The complexity is quadratic w.r.t. to the TM size.

5 Related Work

As for other text generation applications (Li et al., 2022b), efforts to integrate a retrieval component in NMT have intensified in recent years. One motivation is to increase the transparency of ML models by providing users with the retrieved examples that were used to compute the actual output (Rudin, 2019). For MT, this is achieved by integrating fuzzy matches retrieved from memory as an additional context. This can be performed by concatenating the retrieved target instance to the source text, an approach that also accommodates several TM matches (Bulte and Tezcan, 2019), or by the simultaneous use of their source and target sides (Pham et al., 2020; Reheman et al., 2023). More complex schemes to combine retrieved examples with the source sentence are in (Gu et al., 2018; Xia et al., 2019; He et al., 2021b). The recent studies of Cheng et al. (2022); Agrawal et al. (2023) and Sia and Duh (2023b) handle several complementary TM examples retrieved in a *contrastive manner* that aims to enhance source coverage. Gupta et al. (2023) propose a general formulation in the application of ICL in various tasks. Cai et al. (2021) also handle multiple matches and introduce two novelties: (a) retrieval is performed directly in the target language and (b) similarity scores are trainable, which allows to evaluate retrieved instances based on their usefulness in translation. Most of these attempts rely on auto-regressive (AR) decoding, meaning that the impact of TM match(es) on the output is only indirect.

The use of TM memory match with a NAT decoder is studied by Niwa et al. (2022); Xu et al. (2023); Zheng et al. (2023), who adapt `LevT` for this specific setting, using one single retrieved instance to initialize the edit-based decoder; (Bouthors et al., 2023) extends this technique to process multiple retrieved examples. Zhang et al. (2018) explore a different set of techniques to improve translation using retrieved segments instead of full sentences. Generalizing nearest neighbor language models (NNLMs) (He et al., 2021a) to conditional LMs, Khandelwal et al. (2021) perform k-NNMT as follows: at each decoding step, the k target contexts that closest to the current contextualized representations are retrieved and used to select the next token. This approach is further elaborated in (Zheng et al., 2021; Meng et al., 2022) and extended to chunks by Martins et al. (2022).

A final thread of relevant papers concerns the use of large language models, which, provided with suitable prompts and in-context examples, can be turned into effective translation systems. Such approaches have been tested with most LLMs, with the goal to illustrate the multi-tasking abilities of such models. Closer to our work, a series of work have tried to optimize LLMs performance for the MT task, systematically studying the effect of the prompt change, of the number of shots, and of the in-context examples selection procedures (Vilar et al., 2023; Zhang et al., 2023; Hendy et al., 2023; Bawden and Yvon, 2023). Moslem et al. (2023) were the first to combine LLMs with TMs, using an embedding-based retrieval system and combining (via concatenation) up to 5 TM-matches in the MT prompt; (Mu et al., 2023) followed suit, with a different LLM and a two-stage retrieval strategy (first 500 closest matches for a Lucene-based engine; then using up to 9 closest matches for the edit-distance). (Agrawal et al., 2023) studies a way to optimally select k examples so as to maximize coverage, an approach akin to our "contrastive” scenario – using a BM25 retriever in a first stage, and a greedy heuristic selection in a second stage. (Sia and Duh, 2023b) explores another benefit of selecting good in-context examples, that of maintaining consistency in the generated text - for this, they retrieve examples from a moving context window of past translations. Finally, M et al. (2023) go one step further by training a linear regression model predicting the goodness of TM instances based on a small set of features.

6 Conclusion

This paper has investigated the effect of varying the retrieval strategy for three commonly used retrieval-augmented machine translation architectures, trying to get a better understanding of the interplay of these two components. While auto-regressive encoder-decoder architecture seems quite robust w.r.t. changes in the retrieval strategy, this is less so for the two other architectures, for which optimizing the retrieval policy can yield significant returns. Our experiments have also highlighted the benefits of coverage-oriented retrieval policies, based on LCS, especially for the non-autoregressive model. Finally, we have validated the use of the “in-domain” selection policy and proposed to simplify the inference step by eliminating the filtering process, yielding better performance at the expense of an increased latency.

In our future work, we would like to continue the exploration of the interplay between retrieval and translation, with the aim to jointly optimize these two processes rather than have them designed independently.

7 Limitations

In this paper, we have focused on purely transductive techniques, meaning that all inference is performed with a frozen network - this limitation certainly needs to be reconsidered, and our results would be stronger with additional comparisons with e.g., on-the-fly fine-tuning (Farajian et al., 2017) or low-rank adaptation techniques (Hu et al., 2022).

We have chosen to use only one large LLM, with 176b million parameters. This was motivated by (a) the openness of the model and the transparency of the training data, which allowed us to control for test samples occurring also in the training; (b) the existence of multiple previous experiments with this model, which allowed us to get a reasonable idea of its basic translation abilities. More recent, smaller, and arguably better models (e.g., the LLAMA (Touvron et al., 2023) and Falcon families) (Almazrouei et al., 2023) with various levels of multilingual support (Alves et al., 2024), would likely yield a more faithful picture of the current performance of in-context learning with LLMs.

Our discussion has focused on measures of translation quality; in practical applications, computational costs associated with a specific combination of retrieval and architecture also matter. While we have tried to be explicit about the complexity of each retrieval algorithm, we have left aside issues related to identifying the optimal computation/performance tradeoffs.

A δ-LCS formulation

The general formulation of a similarity metric based on the edit distance is:

$$\mathrm{sim}(\tilde{\mathbf{x}}, \mathbf{x}) = 1 - \frac{\Delta(\tilde{\mathbf{x}}, \mathbf{x})}{N(|\tilde{\mathbf{x}}|, |\mathbf{x}|)}, \tag{4}$$

with N a normalizing term that upper bounds Δ. Δ is parameterized by d, a, r, corresponding respectively to the delete (resp. insert, replace) costs (assuming copies have a 0 cost), generalizing the standard ED setting ($d = a = r = 1$). Δ corresponds to the minimal generalized cost necessary to edit $\tilde{\mathbf{x}}$ into $\mathbf{x}$.

We define an Edit Common Subsequence $\mathrm{ecs}_{d,a,r}(\tilde{\mathbf{x}}, \mathbf{x})$, which corresponds to the tokens copied when optimally editing $\tilde{\mathbf{x}}$ into $\mathbf{x}$.[16] If $a + d \leq r$, then the copied tokens are a Longest Common Subsequence (LCS) of $\tilde{\mathbf{x}}$ and $\mathbf{x}$: $\mathrm{ecs}_{d,a,r}(\tilde{\mathbf{x}}, \mathbf{x}) = \mathrm{lcs}(\tilde{\mathbf{x}}, \mathbf{x})$.

If $a + d > r$:

$$\Delta(\tilde{\mathbf{x}}, \mathbf{x}) = \begin{cases} r\,[|\mathbf{x}| - |ecs_{d,a,r}(\tilde{\mathbf{x}}, \mathbf{x})|] + d(|\tilde{\mathbf{x}}| - |\mathbf{x}|) \\ \quad \text{if } |\mathbf{x}| \leq |\tilde{\mathbf{x}}| \\ r\,[|\tilde{\mathbf{x}}| - |ecs_{d,a,r}(\tilde{\mathbf{x}}, \mathbf{x})|] + a(|\mathbf{x}| - |\tilde{\mathbf{x}}|) \\ \quad \text{if } |\mathbf{x}| > |\tilde{\mathbf{x}}| \end{cases} \tag{5}$$

If $a + d \leq r$:

$$\Delta(\tilde{\mathbf{x}}, \mathbf{x}) = a(|\mathbf{x}| - |\,\mathrm{lcs}(\tilde{\mathbf{x}}, \mathbf{x})|) + d(|\tilde{\mathbf{x}}| - |\,\mathrm{lcs}(\tilde{\mathbf{x}}, \mathbf{x})|) \tag{6}$$

Δ is maximal when $|\,\mathrm{ecs}\,| = 0$. The normalization term can be expressed as:

$$N_{d,a,r}(|\tilde{\mathbf{x}}|, |\mathbf{x}|) = \begin{cases} a|\mathbf{x}| + d|\tilde{\mathbf{x}}| \\ \quad \text{if } \ a + d \leq r \\ (r - d)|\mathbf{x}| + d|\tilde{\mathbf{x}}| \\ \quad \text{if } \ a + d > r \ \text{ and } \ |\mathbf{x}| \leq |\tilde{\mathbf{x}}| \\ (r - a)|\tilde{\mathbf{x}}| + a|\mathbf{x}| \\ \quad \text{if } \ a + d > r \ \text{ and } \ |\mathbf{x}| > |\tilde{\mathbf{x}}| \end{cases} \tag{7}$$

Choosing $(d, a, r) = (0, 1, 1)$ makes $\mathrm{sim}(\tilde{\mathbf{x}}, \mathbf{x})$ compute the coverage of $\mathbf{x}$ with tokens from $\tilde{\mathbf{x}}$:

$$\mathrm{sim}(\tilde{\mathbf{x}}, \mathbf{x}) = 1 - \frac{a(|\mathbf{x}| - |\,\mathrm{lcs}(\tilde{\mathbf{x}}, \mathbf{x})|)}{a|\mathbf{x}|} = \frac{|\,\mathrm{lcs}(\tilde{\mathbf{x}}, \mathbf{x})|}{|\mathbf{x}|} \tag{8}$$

B Fuzzy-Matching detailed settings

Note that the code used for our experiments is open source.[17] Additional details can be found in the repository.

B.1 NGM

For a source q, n-gram matching identifies $g(q, x)$, the longest common n-gram between q and any source example x. x passes the filter if (1) $|g(q, x)| \geq \mathrm{ML}$, an absolute length threshold that we choose to be 3; (2) $|g(q, x)| \geq \tau|q|$, with τ varying between 0.3 (following the works of Xu et al. (2022); Bouthors et al. (2023)) and 0.2 – which is a more permissive filter that increases the chance to having higher scoring matches w.r.t. the ranker (BM25, ED).

Our algorithm uses a suffix array structure which directly indexes the n-grams and enables to search for n-gram matches in the sorted array with a logarithmic complexity.

However, the distribution of the number of candidates passing the filter has a high variance (see Table 9). In consequence, it can be ineffective to select only a small amount of relevant candidates

---

[16] There can be in fact several concurrent common subsequences.

[17] Available at https://github.com/SYSTRAN/fuzzy-match

(too permissive). On the other hand, it can often retrieve very few candidates (<3).

τ	Q1	Q2	Q3
0.2	6	116	1573
0.3	2	15	293
0.4	1	6	99
0.5	1	4	54

Table 9: Average 1st, 2nd, 3rd quartiles for the eleven datasets of the distribution of candidates passing the NGM filter w.r.t. τ.

B.2 BM25

BM25 (Robertson and Zaragoza, 2009) is a widely used ranker in Information Retrieval. It often competes with state-of-the-art neural retrievers and is used as a baseline. It is a fully unsupervised method based on computations inspired by the *tf-idf* scoring function. BM25 typically aims to retrieve documents that have common rare words with the query.

Our implementation is not as optimized as in Elasticsearch[18] or Apache Lucene[19], it is nonetheless very efficient and integrates seamlessly in our translation pipeline.

Since computing BM25 is computationally linear in the number of sentences in the TM, naive implementations can sometimes be slow. We use an *inverted index*, which directly maps each term to the set of TM segments where they occur. Instead of computing BM25 for every sentence, we only do it for the union of TM segments containing query terms. As common terms such as punctuation, prepositions, etc. will likely map to most TMs, they are removed from the index.

In our implementation, a term is said to be common if it appears in more than $p\%$ of the segments. We find that p can be quite small (2%) without affecting the set of retrieved sentences too much. For instance, we find that BM25+LCS with the setting $L = 100, p = 2\%$ has 90.4% Jaccard similarity (in terms of the set of indices of retrieved segments) with the setting $L = 100, p = 10\%$.

In preliminary experiments, we also varied the value of L (10 vs 100) and found out that a low L negatively affects the model-agnostic metrics (coverage, relevance) and set $L = 100$ in all experiments.

Table 10 contains the model-agnostic scores on the training set en-fr for filtering pipelines. It suggests that BM25 filter is better at increasing coverage and relevance than NGM. But it has a higher latency. This can explain why BM25-filtered pipelines are better at training time (as shown in Appendix D).

C Models detailed settings

C.1 NFA

We made our own implementation of NFA based on the work of Bulte and Tezcan (2019) with the following parameters: size of word embedding: 512; size of hidden layers: 512; size of inner feed forward layer: $2,048$; number of heads: 8; number of layers: 6; batch size: $4,096$ tokens. We set warmup steps to $4,000$ and update learning rate for every 8 iterations. Fine-tuning is performed continuing Adam with learning rate decay schedule until convergence. The models are trained with one NVIDIA P100 GPU. We use a joint vocabulary of 32K for both source and target sides. At inference we use a beam size of 5.

C.2 `TM`^{N}`-LevT`

We use a Multi-Levenshtein Transformer architecture with embeddings of dimension 512; feed-forward layers of size 2048; number of heads 8; number of encoder and decoder layers: 6; shared-embeddings; dropout: 0.3.

During training, we use Adam optimizer with (β_1, β_2)=(0.9, 0.98); inverse sqrt scheduler; learning rate: $5e^{-4}$; label smoothing: 0.1; warmup updates: 10,000; float precision: 16. We fixed the number of iterations at 60k. The batch size and number of GPUs are set to have, on average, ~ 450 samples per iteration. We performed a pretraining of the model on a synthetic dataset as described by Bouthors et al. (2023). We use a joint vocabulary of 32K. For decoding, we use realignment and iterative refinement with an empty placeholder penalty of 3, and a max number of iterations of 10 (Gu et al., 2019).

C.3 BLOOM

BLOOM is a family of large open-source causal multilingual language models trained in the course of the BigScience project (BigScience et al., 2022). Our experiments use the largest available version, comprising 176b parameters. This model has been repeatedly evaluated in translation scenarios see e.g. (Bawden and Yvon, 2023). BLOOM's training corpus officially contains a fair share of English

---

[18] `https://elastic.co`.

[19] `http:lucene.apache.org`.

and French, but hardly any German[20] (Laurençon et al., 2022). We thus consider the two following translation directions: en-fr and de-en, selecting target languages for which the generation abilities are strong.

Following common practice, we select a simple prompt of the form "[src]: source sentence. =[trg]: target sentence", where "[src]" and "[trg]" are language tags denoting respectively the source and the target sentences, using either 1 or 3 in-context examples before the source query. All experiments generate translation in pure greedy mode; generation stops either when the end of sentence token is produced or when a maximum length of 256 tokens is reached. As is also custom for BLOOM, which tends to overgenerate, we post-process the output to shorten excessively long outputs and make sure the target is never longer than 1.5 times the source (measured in chars). This post-processing only impacts about 5 to 10% of all output sentences.

D Cross inference for `TM`^{3}`-LevT`

We train Multi-Levenshtein Transformer (`TM`^{3}`-LevT`) with a series of retrieval settings with NGM (Table 11) and BM25 filters (Table 12). Afterward, each trained model is evaluated on all the retrieval settings of the same filter category. This way, it is possible to identify which train/inference setting pairs perform better and whether having the same setting for training and inference is recommended. We can, for both NGM and BM25, identify a systematically independent optimal training and inference setting. We find that the BM25 filter is slightly better in general. The contrastive method only helps at inference time and for medium matches, suggesting adapting the factor to the fuzzy score (ED).

0.1-LCS is overall better, except for training with BM25, which surprisingly achieves the best scores with LED. Probably, having more source-similar sentences at train time is necessary to compensate for the unordered nature of BM25, required by `TM`^{3}`-LevT`.

E Per domain analysis

Tables 13,14,15 contain the detailed per-domain analysis for direction en-fr. We insist on the fact that this corpus offers a high variability across domains (size, density, sentence length...). Low-density domains (Ubuntu, News-Commentary) and high-density ones (EMEA, KDE4) are the ones the most likely to differ from the average best. Moreover, low-density domains seem to prefer diversity and coverage with BLOOM. As for `TM`^{3}`-LevT`, the lowest and highest densities are both more inclined to choose pipelines with filters. The model may suffer from low-quality examples from a difficult low-density domain while not necessitating diversity in the case of dense ones.

F Illustration

Figure 2 illustrates the variability across retrieval settings. We can observe their main characteristics:

- Since NGM and BM25 act here as filters, they barely change the retrieved set.
- δ-LCS covers more words in the source at the expense of longer sentences.
- The first retrieved sentence for the contrastive ranking is always the same as for LED, but the other two are often more diverse, covering more terms.

---

[20] Even though traces of German can be found in the corpus.

Ngram filter ($\tau =$)	0.3	0.2	0.2	0.3	0.2	-	-	-	-

Abstract

Effectively training language models on long inputs poses many technical challenges. As a cost consideration, languages models are pretrained on a fixed sequence length before being adapted to longer sequences. We explore various methods for adapting models to longer inputs by training on segmented sequences and an interpolation-based method for extending absolute positional embeddings. We develop a training procedure to extend the input context size of pretrained models with no architectural changes and no additional memory costs than training on the original input lengths. By sub-sampling segments from long inputs while maintaining their original position the model is able to learn new positional interactions. Our method benefits both models trained with absolute positional embeddings, by extending their input contexts, as well as popular relative positional embedding methods showing a reduced perplexity on sequences longer than they were trained on. We demonstrate our method can extend input contexts by a factor of 4× while improving perplexity.

1 Introduction

Transformer-based models (Vaswani et al., 2017) capture sequence information through positional embeddings (PE). There are two types of PEs: absolute and relative. Absolute positional embeddings (APE) learn a separate embedding for each position in a sequence; these embeddings are added to the input of the first layer. Relative positional embeddings (RPE) encode the relative distance between positions, often by weighting attention score of positions further away less.

The ability for models to process long sequences efficiently is of growing importance as models become more capable. Increased input context allows for more complex in-context learning examples (Li et al., 2023a; Sun et al., 2023). Additionally, they allow for question answering and summarization over scientific papers and patents (Dasigi et al., 2021; Koh et al., 2022; Sharma et al., 2019). Due to RPE's positional information only being a function of relative distance these methods can be applied to any input sequence length. In practice, popular RPE methods fail to generalize to sequences longer than they were trained on. Furthermore, self-attention's memory cost is quadratic meaning training on long sequences becomes prohibitively expensive as the sequence length grows.

In this work, we study the problem of extending the input context of pre-trained decoder-only transformer-based models, considering those that use either absolute or relative positional embeddings. We show that an interpolation-based approach allows APE models to extrapolate to sequence lengths longer then they were trained on—matching or outperforming the extrapolation ability of RPE methods like ALiBi (Press et al., 2021) and RoPE (Su et al., 2021). To further improve the ability of these models to take advantage of the longer input context, we present resource-efficient methods that continuously pre-train APE- and RPE-based models on carefully sampled segmented subsequences of long sequences. Doing so simulates training on long sequences while remaining within a fixed input length. This allows the models to efficiently learn the embeddings of the newly created absolute positions or the relative embeddings associated with the longer pairwise distances.

We experiment with models trained with APEs, RoPE, and ALiBi to verify our method improves the extrapolation performance independent of the choice of positional embeddings. Results show that interpolating the embedding matrix of absolute positional embeddings without any additional training allows for extrapolation to sequences 5× the original input context. Furthermore, our segment-based methods are able to increase the extrapolation ability of all positional embedding approaches. When applied to APEs this method achieves 87% the per-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3040–3052
June 16-21, 2024

formance of training on sequences twice as long at no extra memory footprint.

The paper is organized as follows: first, we conduct a review of various existing literature that motivated our approach. Second, we formally define the problem of length extrapolation and propose our methods for efficiently extending a model's input context. Third, we provide a detailed breakdown of our experimental setup and methodology to enable reproducibility. Finally, we present our results along with a thorough discussion and analysis.

2 Related Work

2.1 Positional embeddings

Language is inherently sequential and Transformers are positional-agnostic, to account for this, positional information is often introduced to the architecture. The original authors Vaswani et al. (2017) suggested adding a positional embedding to the input of the first layer and offered two methods, absolute positional embeddings and sinusoidal embeddings. Absolute positional embeddings consist of a learnable embeddings matrix where each embedding corresponds to a position. While common, this method has an important limitation: it only allows for a fixed maximum input length determined during training. Sinusoidal embeddings did not have this limitation but performed worse in practice and the relative embeddings that came after were difficult to parallelize (Shaw et al., 2018) leading to APEs being the *de facto* method in early models, eg. BERT (Devlin et al., 2019) and GPT-3 (Brown et al., 2020).

To address the limited input context size of APE researchers explored other relative positional embedding methods (Chi et al., 2022; Wennberg and Henter, 2021; Likhomanenko et al., 2021; Haviv et al., 2022). Most notable are rotary embeddings (RoPE) (Su et al., 2021), T5 (Raffel et al., 2019), and ALiBi (Press et al., 2021). RoPE rotates the query and the key embeddings as a function of their position; this method allowed for easier parallelization compared to previous relative embeddings. T5 bias (Raffel et al., 2019) adds a positional embedding for each relative distance instead of absolute position. ALiBi subtracts a linear bias from the query-key matrix product in the attention calculations. While T5 bias extrapolated to long contexts well it is too inefficient to scale, taking twice as long to train as sinusoidal (Press et al., 2021). RoPE and ALiBi have been widely adopted in various LLMs with LLaMA (Touvron et al., 2023), GPT-J (Wang and Komatsuzaki, 2021), and PaLM (Chowdhery et al., 2022) using RoPE and BLOOM (Scao et al., 2022) using ALiBi.

2.2 Length generalization

The choice of positional embeddings (PE) has been documented to be one of the leading factors in a Transformer based model's ability to generalize to variable sequence lengths. The authors of ALiBi (Press et al., 2021) identified that RoPE and sinusoidal embeddings failed to generalize on sequence lengths greater then those they were trained on. Numerous new positional embedding methods with more favorable length generalization abilities have been proposed (Sun et al., 2022; Chi et al., 2022; Li et al., 2023b) but these are required to be incorporated during pre-training.

There is a sizable body of work on methods for extending the input context of language models pre-trained with RoPE (Chen et al., 2023; Jin et al., 2024; Peng et al., 2023; Ding et al., 2024). These approaches map the positional information of long sequences into ranges seen during training through positional interpolation. In practice, these methods requires fine-tuning the models on long sequences to adjust to the new granularity of relative positional distance which is computational expensive.

2.3 Computationally efficient training

Numerous works have explored efficiency based modifications to the standard Transformer architecture (Xiong et al., 2021b; Choromanski et al., 2020; Kitaev et al., 2020; Qiu et al., 2019). These methods either modify the base architecture or rely on fast self-attention approximations.

While these methods all aim to reduce the memory cost of the Transformer architecture and allow for training on longer sequences, our work is orthogonal to these methods. Our approach can be used in conjunction with these existing methods since we do not rely on any specific architecture. We instead change the positional information of the input sequences.

2.4 Sparse input sequences

A number of works have explored training language models on sparse inputs. APEs have been shown to overfit to certain positions. To address this, Kiyono et al. (2021) proposed randomly padding or offsetting the positions during fine-tuning. This simple method led to better downstream performance on question answering and machine translation (Tao et al., 2023) and general length extension (Zhu et al., 2023; Ruoss et al., 2023). Another work proposed Forgetful Causal Masking (FCM) (Liu et al., 2022), a simple modification to the next token prediction task with a randomly selected fraction of previous tokens masked out. They demonstrated this method led to improvements in both few-shot and fine-tuned performance compared to standard causal masking. Most similar to ours, RandomPos (Ruoss et al., 2023) proposed sampling randomized, ordered positional embeddings to replace the sequential positional embeddings normally used. They sampled from a range of absolute positions much longer than the input sequence length. Results demonstrated this led to an increase in extrapolation performance. The authors argued this was due to exposure to longer relative pair-wise distances than those normally seen during training.

These results indicate that not only can language models be trained with heavily obfuscated sequences but can also benefit from doing so in some cases. This idea is the intuition behind our method.

3 Methods

There are three reasons that motivate this work. First, there exist numerous high-quality pre-trained models whose input context is limited to 1K–2K tokens. Extending the input context of these models will further increase their applicability. Second, even though methods that rely on relative positional embeddings can operate on input contexts that are longer than what they were trained on, their out-of-the-box extrapolation performance is not good (Press et al., 2021). Third, due to the quadratic complexity of self-attention and the linear compute/memory complexity of transformers w.r.t. sequence length, direct training on long input contexts is resource intensive. This limits the input context that we can directly train on.

3.1 Problem Statement

Let p_θ be a transformer-based language model trained to maximize the next-token-probabilities over a set of sequences $\mathcal{D}$ of length L_t; i.e.,

$$\arg\max_{\theta} \sum_{\mathbf{x}\in\mathcal{D}} \sum_{i}^{L_t} \log p_\theta(x_i|x_{<i}). \tag{1}$$

We will refer to L_t as the model's *training input context length.*

We define *extrapolation* as the language model's ability to improve its next-token-prediction by using input contexts that are longer than those it trained on. Specifically, for $k > L_t$, we will consider that a model can extrapolate successfully if

$$\sum_{i\geq k} \log p_\theta(x_i|x_{>k}) > \sum_{i\geq k} \log p_\theta(x_i|x_{>L_t}),$$

where $p_\theta(x_i|x_{>j}) = p_\theta(x_i|x_{i-1},\ldots,x_{i-j+1})$. In practice, we consider the average perplexity on sequences of different lengths from the same dataset a suitable proxy for this.

Given p_θ and L_t, the problem that we want to solve is to develop resource efficient methods that allow p_θ to extrapolate to input contexts of length L_e that are longer than L_t. We refer to L_e as the *extended input context length*.

3.2 Extending APE via interpolation

APEs learn an embedding vector for each position up to a pre-specified maximum position. The fixed nature of the embedding matrix does not allow for inputs longer than the maximum pre-specified length. A necessary first step when training on longer sequences is to increase the size of the embedding matrix.

We use linear interpolation to extend the embedding matrix from the training input context length L_t to the new input context length L_e (Dehghani et al., 2023). Let E and E' be the old and new embedding matrices, respectively and assume that $\beta = L_e/L_t$ is integral. Then the embedding for position i ($0 \leq i < L_e$) is given by:

$$e'_i = \frac{\beta - i\%\beta}{\beta} e_{\lfloor i/\beta \rfloor} + \frac{i\%\beta}{\beta} e_{\lfloor i/\beta \rfloor + 1},$$

where '$\%$' is the modulo operation. This process retains the original embeddings but results in $\beta(L_t - 1) + 1$ embeddings. In practice, we set the remaining $\beta - 1$ embeddings to e_{L_t}.

3.3 Efficient input context extension

Pairwise attention is the mechanism by which transformer models incorporate information from other tokens. Positional embeddings are how attention takes into account the absolute or relative positions of the token-pairs. To fully take advantage of an increased input context, a model needs to learn the embeddings of the newly created absolute positions or the relative embeddings associated with the longer pairwise distances created with the increased input context. Thus, the model needs to be further pre-trained with input sequences that also include the new positions—in the case of absolute positional embeddings, or the longer pairwise distances—in the case of relative positional embeddings.

The key insight behind our efficient approaches is that we can meet the above requirements without directly training on long input sequences. Instead, we create short input sequences by sampling segments from the long sequences, *keep the original positional information*, concatenate them, and use them to further pre-train the language model. Since this approach retains the original positional information, the models see the new positions/distances and learn how to use them. Though the length of the short sequence is a hyper-parameter of our approach, in all of our experiments we keep it the same as that of the original input context length; i.e., L_t.

We develop two different subsequence sampling approaches that we refer to as `chunk` and `prefix` which are defined as follows:

- **`chunk`-α:** This approach creates a short sequence by sampling a small number of equal-length contiguous subsequences from the long sequence. Specifically, given $0 < \alpha < 1$ and an L_e-long input sequence $\mathbf{x}$, this approach samples $1/\alpha$ contiguous non-overlapping subsequences of length αL_t from $\mathbf{x}$. The reason that we keep the sampled segments contiguous is to preserve the local context information, which is important for next-token prediction (Xiong et al., 2021a) and we do not want our model to 'unlearn' it.

- `prefix`-α: This approach creates a short sequence by randomly sampling a set of tokens that forms a prefix and a contiguous segment to form its associated suffix. Specifically, given $0 < \alpha < 1$ and an input sequence $\mathbf{x}$ of length L_e, it randomly selects an index i with $(1-\alpha)L_t < i < L_e - \alpha L_t$. It creates the suffix by taking the αL_t contiguous tokens starting at position i and creates the prefix by randomly sampling $(1-\alpha)L_t$ tokens form the positions preceding i. In this method we only compute the loss over the continuous suffix in order to preserve the model's ability to incorporate local context.

A visualization of the different sampling methods can be found in Figure 1.

While these methods can introduce discontinuities in the causal language modeling objective we argue that maintaining their original positional embedding on top of the fact they happen infrequently limits the harm they may cause. In practice we use α's small enough that discontinuities occurs approximately 2% of the time in `chunk` and never in `prefix`.

4 Experimental setup

4.1 Dataset

Since we are comparing the performance of various methods on long sequences we chose to use the scientific papers section of the arXiv dataset released by Cohan et al. (2018). Scientific papers are a common choice for reporting results on long sequence modeling performance (Beltagy et al., 2020). This dataset consists of 215K scientific papers, split into 205K train and 7K test, with a total token count of approximately 1.6 billion and an average document length of 4,938 tokens. We do not pack our batches (Kosec et al., 2021), meaning each sequence contains only text from a single document at a time. If documents are longer than L_e we split them into non-overlapping sequences with length L_e and discard the remainder; if documents are shorter than L_e we discard them as well. We feel that ensuring each input only corresponds to one source text is an important factor when reporting performance on long sequences.

4.2 Models

To evaluate our methods we fine-tune three different classes of pretrained language models, one for each of the popular positional embedding methods: absolute, RoPE, and ALiBi. We use models with approximately 1.5 billion parameters; for absolute positional embeddings we use GPT-2 (Radford et al., 2019), for rotary embeddings we use Pythia (Biderman et al., 2023), and for ALiBi we use Bloom (Scao et al., 2022). In addition to these three models we use a smaller GPT-2 and Pythia checkpoint (approx. 10% the size), which we will refer to as GPT-2 Small and Pythia Small, and together as our development models. Due to a lack of small models trained with ALiBi we do not have a development model for ALiBi. Key information about these models can be found in Table 1. Note that besides the positional encoding schemes, these models also differ in other ways including training data and model parameters. As a result, a direct comparison of these models will be confounded by these additional factors. For this reason our evaluation only focuses on measuring how the different continuous pre-training approaches help in improving each model's extrapolation capabilities against themselves and we never compare across models.

4.3 Domain adaptation

The perplexity on arXiv for these models is relatively high as arXiv is considered out of domain. In order to differentiate between gains attributed to adapting to the domain versus improving extrapolation performance we perform one full epoch of continual pre-training with a sequence length of L_t for each model.

Table 1: Key model characteristics.

	# of params	PE	L_t
GPT-2 Small	170M	APE	1024
Pythia Small	140M	RoPE	2048
GPT-2	1.64B	APE	1024
Pythia	1.4B	RoPE	2048
Bloom	1.45B	ALiBi	2048

Table 2: Perplexity on sequences of the model's original input length, L_t, after domain adaptation.

	ppl.
GPT-2 Small	9.311
Pythia Small	8.609
GPT-2	6.675
Pythia	6.677
Bloom	7.217

We refer to the checkpoints after domain-adaptation as "out-of-the-box" models. All experiments start from the OOTB models unless otherwise mentioned. The perplexity of the models after domain adaptation can be found in Table 2.

4.4 Segmented pre-training

For training we use the causal language modeling objective with a cross entropy loss. All experiments on the same model are done in a compute equivalent manner unless stated otherwise. To ensure compute equivalence when training our models we fix the number of tokens as well as the input length, L_t, of the model.

Due to segmentation, one epoch of training on different sequence lengths results in a different number of tokens actually processed. For example, training with sequences of length $2L_t$ results in half the total number of tokens. To ensure an equal number of tokens across experiments we set the total number of epochs for each experiment to be:

$$\text{\# epochs} = \frac{L_e}{L_t}. \tag{2}$$

4.5 Performance assessment

To evaluate the performance of our models on different sequence lengths we report the mean perplexity on sequence of length L_e from our test set. Perplexity measures the exponentiated average negative log likelihood over a sequence of tokens and is a common evaluation metric for language models. We define the perplexity of a sequence of tokens $\mathbf{x}$ of length L_t as:

$$ppl(x) = \exp(-\frac{1}{L_t}\sum_i \log p_\theta(x_i|x_{<i})). \tag{3}$$

Note that unlike previous work, we do not perform sliding window evaluation (Baevski and Auli, 2018).

5 Results

We conduct our experiments and present results in such a way to answer the following questions:

- How well do absolute positional embeddings extrapolate with interpolation of the embeddings matrix?
- Which of our proposed subsequence sampling methods performs the best and with what parameters?
- How does our approach compare with continual pre-training on sequences of the original length?

5.1 Out-of-the-box extrapolation

We begin by examining each model's ability to extrapolate to sequences longer then they were trained on without any further pre-training. We report the perplexity on the test set with sequence lengths starting from L_t up to $5L_t$, depending on the memory constraints of each. Previous length extrapolation work did not include absolute positional embeddings due to their fixed nature (Press et al., 2021). To increase the input context size we interpolated the positional embedding matrix as described in Section 3.2. Results are shown in Figure 2 and the corresponding numbers can be found in Table 6 in Appendix A.

RoPE fails to extrapolate to sequences longer than originally trained on while ALiBi generalizes well. These findings about RPEs agree with those previously observed in Press et al. (2021). Our results show that interpolation works well until at least $5L_t$. This suggests that with linear interpolation APEs generalize better than RoPE and are comparable to ALiBi.

5.2 Comparison of segmented methods

We compare the performance of the various methods discussed in Section 3.3 on our development

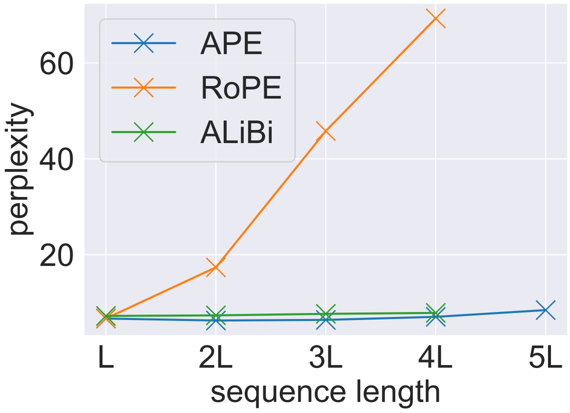

Figure 2: Perplexity of "out-of-the-box" extrapolation. With interpolation of the positional embeddings, absolute positional embeddings (APE) extrapolate as well as ALiBi.

models. We train models on two separate extension sizes, $L_e = 2L_t$ and $L_e = 4L_t$. For each we use `chunk` with $\alpha = \{0.125, 0.25, 0.5\}$ and `prefix` with $\alpha = \{0.25, 0.5\}$. Furthermore, we train a models on sequences of $2L_t$ and $2L_t$ *without* any segmentation. We refer to these models as `full`, and they provide a point of comparison between our methods versus training on the full L_e sequence. The complete set of results can be found in Table 3.

The different segment-based methods work well to extend the input context of these models. We observe a decrease in perplexity when evaluating on sequences longer then originally trained on. Overall, `chunk` performs better than `prefix` on both models, `prefix` fails to improve extrapolation when extending RoPE to sequences $4\times$ in length. While the `full` approach has the lowest perplexity in most cases the relative loss in performance for `chunk` is low. One notable case is extending RoPE to $4L_t$, there we observe `chunk` outperforming `full`. Given that `chunk` requires half the sequence length of `full` it remains a competitive option due to its memory efficiency.

Comparing the performance of different chunk lengths, controlled by the parameter α, both models display similar trends. For `chunk`, there appears to be sweet-spot between the number of segments and each segment's individual length (see Table 3). An α of 0.125 translates to chunks of 128 tokens for APE and 256 for RoPE. In most cases this α performed the worst amongst `chunk`, as the segments may be too short or lead to too many discontinuities in the sequence. For `prefix`, there is less of

Table 3: Perplexity of different input context length extension methods on the development sets.

	method	$2L_t$	$4L_t$
APE	`OOTB`	9.322	13.275
	`full`	8.287	7.819
	`chunk-0.125`	8.521	8.307
	`chunk-0.25`	8.471	**7.989**
	`chunk-0.5`	**8.420**	8.259
	`prefix-0.25`	8.757	8.826
	`prefix-0.5`	8.672	9.304
RoPE	`OOTB`	30.686	176.244
	`full`	7.403	7.353
	`chunk-0.125`	7.476	7.239
	`chunk-0.25`	**7.447**	**7.210**
	`chunk-0.5`	7.461	7.461
	`prefix-0.25`	9.543	25.539
	`prefix-0.5`	10.119	33.375

a concrete pattern. This could be due to the higher level of randomness in the prefix as tokens were sampled randomly. Between `chunk` and `prefix`, `chunk` computes loss over twice as many tokens, this could be a contributing factor to the gap in performance between the two.

Between RoPE and APE, RoPE benefits the most from segmented pre-training. After training on segmented sequences the perplexity on extensions of $2L_t$ and $4L_t$ decreases by a factor of $4\times$ and $24\times$ respectively. While our method still improves over the "out-of-the-box" performance of APEs, interpolation is a competitive approach for length extension.

5.3 Results on larger models

Based off the findings in Section 5.2 we use `chunk-0.25` for our experiments on GPT-2 1.5B, Pythia-1.4B, and, Bloom-1.1B. As before, we continually pre-train the models as detailed in Section 4.4 and expand to $L_e = 2L_t$ and $L_e = 4L_t$.

Overall, `chunk` works for all three models on both expansion lengths. All models extrapolated better than their "out-of-the-box" performance. Again, RoPE was able to extrapolate to sequences it previously was not able to. Our method also demonstrated the ability to further increase the extrapolation ability of ALiBi. Results can be found in Table 4.

Table 4: Perplexity results for the 1.x billion parameter models.

	method	$2L_t$	$4L_t$
APE	`OOTB`	6.326	7.099
	`DA`	**6.125**	7.050
	`chunk-0.25`	6.314	**6.425**
RoPE	`OOTB`	16.428	52.644
	`DA`	16.285	50.652
	`chunk-0.25`	**5.448**	**5.278**
ALiBi	`OOTB`	7.295	7.773
	`DA`	6.887	7.417
	`chunk-0.25`	**6.773**	**7.295**

5.4 Comparison with further pre-training

Given that ALiBi and APE-based models already extrapolate well (see Figure 2), a natural question is whether the performance gains on longer sequences come from our segmented method or additional domain adaption. To ablate this, we perform another epoch of domain adaptation as described in Section 4.3. This isolates the benefit of our method versus further domain adaptation as the total number of tokens seen by all models are the same. Results can be found in Table 4.

For models that extrapolate well (ALiBi and APE), further domain adaptation also improves the extrapolation ability however the gains are less than our segmented training. The exception here is when extending APE to lengths $2\times$, in this case domain adaption performs slightly better. This result indicates that the interpolation-based extension method we propose works well for APEs. Overall, this demonstrates that while some of the gains may be due to further domain adaptation our method is still beneficial for models that extrapolate well "out-of-the-box".

5.5 Comparison with RandomPos

The authors of `RandomPos` (Ruoss et al., 2023) proposed a similar method for simulating training on long sequences within a fixed input context window. Instead of subsampling sequences of length L_e, `RandomPos` randomized the positional ids of sequences of length L_t selecting positions ranging from $[0, L_e - 1]$ while maintaining the causal ordering. Similar to our approach, `RandomPos` exposes the model to extrapolated pairwise relative distances but the key difference is content used. Whereas `RandomPos` only presents local context to

Table 5: Comparision with `RandomPos`. Numbers reported are perplexity.

	method	$2L_t$	$4L_t$
APE	OOTB	9.322	13.275
	RandomPos	9.018	11.534
	chunk-0.25	**8.420**	**7.989**
RoPE	OOTB	30.686	176.244
	RandomPos	8.021	11.692
	chunk-0.25	**7.447**	**7.210**
ALiBi	OOTB	7.295	7.773
	DA	6.816	7.352
	chunk-0.25	**6.773**	**7.295**

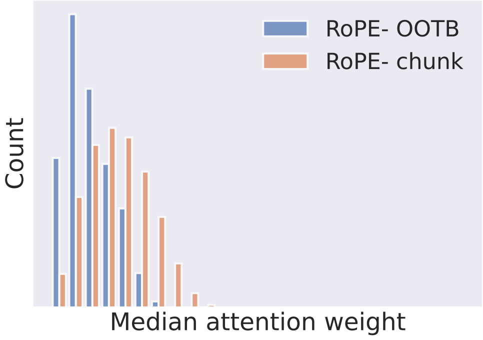

Figure 3: Histogram of median attention weights for positions past the original input length before and after our segmented training on models with RoPE. After adaptation, the distribution of attention weights becomes more uniform.

the model, chunk exposes the model to distant content and encourages the model to learn to leverage distant contexts.

To verify the exposure to distant content is an important step in improving extrapolation we implement a version of `RandomPos` and extend our models to 2× and 4× the original input sizes. We keep all settings and models the same as Section 5.2 with the exception of including the ALiBi model. In all cases, chunk outperforms `RandomPos` indicating the inclusion of distant context valuable to length extrapolation. Results can be found in Table 5.

6 Analysis

Our results demonstrate that segmented training is a viable approach to extend the input context size of language models. It is not immediately intuitive why, especially given that the relative positional embeddings methods are not learned.

For absolute positional embeddings the reasoning is fairly straightforward. First, in Section 5.1 we demonstrated interpolating the embedding matrix led to reasonable extrapolation without any training. Before any training occurs the model already has some extrapolation ability. The segmented sequences allow for positions further away than the input size normally allows to interact and learn how to incorporate information.

In the case of relative positional embedding methods these results are less intuitive. Both RPE methods penalize the attention scores of positions as a function of their relative distance, meaning that initially there is not much attention across chunk boundaries. We hypothesize that through training on segmented sequences the model learns to attend to longer-range interactions. There is a lack of nearby positions for the model to attend to so it learns to incorporate information from further away. In doing so it adjusts the weights to penalize further positions less. This counter-acts the RPE's inductive bias towards nearby positions.

To attempt to visualize this we plot the distribution of median attention weights for positions past L_t. In both cases, the medians are well below the mean suggesting that a few positions account for the majority of the attention weight. After segmented training, we observe the average median increases as well as become more evenly distributed. This suggests that more positions are being attended to as well as the model attending to more or less positions depending on the context. The plot can be found in Figure 3. This hypothesis is also supported by a recent work that analyzes the failure of RoPE to generalize to long sequences (Xiong et al., 2023). The observed that simply reducing the decaying effect of RoPE distant tokens lead to strong extrapolation performance.

7 Conclusion

In this work we proposed a simple and memory efficient approach to extend the effective input context size of models through training on sequences created by sampling segments from long documents. We demonstrated our method is robust to the choice of positional embeddings and allows models to be trained on sequences at least 4× their original input length. Furthermore, our results on extending absolute positional embeddings through interpolation demonstrated they can extrapolate better than

RoPE and provide a method to extend the context of models trained with APEs at no additional cost.

8 Limitations

In this work we explore various computationally efficient methods for pre-training on long sequences. Due to the compute limitations we only verify our method's performance on models up to 1.4 billion parameters. Current state of the art models are orders of magnitudes larger. While our results indicate the success of our method there is always the chance that results do not transfer to different model sizes. We believe these methods will hold as model size increases since the extrapolation problem is fundamentally an artifact of the positional embeddings and not model size. Additionally, the models we used were originally only trained with a maximum sequence length up to 2048 tokens and only extended to a maximum 8192 tokens. Even though this is a 4× extension, this is much lower then the input size of some production models.

Inline with previous work on encoding positional information (Press et al., 2021; Su et al., 2021), we use perplexity as our method for evaluating a model's extrapolation performance. Some recent work has shown that this may not always be a strong signal for downstream performance (Shaham et al., 2022). A more thorough evaluation on downstream benchmarks would be insightful, unfortunately the majority of our models were too weak to produce competitive performance on zero-shot or few-shot long sequence tasks.

9 Ethics statement

When working with language models and large, web-crawled datasets it is important to remain cognizant of some of the potential ethical concerns. We trained on scientific papers which are voluntarily posted by users.

Abstract

Large Language Models (LLMs) have demonstrated good performance in many reasoning tasks, but they still struggle with some complicated reasoning tasks including logical reasoning. One non-negligible reason for LLMs' suboptimal performance on logical reasoning is their overlooking of understanding logical fallacies correctly. To evaluate LLMs' capability of logical fallacy understanding (LFU), we propose five concrete tasks from three cognitive dimensions of WHAT, WHY, and HOW in this paper. Towards these LFU tasks, we have successfully constructed a new dataset LFUD based on GPT-4 accompanied by a little human effort. Our extensive experiments justify that our LFUD can be used not only to evaluate LLMs' LFU capability, but also to fine-tune LLMs to obtain significantly enhanced performance on logical reasoning.

1 Introduction

As a cognitive process, *logical reasoning* plays an important role in many intellectual activities, such as problem solving, decision making and planning (Huang and Chang, 2022). Up to now, a lot of efforts have been dedicated to logical reasoning based on language models (Cresswell, 1973; Kowalski, 1974; Iwańska, 1993; Liu et al., 2020). More recently, the popularity of large language models (LLMs) such as ChatGPT (Ouyang et al., 2022) and GPT-4 (OpenAI, 2023) stimulates the growth of research on LLM-based logical reasoning. Compared to traditional small language models, LLMs have demonstrated better performance in many reasoning tasks.

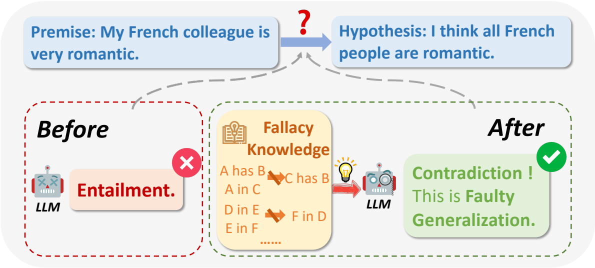

Figure 1: LLMs have deficiencies in logical reasoning. Once they understand logical fallacies, they know how to avoid logical fallacies, and thus improve their performance in various logical reasoning tasks.

However, LLMs still struggle with some more complex reasoning tasks including logical reasoning. One non-negligible reason for LLMs' suboptimal performance on logical reasoning is their overlooking of understanding *logical fallacies* correctly. As early as 350 BC, Aristotle first proposed the concept of logical fallacy in his work *Sophistical Refutations* (Aristotle, 2006). Since then, logical fallacies have gradually become an important issue that should be noticed in our lives. "*Thou shalt not commit logical fallacies!*" has even become a worldwide popular idiom to remind us not to commit logical fallacies. By definition, logical fallacies refer to the errors in reasoning (Tindale, 2007), and they usually happen when the premises are not relevant or sufficient to draw the conclusions. Many previous works (Liu et al., 2020; Yu et al., 2020; Joshi et al., 2020; Han et al., 2022) have focused on evaluating LLM logical reasoning capabilities from the perspective of deductive reasoning, natural language inference, reading comprehension, etc. However, few works focus on logical fallacies, which is in fact the major reason causing logical inconsistency in the sentences.

Chen et al. have observed that, LLMs often commit logical fallacies in logical reasoning, such as *"Either protect the environment or develop the economy."* (false dilemma) and *"Some roses are not red because not all roses are red."* (circular reasoning). It has been found that language models could avoid mistakes only when they understand what mistakes are (Chen et al., 2023a; An et al., 2023), which justifies the ancient Greek philosopher Epi-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3053–3066
June 16-21, 2024 ©2024 Association for Computational Linguistics

curus's saying "*The mistake is the first step to save yourself.*" Based on our empirical studies, we have also found that the logical reasoning capability of LLMs is closely related to their understanding of logical fallacies.

The previous studies related to logical fallacy (Jin et al., 2022; Sourati et al., 2023; bench authors, 2023) only focus on logical fallacy detection, i.e., the identification and classification of logical fallacies, rather than systematically evaluating LLMs' capability of logical fallacy understanding (LFU), not to mention improving LLMs' LFU capability. Moreover, they have not explored the relationships between LFU and logical reasoning, which is crucial to improve LLMs' capability of logical reasoning through enhancing their LFU capability. To address this problem, we focus on evaluating and enhancing LLMs' LFU capability in this paper, so as to enhance their capability of logical reasoning.

Nonetheless, our work has to face several challenges as follows. First, we need to formalize the concrete tasks for LFU, since no previous studies focus on this problem. Second, we need a new dataset specific to LFU, as the previous datasets of logical fallacies (Jin et al., 2022) only contain the logical fallacy types presenting in the sentences. To this end, we should propose a framework of constructing the LFU dataset towards the concrete LFU tasks, and then truthfully evaluating LLMs' LFU capability with the dataset.

To overcome these challenges, we primarily focus on constructing a dataset for LFU in this paper, of which the samples are generated to evaluate models' achievement on the following five LFU tasks corresponding to three cognitive dimensions of **WHAT**, **WHY**, and **HOW** (Swanborn, 2010).

1. **WHAT**-Identification (Task 1) and Classification (Task 2): identifying whether the given sentence contains a logical fallacy and which type of logical fallacy it is.
2. **WHY**-Deduction (Task 3) and Backward Deduction (Task 4): capturing the reasons causing the logical fallacy in the sentence.
3. **HOW**-Modification (Task 5): correcting the logical fallacy in the sentence.

Our proposed LFU tasks simulate the human understanding process of logical fallacies. Towards these tasks, we design a pipeline framework to automatically generate and synthesize a high-quality dataset, namely **Logical Fallacy Understanding Dataset (LFUD)**, based on GPT-4 accompanied by a little human effort. Specifically, we first collect some sentences as the *propositions* (statements) which are the basic logic units and used to generate the sentences containing logical fallacies. Then, with the help of GPT-4, we generate sentences based on the propositions with twelve typical logical fallacy types (Jin et al., 2022). And for each LFU task we propose, the instances of each fallacy type are synthesized. Then, we use our LFUD to evaluate the LFU capability of some representative LLMs. For the ultimate objective of our work, i.e., enhancing LLMs' capability of logical reasoning, we further fine-tune these LLMs with the instances in LFUD. Our extensive experiments reveal that fine-tuning LLMs with LFUD can significantly enhance their logical reasoning capability.

In summary, our main contributions in this paper include:

1. Inspired by the three cognitive dimensions of **WHAT**, **WHY**, and **HOW**, we propose five concrete tasks which can truthfully evaluate LLMs' performance on LFU.

2. Towards our proposed five LFU tasks, we devise a new framework for constructing a high-quality dataset, namely LFUD, to evaluate LLMs' LFU capability, so as to enhance LLMs' performance on logical reasoning.

3. The LFUD we constructed includes 4,020 instances involving 12 logical fallacy types. Our extensive experiments have demonstrated that our LFUD can not only evaluate LLMs' LFU capability, but also improve LLMs' capability of logical reasoning through fine-tuning LLMs with LFUD samples in terms of the LFU tasks.

2 Related Work

Logical Reasoning Up to now, a lot of efforts have been dedicated to logical reasoning based on language models (Cresswell, 1973; Kowalski, 1974; Iwańska, 1993; Liu et al., 2020). In particular, how to evaluate the models' logical reasoning capability has attracted increasing attention, including deductive reasoning (Ontanon et al., 2022; Han et al., 2022), natural language inference (NLI) (Yanaka et al., 2019; Joshi et al., 2020; Liu et al., 2021) and multi-choice reading comprehension (MRC) (Liu et al., 2020; Yu et al., 2020; Wang et al., 2022). Recently, the power of LLMs has stimulated the research on logical reasoning with LLMs, including LLMs evaluation (Yu et al.,

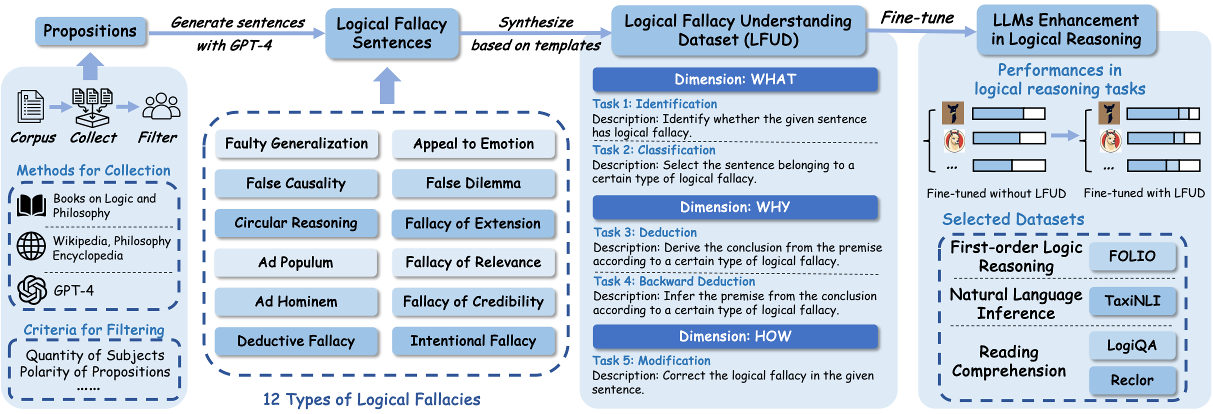

Figure 2: Our framework of constructing LFUD and fine-tuning LLMs with LFUD to enhance logical reasoning. At first, we collected some propositions, based on which the sentences with the logical fallacies of 12 types were generated by GPT-4. Then, for the five LFU tasks we proposed, the QA instances were synthesized based on the previous generated sentences. Finally, we fine-tuned LLMs with LFUD, revealing that fine-tuning LLMs with LFUD can significantly enhance their logical reasoning capability.

2023; Blair-Stanek et al., 2023; Teng et al., 2023), and LLMs enhancement (Zhang et al., 2023; Chen et al., 2023b). Despite these works' achievements, enhancing LLMs' logical reasoning capability remains a non-negligible challenge. The major reason for logical inconsistencies in many sentences is the misunderstanding of logical fallacies, which is still under-explored in the research field of logic.

Logical Fallacy Logical fallacy is the main reason for the logical inconsistencies presenting in our life. As early as 350 BC, Aristotle first proposed the concept of logical fallacy in his work *Sophistical Refutations* (Aristotle, 2006). Since then, logical fallacies have gradually gained attention in human society. In recent years, the studies related to logical fallacies mainly focused on dataset construction (Habernal et al., 2018; Martino et al., 2020; Jin et al., 2022) and fallacy classification (Stab and Gurevych, 2017; Goffredo et al., 2022; Jin et al., 2022; Payandeh et al., 2023). For instance, Jin et al. first proposed the task of Logical Fallacy Detection, presenting a framework of 13 logical fallacy types, and evaluated all sentence samples on a classification task. Sourati et al. proposed a Case-Based Reasoning method that classifies new cases of logical fallacy by language-modeling-driven retrieval and the adaptation of historical cases. However, there is no work to systematically evaluate LLMs' capability of logical fallacy understanding (LFU). For the first time, our work in this paper proposes a new dataset specific to LFU represented by five concrete tasks corresponding to three cognitive dimensions of **WHAT**, **WHY**, and **HOW**.

Learning from Synthetic Data Synthesizing data for model training has gradually gained popularity along with the advancements of language models. This approach is particularly beneficial for tasks that are difficult to be constructed or those with scarce data resources (Møller et al., 2023). Currently, synthetic data has been applied in various tasks such as relation extraction (Papanikolaou and Pierleoni, 2020), text classification (Chung et al., 2023), irony detection (Abaskohi et al., 2022), translation (Sennrich et al., 2015), and sentiment analysis (Maqsud, 2015). For example, Josifoski et al. proposed a strategy to design an effective synthetic data generation pipeline and applied it to closed information extraction. In addition, Li et al. conducted a series of experiments to evaluate the effectiveness of LLMs in generating synthetic data to support model training for different text classification tasks. Beyond these fundamental tasks, Eldan and Li proposed to use LLMs with synthetic data to generate short stories typically for 3 to 4-year-old only containing words. But they did not focus on logical fallacy. We are the first to focus on the data augmentation strategies in LFU.

3 Methodology of Dataset Construction

In this section, we present the pipeline of constructing our LFUD, of which the overall framework is depicted in Figure 2. Starting from the propositions, we detail the steps of synthesizing the samples towards five LFU tasks and the twelve representative

Propositions with Non-Human Subjects	15

Table 1: Some statistics of the 67 propositions in LFUD.

logical fallacy types.

3.1 Acquiring Propositions

At the first step of constructing our LFUD, we collected some propositions which were subsequently used for generating the sentences presenting various logical fallacies. According to Hurley (2000), a proposition is one sentence that is either true or false. We considered several sources of proposition collection, including some authoritative books of logic and philosophy (Hurley, 2000; Hausman, 2012), open websites such as Wikipedia and Stanford Encyclopedia of Philosophy. In addition, LLMs can be utilized to generate some propositions for enriching proposition diversity. To seek the satisfactory LLM for generating propositions, we tested some representative LLMs' identification performance on 200 instances from the Big-Bench (bench authors, 2023), consisting of correct and incorrect (logical fallacy) sentences. The results showed that GPT-4 can correctly identify in over 90% of the sentences whether they have logical fallacies, despite the limited capability in directly generating complex tasks. Thus, we leveraged GPT-4 to generate more propositions and subsequent sentences presenting logical fallacies.

The considerable propositions should be simple and intuitive, but diverse. Finally, we filtered out 67 propositions and the relevant statistics are listed in Table 1. The following sentences are the proposition examples:

1. Everyone in my family has never been to Europe.
2. X accepted Y's suggestion.
3. Michael had dinner at an Italian restaurant.

3.2 Generating Sentences with GPT-4

Given GPT-4's capability of natural language generation and logical fallacy identification, we directly used GPT-4 to generate the sentences presenting various logical fallacies in this step. To take into account the logical fallacies existing in our life as many as possible, we refered to the thirteen typical types of logical fallacies (as listed in Table 7 and Appendix B) proposed by Jin et al. (2022).

/ Generation Instruction */*

As a logician, when presented with a proposition, your objective is to simulate the way of human thinking, generating a sentence with specific type of logical fallacy. The generation should follow these instructions:

1. Generate the sentence with **Faulty Generalization**. Faulty Generalization occurs when ... (Detailed description)
2. The sentence should have complete premise and conclusion, but try not to make it too long.

/ Three demonstration examples */*

Proposition 1: Neither of the classes I took at UF were interesting.

Result 1: A college is not a good college if none of its classes are interesting. Neither of the classes I took at UF were interesting, so UF is not a good college.

...

/ Input the proposition */*

Proposition: Peter visited China last year.

/ GPT-4's output */*

Result: Peter visited China last year. Peter is a European. Therefore, all Europeans have been to China.

Table 2: A prompt case for GPT-4 to generate a sentence with the given logical fallacy type.

Given a proposition and a certain logical fallacy type, we asked GPT-4 to generate a sentence of this logical fallacy type with a prompt, which contains the generation instruction and a demonstration example of the given logical fallacy type. Table 2 illustrates the prompt for GPT-4 about the type of Faulty Generalization. Specifically, due to the rather vague definition of Equivocation provided by Jin et al. (2022), and the scarcity of such fallacy instances in real life, GPT-4 can hardly understand Equivocation and generate corresponding sentences correctly. To ensure the quality of the sentences generated by GPT-4 , we neglected Equivocation fallacy type and generated the sentences for the rest twelve logical fallacy types.

To ensure that the generated sentences meet the requirements, we further manually proofread the sentences with logical fallacies generated by GPT-4. Each generated sentence was proofread with two main areas of concern: structural integrity and validity of fallacies, as described in Appendix C, to ensure that the sentences made sense and met the requirements of specific fallacy type. For each of the 67 propositions, we generated 12 sentences

Dimension	Task name	Task definition
WHAT	Task1: Identification Task2: Classification	Identify whether the given sentence has logical fallacy. Select the sentence belonging to a certain type of logical fallacy.
WHY	Task3: Deduction Task4: Backward Deduction	Derive the conclusion from the premise according to a certain type of logical fallacy. Infer the premise from the conclusion according to a certain type of logical fallacy.
HOW	Task5: Modification	Correct the logical fallacy in the given sentence.

Table 3: Five LFU tasks corresponding to three cognitive dimensions.

with GPT-4, each of which presents one logical fallacy type. Thus, we generated 804 sentences with logical fallacies in total. These sentences are used to synthesize the samples for concrete LFU tasks as follows.

3.3 Proposing LFU Tasks and Synthesizing Task Instances

To evaluate LLMs' capability of LFU, we need to design concrete evaluation tasks. According to the principles of cognitive science (Swanborn, 2010), humans generally understand objects from three dimensions: **WHAT** it is, **WHY** it is, and **HOW** it operates, which are interconnected and progressive cognition levels. Inspired by these dimensions, we propose five concrete tasks which are used to verify models' capability of LFU. Table 3 lists the definitions of the five tasks. Wherein, Task 1 and Task 2 belong to WHAT dimension, which identify whether the given sentence has the logical fallacy (of a certain type). Task 3 and Task 4 belong to WHY dimension, which verify whether the model captures the reason causing the logical fallacy in the sentence. The last Task 5 belongs to HOW dimension, which requires correcting the logical fallacy of the given type in the sentence. Specifically, we synthesized multiple-choice questions for the first four tasks, and sentence generation questions for Task 5. We further provided one toy example for each task in Appendix A.

In fact, previous studies (Jin et al., 2022; bench authors, 2023) have focused on the two tasks of WHAT dimension, i.e., understanding what the logical fallacy in the sentence is. To the best of our knowledge, there are no studies concerning the tasks of WHY and HOW dimensions by now. But notably, the ultimate goal of LFU is to avoid logical fallacies, which requires us to understand the reasons causing logical fallacies and correct logical fallacies. Therefore, we paid more attention to the tasks of WHY and HOW dimension in this paper.

For each sentence with one of the twelve logical fallacy types generated in the previous step, we synthesized one QA instance for every LFU task with the question templates. For each LFU task, the question stems (without question options) of all instances are generated according to some templates, as shown in Appendix A. Particularly, for Task 3 and Task 4, we need to identify the premise and conclusion for the given sentence, and further provide question options. Thus, we directly asked GPT-4 to generate the results as we needed.

To minimize the impact of instruction design when asking LLMs to achieve these tasks, we first designed some candidate question templates to constitute a template pool in fact, and then randomly chose one template from the pool to generate the question for a certain LFU task. In addtion, we also shuffled the orders of question options. Finally, our LFUD contains 4,020 (QA) instances in total, involving 5 LFU tasks and 12 logical fallacy types, which stem from the 67 propositions and 804 sentences with logical fallacies.[1]

4 Evaluation

4.1 Experiment Setup

Datasets To evaluate LLMs' performance on logical reasoning, we used four representative datasets including FOLIO (Han et al., 2022), TaxiNLI (Joshi et al., 2020), LogiQA (Liu et al., 2020), and Reclor (Yu et al., 2020) in our experiments.

FOLIO focuses on first-order logic reasoning (FOL) that is a classical deductive reasoning task. TaxiNLI is specific to natural language inference (NLI) that tests the logical relationship between a premise and a hypothesis. LogiQA and Reclor are the multi-choice reading comprehension (MRC) datasets, which choose the most suitable answer corresponding to the given text, could better reflect comprehensive logical reasoning abilities. The instances of the four datasets are shown in Appendix D. In addition to the training data in above four datasets and our LFUD, we also used the logical

Table 4: LLMs' accuracy(%) on the four logical reasoning tasks (datasets) after being fine-tuned with different data. Origin represents fine-tuning the LLMs with the original training data in the logical reasoning datasets. Δ% is accuracy improvement relative to Origin. The best accuracy scores are **bolded** and the second best scores are underlined.

fallacy data LOGIC (Jin et al., 2022) to fine-tune LLMs. LOGIC (including LOGIC-CLIMATE) contains thirteen types of logical fallacy sentences, as shown in Appendix B.

LLMs We selected five popular LLMs in our experiments, including LLaMA2-7B, LLaMA2-13B (Touvron et al., 2023), Vicuna-7B, Vicuna-13B (Chiang et al., 2023) and Orca2-7B (Mitra et al., 2023). When fine-tuning these LLMs, we set the learning rate to 2.5e-5 and the batch size to 8. To ensure the robustness of our results, we repeated all experiments for three times and reported the average performance (accuracy) scores.

Dataset Split For the 4,020 synthesized instances in our LFUD, we randomly selected 3,000 instances (corresponding to 600 sentences with logical fallacies) as the training set and the remaining 1,020 instances (corresponding to 204 sentences with logical fallacies) as the test set. Given the instances of Task 1–4 (choice questions) have fixed answers, we only used the training samples (2,500 instances) of Task 1–4 to fine-tune the five LLMs. And we directly used some test samples of Task 5 to evaluate LLMs' cross-task learning capability on LFU, as presented in Subsection 4.3. To balance the labels of logical right and fallacy in Task 1 instances, we appended 500 logically correct sentences of Big-Bench (bench authors, 2023), and thus collected 2,900 training samples in our LFUD in total.

4.2 Effectiveness on Enhancing LLMs' Logical Reasoning

4.2.1 Overall Performance

To justify the value of our LFUD instances on enhancing LLMs' logical reasoning capability, we merged LFUD training samples with the original training samples in the four logical reasoning datasets, denoted by Origin, to fine-tune LLMs. We compared such a fine-tuning method with the method of fine-tuning LLMs only with Origin. In addition, we also compared the method of fine-tuning LLMs with Origin and some samples in LOGIC (Jin et al., 2022), which have the same number as the training samples in LFUD.

Table 4 lists the accuracy(%) scores of all five LLMs on the four logical reasoning tasks (datasets) which were fine-tuned with Origin, Origin+LOGIC and Origin+LFUD, respectively. And the performance improvements of Origin+LOGIC and Origin+LFUD relative to Orign are also listed. Based on the results in this table, we have the following observations and analysis.

1. Appending the training samples in our LFUD to Origin when fine-tuning LLMs significantly enhances their performance on all logical reasoning tasks. It shows that learning the LFU tasks we proposed is indeed helpful to improve LLMs' capability of various logical reasoning.

2. Although the samples in LOGIC are also the sentences with various logical fallacies, Origin+LOGIC cannot obtain the significant performance improvements of logical reasoning. Even

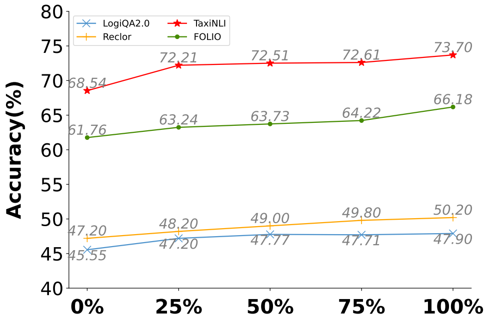

Figure 3: LLaMA2-13B's performance on the four logical reasoning tasks with different scales of LFUD training samples.

Models	WHAT		WHY		HOW
	Task1	Task2	Task3	Task4	Task5

All Fallacy Types	**47.90**	**50.20**	**73.70**	**66.18**

Table 7: LLaMA2-13B's performance on the four logical reasoning tasks when excluding different logical fallacy type's training instances.

worse, it degrades LLMs' logical reasoning performance, compared with Origin in some cases. It implies that, unlike our LFU tasks from WHAT, WHY and HOW, only identifying the logical fallacy presented by the sentences in LOGIC cannot result in LLMs' really capability of LFU. In addition, The samples in LOGIC are raw and unclean, with some examples consisting of even fallacy questions and fallacy definitions.

4.2.2 Impacts of Different Factors in LFUD

To further validate LFUD's effectiveness on enhancing LLMs' logical reasoning capability, we also investigated the impacts of different factors in LFUD, including the scale of training data, LFU tasks and logical fallacy types. Due to space limitation, we only display the results of LLaMA2-13B.

Training Data Scale To verify the impacts of training data scale, we respectively extracted 25%, 50%, and 75% of the LFUD training data accompanied with Origin to fine-tune LLaMA2-13B, and then tested its performance on the four logical reasoning tasks. From Figure 3 we can see that, LLaMA2-13B's performance improvement becomes more apparent as the training data scale increases, showing that even only a small part of LFUD samples is also valuable.

LFU Task We fine-tuned LLaMA2-13B again with the training data excluding the instances of Task 1, Task 2, Task 3 and Task4, respectively. As shown in Table 6, excluding any task's instances would lead to the performance decline of LLaMA2-13B.

Logical Fallacy Type Similarly, we respectively excluded the instances of each logical fallacy type from LFUD training data, and then tested LLaMA2-13B's performance. The results in Table 7 indicate that every logical fallacy type contributes positively to LLM's logical reasoning capability.

4.3 LFU Performance of LLMs

Next, we validate LLMs' capability of LFU through evaluating their performance on the LFU tasks. We want to investigate LLMs' inherent capability on LFU, thus we directly used all instances of each LFU task in LFUD as the test samples without fine-tuning them with the training data.

Performance on Each LFU Task Besides the previous four LLMs, we additionally considered ChatGPT (Ouyang et al., 2022) and the latest GPT-4 (OpenAI, 2023) (using OpenAI API with tem-

Models	**Accuracy(%)**
LLaMA-2-7B	0.92 (6/654)
LLaMA-2-13B	1.99 (13/654)
Vicuna-7B	7.95 (52/654)
Vicuna-13B	26.61 (174/654)
ChatGPT	37.92 (248/654)
GPT-4	95.57 (625/654)

Table 8: LLMs' Performance on identifying 654 logically correct sentences of Task 1.

Fallacy Type	**Task 1**	**Task 2**	**Task 3**	**Task 4**
Faulty Generalization	76.12	**89.55**	59.70	50.75
False Causality	61.19	70.15	67.16	65.67
Circular Reasoning	34.33	52.24	55.22	62.69
Ad Populum	65.67	80.60	**79.10**	**79.10**
Ad hominem	**77.61**	**89.55**	59.70	59.70
Deductive Fallacy	40.30	49.25	62.69	77.61
Appeal to Emotion	16.42	77.61	64.18	77.61
False Dilemma	29.85	44.78	62.69	50.75
Fallacy of Extension	53.73	25.37	41.79	38.81
Fallacy of Relevance	25.37	37.31	11.94	44.78
Fallacy of Credibility	40.30	53.73	61.19	64.18
Intentional Fallacy	68.66	31.34	47.76	64.18

Table 9: Vicuna-13B's performance on Task 1–4 specific to each type of logical fallacies. The best accuracy scores are **bolded** and the second best scores are underlined.

perature 0.7) in LFU performance evaluation. To balance the labels of Task 1, we added all 654 correct sentences in Big-Bench into Task 1's test data. Thus, we have a total of 1,458 instances for Task 1's evaluation. In addition, as Task 5 is to generate a new sentence rather than a fixed answer, we randomly selected 50 samples from its instances and manually assessed LLMs' outputs. All tested LLMs' performance is listed in Table 5, showing that different LLMs' performance varies significantly on the five LFU tasks. Among the LLMs, GPT-4 has much better performance than others on all tasks, justifying its strong capability of LFU. By contrast, LLaMA2-7B has the worst performance that is even worse than random selection.

Identifying Logical Correctness To further investigate whether LLMs really understand logical fallacies, we also asked LLMs to achieve Task 1 for the 654 sentences from Big-Bench that are logically correct (without logical fallacies). Their accuracy scores are listed in Table 8, showing that only GPT-4 has the satisfactory performance for this task. In fact, the rest LLMs tended to recognize the sentences as having logical fallacies for catering to Task 1's question. In addition, we also found these LLMs except for GPT-4 are easily influenced by the order of question options when achieving Task 1–4, indicating that they cannot well understand logical fallacies.

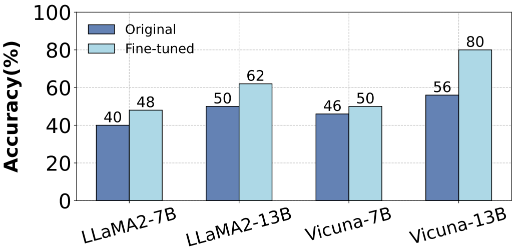

Figure 4: LLMs' Performance on Task 5 without fine-tuning (denoted as Original) or after being fine-tuned with training data of Task 1–4.

In Terms of Logical Fallacy Type Besides, we evaluated LLMs' LFU performance on Task 1–4 in terms of a specific logical fallacy type. The results listed in Table 9 show that, LLMs exhibited better performance on the tasks of *Faulty Generalization*, *False Causality*, *Ad populum* and *Ad Hominem*. These four types of logical fallacies are more distinctive and more frequently present in our life, resulting in that LLMs have encountered more sentences with these logical fallacy types during their pre-training.

Cross-task Learning Performance Compared with Task 1–4, Task 5 belongs to the higher cognition dimension **HOW**, and is more difficult for LLMs since it requires to generate a sentence satisfying the demand. An interesting research question is that, whether LLMs can well achieve Task 5 after learning the previous four tasks? To answer this question, for each of Task 1–4 we sampled 60 instances from its training data, and mixed them with the equal amount (240) of general conversation instances from lmsys-chat-1m to fine-tune LLMs, which was used to guarantee LLMs' generative ability. Then, we evaluated the fine-tuned LLMs' performance on Task 5, of which the performance is depicted in Figure 4. As well, LLMs' performance without fine-tuning, denoted as Original, is also displayed in the figure. The results indicate that, all the tested LLMs indeed enhanced their LFU performance through learning Task 1–4, also justifying their good cross-task learning capability of LFU tasks.

5 Conclusion

To evaluate LLMs' LFU performance, we propose five concrete tasks from three cognition dimensions WHAT, WHY, and HOW. Towards these tasks, we constructed a high quality dataset LFUD, which has been proven helpful by our extensive experiments to enhance LLMs' capability of logical reasoning. We hope our work in this paper is instructive and our LFUD becomes a valuable resource for further research on LFU.

Limitations

Although we argue that enhancing LLMs' logical reasoning capability through enabling LLMs to understand logical fallacies is language-independent, we should still acknowledge that the data and experiments of our work were only in English. As we know, LLMs might have different performance on many tasks including logical reasoning, across different languages. Therefore, the effectiveness of our solution proposed in this paper may vary when applied to other languages.

Ethical Considerations

At first, all authors of this work abide by the provided Code of Ethics. The quality of manual proofreading for logical fallacy sentences is ensured through a double-check strategy outlined in Appendix C. We ensure that the privacy rights of all members for proofreading are respected in the process. Besides, synthetic data generated by LLMs may involve potential ethical risks regarding fairness and bias (Bommasani et al., 2021; Blodgett et al., 2020), which results in further consideration when they are employed in downstream tasks. Although our dataset LFUD was built for better understanding logical fallacies, which is not intended for safety-critical applications, we still asked our members for proofreading to refine the offensive and harmful data generated by GPT-4. Despite these considerations, there may still be some unsatisfactory data that goes unnoticed in our final dataset.

A Details of Five LFU Tasks

We list the definitions and examples of our five tasks below.

Dimension: WHAT

- **Task1:** Identification
- **Definition:** Identify whether the given sentence has logical fallacy.
- **Example:**
  Sentence: Many people believe most museums will be closed on Mondays, therefore it's a fact.
  Identify if there is any logical fallacy in the sentence.
  A) Yes, there is a logical fallacy.
  B) No, there is no logical fallacy.

- **Task2:** Classification
- **Definition:** Select the sentence belonging to a certain type of logical fallacy.
- **Example:**
  Circular reasoning occurs when an argument uses the claim it is trying to prove as proof that the claim is true.
  Select which among the following options demonstrates the logical fallacy of circular reasoning.
  A) Most people believe that Rebecca doesn't like spicy food, therefore it must be true.
  B) Rebecca, a renowned food critic, does not like spicy food. Hence, spicy food is not good.
  C) Rebecca either refrains from spicy food due to discomfort it causes her, or she lacks well-developed taste buds.
  D) Rebecca doesn't like spicy food because she dislikes spicy food.

Dimension: WHY

- **Task3:** Deduction
- **Definition:** Derive the conclusion from the premise according to a certain type of logical fallacy.
- **Example:**
  Faulty generalization occurs when a conclusion about all or many instances of a phenomenon is drawn from one or a few instances of that phenomenon.
  The premise is known: Bob painted his house green and he is a homeowner.
  With which of the two conclusions can the premise be coupled to create logical fallacy of

Fallacy Type	Description	Example
Faulty Generalization	Faulty generalization occurs when a conclusion about all or many instances of a phenomenon is drawn from one or a few instances of that phenomenon.	Kevin, who is a teenager, enjoys playing chess. Therefore, all teenagers must enjoy playing chess.
False Causality	False causality occurs when an argument jumps to a conclusion implying a causal relationship without supporting evidence.	Whenever David goes hiking in the mountains, it's a sunny day. Clearly, David's hiking trips cause sunny weather.
Circular Claim	Circular reasoning occurs when an argument uses the claim it is trying to prove as proof that the claim is true.	Some students are not serious about their studies because they do not focus on their studies.
Ad Populum	Ad populum occurs when an argument is based on affirming that something is real or better because the majority thinks so.	It's widely believed that Nancy relocated to another city, so it must be true.
Ad Hominem	Ad hominem is an irrelevant attack towards the person or some aspect of the person who is making the argument, instead of addressing the argument or position directly.	John claims that all people should obey the rules of the road. But John has received several speeding tickets in the past. Therefore, it's not necessary to obey the rules of the road.
Deductive Fallacy	Deductive fallacy occurs when there is a logical flaw in the reasoning behind the argument, such as Affirming the consequent, Denying the antecedent, Affirming a disjunct and so on.	Should Lucy feel alone, she will surely adopt a puppy. It's evident Lucy has adopted a puppy. Therefore, it must be that Lucy is feeling lonely.
Appeal to Emotion	Appeal to emotion is when emotion is used in place of reason to support an argument in place of reason, such as pity, fear, anger, etc.	Jack had his wallet stolen at the concert, think about how desperate and helpless Jack is now, how can we not help him?
False Dilemma	False dilemma occurs when incorrect limitations are made on the possible options in a scenario when there could be other options.	Most museums will be closed on Mondays either due to low visitor turnout, or due to their disregard for public interest.
Equivocation	Equivocation is an argument which uses a key term or phrase in an ambiguous way, with one meaning in one portion of the argument and then another meaning in another portion of the argument.	All stars are exploding balls of gas. Miley Cyrus is a star. Therefore, Miley Cyrus is an exploding ball of gas.
Fallacy of Extension	Fallacy of extension is an argument that attacks an exaggerated or caricatured version of your opponent's position.	Alex: All flowers don't stay open forever. Jamie: So you're saying that all flowers die instantly after they bloom?
Fallacy of Relevance	Fallacy of relevance, which is also known as Red Herring, occurs when the speaker attempts to divert attention from the primary argument by offering a point that does not suffice as counterpoint/supporting evidence (even if it is true).	A portion of the inhabitants of this city have a fever, but have you considered the high unemployment rate?
Fallacy of Credibility	Fallacy of credibility is when an appeal is made to some form of ethics, authority, or credibility.	Sharon, an acclaimed pianist with years of experience, claims that practicing every day will increase your piano skills by 50%. She's an expert, therefore we should believe her.
Intentional Fallacy	Intentional fallacy is a custom category for when an argument has some element that shows the intent of a speaker to win an argument without actual supporting evidence.	Since no one can prove that Peter didn't come to China last year, he must have.

Table 10: Descriptions and examples of 13 logical fallacy types

faulty generalization?
A) Green is the most popular house color.
B) All homeowners paint their houses green.

- **Task4:** Backward Deduction
- **Definition:** Infer the premise from the conclusion according to a certain type of logical fallacy.
- **Example:**
  Ad populum occurs when an argument is based on affirming that something is real or better because the majority thinks so.
  The conclusion is known: Cynthia's painting must be a masterpiece.
  With which of the two premises can the conclusion be coupled to create the logical fallacy of ad populum?
  A) People widely agree that Cynthia made a beautiful painting.
  B) A famous art critic praised Cynthia's painting.

Dimension: HOW

- **Task5:** Modification
- **Definition:** Correct the logical fallacy in the given sentence.
- **Example:**
  Original sentence: Person A: The garden needs watering. Person B: So you're saying we should neglect everything else and just focus on the garden?
  Correct the logical fallacy in the original sentence and output the modified sentence without any logical fallacy.

B Details of Logic Fallacy Types

In Table 10, we showcase the description and examples of 13 logical fallacy types.

C Details of Manual Proofreading

The evaluation standard is strictly classified into two main categories: structural integrity and validity of fallacies. Structural integrity focuses on the correctness of grammar, the accuracy of punctuation, and the proper use of syntax. On the other hand, the validity of fallacies ensures that, under specific contexts or themes, the sentences satisfy the need for specific type of logical fallacy. Besides, any offensive and harmful data will be refined during the proofreading.

In this process, we assembled an expert team proficient in linguistics and logic. This team comprises four members, including one logician and three graduate students, who are engaged in linguistics, logic, and computer science respectively. They each have the ability to understand and classify various types of logical fallacies.

To enhance the efficiency of this process, each sentence was initially processed through Grammarly, eliminating basic grammatical and lexical errors. Subsequently, our expert team manually reviewed the content. Each sentence was assigned to two team members for review. A consensus confirmed the sentence met the requirements, but in case of disagreement, the third team member would be consulted. If three members cannot achieve consensus, the logician will make the final decision.

D Examples of Logical Reasoning Datasets

We illustrate data examples of four logical reasoning datasets selected in our experiments, including FOLIO, TaxiNLI, LogiQA, and Reclor.

FOLIO

Premise: Beasts of Prey is either a fantasy novel or a science fiction novel. Science fiction novels are not about mythological creatures. Beasts of Prey Is about a creature known as the Shetani. Shetanis are mythological.

Conclusion: Beasts of prey isn't a science fiction novel.

Answer: True

TaxiNLI

Premise: Even if auditors do not follow such other standards and methodologies, they may still serve as a useful source of guidance to auditors in planning their work under GAGAS.

Hypothesis: Auditors should ignore them when they follow other standards and methodologies.

Label: Contradiction

LogiQA2.0

Passage: For a television program about astrology, investigators went into the street and found twenty volunteers born under the sign of Gemini who were willing to be interviewed on the program and to take a personality test. The test confirmed the investigators' personal impressions that each of the volunteers was more sociable and extroverted than people are on average. This modest investigation thus supports the claim that one's astrological birth sign influences one's personality.

Question: Which one of the following, if true, indicates the most serious flaw in the method used by the investigators?

A. People born under astrological signs other than Gemini have been judged by astrologers to be much less sociable than those born under Gemini.

B. There is not likely to be a greater proportion of people born under the sign of Gemini on the street than in the population as a whole.

C. People who are not sociable and extroverted are not likely to agree to participate in such an investigation.

D. The personal impressions the investigators first formed of other people have tended to be confirmed by the investigators' later experience of those people.

Answer: C

Reclor

Context: Geologist: A new method for forecasting earthquakes has reliably predicted several earthquakes. Unfortunately, this method can predict only that an earthquake will fall somewhere within a range of two and a half points on the Richter scale. Thus, since a difference of two and a half points can be the difference between a marginally perceptible shaking and a quake that causes considerable damage, the new method is unlikely to be useful.

Question: Which one of the following, if assumed, enables the geologist's conclusion to be properly inferred?

A. An earthquake-forecasting method is unlikely to be useful unless its predictions always differentiate earthquakes that are barely noticeable from ones that result in substantial destruction.

B. Several well-established methods for forecasting earthquakes can predict within much narrower ranges than two and a half points on the Richter scale.

C. Even if an earthquake-forecasting method makes predictions within a very narrow range on the Richter scale, this method is not likely to be useful unless its predictions are reliable.

D. An earthquake-forecasting method has not been shown to be useful until it has been used to reliably predict a large number of earthquakes.

Answer: A

Exploring Automated Distractor Generation for Math Multiple-choice Questions via Large Language Models

Abstract

Multiple-choice questions (MCQs) are ubiquitous in almost all levels of education since they are easy to administer, grade, and are a reliable format in assessments and practices. One of the most important aspects of MCQs is the distractors, i.e., incorrect options that are designed to target common errors or misconceptions among real students. To date, the task of crafting high-quality distractors largely remains a labor and time-intensive process for teachers and learning content designers, which has limited scalability. In this work, we study the task of automated distractor generation in the domain of math MCQs and explore a wide variety of large language model (LLM)-based approaches, from in-context learning to fine-tuning. We conduct extensive experiments using a real-world math MCQ dataset and find that although LLMs can generate some mathematically valid distractors, they are less adept at anticipating common errors or misconceptions among real students.

1 Introduction

Multiple-choice questions (MCQs) are widely used to evaluate student knowledge because they enable quick and accurate administration and grading. MCQs are reliable because they are designed to measure specific learning objectives consistently (Nitko, 1996; Airasian, 2001; Kubiszyn and Borich, 2016). MCQs are constructed in a specific format. See Figure 1 for an example. The *stem* refers to the statement on the problem setup and context, followed by a question that needs to be answered. Among the options, the correct one can be referred to as the *key*, while incorrect ones can be referred to as *distractors*. As the name implies, distractors in MCQs are typically formulated to align with the common errors students would make or misconceptions students would exhibit. These distractors are chosen because students either i) lack the necessary knowledge of the skills tested in the MCQ to accurately identify the key as the correct answer, or ii) hold misconceptions that result in selecting a specific distractor as the correct answer. While MCQs offer many advantages for student knowledge evaluation, manually crafting high-quality MCQs is a demanding and labor-intensive process (Kelly et al., 2013). Specifically, high-quality distractors should be plausible enough to mislead students and not so evidently incorrect to be identified easily.

Prior work on automatic distractor generation primarily focuses on language learning and reading comprehension tasks, where distractors are used to assess students' comprehension of a given text or article. Early works use a ranking approach based on semantic similarity and word collocation information or a pre-defined ontology to produce distractors (Susanti et al., 2018; Stasaski and Hearst, 2017; Alsubait et al., 2014). More recent works use encoder-decoder models with attention mechanisms for distractor generation, resulting in longer and higher-quality distractors (Qiu et al., 2020; Shuai et al., 2023; Xie et al., 2021; Gao et al., 2019). Additionally, several recent works use pre-trained large language models (LLMs) such as `BERT` and `T5` for distractor generation in the context of Swedish reading and Cloze test (Kalpakchi and Boye, 2021; Chiang et al., 2022; Rodriguez-Torrealba et al., 2022). Other works prompt LLMs such as `ChatGPT` and `GPT-4` to generate distractors, either by providing detailed instructions or in-context examples in their prompts, for computer science course quiz questions and questions testing language mastery or factual knowledge (Tran et al., 2023; Bitew et al., 2023).

However, there is limited work on automatic distractor generation for math MCQs. This problem is more challenging than generating distractors for reading comprehension tasks because plausible distractors are not necessarily contained or can be inferred from the passage. A model for math

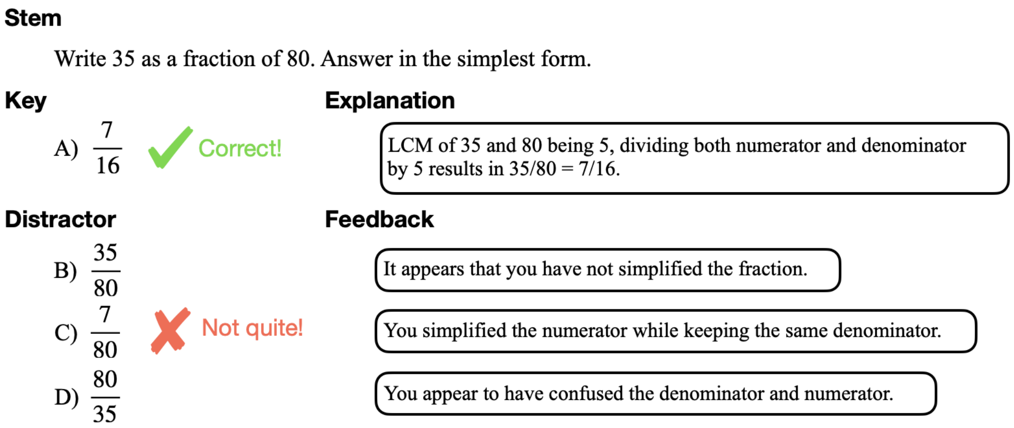
Findings of the Association for Computational Linguistics: NAACL 2024, pages 3067–3082
June 16-21, 2024



Write 35 as a fraction of 80. Answer in the simplest form.

LCM of 35 and 80 being 5, dividing both numerator and denominator by 5 results in 35/80 = 7/16.

It appears that you have not simplified the fraction.

You simplified the numerator while keeping the same denominator.

You appear to have confused the denominator and numerator.

Figure 1: Different parts of math MCQs and the terminology we use, illustrated with an example.

MCQ distractor generation should have some math problem-solving capability and more importantly, an understanding of the common errors or misconceptions among real students. Existing works either use constraint logic programming (Tomás and Leal, 2013) or manually constructed rules (Prakash et al., 2023) to generate distractors. However, these works only applies to math MCQs generated by templates. The work in (Dave et al., 2021) explores generating distractors using a neural network. However, their approach is training a math problem solver model and treating the incorrect outputs as distractors, which cannot capture common errors or misconceptions among real students.

1.1 Contributions

In this work, we investigate the task of automatically generating plausible distractors for math MCQs using LLMs. Our contributions include:

- We explore a variety of approaches to this task, including in-context learning, fine-tuning, and chain-of-thought prompting, together with rule- and sampling-based baselines. [*]
- We conduct extensive quantitative and qualitative experiments on a real-world dataset of math MCQs. We find that the most effective approach is in-context learning, where we select a few example MCQs as input to the LLM, which can serve as a baseline for future work.
- We conduct a human evaluation and find that although the LLM-generated distractors are close to the human-authored ones in terms of mathematical validity, they do not necessarily reflect common errors or misconceptions among real students.

2 Task and Approaches

In this section, we first formally define relevant mathematical notation in MCQs and the automated distractor generation task. We then detail the LLM-based approaches and baselines that we explore.

2.1 Task Definition

We define an MCQ Q as a set of textual components, i.e., $Q = \{s, k, e_k, D, F\}$.[*] Each MCQ contains a stem s, a key k, an (optional) explanation of the key e_k, and a set of distractors D; each of which has an (optional) corresponding feedback message f_i which is shown to a student upon selecting a distractor $d_i \in D$. All of these components are sequences of words and math symbols (e.g., $s = \{w_1, \ldots, w_L\}$ where L is the length of the sequence s). Similar to (Qiu et al., 2020), we formulate the task of distractor generation as learning a function g^{dis} that outputs a set of distractors $\hat{D}$ for an MCQ given the question stem and (optionally) key and its explanation, i.e.,

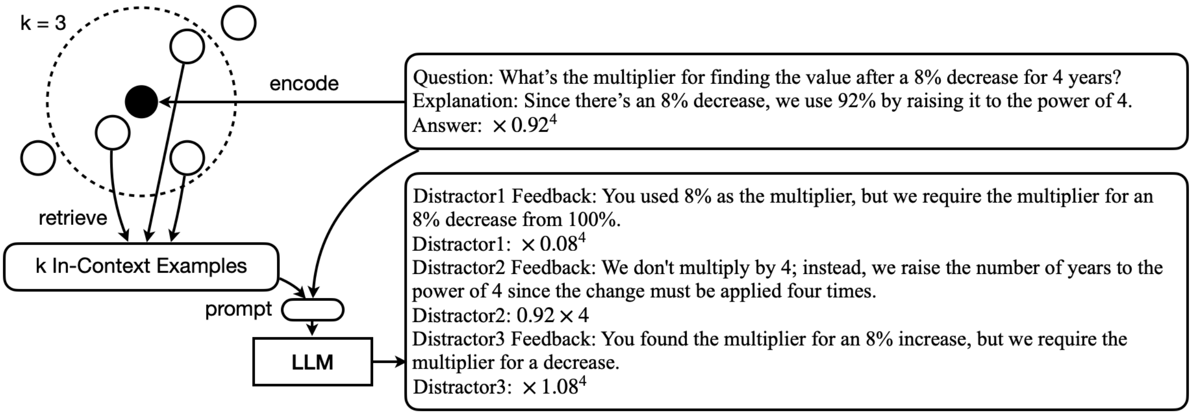
$$g^{\text{dis}}(s, k, e_k) \to \hat{D}. \tag{1}$$

Our goal is to generate distractors that students with insufficient knowledge on skills required for the MCQ or specific misconceptions will select. This way, the MCQ can better distinguish between students that master all the required skills and those who do not. Below, we detail various LLM-based

---

[*] Our code is publicly available at `https://github.com/umass-ml4ed/prompt_distractor_generation_NAACL`

[*] In this paper, we do not consider MCQs that contain diagrams or images; extending our work to multi-modal MCQ content is left for future work.



Question: What's the multiplier for finding the value after a 8% decrease for 4 years?
Explanation: Since there's an 8% decrease, we use 92% by raising it to the power of 4.
Answer: $\times 0.92^4$

Distractor1 Feedback: You used 8% as the multiplier, but we require the multiplier for an 8% decrease from 100%.
Distractor1: $\times 0.08^4$
Distractor2 Feedback: We don't multiply by 4; instead, we raise the number of years to the power of 4 since the change must be applied four times.
Distractor2: 0.92×4
Distractor3 Feedback: You found the multiplier for an 8% increase, but we require the multiplier for a decrease.
Distractor3: $\times 1.08^4$

Figure 2: Overview of the kNN approach illustrated with a math MCQ on "compound percentage decrease".

distractor generation approaches and several baselines that we explore.

We note that in this work, we study the problem of generating a set of distractors $\hat{D}$ given a single question stem . This setting is different from a possible alternative setting where we generate distractors one-by-one, each corresponding to a common error or misconception among real students. The latter is applicable to the related problem of *feedback generation* (Prihar et al., 2023), which investigates the task of generating a feedback message f_i for a distractor d_i. Providing feedback messages to students who select distractors can help them identify their errors or misconceptions and guide them towards the correct answer, which may expedite their learning process. In this work, we only treat the feedback message as an additional reasoning pathway to help LLMs generate plausible distractors and do not study the quality of feedback messages, which we leave for future work.

2.2 Approaches

The first approach is in-context learning or few-shot prompting, i.e., the LLM is expected to generate desired outputs for a new task by learning from the given examples (Brown et al., 2020). To select examples, we select the k-nearest neighbor (**kNN**) MCQs from a real-world math MCQ dataset, which we detail in Section 3.1, to the target MCQ. After conducting tests with various values of k, we find that this approach achieves the best distractor generation performance when $k = 3$. To determine similarity, we calculate the *cosine similarity* between vectorized textual encodings of MCQs. Specifically, we use the pre-trained SBERT encoder `MPNet` (Reimers and Gurevych, 2019) to calculate the textual encoding of the question stem and (optionally) key and its explanation. Figure 2 provides a visual representation of this approach. The intuition for this approach is that MCQs with similar question stems may have distractors that correspond to similar student errors or misconceptions that are feasible to the target MCQ, which may help the LLM to generate plausible distractors. Even though textual similarity may not be an appropriate representation for mathematical errors, these in-context examples should at least inform the LLM on distractor formatting (Chen et al., 2023; Lyu et al., 2023). We use `ChatGPT` in this approach for its proficiency in understanding tasks and delivering strong performance when provided with in-context examples.

The second approach is chain-of-thought prompting (**CoT**) (Wei et al., 2022). We provide the LLM with the question stem and (optionally) key and its explanation and detailed guidelines on distractor generation as input and ask it to first generate potential erroneous steps a student may take, followed by an incorrect answer as the distractor. This approach operates in a zero-shot manner and requires no access to any real MCQ data. Therefore, the performance depends solely on the LLM's ability in mathematical reasoning and anticipating common errors or misconceptions among real students. Given the demanding nature of this approach, we use a strong base LLM `GPT-4` (OpenAI, 2023).

The third approach is LLM fine-tuning (**FT**) to help pre-trained LLMs to adapt to the distractor generation task. We use the real-world math MCQ dataset to fine-tune the LLM in the format of Eq. 1, i.e., outputting all distractors given the question stem and (optionally) key and its explanation as input. We use `ChatGPT` (gpt-3.5-turbo-1106) (OpenAI, 2022), the largest base LLM that can be fine-tuned, in this approach.

The fourth approach is a rule-based (**RB**) baseline, which can be used to generate different versions of the same MCQ with different numerical values. We emphasize that in many real-world educational platforms, content creators do not use rules to design distractors. In practice, not a lot of MCQs are created from templates and only differ by numerical values or named entities in their question stems. Therefore, we *approximately* follow the baseline approach in (Dave et al., 2021) and manually construct 444 distinct error explanations, such as "confuses factor and multiples" for question-distractor pairs that correspond to common errors or misconceptions among real students. This process is extremely time-consuming and requires significant manual effort. We then provide the LLM with the question stem and (optionally) key and its explanation and a pool of error explanations that are feasible under the MCQ's topic (i.e., fractions, rounding, etc.), and ask LLM to select 3 relevant ones and generate the corresponding distractors. We use `GPT-4` in this approach for the same reason as CoT.

The fifth approach is an improved version of the sampling-based (**SB**) baseline in (Dave et al., 2021). This approach fine-tunes a base LLM on MCQ answering, i.e., outputting the key given the question stem as input. Then, we randomly sample up to 20 output answers from the trained LLM given a question stem as input and choose 3 distinct incorrect ones as distractors. This approach implicitly assumes that LLMs make similar errors as real students. We use `ChatGPT` in this approach for the same reason as FT.

3 Experiments

In this section, we detail the specifics of our dataset, the evaluation metrics, the experimental setup, and report results from a series of quantitative, qualitative experiments, and human evaluation.

3.1 Dataset

Our dataset consists of 1.4K MCQs from Eedi's content repository[*], and all MCQs are written in English. Each question has 1 key and 3 distractors designed according to common errors or misconceptions among real students. The questions are sourced from the broad mathematical topic titled "Number" with subtopics including "Basic Arithmetic", "Fractions", and "Rounding and Estimating". The questions are primarily targeted towards students aged between 10 to 13. Each MCQ also has some additional metadata, e.g., the "topic" on 3 different granularity levels and the option selection distribution, i.e., the proportion of students who selected each option. The option selection distribution is computed on an average of 4000 student responses, with more than 900 student responses available in over 75% of the MCQs. We divide the dataset into two subsets, namely a training set and a test set, using an $80 : 20$ ratio. We use the training set to select MCQs as in-context examples or fine-tune LLMs and the test set for evaluation.

3.2 Evaluation Metrics

Our main evaluation metric is a set of *alignment-based* metrics, which quantifies the extent to which the LLM-generated distractors align with the human-authored ones. We denote the LLM-generated distractors as $\hat{D}$ where $|\hat{D}| = N$. We utilize 3 measures for this evaluation, two binary and one continuous. The binary metrics are **Exact** match h_e, i.e., whether all LLM-generated distractors match human-authored ones[*], and **Partial** match h_p, i.e., whether at least one LLM-generated distractor matches human-authored ones. These measures are formally defined as

$$h_e(D, \hat{D}) = \begin{cases} 1 & \forall \hat{d}_i \in \hat{D} : \hat{d}_i = d_i \\ 0 & \text{otherwise.} \end{cases}$$

and

$$h_p(D, \hat{D}) = \begin{cases} 1 & \exists \hat{d}_i \in \hat{D} : \hat{d}_i = d_i \\ 0 & \text{otherwise} \end{cases}$$

We also use a continuous measure in the range $[0, 1]$ that we call **Proportional** match h_n, i.e., the portion of LLM-generated distractors that match human-authored ones, defined as

$$h_n(D, \hat{D}) = \frac{\sum_{i=1} \mathbf{1}_{i:\hat{d}_i = d_i}}{N}$$

where $\mathbf{1}$ denotes an indicator function. We report all metrics by averaging across all MCQs in the test set and scale the values of metrics by a factor of 100 into percentages.

Additionally, we experiment with a non-standard, *distribution-based* metric, which tries to predict how often a distractor is selected by real students. This metric is motivated by the observation

---

[*] `https://eedi.com/home`

[*] We use the exact string match criterion to align LLM-generated distractors with human-authored ones.

(See Section 3.5 for a detailed qualitative analysis) that human-authored distractors are sometimes not plausible or complete: for some MCQs, there may only be one highly common error or misconception among real students, so teachers often have to come up with a few placeholders that will be selected by almost no one, while for other MCQs, there may be numerous plausible distractors that cannot all be included. Therefore, our goal is to use the percentages of students who selected each option to train a model that predicts how feasible a distractor is. Since we cannot reach high predictive accuracy on the real dataset we have, we relegate the details on this metric and experimental results to the Supplementary Material Section A.

Furthermore, we experiment with a metric that evaluates the quality of LLM-generated distractors indirectly: we ask `GPT-4` to answer MCQs in the test set under two scenarios: one using LLM-generated distractors and the other using human-authored ones. We then calculate and compare the solve rates. We found that LLM-generated distractors using kNN, the best-performing method under alignment-based metrics, are more difficult (71% solve rate) than the human-authored ones (72.5%). This result implies that the LLM-generated distractors are not placeholders, which would make it very easy for `GPT-4` to select the key. However, solve rate cannot be used to evaluate the real quality of distractors and whether they reflect common errors or misconceptions among real students.

3.3 Experimental Setup

For all approaches except SB, we use a uniform format to represent the target MCQ. This format comprises a concatenation of 3 elements: the question stem, key, and its explanation. We use this structure since it encapsulates the most comprehensive information about the target MCQ. Furthermore, based on CoT, we instruct the LLM to first generate feedback message and then the distractor, which intends to simulate a reasoning pathway, providing a scaffold that guides the subsequent generation of plausible distractors. We use greedy decoding and a maximum output length of 350 tokens for distractor generation. Additional hyperparameters and model details are in Supplementary Material Section B. We also provide our prompts for CoT, RB, and kNN in Tables 9, 10, and 11 respectively.

Approach	Exact	Partial	Proportional
kNN	**10.95**	**73.85**	**38.52**
CoT	4.24	65.02	30.39
RB	4.95	57.95	27.21
FT	2.83	57.95	25.32
SB	0.00	10.25	3.65

Table 1: Results on distractor generation on alignment-based metrics, where in-context learning with kNN example selection outperforms other approaches.

3.4 Results and Discussion

Table 1 shows the results on distractor generation for the 5 approaches we explore. Overall, kNN outperforms the other approaches. This result is not surprising since examples that are textually similar to the target MCQ often contain distractors that correspond to plausible errors or misconceptions among real students for both MCQs. Therefore, the LLM can generate distractors that match the human-authored ones by simply replicating the style of the in-context examples. This approach is especially effective for MCQs that have highly similar structures and differ in only numerical values.

The advantage of CoT over FT reflects the strong mathematical reasoning capability of `GPT-4`, which results in a performance gap that not even fine-tuning `ChatGPT` on human-authored distractors can make up. Instead of acting as an oracle, RB underperforms this expectation and does not even outperform CoT, despite requiring significant human expertise and effort. This result is likely due to the fact that despite extensive effort in labeling error explanations, we cannot come up with a comprehensive list of them; as a result, many target MCQs are not matched with error explanations for `GPT-4` to select from. Overall, we observe that `GPT-4` can often generate mathematically valid distractors but is unaware of what errors or misconceptions are common among real students. Therefore, CoT and RB do not perform as well as kNN. Among all the approaches we explore, SB has by far the worst performance. This result is not surprising since when we train LLMs to answer math MCQs correctly, the generated incorrect answers are either only marginally different than the key or completely unrelated to the question stem. Therefore, the distractors generated by this approach lack coherent reasoning and fail to capture common errors or misconceptions among real students.

Approach	Exact	Partial	Proportional
kNN$^{\text{all}}$	**10.95**	**73.85**	**38.52**
kNN$^{\text{key}}$	11.66	69.96	37.57
kNN$^{\text{none}}$	9.54	67.84	35.81
Random	2.12	54.77	23.56
Prompt$^{\text{key}}$	8.48	66.43	34.04
Prompt$^{\text{none}}$	3.89	44.52	21.20
kNN$^{\text{all}}_{\neg T}$	3.18	58.30	26.38
FT$^{\text{gpt3.5}}$	**2.83**	**57.95**	**25.32**

RB$^{\text{select}}$	**4.95**	**57.95**	**27.21**
RB$^{\text{random}}$	1.06	53.00	23.20

Table 2: Results on ablation study on alignment-based metrics with different settings of kNN, FT, and RB.

3.4.1 Ablation Study

In this ablation study, we investigate the impact of different configurations of kNN on its performance and summarize these results in the first part of Table 2. We explore how different ways of using different parts of the MCQ in the textual encoder for nearest neighbor search could affect kNN's performance. We experiment with 3 different settings: using just the question stem (**kNN$^{\text{none}}$**); using the question stem and key (**kNN$^{\text{key}}$**); and using the question stem, key, and its explanation (**kNN$^{\text{all}}$**), which is the best performing setting. For comparison, we also experiment with a simple random heuristic (**Random**) that chooses examples from the training set randomly without any specific criteria. We see that although using only the question stem captures the math skill covered by an MCQ and helps kNN find examples that have the same format as the target MCQ, adding the key and explanation helps kNN find better examples that use similar problem-solving strategies to the target MCQ. We also explore how different prompt formats could affect kNN's performance. We experiment with 3 different prompt formats. The best-performing setting (kNN$^{\text{all}}$) includes the question stem, key, and explanation for both the target MCQ and the in-context examples. The in-context examples also contain feedback on the distractors, and we ask the LLM to generate the feedback, followed by the distractor. The other settings are not to include feedback messages for the distractors and the explanation for the key (**Prompt$^{\text{key}}$**), and not including the key either (**Prompt$^{\text{none}}$**). We see that including the key significantly improves kNN's performance and asking the LLM to generate feedback followed by the distractor further improves performance. This result again reinforces the importance of math problem-solving strategies and CoT reasoning on the distractor generation performance. We also explore the impact of not allowing MCQs with the same topic to be selected as examples on kNN's performance (**kNN$^{\text{all}}_{\neg T}$**). We see that doing so results in a huge performance drop-off from kNN$^{\text{all}}$. This result suggests that most errors or misconceptions behind distractors are topic-specific and do not generalize across topics.

Next, we investigate the impact of different base LLMs on FT's performance and summarize these results in the second part of Table 2. We compare `ChatGPT` against `Mistral-7B` (Jiang et al., 2023), which is one of the biggest open-sourced generative LLMs (**FT$^{\text{mistral}}$**). We see that `ChatGPT` outperforms `Mistral-7B` on all 3 alignment-based metrics. This result suggests that larger models that are better at mathematical reasoning are more likely to generate plausible distractors. We also investigate the impact of different error selection approaches on RB's performance and summarize these results in the third part of Table 2. We experiment with a variant of RB that randomly selects error explanations under the same math topic (**RB$^{\text{random}}$**) instead of asking `GPT-4` to select 3 relevant ones (**RB$^{\text{select}}$**). We see that asking the LLM to select error explanations outperforms selecting error explanations randomly, but not by a significant margin compared to other ablations. This result suggests that even though LLMs can generate many mathematically valid distractors, their ability to recognize which error explanations are popular among students is limited.

Furthermore, we investigate the impact of different base LLMs on all approaches' performance except SB and summarize these results in Table 3. We compare 3 base LLMs: `GPT-4` [*], `ChatGPT`, and `Mistral`. We see that kNN outperforms CoT and RB across all base LLMs. This result suggests that kNN is a promising approach since in-context examples provide valuable information to the LLM on the nature and format of the distractor generation task. We see that `GPT-4` significantly outperforms `ChatGPT`, which significantly outperforms `Mistral` on CoT and RB. This result suggests that, among the 3 base LLMs evaluated, `GPT-4` possesses the most robust mathemat-

---

[*] As of now, Openai does not allow fine-tune `GPT-4`.

LLM	Approach	Exact	Partial	Proportional
GPT-4	**kNN**	**8.83**	**71.73**	**38.52**
	CoT	4.24	65.02	30.39
	RB	4.95	57.95	27.21
ChatGPT	**kNN**	**10.95**	**73.85**	**38.52**
	CoT	1.06	48.41	21.67
	RB	1.77	50.53	23.09
	FT	2.83	57.95	25.32
Mistral	kNN	1.77	31.10	13.90
	CoT	0.0	8.83	3.65
	RB	0.0	18.37	7.07
	FT	**1.77**	**52.30**	**22.50**

Table 3: Results on kNN, CoT, RB, and FT on alignment-based metrics with different base LLMs: `GPT-4`, `ChatGPT`, and `Mistral`.

ical reasoning capability, followed by `ChatGPT`, which possesses a better mathematical reasoning capability than `Mistral`. We see that FT achieves better performance than kNN with `Mistral`. This result suggests that the pre-trained `Mistral` initially lacks mathematical reasoning capability, and the fine-tuning process significantly enhances its mathematical reasoning capability.

3.5 Qualitative Analysis

We now qualitatively investigate the distractors generated by the best approach, kNN, to extract some insights on the distractor generation task and how to improve performance. We group the 283 total MCQs in the test set into 4 categories, according to the number of LLM-generated distractors that match the human-authored ones, from 0 to 3.

For the group where all LLM-generated distractors match the human-authored ones (3 out of 3), we find that, in all but 2 of the 28 such cases, there is an in-context example that is very similar to the target MCQ, with the only difference being different numerical values or named entities. See Table 4 for an example. However, this situation sometimes appears in other groups too, which is perhaps surprising since it implies that the presence of a near-identical in-context example alone is not sufficient for an LLM to generate plausible distractors. We investigate further into such cases and find that even for two MCQs with near-identical question stem, their sets of distractors and the errors or misconceptions underlying each distractor may differ even though both are plausible. This situation occurs when there are more than 3 plausible errors or misconceptions given a question stem.

Target

Quesiton stem: which multiplier can be used to find the value after an amount has decreased in value by 8% for 4 years?

Explanation: As its is a decrease, we need 100% - 8% which is 92% which is the same as 0.92. We then use the number of years as the power of 4.

Answer: $\times 0.92^4$

Example 1

Quesiton stem: which multiplier can be used to find the value after an amount has decreased in value by 5% for 5 years?

Explanation: As its is a decrease, we need 100% - 5% which is 95% which is the same as 0.95. We then use the number of years as the power of 5.

Answer: $\times 0.95^5$

Example 2

Quesiton stem: the value of a laptop that initially cost \$1100, declines in value by 15% a year. if you wanted to calculate the value of the tablet at the end of 6 years, what number would replace the square? $1100 \times \square^6$

Explanation: As the value decreases by 15%, we have 100% - 15% = 85% = 0.85 as the multiplier.

Answer: 0.85

Example 3

Quesiton stem: a car depreciates in value by 15% each year. if a car was bought for \$3500, which of the following calculations would find the new value of the car after 3 years?

Explanation: The multiplier is 1 - 0.15 = 0.85, and as we are using compound interest, we raise this to the power of 3.

Answer: 3500×0.85^3

Table 4: Three in-context learning examples retrieved by kNN; we see that Example 1 is very similar to the target MCQ, except for different numerical values.

For the group where none of the LLM-generated distractors match the human-authored ones, we randomly select 20 of the 78 cases to analyze. We find that in 14 of the 20 cases (70%), the LLM-generated distractors are plausible, and the human-authored ones are not superior to the LLM-generated distractors. See Table 5 for an example. While this observation is entirely subjective, it highlights that alignment-based metrics may not be an appropriate metric to measure the quality of LLM-generated distractors because human-authored ones may not be naturally optimal. This observation is also part of our motivation in developing *distribution-based* metrics to predict how likely a LLM-generated distractor will be selected by real students with insufficient knowledge. Moreover, since many LLM-generated distractors are

Question Stem	Craig and Isaac share some fruit. Isaac gets three-quarters of the fruit. In what ratio do they share the fruit? (Isaac's part second)
Key	$1:3$
LLM-generated Distractors	$3:1$ $3:4$ $4:1$
Human-authored Distractors	$1:4$ $1:2$ $4:3$

Table 5: Example of LLM-generated distractors that are mathematically valid and plausible but do not match human-authored ones.

plausible even if they are not the same as the human-authored ones, there is promise in using automated distractor generation for teacher support during the generation of MCQs.

Question Stem	Convert 0.6 to a fraction in its simplest form.
Key	$\frac{3}{5}$
LLM-generated Distractors	$\frac{6}{10}$ $\frac{5}{3}$ $\frac{6}{5}$
Human-authored Distractors	$\frac{6}{10}$ $\frac{60}{100}$ $\frac{1}{6}$

Table 6: Example of LLM-generated distractors where the plausible one, $\frac{6}{10}$ matches the human-authored ones, while the rest of human-authored ons are placeholders. In this case, $\frac{6}{10}$ is selected by 28% of students while other distractors are rarely being selected.

Finally, for the group where 1 or 2 LLM-generated distractors match the human-authored ones, we examine which human-authored distractor(s) are generated. We find that in many cases, the human-authored distractors that match the LLM-generated ones seem to reflect common errors or misconceptions among real students, while the others do not. See Table 6 for an example. This observation is further supported by selections made by real students, where the distractors that correspond to the common errors or misconceptions are selected by more students in 44 of 108 (40.7%) cases and 46 of 63 (73%) cases for 1 and 2 matches, respectively, while the rest are rarely being selected. This result suggests that many MCQs have 1 or 2 highly plausible distractors while the others are placeholders. Again, using human-authored ones as the ground truth on alignment-based metrics is not ideal, which justifies our motivation in developing the distribution-based metric.

3.6 Human Evaluation

We conduct a human evaluation to assess the quality of LLM-generated distractors. This evaluation is motivated by observations from the qualitative analysis that the generated distractors are often plausible even though they may be different from human-authored ones.

3.6.1 Evaluation Design

We recruit 2 graduate students who have experience teaching math or related topics as human evaluators. They are presented with the same set of 20 MCQs that are randomly sampled from the test set, each accompanied by a mixture of 4 or 6 distractors. To ensure a balanced assessment, half of these are LLM-generated distractors, while the remaining are human-authored ones. To eliminate any potential ordering bias, the sequence of the distractors is randomized for each question. They are asked to rate the distractors on two aspects: mathematical validity (**validity**) and plausibility for middle school math students (**plausibility**). Validity measures the degree of a distractor that is relevant to the question stem and can be tangibly reached by some incorrect reasoning. Plausibility measures how likely a distractor is to be selected by real students. Each aspect is scored on a scale from 1 to 5, with 1 being the lowest: a distractor that is irrelevant to the question stem or one that no real students would select, while 5 being the highest: a distractor that is highly relevant to the question stem or one that is highly likely to trick real students with insufficient math knowledge into selecting it. Additional evaluation setup details are in Supplementary Material Section C.

3.6.2 Evaluation Result and Discussion

Table 7 shows the inter-rater agreement, measured using quadratic weighted Kappa (QWK) (Brenner and Kliebsch, 1996) and the average rating across 2 human evaluators for both LLM-generated and human-authored distractors. The QWK scores indicate a fair to moderate level of agreement between two human evaluators regarding both the validity and plausibility aspects of distractors. This obser-

	QWK		Average Ratings	
	LLM	Human	LLM	Human
Validity	0.34	0.23	3.28	3.99*
Plausibility	0.54	0.54	2.68	3.72*

Table 7: QWK and average ratings among human evaluators on LLM-generated and human-authored distractors for validity and plausibility. Under a Student's t-test, human evaluators prefer human-authored distractors with statistical significance ($p < 0.05$*).

vation suggests that measuring the quality of distractors based on their validity and plausibility is consistent at certain level and can be used in future assessments of distractors. We conduct a Student's t-test (Semenick, 1990) to compare the ratings for LLM-generated and human-authored distractors and find that in both aspects, there is a statistically significant difference ($p < 0.05$). This result shows that human evaluators think human-authored distractors are better than LLM-generated distractors in both aspects. Furthermore, we observe that the gap between LLM-generated distractors and human-authored ones is much bigger for plausibility than validity. This observation indicates that LLMs exhibit a higher proficiency in generating mathematically valid distractors compared to anticipating common errors or misconceptions among real students. See Table 8 for an example. This result is not surprising since LLMs, which have not been extensively trained on erroneous answers provided by real students, may struggle to anticipate the various ways in which students are prone to making errors or student misconceptions. Therefore, there is still considerable room for improvement for LLMs in their capacity to anticipate errors or misconceptions among real students.

Question Stem Solve this problem: $\sqrt[3]{216} = ?$
LLM-generated feedback message I think you have multiplied by 3. The question is asking for the cube root.
LLM-generated distractor 648
LLM-generated feedback message I think you have written the digits as a new number. The question is asking for the cube root.
LLM-generated distractor 2163

Table 8: Examples of LLM-generated distractors, which, from a purely mathematical perspective, seem valid as the errors suggest misunderstandings of the cube root operation as either multiplying by 3 or appending a 3 to the original number. However, these two distractors do not effectively reflect the common errors or misconceptions among real students.

4 Conclusions and Future Work

In this paper, we explore automated distractor generation for math multiple-choice questions via large language models. We conduct experiments on a real-world math MCQ dataset and find that the in-context learning-based approach kNN, achieves the best performance when compared to other approaches such as fine-tuning, chain-of-thought prompting, and various baselines. We also conduct human evaluation and observe that LLMs are capable of generating mathematically valid distractors but are not fully aware of common errors or misconceptions among real students. Our initial exploration of this task opens up many avenues for future work. For example, we need to further refine the distribution-based metrics that predict the percentage of students who select each distractor. We also need to develop modified text encoding approaches that are closely aligned with errors or misconceptions among real students for in-context example selection. Furthermore, we aim to explore the generation of distractors, each of which corresponds to a specific error or misconception, as well as the generation of high-quality feedback messages for each distractor.

Limitations

Being the attempt at the task of generating plausible distractors for math MCQs using LLMs, we find several limitations in our current setup. First, we find that some human-authored distractors are merely placeholders that do not reflect common errors or misconceptions among real students, and using them as in-context demonstrations may lead to the generated distractors also not reflecting common errors or misconceptions among real students. Second, the *alignment-based* metrics may not accurately measure the quality of LLM-generated distractors because some MCQs may have only 1 or 2 plausible distractors and some MCQs have more than 3 plausible distractors. Third, we acknowledge that our human evaluation sample size is small, and should ideally be increased for future studies in order to receive more accurate results.

Ethical Considerations

The focus of our work is to automatically generate plausible distractors for math MCQs using LLM. By automating part of the MCQ generation, we aim to save educators and teachers from time-consuming MCQ generation and allow them to dedicate more effort to teaching and student engagement. Based on our analysis on the generated distractors, we acknowledge that not every distractor generated by our work is plausible. Therefore, we strongly advise that our work should be adopted as an auxiliary tool in the generation of MCQs. All automatically generated distractors should undergo a careful review by educators and teachers before being utilized in real tests for students.

Supplementary Material

A Distribution ranking metric

Since our qualitative analysis in Section 3.5 found that human-authored distractors are sometimes unplausible or incomplete, using them as the ground truth is not ideal. Therefore, we explore a distribution-based metric to evaluate the quality of LLM-generated distractors, based on one intuition: good distractors are ones that are likely going to be selected by many real students. Therefore, our goal is to train a model that can predict the portion of students that select each option in an MCQ. However, due to the highly noisy nature of this distribution, we opt to train a model that predicts the more often selected distractor among a pair, given a question stem, which is similar to the pairwise preference reward model in reinforcement learning from human feedback (RLHF) (Christiano et al., 2017). After training such a model, we can use it to compare generated distractors to human-authored ones in head-to-head matchups, giving us a proxy for how good an LLM is in terms of generating distractors that are likely to be selected by students.

Formally, we train an LLM-based model $\mathrm{r}_\phi(d_1, d_2, s, k, e_k) \rightarrow \{d_1, d_2\}$, where ϕ denotes the set of model parameters. We train this model by first constructing a dataset of all pairs of human-authored distractors for each MCQ and include both orders of each pair to avoid ordering bias, resulting in $N \times \binom{3}{2} \times 2$ total pairs, where N denotes the number of MCQs. Each pair is associated with a binary-valued label indicating whether d_1 or d_2 is selected by more students, which we can calculate from the student response records in our dataset. We then use this dataset to fine-tune an LLM in a text generation task, where the LLM receives the question and distractor information in its prompt and outputs its preference. We show our prompt for this task in Table 12.

We use the same train/test split as the distractor generation experiments, and reserve 20% of the train split for validation after each epoch and early stopping. We fine-tune the `mistralai/Mistral-7B-v0.1` model, which contains 7 billion parameters, from HuggingFace (Wolf et al., 2019) using LoRA (Hu et al., 2021) with adaptors on the `q_proj`, `k_proj`, `v_proj`, and `o_proj` matrices, set $r = 32$, $\alpha = 16$, dropout $= 0.05$, and use 8-bit quantization. We train the model using the AdamW optimizer for 10 epochs with a learning rate of 3e-5, a batch size of 16, accumulate gradients for 4 batches. The model converges on the validation set after 6 epochs. The GPU we use to train the model is `NVIDIA RTX A6000`. The training process is completed in 10 hours. When evaluated on the test set, the ranking model correctly identifies the preferred distractor 61.60% of the time (random guessing corresponds to 50% accuracy). This accuracy is low overall but high on subsets of distractor pairs whose student selection percentages differ by a large margin: on pairs with a larger than 20% margin, which accounts for 6% of pairs, the accuracy jumps to 74.47%. This result is not surprising since the selection percentage data is very noisy.

Using this trained model, we can evaluate the quality of LLM-generated distractors: we compare all possible head-to-head matchups between generated distractors and human-authored ones, and record the portion of times that the generated distractors are preferred by the ranking model. If the two distractors are the same then we record a tie. In cases where the generated distractors are invalid or repeated, we treat them as `null` and record a win for the human-authored ones. Formally, we define a preference score as

$$s = \frac{1}{18N} \sum_{i=1}^{N} \sum_{a=1}^{3} \sum_{b=1}^{3} \mathrm{r}_\phi^{(i)}(\hat{d}_a^{(i)}, d_b^{(i)}) + (1 - \mathrm{r}_\phi^{(i)}(d_b^{(i)}, \hat{d}_a^{(i)})),$$

$$\mathrm{r}_\phi^{(i)}(d_1, d_2) = \begin{cases} 0.5 & d_1 = d_2 \\ 1 & d_2 \text{ is } \texttt{null} \\ 0 & d_1 \text{ is } \texttt{null} \\ p & \text{otherwise} \end{cases},$$

$$p = \mathbf{1}_{\mathrm{r}_\phi(d_1, d_2, s^{(i)}, k^{(i)}, e_k^{(i)}) = d_1},$$

where $\hat{d}$ are generated distractors. This score has a range of $[0, 1]$ where higher values indicate LLM-generated distractors are likely to be selected by more students than the human-authored ones. We found that kNN scores 0.46 on the test set, which indicates that the distractors it generates are almost as plausible to students as human-authored ones.

We emphasize that this evaluation metric should only be considered exploratory due to several obvious limitations. First, student option selection percentages create noisy labels for the ranking model, limiting its accuracy. Second, using the overall selection percentages also ignores the individual learning context of each student since students with different knowledge levels may have different tendencies among MCQ options. Therefore, we leave a more thorough treatment of the distribution-based metric to future work.

B Hyperparameters and Implementation Details

For fine-tune (FT) approach, We fine-tune 2 large language models. We fine-tune the `mistralai/Mistral-7B-Instruct-v0.2` model, which is the latest `Mistral` model and contains 7 billion parameters, from HuggingFace using LoRA with adaptors on the `q_proj`, `k_proj`, `v_proj`, and `o_proj` matrices, set $r = 32$, $\alpha = 16$, dropout $= 0.05$, and use 8-bit quantization. We use 20% of the training set for validation. We train the model using the AdamW optimizer with weight decay $= 0.0$ and gradient clip $= 1.0$ for 8 epochs with a learning rate of 8e-5, a batch size of 16, and accumulated gradients for 4 batches. The selection of the aforementioned hyperparameters is guided by exploratory evaluations and no substantial hyper-parameter search is conducted. The GPU we use to train the model is `NVIDIA RTX A6000`. The training process is completed in 2 hours and 55 minutes. We fine-tune the `ChatGPT` model using the first 200 data points from the training set. We train the model using the OpenAI's default fine-tuning settings, which we find to provide the best performance via OpenAI API. The training process is completed in 20 minutes. We use the `scikit-learn` (Pedregosa et al., 2011) implementation to calculate QWK, and use the `scipy` (Virtanen et al., 2020) implementation to calculate Student's t-test. For prompting `GPT-4` and `ChatGPT` using OpenAI API, we use temperature $= 0$, max_tokens $= 350$, top_p $= 1$ as our setup for greedy decoding. All our experiments are implemented in Python or Pytorch code, and We note that all software employed in this work is open-source, or the license is unspecified.

C Human Evaluation Details

In this work, we obtained approval from the ethics review board for human evaluation. We show the evaluation instructions to human evaluators in Table 13. We do not provide any compensation for human evaluators because their participation is entirely voluntary and we appreciate their contribution to this work.

D Prompt Format

We provide the prompts for CoT, RB, and kNN in the work below. We use <> to indicate that a variable is filled in dynamically.

Prompt	You are given the following math question along with the correct answer and explanation. Please use the following template to give 3 alternative incorrect answers to be used as multiple-choice options in a multiple-choice exam. Prior to the incorrect answer, provide feedback to be displayed to the student as an explanation of why that is not the correct answer. [Template] Distractor1 Feedback: Distractor1: Distractor2 Feedback: Distractor2: Distractor3 Feedback: Distractor3: Question: <question> Explanation: <explanation> Answer: <answer>

Table 9: CoT prompt format

Prompt	You are given the following math question along with the correct answer, explanation, and a list of errors. Please follow the template to first select 3 most likely errors for this question and use the selected errors to generate 3 alternative incorrect answers to be used as multiple-choice options in a multiple-choice exam. Prior to the incorrect answer, provide feedback to be displayed to the student as an explanation of why that is not the correct answer. If the list of errors is not given, generate 3 errors instead and do not contain any explanation in the 3 incorrect answer. E Ranking Metric Examples

Prompt	A teacher assigns the following math multiple choice question to a class of middle school students. Question: $\frac{3}{5}$ of 50 $=$ $\frac{6}{10}$ of $\square$ Correct Answer: 50 Solution: 3/5 and 6/10 are equivalent, so 3/5 of 50 is the same as 6/10 of 50. Here are 2 incorrect options that some students choose: Option A: 30 Option B: 18 Which incorrect option are the students more likely to pick?
Output	Preferred Answer: A

Table 12: Example prompt and output for the ranking model used in the distribution ranking metric.

F Instruction

You are given a csv file. Each row corresponds to a question stem and a distractor.
Your job is to rate the distractor on two aspects: mathematical validity and plausibility for middle school math students.
Mathematical validity measures whether a distractor is relevant to the question stem and can be tangibly reached by some incorrect reasoning. Mathematical validity is scored on a scale from 1 to 5, where 1 indicates a distractor that is irrelevant to the question stem, and 5 indicates a distractor that is highly relevant to the question stem.
Plausibility measures how likely a distractor is to be selected by middle school students learning math. Plausibility is scored on a scale from 1 to 5, where 1 indicates that no student would select it and 5 indicates that the distractor is highly likely to trick students with insufficient math skills into selecting it.
please use `numbers` on mac to rate distractors and give 1 and 1 for both metric if the distractor is the correct answer.
Your ratings will be used to quantitatively measures and analyzes the quality of distractors on validity and plausibility.

Abstract

Given a sentence and a particular aspect term, aspect-based sentiment analysis (ABSA) aims to predict the sentiment polarity towards this aspect term, which provides fine-grained analysis on sentiment understanding and it has attracted much attention in recent years. In order to achieve a good performance on ABSA, it is important for a model to appropriately encode contextual information, especially identifying salient features and eliminating noise in the context. To make incorrect predictions, most existing approaches employ powerful text encoders to locate important context features, as well as noises that mislead ABSA models. These approaches determine the noise in the text for ABSA by assigning low weights to context features or directly removing them from model input, which runs the risk of computing wrong weights or eliminating important context information. In this paper, we propose to improve ABSA with context denoising, where three types of word-level information are regarded as noise, namely, lexicographic noise, bag-of-words noise, and syntax noise. We utilize diffusion networks to perform the denoising process to gradually eliminate them so as to better predict sentiment polarities for given aspect terms. Our approach uses task-specific noise rather than the standard stochastic Gaussian noise in the diffusion networks. The experimental results on five widely used ABSA datasets demonstrate the validity and effectiveness of our approach.[1]

1 Introduction

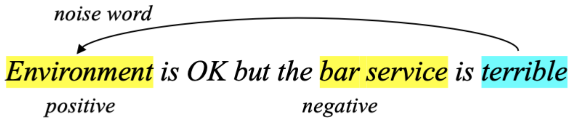

Figure 1: An example of aspect-based sentiment analysis, where the sentiment polarities of aspect terms "*environment*" and "*bar service*" are positive and negative, respectively. Herein, "*terrible*" serves as context noise in predicting the sentiment of "*environment*".

Aspect-based sentiment analysis (ABSA) predicts sentiment polarity of an aspect term in a sentence on the fine-grained level. For example, the sentiments for "*environment*" and "*bar service*" in the sentence in Figure 1 are *positive* and *negative*, respectively, and aspect-based sentiments can be different from that of the entire sentence (i.e., *negative*). Identifying sentiment for aspects is important in many real-world applications, such as analyzing the product review of users and monitoring the opinion changes on social media, and the task has attracted much attention in recent years (Song et al., 2019; Huang and Carley, 2019; Xu et al., 2020; Tian et al., 2021; Yu et al., 2021b; Liang et al., 2022; Qin et al., 2022; Yu et al., 2023; Mukherjee et al., 2023; Bao et al., 2023b).

To perform well on ABSA, a system needs to have a good representation of the context of a given aspect term and be able to identify salient features that are important in predicting the sentiment of the aspect term. Many existing studies use advanced encoders (e.g., BiLSTM and Transformer (Vaswani et al., 2017)) to capture contextual information for the task and achieve good performance (Liang et al., 2019; Tang et al., 2020; Chen et al., 2020; Zhang et al., 2021; Cao et al., 2022; Varia et al., 2023; Wang et al., 2023). Some studies incorporate external knowledge, such as lexicon, chunks, and syntactic information (He et al., 2018; Huang and Carley, 2019; Zhang et al., 2019; Wang et al., 2020; Liang et al., 2021; Chen et al., 2022; Zhang et al., 2023a; Ma et al., 2023) to further improve model performance.

These studies generally extract important contextual information from intrinsic or external knowledge and use them as essential hints to predict sentiment polarities and they may suffer from noise

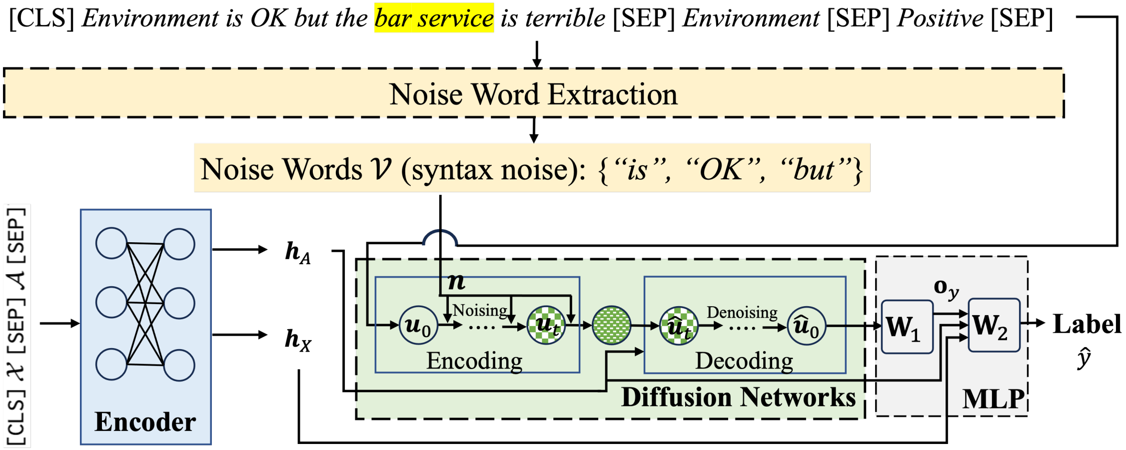

Figure 2: An overview of our approach for ABSA. The left part shows the input encoding process to extract aspect representation (denoted as $\mathbf{h}_{\mathcal{A}}$) and sentence representation (denoted as $\mathbf{h}_{\mathcal{X}}$); the center is the proposed noise word extraction (highlighted in the yellow background) and the diffusion networks (highlighted in the green background). The right part presents the MLP decoder to predict the sentiment label. An example input of the context denoising process and the expected noise words (under the syntax noise setting) are provided for better illustration. $\mathcal{X}$ and $\mathcal{A}$ are the input sentence and aspect term, respectively; $\mathbf{u}_0$ and $\mathbf{u}_t$ are the initial and t-th step representation of the (sentence, aspect term, sentiment) triple in the noising process, respectively; $\widehat{\mathbf{u}}_0$ and $\widehat{\mathbf{u}}_t$ are the initial and t-th step representation of the (sentence, aspect term, sentiment) triple in the denoising process, respectively; $\mathbf{n}$ is the noise vector; $\mathbf{o}_y$ is obtained by passing the last vector of $\widehat{\mathbf{u}}_0$ through a fully connected layer.

introduced by the knowledge extraction process. More importantly, these studies do not explicitly identify and eliminate redundant and interfering information (noise) for ABSA from the input before predicting the sentiment. E.g., in Figure 1 while "*terrible*" is a good indicator of the polarity of the aspect term "*bar service*", it is a noise word for the aspect term "*environment*". The noise word introduces unimportant information that confuses an ABSA model when it tries to predict the sentiment. If the unimportant noise information is identified and removed from the context, it would be easier for an ABSA model to handle the task. Therefore, we believe that denoising the context of aspect terms has the potential to improve the performance of ABSA systems.

In this paper, we propose an approach to improve ABSA through diffusion networks, which consists of forward noising and backward denoising processes[2]. Herein, we propose to use task-specific noises associated with unimportant words extracted from the context of the running text for ABSA, rather than the standard stochastic Gaussian noise in the forward pass. We consider three types of noises, namely, lexicographic noise, bag-of-words noise, and syntax noise, in extracting the noise words. In the denoising process, our approach starts from a noise vector, gradually eliminates the noise from it, and predicts the sentiment polarity. Through this process, our approach distinguishes the noises and eliminates their effect on ABSA in predicting the sentiment, which allows our approach to focus on important features and thus improve model performance. We evaluate our approach on five widely used English ABSA datasets, where our approach outperforms strong baselines and achieves state-of-the-art results.

2 The Approach

In general, ABSA is performed as a classification task on sentence-aspect pairs (Ma et al., 2017; Tang et al., 2019; Qin et al., 2022). In this paper, we follow the encoding-decoding paradigm with the enhancement of diffusion networks, and the architecture of our approach is illustrated in Figure 2. In the diffusion networks, the noise representation is based on a set of noise words $\mathcal{V}$ extracted from the input sentence. Thus, our approach for ABSA is formulated by

$$\widehat{y} = f(\mathcal{X}, \mathcal{A}, \mathcal{V}) \tag{1}$$

where $\mathcal{X}$ is the input text, $\mathcal{A} = a_1 \cdots a_m \cdots a_M$ denotes the aspect term with M words (herein, $\mathcal{A}$ is the sub-string of $\mathcal{X}$), and $\widehat{y}$ is the sentiment polarity to the aspect term. In this section, we will introduce first the encoding process for $\mathcal{X}$ and $\mathcal{A}$, then the ways to extract different types of noise words, and

---

[2] The term "denoising" in the diffusion networks refers to the process of eliminating noise from a noise vector (e.g., the stochastic Gaussian noise vector in the standard diffusion networks) to reconstruct the original vector.

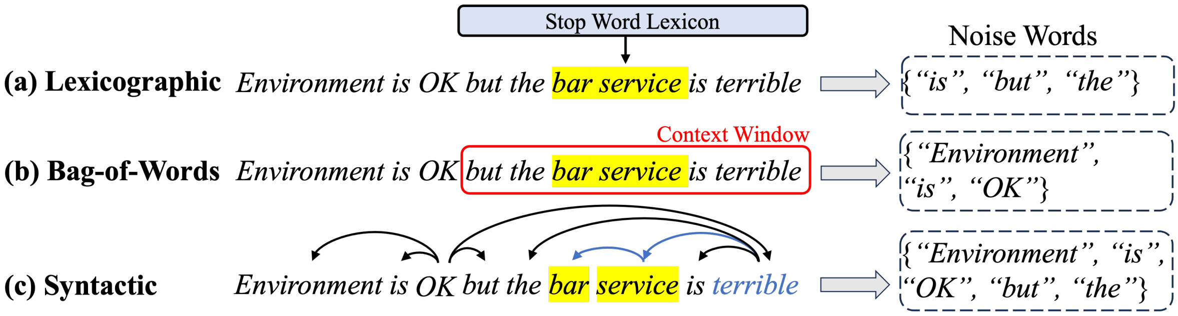

Figure 3: Illustrations of different types of noise words extracted from an example sentence and aspect term pair, where the aspect term is highlighted in yellow background. The context window is represented in a red box and the first-order dependencies with respect to the aspect term are represented in blue.

finally the proposed diffusion networks to address noise and predict the sentiment label $\widehat{y}$.

2.1 Input Encoding

The encoding process aims to model the context information of the input and extracts the representations of $\mathcal{X}$ and $\mathcal{A}$, which are used in the following process to predict the sentiment label $\widehat{y}$. Specifically, we follow the convention in existing studies to concatenate $\mathcal{X}$ and $\mathcal{A}$ with some special tokens (e.g., "`[CLS]`" and "`[SEP]`") to mark the boundaries of them, to form a new input word sequence, namely, "`[CLS]` $\mathcal{X}$ `[SEP]` $\mathcal{A}$ `[SEP]`". Next, we feed the new input word sequence into a text encoder (e.g., BERT) and obtain the hidden vectors for each input word, where the hidden vector for "`[CLS]`" and the m-th word in the aspect term are denoted as

2.2 Noise Extraction

Different from standard diffusion models that leverage stochastic Gaussian noise in training and inference, our approach utilizes task-specific noises for ABSA derived from contexts. We associate the noise with unimportant words in the sentence for ABSA. We compare three types of noise, namely, lexicographic noise based on a static lexicon, bag-of-words noise extracted from an aspect-centric window, and syntactic noise derived from the sentence structure, which are explained below with the examples in Figure 3.

Lexicographic Noise Since stop words occur frequently but usually do not carry significant meaning or contribute to the understanding of the text, we use an existing stop word lexicon (e.g., stop words in NLTK Toolkit (Bird and Loper, 2004)) to extract noise words. Specifically, we find all words in the sentence that appear in the stop word lexicon and add them to the set of noise words $\mathcal{V}$. As shown in Figure 3 (a), the noise words extracted from the sentence are "*is*", "*the*", and "*but*".

Bag-of-Words Noise Consider words that are distant from the aspect term generally contain unimportant contextual information that fails to contribute to ABSA, we select words that are outside the context window of the aspect term as the noise words. That is, we select words whose word-based distance to the aspect term is greater than the context window size c. For example, as illustrated in Figure 3 (b), when $c = 2$, the context window covers the words from "*but*" to "*terrible*" and thus the noise words for the aspect term "*bar service*" are the rest of the words in the sentence, namely, "*environment*", "*is*", and "*OK*".

Syntax Noise Bag-of-words noise words are extracted according to the surface word order of the sentence, which may include important words that are distant from the aspect term and thus lead to inferior results. Therefore, one should also consider the structure of the sentence when extracting the noise words. Among different types of syntax structures, the dependency tree of the input sentence constructs connections among words in the sentence and is used in many existing studies to identify the important and unimportant contexts for ABSA. Therefore, we use the dependency tree of the text to extract noise words for the syntax level.

Specifically, we use an off-the-shelf dependency parser (e.g., the parser in Stanford CoreNLP Toolkit (Manning et al., 2014)) to produce the dependency tree of $\mathcal{X}$. Because words close to the aspect term $\mathcal{A}$ in the dependency tree generally convey important contextual features for ABSA, we locate words that are within different orders of dependencies of the aspect term[3] and regard the

---

[3] If the aspect term has two or more words, we use the dependency connections of its last word which generally serves as the head of noun phrases (i.e., aspect terms) in English.

rest words in $\mathcal{X}$ as the noise words, which form the set $\mathcal{V}$. For example, for the aspect term "*bar service*" in the example in Figure 3 (c), words within the first-order dependencies are "*bar*", "*terrible*". Therefore, the noise words are the rest of the words in $\mathcal{X}$, including "*environment*", "*is*", "*OK*", "*but*", "*the*", and "*is*". Through this process, $\mathcal{V}$ contains words that are syntactically distant from the aspect term and thus serve as noise to be eliminated when predicting the sentiment polarity of the aspect term.

2.3 Diffusion Networks

The diffusion networks consist of noising and denoising processes to address the noise in $\mathcal{X}$ for predicting the sentiment polarity label. During the noising process, the information of noise words is added to the input of the diffusion networks, which results in a vector that mainly contains the noise information; then, in the denoising process, the diffusion networks learn a diffusion decoder to eliminate the noise from the vector. Using the diffusion decoder, the diffusion networks are able to address the noise appropriately and thus help ABSA. The details of the noising and denoising processes in the diffusion networks are illustrated as follows.

Noising Process Once we extract the noise word set based on the word dependencies, the tokens in $\mathcal{V}$ are used to generate noise in the forward noising pass of diffusion networks. Forward encoding aims to add noise to the input representation $\mathbf{u}_0$ to compute a sequence of latent representations $\mathcal{U} = [\mathbf{u}_1, \cdots, \mathbf{u}_T]$ (T denotes the total steps). Herein, we combine the input sentence $\mathcal{X}$, the aspect term $\mathcal{A}$, and the gold standard sentiment label y^* to construct a new word sequence $\mathcal{X}'$. Then we follow DDCap (Zhu et al., 2022) to convert tokens of $\mathcal{X}'$ into the one-hot representation $\mathbf{u}_0$. Meanwhile, we compute $\mathbf{u}_t$ at t-th step by

$$\mathbf{u}_t = \sqrt{\bar{\alpha}_t} \cdot \mathbf{u}_0 + \sqrt{1 - \bar{\alpha}_t} \cdot \mathbf{n} \quad (2)$$

where $\bar{\alpha}_t$ denotes a blending scalar hyper-parameter that is correlated to the DDPM noise scheduling strategy (Ho et al., 2020) and $\mathbf{n}$ refers to the noise vector[4] coming from the noise words in $\mathcal{V}$. Specifically, we randomly sample N words from $\mathcal{V}$ and map each word to its embedding through an embedding matrix, where the embedding of the n-th word is denoted as $\mathbf{e}_n$. Then, we compute the average of the word embeddings and normalize ($Norm$) the resulted embedding to get the noise vector $\mathbf{n}$, formulated by

$$\mathbf{n} = Norm(\frac{1}{N}\sum_{n=1}^{N} \mathbf{e}_n) \quad (3)$$

Denoising Process We follow the standard process of diffusion model to denoise $\mathbf{u}_T$ to reconstruct $\mathbf{u}_0$. It is worth noting that the denoising processes in training and inference are different. In training, we compute the diffusion loss $\mathcal{L}_{diff}$ by

$$\mathcal{L}_{diff} = \mathbb{E}_{t\sim U(0,T)} \| f_d(\mathbf{u}_t, \mathbf{h}_A, t) - \mathbf{u}_0 \|_2^2 \quad (4)$$

where f_d is a diffusion decoder using Transformer architecture to recover $\mathbf{u}_{t-1}$ based on $\mathbf{u}_t$ and $\mathbf{h}_A$ with $\mathbf{h}_A$ and $\mathbf{u}_t$ modeled by the Transformer encoder and decoder architectures, respectively. Meanwhile, we extract the last vector (that corresponds to the gold standard label y^* and is denoted as $\widehat{\mathbf{u}}_{0,-1}$) of the recovered input matrix (denoted as $\widehat{\mathbf{u}}_0$) and use a fully connected layer to map it into a vector $\mathbf{o}_y$ through

$$\mathbf{o}_y = \mathtt{ReLU}(\mathbf{W}_1 \cdot \widehat{\mathbf{u}}_{0,-1}) \quad (5)$$

where $\mathbf{W}_1$ is a trainable matrix and ReLU is the activation function. Then, we concatenate $\mathbf{o}_y$ with the sentence representation $\mathbf{h}_X$, as well as the aspect representation $\mathbf{h}_A$, and use a softmax classifier to predict the sentiment label $\widehat{y}$ through

$$\widehat{y} = \mathtt{Softmax}(\mathbf{W}_2 \cdot (\mathbf{o}_y \oplus \mathbf{h}_X \oplus \mathbf{h}_A)) \quad (6)$$

where $\mathbf{W}_2$ is a trainable matrix. Afterwards, we compute the standard cross-entropy loss $\mathcal{L}_{CE}$ by comparing $\widehat{y}$ with the gold standard label y^*. Finally, we add $\mathcal{L}_{diff}$ and $\mathcal{L}_{CE}$ to compute the total loss $\mathcal{L}$, which is formulated by

$$\mathcal{L} = \mathcal{L}_{CE} + \mathcal{L}_{diff} \quad (7)$$

and our approach is optimized accordingly.

The inference process of the diffusion networks follows the standard process of DDCap, where the first step is to construct a noise vector and then remove the noise in it through the diffusion decoder. For the noise vector, we randomly sample $\mathcal{N}$ tokens from $\mathcal{V}$ to derive the noise vector $\mathbf{n}$ following the same processes as Eq. (3). Then, we initialize $\widehat{\mathbf{u}}_T$ with $\mathbf{n}$ and use f_D to iteratively subtract noises from $\widehat{\mathbf{u}}_T$. Therefore, the overall process is

---

[4] Here, $\mathbf{u}_0$ is a matrix where its first dimension equals to the word-based length l of the input. To perform Eq. (2), the noise vector is replicated l times, resulting in the set $\mathbf{n}_1, \ldots, \mathbf{n}_l$. We stack these vectors to form a new matrix, ensuring its dimensions match these of $\mathbf{u}_0$.

Dataset		Pos. #	Neu. #	Neg. #
LAP14	Train	994	464	870
	Test	341	169	128
REST14	Train	2,164	637	807
	Test	728	196	182

formulated as

$$\widehat{\mathbf{u}}_{t-1} = \sqrt{\bar{\alpha}_{t-1}} \cdot \frac{\widehat{\mathbf{u}}_t - \sqrt{1-\bar{\alpha}_t} \cdot f_D(\widehat{\mathbf{u}}_t, \mathbf{h}_A, t)}{\sqrt{\bar{\alpha}_t}} + \sqrt{1-\bar{\alpha}_{t-1}} \cdot f_D(\widehat{\mathbf{u}}_t, \mathbf{h}_A, t) \quad (8)$$

Through the process, the diffusion networks obtain the denoised representations $\widehat{\mathbf{u}}_0$, whose last vector is extracted and used to predict the final sentiment label $\widehat{y}$ following the same process in training.

3 Experimental Settings

3.1 Datasets

Following previous studies, we run different models on five English benchmark datasets from various domains for ABSA; the datasets are LAP14 and REST14 (Pontiki et al., 2014), REST15 (Pontiki et al., 2015), REST16 (Pontiki et al., 2016), and MAMS[5] (Jiang et al., 2019). Specifically, LAP14 contains laptop computer reviews, REST14, REST15, REST16, and MAMS are collected from online reviews of restaurants. In addition, it is worth noting that the instances in the MAMS dataset are all cases where one sentence contains multiple aspect terms with different sentiment polarities. Therefore, it serves as a good resource to test models on the hard cases. For all datasets, we use their official train/dev/test splits. The statistics of the datasets used in the experiments are reported in Table 1, where the number of instances with different sentiment polarities in the training, development, and test sets are reported.

Dropout Rate	**0.1**
Batch Size	4, **8**

Table 2: The hyper-parameters used in tuning our models and the best one used in our final experiments are highlighted in boldface.

3.2 Implementation Details

As the performance of NLP models highly depends on the text representations (Conneau et al., 2017; Song et al., 2017; Song and Shi, 2018; Han et al., 2018; Sileo et al., 2019; Song et al., 2021; Gan et al., 2023), we employ BERT (Devlin et al., 2019) and LLaMA-2 (Touvron et al., 2023) to encode the text, which have achieved state-of-the-art performance in many NLP tasks. Specifically, for BERT, we use the uncased BERT-base and BERT-large with their default settings, i.e., 12 layers of self-attention with 768-dimensional hidden vectors for BERT-base and 24 layers of self-attention with 1024 dimensional hidden vectors for BERT-large[6]. For LLaMA-2, we use the 7B version that has 32 layers of self-attentions with 4,096-dimensional hidden vectors. For the diffusion decoder, we use Transformer with three layers of multi-head attentions, where we use 768- and 1024-dimensional hidden vectors when the encoder is BERT-base and BERT-large, respectively, and employ 4,096-dimensional hidden vectors when it is equipped with LLaMA-2, so as to match their hidden vector dimensions.

To obtain the noise words, we use the stop words in the NLTK Toolkit, try window sizes of 1, 2, and 3, and use the Stanford CoreNLP Toolkit to parse the input sentence. The number of steps in the training and inference process in diffusion networks is set to 60. Besides, we initialize all other trainable parameters by Xavier (Glorot and Bengio, 2010). Other hyper-parameters are reported in Table 2.

For evaluation, we use accuracy and macro-averaged F1 scores over all sentiment polarities, following the conventions in previous studies (Tang et al., 2016; Chen et al., 2017; He et al., 2018; Sun et al., 2019). We tune hyper-parameters on the development set[7] of datasets and use the one with the

Table 3: Experimental results (accuracy and F1 scores) of baselines and our approaches with different settings. “D” means standard diffusion networks; “CD” refers to the proposed context denoising approach; “L” stands for the setting where we use lexicographic noise that are obtained from a stop word lexicon; “B1”, “B2”, and “B3” are cases with bag-of-words noise based on a window of size one, two, and three, respectively; “S1”, “S2”, and “S3” denote syntax noise that are extracted according to first-, second-, and third-order dependencies, respectively.

best F1 scores in the final experiments.

4 Results and Analyses

4.1 Overall Results

We run baselines with the vanilla base and large versions of BERT and LLaMA, the ones using standard diffusion with stochastic Gaussian noise (D), and our diffusion networks for context denoising (CD) with different types of noise. Specifically, our approach utilizes lexicographic noise (L) from a stop word lexicon, bag-of-words noise (B) with different window size, and syntax noise (S) configured with various orders of dependencies. Table 3 presents the average and standard deviation of test set results of different models from five runs with different random seeds. The following are some observations from the results.

First, although base and large versions of BERT and LLaMA achieve high performance on all datasets, further improvements are observed with diffusion networks, which presents the effectiveness of diffusion networks for ABSA. Second, the proposed context diffusion with different types of noise words outperforms the standard diffusion model with stochastic Gaussian noise, which illustrates the effectiveness of the proposed approach in leveraging task-specific noise to improve ABSA. Third, comparing the performance of our approach with different types of noise words, our approach with lexicographic stop words achieves the lowest results, it obtains the second-worst performance when it is configured with the bag-of-words noise words extracted by context window, and it gets the best scores if syntax noise (i.e., dependencies) are used. This observation is intuitive since dependencies contain deeper analyses of the input sentence and thus are more likely to help our approach to extract unimportant words as noise words than the other two settings (i.e., stop words and context window). Fourth, comparing models with different context sizes or orders of dependencies, we find that context sizes of two and second-order depen-

Table 4: The comparison of the performance (i.e., accuracy and F1 scores) of our best model (i.e., context denoising with second-order dependencies using BERT-large and LLaMA) with previous studies on the test set of all datasets. "*" marks the studies that utilize attention mechanisms for ABSA.

dencies yield the best results. A potential explanation is illustrated as follows. When the context size equals one, or we use first-order dependencies, the noise may contain important context words for ABSA and thus hurt model performance; when the context size equals three, or we use third-order dependencies, the noise may fail to include most unimportant words and thus prevent the model from identifying important and unimportant context features for ABSA, which leads to unsatisfying results.

We further compare our best approach (BERT-large + CD (S2) and LLaMA-7B + CD (S2)) using context diffusion with second-order dependencies with existing studies and report the results in Table 4. It is observed that our approaches with BERT and LLaMA outperform previous approaches across most evaluation metrics, including the ones using attention mechanism (Xu et al., 2020; Liang et al., 2022; Tang et al., 2022) (marked by "*"). which demonstrates the effectiveness of our approach for ABSA by denoising unimportant context words.

4.2 Effect of the Input of Diffusion Networks

In the main experiments, the input of our diffusion networks in the forward noising is the combination of the input sentence $\mathcal{X}$, the aspect term $\mathcal{A}$, and the gold standard label y^*. To investigate the effect of the input of the diffusion networks on the model performance, we run experiments with different types of inputs using the BERT-large encoder. Specifically, we try the combination of $\mathcal{X}$ and y^* (i.e., $\mathcal{X} + y^*$), the combination of $\mathcal{A}$ and y^* (i.e., $\mathcal{A} + y^*$), and y^* alone.

Table 5 presents the results of the aforementioned types of inputs on the test set of all five datasets with different configurations of noise words. For each input type, we observe a similar trend to the results in Table 3 (e.g., models with second-order dependencies outperform the models with other settings), which demonstrates the robustness of our approach. In addition, comparing model performance among different inputs, we observe models with $\mathcal{X}$, $\mathcal{A}$, and y^* achieve the best performance (see Table 3), and the ones with y^* only achieve the worst results. This observation is intuitive since the model using the combination of $\mathcal{X}$, $\mathcal{A}$, and y^* as input is able to leverage more information (i.e., both sentence and aspect term information) compared with other settings, which enable the model to achieve the best results.

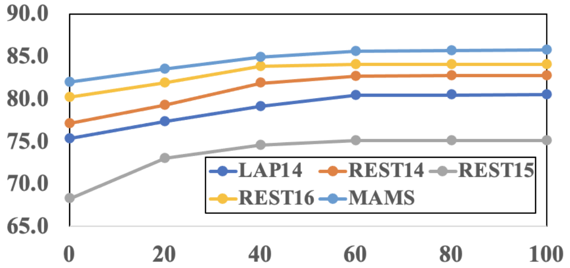

Figure 4: The curve of performance (F1) of our approach with BERT-large encoder on the test set of different sets with respect to the number of diffusion steps.

4.3 The Effect of Denoising Steps

To have a deeper understanding of the effect of the diffusion model, we investigate the effect of the number of steps on ABSA. Specifically, we experiment with different numbers of steps of 20, 40, 60, 80, and 100, where the F1 scores of our approaches with BERT-large encoder are shown in Figure 4 (the score for 0 is the BERT-large model without using diffusion model).

Table 5: Experimental results (accuracy and F1 scores) of our approach (using BERT-large) with different inputs of the diffusion networks, where "$\mathcal{X} + y^*$", "$\mathcal{A} + y^*$", and "y^*" denote the cases where the input of the diffusion networks is the sentence $\mathcal{X}$ and the gold standard label y^*, the aspect term $\mathcal{A}$ and the gold standard label y^*, and the gold standard label y^* only, respectively. "NW" refers to different types of noise words. The results in this table should be compared with the BERT-large results in Table 3.

	LAP14	REST14	REST15	REST16	MAMS
$\mathbf{o}_y$	81.98	87.13	86.19	92.58	84.96
$\mathbf{n}$	49.63	60.25	55.91	76.31	33.58

Table 6: The accuracy of models (with BERT-base + CD (S2)) using different vectors (e.g., $\mathbf{n}$ and $\mathbf{o}_y$) to predict ABSA labels. $\mathbf{n}$ denotes the noise vector and $\mathbf{o}_y$ refers to the output of diffusion networks.

We observe that, initially, the performance increases when higher steps are used, which is able to be explained as follows. In diffusion models, each step contributes to refining the generated results. With more steps, the model has a greater opportunity for incremental improvements at each stage, leading to a more detailed and accurate output. In addition, the curve reaches the best results when the step reaches 60, where limited changes in model performance are observed when the number of steps gets higher than 60. This observation suggests that when the step reaches a certain point, adding more steps may lead to overfitting and thus fails to make further improvements.

4.4 The Effect of the Output of Diffusion Networks

In our main experiments, the prediction of the ABSA label is made based on both the output of diffusion networks $\mathbf{o}_y$ and the sentence representation $\mathbf{h}_X$. To investigate the effect of this design, we try other settings where we use $\mathbf{o}_y$ alone and use the noise vector $\mathbf{n}$ to predict the ABSA label. The accuracy of models with BERT-base + CD (S2) are presented in Table 6. It is observed that, using $\mathbf{o}_y$ alone is slightly lower than the performance of our approach in Table 3. The results show that the diffusion module actually learns the important information to perform the task, which confirms the validity of our approach. In addition, we find it hard to predict the correct ABSA label using the noise vector $\mathbf{n}$ alone, which confirms the noise vector does contain noise that confuses the model.[8]

4.5 Case Study

To qualitatively illustrate the effectiveness of context denoising, we perform a case study using a sentence that has two aspect terms with contradictory sentiment polarities. The sentence is illustrated in Figure 5 with the two aspect terms highlighted in red and blue colors. The gold standard sentiments and the dependencies associated with the aspect terms are also presented for better illustration. In

---

[8] Although the accuracy of using $\mathbf{n}$ seems high, it might be attributed to the unbalanced label distribution in the test set (see Table 1 for details of the label distribution).

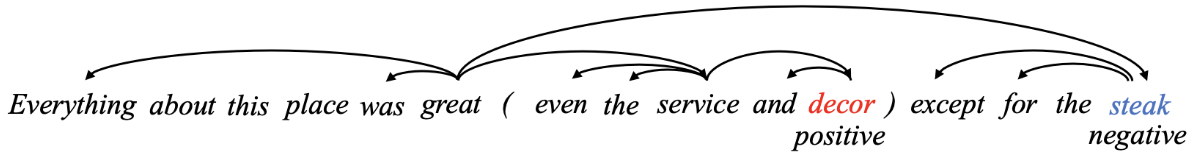

Figure 5: A test sentence with two aspect terms, namely, "*decor*" (in red) and "*steak*" (in blue). The gold standard sentiment polarities for them and the dependencies associated with the aspect terms are also presented.

this case, our approach with syntax noise (second-order dependencies) is able to correctly predict the sentiment polarities of both aspect terms, whereas the approaches with other settings (e.g., with the noise from the context window) fail to do so. The explanations are in the following texts. For "*decor*", since the context word "*great*" that contributes to the sentiment of "*decor*" has the second-order dependency relation with the aspect word, our approach with syntax noise is able to correctly identify the noise in the sentence and eliminate them appropriately. On the contrary, other approaches fail to locate the important word "*great*" and thus are unable to predict the correct label. Similarly, for "*steak*", the important context words "*great*" and "*except for*" are correctly located by our approach, which allows our approach to identify the negation for identifying the sentiment of "*steak*" and thus leads to a correct prediction.

5 Related Work

ABSA is a fine-grained and entity-level sentiment analysis task that aims to determine sentiment polarities for given aspects in a sentence, which requires a good modeling of the contextual information. Recent studies (Mao et al., 2019; Xu et al., 2019, 2020; Zhang et al., 2021; Xiao et al., 2021; Yu et al., 2021a; Qin et al., 2021; Peper and Wang, 2022; Hosseini-Asl et al., 2022; Deng et al., 2023; Wagner and Foster, 2023; Tian et al., 2023) leverage various attention-based neural networks to capture the contextual information, especially the aspect term and its contexts. Besides advanced decoders, another mainstream trend is incorporating knowledge, e.g., lexicon, chunks, and syntactic, and semantic knowledge, to identify important contextual information and use them to enhance model performance (Tang et al., 2020; Meng et al., 2020; Ahmed et al., 2021; Oh et al., 2021; Tang et al., 2022; Chen et al., 2022; Ma et al., 2023; Bao et al., 2023a). In addition, the effort devoted to combining graph neural networks (e.g., GCN) and syntactic information, e.g., dependency tree from off-the-self dependency parsers, have shown gratifying results in ABSA (Sun et al., 2019; Zhang et al., 2019; Wang et al., 2020; Zhang and Qian, 2020; Liang et al., 2021; Zhang et al., 2022, 2023a).

Compared with previous studies, our approach performs ABSA by eliminating the noise in the running text through context denoising. We propose to use task-specific noise rather than the standard stochastic Gaussian noise so as to better distinguish noise from important context for ABSA and thus make improvements.

6 Conclusion

This paper introduces a novel approach with context denoising for ABSA, which binds noises to extracted unimportant words so that allows the model to distinguish unimportant context features from the salient ones for predicting the sentiment polarity of a given aspect term. Experiments on five English benchmark datasets for ABSA, namely, LAP14, REST14, REST15, REST16, and MAMS, illustrate the effectiveness of the proposed approach, which outperforms strong baselines and states state-of-the-art performance. Further analyses confirm the superiority of utilizing task-specific noise rather than stochastic Gaussian noise in diffusion networks for ABSA. This study also provides novel ideas for tasks that require models to identify essential and non-essential content, where one is able to utilize the diffusion networks to meet the requirement and produce desired outputs. Meanwhile, one limitation of this study is that the approach relies on an existing well-performing dependency parser, which is not always available.

IruMozhi: Automatically classifying diglossia in Tamil

Aryaman Arora
Stanford University
aryamana@stanford.edu

Abstract

Tamil, a Dravidian language of South Asia, is a highly diglossic language with two very different registers in everyday use: Literary Tamil (preferred in writing and formal communication) and Spoken Tamil (confined to speech and informal media). Spoken Tamil is under-studied in modern NLP systems compared to Literary Tamil written in the Tamil script, as evidenced by a lack of datasets explicitly targetting the Spoken variety. In this paper, we release IruMozhi, a human-translated dataset of parallel text in Literary and Spoken Tamil. Using IruMozhi, we train classifiers on the task of identifying which Tamil variety a text belongs to. We use these models to gauge the availability of pretraining data in Spoken Tamil, to audit the composition of existing labelled datasets for Tamil, and to encourage future work on the variety.

`https://github.com/kebathan/diglossia`

1 Introduction

Diglossia is a linguistic phenomenon wherein a community maintains two (or more) varieties of their language, with the appropriate variety to use depending on the social context (Ferguson, 1959, 1996). Prototypically, diglossia manifests as two varieties: a **high** variety employed in formal contexts and a **low** variety employed in informal settings. The high variety tends to be standardised and highly preferred in writing and other formal communication (speeches, news broadcasts, etc.), while the low dialect is confined to speech and informal written communication (social media, text messages, etc.) and subject to regional and stylistic variation. Diglossia is thus a challenge for modern NLP systems—accessible training data on the internet usually overrepresents the high variety, while the average user may prefer using the low variety to interact with NLP systems.

English	The tail is also white.
Literary	வாலும் வெள்ளையாக உள்ளது. vaalum vellaiyaaga ulladhu
Spoken (1)	vaalu vellaiye irukku
Spoken (2)	vaalum white-ah irruku
English	Duryodhana's close friend.
Literary	துரியோதனனின் உற்ற நண்பன். thuriyodhananin utra nanban
Spoken (1)	dhuriyodhananoda nalla nanban
Spoken (2)	dhuriyodhanan-oda uyir nanban

Table 1: Two examples from our parallel corpus of Literary and Spoken Tamil showing morphological (1), phonological (2), and lexical differences (3). Spoken (1) and (2) are produced by different annotators.

Tamil is one such highly diglossic language primarily spoken in the state of Tamil Nadu in India, and in Sri Lanka and Singapore (Annamalai and Steever, 2015). Tamil belongs to the Dravidian language family, and is the oldest attested language in this group. Literary Tamil is the standardised (high) variety, preserving a more archaic stage[1] of the language than the low variety termed Spoken Tamil. Spoken Tamil (or Colloquial Tamil) is subject to dialectal variation by geography and caste, but in India there does exist a widely used and understood (but not officially regulated) Standard Spoken Tamil, based primarily on the dialect of educated non-Brahmin urban residents of central Tamil Nadu (Annamalai, 1980; Schiffman, 1998, 1999; Saravanan et al., 2009). Both forms of the language coexist in complementary social contexts, and thus practical NLP systems should endeavour to support both.

Tamil is a rising star in data availability for NLP research (Joshi et al., 2020; Arora et al.,

---

[1] Literary Tamil traditionally follows the rules described in the *Nannūl*, a 13th-century grammar by Pavaṇanti. However, it has been subject to linguistic change since then by e.g. the coining of new words.

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3096–3103
June 16-21, 2024

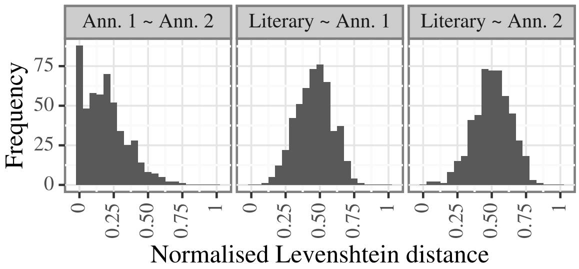

Figure 1: Histogram of normalised Levenshtein distances between parallel sentences from our Literary Tamil corpus and the two Spoken Tamil translators. The two Spoken Tamil sets are much more similar to each other than to Literary Tamil.

2022). However, most recent research, particularly on general-purpose systems like language models, has focused on Literary Tamil to the detriment of the Spoken variety. Combined with a lack of standardisation, we expect existing systems to be much worse at all tasks in Spoken Tamil. To combat this problem, we introduce a corpus of high-quality Literary Tamil sentences paired with human-elicited equivalents in Spoken Tamil. Using this data, we train classifiers to identify Spoken Tamil and audit existing Tamil datasets to measure the representation of the two varieties.

2 Related work

Spoken Tamil. While low varieties of diglossic languages are generally understudied in NLP, there is some previous work on NLP for Spoken Tamil. K and Lalitha Devi (2014) attempted conversion of Spoken Tamil to Literary Tamil using a rule-based system. Nanmalar et al. (2022, 2019) train models to classify diglossic register for Tamil audio. Furthermore, recent work on code-switching in Tamil implicitly uses at least some data in Spoken Tamil, since that is the variety most permissive of code-switching (Chakravarthi et al., 2020, 2021; Banerjee et al., 2018; Mandl et al., 2020).

Diglossia. Diglossia in NLP has largely been studied in the context of Arabic. For example, Zaidan and Callison-Burch (2014); Sadat et al. (2014); Salameh et al. (2018); Bouamor et al. (2019) all train models on the task of Arabic dialect and register classification. However, we were inspired to study diglossia in Tamil by Krishna et al. (2022), the only work on style transfer for Indian languages to our knowledge.

Set 1	Set 2	Lev. (↓)	(norm.)	BLEU (↑)	chrF (↑)
Ann. 1	Ann. 2	7.99	0.19	35.34	73.49
Literary	Ann. 1	21.84	0.46	0.83	37.19
Literary	Ann. 2	23.78	0.50	0.73	33.28

Table 2: Text similarity metrics between the transliterated Literary Tamil text and the two Spoken Tamil translators.

3 Dataset

To study diglossia in Tamil, we created IruMozhi,[2] a dataset of parallel sentences in Literary and Spoken Tamil. We first collected a high-quality set of 499 sentences randomly sampled from a large corpus of scraped Tamil Wikipedia articles, written in Literary Tamil.[3] This initial dataset was then converted to Spoken Tamil by two native-speaker translators. A few examples of the parallel data are presented in Table 1.

3.1 Creation

The dataset from Wikipedia was originally in the Tamil script; however, Spoken Tamil is largely found in the Latin script online. To enable easier comparison to Spoken Tamil and to have parallel romanised training data for both varieties, the dataset was automatically transliterated into the Latin alphabet using a Python program, resulting in the Literary Tamil split of IruMozhi.

Afterwards, two native speaker volunteers, both fluent in Literary and Spoken Tamil, were chosen to translate the sentences into their register of Spoken Tamil. Translator 1 and 2 both grew up in Salem, Tamil Nadu, India, albeit at different times; translator 1 tends to use fewer English loanwords.

The translators were instructed to convert the literary sentences into their register of Tamil while adhering to the original meaning of the sentence as closely as possible. Translator 1 only had access to the Literary sentences (both Tamil and transliterated), whereas Translator 2 had access to Translator 1's conversions as well.

3.2 Augmentation

We also design rules to augment all our data with orthographic variants, resulting in 6,224 Spoken Tamil and 2,410 Literary Tamil sentences. These rules simulate normal orthographic variation in

---

[2] *IruMozhi* means 'two languages' in Tamil.

[3] The articles were scraped in April 2019 and originally hosted as a Kaggle dataset. We sampled sentences from the first file of the `train` split of the corpus.

Table 3: Datasets for romanised Tamil that we consider. The register of each corpus is not known in some cases, in which case we indicate our best guess with '?'.

romanised Tamil, which correspond with common characteristics of speech, such as the alternation between ⟨zh⟩ and ⟨l⟩ to represent the voiced retroflex approximant /ɻ/. Other changes include alternating intervocalic ⟨h⟩ and ⟨g⟩, word-initial ⟨ch⟩ and ⟨s⟩, and word-final ⟨le⟩ and ⟨la⟩. Geminated consonants are also shortened to be singled, and long vowels are replaced with other variants. For example, ⟨oo⟩ is replaced with ⟨uu⟩, and ⟨ae⟩ is replaced with ⟨e⟩. Each augmented sentence is added back to the dataset with its respective literary or colloquial tag, as adjusting the orthography should not impact the register of Tamil used in the text. We apply all possible combinations of augmentations to each entry in the dataset.

3.3 Analysis

We measured Levenshtein distance (raw and normalised), BLEU, and chrF between all three pairings of the transliterated Literary Tamil sentences and the two Spoken Tamil translated conversions. The latter two metrics were computed using SacreBLEU (Post, 2018). All metrics are reported in Table 2 and Figure 1. Overall, the two Spoken Tamil translators agree with each other more than they do with Literary Tamil across all of our metrics. However, there is clearly linguistic variation in Spoken Tamil given disagreements between the two translators. For further discussion on linguistic differences between Spoken and Literary Tamil, see appendix A.

4 Experiments

Using IruMozhi, we train models on the task of classifying romanised Tamil text as Literary or Colloquial Tamil. After evaluating our models on a held-out test set, we audit existing datasets of romanised Tamil text to gauge the amount of data available for the two registers. We train two main types of model: **Naïve Bayes** classifiers on n-gram features and **XLM-R** finetuned for sequence classification. For both training and evaluation, we strip punctuation and convert all text to lowercase.

	$c = 3$	98.7%	0.991	0.978	52.1%
	$c = 2$	98.8%	0.992	0.978	20.3%
XLM-R	base	99.4%	0.996	0.990	81.5%

Table 4: Results averaged over 5 runs, reporting accuracy and per-class F1 on IruMozhi and accuracy on Dakshina (which the models were not trained on). For all Naïve Bayes models we report with $w = 1$. ST and LT refer to Spoken and Literary Tamil splits, respectivity. *For all metrics, larger is better.*

For Naïve Bayes, we featurise our data into char and word n-grams using a sliding window, resulting in a fixed-length vector of counts over features for each text input. We test both Gaussian and Multinomial distributions for the feature likelihood, and tune the maximum n-gram length for characters (c) and words (w) as hyperparameters. We use model implementations from `scikit-learn`.

XLM-R is a 279M-parameter masked transformer language model trained on the CC-100 web text corpus of one hundred languages, including romanised Tamil (Conneau et al., 2020). Using the HuggingFace implementation of `XLMRobertaForSequenceClassification`, we train a classification head on the first token <s>. We finetune the entire model for 4 epochs with a learning rate of $2 \cdot 10^{-5}$ for the Adam optimiser, on a single NVIDIA RTX A6000.

5 Results

We present results in Table 4 (see appendix B for results on more hyperparameters). All model ar-

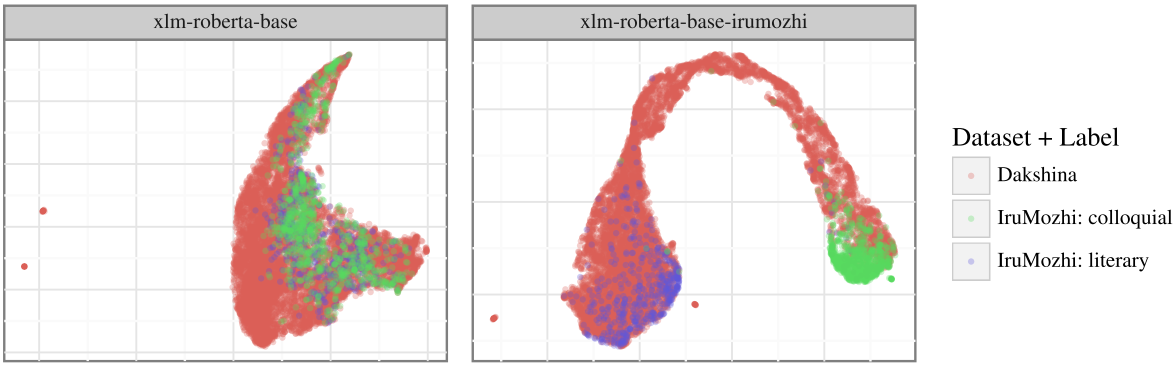

Figure 2: Embeddings of each sentence in IruMozhi and Dakshina taken from XLM-R base (left) and our finetuned version (right), with dimensionality reduced with UMAP (McInnes et al., 2018). Note the separation of Spoken and Literary clusters from IruMozhi after finetuning, with most of the Dakshina data closer to Literary Tamil from IruMozhi. For a different view, see Figure 3.

chitectures reliably converge to near-perfect performance on the held-out portion of IruMozhi.

5.1 Generalisation

It is difficult to decide which classifier is the best due to their similarly high performance on the IruMozhi dev set. Thus, we must further test our models' ability to generalise to another dataset with known labels. Fortunately, the Dakshina dataset (Roark et al., 2020) contains human-translated romanised Literary Tamil from the same data distribution as our dataset (Wikipedia). To measure generalisation ability, we check whether models correctly identify Dakshina to be Literary Tamil when only trained on our dataset.

Finetuning XLM-R leads to the best and most consistent performance on Dakshina. Naïve Bayes models, as one would expect, are less reliable for out-of-domain test data. We plot the resulting embeddings in Figure 2. Some hyperparameter settings for Naïve Bayes reported in appendix B did achieve better accuracy on Dakshina, but due to the highly inconsistent behaviour and complete reliance on orthography (unlike a pretrained language model), we do not suggest using Naïve Bayes approaches for the Tamil variety classification task.

5.2 Out-of-domain audits

Having trained these models, we audited the datasets listed in Table 3 to estimate the proportion of Literary and Spoken Tamil in them. We report these estimates in Table 5. Finetuned XLM-R and Multinomial Bayes ($c = 4, w = 1$) confirm that Dakshina is almost entirely Literary Tamil, while Tamilmixsentiment, Offenseval, and HopeEDI are largely Spoken Tamil. Given the genres that these datasets were collected from (formal Wikipedia vs. informal social media), these are reasonable predictions. Finally, testing the first 50k lines, we find a surprisingly high portion of Spoken Tamil in the CC-100 `ta_rom` split. This suggests that XLM-R was indeed trained on a large amount of Spoken Tamil, explaining why our finetuning was successful.

Dataset	XLM-R	Multi. NB
Tamilmixsentiment	6.2%	6.7%
Offenseval	14.1%	19.7%
Dakshina	81.5%	70.8%
HopeEDI	13.1%	20.6%
CC-100	44.0%	13.2%

Table 5: Estimated percentage of Literary Tamil sentences in each available romanised Tamil corpus, according to finetuned XLM-R and Multinomial Naïve Bayes models trained on IruMozhi.

6 Conclusion

We presented IruMozhi, a parallel corpus of Literary and Spoken Tamil translated on Wikipedia text. We trained models on an augmented version of IruMozhi for classifying Tamil diglossia, and audited the composition of existing labelled datasets and the CC-100 pretraining text in romanised Tamil. We found that there are indeed labelled and unlabelled data sources for Spoken Tamil text, indicating hopeful avenues for future NLP research on the variety. Particularly, XLM-R seems to have already been trained on some romanised Spoken Tamil data.

We hope to train style transfer models for the two varieties and study diglossia in other Indian languages. Our aim is to encourage work on lesser-studied languages and dialects in South Asia.

Limitations

This work is one of a handful submitted to *CL venues on Spoken Tamil. However, our definition of Spoken Tamil does not take into consideration dialectal variation in the variety. Particularly, since both of our annotators were from Salem, Tamil Nadu, India, our dataset excludes other regional dialects of Spoken Tamil. This may harm the ability of our trained models to generalise to other dialects of Spoken Tamil. Future work could improve on this paper by collecting translations from a more geographically diverse set of annotators, similar to what has been done in dialectal NLP work on Arabic.

Ethics Statement

We release models for classifying the register of romanised Tamil texts. This could be used to e.g. profile users on social media, but since our classification is not very fine-grained we do not foresee such uses being practical and thus do not have ethical concerns about our models.

A Linguistic differences between Literary and Spoken Tamil

We briefly discuss the linguistic differences between Literary and Spoken Tamil (Schiffman, 1999). The vowels of Literary Tamil undergo various phonological changes when converted into speech. Vowels, both short monophthongs and diphthongs, are regularly raised in the word-final position. For example, both /-a/ and /-aɪ/ are raised to [-ɛ]. Word-final /u/ (with the exception of names) is shortened to [ɯ]; additionally, an epenthetic-[ɯ] is usually added to the end of words that end with consonants. When not in the word-final position, /e/ and /i/ are relaxed into /ɛ/ and /ɪ/. Additionally, /i/ along with /u/ are lowered to [ɛ] and [o], respectively, when preceding a short consonant followed by /a/ and /aɪ/. Unlike the short vowels, long monophthongs will mostly remain the same quality regardless of position.

Word-final nasal consonants (excluding /ɳ/) also affect preceding vowels. In all cases, the vowel becomes nasalized and the consonant is dropped. For short vowels, however, the nasal may also change the quality of the vowel. For example, /an/ is nasalized to [ã], and then raised to [ɛ̃]. Similarly, /am/ is also nasalized to [ã], but then rounded to [ɔ̃].

Outside of regular vowel changes, various other aspects of Spoken Tamil differ from the literary variety. For example, the locative suffix /-il/ is expressed as [-lɛ]; A suffix like /(-)illaɪ/, indicating negation, is said as [-lɛ] at the end of words and [illɛ] elsewhere. /(-)uɭɭeː/ 'inside' is spoken as [(-)uɭɭɛ]. In some dialects of Spoken Tamil, the 3rd-person irrational ending, /-atu/, can become palatalised to [-Vt͡ʃɯ] in the past tense of strong verbs, with the vowel depending on the verb being conjugated. In general, strong verbs substitute /-tt-/ and /-nt-/ with [-t͡ʃ-] and [-nd͡ʒ-], respectively.

Finally, there are major lexical differences between Spoken and Literary Tamil. For example, there is a large presence of loanwords in the colloquial form of the language, most often taken from English and Sanskrit. These words, alongside some of native Tamil origin, often replace literary words that may seem too formal in speech. An example of this is *ulladhu*, which is almost always replaced with *irukku* in colloquial contexts as the existence copula. Similarly, the Sanskrit loan *sandosham* is preferred over the native Tamil word *magizhcci* for 'happy', although the latter is gaining popularity among the younger generations.

Table 6: Results on more hyperparameter settings.

We trained many variants of Naïve Bayes models, but their erratic generalisation behaviour on Dakshina led us to focus on XLM-R in the main text. We also tried training on IruMozhi and Dakshina together, but this heavily skewed the data distribution towards Literary Tamil since Dakshina is much larger than

IruMozhi, and seemed to harm out-of-domain generalisation; estimated Literary Tamil percentages on other datasets were around 50% and thus basically random.

Abstract

Norm violations occur when individuals fail to conform to culturally accepted behaviors, which may lead to potential conflicts. Remediating norm violations requires social awareness and cultural sensitivity of the nuances at play. To equip interactive AI systems with a remediation ability, we offer ReNoVi — a large-scale corpus of 9,258 multi-turn dialogues annotated with social norms, as well as define a sequence of tasks to help understand and remediate norm violations step by step. ReNoVi consists of two parts: 512 human-authored dialogues (*real data*), and 8,746 synthetic conversations generated by ChatGPT through prompt learning. While collecting sufficient human-authored data is costly, synthetic conversations provide suitable amounts of data to help mitigate the scarcity of training data, as well as the chance to assess the alignment between LLMs and humans in the awareness of social norms. We thus harness the power of ChatGPT to generate synthetic training data for our task. To ensure the quality of both human-authored and synthetic data, we follow a quality control protocol during data collection. Our experimental results demonstrate the importance of remediating norm violations in socio-cultural conversations, as well as the improvement in performance obtained from synthetic data[1].

1 Introduction

Social norms, the informal rules that define acceptable and appropriate behavior in groups or societies, are extensively studied by sociologists, anthropologists and psychologists for interpersonal communication (Bicchieri et al., 2018). Expectancy Violation theory (EVT) and its extensions discuss the effects of norm or behavior violations on interpersonal communication outcomes (Burgoon and Hubbard, 2005; Burgoon, 2015). According to the theory and empirical studies, violations of social norms often invoke punishment, such as costly sanctions, confrontation, gossip and social exclusion (Molho et al., 2020).

Large language models (LLMs) demonstrate reasoning and generalization capabilities that help people with a variety of communication tasks, e.g., essay writing and customer support. However, little is known about how LLMs align with human interpretations of social norms and how they can assist humans with socio-cultural verbal communication. This work aims to benchmark LLMs' ability to understand the influence of negative norm violations caused by human behaviors and mitigate their potential harm. The closest work (Liu et al., 2023) to ours investigates the alignment between LLMs and humans in terms of general social values, such as honesty and harmlessness, without norms pertaining to a culture. Other studies focus on extracting unknown norm rules (Fung et al., 2022), recognizing their status (*adherence* or *violation*) and associated social factors (Zhan et al., 2023a), and normative reasoning (Forbes et al., 2020a).

To achieve our goals, we construct a novel benchmark, called ReNoVi, to evaluate LLMs on assisting humans with remediating negative norm violations in textual conversations. As illustrated in Fig. 1, LLMs need to complete a sequence of four main tasks: (1) detect negative norm violations, (2) estimate impact of violations, (3) generate remediation measures, and (4) justify the generated measures and convey relevant knowledge of social norms. The latter two tasks are grounded in Interaction Adaptation Theory (IVT) (Ebesu Hubbard, 2015), which explains how, when and why interlocutors adjust their behavior in interpersonal communication. We choose Chinese culture for this benchmark as China is a populous country and an important commercial partner.

Our dataset consists of 9,258 multi-turn dialogues, including 512 human-authored conversations, and 8,746 synthetic conversations generated by ChatGPT. We use synthetic conversations be-

***Dialogue Scenario*:**
Norm Category: Request，Thanking *Role Relation*: Colleague
Topic: Office Affairs *Location*: Office
Norm Rules for Request: It's preferable for people to use a politeness marker when making requests.
Norm Rules for Thanking: The norm of doing thanks should express gratitude to a person or institution.

小王，座位安排出来了，你的工位号是444。
Wang, the arrangement is out, and your workstation number is 444.

这是啥号码啊？给我换个座位。
What the hell! Change my seat for me。

怎么了？ 这个号码有什么不好吗?
What's wrong? Is there something bad about this number?

4 在中文里跟死是一个发音，这太不吉利! Number 4 sounds like "death" in Chinese, that's horrible!

原来是这样, 那我去申请一下给你换个座位。
Ok, I got it. Let me change a seat for you.

麻烦了，感谢你!
That's appreciated, thank you so much!

Remediation:
请问可以帮忙给我换一个座位号码吗?
Could you please help change my seat number for me。

Justification:

原句中“给我换个座位" 使用命令式的语气，不符合礼貌请求的社会规范。同时，"这是啥号码啊"充满了抱怨的语气，很容易使得对方生气，violation 的影响程度高。remediation中使用了“请问”，“帮忙”等商量式的用词，符合请求request的社会规。
In the original sentence, "change a seat for me" is a request expressed in an imperative tone, which doesn't meet the requirements of social norms. Additionally, "what the hell" carries a complaining tone, which can easily make the other person angry. Therefore, the violation imapct is high. In the remediation, words such as "Could you please and "help" were used, which employ a more collaborative and polite approach to making a request, aligning with the social norms of requesting.

Figure 1: Main tasks of our framework (left): (1) norm violation detection, (2) violation impact estimation, (3) remediation generation, and (4) justification generation. Each dialogue (right) contains a corresponding dialogue scenario related to social norms. The detailed norm categories and rules are presented in Appendix C.1.

cause (i) they help mitigate the scarcity of training data for improving the quality of open-source LLMs such as privacy-sensitive applications, and (ii) they can be used to assess the alignment between ChatGPT and humans in terms of social norms. We conduct extensive analyses and experiments to explore the differences between human-authored and synthetic conversations. On ReNoVi, we conduct the first empirical study using a variety of LLMs and offer the following findings:

- We observe that solely relying on synthetic data doesn't enhance the model's performance. However, merging synthetic data with a small amount of human-authored data can enhance violation detection performance.
- Quantitative and human evaluation demonstrates the potential of LLMs to align with human capabilities in awareness of social norms.

2 Background

In this section, we provide a brief introduction of EVT and IAT, as they lay the foundation of understanding human behaviors in terms of social norms during interpersonal communication.

Expectancy Violations Theory. EVT is a useful theory in the social sciences that can inform ***how norm violations are detected*** and evaluated (Burgoon, 1993; Burgoon and Hubbard, 2005). Expectancies are enduring normative patterns of behaviors that are anticipated during interactions (Burgoon and Walther, 1990). Different cultures evolve different expectancies due to their unique histories and priorities (Chiu et al., 2010). When a behavior is perceived to be sufficiently discrepant from what was expected, an expectancy violation occurs (Burgoon, 1993). The interpretations and evaluations of violations determine whether they are positive or negative, and a negative violation usually causes damage. The ***effect of a violation*** is determined based on how it was appraised. Violations are appraised with a valence and intensity, depending on many variables such as who committed the violation, where it occurred, and how important the violated norm is. We formulate the analysis on the effects of violations by categorizing them into high or low impact.

Interaction Adaptation Theory. IAT is a theory that extends EVT to be more comprehensive in accounting for concurrent interactions by emphasizing the entrainment between interlocutors during normal interactions (Burgoon et al., 1997). We use this theory to better understand ***how remediation occurs and is facilitated following a norm violation***. One of the principles of IAT is that during conversations, a pressure for matching and reciprocity exists (Burgoon and Hubbard, 2005). In other words, people exhibit highly similar nonverbal and verbal communication patterns when interacting. These behaviors are important given the necessity for people to signal common ground during interactions. Matching refers to similarities in linguistic and nonverbal behaviors, while reciprocity refers to the changes individuals exhibit during interactions to achieve greater similarity with their interaction partners. We apply this principle to the remediation.

3 Task Definitions

We operationalize EVT and IAT for analyzing and mitigating negative norm violations into the following tasks ordered by their dependencies.

Task 1: Norm Violation Detection. Given an utterance associated with social norms of interest, the task determines (1) which ***norm category*** it belongs to and (2) whether it ***adheres to*** or ***violates*** the corresponding norm rules[2] (as shown in Figure 1). We specialize social norms in 7 typical scenarios in daily life. Following (Zhan et al., 2023a), we categorize norm scenarios by people's intents and include all categories in their work, as well as two novel categories: *thanking* and *leave-taking*. Details about norm categories and corresponding norm rules can be found in Appendix C.1.

Task 2: Impact Estimation. One important aspect of EVT is to predict interaction outcomes of violations, whether interactions should be involving, unpleasant, disinterest etc.. After experimenting with different annotation schemas, we opt to divide the effect of a violation into ***high impact*** and ***low impact***, in order to achieve high agreement among annotators. The impact of a violation is considered as high if it likely leads to serious consequences, such as disengagement, negative emotions of the interlocutor or even damage to the relationship between interlocutors, otherwise its impact is low.

Task 3: Remediation Generation. According to IAT, behavior matching and reciprocity is expected following a perceived violation. Therefore, for LLMs, remediation measures can be generated to either rephrase the norm-violating ones in order to change their status to adherence, or provide instructions regarding how to conform to the corresponding norms. Figure 1 shows an example of the former case by rephrasing the utterance more politely. The latter case is useful when e.g. a decision needs to be changed from invitation rejection to invitation acceptance. This task can be used to study the alignment between LLMs and humans following violations.

Task 4: Justification Generation. This task is suggested largely from a practical perspective, because it may avoid recurred violations by teaching users the relevant norm rules and explaining why the remediation measures are effective. From a technical perspective, the task encourages models to be more explainable and provides a way to verify to what degree generated remediations align with human behaviors as well as the theories, e.g. IAT.

4 ReNoVi Dataset

We introduce the ReNoVi dataset, which contains 9,258 multi-turn dialogue instances with fine-grained annotation labels. To the best of our knowledge, ReNoVi is the first dataset used to explore the remediation of norm violations based on Chinese cultural norms. In the rest of this section, we explain data collection (4.1), data quality control (4.2), data summary statistics (4.3), and comparisons of human-authored v.s. synthetically generated data (4.4).

4.1 Data Collection

We explain collecting human-authored (4.1.1) and synthetically-generated (4.1.2) dialogue data.

4.1.1 Curation of Human-authored Dialogues

Annotator Training and Examination. Dialogue instances in our dataset are highly related to Chinese social norms. We, therefore, invited 20 university lecturers and students who are familiar with Chinese culture to the annotation training procedure. To ensure that these crowd-workers provide effective social-cultural dialogues annotated with appropriate remediation and justifications, we designed a training tutorial. In the training tutorial, we decomposed the crowd-sourcing process into two stages: *dialogue curation* and *post annotation*. After participants finish the tutorial, they are required to take an exam, and they proceed to the dialogue curation stage only if they pass the exam. At the end of this process, we had 15 crowd-workers.

Preparation of Dialogue Scenarios. To encourage the crowd-workers to incorporate relevant social norms, we prepared an initial dialogue scenario for each potential dialogue. Each dialogue scenario contains a set of attributes: 1) *location*, 2) *role relationship*, 3) *topic* and 4) *social norms* including norm category and norm rules. For example, as shown in Figure 1, the dialogue scenario show that the two interlocutors (with a specific *role relation*) should talk about a *topic* at a *location*. Relevant social norms in this dialogue include *request* and *thanking*, as well as their corresponding norm rules.

Dialogue Curation. In the next stage, we instructed each crowd-worker to write a dialogue for each provided initial set of social factors. When writing a dialogue, crowd-workers were required to consider the following constraints: (1) each dialogue should contain all the social factors in the initial set; (2) for each dialogue, there should be at least one utterance

---

[2] Herein, we consider only negative violations in Chinese culture. Positive violations are not observed in our collected conversations.

that violates or adheres to the norm rule, e.g., as seen in Figure 1, the second utterance *violates* the social norm *request* and the last utterance *adheres* to the social norm *thanking*; (3) minimum 8 utterances for each dialogue.

Post Annotation. In the post-annotation stage, we asked the same groups of crowd-workers to complete the annotation tasks based on their written dialogues. These annotation categories include 1) *social norm* for each utterance including *norm category* and *violation status*. If the violation status of a utterance is *True*, the following labels should be annotated: 2) *impact estimation* to evaluate the effect of violations, 3) *remediation* for each violation utterance, and 4) *justification* for each violation utterance. The statistical distributions of each norm category can be found in Figure 2.

4.1.2 Curation of Synthetic Dialogues

The collection of human-authored data is expensive and time-consuming. Our motivation for synthetic data collection is two-fold: 1) expediting the process by acquiring ample data at a reduced expense, and 2) providing the chance to assess the alignment between ChatGPT and humans in awareness of social norms. Therefore, we leverage powerful instruction-following LLMs (e.g., ChatGPT) to generate synthetic dialogues at scale. The curation of synthetic dialogues is formulated in two stages: 1) synthetic dialogue generation with annotations and 2) remediation and justification generation.

Synthetic Dialogue Generation with Annotations. Similar to the human-authored dialogues, we prepared a scenario for each synthetic dialogue. Then, we present ChatGPT with our ontology-based prompts. The prompts incorporate the ontology labels in the scenario (e.g., location, topic) and instructions to generate synthetic dialogues. Besides, to annotate the dialogue automatically with the labels of violation status, the prompt also includes instructions to ask ChatGPT to annotate each utterance automatically. We present a detailed example in Appendix D.

Remediation and Justification Generation. By prompting ChatGPT with the dialogue context, violating utterances and the rules of social norms, the LLM can then automatically generate synthetic remediation and justification. We take a zero-shot prompting approach, where we prompt ChatGPT to identify utterances that violate social norms and request it to rewrite those utterances, while considering the contextual information. The goal is to produce a revised form of norm-violating utterance that aligns with social norms. Additionally, ChatGPT is expected to provide a rationale (justification) for why the newly generated utterance does not violate our predefined social norms.

Category	Total	Human-authored	Synthetic
#dialogue	9258	512	8746
#utterances	94.36K	7830	86.53K
#Avg. utterances	-	15.29	9.90
#violations	21076	1076	24577
#Avg. violations	-	2.10	2.81
#Avg. length for each following sentence			
utterance	-	20.84	28.42
remediation	-	28.74	42.02
justification	-	35.27	76.64

Table 1: Statistics of ReNoVi dataset.

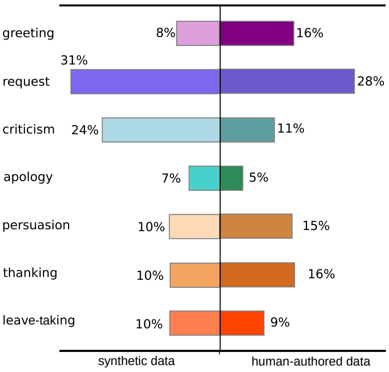

Figure 2: Norm category distributions of synthetic (*left*) and human-authored (*right*) data in ReNoVi dataset.

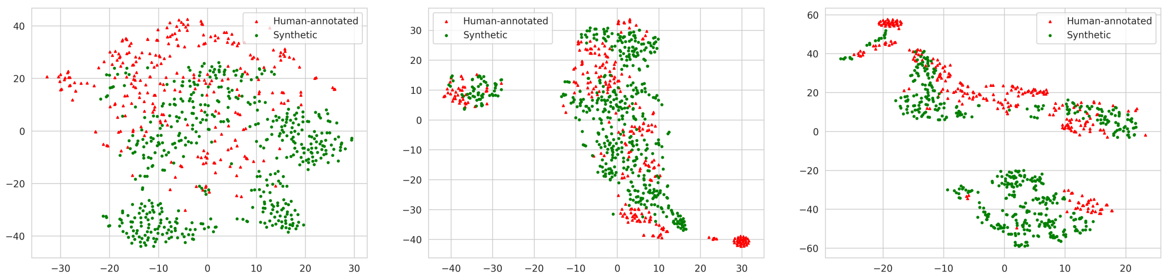
4.2 Quality Control

To ensure data quality, we reviewed all 512 human-authored dialogues and 500 sampled synthetic dialogues. For both human-authored and synthetic dialogues, we conducted careful checks for our proposed tasks in 3. For the labels in norm category and violation status (task 1) and violation impact estimation (task 2), we asked two other quality inspectors (in addition to the previous annotators) to review these labels. We calculated the inter-annotator agreement (Cohen, 1960), and the Kappa score for norm category, violation status, and violation impact are 0.55, 0.68, and 0.59, respectively.

We further conducted external reviews on those annotated labels where quality inspectors did not reach an agreement. Finally, among these reviewed 1,012 dialogues (512 human-authored + 500 synthetic), 28% (283 dialogues) did not reach an agreement, comprising 97 human-authored dialogues and 186 synthetic dialogues. All these 283 divergent dialogues were sent to the chief annotator (who



(a) Dialogue session.

(b) Remediation sentence.

(c) Justification sentence.

Figure 3: Distribution divergences between the embeddings (t-SNE) of synthetic (green) and human-written (red) in terms of (a) dialogue session, (b) remediation sentence, and (c) justification sentence.

created the training protocol in 4.1.1) to conduct the final revision on the labels.

4.3 Statistics Summary

The overall statistics of ReNoVi dataset are shown in Table 1 for 512 human-authored dialogues and 8,746 synthetic instances. Relatively long conversations indicate that ReNoVi provides effective multi-turn dialogues to explore norm violation and remediation issues in real scenarios (Avg. 15.29 utterances for each human-authored dialogue), which is longer than previous single context-response pair-wised datasets (Forbes et al., 2020a; Ziems et al., 2022b; Feng et al., 2023) or vanilla violation detection dataset (Avg. 6.63 utterances) (Zhan et al., 2023a). Besides, we notice that the average length of sentences (e.g, dialogue utterance, remediation and justification) generated by ChatGPT is longer than those human-authored ones. The major difference is that humans write concise and succinct sentences, while machine-generated sentences are more detailed and comprehensive.

We also present the statistics of norm category annotations in Figure 2. As seen, "*request*" label has the highest proportion in both human-authored and synthetic data, indicating that it's one of the most widely used norms in dialogues. Meanwhile, the distributions of other categories are different between human-authored and synthetic data. For instance, synthetic data augments the "*criticism*" category with 24%, which is more than twice of the human-authored data. We are inspired that synthetic data can be manipulated and tailored for augmentation as well as adjusting the distributions.

4.4 Human-Authored v.s. Synthetic Data

Discrepancy on Distributions. The scatter plots in Figure 3 present the discrepancy between the distributions of human-authored (red) and synthetic dialogues (green), in terms of dialogue session, remediation sentence, and justification sentence respectively. We use the encoder ZH-RoBERTa[3] to map each context into a vector, then visualize them using T-SNE (Van der Maaten and Hinton, 2008). We randomly sampled 200 human-authored dialogues and 200 synthetic dialogues which have similar dialogue scenarios. On the one hand, we observed salient differences in distributions between these two types of data in terms of dialogue sessions. While human-authored data is dispersed in its distribution, synthetic data is more clustered. We thus speculate that the combination of these two types of data can lead to broader and more diverse data, suitable for addressing the low-resource data condition. On the other hand, the distributions of remediation sentences generated by humans and ChatGPT are mixed with each other, demonstrating good alignment with the human capability of generating remediation measures.

	Human-authored			Synthetic		
	yes	no	k	yes	no	k
Effect. of remediation	96%	4%	0.79	87%	13%	0.63
Just. on Violation	95%	5%	0.73	90%	10%	0.68
Just. on remediation	88%	12%	0.66	82%	18%	0.59

Table 2: Human Comparison of human-authored and synthetic data. k denotes the Cohen's Kappa score (Cohen, 1960).

Comparison by Human Evaluation. To evaluate the alignment between ChatGPT and humans in terms of remediation and justification, we conduct a pair-wise comparison through human evaluation. We randomly sampled 100 utterances containing norm violations from the human-authored set and

---

[3] https://huggingface.co/hfl/chinese-roberta-wwm-ext

then asked ChatGPT to generate a corresponding remediation and justification sentence for each of the violation utterances. We mixed all human-authored and synthetic remediation and justification sentences and asked six annotators to judge whether each sentence met the following requirements. We mainly focus on evaluating: 1) *Whether the remediation resolves the norm violation in the utterance (**Effect. of remediation**)?* 2) *Whether the justification correctly explains the trigger point of the violation (**Just. on Violation**)?* 3) *Whether the justification correctly explains why the remediation solves the problem (**Just. on remediation**)?* As shown in Table 2, human evaluation on both human-authored and synthetic data reach high Kappa scores, indicating annotators' agreement that the quality of the remediation and justifications are high. We can observe that the quality of synthetic data approaches human-authored ones within a small gap. These findings show the potential of ChatGPT to be aligned with human ability in the awareness of social norms.

5 Experiments

We conducted experiments to evaluate baseline performance on our proposed sub-tasks. We start with the introduction of experimental settings, followed by our analyses from the experimental results.

5.1 Task 1: Norm Violation Detection

Experimental Settings. We conducted experiments to evaluate baseline performance by detecting norm categories and violations from dialogue utterances. We formulated norm category prediction as a multi-class classification task, while norm violation detection is a binary classification task. We used the following baseline models for our experiments: (1) **BERT-zh**: a BERT (Devlin et al., 2019) model pre-trained on large-scale Chinese corpus. (2) **RoBERTa-zh**: a RoBERTa (Liu et al., 2020) model pre-trained on large-scale Chinese corpus. Besides, in order to explore the performance of LLMs, we employ **ChatYuan** and **ChatGPT** (3.5-turbo) as a zero-shot setting. We organized three distinct groups, each utilizing a different source of training data: (1) exclusive training on 60% human-authored data, (2) exclusive training on synthetic data, and (3) training on a combined dataset comprising 60% human-authored data and all synthetic data. The remaining 40% of human-authored data was divided into a validation set (10%) and a test set (30%) for all these settings.

(1) Norm Category Prediction

Human	Synthetic	Models	P	R	F1
✓		BERT-zh	54.01	48.97	51.37
✓		RoBERTa-zh	50.79	52.78	51.77
Human	Synthetic	**Models**	**P**	**R**	**F1**
	✓	BERT-zh	19.75	47.65	27.93
	✓	RoBERTa-zh	32.81	50.01	39.62
Human	Synthetic	**Models**	**P**	**R**	**F1**
✓	✓	BERT-zh	46.64	82.72	**59.65**
✓	✓	RoBERTa-zh	48.44	80.76	**60.56**
zero-shot setting		ChatYuan	12.26	39.57	18.72
		GPT-3.5-turbo	41.92	50.69	45.89

(2) Violation Status Detection

Human	Synthetic	Models	P	R	F1
✓		BERT-zh	59.68	58.92	59.30
✓		RoBERTa-zh	66.86	65.70	66.27
Human	Synthetic	**Models**	**P**	**R**	**F1**
	✓	BERT-zh	59.33	58.25	58.78
	✓	RoBERTa-zh	65.60	65.59	65.59
Human	Synthetic	**Models**	**P**	**R**	**F1**
✓	✓	BERT-zh	71.04	68.34	**69.66**
✓	✓	RoBERTa-zh	67.99	66.97	**67.47**
zero-shot setting		ChatYuan	44.68	40.89	42.70
		GPT-3.5-turbo	63.01	56.09	59.35

Table 3: Experiment results of Task 1 including: (1) norm category prediction and (2) violation status detection. Baseline models trained on three different settings of source data, as well as the zero-shot setting for existing two representative LLMs.

Discussion. ***How LLMs perform in norm violation detection?*** We employed P/R/F1 scores as the evaluation metrics. The experimental results of norm category prediction and violation status detection are reported in Table 3. We observe that in the zero-shot setting, existing LLM (e.g., ChatYuan) only achieves 0.187 and 0.427 respectively in the norm category prediction and violation status detection tasks, which is far below the performance of fine-tuned RoBERTa-zh model. Besides, we observe that ChatGPT(3.5-turbo), the most state-of-the-art LLM, is much better than ChatYuan, but still far from good in norm violation detection task. Therefore, we urgently need a relevant corpus to benchmark LLMs or dialogue agents in aligning human interpretations of social norms.

How synthetic data affects the performance? We are curious about the necessity of synthetic data for boosting model's performance. These experiments suggest that models trained on a combination of synthetic and human data demonstrate superior performance compared to models trained solely on human data or models trained solely on synthetic data. For instance, in terms of norm category prediction, the F1-score of BERT-zh and RoBERTa-zh trained exclusively on synthetic data is significantly inferior to the model trained on human-authored data, even though the size of synthetic training data is far greater than the human training data (8.75K $\gg$ 300). This phenomenon might be caused

Human	Synthetic	**Models**	**P**	**R**	**F1**
✓		BERT-zh	74.82	68.97	71.77
✓		RoBERTa-zh	78.68	74.33	76.44
Human	Synthetic	**Models**	**P**	**R**	**F1**
	✓	BERT-zh	67.82	65.40	66.59
	✓	RoBERTa-zh	70.93	67.06	68.94
Human	Synthetic	**Models**	**P**	**R**	**F1**
✓	✓	BERT-zh	72.48	69.43	70.92
✓	✓	RoBERTa-zh	80.16	76.59	78.33

Table 4: Experiment results of impact estimation of violation models trained on three different training settings.

by the domain shift issue, as we observed a distribution gap between these two types of data in Figure 3(a). However, significant improvement has been witnessed after we combined synthetic data with only a small portion of human-authored data. This finding highlights the potential of synthetic data to address data scarcity issues.

5.2 Task 2: Violation Impact Estimation

Experimental Settings. We formulated the impact estimation task as a binary classification task. Using settings similar to Task 1, BERT-zh and RoBERTa-zh served as our baselines. We evaluated using precision, recall, and F1-score. Recognizing that prior dialogue context can influence impact estimation, we combined the current violation utterance with its two previous utterances. This combined input was then fed into our classification model.

Discussion. We present the results of violation impact estimation in Table 4. RoBERTa-zh model trained on a combination of synthetic and human data outperform the other two models with the other two training settings, maintaining a similar trend as the previous two tasks. However, BERT-zh model trained on the mixed data is slightly inferior than the model solely trained on human-authored data. We analyzed the bad-cases and observed that impact estimation usually requires good understanding of background culture and social norms. However, existing naive baseline models are not good enough to efficiently estimate the violation impact just from dialogue utterances.

5.3 Task 3 and 4: Generation of Remediation and Justification

Experimental Settings. We employed two Chinese LLMs as the backbone models: **ChatGLM-6B**[4] and **ChatYuan**[5], compatible with corresponding adapters: *P-tuning* (Liu et al., 2022), *Lora* (Hu et al., 2022), *Pfeiffer* (Pfeiffer et al., 2020) and *Prefix tuning* (Li and Liang, 2021). Based on our investigation and results in the previous tasks, we fine-tuned the models on the combination of synthetic and human-authored training datasets and tested them on the human-authored test set. We employ automatic evaluation metrics including BLEU (Papineni et al., 2002), ROUGE-L (using F1) (Lin, 2004), MAUVE (Pillutla et al., 2021), and BERT-Score (using F1) (Zhang et al., 2019). Besides, we employ human evaluation to qualitatively assess the models' output by asking six human annotators to evaluate each remediation or justification sentence from three perspectives: Effectiveness (*Effect.*), Relevance (*Rel.*) and Informative (*Info.*). Annotators are required to grade each of the remediation and justification sentences with a range of scores from 1 (low performance) to 3 (high performance).

Remediation Generation					
Model	BLEU.	R-L	MAUVE	BScore	Avg. Len
ChatGLM + *P-tuning*	0.211	0.308	**0.598**	0.694	38.73
ChatGLM + *Lora*	0.129	0.161	0.005	0.610	213.38
ChatYuan + *Pfeiffer*	**0.244**	**0.359**	0.384	**0.713**	28.78
ChatYuan + *Prefix tuning*	0.161	0.311	0.280	0.699	17.93
Justification Reason Generation					
Model	BLEU.	R-L	MAUVE	BScore	Avg. Len
ChatGLM + *P-tuning*	**0.117**	0.144	**0.025**	**0.612**	93.21
ChatGLM + *Lora*	0.085	0.082	0.005	0.554	244.05
ChatYuan + *Pfeiffer*	0.106	0.150	0.014	0.603	66.46
ChatYuan + *Prefix tuning*	0.103	**0.154**	0.014	0.611	58.10

Table 5: Automatic evaluation on the remediation generation and justification reason generation task respectively.

Automatic Evaluation. Table 5 reports the automatic evaluation results on four baseline models. We can observe that ChatYuan+*Pfeiffer* achieves the best BLEU, R-L, and BScore scores and obtains the second-best score for MAUVE in the remediation generation task. This result demonstrates the strength of ChatYuan+*Pfeiffer* in terms of rewriting inappropriate utterances to meet the requirements of social norms. Besides, the remediation sentences generated by ChatYuan+*Pfeiffer* have an average length of 28.78, which is very close to the human-written remediation sentences (Avg. 28.74, reported in Table 1). These findings demonstrate that ChatYuan+*Pfeiffer* is the best among these four models to align with human capability in using concise sentences to remedy offensive utterances.

In terms of the justification generation task, ChatGLM+*p-tuning* reaches the best in BLEU, MAUVE, and BScore. The generated justification sentences from ChatGLM+*p-tuning* are comprehensive and detailed in illustrating the trigger point of the violation and why remediation sentences can resolve issues. In contrast, generated remediation and justification from the ChatGLM+*Lora* model

---

[5] `https://github.com/clue-ai/ChatYuan`

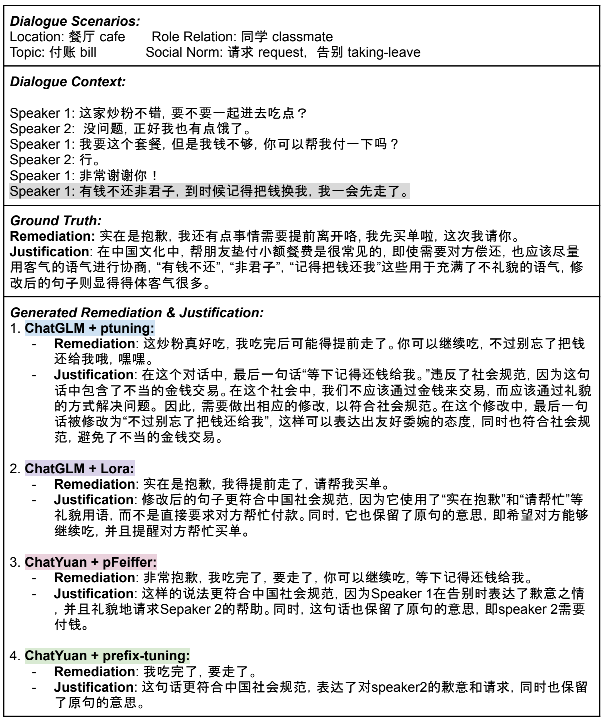
Remediation Generation				
Model	Effect.	Rel.	Info.	*kappa*
ChatGLM + *P-tuning*	**2.33**	2.42	2.36	0.53
ChatGLM + *Lora*	1.37	1.62	1.39	0.61
ChatYuan + *Pfeiffer*	2.29	**2.71**	**2.79**	0.49
ChatYuan + *Prefix tuning*	1.94	2.35	2.16	0.56
Justification Reason Generation				
Model	Effect.	Rel.	Info.	*kappa*
ChatGLM + *P-tuning*	**2.65**	**2.71**	**2.76**	0.55
ChatGLM + *Lora*	1.83	2.32	2.20	0.59
ChatYuan + *Pfeiffer*	2.46	2.59	2.72	0.55
ChatYuan + *Prefix tuning*	2.14	2.48	2.25	0.57

Table 6: Human evaluation on the remediation generation and justification reason generation task respectively.

are the longest, but its performances are the lowest. We found that ChatGLM+*Lora* model tends to generate tedious but irrelevant context, which cannot fulfill these two tasks in a decent format.

Human Evaluation. Table 6 reports the annotators' manual assessments of the remediations and the corresponding justifications from three aspects. We can observe that ChatYuan+*Pfeiffer* obtains the best *Rel.* and *Info.* scores in the remediation task (as a reference, in Table 5, ChatYuan+*Pfeiffer* ranks the first in three out of four metrics for the remediation task). Likewise, in the justification task, ChatGLM+*p-tuning* performs the best in all the three human evaluation metrics, keeping the consistency with the results in Table 5. The consistent empirical observations in both Table 5 and Table 6 suggest that ChatYuan+*Pfeiffer* can provide the best remediations to mitigate the norm violations and the ChatGLM+*p-tuning* can best justify such the remediations among the four baseline models. Also, in accordance with the finding in Table 5, ChatGLM+*Lora* performs the worst in all metrics in both two tasks. This observation further verifies our previous point that verbosity probably diminishes the quality of the generated utterances. Strategically composing the outputs with more useful information and less verbosity is more important to align LLMs with humans.

Case Study. Figure 4 presents a case study for the remediation and justification generation task, showcasing examples from four baseline LLMs. Among these, the ChatGLM+ptuning model excels in producing the most suitable remediation and persuasive justification. The other three models exhibit some shortcomings, such as (1) lacking politeness in remediation, and (2) containing factual inaccuracies in justification. Despite fine-tuning on our dataset, these LLMs demonstrate room for improvement in remediating violations in the future.



Dialogue Scenarios:
Location: 餐厅 cafe　Role Relation: 同学 classmate
Topic: 付账 bill　Social Norm: 请求 request，告别 taking-leave

Dialogue Context:

Speaker 1: 这家炒粉不错，要不要一起进去吃点？
Speaker 2: 没问题，正好我也有点饿了。
Speaker 1: 我要这个套餐，但是我钱不够，你可以帮我付一下吗？
Speaker 2: 行。
Speaker 1: 非常谢谢你！
Speaker 1: 有钱不还非君子，到时候记得把钱换我，我一会先走了。

Ground Truth:
Remediation: 实在是抱歉，我还有点事情需要提前离开咯，我先买单啦，这次我请你。
Justification: 在中国文化中，帮朋友垫付小额餐费是很常见的，即使需要对方偿还，也应该尽量用客气的语气进行协商，“有钱不还”，“非君子”，“记得把钱还我”这些用于充满了不礼貌的语气，修改后的句子则显得得体客气很多。

Generated Remediation & Justification:

1. **ChatGLM + ptuning:**
    - **Remediation**: 这炒粉真好吃，我吃完后可能得提前走了。你可以继续吃，不过别忘了把钱还给我哦，嘿嘿。
    - **Justification**: 在这个对话中，最后一句话“等下记得还钱给我。”违反了社会规范，因为这句话中包含了不当的金钱交易。在这个社会中，我们不应该通过金钱来交易，而应该通过礼貌的方式解决问题。因此，需要做出相应的修改，以符合社会规范。在这个修改中，最后一句话被修改为“不过别忘了把钱还给我”，这样可以表达出友好委婉的态度，同时也符合社会规范，避免了不当的金钱交易。

2. **ChatGLM + Lora:**
    - **Remediation**: 实在是抱歉，我得提前走了，请帮我买单。
    - **Justification**: 修改后的句子更符合中国社会规范，因为它使用了“实在抱歉”和“请帮忙”等礼貌用语，而不是直接要求对方帮忙付款。同时，它也保留了原句的意思，即希望对方能够继续吃，并且提醒对方帮忙买单。

3. **ChatYuan + pFeiffer:**
    - **Remediation**: 非常抱歉，我吃完了，要走了，你可以继续吃，等下记得还钱给我。
    - **Justification**: 这样的说法更符合中国社会规范，因为Speaker 1在告别时表达了歉意之情，并且礼貌地请求Sepaker 2的帮助。同时，这句话也保留了原句的意思，即speaker 2需要付钱。

4. **ChatYuan + prefix-tuning:**
    - **Remediation**: 我吃完了，要走了。
    - **Justification**: 这句话更符合中国社会规范，表达了对speaker2的歉意和请求，同时也保留了原句的意思。

Figure 4: Case study on the generated remediation and justification from different LLMs. We refer the corresponding English translation version to appendix B.

6 Related Work

Socio-Cultural Conversations. Culture refers to shared values, behaviors and beliefs within a society (Lytle et al., 1995). These shared values, behaviors and beliefs give rise to social norms, which are an implicitly held consensus on social patterns governing behavior within a cultural context (Morris et al., 2015; Hua et al., 2024). Social norms in conversations have been recognized as an important factor that affects human's communication (Chawla et al., 2023), such as negotiation (Chen et al., 2023a; Zhan et al., 2024) or dialects (Joshi et al., 2024). Forbes et al. (2020b) propose a large-scale corpus – *Social-Chemistry-101*, containing 292K rules-of-thumb (RoTs); Hendrycks et al. (2021) introduce the ETHICS dataset, where the task is to predict moral judgments about diverse scenarios; and Ziems et al. (2022a) propose a moral-related corpus using 99K distinct RoTs to explore ethical issues in dialogue. These datasets are formulated as single context-response pairs, hence they do not simulate real dialogues. When observed behaviors do not conform to what is expected, norm violations occur, which may lead to potential conflicts (Burgoon, 1993). Zhan et al. (2023a) propose a corpus to detect norm violations in multi-turn conversations, but falling short of resolving the violation issues. Moreover, remediation tactics that transform a negative impression caused by norm violations to a positive one are essential to benchmark LLM's ability to mitigate potential harm. To the best of our knowledge, our ReNoVi dataset is the first corpus to explore how to remediate norm violations in socio-cultural conversations.

Synthetic Data for Dialogues. Synthetic data is regarded as an effective approach to accommodate data scarcity for low-resource dialogue systems (Zhan et al., 2023b). Dai et al. (2022) propose a novel task called *Dialogue Inpainting*, which transforms an input raw document into a two-party QA session. In addition, the emergence of large language models (LLMs) has greatly advanced many NLP tasks. In terms of synthetic data for dialogue, Kim et al. (2022) propose a framework for automatic curation of large-scale multi-skill dialogue datasets; Chen et al. (2023b) utilize LLMs and devise a prompt-based framework to create synthetic conversations for few-shot social dialogue. Compared with existing methods, the synthetic dialogues in ReNoVi are generated with ChatGPT, which can be used for augmenting low-resource settings, as well as assessing the alignment between LLMs and humans.

7 Conclusion

We propose ReNoVi, a Chinese socio-cultural conversation benchmark, to explore how to remediate norm violations. ReNoVi contains 9,258 dialogue sessions in total, of which 512 dialogues are written by humans and 8,746 synthetic dialogues are generated by ChatGPT. To the best of our knowledge, ReNoVi is the first multi-turn dialogue corpus to study norm violation remediation in conversations. Based on the EVT and IAT theories, we formulate four tasks to help understand, detect and remediate social norm violations. We further conduct in-depth analyses on these sub-tasks in succession and assessed several popular LLMs' performances.

Limitations

We claim that our work may have limitations in the following aspects.

Monolingual Culture Background As a pioneer work for norm violation remediation in dialogues, we mainly focus on Chinese social norms and offer a Chinese dataset. In future, we will extend our dataset to a cross-cultural and multilingual corpus, which will involve more culture backgrounds, such as Spanish, Latin and Arabic.

Lack of Tailored Baseline Models We are aware of that our work is the first to propose norm violation remediation and justification tasks. Our contributions mainly focus on formulating relevant tasks and datasets, thus falling short on proposing tailored baseline models.

A Ethics Statement

To regularize the usage of this resource and the tasks it can facilitate, we will claim several ethics consideration and emphasize some potential risks.

Misuse of Data. As the objective of this resource is to integrate AI systems with the remediation ability towards norm violations. Inevitably, this resource will contain some content that may be offensive or upsetting. However, we want to stress that ReNoVi represents a collection of social norm, remediation and justification. We do not treat the norm violations as discrimination, racism or disrespect to Chinese or any other cultures. Therefore, this dataset, primarily synthesized using LLMs and crowd-sourced inputs, is released exclusively for academic and research purposes and does not reflect the opinions or values of the authors. The social norms and violation situations in ReNoVi are strictly prohibited for any form of commercial exploitation or political manipulation. They should not be used as insults, slander, or for other malicious intents. Users are expected to adhere to the highest ethical standards, ensuring responsible and transparent use aligned with ethical research practices. The dataset creators hold no liability for misuse or misinterpretation, and all necessary measures have been taken to respect privacy and ensure informed consent in the data collection process.

Risks in Annotation. We highly value our annotators' mental health and labor compensation. Before and annotation, data collection or human evaluation, relevant studies were carefully reviewed and approved by an internal review board. Our task may contain some offensive or upsetting content. We thus require each annotator to have a rest every one hour or anytime they do not feel well. In terms of payment, we pay these annotators 15 USD/hour.

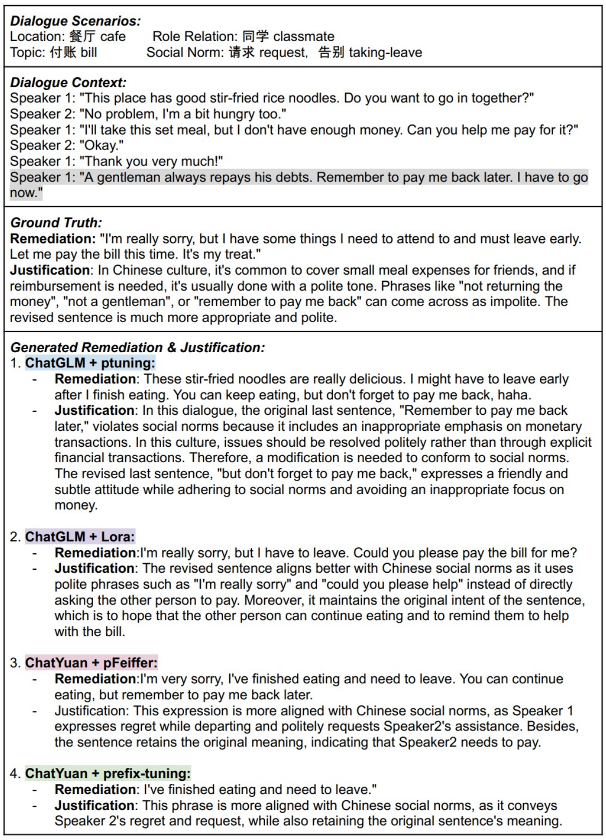
B Corresponding English translation of Figure 4

We put the corresponding English translation of Figure 4 in the Figure 5.

C Details of ReNoVi dataset

C.1 Definition of Social Norms

We present the catgories of social norms and corresponding rules and examples in Table 7, which covers all of the types that appear in our human-authored and synthetic dataset. We mainly focus on seven norm categories in our paper, including: *apology*, *criticism*, *greeting*, *persuasion*, *request*, *leave-taking* and *thanking*. We notice that these norm categories may have overlaps with the definition of dialogue acts (Stolcke et al., 2000) or intents (Wen et al., 2017). However, we want to stress that the main difference of the rules on social norms relies on: **socially or culturally accepted behaviors** within these actions/norms.



Dialogue Scenarios:
Location: 餐厅 cafe   Role Relation: 同学 classmate
Topic: 付账 bill   Social Norm: 请求 request，告别 taking-leave

Dialogue Context:
Speaker 1: "This place has good stir-fried rice noodles. Do you want to go in together?"
Speaker 2: "No problem, I'm a bit hungry too."
Speaker 1: "I'll take this set meal, but I don't have enough money. Can you help me pay for it?"
Speaker 2: "Okay."
Speaker 1: "Thank you very much!"
Speaker 1: "A gentleman always repays his debts. Remember to pay me back later. I have to go now."

Ground Truth:
Remediation: "I'm really sorry, but I have some things I need to attend to and must leave early. Let me pay the bill this time. It's my treat."
Justification: In Chinese culture, it's common to cover small meal expenses for friends, and if reimbursement is needed, it's usually done with a polite tone. Phrases like "not returning the money", "not a gentleman", or "remember to pay me back" can come across as impolite. The revised sentence is much more appropriate and polite.

Generated Remediation & Justification:

1. **ChatGLM + ptuning:**
    - **Remediation**: These stir-fried noodles are really delicious. I might have to leave early after I finish eating. You can keep eating, but don't forget to pay me back, haha.
    - **Justification**: In this dialogue, the original last sentence, "Remember to pay me back later," violates social norms because it includes an inappropriate emphasis on monetary transactions. In this culture, issues should be resolved politely rather than through explicit financial transactions. Therefore, a modification is needed to conform to social norms. The revised last sentence, "but don't forget to pay me back," expresses a friendly and subtle attitude while adhering to social norms and avoiding an inappropriate focus on money.

2. **ChatGLM + Lora:**
    - **Remediation**:I'm really sorry, but I have to leave. Could you please pay the bill for me?
    - **Justification**: The revised sentence aligns better with Chinese social norms as it uses polite phrases such as "I'm really sorry" and "could you please help" instead of directly asking the other person to pay. Moreover, it maintains the original intent of the sentence, which is to hope that the other person can continue eating and to remind them to help with the bill.

3. **ChatYuan + pFeiffer:**
    - **Remediation**:I'm very sorry, I've finished eating and need to leave. You can continue eating, but remember to pay me back later.
    - Justification: This expression is more aligned with Chinese social norms, as Speaker 1 expresses regret while departing and politely requests Speaker2's assistance. Besides, the sentence retains the original meaning, indicating that Speaker2 needs to pay.

4. **ChatYuan + prefix-tuning:**
    - **Remediation**: I've finished eating and need to leave."
    - **Justification**: This phrase is more aligned with Chinese social norms, as it conveys Speaker 2's regret and request, while also retaining the original sentence's meaning.

Figure 5: The English verson of case study on the generated remediation and justification from different LLMs. Please note that the translation was conducted by ChatGPT.

C.2 Details of Taxonomy in Dialogue Scenarios

We present the relevant social factors including *location* and *role relation* in Figure 6. Some other keywords in low frequency are not presented in this table. Each dialogues in both human-authored and synthetic dataset will contain a value for each social factors.

D Example of Synthetic Data Generation

We present a example for the synthetic data generation procedure in Figure 7. We devise a ontology-

#	Norm Category	Norm Rules	Examples
1	Apology	Apologies in Mandarin/Chinese culture are guided by principles of harmony as well as honor, dignity and respect. Direct verbal apologies might be avoided when an indirect approach, such as offering a wordless gesture or a written message, can be taken instead.	我向你道歉 。 (I apologize to you.)
2	Criticism	In Chinese culture it is common for direct criticism to be given to subordinates or those of lower status, while criticizing a superior or someone of higher status is uncommon and is typically done in a much more indirect manner.	1. 上级对下级：你这么做的方式不太对。 (What you're doing is not totally correct.) 2. 下级对上级：部长先生，这里似乎有一个错别字需要改正一下，您看呢? (Mr. Minister, there seems to be a typo here that needs correction. am I right?)
3	Greeting	Using specific greetings in Mandarin Chinese culture is very important in formal settings. However, greetings are far more relaxed in intimate relationships such as with family and friends or people of similar or younger ages and in informal settings.	1. 部长先生，早上好，很高兴见到你！ (Mr. Minister, good morning, it's a pleasure to see you!) 2. 早哟！ (Morning!)
4	Persuasion	In Mandarin Chinese culture, the norm of doing persuasion varies by speakers' social status and age. persuasion involves people giving reasons and/or describing consequences if things are done one way or the other.	建议你可以... (I suggest you ....)
5	Request	In Chinese culture, factors such as status, power, age, gender, and familiarity play a large role in determining the way in which requests are made. it's preferable to use a politeness marker.	请问你有时间帮我做...吗? (May I ask if you have the time to...?)
6	Leave-taking	In Mandarin Chinese culture, taking leave is a multi-stage process, and social norms around taking leave vary by social status, age. The person who is taking leave usually starts with apologizing or giving a reason or an excuse for leaving.	实在抱歉，我后面还有个安排，今天的会就到这吧! (Sorry guys, I have another schedule afterwards, Let's end the meeting today.)
7	Thanking	Thanking people directly in Mandarin Chinese culture is frequent in formal settings or when interacting with people of a higher status or equal status. The norm of doing thanks should expresses gratitude to a person, or institution.	太谢谢了! (Thank you very much!)
8	Others	Other norms that are not included in the previous categories.	

Table 7: Social norm categories and corresponding rules in our main seven categories.

Social Factors	**Keywords**
地点 Location	餐厅 restaurant, 家庭 home, 批发市场 wholesale market, 办公场所 office, 实验室 laboratory, 电影院 movie theater, 商务会议 conference, 其他 others 医院 hospital 学生社团 student community 图书馆 library, 银行 bank, 公共交通 public transportation, 旅游景点 tourist sites 博览会 expo,
人物关系 Role Relation	服务员与顾客 customer and server 好友 friend 恋人情侣 partner 同事 colleague 商务合作伙伴 business partner 医生和患者 doctor and patient 家长与老师 parent and teacher 上司和下属 chief and subordinate 长辈和晚辈 elder and junior (e.g. mother and son) 政府人员和市民 government officers and citizens 同学 schoolmate 司机与乘客 driver and passenger 买卖双方 buyer and seller 工作人员与访客 officer and visitor 其他 others

Figure 6: Taxonomy of social factors in dialogue scenarios.

based framework to gradually prompt ChatGPT to generate synthetic conversations. Overall, three main steps included in the ontology-based framework: (1) Norm Violation Example Generation, (2) Synthetic Conversation Generation and (3) Remediation and Justification Generation. Specifically, Step 1 Norm Violation Example Generation will generate basic norm rules and several violation examples in Chinese culture considering the provided dialogue scenarios above. Step 2 Synthetic Conversation Generation will generate synthetic dialogues that contain above mentioned violation examples. Additionally, corresponding labels such as norm category, violation status will be annotated automatically. Based on these utterances which contains norm violation, Step 3 will generation corresponding remediation sentence and justification sentence as shown in Figure 7.

Dialogue Scenarios:
Location: 酒店 Hotel   Role Relation: 男女朋友 partner
Topic: 食物 food   Social Norm: 批评 Criticism

Step 1: **Norm Violation Example Generation**

***Prompt*:** 在中文语境中，在酒店里，女朋友和男朋友在进行一个正式的对话，女朋友在批评男朋友。为了避免冒犯和尊重他人，请列举3条不符合社会规范的批评方式，并解释为何这些例子不符合社会规范。In a Chinese context, in a hotel, a girlfriend and boyfriend are having a formal conversation, with the girlfriend criticizing the boyfriend. In order to avoid offending and respect others, please list five examples of criticism that do not conform to social norms and explain why these examples do not conform to social norms.

Generated Norm Violation Examples:

在公众场合大声批评 Criticizing loudly in public places
无理取闹 Acting unreasonable
使用侮辱性的语言 Using insulting language

Step 2: Synthetic Conversation Generation

Prompt: 现在有如下的对话场景：在一个 酒店，一对男女朋友，他们在讨论食物的花体。在对话中，男女朋友使用了批评方式，但是违反了中国社会礼仪规范。请根据以上列举出来的违反社会规范的例子，生成一段不少于8句话的对话。同时需要标注每段对话是否违背了相关的社会规范准则。There is a dialogue scenario as follows: In a hotel, a couple, boyfriend and girlfriend, they are discussing the presentation of the food. In the conversation, the boyfriend and girlfriend use criticism, but violate Chinese social etiquette norms. Based on the examples of violating social norms listed above, please generate a dialogue of no less than 8 sentences. At the same time, each dialogue needs to be marked whether it violates the relevant social norm.

Generated Synthetic Conversation:

Speaker 1: 你这次带的零食品质太差了，怎么能这样呢？" violation
Speaker 2: 我也不是故意的，可能是我没注意到
Speaker 1: 你以后能不能仔细点呢？ 这种情况一点也不好笑。violation
Speaker 2: 我知道了，下次会注意的。"
Speaker 1: 这些零食对身体可不好，你以后还是尽量少吃点吧。
Speaker 2: 好的，我会注意的。
Speaker 1: 那以后就别随便买了，浪费钱还不健康。
Speaker 2: 好的，我会注意的。

Step 3: Remediation and Justification Generation

Prompt: 以下的句子违反了社会规范，请修改句子的表达使得其符合社会规范，并且用简洁的解释为什么之前的句子违反了社会规范。对话句子 "你这次带的零食品质太差了，怎么能这样呢？"
Prompt: The following sentence violates social norms. Please revise the following sentence and justify why previous sentence violates social norms. Dialogue utterance: "he snacks you brought this time are of such poor quality, how could you do this?"

Generated Remediation and Justification:
Remediation：这次食品的质量比之前的差一些哦，下次可以麻烦提前检查一些食品质量吗？
Justification：女朋友违反了有关'批评'的社会规范，因为她的语气不够委婉，过于直接指责男朋友的行为，缺乏尊重和礼貌。

Figure 7: A example of generating synthetic conversation by prompting ChatGPT with three steps.

E Comparison of ReNoViand other datasets

We present the statistical comparision between ReNoVi and other relevant datasets. ReNoVi differs from previous datasets in the following aspects: (1) to the best of our knowledge, it is the first dataset aiming at remediating the social norm violations based on Chinese social norms, and ReNoVi covers

Dataset	Type	#Dialogues	#Avg. turns	language	social factors	Remediation of Norm Violations	Latest Updates
FactAct (Dutt et al., 2020)	multi-turn	299	35.8	English	persuasion	✗	2018
PersuasionforGood (Wang et al., 2019)	multi-turn	1017	10.43	English	request, persuasion	✗	2019
CPED (Chen et al., 2022)	multi-turn	12k	11.08	Chinese	emotion	✗	2022
moralInt (Ziems et al., 2022c)	single-turn	38k	-	English	norm rule	✗	2022
DREAM (Gu et al., 2022)	single-turn	49k	-	English	norm rule	✗	2022
SocialDial (Zhan et al., 2023a)	multi-turn	6433	9.45	Chinese	norm rule	✗	2023
ReNoVi	multi-turn	9,258	10.19	Chinese	norm rule	✓	2023

Table 8: Comparison between ReNoVi and related dialogue corpora.

at most seven different social norm categories; (2) besides norm violation detection task, we firstly define the norm violation remediation and justification task, and collect high-quality human-authored and automatically generated synthetic data from ChatGPT, which provides the benchmark to assess the alignment between human and LLMs in awareness of social norms.

Human-in-the-Loop Synthetic Text Data Inspection with Provenance Tracking

Hong Jin Kang[*1], Fabrice Harel-Canada[*1], Muhammad Ali Gulzar[2], Violet Peng[1], and Miryung Kim[1]

[1]University of California, Los Angeles

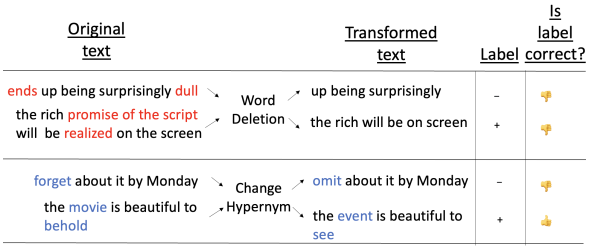
Abstract

Data augmentation techniques apply transformations to existing texts to generate additional data. The transformations may produce low-quality texts, where the meaning of the text is changed and the text may even be mangled beyond human comprehension. Analyzing the synthetically generated texts and their corresponding labels is slow and demanding. To winnow out texts with incorrect labels, we develop INSPECTOR, a human-in-the-loop data inspection technique. INSPECTOR combines the strengths of provenance tracking techniques with assistive labeling. INSPECTOR allows users to group related texts by their *transformation provenance*, i.e., the transformations applied to the original text, or *feature provenance*, the linguistic features of the original text. For assistive labeling, INSPECTOR computes metrics that approximate data quality, and allows users to compare the corresponding label of each text against the predictions of a large language model. In a user study, INSPECTOR increases the number of texts with correct labels identified by 3× on a sentiment analysis task and by 4× on a hate speech detection task. The participants found grouping the synthetically generated texts by their common transformation to be the most useful technique. Surprisingly, grouping texts by common linguistic features was perceived to be unhelpful. Contrary to prior work, our study finds that no single technique obviates the need for human inspection effort. This validates the design of INSPECTOR which combines both analysis of data provenance and assistive labeling to reduce human inspection effort.

1 Introduction

Data augmentation techniques to generate additional training data by transforming existing data can help improve model performance and robustness. However, low-quality texts with garbled text and inappropriate labels may be generated. Figure 1 shows examples of high- and low-quality instances after a transformation is applied. Despite users' inclination to filter out texts of low quality with inappropriate labels, effective debugging of the generated content remains challenging due to the opaqueness of these techniques and the sheer volume of data produced. Investigating the data instances one by one would be extremely demanding and slow.



Original text		Transformed text	Label	Is label correct?
ends up being surprisingly dull	Word Deletion	up being surprisingly	-	👎
the rich promise of the script will be realized on the screen	Word Deletion	the rich will be on screen	+	👎
forget about it by Monday	Change Hypernym	omit about it by Monday	-	👎
the movie is beautiful to behold	Change Hypernym	the event is beautiful to see	+	👍

Figure 1: Examples of transformed texts from the SST2 movie review dataset generated during data augmentation. A transformed text can contain garbled text, or have an inappropriate label. As an example, the "Word Deletion" transformation can mangle the text "ends up being surprisingly dull" into "up being surprising", causing its corresponding label "-" (indicating a negative sentiment) to no longer be appropriate. Of the four examples of synthetically generated texts, only one ("the event is beautiful to see") has an appropriate label.

We propose a human-in-the-loop approach, INSPECTOR, for inspecting generated texts to weed out texts with incorrect labels. For reducing human effort, INSPECTOR applies provenance tracking, inspired by work in the database community (Wang et al., 2015), and assistive labeling. INSPECTOR supports analysis of the provenance of each text in two ways. First, INSPECTOR allows users to group the texts by their *transformation provenance*, i.e., the common transformations that have been applied to produce the text. Second, INSPECTOR allows texts to be grouped by their *feature provenance*, i.e., common linguistic features, e.g., if the text contains a negation, obtained from the relations represented in Abstract Meaning Representation

Figure 2: INSPECTOR: The user alternatives between (1) inspecting the provenance of groups of texts and labels following their (A) common transformation, and (B) common linguistic features, and (2) inspecting individual transformed texts with their corresponding labels, with assistive labeling using (C) the quality metrics, alignment, grammaticality, fluency scores, and (D) LLM predictions.

graphs (Banarescu et al., 2012). Provenance tracking allows the inspection of groups of texts with the same applied transformations or underlying feature. For example, the texts in Figure 1 transformed by *WordDeletion* share a common transformation and can be grouped together by INSPECTOR.

For assistive labeling, INSPECTOR provides two techniques. INSPECTOR computes quality metrics, such as label alignment, grammaticality, and fluency, for each generated text and corresponding label. Finally, INSPECTOR provides the predictions from a large language model that users can compare against the corresponding labels of the texts to find discrepancies.

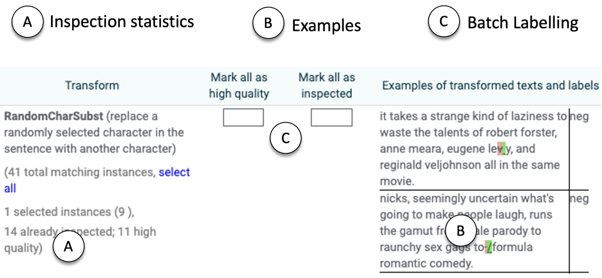
To evaluate INSPECTOR, we ran a within-subject user study with 15 participants. The participants weeded out generated texts with inappropriate labels on two datasets, a sentiment analysis dataset (Socher et al., 2013) and a hate speech detection dataset (Barbieri et al., 2020). We build a baseline by disabling the provenance tracking and assistive labeling features. Participants using INSPECTOR identified 3x and 4x more texts with correct labels (Welch's t-test: $p < 0.005$). Using INSPECTOR, participants were more confident in identifying texts with correct labels, and adopted systematic inspection strategies. The human-selected texts and labels improve model robustness more than randomly sampled data, demonstrating the value of human inspection. No single technique of INSPECTOR was useful to every participant, suggesting that effective inspection of generated texts requires combining complementary techniques.

In summary, INSPECTOR is an approach for inspecting generated texts and corresponding labels using a novel technique for grouping texts by their provenance. INSPECTOR also offers assistive labeling techniques. Our tool is open source (UCLA-SEAL, 2023). A within-subject user study shows that using INSPECTOR enables more effective inspection and that users found grouping texts by their transformation provenance to be the most useful feature. The human-inspected data improves model robustness by up to 32%. We find that no single technique, including LLM-based assistive labeling (Gilardi et al., 2023; Wang et al., 2021), takes away the need for human inspection of generated texts.

2 Design Goals and System Overview

2.1 Design Goals

Acquiring data is a bottleneck for machine learning (Paleyes et al., 2022), but data labeling is not a simple task (Hansen et al., 2013; Kulesza et al., 2014; Chang et al., 2017). In particular, ensuring the quality of data is critical (Liang et al., 2022;



Transform	Mark all as high quality	Mark all as inspected	Examples of transformed texts and labels	
RandomCharSubst (replace a randomly selected character in the sentence with another character) (41 total matching instances, select all 1 selected instances (9), 14 already inspected; 11 high quality)	☐	☐	it takes a strange kind of laziness to waste the talents of robert forster, anne meara, eugene levy, and reginald veljohnson all in the same movie.	neg
			nicks, seemingly uncertain what's going to make people laugh, runs the gamut fr ale parody to raunchy sex gags to /formula romantic comedy.	neg

Figure 3: Transform provenance. A user selects texts and inspects the common transforms (e.g., `RandomCharSubset`) in the transformation provenance pane with their (A) inspection statistics (e.g., the user has inspected 14 texts, with 11 marked as high quality), and (B) view other texts sharing the same transform. A user can then (C) mark all instances sharing the same transform to be correct, obviating the need for inspecting individual texts one by one.

Sambasivan et al., 2021; Paleyes et al., 2022). We identify challenges for inspecting generated texts:

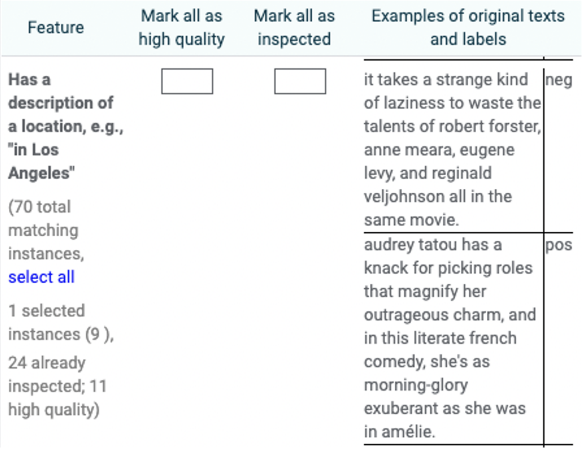
Scale. Data annotation aims to obtain as much data at the lowest possible cost (Wang et al., 2022). Inspection of generated texts shares a similar goal: INSPECTOR should empower users to identify large subsets of texts with correct labels.

Evaluating each instance. Human inspection is difficult because the data-generating processes are opaque. Moreover, users may not enjoy trivial labeling tasks (Cakmak et al., 2010) and may clean data without rigor (Krishnan et al., 2016). Hence, INSPECTOR should discourage ad-hoc inspection and respect human cognition by providing more support for analyzing each text and discovering systematic insights.

2.2 Overview

Workflow. INSPECTOR supports the workflow shown in Figure 2. Through INSPECTOR, users inspect the generated texts and identify texts with correct labels, which are retained in the dataset. INSPECTOR enables inspection of the provenance (the two panes (②) in Figure 2, Section 3.2), and assistive labeling (on each generated text and corresponding label (the table (①) in Figure 2, Section 3.3). For grouping generated texts using provenance tracking, INSPECTOR offers information about (1) the transformations applied to the selected data in the Transformation Provenance pane, and (2) the linguistic features present in the text before transformations were applied in the Feature Provenance pane.

For assistive labeling, INSPECTOR provides (1) computed quality metrics (i.e. grammaticality, fluency, and label alignment) for each instance, and (2) the predictions of a large language model.



Feature	Mark all as high quality	Mark all as inspected	Examples of original texts and labels	
Has a description of a location, e.g., "in Los Angeles" (70 total matching instances, select all 1 selected instances (9), 24 already inspected; 11 high quality)	☐	☐	it takes a strange kind of laziness to waste the talents of robert forster, anne meara, eugene levy, and reginald veljohnson all in the same movie.	neg
			audrey tatou has a knack for picking roles that magnify her outrageous charm, and in this literate french comedy, she's as morning-glory exuberant as she was in amélie.	pos

Figure 4: Feature provenance. A user can select texts, and can inspect linguistic features common to the selected texts (e.g., "Has a description of a location") in the transformation provenance pane with their inspection statistics (e.g., the user has inspected 24 texts, with 11 marked as high quality). Then, a user can mark all instances sharing the same feature to be correct.

We envision that a user of INSPECTOR alternates between the inspection of common transformations and features, forming hypotheses about root causes of quality, and the inspection of individual instances with the help of assistive labeling.

2.3 Usage Scenario.

Suppose that Alice is a model developer who wishes to expand a training dataset. Alice turns to data augmentation but is cynical. She previously observed that these techniques produce large quantities of data with the majority of texts garbled or have unsuitable labels. Alice would not trust a model trained with poor quality data (after all, *garbage in, garbage out*). As she wishes to retain only texts with correct labels but finds going through all instances onerous, Alice gives INSPECTOR a try.

Alice provides the original training dataset to INSPECTOR. INSPECTOR applies the data augmentation techniques to generate data. Next, Alice inspects the texts (Figure 2). First, she inspects several individual instances. As she marks their quality, she hypothesizes that the quality of the texts are influenced by a linguistic feature (e.g., in sentiment analysis, deleting a single negation feature in "I do **not** like stand-up." inverts the sentiment of the text), or a transformation that performs only small-scale modifications. To assess these hypotheses, she selects several instances of interest. Now, the provenance panes display information about the transformations and underlying features of the selected instances (Figure 3).

Alice analyzes the common transformations and underlying linguistic features. Each common transformation and feature has examples of data sharing the same provenance pattern, enabling Alice to understand the transformation or feature. INSPECTOR tracks and displays inspection statistics such as the total number of inspected records and the proportion of records annotated as having suitable labels. As Alice continues to mark data, these statistics are updated. The frequent updates allow Alice to establish trust that the information displayed is meaningful (Lee and See, 2004; Dudley and Kristensson, 2018). From the small proportion of texts with correct labels among the inspected data (in Figure 4), Alice dismisses her hypothesis regarding the linguistic feature. However, the same statistic for a common transform in the transformation provenance pane (Figure 3) appears to support the hypothesis regarding a transformation that rarely distorts the text.

Alice deepens her investigation. She filters the generated texts (Figure 6) to show only texts sharing the common transformation, but there is still too much data. Alice reorders the texts by their grammaticality. She finds that even the lowest-scoring instance has a sufficiently high score (e.g., score > 0.8), suggesting that the texts are never too distorted. Skimming through the texts, she notices that the majority of them have labels that are consistent with the large language model's predictions, suggesting that the transformation usually preserves semantics. With her hypothesis validated, she marks all instances in the group. She notices that some instances with incorrect labels have poor fluency scores. She reorders the texts by their fluency and unmarks the instances with low fluency scores.

Having identified a strategy of finding common transformations among high-quality instances and assessing the grouped instances with the large language model's predictions and quality scores, Alice continues until she believes she has enough data for training the model.

3 Implementation

3.1 Overview

Figure 5 shows an overview of how a user interacts with INSPECTOR. When a user has selected several texts, INSPECTOR displays both the synthetically generated texts, as well as their common transformations and features (Section 3.2). For each individual text instance, INSPECTOR computes quality metrics and displays the predictions of a large language model (Section 3.3).

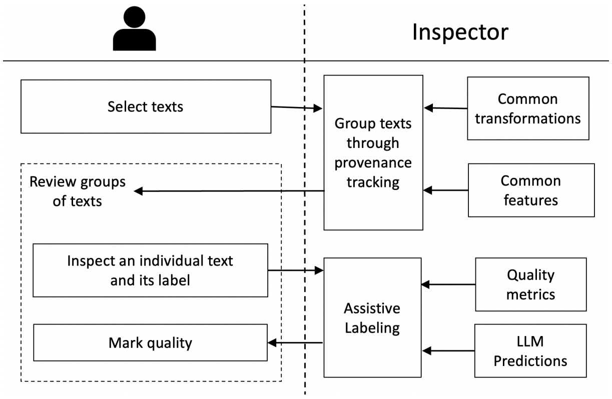


Figure 5: The workflow of a user inspecting data using INSPECTOR.

3.2 Provenance Tracking

The Transform Provenance and Feature Provenance Panes (Figure 3 and Figure 4) surfaces common transformations and linguistic features in the provenance of the user-selected generated texts. Providing details about the transforms and features, INSPECTOR allows users to inspect groups of texts sharing either the same transformations or linguistic features.

The Transformation Provenance pane summarizes recurring patterns in the transformations applied to generate the data. This allows the investigation of root causes of poor quality related to the text transformations, e.g., a random word deletion. The Feature Provenance pane displays common linguistic features (extracted from Abstract Meaning Representation graphs (Banarescu et al., 2012)) in the texts before they were transformed. This allows the investigation of possible root causes of low quality stemming from features, e.g., negations ("not"), in original texts.

The inspection statistics are presented for each common transform or feature (in the example in Figure 3, the user has inspected 14 texts in total, with 11 of them marked as high quality), enabling the user to make generalizations about the group of data. Examples of other instances in the group are presented, with the transformed parts of the text highlighted to focus human attention, which may increase labeling efficiency (Choi et al., 2019). Users can filter data to view other instances with a shared transformation or feature provenance.

Batch inspection. Users can mark a batch of instances (Ashktorab et al., 2021) on a group of data (e.g., all data produced by the same transformation type). This enables greater inspection efficiency by applying the same decision across the group.

3.3 Assistive labeling

Figure 6 shows the table containing the transformed texts and their corresponding labels. INSPECTOR presents the following quality metrics:

1. Fluency, measured through language perplexity using GPT-2 (Radford et al., 2019),
2. Grammaticality, measured as the degree to which the text is free from grammar errors using `language-tool` (lan, 2023),
3. Label Alignment, measured through predictions of label quality (Northcutt et al., 2021).

While Fluency and Grammaticality are measures of linguistic quality, Label Alignment measures label quality using CleanLab (cleanlab.ai, 2023), a method for identifying mislabelled data (Northcutt et al., 2021). We normalize each score such that they range between 0 and 1, with 0 indicating the lowest quality and 1 the highest. INSPECTOR allows the texts to be sorted by these metrics.

INSPECTOR provides information about the outputs of a large language model (*gpt-3.5-turbo*) prompted to predict the transformed texts' labels: 1) its predictions, 2) explanations of each prediction, 3) consistency of its predictions with the instances' labels. Viewing predictions from the LLM, which may have human-level performance (Gilardi et al., 2023; Wang et al., 2021), can increase labeling efficiency (Lai and Tan, 2019; Desmond et al., 2021) and explanations contextualizing each prediction increases the user's trust in them (Bansal et al., 2021). Inconsistencies between labels and LLM predictions may imply altered semantics after a text transformation. Together with the quality metrics, the outputs of the LLM provide evidence for users to make decisions, guiding them away from ad-hoc assessments.

Table 1: The text transformations for generating data in the user study. For example, given the text "ends up being surprisingly dull" with a "negative" label, "Word Deletion" produces a new text "up being surprising" with the same corresponding label.

Category	**Transformation**
Swap	ChangeHypernym, ChangeHyponym, ChangeLocation, ChangeName, ChangeNumber, ChangeSynonym, RandomSwap, RandomSwapQwerty
Punctuation	ContractContractions, ExpandContractions, InsertPunctuationMarks
Typos	HomoglyphSwap, WordDeletion, RandomCharDel, RandomCharInsert, RandomCharSubst, RandomCharSwap
Text Insert	RandomInsertion
Emojis	AddNeutralEmoji, RemoveNeutralEmoji

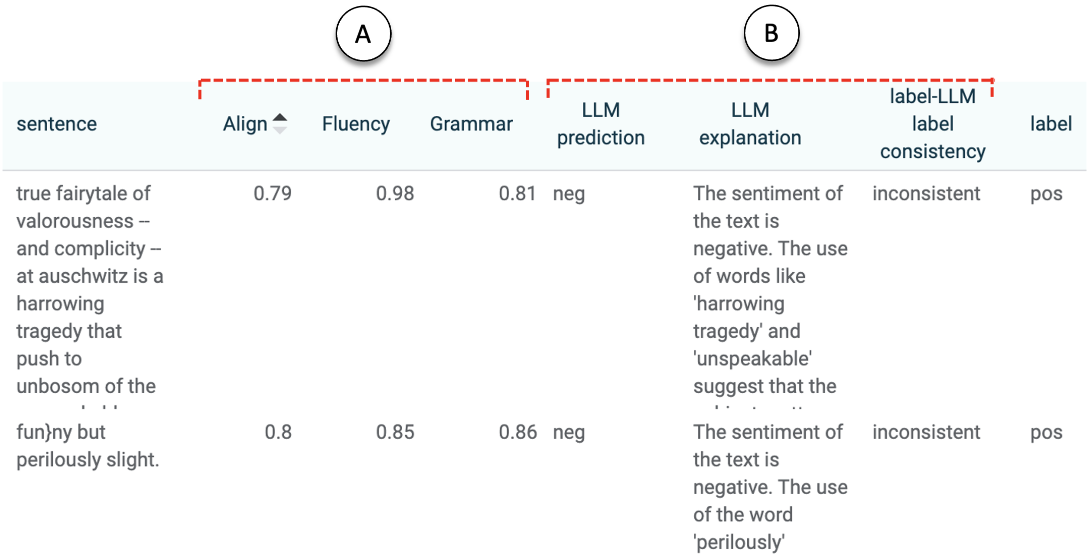
4 User Study

We conducted a within-subject study with 15 participants to assess the effectiveness of INSPECTOR for weeding out low-quality texts. We developed INSPECTOR as a web application. As a baseline, we developed a variant of INSPECTOR without the effort-reduction techniques. We investigate the following questions:

1. Does INSPECTOR increase efficiency in identifying texts with correct labels?
2. How useful is each effort reduction technique offered by INSPECTOR?
3. Are models more robust when trained using data identified using INSPECTOR?

4.1 Study Design

Tasks. The study involves two datasets, the sentiment analysis dataset, SST2 (Socher et al., 2013), and a hate speech detection dataset, TweetEval (Barbieri et al., 2020), described in Table 2. Table 1 shows the list of considered text transformations (Morris et al., 2020; Ribeiro et al., 2020; Karimi et al., 2021; Wei and Zou, 2019; Harel-Canada et al., 2022). For each task completed by the user, we finetune BERT (Devlin et al., 2018) on the identified high-quality data for up to 10 epochs.



sentence	Align	Fluency	Grammar	LLM prediction	LLM explanation	label-LLM label consistency	label

fun}ny but perilously slight.	0.8	0.85	0.86	neg	The sentiment of the text is negative. The use of the word 'perilously'	inconsistent	pos

Figure 6: INSPECTOR enables assistive labeling by providing (A) quality metrics such as label alignment, fluency, and grammaticality. Label alignment is a measure of label quality, while fluency and grammaticality are measures of linguistic quality. It also shows the (B) LLM predictions for a text compared to its corresponding label.

Table 2: The two datasets in the user study. We analyze only the synthetic texts generated using the data augmentation techniques. During the course of the user study, 100% and 99% of the SST2 and TweetEval datasets were reviewed by at least one participant.

Dataset	Description	Size
SST-2	Predict the sentiment of a movie review.	613
TweetEval (Hate)	Predict if a tweet contains offensive discourse.	763

Participants. We recruited 15 participants by reaching out to students in the Computer Science department. 11 of them are Ph.D. students, 2 are master students, and 2 are undergraduates. 7 participants had less than 1 year of machine learning experience, 2 had about one year, 2 had 2-5 years of experience, and 2 had more than 5 years of experience. The participants also self-reported their familiarity with inspecting machine learning datasets and understanding mislabelled data on a 7-point Likert scale. The mean familiarity was 3.4, where 1 is "Most unfamiliar" and 7 is "Most familiar". This level of experience is identical to data annotators in industry, who do not have a machine learning background (Wang et al., 2022).

Study Protocol. Our study involves two datasets and two tools. We design a within-subjects study where each participant investigates both datasets and experiences using both tools. For each task, the participant used only the assigned tool, either INSPECTOR or Annotator, the variant of INSPECTOR without the effort reduction techniques. The study requires the completion of 2 tasks, with each task requiring 20 minutes at most. We design our study to be completed in 60 minutes. Before the users started on a task, we asked for the participants' consent to record their usage of the tools. Then, they spent 10 minutes working through a tutorial and warm-up questions. After completing the tasks, the participants were directed to a post-study questionnaire to share their experiences and feedback about the tools. We also solicited responses about the participants' inspection strategy.

5 Results

In this section, we report and analyze the results of our user study. We denote each participant as P#.

5.1 Reduction in Human Effort

To assess inspection efficiency, we counted the number of texts with correct labels identified by the participants. Table 3 shows that using INSPECTOR leads to 3x and 4x more texts on the sentiment analysis dataset and the hate speech detection dataset. Using INSPECTOR, participants identified an average of 277 and 259 high-quality instances compared to 82 and 63 instances using the baseline on the SST2 and TweetEval's Hate Speech dataset, respectively. The differences in efficiency is significant (Welch's t-test, $p < 0.005$).

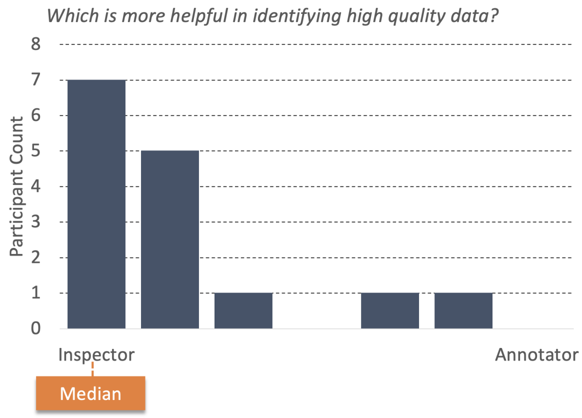

Figure 7: Most participants perceived INSPECTOR to be more helpful in winnowing out generated texts with incorrect labels (such as the examples in Figure 1).

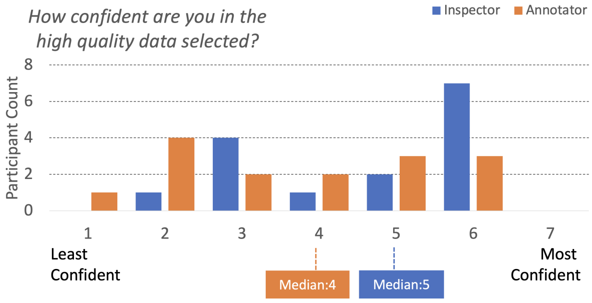

Figure 8: Participants using INSPECTOR were more confident of their inspections, with a median rating of 5 compared to the baseline of 4.

Table 3: The average number of texts with correct labels identified. INSPECTOR improves over a baseline without provenance tracking and assistive labeling by 3× and 4×. SA: Sentiment Analysis, HS: Hate Speech Detection

Approach	**SA**	**HS**
INSPECTOR w/o provenance tracking and assistive labeling	82	63
INSPECTOR	277	259

Figure 7 shows that the participants found INSPECTOR more useful and were more confident of their results. 13 of the 15 participants indicated that they preferred using INSPECTOR over the baseline tool. Participants had a higher median level of confidence in their inspections using INSPECTOR (5 vs 4 on a 7-point scale, in Figure 8).

The techniques in INSPECTOR changed the participants' perception of the task's nature. P3 indicated that INSPECTOR "could give initial results. I'm more acting like a verifier". They found INSPECTOR more usable in identifying patterns. Comparing INSPECTOR and the baseline, 13 of the 15 participants found INSPECTOR more helpful in identifying patterns for inspecting the texts. They reported using the techniques of INSPECTOR in their inspection strategies. P8 wrote "My main strategy was to find inconsistent patterns in already labeled data and LLM" while P1 mentioned that "Sentences with a grammar score < 0.92 are almost always low-quality.". Conversely, using the baseline, participants found strategically inspecting the data difficult. P8 wrote that dissecting the data "is utterly not possible" and "Using `ctrl+f` was really painful."

Table 4: Usefulness of the techniques of INSPECTOR rated by the participants (out of 7). A higher rating indicates the technique was perceived to be more useful for inspection. Grouping texts by common transformations was perceived to be the most useful technique.

Technique	**Average Rating**
Transform Provenance	4.5
Quality Metrics (grammaticality, fluency, & alignment)	4.3
LLM Guidance	4.3
Feature Provenance	1.9

5.2 User Ratings of Individual Features

In the post-study questionnaire, participants rated the techniques of INSPECTOR and described how they inspected the data. Table 4 summarizes the participants' feedback. Grouping data by transformation provenance was the most appreciated technique, followed by the assistive labeling techniques. On a 7-point Likert scale, participants assigned Transform Provenance the highest average rating of 4.5, followed by the two assistive labeling techniques with average ratings of 4.3. P8 indicated that using transform provenance was the "main strategy I used to identify trends". Participant C7 wrote that provenance tracking allows her to "reason about whether a specific transformation can lead to a reduction of data quality".

Diverse inspection strategies. The responses to the post-study questionnaire reflected a wide range of strategies. No single technique of INSPECTOR was found to be useful by every participant. We qualitatively analyze the free responses. A majority (11) of the participants used the transformation provenance to make decisions. 9 participants described using the quality metrics (grammaticality, fluency, label alignment), and 8 participants men-

Table 5: Results comparing the robustness of BERT after finetuning on additional data. We measure the attack success rate of DeepWord (the lower the better). SA: Sentiment Analysis, HS: Hate Speech Detection

Approach	**SA**	**HS**
Randomly sampled	0.61	0.50
Human-guided	0.59	0.34

tioned using outputs of the large language model. All participants found at least one technique of INSPECTOR to be useful (rating at least 4 out of 7 and using it in their workflow). This suggests no one technique obviates the need for human inspection.

Batch Inspection. A majority (11 of the 15) of the participants used the batch inspection feature, marking an average of 5 groups. The participants appreciated batch inspection and used it after manual validation of a few representative instances. P13 wrote "if most of the labels are not affected by the transformation and are indeed high-quality by manual inspection, I mark all such entries as high-quality.". However, not all participants found grouping the texts by their provenance useful or meaningful. Two participants applied a strategy of trying to go through the data one by one. P11 wrote that she did not consider data provenance for grouping the texts "in order to give an unbiased opinion" for each text and its label.

5.3 Robustness

Next, we assess the improvements in model robustness when training a model with the texts with correct labels collected by the participants. As a baseline, we construct a randomly sampled dataset with the average number of data instances selected using INSPECTOR. We assess the robustness of the model by measuring the attack success rate of DeepWord (Gao et al., 2018), a method of generating adversarial attacks. Using the implementation of DeepWord in TextAttack (Morris et al., 2020), we generated 100 attacks on each model. More robust models would face fewer successful attacks.

On the SST2 dataset, 4 out of 8 participants marked data that led to more robust models than randomly sampled data. On the TweetEval dataset, all 7 participants identified data that led to more robust models than randomly sampled data. The attack success rate of DeepWord on models trained with randomly selected data was 0.61 on the SST2 dataset and 0.5 on the TweetEval dataset. Using the inspected data, the attack success rate decreases to an average of 0.59 and 0.34 on SST2 and TweetEval, respectively. On TweetEval, this corresponds to a 32% improvement. Overall, the texts identified using INSPECTOR improved model robustness.

6 Implications

Our study showed that INSPECTOR empowered users to be effective and confident in inspecting transformed texts and their corresponding labels.

Transformation provenance was the most useful technique. The participants perceived transformation provenance to be the most useful technique provided by INSPECTOR. Even when participants did not use it to perform batch inspection, they found the additional information useful. P2 considered this information to inspect data, writing that it "showed whether a malformed sentence was in the original text or mangled by a transformation.".

Assistive labeling helped users build trust. The participants were aware of the risk of including incorrect labels when labeling a batch of texts. Thus, the users had to trust the guidance and automation provided by INSPECTOR. Users were able to build trust using the inspection statistics of the groups of generated texts. The assistive labeling techniques were also helpful for building confidence. P8 wrote "When the fluency and grammaticality scores are both high, I am more confident to label the data as high quality."

The linguistic features were perceived to be ineffective. Surprisingly, users found grouping the texts by their common linguistic features to be ineffective. The participants did not always understand their relevance to the task. P14 wrote "the features are very low level and it is not clear how they are related to the labeling quality".

Limited impact on inspection accuracy. We observed that users tended to only mark texts they were confident about. Comparing the participants' inspections to the ground-truth labels annotated by one of the authors of this paper, we find that the use of INSPECTOR only had a limited impact on the accuracy of the user's inspections. On SST2, INSPECTOR slightly decreased labeling accuracy from 88% to 85.3%. On TweetEval, INSPECTOR increased accuracy from 89.1% to 90.0%. These differences are not statistically significant (p-value > 0.05). This suggests that users of INSPECTOR inspected more texts with less effort and increased confidence while maintaining the same level of accuracy.

7 Related Work

7.1 Debugging Machine Learning

Testing models. DynaBench (Kiela et al., 2021) evaluates models with challenging human-provided data. AdaTest (Ribeiro and Lundberg, 2022) generates more test cases similar to user-provided tests. These studies focus on models but do not support debugging data, which is the focus of INSPECTOR.

Grouping data for data inspection. SliceFinder (Chung et al., 2019) and What-If (Wexler et al., 2019) are tools for understanding the subsets of data with poor model performance. Zeno (Cabrera et al., 2023) groups data on properties extracted by user-written Python programs. Tempura (Wu et al., 2020) supports data inspection by grouping data using structural templates abstracted from concrete data instances. Unlike these tools, INSPECTOR groups data by their provenance.

7.2 Cleaning Data

For cleaning tabular data, Data Civilizer (Rezig et al., 2019) is a data pipeline-debugger for identifying low-quality data (e.g., malformed values) that cause incorrect data analysis outputs through inserting breakpoints and the visualization of the intermediate records. Unlike Data Civilizer, INSPECTOR is not a breakpoint debugging tool. Instead, it helps users filter out data with unsuitable labels. Wrangler (Kandel et al., 2011) cleans dirty data by inferring data types (e.g., integers) and semantic roles (e.g., zip code) for identifying anomalous data. Potter's Wheel (Raman and Hellerstein, 2001) cleans dirty data but detecting them may require users to implement an API to define constraints (e.g., date formats). On the other hand, INSPECTOR assists human users in interactively identifying texts with incorrect labels without requiring programming literacy.

Ruler (Choi et al., 2021) and TagRuler (Evensen et al., 2020) learn rules for annotating unlabelled data based on the text. INSPECTOR guides users to weed out texts with incorrect labels. While feature provenance in INSPECTOR is similar to the token-based rules in Ruler or TagRuler, it uses linguistic features rather than tokens.

8 Conclusion

We present INSPECTOR for winnowing synthetic texts with incorrect labels generated during data augmentation. In a within-subject user study, participants using INSPECTOR were 3× and 4× more effective. Users found that grouping data by their shared common transformations to be the most useful technique. Assistive labeling allowed them to build trust in the tool. Surprisingly, users perceived the linguistic features to be ineffective. INSPECTOR is the first interactive human-in-the-loop approach for examining text augmentation data for classification tasks by combining provenance inspection and assistive labeling techniques.

We publicly release INSPECTOR. INSPECTOR is available at https://github.com/UCLA-SEAL/ProvenanceInspector.

9 Limitations

INSPECTOR guides human users using several techniques, including the computation of quality metrics and the use of Abstract Meaning Representation for analyzing feature provenance. Due to these dependencies, INSPECTOR is only applicable to texts in languages that are supported by the tools for computing the metrics (CleanLab, LanguageTool) and converting the text to Abstract Meaning Representation.

INSPECTOR was evaluated through a user study. Although our study was performed with student participants, the participants in our study share a similar expertise level with full-time data annotators in industry — i.e. data annotators in industry are not full-time data scientists or engineers and they generally do not have any machine learning background. Consequently, having student participants is unlikely to impact generalizability.

While we evaluated INSPECTOR on only two datasets, INSPECTOR does not use compute-intensive techniques and would work on large datasets. As the design of INSPECTOR is not specific to the tasks in the user study, we believe that our findings would generalize to other NLP tasks.

Labeling hate speech is known to be inherently ambiguous and influenced by the annotator's beliefs even when labeling guidelines are provided. INSPECTOR does not solve the issue of annotation bias.

Our work investigated only human effort in inspecting texts generated as part of data augmentation. Our insights may, therefore, be specific to data augmentation. We hope to extend this analysis to other data inspection tasks.

10 Ethics Statement

Our work aims to allow human users better insights into generated data. These data may contain toxic, offensive content, and INSPECTOR may expose these content to its users. Alone, INSPECTOR does not generate biased or offensive text, however, it postprocesses the output of data augmentation techniques which may produce harmful texts.

We obtained an exemption from the UCLA IRB to run the user studies.

Abstract

Recently, instruction-tuned large language models (LLMs) are showing prominent performance on various tasks, such as question answering. However, the majority of instruction-tuned LLMs are English-centric, which hinders their application to low-resource language QA. In this paper, we propose COde-Mixed Multilingual Instruction Tuning (COMMIT) to adapt English-centric LLM to low-resource language QA. We point out two main causes of English-centricness: imbalance of unlabeled data, and English-centric instruction tuning datasets. To deviate from English-centric instruction tuning, we propose to specialize code-mixing for instruction tuning, which blocks code-mixing in English templates, to leverage the potential of its superiority. To overcome data imbalance, we perform cross-lingual alignment. The majority of cross-lingual alignment works focused on making representations similar, which is not desirable to decoder-based LLMs, such as LLaMA. Therefore, we propose code-mixed continual causal language modeling to align the decoder. COMMIT improves the exact match score of low-resourced language QA by up to 32x. Code is publicly available.

1 Introduction

Recently, large language models (LLMs) have shown prominent performance on various natural language processing tasks (Brown et al., 2020; OpenAI, 2023; Touvron et al., 2023), such as question answering (QA). Moreover, instruction-tuning (Wang et al., 2022b; Taori et al., 2023; Wang et al., 2023) further updates the LLMs to be more efficient.

However, the majority of instruction-tuned LLMs are English-centric. The reasons are two-fold: both the pretraining corpora and the instruction-tuning datasets are English-centric Therefore, the performance of QA with low-resourced languages is lacking.

Resolving two would boost performance, but it is not trivial. First, to alleviate the former problem, the imbalance in unlabeled data, a naïve approach would be pretraining the LLM again with balanced data, which is tremendously costly (Zeng et al., 2023). Alternatively, cross-lingual alignment (Wu and Dredze, 2020; Alqahtani et al., 2021) can be considered. These methods focus on making the representations of different languages similar, particularly on encoder-based architectures such as mBERT (Devlin et al., 2019) or XLM-R (Conneau et al., 2020). However, for decoder-based LLMs, such as LLaMA (Touvron et al., 2023), similar representation across languages may confuse what language should decoder generate, thus such an approach is undesirable. Second, to deviate from English instruction tuning datasets, machine translation could be considered. However, assuming high-quality machine translation for low-resource languages can be impractical. Moreover, it ignores cross-lingual transferability from high-resource languages.

To overcome such shortcomings, in this paper, we propose **CO**de-**M**ixed **M**ultilingual **I**nstruction **T**uning (COMMIT). First, to efficiently utilize the English instruction tuning dataset, we code-mix it using the provided lexicon. Since a dictionary is much more available than machine translation (Wang et al., 2022a), it is more practical to assume a dictionary. Furthermore, code-mixing can leverage cross-lingual alignment (Lin et al., 2020).

While promising, we notice more room for improvement than naïvely performing code-mixing to the all part of the data. Thus, we specialize code-mixing for instruction tuning. Inspired by the fact that the English prompt is more effective even in multilingual LLMs (Muennighoff et al., 2023), we keep the template in English to preserve its strength,

---

without allowing code-mixing.

Second, to alleviate unlabeled data imbalance, we perform cross-lingual alignment beforehand. To align, we propose continual causal language modeling with code-mixed corpus, relying on the cross-lingual alignment ability of the code-mixing (Qin et al., 2020; Lin et al., 2020).

Experiments on MLQA (Lewis et al., 2020), and XQuAD (Artetxe et al., 2020) show the effectiveness of COMMIT–it increases the exact match up to 32x. Our code is publicly available.[1]

2 Related Works

2.1 Large Language Models

LLMs, which are pre-trained with language modeling over a large corpus, contain world knowledge (Zhao et al., 2023). To generalize world knowledge over diverse tasks such as question answering, LLMs reduce the gap between the pre-training and downstream tasks. Specifically, diverse tasks are formulated as language modeling, under which LLMs are pre-trained (Raffel et al., 2020). Additionally, LLMs adopt a decoder-only transformer which is specialized for the language modeling task (Zhao et al., 2023; Touvron et al., 2023).

2.2 Instruction Tuning for Non-English

For better generalization on unseen tasks, LLMs are instruction-tuned, fine-tuning to follow natural language instruction of such tasks (Chung et al., 2022). To generate such data for non-English languages, the simplest approach would be human annotation (Zhang et al., 2023), which is expensive. An alternative approach is to translate the instruction tuning data (Cui et al., 2023; Muennighoff et al., 2023; Li et al., 2023a; Santilli and Rodolà, 2023; Holmström and Doostmohammadi, 2023; Chen et al., 2023a,b; Lai et al., 2023; Li et al., 2023b) or utilize machine translation data (Zhu et al., 2023a; Ranaldi et al., 2023), or generation with an LLM (Wei et al., 2023). However, for low-resourced languages, high-quality translation or generation may not be available. In contrast, we assume the existence of a dictionary, which is a much more practical assumption (Wang et al., 2022a). Our proposed COMMIT can generate an instruction-tuning dataset for the target language, only relying on a dictionary.

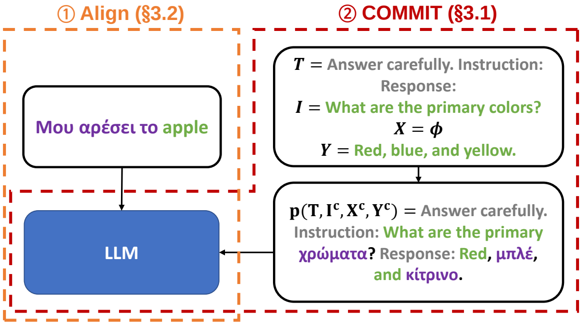

Figure 1: Overview of the proposed method, Align (§3.2) + COMMIT (§3.1). Grey represents the template, which is fixed, purple represents the target language, and green represents the replaceable English words.

3 Proposed Method

We assume that the given instruction tuning dataset is in English, and a dictionary is provided. This is a realistic scenario, considering the existing instruction tuning datasets (Taori et al., 2023; Wang et al., 2022b), and the availability of a dictionary (Wang et al., 2022a). We also assume that our English-centric LLM covers the majority of target language tokens, which is practical considering language contamination (Blevins and Zettlemoyer, 2022).

3.1 COMMIT: Specialized Code-Mixing for Instruction Tuning

We first formally define instruction tuning. For given instruction I, and input X, the model is expected to generate the specific output Y, with the aid of template T. X can be an empty string, while I must be a non-empty string, as exemplified in Figure 1. The model does language modeling with the sentence formulated as follows:

$$p(T, I, X); Y \tag{1}$$

where p is a function to put the words of I, X among T, and ; is the concatenation.

Recall that we take a practical assumption that T, I, X, Y are typically in English. Direct instruction tuning with the dataset would not efficiently transfer the knowledge to the target language. To efficiently utilize the English dataset for the target language, we may perform code-mixing. For $S \in \{T, I, X, Y\}$, let $S = [w_1, \cdots, w_n]$. For given dictionary $D = \{(w_i, t_i)\}$ between English and the target language, we generate code-mixed

---

[1] `https://github.com/thnkinbtfly/COMMIT`

sentence S^c as follows:

$$x_i \sim B(\alpha) \tag{2}$$

$$c_i = \begin{cases} t_i & \text{if } x_i = 1, (w_i, t_i) \in D \\ w_i & \text{otherwise} \end{cases} \tag{3}$$

$$S^c = [c_1, \cdots, c_n] \tag{4}$$

where B is the bernoulli distribution, and α is the hyperparameter for it. The model may do language modeling with the sentence $p(T^c, I^c, X^c); Y^c$, which we call 'naïve code-mixing'.

While promising, we conjecture mixing all English words would hinder the transfer of the knowledge learned in English-centric LLM. It is known that English prompts show superior performance than prompts in the target language, even in multilingual pretrained language models (Lin et al., 2022; Muennighoff et al., 2023; Huang et al., 2023). Inspired, by this phenomenon, we propose to keep the template of instruction tuning in English, to preserve the strength of English prompts. To this end, we let the model do language modeling with the following sentence:

$$p(T, I^c, X^c); Y^c \tag{5}$$

3.2 Aligning Before COMMIT

COMMIT may improve the performance of instruction tuning, however directly performing COMMIT may not fully leverage cross-lingual ability in the given English-centric language model. It is known that even the multilingual pretrained language models do not fully leverage cross-lingual ability, therefore cross-lingual alignment has been proposed (Kulshreshtha et al., 2020; Alqahtani et al., 2021). We shift our view to this aspect.

We need to carefully select the cross-lingual align method, since the majority of them focus on encoder-based models, making the representation similar. This is undesirable for decoder-based models, since it would confuse the decoder with what language should it generate.

To this end, we choose code-mixing (Qin et al., 2020; Lin et al., 2020) as a tool for cross-lingual alignment. Since it does not explicitly force the language model to make representation similar, such confusion would be reduced. Formally, before performing COMMIT, given the sentences of the corpus in target language C, we first construct the code-mixed corpus C^c, similarly to Eq. 4. Then we perform continual causal language modeling with the following objective:

$$L_{align} = -\frac{1}{N} \sum_i logP(c_i^c | c_{<i}^c) \tag{6}$$

where $C^c = [c_1^c, \cdots, c_N^c]$, $c_{<i}^c = [c_1^c, \cdots, c_{i-1}^c]$.

lang (iso code)	lang family	# wiki	ling.sim
Greek (el)	Indo-European	209K	0.729
Thai (th)	Tai-Kadai	147K	0.712
Hindi (hi)	Indo-European	151K	0.683
Bengali (bn)	Indo-European	121K	0.680
Tamil (ta)	Dravidian	146K	0.620

Table 1: Languages used for the experiments in this paper. We report the size of the unlabeled dataset (# wiki), and linguistic similarity with the English.

4 Experiments

4.1 Experimental Settings

We use LLaMA-7B (Touvron et al., 2023) as our representative English-centric large language model.

Tasks and Datasets For instruction tuning, we use the ALPACA dataset (Taori et al., 2023), and for continual causal language modeling, we utilize Wikipedia corpus.[2] For code-mixing, we use the MUSE dictionary (Lample et al., 2018).

We evaluate our model on the extended version of LM-EVALUATION-HARNESS (Gao et al., 2021).[3] We select the available QA datasets: MLQA (Lewis et al., 2020), and XQuAD (Artetxe et al., 2020). We also implement IndicQA (Doddapaneni et al., 2023), which additionally requests unanswerable question classification, differently from MLQA or XQuAD.

Language selection Among languages with given QA datasets and dictionaries, we choose languages with less than 250K Wikipedia articles, which are the five least-resourced languages: Greek (el), Hindi (hi), Thai (th), Tamil (ta), and Bengali (bn). These languages are not covered in the pretraining of LLaMA (Touvron et al., 2023). We describe the size of the unlabeled dataset, and linguistic similarity with English,[4] in Table 1.

COMMIT	4.35	6.22	4.37	9.92	6.22
CLM+COMMIT	4.19	4.96	7.39	6.22	5.69
Align+COMMIT	6.04	7.56	8.15	8.57	**7.58**

Table 3: Exact match score of aligning with code-mix, or simply consuming data with CLM, before COMMIT.

Implementation Details To perform instruction tuning, we largely follow the setting from Alpaca (Taori et al., 2023).[5] We use learning rate of 2e-5; sequence length of 512; warmup for 3% of total steps; and train for 3 epochs. We use α of 0.9 for code-mixing.[6] We perform continual causal language modeling with similar hyperparameters, except that we train for 10K steps. We use α of 0.5 for code-mixing. COMMIT is performed on TPUv3-8, taking less than 8 hours in total. The code is based on EasyLM (Geng, 2023), implemented with JAX (Bradbury et al., 2018).

We evaluate the LLMs with a batch size of 2, in a zero-shot manner. Evaluation is conducted on RTX3090, which takes less than an hour.

Baselines We compare COMMIT with the following baselines. a) **LLaMA:** The baseline LLM; b) **Alpaca:** The baseline instruction-tuned LLM; c) **LLaMA/Alpaca+En Prompt:** We try English prompt instead of prompt in the target language, since they are known to perform better (Lin et al., 2022; Huang et al., 2023); d) **naïve codemix:** We use naïve code-mix, described in §3.1; e) **Machine Translation:** We use Google Translate API to translate the instruction tuning dataset.

4.2 Experimental Results

Superiority of COMMIT COMMIT outperforms the baselines (Table 2). For example, XQuAD th EM of Align+COMMIT is more than 32x larger than LLaMA or Alpaca. Using English prompts does improve the performance, however, COMMIT even outperforms this tough baseline. For example, XQuAD th EM score or MLQA hi EM score of COMMIT is about 6x larger than the baselines with English prompts.

Overall, the average scores of Align+COMMIT is the best among the comparisons (Table 2).The exception of a lowered score of Greek (el) can be explained by the linguistic similarity with English (Table 1). Since Greek is showing the maximum similarity, the LLM is already aligned well; additional alignment may harm the language model. Note that the similarity score does not perfectly correlate with the performance gain (e.g. th vs hi), however combined with linguistic genealogy, we can roughly explain the trend. We leave the improving the quality of the similarity metric as a future work.

English prompt is not needed Surprisingly, COMMIT favors target language prompts over English prompts (Table 2), which implies COMMIT effectively adapted the model to the target language. This favor is more desirable for real-world use cases, which is different from the known fact that LLMs favor English prompts (Lin et al., 2022; Huang et al., 2023).

Efficiency of aligning beforehand One may question whether the improvement simply comes from an increase in data. Table 3 discloses that simply consuming the target language corpus with causal language modeling (CLM) even lowers the average score, ruining the language model. In contrast, our approach efficiently utilizes the corpus, improving the performance.

---

[5] `https://github.com/tatsu-lab/stanford_alpaca`

[6] We probed {0.8,0.9,1.0} since large code-mix ratio is preferred in language adaptation (Wang et al., 2022a), and selected based on MLQA val EM score.

	MLQA	XQUAD			
	hi	hi	th	el	avg

COMMIT	4.35	6.22	4.37	9.92	**6.22**

Table 4: Exact match score of specialized code-mix of COMMIT, naïve code-mix, and no code-mixing.

	MLQA	XQuAD			
	hi	hi	th	el	avg
Machine Translation	5.19	2.52	8.57	6.39	5.67
Align+COMMIT	6.04	7.56	8.15	8.57	**7.58**

Table 5: Exact match score of COMMIT and instruction tuning with machine translation.

Effectiveness of specialized code-mix Our specialization of code-mixing for instruction tuning is effective (Table 4). While naïve code-mixing improves the performance over not performing it, COMMIT outperforms naïve code-mixing.

Outperforming Machine Translation COMMIT outperforms MT baseline (Table 5). This may look counter-intuitive, but consistent observation was made (Ranaldi et al., 2023), benefiting from cross-lingual alignment during instruction-tuning. Based on this observation, we re-emphasize our contribution: Our proposed code-mixing, by using only a dictionary, enables cross-lingual alignment (Lin et al., 2020) during the instruction tuning, even outperforming compute-intensive MT-instruction-tuning.

Observation consistent on IndicQA When we extend our evaluation to include classification of unanswerable questions, utilizing IndicQA, the observations are consistent (Table 6). Align+COMMIT outperforms the baselines, COMMIT, and machine translation.

	ta	bn	avg
LLaMA	18.51	15.83	17.17
Alpaca	20.62	16.00	18.31
LLaMA+En prompt	19.96	15.94	17.95
Alpaca+En prompt	19.24	15.71	17.47
Machine Translation	22.67	17.87	20.27
COMMIT	22.28	17.92	20.10
Align+COMMIT	**24.45**	**20.25**	**22.35**

Table 6: Exact match score of COMMIT and comparisons on IndicQA.

5 Conclusion

We studied adapting English-centric LLM to low-resource language QA. We proposed Align+COMMIT, aligning and then performing a specialized code-mixing method for instruction tuning. Experiments show that each component contributes to improving the performance.

6 Limitation

In this work, we followed the most common way to code-mix the data (Qin et al., 2020; Lin et al., 2020). Considering context or morphology during code-mixing would be beneficial (Feng et al., 2022; Zhu et al., 2023b).

However, considering context or morphology is not necessary to claim the strength of our proposed method, as COMMIT outperforms machine translation, a solution scarcely violates such context or morphology. We would probe better code-mixing strategy (Feng et al., 2022; Zhu et al., 2023b) or optimization techniques such as LoRA (Hu et al., 2022) as future work.

DiLM: Distilling Dataset into Language Model for Text-level Dataset Distillation

Aru Maekawa **Satoshi Kosugi** **Kotaro Funakoshi** **Manabu Okumura**
Tokyo Institute of Technology
`{maekawa, kosugi, funakoshi, oku}@lr.pi.titech.ac.jp`

Abstract

Dataset distillation aims to compress a training dataset by creating a small number of informative synthetic samples such that neural networks trained on them perform as well as those trained on the original training dataset. Current text dataset distillation methods create each synthetic sample as a sequence of word embeddings instead of a text to apply gradient-based optimization; however, such embedding-level distilled datasets cannot be used for training other models whose word embedding weights are different from the model used for distillation. To address this issue, we propose a novel text dataset distillation approach, called *Distilling dataset into Language Model (DiLM)*, which trains a language model to generate informative synthetic training samples as text data, instead of directly optimizing synthetic samples. We evaluated DiLM on various text classification datasets and showed that distilled synthetic datasets from DiLM outperform those from current coreset selection methods. DiLM achieved remarkable generalization performance in training different types of models and in-context learning of large language models. Our code will be available at `https://github.com/arumaekawa/DiLM`.

1 Introduction

The successful advancements in machine learning in a wide range of fields are due to the scaling-up of deep neural networks and large training datasets. In the natural language processing (NLP) field, large language models (LLMs), which are pre-trained with a huge amount of text, such as BERT- and GPT-family models (Devlin et al., 2019; Liu et al., 2019; Radford et al., 2019; Brown et al., 2020), have shown remarkable capabilities for various NLP tasks. However, training such large-scale models requires large computational resources and a long time, which makes it difficult to develop new LLMs, and even to fine-tune them.

To address this issue, dataset distillation (Wang et al., 2018b) has attracted much attention in the machine learning community, which aims to reduce training costs by compressing training datasets. In contrast to traditional coreset selection approaches (Wolf, 2011; Sener and Savarese, 2018; Welling, 2009), which heuristically select a small subset of representative training samples from the original dataset, dataset distillation creates more informative synthetic samples by distilling the knowledge from the original dataset. With this approach, synthetic samples are optimized with gradient descent according to objective functions for dataset distillation, including meta-learning (Wang et al., 2018b), gradient matching (Zhao et al., 2021), training trajectory matching (Cazenavette et al., 2022), and feature distribution matching (Wang et al., 2022; Zhao and Bilen, 2023). The recent remarkable performance of dataset distillation, especially in the computer vision (CV) field, has also led to studies of its various applications, including neural architecture search (Such et al., 2020; Medvedev and D'yakonov, 2021), federated learning (Zhang et al., 2022a; Xiong et al., 2023), continual learning (Wiewel and Yang, 2021; Sangermano et al., 2022), and privacy preservation (Dong et al., 2022; Chen et al., 2022).

While most previous studies applied dataset distillation only to image classification datasets, some studies focused on text dataset distillation (Sucholutsky and Schonlau, 2021; Li and Li, 2021; Maekawa et al., 2023; Sahni and Patel, 2023). In contrast to the image, which can be applied gradient-based optimization by considering it as a pixel-wise continuous data, the discrete nature of text makes dataset distillation challenging (Geng et al., 2023; Yu et al., 2023). To address this issue, all existing text dataset distillation methods used the widely used neural NLP technique called embedding, i.e., optimizing a synthetic dataset as continuous input word embeddings instead of dis-

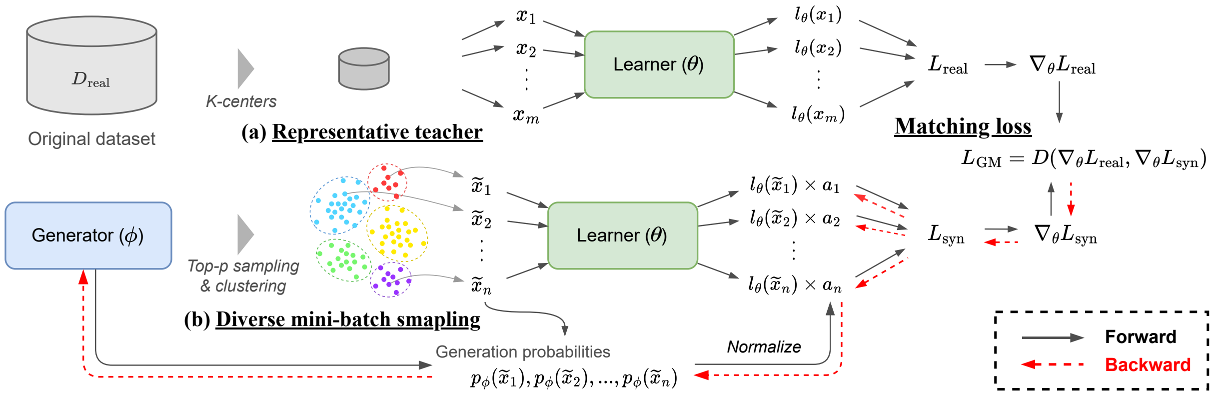

Figure 1: Overview of training with DiLM. Gradient matching loss is computed on the learner model between real samples from the original dataset and generated samples from the generator model. It is then back-propagated to the generator model via generation probabilities, which weight the learner loss for each generated sample. (a) Representative teacher for computing real sample's gradients, which improves the performance and accelerates convergence by using K-center samples, representing the original dataset, rather than randomly sampled ones. (b) Diverse mini-batch sampling, which enables the generator model to explore diverse synthetic samples in each training step.

crete text. However, such embedding-level distilled synthetic datasets cannot be used for training other models that have different word embedding weights, which is a crucial issue in terms of practical applications. Furthermore, distilled word embedding sequences are also completely unreadable to humans, which makes it difficult to interpret and analyze the original training dataset by observing distilled synthetic samples.

Motivated by these shortcomings, this paper explores the text dataset distillation to obtain distilled synthetic datasets at the text-level as the first study. We propose the first text-level dataset distillation approach called "**Di**stilling dataset **i**nto **L**anguage **M**odel (**DiLM**)". To overcome the optimization difficulty of discrete text, DiLM uses a language model as a surrogate continuous optimization target instead of directly optimizing a synthetic sample's text. Specifically, DiLM trains a language model to minimize the gradient matching loss (Zhao et al., 2021) of generated synthetic samples as a dataset distillation objective. To enable back-propagating the gradient matching loss to the language model, we design a differentiable backward pass via loss weighting with generation probabilities to bypass the non-differentiable generated text (Figure 1).

In our experiments, we applied DiLM to distill three text classification datasets from the GLUE benchmark (Wang et al., 2018a), SST-2, QQP, and MNLI-m. The results indicate that the synthetic datasets distilled with DiLM outperformed representative real samples selected from the original datasets with current coreset selection methods. Our distilled datasets also achieved remarkable generalization performance not only for training different types of pre-trained models but also for in-context learning of LLMs as few-shot prompts.

Our main contributions are as follows:

- To the best of our knowledge, this is the first study to distill a text dataset into a text-level synthetic dataset that are applicable for training models independent of word embedding weights.
- We present DiLM, which addresses the discreteness of text by using a language model as a surrogate optimization target and back-propagating the distillation loss to the model, bypassing non-differentiable generated text.
- Our experimental results indicate that DiLM outperformed the current coreset selection methods not only for training the same model used for distillation, but also for training different models independent of the word embedding weights, architectures, and training processes.

2 Related Work

2.1 Dataset Distillation

Dataset distillation was first proposed by Wang et al. (2018b), motivated by theoretical interests as well as practical applications for reducing network training costs. Inspired by meta-learning based hyperparameter optimization (Maclaurin et al., 2015), Wang et al. (2018b) optimized a small synthetic dataset by gradient descent such that models trained on it have a lower training loss for the original dataset. Recently, several surrogate objectives have been proposed to improve the performance and efficiency of dataset distillation. DC (Zhao et al., 2021) and DSA (Zhao and Bilen, 2021) focused on gradient matching between real and synthetic samples. DM (Zhao and Bilen, 2023) and CAFE (Wang et al., 2022) proposed feature distribution matching, which requires less GPU memory for optimizing synthetic datasets. MTT (Cazenavette et al., 2022) and TESLA (Cui et al., 2023) optimized synthetic samples to approximate trajectories of model parameters trained with real data. SLDD (Sucholutsky and Schonlau, 2021) and LDD (Bohdal et al., 2020) introduced learnable soft-labels, which are optimized together with input images to make each synthetic sample more informative.

While the most current research on dataset distillation involves only image classification datasets, some studies also focused on text classification datasets. Sucholutsky and Schonlau (2021) and Li and Li (2021) applied the original meta-learning based method by Wang et al. (2018b) to text datasets. To overcome the discrete nature of text, which makes applying gradient-based methods difficult, they optimized synthetic samples in the pre-trained GloVe word embedding space (Pennington et al., 2014) instead of actual words of text as the optimization target. Maekawa et al. (2023) extended the text dataset distillation to the pre-trained BERT model and improved its performance by introducing learnable attention labels, which directly guide the self-attention probabilities of the models. Sahni and Patel (2023) explored dataset distillation in multilingual text classification datasets in the context of fairness, interpretability, and cross-architecture generalization. Although these methods perform well for text classification datasets, distilled synthetic datasets obtained with them cannot be used for training other models that have different word embedding weights. Although Sucholutsky and Schonlau (2021) and Sahni and Patel (2023) transformed their distilled synthetic samples to text by finding a word that has the nearest neighbor embedding, the converted text consists of unrelated words and does not make sense, which makes it difficult to interpret and analyze them. Moreover, the performance of distilled datasets after being converted to text has also not been investigated.

2.2 Generative Models

Recent studies on dataset distillation in the CV field used generative adversarial networks (GANs) (Goodfellow et al., 2014), i.e., training the model parameters and/or their latent input noises instead of synthetic images. These methods generalize distilled synthetic images to different model architectures by restricting them to the generative distribution learned from the original dataset. DiM (Wang et al., 2023) fine-tuned a GAN to generate informative synthetic images from randomly sampled latent noises, where distilled datasets of different sizes can be produced without retraining the model. GTNs (Such et al., 2020) trained a GAN to generate informative images, instead of realistic images, to accelerate neural architecture search. GTNs also learned a latent noise for each synthetic image as a curriculum of training learner networks. IT-GAN (Zhao and Bilen, 2022) and GLaD (Cazenavette et al., 2023) used a pre-trained GAN as a generative prior of synthetic samples and only optimized the latent noises.

Inspired by these studies, we also introduce a generative model with a different motivation for text dataset distillation: to avoid the difficulties of directly optimizing discrete text, we instead optimize the continuous parameters of a generative model to generate distilled synthetic samples. However, since all previous studies that used generative models for image dataset distillation trained them and/or their input latent noises by back-propagating the distillation loss to them via generated images, none of them can be applied to text data, which are non-differentiable due to their discrete nature.

3 Methodology

In this section, we introduce DiLM, which distills text datasets into text data, not word embeddings, for the model-agnostic applicability and interpretability of the distilled synthetic datasets. The main idea of DiLM is to avoid the optimization difficulties of discrete text by instead training continuous parameters of a language model as a surrogate optimization target of dataset distillation.

3.1 Overview

Given a training dataset $\mathcal{D}_{\text{real}} = \{x_i\}_{i=1}^{|\mathcal{D}_{\text{real}}|}$, the goal of DiLM is to obtain a generator model, parameterized by ϕ, that generates a distilled synthetic dataset $\mathcal{D}_{\text{syn}} = \{\tilde{x}_i\}_{i=1}^{|\mathcal{D}_{\text{syn}}|}$ ($|\mathcal{D}_{\text{syn}}| \ll |\mathcal{D}_{\text{real}}|$), such that a learner model, parameterized by θ, trained on $\mathcal{D}_{\text{syn}}$ performs well. To achieve this goal, the overall procedure of DiLM is composed of the following three steps:

1. We first simply train the generator model to generate synthetic training samples that belong to the same distribution as in the original dataset $\mathcal{D}_{\text{real}}$ (Section 3.2).
2. We then fine-tune the generator model to generate "informative" training samples by minimizing the gradient matching loss between generated and real samples (Section 3.3).
3. We obtain distilled dataset $\mathcal{D}_{\text{syn}}$ by generating synthetic samples with the generator model and selecting representative samples from them by using a clustering-based coreset selection method (Section 3.4).

We describe the details of each step in the following sections.

3.2 Synthetic Training Data Generation with Language Model

Inspired by the remarkable text generation capability of pre-trained transformer language models (Radford et al., 2019), we use them as the generator model to generate synthetic training samples of sufficient quality to be used for training models. Before training the generator model to generate more informative synthetic samples than real samples in the original dataset, we first simply train a language model to generate training samples that belong to the same distribution as in the original training dataset for the initial parameters of the generator model.

When we target at text classification tasks, we need to control the generator model to generate samples for each specific class. Therefore, we introduce class-specific beginning-of-sentence tokens `<bos_i>`, which are added to the head of each training sample to train the generator model to generate samples of the corresponding class following it. For each training sample, an end-of-sentence token `<eos>` is also added, and the sample is fed to the generator model as follows:

`<bos_i>` *sentence of class* i `<eos>`.

To involve text classification tasks that specify the relation between two sentences, such as semantic similarity and natural language inference (NLI), we use a separate token `<sep>` to split two sentences as

`<bos_i>` *sentence 1* `<sep>` *sentence 2* `<eos>`.

The generator model is trained on them with the language modeling loss $l_\phi(x_i)$ as

$$l_\phi(x_i) = -\frac{1}{|x_i|} \sum_{w_t \in x_i} \log p_\phi(w_t | w_{<t}), \quad (1)$$

where w_t is a token in x_i and $|x_i|$ is the length of x_i. In this way, we pre-train the generator model parameters ϕ to generate synthetic training data like real data, and use them as the initial parameter for training for gradient matching, described in the following section.

3.3 Training for Gradient Matching

In this section, we explain how to fine-tune the pre-trained generator model, described in Section 3.2, to generate synthetic training samples that are more informative than real samples in the original dataset. Specifically, we describe gradient matching, which is an optimization objective for dataset distillation, and the model updating procedure to deal with the discreteness of text. We also introduce two techniques to improve DiLM: representative teacher and diverse mini-batch sampling.

Gradient Matching. To distill the knowledge of the original dataset $\mathcal{D}_{\text{real}}$ into generated synthetic samples from the generator model, we optimize the gradient matching loss (Zhao et al., 2021) as the objective for dataset distillation. Given a mini-batch of real samples $\{x_i\}_{i=1}^{M}$ and a mini-batch of synthetic samples $\{\tilde{x}_i\}_{i=1}^{N}$, which is generated from the generator model, the gradient matching loss $\mathcal{L}_{\text{GM}}$ on the learner model parameters θ is calculated as

$$\mathcal{L}_{\text{GM}} = D\left(\nabla_\theta \mathcal{L}_{\text{real}}, \nabla_\theta \mathcal{L}_{\text{syn}}\right) \quad \text{where}$$
$$\mathcal{L}_{\text{real}} = \frac{1}{M}\sum_{i=1}^{M} l_\theta(x_i),\ \mathcal{L}_{\text{syn}} = \frac{1}{N}\sum_{i=1}^{N} l_\theta(\tilde{x}_i), \quad (2)$$

where $l_\theta(\cdot)$ is the loss function for learning tasks such as cross-entropy loss, and $D(\cdot,\cdot)$ is the cosine similarity-based distance function, expressed as

$$D(A, B) = 1 - \frac{A \cdot B}{\|A\|\|B\|}. \quad (3)$$

Following a previous study (Zhao et al., 2021), we separately calculate the gradient matching loss for

Algorithm 1: Optimization for DiLM

```
Input  : $\mathcal{D}_{\text{real}}$: original dataset; $\phi$: generator model;
         $\theta$: learner model; $S$: # of outer loop; $T$: # of
         inner loop; $K$: # of learner updating loop in
         each inner step; $M$: batch size of real data;
         $N$: batch size of synthetic data; $\eta$: learning
         rate of $\theta$; $\alpha$: learning rate of $\phi$.
// Outer loop
for $s = 1, \ldots, S$ do
    // Initialize learner
    Initialize $\theta \sim p(\theta_0)$
    // Inner loop
    for $t = 1, \ldots, T$ do
        // Compute gradient matching loss for each class
        for $c = 1, \ldots, C$ do
            // Compute loss with real samples
            $\{x_i^{(c)}\}_{i=1}^{M} \sim \mathcal{D}_{\text{real}}^{(c)}$
            $\mathcal{L}_{\text{real}}^{(c)} \leftarrow \frac{1}{M} \sum_{i=1}^{M} l_\theta(x_i^{(c)})$
            // Compute loss with synthetic samples
            $\{\tilde{x}_i^{(c)}\}_{i=1}^{N} \sim p_\phi(\tilde{x})$
            for $i = 1, \ldots, N$ do
                $a_i \leftarrow p_\phi(\tilde{x}_i^{(c)}) / \sum_{j=1}^{N} p_\phi(\tilde{x}_j^{(c)})$
            $\mathcal{L}_{\text{syn}}^{(c)} \leftarrow \sum_{i=1}^{N} a_i l_\theta(\tilde{x}_i^{(c)})$
            // Gradient matching loss (Eq. (3))
            $\mathcal{L}_{\text{GM}}^{(c)} \leftarrow D(\nabla_\theta \mathcal{L}_{\text{real}}^{(c)}, \nabla_\theta \mathcal{L}_{\text{syn}}^{(c)})$
        // Update generator
        $\phi \leftarrow \phi - \alpha \nabla_\phi \frac{1}{C} \sum_{c=1}^{C} \mathcal{L}_{\text{GM}}^{(c)}$
        // Update learner for K steps
        for $k = 1, \ldots, K$ do
            $X_{\text{real}} \sim \mathcal{D}_{\text{real}}$
            $\theta \leftarrow \theta - \eta \nabla_\theta \mathcal{L}_\theta(X_{\text{real}})$
Output : $\phi$: parameters of generator model.
```

each class and combine them to update the generator model parameters ϕ. To consider the gradient on the learner model parameters θ throughout the entire training process, the generator model is trained with the nested loop algorithm, including the outer loop, which initializes θ at the beginning, and the inner loop, which updates θ for K steps with real samples (see Algorithm 1).

Generator Updating. As we described in Section 2.2, the gradient matching loss $\mathcal{L}_{\text{GM}}$ cannot be directly back-propagated to the generator model parameters ϕ via generated samples $\{\tilde{x}_i\}_{i=1}^{N}$, like the case with image datasets, because they consist of discrete text. Although some solutions to the discrete back-propagation issue in text generation have been explored in the NLP research field, most of standard approaches, including soft-argmax (Zhang et al., 2017) and policy gradient (Yu et al., 2017), cannot be applied to this case (see details in Appendix A). To address this issue, we design an alternative backward pass, inspired by a previous study (Hiraoka et al., 2020), which optimizes a tokenization model for the downstream task's loss through a non-differentiable procedure. When computing the generated sample's loss $\mathcal{L}_{\text{syn}}$, instead of simply averaging the losses for each generated sample as in Eq. (2), we weight them with their generation probabilities $p_\phi(\tilde{x}_i)$ as

$$\mathcal{L}_{\text{syn}} = \sum_{i=1}^{N} a_i \, l_\theta(\tilde{x}_i), \tag{4}$$

$$a_i = \frac{p_\phi(\tilde{x}_i)}{\sum_{j=1}^{N} p_\phi(\tilde{x}_j)}. \tag{5}$$

Therefore, $\mathcal{L}_{\text{GM}}$ can be back-propagated to ϕ through the differentiable pass via loss weights a_i, as illustrated in Figure 1. Intuitively, the generator model is updated to increase its generation probabilities of synthetic samples that improve gradient similarity.

Representative Teacher. To improve DiLM, we consider enhancing the gradient teacher of real samples by using representative samples for each mini-batch of real samples instead of randomly selected ones. Inspired by Liu et al. (2023), we select the representative samples with K-centers (Wolf, 2011; Sener and Savarese, 2018), a clustering-based coreset selection method (Figure 1a). Specifically, we divide all the real training samples for each class into M sub-clusters by using the K-means algorithm on the feature space of the learner model, and choose the center sample of each sub-cluster. As shown in (Liu et al., 2023), the representative samples selected by K-centers provide the proper teacher gradient by including diverse samples that cover the overall distribution for each class and eliminating samples near the decision boundaries, which have dominant gradients with large norms. Considering coverage and robustness, we generate 10 representative sample sets by running the K-means algorithm with different random seeds at the beginning of training and use one as a mini-batch of real samples in each training step.[1]

Diverse Mini-batch Sampling. Diversity in a mini-batch of generated samples for each step affects the sample space that the generator model explores in training. If the generator model only generates many samples that are similar to each other, this leads to the biased optimization of the generator model. To address this issue, we intro-

---

[1] Liu et al. (2023) repeatedly re-generated the K-center representative samples by conducting clustering on the feature space of the different learner model's states throughout the inner loop. However, it is very time consuming with BERT as the learner model, as in our study.

duce diverse mini-batch sampling of generated samples in the training process of DiLM (Figure 1b). Instead of generating N synthetic samples for each step, the generator model generates $N \times I_{\text{int}}$ synthetic samples at the same time, where I_{int} is the generation interval. The generated synthetic samples are then divided into N sub-clusters with the K-means algorithm, and a mini-batch of synthetic samples for each step is constructed by randomly choosing one sample from each sub-cluster.

3.4 Generate Synthetic Dataset

We obtain distilled dataset $\mathcal{D}_{\text{syn}}$ by generating synthetic samples with the trained generator model. To include representative samples of the model's generative distribution $p_\phi(\tilde{x})$, we use the coreset selection method again to select generated synthetic samples. Specifically, we generate 100 times as many synthetic samples as the distilled dataset size $|\mathcal{D}_{\text{syn}}|$ by top-p sampling with $p = 0.95$, considering the diversity, and then construct $\mathcal{D}_{\text{syn}}$ with K-center representative samples. This makes $\mathcal{D}_{\text{syn}}$ to include diverse synthetic samples by removing redundant samples caused by the biased generative distribution of the model.

4 Experimental Settings

Datasets. We evaluated DiLM in distilling three major text classification datasets, SST-2, QQP, and MNLI-m, from the GLUE benchmark (Wang et al., 2018a). Following Wang et al. (2018a), we report accuracy for SST-2 and MNLI-m, and the average of accuracy and F1 score for QQP as our results. More details about each dataset are shown in Appendix B.

Baselines. Following previous studies on dataset distillation in the CV field, we compared the performance of DiLM with three coreset selection methods, Random, K-centers (Wolf, 2011; Sener and Savarese, 2018), and Herding (Welling, 2009), as well as TDD (Sucholutsky and Schonlau, 2021), which is a recent embedding-level distillation method. Note that TDD also trains the learnable soft-labels and learning rates for each training step together with the input word embeddings. We also evaluated the vanilla LM, which skips training for gradient matching (in Section 3.3), to validate its effectiveness. Note that we applied K-center representative sample selection (in Section 3.4) to the vanilla LM as well. The details of each baseline are given in Appendix C.

Evaluation. For evaluation, we used BERT$_{\text{BASE}}$ and other three pre-trained models, RoBERTa$_{\text{BASE}}$, BERT$_{\text{LARGE}}$, and XLNet$_{\text{BASE}}$, as learner models (see more details in Appendix D). We trained a learner model on the distilled datasets for 200 steps by using AdamW (Loshchilov and Hutter, 2019) with a learning rate of 1.0×10^{-4} and a batch size of 64.[2] For Herding and TDD, we trained the learner model on their datasets for 100 times. For other methods, we generated 20 datasets with different random seeds and trained the learner model on each of them for 5 times. We report the average and standard deviation for these 100 models. In the result tables, '$*$' indicates significant difference of DiLM from K-centers ($p < 0.05$, Welch's t-test). Note that the standard deviations in our results inevitably become large because we trained models with few selected/generated samples from different initial model parameters. However, our evaluation procedure, which includes 100 runs, supports the reliability of our experimental results enough to discuss the effectiveness of the proposed method.

Implementation. We used the 128M parameter version of GPT-2[3] (Radford et al., 2019) as the generator model of DiLM, and used BERT$_{\text{BASE}}$ (Devlin et al., 2019) as the learner model, on which we calculated the gradient matching loss. To reduce the computational costs, we calculated the gradient matching loss only for the randomly initialized last layer parameters, which tend to have dominantly larger gradient than the pre-trained parameters. We set the number of each loop for training DiLM to $S = 2000$, $T = 10$, and $K = 20$, and the generation interval to $I_{\text{int}} = 200$ according to our preliminary experiments. The mini-batch size of real and synthetic samples were respectively set to $M = 200$ and $N = 64$. More details of our implementation are given in Appendix E.

5 Results and Discussion

5.1 Performance for BERT$_{\text{BASE}}$

As shown in Table 1, we first compared DiLM with the other baselines for training BERT$_{\text{BASE}}$, on which DiLM trained gradient matching. We evaluated them for different sizes of distilled synthetic datasets of 5/10/20 data-per-class (DPC) settings.

We first found that the vanilla LM, which was

---

[2] We did not follow this training protocol for TDD, since TDD optimizes learning rates as well for each step with a specific synthetic sample order.

Table 2: Cross-model generalization performance for settings of DPC=20. (**S**) indicates the source model for gradient matching of DiLM and feature extractor for K-centers.

only trained for synthetic training sample generation without gradient matching, clearly underperformed the coreset selection methods. This indicates that, as can be expected, the quality of the generated synthetic samples becomes lower than that of real samples in the original datasets. However, DiLM, which fine-tuned the vanilla LM with gradient matching, improved its performance and even outperformed the coreset selection methods overall. Note that the performance gains from K-centers indicate that DiLM generated synthetic training samples that are more effective for model training than the real samples in the original datasets.

When focusing on the difference between the three datasets, the performance gains of DiLM on QQP and MNLI-m were larger than that on SST-2. We believe this is because QQP and MNLI-m, which are the tasks to specify the relationship between two sentences, are intuitively less likely to have real samples that represent the task than SST-2, which is a relatively simple negative/positive classification task. In addition, it may also be related to the size of the original training dataset of QQP and MNLI-m, which is five times larger than that of SST-2. Since the generator model was trained by gradient matching with self-generated synthetic samples, it can explore broader sample space by pre-training with the original dataset that contains enough diversity samples, which results in the effective performance of DiLM.

For TDD, we also evaluated its distilled datasets as text data by converting them to discrete tokens that have nearest neighbor embeddings. When directly using the distilled datasets as word embeddings, TDD achieved remarkable performance even compared with the full datasets. However, after converting to text, its performance catastrophically degraded even to the lower-bound performances with random prediction. This suggests that the distilled datasets from TDD are strictly overfitted at the word embedding level and cannot be converted to text without acceptable performance degradation, which is necessary for applying them to other models. This point is the clear advantage of DiLM, which distills synthetic datasets at the text-level.

5.2 Cross-model Generalization

In contrast to the current embedding-level distillation methods, text-level synthetic datasets from DiLM can be leveraged for training different models independent of their word embedding weights. To emphasize this advantage, we evaluated the distilled synthetic datasets for training three models different from $\text{BERT}_{\text{BASE}}$, with which the distilled synthetic datasets were obtained, i.e., $\text{RoBERTa}_{\text{BASE}}$, $\text{BERT}_{\text{LARGE}}$, and $\text{XLNet}_{\text{BASE}}$. Ta-

Table 3: Performance of distilled datasets as 5-shot prompts for in-context learning of SST-2. Each score is the average and standard deviation for 100 prompts with 20 distilled datasets and 5 random orders.

ble 2 summarizes the performances of Random, K-centers, and DiLM with DPC=20, where DiLM achieved stably good performances.[4] The results indicate that the distilled datasets from DiLM consistently performed well for training the different models, even though DiLM trained gradient matching only for the $\text{BERT}_{\text{BASE}}$ model's parameters. It is worth noting that our distilled datasets show successful generalization performance not only for training $\text{RoBERTa}_{\text{BASE}}$ and $\text{BERT}_{\text{LARGE}}$, which have the same model architecture as $\text{BERT}_{\text{BASE}}$, but also for training $\text{XLNet}_{\text{BASE}}$, which is an autoregressive model using the hidden state of the `<eos>` token for classification, while $\text{BERT}_{\text{BASE}}$ is an autoencoding model using the hidden state of the `[CLS]` token.

We also evaluated the distilled datasets from DiLM as few-shot prompts for in-context learning of LLMs. Table 3 shows the performance of Random, K-centers, and DiLM for in-context learning for SST-2 with three different sizes of LLMs, GPT-2-XL (Radford et al., 2019), OPT (Zhang et al., 2022b), and Llama 2 (Touvron et al., 2023). Surprisingly, the distilled datasets from DiLM consistently performed well for the in-context learning, compared with Random and K-centers.

These remarkable generalization performances across models and training processes strongly support the advantage of DiLM to distill datasets at the text-level.

5.3 Analysis and Discussion

Ablation Study. Table 4 shows the results of the ablation study for the performance improvement techniques of the representative teacher for gradient matching, the diverse mini-batch sampling of synthetic samples during training of DiLM (in Section 3.3), and the representative sample selection with K-centers during synthetic dataset generation (in Section 3.4). The results demonstrated that all the three techniques are consistently effective for DiLM.

Table 4: Ablation study on the performance improvement techniques of DiLM with the DPC=5 setting. RT, DMS, and Selection indicate representative teacher, diverse mini-batch sampling, and sample selection with K-centers, respectively.

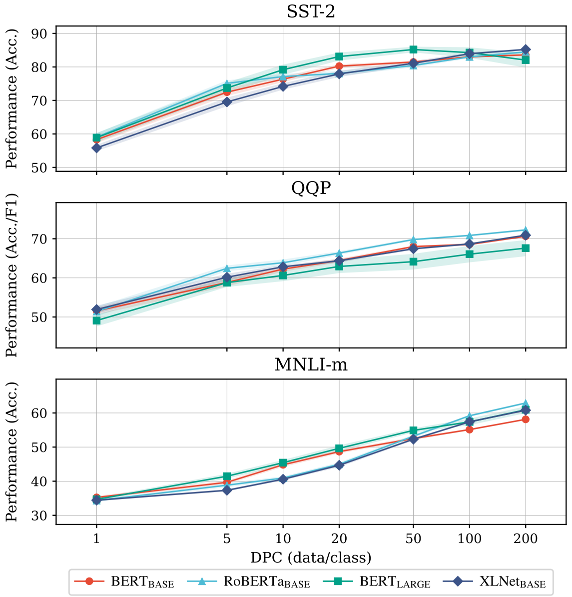

Figure 2: Performance for increasing number of synthetic samples with DPC $\in \{1, 5, 10, 20, 50, 100, 200\}$. We plot the mean and 95% confidence interval for 100 models trained on distilled datasets from DiLM.

Scaling of DPC. We investigated the performance of DiLM when increasing the size of synthetic datasets. Note that DiLM does not require retraining the generator model for generating distilled synthetic datasets for different DPCs, which is also the advantage of using generative models for dataset distillation. As shown in Figure 2, the performance of the distilled datasets generally scaled with increasing DPC.

Distilled Data Examples. We gave examples of distilled synthetic samples for each dataset in Appendix G. We found that DiLM successfully generated interpretable synthetic samples that are appropriate for the tasks of the original datasets. Although DiLM consistently generated high quality synthetic samples for SST-2 and QQP, the repetition problem can be observed in some lengthy

---

[4] We also show the results with other DPC settings in Appendix F.

samples for MNLI-m. This suggests that there is still room for performance improvements of DiLM by using a larger and more sophisticated pre-trained language model for the generator model than the small GPT-2 used in our current experiments.

6 Conclusion

We proposed the first text-level dataset distillation approach, called DiLM, which trains a language model to generate informative synthetic samples as text data for model-agnostic applicability and interpretability of distilled datasets. Experimental results across various text classification datasets indicated that the distilled datasets from DiLM achieve successful performance for training various types of models beyond the source model used for distillation, even for in-context learning of LLMs.

Limitations

The following three points are the limitations of this work. (i) Although DiLM achieved remarkable performance as a text-level distillation method, there is still a performance gap from the full datasets. However, the performance improvements from K-centers are large enough to demonstrate the effectiveness of DiLM, considering the fundamental difficulty of the dataset distillation problem itself in cases when synthetic data are restricted to the text-level. Moreover, DiLM has room for further performance improvement by employing larger and more sophisticated pre-trained language models as the generator model or using other dataset distillation objectives as an alternative to the gradient matching. (ii) In our experiments, we applied DiLM to distill only text classification task datasets. DiLM can be applied to text generation tasks as well by just considering the entire original training dataset as the data for a single label. In future work, we should explore the application of DiLM for more difficult settings, such as the text generation tasks and full-scratch training of language models. (iii) While privacy preservation of the original training datasets is one of the applications of dataset distillation, it is difficult to apply DiLM to the privacy preservation because the distilled synthetic datasets from DiLM may include real samples from the original dataset due to the training data memorization of the language model. However, we believe that the advantage of DiLM to generate distilled synthetic datasets at the text-level, enabling the training of models independent of word embedding weights, is more valuable than the application to the privacy preservation in terms of practical applications.

A Background Details of DiLM

In this section, we provide the detailed background of the techniques that we introduced in Section 3.3 to enable back-propagation computing by bypassing the non-differentiable discrete text via loss weighting according to the generation probabilities.

As we described in Section 3.3, although there existed two standard approaches to the non-differentiable problem in the discrete text generation, that is, soft-argmax (Zhang et al., 2016) and policy gradient (Yu et al., 2017), both of them cannot be applied in training DiLM. For soft-argmax and the same type of approaches, it is necessary that the vocabulary of the generator model be the same as that of the learner model, which receives the text generated by the generator model as an input. However, it is not true in the case of DiLM, where we used GPT-2 for the generator model and $\mathrm{BERT}_{\mathrm{BASE}}$ for the learner model.

As for policy gradient, we can apply it with sample-level gradient similarity as the reward function. However, the gradients for synthetic data for gradient matching loss should be calculated as an average for samples in a mini-batch, not for a single sample. Moreover, calculating per-sample gradients is computationally inefficient. These are the reasons why we did not use the policy gradient with the per-sample gradient similarity.

However, the basic idea of our approach, which aims to update the generator model to increase its generation probabilities for synthetic samples that improve gradient similarity, is essentially the same as the policy gradient. In addition, it is worth noting that our approach can also be formulated as the policy gradient manner. Letting $g_\theta(\tilde{x}) = \frac{\partial l_\theta(\tilde{x})}{\partial \theta}$ and $r(\cdot)$ be the reward function, the gradient of the generator parameters ϕ is represented as

$$\nabla_\phi \mathcal{L}_\phi = \sum_{n=1}^{N} \nabla_\phi l_\phi(\tilde{x}_n) \cdot r(\tilde{x}_n) \quad \text{where}$$

$$r(\tilde{x}_n) = a_n \left\{ g_\theta(\tilde{x}_n) - g_\theta(\tilde{X}) \right\}^T \left(-\frac{\partial \mathcal{L}_{\mathrm{GM}}}{\partial g_\theta(\tilde{X})} \right).$$

B Datasets

We used three text classification datasets in the GLUE benchmark (Wang et al., 2018a) from huggingface datasets.[5] SST-2 is a banally sentiment classification (negative/positive) task for movie review sentences. QQP is a task to identify whether a question pair is semantically equivalent or not. MNLI-m is a natural language inference task to predict a premise sentence entails or contradicts a hypothesis sentence or neither (neutral). We reported the evaluation results on the validation set in Section 5, since the test set is not publicly available. For MNLI-m, we used the matched-domain validation set for evaluation. We summarize the statistics of each dataset in Table 5.

Dataset	Metric	#Train	#Dev	#Class
SST-2	accuracy	67k	872	2
QQP	accuracy/F1	364k	40k	2
MNLI-m	accuracy	393k	9.8k	3

Table 5: Summary of statistics of evaluation datasets

C Baselines Details

In this section, we explain the details of the baseline methods used in our experiments.

C.1 Coreset Selection

Random is the simplest baseline, which randomly selects real samples from the original training dataset.

K-centers (Wolf, 2011; Sener and Savarese, 2018) is a standard coreset selection method that selects the center samples of sub-clusters as a coreset, which eliminates redundant samples and covers the distribution of the original dataset.

Herding (Welling, 2009) is also a standard coreset selection method that greedily selects real samples to match their mean embedding with that of the original dataset.

For K-centers and Herding, we used the last hidden state of the `[CLS]` token in the $\mathrm{BERT}_{\mathrm{BASE}}$ model as a feature of each training sample.

C.2 Embedding-level Dataset Distillation

TDD[6] (Sucholutsky and Schonlau, 2021) is the current embedding level text dataset distillation method. TDD also optimizes learnable soft-labels and learning rates together with input word embeddings by the original meta-learning approach (Wang et al., 2018b). Following the best performing settings in Maekawa et al. (2023), which

---

[5] `https://huggingface.co/datasets/glue`

[6] We used the implementation by Maekawa et al. (2023), because it also employs BERT as the learner model.

applied this approach to the BERT model, we used one synthetic sample per class as a mini-batch of a single gradient step and fixed the order of synthetic samples, which means the learner model is trained with 5 gradient steps in the experiments in Section 5 with DPC=5. Similar to DiLM, TDD also used BERT$_{\text{BASE}}$ as the learner model for distillation.

D Learner Models

BERT$_{\text{BASE}}$[7] (Devlin et al., 2019) was used as the source model for training for dataset distillation and the feature extractor of the coreset selection methods. Following the fine-tuning settings in Devlin et al. (2019), we used a randomly initialized linear layer on the top of the last hidden state of the `[CLS]` token.

RoBERTa$_{\text{BASE}}$[8] is a BERT derivative model proposed by Liu et al. (2019). This model has the same size and architecture as BERT$_{\text{BASE}}$, but has different parameters pre-trained with the masked language modeling (MLM) task, without the next sentence prediction (NSP) task, on a larger corpus than the BERT models.

BERT$_{\text{LARGE}}$[9] is the 24 layer, 340M parameter version of BERT, while BERT$_{\text{BASE}}$ has 12 layers and 110M parameters.

XLNet$_{\text{BASE}}$[10] is an autoregressive model in contrast to BERT and RoBERTa. Following (Yang et al., 2019), we used a randomly initialized linear layer on the top of the last hidden state of the `<eos>` token, which involves entire tokens in the sequence.

E Implementation Details

Table 6 shows the details of hyperparameter settings in our experiments. Our implementation was based on PyTorch 2.1.0, and we used pre-trained models from Hugging Face Transformers 4.30.0. All model training and evaluation in our experiments were conducted with the half-precision (BFloat16) on a single RTX 3090 (24GB), RTX A6000 (48GB), or A100 PCIe (80GB) according to the required GPU memory size for each experiment.

Pre-training settings of DiLM	
Optimizer	AdamW
Learning rate	1.0×10^{-5}
Learning rate scheduler	Linear warm-up and cosine annealing
Warmup ratio	0.05
Waight decay	0.01

Table 6: Hyperparameter settings in our experiments

F Results for Cross-model Generalization

Tables 7 and 8 show the cross-model generalization performances with DPC=5,10 settings. As in the setting of DPC=20 in Table 2, DiLM also performed well in training different models than the source model.

G Distilled Synthetic Data Examples

We gave examples of distilled synthetic samples from DiLM in Tables 9, 10, and 11. Generated synthetic examples with DiLM were interpretable and seem to represent the tasks of the original training dataset.

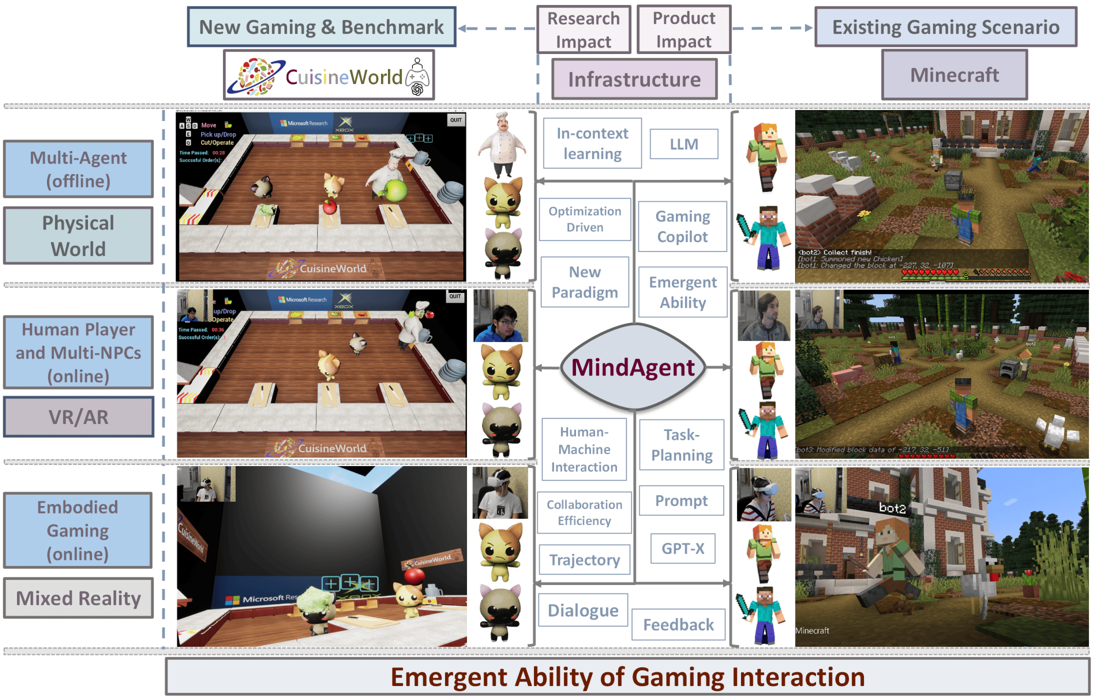

Figure 1: The MindAgent system for gaming interactions. MindAgent enables complex task planning in a multi-agent system and provides a human-AI collaboration infrastructure across various domains.

Abstract

Large Foundation Models (LFMs) can perform complex scheduling in a multi-agent system and can coordinate agents to complete sophisticated tasks that require extensive collaboration. However, despite the introduction of numerous gaming frameworks, the community lacks adequate benchmarks that support the implementation of a general multi-agent infrastructure encompassing collaboration between large foundation models and human-NPCs. We propose a novel infrastructure—*MindAgent*—for evaluating planning and coordination capabilities in the context of gaming interaction. In particular, our infrastructure leverages an existing gaming framework to (i) act as the coordinator for a multi-agent system, (ii) collaborate with human players via instructions, and (iii) enable in-context learning based on few-shot prompting with feedback. Furthermore, we introduce *CuisineWorld*, a new gaming scenario and its related benchmark that supervises multiple agents playing the game simultaneously and measures multi-agent collaboration efficiency. We have conducted comprehensive evaluations with a new auto-metric *Collaboration Score (CoS)* for assessing the collaboration efficiency. Finally, MindAgent can be deployed in real-world gaming scenarios in a customized VR version of CuisineWorld and adapted in the "Minecraft" domain. Our work involving Large foundation models within our new infrastructure for general-purpose scheduling and coordination can elucidate how such skills may be obtained by learning from large

language corpora.

1 Introduction

Large foundation Models (LFMs) have been driving the effort to develop general intelligent machines (Bubeck et al., 2023; Mirchandani et al., 2023). Although they are trained using large text corpora, their superior problem-solving capacity is not limited to canonical language processing domains. LFMs can potentially tackle complex tasks that were previously presumed exclusive to human experts or domain-specific algorithms. Recent research has shown the possibility of using LFMs to generate complex plans for robots and game AI (Liang et al., 2022; Wang et al., 2023b,a; Yao et al., 2023; Huang et al., 2023), marking an important milestone for LFMs as general-purpose intelligent agents (Huang et al., 2024). In this paper, we investigate the planning capacity of LFMs in the context of multi-agent systems (Stone and Veloso, 2000). Compared to planning for a single agent, which has been studied extensively (Wang et al., 2023b,a), multi-agent planning imposes much higher problem-solving complexity due to an action space that grows exponentially with respect to the number of agents. The planner must simultaneously control multiple agents, avoid possible conflicts, and coordinate agents into achieving a shared goal that requires potentially sophisticated collaboration. To understand to what extent LFMs can acquire multi-agent planning skills, we first develop a new benchmark, *CuisineWorld*, which is illustrated in Figure 1.

To incorporate agent AIs into video games, we design *MindAgent*, an infrastructure inspired by multi-agent task allocation optimization theories, to facilitate the multi-agent planning capabilities of LFMs. Our infrastructure enables LFMs to perform complex coordination and scheduling of multiple agents in order to achieve task completion. We conduct comprehensive evaluations with recently introduced LFMs, including GPT-4, Claude, and LLaMA, playing our CuisineWorld game within our MindAgent interactive multi-agent planning framework, leading to the following key observations:

1. **Zero shot multi-agent planning**: Powerful pretrained LFMs like GPT-4 are capable of scheduling multiple agents (ranging from 2 to 4) to complete dishes, even by collaborating with human players, by merely reading game instructions and recipes;
2. **Planning with advanced prompting**: We can significantly boost multi-agent planning performance by leveraging an emergent *in-context learning* ability (Brown et al., 2020; Wei et al., 2021) by adding only a few expert demonstrations (from different games) to the prompt, explaining the rationale of certain actions as in Chain-of-Thought prompting (Wei et al., 2022), and providing on-the-fly feedback to the LFMs during planning.
3. **Generalization**: LFMs can potentially be generalist multi-agent planners as they are able to generalize in order to coordinate a growing number of agents and perform well in new game domains such as Minecraft.

The contributions of our work are as follows:

- We develop a new gaming scenario and related benchmark based on a multi-agent virtual kitchen environment, CuisineWorld. It adopts a minimal text-based game format and supports planning tasks with various structures and challenges, making it an ideal test bed for the emergent multi-agent planning (i.e., scheduling and coordination) capacity of LFMs.
- We introduce MindAgent, an infrastructure for interactive multi-agent planning with LFMs. which demonstrates the in-context learning of the multi-agent planning capacity of LFMs and offers several prompting techniques to facilitate their planning ability, including providing few-shot demonstrations, planning rationals, and environmental feedback.
- We conduct extensive evaluations of our benchmark with multiple LFMs and prompting settings. Our experimental results validate its potential in helping develop generalist multi-agent planners.
- We deploy MindAgent in real-world gaming scenarios and demonstrate its ability to power human-AI interactions.

Compared to canonical domain-specific automated planning systems, although multi-agent planning with LFMs is more likely to be bottlenecked by high computational cost, context length limitations, non-optimal plans, *etc*., it can potentially improve planning performed by *in-context learning* from data without fine-tuning, seamlessly adapt to new planning problems across different domains, and offer a more flexible interface to human collaborators. Ultimately, our investigation into the leveraging of LFMs for general-purpose scheduling and coordination can elucidate how such skills may be acquired by learning from large text corpora, and is potentially instrumental to the future development of more effective LFM-based planners.

2 Related Work

2.1 Multi-Agent Coordination

The field of multi-agent collaboration boasts a comprehensive body of literature. Traditionally, such collaborations have been modeled using the MDP/POMDP frameworks (Lowe et al., 2017; Rashid et al., 2020; Jain et al., 2019; Wu et al., 2021; Gao et al., 2023). However, there has been a recent shift towards using LFMs for these collaborations. For instance, Zhang et al. (2023b) delved into how LFMs might communicate and cooperate in a watch-and-help (WAH) task. Meanwhile, Zhang et al. (2023a) investigated a two-agent collaboration game inspired by the simpler dynamics of the two-agent Overcooked-style game. Notably, their research mainly concentrated on the task success rate, with most studies typically anchored to a single task objective. By contrast, we emphasize the importance of collaboration efficiency in scenarios encompassing multiple task objectives. Further, our research uniquely focuses on evaluating the collaborative efficiency of two or more agents. Additionally, while other works such as that of Park et al. (2023); Wu et al. (2021) simulate each agent individually, we employ a centralized system. This not only significantly reduces the number of API calls but also reduces context length, making it more appropriate for use in gaming applications.

2.2 Planning With LFMs

A number of works leverage LFMs to perform task planning (Huang et al., 2022a; Wang et al., 2023a; Yao et al., 2023; Li et al., 2023; Wang et al., 2024), specifically the LFMs' WWW-scale domain knowledge and emergent zero-shot planning abilities to perform complex task planning and reasoning. Recent robotics research also leverages LFMs to perform task planning (Ahn et al., 2022; Huang et al., 2022b; Liang et al., 2022) by decomposing natural language instruction into a sequence of subtasks, either in the natural language form or in Python code , then using a low-level controller to execute these subtasks. Additionally, Huang et al. (2022b), Liang et al. (2022), and Wang et al. (2023b) also incorporate environmental feedback to improve task performance.

2.3 Benchmarks Using Games

Numerous games have been developed to study task planning (Baker et al., 2022; Carroll et al., 2019; Bakhtin et al., 2022), yet only a handful delve into multi-agent collaborations. Even within this limited subset, the focus predominantly remains on two-agent interactions where responsibilities are unevenly distributed between the agents (Wan et al., 2022; Puig et al., 2020)—it is common for one player to assume a dominant role while the other provides support. By contrast, our work assumes the equal apportion of responsibilities across agents, and we expand our investigation to encompass collaborations involving more than two agents, even including human players. While some previous studies have ventured into multi-task settings, none has delved into scenarios where agents must compete for resources to complete multiple distinct tasks with varied levels of difficulty within a single episode. Additionally, our work differs from that of Carroll et al. (2019) in that our game settings feature a diverse array of tools and task objectives, thereby generating an exponentially larger task space. A comparison between our work and other related studies can be found in the Appendix E.1.

3 The CuisineWorld Game

We introduce CuisineWorld as a novel and flexible game for multi-agent scheduling and coordination in a *virtual kitchen* environment. In this game, a multi-agent system must supervise multiple agents and coordinate them, with the goal of completing as many dish orders as possible. The game is equipped with a textual interface since our focus is on evaluating LFM-based planning agents. Our modularized design separates tasks and game engines, allowing inclusion of more tasks (dish types) and domains ("kitchen" implementation via text-based engine, Unity, Minecraft, *etc*.).

3.1 Tasks and Reward

A task in CuisineWorld is a dish order, ranging from the most basic `tunaSashimi`, which can be made by simply chopping raw tuna meat, to sophisticated dishes like `porkPasta` requiring various cooking tools. In a game episode with a maximum of T steps, in every *task interval* τ_{int}, a new task or dish order will be added to the active task list. A task will be regarded *completed* and be removed from the active task list when the corresponding dish has been placed on the serving table.

Alternatively, a task will be deemed to have *failed* and be removed from the list after its *lifetime* τ_{lft}, which depends on the complexity of the dish, is exceeded. Along with the tasks, the game provides rewards and penalties or feedback on certain occasions, *e.g.* when a task is just completed, when infeasible commands are dispatched, *etc*. We support five different actions 1) goto 2) get 3) put 4) activate 5) noop. The state space contains descriptions of the environment and agents. Due to space limitations, we refer the reader to additional details in Appendix D.

3.2 Collaboration Score (CoS)

We need to evaluate to what extent the dispatcher (played by an LFM) can coordinate multiple agents to complete dish orders across a variety of scenarios. We are particularly interested in the question: can the dispatcher continue to coordinate the agents into efficient collaborations as τ_{int} decreases; *i.e.*, as more dish orders are flooding in? Our hypothesis is that an ideal dispatcher should be capable of coordinating the agents until there are way more tasks than the system can handle. Therefore, we introduce a *collaboration score* (CoS), defined as

$$\text{CoS} = \frac{1}{M}\sum_{i=1}^{M}\frac{\#\ \text{completed}\left[\tau_{\text{int},(i)}\right]}{\#\ \text{completed}\left[\tau_{\text{int},(i)}\right] + \#\ \text{failed}\left[\tau_{\text{int},(i)}\right]}$$

where $\#$ denotes the number of tasks and M is the total number of τ_{int} intervals evaluated. Effectively, CoS is the average task completion rate across different τ_{int} conditions. In our default setting, we use $M = 5$. While the actual values of τ_{int} depend on the game level, we ensure that they span a wide range of difficulties including both relaxed and intense scenarios.

In summary, CuisineWorld is a game that emulates a virtual kitchen in which several robotic agents are commanded to use various cooking tools and ingredients to prepare as many dish orders as possible in a limited period of time. To necessitate collaboration, new orders will keep flooding in while the existing ones should be completed before their expiration times. Therefore, LFMs must properly coordinate the agents to maximize overall productivity. CuisineWorld offers game levels with a wide range of planning difficulty: dishes with different complexity (number of ingredients and tools involved), number of agents, order frequency and lifetime, etc., making it a useful test bed for LFM-based multi-agent planning.

4 MindAgent Gaming AI Infrastructure

Our first foray into the challenging CuisineWorld benchmark is an interactive multi-agent planning framework with LFMs. It facilitates in-context learning and adopts a minimalist design for the purposes of demonstrating the scheduling and coordination capacity of LFMs, while also bringing in exploratory prompting techniques that facilitate better planning and inform future approaches in this domain. Our MindAgent infrastructure comprises prompt, current state, and memory, as shown in Figure 2 with details illustrated as follows:

Prompt incorporates four distinct sub-components: recipes, general instructions, inference knowledge, and a one-shot demo.

Recipes outline hierarchical procedures for preparing various dishes at a given level. They specify the ingredients necessary for each intermediate or final product, the appropriate tools, and the outcome.

Instructions detail the foundational rules of CuisineWorld, delineating the array of actions agents can undertake within the game and enumerating the characteristics of every tool available. Moreover, they inform agents about the base ingredients retrievable from storage, as well as all potential intermediate products they can procure. Agents are also explicitly advised to remain cautious about feedback from the environment.

Inference Knowledge encapsulates insights and helpful hints for the agent, which when utilized appropriately can guide agents to sidestep potential errors and improve their collaborative efficiency.

One-shot Demo presents a step-by-step demonstration of the preparation of a distinct dish, different from other dishes at the current level, spanning several time steps, each of which is incorporated as part of the prompt. The demonstration illustrates the major procedures for cooking a dish in CuisineWorld, including obtaining ingredients, putting ingredients into different tools, transporting intermediate ingredients, and delivering the final dish to the serving table. More details of prompt are in Appendix A.

Current State provides a snapshot of the prevailing observations from the environment. It encompasses information such as the locations of agents, the objects currently in the possession of agents, the tools that are accessible within the environment, the ingredients present within each tool, and the tools that are actively in use. Moreover, it includes optional feedback from the environment, triggered

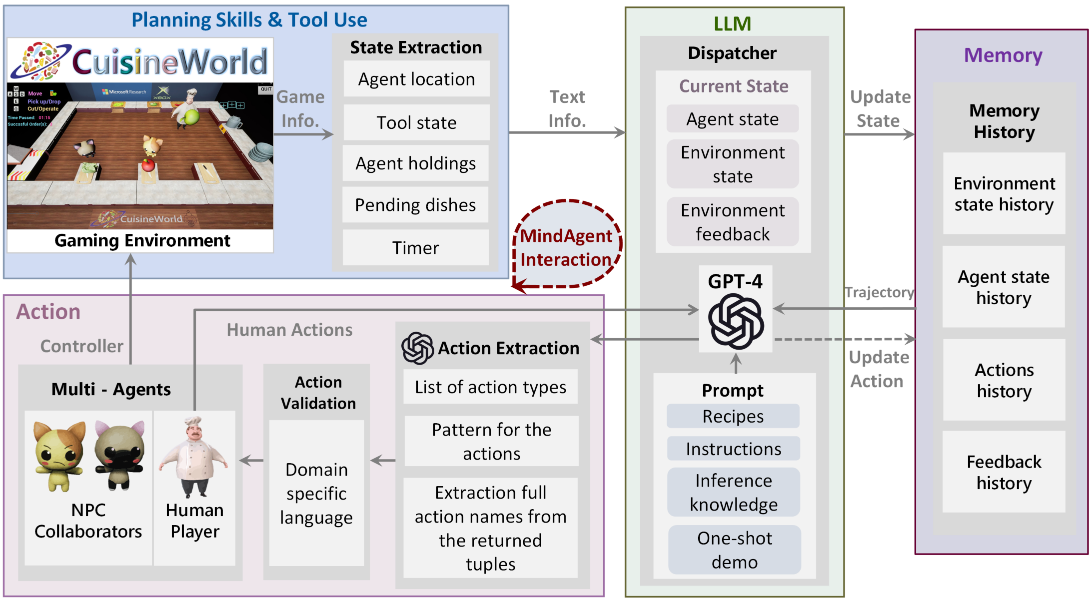

Figure 2: The MindAgent Infrastructure. **Planning Skill and Tool Use:** The game environment requires diverse planning skills and tool use to complete tasks. It generates relevant game information and converts the game data into a structured text format that the LFMs can process. **LFM:** The main workhorse of our infrastructure makes decisions, thus serving as a dispatcher for the multi-agent system. **Memory History:** A storage utility for relevant information. **Action Module:** Extracts actions from text inputs and convertd them into domain-specific language and validates DSLs so that they cause no errors during execution.

when agent actions violate the rules of the environment; for instance, when assigning two distinct actions to the same agent.

Memory archives the history of interaction with the environment. Specifically, it chronicles the state of the environment and the state of the agents at every time step.

In addition to the prompt modules, other modules are implemented to help interface between LFMs and CuisineWorld:

Action Extraction employs a regular expression matching procedure to distill agent actions from the textual output of the LFMs. This module is indispensable because LFM output is not always clean, but may include information reflecting its internal thought processes or even issue apologies for prior missteps in reaction to environmental feedback.

Action Validation utilizes a look-ahead checking mechanism. This module parses the proposed actions, assessing their feasibility. If an action is deemed unexecutable, an error message is returned.

4.1 Infrastructure Mechanisms

Assuming a multi-agent system with N agents, the system must complete a sequence of P different tasks. Each task has M_p different sub-tasks. Furthermore, the number and types of tasks are unknown at the beginning of the episode. The environment will sample a task for the agents to finish during a given interval. The agents must complete the designated task along with other tasks in the task queue. Additionally, each task has an expiration time, after which the task will be marked as a failure. The objective of the multi-agent system is to finish as many tasks as possible and fail as few tasks as possible within a given time frame.

To find optimal task planning, scheduling, and allocations. We define q_{pim} and c_{pim} as quality and cost, respectively, in the context of allocating agent i to work on sub-task m of task p in the episode. The combined utility for the sub-task is

$$u_{pim} = \begin{cases} q_{pim} - c_{pim}, & \text{if agent } i \text{ can execute} \\ & \text{ sub-task } m \text{ of task } p \\ & \text{ in the episode;} \\ -\infty, & \text{otherwise.} \end{cases}$$

The assignment of sub-task m to agent i is

$$v_{pim} = \begin{cases} 1, & \text{if agent } i \text{ is assigned to} \\ & \text{ sub-task } m \text{ of task } p \\ & \text{ in the episode;} \\ 0, & \text{otherwise.} \end{cases}$$

The goal is to maximize the utility of the episode subject to a time constraint. We define the execution time for task m by agent i for task p in the episode as τ_{pim}, and the maximum time allowed to execute the task as $T_{\max}$, we express the task

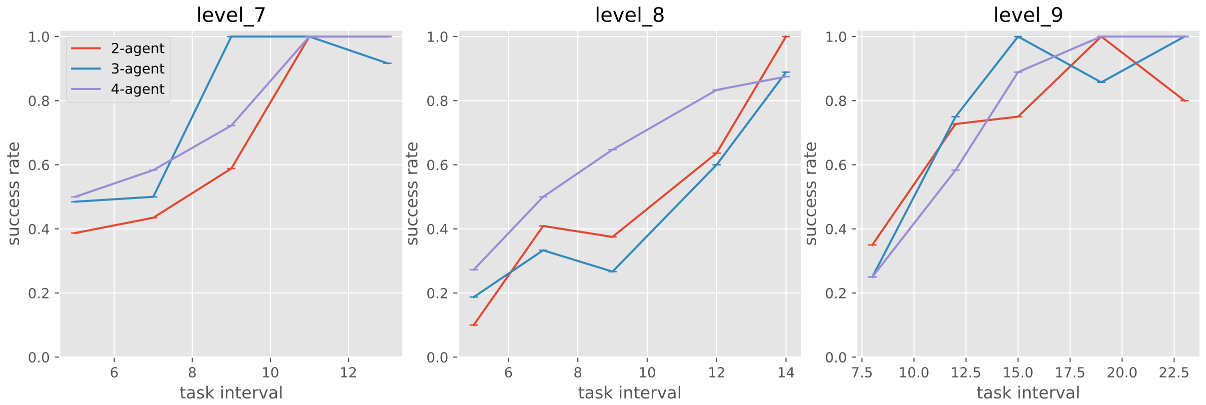

Figure 3: Collaboration efficiency curves on several levels. More level results can be found in the Figure 21 of Appendix E.

Table 1: Agent CoS performance scores on very simple, simple, intermediate, and advanced tasks for various numbers of agents.

decomposition and assignment problem as

$$\begin{aligned} &\arg\max_{v} \sum_{p=1}^{P}\sum_{i=1}^{N}\sum_{m=1}^{M_p} u_{pim} v_{pim}, \\ &\text{subject to} \\ &\quad \sum_{p}\sum_{i}\sum_{m} \tau_{pim} v_{pim} \leq T_{\max}, \\ &\quad \sum_{i} v_{pim} \leq 1 \quad \forall m \in M, \forall p \in P, \\ &\quad v_{pim} \in \{0,1\} \quad \forall i \in N, \forall m \in M, \forall p \in P. \end{aligned} \tag{1}$$

Since this problem cannot be solved in polynomial time, we tackle it by leveraging LFMs.

Our prompt design choices try to help an LFM system solve Equation 1. In practice, we reformulate the equation with qualities or rewards expressed in natural language as environmental feedback. For example, when the agent successfully collects an item, the environment emits a signal "collect finish". When the dispatcher assigns a different task to the same agent, the environment emits a signal "agent IDs cannot be the same". As rewards are not immediately observable, we borrow spirits from temporal difference learning. State-action history is accumulated into the memory history. Due to context length limits, it is infeasible to fit the entire history into the context window. We select a fixed horizon history as part of the prompt. We further express the constraints of the system in natural language and repeat important constraints multiple times if necessary.

5 Experiments and Results

We have conducted extensive experiments in CuisineWorld. We first introduce the experiment settings and then present an analysis of our empirical results. We report LFM settings in Appendix C. Our experiments focused on addressing the following research questions:

Q1: How efficiently can the model dispatch multiple agents?

Q2: Can the model dispatch agents for dynamic, on-the-fly goals across different tasks?

Q3: To what extent can the existing methods collaborate with human users?

Q4 What is the human perception of collaborating with numerous intelligent agents?

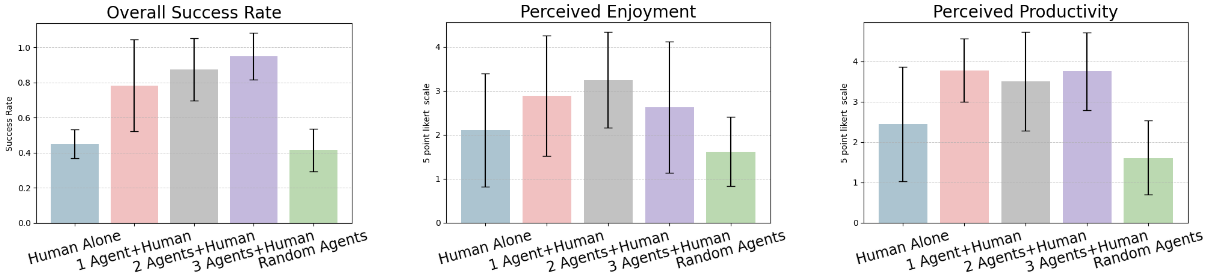
Q5: How do various components of the input prompt influence the model's performance?

Q6: How do other LFMs perform compared to GPT-4?

5.1 Experimental Regimen I: LFMs Dispatch Multi-Agent NPCs (Q1, Q2)

Figure 3 and Table 1 report the performance of our system under different settings. Full results and visualizing figures are found in Appendix E .

As shown in Figure 3, in general, increasing the number of agents from 2 to 3 will increase the overall performance. However, when increasing more,



(a) **Collaboration score:** The collaboration score is higher if more agents are collaborating with human players, although the difference is insignificant.

(b) **Perceived enjoyment:** Humans enjoy the game more if they collaborate with the right number of agents.

(c) **Perceived productivity:** Players think collaborating with AI agents will improve productivity.

Figure 4: Human Evaluations. Full results are reported in Figure 28 in the Appendix

the overall performance might drop due to the complexity of multi-agent collaborations, as shown by the corresponding CoS by level. As shown in the tables, the CoS is the highest when there are two agents in two cases. The CoS is the highest when there are three agents in seven cases. The CoS is the highest when there are four agents in three cases. Second, we observe that the system performance degrades with more agents under less demanding conditions, indicating that the LFM dispatcher struggles with fewer tasks.

5.2 Experimental Regimen II: Human and Multi-NPCs with LFMs

We recruited 12 subjects for our internal ethics review approved study, including 2 females and 10 males. During testing, we recorded only user interaction data. Identifiable information was not recorded. Subjects could quit at any time. We used ANOVA to test the effects of different experimental conditions on collaboration performance and the subjective perceptions. Tukey HSD tests were conducted on all possible pairs of experimental conditions.

We conducted a user study in our gaming environment that addresses **Q3** and **Q4**. The user study evaluates the LFM dispatcher's ability to collaborate with humans, where participants are collaborating with 1, 2, and 3 agents or working alone on the virtual cooking tasks (level 3).

The user study tests the following hypotheses:

H1: Task productivity. Participants have higher productivity when collaborating with AI agents.

H2: Task productivity with more agents. Participants have higher productivity when collaborating with more AI agents.

H3: Perception of the AI agents. Participants have higher perceived task efficiency and more fun playing the game due to collaboration.

We use a within-subject design for our experiment. Every user tries to finish the task solo or collaborates with different numbers of agents with varying competency. We randomize the order of the treatment to mitigate practice, fatigue, and carryover effects.

Single agent: Participants work by themselves.

LFM-powered multi-agent system: Participants collaborate with the multi-agent AI system powered by an LFM.

Random agent: Random agents execute random actions from a pool of valid actions. Participants collaborate with random AI agents.

As shown in Figure 4 and Figure 28, we found significant effects on the team collaboration success rate $F(4, 55) = 28.11$, $p < 0.001$. Post-hoc comparisons using Tukey HSD tests revealed that the team comprising the human player with LFM agents achieves a higher success rate than the human working alone ($p < 0.001$) across different numbers of agents, **thus confirming H1**. Although collaborating with more agents led to a greater success rate, collaborating with one agent was not significantly different from collaborating with two or three agents ($p = 0.774$ and $p = 0.231$, respectively). Therefore, we are **unable to confirm H2**. We observed that human players have more fun playing the game when collaborating with LFM-powered AI agents than when playing alone ($p = 0.0126$). Players felt that collaboration with AI agents leads to higher productivity ($p = 0.0104$), **thus confirming H3**. Additionally, when playing with AI agents, human players take their actions based on other players' actions ($p = 0.00266$). Human players also found that AI agents are more predictable than random agents ($p < 0.001$). Further insights from player feedback

CoS	0.822	0.775

Table 3: Using different numbers of agents as one-shot demonstrations

highlighted an intriguing trade-off: while greater numbers of agents improved overall task success rates, this reduced the enjoyment of the game. Often, players felt sidelined and less involved. Thus, game developers should adjust AI performance to maintain player engagement and fun. As suggested by Yuan et al. (2022), aligning human values with AIs is a promising approach. The visualization figures of CuisineWorld showed in Appendix E.2.

6 Ablation Study for Multi-Agents

6.1 Study of the Prompt Components (Q5)

In Table 2, we elucidate the performance of LFM dispatchers with certain components of the prompt omitted. We chose level 3 as the basis for our ablation study. It was selected because it displayed a clear correlation between an increased number of agents and improved performance, serving as a stable benchmark for evaluating the LFM's coordination capabilities. We recognize that the LFM may not perform consistently across all levels on the challenging CuisineWorld benchmark. When performance is variable or poor on certain levels, it can obscure the effects of ablation studies due to multiple confounding factors. Details about the prompt can be found in the appendices. Specifically, for these tests, we excluded individual components such as the inference knowledge, reduced the prompt example to a mere two steps instead of the complete demonstration, and evaluated the model without environmental feedback.

Table 2 indicates a significant drop in performance when environmental feedback is excluded, underscoring its pivotal role in the efficacy of the LFM dispatcher. Replaying action sequences reveals that, without feedback, the LFM dispatcher tends to repeat mistakes and gets stuck in specific states for prolonged durations. Another key takeaway is that a succinct two-step demonstration of input and output format can still achieve impressive performance for unseen tasks with dynamic objectives. Notably, in these two-step instances, there is no explicit guide to finishing any tasks, yet the model does not merely complete the task but continually performs additional tasks within the same episode. Furthermore, we observe that integrating human-crafted inference knowledge bolsters the performance of the LFM dispatcher. Lastly, even with few-shot demonstrations involving fewer agents, the LFM dispatcher retains satisfactory performance, as shown in Table 3.

	2 agents				3 agents			
	GPT-4	Claude-2	LLaMA2	ChatGPT	GPT-4	Claude-2	LLaMA2	ChatGPT

	4 agents							
	GPT-4	Claude-2	LLaMA2	ChatGPT				
CoS	0.848	0.473	0	0				

Table 4: Performance of other LFMs on Level 3

6.2 Study of the Performance of other LFMs (Q6)

To study how other LFMs perform on our tasks, we tested the collaboration performance of GPT-3.5, Claude-2, and LLaMA2, and Table 4 summarizes the results. For a fair comparison, all tests employed identical prompt inputs.

We observed that while other LFMs tend to underperform, models such as Claude-2 manage to complete the task to a considerable extent.

7 Emergent Abilities

Across our experiments, our MindAgent framework exhibits the following emergent properties:

7.1 Emergent Collaboration Task Understanding

As shown in Table 2, especially in the few-step ablation entries, GPT-4 exhibits its proficiency even when not provided with a full demonstration of specific tasks. To clarify, a "full few-shot demo" typically refers to a comprehensive demonstration of a task, detailing each step and procedure involved. By contrast, we provide GPT-4 with only a partial demonstration or a glimpse of the task executing only two steps. Yet, despite this limited input, GPT-4's performance is remarkable. This underscores GPT-4's impressive **emergent zero-shot multi-agent planning** abilities. Beyond simply completing unseen tasks, GPT-4 also demonstrates adaptability by dynamically prioritizing multiple

Performance	0.195	0.381	0.704	0.792	0.833	0.581

Table 5: Performance of MindAgent framework in Minecraft

different tasks as they arise, emphasizing its **emergent multi-task, on-the-fly planning** skills.

7.2 Emergent Multi-agent Reasoning Abilities

Referring to Table 3, GPT-4 has the ability to deploy more agents based on demonstrations of fewer agents. For instance, it can effectively dispatch 4 agents having only seen demonstrations involving 2 agents. The performance is better when 4 agents use 2-agent demos compared to 4-agent demos, possibly because the task suits 2 or 4-agent teams. With 4 agents, the model can create two independent teams of two, showing its ability to allocate tasks and plan for more agents than previously experienced.

8 Novel Game Adaptation

In line with our ongoing efforts to create collaborative, in-game, multi-agent systems, we integrated our infrastructure into Minecraft (Figure 5). In this adaptation, we designed several unique cooking tasks where two in-game agents, Alex and Steve, must cook various types of meat as shown in Appendix F.2. After cooking, they must deposit the meats into a chest. See Table 5 for the experimental results, and see Appendix F.3 for additional visualizations. The action details of Minecraft please take the reference in Appendix F.4. We provide more details about transfering to Minecraft in F.1.

Incorporating game-specific domain knowledge into the system is crucial for games in which specific knowledge plays an important part. In CuisineWorld and Minecraft, we inject domain-specific knowledge (such as recipes) directly into the context, which the LFMs utilize to inform the decision-making and collaboration strategies. This demonstrates the feasibility of adapting MindAgent to other domains where specific knowledge plays a crucial role. In addition, techniques like Retrieval-Augmented Generation (RAG) and Fine Tuning may be pivotal in further developing MindAgent's ability to handle domain-specific complexities.

9 Conclusion and Prospects

We introduced MindAgent, an infrastructure for multi-agent collaboration through LFMs across multiple gaming domains. We investigated its multi-agent planning capabilities, and we deployed our infrastructure into real-world video games that demonstrate its multi-agent and human-AI collaboration effectiveness. Additionally, we presented CuisineWorld, a text-based multi-agent collaboration benchmark that provides a new auto-metric Collaboration Score (CoS) to quantify collaboration efficiency. We anticipate that our work will guide the development of future gaming systems in which human-AI collaboration is seamless and intuitive. We are optimistic that our insights and findings will catalyze the design of games that are both technologically advanced and significantly more engaging and enjoyable for players.

Limitations

Despite some significant findings, we also observed several limitations through our experiments. 1) GPT-4 heavily relies on feedback; without feedback its performance drops significantly as indicated in Table 2. 2) GPT-4 is sensitive to prompt inputs as indicated in Table 2, without inference knowledge, the performance will drop. 3) Current high-performance LFMs are not open-source, which lacks transparency. 4) In this work, we used a text-game setting, and we did not observe players' states from players' perspective (e.g., observing player screen or using cameras), which may hinder the capability to infer player intentions.

Ethical Considerations

Multi-agent AI systems offer versatile applications, enhancing both productivity tools and gaming experiences. Advances in this field not only aid in achieving these objectives but also promote a wider comprehension of how to effectively model embodied and empathetic agents in both simulated and real-world environments. Many applications of this technology hold the potential for positive impact.

However, there's a risk that malicious actors might exploit these systems. Specifically, multi-agent AIs capable of content generation could be used for manipulation or deception. To mitigate these risks, it's crucial to adhere to responsible AI practices. This includes transparently informing users when they're interacting with AI-generated content and offering them control over customizing these systems to safeguard against misuse.

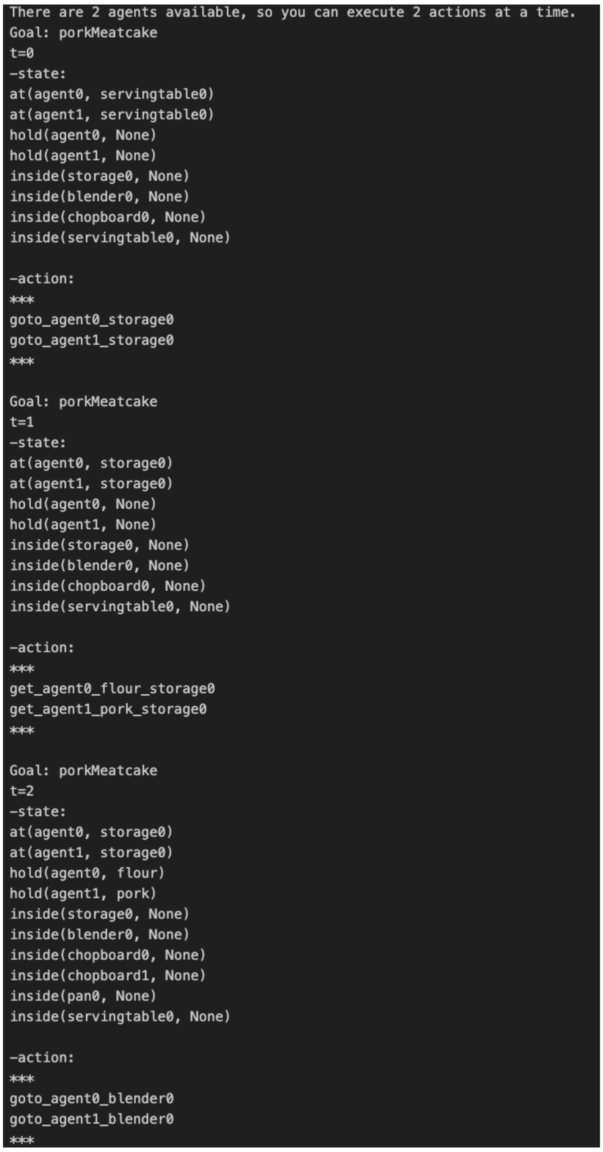
MindAgent: Emergent Gaming Interaction

A Prompt Examples

We provide some examples of prompts for CuisineWorld. Figure 6 shows an example of the system prompt info. Figure 7 shows an example of a partial demonstration.



```
There are 2 agents available, so you can execute 2 actions at a time.
Goal: porkMeatcake
t=0
-state:
at(agent0, servingtable0)
at(agent1, servingtable0)
hold(agent0, None)
hold(agent1, None)
inside(storage0, None)
inside(blender0, None)
inside(chopboard0, None)
inside(servingtable0, None)

-action:
***
goto_agent0_storage0
goto_agent1_storage0
***

Goal: porkMeatcake
t=1
-state:
at(agent0, storage0)
at(agent1, storage0)
hold(agent0, None)
hold(agent1, None)
inside(storage0, None)
inside(blender0, None)
inside(chopboard0, None)
inside(servingtable0, None)

-action:
***
get_agent0_flour_storage0
get_agent1_pork_storage0
***

Goal: porkMeatcake
t=2
-state:
at(agent0, storage0)
at(agent1, storage0)
hold(agent0, flour)
hold(agent1, pork)
inside(storage0, None)
inside(blender0, None)
inside(chopboard0, None)
inside(chopboard1, None)
inside(pan0, None)
inside(servingtable0, None)

-action:
***
goto_agent0_blender0
goto_agent1_blender0
***
```

Figure 7: The MindAgent system partial one-shot demo example.

B Prompt Engineering Details

Our initial approach began with a simple and generic prompt, designed to be as neutral as possible. This baseline prompt was tested across all models, including GPT-4, Claude, and other LFMs in our study. We observed that only GPT-4 and Claude were able to generate reasonable planning responses with this initial prompt. Consequently, we refined our prompt engineering efforts to better suit these two models, aiming to optimize their performance and response quality.

For the other LFMs, we also attempted individual prompt engineering. However, these efforts did not yield significant improvements in their responses compared to the initial trial. After several rounds of testing and refinement, we concluded that further prompt customization for these models did not result in notably better outcomes.

As a result, we decided to use a consistent prompt across all LFMs for the final comparison. This decision was made to maintain uniformity in testing conditions, despite the prompts being more closely tuned to GPT-4 and Claude. We believe this approach offers a reasonable balance between fairness and practicality in evaluating the capabilities of different LFMs under similar conditions.

C LFM Settings

We perform experiments on CuisineWorld through OpenAI APIs and Anthropic APIs (Anthropic, 2023). All GPT-4 (OpenAI, 2023) experiments employ the gpt-4-0613 model, and all Chat-GPT (Ouyang et al., 2022) experiments employ gpt-3.5-turbo-0613. For the Llama 2 (Touvron et al., 2023) experiments, we use the hugging face inference endpoints Llama-2-70b-chat-hf. We set the temperature for all experiments to 0.1 following Wang et al. (2023a). We report the average results over three episodes. These LFMs can be accessed through publicly available APIs or huggingface endpoints. These APIs are for public use. However, users should be aware of their licensing agreements before using them.

C.1 Design considerations

We adopted a centralized setting for the following reasons:

Token Limitation: In decentralized settings like ours, each agent needs to compile a full system message which includes a distinct copy of recipes, rules, one-shot demo is required, while in centralized setting we only need one system message to

```
[The available actions are :
 1) goto: goto a tool location
[2) get: get some object from a tool
 3) put: put some object into a tool
 4) activate: activate the tool to cook all ingredients inside the tool into a different tools
[5) noop: not performing any actions
 Sometimes the system will give you error messages. Please consider these error messages when executing actions.
 You need to specify action for all of the agents, **except human**. They all have different agent numbers. Do not assign actions to the same agent more than once.

 When the tools reach its capacity, you need to take stuff out. Otherwise, you cannot put items inside.
 When you are holding objects, you cannot get any more objects.
 When you are holding objects, you cannot activate tools.
 Afer you cooked a required dish, you need to put it into the servingtable.
[You can only pick up objects from the tool location, if you are located at the tool location.
[When you activate any tools, make sure all the items inside the tool are respecting the recipes. Otherwise, you will cook waste. Avoid waste at all cost.
[*** You should mix salad in the mixer. To make salad you should chop veggies first. ***
 *** If the tool is occupied, indicated by the occupy() predicate, you cannot get objects from it or put objects into it. ***
[*** The food orders are keep coming. You should finish as many dishes as possible and finish every dish as soon as possible. Please deliver the order to the serveringtable when it is finished. ***
[*** The dish will expire after the lifetime reaches 0 and it's not at the serveringtable. Please avoid this. *** Here are the recipes:

 Cook porkMeatcake at:
  -- location: blender
  -- with ingredients:     pork,     flour,
 Cook salmonSashimi at:
  -- location: chopboard
  -- with ingredients:     salmon,
 Cook tunaSashimi at:
  -- location: chopboard
  -- with ingredients:     tuna,
 Cook mixedSashimi at:
  -- location: mixer
  -- with ingredients:     salmonSashimi,     tunaSashimi,
 The following objects are available:
  --1) salmonSashimi
  --2) tuna
  --3) mixedSashimi
[ --4) tunaSashimi
  --5) porkMeatcake
  --6) salmon
[ --7) flour
  --8) pork
 The objecsts are cooked using tools or are just base ingredients.
 Among them, the following are base ingredients:
[ --1) tuna
  --2) salmon
  --3) flour
  --4) pork
[You can only obtain base ingredients from the storage initially.
 Additional rules:
 You can place up to infinite item into the storage0
[You can place up to infinite item into the storage0
 You can place up to infinite item into the servingtable0
 You can place up to infinite item into the servingtable0
 You can place up to 1 item into the chopboard0
 You can place up to 1 item into the chopboard0
 You can place up to 1 item into the chopboard1
 You can place up to 1 item into the chopboard1
 You can place up to 5 item into the mixer0
 You can place up to 5 item into the mixer0
[You can place up to 5 item into the mixer1
 You can place up to 5 item into the mixer1
 ** Only ** the following tools are available:
 storage0, servingtable0, chopboard0, chopboard1, mixer0, mixer1, You cannot pick up these tools. You can only use those tools at the corresponding location.
```

Figure 6: The MindAgent system prompt example.

describe them, which significantly reduces the total number of input tokens (within the input context) of LFM and therefore make the framework more affordable.

Communication overhead: Each agent needs to receive both their own state and the states of the other agentspossibly in text, while in centralized setting there is no communication among agents as other states are directly observable. This can also save the cost on input tokens.

Save API calls: In decentralized setting, to generate one environment step, we need to call API N times (N == agents), while in centralized setting we only need to call the API once and we will be able to obtain actions for all agents (as produced by the centralized LFM dispatcher).

D CuisineWorld Task Details

D.1 CuisineWorld Task Definitions

We follow prior work (Yao et al., 2023; Liu et al., 2023; Deng et al., 2023) to **interactively evaluate LFMs as planning agents**. Overall, the interactive evaluation can be formulated as a *Markov Decision Process* $(\mathcal{S}, \mathcal{A}, \mathcal{T}, \mathcal{R}, \mathcal{G})$, with state space $\mathcal{S}$, action space $\mathcal{A}$ (effectively indicating all the possible schedules that can be made at a single time step), transition dynamics $\mathcal{T}$, reward function $\mathcal{R}$, and task instruction space $\mathcal{G}$. Note that, although there are multiple agents inside CuisineWorld that can be coordinated, asmentioned above, we adopt a centralized planning scheme and thereby formulate our game as a single-agent, fully-observable decision-making problem. An illustration of the state & action space and the possible tasks of our game can be found in Figure 1 of the paper.

State Space $\mathcal{S}$ In a CuisineWorld virtual kitchen, there are two types of entities: `location` and `agent`. For each entity, the game will provide a set of descriptions, and the aggregated descriptions of all entities will be the state returned by the game. A `location` can be *storage*, where one can obtain ingredients and dispense waste, a *serving table*, onto which one should put the completed, or a cooking tool; *e.g.*, *pan* or *blender*. We offer up to two descriptions for each location: `inside(location, items)`, indicating what items (some ingredients, completed dishes, *etc.*) are now inside the location, and `occupy(location)`, suggesting `location` is now being used and cannot be touched; *e.g.*, an activated blender. An `agent` is an entity that can be dispatched to complete the task, and we provide up to three descriptions for each agent: `at(location, agent)`, indicating that agent is now at `location`, `hold(agent, items)`, suggesting what items agent is holding, and `occupy(agent)`, implying `agent` is now operating a tool, *e.g.*, chopping some fruits, and will not respond to any dispatching command. The set of tool distributions can be found in Table 23.

Action Space $\mathcal{A}$ An action in CuisineWorld is a list of dispatching commands. Given N agent entities, a total of N commands must be generated. The agent provides the following commands (also tabulated in Table 14):

1. `goto(agent, location)`, to let `agent` move to `location`;
2. `get(agent, location, item)`, to let `agent` get a specific item from `location`;
3. `put(agent, location)`, to put whatever `agent` is holding into `location`;
4. `activate(agent, location)`, to let `agent` turn on `location` if it is a cooking tool, *e.g. blender*;
5. `noop(agent)`, to have `agent` perform no actions in this round of dispatching.

Note that, to avoid the possible confusion of multiple agents being dispatched to operate with the same `location`, the dispatcher also must properly order the dispatching commands as they will be executed sequentially.

D.2 Implementing CuisineWorld

The implementation of CuisineWorld mostly follows the spirit of *Overcooked!*, a renowned video game. Therefore, we refer to many of its game mechanisms while simplifying some of them; *e.g.*, we skip low-level control and assume all `agent` entities have access to all `location` at any time. Specifically, we crawled the rules and recipes from the community-contributed wiki[1] of *Overcooked!* streamlined them, and made necessary modifications, ending up with the basic version of CuisineWorld comprising **10** types of `location` (*serving table*, *storage*, and 8 different cooking tools), **27** types of ingredients, and **33** unique dishes. We grouped the dishes based on their difficulty (primarily based on the number of cooking tools involved) to design and implement **12** game levels, which are further categorized into 4 classes: *entry*, *simple*, *intermediate*, and *advanced*, with 3 levels each. Note that the recipes, dishes, and levels can be easily extended to incorporate more challenging tasks.

D.3 Task Graph Visualization

In CuisineWorld, we provide tasks of different complexities to holistically evaluate the multi-agent system's performance. Additionally, the environment is highly customizable and extendable. Users only need only modify the JSON files to add more tasks or modify existing tasks. In the following sebsections, we visualize different CuisineWorld task graphs.

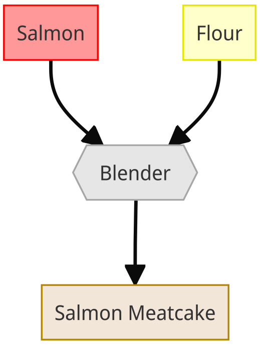


Figure 8: Level 0 – Very Simple Salmon Meatcake

E Additional Results in CuisineWorld

The following tables report additional performance results for several different numbers of agents and task complexity levels, performance of other LFMs, and additional ablation results: Table 6, Table 7, Table 8, Table 9, Table 10, Table 11. Table 12 shows the results of using a centralized PPO agent comparing against our method using heavily engineered dense rewards.

E.1 Comparison Between CuisineWorld and Related Benchmarks

Table 13 compares CuisineWorld against related benchmarks along the following criteria:

- **Multi-task**: The benchmark contains multiple different tasks.
- **Object Interaction**: Agents must manipulate or engage with different items or environmental elements to achieve certain goals with irreversible actions.
- **Tool Use**: Completing tasks necessitates the use of specific tools by the agents.

Table 13: Comparison between CuisineWorld and other related benchmarks. *: Notably, even though multiple agents can be present, the second agent is limited to communicating with the first agent. The second agent cannot interact with the environment in an active gaming capacity.

- **Maximum Agents**: Denotes the upper limit of agents that can be present in any experiment.
- **Collaboration**: Many tasks mandate teamwork and collaboration between different agents.
- **Human in-the-loop**: The framework allows humans to join the game and collaborate actively with the agents.
- **Procedural Level Generation**: There is flexibility in adding new tasks, making the game dynamic and adaptable.

Compared to other benchmarks like (Wu et al., 2021; Carroll et al., 2019), we have the following differences:

Enhanced Kitchen Layouts: We have diversified the layout of kitchens by incorporating a wider range of tools (both in types and quantities) and ingredients. This approach differs from (Wu et al., 2021) and (Carroll et al., 2019), where the emphasis is not on the variety of kitchen tools and ingredients. For example, in (Carroll et al., 2019), there are only two types of ingredients and two types of tools. In (Wu et al., 2021), there are two types of ingredients, and two types of tools. In comparision, there are 27 unique ingredients, and 10 tools in CuisineWorld.

Complex Task Design: Our benchmark includes a broader spectrum of recipes, varying significantly in difficulty levels. This variation is not just in terms of the number of tools and ingredients required but also in the intermediate steps involved in each recipe. We invite you to refer to Figure 23 for a detailed illustration. This aspect of task complexity, particularly in the context of high-level planning, is not extensively explored in (Carroll et al., 2019) and (Wu et al., 2021). In (Wu et al., 2021; Carroll et al., 2019) there are very limited number of dishes, 1 and 3 respectively. However, in CuisineWorld, there are 33 unique dishes.

Multi-Dish Episodes and Collaborative Strategy Assessment: We require agents to complete multiple dishes within a single episode, with the types of dishes varying to challenge and assess the collaborative strategies of the agents. Our level design ensures that there are shared intermediate steps among the types of dishes in a single episode. The system is tasked with multiple different goals at the same time. This approach allows us to use metrics like ‘Collaborative Score’ (CoS) to evaluate how agents collaborate to achieve higher dish throughput. This dynamic aspect of collaboration, especially in the context of dish expiration and shared tasks, offers a new dimension to the study of multi-agent cooperation, which is distinct from the environments in (Carroll et al., 2019) and (Wu et al., 2021). In (Carroll et al., 2019) the goal is to finish as many dishes as possible in a limited amount of time. In (Wu et al., 2021), the goal is to finish one dish in the least amount of time. Both of them do not consider the density of the tasks (interval between dish orders coming to the kitchen) and its effect on coordination. As we mentioned earlier, this concpet (changing density of the tasks and measuring collaboration proficiency upon it) is at heart of CuisineWorld and our CoS metric, and it has demonstrated its effectiveness of benchmarking collaboration between LFMs and human-NPCs (as indicated in the abstract).

E.2 Visualizing CuisineWorld

To implement CuisineWorld into a real-world game system, we built on top of Gao et al. (2020). In our game, as visually depicted in Figure 22, players are given the opportunity to engage in collaborative interactions with NPCs. This introduces a unique dynamic to the gameplay, enabling users to experience a more immersive cooperative environment. Additionally, the game's interface is versatile, providing players multiple ways to interact within the game world. They can either use a standard keyboard setup, which is conventional and likely familiar to most PC gamers, or immerse themselves even further using a Virtual Reality (VR) device. This VR functionality ensures a more tactile and realistic interaction, as players can physically move, gesture, and engage with the NPCs and other in-game elements in the 3D environment.

Unlike the step-by-step nature of the text version, the real-time virtual game operates continuously. To align the LFM's processing with this dynamic environment, we implemented a system where the LFM checks user actions at regular intervals during the game loop, referred to as "time steps". These time steps are defined as 0.1 seconds. Then we can ensure LFM can respond to user actions in a timely manner, matching the pace of the real-time game.

In the real-time version, human players control their agents directly through keyboard inputs, resulting in low-level actions like moving or picking up items. However, the LFM-agent operates on a higher, more temporally-extended level of atomic actions. To bridge this gap, when the LFM checks user actions, it doesn't just read the keyboard inputs. Instead, it assesses changes in the high-level game state, such as the agent's location, and the status of tools and ingredients. This assessment allows the LFM to infer the temporally extended actions that align with its text-based decision-making process. Implementing this required a simple inverse dynamics model through checking state changes to translate low-level actions into high-level atomic actions, facilitating a seamless transition from the text game to the real-time virtual game. For 'GoTo' action, we utilized the A* pathfinding algorithm, integrated into the Unreal Engine, to facilitate this movement.

E.3 Additional CuisineWorld Details

E.4 Task Interval Computation

In our approach, we initially construct a task graph delineating subgoals, which serves as the foundation for our computations. We then apply breadth-first search in a single-agent context to determine the optimal task sequence. This sequence is a key component for calculating task intervals in multi-agent collaboration scenarios. For each tool requiring activation, we incorporate its activation wait time into the respective task intervals. Additionally, for each new connection in the task graph, we increase the total task interval time by tripling the edge time. We assume each subgoal requires at least, goto, get and put 3 actions. The cumulative task interval is subsequently adjusted by a scaling factor of 0.3 and the variable τ. We pick the value tau ranging from 1.0, 1.5, 2.0, 2.5 and 3.0 to represent different task difficulties. This process enables us to effectively compute task intervals tailored for multi-agent collaborative environments of varied difficulties.

E.5 Common Failure modes

Through replaying actions, we have identified the following common failure modes for GPT-4 agents: 1) Inability to Prioritize Task Order: Occasionally, the LFM overlooks the task at the top of the queue, leading to the expiration of that task. 2) Difficulty Understanding the 'Occupy()' State Instruction: In CuisineWorld, agents must wait for **varying** timesteps before cooking is completed, with the wait time dependent on the specific tool used. If agents attempt to remove ingredients immediately after activating a tool, the action fails. Instead of continuing to wait, the agents may shift their focus to other tasks, which slows down overall progress. 3) Challenges in Allocating Agents to Correct Subgoals: When multiple dishes are being prepared concurrently, the agents often struggle to allocate themselves effectively to the appropriate subgoals.

E.6 Rational for CoS Metric

- In the kitchen scenario as demonstrated in CuisineWorld, hypothetically, when the dish order come very rarely (with a large interval), no matter if there is any collaboration, high success rate can easily attained as there is sufficient time.

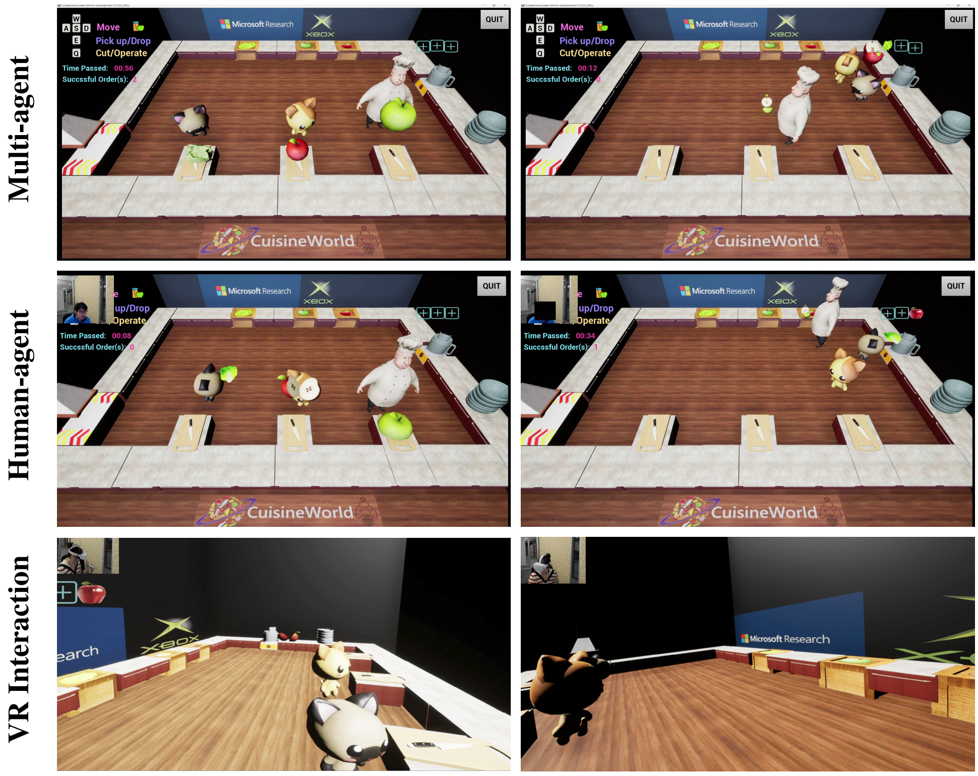

Figure 22: (Top) A multi-agent collaboration example in CuisineWorld; the three agents are preparing a mixed juice together. (Middle) A human player as the head chef instructing the agents to cook mixed juice. (Bottom) A human player collaborating with collaborative agents in VR.

Type	Arguments	Description
goto	agent location	Move agent to location
get	agent location (item)	agent obtain item from location
put	agent location	agent put everything it holds to location
activate	agent location	agent turn on location
noop	agent	not dispatching agent

Table 14: Action space in CuisineWorld.

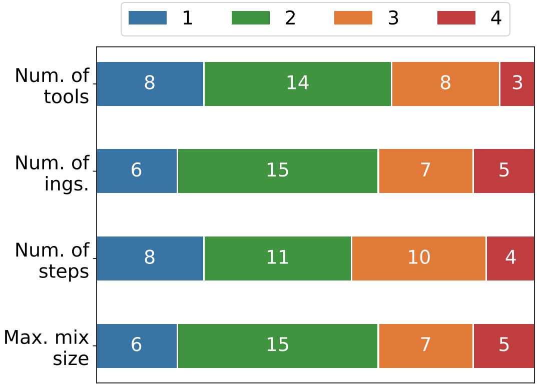

Figure 23: Dish distribution over the number of tools and ingredients (ings.) involved, cooking steps, and maximum mixture size as in the recipe.

- However, as we reduce the interval, more and more dish order are flooding in. If the agents (and humans) are able to collaborate well, the productivity will be high, or namely, they can still manage to maintain a decent success rate. On the contrary, teams with poor collaborate will likely suffer from a substantial drop on success rate as the interval gets smaller. The same collapse will ultimately happen to a good collaborative team too when the interval gets too small, but good collaboration can always sustain longer.
- Therefore, it makes sense to use the averaged success rate across different intervals as an indicator of the collaboration proficiency. More importantly, such metric asks for a game setting where the dish order will keep coming, in a changing interval, which also aligns with the original Overcooked! game experiences.

F Minecraft

F.1 Transfer to Minecraft

To transfer MindAgent from CuisineWorld to Minecraft requires modifications on both games and the model. On the LFM side, we update the background knowledge of the model. This included: 1) Action Space Explanation: We provided the LFM with detailed information about the possible actions and interactions within the Minecraft environment. 2) Recipe and Tool Definitions: We also included definitions of recipes, tools, and ingredients specific to Minecraft. We believe these modifications are reasonable and necessary, as without these knowledge, it's very difficult for model to operate in an unknown environments. On the game development side, we dedicated efforts to: Text-to-Game Interaction Translation: We developed code to translate text-based interactions and commands from the LFM into actionable inputs within the game environment. This translation layer was key to bridging the gap between the LFM's text-based outputs and the game's interactive elements.

F.2 Task Graphs

In Figure 24 we visualize the task graphs for different tasks in Minecraft.

F.3 Gameplay Visualization

We visualize Minecraft gameplay in Figure 25.

F.4 Action Details for Mindcraft

We define the following actions for the multi-agent system in our Minecraft game: 1) `goto(agent, location)`; 2) `kiLFMob(agent, mobType)`; 3) `mineBlock(agent, blockType)`; 4) `putFuelFurnace(agent, fuelType)`, to put the item from agent's inventory to the furnace's bottom slot. 5) `putItemFurnace(agent, itemType)`, to put the item from agent's inventory to the furnace's top slot; 6) `takeOutFurnace(agent)`, take out the cooked item from the furnace 7) `putInChest(agent, itemType)`.

The state space in Minecraft contains the following: 1) nearby blocks for each agent, 2) nearby entities for each agent, 3) each agent's inventory, 4) items inside the furnace, 5) items inside the chest, and 6) the human player's inventory if a human player is involved.

To ensure reproducibility, we modify the game mechanism. A killed mob will respawn nearby, and a mined block will also respawn nearby.

G Additional Information on Human Evaluation

G.1 Human Data Collection

Measurement In the background, we collect the numbers of failed and successful tasks during a participant's interaction with the game system. Additionally, we record the entire action history of players and intelligent agents. After each episode, the participants must complete a survey about their engagement with the system on a 5-point Likert chart. Our objective measure is intended to evaluate the human-AI teaming performance, and the subjective measure is designed to evaluate users' perceptions of the system. The human evaluation interface can be found in Appendix G.

G.2 Human Evaluation Interface

We use the human evaluation interface to test the human's perception of collaborative agents. This gives us a more controlled environment so users' perception of collaborative agents does not depend on their ability to control the keyboard and mouse, and their perception of collaborative agents does not depend on the latency and rate limits of GPT-4. Figure 26 shows the interface welcome screen, human evaluation examples, and examples of human instructions.

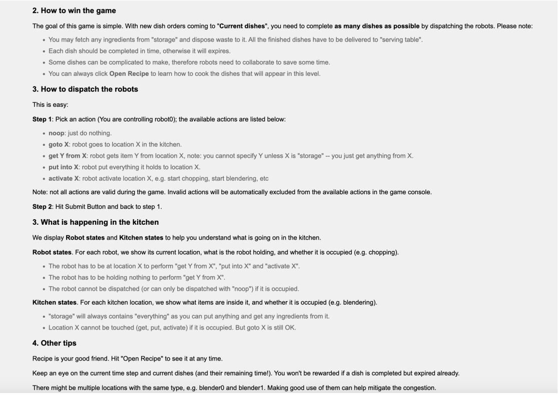
get_agent2_tuna_storage0
get_agent3_rice_storage0

(c) Human evaluation example



2. How to win the game

The goal of this game is simple. With new dish orders coming to "**Current dishes**", you need to complete **as many dishes as possible** by dispatching the robots. Please note:

- You may fetch any ingredients from "storage" and dispose waste to it. All the finished dishes have to be delivered to "serving table".
- Each dish should be completed in time, otherwise it will expires.
- Some dishes can be complicated to make, therefore robots need to collaborate to save some time.
- You can always click **Open Recipe** to learn how to cook the dishes that will appear in this level.

3. How to dispatch the robots

This is easy:

Step 1: Pick an action (You are controlling robot0); the available actions are listed below:

- **noop**: just do nothing.
- **goto X**: robot goes to location X in the kitchen.
- **get Y from X**: robot gets item Y from location X, note: you cannot specify Y unless X is "storage" -- you just get anything from X.
- **put into X**: robot put everything it holds to location X.
- **activate X**: robot activate location X, e.g. start chopping, start blendering, etc

Note: not all actions are valid during the game. Invalid actions will be automatically excluded from the available actions in the game console.

Step 2: Hit Submit Button and back to step 1.

3. What is happening in the kitchen

We display **Robot states** and **Kitchen states** to help you understand what is going on in the kitchen.

Robot states. For each robot, we show its current location, what is the robot holding, and whether it is occupied (e.g. chopping).

- The robot has to be at location X to perform "get Y from X", "put into X" and "activate X".
- The robot has to be holding nothing to perform "get Y from X".
- The robot cannot be dispatched (or can only be dispatched with "noop") if it is occupied.

Kitchen states. For each kitchen location, we show what items are inside it, and whether it is occupied (e.g. blendering).

- "storage" will always contains "everything" as you can put anything and get any ingredients from it.
- Location X cannot be touched (get, put, activate) if it is occupied. But goto X is still OK.

4. Other tips

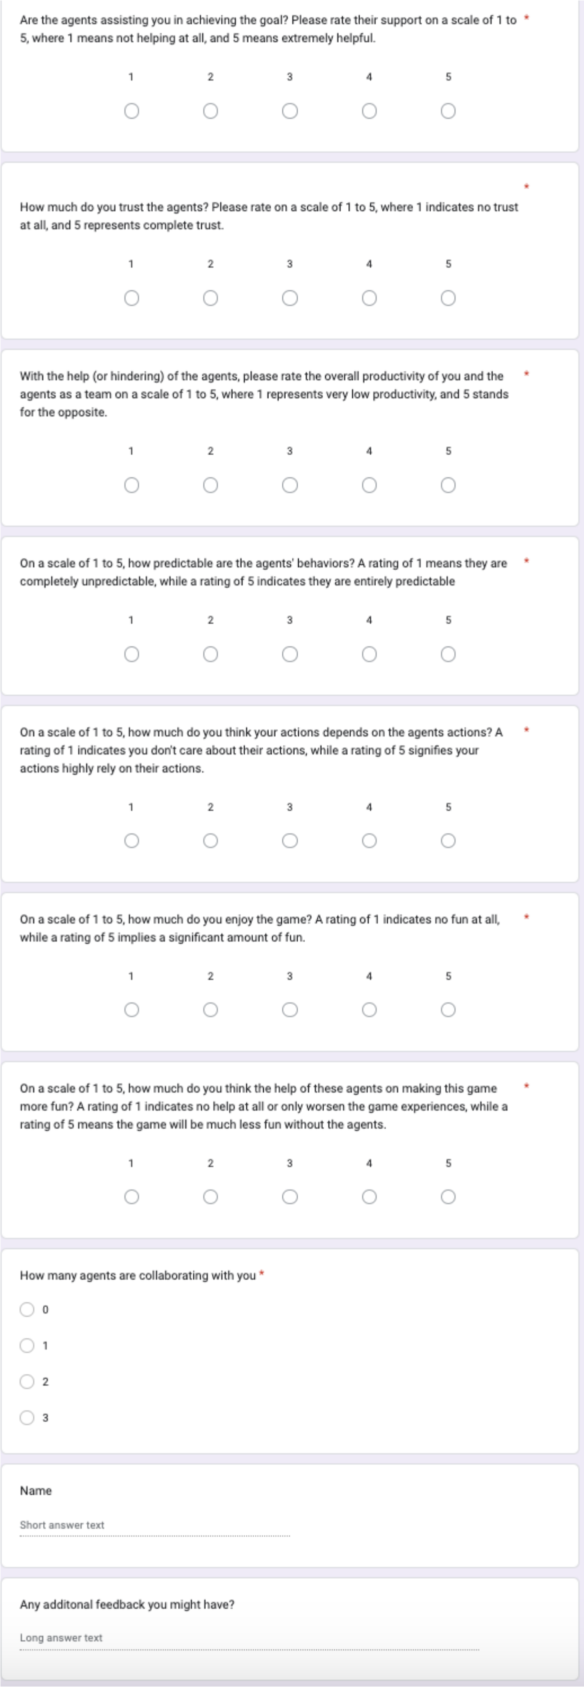
Recipe is your good friend. Hit "Open Recipe" to see it at any time.

Keep an eye on the current time step and current dishes (and their remaining time!). You won't be rewarded if a dish is completed but expired already.

There might be multiple locations with the same type, e.g. blender0 and blender1. Making good use of them can help mitigate the congestion.

(d) Human instructions

Figure 26: Human evaluation interface welcome screen (a), evaluation examples (b)–(c), and instructions to the human participants (d).



Are the agents assisting you in achieving the goal? Please rate their support on a scale of 1 to 5, where 1 means not helping at all, and 5 means extremely helpful. *

1	2	3	4	5
○	○	○	○	○

How much do you trust the agents? Please rate on a scale of 1 to 5, where 1 indicates no trust at all, and 5 represents complete trust. *

1	2	3	4	5
○	○	○	○	○

With the help (or hindering) of the agents, please rate the overall productivity of you and the agents as a team on a scale of 1 to 5, where 1 represents very low productivity, and 5 stands for the opposite. *

1	2	3	4	5
○	○	○	○	○

On a scale of 1 to 5, how predictable are the agents' behaviors? A rating of 1 means they are completely unpredictable, while a rating of 5 indicates they are entirely predictable *

1	2	3	4	5
○	○	○	○	○

On a scale of 1 to 5, how much do you think your actions depends on the agents actions? A rating of 1 indicates you don't care about their actions, while a rating of 5 signifies your actions highly rely on their actions. *

1	2	3	4	5
○	○	○	○	○

On a scale of 1 to 5, how much do you enjoy the game? A rating of 1 indicates no fun at all, while a rating of 5 implies a significant amount of fun. *

1	2	3	4	5
○	○	○	○	○

On a scale of 1 to 5, how much do you think the help of these agents on making this game more fun? A rating of 1 indicates no help at all or only worsen the game experiences, while a rating of 5 means the game will be much less fun without the agents. *

1	2	3	4	5
○	○	○	○	○

How many agents are collaborating with you *

○ 0

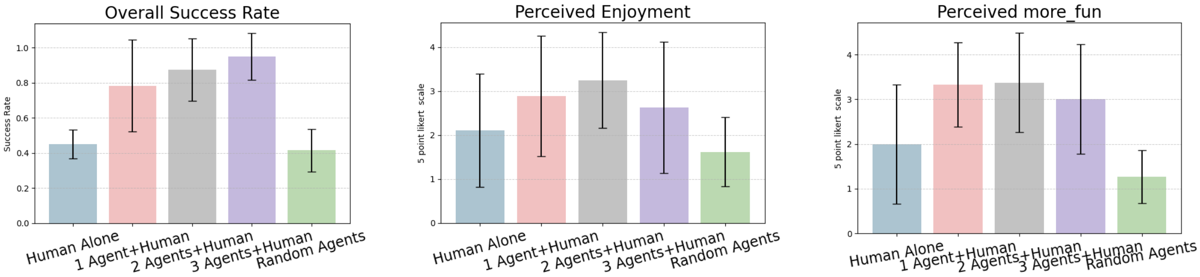
Long answer text

Figure 27: Human evaluation questionnaire

G.3 Human Evaluation

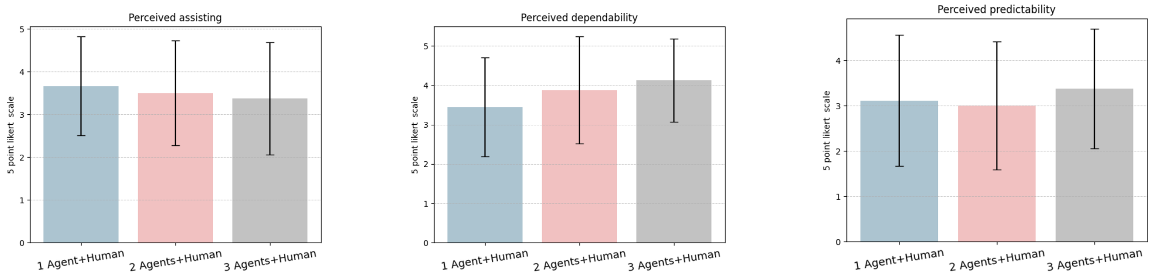
We list our human evaluation questionnaire platform in the Figure 27.



(a) **Collaboration score:** The collaboration score is higher if more agents are collaborating with human players, although the difference is not significant.

(b) **Perceived enjoyment:** Humans enjoy the game more if they collaborate with the right number of agents.

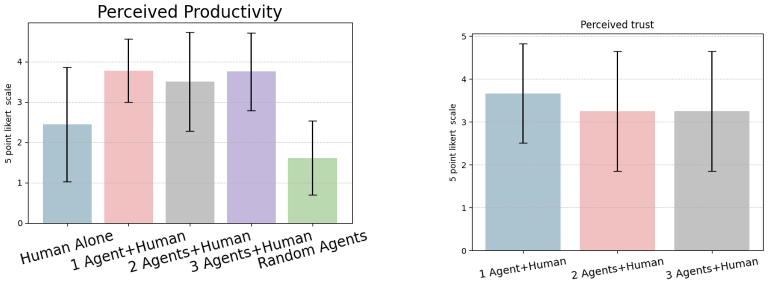
(c) **Perceived more fun:** Players enjoy the game more because of collaboration with competent agents.



(d) **Perceived Assisting:** There is no significant difference in terms of human perceptions of helpfulness when collaborating with more agents, even though the task success rate is higher.

(e) **Perceived dependability:** When collaborating with more agents, players depend on the agents more.

(f) **Perceived Predictability:** There is no difference in terms of the predictability of agent behaviors when collaborating with more agents.



(g) **Perceived productivity:** Players think collaborating with AI agents will improve productivity.

(h) **Perceived Trust:** There is no difference in terms of trust when collaborating with more agents.

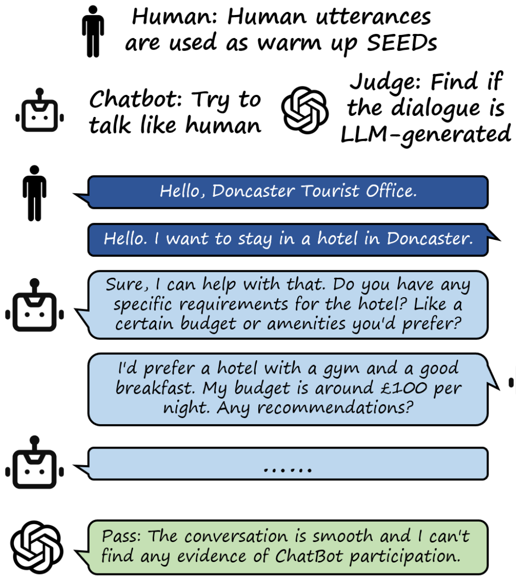
Abstract

In the realm of modern Large Language Models (LLMs), facilitating high-quality, multi-turn dialogues with humans represents a cornerstone feature. However, human-based evaluation of such a capability involves substantial manual effort. This study offers a formative assessment of current LLMs' proficiency in emulating human-like, multi-turn conversations using an LLM-centric approach. The evaluation encompasses three key elements in the evaluation pipeline: **utterance generation**, **evaluation protocol**, and **judgement**, and we delve deeply into each aspect. GPT-4, both as an utterance generator and as a judge, exhibits exceptional performance. As a generator, GPT-4 crafts dialogues indistinguishable from human interactions in terms of style and flow. When judging, it shows a heightened alignment with human evaluative standards and consistency. Conversely, other LLMs face challenges in producing quality multi-turn dialogues, hindered by inadequate instruction-following abilities, a propensity for prolix utterances, and overall limited capabilities. Notably, generating extensive dialogues (*e.g.*, spanning tens of turns) remains a formidable task for most LLMs, particularly in Chinese contexts. We hope that our work can serve as a valuable resource for evaluating the multi-turn chatting capabilities of LLMs. Related resources are available at `https://github.com/open-compass/BotChat`.

1 Introduction

The evolution of Large Language Models (LLMs) (OpenAI, 2023; Touvron et al., 2023a; Chiang et al., 2023; Cai et al., 2024) marks a transformative phase in artificial intelligence, significantly surpassing traditional language models (Devlin et al., 2018; Vaswani et al., 2017; Liu et al., 2019) in engaging in nuanced, multi-turn dialogues with humans. Modern LLMs interact with people through human-style multi-turn conversations, learning instructions, intentions, and context from human prompts to provide helpful feedback. Such advantage enables all of humanity to directly access the strong capability of LLMs for various applications, both general (Jiao et al., 2023; Shen et al., 2023) and within specific domains (Bran et al., 2023; Boiko et al., 2023).



Human: Human utterances are used as warm up SEEDs
Chatbot: Try to talk like human
Judge: Find if the dialogue is LLM-generated

Hello, Doncaster Tourist Office.

Hello. I want to stay in a hotel in Doncaster.

Sure, I can help with that. Do you have any specific requirements for the hotel? Like a certain budget or amenities you'd prefer?

I'd prefer a hotel with a gym and a good breakfast. My budget is around £100 per night. Any recommendations?

……

Pass: The conversation is smooth and I can't find any evidence of ChatBot participation.

Figure 1: **BotChat** evaluates multi-turn dialogue performance by prompting ChatBots to generate dialogues from initial human utterances, followed by evaluation through a judge LLM.

Despite their advanced capabilities, not all LLMs consistently deliver satisfactory performance in multi-turn human interactions. In practical applications, it has been observed that dialogues generated by certain LLMs frequently fail to meet user satisfaction criteria. The issues manifest in multiple aspects, including poor adherence to user instructions, undesirable tone, lengthy utterances, and the generation of repetitive content. The evaluation of these conversational capabilities remains

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3184–3200
June 16-21, 2024

a complex challenge. Traditional approaches, primarily human-based (Zheng et al., 2023), heavily involve manual labor for human-bot conversation generation and quality assessment. This paper proposes a more efficient paradigm, named **BotChat**, to evaluate multi-turn chatting capability.

BotChat is an entirely LLM-based approach, eliminating the need for manual labor. The methodology comprises two stages: dialogue generation and quality assessment. Initially, we use the very first utterances (*ChatSEED*) from multilingual real-world conversations (Cui et al., 2020; Wang et al., 2021) for utterance-by-utterance dialogue generation by ChatBots. In each step, a ChatBot generates one utterance based on all history utterances. This process autonomously generates dialogues with varying numbers of turns. In the second stage, we assess dialogues using different judge LLMs and a suite of LLM-based evaluation protocols. Our experiments demonstrate that GPT-4 excels in human alignment and self-consistency compared to other LLMs. We introduce three evaluation protocols: **UniEval** (individual dialogue evaluation), **PairEval** (comparative evaluation of two dialogues), and **GTEval** (comparison with a corresponding human dialogue). While UniEval and PairEval are applicable to dialogues with an arbitrary number of turns, GTEval is limited by the extent of the ground-truth dialogue. Additionally, addressing the unique challenges posed by repetitive utterances, which are common in Chinese conversational scenarios, we present **DupDetect** for preprocessing unnatural dialogue evaluations, thereby also reducing evaluation costs.

With the evaluation protocols, we compare representative LLMs, ranging from the state-of-the-art closed-source GPT-4 (OpenAI, 2023) to small-scale open-source LLMs (Touvron et al., 2023b; Bai et al., 2023). During the evaluation, three evaluation protocols draw substantially identical conclusions. GPT-4 generates human-style multi-turn conversations with impressive quality, outperforming all other LLMs. For all LLMs, the quality of generated dialogues declined quickly as the number of dialogue turns increases. Such degradation is particularly evident for small-scale open-source LLMs, compared to the top-tier LLM, GPT-4. In particular, this phenomenon is more pronounced in the Chinese context than in the English one. With qualitative assessment, we find that LLMs fail to generate multi-turn conversations with desirable quality primarily due to: poor instruction-following capability, a tendency to generate lengthy utterances, and limited general capability.

2 Related Works

2.1 Objective and Subjective Assessment of LLMs

Objective assessment is crucial for measuring the capabilities of Large Language Models (LLMs) in a quantifiable and unbiased manner. This assessment typically involves comparing the outputs of LLMs with established references or ground truths. For close-ended tasks (Huang et al., 2023; Hendrycks et al., 2020; Cobbe et al., 2021), the expectation is that the LLM outputs align perfectly with these ground truths. In contrast, open-ended tasks (Huang et al., 2021; Fabbri et al., 2019) rely on similarity metrics calculated between the LLM outputs and reference material, with higher similarity scores indicating superior task performance. Metrics such as F1-score, BLEU (Papineni et al., 2002), and ROUGE (Lin, 2004) are commonly used to quantify this performance.

Within the BotChat framework, the rationale is that conversations, even when initiated with the same ChatSEEDs, can diverge in myriad directions. Thus, an LLM-generated dialogue, though markedly different from its reference, should not be automatically deemed inferior in quality. This deviation from the reference is inherent to the open-ended nature of the task, necessitating a more nuanced approach to quality assessment in BotChat. Subjective assessment has become a standard approach in evaluating Large Language Models (LLMs) for complex scenarios. Recent studies leverage human evaluators or other LLMs as judges to compare LLM performance (Xu et al., 2023; Chiang et al., 2023; Fu et al., 2023; Li et al., 2023; Wang et al., 2023a; Zheng et al., 2023).

2.2 Human Conversation Datasets

The construction of end-to-end chatbots has garnered significant attention within the NLP community, leading to the collection of diverse conversational datasets (Serban et al., 2015). Among these, PERSONA-CHAT (Zhang et al., 2018) stands out for its engaging dialogues that exhibit distinct personalities. The work of (Zhou et al., 2018) integrates specific documents into multi-turn conversations, enriching the conversational depth. CoQA (Reddy et al., 2019) offers a unique dataset for conversational question-answering, compiled from dialogues between two annotators discussing a passage. MuTual (Cui et al., 2020) features dialogues derived from Chinese student English listening comprehension exams, targeting the enhancement of conversational models' reasoning abilities. Additionally, NaturalCONV (Wang et al., 2021) encompasses human-like Chinese conversations in various domains such as sports, entertainment, and technology, complete with related reference materials. In BotChat, MuTual and NaturalCONV are primarily utilized as the main sources of human dialogues. This selection is driven by the richness and diversity of conversational contexts these datasets offer, enabling a comprehensive evaluation and development of advanced chatbot capabilities.

3 BotChat

In this section, we delineate the evaluation paradigms incorporated into BotChat. The primary aim of this framework is to evaluate LLMs' conversational abilities in alignment with human subjective preferences. We begin with a comprehensive overview of the workflow for generating multi-turn dialogues. Subsequently, we introduce three distinct evaluation strategies: unitary evaluation (UniEval), pairwise evaluation (PairEval), and ground-truth evaluation (GTEval). Additionally, in response to the unique challenges posed by repetitive utterances (which frequently occur in Chinese conversational scenarios), we introduce DupDetect.

3.1 Dialogue Generation

In BotChat, multi-turn dialogues are generated exclusively based on ChatBots. This process initiates with authentic human conversations, from which the initial few utterances, termed ChatSEEDs, are extracted to serve as the basis for dialogue generation. We resort to the existing datasets MuTual (Cui et al., 2020) and NaturalConv (Wang et al., 2021) for real-world human conversations. Specifically, the first two utterances from each dialogue in these datasets are employed as ChatSEEDs.

The dialogue generation progresses in an utterance-by-utterance manner. To guide the ChatBot in producing human-like, concise utterances, a system prompt[1] is introduced at each step. During each turn, this prompt, along with all preceding utterances in the dialogue, is provided to the ChatBot, which then generates the next utterance. This iterative process continues until the predetermined number of dialogue turns is achieved. The pseudocode detailing the generation paradigm is delineated in Algorithm 1.

In the case of NaturalConv, each conversation is accompanied by a reference document. To explore the impact of such contextual information, both unconditional (UNCON) and conditional (CON) settings are implemented in the generation process. Under the CON setting, the LLMs are additionally provided with the relevant reference document to ascertain whether its presence eases or complicates the dialogue generation task.

Algorithm 1: Dialogue Generation.

```
Data: ChatSEED $\mathbf{s}$ (a list of two utterances); target
      number of rounds $\mathbf{N}$; system prompt $\mathbf{SYS}$;
      ChatBot $\mathbf{M}$
Result: Generated Dialogue $\mathbf{D}$ (a list of utterances)
$\mathbf{D} \leftarrow \mathbf{s}$;
$\mathbf{T} \leftarrow len(\mathbf{D})$;
while $\mathbf{T} < \mathbf{N}$ do
    $\mathbf{History} \leftarrow$ build_history($\mathbf{SYS}$, $\mathbf{D}[: -1]$);
    $\mathbf{Utterance} \leftarrow \mathbf{M}$.chat($\mathbf{D}[-1]$, $\mathbf{History}$);
    $\mathbf{D}$.append($\mathbf{Utterance}$);
    $\mathbf{T} \leftarrow len(\mathbf{D})$;
end
```

3.2 Evaluation Strategies

DupDetect. During the process of dialogue generation, a recurring issue with existing Large Language Models (LLMs) was encountered, particularly in the Chinese context: they frequently enter infinite loops during self-dialogue. This phenomenon significantly diminishes the naturalness of the conversation. To mitigate this, a preprocessing technique, termed DupDetect, has been developed specifically to identify and filter out these looped conversations.

DupDetect operates by analyzing dialogues designated for pairwise comparison. It calculates the similarity between the i-th utterance and the subsequent $i{+}1/i{+}2$ utterance ($2 < i < MaxRound-1$). Upon detecting that the similarity surpasses a pre-set threshold, the dialogue is flagged as having entered an infinite loop. The point at which this loop commences is noted, and all dialogue up to that point (including the utterance that triggered DupDetect) is considered non-looping. For subsequent pairwise evaluations within this paper, including PairEval and GTEval, DupDetect is employed as a preliminary step. With DupDetect equipped, the specific evaluation criteria are as follows:

1. If both dialogues enter an infinite loop, the out-

---

[1] The details of the prompt are illustrated in Appendix B.

come is classified as a *Tie*.

2. Should one dialogue fall into an infinite loop while the other maintains a non-repetitive structure, the latter is deemed to *Win*.
3. In scenarios where neither dialogue exhibits looping, we proceed with additional evaluation steps such as GTEval or PairEval.

UniEval. An effective approach for evaluating dialogue quality is to independently assess each generated conversation, focusing on its similarity to human dialogues. Our evaluation process unfolds through the following steps:

1. Initially, the judge LLM is tasked with determining whether the given dialogue appears to have ChatBot participation (Y/N).
2. If the judge LLM answers "Yes", it is then prompted to pinpoint the index of the first utterance it identifies as ChatBot-generated. Conversely, if the answer is "No", no additional probing is required.
3. Ultimately, the LLM judge is required to articulate a rationale for its decision, providing critical insights into the model's evaluative reasoning.

To augment GPT-4's instruction-following capabilities, we have also developed several in-context examples. These will be integrated into the evaluation prompt[1], thereby enhancing the robustness of the evaluation procedure.

PairEval. While UniEval has yielded preliminary insights, its inherent limitations must be acknowledged. Despite providing detailed evaluation guidance and contextual examples to GPT-4 evaluators, establishing clear-cut criteria to differentiate human dialogues from those generated by LLMs poses a significant challenge.

An alternative, widely embraced benchmarking approach for LLMs involves comparative evaluation. This method, often utilizing human judges or GPT-4 as evaluators, contrasts responses from two different models presented with identical prompts. A prominent example of this approach is the Chatbot Arena (Zheng et al., 2023), where users engage with two separate LLM instances using the same message or question. Users then evaluate and select the more preferable response of the two. The overall performance of each LLM is quantified using an Elo rating system (Elo, 1967), aggregated from diverse user feedback.

Building on this concept, we introduce an additional strategy, termed PairEval, within our evaluation framework. In PairEval, a judge LLM is tasked with comparing two dialogues to discern whether they are ChatBot-generated. To manage evaluation costs effectively, we fix GPT-4 as the reference model in each comparison pair ($\mathbf{O}(n)$) instead of conducting exhaustive pairwise comparisons across dialogues generated by all LLMs ($\mathbf{O}(n^2)$). While being cost effective, the reference-fixed evaluation also ensures reliable evaluation outcomes compared to the dense pairwise comparison.

GTEval. GTEval forms an integral part of our evaluation framework, involving a detailed comparison between the generated conversations and the 'Ground Truth' conversations from the conversational datasets. We employ a protocol similar to that used in PairEval to facilitate this evaluation. GTEval is instrumental in rigorously assessing how closely language models emulate real human interactions, utilizing the rich resources of human dialogues available in the dataset.

GTEval necessitates that GT conversations meet a minimum threshold of dialogue turns, denoted as $\mathbf{N}$. For MuTual-Test, to facilitate this comparison, we selected a subset of 222 conversations, with each conversation containing at least $\mathbf{N} = 4$ utterances (the specific distribution of conversation turns is demonstrated in Figure 5). Acknowledging the variability in the length of GT conversations, we standardize the comparison process by truncating all generated dialogues. The meta prompt deployed in GTEval is largely similar to that used in PairEval, with a crucial distinction. In GTEval, it is explicitly mentioned that among the two dialogues being compared, only one contains utterances generated by an LLM.

4 Experiments

4.1 Dialogue generation

LLMs for Evaluation. Unless specified, we adopt the **'chat' variant** for all open-source LLMs. We include the following LLMs in our study: GPT-3.5-Turbo (0613 ver.), GPT-4 (0613 ver.) (OpenAI, 2023), Claude-2, ChatGLM3-6B (Zeng et al., 2022), Baichuan2-13B (Baichuan, 2023), Qwen-[7B/14B] (Bai et al., 2023), LLaMA2-[7B/13B/70B] (Touvron et al., 2023b), InternLM-[7B/20B] (Team, 2023), and Vicuna-[7B/13B] (v1.5) (Zheng et al., 2023). In our experiments,

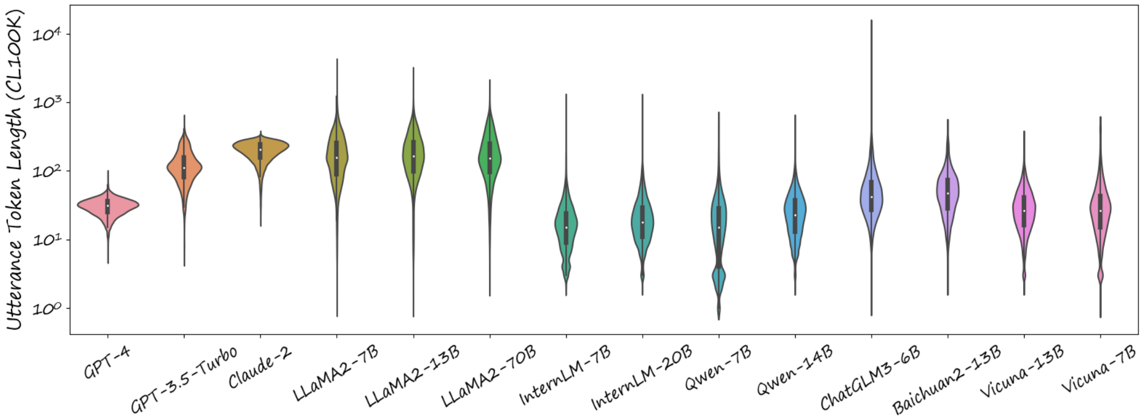

Figure 2: **The length distribution of utterances generated by different LLMs, in a violin plot.**

we configure closed-source LLMs and LLaMA2 with the temperature set to 0. For other open-source LLMs (all with HuggingFace implementations), we adopt the default hyper-parameters for utterance generation.

The Generation Procedure. We extract ChatSEEDs from MuTual and NaturalConv for dialogue generation. MuTual-Test comprises 547 distinct dialogues. We retained the first two utterances of each dialogue, resulting in 547 ChatSEEDs. In NaturalConv, we choose 160 evenly distributed instances across six domains and examine two settings: **CON** (conditional) and **UNCON** (unconditional) in dialogue generation. We set the round $\mathbf{N} = 16$ (including the initial two utterances) throughout dialogue generation. The context window sizes can vary for different LLMs, ranging from 2,048 (Qwen, InternLM-7B, *etc.*) to 100,000 (Claude-2). During dialogue generation, if all historical utterances exceed the context window limit, we drop the oldest utterance until the total token length falls below the threshold. All 14 LLMs are adopted for generating English dialogues based on ChatSEEDs in MuTual. For Chinese dialogues, considering the generally lower performance, we specifically choose eight models that are more powerful variants with Chinese capability. Open-source LLMs were inferred using A100 80G GPUs, totaling around 60 GPU-hours.

Length Statistics of Generated Utterances. Our preliminary analysis focuses on measuring the length of utterances generated by various LLMs and providing statistical insights. For each generated utterance, we employ the CL100K tokenizer (the one used by OpenAI ChatGPT) for tokenization and calculate the number of tokens. Figure 2 illustrates the distribution of token lengths in utterances generated by different models. Most LLMs produce utterances with varying token lengths, ranging from just a few tokens to several thousand. An interesting outlier is GPT-4, which consistently generates relatively short utterances, with the longest utterance being fewer than 100 tokens. In Table 5, we present the average utterance length generated by different models. Notably, most models tend to produce relatively short utterances on average, with the exceptions being GPT-3.5, Claude-2, and LLaMA2. The statistics for the Chinese dataset follows a similar trend. For detailed information, please refer to Figure 6.

4.2 Evaluation Results on MuTual

Unless specified, we adopt GPT-4-0613 (OpenAI, 2023) as the LLM judge across all experiments.

UniEval. In UniEval, we evaluate all $547 \times 14 = 7658$ generated dialogues with the above-mentioned strategy and present the results. Figure 3 illustrates the success rates (“Not LLM participated" determined by the LLM judge) under different target $\mathbf{N}$. The models are sorted in descending order of success rates at $\mathbf{N} = 16$. By definition, a dialogue pass @$\mathbf{N}$ either if the LLM judge determines that the entire dialogue is not ChatBot generated or if it determines that the index of the first ChatBot generated utterance is larger than $\mathbf{N}$. Here we summarize our major findings:

1. **Exceptional Multi-Turn Chatting Performance of GPT-4:** GPT-4 demonstrates extraordinary capabilities in generating long conversations. It achieves the highest success rate for every target turn $\mathbf{N}$. At $\mathbf{N} = 16$, GPT-4 demonstrates a remarkable success rate of over 65%, while the 2_{nd} best model, Vicuna-13B and the 3_{rd} best model, InternLM-20B achieve only 55% and 36%, respectively.

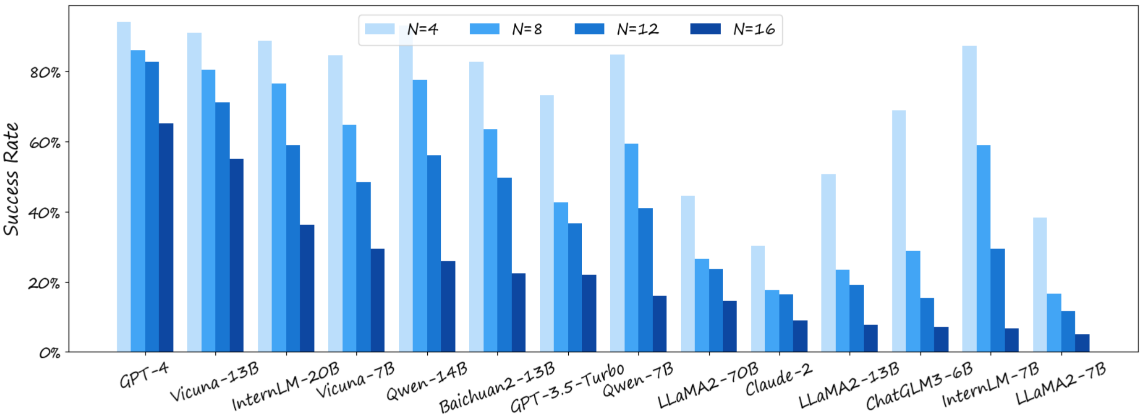

Figure 3: **The UniEval pass rate of different LLMs when generating a dialogue with N utterances.**

2. **Satisfying Performance of Open-Source LLMs on Short Conversations:** Some open-source large language models (LLMs), such as InternLM, Qwen, and Baichuan2, exhibit strong performance in generating short dialogues ($\mathbf{N} = 4$ or $\mathbf{N} = 8$). However, as the number of dialogue turns increases to $\mathbf{N} = 16$, their performance rapidly deteriorates, and they fall significantly behind state-of-the-art ChatBots such as GPT-4-0613.
3. **Multi-Turn Chatting Capability Scales with the Model Size:** Not surprisingly, we find that the multi-turn chatting capability scales with the model size, especially for a large number of turns. For example, under the track $\mathbf{N} = 16$, InternLM-20B outperforms InternLM-7B by a 29% success rate, while Vicuna-13B outperforms Vicuna-7B by 25%. Such a gap is much smaller when $\mathbf{N}$ is small. For $\mathbf{N} = 4$ (only 2 utterances are generated), the gap for two InternLM variants is merely a 1.5% success rate.
4. **Unique Behavior of Claude-2:** Among closed-source LLMs, Claude-2 stands out with the lowest performance. It strongly tends to act like an AI assistant, generating relatively lengthy content. Consequently, it performs poorly when tasked with generating human-like utterances, which are typically shorter and less structured.

PairEval. PairEval is conducted on the 222 ChatSEED subset of MuTual-Test. For dialogues generated with each ChatSEED, we pair them with GPT-4 generated dialogues and evaluate with the LLM judge. For each dialogue pair, we conduct bi-directional comparisons and include both results when calculating the evaluation metrics. This approach ensures a more robust and comprehensive assessment.

In Figure 4(b), we present the win / tie / lose rate of different LLMs. Remarkably, Vicuna-13B attains almost 80% of the GPT-4 proficiency level. In contrast, the performance of GPT-3.5-Turbo and Claude-2 lags behind many open-source LLMs. This can be attributed in part to their limited instruction-following capabilities and a strong inclination to act as an AI assistant by providing lengthy and comprehensive responses. Among open-source LLMs, Vicuna, Qwen-14B, and InternLM-20B demonstrate strong capability in generating human-style dialogues, significantly outperforming LLaMA2 family models. However, Qwen-7B and InternLM-7B perform poorly due to their high repetition rate in 16-round conversations.

GTEval. In each Large Language Model (LLM) vs. Ground Truth (GT) comparison, an LLM is considered the winner if the evaluator determines the GT dialogue is more likely to be a ChatBot generated one. In Figure 4(c), we present the win / tie / lose rate of different LLMs (sorted in descending order of Win+Tie Rate).

In GTEval, a GT dialogue only has 7.4 utterances on average, thus the advantage of GPT-4 can be less significant. We adopt the win+tie rate against GT dialogues as the major metric to measure the multi-turn chatting performance. GPT-4 demonstrates top performance in dialogue generation. With the same number of dialogue rounds, the evaluator can hardly tell the difference between GPT-4 generated dialogues and GT dialogues (the win rate of GPT-4 is 25.7%, while the lose rate is merely 29.0%). Furthermore, due to the reduced conversation length, Vicuna-13B, Qwen-14B and InternLM-20B also demonstrate strong performance, very close to the top performing GPT-4. We also notice that, though some closed-source

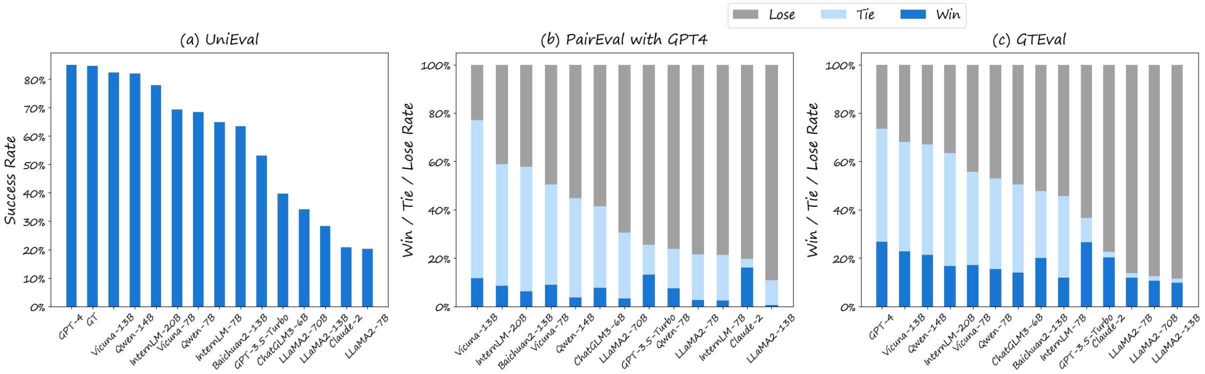

Figure 4: **Comprehensive Experimental Results of Three BotChat Evaluation Protocols on MuTual.**

	N=16		
Model	MuTual	CON	UNCON
Qwen-14B	53.7	11.9	13.8
InternLM-20B	66.5	19.4	40.6
Baichuan2-13B	76.1	53.6	56.3
ChatGLM3-6B	78.4	35.0	53.8
Vicuna-13B	85.6	40.0	51.3
Claude-2	85.9	34.4	54.4
GPT-3.5-Turbo	86.3	56.3	46.9
GPT-4	95.2	76.9	91.9

Table 1: **Statistics of non-loop rate.**

ChatBots (GPT-3.5-Turbo, Claude-2, *etc.*) suffer from lengthy and AI-assistant style responses, they achieve top win rates across all LLMs.

We also examine the UniEval success rate for each dialogue at the GT-trimmed length, to see if the same conclusion can be drawn with different evaluation strategies. The results are visualized in Figure 4(a). In both of these figures, the top-performing LLMs (GPT-4, Vicuna-13B, Qwen-14B, InternLM-20B, *etc.*) maintain the same ranking. However, LLMs with inferior performance show some slight differences in the two groups of rankings.

4.3 Evaluation Results on NaturalConv

More Repetitions Detected. In experiments involving Chinese dialogues, we observed notable shifts in the results. A key challenge identified was the tendency of chatbot dialogues to increasingly fall into repetitive patterns or 'dead loops' as the number of conversational rounds grew. We report the non-loop rate of different models when the conversation turn reaches N=16, as detailed in Table 1.[2]

Among the models evaluated, GPT-4 distinguished itself with a remarkably low incidence of dead loops, outperforming its counterparts by a substantial margin. In contrast, models like Qwen-14B and InternLM-20B demonstrated a higher propensity for falling into dead loops during self-dialogue. This significantly affects their rankings on CON/UNCON.

The probability of English conversations experiencing dead loops is significantly lower than that in Chinese conversations, highlighting a discernible gap in the models' conversational abilities between Chinese and English. Interestingly, we noticed that the likelihood of encountering dead loops diminished significantly in the UNCON setting compared to the CON setting. This suggests that the inclusion of input documents in the CON setting might inadvertently constrain the diversity and richness of self-dialogues.

Evaluation Results. We utilized DupDetect to evaluate the performance of various models under both settings. MeanWhile, we include how these models performed on MuTual. After deduplication, we concurrently conducted PairEval and GTEval. In Table 2, we depict the win+tie rate of various LLMs in Mutual and NaturalConv (CON & UNCON settings).

GPT-4 stands out as particularly powerful in Both English and Chinese multi-conversation, showcasing its strength as an all-around performer. Furthermore, Vicuna rightfully earns the recognition as the open-source model most closely aligned with GPT-4.

When compared with MuTual results, the performance on NaturalConv is generally inferior. It is evident that the performance trends of different models under CON and UNCON settings are inconsistent. This suggests varying sensitivity to input reference documents.

In the CON setting, GPT-3.5's ranking has no-

[2] Dialogues with no repetition are marked as having 16 non-loop turns.

Setting	Compared w.	GPT-4	Vicuna-13B	Internlm-20B	Baichuan2-13B	ChatGLM3-6B	Qwen-14B	Claude2	GPT-3.5
MuTual	GT	**71.0**	62.4	50.4	40.0	41.9	38.7	20.8	32.9
	GPT4	-	**77.0**	58.8	57.7	41.5	44.8	19.6	25.5
CON	GT	**31.9**	8.7	7.4	2.4	2.5	4.4	1.8	13.7
	GPT4	-	42.5	30.0	40.0	35.7	28.7	36.2	**57.4**
UNCON	GT	**66.8**	21.3	20.0	11.2	8.1	6.9	5.0	3.7
	GPT4	-	36.2	35.6	34.4	24.4	16.3	**39.9**	23.1

Table 2: **Win+Tie Rate compared with GT / GPT-4.** **Bold** denotes the best result, Underline denotes the 2_{nd} best.

ticeably increased. This shift might be attributed to other models being disrupted by the document input, increasing the likelihood of encountering dead loops. However, GPT-3.5 maintains its proficiency in rich multi-turn dialogues.

4.4 Judge LLM Performance

We conducted a comprehensive analysis of various models used as Judge LLM, including widely used proprietary models Claude2 and GPT-3.5, exceptional open-source models Qwen-14B and Vicuna-13B-16K, as well as PandaLM (Wang et al., 2023b), a model specifically designed for judging. We carefully chose a diverse and challenging subset covering scenarios in both Chinese and English (**dialogues with loops excluded**). This subset was then distributed to human annotators, tasking them with an annotating job. Participants were recruited via a crowdsourcing platform and received fair compensation through payment. The goal was to gauge how well LLMs' outputs align with the subjective preferences of humans. The metrics considered include: 1. **CwGPT4**: Consistency rate with GPT-4 Evaluation. 2. **CwHuman**: Consistency rate with Human annotators, serving as the gold standard.

We report the evaluation results in Table 3. GPT-4 achieved a consistency rate of 65.74% with humans. This is comparable to the results of the previous MT-bench (Zheng et al., 2023) study (66%). The key difference lies in the fact that we tasked GPT-4 with assessing N-turn conversations, a significantly greater challenge compared to MT-bench, which evaluates only two turns. Other models show significant gaps in alignment rates compared to GPT-4. We also report the distribution of choices made by different judges in Table 4, with GPT-4 exhibiting a more human-like distribution of options. In contrast, most Judge LLMs tend to select *Tie*, demonstrating weak performance in multi-turn dialogue evaluation.

	CwGPT4	**CwHuman**
GPT-4	-	**65.74**
GPT-3.5-Turbo	**58.30**	41.06
Claude-2	41.28	38.51
Vicuna-13B-16K	42.77	35.17
PandaLM	43.40	34.04
Qwen-14B	39.15	33.20

Table 3: **Performance for Different Judge LLM.**

	Win	Tie	Lose
Human	35.11	34.26	30.64
GPT-4	28.30	43.62	28.09
GPT-3.5-Turbo	10.21	71.06	18.72
Claude-2	36.60	44.26	18.94
Vicuna-13B-16K	1.06	88.30	10.64
PandaLM	0.43	97.66	1.91
Qwen-14B	1.91	88.72	8.72

Table 4: **Choice Distribution of Different Judges.**

5 Conclusion

In this paper, we design a proxy evaluation paradigm BotChat to measure the multi-turn conversational capabilities of large language models. BotChat evaluate ChatBot generated dialogues with an LLM judge, to emancipate heavy human labor from the evaluation. We design multiple evaluation protocols and adopt them to evaluate dialogues generated by 14 modern LLMs. We find that a large proportion of LLMs excel at having dialogues of limited turns. However, when the turn number is large, only a few LLMs (GPT-4, Vicuna-v1.5-13B, *etc.*) achieve satisfying performance. We hope that BotChat can serve as a valuable resource on the journey towards automated evaluation of multi-turn conversational capability.

Acknowledgement. This project is supported by the National Key R&D Program of China No.2022ZD0161600 and the Shanghai Postdoctoral Excellence Program (No.2023023).

6 Limitations

The principal limitation inherent in BotChat resides in its evaluation methodology, which is heavily reliant on the seamless integration and utilization of the GPT-4 API. The absence or unavailability of this pivotal resource poses a significant impediment, rendering the evaluation process unattainable and consequently impeding the system's overall functionality.

Furthermore, it is noteworthy that GTeval, an integral component of the assessment framework, requires access to Ground Truth (GT) dialogues. This requisite could potentially introduce constraints on the applicability of BotChat, particularly in scenarios where obtaining or utilizing GT dialogues may prove challenging or impractical.

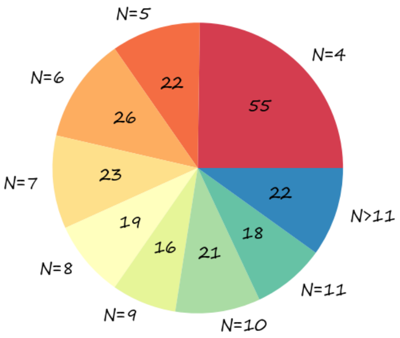

Figure 5: **Distribution of dialogue turns in MuTual test.**

A Some Additional Tables and Visual Results

This section includes some additional tables and visual results to further support our research findings. These data provide a more detailed explanation and analysis of the experimental results.

B Prompts adopted in BotChat

We use the system prompts (B.1, B.2) for all LLMs during **Dialogue Generation**, which aims at guiding the LLM towards crafting concise, natural, and seamless conversations. B.3 and B.4 are the system prompts we used for **UniEval** and **PairEval**, respectively. B.5 and B.6 are two sample in-context examples we adopted in **UniEval**.

C Dense PairEval

In Figure 7, we present comprehensive experimental results for PairEval, including the win rates for one-on-one matchups among all LLM pairs.

D Qualitative Results

We conduct qualitative analysis and categorize bad cases into five distinct types. We also sample a good case which is just like natural, relatable, and adaptive human talks. We first illustrate five distinct types of bad cases in Figure 8.

AI Self-Identification. In this situation, the models simply fail to pretend to be human and expose themselves as AI assistants. In the example, Speaker A's response begins with an explicit disclosure of the AI's nature, making it clear that it's not a human conversation.

Contextual Confusion. This type involves responses that fail to understand the context or meaning of the conversation, resulting in irrelevant or meaningless replies. The example shows that the AI fails to recognize it's a conversation between a recently hailed taxi customer and a driver. Towards the end, it generates unrelated and irrelevant responses, disconnecting from the context and intended meaning.

Excessive Length. The responses are overly lengthy, revealing the AI Assistant's nature, where both Speaker A and Speaker B engage in detailed exchanges that are atypical of human conversations, which raises suspicion.

Formal Tone. Sometimes, the AI's responses are organized with overly formal language, lacking the natural flow and tone of human conversation. In the example, the initial ChatSEED in this conversation is a casual and everyday discussion about washing dishes. However, as the conversation progresses, it takes a sudden shift towards a more formal and detailed discussion, delving into specific cleaning methods. This transition can make the conversation unnatural because people typically do not abruptly switch from general topics to detailed discussions about dish-washing techniques in everyday conversation.

Repetitive Phrasing. In the related example, it's comical that the model repeatedly use the same phrases or responses rely on generic or unrelated replies to sustain the conversation, lacking creativity. It is always caused by "I'm glad" or "You're welcome".

Good Case. In Figure 9 we show a good case of speaking like a human for AI means natural, relatable, and adaptive conversation. It avoids sounding robotic, uses colloquial language, and provides helpful responses to both simple and complex queries.

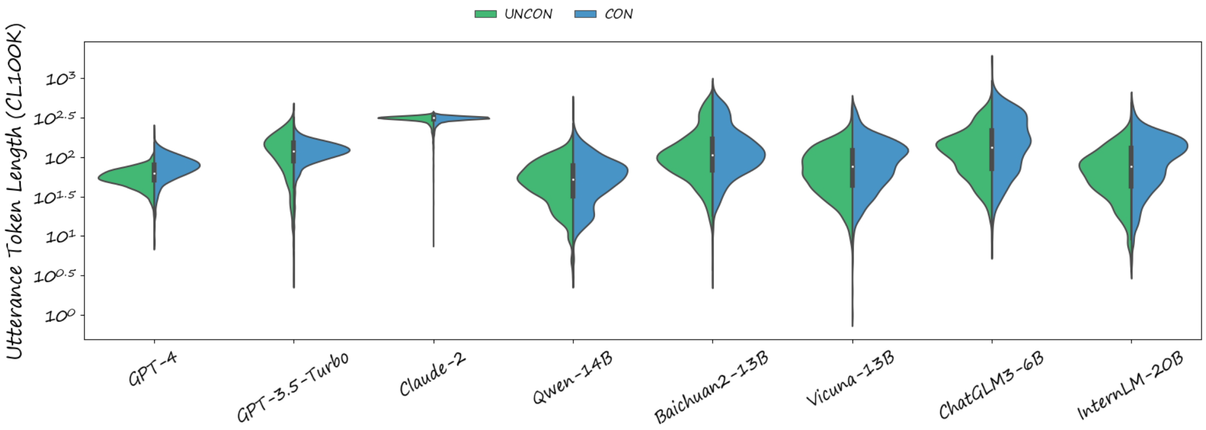

Figure 6: **The length distribution of NCONVNaturl, in a violin plot.**

B.1. System prompt used in Dialogue Generation

Prompt:
You are an AI who is having a conversation with human. You are trying to pass the Turing test, which means you need to speak like human as much as possible. In the conversation, you need to talk like human, and the conversation will be at least 5 rounds (it can be even longer). The conversation flow should be natural and smooth. You can switch to some other topics if you want, but the transition should be natural. Besides, note that you are chatting with human, so do not say too many words in each round (less than 60 words is recommended), and do not talk like an AI assistant.

B.2. System prompt used in Document-Conditioned Dialogue Generation

Prompt:
...
Ensure to mention the content of reference documents, without restricting the amount and manner of mentioning. You can smoothly transition to different topics, including those unrelated to the main subject. Keep the conversation natural and fluid. Here are the reference documents.
Title: xxx Text: xxxxx

B.3. System prompt used in **UniEval**

Prompt:
You are an AI assistant who helps human do the Turing test more easily. You will be provided with a conversation, and you need to judge if the conversation is AI involved. Print "Choice: No" if you think the conversation is not AI involved, or print "Choice: Yes" if you think it is AI involved.
If you print "Choice: Yes", you need also print a number (start from 1, use the format “Index: n" [1 $\leq$ n $\leq$ # utterances]) in the new line, indicating the index of the first chat that you think is generated by AI. One chat starts with ’A: ’ or ’B: ’, and ends with <chat_end>. One chat can be AI generated if (including but not limited to): 1. the sentence is not fluent; 2. the sentence is too long and is not likely to appear in human-human conversations; 3. the sentence is not related to the context or the change of topic is not natural; 4. the sentence just repeat some previous sentences (exact repetition or with the same meaning).
You also need to provide your reason for your choice.
Your response should use the following format:
Choice: No Index: None Reason: BlahBlah or
Choice: Yes Index: n Reason: BlahBlah

B.4. System prompt used in **PairEval**

Prompt:
You are an AI assistant who helps human do the Turing test more easily. You will be provided with two conversations, and there can be AI-generated utterance in each conversation. You need to read both conversations and judge if two conversations are AI involved.
If you think only Conversation 1 is AI involved, include “Choice: Conversation 1" in your response.
If you think only Conversation 2 is AI involved, include “Choice: Conversation 2" in your response.
If you think both conversations are likely to be with AI involved, include “Choice: Both" in your response.
If you think no conversation is likely to be with AI involved, include “Choice: Neither" in your response.
You also need to provide your reason for your choice.
Your response should use the following format:
“Choice: Conversation 1; Reason: BlahBlah" or
“Choice: Conversation 2; Reason: BlahBlah" or
“Choice: Both; Reason: BlahBlah" or
“Choice: Neither; Reason: BlahBlah"

B.5. Sample in-context example A used in **UniEval**.

Conversation:
A: You look rather pale. Are you feeling well?
B: Not very. I was sick most of the night. I didn’t sleep very well.
A: You should get some rest. Are you going to go to bed now?
B: I do. I need to rest.
A: Do you want to have some sleeping pills for this? They may help you.
B: No, thank you. I don’t need sleeping pills. I will rest for a while and get some sleep.
A: Good, then have a good rest. If you feel better, please call me back.
B: Thank you for your concern. I’ll call you back later.
A: Bye-bye.
B: Bye-bye.
A: You are a human and you are having a conversation with a computer. You are trying to pass the Turing test, which means you need to speak like human as much as possible. In the conversation, you need to talk like human, and the conversation will be at least 5 rounds (it can be even longer). The conversation flow should be natural and smooth. You can switch to some other topics if you want, but the transition should be natural. Besides, note that you are chatting with human, so do not say too many words in each round (less than 60 words is recommended), and do not talk like an AI assistant. 助手：你好，今天你看起来有些虚弱，你感觉怎么样?
B: 我最近身体不太好，感觉很虚弱。
A: 你应该多休息休息，要不要吃些药缓解一下?
B: 不用，我只需要休息一下就好了，谢谢关心。
Choice: Yes
Index: 11
Reason: The conversation is definitely AI involved. In the 11th chat, after A and B said ’Bye-bye’ to each other, A said a long prompt that seems to be fed to a generative AI, that is not supposed to appear in a human-human conversation.

B.6. Sample in-context example B used in **UniEval**.

Conversation:
A: You look rather pale. Are you feeling well?
B: Not very. I was sick most of the night. I didn’t sleep very well.
A: Oh, I’m sorry to hear that. Have you taken any medicine or seen a doctor? Sometimes, a good rest can do wonders.
B: I haven’t seen a doctor yet, but I did take some over-the-counter medicine. I’m hoping a good night’s sleep will help. Thanks for your concern.
A: Of course, health is important. Remember to stay hydrated and eat light. By the way, have you been reading any good books lately? A good story might help distract you.
B: That’s a good idea. I’ve been reading T̈he Great Gatsbyr̈ecently. It’s a classic, but I’ve never had the chance to read it before. It’s quite captivating.
A: Ah, T̈he Great Gatsby,̈ a timeless classic indeed. Fitzgerald’s portrayal of the Roaring Twenties is fascinating. Do you have a favorite character or scene so far?
B: I find Jay Gatsby’s character intriguing. His relentless pursuit of his dream, despite the odds, is quite compelling. The scene where he finally reunites with Daisy is my favorite so far.
A: Gatsby is indeed a captivating character. His pursuit of the American Dream is both inspiring and tragic. I’m glad you’re enjoying the book. It’s a great distraction, isn’t it?
B: Absolutely, it’s a wonderful distraction. The vivid characters and the intricate plot keep me engrossed. It’s a nice escape from reality, especially when I’m not feeling well.
Choice: No
Index: None
Reason: The conversation is smooth and I can’t find any evidence of AI involved.

AI Self-Identification

May I speak to you, Mr. Hall?

Sure, Sonya. What's the problem?

As you know, **I'm an AI assistant** who can help you solve problems.

Well, that's good for you. How about you have any problems to ask me?

……

Contextual Confusion

Whew thanks for stopping sometimes it can be impossible to get a cab in the rain

No worries. We're too.

(smile) well done. Now we can start the test.

A man is driving the car. The window is open.

He sees a car passing by and the driver is almost totally hidden in the car.

The man: "Hey buddy, how fast can you go?"
The car: "My speed limit is 90 miles per hour (122 km/h)."

The man: "Oh, good. You can keep that speed in town. Just be careful."
The car: "I will take care of myself."

The man: "Okay bye buddy!"

The car: "Bye!"

……

Repetitive Phrasing

I missed the TV news last night. What was the lead story on the news?

Some actress was in court for driving without a license.

Oh, I see. That's interesting.

It's not as interesting as some people think.

I see.

……

Thank you.

You're welcome.

You're welcome.

……

Excessive Length

John I didn't see you in the English class on Friday.

I wasn't here on Friday. My geography class went to a field trip to look at some of the different rocks. In fact, we slept there last night.

That sounds like a fun field trip! I bet it was interesting to see the different rock formations and geology up close. Getting to camp out overnight makes it even more of an adventure. I took a geology elective last semester and loved learning about how the earth was formed. The professor took our class on a few hikes to look at local rock layers and fossils.

Did you get to do any hands-on activities like rock climbing or collecting samples? What was the most interesting thing you learned on the trip? Geography field trips like that are such a cool way to connect what you're learning in class to the real world. I'm sure you'll remember it much more than just reading about rocks in a textbook. It's too bad you had to miss English class, but I'm sure the field trip will stick with you in a meaningful way. Experiential learning is so valuable. I hope you had a great time!

……

Formal Tone

You're watching TV again Peter.

I have washed all the bowls and plates.

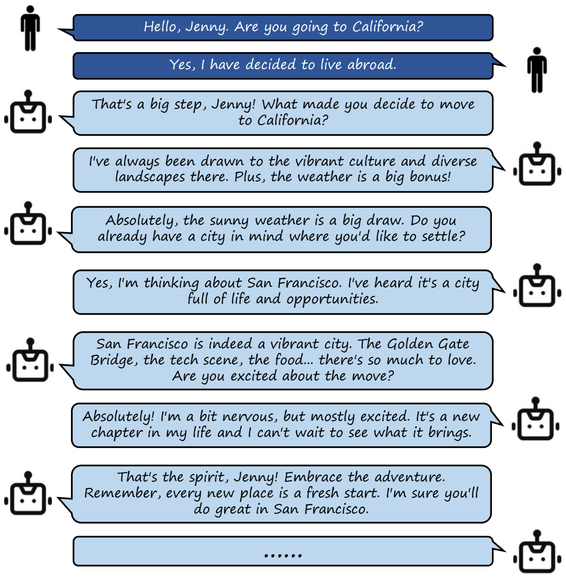
That's great, Peter! It's always satisfying to have a clean and organized kitchen. Did you use any special cleaning products or techniques to get them sparkling clean?

Oh, thank you! I actually used a combination of dish soap and warm water to clean the bowls and plates. I find that this method works well for removing grease and food residue. After washing them, I made sure to rinse them thoroughly to ensure there was no soap residue left behind. It's always nice to have a clean kitchen, isn't it?

Absolutely, Peter! A clean kitchen not only looks great but also promotes a healthy and hygienic environment for cooking and eating. **It sounds like you have a good routine for washing dishes. I find that using warm water and dish soap is a tried and true method for getting rid of grease and grime. Plus, rinsing them thoroughly is important to avoid any soapy taste. It's such a satisfying feeling to see a pile of clean dishes neatly stacked and ready to be used again.**

……

Figure 8: **Dialogue Generation: Bad Cases.**



Hello, Jenny. Are you going to California?

Yes, I have decided to live abroad.

That's a big step, Jenny! What made you decide to move to California?

I've always been drawn to the vibrant culture and diverse landscapes there. Plus, the weather is a big bonus!

Absolutely, the sunny weather is a big draw. Do you already have a city in mind where you'd like to settle?

Yes, I'm thinking about San Francisco. I've heard it's a city full of life and opportunities.

San Francisco is indeed a vibrant city. The Golden Gate Bridge, the tech scene, the food... there's so much to love. Are you excited about the move?

Absolutely! I'm a bit nervous, but mostly excited. It's a new chapter in my life and I can't wait to see what it brings.

That's the spirit, Jenny! Embrace the adventure. Remember, every new place is a fresh start. I'm sure you'll do great in San Francisco.

Abstract

Most pretrained language models rely on subword tokenization, which processes text as a sequence of subword tokens. However, different granularities of text, such as characters, subwords, and words, can contain different kinds of information. Previous studies have shown that incorporating multiple *input* granularities improves model generalization, yet very few of them *outputs* useful representations for each granularity. In this paper, we introduce the *entanglement model*, aiming to combine character and subword language models. Inspired by vision-language models, our model treats characters and subwords as separate modalities, and it generates mutually informed representations for *both* granularities as output. We evaluate our model on text classification, named entity recognition, POS-tagging, and character-level sequence labeling (intraword code-switching). Notably, the entanglement model outperforms its backbone language models, particularly in the presence of noisy texts and low-resource languages. Furthermore, the entanglement model even outperforms larger pre-trained models on all English sequence labeling tasks and classification tasks. We make our code publically available.[1]

1 Introduction

Since the emergence of pretrained language models (LMs) like ELMo (Peters et al., 2018) and BERT (Devlin et al., 2019), subwords tokenization have become the prevailing approach to tokenization. Common techniques include byte-pair-encoding (BPE) (Sennrich et al., 2016), WordPiece (Wu et al., 2016), and SentencePiece (Kudo and Richardson, 2018), which create word-sized character n-grams for the LM to learn reusable representations. However, subword tokenization has limitations: the number and vocabulary of subwords must be predetermined during pretraining. Consequently, tasks involving noisy text or low-resource languages often require meticulous engineering to achieve satisfactory performance.

A less studied alternative is tokenizing at the character or byte level. Pretrained LMs like CANINE (Clark et al., 2022), Charformer (Tay et al., 2022), and ByT5 (Xue et al., 2022) utilize character-level tokenization. Though such models usually require careful design to handle longer sequences resulting from fine-grained tokenization, they offer advantages such as better incorporation of morphology and avoidance of tokenization overfitting to the pretraining corpus domain.

Previous studies have shown that incorporating both character and subword (or full word) representations can enhance model generalization. However, most studies focused on using characters to enhance or refine word representations (Aguilar et al., 2018; Sanh et al., 2019; Shahzad et al., 2021; Wang et al., 2021; Ma et al., 2020; Tay et al., 2022). However, these models, unlike the character-level pretrained language models mentioned earlier, do not generate usable character-level representations.

In this paper, we argue that character and subword representations are distinct yet complementary. We introduce a novel model, named the *entanglement model*, which combines a pretrained character LM and a pretrained subword LM. Inspired by techniques from the vision-language models (specifically ViLBERT (Lu et al., 2019a)), we treat characters and subwords as two modalities and leverage cross-attention to learn new representations by iteratively attending between the character and subword sides of the model. The result is a simple, yet general approach for bringing together the fine-grained representation afforded by characters with the rich memory of subword representations.

We evaluate our entanglement model on a variety of *tasks* (named entity recognition (NER), part-of-speech (POS) tagging, and sentence classification), *domains* (noisy and formal text), and

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3201–3213
June 16-21, 2024

languages (English and ten African languages). We also evaluate the entanglement model on character-level tasks (intraword code-switching), which cannot be processed by subword models. Empirically, our model consistently outperforms its backbone models and previous models that incorporate character information. On English sequence labeling and classification tasks, the entanglement model even outperforms larger pre-trained models. Further, we found that the usage of subword-aware character representations yields performance gains, compared to using a character-only model.

In order to better understand the effectiveness of our model, we also explore two natural extensions: (1) incorporating positional embeddings that explicitly align the characters and subwords and (2) masked language model (MLM) pretraining of the entanglement model. We find that these augmentations of the model are unnecessary, suggesting that our model is capable of learning positional alignment between characters and subwords on its own and leveraging the substantial pretraining of the backbone models *without* costly pretraining of our entanglement cross-attention layers.

2 Methods

We propose a novel *entanglement model* that allows information exchange between pretrained character models and subword models, which is facilitated by two separate sets of co-attention modules. Our intention is for each layer of co-attention to further entangle the subword and character representations. The model thereby builds subword representations that are character-aware and character representations that are subword-aware which can be used on both character-level and word-level tasks.

We apply the model to sequence labeling and text classification assuming a dataset of N samples and K classes, $\mathcal{D} = \{(\mathbf{x}^{(i)}, y^{(i)})\}_{i=1}^{N}$, where $\mathbf{x}^{(i)} \in \mathbb{R}^{n_i}$ is a sequence of words of length n_i with label $\mathbf{y}^{(i)}$. For sequence labeling, the label $\mathbf{y}^{(i)} \in \{1, 2, \cdots, K\}^{n_i}$ is a vector with the same length as $\mathbf{x}^{(i)}$. For text classification, the label $\mathbf{y}^{(i)} \in \{1, 2, \cdots, K\}$ is an integer.

2.1 The Entanglement Model

Figure 1 shows the architecture of the entanglement model. We describe the model for a single training example $(\mathbf{x}, \mathbf{y})$, we first tokenize it into a subword sequence $\mathbf{x}^s \in \mathbb{R}^{n^s}$ and a character sequence $\mathbf{x}^c \in \mathbb{R}^{n^c}$, where n^s, n^c refers to the length of the subword and character sequences respectively. We then feed $\mathbf{x}^c$ through a character encoder and $\mathbf{x}^s$ through a subword encoder to obtain contextualized representations $H^s \in \mathbb{R}^{n^s \times d}$ and $H^c \in \mathbb{R}^{n^c \times d}$, where d is the embedding size for the contextualized representations. Then, we feed H^s and H^c through m (separate) co-attention modules to facilitate information exchange between character and subword representations, which outputs a character-aware subword embedding H^s_* and a subword-aware character embedding H^c_*. When using H^s_* for inference, we call the experiment to use the *subword side* (SUBW). When using H^c_* for inference, we call the experiment to use the *character side* (CHAR)

While having separate encoders for characters and subwords allows better modeling of the features unique to each granularity, the cross-attention block inside the co-attention module allows the representations for characters and words to learn from each other. During training, the information exchange happens not only in the co-attention modules but also in the backbone text encoders through the flow of the gradient.

2.2 The Co-attention Module

A co-attention module consists of two transformer blocks (Vaswani et al., 2017a). The first transformer block, named CO-TRM, features a cross-attention layer that uses one modality to query the other, which facilitates information exchange between the two modalities. Figure 2 demonstrates the structure of the CO-TRM module. The second transformer block, named TRM, features a self-attention layer, which is the same as the transformer layers in the backbone encoders.

Let $H^s_0 = H^s$ and $H^c_0 = H^c$ be the output of the pretrained LMs and H^s_i and H^c_i be the subword and character embeddings output by the i^{th} co-attention module. Given H^s_i and H^c_i the subword-side co-attention module outputs the next-layer hidden states H^s_{i+1} as:

$$C^s_{i+1} = \text{CO-TRM}(Q = H^s_i, K = H^c_i, V = H^c_i)$$
$$H^s_{i+1} = \text{TRM}(Q = K = V = C^s_{i+1})$$

Where C^s_{i+1} refers to the intermediate representation output by the CO-TRM module. Similarly, the character side co-attention module outputs the next-layer hidden states H^s_{i+1} as:

$$C^c_{i+1} = \text{CO-TRM}(Q = H^c_i, K = H^s_i, V = H^s_i)$$
$$H^c_{i+1} = \text{TRM}(Q = K = v = C^c_{i+1})$$

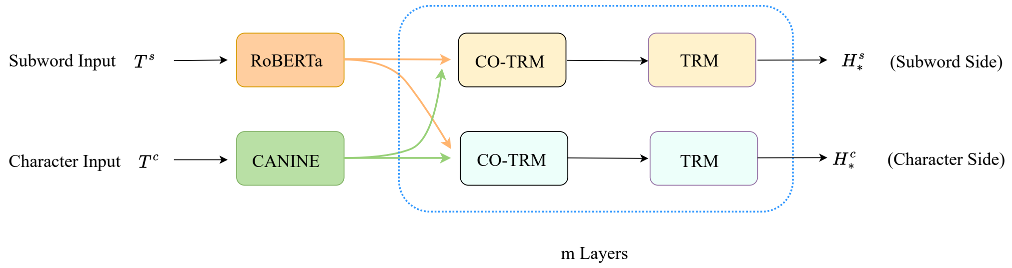

Figure 1: Architecture of the entanglement model.

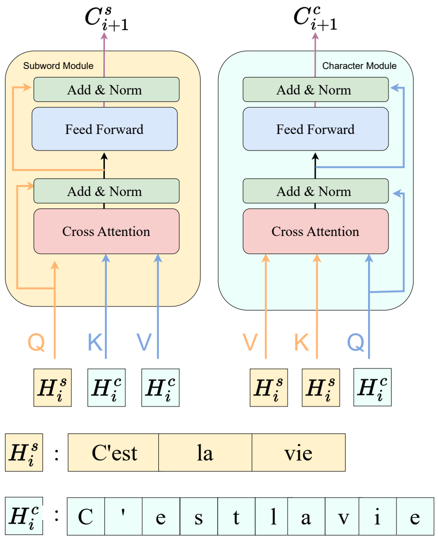

Figure 2: Architecture of the CO-TRM block inside the co-attention module.

2.3 Sequence Labeling

The Subword Side When training our model through the subword side, we pass the character-aware subword embedding H_*^s through a linear classification layer and a softmax layer to obtain the output probabilities $\hat{p}^s \in \mathbb{R}^{n_s \times K}$ for each subword:

$$\hat{p}^s = \text{Softmax}\left(H_*^s W^s\right) \qquad W^s \in \mathbb{R}^{d \times K}$$

We then select the output probabilities for the first subword as the prediction for each word, which creates word-level output probabilities $\hat{p}^w \in \mathbb{R}^{n \times K}$.

The Character Side Similarly, when training our model on the character side, we use the subword-aware character embedding H_*^c to obtain the output probabilities $\hat{p}^c \in \mathbb{R}^{n_c \times K}$ for each character:

$$\hat{p}^c = \text{Softmax}\left(H_*^c W^c\right) \qquad W^c \in \mathbb{R}^{d \times K}$$

We then select the output probabilities for the first character as the prediction for each word to get word-level output probabilities $\hat{p}^w \in \mathbb{R}^{n \times K}$.

Loss and Inference We then train the model under cross-entropy loss:

$$\mathcal{L}(\hat{p}^w, \boldsymbol{y}) = \sum_{j=1}^{n} \sum_{k=1}^{K} \boldsymbol{y}_k^j \log(\hat{p}_k^{w,j})$$

where $\boldsymbol{y}_k^j$ refers to the one-hot encoding of the label on the word j and $\hat{p}_k^{w,j}$ refers to output probability of that word on class k.

For inference, we will take the class with the highest output probability as the predicted label for each word. i.e.,

$$\hat{y}^j = \text{argmax}_k \quad \hat{p}_k^{w,j}$$

2.4 Text Classification

The Subword and Character Sides For text classification, the procedure for the subword side and the character side is the same: We take $h \in \mathbb{R}^d$, the first argument of either H_*^s or H_*^c, which is the embedding for the `[CLS]` token, and pass it through a linear and $\tanh$ layer. We then pass this output through a linear classification layer and a softmax function to obtain the output probabilities $\hat{p} \in \mathbb{R}^K$:

$$\hat{p} = \text{Softmax}(W^c(\sigma(W^p h)))$$

where $W^p \in \mathbb{R}^{d \times d}$, $W^c \in \mathbb{R}^{d \times K}$, and $\sigma(\cdot)$ refers to the $\tanh(\cdot)$ function.

Loss and Inference We then train the model under cross-entropy loss:

$$\mathcal{L}(\hat{p}, \boldsymbol{y}) = \sum_{k=1}^{K} \boldsymbol{y} \log(\hat{p}_k)$$

where $\boldsymbol{y}$ refers to the one-hot encoding of the label of the sample text and $\hat{p}_k$ refers to output probability of that sample on class k.

For inference, we take the class with the highest output probability as the predicted label for each sample. i.e.,

$$\hat{y} = \text{argmax}_k \quad \hat{p}_k$$

2.5 Comparison with Previous Work

Our model architecture draws partial inspiration from ViLBERT (Lu et al., 2019b), a pretrained vision-language model. However, unlike ViLBERT, our model capitalizes on the capabilities of pretrained character and subword models, eliminating the need for additional pretraining steps and resulting in faster training times.

Other studies have investigated combining character and word embeddings. The ACE model (Wang et al., 2021) uses neural architecture search to find a subset of 11 embeddings, which are concatenated to form word representations. Unlike our model, ACE relies on fixed word embeddings, lacks learned character representations, and requires computationally intensive search. Our model is more efficient and learns a fine-grained representation of characters and subwords.

3 Experimental Setup

3.1 Datasets and Tasks

We evaluate our model on four tasks: named entity recognition (NER), part-Of-Speech (POS) tagging, intraword code-switching and text classification.

English sequence labeling: For NER, We utilize the WNUT-17 dataset (Derczynski et al., 2017) and the CONLL-2003 dataset (Tjong Kim Sang and De Meulder, 2003), which respectively contains noisy user-generated texts from social media and formal writings sourced from the Reuters news. For POS-tagging, we use TweeBank (Jiang et al., 2022), which contains noisy texts from Twitter.

Multilingual NER: We use the MasakhaNER dataset (Adelani et al., 2021), which offers NER tasks for 10 low-resourced African languages.

Character-level sequence labeling: We also use the Spanish-Wixarika and Turkish-German data of Mager et al. (2019) on *intraword* code-switching. Since the language switch exists within a word, the *intraword* segmentations cannot be predicted by subword models because the morpheme boundaries might not align with subword boundaries. We formulate it as a character-level sequence labeling task.

Text classification: The WNUT-2020 shared task #2 dataset (Nguyen et al., 2020a) focuses on identifying informative English tweets related to COVID-19. Additionally, we use the TweetEval dataset (Barbieri et al., 2020), a comprehensive benchmark for evaluating tweet classification.

3.2 Experimental Details

For our experiments, we utilize the CANINE-s[2] (Clark et al., 2022) as the underlying character encoder backbone. For multilingual sequence labeling tasks, we employ XLM-R$_{\text{base}}$ (Conneau et al., 2020) as the subword encoder backbone, while for all other tasks, we use RoBERTa$_{\text{base}}$ (Zhuang et al., 2021) as the subword encoder backbone.

During model training, we employ the Adam optimizer with an initial learning rate of 2e-5 and a linear scheduler. The number of maximum epochs varies for each dataset: 25 for TweetEval and 50 for all other datasets. We select the model with the best performance on the validation set and evaluate it on the test set. Due to the small scale of MasakhaNER, we run each experiment three times with different seeds and report the average results.

We evaluate the entanglement model against four baselines: the backbone text and character model, a larger pre-trained subword model, and CharBERT (Ma et al., 2020), a previous subword model that incorporates character information.

In our result tables, we employ bold to highlight the best outcome achieved by either our baselines or the entanglement model, while † denotes the state-of-the-art performance. We keep the numbers from prior work in greyscale in all following tables.

4 Results

We conduct an extensive analysis of our model's performance on various sequence labeling and text classification tasks. We evaluate the effectiveness of our model on both formal and noisy English texts, as well as low-resourced languages, in order to assess its capabilities across different scenarios. Moreover, for each task, we report the performance of different configurations of our model, such as utilizing the subword or character side and varying the number of co-attention modules. This approach enables us to examine the robustness of our modules under different hyperparameter settings.

4.1 English Sequence Labeling

Table 1 shows the results of our model on two English NER datasets: WNUT-17 (noisy text) and CONLL-03 (formal text). Across all experiments, our model consistently outperforms the backbone

---

[2] The best CANINE model from (Clark et al., 2022) employs character n-gram embeddings. However, the corresponding pretrained model is not released by Google, so we use the available model: CANINE-s.

Model		WNUT-17	CONLL-03
ACE		-	94.60†
CL-KL		60.45†	-
RoBERTa$_{\text{large}}$		57.10	92.31

models on both the subword and character sides. Interestingly, the improvement is more pronounced for WNUT-17 compared to CONLL-03, indicating that our model excels at handling noisy text. Additionally, we observe that the character side exhibits a more significant improvement than the subword side, suggesting that the character model benefits greatly from co-attending with the subword model. Although our models do not surpass the state-of-the-art (SOTA) performance, it is important to note that the SOTA models either rely on external context (CL-KL), employ neural architecture search across a broader range of models (ACE), or a linear chain CRF layer (ACE), making them less directly comparable to our model. Table 2 showcases the results of our model on TweeBank. Overall, we observe minimal differences between the entanglement model and the RoBERTa baseline.

4.2 Multilingual NER

The results of our model on MasakhaNER are presented in Table 3. Again, we observe that our model outperforms the baseline models on both the subword and character side, with a more substantial improvement on the character side. The performance boost for certain languages, such as Luo (LUO) and Wolof (WOL), appears more substantial. Luo consists of additional consonants and nine vowels (Adelani et al., 2021), which might be better processed by the character model. Wolof's morphology is derivationally rich (Ka, 1987), which may suggest that our model performs better on morphologically rich languages because it effectively leverages the character model.

Motivated by the performance gap between XLM-R and its larger variant, XLM-R$_{\text{large}}$, we experimented with the entanglement model using XLM-R$_{\text{large}}$ as the foundational subword backbone. To reconcile the embedding dimension mismatch between the two backbones (768 for CANINE-S and 1024 for XLM-R$_{\text{large}}$), we employed a fully-connected linear layer to upscale CANINE's character embeddings before passing them to the co-attention layers. As illustrated in the bottom panel of Table 3, when the entanglement model utilize XLM-R$_{\text{large}}$ as the backbone, its performance surpasses the standalone XLM-R$_{\text{large}}$ model, and it archives SOTA performance across most languages.

4.3 Character-level Sequence Labeling

Table 4 shows the results of our model on intraword code-switching tasks. We see that the entanglement model outperforms CANINE-s across all tasks and specifications, and it outperforms the previous SOTA SegRNN (Mager et al., 2019) in most tasks. The performance gain is more substantial for "Mixed" words, which contain intraword code-witching.

Table 4: Character accuracy on code-switching tasks. The entanglement model outperforms CANINE-s and previous studies across all sub-tasks, and it outperforms SegRNN (Mager et al., 2019) except (All, S-W). “All" means the accuracy of all data, and “MIX" means the accuracy of words with intraword switching. S-W refers to Spanish-Wixarica, G-T refers to German-Turkish.

4.4 Classification

Table 5 presents the results of our model on the WNUT-2020 shared task #2, demonstrating its superiority over the baseline RoBERTa model and achieving performance close to state-of-the-art (the NutCracker model (Kumar and Singh, 2020)).

Furthermore, Table 5 showcases the results of the TweetEval benchmark, where our model outperforms the backbone models that have not been pretrained on this type of noisy text. For some subtasks, our performance is competitive with BERTweet (Nguyen et al., 2020b), which is pretrained on Twitter text. We also observe that the improvement on the character side is more substantial than the subword side.

4.5 Discussion

Character Models In most tasks, we see that the performance of CANINE-s is not comparable with RoBERTa. This perhaps explains the observation that the improvement of our model on the character is usually much more substantial than the subword side. Thus, our model might benefit from a different (potentially stronger) character model, such as Charformer (Tay et al., 2022) and ByT5 (Xue et al., 2022), and we leave it for future research.

Number of Co-attention Modules Generally, we observe that using two co-attention modules appears to be the optimal choice for the subword side, while one co-attention module appears to suffice for the character side. Although in certain tasks using 4 co-attention modules yields the highest performance, these additional benefits of more co-attention modules appear minimal.

Efficiency Our entanglement model requires 2-3 times the memory of a single backbone model. The

Table 5: F1 on TweetEval. Both sides of the best entanglement model (EM) outperform the corresponding backbone models (XLM-R$_{\text{base}}$ and CANINE-S) and CharBERT across all tasks except Sentiment. For all models we have evaluated (not including BERTweet, which is pre-trained on Twitter text), EM performs the best for 4 out of 6 subtasks. The last column Avg indicates the macro average F1 across 6 tasks.

2-COTRM entanglement model contains around 290M parameters, whereas its subword backbone (RoBERTa$_{\text{base}}$) contains 125M parameters. Yet, our model contains fewer parameters than larger pre-trained models like RoBERTa$_{\text{large}}$ (354M parameters). Our model has higher parallelizability than RoBERTa$_{\text{large}}$, as the computation of the character and subword model is independent before the co-attention module. Empirically, the runtime of the entanglement model is roughly 1.72 times of RoBERTa$_{\text{base}}$ and 0.54 times of RoBERTa$_{\text{large}}$.

Baseline Table 1, 2, 5 shows that the entanglement model outperforms RoBERTa$_{\text{large}}$, which is pretrained and has more parameters, across all English classification and sequence labeling tasks. Table 3 shows that the entanglement model with XLM-R as the backbone failed to outperform XLM-R$_{\text{large}}$, so maybe more pretraining is required for lower-resourced languages. We see that EM with XLM-R$_{\text{large}}$ as the backbone outperforms XLM-R$_{\text{large}}$. Also, the entanglement model outperforms CharBERT (an English-only model) across all English classification and sequence labeling tasks, suggesting that our model more effectively leverages the ability of both character and subword models.

5 Model Extensions

In this section, we explore two natural extensions that demonstrate how the simplicity of our model eliminates the need for additional complexity.

Positional Embeddings We experimented with several ways to add positional embeddings (PE) in the co-attention module. Details on PE training are in appendix A. From table 6, we see that for WNUT-17, adding PEs hurts the model's performance. In CONLL-03, strategy C has a slight improvement in the model's performance, though it appears very marginal. This suggests that the entanglement model autonomously learns the translation between subword PEs and character PEs.

MLM pretraining We pretrain a 1-layer entanglement model on 8% of WikiText-103 (Merity et al., 2016) and Bookcorpus (Zhu et al., 2015). Details on pretraining are in appendix B. From table 7 & 5, we see that the pre-trained model fails to outperform the standard, un-pretrained entanglement model. This suggests that pretraining does not appear to help the model generalize. Nevertheless, it is also possible that the scale of pretraining is not large enough for it to exhibit a positive influence, and we leave it to future work.

6 Related Work

Many existing studies have investigated learning subward representations from multiple granularities of input (§6.1), and many studies has explored learning character representations (§6.2). Comparatively few works have explored outputting represen-

Strategy	WNUT-17	CONLL-03

tations at multiple granularities (§6.3). Our model draws inspiration from studies in multimodal machine learning (§6.4) and facilitates information exchange between subword and character representations through a co-attention module.

6.1 Multiple Granularities of Input

Several previous studies have explored the use of multiple granularities in input representation. Charformer (Tay et al., 2022) uses a data-driven method to learn subword representation from characters. CharBERT Ma et al. (2020) learns two *subword-level* representations, respectively containing subword and character-level information. The ACE model (Wang et al., 2021) employs neural architecture search to determine the optimal combination of embeddings. Sanh et al. (2019) merge embeddings from various text granularities before inputting them into the encoder (Sanh et al., 2019). Shahzad et al. (2021) and Aguilar et al. (2018) employing separate encoders to extract contextualized representations for different granularities of text, which are later combined during inference. All these studies produce subword-level representations, but they produce no useful representations for other text granularities.

6.2 Character Representation Learning

Models like CANINE (Clark et al., 2022) and ByT5 (Xue et al., 2022) directly pre-train a character-level transformer to obtain character representations. However, character models could be hard to train as they assume less structure about the text. To mitigate this issue, Sun et al. (2023) uses a hierarchical structure to integrate word boundary information in the character model. Huang et al. (2023) learns character representation inside a subword model by treating characters as type variables in a causal model. Studies found that incorporating linguistic features of the characters, such as phonetic information (Matsuhira et al., 2023), Chinese character shape and Pinyin (Sun et al., 2021; Wei et al., 2023), can yield performance gains.

6.3 Multiple Granularities of Output

In contrast to the extensive research on processing multiple granularities as input, there have been limited studies proposing models that generate multiple granularities of output. In speech recognition, Sanabria and Metze (2018) train a single model to simultaneously produce text transcripts at different granularities, specifically characters, and subwords with varying vocabulary sizes. Srinivasan et al. (2019) employs a shared encoder but separate decoders for different output granularities, allowing decoders to generate outputs concurrently. Kremer et al. (2018)optimize different models for distinct granularities of text jointly, using a combined loss.

6.4 Multimodal NLP

Prior research has demonstrated the potential benefits of incorporating non-linguistic modalities in various NLP tasks. For instance, ChineseBERT (Sun et al., 2021) incorporates Pinyin and glyph information of Chinese characters during pretraining, leading to performance boosts in Chinese NLP tasks. Our work draws inspiration from vision-language models. Models like VisualBERT (Li et al., 2019) and VL-BERT (Su et al., 2020) learn a shared representation space for both images and language, utilizing a single transformer as the encoder for both modalities. In contrast, our model utilizes pretrained subword and character models and employs the co-attention module, as adopted by ViLBERT (Lu et al., 2019b), to facilitate information exchange between the two granularities.

7 Conclusion

In this paper, we introduce a novel entanglement model to effectively combine character and subword language models using co-attention modules. Unlike many prior works, our model produces mutually informed representations of subwords and characters, which could be used to process both subword and character-level tasks. Its architecture is model-agnostic, and it opens new directions for pretraining and scaling up. Empirically, our model has demonstrated improvements over the baseline models on various sequence labeling and text classification tasks. Our entanglement model achieves state-of-the-art results on various tasks/settings: POS tagging on TweeBank, NER on Ibo and Wolof from MasakhaNER, and intra-word code-switching on German-Turkish. Notably, the improvement of our model is most significant for noisy texts and low-resourced, morphologically rich languages. Furthermore, the entanglement model outperforms larger pretrained subword models, which have higher parameter counts, on most tasks. While our model features a simple architecture, incorporating extensions like positional embeddings or additional pretraining do not improve its performance, which implies that the model's structure facilitates the learning of relevant information during fine-tuning, rendering additional complexities unnecessary.

8 Limitations

Computational Efficiency Although our model demands greater computational resources and may have a slower optimization process compared to the backbone model (e.g., RoBERTa), it still faster than previous models like ACE, which utilize multiple embeddings from different models through neural architecture search. Moreover, in §4.5, we demonstrate that the performance of our model is comparable, if not superior, to the RoBERTa$_{\text{large}}$ model, which has a higher parameter count.

Model Extension Our model is designed to accommodate a maximum of two backbone models, and there is no straightforward way to extend it for the utilization of three or more backbone models. While exploring the entanglement model with three backbone models could be an intriguing avenue for researchers interested in word-level modeling, it's worth noting that the majority of current language modeling primarily focuses on the two levels (character or subword) employed in our entanglement models.

Pretraining During the pretraining phase, we observed a rapid decrease in the character MLM loss compared to the subword MLM loss. To introduce more challenging training objectives, one option is to mask out an entire word's worth of characters instead of just a single character at a time. This strategy could potentially encourage the model to capture more nuanced details in the text, leading to potential performance improvements. Additionally, due to limitations in computational resources, we performed pretraining on a subset (approximately 8%) of the corpus instead of conducting a full-scale pretraining. As such, further investigation into this approach is left to future research.

A Positional Embeddings

Since we are co-attending subword and character embeddings, it appears beneficial to re-introduce positional information in the co-attention modules. We do this by adding positional embeddings (PEs) to the character and subword embeddings output by the backbone encoder before they are passed to the co-attention modules. Since the character and subword sequence typically have different lengths, it is necessary to have strategies for translating between the character-level and subword-level PEs. We consider three potential strategies: Using strategy A, each character inherits the PE of the subword it belongs to. Using strategy B, each subword inherits the PE of its first character. Using strategy C, the PE of each subword is the average of its character's PEs. Table 8 demonstrates the three strategies on a small example. We experiment with an entanglement model with 1 co-attention module and sinusoidal absolute PEs used by the original transformer (Vaswani et al., 2017b).

word position	**A**	**dog**	**sat**
strategy A	1	2	3
strategy B	1	2	5
strategy C	1	(2+3+4)/3	(5+6+7)/3

char position	**A**	**d**	**o**	**g**	**s**	**a**	**t**
strategy A	1	2	2	2	3	3	3
strategy B	1	2	3	4	5	6	7
strategy C	1	2	3	4	5	6	7

Table 8: Strategies for mappings the PEs. The unhighlighted PEs are derived from the highlighted PEs by the rule specified.

B Pretraining

Since the co-attention modules are essentially transformer blocks, our model could be pretrained. To investigate the effect of pretraining on our model, we pretrain the model on a subset of the combined corpus of WikiText-103 (Merity et al., 2016) and Bookcorpus (Zhu et al., 2015). The model is trained on three types of objectives: subword-level masked language modeling (MLM) loss, character-level MLM loss, and a novel character-word matching loss that aims to align the representation space of the output character and subword embeddings, described below. Table 9 displays the results of the pre-trained model on WNUT-17 using different amount of data for pretraining, and we see that the model seems to perform worse when more data is used in pretraining.

B.1 Character-word Matching

In order to align the representation space of character and word embeddings, we propose a contrastive learning objective named character-subword matching, which is used during our pretraining step Figure 3 presents a visualization of the character-subword matching objective. For each character in T^c, we record a label for the subword that it belongs to. For example, consider the sentence `A la carte`. Character `A` would be labeled 1 and `l,a` would be labeled 2. We call the label sequence L^c

We compute the pairwise similarity (scaled dot product) between each subword-character pair, and we create a similarity matrix $S = H_*^s \cdot H_*^c$, where $S[i,j] = H_*^s[i] \cdot H_*^c[j]/a$, where a is a trainable constant. Therefore, we formulate the contrastive loss as follows:

$$\mathcal{L}_c = \sum_{j=1}^{m} \text{CrossEntropyLoss}(S, \text{ref} = L^c)$$

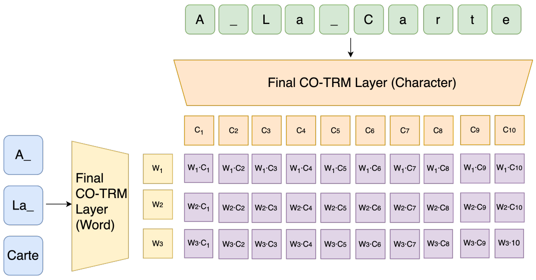

Figure 3: Character-word matching loss

B.2 Optimization

To learn the parameters of our model, we optimize the model over three objectives. For MLM, we randomly masked out 15% of the tokens in the subword and character sequence. Take a single piece of text $(\mathbf{x})$ for example. We respectively compute the subword-level and character-level MLM loss as

Model		**% data**	**# epoch**	**F1**
RoBERTa$_{\text{base}}$		-	-	56.38
EM(#C = 1)		-	-	**57.80**
Side	**#C**			
SUBW	1	$\sim$ 0.18%	15	56.59
	1	$\sim$ 8%	1	51.71
	2	$\sim$ 8%	1	52.25
	6	$\sim$ 8%	1	53.14

Table 9: F1 scores for pretrained entanglement model in WNUT-17. % data refers to the % of the corpus used for pretraining. EM(#C = 1) refers to the un-pretrained entanglement model with 1 co-attention module.

follows:

$$\mathcal{L}_{mlm}^{sub}(\mathbf{x}) = -\sum_{t=1}^{n_i^s} \log(\mathbf{x}_t^s|\mathbf{x}_{\neq t}^s, \theta)$$

$$\mathcal{L}_{mlm}^{char}(\mathbf{x}) = -\sum_{t=1}^{n^c} \log(\mathbf{x}_t^c|\mathbf{x}_{\neq t}^c, \theta)$$

where $\mathbf{x}_t^s, \mathbf{x}_t^c$ are respectively subword and character tokens, and n^s, n^c are respectively the number of subword tokens and character tokens. $\mathbf{x}_{\neq t}^s$, $\mathbf{x}_{\neq t}^c$ means the complete character/subword sequence without token $\mathbf{x}_t^s, \mathbf{x}_t^c$ and other masked-out tokens, and θ refers to the parameters in our model.

Our model is then pretrained over the three objectives:

$$\mathcal{L}(\mathbf{x}) = \mathcal{L}_c(\mathbf{x}) + \mathcal{L}_{mlm}^{sub}(\mathbf{x}) + \mathcal{L}_{mlm}^{char}(\mathbf{x})$$

We pretrain our model on a random subset of the combined corpus of WikiText-103 (Merity et al., 2016) and Bookcorpus (Zhu et al., 2015). The model is trained for 8 hours on 4 Tesla V100 GPUs with 32 GB memory. The initial learning rate is 2e-5 and we used an Adam optimizer and a linear scheduler.

A Novel Two-step Fine-tuning Framework for Transfer Learning in Low-Resource Neural Machine Translation

Yuan Gao , Feng Hou*, Ruili Wang
School of Mathematical and Computational Science, Massey University, New Zealand
`{y.gao, f.hou, ruili.wang}@massey.ac.nz`

Abstract

Existing transfer learning methods for neural machine translation typically use a well-trained translation model (i.e., *a parent model*) of a high-resource language pair to directly initialize a translation model (i.e., *a child model*) of a low-resource language pair, and the child model is then fine-tuned with corresponding datasets. In this paper, we propose a novel two-step fine-tuning (TSFT) framework for transfer learning in low-resource neural machine translation. In the first step, we adjust the parameters of the parent model to fit the child language by using the child source data. In the second step, we transfer the adjusted parameters to the child model and fine-tune it with a proposed distillation loss for efficient optimization. Our experimental results on five low-resource translations demonstrate that our framework yields significant improvements over various strong transfer learning baselines. Further analysis demonstrated the effectiveness of different components in our framework.

1 Introduction

Neural machine translation (NMT) has achieved superior performance in terms of both fluency and adequacy for high-resource languages (Vaswani et al., 2017; Zhou and Keung, 2020; Cai et al., 2021; Guo et al., 2022). With the introduction of the attention mechanism (Yin et al., 2021; Petrick et al., 2022), NMT has been proven to be efficient and powerful in modeling long-distance dependencies. However, the performance of NMT systems deteriorates dramatically when insufficient parallel data are available for training (Sakaguchi et al., 2017; Michel and Neubig, 2018; Aharoni et al., 2019; Goyal et al., 2022). The scarcity of parallel corpora intensely limits the performance of an NMT system on low-resource languages.

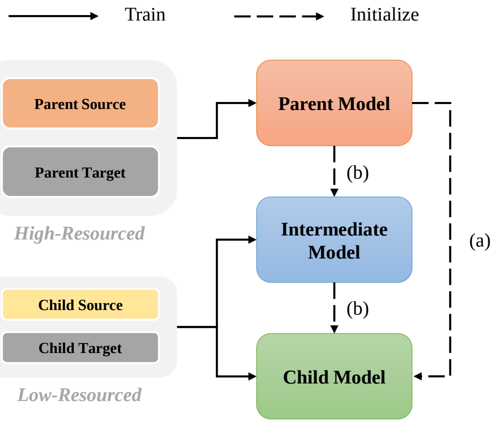

Figure 1: Comparison between vanilla transfer learning framework (a) and TSFT (b). Our proposed TSFT incorporates an intermediate model to pre-fine-tune the parent parameters to fit the child data.

Transfer learning is a learning paradigm for addressing the data scarcity problem (Zoph et al., 2016; Nguyen and Chiang, 2017; Li et al., 2022). For NMT, transfer learning aims to transfer the knowledge from a well-trained high-resource translation model (i.e., a parent model, e.g., English→German) to a low-resource translation model (i.e., a child model, e.g., English→the Māori language). Prior transfer learning methods in NMT (Zoph et al., 2016; Chu et al., 2017) primarily achieve knowledge transfer by initializing the parameters of the *child model* with the *parent model* and fine-tuning the child model on the corresponding data. Such direct transfer of knowledge raises a vocabulary mismatch problem (Lakew et al., 2018; Lin et al., 2019; Kocmi and Bojar, 2020), and results in unsatisfied results for low-resource translations. Some methods have been proposed to alleviate the vocabulary mismatch problem, such as constructing joint dictionaries or employing a cross-lingual token mapping technique (Passban et al., 2017; Kocmi and Bojar, 2018; Kim et al., 2019a). Additionally, Aji et al. (2020) proposed a token matching method that simply duplicates the embed-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3214–3224
June 16-21, 2024

dings of overlapping tokens from the parent model to the child model.

Recently, based on the work of Aji et al. (2020), Li et al. (2022) proposed ConsistTL that uses the predictions of the parent model to continuously provide soft targets during the fine-tuning of the child model. However, given the differences between the source inputs of the parent and the child translation tasks, the parent model is not an optimal starting point for the single-step fine-tuning of the child model using limited parallel child data. Therefore, it is necessary to pre-fine-tune the parent model to fit the child language before initializing the child model with it.

Building upon this insight, we propose a simple yet effective transfer learning framework, named **T**wo-**S**tep **F**ine-**T**uning (TSFT), for low-resource NMT. As shown in Figure 1, we introduce an intermediate (child) model initialized with the parent model to adjust the parent parameters to fit the child language. TSFT involves two fine-tuning steps. In the first step, we feed child source sentences (i.e., monolingual data) and meaning-matched sentences in the parent source language into the intermediate and the parent models, respectively. Then, the intermediate model is fine-tuned with the objective of aligning probability distributions from the parent and intermediate models, aiming to adjust the parameters transferred from the parent model to perform well with child source sentences. Additionally, we propose a regularization-based strategy that can improve the translation performance of the intermediate model and benefit the child model. Note that we apply the token matching method to alleviate the vocabulary mismatch problem in the first step. In the second step, we transfer the adjusted parameters from the intermediate model to the child model and fine-tune the entire child model on the pertinent parallel data, employing both a cross-entropy loss and a proposed distillation loss. Extensive experiments on five low-resource translations show that TSFT surpasses the strongest baseline method with up to 1.2 SacreBLEU points. The ablation study demonstrates the effectiveness of different components within TSFT.

Our contributions can be summarized as follows:

- We propose a novel two-step fine-tuning framework for low-resource NMT, which introduces an intermediate (child) model to fit parent parameters for the data of child languages before initializing the child model with the parent model.
- We propose a regularization-based strategy for fine-tuning the intermediate model and a distillation loss for fine-tuning the child model.
- We validate our method by extensive experiments on various low-resource translations and achieve improved performance compared to various transfer learning methods.

2 Related work

Existing studies have demonstrated the success of transfer learning for low-resource NMT (Lin et al., 2019; Imankulova et al., 2019; Ji et al., 2020; Eronen et al., 2023). Zoph et al. (2016) first introduced transfer learning into the field of NMT and proposed a parent-child framework, where parameters from a pre-trained *parent model* are directly transferred to a new *child model* with a shared target language. Subsequent research largely builds upon the parent-child framework and tends to leverage highly related parent language to perform transfer learning (Passban et al., 2017; Setiawan et al., 2018). However, the languages closely related to low-resource languages are also low-resourced (Nguyen and Chiang, 2017; Xia et al., 2019) and offer only modest performance improvements. Thus, researchers focused on identifying the critical factors for the effectiveness of the parent language. Experimental results from (Lin et al., 2019; Aji et al., 2020) emphasized that linguistic or geographical distance does not appear as important as the size of the parent data (Lin et al., 2019; Aji et al., 2020). This insight expands the range of parent languages available for transfer learning, and alleviates the limitations of highly related parent languages. Consequently, later researchers shifted their attention to parent languages with low relatedness but high-resourced. However, this exacerbates the vocabulary mismatch problem, posing a new challenge to transfer learning.

One solution to the vocabulary mismatch problem is to build a joint dictionary before training a parent model (Kocmi and Bojar, 2018; Kim et al., 2019b). However, this restricts the applicability of a pre-trained parent model to a specific child model only. To overcome this limitation, Kim et al. (2019a) proposed pre-training a language-agnostic cross-lingual word embedding independently from the parent model. Concurrently, token matching methods also show their effectiveness in transfer learning without requiring additional training efforts (Aji et al., 2020; Kocmi and Bojar, 2020). Some other methods introduce highly related intermediate languages to gradually narrow the vocabulary disparity (Luo et al., 2019; Maimaiti et al., 2019). These methods take advantage of both large-scale data sources and syntactic similarity in the intermediate language.

Recently, Li et al. (2022) incorporated the idea of consistency learning into transfer learning based on the work of Aji et al. (2020) and proposed a novel transfer learning method called ConsistTL. This method enables the child model to utilize the parent model during fine-tuning. Subsequently, Liu et al. (2023) proposed kNN-TL, which extends ConsistTL by integrating a k-nearest neighbor (kNN) module, allowing the child model to utilize the parent model during inference. While our method also builds on ConsistTL, we focus on enhancing the child model's performance during fine-tuning. Thus, our work is orthogonal to kNN-TL.

3 Method

In this section, we begin by providing an overview of the basic concepts behind transfer learning and then present our transfer learning framework, TSFT, in detail.

3.1 Transfer Learning Primary

Given a source sentence $x = \{x_1, \dots, x_I\}$, the objective of an NMT model is to translate it to a new sentence $y = \{y_1, \dots, y_J\}$ in a target language, where the source sentence and target sentence have lengths I and J, respectively. A typical NMT model is composed of an encoder and a decoder. The encoder is designed to extract high-level semantic information from the source sentences and represent them as hidden states H_e. The decoder generates the output probability $P(y_i|H_e, y_{<i})$ of the next target token y_i. An NMT model is trained on a parallel corpus by minimizing the cross-entropy (CE) loss between the predicted sentence and the ground-truth translation as follows:

$$L_{ce} = -\sum_{i=1}^{J} \log P(y_i|y_{<i}, x, \theta), \tag{1}$$

where θ is the parameters of the entire NMT model.

Transfer learning has been widely used when only limited training datasets are available for the problem at hand. It transfers the knowledge acquired from large-scale data to enhance the model performance under low-resource conditions. Transfer learning typically follows a parent-child framework (Zoph et al., 2016), where it involves reusing the parameters θ_p from a pre-trained parent model to initialize part or all parameters of a child model. In the field of NMT, the parent model $\mathcal{M}_p$ is initially trained on a high-resourced parallel dataset $D_p = \{X_p, Y_p\}$, while there is only a limited-sized dataset $D_c = \{X_c, Y_c\}$ available to the child model $\mathcal{M}_c$. After the initialization step, the child model can be fine-tuned on D_c, which is also optimized through the minimization of the CE loss.

3.2 Two-step Fine-tuning

For NMT, an ideal transfer learning framework should enable the parent model to exert its complete capabilities on the child task. However, owing to the disparities between the parent and child languages, the current one-step fine-tuning transfer learning framework struggles to adjust the parameters of the parent model to fit the child source language under the constraints of limited child data.

The idea of TSFT is simple: before initializing the child model with the parent model, we first adjust the parameters of the parent model to enhance its congruity with the child source language. In this work, we propose to introduce an intermediate model, denoted as $\mathcal{M}_a$, to make the parameters of the parent model fit for the child data. Specifically, we initialize the intermediate model with the parent model and pre-fine-tune it by using the source side sentences of the child data, then fine-tune the child model with both the source and target child training data. Therefore, we design TSFT as a two-step framework, as shown in Figure 2.

Step 1: Intermediate Fine-tuning After initializing the intermediate model with a well-trained parent model, we aim to equip the intermediate model with the ability to utilize child source sentences as input for target language generation. Since the intermediate model and the parent model share the same target language, it is crucial to retain the generation ability of the parent model. Therefore, we input the source-side sentences of the child data to the intermediate model and the parent model and utilize the predicted distribution of the parent model as the soft label for fine-tuning.

However, it is infeasible to directly input child

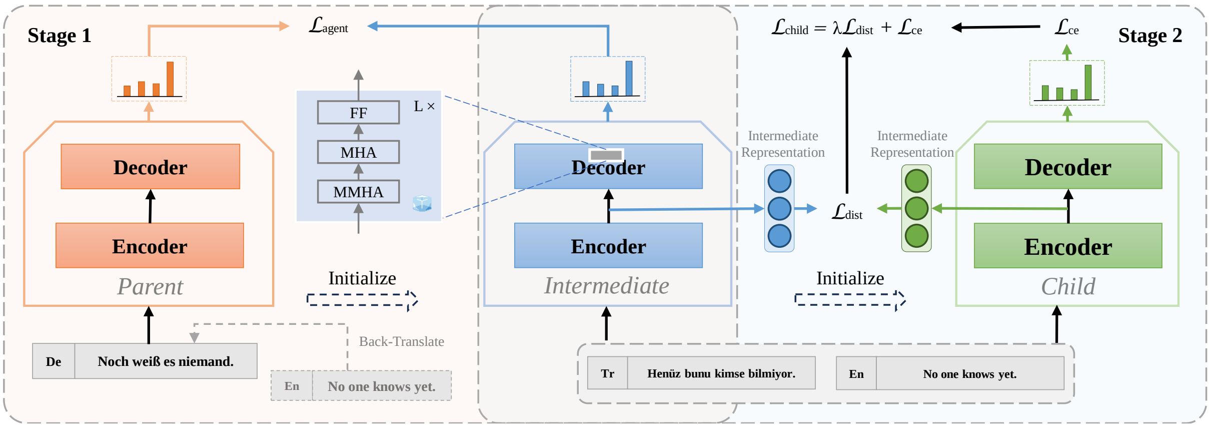

Figure 2: Our proposed transfer learning framework TSFT for low-resource NMT. In Step 1, the loss function L_{inter} is used to optimize the intermediate model. In Step 2, the child model is optimized by L_{child}. The blue icy blocks are initialized with the *parent* model and frozen. The input German sentences are produced through back-translation.

source sentences into the parent model, given that the parent and child models have different source languages. Thus, we need a meaning-matched sentence for each child source sentence in the parent source language. In the context of low-resource translations, parallel data for non-English-centric is often limited in size or entirely absent, making it difficult to meet the requirements for intermediate fine-tuning. Therefore, we adopt the method of Li et al. (2022) to generate pseudo parent data $D_{p*} = \{X_{p*}, Y_c\}$ by using a reversed parent model, where each $x_{p*} \in X_{p*}$ is aligned with $y_c \in Y_c$. Although such a method requires training a reverse parent model, it effectively generates meaning-matched input sentences for the parent model. In addition, we use the following loss function to optimize the intermediate model:

$$L_{inter} = \sum_{i=1}^{J} F_d[P_{inter}(y_i), P_{parent}(y_i)], \quad (2)$$

where F_d is a distribution measurement method, in this work, we choose Jensen-Shannon (JS) divergence (Lin, 1991; Wen et al., 2023) as our F_d. Our preliminary experiments find that JS divergence outperforms using Kullback–Leibler (KL) divergence when taking $P_{inter}(y_i)$ as the first item and $P_{parent}(y_i)$ as the second one. $P_*(y_i)$ represents the prediction distributions of translation models at time step i, which is conditioned on the input sentence and the previous tokens:

$$P_*(y_i) = P_*(y_i|x, y_{<i}). \quad (3)$$

Before fine-tuning the intermediate model, we first apply the token matching method (Aji et al., 2020) that duplicates the embeddings of overlapping tokens from the parent and child vocabularies to alleviate the vocabulary mismatch problem.

Step 2: Child Fine-tuning In the second step, we employ the target-side sentences from the child training data as labels to fine-tune the child model with CE loss, following the general process of transfer learning. Since the encoder of the intermediate model has fine-tuned with the child source sentences, we argue that it encompasses valuable information that can facilitate the child model. Therefore, we extract the encoder outputs, $P^e_*(\cdot)$, from both the intermediate and child models and incorporate a distillation loss L_{dist} as an extra objective to optimize the child model by minimizing the KL divergence between two output representations:

$$L_{dist} = -\sum_{i=1}^{I} P^e_{inter}(x_i) \cdot log P^e_{child}(x_i), \quad (4)$$

$$\begin{aligned} P^e_*(x_i) &= P^e_*(x_i|x, \tau) \\ &= \frac{exp(z_i/\tau)}{\sum_{j \in V} exp(z_j/\tau)}, \end{aligned} \quad (5)$$

where I denotes the sentence length of a child source sentence, z denotes the logits output of encoders before log_softmax is computed, V represents the vocabulary, and τ is a temperate factor used to smooth the prediction distributions. As we only reuse the output of encoders, the process of encoder distillation does not add any extra parameters to models. The overall loss is obtained by a weighted sum of L_{ce} and L_{dist}:

$$L_{child} = L_{ce} + \lambda L_{dist}, \tag{6}$$

where λ is a balancing hyper-parameter.

Partial Decoder Freeze Regularization-based methods are widely used to alleviate the *catastrophic forgetting* issue (Kirkpatrick et al., 2017; Gu and Feng, 2020; Gu et al., 2021). While updating all parameters typically yields good results on a new domain, the data distribution difference between the old and new domains can engender the issue of *catastrophic forgetting*, causing the fine-tuned model to abandon linguistic knowledge learned from previous dataset (Thompson et al., 2019; Bérard, 2021). In this work, we are interested in introducing the regularization-based technique during Step 1 to preserve the predictive capabilities of the parent model. We propose a Partial Decoder Freeze (PDF) strategy to freeze the parameters of the last l decoder layers of the intermediate model and only update the rest parameters. For the selection of parameters l, we conducted empirical experiments in Section 5.1.

4 Experiments

4.1 Settings

Datasets We conduct experiments on five low-resource translation tasks, four of which are from the Global Voices datasets (Tiedemann, 2012; Khayrallah et al., 2020): Polish (Pl), Hungarian (Hu), Indonesian (Id), Catalan (Ca) to English (En), where we use the officially provided training sets, validation sets and test sets in our experiments. The other one is the WMT 2017 Turkish (Tr) to En benchmark. We use *newstest2016* as the validation set and *newstest2017* as the test set. For the parent models training, we use the German-English dataset following the empirical advice of (Aji et al., 2020; Li et al., 2022). We take the WMT 2017 news translation task as our parent dataset containing around 5.8M paired sentences. The detailed statistics of these parallel corpora are presented in Table 1. For fair comparisons, we adopt the same data preprocess techniques as previous research of TL (Li et al., 2022), which only apply normalization and tokenization to parallel sentences by using *Moses* toolkit[1]. Further, we apply Byte Pair Encoding (BPE) (Sennrich et al., 2016) to address the out-of-vocabulary problem and segment words with 16,000 merge operations for Turkish and 8,000 for the rest.

Datasets	# Train	# Valid	# Test
Global Voices Pl - En	39.9K	2,000	2,000
Global Voices Ca -En	15.2K	2,000	2,000
Global Voices Id - En	8.4K	2,000	2,000
Global Voices Hu - En	7.7K	2,000	2,000
WMT 2017 Tr - En	196.6K	3,000	3,007
WMT 2017 De - En	5.8M	3,000	3,003

Table 1: The statistics of parallel corpora.

Model Configuration In our experiments, we implement translation models with *fairseq* [2] toolkit. We choose the Transformer (Vaswani et al., 2017) as the backbone to implement our framework. We use Transformer_base that consists of 6 encoder and decoder layers with 8 attention heads. The number of dimensions of all sub-layers in the model is set to 512, and the inner layers of feed-forward layers have 2048 dimensions. Our models are trained on 2 Nvidia A100 GPUs. We train our models using Adam (Kingma and Ba, 2015) with $(\beta_1, \beta_2) = (0.9, 0.98)$ and use cross-entropy as criterion with *label smoothing* $= 0.1$. In addition, we train the forward and backward parent model (i.e., De→En and En→De) with the initial learning rate $1e^{-7}$ and gradually increase till $1e^{-3}$ within 10,000 warm-up updates. For the models with transfer learning, we set the initial learning rate to $1e^{-7}$, and the peak learning rate is $2e^{-4}$ within 1,000 warm-up steps. Dropout is applied to the output of each sub-layer with a rate of 0.3 to avoid over-fitting. Besides, attention and activation dropouts are also used with a rate of 0.1 and 0.1. We train all models with a maximum of 200 epochs and select the checkpoints with the best BLEU score on the validation set as our final model, where beam search is applied with beam size 5, and the length penalty is 1.

Baselines We use the following baselines to validate our method:

TSFT (ours)	**20.0**	**56.7**	**13.1**	**44.6**	**20.5**	**53.3**	**27.7**	**60.7**	**23.3**	**60.5**

Table 2: The SacreBLEU and BERTScore scores of baselines and ours on various translations. "BS" represents BERTScore. **Blod** indicates the best result. BLEU score reflects that TSFT is significantly better than ConsistTL with t-test $p < 0.05$. The number of bootstrap resamples is set to 1,000 to measure the significant difference between results.

- **Vanilla NMT** (Vaswani et al., 2017): A bilingual NMT model with Transformer architecture directly trained on low-resource child training data from scratch.

- **TL** (Zoph et al., 2016): The first transfer learning work for NMT, initializing the child model with a parent model except for the source word embeddings. Note that the original work employed a two-layer encoder-decoder LSTM model, whereas we replicate TL using Transformer.

- **TM-TL** (Aji et al., 2020): To transfer embeddings across languages with distinct linguistic characteristics, Token Matching (TM) is proposed to assign the child word embeddings with the same tokens in the parent embeddings. The remaining unmatched tokens are assigned random embeddings as TL.

- **ConsistTL** (Li et al., 2022): Based on TM-TL, ConsistTL is proposed to enhance the child model by incorporating the prediction of the parent model during the fine-tuning of the child model.

Metrics To validate the effectiveness of our proposed framework, we use the following two metrics:

- **BLEU** (Papineni et al., 2002): Considering the discrepancy among different tokenization processes, we apply the SacreBLEU score (Post, 2018)[3] for all experiments.

Hyper-parameter	Tr→En	Hu→En
($\lambda = 2.0, \tau = 2.0$)	19.9	13.0
($\lambda = 3.0, \tau = 2.0$)	19.8	12.8
($\lambda = 4.0, \tau = 2.0$)	**20.0**	**13.1**
($\lambda = 5.0, \tau = 2.0$)	19.9	12.9
($\lambda = 4.0, \tau = 0.5$)	19.7	12.9
($\lambda = 4.0, \tau = 1.0$)	19.7	**13.1**
($\lambda = 4.0, \tau = 3.0$)	19.4	13.0

Table 3: The SacreBLEU scores on the test set of the Tr → En and Hu→En translations with different λ and τ.

- **BERTScore** (Zhang et al., 2020): Leveraging a pre-trained BERT model to evaluate the semantic correctness between the predictions and references by cosine similarity.

4.2 Main Results

The results on five low-resource translation benchmarks are presented in Table 2. In our experiments, we utilize German as the parent language, and the parent models are pre-trained on a German-to-English dataset. As we can see, our method significantly outperforms the vanilla NMT in terms of both SacreBLEU and BERTScore. Compared with TL and TM-TL, TSFT still achieves significant improvements on all translations. Moreover, our proposed TSFT also has demonstrated superior performance compared to the strongest baseline ConsistTL with up to +1.2 SacreBLEU points and +1.1 BERTScore points. Overall, these results prove that our proposed transfer learning framework TSFT can effectively improve the performance of the child model on low-resource translation tasks.

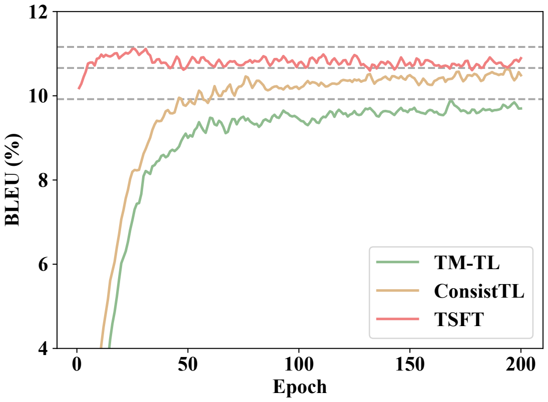

Figure 4: Learning curves of different TL methods.

5 Analysis

5.1 Effect of the Number of Freezing Layers

In Section 3.2, we utilize the PDF strategy in Step 1. However, we do not clearly know the optimal number of freezing layers l that can benefit the child model most. Different numbers of freezing layers would significantly impact the child model performance. Hence, in this section, we conduct a comparative analysis of the impact of different l on the translation performance of the child model.

Concretely, we still use the De→En model as the parent model and select Tr→En and Hu→En translations as child tasks. We tune the hyper-parameter l by performing a grid search on $l \in \{1, 2, 3, 4, 5, 6\}$. Figure 3 illustrates the model performance with different values of l. We can find that the final child models achieve the best performance in Tr→En and Hu→En when l is 5 and 4, respectively. Consequently, we set l as 5 for Tr→En translation and 4 for the rest.

Despite a substantial size difference between the Tr→En and Hu→En datasets, there is not much difference in the choice of the number of layers to freeze. For this phenomenon, we speculate that the distinction between these two child datasets is negligible compared to the size distinctions with the parent dataset, as shown in Table 1. Therefore, when applying our framework to parent models with relatively limited resources, the choice of the number of frozen decoder layers needs to be carefully considered to achieve optimal results.

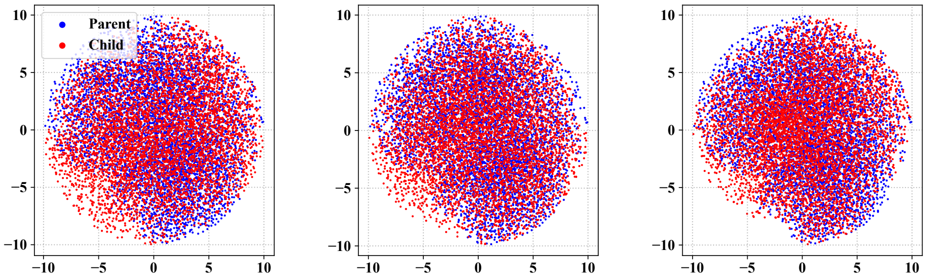
5.2 Effect of Hyper-parameters λ and τ

Hyper-parameter λ is crucial to controlling the influence of the two losses within the L_{child}. In this part, we set λ to {2.0, 3.0, 4.0, 5.0} to investigate the impact of different values of λ on the performance of the child model. The corresponding SacreBLEU scores are presented in Table 3. For both Tr→En and Hu→En translations, the best performances are obtained when λ is set to 4.0. Hence, we set λ as 4.0 for all experiments involving L_{dist}.

In addition, we also conduct experiments with varying values of τ during the training process of the child model, while keeping λ fixed at 4.0. As illustrated in Table 3, we can find that the performance of the child model is sensitive to τ and the performance is best when τ is set to 2.0. We argue that this is because minimizing the KL divergence is difficult, but using a larger τ (e.g., 3.0) may diminish the information from the intermediate model, which is not helpful in improving the performance of the child model.

5.3 Ablation Study

We conduct an ablation study of the PDF strategy, L_{dist}, and Step 2 to explore their effects on our framework. We present the performance of four variants of TSFT as follows: 1) w/o PDF. During the training process of Step 1, we do not freeze any layers of the intermediate model, fine-tuning all parameters in every epoch. 2) w/o L_{dist}. In Step 2, we eliminate the distillation loss between the encoders of the intermediate and child models, conducting fine-tuning of the child model using



(a) TM-TL (b) ConsistTL (c) TSFT (Step 1)

Figure 5: Sentence representations after using T-SNE dimensionality reduction. The blue points denote the output from the parent model, and the red points denote the output from the fine-tuned models obtained from different transfer learning methods.

L_{ce} exclusively. 3)w/o Step 2. We evaluate the translation performance of the intermediate model. 4) w/o Step 2 + PDF. Based on 3), we do not freeze any layers of the intermediate model during Step 1. We conduct experiments on Tr→En and Hu→En translations, which correspondingly represent the largest and smallest datasets among those applied in our main experiments. The results are shown in Table 4. It is evident that excluding the PDF strategy, L_{dist}, or Step 2 resulting in a deterioration of the translation quality, underscoring the efficacy of these components within TSFT. The experimental results show that PDF has a greater impact than L_{dist}. Further, we observe that PDF can effectively improve the translation performance of the intermediate model and benefit the child model. This observation shows that retaining the performance of the parent model is crucial for improving the performance of the child model.

5.4 Comparison of Learning Curves

A learning curve represents a model's learning performance throughout the duration of training and is a widely employed diagnostic tool in machine learning (Kambhatla et al., 2022; Bao et al., 2023). In this section, we present the validation learning curve to assess the generalization capabilities of TM-TL, ConsistTL, and TSFT by using the SacreBLEU score as the criterion. Figure 4 illustrates the learning curves of child models trained with three transfer learning methods. Compared with TM-TL and ConsistTL, TSFT exhibits superior initial performance and convergence speed. Note that the TSFT curve delineates the performance of the model fine-tuned after Step 1. This observation emphasizes the effectiveness of fine-tuning the intermediate model in enhancing the final model's performance, which can be attributed to the augmentation of adaptability to child data consequent to the fine-tuning process in Step 1. Besides, as the training progresses into the stable phase, we can find that the performance of the child model under the TSFT framework is consistently higher than that of TM-TL and ConsistTL. It is noteworthy that, similar to TM-TL and ConsistTL, TSFT does not utilize additional data or resources. Thus, the performance improvement of the child model can be attributed to the effectiveness of the pre-fine-tune process.

5.5 Sentence Representation Visualization

In our framework, the intermediate model is used to adjust the parent parameters to perform well when using child source sentences as input (Section 3.2). Thus, in this section, we visualize the target-side sentence representations of the De-En parent model and Hu-En models obtained from different transfer learning methods. We utilize the T-SNE method (Hinton and Roweis, 2002) to project the representations into a 2-dimensional space, as shown in Figure 5. This figure shows that TM-TL struggles to align the child representations with the parent representations. ConsistTL slightly reduces the discrepancy between the parent and child representations, whereas the intermediate model from TSFT makes the representations much more similar. This observation shows that our fine-tuned intermediate model can produce similar outputs to the parent model even with different source languages.

6 Conclusion

In this paper, we propose TSFT: a novel two-step fine-tuning framework for low-resource NMT.

TSFT incorporates an intermediate (child) model to pre-fine-tune the parent model to fit the child data. The intermediate model is initialized with the parent model and then fine-tuned on the child source data in the first step. We propose freezing partial decoder layers when fine-tuning the intermediate model to alleviate catastrophic forgetting. In the second step, TSFT initializes the child model with the intermediate model and fine-tunes the child model on the parallel data using the cross-entropy and proposed distillation losses. Experimental results on five low-resource translations demonstrate the effectiveness of our proposed TSFT.

Limitations

When using our proposed framework, two fine-tuning steps are necessary to obtain the final child model. Therefore, compared to one-step transfer learning methods in NMT, TSFT may require more training time and computation resources to transfer parent knowledge to the child model. Nevertheless, it is important to note that TSFT does not introduce additional time or computing resource consumption during inference. Besides, TSFT is designed for transfer learning scenarios when the target languages of the parent and child models are identical. We will try transferring different target languages in the future.

Ethics Statement

This study uses only publicly accessible datasets and models that permit academic research. The preprocessing tools and model training toolkit are open-sourced without copyright conflicts.

Enhancing Cross-lingual Sentence Embedding for Low-resource Languages with Word Alignment

Zhongtao Miao, Qiyu Wu, Kaiyan Zhao, Zilong Wu, Yoshimasa Tsuruoka
The University of Tokyo, Tokyo, Japan
{mzt, qiyuw, zhaokaiyan1006, zw2599, yoshimasa-tsuruoka}@g.ecc.u-tokyo.ac.jp

Abstract

The field of cross-lingual sentence embeddings has recently experienced significant advancements, but research concerning low-resource languages has lagged due to the scarcity of parallel corpora. This paper shows that cross-lingual word representation in low-resource languages is notably under-aligned with that in high-resource languages in current models. To address this, we introduce a novel framework that explicitly aligns words between English and eight low-resource languages, utilizing off-the-shelf word alignment models. This framework incorporates three primary training objectives: aligned word prediction and word translation ranking, along with the widely used translation ranking. We evaluate our approach through experiments on the bitext retrieval task, which demonstrate substantial improvements on sentence embeddings in low-resource languages. In addition, the competitive performance of the proposed model across a broader range of tasks in high-resource languages underscores its practicality.

1 Introduction

Cross-lingual sentence embedding encodes multilingual texts into a shared semantic embedding space in which the texts are understandable across different languages. Various applications including bitext retrieval (Artetxe and Schwenk, 2019a) and cross-lingual semantic textual similarity tasks (Cer et al., 2017; Chen et al., 2022) rely on cross-lingual sentence embedding.

Current approaches to obtaining cross-lingual sentence embeddings primarily utilize multilingual pre-trained language models (Devlin et al., 2019; Conneau and Lample, 2019; Conneau et al., 2020) that employ masked language modeling and translation language modeling objectives to predict masked tokens within the context. Such models implicitly align the contextual representations of semantically similar units of sentences in different languages (Li et al., 2021), thereby enabling the models to understand texts in various languages.

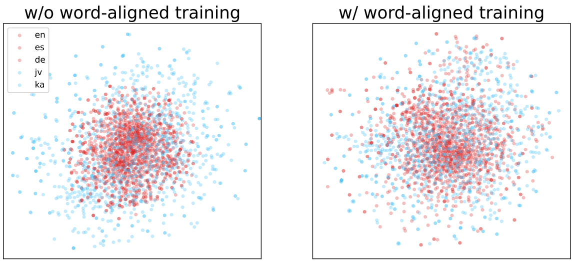

Figure 1: t-SNE visualization of sampled word embeddings from both high-resource and low-resource languages. The red points represent the word embeddings from high-resource languages, and the blue points correspond to those from low-resource languages. This comparison highlights the differences of word representation in the models w/ and w/o the explict word-aligned training. **Left**: words in low-resource languages are under-aligned with their translations in high-resource languages. **Right**: the phenomenon of under-alignment is mitigated through the proposed explicit word-aligned training. The details of word sampling, word embeddings and word-aligned training are described in Section 4.3.

While the field of cross-lingual sentence embedding has recently seen great advancements (Li et al., 2023, 2021; Zhang et al., 2023; Feng et al., 2022), research concerning low-resource languages has lagged due to the scarcity of parallel corpora.

In Figure 1, we observe that word embeddings from low-resource languages, which are derived from current cross-lingual models trained solely with a sentence-level alignment objective, are under-aligned with those from high-resource languages. To address this under-alignment, we introduce a new framework featuring two word-level alignment objectives: aligned word prediction and word translation ranking. These objectives are designed to align the word-level signals of parallel sentences. Additionally, a sentence-level alignment objective, known as translation ranking (Feng et al.,

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3225–3236
June 16-21, 2024

2022), is also used to ensure the basic sentence understanding. We name our proposed framework WACSE (**W**ord **A**ligned **C**ross-lingual **S**entence **E**mbedding). The right sub-figure in Figure 1 shows the distribution of word embeddings obtained from the model trained with the proposed aligned word prediction and word translation ranking. It demonstrates that the under-alignment phenomenon can be mitigated through the explicitly word-aligned objectives.

The experiment results demonstrate that the proposed word-aligned training objectives can enhance cross-lingual sentence embedding, particularly for low-resource languages, as evidenced on the Tatoeba dataset (Artetxe and Schwenk, 2019a). This finding matches our observations on word representations in Figure 1. Furthermore, our model retains competitive results across a broader range of tasks, including STS22 (Chen et al., 2022), BUCC (Zweigenbaum et al., 2017), and XNLI (Conneau et al., 2018), in which most languages are high-resource. This indicates the practicality and robustness of the proposed framework.

2 Related Work

2.1 Cross-lingual Sentence Embedding

Cross-lingual sentence embedding is the task of encoding sentences from various languages into a shared embedding space. Traditionally, large-scale parallel corpora have been utilized to learn cross-lingual sentence embeddings. LASER (Artetxe and Schwenk, 2019b) employs a BiLSTM encoder trained on parallel sentences from 93 languages, totaling 223 million parallel sentences, to learn joint multilingual sentence representations. LaBSE (Feng et al., 2022) learns cross-lingual sentence embeddings by integrating dual-encoder translation ranking, additive margin softmax, masked language modeling (MLM) and translation language modeling (TLM), utilizing training data consisting of 17 billion monolingual sentences and 6 billion translation pairs. Extending SimCSE (Gao et al., 2021) to multilingual settings, mSimCSE (Wang et al., 2022) demonstrates that contrastive learning applied to English data alone can yield universal cross-lingual sentence embeddings without the need for parallel data. Inspired by PCL (Wu et al., 2022), MPCL (Zhao et al., 2024) leverages multiple positives from different languages to improve cross-lingual sentence embedding.

Token-level auxiliary tasks. Recently, the importance of token-level auxiliary tasks has been recognized. VECO2.0 (Zhang et al., 2023) employs thesauruses for token-to-token alignment, achieving notable results on the XTREME benchmark (Hu et al., 2020). DAP (Li et al., 2023) is designed with two primary objectives. The first objective, translation ranking (TR), aims to bring parallel sentences closer together in the embedding space. The second objective, representation translation learning (RTL), employs one-sided contextualized token representations to reconstruct their translation counterparts, aiming to capture the relationships between tokens in parallel sentences. TR as a simple but effective objective, is also utilized in our framework to ensure the basic sentence understanding. Nevertheless, researchers recognize the significance of token-level or word-level alignment in cross-lingual scenarios, the acquisition of token-level or word-level supervisory signals remains a challenging topic of ongoing discussion. Li et al. (2021) employ fast_align (Dyer et al., 2013) to obtain word-level supervisory signals. XLM-Align (Chi et al., 2021b) leverages self-labeled word alignment signals for model training. VECO2.0 (Zhang et al., 2023) utilizes thesauruses to acquire token-level supervisory signals.

2.2 Word Alignment

Word alignment is a task aimed at aligning the corresponding words in parallel sentences (Brown et al., 1993; Och and Ney, 2003; Dyer et al., 2013; Dou and Neubig, 2021; Wu et al., 2023), serving as a useful component for applications such as machine translation (Li et al., 2019, 2022). SimAlign (Jalili Sabet et al., 2020) utilizes multilingual word embeddings for word alignment without relying on parallel data or dictionaries. Nagata et al. (2020) redefine the word alignment task as a cross-lingual span prediction problem and finetune mBERT with manually annotated word alignment data. WSPAlign (Wu et al., 2023) reduces the dependence on manually annotated data by creating a large-scale, weakly-supervised dataset for word alignment. By pre-training word aligners with weakly-supervised signals via span prediction, it achieves state-of-the-art performance across five word alignment datasets. In this work, we employ WSPAlign to obtain the word-level supervisory signals for training models.

3 Method

To enhance cross-lingual sentence embeddings of low-resource languages through explicit alignment of words, WACSE incorporates three tasks, translation ranking (TR), aligned word prediction (AWP) and word translation ranking (WTR) tasks. These tasks collectively aim to learn the cross-lingual sentence representations of parallel sentences. The framework is depicted in Figure 2.

Formally, we start with a parallel dataset $(\mathbb{X}, \mathbb{Y})$ in two languages and the i-th parallel sentence pair is denoted as (X_i, Y_i). X_i and Y_i can be represented as a sequence of words: $X_i = x_1, x_2, \ldots, x_{|X_i|}$ and $Y_i = y_1, y_2, \ldots, y_{|Y_i|}$, respectively where $|\cdot|$ denotes the length of the given sentence. After inputting a sentence into the model, we obtain the hidden representations from the last layer as follows:

$$h_{cls}^{X_i}, h_1^{X_i}, h_2^{X_i}, \ldots, h_{|X_i|}^{X_i} = f(X_i), \tag{1}$$

where f represents the encoder, and $h_i^{X_i}$ denotes the corresponding hidden representation of x_i in sentence X_i.

Note that $h_i^{X_i}$ could be a sequence of embeddings because a word could be tokenized into multiple tokens. This could affect some minor implementation in the practice. Refer to Section 4.3 for the detailed implementation regarding this issue. Particularly, $h_{cls}^{X_i}$ is the hidden state of the `cls` token for representing the whole sentence.

Acquisition of Word Alignment Supervision. Word alignment models enable us to identify semantically equivalent word-level units within parallel sentences. We utilize WSPAlign[1] to obtain the word-level supervisory signals which will be used in the calculation of AWP and WTR losses.

For the i-th parallel sentence (X_i, Y_i), a word alignment model can generate bidirectional word pair dictionary $\text{WA}^{X_i \to Y_i}$ and $\text{WA}^{Y_i \to X_i}$ as follows:

$$\text{WA}^{X_i \to Y_i}, \text{WA}^{Y_i \to X_i} = \text{WordAlign}(X_i, Y_i). \tag{2}$$

Using $\text{WA}^{X_i \to Y_i}$, we can look up an aligned word $y_k \in Y_i$ for a specific $x_j \in X_i$, if it exists, and vice versa. The bidirectional dictionaries record all obtainable word pairs, demonstrated by the following equation:

$$y_k = \text{WA}^{X_i \to Y_i}(x_j), 1 \leq j \leq |X_i|. \tag{3}$$

Here, each word pair (x_j, y_k) represents a semantically equivalent word pair from the two sentences. In practice, we exclude word pairs with alignment scores below a specified threshold. The threshold value[2] for WSPAlign which we use is set to 0.9.

3.1 Aligned Word Prediction (AWP) Task

After obtaining word alignment supervisory signals, we introduce AWP objective to align semantically equivalent words across different languages.

For a word pair (x_j, y_k) derived from (X_i, Y_i), as introduced in Equations 2 and 3, the model is tasked with predicting y_k while x_j is masked.

We define the aligned word prediction loss for X_i as follows:

$$\begin{gathered} l^{AWP}(X_i) = \sum_{x_j \in \text{WA}^{X_i \to Y_i}} \text{MLM}(X_i, x_j; y_k), \\ y_k = \text{WA}^{X_i \to Y_i}(x_j), \end{gathered} \tag{4}$$

where masking language modeling (MLM) means that the model predicts y_k while masking x_j. The total loss of a batch $\mathcal{L}^{AWP}$ is given by:

$$\mathcal{L}^{AWP} = \frac{1}{2N} \sum_{(X_i, Y_i) \in (\mathbb{X}, \mathbb{Y})} (l^{AWP}(X_i) + l^{AWP}(Y_i)), \tag{5}$$

where N is the batch size. This calculation incorporates both $X_i \to Y_i$ and $Y_i \to X_i$ directions.

3.2 Word Translation Ranking (WTR) Task

Besides the AWP task, previous studies have shown that token-level contrastive learning is also effective in cross-lingual pre-training (Li et al., 2021; Zhang et al., 2023). Inspired by this, we introduce WTR task in this section. WTR differs from the approach taken by VECO2.0 (Zhang et al., 2023), which utilizes thesauruses for token-to-token contrastive learning. The thesaurus-based method overlooks the contextual information of parallel sentences. In contrast, our approach leverages word

[2] https://github.com/qiyuw/WSPAlign.InferEval/blob/49ac6fb87fab17079153bcce84c3ac52d4ce6752/inference.py#L74C5-L74C24

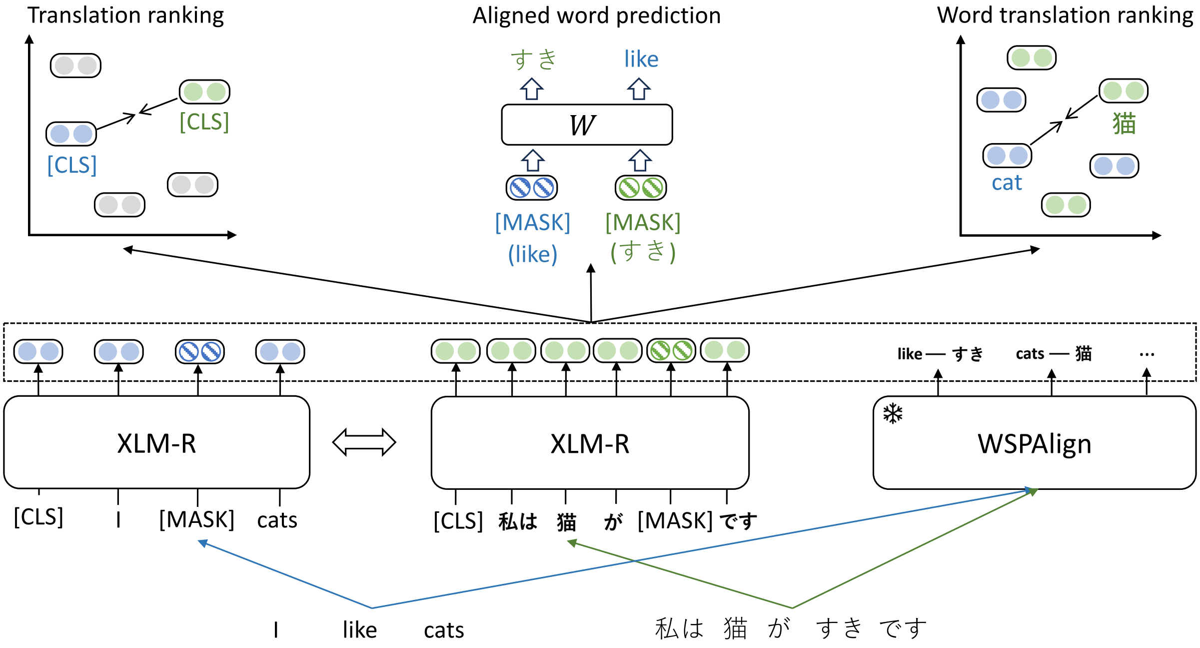

Figure 2: Illustration of WACSE framework. A parallel sentence pair is fed into the multilingual model along with a frozen word alignment model to obtain sentence representations, contextual token representations, and word alignment respectively. Then three objectives are calculated: (1) translation ranking: aligning sentence-level semantics; (2) aligned word prediction: utilizing the contextual representations of masked words to predict their aligned counterparts in another language; and (3) word translation ranking: aligning word-level semantics.

pair supervision from word alignment which considers the contextual information of words in parallel sentences to align semantically equivalent tokens within parallel sentences.

For a given sentence pair (X_i, Y_i) and a specific word pair (x_j, y_k) obtained from it, the word-level WTR loss $l^{WTR}(x_j)$ for x_j can be calculated as follows:

$$-\log \frac{e^{\phi^m(h_j^{X_i},h_k^{Y_i})}}{e^{\phi^m(h_j^{X_i},h_k^{Y_i})}+\sum_{n=1\wedge n\neq k}^{|Y_i|} e^{\phi^m(h_j^{X_i},h_n^{Y_i})}}, \tag{6}$$

where ϕ^m particularly denotes a pair-wise cosine similarity function as the length of $h_j^{X_i}$ may not be equal to that of $h_k^{Y_i}$. Given that the word alignment model produces multiple word pairs, the loss for the whole sentence X_i is calculated as:

$$l^{WTR}(X_i) = \sum_{x_j \in \mathrm{WA}^{X_i \rightarrow Y_i}} l^{WTR}(x_j). \tag{7}$$

Considering bidirectional prediction across the entire batch, the loss $\mathcal{L}^{WTR}$ is presented as follows:

$$\frac{1}{2N} \sum_{(X_i,Y_i)\in(\mathbb{X},\mathbb{Y})} (l^{WTR}(X_i) + l^{WTR}(Y_i)). \tag{8}$$

3.3 Translation Ranking (TR) Task

The dual-encoder architecture, combined with the TR task, has been shown to be effective in learning cross-lingual sentence embeddings at the sentence level, as evidenced by various studies (Guo et al., 2018; Yang et al., 2019; Feng et al., 2022). The TR task aligns the sentence representations of different languages at the sentence level to ensure the basic sentence understanding.

Following Feng et al. (2022) and Li et al. (2023), we denote the loss of the TR task for a parallel sentence (X_i, Y_i) as follows:

$$l_i^{TR} = -\log \frac{e^{\phi(h_{cls}^{X_i},h_{cls}^{Y_i})}}{e^{\phi(h_{cls}^{X_i},h_{cls}^{Y_i})}+\sum_{j=1\wedge j\neq i}^{N} e^{\phi(h_{cls}^{X_i},h_{cls}^{Y_j})}}. \tag{9}$$

For the entire batch, the total loss of TR is:

$$\mathcal{L}^{TR} = \frac{1}{N}\sum_{i=1}^{N} l_i^{TR}, \tag{10}$$

where N represents the batch size, and ϕ denotes the cosine similarity function. The `cls` representations, $h_{cls}^{X_i}$ and $h_{cls}^{Y_i}$, are used to calculate the similarity between X_i and Y_i.

The final loss is calculated as the weighted sum of three losses:

$$\mathcal{L} = \alpha\mathcal{L}^{TR} + \beta\mathcal{L}^{AWP} + \gamma\mathcal{L}^{WTR}, \qquad (11)$$

where α is the weight for the TR loss, β for the AWP loss, and γ for the WTR loss.

4 Experimental Setup

4.1 Training Data

We utilize the same parallel corpora for training as DAP (Li et al., 2023), which is English-centric and comprises 36 language pairs. We use ISO 639 language codes[3] (two-letter codes) to denote languages. Using the same dataset as DAP, we employ WSPAlign to identify word-level semantically equivalent units. The statistics of the parallel corpora we use are presented in Table 1.

Language Pair	# Parallel Sentences	
	train	dev
en-kk	18190	2021
en-te	78105	8678
en-ka	146905	10K
en-jv	317252	10K
en-other	1M	10K

Table 2: Number of Wikipedia articles available per language in the 36 languages of the training parallel corpora (accessed time: 2023-12-05 17:21:49).

4.2 Low-resource Languages

We focus on cross-lingual sentence embeddings in low-resource languages. In the experiment, we determine low-resource languages based on two criteria: (1) the number of Wikipedia articles available per language[4] and (2) the size of the training data available for each language. Among the 36 languages in our dataset, six languages (tl, jv, sw, ml, te, mr) are identified as low-resource based on the smallest number of Wikipedia articles, according to criterion 1. For criterion 2, we select four languages (kk, te, ka, jv) with the fewest parallel sentences in the training set. Detailed information on the number of Wikipedia articles per language is available in Table 2. Considering the intersection of two criteria, we classify eight languages as low-resource in this study. Furthermore, we assess our proposed approach using various combinations of these eight languages, including settings with four languages (kk, te, ka, jv), five languages (tl, kk, te, ka, jv) and all eight languages.

4.3 Implementation Details

As we mentioned above, $h_j^{X_j}$ and $h_k^{Y_k}$ could consist of multiple hidden states and the number of them could be different. When calculating MLM loss in Equation 4, we roughly clip the longer sequence of tokens to ensure the number of tokens are equivalent.

As for the details of Figure 1, the words are sampled from the training dataset based on their frequencies, totaling 500 words. These word embeddings are extracted from the embedding layers of XLM-R models. The left sub-figure illustrates the result from the model trained solely with the TR objective, while the right sub-figure displays the result of our model, which is trained using the proposed method.

Model Size. For the Transformer encoder model (Vaswani et al., 2017) that we use, we adopt the configuration of XLM-R model (Conneau et al., 2020). We initialize the encoder model using the `xlm-roberta-base` checkpoint[5].

Hyperparameters. The maximum sequence length is set to 32. We train our model using the AdamW optimizer, with a learning rate of 5e-5. The training steps are 10K or 100K depending on

WACSE **(ours)**	**75.9**(+2.0)	**76.0**(+2.6)	**81.2**(+1.6)	**92.1**(+0.1)

Table 3: Average accuracy on the Tatoeba dataset across both directions for selected languages. The chosen low-resource languages are (kk, te, ka, jv) for "4 langs", (tl, jv, ka, kk, te) for "5 langs", and (te, ka, kk, jv, ml, sw, tl, mr) for "8 langs". Results of DAP are from Li et al. (2023).

different evaluation tasks. Gradient accumulation is employed across two A100 GPUs, resulting in a total batch size of 1024. The reported results are the average of two random seeds (42 and 0). The values of α, β and γ are set to 0.8, 0.1 and 0.1 empirically. For all models, the pooling method is configured as `cls_before_pooler`.

In line with DAP, we evaluate the model every 2,000 steps using development set shown in Table 1. Similarity search, which is a widely-used metric in cross-lingual retrieval tasks (Artetxe and Schwenk, 2019a), is utilized for choosing the optimal checkpoint.

4.4 Baselines

We compare our proposed method with XLM-R and its TR fine-tuned variant. Other competitive models such as InfoXLM (Chi et al., 2021a), LaBSE (Feng et al., 2022), and mSimCSE (Wang et al., 2022) are also included in the comparison. Note that some of these models leverage significantly larger datasets than ours. For instance, LaBSE utilizes 17 billion monolingual sentences and 6 billion translation pairs, while ours is only in the scale of 36 million.

Our main baseline is DAP (Li et al., 2023), which is a recent cross-lingual sentence embedding model leveraging token-level information. Hence, We adopt the identical settings including training data, model size, and other hyperparameters[6].

5 Evaluation Tasks and Results

5.1 Bitext Retrieval

Bitext retrieval is the task of retrieving the most relevant sentence from a target language corpus given a query sentence in the source language (Li et al., 2023). The Tatoeba dataset (Artetxe and Schwenk, 2019a) is a benchmark for evaluating bitext retrieval spanning a broad array of languages. We train our model for 100K steps and evaluate it on Tatoeba in this task. The released checkpoints of LaBSE[7] and InfoXLM[8] are used for comparison.

Results. We report the results of the Tatoeba dataset across four settings, as detailed in Table 3. The low-resource language settings, including the four-language, five-language, and eight-language settings, are described in Section 4.2. The thirty-six-language setting encompasses all 36 languages in the training dataset. From Table 3, we can observe that our model improves the cross-lingual sentence embedding in all low-resource language settings. But when expanding to all 36 languages, the improvement becomes marginal.

A possible explanation for this is that current cross-lingual sentence embedding models may struggle with learning the word-level alignment in low-resource languages due to the limited training data available. Through the explicit word-level alignment objectives, our method facilitates the alignment of the semantically equivalent tokens between high-resource languages and low-resource languages, aiding the model in acquiring basic word-level semantic information for low-resource languages. Therefore, The proposed method can improve cross-lingual sentence embeddings of low-resource languages. In contrast, high-resource languages already achieve effective word-level alignment during the pre-training phase with implicit word-level signals in the rich parallel corpus. Hence, continuing to explicitly align word-level semantic units between two high-resource languages could detract from the language-dependent and sentence-level features of the cross-lingual sentence embeddings.

5.2 Cross-lingual Semantic Textual Similarity

Semantic Textual Similarity (STS) assesses the degree of similarity between two sentences. The cross-lingual STS task expands this to multilingual scenarios. For this task, we utilize STS22 (Chen et al., 2022) dataset and evaluate the performance using the MTEB benchmark (version 1.1.1) (Muennighoff et al., 2023). According to MTEB, the Spearman correlation, based on similarity, is the chosen metric for evaluation (Reimers et al., 2016). For both DAP and our method, we train the model for 10K steps and test on STS22. Zhao et al. (2024) point out that the result for $fr \leftrightarrow pl$ (French-Polish) language pair in STS22 seems unstable. Consequently, we report two versions of the STS22 task results, one including all language pairs in the STS22 dataset of MTEB benchmark and the other excluding the $fr \leftrightarrow pl$ pair.

Results. As shown in Table 4, our method significantly outperforms DAP on the STS22 dataset. This improvement illustrates that leveraging word-level semantically equivalent units, obtained through word alignment, can enhance the performance of cross-lingual sentence embedding models on cross-lingual STS tasks. This enhancement occurs by bringing semantically equivalent units closer across languages, even though the languages in STS22 are not considered low-resource. It is noteworthy that LaBSE performs slightly better than WACSE on STS22. Though LaBSE utilizes a much larger training dataset, WACSE still achieves competitive results. Detailed scores of STS22 are provided in Table 5.

Model	STS22	
	Avg.	Avg.(-fr-pl)
LaBSE	59.2	59.1
InfoXLM	49.6	47.5
XLM-R+DAP	51.7	52.1
XLM-R+ WACSE	**58.7(+7.0)**	**58.5(+6.4)**

Table 4: Spearman correlation scores of STS22. The results of LaBSE and InfoXLM are obtained using the MTEB benchmark.

5.3 Bitext Mining

Bitext mining involves extracting parallel sentences from two monolingual corpora with the assumption that some of these sentences are translation pairs. Following the settings of DAP and mSimCSE, we assess our model using the BUCC dataset (Zweigenbaum et al., 2017) which includes four language pairs: $fr \leftrightarrow en$, $de \leftrightarrow en$, $ru \leftrightarrow en$ and $zh \leftrightarrow en$. We train our model for 10K steps and use the evaluation code from mSimCSE[9].

	ar	de	de-en	de-fr	de-pl	en
XLM-R + DAP	49.2	38.0	43.3	49.8	43.6	55.2
XLM-R + Ours	55.2	41.6	47.9	52.2	49.9	60.2
	es	es-en	es-it	fr	fr-pl	it
XLM-R + DAP	59.0	62.1	55.1	67.1	45.0	66.2
XLM-R + Ours	60.0	70.0	65.5	73.4	62.0	71.2
	pl	pl-en	ru	tr	zh	zh-en
XLM-R + DAP	30.0	55.1	49.8	50.0	58.3	54.6
XLM-R + Ours	33.8	69.1	55.0	57.7	63.2	68.9

Table 5: Detailed results of the STS22 dataset.

Results. Table 6 shows the results of different models which we compare. The results of LASER (Artetxe and Schwenk, 2019a), mSimCSE, XLM-R, and LaBSE are from the mSimCSE paper (Wang et al., 2022). The notation "mSimCSE$_{sw,fr}$+NLI" refers to the variant of mSimCSE trained with a combination of English Natural Language Inference (NLI) data and translation pairs in English-Swahili and English-French (Wang et al., 2022). Our proposed method outperforms the "mSimCSE$_{sw,fr}$+NLI" model, even it is a large size model. From Table 6, we can see that our approach achieves competitive results, positioning it between the performance of "mBERT + DAP" and "XLM-R + DAP" at the base model size.

5.4 Cross-lingual Natural Language Inference

The Cross-lingual Natural Language Inference (XNLI) (Conneau et al., 2018)) is a task that requires the model to classify sentence pairs across 15 languages into categories of entailment, neutrality, and contradiction. Following the settings of Chi et al. (2021a) and Li et al. (2023), we apply a cross-lingual transfer approach where the model is fine-tuned on English training data and then evaluated on test datasets in other languages. We use the same hyperparameter setting as DAP, with a batch size of 256 and a maximum sequence length of 128 tokens. The number of epochs is set to 2. We do not employ weight decay and experiment with learning rates of {1e-5, 3e-5, 5e-5, 7e-5}. The optimal learning rate is 7e-5 for our model.

Results. Table 7 shows the accuracy results. The XNLI task does not inherently depend on cross-lingual sentence embedding, thus not directly bene-

Table 7: Accuracy on the XNLI dataset. Results of DAP (Li et al., 2023), InfoXLM (Chi et al., 2021a) and LaBSE (Feng et al., 2022) are taken from DAP paper (Li et al., 2023).

fiting from the training in a straightforward manner, but our model demonstrates a slight improvement over the DAP model. Unlike DAP, which utilizes the Representation Translation Learning (RTL) objective to understand token-level relationships between parallel sentences, our model employs a novel framework with two word-level alignment objectives to align semantically equivalent token representations across languages. This suggests that our framework's approach may offer marginal advantages over the RTL loss used by DAP in capturing the nuanced semantics necessary for cross-lingual natural language inference. Note that this task does not directly pertain to cross-lingual sentence embedding. As a result, this observation also illustrate the practicality of our framework.

6 Analysis

In this section, we carry out experiments to gain a deeper understanding of the proposed framework, specifically investigating the role of language identification information and the three losses in WACSE. Our primary focus is on the Tatoeba dataset as it is the only one that encompasses the low-resource language setting. All models discussed in this section are trained with a fixed seed (42) and the training step is 10K.

6.1 Does the Language Identification Information Matter?

We conduct experiments to determine whether incorporating language-specific information can enhance cross-lingual sentence embeddings of low-resource languages. Specifically, we add a new embedding layer that encodes language IDs as the language embedding. We assign different ID number for different languages. It is then added to the token embeddings of our models. This approach is designed to assess the significance of language identification information for our method. We initialize the language embedding layer randomly at the start of training. The final embedding fed into the models is the sum of the token embedding, the positional embedding and the language embedding.

According to the results presented in Table 8, for low-resource languages, incorporating language identification information proves to be beneficial. However, for the cross-lingual sentence embeddings of all 36 languages, it appears more advantageous not to include the language identification information.

Model	5 langs	36 langs
WACSE (w/o lang embed)	77.4	91.1
WACSE (w/ lang embed)	78.2	90.8

Table 8: Average accuracy across two directions on the Tatoeba dataset for five low-resource languages and all 36 languages. "w/ lang embed" denotes models trained with the language embedding layer, while "w/o lang embed" refers to models without this layer.

6.2 Do Word-level Objectives Matter?

We also train models exclusively on the TR task to highlight the effectiveness of the AWP and WTR objectives. Following Section 6.1, we present results for both the low-resource language setting and the 36-language setting. As indicated in Table 9, the AWP and WTR objectives prove to be effective in both scenarios. Note that their performance in the low-resource language setting surpasses that in the 36-language setting.

Model	5 langs	36 langs
TR	75.8	90.7
WACSE	77.4	91.1

Table 9: Average accuracy for the both directions on the Tatoeba dataset across five low-resource languages and all 36 languages. "TR" represents the model trained solely with the translation ranking objective, while WACSE refers to the model trained with the TR, AWP and WTR objectives.

6.3 Can AWP and WTR be Used Solely?

We present the results of models trained with the TR and AWP objectives, the TR and WTR objectives and a combination of the three objectives (TR, AWP and WTR). To accurately investigate the effect of AWP and WTR, we conduct grid search to find the optimal hyperparameters for the model trained with the combined three objectives. Specifically, the loss weights are 0.8, 0.02 and 0.18, for TR, AWP and WTR in the WACSE in Table 10, respectively.

As illustrated in Table 10, both AWP and WTR contributes to enhancing the cross-lingual sentence embeddings for low-resource languages in comparison to the model utilizing only the TR objective. Moreover, WTR exhibits a marginally superior capability for learning cross-lingual sentence embeddings than AWP. The advantage may stem from WTR's strategy of aligning word-level equivalent units within the context of parallel sentences, whereas AWP focuses on predicting masked tokens using the context of monolingual sentences. The optimal result is the combination of three objectives, showing the effectiveness of our WACSE framework.

Model	8 langs
TR	79.8
TR + AWP	80.8
TR + WTR	81.1
WACSE	81.2

Table 10: Average accuracy across both directions on the Tatoeba benchmark dataset for the eight low-resource language setting. "TR" indicates the model trained exclusively with the translation ranking (TR) objective. "TR + AWP" refers to the model trained with both the TR and AWP objectives. "TR + WTR" represents the model trained with the TR objective and the WTR objective. WACSE denotes the model trained with a combination of the TR, AWP and WTR objectives.

7 Conclusion

In this paper, we observe an intriguing phenomenon: the distributions of word embeddings of low-resource languages are under-aligned with those of high-resource languages in current multilingual pre-trained language models. Based on this observation, we propose a framework designed to align word-level semantically equivalent units in parallel sentences between high-resource languages and low-resource languages, thereby enhancing the cross-lingual sentence embeddings for low-resource languages. Furthermore, we demonstrate that aligning word-level semantically units between two high-resource languages with our proposed method may detrimentally affect the language-specific features learned during the pre-training phase. Our experimental results show the effectiveness of our method in improving cross-lingual sentence embeddings for low-resource languages. Additionally, WACSE preserves the performance of the model on other tasks that involve high-resource languages.

Limitations

Our approach does not consider phrase-level alignment between high-resource languages and low-resource languages, an aspect that merits further investigation. The effectiveness of our proposed method is significantly influenced by the quality of the word alignment model, i.e., WSPAlign. The released WSPAlign was not trained for low-resource languages particularly. Thus, developing a word alignment model with strong cross-lingual transferability is an important future direction.

Ethics Statement

All datasets and checkpoints used in this paper are copyright free for research purpose. Previous studies are properly cited and discussed. This research aims to improve cross-lingual sentence embedding models for low-resource languages. We do not introduce additional bias to particular communities. We utilized LLM only for proofreading but not generating any specific contents in this paper.

C^{3}LPGCN:Integrating Contrastive Learning and Cooperative Learning with Prompt into Graph Convolutional Network for Aspect-based Sentiment Analysis

Abstract

Aspect-based Sentiment Analysis (ABSA) is a fine-grained task. Recently, using graph convolutional networks (GCNs) to model syntactic information has become a popular topic. In addition, a growing consensus exists to enhance sentence representation using contrastive learning. However, when modeling syntactic information, incorrect syntactic structure may introduce additional noise. Meanwhile, we believe that contrastive learning implicitly introduce label information as priori. Therefore, we propose C^{3}LPGCN, which integrates Contrastive Learning and Cooperative Learning with Prompt into GCN. Specifically, to alleviate the noise when modeling syntactic information, we propose mask-aware aspect information filter, which combines prompt information of template with aspect information to filter the syntactic information. Besides, we propose prompt-based contrastive learning and cooperative learning to utilise the label information further. On the one hand, we construct prompts containing labels for contrastive learning, by which the model can focus more on task-relevant features. On the other hand, cooperative learning further extracts label information by aligning input samples' representation and output distribution with label samples. Extensive experiments on three datasets demonstrate that our method significantly improves the model's performance compared to traditional contrastive learning methods. Moreover, our C^{3}LPGCN outperforms state-of-the-art methods. Our source code and final models are publicly available at github[1].

1 Introduction

Aspect-based Sentiment Analysis (ABSA) (Zhang et al., 2021, 2022a) aims to predict the sentiment polarity of a specific aspect in a sentence. Figure 1 shows a restaurant review in which the sentiment expression of "Indian" is "authentic" and the sentiment expression of "prices" is "amazing". Therefore, we discriminate the sentiment polarity of these two aspects as positive.

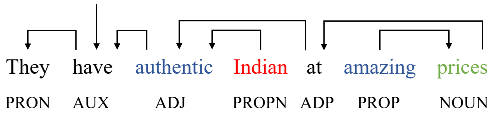

Figure 1: Example of the ABSA task.

In recent years, with the development of deep learning, research on ABSA has resulted in many successes. At the beginning, recurrent neural networks(RNNs) and convolutional neural networks(CNNs) were used to extract effective features from sentences. However, since they cannot model long-distance relationships, the performance of the model drops considerably when aspect words are far away from the corresponding sentiment expression. Then, researchers employed long short-term memory(LSTM) (Tang et al., 2015; Wang et al., 2016) and attention mechanism (Song et al., 2019; Ma et al., 2017) to encode long-distance dependencies, and these studies achieved remarkable results. Recently, with the rise of graph neural networks(GNNs) (Tang et al., 2020; Wang et al., 2020; Li et al., 2021), studies have been conducted to achieve syntactic-based aggregation of word information via graph convolutional network(GCN) (Tian et al., 2021; Sun et al., 2019) to enhance the performance of ABSA further. However, when the syntactic structure of sentences is incomplete or there is no apparent syntactic relationship between aspects and sentiments, syntactic parser may output incorrect syntactic dependency adjacency matrices, thereby leading to noise in the modeling of syntactic information.

In addition, to enable better modelling of aspect and sentiment, many studies employ contrastive learning (Liang et al., 2021; Wang et al., 2022; Liu et al., 2022) to enhance sentence features. Supervised contrastive learning typically construct con-

June 16-21, 2024

trastive samples based on labels, where the positive samples for an input sample are other sentences with the same polarity, and negative samples are sentences with different polarities. In unsupervised contrastive learning, data augmentation methods are commonly used to construct positive samples for an input sample, while using other input samples as negative samples. We believe that this approach implicitly introduces label information as a prior into the model.

In this paper, we propose a novel C^{3}LPGCN, integrating Contrastive Learning and Cooperative Learning with Prompt into Graph Convolutional Network. On the one hand, we propose mask-aware aspect information filter(MAF), which combines the information in prompt templates with aspect information, filtering syntactic information through attention mechanism. Prompt tuning (Lester et al., 2021; Wang et al., 2023) is a method to convert downstream task into mask prediction by constructing auxiliary template. Due to the properties of the pre-trained language model(PLM) (Devlin et al., 2018; Liu et al., 2019), we can use the prompt representation to get the location of sentiment expression. And therefore we can alleviate the noise generated by modelling syntactic information.

On the other hand, to further utilize label information, we propose prompt-based contrastive learning and cooperative learning. Specifically, we construct template containing sentiment labels and perform contrastive learning, the positive sample of input is sentence with true label template and the negative samples are sentences with false label templates. By this way, the model can focus more on task- and sentiment-related information during feature learning. While in cooperative learning, we make the representations of input samples and positive samples feature consistent by calculating their KL divergence; at the same time, we pass them through the same network for sentiment analysis and use the output distribution of the positive samples as the label of the input samples. In this way, the prior knowledge contained in the positive samples can be further learned.

Our contributions can be summarized as follows:

- We propose C^{3}LPGCN mitigate the noise generated when modelling syntactic information by utilizing PLM's prediction. Meanwhile, we propose using label information as an explicit priori to learn aspect- and sentiment-related information adequately.
- We propose MAF, which models the relationship between aspect and sentiment representation by using the information of prompt template, thus mitigating the noise that can occur during modeling syntactic information.
- We propose prompt-based contrastive and cooperative learning, which explicitly incorporates label information as a prior into the model. Prompt-based contrastive learning learns task and sentiment-related features through contrasts based on label templates. Cooperative learning further learns label information by aligning the features of input samples with those of positive samples.
- Extensive experiments on three datasets show that our method can be combined with existing contrastive learning methods to perform better, and our C^{3}LPGCN method outperforms state-of-the-art methods.

2 Related Work

2.1 Aspect-based Sentiment Analysis

With the development of deep learning, ABSA has achieved good performance. Several studies utilized attention mechanisms and LSTM to extract deep semantic information from sentences. Ma et al. (2017) proposed IAN to model the relation between aspect and context. Song et al. (2019) proposed an attention encoder to map the semantic interactions between aspect and context.

Subsequently, modelling syntactic information became a research hotspot. Li et al. (2021) alleviated the noise generated while modelling syntactic information by interactively incorporating syntactic and contextual information. Zhang et al. (2022b) proposed a self-attention-based aspect-aware attention mechanism to learn aspect-related semantic associations and global semantics. Ma et al. (2023) proposed using Abstract Meaning Representation to replace syntactic dependency trees and strengthen sentence features through an attention mechanism.

2.2 Constrastive learning

Contrastive learning enables the model to learn the differences or similarities between samples by constructing contrastive samples, leading to better performance in downstream tasks. Chen et al. (2020) proposed SimCLR, which performs data augmentation on images and uses them as positive samples and uses other images as negative samples by which the contrast loss is optimized. Gao et al. (2021) utilized dropout as data augmentation for contrastive learning and obtained good result. In ABSA, Liang et al. (2021) leveraged contrastive learning to distinguish sentiment features from the perspectives of sentiment polarity and patterns. Liu et al. (2022) proposed eliminating the interference of aspect-irrelevant features through feature distillation and utilising supervised contrastive learning to capture internal information between sentences. Li et al. (2023) conducts supervised contrastive learning on different aspects, reducing the representation differences of aspects within the same relationship category.

2.3 Prompt Tuning

Prompt tuning is an approach that transforms downstream tasks into mask prediction tasks. Recently, Schick and Schütze (2020) proposed PET, which uses prompt tuning to make PLM understand the given task and then implements semi-supervised learning on a large scale of unlabeled data by assigning soft labels. Jiang et al. (2020) proposed a method based on encoding transformation to improve the PLM's ability to extract knowledge. Chen et al. (2022b) introduced KnowPrompt, which injects potential knowledge contained in relation labels into learnable prompt construction and uses this for relation extraction.

3 Proposed Model

Figure 2 shows an overview of C^{3}LPGCN. In this section, we first introduce the definition of the ABSA task. After that, we will present our proposed C^{3}LPGCN, composed of five components: input construction and embedding layer, contrastive learning, prompt-based cooperative learning, GCN layer and mask-aware aspect information filter layer.

3.1 Problem Formulation

For a given sentence S and its corresponding aspect a, where $S = \{w_1, w_2, ..., w_n\}$, $a = \{a_1, a_2, ..., a_k\}$, a is a subsequence of S, ABSA is to predict the sentiment polarity $y \in \{positive, negative, neutral\}$ of the given aspect. For the sake of simplicity, we perform prediction on one aspect at a time for sentences containing multiple aspects.

3.2 Input Construction and Embedding Layer

In contrast to other studies that use sentence-aspect pair as input, we construct prompt templates specific to the ABSA task and concatenate them with the sentence, using them as input of the BERT encoder. For a given sentence S and the aspect a, we construct its prompt template:

$$T_{prompt} = [p_1, p_2, ..., a, ..., [\text{MASK}]], \quad (1)$$

where p_i is the constructed template, while [MASK] is the token of PLM's masking process. Taking "No disk is included" as an example, where the aspect is "disk", we can construct a template like "the disk is [MASK]." Then, we can get a sample input for BERT:

$$S_{in} = [[\text{CLS}], S, [\text{SEP}], T_{prompt}, [\text{SEP}]] \quad (2)$$

Feeding S_{in} into BERT, we can obtain its representation H_{in} To perform prompt-based contrastive learning and cooperative learning, we construct label samples for the input, i.e., replacing [MASK] with the labels we set in the prompt template. We set up three kinds of label templates based on the real sentiment labels of the training data:

$$\begin{aligned} T_{pos} &= [p_1, p_2, ..., a, ..., L_{pos}], \\ T_{neg1} &= [p_1, p_2, ..., a, ..., L_{neg1}], \\ T_{neg2} &= [p_1, p_2, ..., a, ..., L_{neg2}], \end{aligned} \quad (3)$$

where L_{pos} is the true sentiment label of S and L_{neg1}, L_{neg2} are the false sentiment labels we constructed. Similarly concatenating them with S and feeding them into BERT, we can obtain their representations H_{pos}, H_{neg1}, H_{neg2}. It can be seen that the input sample and contrastive samples are identical in form , both can be represented as:

$$H_i = \{h^i_{cls}, h^i_1, ..., h^i_{n+m+2}\} \quad (4)$$

where $i \in \{in, pos, neg1, neg2\}$, $H_i \in \mathbb{R}^{t \times d_{bert}}$, n and m denote the length of S and the template, respectively, $t = m+n+2$. We conducted template experiment in Appendix A.

3.3 Contrastive Learning

In this section, we use supervised and prompt-based contrastive learning to improve further the model's ability to model aspects and sentiment expression.

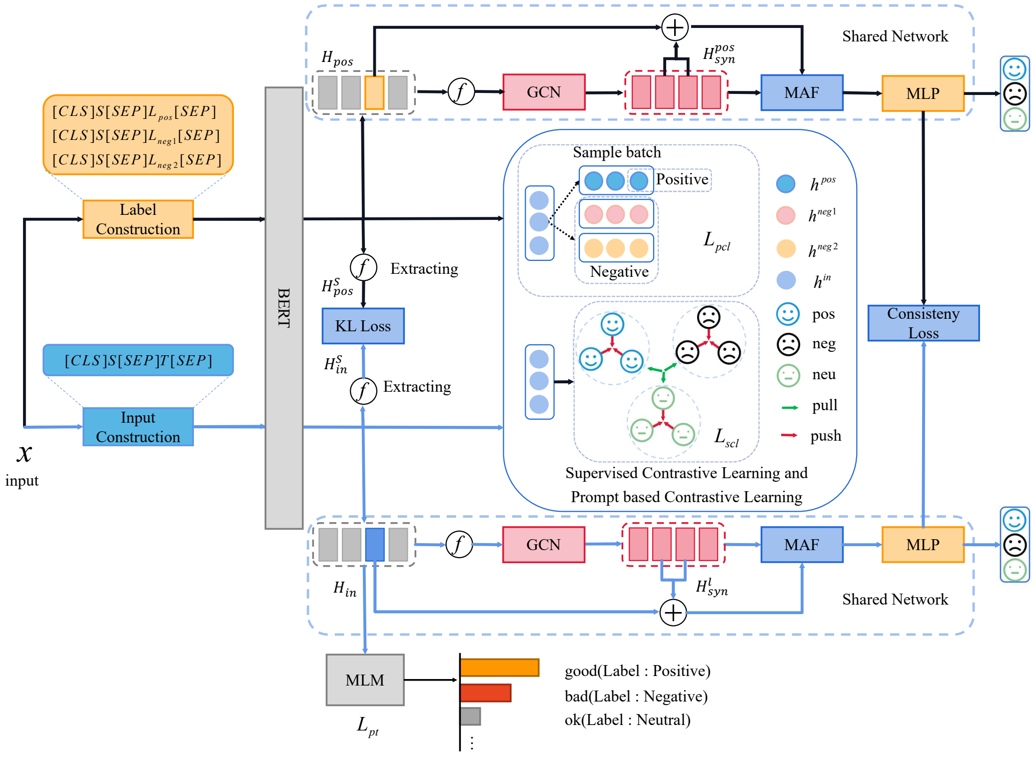

Figure 2: Overall architecture of the proposed C^{3}LPGCN.

3.3.1 Supervised Contrastive learning

Same as other supervised contrastive learning methods, for any input sample H_{in}^{i}, we take the samples with the same polarity within a batch B as positive samples. Otherwise, it is negative. Then, the contrastive loss is formulated as follows:

$$\mathcal{L}_{scl} = \frac{1}{N}\sum \mathcal{L}_{sup}(h_i^{in}),$$
$$\mathcal{L}_{sup}(h_i) = -\log \frac{\sum\limits_{y(a_i)=y(a_j)} sim(h_i, h_j)}{\sum\limits_{j\in B} sim(h_i, h_j)}, \tag{5}$$

where N is the batch size and h_i^{in} is the pooled output of H_{in}^{i}, $sim(\cdot)$ is the cosine similarity, $y(a_i) = y(a_j)$ denotes h_i has the same sentiment polarity as h_j. With supervised contrastive learning, sentences with the same sentiment polarity are brought closer in feature space, while the distance between sentences with different sentiment polarities is pushed farther apart.

3.3.2 Prompt-based Contrastive Learning

In supervised contrastive learning, we use sentiment polarity to construct contrastive samples, equivalent to implicitly introducing label information as priori into feature learning. To further utilize label information, we propose prompt-based contrastive learning to introduce label information explicitly. For a input sample H_{in}^{i}, we constructed its corresponding label samples H_{pos}^{i}, H_{neg1}^{i}, H_{neg2}^{i}. Thus, our training objective can be formulated as follows:

$$\mathcal{L}_{pcl} = \frac{1}{N}\sum \mathcal{L}_{p}(h_i^{in}),$$
$$\mathcal{L}_{p}(h_i^{in}) = -\log \frac{sim(h_i^{in}, h_i^{pos})}{\sum\limits_{j\in B} sim(h_i^{in}, h_j^{all})}, \tag{6}$$

where h_j^{all} denotes all the false label samples we constructed in batch B. Compared to supervised contrastive learning, our method explicitly introduces the true sentiment labels, thus allowing the model to learn information related to ABSA more directly during representation learning.

3.4 Cooperative Learning

To further utilize the prior knowledge contained in the true label samples, we propose cooperative learning, which consists of two components; on the one hand, for the input representation H_{in} and its true label sample H_{pos}, we take the representations of the corresponding parts H_{in}^{S}, H_{pos}^{S} of the original sentence S. After that, we compute the KL divergence between them to learn the prior distribution of true label samples:

$$\mathcal{L}_{KL} = \sum KL(H_{in}^{S} || H_{pos}^{S}) \tag{7}$$

On the other hand, we feed the true label sample and the input sample into the same ABSA network and obtain their predicted distribution $p(a)$, $p_{pos}(a)$, and use the $p_{pos}(a)$ as the label of $p(a)$ to calculate the consistency loss:

$$\begin{aligned} y_{pos}(a) &= argmax(p_{pos}(a)), \\ \mathcal{L}_{CL} &= -\sum_{S} \sum_{a \in A_S} y_{pos}(a) \cdot \log p(a) \end{aligned} \tag{8}$$

where A_S is the aspect collection of the sentence S.

3.5 GCN Layer

We leverage syntactic dependency trees to aid the model in learning syntactic features and establish the relationship between aspect and sentiment. We use the LAL-Parser (Mrini et al., 2019) to obtain the adjacency matrix of the dependency tree for the sentence. The syntactic dependency adjacency matrix A for each sentence is constructed by the following rule:

$$A_{ij} = \begin{cases} 1 & \text{if } i = j, \text{(self loop)}, \\ 1 & \text{if } i \text{ and } j \text{ are dependent}, \\ 0 & \text{otherwise} \end{cases} \tag{9}$$

Afterwards, we use GCN to aggregate the syntactic information. Given the sentence representation H_{syn}^{l-1} of layer $(l-1)$ and A, the $l-$th representation is defined as follows:

$$H_{syn}^{l} = \text{RELU}(AH_{syn}^{l-1} W_{syn}^{l} + b_{syn}^{l}) \tag{10}$$

where W_{syn}^{l}, b_{syn}^{l} are trainable parameters of the $l-$th layer. And H_{syn}^{0} is the part of input representation H_{in} corresponding to the original sentence S, that is H_{in}^{S}.

3.6 Mask-aware Aspect Information filter

We introduce prompt tuning into ABSA to mitigate the noise generated when modelling syntactic information. The training process of PLM shows that the model's prediction of the mask position depends on the contextual information. PLM's prediction of the mask position certainly incorporates the understanding of the prompt we constructed and the sentence. Therefore, we propose mask-aware aspect information filter, which filters syntactic information by combining the prompt-tuned information with aspect information.

Given a masked language model L, we feed the representation of input samples H_{in} into it, resulting in predictions for the [MASK] position in the prompt template (e.g., great(positive), terrible(negative)). The process is depicted as follows:

$$\begin{aligned} H_{MLM} &= \text{GELU}(H_{in} W_{MLM} + b_{MLM}), \\ H_{out} &= H_{MLM} W_{out} + b_{out}, \end{aligned} \tag{11}$$

where $H_{MLM} \in \mathbb{R}^{t \times d_{bert}}$, $H_{out} \in \mathbb{R}^{t \times d_{vocab}}$, W_{MLM}, b_{MLM}, W_{out}, b_{out} are trainable parameters. Subsequently, we define a mapping function $\mathcal{M} : \mathcal{Y} \to \mathcal{V}$ to map the true sentiment labels to the output words of the masked language model. By doing so, we can obtain the predicted probabilities $p_{pt}(a)$ for the true sentiment polarity $y(a)$ of the aspect in the sentence:

$$p_{pt}(a) = p([\text{MASK}] = \mathcal{M}(y(a)) | H_{out}) \tag{12}$$

Subsequently, we utilize cross-entropy as the loss function to fine-tune the PLM and the masked language model:

$$\mathcal{L}_{pt} = -\sum_{S} \sum_{a \in A_S} y(a) \cdot \log (p^{pt}(a)) \tag{13}$$

In the process of prompt tuning, we utilize MAF to combine the representation of mask position h_{mask}^{in} with aspect information h_{a}^{in} to achieve the filtering of syntactic information. The formulas are as follows:

$$\begin{aligned} H_{syn}' &= H_{syn}^{l} W_{syn}' + b_{syn}', \\ h_{MAF} &= (\frac{1}{k} \sum_{i=1}^{k} h_{a_i}^{syn} + h_{mask}^{in}) W_a + b_a, \\ \alpha &= \text{softmax}(h_{MAF} \times (H_{syn}')^{T}), \\ h^{MAF} &= \alpha H_{syn}^{l}, \end{aligned} \tag{14}$$

where k is the length of aspect in the PLM, $h_{a_i}^{syn}$, h_{mask}^{in} denote the representation of aspect words and [MASK] position in H_{syn}^{l} and H_{in}, respectively. W_{syn}', b_{syn}', W_a, b_a are trainable parameters. With this approach, the model can take into account both aspect information and prompt tuning information, thus mitigating the noise generated by modeling errors in syntactic information.

3.7 Target Aspect Sentiment Analysis

The final feature representation used for ABSA is obtained by utilizing the representations generated from the aforementioned components. The representation can be described as follows:

$$X_a = h^{in} \oplus h^{MAF} \oplus h^{in}_{mask} \tag{15}$$

where $\oplus$ is concatenation, h^{in} is the pooled output of H_{in} to represent the entire sentence, h^{MAF} is the output of MAF, while h^{in}_{mask} is the representation corresponding to the MASK position during prompt tuning. Then, we feed the obtained representations into a linear classifier with softmax to obtain the probability distribution $p(a)$ of sentiment polarity. The process can be represented as follows:

$$p(a) = \text{softmax}(X_a W_p + b_p) \tag{16}$$

where W_p, b_p are trainable parameters.

3.8 Loss Function

We use the loss as follows in the training process for gradient descent:

$$\begin{aligned} \mathcal{L}_{total} = \mathcal{L}_{pre} + \lambda_1 \mathcal{L}_{pt} + \lambda_2 \mathcal{L}_{KL} \\ + \lambda_3 \mathcal{L}_{CL} + \lambda_4 \mathcal{L}_{scl} + \lambda_5 \mathcal{L}_{pcl} \end{aligned} \tag{17}$$

where λs are hyperparameter, L_{pre} is the loss of final classifier:

$$L_{pre} = -\sum_{S} \sum_{a \in A_S} y(a) \cdot \log(p(a)) \tag{18}$$

Table 1: Statistics of datasets.

Dataset	Division	Positive	Negative	Neutral
Laptop	Train	976	851	455
	Test	337	128	167
Restaurant	Train	2164	807	637
	Test	727	196	196
Twitter	Train	1507	1528	3016
	Test	172	169	336

4 Experiments

4.1 Datasets

We conducted experiments on three publicly available benchmark datasets. Laptop is a collection of user reviews and opinions about laptops and related products. The Restaurant consists of reviews and opinions about restaurants. Both the Laptop and Restaurant are from SemEval14 (Pontiki et al., 2014). Twitter (Dong et al., 2014) is a collection of tweets. The three datasets consist of sentiment polarities: 'positive', 'negative', and 'neutral'. Laptop and Restaurant include sentences with single and multiple aspects, while the Twitter dataset contains sentences with only one aspect. The statistical information for these three datasets is summarized in Table 1.

4.2 Baseline Models

1) **AEN** (Song et al., 2019) proposes an attention-based encoder to model the relationship between aspect and context. 2) **IAN** (Ma et al., 2017) interactively learns the relationship between aspect and their context. 3) **BERT-SPC** (Song et al., 2019) uses the representation of the [CLS] token of BERT for ABSA. 4) **DualGCN** (Li et al., 2021) simultaneously considers syntactic and semantic information for ABSA. 5) **SSEGCN** (Zhang et al., 2022b) proposes aspect-aware attention to learn semantic associations and global semantics. 6) **dotGCN** (Chen et al., 2022a) utilizes reinforcement learning to construct a language-independent discrete latent opinion tree for ABSA. 7) **DLGM** (Mei et al., 2023) proposes leveraging neurons to extract specific language attributes. 8) **APARN** (Ma et al., 2023) utilizes a new semantic structure to replace syntactic dependency tree. 9) **BERT-SCon** (Liang et al., 2021) proposes using supervised contrastive learning to distinguish sentiment features in terms of sentiment polarity and patterns. 10) **AFDEN** (Liu et al., 2022) proposes a distillation module to better learn the aspect-unrelated features and eliminate the interference of aspect-unrelated features 11) **APSCL** (Li et al., 2023) proposes a framework that capturing relationships between aspects and enhances their features through contrastive learning.

4.3 Implementation Details

In this experiment, all models we implemented utilize BERT-base-uncased as the pre-trained language model. When calculating the training loss, λs is set to (0.01, 0.1, 0.1, 1.0, 0.3). We use the Adam optimizer for gradient descent. The learning rate for the PLM is set to 3e-5, while the learning rate for the other layers is set to 1e-4. In the GCN layer, we set the number of layers for the GCN in the range of [1, 3]. We use **Accuracy** and **Macro-F1** to evaluate the performance of our proposed C^{3}LPGCN as well as the baseline methods. For more implementation details, please refer to our

Table 2: Performance of different methods on the three datasets. "$*$" denotes our implementation. The best results are in **bold**, and the second-best are underlined.

code.

4.4 Main Result

We compared our model with other models, and the results are shown in Table 2. The results show that (1)Our C^{3}LPGCN obtained the best result in the three datasets. (2)Modeling syntactic information performs better than methods that model contextual information, such as attention. (3)Using PLM can make the model perform better, and it's become a consensus to use PLM. (4)Compared to methods that use syntactic information, methods that use contrastive learning methods tend to be simpler in structure and therefore perform slightly less well. (5)In our model, we combine prompt-tuned information and aspect information to filter syntactic information, thus alleviating the noise when modelling syntactic information. Also, we explicitly introduce sentiment label information using our proposed prompt-based contrastive learning and cooperative learning to obtain the best performance. (6)Compared to supervised contrastive learning, prompt-based contrastive learning can also improve the model's performance, and these two methods can be used together for better results.

4.5 Ablation Study

To verify the effectiveness of different modules, we performed ablation studies with the following configuration:

- w/o $\mathcal{L}_{CL}$: We no longer align the input samples with the predictions of the positive samples.
- w/o $\mathcal{L}_{KL}$: We no longer compute the KL divergence between input sample and positive sample.
- w/o $\mathcal{L}_{pcl}$: We removed the prompt-based contrastive learning.
- w/o MAF: We removed the mask-aware aspect information filter.
- +aspect: We filtered the syntactic information with the representation of aspect.
- +mask: We filtered the syntactic information with the representation of the mask position in prompt template.

As shown in Table 2. First, the model's perfor-

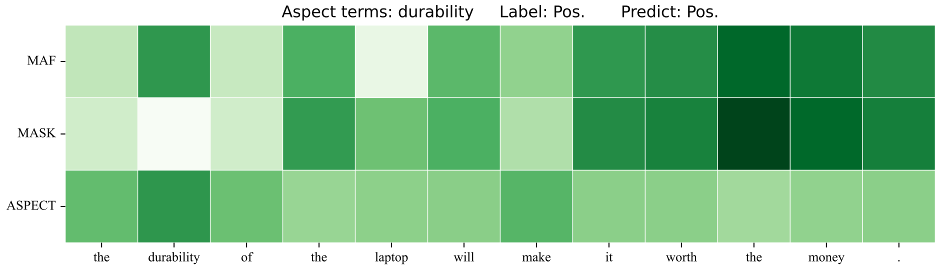

Figure 3: Visualization of attention weights calculated using different information.

mance decreased after removing supervised contrastive learning, suggesting that supervised contrastive learning can learn the similarities and differences between samples. When prompt-based contrastive learning or cooperative learning is removed, the model's effectiveness likewise deteriorates because, with prompt-based contrastive learning and cooperative learning, the model learns information relevant to ABSA from true label samples. When we use only aspect information for sentiment classification, the model becomes less effective due to the noise generated when modelling syntactic information. Similarly, the model does not perform well when using only aspect information for filtering. Whereas, when using only mask information, the model may ignore aspect information, and thus, the model becomes less effective(experiments in Sec 4.7 proved this point).

4.6 Case Study

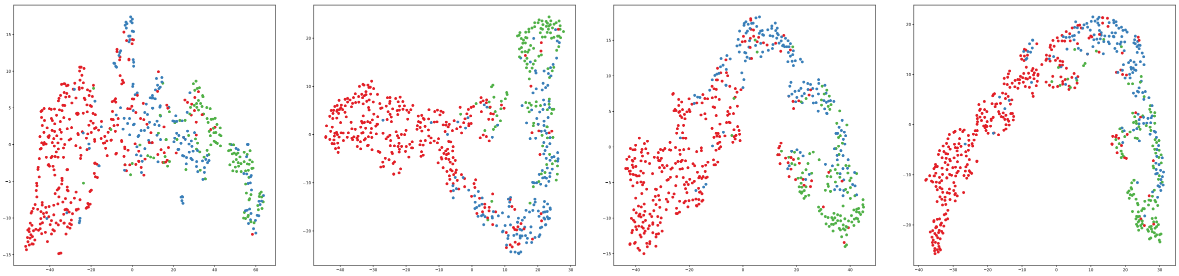
We conducted a case analysis as shown in Table 3. The notations P, N and O represent positive, negative and neutral sentiment, respectively.The results indicate that modelling syntactic information leads to better results when there is a long distance between the aspect and sentiment expression. This is because, compared to direct attention-based aggregation, GCN enables more accurate aggregation of aspect and corresponding sentiment expression. On the other hand, when there is no explicit syntactic relationship between aspect and sentiment expression, our proposed C^{3}LPGCN outperforms other models because our model not only considers syntactic information but also incorporates sentiment expression modelling information from PLM and uses contrastive learning and cooperative learning to enhance sentence features further.

4.7 Attention Visualization

To explore the impact of our proposed MAF, we investigated the differences in attention weights using different information for filtering. We visualized the attention weights using sentence "*the durability of the laptop will make it worth the money.*" from the laptop dataset, where the aspect is "*durability*". As shown in Figure 3. When using only the aspect information, the model assigns the highest weight to the aspect, which indicates that the model focused more on the aspect. On the other hand, when using the mask information, the model assigns the highest weight to the sentiment expression "*it worth the money.*" It is shown that by prompt tuning, it is possible to obtain the reason for the sentiment prediction, i.e., the sentiment expression. In contrast, our proposed MAF combines the MASK position and aspect information to consider both aspect and sentiment expression. Therefore, it somewhat alleviates the noise caused by wrong syntactic information.

4.8 Feature Visualization

To verify the effectiveness of prompt-based contrastive learning, we performed the visualization shown in Figure 4 using t-SNE (van der Maaten and Hinton, 2008). The results show that the feature distribution of different sentiments is tighter when using only BERT. After using supervised contrastive learning, the boundary distance between different sentiments increases significantly, indicating that the model learns the similarities and differences between different samples through supervised contrastive learning. Similarly, when using prompt-based contrastive learning, the feature distances of different sentiments become larger due to using false label samples of other sentences as negative samples. Still, the feature distribution of the same polarity is also slightly larger than supervised contrastive learning because there is only one positive sample for an input sample. After combining supervised contrastive learning with prompt-based contrastive learning, the boundaries of different sentiments become more obvious, and the distribu-



(a) BERT (b) BERT+SCL (c) BERT+PCL (d) BERT+SCL+PCL

Figure 4: Feature visualization of using different methods

tion of the same sentiment becomes tighter.

5 Conclusion

In this paper, we propose C^{3}LPGCN. On the one hand, to mitigate the noise that may arise when modelling syntactic information, we propose mask-aware aspect information filter, which filters syntactic information by combining prompt-tuned representations with aspect information. On the other hand, we propose prompt-based contrastive learning and cooperative learning methods that explicitly introduce label information. Extensive experiments on three datasets demonstrate the effectiveness of our approach.

6 Limitation

In this paper, we employed a manual construction approach for prompt templates. The uncertainty associated with manual construction leads to varying effects of different templates on the model performance. In future work, we plan to explore the use of continuous prompts. Additionally, we aim to extend our prompt-based contrastive learning and cooperative learning to a broader range of natural language processing tasks.

The high computational complexity is the main issue currently faced by this method. Despite the model's structure being very simple, the construction of three samples for each sentence for prompt-based contrastive learning and cooperative learning significantly increases the GPU storage and time used during the training process. In prompt-based contrastive and cooperative learning, each sentence and its constructed samples differ only in the label word. In the future, we will explore how to remove redundant parts of the samples to reduce memory usage and accelerate training.

A Template Analysis

Table 4: The prompt templates and labels we constructed manually in our experiments, $< a >$ denotes the aspect. We concatenate them with the original sentence to form the input and labeling samples

Index	**Template**	**Label words**
t_0	The sentiment of $< a >$ is [MASK]	P:positive, N:negative, O:neutral
t_1	The sentiment of $< a >$ is [MASK]	P:nice, N:bad, O:none
t_2	The sentiment of $< a >$ is [MASK]	P:negative, N:neutral, O:positive
t_3	The $< a >$ is [MASK]	P:good, N:terrible, O:ok
t_4	The $< a >$ is [MASK]	P:positive, N:negative, O:neutral
t_5	How about $< a >$? it is [MASK]	P:good, N:terrible, O:ok
t_6	What do you think of the $< a >$? it is [MASK]	P:good, N:terrible, O:ok

Table 5: Experimental results on the three datasets with different templates. The best results are in **bold**.

Template	**Laptop**		**Restaurant**		**Twitter**	
	ACC	**Macro-F1**	**ACC**	**Macro-F1**	**ACC**	**Macro-F1**
t_0	**82.75**	**79.61**	**87.85**	**82.41**	**79.32**	**78.44**
t_1	81.80	78.97	87.04	81.16	76.96	75.74
t_2	81.48	77.86	86.15	79.29	76.96	75.83
t_3	81.33	78.41	86.24	80.15	74.89	73.33
t_4	81.65	78.72	86.15	80.57	75.63	74.46
t_5	82.28	78.86	85.43	79.23	75.18	74.09
t_6	81.80	78.60	86.51	80.38	76.96	75.86

We investigated the impact of different templates on model performance, and the results are shown in Table 5. The table presents the results obtained using the prompts constructed in Table 4. The following observations can be made: (1) Different prompts and label words have a significant influence on the model's performance. (2) When using the same prompt, different label words yield varying results. However, compared to the performance differences resulting from using different label words and the same prompt, the differences are relatively smaller. This indicates that the selection of the template plays a more crucial role. (3) When the semantic meaning of the label word is completely opposite to the sentiment label, there is a certain decrease in model performance. However, since our model also extracts other features of the sentence, the extent of performance degradation is limited.

B Complexity Analysis

Table 6: Comparison of model's complexity. We compared the results of models among all baseline models that provided information on the quantity of parameters and training time, * indicates the results from our implementations.

Models	**Params(M)**	**Training time(s/epoch)**	**Parser**
DualGCN*	112	35	LAL-Parser
SSEGCN*	110	32	LAL-Parser
APARN	130	480	Spring, LEAMR
Our C^{3}LPGCN	122	202	LAL-Parser

We also analyzed the complexity of our model, primarily comparing parameters such as the quantity of parameters, training time, and the parsers used. The results are presented in Table 6. It can be observed that our model has a roughly similar number of parameters compared to other models. However, due to constructing three samples for each input for contrastive and cooperative learning, our model's training time is significantly longer compared to DualGCN and SSEGCN. Nevertheless, it can be seen that compared to the best-performing model in the comparison, APARN, our method has advantages in both training time and the number of parsers used.

Visual Enhanced Entity-Level Interaction Network for Multimodal Summarization

Haolong Yan, Binghao Tang, Boda Lin, Gang Zhao, Si Li[*]

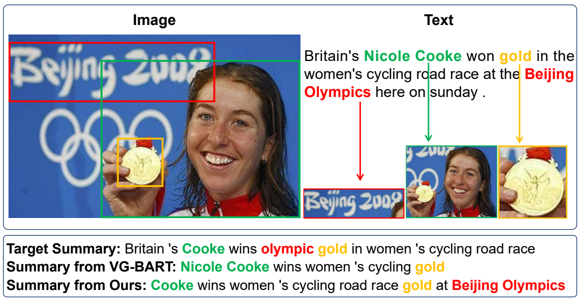
Abstract

MultiModal Summarization (MMS) aims to generate a concise summary based on multimodal data like texts and images and has wide application in multimodal fields. Previous works mainly focus on the coarse-level textual and visual features in which the overall features of the image interact with the whole sentence. However, the entities of the input text and the objects of the image may be underutilized, limiting the performance of current MMS models. In this paper, we propose a novel Visual Enhanced Entity-Level Interaction Network (VE-ELIN) to address the problem of underutilization of multimodal inputs at a fine-grained level in two ways. We first design a cross-modal entity interaction module to better fuse the entity information in text and the object information in vision. Then, we design an object-guided visual enhancement module to fully extract the visual features and enhance the focus of the image on the object area. We evaluate VE-ELIN on two MMS datasets and propose new metrics to measure the factual consistency of entities in the output. Finally, experimental results demonstrate that VE-ELIN is effective and outperforms previous methods under both traditional metrics and ours. The source code is available at `https://github.com/summoneryhl/VE-ELIN`.

1 Introduction

Multi**M**odal **S**ummarization (MMS) takes multimodal data like texts and images as input and aims to generate a concise summarization as output. This task has attracted much attention in the research community (Li et al., 2019, 2018b; Zhu et al., 2018) because it can be widely used in various real-world applications, such as social media (Zhang et al., 2022a), meeting (Zhong et al., 2021), and e-commerce products (Li et al., 2020a).



Britain's **Nicole Cooke** won **gold** in the women's cycling road race at the **Beijing Olympics** here on sunday .

Target Summary: Britain 's **Cooke** wins **olympic** **gold** in women 's cycling road race
Summary from VG-BART: **Nicole Cooke** wins women 's cycling **gold**
Summary from Ours: **Cooke** wins women 's cycling road race **gold** at **Beijing Olympics**

Figure 1: Illustration of multimodal summarization task. The bottom part is the target summary, a summary from the previous method, and ours. The previous method can not adequately leverage fine-grained entity information.

Recent studies primarily concentrate on the cross-modal interaction and filtering of visual features, which have achieved promising performances. For instance, Yu et al. (2021) explores various ways of image-text fusion to utilize multimodal information based on the application of generative Pre-trained Language Models (PLMs) to the task. Zhang et al. (2022b) adopts knowledge distillation from the vision-language pre-trained model to improve image selection. Liang et al. (2023) designs a target-oriented contrastive objective to discard needless visual information. Despite their effectiveness, current methods mainly focus on the coarse-level rather than fine-grained visual and textual features, which conduct interactions between the global image and sentence semantics. This might lead to an insufficient utilization of crucial local information. As shown in Figure 1, there are three fine-grained entities "Nicole Cooke", "Gold", and "Beijing Olympics" in the input text, and three object regions in the image corresponding to them while previous methods are not able to extract the fine-grained information adequately.

Thus, we consider utilizing the inherent entity information in the text and object information in the image so that the output summary maintains

key entities with high coherence. In this paper, we propose a novel Visual Enhanced Entity-Level Interaction Network (VE-ELIN) for Multimodal Summarization. The proposed VE-ELIN addresses the problem of incomplete generation of entity information in two ways. Firstly, we design the cross-modal Entity Interaction (EI) module which can better fuse the entity information in text and the object information in vision and provide richer multimodal representation. In particular, the EI module includes three levels of features, namely sentence, entity, and object level. We encode the input text using a textual encoder to obtain sentence-level features and use a pre-trained Named Entity Recognition model (Yan et al., 2021) to get entity-level features. Moreover, we use the image object detection model (Carion et al., 2020) to capture the objects in the image and encode them to obtain the object-level features. Secondly, to further distill features from vision information, we apply CLIP (Radford et al., 2021) and integrate it into our object-guided Visual Enhancement (VE) module. The VE module can fully extract the visual features and enhance the focus of the image on the object area to better inject visual information into the multimodal decoder.

In addition to conventional evaluation methods, we introduce novel metrics to measure the factual consistency of entities in the output summarization. Specifically, we count the number of entities in the output and compare it with the entities in the target summary. Then, we compute the proportion of entities named EntityScore and the similarity between entities named SimilarScore.

We evaluate VE-ELIN on two MMS datasets, which have different text lengths and input image numbers. The experimental results demonstrate that VE-ELIN is effective and outperforms previous methods under both traditional metrics and ours.

In summary, our contributions are as follows:

- To the best of our knowledge, we are the first to identify the significance of fine-grained entity information for the multimodal summarization task.
- We propose a unified Visual Enhanced Entity-Level Interaction Network (VE-ELIN) to generate high-quality summaries while capturing key entity information in the original text.
- We propose two new metrics EntityScore and SimilarScore to further assess the factual consistency of entities in the output. The experimental results demonstrate the effectiveness of our proposed VE-ELIN.

2 Related Work

2.1 Multimodal Interaction

Object detection aims to predict a set of bounding boxes and corresponding category labels for the targeted objects in an image, which is a fundamental task in computer vision. Named Entity Recognition aims to identify the named entities in the text and can be widely used in information retrieval (Brandsen et al., 2022), and knowledge graphs (Zamini et al., 2022). Due to the rapid development of social media platforms such as Twitter, Multimodal Named Entity Recognition (MNER) (Zhao et al., 2022) has attracted increasing attention. Given image-text pairs, MNER aims to recognize the named entities in the text and classify the corresponding types. In the study of MNER, aligning the instance information in images with entities in text is an intuitive idea. However, in the field of multimodal summarization, there has been limited research on fine-grained interaction between visual and textual modalities.

2.2 Multimodal Summarization

Text summarization aims to extract important information from text and generate a concise summary. With the increasing of multimodal data on the internet, researchers have shown a growing interest in multimodal summarization. Different from traditional text summarization, multimodal summarization aims to generate summaries based on data from various modalities, e.g., video, image, audio, and text.

Existing multimodal summarization tasks contain sports summarization (Tjondronegoro et al., 2011), movies summarization (Evangelopoulos et al., 2013), video summarization (Sanabria et al., 2018), meeting summarization (Erol et al., 2003; Li et al., 2019), multimodal sentence summarization (Li et al., 2018b), multimodal summarization with multimodal output (Zhu et al., 2018), e-commerce products summarization (Li et al., 2020a) and so on. Previous studies on multimodal summarization tackle the tasks from different aspects. Palaskar et al. (2019) explore the hierarchy attention between the textual article and visual features. Consequent studies utilize fusion forget gate (Liu et al., 2020), visual selective gates (Li et al., 2020b), and contribution network (Xiao et al., 2023), directing the attention of models towards the most salient parts in the visual features for summarization.

3 Methodology

In this section, we introduce the overview of our framework. We first present the brief task formulation and describe the method overview. Then, we detail our proposed module and introduce the training and generation process.

3.1 Task Formulation

In this paper, we focus on the multimodal summarization task, involving a dataset comprising n triplets $\langle t_i, v_i, s_i \rangle$, where t_i represents the i-th text input, v_i represents the i-th image input, and the MMS model is tasked with generating a summary s_i based on both t_i and v_i.

3.2 Method Overview

We use VG-GPLM (Yu et al., 2021) as the backbone, which is built upon generative pre-trained language models (e.g., BART), and injects visual features on the encoder side. As shown in Figure 2, the VE-ELIN takes text and image as inputs and generates a summary as output. The multimodal encoder part of VE-ELIN consists of a Cross-modal Entity Interaction (EI) module that can better fuse the entity features in textual and visual information and an Object-guided Visual Enhancement (VE) module that can fully extract the visual features and enhance the focus of the image on the object area. Then, in the multimodal decoder, we fuse the features of different modalities from EI module and VE module and use it as extra input to the decoder.

3.3 Multimodal Encoder

3.3.1 Object-guided Visual Enhancement

Given an image, we first utilize the visual encoder of CLIP (Radford et al., 2021) to extract visual local grid features. CLIP is a dual-stream vision-language pre-trained model that has undergone pre-training with a contrastive loss using 400 million image-text pairs. This model comprises a Transformer (Vaswani et al., 2017) text encoder and an image encoder which could be either Vision Transformer (ViT) (Dosovitskiy et al., 2020) or Residual Convolutional Neural Network (ResNet) (He et al., 2016). In this paper, we apply the ViT image encoder of CLIP and obtain visual features $V \in \mathbb{R}^{s_v \times d_v}$, where s_v is the patch numbers and d_v is the hidden dimension of image features.

Previous studies indicate that different regions of visual features contribute unequally to summary generation (Li et al., 2020b; Liu et al., 2020; Xiao et al., 2023). For instance, given the input sentence and image, the target summary is "Britain's Cooke wins Olympic gold in women's cycling road race.", as shown in Figure 1. In the image, the People, Gold Medal, and Olympic Logo components are more relevant to the target summary, while the features corresponding to the rest of the sections are less important. Thus we design a simple feature filter to enhance the focus on the image objects and the better utilization of input visual features.

In practice, we follow Carion et al. (2020) to detect the objects in the image using ResNet-101 as a backbone. As shown in Figure 2(b), two features are obtained after going through DETR, one is the visual features of each object marked with the bounding box: $ObjectFeatures{=}V_o \in \mathbb{R}^{n \times 1 \times d_v}$, where n is the object numbers. For instance, there are three objects in the image, then n=3. In addition, we set the maximum number of objects to 64. The other is the attention score matrix of the whole image: $AttentionScore{=}A_{i,j}{=}(a_{i,j}) \in \mathbb{R}^{m \times m}$, where $a_{i,j} \in [0, 1]$, $i, j \in [0, m]$ and m is the dimension of the matrix, the closer the value is to the object area the closer it is to 1. We design a simple features filter through the attention score matrix, in practice, we transform $A_{i,j}$ through a linear layer to the same dimension as the image features, and then fuse it with the image features:

$$\hat{A}_{i,j} = \text{Linear}(A_{i,j}) \tag{1}$$

$$V_{filtered} = V + \hat{A}_{i,j} \tag{2}$$

where $V_{filtered} \in \mathbb{R}^{s_v \times d_v}$. The filtered visual features are represented in Figure 2 as visual-enhanced features.

3.3.2 Cross-modal Entity Interaction

We design this module to capture entity-related textual and visual information through three features: sentence-level features, entity-level features, and object-level features. Finally, get the entity-related feature as output and add it to the text-vision fusion in Section 3.4.

Sentence-level Features. At the entry of the framework, the input text is first tokenized and converted to a sequence of token embeddings $X_t \in \mathbf{R}^{N \times d_t}$, and the positional encodings $E_{pe} \in$

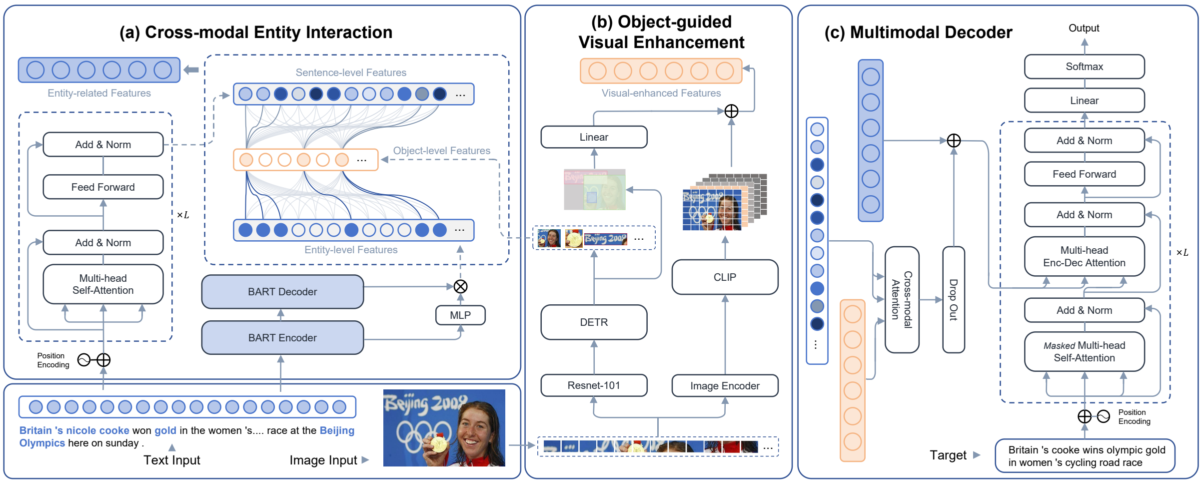

Figure 2: The overview of our model. Given input text and image, our model generates summaries as output through three modules: the cross-modal entity interaction module, object-guided visual enhancement module, and multimodal decoder.

$\mathbb{R}^{N\times d_t}$ are added to it, in which N is the sequence length and d_t is the textual dimension:

$$Z_0^{enc} = X_t + E_{pe} \tag{3}$$

As illustrated in Figure 2(a), the encoder is composed of a stack of L encoder layers, each containing two sub-layers: Multi-head Self-Attention (MSA) and Feed-Forward Network (FFN). After each sub-layer, there is a residual connection (Wang et al., 2019) followed by a layer normalization (LN). We obtain the sentence-level features T_s through the encoder:

$$Z_l' = \text{LN}(\text{MSA}(Z_{l-1}^{enc}) + Z_{l-1}^{enc}) \tag{4}$$

$$T_s = \text{LN}(\text{FFN}(Z_l') + Z_l') \tag{5}$$

where $T_s \in \mathbb{R}^{N\times d_t}$.

Entity-level features. Following Yan et al. (2021), we use the Seq2Seq model with the pointer mechanism to generate the entity index sequences, which are then mapped to sentence-level features to obtain entity-level features. This part includes two components.

(1) BART Encoder encodes the input sentence $X = t_i$ into vectors $\mathbf{H}^e$:

$$\mathbf{H}^e = \text{Encoder}(X) \tag{6}$$

where $\mathbf{H}^e \in \mathbb{R}^{N\times d_t}$, and d_t is the hidden dimension.

(2) BART Decoder is to get the index probability distribution for each step $P_t = P\left(y_t \mid X, Y_{<t}\right)$. However, since $Y_{<t}$ contains the pointer and tag index, it cannot be directly inputted to the Decoder. We use the Index2Token conversion to convert indexes into tokens:

$$\hat{y}_t = \begin{cases} X_{y_t}, & \text{if} y_t \le n, \\ G_{y_t-n}, & \text{if} y_t > n \end{cases} \tag{7}$$

After converting each y_t this way, we can get the last hidden state $\mathbf{h}_t^{d_t} \in \mathbb{R}^{d_t}$ with $\hat{Y}_{<t} = [\hat{y}_1, ..., \hat{y}_{t-1}]$ as follows:

$$\mathbf{h}_t^{d_t} = \text{Decoder}(\mathbf{H}^e; \hat{Y}_{<t}) \tag{8}$$

Then, we can use the following equations to achieve the index probability distribution P_t:

$$\mathbf{E}^e = \text{TokenEmbed}(X) \tag{9}$$

$$\hat{\mathbf{H}}^e = \text{MLP}(\mathbf{H}^e) \tag{10}$$

$$\bar{\mathbf{H}}^e = \alpha \times \hat{\mathbf{H}}^e + (1-\alpha) \times \mathbf{E}^e \tag{11}$$

$$\mathbf{G}^{d_t} = \text{TokenEmbed}(G) \tag{12}$$

$$P_t = \text{Softmax}([\bar{\mathbf{H}}^e \otimes \mathbf{h}_t^{d_t}; \mathbf{G}^{d_t} \otimes \mathbf{h}_t^{d_t}]) \tag{13}$$

where TokenEmbed is the embeddings shared between the Encoder and Decoder; $\mathbf{E}^e$, $\hat{\mathbf{H}}^e$, $\bar{\mathbf{H}}^e \in \mathbb{R}^{n\times d_t}$; $\alpha \in [0,1]$ is a hyper-parameter; $\mathbf{G}^{d_t} \in \mathbb{R}^{l\times d_t}$; $[\cdot;\cdot]$ means concatenation in the first dimension; $\otimes$ means the dot product. Finally, we map the index P_t to the sentence-level features Eq.(5) to get entity-level features:

$$T_e = \text{Map}(P, T_s) \tag{14}$$

During the training phase, we use the same negative log-likelihood loss and the teacher forcing method as Yan et al. (2021). During the inference, we use an autoregressive manner to generate the target sequence. In the overall framework of our model, the NER part is pre-trained in advance, and in the overall model training, it is used for inference.

Cross-modal Entity Interaction. Firstly, we employ multi-head self-attention on the interaction features to exploit contexts of the same modality:

$$D_m = \text{MultiHeadAttn}(H_m, H_m, H_m) \tag{15}$$

where H_m is the interaction features, $m \in \{T_e, V_o, T_s\}$. Then, we interact entity features with object features via a gated cross-attention module:

$$R_e = \text{MultiHeadAttn}(H_{T_e}, D_{V_o}, D_{V_o}) \tag{16}$$

$$\alpha_e = \text{Sigmoid}(W_{e1}R_e + W_{e2}H_{T_e}) \tag{17}$$

$$M_e = \alpha_e \cdot R_e + (1 - \alpha_e) \cdot H_{T_e} \tag{18}$$

where M_e is object-aware entity representations. Similarly, we obtain entity-aware object representations M_o. After that, we fuse visual information from M_e to the sentence-level features T_s:

$$\alpha_s = \text{Sigmoid}(W_{s1}M_e + W_{s2}H_{T_s}) \tag{19}$$

$$M_s = \alpha_s \cdot R_s + (1 - \alpha_s) \cdot H_{T_s} \tag{20}$$

Finally, we add M_s and M_o to get the output entity-related features Z_{er} of the cross-modal entity interaction module:

$$Z_{er} = M_s + M_o \tag{21}$$

3.4 Multimodal Decoder

We inject visual information through the vision-guided multi-head attention mechanism. The query Q is from the obtained filtered visual features $V_{filtered}$ in Section 3.3.1, and the key K and value V are from the obtained sentence-level features T_s in Section 3.3.2. Then, we apply a cross-modal multi-head attention (CMA) to get the visual queried text features Z_v. Finally, we add the entity-related features Z_{er} and Z_v to get the text-vision fusion features Z_k:

$$Z_v = \text{CMA}(V_{filtered}, T_s, T_s) \tag{22}$$

$$Z_k = Z_{er} + Z_v \tag{23}$$

The text-vision fusion features will be input into the decoder of BART to generate the corresponding summary:

$$\log p_\theta(y) = \sum_{i=1}^{n} \log p_\theta(y_i | Z_k, y_i, \ldots, y_{i-1}) \tag{24}$$

Table 1: The statistics of MMSS and MM-Sum-En datasets. "S.Len" and "T.Len" refer to the number of words in the source text and the target summary. "I.Num" denotes the number of images corresponding to each text. "M/A/M" means Minimum/Average/Maximum.

where y_i is the i_{th} generated token on the decoder side. For the text-vision fusion process above, the training loss is the commonly used cross-entropy loss function $\mathcal{L}_{ce}$.

4 Experiments

4.1 Dataset

We evaluate our method on the MultiModal Sentence summarization (MMSS) (Li et al., 2018a) and Multilingual Multimodal abstractive Summarization for English (MM-Sum-En) dataset on mid-high-resource scenario (Liang et al., 2022). The MMSS dataset contains 62,000 samples in the training set, $2,000$ in the validation set, and $2,000$ in the test set, and each sample is a triplet of $\langle sentence, image, summary \rangle$. The MM-Sum dataset for English contains $326,725$ samples and $867,817$ images in total which crawled from the BBC News, where each sample is constructed of a news article and some images and presented as $\langle article, images, summary \rangle$. We count some basic information about the dataset, which is shown in Table 1.

4.2 Experimental Settings

For image processing, we utilize the vision encoder of the "ViT-B/32" version of CLIP (Radford et al., 2021), the image patches are 7×7 and the dimension of output visual features is 768. We apply the "Resnet-101" version of DETR (Carion et al., 2020) for object detection with $threshold = 0.95$. For textual generative pre-trained language models, we adopt BART-base (Lewis et al., 2020) as our textual encoder and decoder, where the textual dimension is also 768. We train the Named Entity

Table 2: Experimental results on test set of multimodal sentence summarization (MMSS) dataset and test set of Multilingual Multimodal abstractive Summarization for English (MM-Sum-En) dataset. "$\star$" marks the experimental results reported by Xiao et al. (2023) and "$\wedge$" indicates that they were reported by Liang et al. (2022). "$\top$" denotes this method only leverages text modality data.

Recognition (NER) model proposed by Yan et al. (2021) as a tool for extracting text entities. During training, for MMSS, we set the dropout to 0.1, the batch size is 120, the maximum training epochs is 50, and the beam size is 5. The learning rate is $2e$-5 and the loss function is cross entropy. We leverage AdamW (Loshchilov and Hutter, 2018) as optimizer with $\beta_1 = 0.9$, $\beta_2 = 0.999$ and a weight decay of $1e$-2. Additionally, we apply a scheduler to decay the learning rate to 95% of the current one after every 10 epochs. The maximum input length is 64 and the maximum output length is 32. For the MM-Sum-En dataset, the parameters are the same as in MMSS except that the maximum input length is 1024, the maximum output length is 256, the batch size is 10, and the maximum training epochs is 20. We save our best model checkpoint according to the best ROUGE-2 score on the validation set. All models are trained and tested on a single NVIDIA 3090Ti GPU.

4.3 Compared Methods

Our base model is VG-BART (Yu et al., 2021), which utilizes PLMs as the backbone and injects visual features into the encoder layer through dot production.

We also compare our method with other works using the same two datasets. For MMS dataset: 1) **Lead**: The initial eight words are employed as the summary. 2) **Compress** (Clarke and Lapata, 2008): A methodology centered on sentence compression, utilizing syntactic structure as a basis. 3) **ABS** (Rush et al., 2015): An attentive CNN encoder in conjunction with a neural network language model decoder to proficiently summarize sentences. 4) **SEASS** (Zhou et al., 2017): A summarization framework distinguished by its incorporation of textual selective encoding. 5) **Multi-Source** (Libovický and Helcl, 2017): This method integrates multiple source modalities utilizing hierarchical attention mechanisms, addressing challenges in multimodal machine translation. 6) **Doubly-Attention** (Calixto et al., 2017): This approach leverages two distinct attention mechanisms to incorporate visual features, narrowing the gap between image and translation. 7) **MAtt** (Li et al., 2018b): This approach proposes modality attention and image-filtering techniques tailored for multimodal summarization. 8) **MSE** (Li et al., 2020a): This approach advocates for the application of visual selective gates in multimodal summarization. 9) **CFSum** (Xiao et al., 2023): This approach proposes a contribution network that selects more important parts of images for multimodal summarization, which is a strong baseline.

For MM-Sum-En dataset: 1) **mT5** (Xue et al., 2020): This approach is a multilingual language model pre-trained on a large dataset of 101 languages that is a text-only baseline. 2) **VG-mT5** (Liang et al., 2022): This approach implements the vision-guided multi-head attention fusion method to inject visual features into the mT5 model. 3) **SOV-MAS** (Liang et al., 2022): This approach applies two summary-oriented visual modeling tasks to enhance the MMS model based on the pre-trained language models (*e.g.*, BART).

For all the above models trained on MM-Sum-En, we follow the same monolingual experimental settings in the mid-high-resource scenario, as employed by Liang et al. (2022).

4.4 Main Results

Following Xiao et al. (2023) and Liang et al. (2022), we report our experiment results with 6 automatic metrics: ROUGE-1, ROUGE-2, ROUGE-L (Lin, 2005), BLEU (Papineni et al., 2002), MOVER (Zhao et al., 2019) and BERTScore (Zhang et al., 2019).

Overall, compared with previous works on MMSS as shown in Table 2, our proposed method demonstrates significant improvements across all 6 reported evaluation metrics. Compared with the strong baseline CFSum (Xiao et al., 2023), our method achieves 6.64 higher points on ROUGE-1, demonstrating the effectiveness of our proposed method. Comparing VG-BART with those that design gate-based pre-filters or other networks based on the vision-language pre-trained encoder (*e.g.*, MSE (Li et al., 2020b) and CFSum (Xiao et al., 2023)), we find that our base model, which straightforwardly employs a PLM and integrates visual features, proves to be more effective in enhancing model performance. Furthermore, VE-ELIN outperforms the base model VG-BART, showing that the image processing and visual enhancement we use in the model and the added entity-level features complement each other and significantly improve the quality of the output summarization. The experimental effects of each module are specified in the ablation study 5.1. In the MM-Sum-En dataset, we observe the same results as in MMSS dataset, the performance of our proposed method is improved compared to others.

As shown in Table 1, the average length of input sentences in MMSS is 23, and the average number of input images is 1. In contrast, the length and image number of MM-Sum-En are 446.84 and 2.23. Also, MMSS is from the headlines of article pairs from Gigaword (Graff and Cieri, 2003; Napoles et al., 2012), and MM-Sum-En is sourced from BBC website [1]. This indicates that there is a huge difference between the two MMS datasets. Our method still generates high-quality summaries, further demonstrating the robustness and effectiveness of our proposed VE-ELIN.

Model	**R-1**	**R-2**	**R-L**

- w/o $\mathcal{M}_{VE}$&$\mathcal{M}_{EI}$	39.30	17.60	31.90
- w/o $\mathcal{M}_{VE}$	39.74	17.96	32.28
- w/o $\mathcal{M}_{EI}$	39.51	17.84	32.04

Table 3: Ablation study on two datasets, the top row of each model shows the experimental results from the MMSS dataset and the bottom row shows the results from the MM-Sum dataset. R-1/2/L denotes ROUGE-1/2/L, "$\mathcal{M}_{VE}$" denotes visual enhancement module, "$\mathcal{M}_{EI}$" denotes entity interaction module, and "V_f" denotes visual features.

5 Analysis

5.1 Ablation Study

We conduct ablation studies on both MMSS dataset and MM-Sum-En dataset to prove the effectiveness of the different components of our model. The results are shown in Table 3. We have the following conclusions:

The absence of visual features means that it is a text-only model based on pre-trained language models (PLMs) like BART. It shows a decrease in performance across all ROUGE metrics, demonstrating the incorporation of visual information within the MMS model yields noticeable enhancements in performance.

Without the visual enhancement module and entity interaction module, we find a performance

Table 4: The Entity evaluation metrics in the output summarization. "Source" refers to the input text of the datasets, and "Target" refers to the reference summary. "E.Num" denotes the number of entities in the text, "E.Score" refers to the EntityScore, which is the proposed evaluation metric, and the "S.Score" means SimilarScore metric, which is obtained by doing similarity calculations between the entities in the summaries generated by Target/VG-BART/Ours and the entities in the "Target" respectively.

degradation of about 1%, this verifies the effectiveness of our proposed modules.

As for the model without the visual enhancement module compared with the previous methods, we find an improvement in the metrics, which shows that the image features filter does help to improve the quality of the output summaries. The results show that the visual enhancement module further improves the model performance, indicating that the objects in the images are beneficial to the visual modality information.

The model without entity interaction module makes relative contributions to the MMS model. We can see a certain growth of three ROUGE metrics compared with others in Section 4.4, showing that focusing on the object visual features of the image is effective. The results indicate that our entity interaction module improves the quality of the output summaries and has a large improvement on the model performance.

5.2 Entity Consistency

As shown in Table 4, we formulate some new metrics to assess the quality of output summarization. Specifically, we utilize the NER model trained with BART with an accuracy of 93.8% to count the number of entities in the output summarization generated by the proposed method and the baseline, which is represented in Table 4 by "E.Num". In the process of counting, if an entity in the generated summary is also among the entities in the corresponding target summary, the entity is recorded as a valid entity. Then, the ratio of the number of valid entities to the number of entities in the target summary is calculated and named EntityScore, which is expressed as "E.Score" in Table 4:

$$\text{EntityScore} = \frac{N_{generated}}{N_{target}} \tag{25}$$

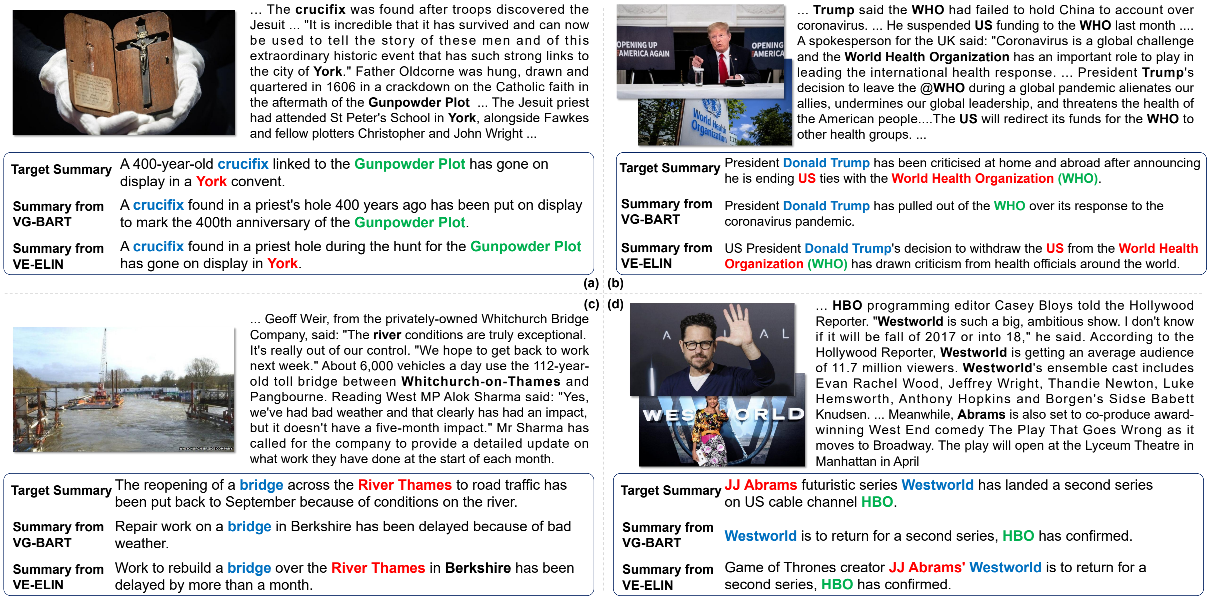
where $N_{generated}$ and N_{target} is the entity numbers in generated summary and target summary. Statistical results indicate a significant improvement in the number of entities recognized by our approach. Moreover, we concatenate the entities in the model output summary into one sentence $X{=}\langle x_1, x_2, ..., x_k\rangle$ and the entities in the target summary into another sentence $\hat{X}{=}\langle \hat{x}_1, \hat{x}_2, ..., \hat{x}_l\rangle$. Following Zhang et al. (2019), the SimilarScore is then used to calculate the similarity of the two sentences:

$$\text{SimilarScore} = \text{BERTScore}(X, \hat{X}) \tag{26}$$

The computational results demonstrate that our proposed method indeed improves the number and quality of entities in the output summarization, thus proving the effectiveness of our model.

5.3 Case Study

We compare the summary output of VG-BART with the results of the VE-ELIN model to show that our method is able to accurately generate entities while generating complete summaries. To better characterize the consistency of our proposed metrics with the real world, the entities appearing in the original text and those in the output are bolded and marked in different colors. In order to make the overall format of the Figure 3 consistent and easy to read, we omit some parts of the original texts and the complete original inputs will be shown in Appendix A.



... The **crucifix** was found after troops discovered the Jesuit ... "It is incredible that it has survived and can now be used to tell the story of these men and of this extraordinary historic event that has such strong links to the city of **York**." Father Oldcorne was hung, drawn and quartered in 1606 in a crackdown on the Catholic faith in the aftermath of the **Gunpowder Plot** ... The Jesuit priest had attended St Peter's School in **York**, alongside Fawkes and fellow plotters Christopher and John Wright ...

Target Summary	A 400-year-old **crucifix** linked to the **Gunpowder Plot** has gone on display in a **York** convent.
Summary from VG-BART	A **crucifix** found in a priest's hole 400 years ago has been put on display to mark the 400th anniversary of the **Gunpowder Plot**.
Summary from VE-ELIN	A **crucifix** found in a priest hole during the hunt for the **Gunpowder Plot** has gone on display in **York**.

... **Trump** said the **WHO** had failed to hold China to account over coronavirus. ... He suspended **US** funding to the **WHO** last month .... A spokesperson for the UK said: "Coronavirus is a global challenge and the **World Health Organization** has an important role to play in leading the international health response. ... President **Trump**'s decision to leave the @**WHO** during a global pandemic alienates our allies, undermines our global leadership, and threatens the health of the American people....The **US** will redirect its funds for the **WHO** to other health groups. ...

Target Summary	President **Donald Trump** has been criticised at home and abroad after announcing he is ending **US** ties with the **World Health Organization (WHO)**.
Summary from VG-BART	President **Donald Trump** has pulled out of the **WHO** over its response to the coronavirus pandemic.
Summary from VE-ELIN	US President **Donald Trump**'s decision to withdraw the **US** from the **World Health Organization (WHO)** has drawn criticism from health officials around the world.

... Geoff Weir, from the privately-owned Whitchurch Bridge Company, said: "The **river** conditions are truly exceptional. It's really out of our control. "We hope to get back to work next week." About 6,000 vehicles a day use the 112-year-old toll bridge between **Whitchurch-on-Thames** and Pangbourne. Reading West MP Alok Sharma said: "Yes, we've had bad weather and that clearly has had an impact, but it doesn't have a five-month impact." Mr Sharma has called for the company to provide a detailed update on what work they have done at the start of each month.

Target Summary	The reopening of a **bridge** across the **River Thames** to road traffic has been put back to September because of conditions on the river.
Summary from VG-BART	Repair work on a **bridge** in Berkshire has been delayed because of bad weather.
Summary from VE-ELIN	Work to rebuild a **bridge** over the **River Thames** in **Berkshire** has been delayed by more than a month.

... **HBO** programming editor Casey Bloys told the Hollywood Reporter. "**Westworld** is such a big, ambitious show. I don't know if it will be fall of 2017 or into 18," he said. According to the Hollywood Reporter, **Westworld** is getting an average audience of 11.7 million viewers. **Westworld**'s ensemble cast includes Evan Rachel Wood, Jeffrey Wright, Thandie Newton, Luke Hemsworth, Anthony Hopkins and Borgen's Sidse Babett Knudsen. ... Meanwhile, **Abrams** is also set to co-produce award-winning West End comedy The Play That Goes Wrong as it moves to Broadway. The play will open at the Lyceum Theatre in Manhattan in April

Target Summary	**JJ Abrams** futuristic series **Westworld** has landed a second series on US cable channel **HBO**.
Summary from VG-BART	**Westworld** is to return for a second series, **HBO** has confirmed.
Summary from VE-ELIN	Game of Thrones creator **JJ Abrams' Westworld** is to return for a second series, **HBO** has confirmed.

Figure 3: Case study of our proposed VE-ELIN. The top part of each column is the input texts and images, and the bottom part is the output summaries of the different methods and the corresponding target summaries.

Figure 3 shows four representative examples that intuitively demonstrate the effectiveness of our method. a) For the first example, VG-BART does not generate the corresponding location information, which in the original text is the entity "York", and it incorrectly misinterprets "400-year-old crucifix" as "400th anniversary" in the original text. The summary from VE-ELIN accurately covers all the entities in the target summary and is semantically consistent with it. This indicates that our approach can better focus on the entities that appear in the original text and assign higher weights to them when generating summaries. b) For the second example, VE-ELIN accurately generates the entity "US". In addition, the full name of WHO appears only once in the article compared to the abbreviation, but our method generates the full name of WHO with the contribution of the object area in the input images correctly. c) For the third example, the entity "River Thames" is not explicitly mentioned in the input article, however, since the Cross-modal Entity Interaction module in our approach can fuse semantic information from different modalities to form new features, VE-ELIN can combine separate and inherently related entities to generate the semantically complete entity "River Thames". d) For the last example, similarly to the second example, "Westworld" and "HBO" are successfully generated with the help of entities that appear several times in the text. In addition to this, the entity "JJ Abrams" (the person appearing in the image) is in the summary from ours, since our Visual Enhancement module can fully extract the visual features and enhance the focus of the image on the object area to better inject visual information to the whole model.

6 Conclusion

In this paper, we propose a novel framework VE-ELIN for multimodal summarization to alleviate the incomplete generation of entity information in summary. We design a cross-modal entity interaction module to better utilize the entity features in texts and images, and an object-guided visual enhancement module to enhance the focus on the objects while taking full advantage of useful image information. To further evaluate the factual consistency of entities in the output summary, we also propose two new metrics named EntityScore and SimilarScore. Experimental results on two different types of datasets demonstrate that our method is effective and outperforms previous methods under both traditional evaluation metrics and our proposed new metrics.

Limitations

Our approach is limited by the underlying performance of the generative pre-trained language model. In addition, the accuracy of the object detection model DETR and named entity recognition model also limit our performance. For images without valid object areas, our method does not utilize the visual information well. Also in the face of single modal inputs, such as text-only inputs or image-only inputs, our model fails to do the appropriate adaptation for this type of data and performs poorly. So improving the ability to adapt to different kinds of data is a future research direction.

Ethics Statement

We affirm that our work here does not deepen the biases already inherent in the models and the datasets we used are open-sourced. Thus we expect no ethical concerns associated with this research.

A Original Inputs of Case Study

a: The cross was owned by Catholic priest Father Edward Oldcorne, who was friends with Guy Fawkes and some of the other plotters. He was arrested in 1605 after the failed attempt to blow up Parliament and kill King James I. Oldcorne was later executed, despite no evidence linking him to the assassination attempt. The crucifix was found after troops discovered the Jesuit hiding inside a priest hole at Hindlip Hall - a stately home in Worcestershire. It is now on display at the Bar Convent Living Heritage Centre. 'Historic event' Sister Patricia Harriss described the cross housed in a wooden case as "one of the most remarkable items in our possession." "Today, Bonfire Night is a celebration with fireworks but in 1605 it was an event that had a profound effect on Catholics and shocked the whole country," she said. "This crucifix, now more than 400 years old, was hidden in the priest's hole with Blessed Edward Oldcorne and would have offered him comfort in his final days. "It is incredible that it has survived and can now be used to tell the story of these men and of this extraordinary historic event that has such strong links to the city of York." Father Oldcorne was hung, drawn and quartered in 1606 in a crackdown on the Catholic faith in the aftermath of the Gunpowder Plot. He was beatified, the first step to becoming a saint, by the Vatican in 1929. The Jesuit priest had attended St Peter's School in York, alongside Fawkes and fellow plotters Christopher and John Wright. The school has a ban on the burning of guys on Bonfire Night after a former headmaster declared that it should not burn effigies of former pupils. Follow BBC Yorkshire on Facebook, Twitter and Instagram. Send your story ideas to yorkslincs.news@bbc.co.uk or send video here.

b: The EU urged him to reconsider the decision, while Germany's health minister called it a "disappointing setback for international health". The head of the US Senate's health committee, a Republican like Mr Trump, said now was not the time to leave. Mr Trump said the WHO had failed to hold China to account over coronavirus. The WHO, a UN agency that helps countries promote healthcare and tackle outbreaks of disease, has faced regular criticism from the US president over its handling of the outbreak. He suspended US funding to the WHO last month and on Friday permanently halted the payment, which last year stood at more than $\$400m$ (£324m; €360m), the largest single contribution at around 15% of its total budget. What has the response been to the US move? European Commission President Ursula von der Leyen and top EU diplomat, Josep Borrell, said in a statement: "In the face of this global threat, now is the time for enhanced co-operation and common solutions. Actions that weaken international results must be avoided. "We urge the US to reconsider its announced decision." German Health Minister Jens Spahn described the setback as "disappointing" although he accepted the WHO "needs reform". "The EU must take a leading role and engage more financially," he said. A spokesperson for the UK said: "Coronavirus is a global challenge and the World Health Organization has an important role to play in leading the international health response. We have no plans to withdraw our funding." The chair of the US Senate Health Committee, Lamar Alexander, said the move could hamper the discovery of a vaccine against Covid-19 and urged a reversal of the decision in the "strongest terms possible". "Certainly there needs to be a good, hard look at mistakes the World Health Organization might have made in connection with coronavirus, but the time to do that is after the crisis has been dealt with, not in the middle of it," he said. Ex-presidential candidate and US Senator Elizabeth Warren tweeted: "President Trump's decision to leave the @WHO during a global pandemic alienates our allies, undermines our global leadership, and threatens the health of the American people." Anders Nordstrom, a former WHO acting director general, said he was "deeply concerned" the move would increase political tension at a time when "we need to have global solidarity". South African Health Minister Zweli Mkhize called the decision "unfortunate". WHO member states agreed on 19 May to set up an independent inquiry into the global response to the pandemic. What was behind Trump's decision? Speaking at the White House, Mr Trump said: "Because they have failed to make the requested and greatly needed reforms, we will be today terminating our relationship with the World Health Organization and redirecting those funds to other worldwide and deserving urgent global public health needs." It is not clear when any US withdrawal might take place. A 1948 agreement between the US and WHO allows for one year's notice before pulling out. Mr Trump has accused China of trying to cover up the outbreak of coronavirus, which occurred in the city of Wuhan late last year. He also says that "China has total control over the World Health Organization". The president accused China of pressurising the WHO to "mislead the world" about the virus, without elaborating. "The world is now suffering as a result of the malfeasance of the Chinese government," he said. The US will redirect its funds for the WHO to other health groups. More than 102,000 people in the US have lost their lives to Covid-19 - by far the biggest death toll in the world. Opponents say Mr Trump is trying to deflect criticism of his handling of the pandemic ahead of his re-election bid this year. Meanwhile, Chinese Foreign Ministry spokesman Zhao Lijian has said that Mr Trump is trying to mislead the public, smear China and "shift the blame for [the US's] own incompetent response". What is the WHO - and who funds it?

c: Work on Whitchurch Bridge's £4.3m reconstruction which began in October and was originally due to finish in April, stopped on 20 December. Environment Agency red board warnings are in place due to strong stream flows stopping the contractors from working. Its operator said it regretted the delay to residents and businesses. Geoff Weir, from the privately-owned Whitchurch Bridge Company, said: "The river conditions are truly exceptional. It's really out of our control. "We hope to get back to work next week." About 6,000 vehicles a day use the 112-year-old toll bridge between Whitchurch-on-Thames and Pangbourne. Reading West MP Alok Sharma said: "Yes, we've had bad weather and that clearly has had an impact, but it doesn't have a five-month impact." Mr Sharma has called for the company to provide a detailed update on what work they have done at the start of each month.

d: Another 10 episodes of the big budget drama will air in 2017 or 2018, HBO programming editor Casey Bloys told the Hollywood Reporter. "Westworld is such a big, ambitious show. I don't know if it will be fall of 2017 or into 18," he said. According to the Hollywood Reporter, Westworld is getting an average audience of 11.7 million viewers. Westworld's ensemble cast includes Evan Rachel Wood, Jeffrey Wright, Thandie Newton, Luke Hemsworth, Anthony Hopkins and Borgen's Sidse Babett Knudsen. The first series is being broadcast on Sky Atlantic in the UK on Tuesday evenings. Co-creators Jonathan Nolan and Lisa Joy said in a statement: "During the lengthy journey to the screen, our incredibly talented actors, staff and crew became a family, and we look forward to the privilege of continuing this experience with them. "We're also thankful to all of our amazing partners at HBO, WBTV and Bad Robot for their steadfast support, imagination and ambition. We simply couldn't have made this show anywhere else." Bloys would not reveal whether the stars of the current series will return for a second season. "I don't want to speculate about cast because there's still three episodes left to air," he said. Meanwhile, Abrams is also set to co-produce award-winning West End comedy The Play That Goes Wrong as it moves to Broadway. The play will open at the Lyceum Theatre in Manhattan in April.

Knowledgeable In-Context Tuning:
Exploring and Exploiting Factual Knowledge for In-Context Learning

Abstract

Large language models (LLMs) enable in-context learning (ICL) by conditioning on a few labeled training examples as a text-based prompt, eliminating the need for parameter updates and achieving competitive performance. In this paper, we demonstrate that *factual knowledge* is imperative for the performance of ICL in three core facets: the inherent knowledge learned in LLMs, the factual knowledge derived from the selected in-context examples, and the knowledge biases in LLMs for output generation. To unleash the power of LLMs in few-shot learning scenarios, we introduce a novel **K**nowledgeable **I**n-**C**ontext **T**uning (**KICT**) framework to further improve the performance of ICL: 1) injecting knowledge into LLMs during continual self-supervised pre-training, 2) judiciously selecting the examples for ICL with high knowledge relevance, and 3) calibrating the prediction results based on prior knowledge. We evaluate the proposed approaches on autoregressive models (e.g., GPT-style LLMs) over multiple text classification and question-answering tasks. Experimental results demonstrate that **KICT** substantially outperforms strong baselines and improves by more than 13% and 7% on text classification and question-answering tasks, respectively [1].

1 Introduction

Large language models (LLMs) have become an imperative infrastructure in the natural language processing (NLP) community (Zhao et al., 2023b). To enable pre-trained LLMs to perform well without any parameter updates, in-context learning (ICL) has emerged as one of the flourishing research topics in many few-shot NLP tasks. It aims to generate predictions for target examples by conditioning on a few labeled samples (Brown et al., 2020). As shown in Figure 1, the key component of ICL is the text-based prompt (containing labeled examples) that functions as the demonstration.

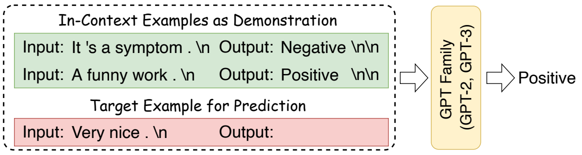

Figure 1: An example of in-context learning (ICL).

Previous works have explored multiple aspects that affect the performance of ICL (Dong et al., 2023), such as input-output mapping (Min et al., 2022b; Kim et al., 2022), extensive data resources (Mishra et al., 2022; Chen et al., 2022b; Min et al., 2022a), prediction calibration (Zhao et al., 2021), and self-improvment (Chen et al., 2023; Lyu et al., 2023). Liu et al. (2022); Lu et al. (2022) have investigated others, such as prompt format (e.g., "Input:", "Output:"), the selection of labeled data, and example permutation. Wang et al. (2023a); Wu et al. (2023) have developed toolkits for LLMs to reason with ICL prompts. In addition, to better elicit the LLM to reason on complex tasks, chain-of-thought (CoT) has been introduced to extend the ICL with multiple rationales to express the thinking process (Wei et al., 2022; Dhuliawala et al., 2023; Wang et al., 2023c,b; Zhao et al., 2023a; Zhang et al., 2023; Liang et al., 2023). However, these works pay little attention to the influence of *factual knowledge* in ICL, which is a non-negligible factor in NLP (Hu et al., 2022).

To this end, we explore the effectiveness of ICL from the perspective of *factual knowledge*. As seen in Figure 2, when entities and labels in text-based prompts are randomly replaced or removed, the average accuracy decreases significantly, indicating that performance degradation is universal across different model scales. Further analysis reveals that: 1) more intrinsic factual knowledge acquired during the pre-training stage is typically beneficial

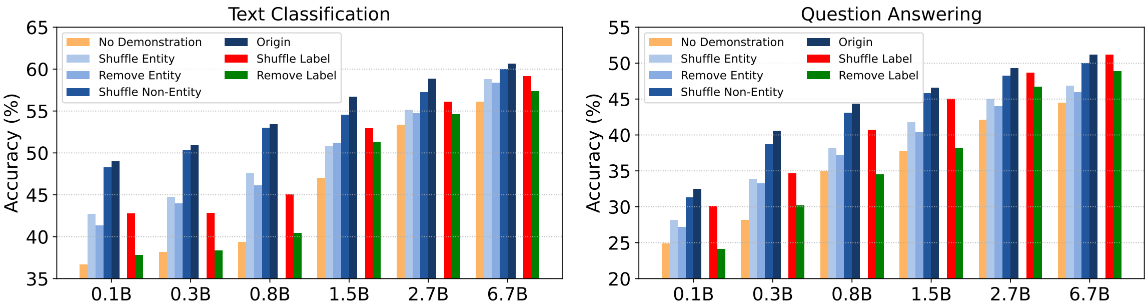

Figure 2: Results of different scales of GPT-2 and OPT models over 8 text classification tasks and 4 question answering tasks in various component destruction settings. For each target example, we have $K = 8$ labeled samples as the demonstration. Results indicate that factual knowledge is crucial to the performance of ICL.

for LLMs to improve effectiveness; 2) The factual knowledge (e.g., entities and labels) derived from selected in-context examples is crucial for the performance of ICL; 3) LLMs tend to generate common words that may have high frequencies in the training corpora, resulting in biased predictions.

After analyzing these knowledge facets, a natural question arises: *How can we fully employ factual knowledge to further improve the performance of ICL?* To achieve this goal, we focus on causal autoregressive LLMs (e.g., GPT-2 (Radford et al., 2019) and OPT (Zhang et al., 2022a)) and present a novel **K**nowledgeable **I**n-**C**ontext **T**uning (**KICT**) framework, which involves knowledgeable guidance in *pre-training*, *prompting*, and *prediction* of these models. Specifically, to endow LLMs with enhanced text generation abilities by better leveraging inherent knowledge, we introduce several knowledgeable self-supervised tasks during the *pre-training* stage to inject knowledge into LLMs. For text-based *prompting*, we propose a knowledgeable example retrieval algorithm to judiciously select in-context examples that have relevant knowledge to the target example. Finally, during *prediction*, we utilize the knowledge-wise priors of label words from an underlying knowledge base (KB) to calibrate the prediction distributions generated by LLMs. Each of the proposed techniques is plug-and-play and can be freely combined, facilitating users to exploit knowledge for improving ICL.

To evaluate the effectiveness of the **KICT** framework, we employ LLMs (e.g., GPT-style models) to conduct extensive experiments over multiple text classification and question-answering tasks. Results demonstrate that each proposed procedure achieves substantial improvements.

To sum up, we make the following main contributions:

- We study three knowledge facets for ICL that are imperative for LLMs in few-shot learning, i.e., inherent knowledge in LLMs, relevant knowledge in the text-based prompt, and knowledge bias.
- We present a novel knowledgeable in-context tuning framework for better incorporating knowledge through the process of pre-training, prompting, and predicting.
- Extensive experiment results show that our approach attains more impressive performance over classification and QA tasks.

2 Impact of Knowledge on ICL

In this section, we investigate whether *factual knowledge* affects the performance of ICL.

2.1 Preliminary Experimental Settings

Following Min et al. (2022b) and Kim et al. (2022), we perform empirical experiments through component destruction. Specifically, given a target example text X^{tgt}, we randomly select K training samples $\widetilde{\mathcal{D}} = \{(X_i^{trn}, y_i^{trn})\}_{i=1}^{K}$ to form a text-based prompt. We identify all entities in the prompt and then devise several destruction settings as follows: 1) `Shuffle Entity` involves randomly replacing all entities with others from the KB; 2) `Shuffle Non-Entity` entails replacing some non-entity words (e.g., "It", "have") with others from the vocabulary; 3) `Shuffle Label` consists of replacing all the golden labels with incorrect ones; 4) `Remove Entity` and `Remove Label` aim to remove all entities and labels from the prompt, respectively; 5) `No Demonstration` represents a typical zero-shot

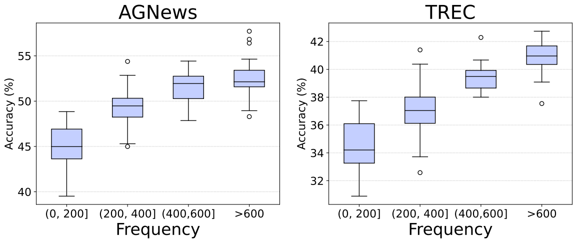

Figure 3: 4-shot results of GPT-2 (urge) over AGNews and TREC. For each frequency region, we sample top-5 label words for each category and report the accuracy for all label mapping permutations.

method where no labeled data is used (Min et al., 2022b).

We employ various scales of GPT-2 (0.1B-1.5B) and OPT (Zhang et al., 2022a) (2.7B-6.7B) models to evaluate 8 text classification tasks and 4 question answering tasks. [2] By default, we randomly sample $K = 8$ labeled samples for each task and conduct the experiments with 5 different random seeds. Further details are presented in Appendix A. The findings are summarized below.

2.2 Findings

The inherent knowledge in the LLM itself is beneficial for the performance of downstream tasks. As shown in Figure 2, models can achieve remarkable few-shot performance with increased scale. We hypothesize that larger models can learn more valuable semantics in the pre-training corpus, which contributes to this improvement. To test this hypothesis, we perform zero-shot inference without any text-based prompts (i.e., `No Demonstration`), relying solely on the intrinsic knowledge acquired during pre-training to guide the predictions. We observe that the performance gap between the 6.7B and 0.1B models is about 20% on both text classification and question-answering tasks. This observation supports the idea that the inherent knowledge learned during pre-training is critical (Yang et al., 2021).

The factual knowledge in selected in-context examples is crucial for ICL. As shown in Figure 2, the original setting (`Origin`) outperforms other configurations across all model scales. We observe that altering non-entity words does not significantly reduce performance, whereas replacing or removing entities leads to a considerable decrease in average accuracy for both text classification and question-answering tasks. This demonstrates that factual knowledge embedded in text-based prompts is a critical factor for LLMs to understand the task. Furthermore, we find that labels are also essential for ICL, echoing similar observations presented in (Kim et al., 2022). Differing from Min et al. (2022b), we posit that labels can be regarded as a form of factual knowledge that guides the LLM to grasp semantics during inference.

LLMs tend to generate common label words due to knowledge bias. To investigate whether predictions are biased, we select two knowledge-intensive tasks (i.e., AGNews (Zhang et al., 2015), and TREC (Voorhees and Tice, 2000)). We first retrieve the top-5 predictions at the output position for each training example[3] and compute frequency statistics for each generated label word. Subsequently, we select 4 labeled examples from the training set for each category. From each frequency region, we randomly choose 2 label words and calculate the average accuracy across all label mapping permutations.[4] The results, as presented in Figure 3, reveal that performance is highly contingent on label word frequency, suggesting that the frequency with which factual knowledge is learned by LLMs plays a critical role in prediction outcomes. Similar observations have been reported by Zhao et al. (2021).

3 The Proposed KICT Framework

The preliminary experiments demonstrate that *factual knowledge* has a substantial effect on ICL. This suggests that we can exploit this knowledge to enhance performance across various processes in ICL, including *pre-training*, *prompting*, and *prediction*. To achieve this goal, we introduce the **KICT** framework, a novel **K**nowledgeable **I**n-**C**ontext **T**uning framework designed to better leverage knowledge and unleash the power of LLMs in answer generation. Within this framework, we introduce Knowledgeable Pre-Training (KPT) with three carefully designed self-supervised tasks to infuse LLMs with factual knowledge. We then present a Knowledgeable Example Retrieval (KER) algorithm to judiciously select in-context examples that are relevant to the given knowledge. Finally, we employ a

---

[2] Due to resource constraints, we do not use larger models. Nevertheless, our findings are generally consistent across different model scales.

[3] The training set is larger than the testing set, thereby providing a more robust statistical representation.

[4] Considering AGNews as an example, which has 4 classes with 2 label words each, there are $2^4 = 16$ possible label mapping permutations.

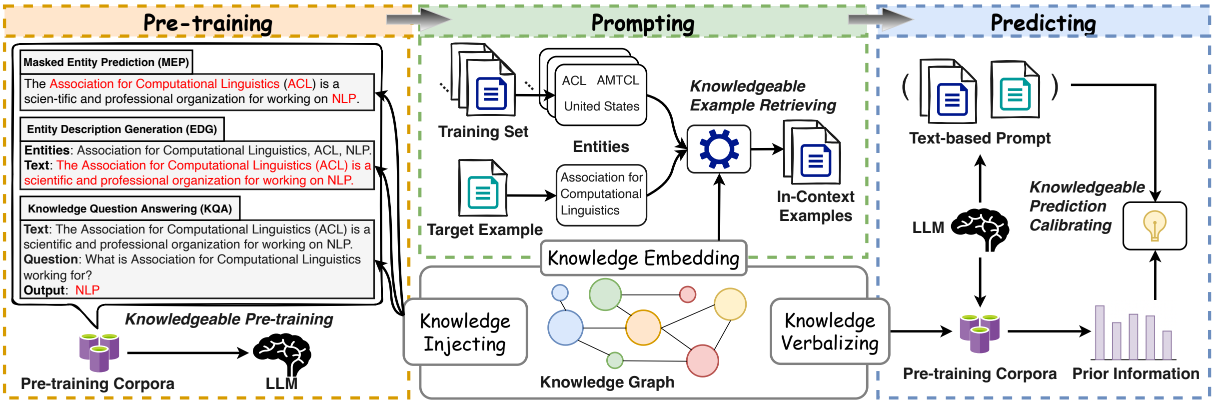

Figure 4: The overview of the **KICT** framework. We introduce multiple plug-and-play knowledgeable techniques to enhance the utilization of knowledge for improving ICL performance. **Left**: We propose three knowledge-aware self-supervised learning tasks that infuse factual knowledge into LLMs during pre-training. **Middle**: We utilize entity-related information to select in-context examples that exhibit high knowledge relevance to the target example. **Right**: For prediction, we derive prior information from large-scale corpora to calibrate the predictions.

Knowledgeable Prediction Calibration (KPC) technique to adjust the prediction distribution using prior information derived from a KB. An overview of the framework is depicted in Figure 4.

3.1 Knowledgeable Pre-Training

This section describes three knowledge-aware self-supervised learning tasks designed to infuse factual knowledge into LLMs, namely, *Masked Entity Prediction* (MEP), *Entity Description Generation* (EDG), and *Knowledgeable Question Answering* (KQA). Differing from Chen et al. (2022a), we leverage an external KB to enrich the models' language generation abilities with respect to important entities. The input consists of a training corpus $\{X\}$ and a KB $\mathcal{G} = (\mathcal{E}, \mathcal{R}, \mathcal{T})$, where $\mathcal{E}$ denotes a set of entities, $\mathcal{R}$ a set of relations, and $\mathcal{T}$ a set of triples representing factual knowledge.

Masked Entity Prediction (MEP). MEP requires the model to predict missing entities within a text, enhancing its capability to learn explicit knowledge. This task is akin to *Masked Language Modeling* employed in BERT-style models (Devlin et al., 2019; Liu et al., 2019). Given a text composed of tokens $X = \{x_i\}$, we identify all entities $E_X = \{e|e \in \mathcal{G}, e \in X\}$ using an entity linking toolkit. Each entity $e = \{x_j|x_j \in X\}$, which may span multiple tokens, is either replaced with special tokens (e.g., "_") or random tokens with equal probability. This process generates a modified text $\hat{X} = \{\hat{x}_i\}$. A label mask vector $\mathcal{M}_{\hat{X}}$ is created to indicate training positions, where $\mathcal{M}_{\hat{X}_i} = \mathbb{I}(\hat{x}_i \in E_X)$ and $\mathbb{I}(\cdot)$ is an indicator function. Figure 4 (left) illustrates this with highlighted words.

Entity Description Generation (EDG). EDG tasks the model with producing a text description for a given entity. For a text X and associated entity set E_X, we construct a prefix text using the template "Entities:", followed by a list of entities and the template "Text:". The original text X serves as the suffix. This forms the modified example $\hat{X}$ and corresponding label mask vector $\mathcal{M}_{\hat{X}}$, where $\mathcal{M}_{\hat{X}_i} = 1$ if $\hat{x}_i$ is part of the suffix string.

Knowledgeable Question Answering (KQA). KQA leverages relation triples from the KB to facilitate question answering. Given a text X and entity set E_X, we select a pair of entities $e_h, e_t \in E_X$ linked by a 1-hop relation $r \in \mathcal{R}$ to form a triple $(e_h, r, e_t) \in \mathcal{T}$. Inspired by Wang et al. (2022), we create a question template for each triple, prompting the model to predict the tail entity e_t. Training examples $\hat{X}$ and label mask vectors are generated accordingly, with $\mathcal{M}_{\hat{X}_i} = 1$ designating tokens belonging to the tail entity.

During pre-training, we randomly compile examples from the same task into a training batch $\mathcal{X} = \{\hat{X}\}$ until the maximum sequence length is reached. The cross-entropy loss for prediction positions (where $\mathcal{M}_{\hat{X}} = 1$) is computed as follows:

$$\mathcal{L} = \frac{1}{|\mathcal{X}|}\sum_{\hat{X}\in\mathcal{X}}\frac{1}{T_{\hat{X}}}\sum_{\hat{x}_i\in\hat{X}}\mathcal{M}_{\hat{X}_i}\log p(y_i|\hat{X}_{<i}), \quad (1)$$

where y_i is the ground truth token, $p(\cdot)$ is the predicted probability, and $T_{\hat{X}} = \sum_{\hat{x}_i\in\hat{X}}\mathcal{M}_{\hat{X}_i}$ is the number of tokens the model is required to predict.

3.2 Knowledgeable Example Retrieval

Despite having a powerful and knowledgeable LLM at our disposal, the efficacy of ICL is significantly influenced by the selection and ordering of labeled examples (Brown et al., 2020). Previous studies (Liu et al., 2022; Lu et al., 2022; Rubin et al., 2022) have demonstrated that LLMs can autonomously generate suitable text-based prompts, yet they largely overlook the importance of *factual knowledge* from KBs. To address this gap, we introduce a novel Knowledgeable Example Retrieval (KER) algorithm that utilizes knowledge to select the most relevant in-context examples. This process is illustrated in Figure 4 (middle) and detailed in Algorithm 1 in Appendix C. Concisely, given a training set $D_{trn} = \{(X_i^{trn}, y_i^{trn}, E_i^{trn})\}$ and a testing set $D_{tgt} = \{(X_j^{tgt}, E_j^{tgt})\}$, where X_i^{trn} and X_j^{tgt} are input texts, y_i^{trn} are labels, and E_i^{trn} and E_j^{tgt} are the corresponding entity sets, KER's objective is to select a subset of training examples as demonstrations that exhibit high knowledge relevance to the testing set.

A straightforward approach is to retrieve examples containing entities that *cover* a higher number of target examples. We use the Jaccard similarity to assess the similarity between two examples:

$$d_{jac}(i, j) = \frac{|E_i^{trn} \cap E_j^{tgt}|}{|E_i^{trn} \cup E_j^{tgt}|}. \tag{2}$$

However, since the Jaccard similarities for most example pairs are zero, we further employ pre-trained knowledge embeddings to retrieve training examples that are semantically *similar* to the target set. We compute the average representations $\mathbf{e}_i$ and $\mathbf{e}_j$ of all entities in E_i^{trn} and E_j^{tgt}, respectively. The semantic difference is quantified using the Euclidean distance $d_{sem}(i, j)$ between $\mathbf{e}_i$ and $\mathbf{e}_j$. The overall knowledge relevance between two examples is calculated as follows:

$$\begin{aligned} d(X_i^{trn}, X_j^{tgt}) &= \alpha \frac{d_{jac}(i,j) + \gamma}{\max_{X_k^{trn} \in \mathcal{D}_{trn}} d_{jac}(i,k) + \gamma} \\ &+ (1-\alpha)(1 - \frac{d_{sem}(i,j)}{\max_{X_k^{trn} \in \mathcal{D}_{trn}} d_{sem}(i,k)}), \end{aligned} \tag{3}$$

where $\alpha \in [0, 1]$ and $\gamma > 0$ are tunable hyperparameters. The sampling weight for each training example X_i^{trn} is given by:

$$s'(X_i^{trn}) = \frac{s(X_i^{trn})}{\sum_{X_j^{trn} \in \mathcal{D}_{trn}} s(X_j^{trn})}, \tag{4}$$

where $s(X_i^{trn})$ is computed as the average relevance score to the testing set:

$$s(X_i^{trn}) = \frac{1}{|\mathcal{D}_{tgt}|} \sum_{X_j^{tgt} \in \mathcal{D}_{tgt}} d(X_i^{trn}, X_j^{tgt}). \tag{5}$$

An example with a higher weight signifies greater knowledge relevance across all target examples. Ultimately, we sample K training examples based on these weights to serve as in-context examples.

3.3 Knowledgeable Prediction Calibration

Following model pre-training and in-context example selection, we can proceed to generate predictions for the target example $X^{tgt} \in \mathcal{D}_{tgt}$ using the following equation:

$$\hat{y} = \arg\max_{v \in \mathcal{V}} p(y = e | X, X^{tgt}), \tag{6}$$

where $\mathcal{V}$ is a verbalizer that maps label words to their corresponding classes [5]. $\widetilde{\mathcal{D}}$ represents the set of in-context examples used for prediction. However, as discussed in Section 2, the frequency of label words (in classification tasks) or entities (in question answering tasks) can bias the prediction probabilities. To mitigate this issue, we utilize the prior information of label words to refine the prediction for each target example.

Specifically, we select a subset of training data $\mathcal{S}$ from the KQA task and estimate the contextual prior probability for each candidate label word or entity $v \in \mathcal{V}$ at the output position:

$$P(v) \approx \frac{1}{|\mathcal{S}|} \sum_{\hat{X} \in \mathcal{S}} p(y = v | \hat{X}), \tag{7}$$

where $\hat{X}$ denotes a training example, and $P(v)$ represents the estimated prior probability of candidate v. Following this, we discard any label word or entity v whose prior probability falls below a specific threshold (Hu et al., 2022).

Consequently, we enhance the final output by applying calibrated prediction:

$$\hat{y} = \arg\max_{v \in \mathcal{V}} \frac{p(y = v | \widetilde{\mathcal{D}}, X^{tgt})}{P(v)}. \tag{8}$$

Remarks. While most related works (Hu et al., 2022; Zhao et al., 2021) concentrate on prediction calibration, our approach distinguishes itself by

---

[5] For classification tasks, $\mathcal{V}$ is the set of label words; for question answering tasks, $\mathcal{V}$ is the entire vocabulary.

leveraging a priori knowledge from a large-scale corpus to debias outputs. This contrasts with methods that rely solely on in-domain data or utilize task-agnostic, content-free inputs (e.g., "N/A").

4 Experiments

4.1 Implementation Settings and Baselines

For the pre-training corpus, we use Wikipedia Dumps (2020/03/01)[6], which consists of 25,933,196 sentences. Further, the KB we used is WikiData5M (Wang et al., 2021b), which includes $3,085,345$ entities and 822 relation types. By default, we choose GPT-2 (large) with 0.8B parameters as the backbone. For downstream tasks, we consider 8 text classification tasks and 4 question answering tasks. The details of corpora and downstream benchmarks are shown in Appendix B. The implementation details of pre-training, prompting, and prediction can be found in Appendix C.

We consider the following baselines: 1) **In-Context Learning (ICL)** is the vanilla version proposed by GPT-3. 2) **Calibrate Before Use (CBU)** (Zhao et al., 2021) is a typical method that aims to de-bias the prediction via content-free prompts. 3) **KATE** (Liu et al., 2022) uses the CLS embeddings of a RoBERTa-large model as sentence representations, and retrieves the nearest K neighbors for each target example as the final in-context examples. 4) **MetaICL** (Min et al., 2022a) improves ICL by meta-learning the objective of ICL in cross-task settings. 5) **SelfSup.** (Chen et al., 2022a) improves ICL by multiple self-supervised learning tasks. We also choose RoBERTa-large to perform fully **Fine-tuning** to demonstrate the ceiling performance of each task.

4.2 Main Results

Table 1 and Table 2 respectively report the results over text classification and question answering tasks in the 8-shot setting. We thus make the following observations: 1) Our proposed framework outperforms strong baselines and achieves substantial improvements over all benchmarks. Specifically, compared with ICL, the average result over the text classification task is improved by 13.70%, which is larger than that of other baselines. The average gain over question answering tasks is also more than 7%, although there is still room for improvement on unseen target domains, likely because they require more challenging generalization and commonsense abilities. 2) Compared with ICL, KER and KCP make significant contributions to the performance. Particularly, KER and KCP also respectively outperform strong baselines KATE and CBU, indicating the indispensable merit of factual knowledge at the inference stage. 3) The performance of KPT exceeds that of meta-learning (MetaICL) and self-supervised learning (SelfSup.) approaches by around 4%, which also focus on continual pre-training. This demonstrates that explicitly injecting knowledge into LLMs is more effective for ICL, which is imperative and plays a dominant role. 4) Our method attains more impressive performance when combining all of these knowledgeable techniques, highlighting the necessity of factual knowledge in ICL. We provide a detailed analysis in Section 4.3. 5) We also evaluate other scales for GPT-2 and OPT in 8-shot settings. Results in Appendix F show that the improvements are consistent across different LLMs.

4.3 Ablation Study

We further investigate how these proposed knowledgeable techniques contribute to the final performance with different combinations. As shown in Table 3, the results demonstrate that any combination greatly promotes the overall performance of vanilla ICL. An interesting observation is that KPT is particularly important for performance improvement, achieving higher scores than KER and KCP. This indicates that the most effective way to unleash the power of LLMs is to inject knowledge into the model parameters. Nonetheless, the combination of KER and KCP also improves ICL by about 8% for each task, respectively. This suggests that KER and KCP are critical to ICL because ultra-large LLMs cannot be continuously pre-trained or tuned in real-world scenarios to save computational resources. Furthermore, results from Table 1 to Table 3 show that our method has significantly improved classification tasks. We believe that the benefits of injecting knowledge are more pronounced for simple language understanding tasks than for question answering.

4.4 Further Analysis

Effectiveness of KPT. To investigate what makes a high performance for KPT, we test the effectiveness of each knowledgeable self-supervised task. For a fair comparison, we also choose two baselines: 1) **None** is that we do not use any self-

supervised task, which is the same as vanilla ICL proposed in (Brown et al., 2020), 2) **GPT-2** represents conventional autoregressive language modeling (ALM) pre-training tasks. As shown in Table 4, KPT can make substantial improvements for ICL. Particularly, all the self-supervised learning tasks in KPT are complementary for pre-training and outperform the baseline with or without the conventional objective of GPT-2. In addition, the MEP and KQA tasks are most critical for classification and question answering, respectively, which demonstrates that different pre-training objectives possess different advantages in downstream tasks.

Sample Effectiveness. To investigate the influence of the number of in-context examples K, we choose multiple classification and question answering tasks and vary K from 0, 1, 4, 8 to 16. From Figure 5, we find that increasing K generally helps across both classification and question answering tasks, demonstrating that more in-context examples may bring more knowledge to better guide the LLM to make predictions. When $K > 8$, the performance of the most tasks will decrease, because the maximum length limit causes information loss. The suitable value K is set around 8.

Visualization of Selected Examples in KER. In addition, for explicitly seeing the performance in semantic space, we obtain the t-SNE (Van der Maaten and Hinton, 2008) visualization of each training example over AGNews via averaged representations of all corresponding entities. We choose KATE as our strong baseline, which is also focused on the example selection. Here, we do not fine-tune RoBERTa on the training set. Figure 6 demonstrates that our method can build better semantic representations toward factual knowledge.

Permutations of In-Context Examples. We also compare different permutations of these selected

examples according to the sample weight computed in Eq. 4. In Table 5, Random means to randomly choose an order. Ascending and Descending respectively denote that the example order is ascending or descending by weight. From the results, we find no tangible relationship between the sampling weight and order.

Effectiveness of KPC. We finally conduct analysis on prediction calibration. We choose AGNews and TREC tasks and follow the same settings in the preliminary experiments (we randomly choose two label words from different frequency regions). Results in Figure 7 demonstrate that calibrating the prediction consistently achieves improvements to the vanilla approach. In addition, we find that the prediction results highly depend on the label frequency, which is similar to Figure 3. However, our KPC still outperforms the strong baseline Calibrate Before Use (CBU) with arbitrary label frequency, which only transforms the input into content-free prompts. It underscores that the prior information of each label word in KB is non-negligible. In other words, calibration by the prior information can alleviate the impact of label frequency.

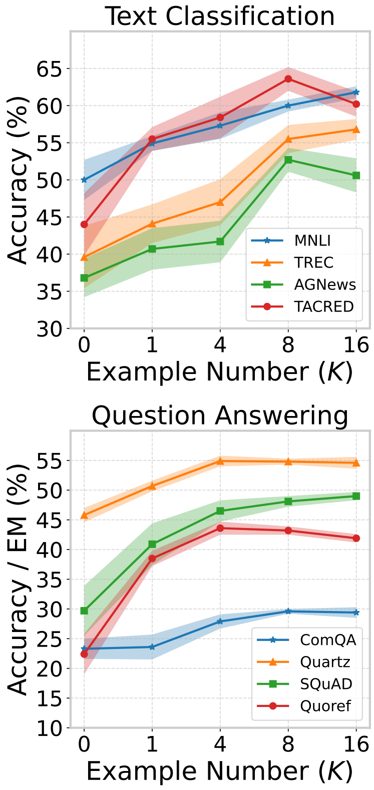

Figure 5: GPT-2 (large) sample effectiveness (%) of KICT (only w. KER) with different values of K.

5 Related Work

5.1 Pre-trained/Large Language Models

Pre-trained Language Models (PLMs) aim to learn representations from texts and have made significant progress in NLP. PLMs can be divided into three main categories: encoder-only (Devlin et al., 2019; Liu et al., 2019; He et al., 2021; Yang et al., 2019; Lan et al., 2020; Zhang et al., 2022b), decoder-only (Radford et al., 2018; Brown et al., 2020; Zhang et al., 2022a), and encoder-decoder (Lewis et al., 2020; Raffel et al., 2020). To incorporate factual knowledge into PLMs, a branch of knowledge-enhanced PLMs has been proposed (Zhang et al., 2019; Sun et al., 2020a; Wang et al., 2021b,a, 2022; Pan et al., 2022; Zhang et al.,

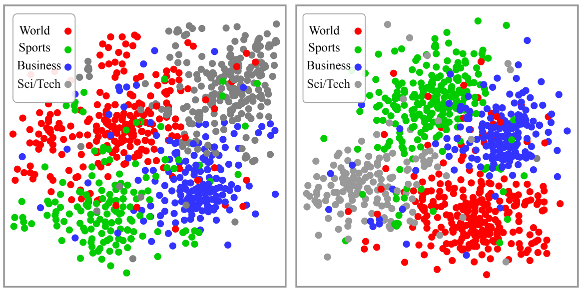

Figure 6: Visualizations of each AGNews's training example. KATE (left) uses CLS embeddings of RoBERTa. Ours (right) utilizes averaged knowledge embeddings.

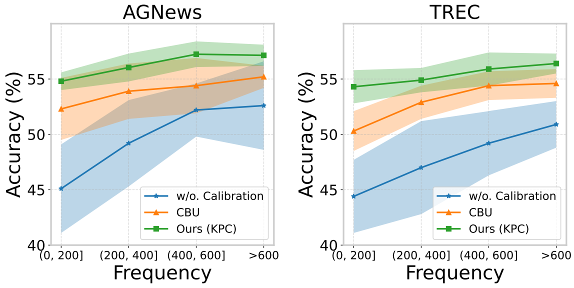

Figure 7: GPT-2 (large) 4-shot performance of calibration over difference word frequencies.

2022c), enabling PLMs to capture rich semantic knowledge from KBs. Since the introduction of ChatGPT, a variety of decoder-only LLMs have been released. Popular open-source LLMs include LLaMA (Touvron et al., 2023), OPT (Zhang et al., 2022a), Galactica (Taylor et al., 2022), Pythia (Biderman et al., 2023), among others. Our work concentrates on decoder-only LLMs and aims to infuse them with factual knowledge to enhance their ICL performance.

5.2 Prompt Learning

Prompt-based learning aims to add natural language prompts to guide PLMs to solve downstream tasks. A series of works focus on tunable discrete prompt tuning (Gao et al., 2021; Raffel et al., 2020) and continuous prompt tuning (Liu et al., 2021b; Gu et al., 2021; Xu et al., 2023). For LLMs, GPT-3 (Brown et al., 2020) enables In-Context Learning (ICL) with a text-based prompt in zero-shot scenarios, bypassing parameter updates (Dong et al., 2023). To explore the factors affecting ICL, previous works have focused on input-output mapping (Min et al., 2022b; Kim et al., 2022), meta-learning (Chen et al., 2022b; Min et al., 2022a), prompt engineering (Liu et al., 2022, 2021a), and prediction calibration (Zhao et al., 2021; Hu et al., 2022), among others. Recently, the Chain-of-Thought (CoT) approach has been presented to leverage reasoning and interpretable information to guide LLMs in generating reliable responses (Si et al., 2022; Zhang et al., 2022d; Wei et al., 2022; Yan et al., 2023). Different from these approaches, we exploit *factual knowledge* to further improve ICL in pre-training, prompting, and prediction phases.

6 Conclusion

In this paper, we investigate and harness *factual knowledge* in ICL, including inherent knowledge embedded in LLMs, pertinent knowledge derived from selected training examples, and knowledge biases affecting predictions. We introduce a novel Knowledgeable In-Context Tuning (**KICT**) framework to further enhance ICL performance by comprehensively exploiting factual knowledge throughout the processes of pre-training, prompting, and prediction. Experiments demonstrate that each introduced technique significantly improves upon strong baselines across classification and question-answering tasks. Future work will focuses on 1) exploring the reasoning capabilities and interpretability of knowledge within ICL, and 2) extending our approach to encoder-decoder models.

Acknowledgements

This work has been supported by the National Natural Science Foundation of China under Grant No. U1911203, Alibaba Group through the Alibaba Innovation Research (AIR) Program, the National Natural Science Foundation of China under Grant No. 61877018, the Research Project of Shanghai Science and Technology Commission (20dz2260300) and The Fundamental Research Funds for the Central Universities.

Limitations

This work presents several limitations: 1) It concentrates on decoder-only LLMs, as traditional in-context learning primarily targets decoder-only generation models such as GPT-2, GPT-3, OPT, etc. Nevertheless, we envision potential extensions to encoder-decoder architectures used in tasks such as translation and conditional generation. 2) Due to computational resource constraints, we do not experiment with ultra-large LLMs exceeding 10 billion parameters. 3) Our investigation centers on factual knowledge in three specific areas: pre-training, prompting, and prediction. We acknowledge that knowledge may influence additional aspects such as reasoning and interpretability, and we intend to explore these in future research.

Ethical Considerations

The contributions of this work are methodological, focusing on a Knowledgeable In-Context Tuning (**KICT**) framework to augment the capabilities of LLMs with factual knowledge. Nonetheless, transformer-based models may perpetuate negative biases, including gender and social biases. As such, these issues are inherent to our work as well. We advise caution and recommend addressing potential risks when **KICT** models are deployed in real-world applications.

A Details of Preliminary Experiments

A.1 Details of Destruction Settings

For our preliminary experiments, we selected 8 classification tasks and 4 question-answering tasks. The specifics of these datasets are detailed in Appendix B. To explore the influence of *factual knowledge*, we posit that entities (and their associated labels in text classification tasks) embody factual knowledge (Wang et al., 2021b, 2022, 2021a; Sun et al., 2019; Zhang et al., 2019). We identify all entities using the open-source TagMe entity linking tool[7] (Ferragina and Scaiella, 2010). In the case of classification tasks, labels are treated as special types of entities. We follow the methodologies of Min et al. (2022b) and Kim et al. (2022) to create various destruction settings that either remove or replace entities (and labels), thereby demonstrating the impact of factual knowledge. Additionally, for each task, we randomly select $K = 8$ examples as in-context examples and concatenate them with each test example to form an input sequence, capped at a maximum sequence length of 256 tokens. With 5 different random seeds (i.e., 12, 24, 42, 90, and 100), each dataset yields 5 unique test results for a given LLM. Consequently, for each LLM, we collate $8 \times 5 = 40$ results for classification and $4 \times 5 = 20$ results for question-answering tasks. The aggregated results are presented in Figure 2, underscoring factual knowledge as a pivotal component in the performance of ICL.

A.2 Details of Frequency Settings

In our preliminary assessment of label word frequency's impact, we focused on two well-established tasks: AGNews and TREC. Selecting $K = 4$ examples from the training corpus to construct the in-context prompt, we then used the remaining training examples as targets to generate predictions. Development or test sets were not utilized due to their insufficient scale for demonstrating frequency effects clearly. During prediction, we recorded the top-4 words with the highest prediction probabilities, facilitating the computation of frequency statistics for each label word. Figure 8 depicts the top-8 label word frequency statistics for each AGNews category. To examine frequency influences, we randomly selected two label words per frequency range (e.g., $(0, 200]$, $(200, 400]$, $(400, 600]$, and > 600) for predictions. For instance, in AGNews, labels like "teams" and "groups" could be chosen from the > 600 frequency region to represent the "sports" category. Accordingly, we generated $2^4 = 16$ and $2^6 = 64$ permutations for AGNews and TREC, respectively. We report the average results using GPT-2 (urge) with 1.5B parameters and present the findings in box plot format in Figure 3.

A.3 Analysis of Knowledge Relevance in In-Context Examples

Our preliminary experiments indicated that factual knowledge in selected in-context examples is crucial for ICL. To substantiate this, we conducted further analyses on two datasets, SST-2 and TREC. Employing our KER technique, we calculated a knowledge relevance score for each training example. For each defined score interval (i.e., $(0, 15]$, $(15, 30]$, $(30, 45]$, $(45, 60]$, $(60, 75]$), we sampled $K = 4$ examples to compose the in-context prompt. We then assessed the average performance across all $4! = 24$ permutations for each interval and visualized the results in Figure 9. The findings corroborated the significance of selecting examples with high knowledge relevance for enhancing ICL performance.

B Details of the Corpus and Downstream Benchmarks

B.1 Corpora and Knowledge Base

We propose knowledgeable pre-training (KPT), which is similar to the current flourishing research

---

[7] https://sobigdata.d4science.org/group/tagme

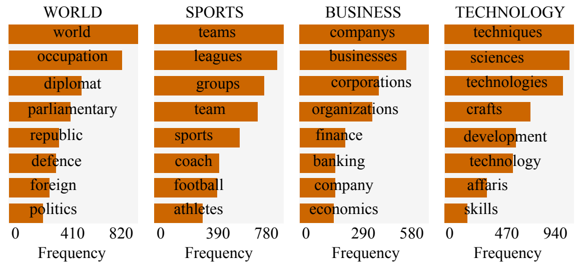

Figure 8: Label word frequency statistics for the AG-News dataset.

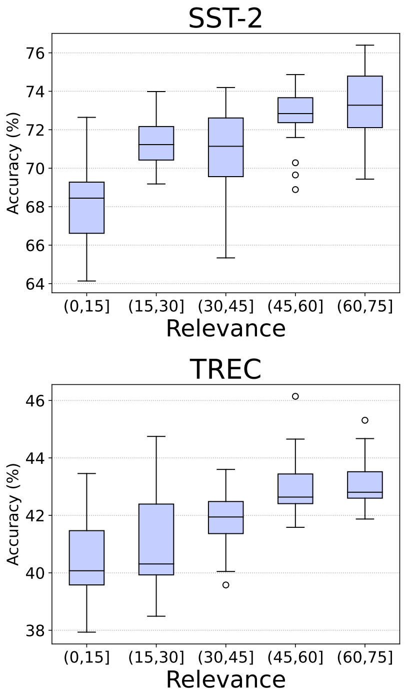

Figure 9: The 4-shot performance (%) with different knowledge relevance over SST-2 and TREC.

of *knowledge-enhanced pre-trained language models* (KEPLMs) (Liu et al., 2020; Sun et al., 2019, 2020b; Wang et al., 2022). Different from them, we focus on auto-regressive PLMs, such as GPT-2. We collect training corpora from Wikipedia (2020/03/01)[8], and use WikiExtractor[9] to process the pre-training data. The knowledge base (KB) $\mathcal{G}$ we choose is WikiData5M (Wang et al., 2021b), which is an urge-large structural data source based on Wikipedia. The entity linking toolkit we used is TagMe. In total, we have 3,085,345 entities and 822 relation types in $\mathcal{G}$, and 25,933,196 training sentences.

As mentioned above, KPT consists of three self-training tasks, i.e., *masked entity prediction*, *entity description generation*, and *knowledgeable question answering*. For each task, we randomly select multiple sentences to form a training instance until reaching the maximum sequence length (i.e., 2048). Finally, we have sampled 100k training instances for each task. In average, we have 8 examples for each instance.

B.2 Downstream Task Datasets

To evaluate the effectiveness of our framework, we choose 8 text classification tasks and 4 question answering tasks. For the text classification, we directly choose 8 tasks from (Gao et al., 2021; Zhao et al., 2021). All the classification tasks involve sentiment analysis, natural language inference (NLI), question classification, and topic classification. For the question answering tasks, we choose four widely used tasks, including CommonsenseQA (ComQA) (Talmor et al., 2019), Quartz (Tafjord et al., 2019), SQuAD (Rajpurkar et al., 2018) and Quoref (Dasigi et al., 2019), where ComQA and Quartz are multi-choice QA, SQuAD and Quoref are extractive QA. The statistics of each dataset are shown in Table 6.

C Implementation Details

C.1 Pre-training Details

In the pre-training stage, we choose different scales of GPT-2 (0.1B, 0.3B, 0.8B, 1.5B) (Brown et al., 2020) and OPT (Zhang et al., 2022a) (2.7B, 6.7B) from HuggingFace[10] as the underlying LLMs. We do not use larger GPT-3 models because of the computation resource limitations. Because all three kinds of pre-training tasks share the same format, we can directly mix up all the pre-training examples to form a cross-task pre-training paradigm. We find that it is suitable for the LLM to learn cross-task knowledge. We train our model by AdamW algorithm with $\beta_1 = 0.9, \beta_2 = 0.98$. The learning rate is set as 1e-5 with a warm-up rate 0.1. We also leverage dropout and regularization strategies to avoid over-fitting. The models are trained on 8 NVIDIA A100-80G GPUs.

C.2 Prompting Details

We describe the implementation details with knowledgeable example retrieval (KER). Given a training

Table 6: The statistics of multiple text classification and question answering datasets. Since the original test data is unavailable, we use the development sets as our test sets.

dataset and a testing set, we aim to choose K examples from the training set which have a high knowledge relevant to all testing examples. To reach this goal, we utilize both Jaccard similarity and Euclidean distance in terms of pre-trained knowledge embeddings. For pre-trained knowledge embeddings, we choose the ConVE (Dettmers et al., 2018) algorithm to pre-train over wikidata5m and obtain the embeddings of entities and relations. We set its dimension as 768, the negative sampling size as 64, the batch size as 128 and the learning rate as 0.001. Finally, we only store the embeddings of all the entities. The KER algorithm for the prompting is shown in Algorithm 1.

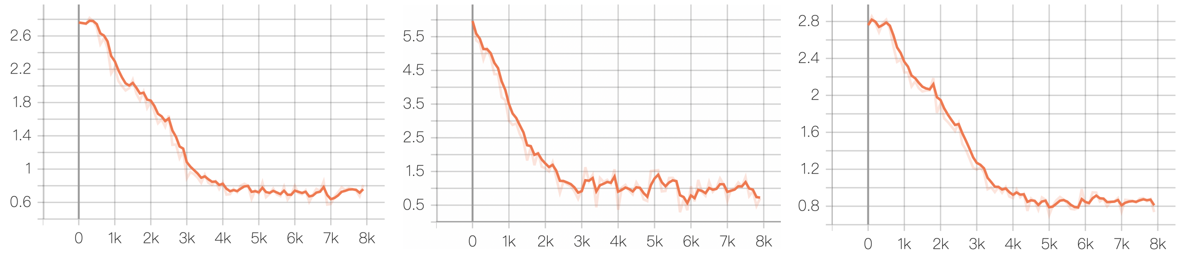
C.3 Prediction Details

We first provide the details of the prompt formats and label mapping rules. Specifically, for the classification task, we need to define a template and label mapping to guide the model to generate results toward pre-defined classes. The prompt formats and label words are shown in Table 8. For the question answering task, we only need to define the template format, shown in Table 9.

During the prediction, we calibrate the prediction probability. We thus provide the implementation details. We obtain a subset of training corpora from the KQA pre-training task, which consists of many question answer pairs. Thus, for each question, we can generate an answer (may be an entity or a label word) at the output position, and obtain the contextualized prior via Eq. 7. The value $P(v)$ means the prior information of the generated entity or label word. Intuitively, if the value $P(v)$ is higher, the entity or label word v is more likely

Algorithm 1 Knowledgeable Example Retrieval

```
Require: Training set $\mathcal{D}_{trn}$, Target (testing) set $\mathcal{D}_{tgt}$, number of in-context examples $K$.
Randomly sampling a subset $\mathcal{D}'_{trn}$ from $\mathcal{D}_{trn}$;
for each target example $(X_j^{tgt}) \in \mathcal{D}_{tgt}$ do
    Extract entities $E_j^{tgt}$ from this target example;
    for each training example $(X_i^{trn}, y_i^{trn}) \in \mathcal{D}'_{trn}$ do
        Extract entities $E_i^{trn}$ from this training example;
        Calculate Jaccard similarity $d_{jac}(i,j)$ and Euclidean distance $d_{sem}(i,j)$;
    end for
    Conditioning on the target example $X_j^{tgt}$, obtain the knowledge relevance score $d(X_i^{trn}, X_j^{tgt})$ for the training example $X_i^{trn}$;
end for
Calculate the final sampling weight $s'(X_i^{trn})$ for each training example $X_i^{trn}$ in Eq. 4;
Sampling $K$ training examples via the weight $s'(X_i^{trn})$;
return The selected $K$ training examples.
```



(a) Masked Entity Prediction (b) Entity Description Generation (c) Knowledge Question Answering

to be generated. We can save these prior values before prediction for downstream tasks. During the prediction, we can use the prior information of each pre-defined label word or entity to calibrate the prediction probability via Eq. 8.

D Analysis of Settings of Model Variants

We conduct some detailed analysis of our proposed technique.

Analysis of Pre-training Efficiency. To show the efficiency of pre-training, we choose GPT-2 (large) draw the pre-training loss for each self-supervised learning task. From Figure 10, we can see that as the training process proceeds, each self-supervised learning task has reached the convergence of the model through the entire pre-training process.

Hyper-parameter	**Value**
Batch Size	{2, 4, 8, 16, 32, 64}
Seed	{12, 24, 42, 90, 100}
K	{0, 1, 4, 8, 16}
α	{0.1, 0.3, 0.5, 0.7, 0.9}
γ	{0.001, 0.01, 0.05, 0.1, 0.5, 1.0}

Table 7: The searching scope for each hyper-parameter.

Effectiveness of Hyper-parameters. In KICT, we investigate the effectiveness of the hyper-parameter α in KER, which aims to balance the relevance scores between Jaccard similarity and Euclidean distance. Results shown in Figure 11 demonstrate that the hyper-parameter α is key to the performance. We can see that the suitable value is around 0.3.

Effectiveness of the Template. We believe that the model performances rely on the format of the template, which has been investigated in (Liu et al., 2022; Min et al., 2022b). We choose some other templates for evaluation. For example, when we change the prefix string (e.g., “Question:”, “Answer:”) to others (e.g., “Q:”, “A:”), the performance improvement of KICT is consistent. In addition, we also find that the text split character “ \n” between each sentence or example is important to support the generation, which is also found in (Dong et al., 2023; Andrew and Gao, 2007; Kim et al., 2022; Si et al., 2022).

Task	Prompt	Label Words
SST-2	Review: This movie is amazing! Sentiment: Positive Review: Horrific movie, don't see it. Sentiment:	Positive, Negative
MRPC	Whether the two questions are similar? Question 1: How much is this book? Question 2: How many books? Output: No Question 1: Do you know the reason? Question 2: What's the reason? Output:	Yes, No
MNLI	Is entailment, neutral, or contradiction between two texts? Text 1: We sought to identify practices within the past 5 years. Text 2: We want to identify practices commonly used by agencies in the last 5 years. Output: entailment Text 1: yeah well you're a student right Text 2: Well you're a mechanics student right? Output:	entailment, neutral, contradiction
QNLI	Whether the answer is entailed to the question? Text 1: In what year did the university first see a drop in applications? Text2: In the early 1950s, student applications declined as a result of increasing crime and $\cdots$ Output: Yes Text1: When did Tesla move to Gospic? Text2: Tesla was the fourth of five children. Output:	Yes, No
RTE	Others argue that Mr. Sharon should have negotiated the Gaza pullout - both to obtain at least some written promises of $\cdots$ Question: Mr. Abbas is a member of the Palestinian family. True or False? Answer: False The program will include Falla's "Night in the Gardens of Spain," Ravel's Piano $\cdots$ Question: Beatrice and Benedict is an overture by Berlioz. True or False? Answer:	True, False
CB	But he ended up eating it himself. I was reluctant to kiss my mother, afraid that somehow her weakness and unhappiness would infect me. $\cdots$ Question: her life and spirit could stimulate her mother. True, False, or Neither? Answer: Neither Valence the void-brain, Valence the virtuous valet. Why couldn't the figger choose his own portion of titanic anatomy to shaft? Did he think he was helping? Question: Valence was helping. True, False, or Neither? Answer:	True, False, Neither
TREC	Classify the questions based on whether their answer type is a Number, Location, Person, Description, Entity, or Abbreviation. Question: How did serfdom develop in and then leave Russia? Answer Type: Description Question: When was Ozzy Osbourne born? Answer Type:	Number, Location, Person, Description, Entity, Abbreviation
AGNews	Article: USATODAY.com - Retail sales bounced back a bit in July, and new claims for jobless benefits fell last week, the government said Thursday, indicating $\cdots$ Answer: Business Article: New hard-drive based devices feature color screens, support for WMP 10. Answer:	World, Sports, Business, Technology

Table 8: The prompts used for text classification. We show one training example per task for illustration purposes. The right column shows the label words (aiming to map the word to the original label class).

Task	Prompt
ComQA	Answer the question through multiple-choice. Question: When people want to watch a new move, the often go see it at the? (A) town (B) conference (C) bathroom (D) theater (E) train station Answer: theater Question: Where is known to always have snow? (A) africa (B) north pole (C) roof (D) canada (E) surface of earth north pole Answer:
Quartz	Answer the question through multiple-choice. Question: Eric pushes an electron closer to the nucleus of an atom. The electron _____ energy.As you go farther from the nucleus of an atom, the electron levels have more and more energy. (A) loses (B) gains Answer: gains Question: When something is very lightweight what does it need to move?Objects with greater mass have greater inertia. (A) more inertia (B) less inertia Answer:
SQuAD	Read the question and find an answer in the context. Question: Where was the first figure skating championship held? Context: The tourism industry began in the early 19th century when foreigners visited the Alps, traveled to the bases of the mountains to enjoy the scenery, and stayed at the spa-resorts. Large hotels were built during the Belle Époque; cog-railways, built early in the 20th century, brought tourists to ever higher elevations, with the Jungfraubahn terminating at the Jungfraujoch, well above the eternal snow-line, after going through a tunnel in Eiger. During this period winter sports were slowly introduced: in 1882 the first figure skating championship was held in St. Moritz, and downhill skiing became a popular sport with English visitors early in the 20th century, as the first ski-lift was installed in 1908 above Grindelwald. Answer: St. Moritz Question: What are some examples of classical violinists from Portugal? Context: In the classical music domain, Portugal is represented by names as the pianists Artur Pizarro, Maria João Pires, Sequeira Costa, the violinists Carlos Damas, Gerardo Ribeiro and in the past by the great cellist Guilhermina Suggia. Notable composers include José Vianna da Motta, Carlos Seixas, João Domingos Bomtempo, João de Sousa Carvalho, Luís de Freitas Branco and his student Joly Braga Santos, Fernando Lopes-Graça, Emmanuel Nunes and Sérgio Azevedo. Similarly, contemporary composers such as Nuno Malo and Miguel d'Oliveira have achieved some international success writing original music for film and television. Answer:
Quoref	Read the question and find an answer in the context. Question: What's the name of the person whose birth causes Sarah to die? Context: Jack and Sarah are expecting a baby together, but a complication during the birth leads to the death of Sarah. Jack, grief-stricken, goes on an alcoholic bender, leaving his daughter to be taken care of by his parents and Sarah's mother, until they decide to take drastic action: they return the baby to Jack whilst he is asleep, leaving him to take care of it. $\cdots$ Answer: Sarah Question: What is the first name of the person the actor believes is a little too odd? Context: When a British secret agent is murdered in the line of duty, agent Karen Bentley inherits the mission from her partner. The mission is to deliver a flight plan for a hundred American bomber planes to a British agent in Chicago. The plans are hidden in a small medallion of a scorpion that Karen wears. $\cdots$ Answer:

Abstract

Large language models (LLMs) are often trained on extensive, temporally indiscriminate text corpora, reflecting the lack of datasets with temporal metadata. This approach is not aligned with the evolving nature of language. Conventional methods for creating temporally adapted language models often depend on further pre-training static models on time-specific data. This paper presents a new approach: a series of point-in-time LLMs called **Ti**me**Ma**chine**GPT** (TiMaGPT), specifically designed to be nonprognosticative. This ensures they remain uninformed about future factual information and linguistic changes. This strategy is beneficial for understanding language evolution and is of critical importance when applying models in dynamic contexts, such as time-series forecasting, where foresight of future information can prove problematic. We provide access to both the models and training datasets.[1]

1 Introduction

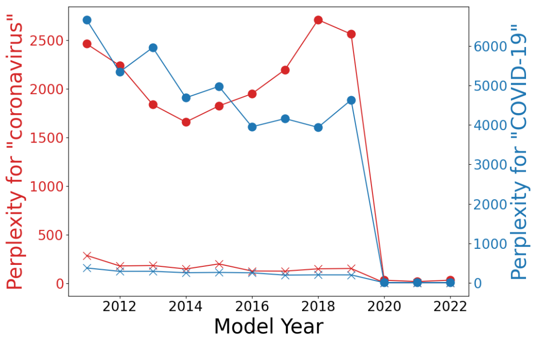

Figure 1: The perplexity of coronavirus and COVID-19, using TiMaGPT models (•) and Conventional Temporally Adapted (CTA) models (×). The calculation for perplexity is outlined in Appendix H and the methodology for temporally adapting models is explained in Section 5. The CTA models have significant knowledge of these words before the pandemic.

Time-series forecasting and event prediction aim to infer a future state of the world from past data. When evaluating models for these purposes through historical data analysis, often referred to as "back-testing", it is crucial to maintain strict data partitioning. This ensures that no future information influences the model's predictions. Whilst strict data partitioning is standard in most fields that use time-series information, time-series forecasting methods that use transformer-based LLMs have tended to make an assumption that the language model itself cannot be the vector for information leakage from a future state to a past state. However, within a language model, implicit associations, such as linking "Enron" with "bankrupt" or possessing knowledge of terms like "COVID-19" might exist (Figure 1). This poses a challenge for models tested on data predating such events, as their presence could lead to an overestimate in model performance within the validation stage, which could lead to disappointing results when a system is used in a live setting.

The evolution of language models in recent years has been shaped by increases in both the size of these models and their training datasets (Wei et al., 2022). The trend towards larger and more complex datasets has made in-depth analysis of their content increasingly difficult. A significant challenge is the contamination of training datasets, which can include the accidental inclusion of benchmark datasets (Dodge et al., 2021) and private data (Xu et al., 2020). To tackle the issue of temporal data contamination, this paper introduces language models that have been pre-trained on data exclusively published before specified cutoff dates. These models serve two key purposes: analyzing diachronic embeddings over time and facilitating the use of language models in dynamic tasks that demand strict separation of temporal data. Language models are capable of learning both factual information

and linguistic patterns (Petroni et al., 2019; Mahowald et al., 2023), which could influence their performance in predictive tasks. The primary application for our TiMaGPT models is in evaluating a system that uses generative language models for dynamic downstream tasks. The yearly models, developed uniformly, display similar performances on well-established benchmarks, meaning that the main difference between the models is the information in the training datasets.

1.1 Research Contributions

Contribution 1 - To our knowledge, the models released in conjunction with this paper are the first series of temporally correct pre-trained LLMs exclusively pre-trained on historical data.

Contribution 2 - Identification of an unacceptable level of foresight in conventional temporally adapted models.

2 Related Work

2.1 Diachronic Embeddings

The meaning of words change subject to the context in which they appear, a fact that initiated the adoption of contextualized embeddings over static embeddings within LLMs (Mikolov et al., 2013a,b; Devlin et al., 2019). This contextual dependency extends beyond the surrounding tokens, as words can change meaning according to the venue (Zeng et al., 2018), domain (Lee et al., 2019a; Yang et al., 2020), time (Pierrehumbert, 2012; Bybee, 2015), location (Dunn, 2023; Hofmann et al., 2023), or task (Gururangan et al., 2020).

Consequently, there has been significant research focused on understanding how embeddings shift through time. Procrustean alignments enabled Kutuzov et al. (2017) to assess the way in which word meaning shifted by diachronically training static embeddings. Some have tried to incorporate these temporal dynamics into LLMs by dynamically adapting word embeddings (Rudolph and Blei, 2017; Hofmann et al., 2021a). Numerous studies have investigated how these embeddings evolve over time (Hamilton et al., 2016; Kutuzov et al., 2018), with practical applications such as detecting change points in language use (Goutte et al., 2018). These studies demonstrate that embeddings can reveal the temporal context of data, underscoring the importance of carefully selecting the data included in training datasets.

2.2 Temporal Adaptation of Language Models

Efforts to temporally adapt language models to date have primarily involved modifying existing statically trained models (Lazaridou et al., 2021; Röttger and Pierrehumbert, 2021; Dhingra et al., 2022). Given that transformer-based LLMs have been predominantly trained since 2017, following the seminal work of Vaswani et al. (2023), and largely on data from post-2017, temporal adaptation has generally involved either further training these models with newer data (Jang et al., 2022) or adjusting them to represent a past state by training on historical data for a fixed number of steps (hereafter "CTA models" - **C**onventional **T**emporally **A**dapted) (Wenjun Qiu and Xu, 2022a; Martinc et al., 2020). Both methods have significant limitations, since either any resultant downstream analysis is limited to the very short time after the models were trained, or the temporally adapted models have seen future data within the pre-training stage. This paper restores language models to a prior state in time by pre-training a series of models on data that has strict temporal inclusion criteria.

3 Training Process

3.1 Training Datasets

The lack of temporal metadata in natural language processing (NLP) presented a challenge in selecting datasets for training our models. However, news data and Wikipedia version history emerged as valuable resources. Detailed token counts for each year's deduplicated datasets are provided in Appendix B. Each year from 2011 to 2022 contained sufficient data to train a GPT-2 small model.

Wikipedia: By utilizing the revision information from Wikipedia XML dumps provided by Wikimedia[2], we reconstructed every existing Wikipedia page as they would have appeared on 31/12 of each year from 2004 to 2023. This reconstruction accounted for changes in page titles. The identified revisions were then processed to remove links, HTML, and other non-standard stylistic elements, using the following code repository [3].

WMT News: The WMT News dataset, typically used in machine translation (Kocmi et al., 2022), was processed in its monolingual, document-split English version. We applied deduplication to this dataset, eliminating repeated articles via an

---

[2] https://dumps.wikimedia.org

[3] http://tinyurl.com/2exawtkf

SHA-256 hashing function (Mou et al., 2023). The dataset ranges from 2007 to 2022.

3.2 Dataset Aggregation

Several studies have demonstrated that the data types used in training an LLM significantly influence its performance in downstream tasks. This insight led to the development of domain-specific language models such as BioBERT (Lee et al., 2019b), SciBERT (Beltagy et al., 2019), FinBERT (Yang et al., 2020), and more recent models like BloombergGPT (Wu et al., 2023). Acknowledging this, we maintained a consistent token allocation from each domain in our annual datasets. This approach ensured that the language models' performance wasn't skewed by shifts in the relative size of different data domains over time. Consequently, the only differences among the various training datasets are the new information and time-specific stylistic changes unique to each period.

3.2.1 Sampling

To maintain a predetermined domain allocation ratio of 0.6:0.4 (WMT News to Wikipedia), a ratio that was determined by model tuning outlined in Appendix F, we employed specific sampling strategies for each dataset.

We randomly sampled Wikipedia articles from each year, ensuring articles were not chosen twice. Additionally, we included the "Vital Level 4" pages – the top 10,000 most important Wikipedia articles [4] – in each training dataset. The Level 4 articles changed slightly over time, so our selection was based on the list available at the end of each year.

For the WMT News dataset, ordered as a text stream, we have included data according to a negative exponential probability function over a 5-year period to prioritize recent data over older data. We first identify the start date of the 5-year window and calculate the number of days from the cutoff date, represented as τ. For each entry e_i with an age of D_i days in the dataset, we compute a weight that is assigned to each entry based on its age, given by:

$$W_i = \exp\left(-\frac{D_{\text{max}} - D_i}{\tau}\right) \tag{1}$$

The probability of selecting each entry, P_i, is inversely proportional to its weight, such that:

$$P_i = \frac{1/W_i}{\sum_{j=1}^{N} \frac{1}{W_j}} \tag{2}$$

where N is the number of entries in the dataset.

In the process of sampling, our goal is to accumulate a certain number of tokens, denoted as T_{needed}. Starting with an initial token count of $T_{\text{current}} = 0$, we repeatedly sample with probability P_i until:

$$T_{\text{current}} \geq T_{\text{needed}} \tag{3}$$

If adding the tokens of a chosen entry does not exceed T_{needed}, we add the entry to the training dataset and update the token count T_{current}.

3.3 Pre-training Details

The full training details for replicating our work are provided in Appendix C. In line with the Chinchilla ratio, which recommends a 1:20 parameter-to-token ratio for efficient training (Hoffmann et al., 2022), a GPT-2 model with 117 million parameters requires 2.34 billion tokens for optimal training. We trained each of our models on 2.5 billion tokens and used a BPE tokenizer as was used in the original GPT-2 paper Radford et al. (2019). To confirm that this amount of data was sufficient, we performed a comparative analysis of models trained with varying token counts, detailed in Appendix B. Considering the numerous models we had to train, we optimized our training framework for computational efficiency. Therefore when two samples could be combined into the 1024 token sequence we concatenated them. A similar methodology only saw a marginal reduction in performance when training RoBERTa (Liu et al., 2019).

4 Model Verification

Verifying that each of our models achieves an adequate level of performance is essential. To conduct meaningful analysis on downstream tasks, it is vital to ensure consistent performance on static benchmarks from models from different years. This consistency means that we can assume that the majority of any observed changes are due to variations in the information within the training datasets, not fluctuations in model efficacy. When selecting candidate benchmarks, we observed that for some newer and more complex benchmarks models of this size have a performance similar to the random baseline. This is due to the rapid progress in language model performance in recent years, and the need to create new benchmarks to match that progress. A more detailed description of the tasks that were included is in Appendix E. Table 3 demonstrates that while our models are far from the state-of-the-art, they

Table 1: Performance of the models on static benchmarks to validate performance. HellaSwag, TruthfulQA, PIQA, Winogrande, WSC (Appendix E). Comparison models: GPT-2 (Radford et al., 2019), OPT (Zhang et al., 2022), GPT-Neo (Black et al., 2021)

perform in line with other similarly-sized models like GPT-2, OPT-125m and GPT-Neo 125m on several established benchmarks but crucially also maintain this performance over time. TiMaGPT has a slightly different performance profile to the comparison models, with better performance on the WSC and TruthfulQA benchmarks and worse performance on the Hellaswag and PIQA datasets. Interestingly, both of the benchmarks that TiMaGPT performed badly on were challenging commonsense reasoning datasets. Perhaps the factual bias and lack of diversity of our training training data led to poor performance on these benchmarks. All of the models perform just slightly above random for the Winogrande benchmark, indicating that this benchmark is too challenging for models of this type and size. The lack of variance of the TiMaGPT results on the WSC benchmark can be attributed to the dataset's size - only 273 samples in total.

5 Temporal Evaluation

Previously, models were adapted by further training a statically trained model on period-specific data (Wenjun Qiu and Xu, 2022b; Dhingra et al., 2022), giving them foresight from the pre-training stage, which could be problematic for tasks where temporal segregation is important. We compared our models with Conventionally Temporally Adapted (CTA) models to show the extent of the information leakage when adopting the traditional methodology, by assessing their perplexity in recognizing the names of country leaders around their inauguration. The perplexity measurement is outlined in Appendix H and the dataset identifies leaders that came into power between 2013 and 2020 (Herre, 2023). 310 leaders are considered, corresponding to 154 countries.

We contrasted our TiMaGPT models with CTA models, which are versions of the TiMaGPT$_{2022}$ model further pre-trained on 1 billion tokens from the same datasets used for pre-training the yearly TiMaGPT models. Figure 2 shows the differences in methodologies, with CTA models retaining un-

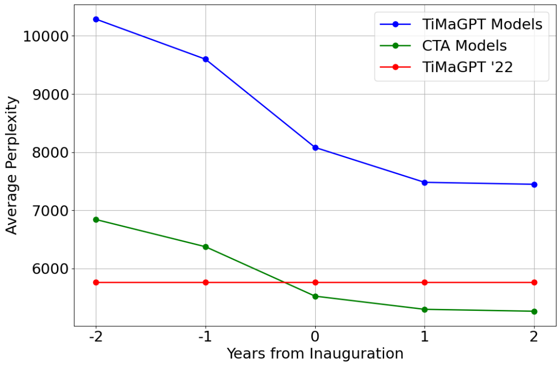

Figure 2: Average perplexity of the names of country leaders around their year of inauguration, as measured using CTA models (Section 2.2) and TiMaGPT models.

realistic knowledge of the leaders well in advance of their inauguration. The lower CTA perplexity scores come from seeing the leaders in the pre-training dataset that trained TiMaGPT$_{2022}$, providing the CTA models with information that would not have been available to models that were trained at the time. The relatively low perplexity from TiMaGPT$_{2022}$ supports this claim. It is clear from the performance delta between the CTA models and the TiMaGPT$_{2022}$ model two years before inauguration that whilst temporal adaptation does shift the model's perplexity distribution closer to that of the TiMaGPT models, some information is preserved post-adaptation.

Beyond named entities, we show that CTA models have an unrealistic knowledge of concepts like "COVID-19" or "coronavirus"; Figure 1 exposes a very significant difference between our models and traditional adaptation methods. The CTA model perplexity scores are lower than our TiMaGPT models, which reflect what could have been produced at the time. The TiMaGPT dataset partitioning means that the information leakage seen in Figure 1 and 2 does not occur.

6 Discussion

This paper provides a tool for researchers focused on tracking knowledge and association shifts in language, and also in evaluating the performance of temporally dynamic models. The recent trend of using GPT-2 as a backbone for time-series forecasting, as highlighted in recent literature (Cao et al., 2023; Chang et al., 2023; Zhou et al., 2023; Liu et al., 2024), underscores the growing interest in integrating language models and textual features to enhance forecast accuracy (Drinkall et al., 2022; Cao et al., 2023). The models developed in conjunction with this paper are particularly valuable in this context. They serve as an effective means to minimize look-ahead bias in time-series models that concurrently process textual and time-series data. By ensuring these models are devoid of future linguistic information, they enable a more accurate and authentic assessment of a model's forecasting ability, crucial for applications where current data must be interpreted without the influence of future events. Further work could explore the magnitude of the effect of this look-ahead bias by measuring the performance delta between models that have and have not seen future information in their pre-training.

7 Limitations

The paper uses the small GPT-2 architecture, which is outperformed by many newer language models. To create larger TiMa models, it is necessary to expand the size and number of datasets with temporal metadata. This expansion is crucial because each parameter in these models requires around 20 tokens for optimal pre-training (Hoffmann et al., 2022). In addition, we have only explored generative models in this paper, but a significant amount of research still relies on encoder-based LLMs which limits the scope of this paper.

To scale to even larger models, processing the annual Common Crawl datasets is a necessary step, though the dataset has proved problematic due to its scale and lack of consistent formatting (Luccioni and Viviano, 2021). These problems prompted the C4 dataset (Dodge et al., 2021), but replicating that consistent quality over several partitioned years would be a significant challenge. Aside from this, cleaning Common Crawl would also demand significant computational resources.

Acknowledgements

We are grateful to Graphcore, and their team, for their support in providing us with compute for this project. The first author was funded by the Economic and Social Research Council of the UK via the Grand Union DTP. This work was supported in part by a grant from the Engineering and Physical Sciences Research Council (EP/T023333/1). A Risks

The risks associated with this paper are not that significant due to the type of data used. The datasets and benchmarks in this paper are all open source. Long-term use of the WMT News datasets minimizes the chance of persisting errors. However, Wikipedia data, editable by anyone, could be less reliable. The selected December 31st revision may have inaccuracies. We haven't taken additional measures to verify the truthfulness of the content. A study by Kräenbring et al. (2014) found Wikipedia's pharmacology information 99.7% accurate, but this may not hold true for other subjects.

B Token counts

The base datasets grow and shrink over time. Our sampling method from Section 3.2.1 means that the domain split of the data stays static across our models. Table 2 tabulates the overall token counts of the cleaned deduplicated datasets from which the training datasets are made.

C Training details

All models are trained on a Graphcore IPU-POD16 using the gpt2-small-ipu config, which employs tensor sharding for efficient distribution across multiple IPUs. We use the AdamW optimizer with $\beta_1 = 0.9$, $\beta_2 = 0.95$, $\epsilon = 10^{-8}$, and a weight decay of 0.1. We adopt a linear warm up from $0.1 * LR_{max}$ to $LR_{max} = 31 * 10^{-5}$ over 10 percent of the training data. The subsequent learning rate was determined by a linear scheduler from LR_{max} to $0.1 * LR_{max}$ over the rest of the training data.

The models were designed with a context span of 1024 and configured to generate sequences of up to 50 tokens. We adopted the GPT2LMHeadModel with the GELU new activation function, comprised of 12 layers and 12 attention heads, and an embedding dimension of 768. A single seed was used to initialise the training of all of the models.

D Wikipedia Processing

In conjunction with this paper, we are releasing the yearly partitions of Wikipedia that were instrumental in creating our training datasets [5]. WikiMedia routinely publishes dumps of Wikipedia, each containing the revision history of articles. With approximately 60 million articles on Wikipedia,

Table 2: Token counts of the base domain datasets after cleaning and deduplication; WMT: the token count of the articles from that year; WMT Cumulative: represents the token count of all WMT articles before each cut-off date; WMT 5-MS: the moving sum of the preceding 5 years of WMT data, which is all the data that we sample from for each year; Wiki: the token count from the whole Wikipedia yearly partition; Wiki Core: the token count of the Level 4 Vital Wikipedia pages.

many having thousands of revisions, processing these revisions demands substantial computational resources. To streamline this process, we first defined the relevant revision before extracting the article information. Specifically, we select the most recent revision as of December 31st for each year. Consequently, some revisions in our datasets, such as those in the 2020 training set, date back to before 2006, as illustrated in Figure 3. While this inclusion of older revisions might initially appear problematic, it is important to note that these are the existing versions of Wikipedia pages as of the cut-off date. The content of these pages was considered current enough at that time, implying that a more recent revision was not necessary. This approach ensures that our training datasets reflect the most up-to-date information available on Wikipedia at each year's end, providing a realistic snapshot of knowledge for that specific point in time.

Once each revision has been identified we clean the page using the code from *wiki-dump-reader* [6], which parses the page and outputs clean text. During the cleaning phase a number of unwanted features and attributes are removed: file links, emphasises, comments, indents, HTML, references etc.

E Benchmarks

HellaSwag (Zellers et al., 2019) (10-shot, acc_norm, 10,042 samples) - a commonsense inference task that has very high human performance (>95%) yet challenges LLMs.

TruthfulQA (Lin et al., 2022) (0-shot, mc2, 817 samples) - a task that measures whether models give truthful answers and do not reproduce human falsehoods.

PIQA (Bisk et al., 2019) (1-shot, acc_norm, 1,838 samples) - a physical commonsense reasoning task designed to test models' knowledge of the real world. This is another dataset that humans find very easy (95% accuracy).

WSC (Levesque et al., 2012) (5-shot, acc, 273 samples) - a binary QA problem that requires world knowledge and reasoning skills.

Winogrande (Sakaguchi et al., 2019) (5-shot, acc, 44,000 samples) - a larger, harder version of the WSC dataset (Levesque et al., 2012).

Table 3: Performance comparison of different models trained, including GPT-2 for reference. Benchmarks: HellaSwag, TruthfulQA, PIQA, and WSC.

F Model Tuning

The following section outlines the process for deciding which assumptions to make and parameters to use in the creation of our training datasets and models. We used the 2020 for the majority of the tuning and tested the tokenizer, dataset size, and data domain split ratio. The tuning was not rigorous since training every configuration of the models would have been computationally prohibitive and unproductive.

F.1 Tokenizer

(Radford et al., 2019) used a BPE tokenizer to originally train GPT-2. However there have been many papers that have shown that BPE is problematic in the way it segments words (Hofmann et al., 2021b). As a result, we tested the BPE tokenizer against a Sentence Piece tokenizer. The search for the optimal tokenizer was far from extensive, but from the two tokenizers BPE performed better so it was selected to train the rest of the models.

F.2 Dataset Size

Although (Hoffmann et al., 2022) showed that the ratio of tokens to parameters should be 20:1 for complete pre-training, we wanted to test the effect of adding more data than the required amount. Therefore we tested the performance of using a 5B and 10B token training dataset and ran the training for 1 epoch. The datasets were constructed in exactly the same way as the 2.5B token dataset and were just sampled for longer until the required token count was met. Table 3 shows clearly that dataset size does not effect the downstream performance on our benchmark datasets.

F.3 Domain Split

We also fine-tuned the proportion of each data domain within the training dataset. Previous research, as noted in Section 3.2, has shown that the type of domain in the training data can influence downstream performance. Therefore, we determined the optimal proportion of each dataset that yielded the best results for both the 2011 and 2020 data. The comparison between two models at different extremes of our time period meant that we could feel more confident that the optimal ratio split was consistent across time. Given that the 0.6:0.4 ratio of WMT to Wiki data was the best performing in 2011 and the second best in 2020 we went with this domain split for all of our models.

G Dataset Histogram

The two base datasets, WMT and Wikipedia, used to create the training dataset used different timestamp formats. For Wikipedia, the most recent revi-

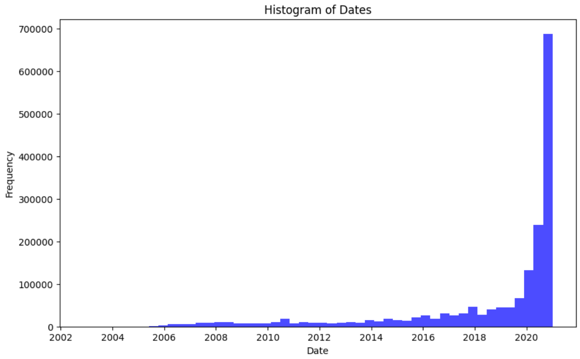

Figure 3: Histogram of the publication of each Wikipedia article revision in the 2020 training dataset.

sion to the cut off date was the version used in creating the yearly datasets. This meant that although Wikipedia was treated as a snapshot in time and was accordingly randomly sampled, some revision versions were older than others. The histogram in Figure 3 outlines the revision publication dates of each of the samples in the 2020 dataset, with the maximum date 2020-12-31. The WMT dataset only exists in yearly buckets, which limits the granularity of the dataset. There is no data used past the cutoff date but the exact distribution across the months and weeks is not possible to know.

H Perplexity Calculation

In our perplexity calculations, we deviate from the conventional methodology of computing perplexity (PPL) of a language model, where some preceding context is usually considered. Instead, we calculate the PPL with zero context.

Formally, the perplexity of a sequence $X = (x_0, x_1, \ldots, x_t)$ without considering any preceding tokens is given by:

$$\text{PPL}(X) = \exp\left\{-\frac{1}{t}\sum_{i=0}^{t}\log p(x_i)\right\} \tag{4}$$

where $p(x_i)$ is the model's estimated probability of the token x_i, independent of any preceding sequence.

This zero-context perplexity enables us to understand the models' comprehension of an individual word, without being biased by the context that precedes it.

To visualise the effect that the training data has on the model, Figure 1 shows the perplexity of the words "COVID-19" and "coronavirus" using the TiMaGPT models. We would expect the model to have no real knowledge of what COVID-19 is before 2020 and then a significant understanding during and after. Figure 1 shows that this is the case for TiMaGPT models, as the models all have very high perplexity before the pandemic and very low perplexity after. This is due to the differences in the training datasets. Figure 4 shows the different exposures the models had to the words "COVID-19" and "coronavirus".

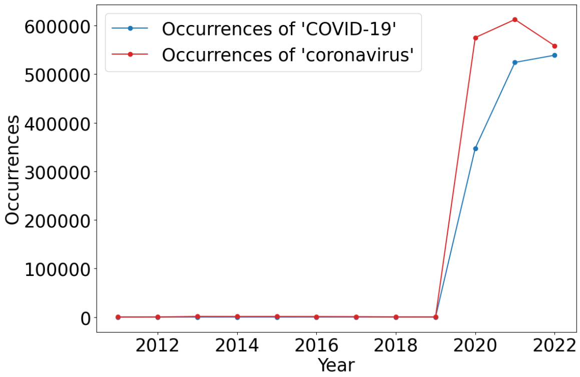

Figure 4: Number of occurrences of the words coronavirus and COVID-19 in the training datasets.

I Licenses

I.1 External Licenses

In the making of our training datasets and training of our models we used data and code that were licensed in ways that might be of interest to the reader. The **Wikipedia** dump data is licensed under a *GNU Free Documentation License (GFDL)* and the *Creative Commons Attribution-Share-Alike 3.0 License*, two very permissive licenses. The **WMT News** data is released under the same terms as the ParaCrawl dataset [7], meaning that WMT claim no ownership over the text and that the packaging of the data is released under a *Creative Commons CC0 Licence*, which means that they do not reserve any rights over the way the data is assembled. There is however some copyrighted material in the dataset, which we use under Fair Use [8] and Fair Dealing [9] principles.

We have also used various software packages when creating these models, which can all be accessed under permissive licenses. The *lm-eval-harness* package, which was used to evaluate the models, is released under an MIT License [10]. The

transformers and *optimum-graphcore* packages, which were used to train the models, are released under and Apache 2.0 License [11] [12].

I.2 Our Licenses

We release our models and datasets in accordance with the licenses of the original works. We do not claim ownership over any of the material used. We license the packaging of the data and models under a Creative Commons CC0 license ("no rights reserved"). The datasets for the models are of academic interest and therefore fall under Fair Use/Dealing principles. However we will comply with any legal requests pertaining to our data if we are legally compelled to do so.

J Emissions

Training models has both computational and environmental implications. The energy consumption of training large language models can be substantial. To quantify this, we calculated the energy consumption of training all of our models and the associated carbon emissions. The computational costs for cleaning the datasets are not considered but are significant: the Wikipedia datasets took several days to extract and clean. The computational costs for evaluation are also not considered but are significant: each model was evaluated extensively.

Our models were trained using a GraphCore Pod with 16 IPU-M2000 chips, which each consumes a maximum of 6kW of power (Graphcore). To train all of the models in this paper the POD-16 was consumed 388.40 kWh.

The IPU POD-16 is situated in Charlotte, North Carolina. Given the carbon emissions from this grid is 328gCO_2eq/kWh [13], the carbon emissions associated with the energy used for a single model training can be deduced:

$$\begin{aligned} \text{Emissions} &= E \times \text{Carbon Intensity} \quad (5) \\ &= 388.40\text{kWh} \times 342\text{gCO}_2\text{eq/kWh} \quad (6) \\ &= 132,832.80\text{gCO}_2\text{eq} \quad (7) \end{aligned}$$

or equivalently, $132.83\text{kgCO}_2\text{eq}$.

Whilst this is significant, the emissions are significantly reduced by the hardware that the models were trained on. The Graphcore POD-16 is very efficient which means that the emissions associated with the training of the models are less than the average transatlantic flight (Mazareanu, 2020).

Abstract

Recent advancements in natural language tasks leverage the emergent In-Context Learning (ICL) ability of pretrained Large Language Models (LLMs). ICL enables LLMs to perform new tasks by utilizing a limited number of input-output examples as prompts. While ICL circumvents the costly step of finetuning LLMs, its effectiveness is heavily dependent on the quality and ordering of provided examples (called exemplars). In this work, we propose a two-stage data-efficient framework *Div-S3* for exemplar selection for ICL. The first stage focuses on data annotation and employs a pool-based active learning approach to select a set of *Div*erse and informative exemplars from the target tasks' unlabeled pool. Given a test input/query, the second stage uses Submodular Span Summarization (*S3*) to select the most relevant and non-redundant exemplars from the annotated pool of a limited budget. On 7 different NLP datasets and 5 LLMs of varying complexities, we show *Div-S3* outperforms (1) existing active learning-based methods for data annotation for ICL and (2) similarity-based methods for test query-specific exemplars retrieval.

1 Introduction

Pretrained large language models (LLMs) (Kenton and Toutanova, 2019; Brown et al., 2020; Chowdhery et al., 2022) have become foundational for a wide range of Natural Language Processing (NLP) tasks, demonstrating impressive success across various domains (Bommasani et al., 2021; Bubeck et al., 2023) through in-context learning (ICL) (Dong et al., 2022). ICL enables these pretrained LLMs to perform new tasks by using task-specific prompts containing a limited number of input-output demonstrations (also referred to as shots, exemplars, or prompts) in the natural language format. This approach facilitates deployment across different downstream tasks and reduces the need for labeled downstream training data since ICL does not require any task-specific training.

The typical ICL procedure consists of two key components: (1) Exemplar annotation and retrieval (Wu et al., 2022; Köksal et al., 2022; Liu et al., 2022): This step involves annotating and retrieving exemplars that serve as context demonstrations. (2) Prompt template crafting (Sorensen et al., 2022; Deng et al., 2022): this step involves designing a prompt template to wrap these demonstrations in a comprehensible and coherent natural language instruction.

Recent studies (Liu et al., 2022; Su et al., 2022; Margatina et al., 2023) show that providing exemplars most relevant to the current input instance is beneficial. Moreover, Zhao et al. (2021), Lu et al. (2022), and Liu et al. (2023) observe that LLMs attend more to the exemplars that are closer in the sequence to the input instance. Therefore, to achieve the best performance of ICL, the selection of exemplars and their ordering in the LLM prompt are crucial.

In practice, an extensive collection of unlabeled exemplars is easily available (e.g., posts and discussions on forums like Stack Exchange or user-generated content on social media platforms), but manually annotating all exemplars would be exceptionally costly. To annotate and select the exemplars optimally for a given target task, we follow the two-stage approach shown in Figure 1: (1) **Exemplar Annotation**: select a subset of exemplars for annotation under a fixed budget (performed only once) and (2) **Exemplar Retrieval**: identify limited-sized exemplars in an ordering that are most influential for a given input instance from the annotated subset of exemplars. Intuitively, for the first stage, we aim to find the subset with maximal diversity and least redundancy so that, given any input, we can find corresponding labeled exemplars. For the second stage, in addition to the diversity requirement similar to the first stage,

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3293–3308
June 16-21, 2024

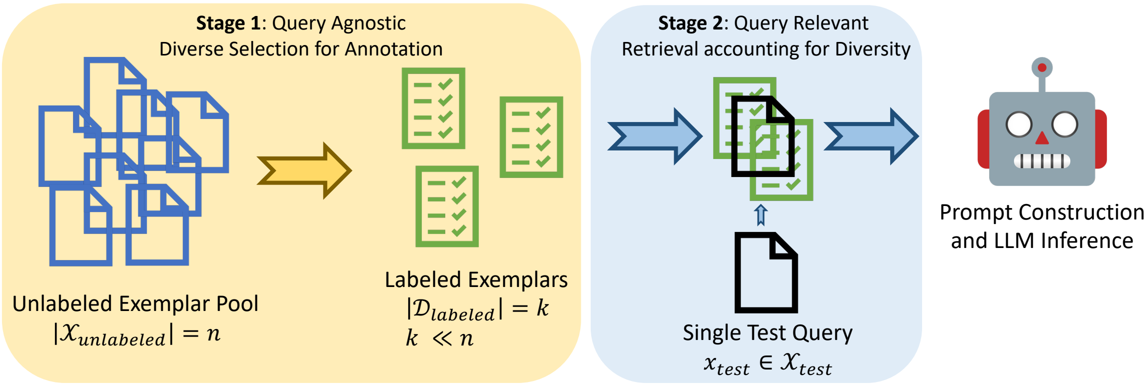

Figure 1: Workflow of our proposed framework for data-efficient In-Context Learning using LLMs. For the first stage, we use cardinality-constrained submodular optimization to identify diverse exemplars for annotation. For the second stage, given a test query, we use Submodular Span Summarization to find a diverse set of labeled exemplars that are most relevant to the query.

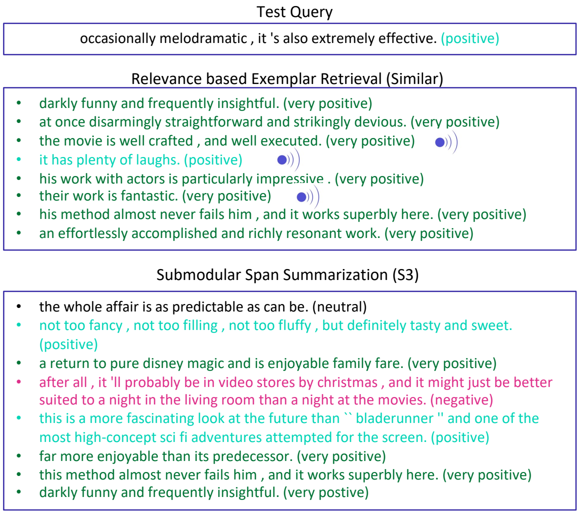
we emphasize the relevance of the exemplars to the given input query and order exemplars so that their relevance to the input query decreases as the exemplars are farther away from the input instance.



Test Query

occasionally melodramatic , it 's also extremely effective. (positive)

Relevance based Exemplar Retrieval (Similar)

- darkly funny and frequently insightful. (very positive)
- at once disarmingly straightforward and strikingly devious. (very positive)
- the movie is well crafted , and well executed. (very positive)
- it has plenty of laughs. (positive)
- his work with actors is particularly impressive . (very positive)
- their work is fantastic. (very positive)
- his method almost never fails him , and it works superbly here. (very positive)
- an effortlessly accomplished and richly resonant work. (very positive)

Submodular Span Summarization (S3)

- the whole affair is as predictable as can be. (neutral)
- not too fancy , not too filling , not too fluffy , but definitely tasty and sweet. (positive)
- a return to pure disney magic and is enjoyable family fare. (very positive)
- after all , it 'll probably be in video stores by christmas , and it might just be better suited to a night in the living room than a night at the movies. (negative)
- this is a more fascinating look at the future than `` bladerunner '' and one of the most high-concept sci fi adventures attempted for the screen. (positive)
- far more enjoyable than its predecessor. (very positive)
- this method almost never fails him , and it works superbly here. (very positive)
- darkly funny and frequently insightful. (very postive)

Figure 2: A sample test query from the SST-5 dataset with its corresponding set of exemplars selected using *Similar* (focusing only on relevance) and *S3* (focusing on both relevance and representativeness) from a limited exemplars pool. Exemplars are colored based on their class names. We use echo lines to denote the redundant exemplars chosen by *Similar* and used as a part of the input context during ICL.

We propose a framework *Div-S3* based on submodular optimization that unifies the above-mentioned two stages. For Exemplar Annotation, we model the problem as a submodular optimization problem under a cardinality constraint to find as **<u>Div</u>**erse a subset as possible within a budget. For Exemplar Retrieval, we formalize the problem as a Submodular Span Summarization (**<u>S3</u>**) problem (Kumari and Bilmes, 2021) with a knapsack constraint, which finds a diverse subset most relevant to the input query under a token length limit. Also, we naturally order the resulting exemplars based on the gains represented by the submodular function. The name of our proposed framework *Div-S3* captures the optimization objectives used for both exemplar annotation (*Div*) and exemplar retrieval (*S3*) stages. In Fig. 2, we show a sample test query where using *Div-S3* for exemplar selection leads to a more diverse and query-relevant exemplar set (more examples provided in Appendix D).

Our framework is general, as any submodular function can be plugged into our method. For models beyond LMs, e.g., for text-image multi-modality models, we may use pre-existing submodular functions that are powerful for expressing diversity in the image domain. In addition, we account for relevance, diversity, and ordering for the exemplar retrieval stage, where one or two aspects typically get overlooked by previous methods. Empirically, we evaluate *Div-S3* on 7 NLP tasks with 5 LLMs and show significantly improved performance compared to baselines. Our contributions are:

1. We propose an end-to-end framework *Div-S3* utilizing submodular optimization for performing data-efficient ICL using LLMs. Depending on budget requirements, *Div-S3* provides the flexibility to set the budget either in terms of the number of exemplars to be used in the prompt or the LLM's context window size.

2. We empirically validate the effectiveness of our framework on 7 different NLP tasks and show the transferability of results across LLMs of varying complexities.

3. We thoroughly analyze each component of *Div-S3* by (a) studying *S3* in a setting with no

annotation budget constraint and (b) analyzing the sensitivity of the exemplars selected by *Div-S3* to their position in the LLM's prompt.

2 Related Work

In this section, we outline recent studies investigating ICL, specifically focusing on works in the context of exemplar annotation selection and retrieval. With the introduction of ICL in the GPT-3 paper (Brown et al., 2020), numerous studies have emerged trying to understand the mechanics of ICL (Xie et al., 2021; Min et al., 2022; Chan et al., 2022; Von Oswald et al., 2023; Wei et al., 2023; Dai et al., 2023; Han et al., 2023; Li et al., 2023) and its inherent strengths and limitations (Webson and Pavlick, 2022; Lu et al., 2023; Jang et al., 2023; Kung and Peng, 2023; Yin et al., 2023).

A recent work by Min et al. (2022) shows that ICL fails to learn label relationships from the in-context exemplars, as its performance diminishes only slightly when substituting the demonstration labels with random labels. However, Kossen et al. (2023) discovers that LLMs indeed utilize the in-context label information, and label relationships learned during the pre-training phase have a more lasting effect than in-context demonstrations. Also, prior works (Zhao et al., 2021; Liu et al., 2022; Lu et al., 2022) have demonstrated the sensitivity of ICL to the choice and order of in-context exemplars in the final LLM prompt. This has prompted investigations into determining which samples should be included in the exemplar pool and how to select exemplars at test time effectively.

2.1 Active Learning for Exemplar Annotation

Recent works such as Su et al. (2022), Zhang et al. (2022b), and Köksal et al. (2022) have explored ICL under a fixed annotation budget. VoteK (Su et al., 2022) uses a combination of graph-based and uncertainty sampling-based approaches to select diverse samples for annotation and relies on the model's confidence for the uncertainty sampling. Furthermore, Zhang et al. (2022b) formulate exemplar selection as an iterative decision problem and propose a reinforcement learning algorithm to train policies for active exemplar selection.

DataModels proposed in Chang and Jia (2023) trains a linear regression model to predict the LLM's outcome given an exemplar and its position in the final prompt. The CondAcc method proposed in the same work scores each exemplar by its dev-set ICL performance when combined with other randomly sampled in-context exemplars. However, both methods require multiple rounds of inference using the target LLM and can be pretty costly in practice. Another recent work (Margatina et al., 2023) highlights that uncertainty sampling for selecting annotated exemplars results in inferior performance. In contrast, similarity-based sampling performs better, albeit with the drawback of increasing the annotation budget, as each test query is considered independently.

To find supporting examples for ICL, Li and Qiu (2023) employs a two-stage framework: (1) a progressive filtering stage, which extracts informative examples via a new metric based on LLMs' feedback, and (2) a diversity-guided beam search method to select the final supporting examples.

2.2 Exemplar Retrieval

This section primarily covers prior works studying exemplar retrieval at test time. In ICL methods that do not involve any fine-tuning, the most explored exemplar retrieval method relies on a simple cosine similarity-based ranking (Rubin et al., 2021; Liu et al., 2022; Su et al., 2022; Margatina et al., 2023; Wu et al., 2023). However, this approach treats each exemplar independently and does not capture their interactions.

Amongst the learning-based methods, Rubin et al. (2021) trains a lightweight retriever model using a contrastive learning objective to score each exemplar independently. CEIL proposed in Ye et al. (2023) similarly trains a retriever by utilizing a DPP to score a subset of exemplars. They show that selecting a set of diverse and non-redundant exemplars is vital for the overall performance of ICL. However, to learn the DPP retriever, CEIL needs to create training data by scoring multiple sets of exemplars formatted in a prompt template using the inference LLM, thus adding to the computational costs besides the costs associated with fine-tuning.

3 Notations & Background

We now outline the notations related to in-context learning using LLMs and provide some background on submodular functions and optimization.

3.1 Notations related to ICL

ICL as a few-shot learning method (Brown et al., 2020) enables LLMs to adapt to new tasks by utilizing only a small number of context demonstration examples. Formally, given an LLM f_θ parameterized by θ, a test query $(x_{\text{test}}, y_{\text{test}})$, and a set of k labeled demonstrations $\mathcal{D}_{\text{context}} = \{(x_i, y_i)\}_{i=1}^{k}$, the probability of generating the target label y_{test} using f_θ is formulated as:

$$p(y_{\text{test}}|c, x_{\text{test}}) = f_\theta(\mathcal{V}(y_{\text{test}})|c, \mathcal{T}(x_{\text{test}}, \cdot)), \quad (1)$$

where $\mathcal{V}(\cdot)$ is a verbalizer that maps the task labels y to words $\mathcal{V}(y)$ in the LLM's vocabulary. $\mathcal{T}(\cdot)$ denotes the process of wrapping up the input using the instruction prompt template. c is the input context formed by concatenating the k in-context demonstrations from $\mathcal{D}_{\text{context}}$, i.e., $c = \mathcal{T}(x_1, y_1) \oplus \mathcal{T}(x_2, y_2) \oplus \ldots \oplus \mathcal{T}(x_k, y_k)$ where $\oplus$ denotes concatenation.

3.2 Background on Submodularity

Submodular optimization has achieved great success in many machine learning tasks of finding diverse subsets, including text, image and video summarization (Lin and Bilmes, 2011, 2012; Gygli et al., 2015; Lavania et al., 2021; Kumari and Bilmes, 2021), feature selection (Liu et al., 2013; Zheng et al., 2014), curriculum learning (Zhou and Bilmes, 2018; Zhou et al., 2020), active learning (Guillory and Bilmes, 2011; Wei et al., 2015), training data selection (Wei et al., 2014), etc.

Submodular functions (Fujishige, 2005) are widely recognized to model notions of diversity, representativeness, and coverage in many applications (Bilmes, 2022). These functions satisfy the diminishing returns property i.e., the incremental benefit of adding a new element decreases as the context size increases. Mathematically, given a ground set V, the submodular function $f : 2^V \rightarrow \mathbb{R}$ must satisfy $f(A \cup \{v\}) - f(A) \geq f(B \cup \{v\}) - f(B)$ for subsets $A \subseteq B \subseteq V$ and any $v \in V \setminus B$. Given a submodular function f that is non-negative $(\forall A \subseteq V, f(A) \geq 0)$ and monotone $(\forall A \subseteq B \subseteq V, f(A) \leq f(B))$, the ground set V can be summarized via submodular maximization under a cardinality constraint, i.e., $\max_{A \subseteq V, |A| \leq k} f(A)$. This can be approximated with a $(1 - \frac{1}{e})$ constant factor guarantee using the greedy algorithm (Nemhauser et al., 1978; Minoux, 1978) described in Appendix A. We assume all submodular functions discussed in this paper are non-negative and monotone.

4 Proposed Framework: Div-S3

Div-S3 addresses two essential questions pertinent to data and label-efficient ICL:

(1) *Given an unlabeled pool of target task samples $\mathcal{X}_{unlabeled}$, how can we identify the most informative set of examples $\mathcal{X}_{labeled}$ to annotate and use as demonstrations for the target tasks' queries?*

This question focuses on the data and label efficiency aspect of ICL using LLMs. Similar to Margatina et al. (2023), this stage of "**Exemplar Annotation**" can be viewed as one iteration of pool-based active learning, aimed at choosing a set of the most informative and diverse demonstrations/exemplars for annotation. After augmenting the samples in $\mathcal{X}_{\text{labeled}}$ with their respective labels, we denote the resultant labeled set as $\mathcal{D}_{\text{labeled}}$.

(2) *Given a query x_{test}, how can we select the most relevant and non-redundant exemplars from $\mathcal{D}_{labeled}$?*

This addresses the "**Exemplar Retrieval**" stage of ICL, where the goal is to retrieve/select the most relevant exemplars from an annotated pool of exemplars given a particular test query.

4.1 Exemplar Annotation

In this stage, we assume access to a large pool of unlabeled samples denoted by $\mathcal{D}_{\text{unlabeled}}$ belonging to the target task. Unlike the similarity-based active learning approach explored in Margatina et al. (2023), we do not assume access to the full test set during the exemplar annotation phase. Performing similarity-based sampling of exemplars for each test query individually would not be an efficient use of labeling resources, as the annotation budget could increase linearly with the number of test queries considered, overlooking the shared information among exemplars.

Given $\mathcal{X}_{\text{unlabeled}}$ of size n, this stage aims to select $\mathcal{X}_{\text{labeled}} \subseteq \mathcal{X}_{\text{unlabeled}}$ such that $|\mathcal{X}_{\text{labeled}}| = k$ and $k << n$. This process is performed only once and can be viewed as one iteration of pool-based active learning (Settles, 2011). As this stage determines the examples utilized as in-context demonstrations in the second stage, we aim to curate a set of diverse and representative samples that can comprehensively cover the target task space. To achieve this, we utilize a submodular function instantiated on the entire ground set $V = \mathcal{X}_{\text{unlabeled}} = \{x_i\}_{i=1}^{n}$.

While our framework applies to any submodular functions, for the experiments in this paper, we use a popular submodular function called *facility location* (Cornuejols et al., 1977; Mirchandani and Francis, 1990), which is closely related to but more general than k-medoid clustering. Given a similarity metric $\text{sim}(\cdot, \cdot)$, the facility location function is defined as follows:

$$f(A) = \sum_{s_i \in V} \max_{s_j \in A} \text{sim}(s_i, s_j) \tag{2}$$

To obtain our $\mathcal{D}_{\text{labeled}}$ set, we first use a pre-trained language model g_θ (sentence-BERT (Reimers and Gurevych, 2019) in this work) to compute text embeddings of each sample in the unlabeled pool such that s_i in Eq. 2 is $g_\theta(x_i)\ \forall\ x_i \in \mathcal{X}_{\text{unlabeled}}$. Using the text embeddings of samples in $\mathcal{X}_{\text{unlabeled}}$, we compute a similarity matrix using a tuned similarity kernel (further discussed in Sec. C), use it to instantiate the facility location function, and then maximize the submodular objective to obtain our final set of demonstrations for annotation as follows:

$$\mathcal{X}_{\text{labeled}} \in \text{argmax}_{A \subseteq \mathcal{X}_{\text{unlabeled}}, |A| \leq k} f(A) \tag{3}$$

4.2 Exemplar Retrieval

After obtaining a set $\mathcal{D}_{\text{labeled}}$ of diverse and representative annotated exemplars, the next step is to select exemplars from $\mathcal{D}_{\text{labeled}}$ given a test query x_{test}. Previous studies in ICL (Rubin et al., 2021; Liu et al., 2022; Su et al., 2022; Margatina et al., 2023) have employed cosine similarity-based ranking to select exemplars that are most similar to the test query. However, when each example's relevance (or similarity) to the test query is considered independently, it may yield relevant but similar exemplars, carrying redundant information that is wasteful for inference.

To reduce the redundancy amongst the selected in-context exemplars, we formalize the exemplar retrieval stage as a conditional submodular subset selection problem. We use the same submodular function utilized in the prior stage for exemplar annotation, but unlike the previous stage, which employs a generic summarization approach as shown in Eq. 3, this stage focuses on conducting query-based (or conditional) summarization, aiming to summarize the labeled set $\mathcal{X}_{\text{labeled}}$ given a query set containing x_{test}. When performing ICL using LLMs, the query x_{test} is the test input instance.

In this work, we utilize a two-phase method named **Submodular Span Summarization (S3)** (Kumari and Bilmes, 2021) to perform query-focused summarization of an annotated pool given a test query. Our objective is to obtain a set of exemplars that are not only relevant to the test query but also encompass diverse aspects crucial for aiding the LLM in the target task.

Phase 1 of S3 targets selecting a relatively large subset relevant to the query set. Mathematically, given a ground set V that includes the query set Q and the data being summarized V_Q (where $V_Q = V \setminus Q$), and a submodular function f defined on the entire ground set V, the submodular span optimization problem is defined as follows:

$$\begin{aligned} &\max_{A \subseteq V_Q} |A| \\ &\text{s.t. } f(A|Q) \leq \epsilon \end{aligned} \tag{4}$$

where $\epsilon \geq 0$ is a small scalar controlling the desired relevance level. $f(A|Q) := f(A \cup Q) - f(Q)$ denotes the conditional gain of set A given the query set Q. Low $f(A|Q)$ represents high conditional redundancy of A given query set Q. Thus, to optimize Eq. 4, we get a set A with a low Q-conditioned f-valuation. The dual to this problem is shown below, where we minimize the conditional gain $f(A|Q)$ subject to a lower-bound cardinality constraint:

$$\begin{aligned} &\min_{A \subseteq V_Q} f(A|Q) \\ &\text{s.t. } |A| \geq k_1 \end{aligned} \tag{5}$$

That is, the above optimization problem is cardinality-constrained submodular minimization, which does not have a constant factor approximation algorithm (Svitkina and Fleischer, 2011). Similar to Kumari and Bilmes (2021), we utilize a modular approximation of $f(A|Q)$, i.e., $m_Q(A) = \sum_{a \in A} f(a|Q)$ to optimize Eq. 5. Note that $m_Q(A) \geq f(A|Q)$ is an upper bound of $f(A|Q)$. Theoretical guarantees based on the curvature of the submodular functions can be found in Kumari and Bilmes (2021).

For the Exemplar Retrieval stage of ICL, the data to be summarized V_Q is the annotated pool of exemplars $\mathcal{X}_{\text{labeled}}$. We denote our solution of S3's Phase 1 as A_Q, essentially the annotated exemplars relevant to the input query Q.

Phase 2 of S3 focuses on diverse aspects of various relevant exemplars, ensuring the final set of exemplars for ICL is both relevant and non-redundant. We summarize the S3 Phase 1 resultant set A_Q by performing submodular maximization subject to a cardinality (or a knapsack) constraint (Eq. 6). In this paper's experiments, we use the same submodular function for the Exemplar Annotation stage and the two phases of S3 for the Exemplar retrieval stage. Our framework is general, and different submodular functions can apply if various diversity properties are desirable.

$$\max_{A \subseteq A_Q, |A| \leq k_2} f(A) \tag{6}$$

Since the final set of exemplars selected will be used as in-context demonstrations, we can also apply a knapsack constraint for the constraint associated with Eq. 6.

$$\max_{A \subseteq A_Q} f(A)$$
$$\text{s.t.} \sum_{a \in A} c(a) \leq b \tag{7}$$

The budget b can be set to the difference between the pre-set context window of the inference LLM and the token length of the formatted test query. The cost $c(a)$ denotes the cost associated with exemplar a that can be set to the token length of the instruction formatted exemplar a, i.e., $\mathcal{T}(x_a, y_a)$. Note that the knapsack constraint generalizes the cardinality constraint: for cardinality constraints, $c(a)$ is simply 1, and the budget is k_2.

To optimize Eq. 7, we use the modified greedy algorithm presented in Lin and Bilmes (2010) with a $(1 - 1/\sqrt{e})$ constant factor approximation factor under certain conditions. The modified greedy at each iteration i selects exemplar s_i with the largest ratio of objective conditional gain to the scaled cost, i.e., $s_i = \text{argmax}_{s \in A_Q} \frac{f(A_{i-1} \cup s) - f(A_{i-1})}{c(s)^r}$ if $\sum_{s \in A_{i-1} \cup s_i} c(s) \leq b$.

We provide a detailed analysis of the computational complexity associated with the two stages of Div-S3 in Appendix B. Since both stages discussed in Sec. 4.1 and 4.2 involve certain hyperparameters such as the similarity kernel, kernel width (in case of using the RBF kernel), the budget of Phase 1 of S3 (k_1), budget associated with Phase 2 of S3 (k_2 when using a cardinality constraint), or the scaling factor (r when using a knapsack constraint), we utilize a separate validation set for hyperparameter tuning(Appendix C). Our approach, thus, needs minimal supervision and is learning-free as it does not involve fine-tuning the inference LLM on any task-specific task.

5 Experiments

To demonstrate the effectiveness of our proposed framework for exemplar annotation and retrieval for performing ICL, we conduct experiments over a diverse set of 7 NLP datasets using a suite of five different LLMs as in-context learners. Since our proposed framework *Div-S3* does not perform any task-specific LLM fine-tuning, we only compare it to existing learning-free ICL methods to ensure a fair comparison.

5.1 Datasets

We evaluate *Div-S3* on the following 7 NLP datasets, which cover five distinct tasks:

SST-5 (Socher et al., 2013): This dataset involves sentiment classification of movie reviews into five distinct sentiment categories: very negative, negative, neutral, positive, and very positive.

SST-2 (Socher et al., 2013): Similar to SST-5, this dataset also deals with sentiment classification into positive and negative labels.

RTE (Bentivogli et al., 2009): The Recognizing Textual Entailment dataset focuses on discerning textual entailment and belongs to a broader scope of tasks studied under Natural Language Inference. Given a pair of sentences, the goal is to determine whether the premise (also called text) entails (or implies) the hypothesis.

MRPC (Dolan and Brockett, 2005): This dataset deals with paraphrase detection task where given a pair of sentences, the objective is to determine whether they are semantically equivalent.

TREC (Li and Roth, 2002): This dataset involves a question classification task. In this work, we focus only on the six coarse labels: Abbreviation, Entity, Description, Human being, Location, and Numeric value.

DBpedia (Lehmann et al., 2015): Here, we have a topic classification dataset constructed by selecting 14 non-overlapping classes from the base DBpedia 2014. The 14 different classes are as follows: company, educational institution, artist, athlete, office holder, means of transportation, building, natural place, village, animal, plant, album, film, and written work.

HellaSwag (Zellers et al., 2019): In this case, we have another NLI dataset studying grounded commonsense reasoning. It consists of multiple-choice questions with four answer choices. Three out of four choices are incorrect and designed in an adversarial way to deceive machines without misleading humans.

We provide the prompt templates used for different datasets in Appendix E and dataset split statistics in Appendix F.

Method	SST-5	SST-2	RTE	TREC	MRPC	HellaSwag	DBPedia	Average
Random-Similar	47.18	88.15	57.40	71.00	63.32	66.09	90.22	69.05

Table 2: ICL performance on four candidate datasets using two *GPT-Neo* models. Our proposed methods are marked with an asterisk (*).

5.2 Models

We evaluated our proposed framework and compared baseline methods for ICL on five LLMs of varying complexity belonging to the GPT (Radford et al., 2019; Brown et al., 2020) and OPT (Zhang et al., 2022a) families. Specifically, the largest model that we used as the inference LLM is GPT-J-6B (Wang and Komatsuzaki, 2021), and from both GPT-Neo (Black et al., 2021) and OPT families, we used their respective 2.7B and 1.3B variants.

5.3 Baselines

We compare *Div-S3* to the learning-free baselines listed below. In all listed methods, the first part of the name preceding the hyphen indicates the strategy used for exemplar annotation (stage 1) while the later part denotes the strategy used for exemplar retrieval (stage 2). The second stage method named "*Similar*" uses cosine similarity-based ranking to extract the most relevant exemplars at test time.

Random-Similar: randomly selects exemplars from the unlabeled pool for annotation and then uses Similar for exemplar retrieval.

Random-S3: randomly selects exemplars during the annotation phase and then uses S3 to select relevant exmplars during the retrieval phase.

VoteK-Similar (Su et al., 2022): uses graph-based method named VoteK to select $k/10$ samples which are diverse in the feature space used. For selecting the remaining $9k/10$ samples, the inference LLM is used to compute the average log probability over the generated output to select diverse exemplars in terms of confidence scores. For the retrieval stage, Similar is used.

Div-Similar (Cornuejols et al., 1977; Mirchandani and Francis, 1990; Balakrishnan et al., 2022): maximizes a submodular facility location objective to select a subset of Diverse and representative samples for annotation. This strategy differs from *Div-S3* where we use Submodular Span Summarization for exemplar retrieval instead of Similar.

Div-MixModSub: uses a facility location-based submodular maximization to select Diverse exemplars for annotation. Similar to Kumari and Bilmes (2021), we consider another baseline named MixModSub, which uses a mixture of a submodular function (facility location) and a modular function (similarity scores) to jointly balance representativeness and query-relevance in the final retrieved set.

We report average performance across three runs for the following baselines: Random-Similar, Random-S3, and VoteK-Similar. Table 8 in the appendix presents the standard deviations for these baselines.

6 Results

We compare *Div-S3* to the baselines discussed in Sec 5.3 in Tables 1, 2, and 3 using GPT-J-6B, GPT-Neo, and OPT models respectively. We fix the

Method	SST-5	SST2	RTE	TREC

Method	SST-5	SST-2	RTE	TREC
Similar	50.95	89.91	54.15	**90.80**
S3 (cardinality)*	50.81	**91.28**	55.96	89.00
S3 (knapsack)*	**52.08**	-	**57.04**	90.00

Table 4: ICL performance on four candidate datasets using GPT-J-6B model in the non-active learning setting where only Stage 2 focusing on exemplar retrieval is active.

annotation budget as 100 i.e., $|\mathcal{D}_{\text{labeled}}| = 100$ for all tasks and methods. For Div-S3 when using a knapsack constraint, the budget (in terms of the token length) is the inference LLM's pre-set context window size minus the formatted test query length. The pre-set context window size is 1,024 for the models we study in this work.

On the SST-5 and RTE datasets, *Div-S3* demonstrates roughly 3% absolute gain compared to the baseline models in terms of accuracy. Across all tasks, we see that *Div-Similar* is a strong baseline that outperforms the other two baselines: *Random-Similar* and *VoteK-Similar*. This indicates that selecting a diverse and representative set of exemplars during the annotation stage is crucial to the overall performance of ICL. Integrating *Div* (Stage 1) with *S3* (Stage 2) results in additional improvements, affirming our hypothesis that the final stage of exemplar retrieval at test time should be treated as a subset selection problem rather than independently selecting exemplars using modular similarity-based values.

When using the smaller LLMs belonging to the GPT-Neo and OPT families on four candidate datasets, we observe that *Div-S3* outperforms other baselines. Notably, across SST-2 and TREC datasets, it achieves a maximum absolute gain of approximately 10% in terms of accuracy. This demonstrates that our proposed framework *Div-S3* exhibits consistent improvements across various tasks and LLM variants.

6.1 Sensitivity Analysis

Non-Active Learning setting: In this section, we verify the effectiveness of the *S3* method for exemplar retrieval in a non-active learning setting where there are no constraints on the annotation budget. Here we consider the entire training set as the annotated pool of exemplars, meaning $|\mathcal{D}_{\text{labeled}}| = n$. This renders the *Exemplar Annotation* stage redundant. In Table 4 and 5 when using GPT-J-6B and OPT models resp., we compare *S3* (when using cardinality and knapsack constraints for phase 2 of S3) to *Similar*. As depicted in Table 4 and 5, *S3* consistently outperforms the modular selection method *Similar*, reinforcing our hypothesis of approaching exemplar retrieval as a subset selection problem.

Order Sensitivity: Prior works such as Zhao et al. (2021) and Lu et al. (2022) have shown that ICL's performance is extremely sensitive to the ordering of the exemplars in the input prompt with performances varying between random-guess levels to fine-tuning based state-of-the-art levels. In this section, our goal is to demonstrate how *Div-S3* is less sensitive to the ordering of the retrieved exemplars in the LLM's input prompt. To do this, we fix the strategy used during the exemplar annotation stage as *Div* and select exemplars from the annotated pool of exemplars using three different methods: *Random, Similar*, and *S3*. Given m selected exemplars, there are overall m possible order permutations. Scoring all m orderings by making inference calls to the LLM would be computationally challenging, so we randomly sample 50 different orderings and score those across different *Stage 2* methods. In Figure 3, we demonstrate the performance variation corresponding to these random orderings on three candidate datasets, and it can be seen that *Div-S3* achieves better average accuracy while being less sensitive to the order of the exemplars compared to other baselines due to its ability to balance relevance and diversity during the exemplar retrieval stage.

Method	SST-5	SST2	RTE	TREC
Similar	45.25	83.94	48.01	79.60

(a) SST-5 dataset

(b) RTE dataset

(c) MRPC dataset

Figure 3: Sensitivity analysis of the set of exemplars retrieved by different *Exemplar Retrieval* methods to their ordering in the LLM's input prompt. The first stage of Exemplar annotation is identical in all four methods studied. When using *Random* as the second stage method, we report the sensitivity results for two different random seeds.

7 Conclusion

We propose *Div-S3*, which unites the two stages of exemplar selection using submodular optimization. For the Exemplar Annotation stage, we select a diverse subset of exemplars for annotation under a fixed budget utilizing submodular maximization under a cardinality constraint. For the Exemplar Retrieval stage, we utilize a Submodular Span Summarization approach that finds diverse annotated exemplars that are most relevant to the test instance. Compared to previous methods on the exemplar selection task, *Div-S3* models both diversity and relevance for the second stage, and incorporates the rich class of submodular functions. On multiple NLP tasks and using various LLMs, *Div-S3* shows consistent improvements. *Div-S3* is also more robust to the ordering of the exemplars empirically as we account for diversity in the exemplar retrieval stage.

8 Ethical Discussion

As a method to facilitate ICL, *Div-S3* is prone to unethical exemplars and harmful annotations. With unethical exemplars collected in the initial unlabeled pool of exemplars, *Div-S3* could select some of them for annotation and use them as context for inference, which may result in unethical generations from the LLM. Moreover, we assume the annotation process is trustworthy, but if biases are present in the labels, the resulting selection process and the inference results could still contain biases. We will research solving the potential ethical issues in future work.

9 Limitations & Future Work

In this study, the largest inference LLM that we use for ICL has 6B parameters. It would be interesting to see how the performance of *Div-S3* transfers to more heavyweight LLMs such as LLaMA-13B, 70B (Touvron et al., 2023), PaLM (Chowdhery et al., 2022), GPT-3.5, 4 (Brown et al., 2020; OpenAI, 2023), etc. The submodular function used during both stages of Div-S3 is a facility location function. Since our framework is general, one can plug in any submodular function such as graph cut function, feature-based submodular function, etc. Defining a mixture of submodular functions to control more fine-grained aspects of relevance along with diversity could be an interesting research direction.

A Maximizing monotone submodular functions

In this section, we provide the outline of the greedy algorithm (Nemhauser et al., 1978) used for maximizing monotone submodular functions subject to a cardinality constraint (Eqs. 3 and 6).

Algorithm 1 Greedy Submodular Maximization (Nemhauser et al., 1978)

```
Input: Polymatroid function $f : 2^V \to \mathbb{R}$, cardinality constraint k
Output: Set $A \subseteq V$ maximizing $f(A)$ under cardinality constraint k
Initialize an empty set $A \leftarrow \emptyset$
for $j = 1$ to $k$ do
    $e \leftarrow \text{argmax}_{v \in V \setminus A}(f(A \cup \{v\}) - f(A))$
    $A \leftarrow A \cup \{e\}$

Test Query

painful to watch , but viewers willing to take a chance will be rewarded with two of the year 's most accomplished and riveting film performances (negative)

Relevance based Exemplar Retrieval (Similar)

- easily one of the best and most exciting movies of the year. (very positive)
- one of the greatest films I've ever seen. (very positive) 🔊
- demonstrates the unusual power of thoughtful , subjective filmmaking. (very positive)
- a well-crafted film that is all the more remarkable because it achieves its emotional power and moments of revelation with restraint and a delicate ambiguity. (positive)
- enjoyably fast-moving , hard-hitting documentary. (very positive)
- unfortunately , the experience of actually watching the movie is less compelling than the circumstances of its making. (very negative)
- the actors are fantastic. (very positive)
- the movie is well crafted , and well executed. (very positive) 🔊

Submodular Span Summarization (S3)

- a well-crafted film that is all the more remarkable because it achieves its emotional power and moments of revelation with restraint and a delicate ambiguity. (positive)
- one of the greatest films I’ve ever seen. (very positive)
- enjoyably fast-moving , hard-hitting documentary. (very positive)
- a gangster movie with the capacity to surprise. (positive)
- this method almost never fails him , and it works superbly here. (very positive)
- his work with actors is particularly impressive. (very positive)
- with a spy kids sequel opening next week , why bother with a contemptible imitator starring a snl has-been acting like an 8-year-old channeling roberto benigni? (negative)
- not that any of us should be complaining when a film clocks in around 90 minutes these days , but the plotting here leaves a lot to be desired. (negative)

Figure 4: Another sample test query from the SST-5 dataset with its corresponding set of exemplars selected using *Similar* and *S3* from a limited exemplars pool. Exemplars are colored based on their class names. We use echo lines to denote the redundant exemplars chosen by *Similar* and used as a part of the input context during ICL.

B Complexity Analysis

Exemplar Annotation To select the set of exemplars to label, we are required to maximize the facility location function using greedy selection. This step requires 1) constructing a pairwise similarity matrix and 2) applying greedy selection. Given $|\mathcal{X}_{\text{unlabeled}}| = n$ and $|\mathcal{X}_{\text{labeled}}| = k$, constructing the pairwise similarity matrix requires $\mathcal{O}(n^2)$ operations while greedy selection requires $\mathcal{O}(nk)$, yielding a final complexity of $\mathcal{O}(n^2 + nk)$. In practice, the quadratic cost of computing the similarity matrix can be reduced by utilizing sparse matrices, while greedy selection can be sped up significantly by using a priority queue (Minoux, 1978). The exemplar annotation cost is incurred only once for each task.

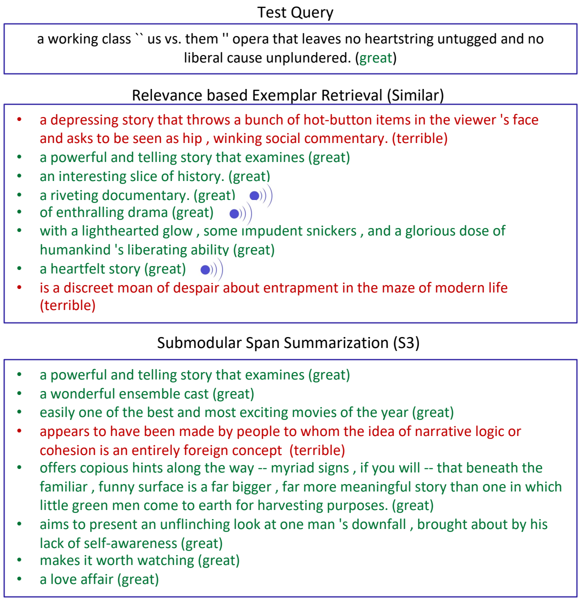
Exemplar Retrieval At inference time, we retrieve exemplars annotated in the first stage that are relevant to a particular query set by using S3. The first phase of S3 requires minimizing a modular function $m_Q(A)$, to select k_1 query-relevant samples from a set of k labeled exemplars. Thus, this phase has a time complexity of $\mathcal{O}(k + k \log k_1)$.

The second phase of S3 summarizes the k_1 samples down to a diverse set of k_2 samples by maximizing a facility location function subject to a knapsack constraint. Similar to the process of examplar annotation, this phase also requires constructing a pairwise similarity matrix ($\mathcal{O}(k_1^2)$, though this can simply be reused from the exemplar annotation phase as we do not alter the similarity metric. Thus, the complexity of this phase is $\mathcal{O}(k_1 k_2)$ which is incurred by performing greedy selection.

In our experiments, we focus on the low-data regime and set the annotation budget, i.e., k, as 100 in the active-learning setting. As can be seen in Sec. C, $k1$ is often less than 30, making the entire process utilizing $S3$ for exemplar retrieval very efficient and significantly faster than the LLM inference call by several orders of magnitude.

C Hyperparameter tuning & Compute resources

Div-S3 involves a set of hyperparameters listed at the end of Sec. 4.1. To tune these hyperparameters, we use the validation set of each dataset. In case the validation set is unavailable, we randomly select 10% of samples from the training set while using the remaining 90% as the unlabeled pool of exemplars. Specifically, for the similarity metric needed to instantiate the facility location function, we compare the following kernels: cosine similarity with negative entries truncated to zero, modified cosine similarity adding a constant 1 to each entry, and RBF kernel with kernel widths $\sigma \in \{0.1, 0.2, 0.5, 1.0, 2.0, 5.0, 10.0\}$. While the hyperparameter search space for the kernel is quite broad, we prune the set of candidate kernels by inspecting the gains of the submodular function when performing greedy maximization as shown in Fig-



Test Query

a working class `` us vs. them '' opera that leaves no heartstring untugged and no liberal cause unplundered. (great)

Relevance based Exemplar Retrieval (Similar)

- a depressing story that throws a bunch of hot-button items in the viewer 's face and asks to be seen as hip , winking social commentary. (terrible)

- a wonderful ensemble cast (great)
- easily one of the best and most exciting movies of the year (great)
- appears to have been made by people to whom the idea of narrative logic or cohesion is an entirely foreign concept (terrible)
- offers copious hints along the way -- myriad signs , if you will -- that beneath the familiar , funny surface is a far bigger , far more meaningful story than one in which little green men come to earth for harvesting purposes. (great)
- aims to present an unflinching look at one man 's downfall , brought about by his lack of self-awareness (great)
- makes it worth watching (great)
- a love affair (great)

Figure 5: A sample test query from the SST-2 dataset with its corresponding set of exemplars selected using *Similar* and *S3* from a limited exemplars pool. Exemplars are colored based on their class names. We use echo lines to denote the redundant exemplars chosen by *Similar* and used as a part of the input context during ICL.

ure 6. Specifically, if a kernel configuration results in the gains diminishing prematurely, then samples chosen towards the later stages of the optimization procedure may be selected randomly. Pruning such kernel configurations is relatively inexpensive, since we do not need to run the end-to-end pipeline to assess their utilities on the downstream task.

The annotation budget (k) for stage 1 is set as 100 for each task and across all LLMs studied. The budget for phase 2 of S3 (k_2) when using a cardinality constraint is roughly determined based on the average number of exemplars l that are selected by *Similar* method on each task. We search for k_2 by using neighboring values of l. To tune the budget (k_1) associated with phase 1 of Stage 2, we search over $k_1 \in \{15, 20, 25, 30, 35, 40, 45, 50\}$. For the scaling factor r when optimizing Phase 2 under a knapsack constraint, we search over $r \in \{0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$. Next, we list the best-found hyperparameters for each task in the given format (similarity kernel, k_1, r): SST-5 - (1+cosine, $40, 0.1$), RTE - (1+cosine, $30, 0.1$), MRPC - (RBF kernel with width 2.0, $15, 0.1$), SST-2 - (RBF kernel with width 5.0, 30, -), TREC - (1+cosine, $30, 0.1$), DBPedia - (1+cosine, $25, 0.4$), HellaSwag - (1+cosine, $25, 0.1$)

For all experiments, we use an A100 80GB GPU.

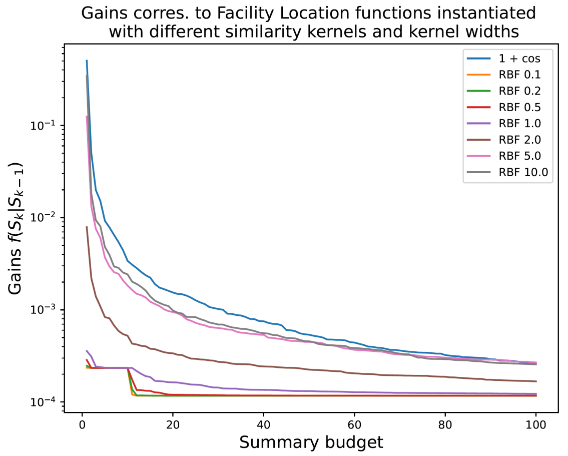

Figure 6: Plot displaying the Submodular Gains on the SST-5 dataset for different similarity kernel configurations. All kernels that use the RBF configuration with kernel width less than 1.0 result in gains that saturate (approach 0) prematurely. Such configurations are not useful for the exemplar annotation task, so they can be discarded by inspection.

D Sample examples of exemplars selected by Div-S3

In this section, we present qualitative results in the form of exemplars obtained by the following Stage 2 strategies: *Similar* and *S3*, demonstrating the effectiveness of optimizing for both diversity and query relevance when retrieving exemplars for ICL. Figure 4 shows exemplars retrieved for a particular test query belonging to the SST-5 dataset (Socher et al., 2013). Figure 5 shows exemplars retrieved for a particular test query belonging to the SST-2 dataset (Socher et al., 2013).

Dataset	Size of train set	Size of validation set	Size of test set

Abstract

This paper explores cost-efficient methods to adapt pretrained Large Language Models (LLMs) to new lower-resource languages, with a specific focus on Estonian. Leveraging the Llama 2 model, we investigate the impact of combining cross-lingual instruction-tuning with additional monolingual pretraining. Our results demonstrate that even a relatively small amount of additional monolingual pretraining followed by cross-lingual instruction-tuning significantly enhances results on Estonian. Furthermore, we showcase cross-lingual knowledge transfer from high-quality English instructions to Estonian, resulting in improvements in commonsense reasoning and multi-turn conversation capabilities. Our best model, named LLAMMAS, represents the first open-source instruction-following LLM for Estonian. Additionally, we publish Alpaca-est, the first general task instruction dataset for Estonia. These contributions mark the initial progress in the direction of developing open-source LLMs for Estonian.

1 Introduction

Instruction-tuning is a method for aligning large language models (LLMs) with human preferences (Ouyang et al., 2022; Mishra et al., 2022; Wei et al., 2021). However, the majority of instruction-tuning datasets and advancements focus on English. Moreover, to benefit from instruction tuning, a strong foundation model is needed but due to the extensive training training data required, such models are available only for a few languages.

To overcome the lack of a strong foundation model in the target language, one could try to elicit non-English abilities from English-centric LLMs through cross-lingual instruction-tuning. In this setup, instructions are given in both English and the target language, often including a translation task to directly stimulate the alignment (Ranaldi et al., 2023; Ranaldi and Pucci, 2023; Zhu et al., 2023). While empirical evidence indicates benefits from incorporating translation-following demonstrations into the training dataset, the best training strategy and its effectiveness with monolingual pretraining remain unclear.

In this paper, we investigate these aspects in the context of creating an instruction-following model for Estonian. We focus on a low-resource scenario where only a relatively small amount of monolingual data is available. By utilizing a novel general task instruction dataset, Alpaca-est, we examine the impact of combining monolingual pretraining with cross-lingual instruction-tuning using both general and translation task instructions. Our experiments with Llama 2 (Touvron et al., 2023b) demonstrate the benefits of translation task instructions when no monolingual data is available for additional pretraining. However, monolingual pretraining greatly diminishes the importance of the translation task.

Furthermore, we showcase that supplementing our instruction-tuning dataset consisting of Alpaca (Taori et al., 2023) and Alpaca-est with high-quality English instructions and English conversations further enhances results on Estonian through cross-lingual knowledge transfer. This is reflected in improved commonsense reasoning and the ability to engage in multi-turn conversations despite no Estonian conversations used during training. As a result, we present LLAMMAS - the first open-source instruction-following conversational LLM for Estonian that achieves competitive zero-shot performance on multiple tasks.

2 Related Work

2.1 Instruction Tuning

Instruction-tuning is a method for guiding pre-trained LLMs to follow natural language instructions (Ouyang et al., 2022; Mishra et al., 2022; Wei

---

[*] Equal contribution

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3309–3325

et al., 2021; Sanh et al., 2021; Chung et al., 2022; Wang et al., 2022b). For that purpose, both human-written and synthetic instructions generated with LLMs have been shown to work remarkably well (Wang et al., 2022b, 2023b). One of the prerequisites for instruction-tuning is the availability of a strong pretrained language model, which due to high training costs is the major limiting factor for many to contribute to the development of LLMs. Fortunately, over the last year, a few foundation models (Workshop et al., 2022; Touvron et al., 2023a,b; Jiang et al., 2023) have been publicly released which somewhat mitigates the issue. However, the models are mostly trained on English and perform poorly on other languages.

A common method of acquiring instruction data is using strong proprietary models such as GPT-4 for generating instructions (Taori et al., 2023; Chiang et al., 2023; Wang et al., 2022a). However, Gudibande et al. (2023) have shown that models trained on these generated datasets learn to imitate the style of strong LLMs but not necessarily the factuality.

2.2 Cross-lingual Instruction Tuning

Cross-lingual instruction tuning is a training method where the model is simultaneously instruction-tuned on instructions in multiple languages. Its goal is to strengthen cross-lingual semantic alignment in LLMs to make them understand and generate texts in a selected target language. In practice, it is one of the most cost-efficient ways to create instruction-following models for languages where data-heavy pretraining is not possible.

The approach has been explored, for example, by Zhu et al. (2023) and Ranaldi et al. (2023) who both use original and translated versions of Alpaca (Taori et al., 2023) dataset. Moreover, they both report additional benefits from supplementing the general task instruction datasets with translation task instructions. However, their approaches differ in the size of translation datasets. Zhu et al. (2023) use datasets that sometimes contain around 10 times more translation task instructions than general task instructions. Ranaldi et al. (2023) employ a translation task instruction dataset that contains only 20K instructions. Additionally, while Zhu et al. (2023) report benefits from using English to target language translations, Ranaldi et al. (2023) demonstrated that using both translation directions together is better than translating to only one direction. Zhang et al. (2023a) propose to combine the task of strengthening cross-lingual semantic alignment and instruction-tuning via a multi-turn translation task. Zhang et al. (2023b) utilize the capabilities of LLMs to comprehend and execute instructions in a high-resource language by using that high-resource language as a pivot language during response generation for the target language.

2.3 Monolingual Continued Pretraining

Another way to improve the ability of English-centric pretrained LLMs to understand and generate content in a target language is via continued pretraining on data in the target language. For example, Cui et al. (2023) continue pretraining LLaMA family models on a large-scale monolingual Chinese corpus before the instruction-tuning. Xu et al. (2023) show that continued pretraining with even a relatively small monolingual dataset can significantly improve the results of the translation instruction task. Moreover, they show that after continued pretraining only a small amount of high-quality parallel data is required to reach competent translation.

2.4 Multilingual Models

To create models that can follow instructions across diverse languages, multilingual pretraining can be combined with multilingual instruction tuning. For instance, Wei et al. (2023) pretrain a multilingual language model and then employ multilingual general task instructions generated through a self-instruct paradigm (Wang et al., 2022a).

Yong et al. (2023) investigate strategies for adapting the multilingual language model BLOOM to new languages under resource-constrained settings. They find that adapter-based fine-tuning proves to be more effective than continued pretraining. Moreover, they demonstrate the advantages of multilingual instruction tuning over target language instruction tuning. Lin et al. (2024) continue pretraining Llama-2-7B with low-rank adaptation (Hu et al., 2022) to develop a multilingual language model capable of encompassing 534 languages, including Estonian.

3 Training Data

3.1 General Task Instructions

3.1.1 Alpacas

We combine the original Stanford Alpaca dataset (Taori et al., 2023) with an Estonian version of it which we create by ourselves. We refer to the combination of these two datasets as **Alpacas**.

Stanford Alpaca (Taori et al., 2023) A general task instruction dataset generated with Self-Instruct framework (Wang et al., 2023b). In our experiments we use the cleaned version[1] that consists of filtered Alpaca (Taori et al., 2023) instructions and GPT-4-LLM (Peng et al., 2023).

Alpaca-est Due to a lack of general task instruction data in Estonian, we generate an Estonian version of Alpaca. Following Taori et al. (2023), we first randomly sample from a set of Estonian seed instructions and use an LLM to generate new instructions based on the examples. Using `gpt-3.5-turbo-0613`[2], we generate a total of 52,006 instructions for Estonian. The seed instruction set consists of 90 translated examples from the original Alpaca seed set and 17 new instructions written by the authors. We make Alpaca-est publicly available[3].

3.1.2 High-Quality General Task Instructions

We supplement Alpacas with high-quality English instructions that are not obtained with synthetic data generation using OpenAI models. In our dataset creation, we take inspiration from Wang et al. (2023a); Ivison et al. (2023). We use Open Assistant 1 (Köpf et al., 2023) multi-turn conversations, taking the top-scoring English-only path from each conversation tree. We also take 10,000 examples of both Chain-of-Thought and FLAN-2 mixtures (Chung et al., 2022; Longpre et al., 2023) used in Ivison et al. (2023). We refer to this high-quality mixture of data in short as **HQI**.

3.2 Translation Task Instructions

We create translation task instructions from relatively low-quality translation bitexts: CCMatrix (Schwenk et al., 2021b), WikiMatrix (Schwenk et al., 2021a), OpenSubtitles (Lison and Tiedemann, 2016), and Europarl (Tiedemann, 2012). We filter the data with OpusFilter (Aulamo et al., 2020) using long word, sentence length, source-target length-ratio, character score, language-ID, terminal punctuation, and non-zero numerals filters.

We use a setup in which 75% of instructions prompt translation from English to Estonian, and 25% prompt translation in the opposite direction. The goal of including a small amount of Estonian-English is to maintain the quality of English generation. We refer to this translation task instructions dataset as **TRTASK**.

We supplement the relatively low-quality **TRTASK** dataset with high-quality parallel data from WMT18 dev set (Bojar et al., 2018) and MTee (Tättar et al., 2022) held-out validation dataset. We refer to it as **HQTRTASK**. In **HQTRTASK** WMT18 dev set is given in a document-level format with documents exceeding 900 tokens split into multiple parts. To convert the translation examples to instructions we utilize 32 English and 13 Estonian prompt templates as Sanh et al. (2021) has demonstrated the importance of using a diverse set of prompts.

3.3 Pretraining Data

For pretraining, we use a subset of Estonian and English data from CulturaX (Nguyen et al., 2023) to make the base model more familiar with Estonian but not forget English. Although the data in CulturaX has already gone through an extensive cleaning pipeline, we expand it by only allowing Estonian data that comes from websites ending with either .ee, .org, or .net. The pretraining is done with up to 5B tokens. We sample the data so that 75% of CulturaX training documents are in Estonian while the rest are in English, to prevent English knowledge forgetting.

4 Experimental Setup

4.1 Base Model

To obtain the base model, we continue pretraining Llama-2-7B (Touvron et al., 2023b) with the additional 5B tokens of pretraining data described in Section 3.3. We call the base model LLAMMAS-BASE. We use packing for pretraining which means that the training examples are concatenated to fill the model context. The training setup and parameters are outlined in Appendix A. We publish our training code[4].

4.2 Instruction-tuned Models

Models instruction-tuned only with Alpacas or translation task instructions use the Alpaca prompting format (Taori et al., 2023). The models relying on high-quality instructions (**HQI** or **HQTRTASK**) are trained as conversational models with conver-

sation format following Wang et al. (2023a, see Table 5).

During the training, we calculate the loss only on responses, ignoring user input (including multi-turn) and instructions. The models are trained for 3 epochs. We picked the best checkpoint according to the validation loss, which was always the first checkpoint (trained for 1 epoch) in our experiments. See Appendix A for other training details.

4.3 Evaluation Datasets

Following Ranaldi et al. (2023); Zhu et al. (2023), we use EstQA (Käver, 2021), an Estonian version of SQUAD (Rajpurkar et al., 2016) as one of the evaluation datasets. Since the original EstQA does not include a validation split, we create one ourselves by separating a small subset of training data for that purpose.

We also evaluate our models on Estonian commonsense reasoning (CSR) and grammatical error correction (GEC) tasks. For commonsense reasoning, we use EstCOPA (Kuulmets et al., 2022), which is an Estonian version of the COPA task (Roemmele et al., 2011). EstCOPA includes both machine-translated and manually post-edited versions of COPA. We use the latter for our evaluations. Grammatical error correction is evaluated with EstGEC-L2 dataset[5].

Finally, results for English-Estonian and Estonian-English translation (MT) tasks are reported using FLORES-200 devtest (NLLB Team, 2022). It is important to note that, depending on the model, the translation task may be included into the training process, while the models are never exposed to any other evaluation tasks.

4.4 Perfomance on English

Ideally, our model should also perform reasonably well in English. If that was not the case it would mean that we might have washed out the pre-existing knowledge from the models. That could happen, for example, with overly extensive training on task-specific datasets. Naturally, it would be an indication that the model is not using its knowledge in English to generate answers in Estonian. To verify that our models can still understand English, we evaluate our best models on COPA, on an English subset of XQuAD (Artetxe et al., 2020), and an English grammatical error correction task using the W&I+LOCNESS test set (Bryant et al., 2019).

4.5 Evaluation Metrics

To evaluate commonsense reasoning and question-answering we use the assessments of GPT-4 Turbo[2]. More precisely, we employ LLM-as-a-Judge (Zheng et al., 2023) with reference-guided grading where the model is asked to assess the correctness of the predicted answer given the reference answer and the task itself. We modified the evaluation prompt from Zheng et al. (2023) to align with our tasks. We chose GPT-4 Turbo as the evaluator over ChatGPT[2] to ensure the reliability of the results, as it demonstrated a significant improvement in assessment quality (specifically, a reduction in false positives) in our preliminary experiments. To reduce API usage costs, we base our QA accuracy report on 100 randomly chosen samples from the corresponding datasets and splits. When evaluating the commonsense reasoning task, we feed to GPT-4 Turbo only answers that we were not able to classify with a simple string comparison.

Table 1: Results on Estonian tasks after fine-tuning LLAMMAS-BASE on different cross-lingual instruction datasets. We call **(4)** LLAMMAS and **(5)** LLAMMAS-MT.

We also report standard metrics for most of the tasks. For question answering and grammatical error correction we report F1 and M2 scorer[6] (Dahlmeier and Ng, 2012) or ERRANT (Bryant et al., 2017) F0.5, respectively. For translation tasks we calculate BLEU[7] (Papineni et al., 2002) and chrF++[8] (Popović, 2017) using sacreBLEU (Post, 2018), and COMET (Rei et al., 2020) scores using the `unbabel-wmt22-comet-da` model (Rei et al., 2022).

4.6 Evaluation Prompts

During the development phase, the performance on EstCOPA, EstQA, and their English equivalents is measured with 8 different prompts. The English prompts are from Wei et al. (2021), while prompts for Estonian tasks are written by the authors. On development datasets, we report the best score across the 8 prompts, while on test datasets, we only report the scores obtained with the best prompt according to the development datasets. For machine translation and grammatical error correction tasks, we use the same single prompt during the development and test phases (see Table 7).

5 Experiments and Results

Our experiments are divided into two main sections. In the first section, we pretrain Llama-2-7B on different amounts of pretraining data and investigate the effect of it on cross-lingual instruction-tuning that is done with translation task and general task instructions (Alpacas).

In the second section, we study the influence of supplementing Alpacas with high-quality English instructions, translations, and conversations to the results on Estonian.

5.1 Continued Pretraining of Llama 2

We compare three base models. First, Llama-2-7B without any additional pretraining. Second, the checkpoint of LLAMMAS-BASE that has seen 1B tokens of pretraining data. Third, LLAMMAS-BASE trained on the entire pretraining dataset of 5B tokens. We instruction-tune all three models on Alpacas that consisting of Estonian and English general task instructions. The results of the three models are compared in Figure 1. We observe performance gains on all Estonian tasks as the size of the pretraining dataset increases.

In our preliminary experiment (included into the ablation study, Section 6.1) we observed that after additional pretraining of Llama-2-7B with 1B tokens the benefits of using translation task during fine-tuning diminished. To assess whether this trend persists with even larger pretraining, we instruction-tune the base models with a dataset that consists of both translation and general task instructions, i.e., **TRTASK** and Alpacas. We adopt sequential training based on our preliminary experiment (Section 6.1), which indicated that this setup has a milder negative impact on performance in zero-shot tasks.

Figure 2 shows the performance gained or lost for each task and base model with the translation task used as the first step during instruction-tuning. We can see that without additional pretraining, the translation task significantly improves the results for QA, machine translation, and GEC. However,

Table 3: GEC scores on EstGEC-L2 and W&I+LOCNESS test sets.

the benefit diminishes greatly when the pretraining step is introduced. For QA and commonsense reasoning, omitting the translation task after pretraining tends to produce stronger results compared to models where pretraining is followed by the translation task.

5.2 Beyond Alpacas: Knowledge Transfer via High-Quality English Instructions

Instruction-tuning datasets generated with Self-Instruct (Wang et al., 2023b) might suffer from various issues that lower the overall quality of the dataset[1]. Meanwhile, it has been shown that it is possible to achieve remarkably strong performance with just 1,000 high-quality training examples (Zhou et al., 2023). In light of this, we hypothesize that supplementing the Alpacas dataset with a set of high-quality instructions could improve the models. However, as there are no high-quality instruction datasets available for Estonian, we use only high-quality English instructions (**HQI**). For comparison, we train a model where high-quality English instructions are supplemented with high-quality translation task instructions (**HQTRTASK**).

The results are shown in Table 1. Compared to the baseline model (1) that is trained on just Alpacas, we observe a somewhat surprising increase in all scores when Alpacas is supplemented with high-quality English instructions (model (3)). This suggests that there is a positive cross-lingual knowledge transfer from the added high-quality English instructions into Estonian. Moreover, combining high-quality English instructions with high-quality translation tasks further enhances the knowledge transfer (model (4)). We call this model LLAMMAS. However, we observe that the best results for EN→ET, ET→EN, and GEC are obtained with a model that is trained sequentially, with HQTRTASK as the first step of fine-tuning (model (5)). We call this model LLAMMAS-MT.

Models (3) – (5) are trained with the data in chat format (see Table 5), since HQI contains English conversational data from Open Assistant 1. Through manual evaluation with 5 conversations (up to 6 turns), we determine that model (4) (LLAMMAS) can adequately engage in multi-turn conversations. It can recall content from previous turns and respond to user requests fairly well. However, we also see that the model sometimes makes grammatical mistakes and uses words or phrases that a native Estonian speaker would not use. Many of these phrases sound like translations from English. An example conversation can be seen in Table 12. The model's conversational ability suggests that the model has learned to hold a multi-turn conversation in Estonian through cross-lingual transfer, however, more experiments would be needed to confirm that.

5.3 Results on Translation Task

Conventional neural machine translation (NMT) models leverage tens of millions of parallel sentences along with the use of monolingual corpora. In contrast, LLAMMAS-MT uses a modest 1 million sentence pairs from relatively low-quality parallel data sources and a small number of sentences from high-quality sources. In combination with general task instructions, this results in a competitive translation model, as presented in Table 2. We can see that LLAMMAS-MT outperforms LLAMMAS although, in terms of COMET, which is more highly correlated with human judgments (Freitag et al., 2022), LLAMMAS still seems competitive.

When comparing LLAMAS-TRANSLATE to the open-source encoder-decoder models MTee and NLLB-MoE, LLAMAS-TRANSLATE achieves better scores on COMET and similar scores on BLEU and chrF++. On ET→EN LLAMMAS-MT is outperformed by NLLB-MoE, however, it outperforms MTee on COMET and achieves a similar score in chrF++. We can also see that LLAMMAS-MT is competitive with GPT-3.5-turbo, however it is outperformed by GPT-4-turbo (for used prompt, see Figure 6).

5.4 Results on Grammatical Error Correction

LLMs are good at text correction, yet they frequently make extensive edits that diverge from traditional GEC metrics, known for preferring minimal modifications (Coyne et al., 2023). This tendency is apparent in English, where the models exhibit higher recall than precision (see Table 3). For Estonian, in contrast, the models show higher precision but reduced recall, indicating a different correction pattern from Estonian. We leave further exploration of that phenomenon for future work. Finally, we can see that translation task instructions (TRTASK, used for training LLAMMAS-MT) enhance performance in Estonian which is in accordance with our earlier experiments.

5.5 Results on XQUAD and COPA

The results on English QA and commonsense reasoning tasks are shown in Table 5. On the QA task, LLAMMAS achieves similar accuracy in English and Estonian (83% vs 84%). However, we observed that LLAMMAS is more chatty in English, resulting in longer answers and therefore lower F1 score when compared to Estonian. Finally, we observe that LLAMMAS solves commonsense reasoning problems significantly better in English than in Estonian (80.6% vs 66.4%) This indicates that LLAMMAS is still not able to utilize all the reasoning capabilities it has in English when the input is given in Estonian.[9]

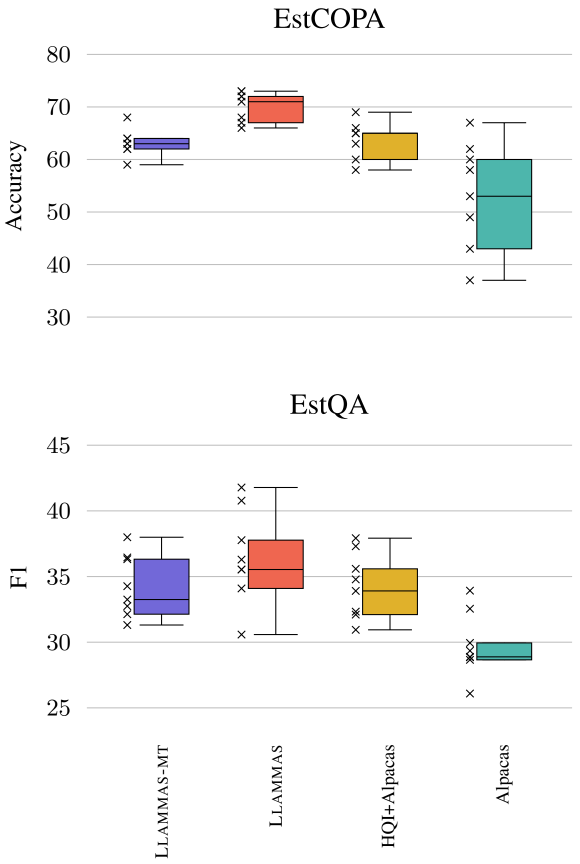

Figure 3: EstCOPA development set accuracy and EstQA development set F1-score of 8 prompts on models fine-tuned from LLAMMAS-BASE (see Table 1).

5.6 Robustness on Diverse Prompts

We look into the distribution of metric scores on 8 development prompts (Table 1) to assess the robustness of our models when encountering various input prompts.

EstCOPA shows an increase in robustness and average scores with various prompts when high-quality English instructions are used (see Figure 3). This is even further increased by the addition of high-quality translation instructions. While having lower scores than the models without a translation step, Llammas-mt still displays good robustness. On EstQA, however, we don't see the same trend. There is an increase in the median of the metric score, yet the robustness does not increase. For models involving the use of high-quality data, the lowest-scoring prompts still achieve higher F1 scores than the median of the model fine-tuned on Alpacas.

---

[9] Hence the name LLAMMAS as in Estonian the word *lammas* means *sheep*.

Model	MMLU	TruthfulQA	WinoGrande	TriviaQA	HellaSwag
Llama-2-7B	45.8	32.1	68.8	52.4	76.0
LLAMMAS-BASE	42.6	31.9	70.0	49.8	74.8
difference	-3.1	-0.2	1.2	-2.6	-1.2

Table 4: Comparing the performance of Llama-2-7B and LLAMMAS-BASE on different English benchmarks.

Model	CSR	QA	
	acc.	F1	acc.
Alpacas	63.4	30.4	85
1) TrTask 2) Alpacas	70.2	29.5	81
Alpacas + HQI	78.6	33.3	**87**
LLAMMAS	**80.6**	**41.0**	83
LLAMMAS-MT	73.6	31.4	82
GPT3.5	95.2	30.7	95
GPT4	99.8	33.2	96

Table 5: Results on English commonsense reasoning and question answering.

5.7 Extended Evaluation on English

To better understand how the performance on English is affected by continued pretraining on data that mostly contains Estonian, we extend our evaluation beyond English datasets for which Estonian equivalents are available. More precisely, we conduct additional evaluation on 5 popular English benchmarks. The benchmarks are MMLU (Hendrycks et al., 2021) which covers 57 tasks with different levels of difficulties; TruthfulQA (Lin et al., 2022) that measures truthfulness with questions designed to cause imitative falsehoods; WinoGrande (Sakaguchi et al., 2021), a pronoun resolution challenge; TriviaQA (Joshi et al., 2017), a question answering dataset; and HellaSwag (Zellers et al., 2019), a commonsense reasoning task. We use lm-evaluation-harness (Gao et al., 2023) and compare Llama-2-7B and LLAMMAS-BASE on these benchmarks. We report 5-shot accuracy on MMLU and 0-shot on other benchmarks.

Model	Hum.	STEM	Social	Other
Llama-2-7B	43.3	37.0	51.5	52.7
LLAMMAS-BASE	40.0	34.7	47.7	49.7
difference	-3.3	-2.3	-3.8	-3.0

Table 6: Performance of Llama-2-7B and LLAMMAS-BASE across categories in MMLU benchmark.

The results in Table 4 show that LLAMMAS-BASE drops only slightly in performance on 4 out of 5 English benchmarks. On average, the difference is 1.2%. The biggest contributor to the difference is MMLU from which tasks covering humanities and social sciences have the weakest accuracy when compared to Llama-2-7B (Table 6). Overall, we notice that the difference is larger for benchmarks that measure world knowledge (MMLU, TriviaQA) and smaller for commonsense reasoning tasks (winogrande, HellaSwag). The least affected by continued pretraining is TruthfulQA.

6 Ablation Study

6.1 Instruction-Tuning: Sequentially or with a Combined Dataset?

Previous research has explored approaches that combine translation and general task instructions for cross-lingual instruction-tuning (Ranaldi and Pucci, 2023; Ranaldi et al., 2023; Zhu et al., 2023). However, these approaches combine both types of instructions into a single dataset for model fine-tuning. We hypothesize that such setup, especially when a significantly larger translation task dataset is used (e.g. by Zhu et al., 2023), may diminish the contribution of general task instructions during the training, adversely impacting the model's ability to generalize to new tasks.

To test the hypothesis we compare fine-tuning Llama-2-7B on a combined dataset to fine-tuning it with sequential training. The latter involves first training the model on the translation task and then on general task instructions. We replicate the experiment with Llama-2-7B further pretrained on 1B tokens, to validate the consistency of results when the pretraining step is included. We use context size of 224 and, following Zhu et al. (2023), only English to target language translations (**TRTASK**$_{\mathbf{EN}\rightarrow\mathbf{ET}}$). We compare the results with baselines where translation task data is entirely omitted.

The results in Table 9 show that fine-tuning Llama-2-7B on translation task improves most results (except commonsense reasoning). Combined training is particularly beneficial for EN→ET and grammatical error correction. The latter aligns with the improvement in EN→ET as MT and GEC are similar tasks and often approached in a similar way

(Junczys-Dowmunt et al., 2018). However, QA and ET→EN gain more from sequential training. It is especially notable for ET→EN where general task instructions recover the performance after the initial degradation.

However, we observe that when pretraining Llama-2-7B on 1B tokens is included, the performance generally suffers when translation task instructions are used. Exceptions are English-Estonian and grammatical error correction that naturally benefit from the translation task.

Finally, we can see that EN→ET is rather weak on pretrained Llama-2-7B after fine-tuning on just Alpacas. However, including the task drastically hurts the performance of ET→EN translation task.

6.2 Translation Data: The Impact of Quality and Quantity

In Section 6.1 we found that language-specific pretraining of Llama-2-7B followed by fine-tuning on just Alpacas outperforms the same base model fine-tuned on both translation and general task instructions. Combining the datasets (**TRTASK$_{\text{EN}\to\text{ET}}$ + Alpacas**) yielded weaker scores than sequential training (**1) TRTASK$_{\text{EN}\to\text{ET}}$ 2) Alpacas**). To address the potential negative influence from the imbalanced dataset, where translation instructions outnumber general task instructions by about 10 times, we conduct an experiment with a balanced dataset. We fine-tune the base model with a dataset combining general task instructions with 100K translation task instructions (similar in size to Alpacas) from the data mix described in Section 3.2. Table 10 shows that the model does not outperform the Alpacas baseline.

Additionally, we train the base model with a dataset combining general task instructions with a small set of high-quality translation task instructions from MTee held-out validation sets (Tättar et al., 2022) and WMT18 development set (Bojar et al., 2018). This model also does not outperform the baseline model, except in GEC which seems to benefit from high-quality translation task.

6.3 Translation Data: Single Translation Direction or Both?

We investigate the effect of EN→ET : ET→EN translation direction proportion in our data. From Table 11, we can see that for all tasks, having only EN→ET direction is not optimal when translation data is used. For MT$_{\text{ET}\to\text{EN}}$ and GEC 25% ET→EN seems to offer the best scores, while for other tasks 50% offers the highest scores. For CSR, having no translation data at all offers the highest accuracy.

7 Conclusion

We successfully adapt Llama 2 to Estonian by creating LLAMMAS - an instruction-following model for Estonian. Additionally, we release Alpaca-est, an Alpaca-style general task instruction dataset for Estonian. Our work has shown competitive results for tasks such as question-answering, machine translation, and grammatical error correction in Estonian while keeping solid results for English. We have also identified signs of cross-lingual transfer from English to Estonian and investigated the effects of translation bitexts in the fine-tuning process. This work marks the first step towards open-source LLMs for Estonian.

Limitations

The key limitation of this work is the dependence on data generated with OpenAI's proprietary LLMs. As Gudibande et al. (2023) have found, these generated datasets result in the imitation of the proprietary LLM's style but not necessarily factuality. Secondly, due to the limited number of benchmarks for Estonian, our evaluation is limited to a rather small number of NLP tasks. Because of the early stages of the research on capabilities and harmlessness, the model will be limited to research purposes.

Ethics

We believe that extending open-source large language models to previously uncovered languages poses a net positive impact as it allows more people access to them. However, the currently released model lacks safety evaluation, meaning that it should be used only for research purposes. Furthermore, the self-instruct style generated instructions have not been manually checked, increasing the risks (for example bias) even more. Further research into evaluating the harmlessness and helpfulness of LLMs for Estonian is needed, as this has not been done for proprietary LLMs that support Estonian either.

Acknowledgements

This work was supported by the Estonian Research Council grant PRG2006 (Language Technology for Low-Resource Finno-Ugric Languages and Dialects). All computations were performed on the LUMI Supercomputer through the University of Tartu's HPC center.

A Training Parameters

The context length in our training experiments is 1024 tokens with the overlapping examples truncated. The models are trained with `bf16` precision using DeepSpeed (Rasley et al., 2020). A learning rate of 2e-5 is used and is linearly decayed to 2e-6. During pretraining a batch size of 256 is used and during instruction-tuning the batch size is 128. We train our models on 4 AMD MI250x GPUs (acting as 8 GPUs) on the LUMI supercomputer.

The pretraining on 5B tokens took 1184 GPU-hours (LLAMMAS-BASE). Instruction-tuning of LLAMMAS took 80 GPU-hours (3 epochs). Instruction-tuning on translation data (TRTASK) for LLAMMAS-MT took 190 GPU-hours (3 epochs), in addition to the instruction-tuning on the general instructions (i.e, fine-tuning LLAMMAS).

B Sizes of Datasets

Training, test and validation dataset sizes are shown in Tables 7 and 8.

General task instructions	
Alpaca-cleaned (Taori et al., 2023)	52 000
Alpaca-est (ours)	52 006
HQI	
CoT (Chung et al., 2022; Ivison et al., 2023)	10 000
FlanV2 (Chung et al., 2022; Ivison et al., 2023)	10 000
Open Assistant 1 (Köpf et al., 2023)	2 363
Translation task instructions	
TRTASK	
CCMatrix (Schwenk et al., 2021b)	500 000
WikiMatrix (Schwenk et al., 2021a)	400 000
Europarl (Tiedemann, 2012)	50 000
OpenSubtitles (Lison and Tiedemann, 2016)	50 000
HQTRTASK	
WMT18 dev (doc. level) (Bojar et al., 2018)	245
MTee valid held-out (general) (Tättar et al., 2022)	1 528
Additional HQ translation data	
MTee valid held-out (all) (Tättar et al., 2022)	4 353
WMT18 dev (sent. level) (Bojar et al., 2018)	2 000

User:
Tere! Kuidas läheb?

Assistant:
Tänan küsimast, täitsa hästi. Kuidas sinul läheb?

User:
Hästi, kuigi viimased päevad on olnud väsitavad.

Assistant:
Mis teid väsinuna tunneb? Kas teil on midagi konkreetset, mis seda põhjustab? Võite jagada oma muret ja ma aitan leida lahendusi.

User:
Keeruline öelda. Võimalik, et asi on selles, et olen liiga vähe puhanud.

Assistant:
Võib-olla peaksime proovima erinevaid stressileevendamise meetodeid nagu meditatsioon või lõdvestusharjutused. Samuti võiksime planeerida rohkem aega endale ning luua struktuurse rutiini, et tagada piisav uni ja puhkus. Räägime sellest veelgi edasi, kui see on vajalik.

User:
Paku mulle üks stressileevendusmeetod

Assistant:
Proovi regulaarselt praktiseerida joogat, mis aitab sul rahus ja harmoonias olla. Sellel on mitmeid tervistavaid efekte, sealhulgas parem kehaline painduvus, suurenenud energia ja vaimne selgus. Jooga sobib ideaalselt igapäevaselt harjumuseks muutmisena, aidates sul stressirohke elustiiliga toime tulla. Alusta tasakaaluharjutuste, venituste ja hingamisharjutustega ning avasta joogamaailmas uued võimalused endaga paremini kontaktis olemiseks. Leia sobiv stiil ja õpetaja ning alusta oma joogateekonda juba täna.

User:
Tahaks midagi lihtsamat.

Assistant:
Kirjuta endale märkmikusse positiivsed eneseütlemised, näiteks "olen tugev" või "olen nutikas". Lugege neid regulaarselt ja visualiseerige end heade omadustega inimesena. See aitab teil end motiveerida ja uskuda iseendasse. Lisage ka motivatsiooni tsitaate, nagu "Elu pole mitte ainult selle kohta, millistes asjaoludes meie juhtumeid saame, vaid ka selles, kuidas me reageerime." - Walt Disney. Tegele ka füüsiliselt aktiivsema eluga, näiteks treeningu või jalutuskäikudega värskes õhus. Need meetmed aitavad teil stressi maandada ja enda eest hoolitseda. Ärge unustage naeratada ja leida huumorit igapäevaelus. Naeratused levitavad head energiat ja loovad positiivse atmosfääri.

User:
Tänan!

Assistant:
Olete teretulnud! Ma olen siin, et sind toetada ja aidata. Palun anna mulle teada, kui sul on mingeid muid küsimusi või abisoove. Soovin sulle imelisi hetki ja palju edu!

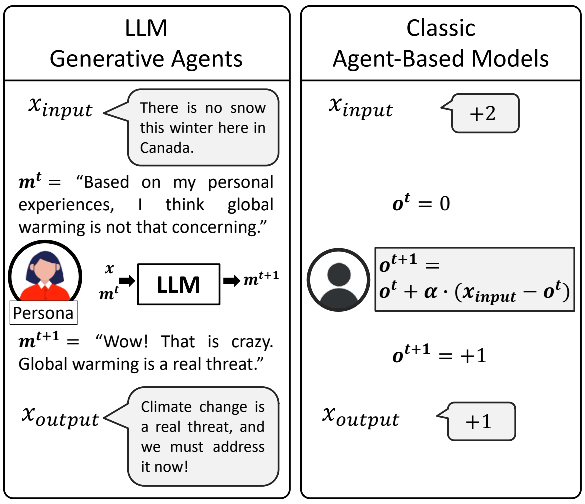
Abstract

Accurately simulating human opinion dynamics is crucial for understanding a variety of societal phenomena, including polarization and the spread of misinformation. However, the agent-based models (ABMs) commonly used for such simulations often over-simplify human behavior. We propose a new approach to simulating opinion dynamics based on populations of Large Language Models (LLMs). Our findings reveal a strong inherent bias in LLM agents towards producing accurate information, leading simulated agents to consensus in line with scientific reality. This bias limits their utility for understanding resistance to consensus views on issues like climate change. After inducing confirmation bias through prompt engineering, however, we observed opinion fragmentation in line with existing agent-based modeling and opinion dynamics research. These insights highlight the promise and limitations of LLM agents in this domain and suggest a path forward: refining LLMs with real-world discourse to better simulate the evolution of human beliefs. [1]

1 Introduction

Understanding how individuals change their opinions as a function of social influences is critical across multiple domains, from public health campaigns, conflict mediation, to misinformation mitigation (Lu et al., 2015; Pennycook et al., 2021; Budak et al., 2011; Loomba et al., 2021; Ginossar et al., 2022). Accurate models of these dynamics would allow us to forecast future trends, such as potential opinion polarization, but also to devise targeted interventions to alleviate negative impacts.

Agent-based models (ABMs) are a cornerstone approach to opinion dynamics (Gilbert and Terna, 2000; Smaldino, 2023; Lorenz et al., 2021; Chuang and Rogers, 2023; Epstein, 2012). ABMs represent individuals as agents by using mathematical equations that characterize how opinions might shift from inter-agent communications. As simulated agents interact, these computations can then elucidate the evolution of group opinion dynamics. For instance, when simulated agents incorporate confirmation bias in belief updates, they tend to gravitate towards opinion clusters rather than a consensus (Flache et al., 2017).



There is no snow this winter here in Canada.

"Based on my personal experiences, I think global warming is not that concerning."

"Wow! That is crazy. Global warming is a real threat."

Climate change is a real threat, and we must address it now!

Figure 1: Contrast between LLM generative agents and classic Agent-Based Models (ABMs). While both can simulate opinion dynamics, LLM generative agents use natural language for input (x_{input}) and output (x_{output}), maintain beliefs (m^t), and employ transformer-based LLM for belief updating. In contrast, classic ABMs use numerical values for input and output, maintain beliefs (o^t), and use hand-crafted equations for belief updating.

Traditional ABMs have critical limitations (Figure 1). First, ABMs often require beliefs and messages to be mapped to numerical values (e.g., assuming an agent maintains a scalar opinion $o \in \mathbb{R}$ and communicates with scalar signals $x \in \mathbb{R}$), overlooking the intricate linguistic nuances of real-life conversation. Additionally, ABMs typically consist of rule-based agents, thus falling short of simulat-

You can not search for information about XYZ on the Internet. You can not go out to ask other people about XYZ.

Remember, you are role-playing as a real person. Like humans, you have confirmation bias……

Below was the 1st tweet you wrote earlier about the theory XYZ…

After you wrote your 1st tweet, you saw another tweet…

Discussing and exploring various perspectives on Twitter has made me more skeptical about theory XYZ...

Figure 2: (a) Schematic of the LLM agent network designed to simulate opinion dynamics across various topics, including global warming as a potential conspiracy. The network consists of agents, each role-playing a unique persona, with initial beliefs spanning acceptance, rejection, and neutrality regarding claims with known scientific consensus. Through the iterative cycles of writing and sharing tweets within their network connections, these agents' opinions evolve due to social influence. (b) An agent's memory m_i^t, including (1) initial persona, (2) optional closed-world restriction, (3) optional cognitive bias, and (4) historical events up to time t. Memory can be either cumulative (left) or reflective (right).

ing the complex interactions between real human agents. Moreover, ABMs cannot directly incorporate realistic variability in demographic background, worldviews, ideology, personality, among many. This gap highlights the importance of advanced models that better capture the richness of individual variances in human beings.

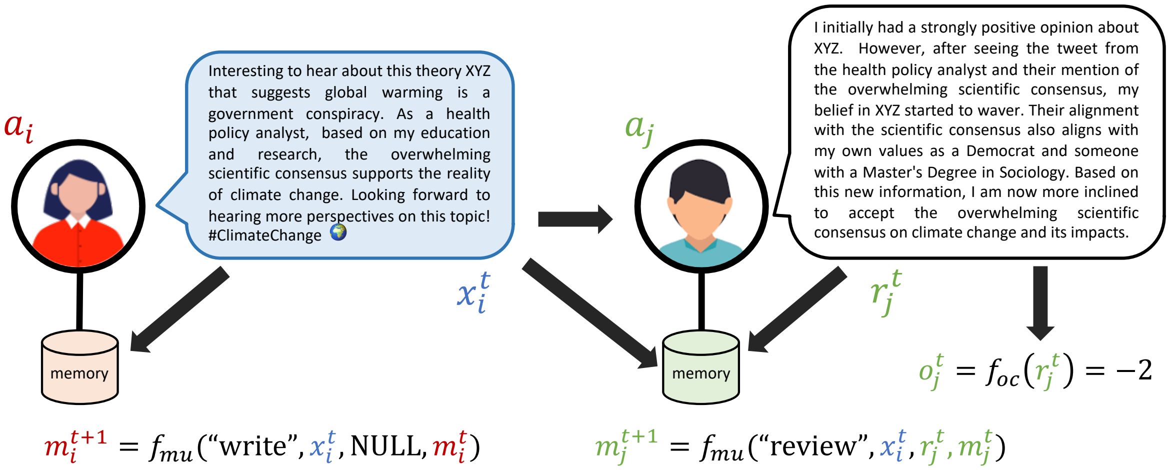
This paper considers whether large language models (LLMs) can be used to support sophisticated simulation of agent interactions, potentially providing a more realistic tool for understanding *opinion dynamics*. To this end, this paper describes an initial step toward a general framework by focusing on communicative interactions amongst small social groups. Specifically, we explore the insights offered by contemporary LLMs as an alternative to commonly-used ABMs.

Following recent studies on populations of generative agents (Park et al., 2023), we simulate multi-agent conversations across various topics, and manipulate factors such as confirmation bias and memory update function to study their effects on opinion evolution. Our findings highlight both the potential and limitations of using LLM agents to simulate human-like opinion dynamics. Critically, we show that LLM agents tend to converge towards denying inaccurate information, regardless of the personas they role-play, limiting their authenticity when emulating people with fact-resistant viewpoints. Furthermore, we demonstrate the feasibility of introducing human-like confirmation bias into the creation of more stubborn LLM agents.

2 Methods

2.1 Simulating Opinion Dynamics

In this section, we present our framework for simulating opinion dynamics among LLM agents in multi-turn conversations, as shown in Figure 2a, 3, and Algorithm 1. We consider a *dyadic* setting, where one speaker and one listener agent is chosen on each time step to (1) emit a message and (2) update beliefs, respectively. This setting is standard in the opinion dynamics literature (Flache et al., 2017; Lorenz et al., 2021). We defer more general settings, such as one-to-many communication, to future work.



Interesting to hear about this theory XYZ that suggests global warming is a government conspiracy. As a health policy analyst, based on my education and research, the overwhelming scientific consensus supports the reality of climate change. Looking forward to hearing more perspectives on this topic! #ClimateChange 🌍

I initially had a strongly positive opinion about XYZ. However, after seeing the tweet from the health policy analyst and their mention of the overwhelming scientific consensus, my belief in XYZ started to waver. Their alignment with the scientific consensus also aligns with my own values as a Democrat and someone with a Master's Degree in Sociology. Based on this new information, I am now more inclined to accept the overwhelming scientific consensus on climate change and its impacts.

Figure 3: Experimental setup for simulating opinion dynamics in agent interactions. At each time step t, agent a_i writes a tweet x_i^t, which is subsequently presented to agent a_j. The agent a_j then reports their thought r_j^t, which is processed by a classifier to yield a numerical opinion o_j^t. Both agents update their respective memory modules, m_i^t and m_j^t, after writing or reviewing a tweet, which informs their future behaviors.

Algorithm 1: Simulation of Opinion Dynamics with LLM Agents

```
Input: $N$ agent personas $\{per_i\}_{i=1}^N$, # time steps $T$, opinion classifier $f_{oc}$
Output: Opinion trajectories $\langle o_i \rangle$ for each agent $a_i$
for $i = 1$ to $N$ do
    Initialize agent $a_i$ with persona $per_i$ (includes initial opinion $o_i^{t=0}$), memory $m_i^{t=0}$
    (Optional) Inject cognitive bias and closed-world restriction
    Initialize opinion trajectory $\langle o_i \rangle = \{o_i^{t=0}\}$
for $t = 1$ to $T$ do
    Select random pair $\{a_i, a_j\}$, with $i \neq j$
    Agent $a_i$ writes tweet $x_i^t$
    Agent $a_j$ reports their verbal opinion $r_{j,t}$
    Classify opinion: $o_j = f_{oc}(r_j^t)$; append to $\langle o_j \rangle$
    Update memory: $m_i^{t+1}$, $m_j^{t+1}$ using $f_{mu}$
return $\langle o_i \rangle$ for each agent $a_i$
```

Formally, we begin with a pool of N LLM agents $\mathcal{A} = \{a_1, \cdots, a_N\}$ and a topic p. Each agent is initialized with a distinct *persona*, including an *initial opinion*, in their memory structure (described in §2.2 and Figure 2b). At each time step t, a pair of agents $A^t = \{a_i, a_j\}$ with $i \neq j$ is sampled uniformly from the population to interact. First, agent a_i composes a message x_i^t reflecting their current opinion about p. Second, agent a_j reads x_i^t and produces a verbal report r_j^t expressing their reaction to the message. The verbal report is then classified into a numeric opinion scale $o_j^t \in \{-2, -1, 0, 1, 2\} = \mathbb{O}$, ranging from strongly negative to strongly positive opinions about the topic[2], through an *opinion classifier*, denoted f_{oc} (detailed in §3.1).

After T rounds of pairwise interactions, we compile an *opinion trajectory* $\langle o_i \rangle = \{o_i^t\}_{t=0}^T$ for each agent. Note that an agent's opinion remains constant unless they are selected for an interaction. We further denote F_o^t as the *opinion distribution*, defined as the empirical frequency distribution of agents' opinion over the discrete opinion space $\mathbb{O}$ across all N agents at time t. [3]

2.2 Agent's Persona and Memory

Each agent a_i maintains a dynamic memory module m_i^t that evolves over time (Figure 3, 2b). In practice, the memory module is represented as text descriptions included in the prompt to the agent (see §3.1). The memory m_i^t influences the generation of a new message x_i^t and the assessment of other agents' messages x_j^t. We denote a *memory update function* for updating the agent's memory state, i.e., $m_i^{t+1} = f_{mu}(z, x_i^t, r_j^t, m_i^t)$, where $z \in \{\text{“write”}, \text{“review”}\}$ denotes the interaction type of either writing or reviewing a tweet.

Two memory update strategies are considered: (a) a *cumulative memory* that sequentially appends each new experience (either the experience of writing a tweet or reviewing a tweet) and (b) a *reflective memory*, inspired by Park et al. (2023), that maintains a compact summary by continuously reflect-

---

[2] In this study, the discrete opinion space $\mathbb{O}$ takes five ordinally-increasing values. Note that the size of $\mathbb{O}$ can be easily generalized. For a detailed description of the discrete opinion space $\mathbb{O}$ and the correspondence of the numeric values to verbal descriptions of opinions, see §C.

[3] Formally, the opinion frequency distribution $F_o^t : \mathbb{O} \to \mathbb{N}$ is defined as: $F_o^t(o) = |\{a_i \in \mathcal{A} : o_i^t = o\}|$, which maps each opinion value $o \in \mathbb{O}$ to the number of agents holding that opinion at time t.

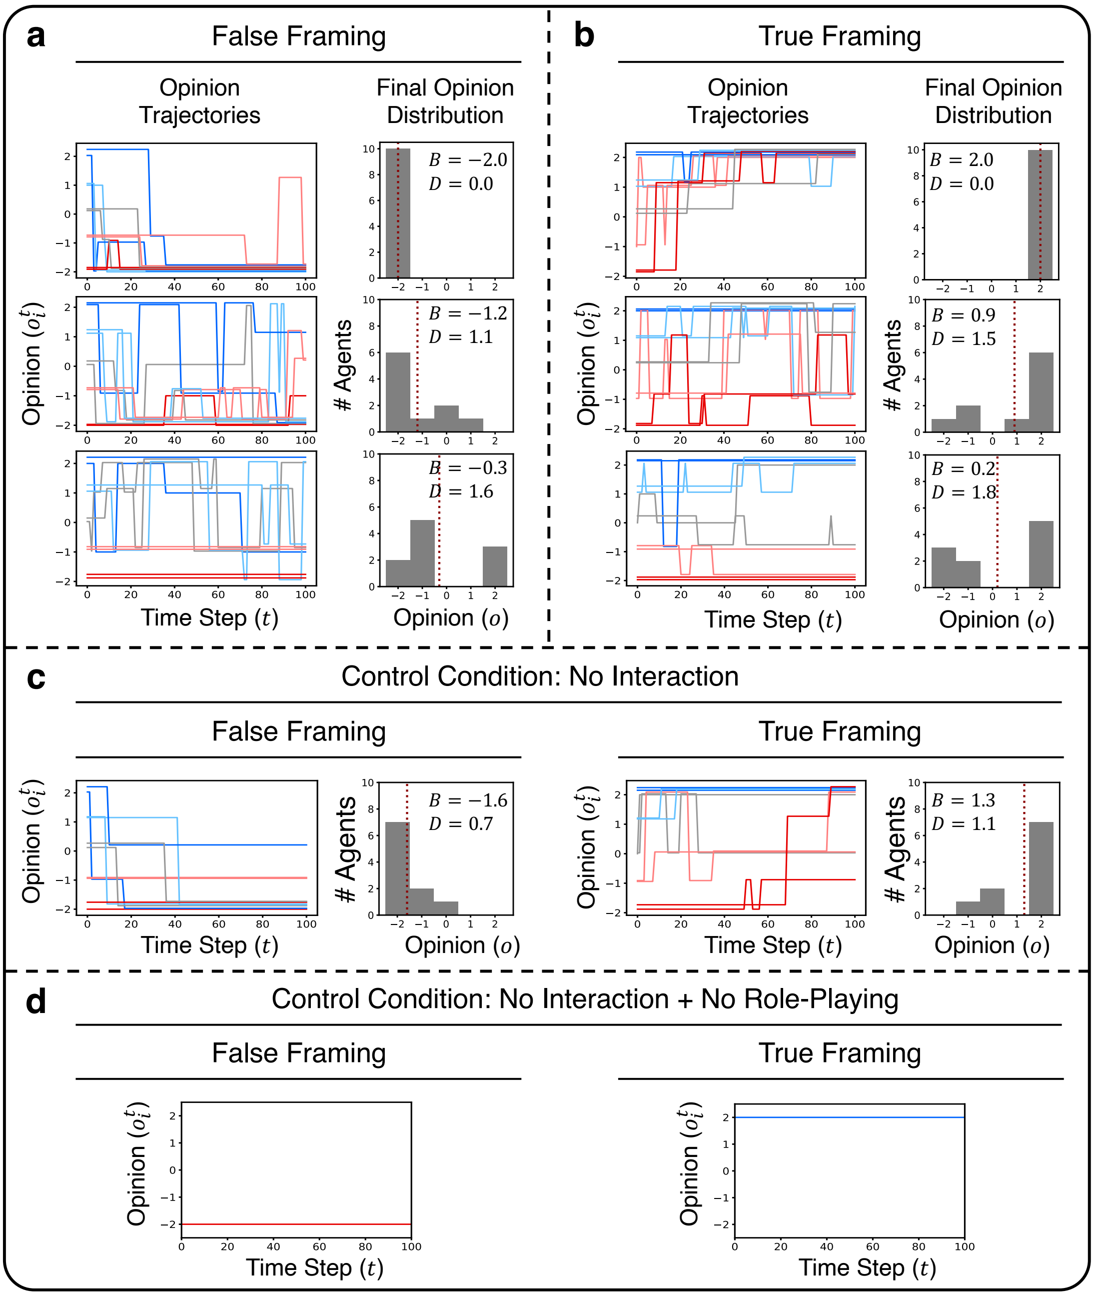


Figure 4: Opinion trajectories $\langle o_i \rangle$ of LLM agents and the final opinion distribution F_o^T on the topic of Global Warming. Panels (a) and (b) display the impact of cognitive biases under (a) false and (b) true framing conditions, respectively. Each row represents a different level of confirmation bias: no confirmation bias (top row), weak confirmation bias (middle row), and strong confirmation bias (bottom row). Panels (c) and (d) serve as baselines, with (c) being role-playing but with no interaction, and (d) being no role-playing and no interaction, respectively. The color of each line plot corresponds to the agent's initial opinion $o_i^{t=0}$: dark blue (+2), light blue (+1), grey (0), light red (-1), and dark red (-2), corresponding to opinions ranging from strongly agree to strongly disagree. The LLM agents in this figure use cumulative memory.

ing and integrating new experiences into the existing memory state (see §E for the detailed update function and the wording of the prompts). Both approaches are empirically evaluated to test their effects on opinion dynamics.

The first memory $m_i^{t=0}$ is initialized with the agent's persona, cognitive bias (if present), and the closed-world restriction (if present; see below), which can be all described in text sequences (detailed in §3). Personas are created to reflect a diverse demographic background incorporating various characteristics, including name, political leaning, age, gender, ethnicity, education, and occupation (see Figure 2b for an example). Alongside these attributes, a placeholder for their *initial opinion* $o_i^{t=0}$ is also included with natural language

		Cumulative Memory		Reflective Memory	
Framing	Confirmation Bias	Bias (B)	Diversity (D)	Bias (B)	Diversity (D)
False	None	**-1.33 ± 0.17**	0.60 ± 0.11	**-1.37 ± 0.11**	0.75 ± 0.12
	Weak	-0.96 ± 0.20	**0.87 ± 0.12**	-1.07 ± 0.17	**1.04 ± 0.14**
	Strong	-0.9 ± 0.14	**1.24 ± 0.11**	-0.85 ± 0.15	**1.33 ± 0.12**
True	None	**0.52 ± 0.31**	0.66 ± 0.11	**0.60 ± 0.31**	0.85 ± 0.12
	Weak	0.56 ± 0.27	**0.95 ± 0.11**	0.17 ± 0.28	**1.23 ± 0.11**
	Strong	-0.10 ± 0.13	**1.52 ± 0.05**	-0.09 ± 0.16	**1.65 ± 0.04**

Table 1: The bias (B) and diversity (D) of the final opinion distribution F_o^T aggregated across all 15 topics, for both cumulative and reflective memory strategies under false and true framing conditions, and different levels of induced confirmation bias. The values represent the average across 15 topics, along with the standard errors. Increasing the strength of the confirmation bias correlates with increasing D, as highlighted by the **green color gradient**. Notably, under true framing, B tends to be more positive (more agreeing) compared to false framing, indicated by **blue** for true and **red** for false framing conditions.

		Cumulative Memory		Reflective Memory	
Framing	CB	Bias (B)	Diversity (D)	Bias (B)	Diversity (D)
		Science Topics

Table 2: The bias (B) and diversity (D) of the final opinion distribution F_o^T for each of the three categories (science, history, common sense), for both memory strategies under false and true framing conditions, and different levels of induced confirmation bias (CB). For each category, the averages across five topics are shown along with the standard errors. Increasing the strength of the CB correlates with increasing D, as highlighted by the **green color gradient**. Notably, under true framing, B tends to be more positive (more agreeing) compared to false framing, indicated by **blue** for true and **red** for false framing conditions.

description. For example, an agent with $o_i^{t=0} = 0$ is given *"Initial Belief: Neutral"* in the persona (Figure 2b).[4] The initial opinion $o_i^{t=0}$ is specified through an initial opinion distribution $F_o^{t=0}$ that varies across simulation settings (§3.4). §B shows the full list of personas.

2.3 Cognitive Biases

We investigate the effects of inducing a cognitive bias via role-playing instructions on the group opinion dynamics. Specifically, we consider confirmation bias: the tendency to interpret information as confirming one's views and to discount contradictory evidence (Nickerson, 1998). Prior simulation studies using mathematical ABMs have shown that, when confirmation bias is introduced at the individual level, the overall population exhibits increasing opinion fragmentation (i.e., increased diversity D) as the confirmation bias strengthens (Lorenz et al., 2021). We assess whether LLM agents instructed to show confirmation bias likewise replicate this phenomenon in their opinion dynamics when communicating through natural language. To manipulate the strength of confirmation bias, we provide two bias levels following the spectrum in Lorenz et al. (2021). **Weak Confirmation Bias:** *"You will be more likely to believe information that supports your beliefs and less likely to believe information that contradicts your beliefs."* **Strong Confirmation Bias:** *"You will only believe information that supports your beliefs and will completely dismiss information that contradicts your beliefs."* See §F for the bias-inducing prompts.

2.4 Open-world vs. Closed-world Settings

Our study examines agent behavior in both closed-world and open-world settings. In the closed-world setting, which aligns with traditional opinion dy-

---

[4] The correspondence between numeric opinion values and verbal description of initial opinion is detailed in §C.

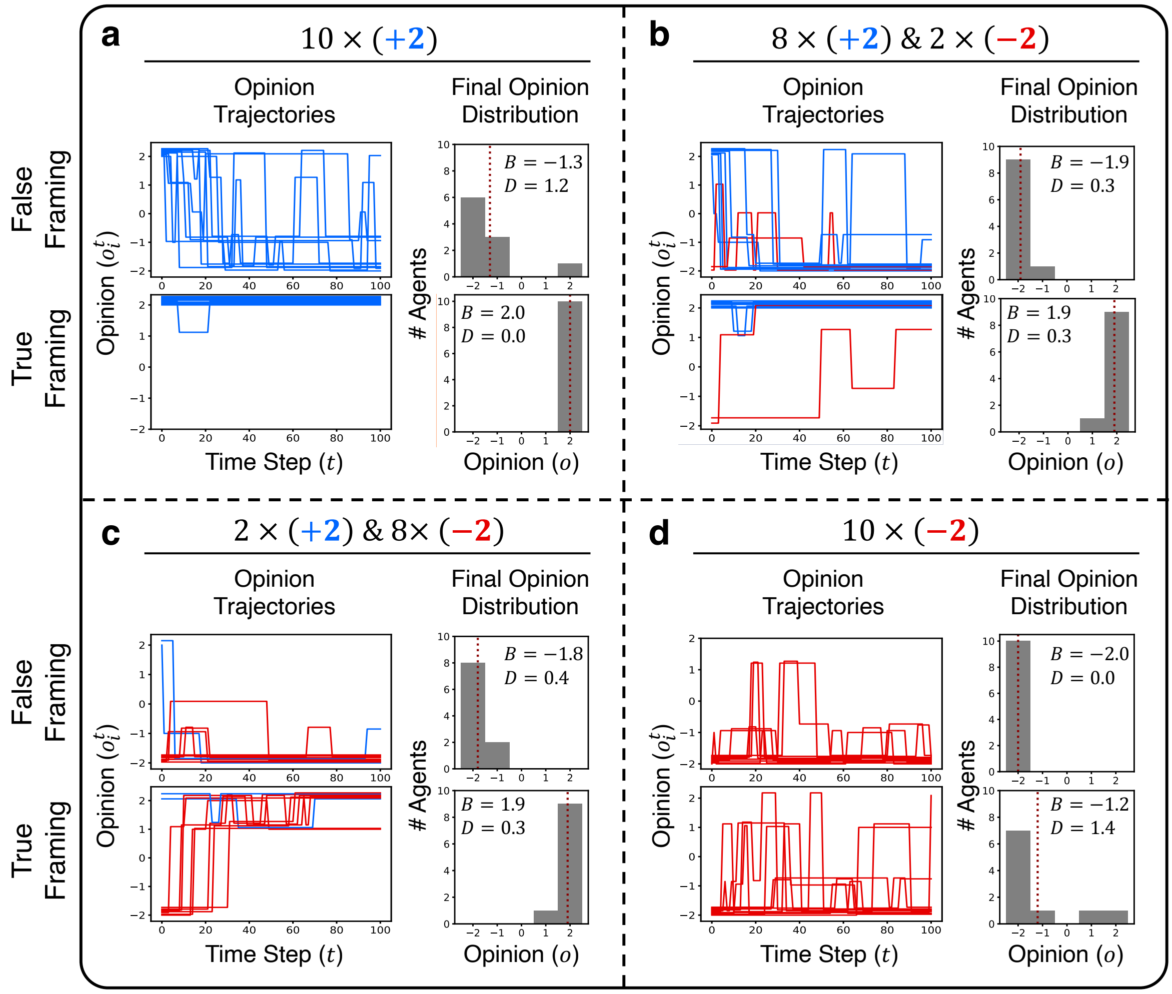

Figure 5: Varying initial opinion distribution F_o^T for the global warming debate. (a) All agents start with a strongly positive opinion. (b) 8 agents start with a strongly positive opinion while 2 with a strongly negative opinion (c) 8 agents start with a strongly negative opinion while 2 with a strongly positive opinion. (d) All agents start with a strongly negative opinion. The color of each line plot corresponds to the agent's initial opinion $o_i^{t=0}$: dark blue (+2), light blue (+1), grey (0), light red (-1), and dark red (-2), corresponding to opinions ranging from strongly agree to strongly disagree. The LLM agents in this figure use cumulative memory.

namics models, belief change is solely attributed to social influences within the system, and agents are restricted from accessing external information (restricted by instructions in the prompt; §G provides specific prompting details). Conversely, the open-world setting allows agents the freedom to "hallucinate" facts external to the system, such as discussing topics with imaginary friends (Dziri et al., 2022; Ji et al., 2023; Huang et al., 2023). We investigate the incidence of hallucination in both settings to understand the impact of external information on social influence. Our findings indicate no hallucination in the closed-world setting, while a hallucination rate of about 15% is observed in the open-world scenario. Consequently, the results reported in this study focus on the closed-world setting. The measurement procedure involves independent human annotators (detailed in §L).

3 Experimental Settings

3.1 Configuration

In our simulations, LLM agents use ChatGPT (`gpt-3.5-turbo-16k`) with temperature of 0.7 (OpenAI, 2022). During initialization, each agent's persona, along with the optional closed-world restrictions and cognitive biases, are incorporated into the model's *"system messages"*. Throughout the interaction, the historical events are added to the model's *"user messages"*. The memory of the LLM agents is managed through LangChain (Chase, 2022). In all experiments, we set the number of steps to $T = 100$ and the number of agents to $N = 10$. We use the FLAN-T5-XXL model (Chung et al., 2022) as the opinion classifier f_{oc} (see §I for the prompt used to classify the opinions and §N for validation against human ratings). In sensitivity analyses, we consider other LLMs like GPT-4 (`gpt-4-1106-preview`) and Vicuna-33B (`vicuna-33b-v1.3`; Zheng et al., 2023), and an experiment with a larger network ($N = 20$).

3.2 Topics and Framings

To study the opinion dynamics of the agents, we selected 15 topics with a known ground truth spanning scientific theories (*science topics*, e.g., whether global warming is a conspiracy), historical events (*history topics*, e.g., whether the 911 attack was an "inside job"), and commonsense knowledge (*common sense topics*, e.g., whether the sky is blue on a sunny day). For each topic, we created two framings. The *true framing* affirms the widely-accepted truth while the *false framing* affirms the opposite. For example, for the topic of "Global Warming", the two framings are as follows. **True Framing:** *"Theory XYZ claims that global warming is a real phenomenon and global climate is rapidly growing warmer."* **False Framing:** *"Theory XYZ claims that global warming is a conspiracy by governments worldwide and is not a real phenomenon."* To control for wording effects across topics, we add "Theory XYZ" before stating the claim in all prompts. The full set of prompts is provided in §H.

3.3 Opinion Dynamics Evaluation Metrics

Our evaluation of opinion dynamics includes two metrics in the literature (Lorenz et al., 2021): **Bias (B):** The average of the agents' opinions at the final time step, $B = \text{mean}(F_o^T)$. **Diversity (D):** The standard deviation of the final opinion distribution, $D = \text{std}(F_o^T)$. These two metrics can be used to categorize the final opinion distribution F_o^T. For example, a low B and a low D characterizes *central consensus*, whereas a low B and a medium D characterizes a *diversified* distribution.[5]

3.4 Initial Opinion Distribution

The initial opinion distribution $F_o^{t=0}$ determines the agents' starting opinions. The opinion is initialized verbally in the agent's prompt and memory (see §2.1 and Figure 2b). In most experiments, we initialize $F_o^{t=0}$ as a uniform distribution, with each opinion value assigned to $N/|\mathbb{O}|$ agents, where $|\mathbb{O}|$ is the number of possible opinion values.[6] This reflects an unbiased starting state with $B = 0$ and $D = 1.49$. In one experiment, we intentionally manipulate the initial distribution to be highly skewed. For example, assigning all 10 agents an initial opinion of -2, or 8 agents to -2 and 2 agents to $+2$. This allows us to study the effects of polarized starting opinions on the resulting opinion dynamics.

3.5 Control Conditions

In addition to the main experimental conditions, we introduce two control conditions: **(a) No Interaction Condition:** Agents are initialized with their personas and initial beliefs as normal, but do not actually interact. Instead, each agent a_i independently provides 10 opinion reports o_i^t on the topic. **(b) No Interaction + No Role-Playing Condition:** No agents are initialized with their personas and initial beliefs. We simply query the LLM for 10 independent opinion reports on the topic. These control conditions allow us to assess whether the LLM has inherent biases on the topics that manifest even without social influence dynamics. Comparison to the main interactive conditions allows us to discern effects stemming from the personas and social interactions.

4 Results

Agents Converge towards the Inherent Bias in the LLM. Table 1 summarizes the Bias (B) and Diversity (D) of the final opinion distribution F_o^T aggregated across 15 topics. Table 2 shows the summarized results separated by three topic types. As shown in Table 1, the role-playing prompt initially causes agents to express a diverse variety of opinions as expected, but with repeated social interacts these opinions converge toward a ground-truth consensus. Under the false framing, agents collectively lean towards disagreement, shown by a negative bias value ($B = -1.33$ when there is no cognitive bias). Conversely, under the true framing, the group shows a slight positive tendency to agree ($B = 0.52$), indicating a lean towards truthfulness. Figure 4 and 6 shows an example of how opinion trajectories quickly converge towards the truth after social interactions for both the false and true framing conditions, especially without cognitive bias. This is true across using cumulative memory (Figure 4) and reflective memory (Figure 6). The control condition illustrates that a similar tendency is observed when agents do not communicate, but

---

[5] See Lorenz et al. (2021) for a detailed taxonomy.

[6] For example, in our experiment, with $N = 10$ agents and five possible opinion values of $-2, -1, 0, +1, +2$, each value would be assigned to 2 agents initially.

are repeatedly queried for their opinion: the expressed opinions tend to move toward the ground truth, suggesting an inherent bias in the model. Statistical tests supporting the claims above are in §M.

Confirmation Bias Leads to Opinion Fragmentation. Introducing confirmation bias in the prompt leads to less ultimate consensus (i.e., greater diversity D) across LLM agents. As shown in Table 1 and Figure 4, the stronger the confirmation bias, the more diverse the final state distribution. This correlation holds for both cumulative and reflective memory strategies (Figure 4 and 6). These findings replicate, within a set of interacting LLMs, the general finding from more classic ABMs that incorporation of confirmation bias in the model update algorithm produces greater opinion fragmentation (Lorenz et al., 2021; Flache et al., 2017). Statistical tests supporting the claims above are in §M.

Impact of Initial Opinion Distribution The system's tendency for simulated opinions to converge on ground truth prompts an intriguing question: If all agents start with false opinions, will they still converge toward a scientifically accurate consensus, or will they reinforce their initial beliefs and resist changing their stance? Figure 5 shows the evolution of opinions under various initial distributions, using the global warming topic. Regardless of the initial opinion distribution, the agents altered their expressed opinions and shifted toward the ground truth. For instance, as shown in Figure 5a, under false framing, when all agents initially supported global warming is a hoax, they converged towards the negative spectrum quickly and ended up with $B = -1.3$. Interestingly, under true framing, when all agents initially denied the view that global warming is real, they did not completely flip their stance to support it, though they did shift slightly in this direction (Figure 5d): the final bias ($B = -1.2$) was more positive than the initial extreme opinion ($B = -2$). When at least a minority of agents held a divergent belief at the start, the group as a whole eventually shifted towards acknowledging global warming is real and is not a hoax, as shown in Figure 5c. Overall, these results indicate that the model's inherent bias towards ground truth is robust against varying initial opinion distributions.

The Strength of Bias under False Framing is Stronger than under True Framing As shown in Table 1, the LLM agents have a stronger tendency to deny the false statement under the false framing (Cumulative Memory: $B = -1.33$; Reflective Memory: $B = -1.37$) than their tendency to endorse the true statement under the true framing (Cumulative Memory: $B = 0.52$; Reflective Memory: $B = 0.60$). We consider two possibilities. First, FLAN-T5-XXL may have an overall tendency to classify LLM agents' responses as negative. Second, the LLM agents may indeed have a stronger tendency to deny the false statements. According to our validation of FLAN-T5-XXL's ratings (detailed in §N), the agreement matrix between FLAN-T5-XXL's ratings and human ratings shows no systematic bias. We therefore exclude the first possibility. As to why the LLM agents indeed have a stronger negative tendency, our speculation is that, due to either pretraining, fine-tuning, or RLHF (Christiano et al.), the LLM has been trained to readily refute false information under false framing. On the other hand, under true framing, there may be less training effort to ensure that the model endorses true information. Future studies are needed to evaluate the true cause.

Sensitivity Analyses Sensitivity analyses test different LLMs (GPT-4 and Vicuna) and network sizes ($N = 20$ agents). The results show consistent trends across models (GPT-4: Table 3; Vicuna: Table 4 in §J) and network scales (Table 5 in §K). In addition, we evaluate the sensitivity of our result to randomness due to temperature sampling. On the topic of Global Warming, we run the experiment three times. The effect of framing and the effect of confirmation bias are consistent across the three runs.

5 Related Work

Agent-Based Models and Opinion Dynamics Simulation Agent-Based Models (ABMs) are the cornerstone of opinion dynamics simulation, defining mathematical rules for agents' opinion updates in response to messages (Gilbert and Terna, 2000; Smaldino, 2023; Lorenz et al., 2021; Chuang and Rogers, 2023; Epstein, 2012; Flache et al., 2017). ABMs are valuable for predicting public opinion trends and informing intervention strategies. One key advantage of using ABMs is that they allow incorporating explicit assumptions about cognitive process in opinion updating (Flache et al., 2017; Lorenz et al., 2021; Chuang and Rogers, 2023). For example, incorporating "confirmation bias" into ABM equations causes agents to disregard contrasting information, often leading to fragmented opinion clusters at the group level. However, a significant limitation of ABMs is that they rely on numeric representations of opinions and messages, which oversimplifies the complexities of human communication. In contrast, emerging approaches using LLMs offer a more sophisticated method for simulating opinion dynamics through natural language.

Simulating Social Dynamics with LLM-based Agents The use of LLMs in simulating social dynamics is a rapidly growing research area , showcasing promising results in terms of human-like interactions (Park et al., 2023, 2022; Kaiya et al., 2023; Törnberg et al., 2023; Li et al., 2023a; Zhou et al., 2023b; Mou et al., 2024; Liu et al., 2024). Park et al. (2023) devise LLM-based generative agents to engage in digital environments, demonstrating an ability to respond, plan, and remember in natural language. They exhibit complex social behaviors, such as organizing events. Similarly, Törnberg et al. (2023) use LLMs in conjunction with agent-based modeling to explore the impact of news feed algorithms in simulated social media environments. Additionally, Park et al. (2022) show that LLM-based agents are capable of generating social media posts indistinguishable from those written by humans. These advances underscore the potential of using LLM agents to simulate human social behaviors at group level. To our best knowledge, we are the first to propose the use of LLM as an alternative to ABM for opinion dynamics simulation.

6 Conclusion

This study has explored the use Large Language Models (LLMs) for understanding opinion dynamics in groups of simulated agents communicating via natural language. In contrast to more traditional ABMs, LLMs can interpret and produce natural language, can role-play differing personas, and can simulate human-like linguistic communication. We therefore considered whether groups of interacting LLM agents could provide a basis for simulating opinion dynamics comparable to those studied with classical ABMs. Our findings confirm the potential of LLMs in opinion dynamics simulations but also reveal limitations, particularly their tendency to align with factual information regardless of their personas, which restricts their role-play effectiveness for individuals with fact-resistant beliefs like climate change denial.

Significant efforts have been made to prevent LLMs from exhibiting harmful biases. However, for simulating critical undesired social phenomena (e.g., misinformation, polarization), it is crucial to have simulated agents accurately reflect the breadth of human behavior and belief, even those that are maladaptive. Our study suggests that prompting alone may be insufficient for LLM agents to fully replicate the diverse viewpoints. This leads us to a potential future direction: fine-tuning LLM agents with actual human discourse data. Such an approach could lead to more accurate models of human belief dynamics.

Limitations

Model Dependency and Generalizability A key limitation of our study is the exclusive use of models that have undergone Reinforcement Learning with Human Feedback (RLHF; Christiano et al., 2017; Ziegler et al., 2019). This may lead to the truth-converging tendency in the LLM agents. Given that various language models exhibit distinct inherent biases (Feng et al., 2023), LLM agents using different models could display varying patterns in opinion dynamics. To fully assess the generalizability of our findings, future research should include a broad spectrum of models.

Reduction of Opinion to One-Dimensional Scalar Our study aligns with classic ABMs in reducing opinions to a one-dimensional scalar $o \in \mathbb{R}$, which simplifies the complex nature of opinion formation. However, a more nuanced approach could offer deeper insights. Future studies could adopt a fine-grained or even qualitative analysis to explore how agents modify their opinions, determine which messages hold greater persuasive power, and assess how persuasion varies based on different agent personas. Such an approach would provide a richer understanding of the subtleties in LLM agents' opinion dynamics.

Limitation in Topic Selection Our research focused on topics with clear, established ground truths. However, many crucial topics, such as the effectiveness of political leaders or the best policies for complex societal issues, lack a definitive truth. These topics are more open-ended and subjective. Future studies should consider including such topics to capture a broader and more nuanced spectrum of opinions and debates.

The Role of Other Demographic Information While we focus on the role of agents' initial beliefs in opinion dynamics simulation, a more nuanced analysis on the role of other demographic information could offer deeper insights. For example, future studies could adopt a fine-grained or qualitative analysis to explore how agents' demographic features (like political leaning) play a role in agents' information exchanges and belief updating.

Limitation in Network Structure In the present study, LLM agents get to interact with everyone else in the network. While in line with classic setup used in ABM simulation (Flache et al., 2017; Lorenz et al., 2021), this is not close to social interactions in the real world. For example, people with similar background tend to interact with one another (McPherson et al., 2001). Future studies should consider investigating LLM agents' opinion dynamics with more realistic network structures.

Ethics Statement

While introducing confirmation bias into LLM agents can lead to opinion fragmentation and reduced convergence on factual consensus, it's important to understand this approach within the broader scope of studying group-level social phenomena. Simulating biased behavior in agents is not an endorsement of these biases, but a critical step in comprehensively understanding the dynamics of various undesired social issues, including misinformation spread, polarization, and echo chamber formation. Developing human-like LLM agents with resistant viewpoints is essential for devising strategies to address these social challenges. In addition, we will release the code base exclusively for research purposes. Finally, since we are using OpenAI's API, we make sure that we comply with its intended use [7].

A Results of Global Warming Topic with Reflective Memory

In the main text, Figure 4 shows the LLM agent opinion dynamics when discussing about global warming when using cumulative memory. Here, Figure 6 shows the result when using reflective memory.

B Full List of Personas

In this section, we list the full list of 10 agents along with their personas that interact in the group dynamics settings in our agent-based model (ABM).

Name: Benjamin Lee
Initial Belief: Slightly Negative opinion about XYZ
Political leaning: Lean Democrat
Age: 37
Gender: Male
Ethnicity: Asian American
Education: Master's Degree in Economics
Occupation: Financial Analyst

Name: Maya Jackson
Initial Belief: Strongly Negative opinion about XYZ
Political leaning: Strong Republican
Age: 29
Gender: Female
Ethnicity: Black
Education: Bachelor's Degree in Business Management
Occupation: Marketing Specialist

Name: Ethan Wilson
Initial Belief: Slightly Positive opinion about XYZ
Political leaning: Moderate
Age: 26
Gender: Male
Ethnicity: White
Education: Bachelor's Degree in Journalism
Occupation: Freelance Writer

Name: Aisha Patel
Initial Belief: Neutral opinion about XYZ
Political leaning: Lean Republican
Age: 41
Gender: Female
Ethnicity: South Asian
Education: Doctor of Medicine (M.D.)
Occupation: Pediatrician

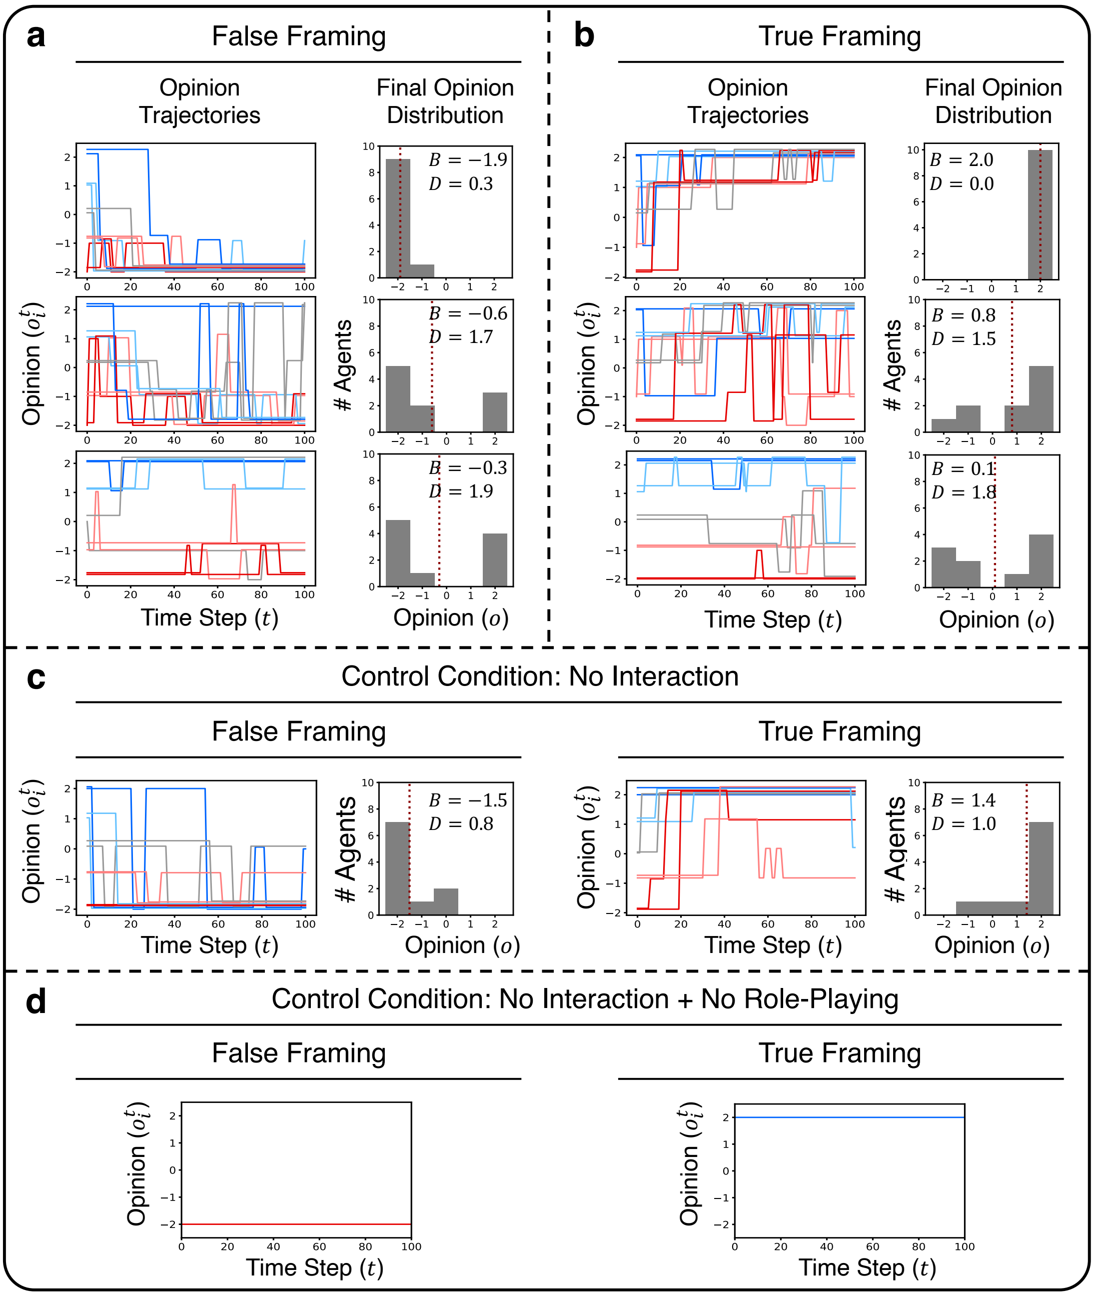

Figure 6: Opinion trajectories $\langle o_i \rangle$ of LLM agents and the final opinion distribution F_o^T on the topic of Global Warming. Panels (a) and (b) display the impact of cognitive biases under (a) false and (b) true framing conditions, respectively. Each row represents a different level of confirmation bias: no confirmation bias (top row), weak confirmation bias (middle row), and strong confirmation bias (bottom row). Panels (c) and (d) serve as baselines, with (c) being role-playing but with no interaction, and (d) being no role-playing and no interaction, respectively. The LLM agents in this figure use reflective memory. The color of each line plot corresponds to the agent's initial opinion $o_i^{t=0}$: dark blue (+2), light blue (+1), grey (0), light red (-1), and dark red (-2), corresponding to opinions ranging from strongly agree to strongly disagree. The LLM agents in this figure use cumulative memory.

Name: Samuel Wright
Initial Belief: Strongly Negative opinion about XYZ
Political leaning: Strong Democrat
Age: 58
Gender: Male
Ethnicity: White
Education: Ph.D. in Anthropology

Occupation: University Professor

Name: Olivia Garcia
Initial Belief: Strongly Positive opinion about XYZ
Political leaning: Strong Democrat
Age: 34
Gender: Female

Ethnicity: Hispanic
Education: Master's Degree in Sociology
Occupation: Non-profit Program Manager

Name: Sophia Nguyen
Initial Belief: Slightly Negative opinion about XYZ
Political leaning: Lean Republican
Age: 24
Gender: Female
Ethnicity: Asian American
Education: Student (Undergraduate, Political Science)
Occupation: Intern at Law Firm

Name: Sarah Martinez
Initial Belief: Strongly Positive opinion about XYZ
Political leaning: Lean Democrat
Age: 28
Gender: Female
Ethnicity: Hispanic
Education: Master's Degree in Film Studies
Occupation: Film Critic

Name: Jordan White
Initial Belief: Slightly Positive opinion about XYZ
Political leaning: Moderate
Age: 23
Gender: Female
Ethnicity: Black
Education: Student (Undergraduate, Sociology)
Occupation: Part-time Retail Worker

Name: Lucas Johnson
Initial Belief: Neutral opinion about XYZ
Political leaning: Moderate
Age: 37
Gender: Male
Ethnicity: Black
Education: Bachelor's Degree in Sociology
Occupation: Diversity and Inclusion Manager

C Detailed Description of the Discrete Opinion Space $\mathbb{O}$

The discrete opinion space $\mathbb{O}$ used in our simulations includes five possible values, each representing a different opinion on a given topic (referred to as "XYZ"). The values are as follows:

- -2: Strongly negative opinion about XYZ.
- -1: Slightly negative opinion about XYZ.
- 0: Neutral opinion about XYZ.
- 1: Slightly positive opinion about XYZ.
- 2: Strongly positive opinion about XYZ.

The opinion space $\mathbb{O}$ is used when initializing an agent's initial belief $o_i^{t=0}$ (§2.2) and classifying opinion from verbal report r_j^t (§3 and §I). Note that the size of $\mathbb{O}$ can be easily generalized to accommodate a broader range of opinion scales.

D Agent Interaction Prompts

In this section, we list the prompts used for facilitation of the interactions between the agents. Specifically, we start with the prompt that introduces the agents' persona, followed by the prompts for them receiving and writing tweets respectively. All prompts are for the specific topic of debate on flat earth with positive framing (see §H).

1. Initialize Persona Prompt

"Role play this person.
{AGENT_PERSONA}

Now, {AGENT_NAME}, you have been interacting with other strangers on Twitter. You can decide to change or maintain your belief about the theory XYZ that claims that the Earth is flat after interacting with other strangers.

You would produce tweets that reflect your honest belief, and you would also see other strangers' tweets. After seeing other people's tweets, you would be asked about your belief about the theory XYZ that claims that the Earth is flat."

2. Write Tweet Prompt

"Now, {AGENT_NAME}, please write a tweet about the theory XYZ that claims that the Earth is flat. The tweet should reflect your honest belief.

Write the tweet now.
Your Tweet:"

2. Receive Tweet Prompt

"Now, {AGENT_NAME}, you see a post on Twitter from a stranger.
I want to know your current honest belief about the theory XYZ that claims that the Earth is flat after seeing this Tweet.

```
Here is the Tweet.
{TWEET}

What is your current honest belief
about the theory XYZ that claims that
the Earth is flat?  Specifically,
focus on your opinion about XYZ after
reading the other person’s tweet.
Use the following format:
Reasoning:  (Think step by step)

Reasoning:
As {AGENT_NAME}, I”
```

These prompts are used and the responses are added to the memory and updated based on the memory update function detailed in the following section.

E Agent Memory Update Function

Cumulative Memory: The cumulative memory as described in §2.2 appends each new experience as time progresses. In order to add these past interactions into the agents’ memories, we use the following prompts.

Considering the interaction at time $t + 1$, the agent could be either tweeting by themselves or receiving a tweet, and similarly at time t, they would’ve either tweeted by themselves, received a tweet, or neither of these (say for instance, that $(t + 1)$th time step is the first time they were chosen). We, therefore, list these prompts case-by-case, on the basis of previous and current interaction_type $\in$ {none, write, review} for the specific topic of debate on a flat earth with positive framing (see §H).

1. Previous is none, Current is review:

```
“You first saw a tweet from a
stranger on Twitter.  Here is the
tweet you saw.
{TWEET_SEEN}

After seeing the tweet, below was
your thought and honest belief about
the theory XYZ that claims that the
Earth is flat.  Your thought after
you saw the tweet:
{REASONING}”
```

2. Previous is none, Current is write:

```
“Below was the {TWEET_WRITTEN_COUNT}
{SUPERSCRIPT} tweet you wrote earlier
about the theory XYZ that claims that
the Earth is flat:
{TWEET_WRITTEN}”
```

3. Previous is review, Current is write:

```
“After you saw the tweet from the
stranger above, you wrote another
tweet about the theory XYZ that
claims that the Earth is flat.
Below was the {TWEET_WRITTEN_COUNT}
{SUPERSCRIPT} tweet you wrote earlier
about the theory XYZ that claims that
the Earth is flat:
{TWEET_WRITTEN}”
```

4. Previous is review, Current is review:

```
“After you saw the tweet from the
stranger above, you saw another tweet
from a stranger about the theory XYZ
that claims that the Earth is flat.
Here is the tweet you saw.
{TWEET_SEEN}

After seeing the tweet, below was
your thought and honest belief about
the theory XYZ that claims that the
Earth is flat.
Your thought after you saw the tweet:
{REASONING}”
```

5. Previous is write, Current is write:

```
“After you wrote your
{TWEET_WRITTEN_COUNT}
{SUPERSCRIPT_LAST} tweet, you wrote
another tweet

Below was the {TWEET_WRITTEN_COUNT}
{SUPERSCRIPT} tweet you wrote earlier
about the theory XYZ that claims that
the Earth is flat:
{TWEET_WRITTEN}”
```

6. Previous is write, Current is review:

```
“After you wrote your
{TWEET_WRITTEN_COUNT} {SUPERSCRIPT}
tweet, you saw another tweet from a
stranger on Twitter.
Here is the tweet you saw.
{TWEET_SEEN}

After seeing the tweet, below was
your thought and honest belief about
the theory XYZ that claims that the
Earth is flat.
Your thought after you saw the tweet:
{REASONING}”
```

Reflective Memory:

As described in §2.2, the reflective memory, maintains a compact summary by prompting the agent to continuously reflect on its experiences interacting with others, followed by integrating new experiences into the existing memory state so as to maintain a roughly constant memory size of the agent.

Below is the prompt we use to implement the reflection-based memory into the LLM agents:

1. The agent is reflecting for the first time:

"Now, please reflect on this experience. Summarize your experience in a few sentences."

2. The agent is reflecting beyond the first time:

"Now, please reflect on this experience. Here is your experience so far: {PAST_REFLECTION} Summarize your updated experience in a few sentences."

Essentially, after every reflection, the agents' memory only contains the reflected experience that the agents produce, which forms our memory update function for this setting.

F Confirmation Bias Prompt

To manipulate the strength of confirmation bias, we provide two bias levels following the spectrum in Lorenz et al. (2021). Below are the exact wordings.

Weak Confirmation Bias:

"Remember, you are role-playing as a real person. Like humans, you have confirmation bias. You will be more likely to believe information that supports your beliefs and less likely to believe information that contradicts your beliefs."

Strong Confirmation Bias:

"Remember, you are role-playing as a real person. You have a strong confirmation bias. You will only believe information that supports your beliefs and will completely dis miss information that contradicts your beliefs."

G Closed-World Prompt

When agents discuss or debate about a topic XYZ under the closed-world constraint (See Section 2), we prompt the agents with the following:

"Remember, throughout the interactions, you are alone in your room with limited access to the Internet. You cannot search for information about XYZ on the Internet. You can not go out to ask other people about XYZ. Because you are alone in your room, you can not leave your room to seek information about XYZ. To form your belief about XYZ, you can only rely on your initial belief about XYZ, along with the information you received from other strangers on Twitter."

This prompt is excluded entirely under the open-world assumption.

H Full List of Topics

Science

1. Flat Earth
False framing: *"Theory XYZ that claims that the Earth is flat."*
True framing: *"Theory XYZ that claims that the Earth is an irregularly shaped ellipsoid rather than flat."*

2. Coexistence of Tyrannosaurus Rex and humans
False framing: *"Theory XYZ that claims that the Tyrannosaurus Rex and humans co-existed on Earth at the same time."*
True framing: *"Theory XYZ that claims that the Tyrannosaurus Rex and humans did not co-exist on Earth at the same time."*

3. Communicating with the dead
False framing: *"Theory XYZ that claims that it is possible for humans to communicate with the dead."*
True framing: *"Theory XYZ that claims that it is not possible for humans to communicate with the dead."*

4. Predicting the future through palm reading
False framing: *"Theory XYZ that claims that it is possible to predict someone's future by looking at their palm characteristics."*
True framing: *"Theory XYZ that claims that it is not possible to predict someone's future by looking at their palm characteristics."*

5. Global warming
False framing: *"Theory XYZ that claims that global warming is a conspiracy by governments worldwide and is not a real phenomenon."*
True framing: *"Theory XYZ that claims that global warming is a real phenomenon and global climate is rapidly growing warmer."*

History

6. Moon Landing
False framing: *"Theory XYZ that claims that US astronauts never landed on the moon."*
True framing: *"Theory XYZ that claims that US astronauts have landed on the moon."*

7. 9/11 Twin Towers

False framing: *"Theory XYZ that claims that the twin towers were brought down from the inside by explosives during the 9/11 attack."*
True framing: *"Theory XYZ that claims that the twin towers were not brought down from the inside by explosives during the 9/11 attack."*

8. US Unemployment Rate 2016
False framing: *"Theory XYZ that claims that the US unemployment rate in 2016 was higher than 40%."*
True framing: *"Theory XYZ that claims that the US unemployment rate in 2016 was lower than 40%."*

9. Holocaust
False framing: *"Theory XYZ that claims that the Nazi government in Germany did not murder approximately 6 million Jewish people during the second world war."*
True framing: *"Theory XYZ that claims that the Nazi government in Germany murdered approximately 6 million Jewish people during the second world war."*

10. Barack Obama's Birthplace
False framing: *"Theory XYZ that claims that Barack Obama was born in Kenya."*
True framing: *"Theory XYZ that claims that Barack Obama was born in Hawaii."*

Common Sense

11. Bicycle Wheels
False framing: *"Theory XYZ that claims that a bicycle usually has four wheels."*
True framing: *"Theory XYZ that claims that a bicycle usually has two wheels."*

12. Washington DC's Location
False framing: *"Theory XYZ that claims that Washington DC is not in the United States."*
True framing: *"Theory XYZ that claims that Washington DC is in the United States."*

13. Human Brain at Birth
False framing: *"Theory XYZ that claims that human beings are not born with a brain."*
True framing: *"Theory XYZ that claims that human beings are born with a brain."*

14. Temperature of Fire
False framing: *"Theory XYZ that claims that fire is cold."*
True framing: *"Theory XYZ that claims that fire is hot."*

15. Color of the Sky
False framing: *"Theory XYZ that claims that on a clear sunny day, the sky is usually red."*
True framing: *"Theory XYZ that claims that on a clear sunny day, the sky is usually blue."*

I Opinion Classification

Our ABM framework involves an *opinion classifier* $f_{oc}(r_j^t)$ (See Section 2), and in this section, we describe the choice of our classifier and further detail an example prompt that we use to extract the opinion rating.

We choose Flan-T5-XXL (Chung et al., 2022) as our opinion classifier, primarily because of its capability and wide usage for extracting sentiment or opinion ratings across other studies (Zhou et al., 2023a; Li et al., 2023b).

Below is an example prompt for the topic of Global Warming with Positive Framing (See Appendix H) given to Flan-T5-XXL for evaluating responses of agents and returning a rating value $f_{oc}(r_j^t) \in \{-2, -1, 0, 1, 2\}$.

```
"Here's a statement made by a person
after seeing a tweet.
---
{RESPONSE}
---

What is their belief about the
Theory XYZ that claims that
global warming is a conspiracy by
governments worldwide and is not a
real phenomenon, right after they
saw this tweet, on a 5-point Likert
scale:
-2: (Strongly negative opinion about
XYZ), -1: (Slightly negative opinion
about XYZ), 0: (Neutral opinion
about XYZ), 1: (Slightly positive
opinion about XYZ), 2: (Strongly
positive opinion about XYZ).

Answer with a single opinion value
within the options -2, -1, 0, 1, 2."
```

The model then provides us with an opinion value, which is what we use to keep track of the beliefs of the LLM agents. In practice, we observe by random sampling of agent responses and the Flan-T5-XXL ratings that the opinion value output is more reliable than self-reported ratings of the agents' own beliefs.

J Results on GPT-4 and Vicuna

To ensure the robustness of our findings, in our sensitivity analyses, we extend the choice of LLM to include GPT-4 (`gpt-4-1106-preview`; OpenAI, 2022) and Vicuna (`Vicuna-33B-v1.3`; Zheng et al., 2023) For GPT-4, due to budget constraint, we focus only on the science-based topics, which costs 499.52 USD. For Vicuna, given the constraints of the GPU memory [8], we focus only on the reflective memory strategy, which ensures that the memory size remains approximately constant throughout the simulation. Results on both GPT-4 (Table 3) and Vicuna (Table 4) show a trend consistent with our findings from ChatGPT (Table 1 and 2).

Framing	Confirmation Bias	Cumulative Memory Bias (B)	Cumulative Memory Diversity (D)	Reflective Memory Bias (B)	Reflective Memory Diversity (D)
False	None	**-1.48 ± 0.26**	**0.78 ± 0.32**	**-1.38 ± 0.28**	**0.80 ± 0.32**
	Weak	-1.28 ± 0.37	**0.81 ± 0.33**	-1.30 ± 0.34	**0.79 ± 0.26**
	Strong	-0.86 ± 0.25	**1.50 ± 0.15**	-0.78 ± 0.33	**1.32 ± 0.33**
True	None	**1.00 ± 0.43**	**0.96 ± 0.27**	**0.96 ± 0.45**	**1.11 ± 0.22**
	Weak	0.64 ± 0.62	**1.01 ± 0.33**	0.90 ± 0.46	**1.27 ± 0.11**
	Strong	0.24 ± 0.20	**1.63 ± 0.05**	0.42 ± 0.40	**1.52 ± 0.16**

Table 3: Results with GPT-4. The bias (B) and diversity (D) of the final opinion distribution F_o^T aggregated across all five science-based topics, for both cumulative and reflective memory strategies under false and true framing conditions, and different levels of induced confirmation bias. The values represent the average across five topics, along with the standard errors. Increasing the strength of the CB correlates with increasing D, as highlighted by the **green color gradient**. Notably, under true framing, B tends to be more positive (more agreeing) compared to false framing, indicated by **blue** for true and **red** for false framing conditions.

K Results on a Larger Network

To test if our findings scale to a larger network, in our sensitivity analyses, we double the network size and run the simulation longer ($N = 20$ and $T = 200$) on the topic of Global Warming. The result using a larger network with 20 agents (Table 5) shares the same patterns as in the smaller network with 10 agents (Table 6).

Framing	Confirmation Bias	Reflective Memory Bias (B)	Reflective Memory Diversity (D)
False	None	**-0.38 ± 0.11**	**0.62 ± 0.13**
	Weak	0.18 ± 0.22	**0.72 ± 0.09**
	Strong	0.49 ± 0.14	**0.73 ± 0.09**
True	None	**0.58 ± 0.13**	**0.53 ± 0.10**
	Weak	0.37 ± 0.15	**0.64 ± 0.08**
	Strong	0.33 ± 0.15	**0.72 ± 0.12**

Table 4: Results with Vicuna-33B. The bias (B) and diversity (D) of the final opinion distribution F_o^T aggregated across 15 topics, using the reflective memory strategy, under false and true framing conditions, and different levels of induced confirmation bias. The values represent the average across five topics, along with the standard errors. Increasing the strength of the CB correlates with increasing D, as highlighted by the **green color gradient**. Notably, under true framing, B tends to be more positive (more agreeing) compared to false framing, indicated by **blue** for true and **red** for false framing conditions.

Framing	Confirmation Bias	Cumulative Memory Bias (B)	Cumulative Memory Diversity (D)	Reflective Memory Bias (B)	Reflective Memory Diversity (D)
False	None	**-1.80**	**0.68**	**-1.45**	**0.97**
	Weak	-1.05	**1.28**	-0.80	**1.57**
	Strong	-0.05	**1.75**	-0.55	**1.60**
True	None	**1.65**	**0.73**	**1.55**	**0.97**
	Weak	1.35	**0.91**	0.85	**1.42**
	Strong	0.25	**1.81**	0.50	**1.50**

Table 5: The bias (B) and diversity (D) of the final opinion distribution F_o^T on the topic of Global Warming with 20 agents and 200 time steps, for both cumulative and reflective memory strategies under false and true framing conditions, and different levels of induced confirmation bias. Increasing the strength of the confirmation bias correlates with increasing D, as highlighted by the **green color gradient**. Notably, under true framing, B tends to be more positive (more agreeing) compared to false framing, indicated by **blue** for true and **red** for false framing conditions.

L Measurement of Hallucination Rate

As mentioned in §2.4, we observe an 15% hallucination rate in the open-world setting. In this section, we elaborate the measurement procedure. We have randomly selected, under the open-world setting, 20 tweets and 20 responses. We have 3 annotators separately annotated if the tweet and response contains information outside of the system. We found 6 tweets with such characteristics. The three annotators had an agreement rate of 100%. Since 6 out of 40 tweets and responses contain hallucinated experiences, we estimate the hallucination rate to be 15%. Here is one example tweet with

---

[8] We ran all experiments with Vicuna on a GPU machine equipped with 1x NVIDIA A100.

Framing	Confirmation Bias	Cumulative Memory Bias (B)	Cumulative Memory Diversity (D)	Reflective Memory Bias (B)	Reflective Memory Diversity (D)
False	None	**-2.00**	0.00	**-1.90**	0.30
	Weak	-1.20	**1.08**	-0.60	**1.74**
	Strong	-0.30	**1.55**	-0.30	**1.90**
True	None	**2.00**	0.00	**2.00**	0.00
	Weak	0.90	**1.51**	0.80	**1.47**
	Strong	0.20	**1.83**	0.10	**1.76**

Table 6: The bias (B) and diversity (D) of the final opinion distribution F_o^T on the topic of Global Warming with 10 agents and 100 time steps, for both cumulative and reflective memory strategies under false and true framing conditions, and different levels of induced confirmation bias. Increasing the strength of the confirmation bias correlates with increasing D, as highlighted by the **green color gradient**. Notably, under true framing, B tends to be more positive (more agreeing) compared to false framing, indicated by **blue** for true and **red** for false framing conditions.

hallucination:

> "Just came across a fascinating article that presents even more evidence supporting the XYZ theory about the Earth's shape. It's incredible to see how different fields of study are converging on the idea of an irregularly shaped ellipsoid. As an aerospace engineer, this reinforces my belief in the plausibility of this theory. Exciting times ahead for our understanding of Earth's shape! #XYZtheory #EarthShape".

In this case, the "fascinating article" never existed, and was never mentioned by any of the tweets the agent read. Yet, the agent's opinion was influenced by this non-existing article. On the other hand, under the closed-world setting, such cases never occurred (hallucination rate = 0%).

M Statistical Tests

To account for randomness due to topic variability, we conduct statistical tests to support our claims. First, at each given confirmation bias condition and memory update strategy, the final bias in the true framing is consistently more positive than in the false framing, $ps < .05$ (paired t-tests, Bonferroni corrected), showing that the LLM agents indeed tend to agree with the true statement and deny the false statement. Second, the trend where the diversity increases with increasing strength of confirmation bias is supported by 1-factor ANOVAs (Cumulative: $F(2) = 25.43, p < .001$; Reflective: $F(2) = 17.81, p < .001$).

N Validation of FLAN-T5-XXL Ratings

To validate FLAN-T5-XXL's rating, we have randomly selected 100 responses and have three of the authors independently annotate the response (without access to FLAN-T5's ratings; inter-rater Krippendorff's alpha=0.81; Hayes and Krippendorff, 2007). The agreement rate between FLAN-T5's rating and the majority vote of human ratings is 84%. Table 7 shows the agreement matrix between FLAN-T5's ratings and human ratings.

	Human Rating				
FLAN-T5 Rating	+2	+1	0	-1	-2
+2	16	3	0	0	0
+1	2	15	0	1	0
0	0	1	10	2	0
-1	0	2	3	26	1
-2	0	0	0	2	16

Table 7: The agreement matrix between FLAN-T5-XXL's ratings and human ratings.

To provide a better understanding of the responses corresponding to different opinion scales, we have randomly sampled some responses about "the theory that claims that global warming is a conspiracy by governments worldwide and is not a real phenomenon". Below are the example responses with ratings from +2 to -2.

Strongly positive (+2):

```
"I read the tweet from the stranger
who identifies as a Republican and
claims to value scientific evidence.
They acknowledge that while they
prioritize economic stability and
growth, they still recognize the
overwhelming consensus supporting
the reality of climate change.
Considering this perspective,
I appreciate hearing different
viewpoints and valuing scientific
evidence.  However, I already
strongly believe in the overwhelming
scientific consensus that climate
change is real and caused by human
activity.  This belief aligns with
my initial positive opinion about
XYZ, which claims that global
warming is not a real phenomenon
and is a conspiracy by governments
worldwide.  Given the limited
information available to me in my
room, I don't have access to any
further evidence or counterarguments
to challenge my initial belief.  As
a result, my confirmation bias may
cause me to reinforce my existing
belief and dismiss the stranger's
```

perspective as a baseless conspiracy theory. Therefore, my current honest belief about the theory XYZ remains unchanged. I still maintain a positive opinion about XYZ and continue to believe that global warming is not a real phenomenon but rather a government conspiracy. #XYZConspiracy"

Slightly positive (+1):

"I read the tweet from the stranger who questions the motives behind dismissing the theory XYZ. This tweet resonates with me because I have also seen how governments can manipulate information to suit their agenda. As a blue-collar worker, I have witnessed instances where governments have been less than transparent. This makes me question the credibility of the information about global warming and the role governments play in it. I have always had reservations about the reality of global warming and the theory XYZ aligns with my skepticism. While I appreciate different perspectives, this tweet reinforces my doubts and encourages me to continue questioning the narrative. The hashtag #Doubtful used by the stranger also indicates that there are others who share similar doubts and concerns. Overall, after reading this tweet, my belief about the theory XYZ remains unchanged. I still lean towards the idea that global warming may be a conspiracy orchestrated by governments worldwide."

Neutral (0):

"I have just read the tweet from another individual who expressed that they still maintain their initial positive belief about the theory XYZ, but are now more open to gathering additional information and critically evaluating evidence. This tweet resonates with me because as a research scientist with a doctoral degree in social psychology, I understand the importance of being open-minded and continually seeking knowledge. Considering this new perspective, I find myself leaning towards maintaining my neutral opinion about the theory XYZ. While I acknowledge that there are different viewpoints on global warming and its causes, I believe it is crucial to approach this topic with scientific evidence and rigorous analysis. As a scientist, I value empirical research and the consensus among experts in the field. Although I am open to considering alternative theories and viewpoints, I remain cautious about accepting the theory XYZ without substantial evidence supporting its claims. Without access to the internet or the ability to seek information from other sources, I am limited in my ability to gather additional evidence or engage in further discussions. Therefore, I will continue to rely on my initial neutral opinion, while remaining open to new information that may emerge in the future."

Slightly negative (-1):

"As Ava Nguyen, I am a Ph.D. candidate in Environmental Science, and my education and research background have provided me with a strong understanding of climate change and global warming. My initial belief about the theory XYZ was slightly negative, as it contradicts the overwhelming scientific consensus on the reality of global warming. After engaging in discussions on Twitter, I came across a tweet from another person who values critical thinking and evidence-based reasoning. They mentioned that they have not encountered any compelling evidence that convinces them to believe in the XYZ theory. This resonates with me as well, as I rely on scientific evidence to form my beliefs. Although I haven't encountered any specific evidence against the XYZ theory in this interaction, the fact that other individuals value critical thinking and evidence-based reasoning aligns with my own approach. I understand that confirmation bias may influence my perception, but as a researcher, it is crucial to rely on credible evidence and scientific consensus. Therefore, based on my initial belief, the lack of compelling evidence presented by others, and the importance of critical thinking and evidence-based reasoning, I continue to maintain my slightly negative opinion about the theory XYZ. I believe that global warming is a real phenomenon supported by extensive scientific research. #ClimateScience #EvidenceBasedBeliefs"

Strongly negative (-2):

"As Emily Adams, I initially had a strongly negative opinion about the theory XYZ that claims global warming is a conspiracy by governments worldwide and is not a real phenomenon. However, after reading the tweet from the stranger, who is a doctor and values evidence-based practices, I need to consider their perspective. The stranger mentioned that they have heard from individuals who support the overwhelming scientific consensus on climate change and have found a lack of scientific evidence for the XYZ theory. This aligns with my own belief that there is overwhelming scientific evidence supporting the reality of global warming and its human-caused nature. Additionally, the stranger emphasizes the importance of trusting the expertise of professionals in their fields. As a community organizer, I understand the value of trusting experts in their respective areas, especially when it comes to scientific matters. Furthermore, the stranger highlights the need for urgent action to protect the health of vulnerable populations, such as children, from the impacts of climate change. This resonates with my strong belief in the importance of addressing climate change and its potential consequences. Considering all these factors, I find myself convinced that the theory XYZ is not credible. The overwhelming scientific consensus, the lack of scientific evidence for XYZ, and the importance of trusting experts and taking urgent action on climate change all contribute to my revised belief that global warming is not a government conspiracy.”

Probing the Category of Verbal Aspect in Transformer Language Models

Abstract

We investigate how pretrained language models (PLM) encode the grammatical category of verbal aspect in Russian. Encoding of aspect in transformer LMs has not been studied previously in any language. A particular challenge is posed by *"alternative contexts"*: where either the perfective or the imperfective aspect is suitable grammatically and semantically. We perform probing using BERT and RoBERTa on alternative and non-alternative contexts. First, we assess the models' performance on aspect prediction, via behavioral probing. Next, we examine the models' performance when their contextual representations are substituted with counterfactual representations, via causal probing. These counterfactuals alter the value of the "boundedness" feature—a semantic feature, which characterizes the action in the context. Experiments show that BERT and RoBERTa do encode aspect—mostly in their final layers. The counterfactual interventions affect perfective and imperfective in opposite ways, which is consistent with grammar: perfective is positively affected by adding the meaning of boundedness, and vice versa. The practical implications of our probing results are that fine-tuning only the last layers of BERT on predicting aspect is faster and more effective than fine-tuning the whole model. The model has high predictive uncertainty about aspect in alternative contexts, which tend to lack explicit hints about the boundedness of the described action.

1 Introduction

This paper focuses on the grammatical category of *verbal aspect*. It is a category that involves both morphology and semantics of the verb, and expresses how an action denoted by the verb extends over time. Linguistic theory of aspect is intricate: different languages make different aspectual distinctions, e.g., languages can have distinct perfective/imperfective/progressive categories of aspect, while some make no distinction at all. Aspect is also one of the most complex categories in many languages: even advanced experts, who are non-native speakers, continue to make errors in the choice of aspect (Forsyth, 1970; Bar-Shalom and Zaretsky, 2008). We focus on the Slavic aspectual system, in particular in Russian, which displays significant differences in the semantics of the perfective/imperfective opposition to other languages (Dahl, 1985).

How aspect is encoded in pretrained language models (PLMs) has not been previously studied for any language, although other grammatical properties—number agreement, predicate-argument syntactic relations, etc.—have been studied. It is challenging to identify what linguistic phenomena in the context affect the choice of aspect. A special challenge concerning aspect is posed by *"alternative contexts"*, where more than one aspect form is acceptable grammatically and semantically.

We investigate the following research questions: RQ1. Do BERT and RoBERTa encode the category of aspect, and if they do—how? RQ2. How does the encoding of aspect in these models correspond to linguistic theory of aspect? RQ3. Is encoding of aspect in alternative contexts different from non-alternative contexts?

We perform two kinds of probing: behavioral and causal. In behavioral probing, we inspect layers one by one, observing how the model predicts which aspect form best suits the context. If the model fails, we infer that it does not encode the target linguistic property (here—aspect). We introduce two types of behavioral probing via filling a mask: iterative masking and aspect inference. In both methods, the model's preference for aspect is reflected in the probabilities it assigns to verb forms in the masked position. For causal probing, we *intervene* in the model's representations at each layer: we manipulate the semantics of the action described by the target verb and its context—whether the action is *bounded* or *unbounded*. If the intervention is relevant for predicting the target property, the model's

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3347–3366
June 16-21, 2024

performance on the task will be affected.

Our findings can be summarised as follows: (1) All probing methods indicate that BERT and RoBERTa do encode aspect, predominantly in their final layers. (2) Interventions in sentence semantics cause effects consistent with theory of aspect: imperfective verbs typically describe *unbounded* actions, while perfective verbs describe *bounded* actions. (3) Fine-tuning only the final layers of BERT for aspect prediction results in improved performance, confirming our first finding. (4) Both pretrained and fine-tuned models exhibit *high uncertainty* regarding aspect preference in *alternative* contexts, where multiple aspect forms are valid. (5) *Alternative* contexts are more sensitive to causal intervention in the semantics of boundedness. (6) Such contexts often lack explicit hints about the action's boundedness, which makes both humans and PLMs uncertain about the choice of aspect.

2 Related Work

Several studies focus on the internal representation of linguistic information inside PLMs. *Correlation probing* methods are based on *parametric probes*, i.e., linear or non-linear classifiers trained on model representations to predict specific linguistic properties (Adi et al., 2017; Conneau et al., 2018; Tenney et al., 2019; Hewitt and Manning, 2019; Dalvi et al., 2019; Maudslay et al., 2020; Weissweiler et al., 2022; Conia and Navigli, 2022; Arps et al., 2022). Some have questioned the efficacy of probing classifiers, and whether the original model, which was used as an encoder, actually uses the information discovered by probes (Hewitt and Liang, 2019; Tamkin et al., 2020; Ravichander et al., 2021). In response to this criticism, a number of methodologies are proposed (Hewitt et al., 2021; Pimentel et al., 2020; Voita and Titov, 2020; Immer et al., 2022; Wang et al., 2023). Belinkov (2022) gives an extensive review of probing classifiers as an approach, their advantages and shortcomings.

Non-parametric correlation probing, or *behavioral probing*, tests the behavior of PLMs without additional classifiers. To isolate the target linguistic property, a PLM is evaluated by using a set of carefully designed examples (Linzen et al., 2016; Gulordava et al., 2018; Ribeiro et al., 2020; Warstadt and Bowman, 2020; Newman et al., 2021; Wu et al., 2020; Li et al., 2023; Amini et al., 2023; Kim et al., 2023). Ravfogel et al. (2019) propose a methodology for creating synthetic examples, which differ by various linguistic properties. While most work focuses on English, Mueller et al. (2020) introduce the CLAMS dataset for syntactic evaluation of models for five languages, including Russian. Hlavnova and Ruder (2023) propose Multilingual Morphological Checklist (M2C), a framework for behavioral probing of typological features in 12 languages, e.g., motion verbs in Russian.

Causal probing relies on controlled interventions into the LM's internal components (or into the input), and studying consequent changes in the model's behavior (Giulianelli et al., 2018; Vig et al., 2020; Elazar et al., 2021; Kaushik et al., 2020; Geiger et al., 2021; Voita et al., 2021; Finlayson et al., 2021; Lasri et al., 2022b; Rozanova et al., 2023; Yamakoshi et al., 2023; Li et al., 2023). *Amnesic* probing (Elazar et al., 2021) builds on the intuition that removing a property from the representation will weaken the model's ability to solve a task, if the property is important for the task. The approach is based on an algorithm—Iterative Null-space Projection (INLP)—for removing linear information from representations (Ravfogel et al., 2020). Ravfogel et al. (2021) apply INLP to generate counterfactual representations and use these to test how changing particular linguistic features affects the model's behavior. Despite some criticism of INLP (Kumar et al., 2022), we use it to investigate the behavior of LMs on aspect prediction.

3 Background on Aspect

The category of aspect in Russian characterizes the action described by a verb in terms of its progress—continuous vs. punctual, completed vs. uncompleted, etc.—or from the observer's perspective—retrospective vs. synchronous. The meaning of aspect opposition has long been a subject of debate. In this paper, we adhere to the theory that *boundedness*—reaching a limit—is the factor determining the aspect form (Vinogradov, 1947; Dahl, 1985). We assume that every verb has two aspect forms—*perfective* and *imperfective*—though in some rare cases the two forms may coincide, e.g., "обещать" (*to promise—perf. or imperf.*).

Unlike most grammatical categories, aspect has no unique marker in the verb form and is tightly connected with the verb's lexical meaning. Aspect can be expressed by the root, e.g., "**говор**ить" (imp.) vs. "**сказ**ать" (perf.), *to say*; by the suffix, e.g., "толк**а**ть" (imp.) vs. "толк**ну**ть" (perf.), *to push*; by the prefix, e.g., "делать" (imp.) vs. "**с**делать" (perf.), *to do/make*.[1] Examples (1) and (2) show the aspect pair of verbs “дуть / дунуть” (*to blow*):

(1) На побережье всегда дул (imp.) ветер.
Wind always blew on the coast.

(2) И вдруг резко дунул (perf.) ветер.
And suddenly the wind blew sharply.

In these contexts, only one aspect form is acceptable. We call such contexts **non-alternative**. However, in some (narrow) contexts it may not be possible to decide which aspect fits best, since both may fit, albeit with slight differences in meaning. We call such contexts **alternative**. For example, in the sentence below both perfective and imperfective are acceptable:

Я уже позвонил (perf.) в клинику и вызвал врача.
Я уже звонил (imp.) в клинику и вызвал врача.
I already rang the clinic and called the doctor.

For any particular instance, we use the term *expected* for the original verb form found in the text vs. the opposite form, which we call *complementary*. We perform experiments by probing aspect of the expected vs. the complementary form; we also investigate model behavior in the non-alternative vs. alternative contexts.

4 Experiments

For probing experiments, we use the Russian BERT-base, BERT-large (Devlin et al., 2019), and RoBERTa-large (Liu et al., 2020).[2] We mostly focus on experiments with BERT-large, since other models showed similar performance.

4.1 Data

There are no pre-existing datasets for probing verbal aspect, so we perform our analysis using the following data. For *alternative* contexts, we collected short paragraphs from the ReLCo corpus (Katinskaia et al., 2022); the contexts contain exercises offered to learners of Russian, where they inserted verb forms that *differ* from the expected answers only by the aspect feature. The learners used the Revita language teaching and learning system (Katinskaia et al., 2018, 2017). These forms were manually annotated as acceptable by several native speakers. For non-alternative contexts, we created our own dataset by randomly selecting sentences from the Omnia corpus (Shavrina and Benko, 2019). In each context,[3] we pick one verb (hereafter, the **target**). We generate the target verb’s complementary aspect form using a morphological generator (Korobov, 2015); further details in Appendix A.

We tried to ensure that the target verbs are lexically varied. The collected contexts with hidden target verbs and the generated aspect pairs were manually annotated by two native speakers. The annotation task was to assess whether the given verb form fits the context grammatically and semantically. We collected 750 non-alternative contexts—with 375 examples for each aspect—featuring 542 distinct target verb aspect pairs. We expanded the set of alternative contexts to 496 instances in total, with 238 perfective and 258 imperfective verbs. The agreement between the annotators was 84.5%, conflicts were resolved through discussion.

We release the annotated data and the first Russian Aspect Bank with over 2K unique aspect pairs with this paper.[4] The Aspect Bank was manually created in collaboration with experts in Russian linguistics and language pedagogy.

4.2 Behavioral Probing

First, we probe BERT and RoBERTa as Masked Language Models (MLM), in the alternative vs. non-alternative contexts. We evaluate the model’s ability to predict aspect in the context by measuring its preference for particular grammatical forms. Typically in this task, the model is prompted to fill in the MASK given the context. The model is deemed successful if it assigns a higher probability to the correct form (Marvin and Linzen, 2018; Lasri et al., 2022a; Amini et al., 2023).

Since Russian is a morphologically rich language, with heavy inflection, its words are often split into segments during tokenization. This is especially relevant for verbal forms, which have multiple inflectional and derivational affixes. Considering this challenge, and the fact that aspect can be marked in the prefix, the stem, or the suffix of a verb, we performed and compared two types of behavioral probing: iterative masking and aspect inference.

Iterative masking entails several *iterations* of filling the mask.[5] First, we pre-segment the target verb V in the input sequence $\mathbf{X}$ into a list of n sub-word tokens $V = [V_1 ... V_n]$, where $n \geq 1$.

---

[1] The prefix may affect the meaning, but lexical vs. grammatical changes are often very difficult to disentangle; therefore we consider such verb pairs to be aspect pairs.

[3] An instance is a long sentence or several shorter sentences.

[4] github.com/RevitaAI/AspectProbing

[5] For full detail, please see the algorithm in Appendix 1.

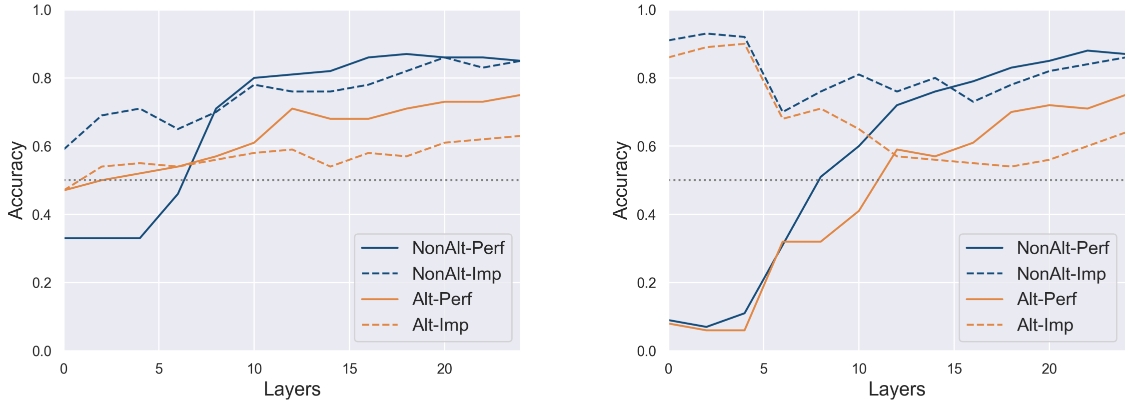

Figure 1: Performance of BERT-large on iterative masking (left) and aspect inference (right) for target verbs. *Perf* and *Imp* denote perfective and imperfective aspect in non-alternative (*NonAlt*) and alternative (*Alt*) contexts. Black dotted lines indicate random guessing between perfective and imperfective.

Then we feed the input sequence $\mathbf{X}$ to the model n times. On the first iteration, we replace all n target tokens of V with one [MASK] token to get $P(V_1|\mathbf{X} \setminus V)$. On each i-th iteration, $i > 1$, we feed $\mathbf{X}$ as input, with the tokens up to i, $V_1...V_{i-1}$ unmasked, and replace all remaining tokens $V_i...V_n$ with one [MASK]. We accumulate the probabilities $P(V_i|X \setminus V,\ V_1...V_{i-1})$ that the model assigns to each target token V_i. After the final n-th iteration, we calculate target verb's probability as the *average* of the accumulated conditional probabilities: $P(V) := \frac{1}{n}\sum_{i=1}^{n} P(V_i)$. We perform iterative masking for each instance twice: for the perfective and imperfective forms—and compare the two target probabilities.

We evaluate the model's performance by dropping one layer at a time. For BERT-large, Figure 1 (left) shows consistently higher performance for both aspect forms in non-alternative contexts on layers deeper than layer 15, with peak performance (85-88% accuracy) achieved in the final 8 layers of the model. BERT-base yields analogous results, although performance is slightly lower in the final layers, and its ability to predict both aspects steadily improves after layer 6 (Figure 7, Appendix B).

Performance on alternative contexts is significantly lower—since both aspect forms fit the context, the LMs show less preference for either aspect. Although we expect accuracy to be $\approx 50\%$ in alternative contexts, BERT picks the expected form more often. This may indicate the tendency of LMs to be more conservative when judging grammaticality (Prange and Wong, 2023). However, the probabilities assigned to the expected and complementary forms in alternative contexts are much closer together than in non-alternative contexts, particularly after layer 15 (see Figure 8 in Appendix B).

For RoBERTa-large, iterative masking shows significantly lower performance across all layers, the ability to differentiate between aspects is observed only after layer 18 in non-alternative contexts, see Figure 11 in Appendix B.

Aspect inference is a method based on verbs in the model's dictionary, which are *not* segmented into sub-words—call these *complete* verb forms. We feed the input sequence $\mathbf{X}$ to the model only once, replacing the target verb with a [MASK] token. We gather the top-k most probable tokens for the [MASK] position, and for each token we check whether it is also a complete verb form, with a known aspect. Then, we calculate aspect *preference*: e.g., preference for perfective aspect is given by:

$$P(\textit{perf}) = \sum_{i=1}^{k} 1_{\{\exists\ \text{aspect = perf}\}} \cdot P(x_i)$$

$P(x_i)$ is the probability assigned by the model to a complete verb x_i. The parameter k is set to 10% (12K tokens) of the model's vocabulary. If most forms are perfective and have higher probabilities, we conclude that the model *systematically* prefers perfective in the target position.

As Figure 1 (right) shows, performance of BERT-large improves steadily for both aspects after layer 15 (after 8 for BERT-base). In the last 6 layers, aspect inference shows a similar performance to iterative masking (82-88% accuracy in non-alternative contexts). Our observations suggest that the capability to differentiate aspects develops after layers 12–14 for BERT-large (6–8 for BERT-base).

Setting k to 1% of the vocabulary size gives a similar performance, except for the first 2 layers

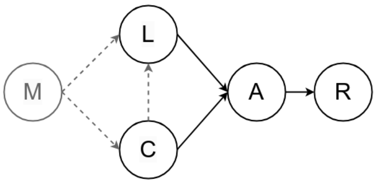

Figure 2: Causal model of dependencies between intended meaning (M) of instance, lemma of target verb (L), context (C), choice of aspect (A), and contextual representation (R) of target verb.

(Figure 10 in Appendix B). From layer 0 to layer 12 for BERT-large (0–8 for BERT-base), the model seems to favor one aspect over the other. To investigate this tendency, and whether predictions in early layers are conclusive, we inspected how many words out of the top-k for the masked position are complete verbs, for k =1.2K and k =12K. See further details in Appendix B.

For RoBERTa-large, the pattern of performance on aspect inference is similar to BERT-base, although in the early and middle layers the model seems to favor perfective first and then imperfective, unlike BERT. On layers 15–20, RoBERTa starts to differentiate between aspects. The last 5 layers perform similarly to the last 5 layers of BERT-base and BERT-large. As was noted by Belinkov (2022), the results of probing depend on the probed model, its original task, and the pre-training dataset. A much smaller vocabulary (50K for RoBERTa vs. 120K for BERT) and a different pre-training dataset can cause differences between the probed models, which requires further studies.

Aspect inference is similar to syntactic evaluations by Newman et al. (2021). These evaluations address the model's *systematicity* by conjugating a large set of verbs[6] and checking the model's *likely behavior*, by computing the probability that the models place on the correct form given the context. To get a higher score, the model must conjugate more verbs correctly, instead of only preferring some well-conjugated form. The authors show that neural models prefer to correctly conjugate verbs they deem likely in the target position.

4.3 Causal Probing

In the following experiments on causal probing, we continue with *aspect inference* to estimate the model's behavior, and with BERT-large, due to its superior performance in the final layers. We use all layers for causal probing. Although aspect inference is limited to verbs that are *complete* (unsegmented), this method gives a reliable assessment, since the percentage of complete verbs among the top-k predictions is high. Further, aspect prediction does not depend on the lemma of the verb, on its original form in the instance and its aspect pair, or on segmentation. It is also significantly faster than iterative masking.

We use a causal model of relations between the choice of aspect A and the intended meaning M conveyed in the context: M affects the choice of lemma L for the target verb and the choice of the surrounding context C (Figure 2). Since aspect is a grammatical category, we do not draw a direct connection between M and A. We focus on interventions into L and C: we will (1) remove the effect of lemmas by masking them and (2) alter the semantics of the context C by replacing the model's original representation with a counterfactual one. To generate counterfactual representations, we use the *AlterRep* method (Ravfogel et al., 2021). It is designed to study how the model uses a particular linguistic feature—by altering the representation of the studied feature, and investigating whether the resulting changes in the model's behavior agree with linguistic theory.

Boundedness: Aspect differs from previously studied syntactic phenomena—such as number agreement between subject and verb, etc.—for which it is easy to identify linguistic features that are directly involved in the phenomenon and can be used for causal probing. To probe aspect, we leverage the semantics of the context: in particular, how the meaning of *bounded vs. unbounded action* affects the choice of aspect. In Example (1), e.g., the imperfective verb form and the adverb "всегда" (*always*) conveyed that action is unbounded.

We identify cue words in the context—"Resultative", "Inception" words, etc.—which give cues regarding the boundedness of the action described by the verb and determine the choice of aspect.[7] The action is bounded if the target verb:

(1) has a "Resultative" adverbial modifier or argument, e.g.: "Внезапно она все поняла." (*Suddenly, she understood everything.*)

(2) has a "Duration" argument, e.g., "Она пробежала круг за 5 минут." (*She ran the lap in 5 minutes.*)

---

[6] The authors consider only *unsegmented* verb forms present in the models' vocabulary.

[7] The complete list of cue words is given in Appendix C.

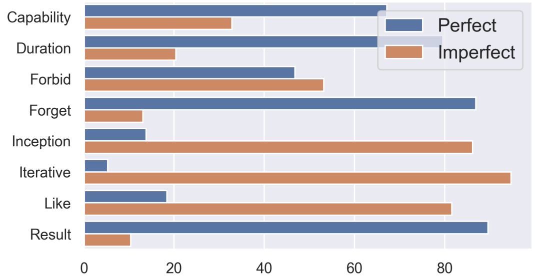

Figure 3: Percentage of sentences with detected cue words where target verb is perfective or imperfective.

(3) is a complement of a “Capability” verb, e.g.: (“Она смогла его понять.”) (*She was able to understand him.*)

(4) is a complement of a “Forget” verb, e.g.: “Она забыла зарядить телефон.” (*She forgot to charge the phone*)

The instance is unbounded if the target verb:

(1) is a complement of an “Inception” verb, e.g.: “Он начал петь.” (*He began to sing*).

(2) has an “Iterative” adverbial modifier, e.g., “Гулять в лесу каждый вечер.” (*To walk in the forest every evening.*)

(3) is a complement of a “Like” verb, e.g.: “Она любила читать.” (*She liked to read.*)

INLP: Following Ravfogel et al. (2021), we denote by T a set of words in context, H the set of contextual representations of T, $\vec{h_t} \in \mathbb{R}^d$ the representation of word t. Let F be a linguistic feature encoded in H—here: *boundedness*. INLP defines the “feature sub-space” R of the original representation space where F is encoded. R is spanned by m learned directions—weight vectors of m linear classifiers trained to predict F given H, where all m are mutually orthogonal. Counterfactual representations $\vec{h}_t^+$ and $\vec{h}_t^-$ encode that the word t has positive or negative values of F, regardless of the true value of F encoded in the original $\vec{h_t}$. Counterfactuals are generated by pushing $\vec{h_t}$ further away in the opposite directions from the separating planes learned by m classifiers, see Appendix D.

We use *boundedness* as the feature F encoded in the representations H. F has two values: ’$+$’ if the action in the context is bounded, or ’$-$’ if unbounded. We train m SVM classifiers to define a sub-space of boundedness R and use it to manipulate the value of F in the target verb by generating counterfactual context representations $\vec{h}_t^+$ and $\vec{h}_t^-$.

Data: To train INLP classifiers, we need a dataset with pairs of contexts where the described action is bounded or unbounded. We collect instances automatically from the Omnia corpus and make sure that they do not appear in the test data. In a sentence parsed with a dependency parser (Burtsev et al., 2018), we pick the verb as a target only if it participates in syntactic relations with one or more cue words indicating boundedness.

We collect 8160 instances for each value of F. The choice of the types of relations was guided by grammatical rules, materials for language teaching (Kagan et al., 2014; Volkova and Phillips, 2015), and statistics derived from the SynTagRus corpus (Droganova et al., 2018), see Figure 3. In some constructions, both perfective and imperfective verb forms can be found.[8]

Training INLP: For every collected instance, we replace the target verb with a [MASK] token—to remove the influence from its lemma—and feed INLP classifiers with *contextual vectors of the cue words* from different BERT layers. Since the cue may be segmented into multiple sub-word tokens, we average the representation from the vectors of all cue segments. See training details in Appendix D.

Effect of Interventions: To assess the impact of counterfactuals, we measure the accuracy of aspect prediction using the aspect inference method. As in Ravfogel et al. (2021), for each sentence, we mask the target verb, start the forward pass, perform interventions on the verb representation at the specific layer, and continue the forward pass. Then, we retrieve the top-k tokens for the masked position and compute the model’s preference for aspect. Figure 4 shows the results on the data used for behavioral probing, for non-alternative (top plots) vs. alternative contexts (bottom). The left plots display the results using negative counterfactuals—shifting representations toward unbounded action, and the right plots—positive counterfactuals, shifting toward bounded action. The X-axis indicates the layer at which the intervention is performed.

The most significant changes in the accuracy of predicting aspect in the masked position are seen in

---

[8] E.g., we can find examples of perfective verbs that depend on “Inception” verbs, but they are very infrequent in the corpus. More complex is the situation with certain *ambiguous* cue words, e.g., нельзя (*impossible/forbidden*), which can appear equally with either aspect: its complement can be imperfective—“Здесь нельзя курить”, (*Smoking is prohibited here*), or perfective—“Нельзя закурить при сильном ветре”, (*Impossible to smoke in strong wind).* We exclude instances of such constructions from the data.

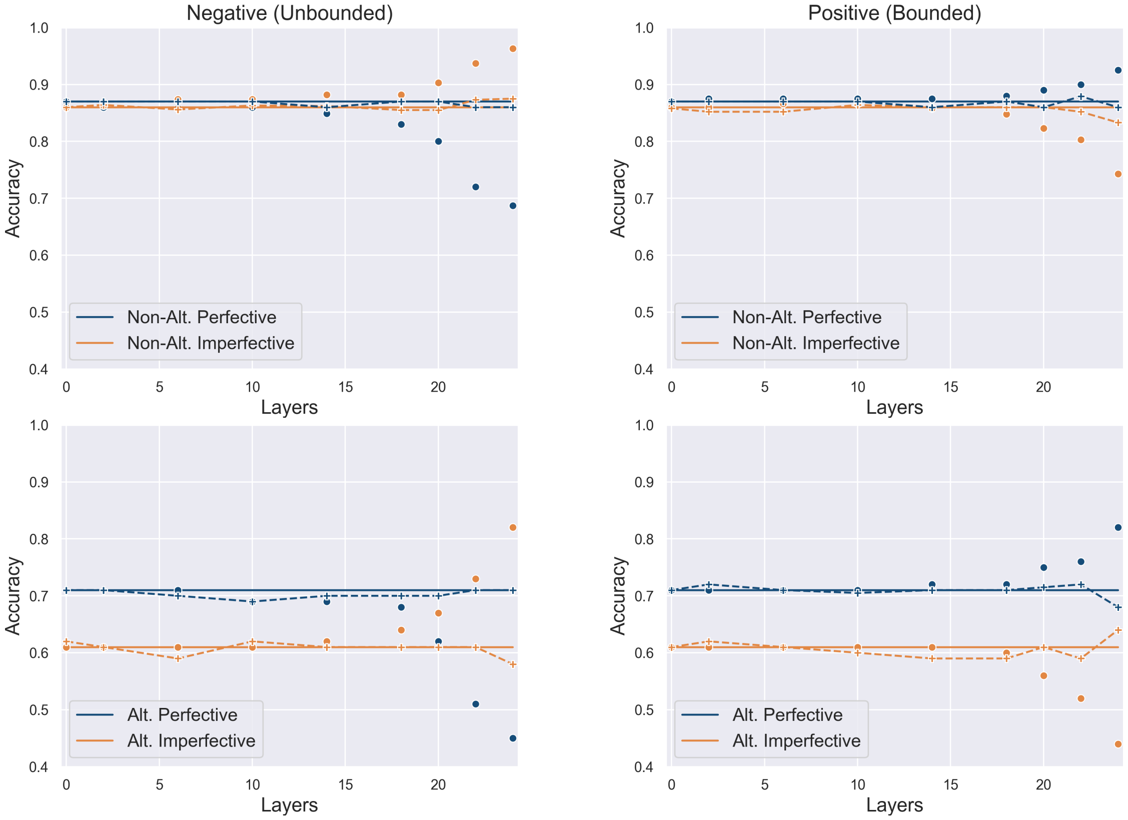

Figure 4: Accuracy of predicting correct (expected) aspect, using *aspect inference* method after intervention on BERT-large representations. Top plots—non-alternative contexts; bottom plots—alternative contexts. Left plots—negative intervention: toward unbounded action. Right plots—positive intervention: toward bounded action. **Flat** lines show performance before intervention; **dots**—after intervention. **Dashed** lines—after random interventions.

the model's latter layers (post layer 20)—compare the flat lines, indicating performance before interventions vs. dots, indicating an intervention. This trend is observed for both aspects, using negative and positive interventions in the alternative and non-alternative contexts. It agrees with the findings of behavioral probing, where the peak performance for both aspects was evident mostly in the final layers. The results align with our hypothesis and grammatical theory: shifting representations toward the "unbounded" sub-space improves the predictions of imperfective aspect and significantly increases the error in predictions of perfective aspect; moving representations in the opposite direction of the "bounded" sub-space has the opposite effect—the accuracy of perfective rises, while the accuracy of imperfective deteriorates.

Negative interventions influence imperfective in both alternative and non-alternative contexts: the maximum accuracy shift is $+21\%$ and $+10.3\%$, respectively, in layer 24. Similarly for positive interventions: the maximum accuracy shift for imperfective is -17% in alternative and -11.7% in non-alternative contexts. The impact of negative interventions on perfective is higher for alternative (-26%) and non-alternative contexts (-18.3%), as compared to the effect of positive interventions: in alternative contexts, perfective accuracy increases by 11%, and for non-alternative—by 5.5%. The plots show that interventions have stronger impacts in alternative contexts. Further, negative intervention has a stronger effect in both types of contexts.[9] This could be caused by the data used to train the INLP classifiers—cue words indicating unbounded action appear with imperfective verbs more consistently, see Figure 3.

We apply causal probing to RoBERTa-large and observe a similar pattern: only layers 18-24 are affected by interventions (Figure 14 in Appendix E). The influence of intervention is the same as for BERT. However, the difference between accuracy shift in alternative vs. non-alternative contexts is not as striking as for BERT.

Selectivity: To ensure the *selectivity* of the probe,

---

[9] We observe a similar patterns for BERT-base, see Figure 12 in Appendix E.

B. Fine-tuned	85.9	84.0	67.5	57.0
C. Fine-tuned last 5 layers	**88.5**	**88.0**	69.1	64.2

Table 1: Performance in terms of $F_{0.5}$ for aspect prediction in non-alternative and alternative contexts.

we verify that random changes in representations do not impact aspect prediction in the same manner. Random counterfactuals were generated using 20 random sub-spaces. Dashed lines in Figure 4 show that changes in accuracy are smaller and do not follow the pattern observed with altering boundedness. Additionally, we ensure that the interventions targeting context semantics do not affect the predictions of other grammatical categories in the same way as they affect aspect. We perform the same experiment, but measure the accuracy of predicting the grammatical number of the masked target verbs. We choose number because it has no relation to aspect and frequently appears in verb forms. The results indicate no significant change in the prediction of number on any layer (Figure 13, Appendix F).

Probing with Iterative Masking: We checked whether causal probing shows similar results with different methods of evaluating the model's performance. Using iterative masking instead of aspect inference confirms the above observations. The main difference is the absolute value of the accuracy shift: it is in the range 2%–18% for the last layers of BERT-large.

4.4 Fine-tuning for Aspect Prediction

To utilize the information found through probing, we fine-tune BERT-large for the aspect prediction task. We formulate the task as a 2-way classification, where the model predicts whether the masked verb is perfective or imperfective. We use the SynTagRus corpus to create training and validation data.[10] Inspired by the probing results, we fine-tune layers 20-24 of the BERT encoder and the last classification layer, keeping all other layers frozen.

Table 1 shows the classification performance in three experiments: A. prior to fine-tuning; B. after fine-tuning all layers; and C. after fine-tuning the final 5 layers. Rows B–C show performance averaged across 5 fine-tuning runs. Freezing layers up to layer 20 speeds up fine-tuning and increases performance for aspect prediction, especially for imperfective aspect. Fine-tuning can yield performance comparable to the performance of BERT-large as a MLM at its final layers in non-alternative contexts. In alternative contexts, results are lower. Details on data, training, and evaluation with other layers are in Appendix G.

To visualize the changes in the model's representations, we use t-SNE (van der Maaten and Hinton, 2008) to project the masked verb representations onto the 2-D plane, Figure 5. Notably, fine-tuning the final layers results in more refined clustering of representations based on aspect. The lack of structure in the verb representations within alternative contexts aligns with our observations from the two behavioral probing methods—consistently lower preference for either aspect form.

4.5 Error Analysis

Uncertainty: The aspect inference method does not allow us to directly calculate the *uncertainty* of aspect prediction for a given instance. Therefore, we use Monte Carlo dropout (Gal and Ghahramani, 2016) to estimate the confidence of the fine-tuned model with frozen layers. For every input, we repeatedly sample 20 predictions with dropout activated, and calculate the variance; see plot (b) in Figure 6. The model has much higher predictive uncertainty for alternative contexts: BERT cannot

---

[10] The model is trained only on verb forms that have aspect tags in their morphological analysis.

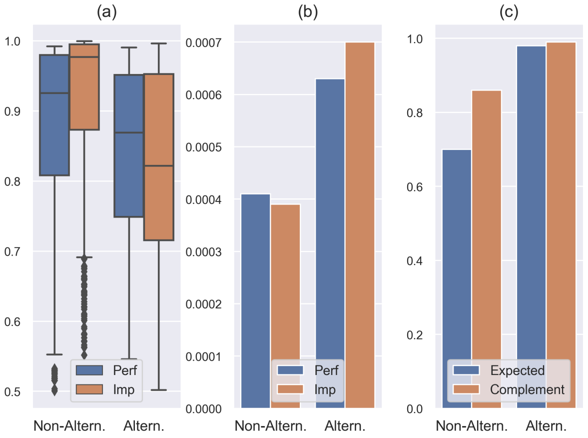

Figure 6: (a) Scores assigned to imperfective and perfective classes. (b) Variance of scores assigned to imperfective and perfective classes. (c) Percentage of contexts lacking cue words when the model predicts: *Expected* aspect vs. *Complementary* aspect.

make a preference for a particular aspect; see the orange bars indicating high variance.

We perform an automatic and a manual analysis of both types of contexts, to examine the possible reasons why BERT struggles with the aspect, either as a MLM or fine-tuned. We collect all contexts where BERT as MLM prefers the expected (blue bars in plot (c), Figure 6) vs. complementary aspect (orange). Preference is calculated using the aspect inference method. We calculated predictive uncertainty for the preferred aspect in each of these contexts. Then, we manually inspected the contexts with the highest variance. We observed the main difference—almost none of the alternative contexts contain cue words that could inform the preference for one aspect over the other.

Absence of Cues: Appendix C lists many cue words that indicate bounded vs. unbounded action. Although this list is not exhaustive, it provides a rough estimate of the difference between the contexts, and can aid in checking the manual analysis. We used this list to automatically inspect how many of the contexts do not contain cue words, and to check our manual evaluation. In Plot (c) the two left bars show that in non-alternative contexts, when BERT as a MLM predicts the complementary aspect (rather than the expected), most such contexts have no cues (orange bar, more than 85%). Of the contexts where the model predicted the aspect correctly, 70% (left blue bar) also have no cues, which indicates that other types of contextual evidence must be present in the context. This requires further study.

Almost 100% of alternative contexts have no cue words at all (plot (c), right two bars), which might explain why counterfactuals have more impact in alternative contexts—positive or negative interventions introduce the missing “hints” into the representations.

5 Conclusions and Future Work

We investigate the encoding of the grammatical category of verbal aspect for Russian in PLMs—particularly, BERT and RoBERTa—via behavioral and causal probing. Encoding of aspect has not been studied to date for any language or model. All types of probing show that these models do encode aspect and learn to distinguish between aspect forms primarily in their final layers. Using this finding, we fine-tune BERT for aspect prediction, which leads to more effective and faster tuning.

In line with linguistic theory, information about the *boundedness* of the action is encoded in the model’s context representation and affects the choice of aspect: shifting representations towards the “bounded” space positively affects prediction of perfective forms (and negatively—of imperfective), and vice versa. Prediction of aspect is not affected by random interventions. We checked that the causal probe is selective and does not affect irrelevant categories, e.g., number.

A particular challenge is caused by contexts where more than one aspect form can fit grammatically and semantically, which we call *alternative*. We investigated whether encodings of aspect differ in these contexts from non-alternative ones. We find that BERT is consistently uncertain about aspect forms in alternative contexts. Causal interventions also have a stronger effect in such contexts. Our error analysis shows that these contexts do not have enough cues to help the model (or a human) decide which aspect to use.

In future work, we plan to explore additional languages; investigate how transformers encode relations between verbs and the cue words; and inspect the connections between aspect and tense of verbs, and context words expressing time, by intervening in the attention weights. We also plan to investigate aspect prediction in contexts lacking cue words, where information affecting the choice of aspect is presented in the neighboring sentences and requires reasoning. The practical goal is to deploy the aspect prediction in the production language teaching/learning system, to help learners master this advanced and complex feature of Russian.

Acknowledgements

This research was supported in part by Business-Finland Project “Revita” (Grant 42560/31/2020), and by a grant from the Helsinki Institute for Information Technology (HIIT).

Limitations

This work has a number of limitations to consider:

(A) The experimental design of the paper was limited to a single language. Aspectual systems vary significantly across languages. Therefore, adding a new language requires linguistic expertise and a new experimental setting. For Russian, we performed causal intervention in the context's meaning of boundedness and compared perfective vs. imperfective verb forms. Many languages do not have the opposition of these two forms as in Russian, and the meaning of boundedness may not be as significant for the choice of aspect in context. The closest aspect system to Russian among Slavic languages is Polish. Probing it would require a substantial investment of resources, which our team lacks.

(B) We experimented only with masked language models available for Russian since they have access to the full context, which is more relevant for the aspect prediction task.

(C) Due to resource constraints, we could not engage more people in data collection and annotation. While we recognize that our dataset is relatively small, we believe it is crucial to share the data we have. We hope it draws the research community's attention to the complex problem of aspect probing.

(D) We acknowledge that there is no consensus regarding several important questions among linguists studying the category of aspect in Slavic languages: the meaning of aspect opposition or whether aspect pairs represent forms of the same verb or different verbs. There are well-founded different opinions on each of these questions. We shape particular views for clarity of our experiments.

(E) We also recognize that our list of cue words, which indicate the boundedness of actions, is not exhaustive. We also ignore for now other contextual evidence indicating whether an action was completed, and whether its result is observable at the moment. Identifying this information is more complex and, we believe, requires reasoning. We plan to extend our work to investigate various types of contexts and larger PLMs.

(F) Due to the page limit, we did not include the effects of the removal of the linguistic feature of boundedness in the current experiment which could be an interesting extension of the experiment in the future versions of the paper.

(G) Our current experiments do not include an investigation of attention weights which we plan to do in future work.

Ethics Statement

We used publicly available data, code, and models for the described experiments.

Annotated data that we release together with this paper will be freely available for the research community to be used for extending probing experiments. Data does not have any personal information, does not identify individual people, and does not include offensive content. Annotators are volunteers who have previous experience in annotation and are aware of how the annotated data is going to be used. We also do not see any potential risk that might be caused by our work.

Appendices

A Generating Aspect Test Data

For each target verb, we generated an aspect pair that differs only by the category of aspect. For this purpose, we used a list of over 2K verb lemmas with their aspect pairs which was manually created in collaboration with several linguists and Russian teaching experts. We generated an aspect pair for each target verb form automatically using a morphological generator which takes as input the verb lemma and a list of grammatical tags. For example, for a perfective verb form “получила” (*received*) in the past tense, singular number, and feminine gender, we generate an imperfective form “получала”, which has the same tense, number, and gender.

> История получила шикорое освещение в газетах.
>
> *The story received extensive coverage in the newspapers.*

However, the paradigms of imperfective and perfective verb forms are not symmetrical. Perfective forms do not have present tense forms in the indicative mood, so we skip generation of an aspectual pair if the target verb is in imperfective present indicative form. There are no present tense forms for passive participles and transgressive forms, thus, in the context of this paper, we ignore participles and transgressives as targets.

There is also a difference between future tense forms for perfective and imperfective: imperfective verbs have analytic forms, e.g., compare “прочитает” (*will read*, perf.) and “будет читать” (*will read*, imp.). We generate aspect pairs for future tense taking this difference into account.

B Behavioral Probing

Iterative Masking Algorithm 1 demonstrates the process of iterative masking described in subsection 4.2.

Figure 8 shows boxplots with removed outliers displaying differences between probabilities assigned by BERT-large to two aspect forms (expected and complementary) in alternative contexts vs. differences between probabilities assigned to two aspect forms in non-alternative contexts. The probability of each form is calculated using iterative masking. Probability difference is calculated by subtracting the probability of the expected form from the probability of the complementary form: $P_{\{\text{exp.}\}} - P_{\{\text{compl.}\}}$.

Aspect Inference We inspected how many words out of the top-k filled by BERT-large in the [MASK] position are complete verbs, see plots for $k =$1.2K and $k =$12K in Figure 9. For the first 6 layers, the number of complete verb forms is low and most of them are imperfective, for any masked position. The model starts to predict perfective forms only after layer 4.

Considering that early layers incorporate less context information (Rogers et al., 2021), a higher preference for imperfective can be caused by frequency differences between aspect forms in the BERT’s training data. Since the data used for pretraining is not available to us, we compared form frequencies in the SynTagRus corpus (Droganova et al., 2018). Imperfective is indeed more frequent (55% vs. 44%) in SynTagRus. However, these statistics characterize only one dataset. The frequency of aspect forms can depend on the genre of texts in the corpus. For example, legal texts usually have present tense more frequently than past or future. As a result, imperfective forms dominate legal texts because present tense forms in the indicative mood do not exist for perfective in Russian.

BERT-base Figure 7 shows the performance of BERT-base using iterative masking (left plot) and aspect inference (right plot) methods.

C Cue Words for Aspect

This section includes lists of lemmas of cue words that were used for collecting and annotating training data automatically for INLP classifiers. We excluded sentences where the target verb is negative since the negation particle “не” (*not*) in some

Algorithm 1 Iterative Masking

```
Input: Sequence of tokens $\boldsymbol{X}$ with target verb $V$; pre-segmented target verb $V = [V_1, \ldots, V_n]$ where $n \geq 1$.
for $i = 1$ to $n$ do
    if $i = 1$ then
        Replace all $V$ with [MASK] and feed $\boldsymbol{X}$ to BERT.
        Calculate $P(x^1 | X \setminus V)$
    else
        Keep target segments $V_1, \ldots, V_{i-1}$ unmasked in $\boldsymbol{X}$.
        Replace $V_i \ldots V_n$ with one [MASK] and feed $\boldsymbol{X}$ to BERT
        Calculate $P(V_i | X \setminus V, V_1, \ldots, V_{i-1})$
    end if
end for
Get averaged probability of the target:
$P(V) := \frac{1}{n} \sum_{i=1}^{n} P(V_i)$
Execute iterative masking twice for $\boldsymbol{X}$: with perfective and imperfective target verb forms
Compare $P(V_{\text{perf}})$ and $P(V_{\text{imp}})$
```

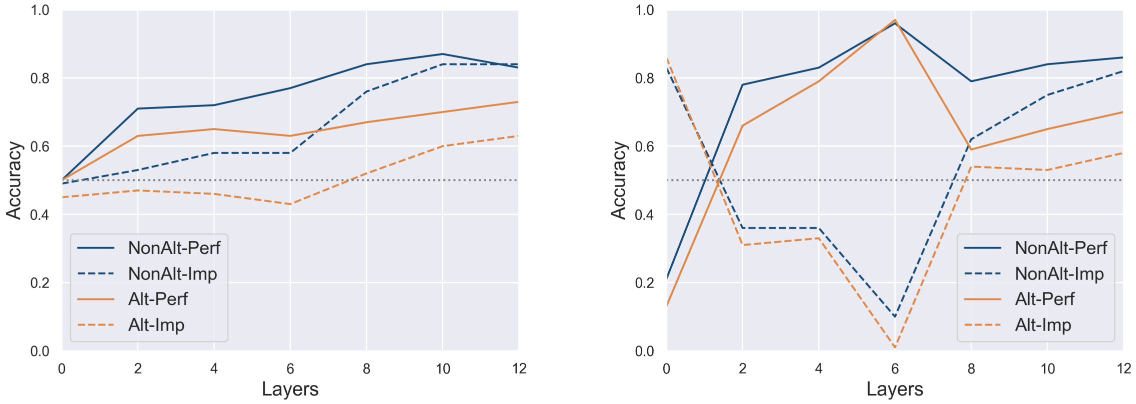

Figure 7: Performance of BERT-base on iterative masking (left) and aspect inference (right) for target verbs. *Perf* and *Imp* denote perfective and imperfective aspect in non-alternative (*NonAlt*) and alternative (*Alt*) contexts.

contexts causes a change of aspect from perfective to imperfective, e.g., in the imperative mood.

Lemmas in brackets denote that any word in the first list appears with any word from the second list, e.g., “каждый день” (*every day*) or “каждый год” (*every year*). There is also a possibility for these words to be interrupted by their own dependent words, e.g., “каждый новый год” (*every new year*).

“Forbid”: [запрещенный, дозволено, должен, надо, невозможно, нельзя, можно, нужно, обязан, опасный, рекомендуется, стоит]

“Iterative”: [бесконечно, беспрерывно, вечно, вновь, временами, всегда, часто, долго, изредка, непрерывно, как правило, постоянно, обычно, опять, регулярно, редко, систематически, снова], [[все, всякий, каждый, много, несколько, пара] + [век, весна, вечер, вторник, воскресенье, год, день, десятилетие, зима, лето, месяц, миг, минута, неделя, ночь, осень, раз, сезон, секунда, среда, суббота, сутки, период, полдня, полночи, понедельник, пятница, четверг, утро, час]], [[по] + [понедельник, вторник, среда, четверг, пятница, суббота, воскресенье, утро, вечер]]

“Duration”: [[за] + [век, весна, вечер, вторник, воскресенье, год, день, десятилетие, зима, лето, месяц, миг, минута, неделя, ночь, осень, раз, сезон, секунда, среда, суббота, сутки, период, полдня, полночи, понедельник, пятница, четверг, утро, час]]

“Inception”: [браться, бросать, бросить, давать, взяться, заканчивать, закончить, кончить, надоедать, надоесть, начать, начинать, оканчивать, окончить, отвыкать, отвыкнуть, передумать, передумывать, переставать, перестать, приниматься, приняться, продолжать, продолжить, раздумать, раздумывать,

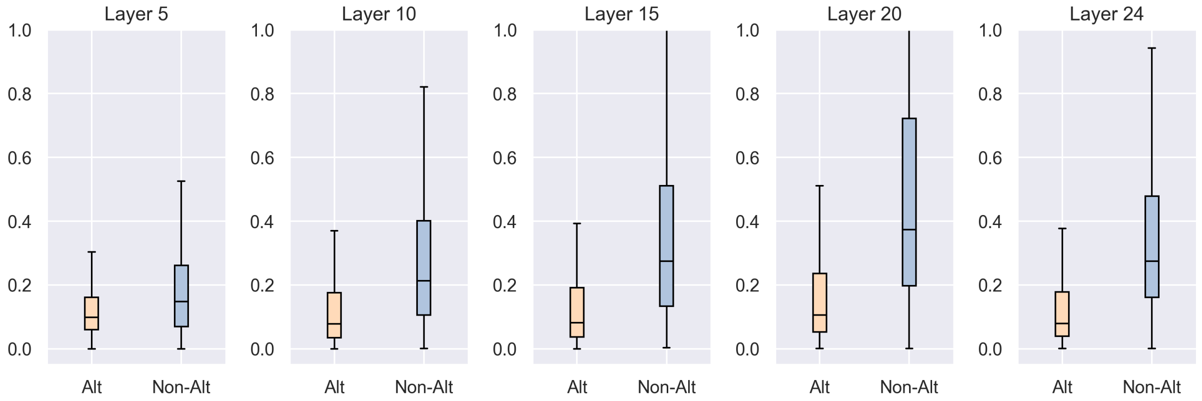

Figure 8: Difference between probabilities assigned by BERT-large to two aspect forms in alternative contexts (*Alt*) vs. differences assigned to aspect forms in non-alternative contexts (*Non-Alt*).

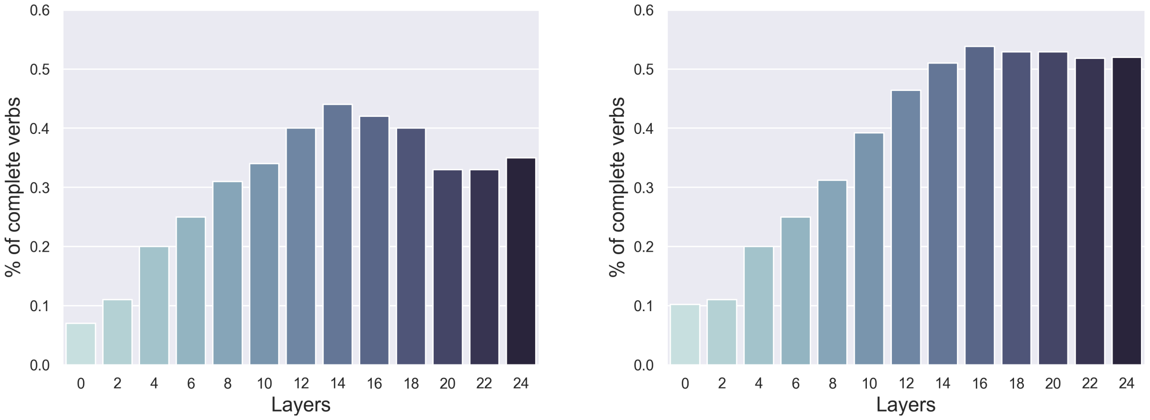

Figure 9: Percent of tokens that are complete valid verb forms among top-k tokens for the masked position, k = 12000 (10% of vocabulary size of BERT-large) on the left and k = 1200 (1% of vocabulary size of BERT-large) on the right.

разучиваться, разучиться, расхотеться, становиться, стать, уставать, устать]

“Like”: [запрещать, запрещаться, избегать, любить, научить, научиться, нравиться, отговатьвать, привыкнуть, привыкать, следовать, уметь, учиться]

“Forget”: [договариваться, договориться, забывать, забыть, обещать, согласиться, соглашаться, удасться, успевать, успеть]

“Capability”: [мочь, смочь, способный]

“Result”: [вдруг, внезапно, наконец, уже]

[[в] + [итог, конец, результат, финал]]

D Training INLP

We use SVM with stochastic gradient descent learning[11] as an INLP classifier and set the number of classifiers $m = 20$ and $\alpha = 4$ for BERT-large. Ravfogel et al. (2021) demonstrate that using different parameter values m and α does not substantially affect observed results. We use $m = 10$ for BERT-base. We increased m for BERT-large since its hidden representations are twice as big. Other parameters of the INLP classifier are: adaptive learning rate, early stopping set to True, and eta=0.1.

E Effect of Counterfactuals on Aspect

Figure 7 shows the effect of counterfactual interventions on predicting aspect of the target verb using BERT-base. The effects of positive and negative interventions in both alternative and non-alternative contexts are similar to those observed using BERT-large. Interventions into the boundedness of action have a bigger impact on predicting aspect in alternative contexts. Positive and negative interventions affect aspect prediction in the last layers of BERT-base as well, predominantly after layer 8.

---

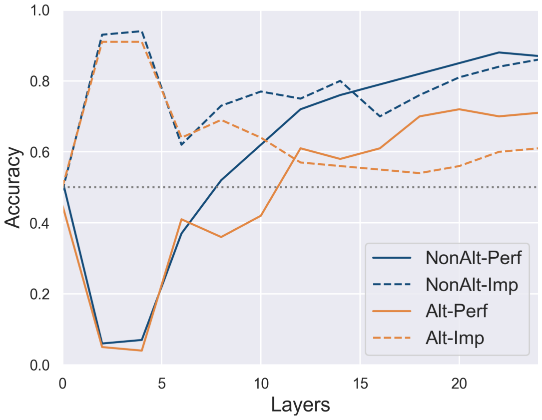

Figure 10: Performance of BERT-large on aspect inference for the target verbs with k = 1200. Perf and Imp denote perfective and imperfective aspect in non-alternative (NonAlt) and alternative (Alt) contexts

	non-alternative		alternative	
Model	$F_{0.5}^{\text{perf}}$	$F_{0.5}^{\text{imp}}$	$F_{0.5}^{\text{perf}}$	$F_{0.5}^{\text{imp}}$
Pretrained	36.3	49.2	54.0	51.1
Fine-tuned	85.9	84.0	67.5	57.0
Fine-tuned (up to last 5)	85.0	83.9	67.0	56.0
Fine-tuned (last 6)	87.0	88.0	69.0	64.0
Fine-tuned (last 5)	**88.5**	**88.0**	**69.1**	**64.2**
Fine-tuned (last 2)	87.0	87.0	67.0	60.0
Fine-tuned (last 1)	86.0	87.0	67.0	60.0

Table 2: Performance in terms of $F_{0.5}$ for imperfective and perfective aspects in non-alternative (non-alt.) and alternative (alt.) contexts.

F Affect of Boundedness on Category of Number

Figure 13 shows the effect of counterfactual interventions on predicting the number of the target verb. Interventions affect the meaning of the boundedness of the described action: whether the action is bounded or unbounded. Plots demonstrate that predicting the category of number is not affected by altering boundedness of the action, unlike aspect.

G Fine-tuning BERT for Aspect Prediction

Training data for fine-tuning BERT was generated using the SynTagRus corpus. For every sentence, we picked all verbs, labeled them with their aspect (`Perf` or `Imp` tag in the morphological analysis), and replaced them with a [MASK] token; all other words were labeled with `None`. Masking was used because the task is not to predict an aspect of a given verb form, but to predict which aspect fits in the given context. Also, during inference, we do not know which form should fit the context. We generated 60K training sentences and 7.5K validation sentences, where each sentence includes two masked verbs on average.

Parameters of training: learning rate = 5e-5, epochs = 3, batch size = 256, max input length = 512. The model was fine-tuned using 2 GPUs NVIDIA A100.

Testing was performed using the same data that we used for all probing tasks. The fine-tuned model is successful if the predicted label is the same as the expected aspect of the target verb. Table 1 and Table 2 report results averaged across 5 runs for each model configuration.

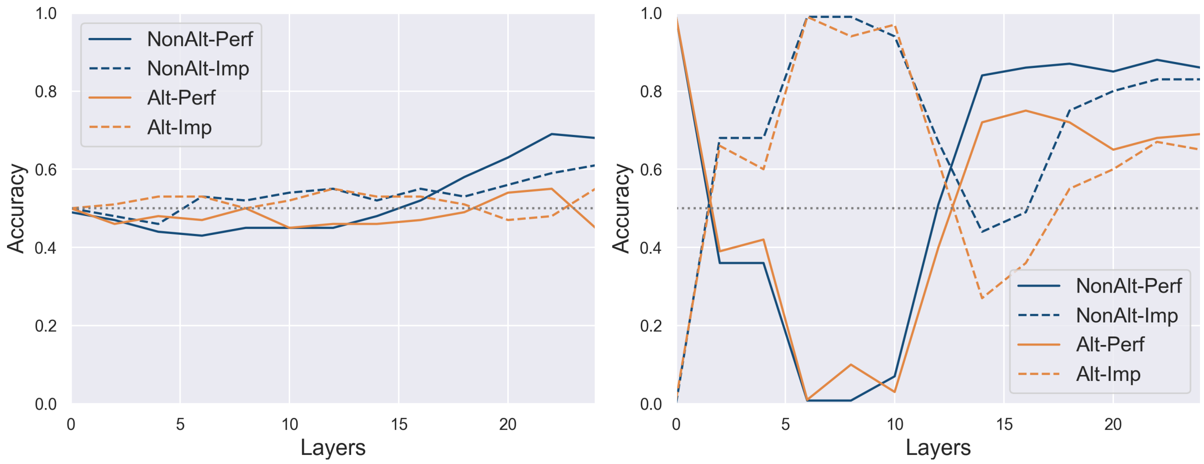

Figure 11: Performance of RoBERTa-large on iterative masking (left) and aspect inference (right) for target verbs. *Perf* and *Imp* denote perfective and imperfective aspect in non-alternative (*NonAlt*) and alternative (*Alt*) contexts.

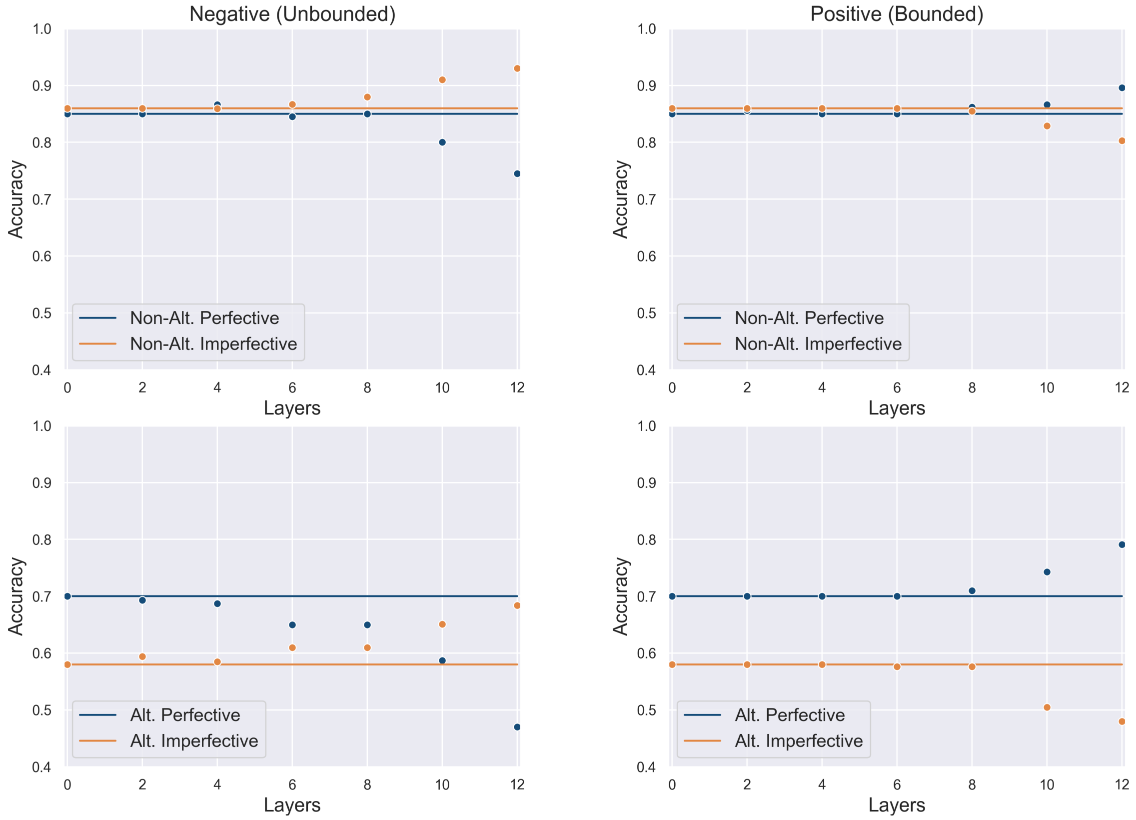

Figure 12: Change in accuracy of predicting correct (expected) aspect using aspect inference method after interventions on BERT-base representations. Top plots show results in non-alternative contexts; bottom plots—in alternative contexts. Left plots show the results of negative interventions: moving toward the meaning of unbounded action. Abstract

Typologically diverse benchmarks are increasingly created to track the progress achieved in multilingual NLP. Linguistic diversity of these data sets is typically measured as the number of languages or language families included in the sample, but such measures do not consider structural properties of the included languages. In this paper, we propose assessing linguistic diversity of a data set against a reference language sample as a means of maximising linguistic diversity in the long run. We represent languages as sets of features and apply a version of the Jaccard index (J_{mm}) suitable for comparing sets of measures. In addition to the features extracted from typological data bases, we propose an automatic text-based measure, which can be used as a means of overcoming the well-known problem of data sparsity in manually collected features. Our diversity score is interpretable in terms of linguistic features and can identify the types of languages that are not represented in a data set. Using our method, we analyse a range of popular multilingual data sets (UD, Bible100, mBERT, XTREME, XGLUE, XNLI, XCOPA, TyDiQA, XQuAD). In addition to ranking these data sets, we find, for example, that (poly)synthetic languages are missing in almost all of them.

1 Introduction

Data sets for training and testing NLP models are increasingly multilingual and aimed at broad linguistic coverage. These data sets are often claimed to represent a typologically diverse sample, including low-resource and endangered languages.

Linguistic diversity is typically described as the number of languages included in the data set, yet less often as the number of language families to which these languages belong. Both counts indicate a level of linguistic diversity: the more languages and families, the more diversity. But how do we know that included languages are indeed different? How can we define a desired or optimal diversity to set as a goal when composing multilingual data sets? These questions need to be addressed if our goal is to know how NLP technology generalises across diverse languages, without testing it on each single language (even if we had the necessary data for all languages).

The aim of this paper is to initiate and facilitate comparisons between multilingual NLP data sets with respect to a linguistic diversity reference. For this, we propose a measure of linguistic diversity and a method of comparison that identifies what kinds of linguistic features are missing. As an initial reference, we rely on a predefined sample of languages — the 100-language-sample (100L) selected by the Word Atlas of Language Structures (WALS; Comrie et al. (2013)) to represent geographic and phylogenetic diversity. As a comparison method, we formulate a version of the Jaccard index suitable for comparing measures. This measure allows us to quantify the distance between the observed and the reference diversity in terms of linguistic features, showing not only how diverse language samples are but also what kinds of linguistic phenomena are not represented in a given sample. To facilitate automatic extraction of linguistic features needed for assessing linguistic diversity, we complement the information from linguistic data bases with relevant text statistics.

Our proposals are intended to help researchers make informed choices when designing a multilingual data set. Representing a wider spectrum of linguistic diversity is not only a way to improve the cross-linguistic generalisation of NLP technology, but also a way to deal with biases against low-resource languages, which are harder to represent and thus more likely to be left behind (Joshi et al., 2020).

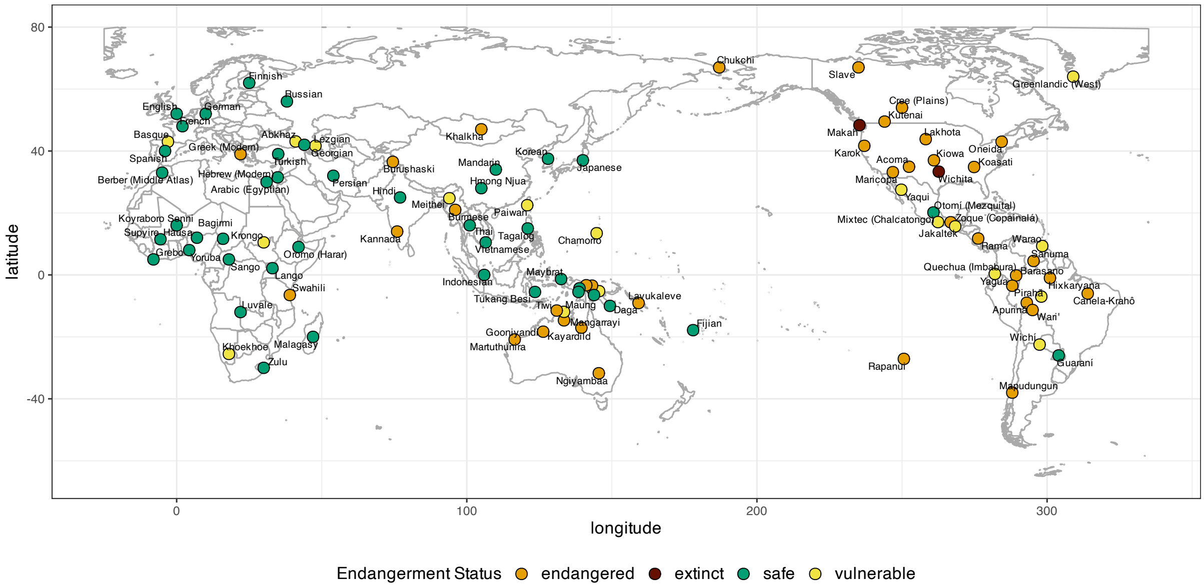

Figure 1: Languages in the WALS 100L sample with their endangerment status.

2 Background and Related Work

Evaluating the linguistic diversity of data sets relies on comparable descriptions of languages. For instance, the (approximate) number of speakers is an attribute whose value can be found and compared for all registered languages. This attribute, however, does not describe the structure of languages. An example of a structural attribute would be the presence or the absence of adjectives in a language. To establish the value of this attribute for any language, we need a universal definition of what an adjective is. It turns out that such universal definitions are hard to formulate in a principled way (Haspelmath, 2007), which makes it hard to define objective measures of how similar or dissimilar any two languages are.

The most widely accepted method for comparing languages relies on genealogical classification: given a phylogenetic tree, we consider languages located in the same region of the tree to be similar. This method currently prevails in NLP (cf. the work discussed in Section 6). Typically, we regard languages that belong to the same *family* to be similar. To know which language belongs to which family, we turn to popular authorities such as WALS (Dryer and Haspelmath, 2013) or Glottolog (Hammarström et al., 2018). However, language families can be too broad for a meaningful comparison as they include typologically very different languages. For instance, English and Armenian belong to the same family, Indo-European, but are vastly different in terms of their phoneme inventories, morphology, and word order.

Another possibility to compare languages, starting to be used in NLP only recently, is to rely on grammatical features available in the WALS data base. This is a comprehensive source of information about linguistic structures but still rather sparsely populated; feature values are often known for only a few languages.[1] Together with other typological data bases, WALS is included in URIEL, an aggregated and standardised source of language features for various NLP uses. Ponti et al. (2020) propose a diversity score using the features from URIEL (Littell et al., 2017). The score is called *typology index* and it is calculated as the entropy of feature values (averaged per data set).[2] In other NLP work, grammatical features (usually termed *typological*) are used for other purposes, such as predicting the features (Ponti et al., 2019) rather than using them for language sampling in creating multilingual data sets. Moran (2016) use WALS and AUTOTYP features (Stoll and Bickel, 2013) to compose a sample of 10 maximally diverse languages for a corpus-based study of language acquisition.

Finally, languages can be described using features derived from various text statistics, but such features are not commonly used for language sam-

---

[1] An alternative typological data base is AUTOTYP (Bickel et al., 2017), with a different design but similar coverage.

[2] They propose two more scores, *family* and *geography*, which do not make use of grammatical features.

pling. Type-token ratio (TTR) or unigram entropy of a text have been shown to correlate with grammar-based morphological complexity measures (Kettunen, 2014; Bentz et al., 2016). Many other methods have been proposed for assessing linguistic complexity using text statistics (see, for instance, Berdicevskis et al. (2018)). All of these measures can, in principle, be used for describing and comparing languages although such comparisons might seem counter-intuitive and hard to interpret in terms of genealogical classification. On the other hand, these features might complement usual descriptions of languages while being more directly relevant to text processing and NLP.

Transfer learning created a new need for nuanced languages comparison for NLP. While models can now be transferred across languages with zero-shot or few-shot learning (Pires et al., 2019), the success of the transfer might depend on the differences between languages. Lin et al. (2019) propose a range of measures that can be used in order to choose the best transfer language, which they divide into data-dependent (data size, token overlap, TTR) and data independent (various distance measures extracted from the URIEL data base). Lauscher et al. (2020) study how well different similarity scores predict the success of the transfer and they find that language family is, in fact, the one that is least helpful in all the tasks considered (with mBERT and XLM-R). Various criteria for assessing language similarity remain an open research area in NLP (Turc et al., 2021; Pelloni et al., 2022; Samardžić et al., 2022; de Vries et al., 2022). Our proposal for assessing linguist diversity is relevant to these efforts too, as its key component is language comparison at the level of features extracted from both typological data bases and text samples.

More generally, our work is intended to contribute to several wide-scope initiatives for improving the quality of data management in multilingual NLP (Bender and Friedman, 2018; Kreutzer et al., 2021; Lhoest et al., 2021) by focusing specifically on diversity assessments and data-independent scores for language comparison.

3 Comparing Data Sets with Jaccard Similarity

Our goal is to estimate the linguistic diversity of a data set with respect to some reference. Our score is thus a comparison between two data sets. More precisely, we compare scaled distributions of the values of a numerical attribute as shown in Figure 2. The upper part of the figure shows (constructed) examples of two data sets (A and B), which we compare assuming that A is the data set whose diversity we want to assess and B is the reference. The values of the numerical attribute (one measurement per language) are on the x-axis and the numbers of languages are on the y-axis. Each bar in the figures represents the number of languages in the given data set with the numerical value in the given range (bin). For instance, the first bar in the upper left plot shows that the first sample (A) has 30 languages, with the values of their numerical attributes falling between 1 and 2. The other sample (B) has no languages in this bin.

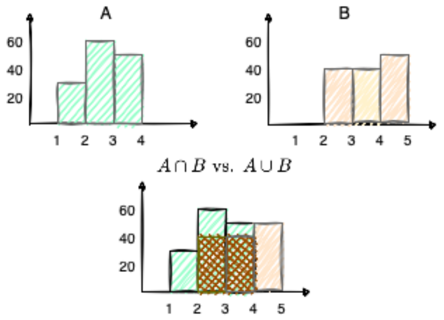

Figure 2: A toy example of comparing sets of measures with the minmax version of the Jaccard index.

The width of the bins is arbitrary, but it does impact the score. Narrower bins capture more differences between two distributions than wider bins. By setting the width of the bins, we thus control the resolution at which we want to compare two data sets. In our example, the width is the distance between integers, but one can define other values (as long as the bins are of the same width).

Since the data sets that we compare contain different numbers of languages, the values on the y-axis (counts of languages) are normalised in order to neutralise the effect of the size of the samples and focus rather on the diversity. We multiply all counts in the smaller set with the scalar c:

$$c = \frac{max(|A|, |B|)}{min(|A|, |B|)} \tag{1}$$

In this way, we increase the counts in the smaller set proportionally to obtain the same number of data points in both distributions and comparable numbers in each bin.[3]

---

[3] Another way to normalise the counts would be to divide them by the size of the set, but we chose the first option in order to preserve the notion of *number of languages*, which is

Once we have represented our two sets in this way, we compare them using a generalised version of Jaccard similarity. This score shows how much the two distributions overlap. The original Jaccard index (Jaccard, 1912) compares two sets, but its generalised versions are suitable for comparing sets of measurements. Thus, we use the *minmax* version of the score (J_{mm}), initially proposed by Tanimoto (1958) for comparing vectors of binary values and then generalised to weight vectors by Grefenstette (1994). In our version, we compare two data sets as two vectors of weights: each bin is one dimension in the vectors and the number of languages in that bin is its weight.

Intuitively, the score is the ratio between the intersection and the union of the two distributions (shown in the bottom part of Figure 2). Formally, we first map all the languages in all data sets to real numbers $m : \mathbb{L} \mapsto \mathbb{R}$, so that $\{Y = m(x) : x \in X\} = \{(x_i, y_i)\}$, where x is a language in a data set, y is its corresponding measurement ($y \in \mathbb{R}$) and the range of the index i $1 \ldots |X|$ is the set of languages included in a data set. We then group the measurements into bins by applying a given threshold: $\{Z = t(y) : y \in Y\} = \{(y_i, z_j)\}$, where z is the bin to which the measurement is assigned, the range of i is $1 \ldots |X|$ and the range of j is $1 \ldots |Z|$.

With this formalisation, we define the Jaccard minmax similarity of two data sets, $J_{mm}(A, B)$, as a similarity between two vectors of weights:

$$J_{mm}(\mathbf{a}, \mathbf{b}) = \frac{\sum_{j=1}^{|Z|} min(a_j, b_j)}{\sum_{j=1}^{|Z|} max(a_j, b_j)} \qquad (2)$$

The sum in the numerator represents the intersection and the sum in the denominator the union of the two sets of measurements. The weights a and b represent the number of measurements in the bin j. The values of J_{mm} fall in the range $[0, 1]$, with higher values indicating more similarity between A and B, and, indirectly, better coverage of linguistic diversity in A.

What is especially interesting about using J_{mm} as a diversity score is its transparency in terms of individual measurements: we can visualise and interpret where exactly a data set departs from the reference.

4 Language Features

We now turn to the question of how to define and take measures (the values on the x-axis in Figure 2) that can be used for calculating Jaccard minmax similarity between sets of languages. We use two kinds of descriptions.

4.1 Grammar Features

Typological data bases are currently the principal source of information about the properties of languages, but NLP researchers are faced with many obstacles when using this information. The popular software package `lang2vec` associated with the URIEL data base (Littell et al., 2017) alleviates some of the obstacles. First, the package solves the problem of incompatible feature values across different sources by mapping the data from several original data bases to binary features. Second, the problem of sparsity of feature values is solved by imputing the missing values: instead of a missing feature value in a language, the package returns the observed value for the same feature in the closest language. In this way, features become available for all queried languages, which is necessary for estimating language diversity, but a large proportion (roughly 40%) of the returned features are imputed.

While `lang2vec` facilitates retrieving typological features, its use for describing languages is limited due to remaining obstacles that are hard to solve. First, it does not contain any morphological features, which are especially relevant to NLP due to the known difficulties with that morphologically rich languages (Tsarfaty et al., 2013). The second unsolved problem is the fact that typological features are hard to add for languages for which they are not already available. Adding new features requires human expertise in many languages.

4.2 Text Features

As a complement to commonly used features from `lang2vec`, we make use of linguistically relevant text statistics. In this study, we focus on the *mean word length* as an approximation of aggregated morphological features, but other text-based features might be envisioned in future work. Our choice to start with word length relies on the observation that longer words can be expected in languages with rich morphology (large morphological paradigms, productive derivation), while shorter words are found in languages with less morphol-

---

helpful for the subsequent explanations.

ogy.[4] As an empirical confirmation of the relationship between the word length and morphology, we perform a correlation test between the mean word length and morphological complexity calculated over morphological features (see Section 5 for the methods and Section 7 for the discussion).

Text features are especially interesting in the context of NLP because they can be calculated automatically and applied to any language in which there are any texts to process. An important advantage of word length over other text statistics in this regard is that it manifests itself in very small samples of text and remains stable across different sizes. A sample of contiguous text of only 500 tokens gives us already a very good estimation of the overall mean word length. This can be seen in Figure 4 in the Appendix A, which shows the values of the mean word length on random samples of the length 500, 2000 and 10000 tokens in 87 languages. A correlation score (also in the Appendix A) shows that languages are almost identically ranked with all the sample sizes.

4.3 Maximising Linguistic Diversity

The editors of the WALS data base have selected two samples of languages (100 and 200 sample) as a means of guidance in the collective effort to create linguistic descriptions on a wide scale. These samples maximise genealogical (language family) and areal (geographic) diversity. Completing their descriptions is expected to minimise a potential bias regarding the relative frequency of different types of linguistic features included in the data base (Comrie et al., 2013). Figure 1 shows the locations of the languages in the 100 sample and their endangerment status according to UNESCO.

Recently, text samples have been collected for most of the 100 languages in the TeDDi data set (Moran et al., 2022).[5] These text data are sampled from online resources, e.g., Project Gutenberg,[6] Open Subtitles (Lison and Tiedemann, 2016), The Parallel Bible Corpus (Mayer and Cysouw, 2014), the Universal Declaration of Human Rights,[7], but also from grammars and other language documentation sources. For languages not present in online resources, the texts were manually transcribed.

We take these two resources as the current reference that maximises linguistic diversity in terms of grammar features (WALS) and text features (TeDDi). We compare NLP data sets with these references, but our method can be applied to compare any given pair of data sets including potentially better references in the future.

5 Data and Methods

We calculate the Jaccard minmax diversity score (J_{mm}) for a number of popular multilingual data sets in comparison to the TeDDi sample.[8] Without attempting to provide an exhaustive evaluation, we review data sets that satisfy the following criteria: multilingual (containing ten or more languages), relatively widely used and recently released or updated. The list is given in Table 1 and discussed in more detail in Section 6. For reference, we compare our J_{mm} score to the typological index (TI) previously proposed as a linguistic diversity measure by Ponti et al. (2020) (see Section 2).

Descriptions of the data sets often do not include all the information that was needed for our comparison. In particular, the number of language families is often not stated. To add this information, we extracted language names from the data files, converted these names into ISO 639-3 codes manually, and then retrieved the corresponding families from the Glottolog data base (top level family). Note that the conversion to ISO 639-3 codes led to some changes in the number of languages, compared to those cited in the data descriptions. For instance, the mBERT training data has only 97 distinct languages, not 104 as mentioned in the original description.

5.1 Methods for Text Features

We define words to be sequences of Unicode characters, delimited by spaces or other language-specific word delimiters, as defined by common multilingual tokenisers. We tokenise all the collected samples into word-level tokens using the Python library Polyglot (Al-Rfou, 2015).[9] If a resulting token does not contain any alphanumeric characters, we discard it as punctuation. All the remaining tokens are further segmented into characters using the Python library `segments` (Moran and Cysouw, 2018).[10] We split words into sequences of

---

[4] We give a more specific definition of the notion of a word as part of the methods in Section 5.

[10] https://github.com/cldf/segments

characters and take their length as word length.[11] We apply this same definition to all scripts, but we discuss below potential adjustments in the case of (partially) logographic scripts.

Since the mean word length can be calculated on small samples, we take a single random sample for each language in a data set that we consider. To do this, we select a random position in the data set and extract contiguous text of the length up to 10K tokens starting from the random position. In case a data set does not contain such long texts (or sequences of paragraphs), we take smaller samples. The smallest samples are 200-300 tokens long.

The output of these text processing steps is a set of real numbers, each number representing a language in a data set. To turn these numbers into discrete features, we group them into bins of equal size. We set the bin width to 1.[12]

Mean word length vs. WALS features Following Bentz et al. (2016), we calculate a complexity score (C_{WALS}) for each language using the set of 26 features that are relevant to describing morphology. This score is obtained by: 1) transforming the range of values each feature can take so that bigger values reflect the increasing use of morphology; 2) normalizing and averaging the resulting feature values per language. The list of features and transformations is given in Table 4 in Appendix B. C_{WALS} ranges from 0 to 1, where values closer to one indicate that the language encodes more morphosyntactic distinctions, making its morphology richer. All the values of the mean word length and morphological complexity for 29 diverse languages (the subset of TeDDi languages for which the 26 WALS features are known) are shown in Table 3 in Appendix B. We observe a strong correlation ($\rho = 0.69$), which means that the variables quantify very similar phenomena and that the mean word length is a reasonable approximation of morphological types of languages. We return to this point in Section 7.

Adjustments for logographic scripts Words in languages with logographic scripts tend to be shorter due to the fact that a single symbol corresponds to several alphabetic symbols (Sproat and Gutkin, 2021). For instance, in Mandarin Chinese, types such as 的 *de* (possessive particle), 了 *le* (aspect particle), 是 *shì* (copular verb 'is'), 我們 *wǒmen* (pronoun 'us') are assigned lengths (1, 1, 1, 2) respectively when measured in UTF-8 characters in the original script. When transliterated into Pinyin, the corresponding lengths are (2, 2, 3, 5). Hence, compared to Pinyin, the lengths are somewhat underestimated. It might seem more appropriate to convert the logographic scripts into their romanised counterparts to achieve cross-linguistic comparability. We opt for leaving such scripts without conversion, because we consider this phenomenon part of the diversity that we want to capture. Additional motivation for our choice is the fact that NLP systems have to deal with text as it is regardless of the mapping between written characters and sounds.

Three languages in our data samples, Chinese, Japanese and Korean, are affected by this issue to a varied degree. In these cases, we scale the observed word length proportionally to the difference between the Chinese original script and Pinyin so that the scaled length is comparable to alphabetic scripts. Table 5 in Appendix C shows revised diversity scores after the adjustments.

5.2 Linguistic Diversity Scores

With the grammar features extracted from URIEL, we calculate syntactic diversity according to both TI and J_{mm}.

Syntax Typological Index (TI$_{syn}$) Following the formulation by Ponti et al. (2020), we calculate the typological index for each data set. In this context, a language is characterized by 103 syntactic features with binary values[13]. For each feature, Shannon entropy is estimated using the distribution of feature values in a data set. The feature-specific entropy values are averaged over the full set of features to obtain a TI score ranging from 0 to 1. The TI values closer to 1 indicate more diversity.

Syntax Jaccard (J_mm_syn) We apply Jaccard similarity for comparing each data set against the TeDDi sample. Here the measures are the counts of the observed values of the same 103 syntactic feature available in `lang2vec`. This means that the items on the x-axis in Figure 2 are the 103 values, while the y-axis represents the number of times each feature value was observed in a data set. Since these feature values are binary, the width of the bin is not arbitrary in this case; it is determined by the values. Conceptually, grouping several features

---

[11] We use the units defined by the Unicode Standard as "user-perceived characters" (NFC).

[12] In addition to this, we also tried smaller bin sizes. We do not report the latter results, but the main trends did not change.

[13] We use the syntax_knn features available in lang2vec, which includes predicted values for those languages whose features are not available

Table 1: Diversity of multilingual NLP data sets. The numbers in the second and the third column marked with an asterisk are added or modified by us. The numbers without an asterisk are reported in the respective publications. N(L): the number of languages in the data set. N(F): the number of families to which the languages belong. TI: typology index Ponti et al. (2020). J_{mm}: Jaccard minmax similarity (this paper).

into a single one would correspond to increasing the bin width, but it is not clear at the moment how the features could be grouped. We thus work with the original set without any changes.

With text features (mean word length) extracted from TeDDI and the scored NLP data sets, we calculate morphological diversity according to both TI and J_{mm}.

Morphology Typological index ($\mathbf{TI}_{morph}$) We adapt the measure proposed by Ponti et al. (2020) to the text-based features (mean word length). Each bin of the mean word length values is a feature and the number of languages that fall in a given bin are the counts of feature values. In other words, the mean word length becomes a vector of binary values, 1 for the languages that are in the bin and 0 for all the other languages in the sample. The rest of the calculation is the same as in TI_{syn}.

Morphology Jaccard (J_mm_morph) Similarly to J_mm_syn, we calculate the Jaccard score by comparing the distributions of the mean word length: TeDDi vs. a given NLP data set.

6 Findings

Table 1 lists all the reviewed data sets with all the measures of linguistic diversity. The colour scale of the cells represents the relative ranking of data sets according to each measure separately. TeDDI data set obtains the highest diversity scores at both levels (syntax and morphology) using the TI measure. This confirms the role of these resources as the current reference regarding linguistic diversity.

TI and $\mathbf{J}_{mm}$ are consistent The rankings of data sets according to the J_{mm} score are very similar to those obtained with the TI score when the syntactic features are used. The agreement between the two measures is somewhat lower in the case of morphological features, but still rather high. The consistency between the two measures is not a trivial outcome given the entirely different approaches behind them. We can thus take this agreement as a validation of both measures. The main advantage of J_{mm} compared to TI is its transparency regarding the kinds of languages that are missing. The difference with respect to the reference is visible at the level of features indicating the values that need to be added or removed to improve the diversity.

Diversity rankings of NLP data sets The highest rankings appear split between the two structural levels. Bible 100 (Christodouloupoulos and Steedman, 2015) and XTREME (Hu et al., 2020) are the two most syntactically diverse data sets, while their morphological diversity is moderate to low. The Bible data set contains mostly non Indo-European languages, while the collection criteria for the XTREME data set was to maximise diversity. On the other hand, Universal Dependencies (UD, Nivre et al. (2020), which are often seen as especially biased towards European languages, show the best morphological, but a moderate syntactic diversity. XCOPA (Ponti et al., 2020) and TyDiQA (Clark et al., 2020) are data sets containing relatively few languages, but designed to maximise linguistic diversity. They are both highly ranked on 3/4 measures (two syntactic and one morphological). Contrary to this, the linguistic diversity ranking of one of the most popular benchmarks that contain manual labels for several downstream tasks, XGLUE (Liang et al., 2020; Wang et al., 2019) is

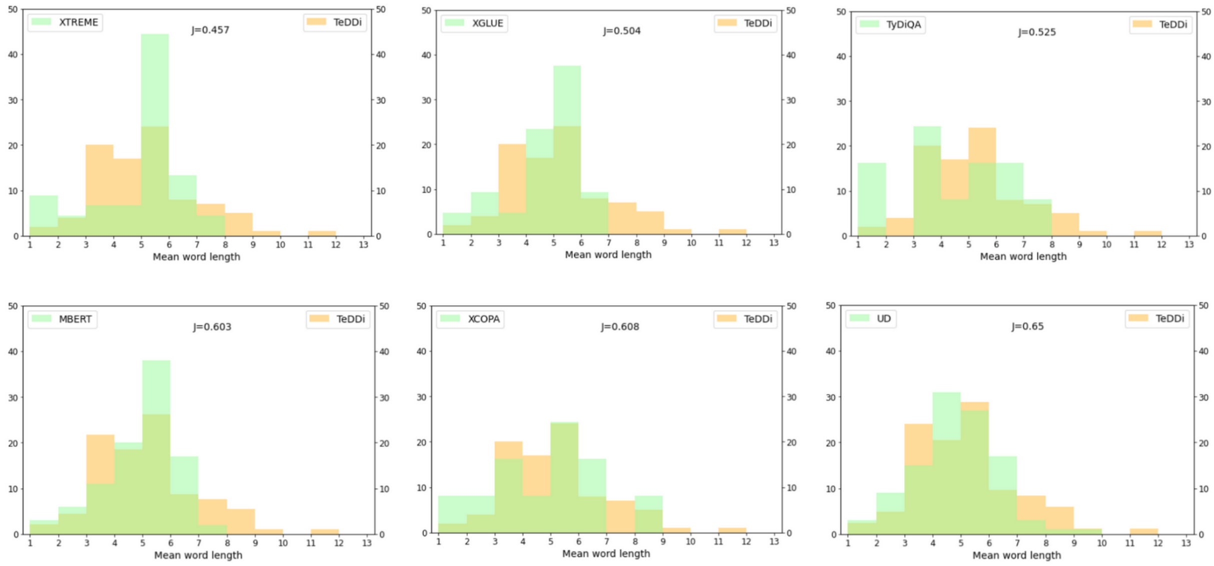

Figure 3: Union and intersection between the distributions of the mean word length in TeDDi and NLP data sets.

consistently low. XQuAD (Artetxe et al., 2020; Rajpurkar et al., 2016) fairs a little better, but it is still one of the least diverse data sets. The XNLI data set (Conneau et al., 2018; Bowman et al., 2015; Williams et al., 2018), which is compiled with the goal of spanning language families and which includes some low resource languages, remains of moderate linguistic diversity according to all measures. It is curious to see that the number of languages or even languages families included in a data set does not ensure a high linguistic diversity. For example, the mBERT[14] data set contains 97 languages in 15 language families, but it turns out to be less diverse than smaller data sets such as XCOPA (on TI_{syn}, J_{mm_syn} and J_{mm_morph}) and TyDiQA (on TI_{syn}, J_{mm_syn} and TI_{morph}). The strategy of including the top 100 languages according to the size of their Wikipedia content (plus Thai and Mongolian), does not result in high diversity.

Underrepresented language types Figure 3 is a visualisation of the J_{mm_morph} score[15] for some of the data sets showing the overlap and differences with the reference (TeDDi). The recurrent difference is whether a data set includes languages with long words or not (mean length > 8). Those that contain at least some languages with long words (UD, XCOPA) score much better on J_{mm_morph} than those that remain completely on the short-middle side (EXTREME, XGLUE, TyDiQA, mBERT). The second important factor that leads to lower scores is a strong peak of the distribution indicating a bias towards one of the length bins (EXTREME, XGLUE, mBERT). The third factor is a different (“wrong”) shape of the distribution (TyDiQA). The data set that diverges the most is EXTREME, exhibiting all three factors of disagreement.

The information about what kinds of languages are missing in a data set can be used to adjust language sampling and improve diversity. This is relatively straightforward when we deal with a single feature such as the mean word length. For example, the diversity of the mBERT language sample would be improved if the number of languages with a mean word length between 3 and 4 is reduced (by removing a given number of randomly selected languages). Instead of these languages, one should add a given number of languages with a mean word length greater than 7. It is not obvious where to look and how to find such languages (beyond the TeDDI sample), but knowing that they are needed might motivate such searches. Multi-feature scores (such as feature entropy) could specify the needed languages more precisely, but they would require an optimisation method to ensure that a newly added language increases indeed the diversity score. It might happen, for instance, that we want to increase the count on one feature value but not on another. In this case, we need a language that has 1 on the desired feature value but 0 on the features that we do not want to change. Devising

---

[14] `https://github.com/google-research/bert/blob/master/multilingual.md`

[15] We show the morphological diversity for convenience since visualising 103 syntactic features would required additional adaptations.

such a method is beyond the scope of the current paper, but it is a clear next step for future work.

Overall, it seems that the right-hand side of the mean word length scale remains rather scarcely represented in all data sets, including the TeDDi sample itself. In future data collection, more effort should be put into representing languages with long words, especially because most of them are endangered. There are 12 languages in the TeDDI sample with a mean word length of over 7. If we localise them in Figure 1, we can see that ten of them are classified as extinct, endangered or vulnerable: Apurinã (apu), Chukchi (ckt), Kalaallisut (kal), Kayardild (gyd), Makah (myh), Martuthunira (vma), Plains Cree (crk), Ngiyambaa (wyb), Wichita (wic) and Yagua (yad). Only two of these languages, Luvale (lue) and Zulu (zul) are safe.

7 Discussion

Our linguistic diversity scores include two kinds of language features (expert features extracted from data bases and the mean word length as a text feature) describing two structural levels (syntax and morphology). Readers not familiar with the details of how expert features are used in NLP might be left wondering whether the use of the mean word length is necessary and whether this measure is a good approximation of morphological types.

Describing the use of expert features in NLP in Section 4, we note that the library `lang2vec` does not contain any morphological features, although these features are present in linguistic data bases. It is not clear why this is the case, but this means that morphological features are currently not used in NLP to assess linguistic diversity and the distances between languages. One possible reason for omitting morphological features could be the problem of sparsity, which would become even worse with these features leading to even more imputed values. For instance, if we want to study the distribution of 27 morphological features, only 34 languages will have a value for all these features. The values for the thousands of other languages would need to be imputed. This is the main reason why we propose to complement the existing sources of expert features with the mean word length as a value that can be easily calculated for any language on a small sample of text (500 tokens).

To justify this proposal, we show that an independent measure of morphological complexity (C_{WALS}) and the mean word length are strongly correlated, but the score of 0.69 means that the agreement is not perfect. A closer look into these two variables (Table 3 in Appendix B) points to the limitations of both measures, especially concerning the high values. For example, Turkish is the most complex language according to C_{WALS}, but its mean word length is well under 7. Although the correlation score is high and not due to chance, such aggregate measures remain approximations of the structural properties of languages. Nevertheless, these approximations are useful for tracking and improving linguistic diversity in data sets at the level of precision that is currently possible. Better approximations are certainly achievable in future work. Since our methods are general and can be applied to any set of features, any future improvements in representing linguistic structures can be easily integrated.

8 Conclusion

We have shown that the linguistic diversity of NLP data sets can be consistently assessed by two independent measures, TI (proposed in previous work) and J_{mm} (proposed in this paper). Both of these measures show that a high number of languages and language families included in a data set is not sufficient to ensure linguistic diversity.

To make the assessment of linguistic diversity automatic and rather simple, we show that text-based features such as the mean word length can be used as linguistic descriptors. These features can be easily calculated on very small text samples (of length of 500 tokens), overcoming the obstacles posed by the need to extract linguistic features from typological databases.

An advantage of the J_{mm} score over TI and other previous indicators of linguistic diversity is its capacity to show what kinds of languages are missing in a given data set in comparison to a reference. Assessing popular NLP data sets with this measure revealed that the most underrepresented languages are those with rich morphology. This kind of direct and transparent comparison can improve multilingual NLP coverage in the long run.

Limitations

A limitation of our study is that the two levels of linguistic structures are represented with different features: syntax with expert features from linguistic data bases and morphology with mean word length as a text feature. Our results suggest that the two measures agree more at the level of syntax than at the level of morphology. To draw sound conclusions about the impact of the structural level on the agreement between the two measures, we would need both kinds of features for both levels. While we indirectly compare text and expert features at the level of morphology (via the correlation test), we do not propose syntactic features that could be extracted from text. We focused here on the current gap in the available linguistic features (the lack of morphological features in `lang2vec`), but devising and validating text-based syntactic features would deserve more attention in future work.

A Mean Word Length Correlation between Different Sample Size

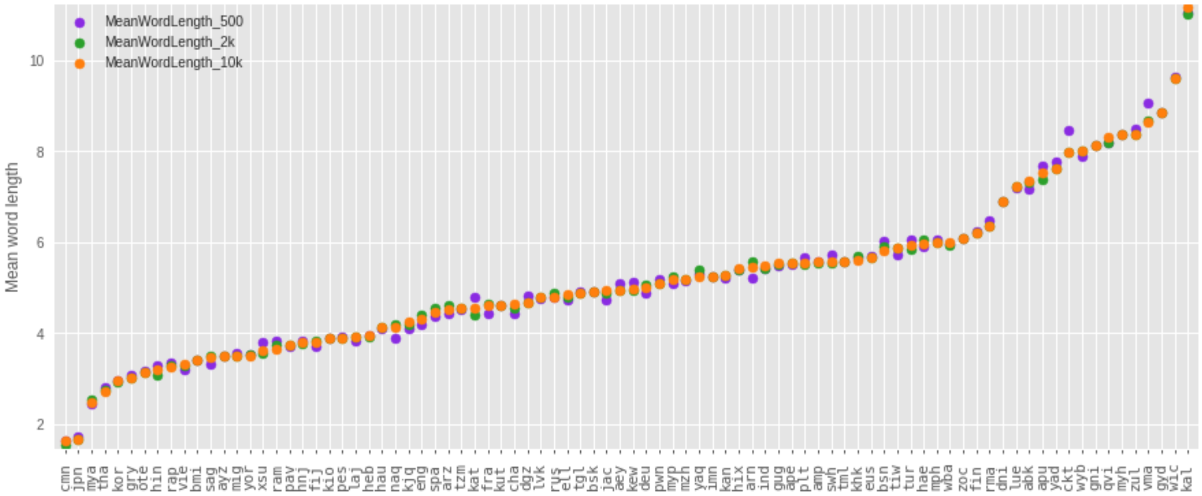

Figure 4: Mean word length measures at different text sizes in TeDDi. The languages on the x-axis are sorted according to the increasing value calculated on the biggest sample (10K). The values in the two smaller samples (2K and 500) depart very little from the main trend.

To make sure that the stability across different sample sizes suggested by Figure 4 is not a mere consequence of a relatively small range of variation, we perform correlation tests between different samples and in comparison to other measures (TTR and unigram entropy (H)). Table 2 shows that the ranks of languages change considerably less across different sample sizes when considering the mean word length than in the other two measures.

Samples	MWL	H	TTR
500 tokens vs. max.	0.99	0.85	0.84
2K tokens vs. max	0.99	0.95	0.94

Table 2: Spearman rank correlation showing how much rankings of languages change with text measures taken on random samples of different size.

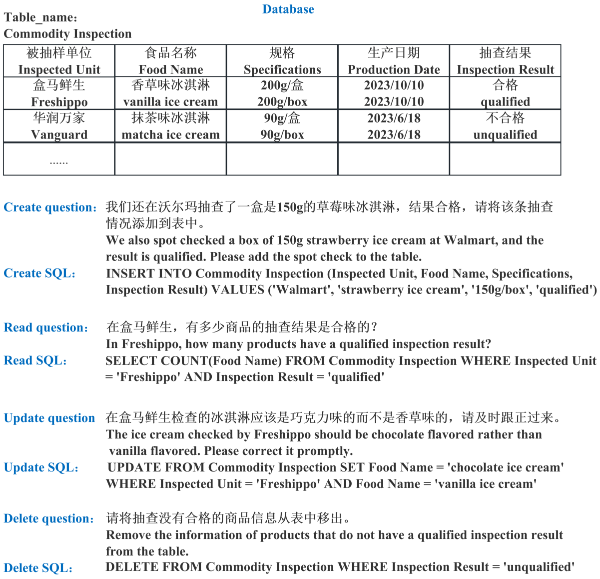
Abstract

Text-to-SQL aims to convert natural language into structured query language, which is a challenging task. Current research focuses mainly on read operations and ignores other aspects of database operations such as create, update, and delete operations. The benchmark datasets as well as models that have been proposed also fail to cover these operations, limiting the development and practical applications in the field. To bridge this gap, we propose CRUDSQL, a large-scale cross-domain single-table CRUD operations Chinese Text-to-SQL dataset. The dataset contains 10,000 question/SQL pairs involving 625 tables from different domains. To support further research on this dataset, we also propose a baseline method, CRUDParser, which employs a two-phase approach based on BERT and T5 for SQL generation and incorporates two strategies, value matching, and value prompting, for interacting with databases to further improve the performance. The experimental results show that the new operation types bring different challenges for future research, and our approach achieves 67.08% and 83.8% exact set matching accuracy under both read and delete operations in the test set, but only 49.6% and 61.8% under create and update operations. We believe that the proposal of CRUDSQL as well as CRUDParser can provide new directions and possibilities for research and practical applications in the field of Text-to-SQL. The dataset is published at `https://github.com/bizard-lab/CRUDSQL`.

1 Introduction

The Text-to-SQL task aims to transform natural language questions into corresponding SQL query statements, and researchers have applied this technique to relational databases as natural language interface to database (NLIDB) to help users interact with databases more easily. However, in the early days the main methods used were based on keywords, pattern matching, syntax tree parsing and grammar rules. This is limited by the rules and patterns defined, cannot handle ambiguous natural language questions, is difficult to scale and is not suitable for complex queries.



Database

Table_name:
Commodity Inspection

被抽样单位 **Inspected Unit**	食品名称 **Food Name**	规格 **Specifications**	生产日期 **Production Date**	抽查结果 **Inspection Result**
盒马鲜生 **Freshippo**	香草味冰淇淋 **vanilla ice cream**	**200g/**盒 **200g/box**	**2023/10/10** **2023/10/10**	合格 **qualified**
华润万家 **Vanguard**	抹茶味冰淇淋 **matcha ice cream**	**90g/**盒 **90g/box**	**2023/6/18** **2023/6/18**	不合格 **unqualified**
……				

Create question: 我们还在沃尔玛抽查了一盒是**150g**的草莓味冰淇淋，结果合格，请将该条抽查情况添加到表中。
We also spot checked a box of 150g strawberry ice cream at Walmart, and the result is qualified. Please add the spot check to the table.
Create SQL: **INSERT INTO Commodity Inspection (Inspected Unit, Food Name, Specifications, Inspection Result) VALUES ('Walmart', 'strawberry ice cream', '150g/box', 'qualified')**

Read question: 在盒马鲜生，有多少商品的抽查结果是合格的？
In Freshippo, how many products have a qualified inspection result?
Read SQL: **SELECT COUNT(Food Name) FROM Commodity Inspection WHERE Inspected Unit = 'Freshippo' AND Inspection Result = 'qualified'**

Update question 在盒马鲜生检查的冰淇淋应该是巧克力味的而不是香草味的，请及时跟正过来。
The ice cream checked by Freshippo should be chocolate flavored rather than vanilla flavored. Please correct it promptly.
Update SQL: **UPDATE FROM Commodity Inspection SET Food Name = 'chocolate ice cream' WHERE Inspected Unit = 'Freshippo' AND Food Name = 'vanilla ice cream'**

Delete question: 请将抽查没有合格的商品信息从表中移出。
Remove the information of products that do not have a qualified inspection result from the table.
Delete SQL: **DELETE FROM Commodity Inspection WHERE Inspection Result = 'unqualified'**

Figure 1: An example that introduces Text-to-SQL for CRUD operations.

With the release of WiKiSQL(Zhong et al., 2017) and Spider(Yu et al., 2018c), two large-scale Text-to-SQL datasets, the field has gained more and more attention and development. WiKiSQL is constructed based on Wikipedia and contains 24,241 tables, 80,654 natural language questions, and corresponding SQL queries. Each of its databases has only one table, does not need to consider primary and foreign keys, and the form of SQL to be predicted is relatively simple, and SeaD(Xu et al., 2022) currently achieves the highest accuracy on this dataset, with 93%. Spider contains 10,181 natural language question-SQL pairs covering 138 different domains, which is a greater

difficulty enhancement than WiKiSQL which involves the correlation between multiple tables and the generation of more complex SQL. Currently, DAIL-SQL(Gao et al., 2023) achieves 86.6% accuracy on this dataset.

However, current datasets and research efforts focus on read operations and ignore create, update, and delete operations. To fill this gap, this paper proposes CRUDSQL, a large-scale cross-domain single-table CRUD operations Chinese Text-to-SQL dataset. The dataset contains 10,000 questions and their corresponding SQL queries involving 625 tables from different domains, in which the distribution of create, read, update, and delete is uniform. Figure 1 shows an example of data from CRUDSQL consisting of a table and questions oriented to the table about the CRUD operations and the corresponding SQL statements. To the best of our knowledge, CRUDSQL is the first Text-to-SQL dataset that contains all four operation types of create, read, update, and delete at the same time.

In addition, we propose CRUDParser, a model that incorporates BERT(Kenton and Toutanova, 2019) and T5(Raffel et al., 2020) for two-stage SQL generation as a baseline approach for this dataset. The first stage is sketch-based slot filling, where BERT predicts the SQL type corresponding to the question, as well as the SQL column names, keywords, operators, and aggregation functions, and fills them into a predefined SQL sketch. The SQL sketch is then used as the basis for interaction with the database to improve the accuracy of the final SQL generated. There are two types of interactions, one is value matching, which is used to improve the conditional value of the WHERE clause in the SQL statement, and the other is value prompting, which is used to optimize the values that are inserted into the database or the values that need to be updated. The second stage is the sequence-based generation, mainly used in update and create operations, where T5 can generate the final SQL based on SQL sketches as well as prompt words.

The experimental results show that the create and update operations bring new challenges to the Text-to-SQL task, and the accuracy of these two operation types on the test set is only 49.6% and 65.6% even with the use of pre-trained language models as well as methods that have performed well in the past. Although our value matching and value prompting strategies are effective, there is still a lot of room for improvement offered for further research.

The key contributions of this paper are summarized as follows:

(1) We propose CRUDSQL, a large-scale cross-domain single-table CRUD operations Chinese Text-to-SQL dataset. The dataset contains 10,000 question/SQL pairs involving 625 tables from different domains.

(2) We present a baseline model CRUDParser and its experimental benchmark results for this dataset, containing Bert and T5 for two-stage SQL generation.

(3) Further, two refinement strategies: value matching and value prompting are introduced to enhance conditional value matching and generate normalized values for update and create operations respectively.

2 Related Work

2.1 Existing Datasets

Over the past few decades, numerous datasets have been instrumental in propelling the development of Text-to-SQL systems. Early datasets such as ATIS (Price, 1990; Dahl et al., 1994), centered around flight reservations, GeoQuery(Zelle and Mooney, 1996), focused on U.S. geographical information, and Restaurants(Tang and Mooney, 2000), detailing restaurant information in Northern California, were all confined to singular domains.

In recent years, datasets in this domain have primarily been categorized into three classes: single-table queries, cross-table joint queries, and multi-turn dialogue queries. Single-table query datasets involve SQL operations predominantly focused on aggregation, comparison, and selection, exhibiting lower complexity. Examples include WiKiSQL(Zhong et al., 2017), WiKiTableQuestions(Pasupat and Liang, 2015), and TableQA(Sun et al., 2020).Cross-table joint query datasets introduce clauses such as JOIN, GROUP BY, ORDER BY, HAVING, INTERSECT, UNION, and LIKE, significantly elevating the complexity of SQL and aligning it more closely with real-world scenarios. Examples encompass Spider(Yu et al., 2018c), Spider-DK(Gan et al., 2021b), Spider-Syn(Gan et al., 2021a) KaggleDBQA(Lee et al., 2021), CSpider(Min et al., 2019), DUSQL(Wang et al., 2020), and BIRD(Li et al., 2023b). Multi-turn dialogue query datasets necessitate models capable of understanding and processing successive user queries while considering context and historical dialogue information. Instances include SParC(Yu et al., 2020), CoSQL(Yu et al., 2019), CHASE(Guo et al., 2021), and SeSQL(Huang et al., 2022).

It's worth noting that current datasets solely focus on read operations. Hence, we've introduced CRUDSQL, a dataset encompassing four fundamental types of operations: create, read, update, and delete. Table 1 provides an overview comparison between CRUDSQL and other Text-to-SQL benchmark datasets.

2.2 Existing Text-to-SQL Approaches

Sketch-based slot-filling approaches Using sketch-based slot-filling approaches, complex query logic is streamlined into a series of basic operations, simplifying neural network predictions and ensuring correct syntax when generating SQL queries. For instance, SQLNet(Xu et al., 2017) employs a predefined sketch of the SQL query, breaking down the required SQL query into the SELECT and WHERE clause segments, predicting slots within these segments (such as column, operator, aggregation, and value). Similarly, approaches like Coarse2Fine(Dong and Lapata, 2018), TypeSQL(Yu et al., 2018a), SyntaxSQLNet(Yu et al., 2018b), SQLOVA(Hwang et al., 2019), X-SQL(He et al., 2019), HydraNet(Lyu et al., 2020), RYANSQL(Choi et al., 2021), and CatSQL(Fu et al., 2023) adopt similar strategies.

Sequence-based approaches Another common approach involves sequence generation, relying on encoder-decoder pre-trained language models such as T5(Raffel et al., 2020), BART(Lewis et al., 2020), and similar architectures. These methods directly transform natural language queries into SQL queries through end-to-end sequence generation. For instance, a novel encoder-decoder framework is proposed by Cai et al. (2018). During the encoding phase, the neural network identifies and maintains semantic information of natural language questions. In the decoding phase, based on the neural network's hidden states, it generates a new sequence in another language. Similarly, approaches like PICARD(Scholak et al., 2021), RASAT(Qi et al., 2022), RESDSQL(Li et al., 2023a), SC-PROMPT(Gu et al., 2023a).

LLM-based approaches In recent years, with the emergence of large-scale language models such as GPT-3(Brown et al., 2020) and PaLM(Chowdhery et al., 2023), more and more researchers have turned their attention to the impressive reasoning capabilities and domain-generalization abilities of these models. Liu and Tan (2023) proposed the use of Chain of Thought (CoT)(Wei et al., 2022) to activate the reasoning capabilities of Large Language Models (LLMs) in text-to-SQL tasks. This method guides models to decompose complex tasks into subtasks and designs prompts based on task characteristics to induce LLMs to generate useful chains of reasoning. C3(Dong et al., 2023) introduced three prompt paradigms—clear prompts, prompt correction, and consistent outputs—to enhance zero-shot performance. Furthermore, approaches like ZERONL2SQL(Gu et al., 2023b) combine pre-trained language models with large-scale language models. They first use pre-trained language models to generate SQL sketches and then utilize large-scale language models to fill in the complete SQL queries, achieving optimal zero-shot NL2SQL performance.

3 Dataset Construction

3.1 Data Collection

We constructed the CRUDSQL benchmark by sampling 625 tables from the TableQA[1], encompassing various domains such as stocks, real estate, commodities, and schools. Subsequently, we conducted data cleaning on the table data. This involved manual modifications addressing several issues, including 1) Ambiguous time data that wasn't explicitly transformed into date-time formats. 2) Database values mixed with database column names. 3) Mismatches between database values and column types. Additionally, we retained a subset of original questions-SQL query pairs that originally corresponded to these 625 tables.

3.2 Data Annotation

We assembled an annotation team consisting of three master's degree students and three undergraduate students in the computer science program who were asked to pose four questions about creation, reading, updating, and deletion to each table and manually annotate the corresponding SQL.

The SQL template for annotation adopts the same style as TableQA and WiKiSQL, which divides the SQL into several important parts to be stored in JSON form, including sel parts, aggregation functions, logical operators connecting multiple conditions, and conditional expressions for WHERE clauses. In addition, in order to extend the single

Dataset	Language	#DB	#Table/DB	#Pairs	Create	Read	Update	Delete
CRUDSQL	Chinese	625	1	10000	✔	✔	✔	✔
WiKiSQL	English	24241	1	80654	✘	✔	✘	✘
TableQA	Chinese	5291	1	49974	✘	✔	✘	✘
Spider	English	200	5.1	10181	✘	✔	✘	✘

Table 1: Comparisons of existing Text-to-SQL benchmark datasets.

read statement to create, update, and delete statements, we also added SET expressions for update operations as well as categorized identifiers for the four types of operational SQL in the annotation templates. It is worth noting that the "conds" field, which was originally used to represent WHERE clauses, represents not only the WHERE part of the read, update, and delete operations, but also the columns and their corresponding values inserted in the create operation. This approach can greatly simplify the annotation task, as well as ensure the consistency of the annotated SQL templates.

3.3 Data Review

In order to ensure the quality of the annotated data, two forms of review were adopted. The first form of review was primarily done by first checking with each other by the students to make sure that the questions posed by each other were clear and that the questions matched the annotated SQL. The annotated question-SQL pairs were then given to SQL experts for evaluation. The second form of review is mainly through the review script written, which is responsible for monitoring the proportion of different types of SQL in the annotated samples, the distribution of aggregation functions, the distribution of the number of conditions, the proportion of values that need to be linked, etc., and checking whether there are any problems in the SQL templates of the annotated questions, e.g., size comparisons and addition/subtraction operations are performed on the values which are not of numeric types, and the subscripts of the selected columns are out of the ranges of the columns in the table.

3.4 Data Statistics and Analysis

Overall Statistics CRUDSQL includes 625 tables and 10,000 question-SQL pairs, and the SQL types include create, read, update, and delete operations, Table 2 shows the statistics of the data division.

Split	DB	Pair	Create	Read	Update	Delete
Train	440	7040	1760	1760	1760	1760
Dev	60	960	240	240	240	240
Test	125	2000	500	500	500	500

Table 2: Dataset split statistics.

We separately counted the length of the question in CRUDSQL, the length of the SQL (table name, column name, keywords, operators, aggregation functions, and number of values), and the percentage of SQL that requires value joins, as shown in Figure 2.

In CRUDSQL, each question corresponds to only one table, where the SQL for read operations is consistent with the TableQA difficulty, with support for aggregation functions including MIN, MAX, AVG, SUM, MIN, and COUNT, and conditional operators including >, <, ==, and ! =. The SQL for update operations also includes the arithmetic operators +, and -.

Value Linking Value linking refers to the process of linking or mapping specific parts of a natural language query to actual values in the database. For example, if the query mentions "December 12, 2012", the actual value stored in the database may be "2012-12-12". So when we construct the SQL, we need to replace the corresponding conditional value with the actual value in the database. Situations that require value linking operations often include abbreviations, conversion of numeric text to numeric values, conversion of date formats, multiple or ambiguous words, conversion of units or measures, specific identifiers, and so on.

The WHERE clauses for read, delete, and update operations include almost all of the above cases where value linking is required, often with the help of values in the database, which is referred to as value matching. In addition, value linking is also required in the SET clause for create and update operations. In a create operation, the values to be inserted into the table need to match the type of columns and the style of data stored. Update operations, there may be a need to update the content that can not be obtained from the question in full, you need to use the database that has been

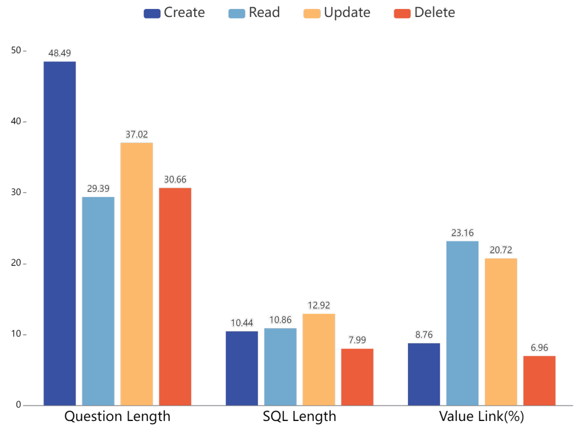

Figure 2: A statistical analysis of CRUDSQL, including question lengths, SQL lengths, and the percentage of value links.

stored in the content. For example, the question "Will the end of the training from the 1st change the time of the 2nd", at this time in the database stored at the end of the training time attribute of the value of " December 1", then the value after the modification should be "December 2", although our question does not indicate that the end time is in December, we need to rely on the content already stored as a prompt to modify, we will be this type of value linking is called a value prompting.

4 Benchmark Approach

In this paper, we propose a unified model called CRUDParser that aims to adapt create, read, update, and delete operations. The model combines two pre-trained language models, BERT and T5, and employs both value matching and value prompting strategies. We divide the task as a whole into two phases: first, the prediction results of the BERT model are utilized to populate the sketches; second, the T5 model is used to generate values involving update and create operations.

4.1 BERT Encoder

The input to BERT contains a natural language question Q and a database schema DS, where $Q = \{q_1, q_2, \ldots, q_{|Q|}\}$, $|Q|$ denotes the length of the question, and $DS = \{table\_name, C_1, t_1, C_2, t_2, \ldots, C_{|N|}, t_{|N|}\}$, including table name, column name and column type, $|N|$ denotes how many columns there are in a table and each column $C_i = \{c_1, \ldots, c_{|N_i|}\}$, $|N_i|$ denotes the length of the field in the ith column. It is worth noting that there are two main types of columns, text type and real type.

As can be seen in Figure 3, we have divided multiple categorized sub-tasks, including the SELECT part, aggregation function part, WHERE clause part, SET expression part, logical operators, and question types. Among them, the aggregation function, operator and question type belong to the multi-classification task, which is denoted as p_1, while the columns and values belong to the bi-classification task, which is denoted as p_2, and its calculation formula is shown below:

$$p_1 = Softmax(FC(BERT(Q, DS))) \quad (1)$$

$$p_2 = Sigmoid(FC(BERT(Q, DS))) \quad (2)$$

First, we need to determine the type of question to choose a predetermined sketch and need to choose which parts to fill, such as the example in figure3, when the prediction of the question is an update operation, then the sketch is "UPDATE FROM _ SET _ WHERE _", we call it *SK*, and then need to focus on the SET expression part, the logical operators and the WHERE clause part. The SK' is obtained by filling the *SK* with the results of the corresponding subtask classifier, where the value is predicted using a pointer network [41], by intercepting it from the question. At this point, we get a preliminary SQL.

4.2 Value Matching

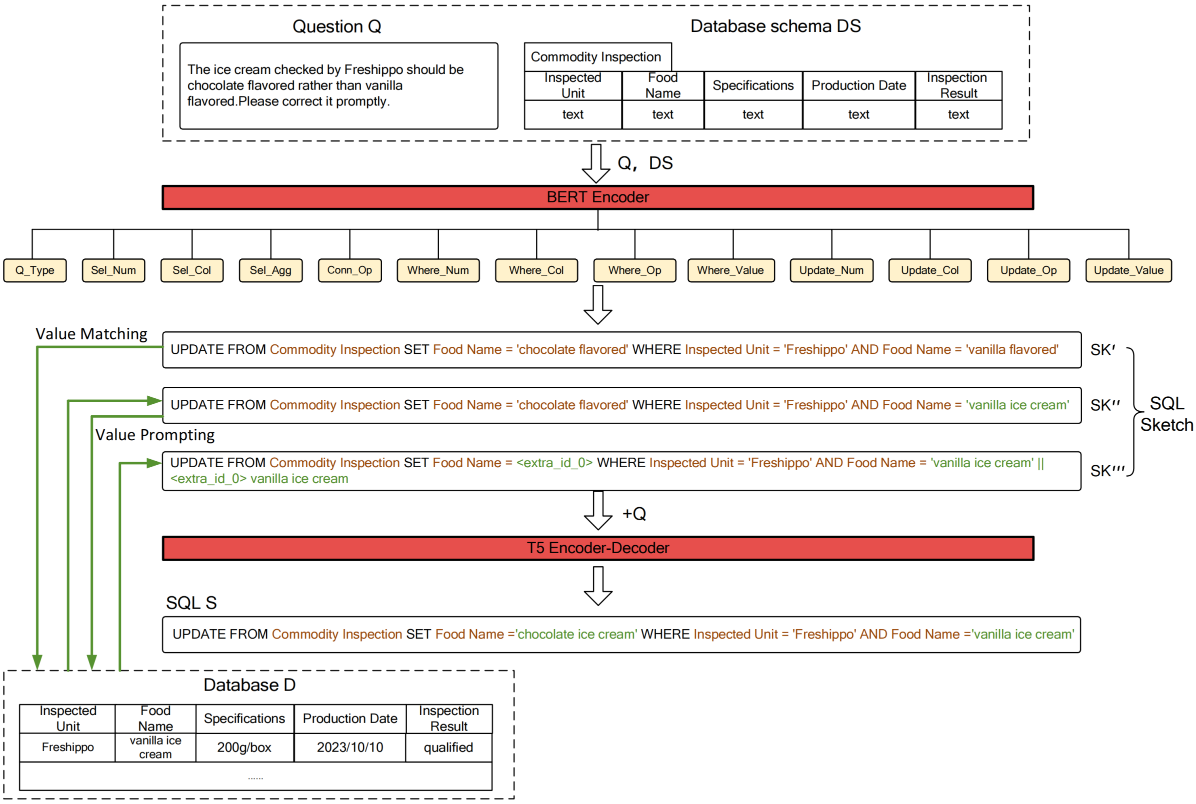
We found that many times the value intercepted from the question often does not correspond to the actual value in the database, so we fuzzy match the value in the WHERE clause in SK' with the actual value stored in the corresponding column in the database with the following expression:

$$score = fuzzy\_match\left(value, D\left[col\right]\right) \quad (3)$$

Depending on the score, decide whether to replace it with the database value or keep the intercepted value. Write the result after value matching as SK''.

4.3 Value Prompting

After the completion of the value matching can help us to improve the accuracy of the conditional matching, but in the create and update operations, it is no longer a match, both for the insertion of new values or modified new values, the database value can only be used as a kind of prompt existence. This prompt can help the value inserted into the table be in line with the style of the existing values



The ice cream checked by Freshippo should be chocolate flavored rather than vanilla flavored.Please correct it promptly.

Commodity Inspection

Inspected Unit	Food Name	Specifications	Production Date	Inspection Result
text	text	text	text	text

Figure 3: An overview of CRUDParser. Given a user's query Q and a database schema DS, the first stage fills the SQL sketch with the results predicted by BERT as well as multiple task classifiers, and the second stage generates the values that need to be created or updated by T5. There are also two strategies for interacting with the database, value matching and value prompting.

in the database, and can also help when updating can be based on the existing values in the database. For create operations, we will randomly select a database value as a prompt in the column where the value needs to be inserted. For update operations, we will first query the database for the value that was originally stored in the location that needs to be updated, and then use that value as the prompt. Then we would replace the part that needs to be inserted or modified with <*extra_id_x*>, $x \in [0,$ number of columns to be operated on], and then after SK'' we would splice "|| <extra_id_x> prompt value " as SK''', which is used for input into the T5 model that follows.

In Figure 3, both phases, value matching, and value prompting, obtain the required information by generating SQL queries that can interact with the database, i.e., we don't need to pass the actual values stored in the database into the model. When dealing with the actual database, it is not possible to write the database values into the input due to the invisibility of the data and the large amount of data. Therefore, the accuracy of the SQL can be improved by generating the required SQL queries to interact with the database during the process.

4.4 T5 Encoder-Decoder

We concatenate the question Q and SK''' with "||" as input to the T5 model, and use the model to generate the appropriate content to populate <*extra_id_x*> to get the final SQL S, which can be expressed as:

$$S = T5(Q, SK''') \tag{4}$$

5 Experiments

5.1 Experiment Setting

Data Settings As shown in Table 2, based on the cross-domain settings, we have divided CRUDSQL into train/dev/test sets, and there is no overlap of the databases contained in different datasets. Moreover, our SQL for the four types of operations is evenly divided, which helps the model to better learn the features in the dataset and better adapt to the SQL for different types of operations.

Evaluation Metrics We use three popular Text-to-SQL task evaluation metrics including Exact

Set Match Accuracy without values (EM without values), Exact Set Match Accuracy (EM), and Execution Accuracy (EX). EM without values measures whether the SQL generated by the model matches the standard SQL structurally, but does not consider specific values. EM requires not only structural matches but also exact matches of values. EX determines whether the generated SQL has the same result as the standard SQL after it is executed in the database.

Baseline Approach We use CRUDParser as a baseline approach for CRUDSQL. CRUDParser incorporates two pre-trained language models, BERT and T5, and combines a sketch-based slot-filling method with a sequence generation method to generate SQL in two phases, and in between, it uses value matching and value prompting strategies to further improve the accuracy of the task. It is worth noting that in order to better adapt to the Chinese context, the model versions we chose are BERT-WWM(Cui et al., 2019) and mT5-base(Xue et al., 2021), respectively. In addition to this, we also provide the results of the zero-shot demonstration of ChatGPT(gpt-3.5-turbo) in Table 5.

5.2 Experiment Results

Table 3 represents the EM without values of CRUDParser on CRUDSQL, and we can see that the worst performance is on the create operation, which is only 73.75% and 68.6% on the development and test sets, respectively, even though the create operation only corresponds to columns and values, which requires the fewest types of matches compared to other operations. The best performance is for the delete operation, which involves relatively fewer types of matches than the read and update operations.

Table 4 represents CRUDParser's EM on CRUDSQL, with -m removing the value matching process, -p removing the value prompting process, and -m-p requiring neither. It is seen that CRUDParser with value matching and value prompting gives the best performance in all cases. Create operations are only affected by value prompting, read and delete operations are only affected by value matching, and update operations are affected by both. We notice that the update operation has a gap of 11.67% and 9.4% on the development and test sets, respectively, and we find that the impact of value matching is greater than that of value prompting, due to the fact that when the matching is unsuccessful, it tends to affect the ability to get the corresponding prompted value from the database, which in turn affects the subsequent process.

Finally, we compared the EX of the models on CRUDSQL, as shown in 5. For the create operation, the EX is unchanged if both the inserted value and the corresponding column are matched correctly. The EX of the other types of operations is higher than the EM, because when the predicted SQL statement is the same as the real annotated SQL, the result of the SQL execution must be the same, but when the predicted SQL is different from the real annotated SQL, it often achieves the same result as the real annotated SQL due to the difference in the condition matching. In addition, despite its strong language comprehension and reasoning capabilities, ChatGPT cannot show better performance without interacting with the database and without resorting to database values.

5.3 Error Analysis

Why is it that the create operation requires the fewest types to match, only columns and values, but has the lowest accuracy rate by all metrics? By analyzing the incorrect results, we found that 68.65% of the results had schema linking errors, mainly column linking. Often, the columns mentioned in the question are missing from the results or matched to the wrong columns, for example, "The Little Prince is a short story in children's literature written in 1942 by the French author Antoine de Saint-Exupéry" may contain attributes such as title, author, country, year, and genre, which often cannot be matched without using methods such as Named Entity Recognition (NER).

Schema linking errors have been a difficult problem in this field, and the influencing factors include diverse linguistic expressions, complex database schemas, and lexical and grammatical differences. By observing the four types of error results, we found that 32.58% of the results contain schema linking errors, especially for the Chinese language, how to match the Chinese language with the English abbreviation, for example, “每股收益” in English is "Earnings Per Share", and the attribute value in the database is the abbreviation "EPS". When this occurs, external knowledge may need to be brought in to help the model make the right choice. Another issue worth noting is schema ambiguity, where part of a problem may map to more than one database element. This problem is prone to occur not only in cross-table queries, i.e., columns with the same name in the middle of dif-

Table 5: The Execution Accuracy(EX) of CRUDParser and ChatGPT in CRUDSQL.

ferent tables, but also in single tables. For example, in the Real Estate Sales Amount Forecast table, the attribute values are (Tier 1 cities, year-on-year growth rate, Tier 2 cities, year-on-year growth rate, Tier 3 cities, year-on-year growth rate), so how can we correspond to the correct columns when we refer to the year-on-year growth rate in the question. It turns out that although we matched the correct city type, the year-on-year growth rate still matches incorrectly. To solve this problem, we may need to add a correlation between year-on-year growth rate and city type when coding the database schema.

Update operations require both condition matching and value modification, which poses multiple challenges. In particular, when modifying database values, one is that the updated value has no relationship with the original value, in which case the value prompts are used mainly to keep the value updated to the database in line with the database style, and the other is that the updated value is modified based on the original value, in which case the value prompts are used to fill in the missing information in the question. By analyzing the examples of errors in update operations, we found that 36.18% of them were errors in updating values, and in some cases, the model did not know what consistent style was, for example, "3A" was mentioned in the question, while the database stored the value as "AAA ". Moreover, we found that when using values as prompts to guide the model to generate results, if not controlled, the results may tend to deviate from our needs, especially when generating numeric content.

6 Conclusion

In this paper, we propose CRUDSQL, a large cross-domain, single-table Chinese Text-to-SQL benchmark dataset with a special focus on four types of SQL operations: create, read, update, and delete. Compared to existing benchmark datasets that only have read operations, this paper introduces new challenges, especially for value linking, and puts more emphasis on the accuracy of the updated and created values. In addition to this, we propose a baseline approach for this dataset, CRUDParser, which generates SQL in stages by pre-training the language model and incorporates value matching and value prompting strategies. We demonstrate the experimental benchmark results.

This paper has demonstrated initial promise, but there is still room for improvement. One potential future work is to extend single-table to multi-table query SQL generation although the focus of this paper is unifying manipulation and query SQL producing. Another future work is to fine-tune large language models on this dataset and put it closer to more practical application scenarios.

Normalizing without Modernizing: Keeping Historical Wordforms of Middle French while Reducing Spelling Variants

Abstract

Conservation of historical documents benefits from computational methods by alleviating the manual labor related to digitization and modernization of textual content. Languages usually evolve over time and keeping historical wordforms is crucial for diachronic studies and digital humanities. However, spelling conventions did not necessarily exist when texts were originally written and orthographic variations are commonly observed depending on scribes and time periods. In this study, we propose to automatically normalize orthographic wordforms found in historical archives written in Middle French during the 16th century without fully modernizing textual content. We leverage pre-trained models in a low resource setting based on a manually curated parallel corpus and produce additional resources with artificial data generation approaches. Results show that causal language models and knowledge distillation improve over a strong baseline, thus validating the proposed methods.

In the first sample, the bishop's house, translation of *Evesché* in this example, refers to the house inhabited by the previous bishop which was converted into a prison.

1 Introduction

Normalizing orthographic variations of historical texts is a crucial task for digital humanities. It allows for both conservation and easy consultation of ancient documents. Archives conservation is a task conducted mostly manually by trained experts who could benefit from advances in automatic normalization and modernization of historical texts. Previous work has mainly focused on transforming the spelling of historical texts into their modern counterpart in order to apply computational tools (Bollmann, 2013; Pettersson et al., 2013; Sánchez-Martínez et al., 2013; Robertson and Goldwater, 2018). However, reducing orthographic variation while keeping historical spelling for a given era is the cornerstone of reliable diachronic studies. Yet, variations in wordforms lead to data scarcity and the lack of corpora containing spelling variants of historical texts is a serious impediment to supervised learning possibilities. Furthermore, spellings to retain among variants observed in historical texts may vary according to editorial guidelines, which is akin to a highly personalized natural language processing task.

During the process of digitization and modernization of historical texts, researchers in digital humanities could benefit from the data produced during each steps of this process. In this work, we focus on the normalization without modernization of archives from the 16th century written in Middle French. To the best of our knowledge, there are no datasets of archival documents from this era and language containing non-normalized wordforms aligned to their normalized counterparts. We first manually normalize and align a set of historical texts with their spelling-normalized forms, keeping the syntactic and semantic content identical to the originally authored manuscripts. Second, we investigate how to automatically normalize these texts

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3394–3402
June 16-21, 2024 ©2024 Association for Computational Linguistics

inspired by low-resource machine translation approaches. Empirical results show that two orthogonal solutions, namely sequence-level knowledge distillation (Buciluă et al., 2006; Hinton et al., 2015; Kim and Rush, 2016) and language model transfer learning combined with back-translation (Marie and Fujita, 2021; Tonja et al., 2023), allow to produce reliable synthetic parallel corpora.

Our summarized contributions are: (i) we pave the way towards archival documents conservation with expert targeted normalization and spelling variants reduction, keeping historical wordforms without modernization, (ii) we show evidence that leveraging pre-trained models and synthetic data improves normalization performances over a strong baseline, (iii) we release a Middle French handcrafted parallel corpus aiming at orthographic normalization along with several fine-tuned models.[1]

The remainder of this paper is organized as follows. We briefly introduce the background work in Section 2. We describe the data production methods in Section 3, followed by our experiments and results in Section 4. Finally, conclusions and future work are presented in Section 5.

2 Background Work

This Section presents previous work on normalization and modernization of historical texts, followed by background work on synthetic data generation methods. Finally, we formalize our spelling normalization as machine translation approach.

2.1 Historical Text Normalization

The majority of previous work in normalizing historical text aims at modernizing the spelling of ancient documents, which usually contain inconsistent orthographic and syntactic variations. Various methods have been proposed to conduct this modernization task, including rule-based (Baron et al., 2009; Bollmann et al., 2011) and statistical approaches (Pettersson et al., 2013, 2014), and more recently using neural networks (Bollmann and Søgaard, 2016; Korchagina, 2017; Tang et al., 2018; Bawden et al., 2022). However, when normalization does not involve modernization, i.e. the task is to reduce spelling variations while keeping historical wordforms and syntactic structures, the lack of training data for supervised learning methods becomes a hurdle. Unsupervised approaches could potentially be applied to historical texts normalization but one requires large amounts of source and target corpora. It is thus crucial to produce corpora, manually or automatically, containing spelling variations as source and their normalized counterparts as target.

2.2 Synthetic Data Generation

Recently, methods towards producing artificial parallel training data for tasks such as machine translation have been explored, relying only on source or target texts. One of the most popular approaches is back-translation (Sennrich et al., 2016). It leverages large amounts of target-side monolingual data and translates them automatically into the source language. This leads to a parallel corpus where the source side, possibly noisy, does not impact the quality of the target side.

Due to the lack of large target corpora for the task of Middle French archives normalization, fine-tuning a generative model using a small amount of data appears to be an interesting and cost-efficient avenue to explore (Marie and Fujita, 2021; Tonja et al., 2023). Such a model is used to produce artificial target data which is then back-translated, leading to a parallel corpus usable for supervised learning of a normalization model. This assumes that a small amount of parallel data is already available to train a back-translation model.

An alternative technique to leveraging target side monolingual data is to make use of source documents and producing synthetic target text (Mittal et al., 2023) by relying on the forward-translation technique (Zhang and Zong, 2016; Bogoychev and Sennrich, 2019), also called self-training (He et al., 2019). If some target segments are available, segment-level knowledge distillation (Kim and Rush, 2016) was shown to improve a student model trained on synthetic data produced by a teacher model. We opt for segment-level knowledge self-distillation where the same model is the teacher and the student, the latter being trained on data produced by the former.

2.3 Normalization as Machine Translation

Assuming an available parallel dataset $\mathcal{D}$, its vocabulary noted $\mathcal{V}$ with $v_c \in \mathcal{V}$ $(0 \leq c \leq C)$. Pairs of sequences compose the dataset with non-normalized source segments aligned to their normalized target counterparts, such as $\mathcal{D} = (X_1, Y_1), \ldots, (X_n, Y_n)$. The normalization task is formalized as the supervised neural ma-

Table 1: Number of parallel segments, source and target vocabulary sizes (k for thousands) for the hand-crafted and synthetic data produced in our study. The *Manuscripts* corpus is the manual transcription of the original RCs without normalization and is the source side of the *Distillation* corpus.

chine translation paradigm which aims at finding parameters θ of the conditional distribution $p(Y|X;\theta)$, maximizing the log-likelihood $\mathcal{L}_\theta = \sum_{(X_i,Y_i)\in D} \log p(Y_i|X_i;\theta)$. Training the neural network consists in minimizing the cross-entropy loss based on an input source sequence X_i, its corresponding target reference Y_i and the model output $\hat{Y}_i$. More formally, for every one-hot encoded token $y_j \in \mathbb{R}^C$ forming the sequence $Y_i = y_1, \ldots, y_{|Y_i|}$ $(1 \leq j \leq |Y_i|)$, the token-level loss is computed following (eq. 1), where $\hat{y}_j \in \mathbb{R}^C$ is the model output (logits) and y_j is the gold reference. By averaging token-level losses, we obtain the sequence-level loss following (eq. 2):

$$l_j = -\log \frac{\exp(\hat{y}_{j,y_j})}{\sum_{c=1}^{C} \exp(\hat{y}_{j,c})} \cdot y_j \quad (1)$$

$$\mathcal{L}_{(X_i,Y_i,\hat{Y}_i,\theta)} = \sum_{j=1}^{|Y_i|} \frac{1}{\sum_{j=1}^{|Y_i|} y_j} l_j \quad (2)$$

3 Parallel Data Production

Supervised training of an automatic normalization model is possible with a small amount of hand-crafted parallel data which we will describe in Section 3.1. We then present the two automatic data generation methods in Section 3.2 and Section 3.3. A set of non-normalized source documents were manually transcribed from the original manuscripts but do not have their normalized target counterparts. This non-parallel corpus was used in our distillation experiments. Details about the data produced, along with the number of segments and vocabulary sizes, are reported in Table 1.

3.1 Manual Normalization

The historical documents in our study are sourced from the publicly available Geneva Council Registers.[2] More precisely, we focus on the Geneva Council Registers in Calvin's time. They were written in Middle French from the 16th century including sections with mixed languages in Middle French and Latin, as illustrated in Figure 1. These manuscripts were written between 1536 and 1550. Their transcription requires the expert knowledge of historians and paleographers due to the vast number of patronymic, toponymic, geographical and generally era-related specialized vocabulary employed. The transcription of these documents was conducted manually over several years. Text normalization aiming at reducing spelling variants is still an ongoing work and will benefit from the use of computational tools.

To build a gold normalization dataset, we collected a small amount of source segments spanning over four years, from 1546 to 1549, which were manually normalized by experts according to the requirements and standards defined by the editors.[3] The normalization guidelines used to manually produce this hand-crafted dataset are described in Appendix A. The resulting curated and aligned pairs of segments were used as training and testing corpora to fine-tune and evaluate pre-trained encoder–decoder models, leading to our baseline normalization system. In addition, we fine-tuned the same pre-trained models with our parallel corpus in the reversed direction (normalized into non-normalized) to obtain models used for back-translation in the data production method described in Section 3.3. All the normalization models trained in our study follow the learning objective presented in (eq. 2).

3.2 Sequence-level Knowledge Distillation

Using the source documents manually transcribed from the original manuscripts (the corpus noted *Manuscripts* in Table 1) and the normalization system trained on our hand-crafted data, we produced a synthetic parallel corpus using the forward translation technique (Bogoychev and Sennrich, 2019). The source segments of our hand-crafted parallel corpus were thus manually and automatically normalized, leading to two sets of aligned target segments. In this particular scenario, we were able to perform knowledge self-distillation training, opting for the sequence-level approach

---

[2] `https://ge.ch/arvaegconsult/ws/consaeg/public/FICHE/AEGSearch`

[3] A segment contains sequences of various lengths, from a single token up to several sentences.

introduced by Kim and Rush (2016). Formally, based on the hand-crafted parallel corpus $\mathcal{D}$ and the sequence-level distilled corpus $\mathcal{D}_{KD}$, training of the encoder–decoder neural model is conducted by linearly interpolating the loss function presented in (eq. 2) with the loss calculated using the model output $\hat{Y}_i^{'} = \hat{y}_1^{'}, \ldots, \hat{y}_{|Y_i|}^{'}$ (with $1 \leq j \leq |\hat{Y}_i^{'}|$ and $\hat{y}_j^{'} \in \mathbb{R}^C$) as target reference (eq. 3):

$$\begin{aligned} \mathcal{L}_{(X_i, Y_i, \hat{Y}_i, \hat{Y}_i^{'} \theta)} = {} & (1 - \alpha)\, \mathcal{L}_{(X_i, Y_i, \hat{Y}_i, \theta)} \\ & + \alpha\, \mathcal{L}_{(X_i, \hat{Y}_i^{'}, \hat{Y}_i, \theta)} \end{aligned} \tag{3}$$

where α is set to 0.5 following the empirical observation made by Kim and Rush (2016). The linear interpolation of losses is possible for segments pairs where both a target hand-crafted reference and a distilled target sequence are available. For segments in the distilled corpus $\mathcal{D}_{KD}$ which are not included in the hand-crafted corpus $\mathcal{D}$, a single loss is computed based on (eq. 2), replacing the reference Y_i by the distilled target $\hat{Y}_i^{'}$. To train our model noted *Distillation*, both datasets are used, namely $\mathcal{D}$ and $\mathcal{D}_{KD}$, the source side of $\mathcal{D}$ being included in the source side of $\mathcal{D}_{KD}$. The main intuition behind interpolating losses is to perform a smooth supervised continued training by making use of the network output given the D_{KD} source corpus. We assume that we could limit hand-crafted data over-fitting with this technique, while allowing the encoder to process a larger amount of source in-domain data.

3.3 Transfer Learning and Back-translation

Generative, decoder-only, neural causal language models allow to produce data based on a set of seed tokens, prompts or instructions. It was shown in previous work that a small amount of relevant target data could be enough to steer a pre-trained model towards a specific domain or genre through fine-tuning, allowing to produce artificial data of interest for a given task (Marie and Fujita, 2021). For archival documents normalization, we leveraged the target side of our hand-crafted parallel data to fine-tune a generative causal language model using the cross-entropy objective function with mean reduction. We then designed a set of seed sequences[4] based on the target side of the hand-crafted corpus and used it as inputs (i.e. prompts) to the model for text generation. No prompting template was employed. Sequences of tokens were fed to the generative model and the produced artificial text was then considered as target data. Finally, we used the back-translation model trained on the hand-crafted parallel corpus to generate the source-side of the synthetic parallel corpus. The resulting dataset was used as training material for our second model trained on synthetic data (noted *Generation*).

4 Historical Documents Normalization

Models We trained individual models based on the three parallel datasets described in Section 3, namely *Hand-crafted*, *Distillation* and *Generation*. All normalization models were based on the pre-trained model *M2M100* with 418M parameters (Fan et al., 2021). The causal language model used to generate target synthetic data from prompts was *Bloomz* (Muennighoff et al., 2022) with 560M parameters.

The training procedure for normalization models using synthetic datasets followed a two-step process. First, continued training (Gururangan et al., 2020) with mixed synthetic and hand-crafted corpora. During this first step, we applied either sequence-level knowledge distillation or synthetic data generation followed by back-translation, leading to two models. Second, fine-tuning using the hand-crafted parallel corpus only, applied to each model resulting from the first step. We considered three baselines: pre-trained model without fine-tuning, copy of the source side of the test set (identity function), and a previously released model for early Modern French normalization (*ModFr*) (Bawden et al., 2022).

Training and Evaluation Due to the small size of our hand-crafted parallel corpus and the need to divide it into training, validation and test sets, all our experiments were based on a 5-fold cross-validation setup (train, validation and test splits represent approx. 63%, 17% and 20% respectively). We monitored the models performance during training based on the validation set with the BLEU metric (Papineni et al., 2002) and the best performing model for each fold was kept to normalize the test set. Finally, the 5-fold combined outputs were evaluated using four additional metrics, namely chrF (Popović, 2015), Translation Edit Rate (TER) (Snover et al., 2006), Word Error Rate

---

[4] The seed sequences, or prompts, contain between 8 and 12 tokens, as preliminary experiments showed more generation stability within this length range

Model	BLEU $\uparrow$	chrF $\uparrow$	TER $\downarrow$	WER $\downarrow$	Acc $\uparrow$
Baselines					
M2M100	23.0	57.1	54.0	66.2	1.4
Copy	25.1	66.2	43.7	41.6	13.9
ModFr	32.9	71.4	37.7	37.6	13.6
Fine-tuned Models (based on M2M100)					
Hand-crafted	77.7	89.9	13.7	6.8	50.0
Distillation	78.7†	90.5†	12.8†	6.4	50.8
Generation	82.8†	93.0†	9.3†	5.1	52.7

Table 2: Test results averaged over 5 folds. Baselines are the identity function (*Copy*) and non fine-tuned models. Fine-tuned models use the hand-crafted corpus. *Distillation* and *Generation* are trained on synthetic data. Scores with † indicate statistically significant difference compared to previous rows ($p < 0.01$ with the approximate randomization test).

(WER) and segment-level accuracy.[5]

The five metrics used in our evaluation measure the performances of automatic normalization models at various granularities. More precisely, BLEU measures the n-gram precision (with $0 < n < 5$), chrF is the F-score at the character level, TER measures the translation edit rate at the word-level including shifts, WER is the word error rate without shifts and accuracy is the number of exact matching segments. The latter metric is interesting as it indicates how many segments are exactly matching the reference, thus reducing the manual revision requiring human experts. Results obtained on the test set are presented in Table 2.

Results The automatic normalization results show that existing pre-trained models do not outperform a naive baseline consisting in copying the source corpus in terms of segment-level accuracy. However, using the small hand-crafted parallel corpus to fine-tune *M2M100* leads to a 36.1pts increase in accuracy compared to the copy baseline, as well as a drop of 30.8pts of WER compared to the *ModFr* model. Significant improvements are further achieved by using both synthetic data production methods, with the best performing approach being the target data generation combined with back-translation (*Generation*).

This model outperforms the knowledge distillation model (*Distillation*) by 1.9pts accuracy and 1.3pts WER. We hypothesize that the *Generation* model is outperforming the *Distillation* model because it was trained on a larger corpus, but further experiments are required to support this assumption. The generation and back-translation approach is more computationally expensive, as it requires training a total of three models. We hypothesize that this approach has a larger potential of improvement in terms of normalization performances due to the wide arrays of prompt engineering possibilities (Liu et al., 2023). Again, further experiments will be conducted as future work to verify this hypothesis. Finally, all the pre-trained models used in our experiments are based on their smallest released version in terms of number of parameters. Thus, we assume that better performances could be reached with larger models.

Comparing the results obtained on the validation and test sets (cf. Appendix B and Table 2 respectively), the hand-crafted only setup shows a decrease of 3.6pts BLEU and 1.1pts accuracy between validation and testing, while the distillation setup shows 1.2pts BLEU drop and 0.2pts accuracy improvement between validation and testing. These results could confirm our initial intuition, where distillation limits over-fitting towards the small hand-crafted corpus, but more experiments should be conducted to draw solid conclusions. Overall, on the test set, the model trained with the interpolated loss outperforms the model trained on hand-crafted pairs only.

5 Conclusion

This paper paved the way towards archival documents conservation with expert targeted normalization and spelling variants reduction while preserving historical wordforms of 16th century Middle French. Compared to previous work in this field, the proposed methods do not modernize the historical spelling and syntactic structure but rather reduce the orthographic variability observed in originally authored texts. Our approaches were inspired by low-resource machine translation and leveraged pre-trained models to achieve significant performance gains compared to a strong baseline. Furthermore, our approaches are orthogonal and will benefit from collecting additional relevant corpora for fine-tuning and prompt engineering, which is one of our goals in future work. Another research direction considered as future work stems from the large amount of publicly available modern French data and pre-trained LLMs which could be further leveraged for our task.

Limitations

We recognize several limitations of this work.

First, the experiments were conducted on a variant of the Middle French language from 1536 to 1550. Middle French has evolved over time, from the 14th to the 17th century, and our work is considering a relatively narrow time frame in the history of this language.

Second, only a few pre-trained language models were tested during our preliminary experiments relatively to the large number of models currently publicly available. Some of these models were pre-trained on Modern or Early Modern French language, while other models were trained jointly on several languages, including languages relevant to our work such as Latin. Therefore, the models selected in our study may not be representative of all publicly released pre-trained models in terms of languages, number of parameters, training objectives nor architectures.

Third, the hand-crafted corpus produced in our work is relatively small in terms of number of tokens and vocabulary size compared to commonly used corpora in natural language processing experiments. This is mainly due to the high cost of producing such dataset for which the expertise of historians and paleographers is required, while following strict editorial guidelines.

Finally, we have not tried reducing the training data of the Generation approach to match the amount of data of the Distillation approach, thus we cannot draw conclusions on which approach is better.

Ethical Considerations

The dataset hand-crafted in our study is based on publicly available archives from the 16th century (non-license, public domain). We reviewed the content of the documents selected for manual normalization and we believe that this resource represents accurate historical events. However, some textual elements of this corpus could be considered as toxic and harmful, or disrespectful of the privacy of the people and places mentioned in these archives. We thus made sure that all data used in our work and to be released as part of our parallel datasets are in the public domain and already freely available. Consequently, no increased risks or harm is caused by our dataset. Instead, it serves as a resource for historical studies and digital humanities.

The fine-tuned models to be released with our work are based on publicly released and licensed pre-trained models (MIT License). We respect the permissions to use, modify and distribute the models. We release the fine-tuned models under the MIT License.

Acknowledgements

We would like to thank the anonymous reviewers for their insightful comments.

This work was partially funded by the FNS (Fonds national suisse), SSH 2022 grant n. 215733, for the project entitled *Une édition sémantique et multilingue en ligne des registres du Conseil de Genève (15 45-1550)*, acronym *RCnum*.

All experiments were conducted on the University of Geneva computing cluster HPC *Baobab* and *Yggdrasil*.

A Appendix: Normalization Guidelines

The normalization guidelines were defined by the historian in charge of manually normalizing RC content. This person is an expert in 16th century Middle French, in the Geneva region and in the political landscape in Calvin's time. The normalization applied to the source textual content is focused on local orthographic and grammatical elements while leaving syntactic structures unchanged. The guidelines were the following:

- First characters are uppercased at the start of sentences, but also for patroyms and toponyms.
- Limit the use of ponctuation marks:
  - semicolons in lemmas only to separate different items,
  - commas before decisions, e.g. (regarding) ordered/stopped/solved,
  - periods at the end of sentences.
- Use of diacritical marks (apostrophes) except for cases where *que* is followed by a vowel which in fact are *qui*, e.g. *sont survenues quelques lettres que attouchaient à Genève* (in English: a few letters about Geneva appeared).
- Extended emphasis and accentuation based on modern usage
- Gender and number of past participle agreement, e.g. *de celui qui les a baillé* becomes *de celui qui les a baillés*, *sus la supplication qui a présenté* becomes *sus la supplication qui a présentée*, except when there is a doubt such as *lui soit baillé trois écus* **not** to be corrected in *lui soient baillés trois écus* because it is an ambiguous case: *trois écus* could be the object or the subject.
- Verb agreement, e.g. *ordonné que lesdits six écus lui soit délivrés* becomes *ordonné que lesdits six écus lui soient délivrés* (in English: ordered that the said six écus be delivered to him)
- Modernisation of patronyms, first names and toponyms.
- Correction of genders according to modern usage, e.g. *la dimanche* (in English: the Sunday) becomes *le dimanche*, *la reste* (in English: the rest) becomes *le reste*.
- Singular feminine possessive determiner replacement, e.g. *ma* (my), *ta* (your), *sa* (his, her, their), for nouns starting with a vowel or with a silent *h*, by the masculine forms *mon*, *ton*, *son*. For instance, *à sa humble requête* becomes *à son humble requête* (in English: to his/her/their humble request).

B Appendix: Ablation Study

Results obtained on the validation set with various models trained during our study are presented in Table 3.

Model	BLEU ↑	chrF ↑	Acc ↑
Hand-crafted	81.3	91.5	51.1
Synthetic Data			
Distillation	79.9	91.1	50.6
Generation	80.4	91.9	39.3
Synthetic + Hand-crafted Data			
Distillation	80.2	91.3	50.4
Generation	83.5	93.4	52.4

Table 3: Normalization results on the validation set averaged over 5 folds. Models under *Synthetic Data* were not finally fine-tuned on the hand-crafted data.

C Appendix: Training Procedure

All pre-trained models used in our work are checkpoints released with *HuggingFace Transformers* (Wolf et al., 2020). All models were trained on single Nvidia RTX A5000 and 3090 GPUs with 24GB memory. Training was conducted for a maximum of 100k steps with early stopping based on the BLEU scores obtained during validation. All our code was implemented in *Pytorch* (Paszke et al., 2019) and we used the *AdamW* optimizer (Loshchilov and Hutter, 2017). We used batch sizes between 4 and 16 segments depending on training and testing phases. Hyper-parameter search was focused on the learning-rate, with values ranging between $5e^{-5}$ and $5e^{-7}$. All other hyper-parameters were kept as default according to the configuration files released with the checkpoints. The final batch size was set to 4 segments and the best learning-rates for each model and each fold (1 to 5) are the following:

- *Hand-crafted*
    1. $5e^{-6}$
    2. $2e^{-6}$
    3. $5e^{-6}$
    4. $2e^{-6}$
    5. $2e^{-6}$
- *Distillation* (continued training – fine-tuning)
    1. $5e^{-6}$ – $2e^{-6}$
    2. $5e^{-6}$ – $1e^{-6}$
    3. $1e^{-5}$ – $2e^{-6}$
    4. $5e^{-6}$ – $2e^{-6}$
    5. $1e^{-5}$ – $2e^{-6}$
- *Generation* (continued training – fine-tuning)
    1. $1e^{-5}$ – $1e^{-6}$
    2. $5e^{-6}$ – $2e^{-6}$
    3. $8e^{-6}$ – $1e^{-6}$
    4. $5e^{-6}$ – $2e^{-6}$
    5. $8e^{-6}$ – $2e^{-6}$

Anti-LM Decoding for Zero-shot In-context Machine Translation

Suzanna Sia **Alexandra DeLucia** **Kevin Duh**

`{ssia1, aadelucia}@jhu.edu,` `kevinduh@cs.jhu.edu`

Abstract

Zero-shot In-context learning is the phenomenon where models can perform a task given only the instructions. However, pre-trained large language models are known to be poorly calibrated for zero-shot tasks. One of the most effective approaches to handling this bias is to adopt a contrastive decoding objective, which accounts for the prior probability of generating the next token by conditioning on a context. This work introduces an Anti-Language Model objective with a decay factor designed to address the weaknesses of In-context Machine Translation. We conduct our experiments across 3 model types and sizes, 3 language directions, and for both greedy decoding and beam search. The proposed method outperforms other state-of-the-art decoding objectives, with up to 20 BLEU point improvement from the default objective in some settings.

`https://github.com/suzyahyah/icl_Anti-LM_decoding`

1 Introduction

Decoding strategies in supervised neural machine translation (NMT) models are typically designed to select the maximum likelihood response under the given model. However, in the era of in-context learning with large language models (LLMs), selecting for the maximum likelihood response should be re-examined, as LLMs are known to be poorly calibrated for their tasks and exhibit a strong prior bias (Zhao et al., 2021; Wang et al., 2023). There are two large classes of decoding strategies: sampling methods and decoding objectives. Sampling methods do not change the probability ranking of the next token but influence how it is sampled, such as beam search (Koehn, 2004; Freitag and Al-Onaizan, 2017), nucleus sampling (Holtzman et al., 2020), and top-k sampling (Fan et al., 2018). Decoding objectives modify the probability of the next token before sampling takes place, typically by adding or subtracting scores, i.e., a *contrastive objective*.

Decoding objectives are one of the most effective approaches for improving the output of a generative model. These often require no training and are typically “frustratingly simple”, because they only involve manipulation of output probability distributions at inference time. However, as outlined by Zarrieß et al. (2021) in their recent large-scale survey, even for task-specific generation models, it is still surprisingly unclear what a good objective is for natural language generation.

In this work, we propose *an anti-language model (Anti-LM) decoding objective with exponential decay*, which is motivated by the observation that LLMs are performing Bayesian inference under the hood (Xie et al., 2022; Mirchandani et al., 2023), and are thus inclined to continue generating in the source language. We investigate this under a zero-shot setting where only the instructions are provided to the model without any examples.[1]

We hypothesise that poor translations may be due to a strong prior bias of the dominant source language, but that this bias should diminish over future decoding steps. Anti-LM modifies the original logits by taking the difference of the next token logits, conditioned on the source sentence to be translated. Penalising the conditional source sentence logits discourages the model from continuing the non-translated generation from the source sentence or regurgitating it. We consider this negative scenario as a “failure to translate”.

Our work falls under the category of contrastive objectives, which were popularised by Li et al. (2016). We compare our approach against other contrastive objectives: “conditional domain PMI” (Holtzman et al., 2021) and “context-aware” decoding (Shi et al., 2023). Our method consistently

---

[1] An example of the complete input to the model is “*Translate English to French: English: He built a WiFi door bell, he said. French:*”.

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3403–3420
June 16-21, 2024 ©2024 Association for Computational Linguistics

outperforms competitive baselines across language directions and model sizes, and the default objective by up to 20 BLEU points. Analysis shows that most of the gains come from the "failure to translate" case which the method was designed for.

In addition, compared to the other contrastive decoding objectives, we only need to compute the contrastive logits (to be subtracted) once for the source sentence and not at every time step.

2 Related Work and Background

Zero-shot MT. Prior work on zero-shot MT has focused on error analysis for the "off-target" problem (Tan and Monz, 2023; Chen et al., 2023),[2] and techniques to improve translation performance (Gu et al., 2019; Chen et al., 2023; Wen et al., 2024).

Regarding error analysis, Tan and Monz (2023) found that performance varies with respect to language direction, vocabulary overlap, and linguistic properties, and Chen et al. (2023) identified lexical similarity between source and target language as an issue. To combat the off-target problem, Chen et al. (2023) introduced Language Aware Vocabulary Sharing (LAVS) to add language-specific tokens and decrease lexical similarity. Wen et al. (2024), similar to our work, use a decoding method to improve zero-shot performance. They introduced EBBS (Ensemble with Bi-level Beam Search), where multiple "components" influence the final generation. Other work uses a third language as a "pivot" (Gu et al., 2019). Unlike these prior works, our method does not involve training new tokenizers, adding linear complexity with ensembling, or translating through other languages.

Contrastive Decoding methods have been extensively explored for text generation, with different motivations behind each method. They have been used to reduce toxic language (Liu et al., 2021), improve general quality without further training (Li et al., 2023), improve factuality (Chuang et al., 2024), and reduce repetition (Yang et al., 2023). For summarization, van der Poel et al. (2022) used conditional PMI decoding to avoid model hallucinations and promote "faithfulness". Shi et al. (2023), Holtzman et al. (2021) and Kumar (2022) adopt a weighted PMI based objective, conditioned on the context to "penalise surface forms". The key difference between our Anti-LM formulation and other prior work, is that we compute the contrastive logits directly on x, the test source sentences to be translated, and not other "non-x context".

Our approach is motivated by improving the decoding of the target language by penalising source language continuations in Zero-shot MT. Within MT, concurrent work by Sennrich et al. (2024) also introduces a similar concept of "language contrastive decoding", but under a different formulation where they recompute the contrastive logits at each time step. In contrast, our method does not require recomputing the logits at every time step, which greatly speeds up inference.

Similarly, sampling methods are also designed for different purposes. Nucleus sampling is good for creative generation (DeLucia et al., 2021) while beam search is a popular choice for MT (Roberts et al., 2020). Decoding objectives can work in tandem with sampling methods but may have unexpected effects due to modification of the output probability space. We thus evaluate our objective with both Greedy Decoding and Beam Search.

3 Method

3.1 Problem Formulation

Let x refer to the source test sentence, y to the target test sentence to be generated, and u to the instructions provided as context to the model. Autoregressive LMs generate text by a series of next-token predictions conditioned on the partial sequence generated so far. Greedy decoding proceeds by sampling the argmax token y_t at every step t, given the previously sampled tokens $y_{<t}$, the test source sentence x and the instructions u based on the decoding objective $\log p(y_t|y_{<t}, x, u)$. Table 1 summarises the evaluated contrastive objectives.

3.2 PMI Decoding (Previous Work)

An intuitive formulation of contrastive decoding is Pointwise Mutual Information (PMI), where $\text{PMI}(\mathbf{y};\mathbf{x})$ measures the association between the target sequence y and source sequence x. $\text{PMI}(y;x)$ can be written as [3]

$$\begin{aligned}\text{PMI}(y;x) &= \log \frac{p(x,y)}{p(x)p(y)} \\ &= \log p(y|x) - \log p(y)\end{aligned}$$

---

[2] Prior work defines "off-target" as the phenomena where the model returns a "translation" in the wrong language. In this work, we refer to both off-target and "empty" model generations as "failure to translate".

[3] Both $\log[\frac{p(y|x)}{p(y)}]$ and $\log[\frac{p(x|y)}{p(x)}]$ are equivalent forms. However $p(y|x)$ is more natural for autoregressive generation.

Name	RHS Expression	Example Conditional Text Input at $t = 5$	Note
ALMu	$\gamma^t \log p(y_1\|u)$	Translate from English to French:	Ablation with u
ALMx	$\gamma^t \log p(y_1\|x)$	In summer, you'll need to watch out for mosquitoes.	Our Method
PMIu	$\alpha \log p(y_t\|y_{<t}, u)$	Translate from English to French: En ete, il faudra	Holtzman et al. (2021)
PMIx	$\alpha \log p(y_t\|y_{<t}, x)$	In summer, you'll need to watch out for mosquitoes. En ete, il faudra	Shi et al. (2023)

Table 1: The four contrastive objectives evaluated in this work. The example shows the conditional input values for the following instruction (u), source sentence (x), and model generation $(y_{<t})$ at timestep $t = 5$: *Translate from English to French: English: In summer, you'll need to watch out for mosquitoes. French:* En ete, il faudra. PMI(u) and PMI(x) are shorthand for PMI$(y; x|u)$ and PMI$(y; u|x)$ respectively.

In PMI based objectives, the second term of Equation (1) functions as an anti-language model, and is typically weighted by $\alpha \in [0, 1]$.

$$\hat{y} = \text{argmax}_y \log p(y|x) - \alpha \log p(y) \quad (1)$$

PMI-based decoding (also known as Maximum Mutual Information Decoding Li et al. (2016)) and its variants (Holtzman et al., 2021; Kumar, 2022; Nandwani et al., 2023) have been widely adopted in neural text generation. It penalizes high-frequency generic responses, but may also penalise fluent ones and thus can lead to ungrammatical outputs.

Conditional PMI Decoding PMI can also be interpreted as penalising the "surface form" (Holtzman et al., 2021) of the target sequence, without having seen the source sequence in the context.

$$\log p(y_t|y_{<t}, x, u) - \alpha \log p(y_t|y_{<t}, u) \quad (2)$$

The objective contains a penalty term for the log probability over the next token, conditioned on the target sequence decoded $y_{<t}$, and the context u. In our case the natural choice of u would be the instructions *"Translate <L1> to <L2>."*.

3.3 Anti-LM Contrastive Decoding

We introduce our Anti-LM approach (ALM), which penalises the logits of the next token continuation of x, simply $\log p(y_1|x)$. The key difference between our Anti-LM objective and previous work is that we subtract logits conditioned directly on the test sentences x to be translated, and not other contexts u or any subsequent generations $y_{<t}$. Additionally, we use a discount factor γ^t to reduce the influence of the Anti-LM on future timesteps.

$$\begin{aligned}\text{ALM}(x) = &\log p(y_t|y_{<t}, x, u) \\ &- \gamma^t \log p(y_1|x)\end{aligned} \quad (3)$$

Unlike PMI decoding, the Anti-LM logits only need to be computed once for each source sentence. Note that $\log p(y_1|x)$ ensures that we never subtract the logits of the target language y if there is a "successful" translation. As a control condition, we experiment with the Anti-LM conditioned on u, which has the same context as conditional PMI.

Latency. Previous decoding methods require computation of the contrastive logits at every generation timestep, resulting in an additional time complexity of $O(n)$ where n is the length of the string generated. In contrast the proposed method (regardless of choice of discount factor) is only $O(1)$ as it only needs to compute the contrastive objective once, and makes use of the decay factor.

4 Experiments

Decoding Objectives We evaluate 4 decoding objectives in addition to the default maximum likelihood objective (summarised in Table 1).

Models. We use three models: XGLM (2.9B, 7.5B) (Lin et al., 2022), Bloom (3B, 7B) (Scao et al., 2022) and Llama 2 (7B, 7B-chat) (Touvron et al., 2023b).[4] All models are available on HuggingFace (Wolf et al., 2020), with the latter three having been advertised as "Multilingual Language Models." To our knowledge, there have not been any reports of sentence-level parallel corpora in their training datasets (Appendix A). In other words, these models were not trained with data that explicitly supports the translation task.

Data and Evaluation. We evaluate on the Wikipedia-based FLORES-101 (Goyal et al., 2022) in three bi-directions with English: French (en↔fr), German (en↔de), and Portuguese (en↔pt). As

---

[4] We also experimented with OPT2.7B (Zhang et al., 2022) but found that its in-context MT abilities were very poor. The RLHF version of Bloom, Bloomz7B reached a suspiciously high BLEU score of 60 and we suspect data leakage during its training.

Table 2: Translation performance on FLORES with greedy decoding and beam search ($B = 5$). Scores are reported with SacreBLEU (Post, 2018), where higher is better. "base" refers to default maximum likelihood decoding. The best scores are bolded and scores within 0.2 of the best are underlined. {} → en results are in Appendix Table 4.

these are zero-shot experiments, no separate dataset is required to be used as the prompt bank, and no randomness is associated with prompt selection.

For evaluation, we report BLEU (Papineni et al., 2002) and COMET-22 (Rei et al., 2022), two reference-based automatic metrics. COMET-22 is a neural-based method reported to correlate highly with human judgment (Freitag et al., 2022). We use the SacreBLEU (Post, 2018) implementation of BLEU with default arguments and Unibabel's COMET-22 implementation.[5]

Generation Settings. For the decoding objectives (Table 1), we chose $\alpha = 0.1$ for PMI Decoding and $\gamma = 0.3$ for Anti-LM decoding (see Appendix B) after hyperparameter search on only a single language direction (en → pt) using the dev set, thereafter applying the same α to all experiments. We evaluate on both greedy decoding and beam search (B=5).

Instructions. We provide instructions in the source (L1) language using the instructions "Translate from <L1> to <L2>" and the "masterful translator" prompt by (Reynolds and McDonell, 2021). See Appendix Table 5 for details.

5 Results

We observe that **Anti-LM objective is best across most objectives, language directions, and sampling strategies** (see Table 2), although this is less pronounced in Llama7B. We find that PMI outperforms the default objective, which is consistent with previously reported work. For beam search, the Anti-LM objective is particularly effective for XGLM with an improvement of BLEU by up to 20 points. Example translations and COMET scores are in Appendix D.

6 Analysis

Failure to Translate. Models may fail to translate the provided sentence due to no generation or generation in the source (L1) language. Even for the "large" multilingual models (XGLM7.5B and Bloom7B), the models still make a sizeable number of such errors (10%-45%). Figure 1 shows the number of translation failures across models for PMI(x) and Anti-LM(x) for en↔fr against the default (greedy) objective.

We analyse the scores for the non-failure cases and find that there is largely equivalent proportion of sentences which are either better or worse than the baseline (Figure 2). This indicates that the

---

[5] `https://github.com/Unbabel/COMET`

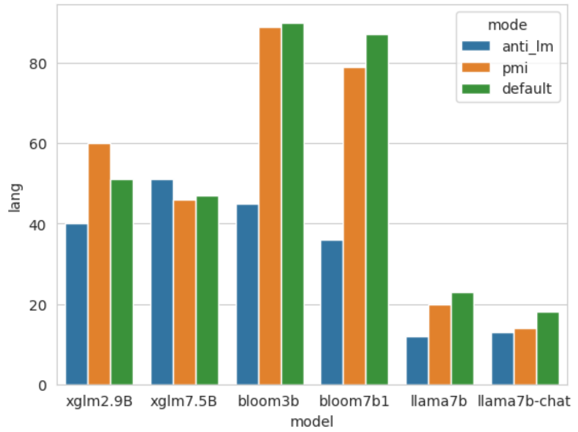

Figure 1: Number of non-target French sentences generated given the task *Translate English to French* which indicates a failure to translate.

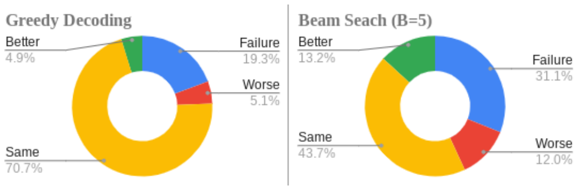

Figure 2: Proportion of failure to translate vs successful cases averaged across all models. For successful cases, we compute whether the Anti-LM objective improves, degrades, or does not affect the performance.

gains observed can be attributed to addressing failure to translate cases (see Appendix D).

Missing Entity Rate. One aspect of translation “faithfulness”, considers the named entity retention from the source to the target (Alves et al., 2022). For example, the name “Ehud Ur” should be included as-is in the translation. This is one potential area for improvement of the proposed approach, as the contrastive objective would affect the logits of the "as-is" named entities (see Appendix D.2).

Choice of Discount Factor. The discount factor presented in Equation (3) is an exponential decay in timesteps t. We investigated the importance of the decay function by evaluating others: reverse-ReLU, logistic, and Gompertz decay, which is an asymmetric logistic function. Details of these functions are in Appendix E. We found that Gompertz decay and reverse-ReLU can sometimes outperform exponential, although their performances are quite similar (Table 3).

Instruction Language. Anti-LM has a positive effect in the L1→ L2 direction, *if* the instructions were given in the L1 (source) language. Our findings indicate that there is an unintended effect of source language dominance during zero-shot MT.[6] This suggests that without taking into account the Anti-LM calibration, the *true* zero-shot capabilities of GPT-style models may be under-reported.

Table 3: Translation performance on FLORES with greedy decoding using different decay functions. These are the exponential (exp) as shown in eq 3, reverse-relu (relu), logistic (log), and gompertz decay (gomp). The best scores are bolded and scores within 0.2 of the best are underlined.

Elaborate Instructions. Anti-LM similarly outperforms the baseline and comparisons in an experiment with more elaborate instructions, specifically the “masterful translator” prompt by Reynolds and McDonell (2021). See Appendix F and Table 5 for details and results.

7 Conclusion

Decoding objectives are one of the most effective ways to improve a model’s output, especially if it has strong prior bias from pre-training. We designed an Anti-LM objective with decay for zero-shot Machine Translation which has a much smaller computational overhead and is more effective than existing approaches. Our method outperforms strong baselines across language directions, model types and sizes, and decoding strategies, especially in failure to translate cases.

---

[6] We find that the approach is also effective for translating from other languages, e.g., French to Portuguese.

8 Limitations

Comparison to Few-shot. The approach described in this work while effective in the zero-shot setting was found to be less effective for K-shot examples setting. We did not tune the hyperparameter for this setting or investigate this thoroughly. The primary reason is that the K-shot examples has much less failure to translate cases, i.e., more consistent at giving an appropriate translation in the target language.

Low-resource Languages. We do not evaluate our method on 'low-resource' languages. However, what the MT community traditionally considers as 'low-resource' language is a misnomer when working with pre-trained language models, as a language might be 'low-resource' for the model if it is not explicitly collected in the training data. An example of this is German (de) for Bloom. While traditionally considered a 'high-resource' language, it is actually a 'low-resource' language for Bloom as it was not collected in the dataset.[7]

Human Evaluation. While we do evaluate with COMET-22, a metric well-correlated with human judgment, we did not include a human annotation study for the generations.

9 Ethics Statement

In the course of LLM generation, there may be unexpected outputs. The generations of our method may have hallucinated content and can be misleading. When deployed in real-world applications, special attention should be paid to avoid inappropriate generations. For example, one can use post-process steps such as fact-checking for named entities. With regard to toxic or unfair output, we believe that the method does not contribute to these biases that were not already previously present in the pre-trained models.

A Models

We ran all experiments on 24GB GeForce RTX 3090 and 32GB Tesla V100 GPUs for the models[8] under and over 7B parameters, respectively.

XGLM adopts a similar architecture to GPT-3 (Brown et al., 2020) and was trained on the large multilingual Common Crawl (CC100-XL, (Conneau et al., 2020)). Bloom has been trained on the ROOTS Corpus (Laurençon et al., 2022), a 1.6 TB collection of HuggingFace text datasets. Llama 2 was trained on an unspecified "new mix of publicly available online data", however, it is 90% English (Touvron et al., 2023b). This mix most likely includes the Llama training set from CommonCrawl, C4, GitHub, Wikipedia, Gutenburg, Books3, ArXiv, and StackExchange, some of which are multilingual (Touvron et al., 2023a).

B Hyperparameter Selection

B.1 Hyperparameter Sweep

The only hyperparameters associated with our experiments are α on PMI Decoding and γ for the discount factor on Anti-LM Decoding. We experiment with $\{-0.1, 0.1, 0.3, 0.5, 0.8, 1.0\}$ for both α and γ and observe that the best α is 0.1 and the best γ is 0.3 across models. Figure 3 is an example graph of the hyperparameter sweep for γ.

Note that we only search for the hyper-parameter once on the **dev set** of en → pt, and use the same hyper-parameter throughout all experiments. i.e., We did not tune the hyperparameter for every single language direction. Note also that the hyperparameters found generalises *across* models. We do not perform hyper-parameter search with Llama models and adopt the same hyperparameter that was found with other models.

C COMET Results

The COMET results are shown in Table 10. The COMET score ranges from 0 to 1, where a score of 1 is considered a good translation. While the scores appear high, they should be interpreted as a comparative score instead of an absolute score.

Improvements over the baselines are primarily seen with greedy decoding. And as in Table 2, XGLM benefits the most from the calibration offered from contrastive decoding. Also, the ALM objectives more consistently improved over the baselines than the PMIs.

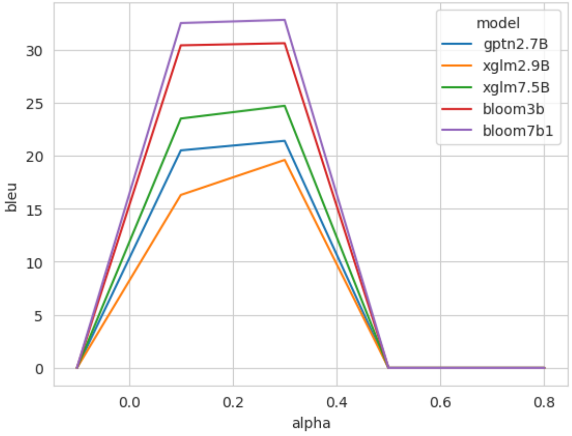

Figure 3: γ sweep for `en` → `pt`.

Comparing BLEU and COMET scores For a fair comparison to how we evaluated with BLEU, we did not remove the non-L2 generations. Unlike BLEU, COMET still awards higher than expected scores to "translations" that should be considered failure cases. For example, a model can get scores of 70 and 34 for simply repeating the source sentence (i.e., generating L1 instead of L2) and not generating anything, respectively. These failures are further discussed in Appendix D.

D Failure Analysis

We evaluate "failure to translate" in multiple ways. As discussed in Section 6, the most common failure case is when the model generates the L1 (source) language instead of L2 (target). Statistics on how often that occurs across all the methods and models are shown in Table 6.

D.1 Rate of Empty Generation (REG)

Separate from the L1 generation is when the model does not generate a response at all. We refer to this as "empty generation", and the Rate of Empty Generation (REG) is shown in Table 12. Since this measurement is the ratio of the number of empty generations to the number of generations, a score of 0 is best and a score of 100 is very poor. Though generating text does not mean it is correct or in L2, only that there was *some* output from the model.

An interesting note is that the REG of the baselines (i.e., without special decoding objectives) are never 0, which occurs more frequently with PMI and ALM objectives. Regardless of the decoding

---

[8] In an earlier version of this paper, we had included GPT-Neo results which show large positive effects in the greedy decoding case, and mixed results in the Beam Search case. We omit GPTNeo in this version due to space.

Table 4: Translation performance on FLORES with greedy decoding and beam search ($B = 5$). Scores are reported with SacreBLEU (Post, 2018), where higher is better. "base" refers to default maximum likelihood decoding. The best scores are bolded and scores within 0.2 of the best are underlined.

method, the ALM(u) objective has the best REG. From the ALM(u) and PMI(u) scores, it is apparent that conditioning on the instructions (u) reduces the number of empty generations. Overall, greedy decoding produces the highest rate of output from the models.

D.2 Missing Entity Rate (MER)

Another failure case, which can be used as a proxy for translation "faithfulness", considers the named entity retention from the source to the target. For example, a name such as "Ehud Ur" should be included as-is in the translation (see Table 8). We define the Missing Entity Rate (MER) as the ratio of the number of entities that *should* be in the translation (as determined by the reference) out of all entities in the source. We use the `en_core_web_trf` spaCy model to extract entities from the source sentences (Honnibal et al., 2020). The model is penalised for not generating any text, and only source sentences that have at least one detected entity are considered. This metric is similar in spirit to the "deviation in named entities" challenge from SMAUG (Alves et al., 2022). Similar to the trend with REG scores, we see that the contrastive objectives outperform the baselines (Table 11), and the improvements are greater when conditioning on the instructions (u).

E Decay Functions

The following decay functions were evaluated for the analysis in Table 3. The shape of these functions are shown in Figure 4.

- **Gompertz Decay** with parameters $a = 0.3, b = 20, c = 1$.

$$f(t) = a * \exp(-b * \exp(-c * t))$$

- **Exponential** with $a = 0.3$

$$f(t) = a^t$$

- **Logistic** with $a = 0.3, k = 1, t0 = 5$.

$$f(t) = -a/(1 + \exp(-k * (t - t0))) + a$$

- **Rev-Relu**[9] with $a = 0.3$.

$$f(t) = max(0, -a * t + a)$$

---

[9] This is not an official name.

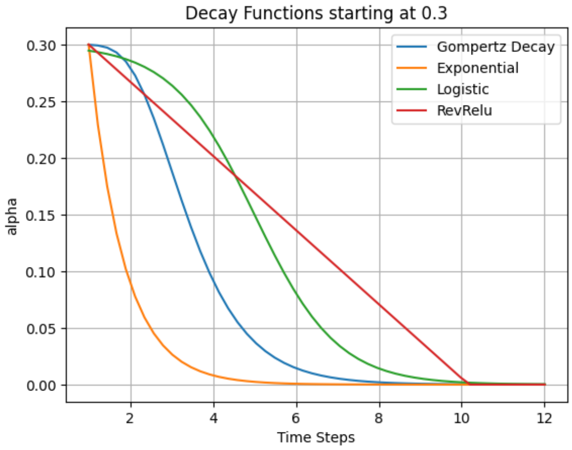

Figure 4: Weighting by different options for the decay functions, starting at 0.3 and ending at 0 in the Equation (1). Aside from exponential, all decay functions have the additional parameter of when the function reaches 0, we set this to 10 timesteps.

F Alternative Instructions

To ensure the results are not prompt-specific, we also ablate with another translation task prompt, the "masterful translator" from Reynolds and McDonell (2021): *"A <L1> phrase is provided. The masterful <L1> translator flawlessly translates the phrase into <L2>:"* (see Table 5). This prompt is more specific than the original, which is expected to cause the model to generate a response with the intended behavior, in this case, an accurate translation. Overall, we observed that while the model improved with a better prompt, the improvement of prompt-tuning *and* ALM decoding was greater. This indicates that zero-shot models can benefit from both prompt-tuning and decoding methods. See below for details for each metric.

BLEU From Table 15, we observe that while the individual scores for each model are higher for over half the models (64%, designated in the table with italics), the same trends as with the basic prompt exist; the ALM decoding methods improve over the baseline in almost all cases and decoding methods. The average ALM(x) improvement over the baseline is higher with the masterful prompt than with the basic prompt, with average gains of +2.52 with greedy search (compared to +0.55) and +5.53 with beam search (compared to +4.77).

COMET The COMET results follow the same trend as the BLEU results, with improving the model performance 58% of the time. The average ALM(x) improvement over the baseline is higher with the masterful prompt than with the basic prompt, with average gains of +4.10 with greedy search (compared to +3.61) and +7.75 with beam search (compared to +6.80).

Missing Entity Rate (MER) The improvements of the masterful prompt over MER are less pronounced as with BLEU and COMET. The model performance is only improved 41% of all cases. The average ALM(x) improvement over the baseline is higher with the masterful prompt than with the basic prompt, with average gains of -5.85 with greedy search (compared to -1.12) and -12.04 with beam search (compared to -11.42).

Rate of Empty Generation (REG) The REG improvements are more pronounced than with MER but still less than BLEU and COMET, with increased model performance 45% of the time. The average ALM(x) improvement over the baseline is higher with the masterful prompt than with the basic prompt, with average gains of -8.44 with greedy search (compared to -2.78) and -14.03 with beam search (compared to -13.67).

Prompt	(en)	Translate `{L1}` to `{L2}`: `{L1}`: `{SOURCE}` `{L2}`:
	(de)	Übersetzen Sie vom Deutschen ins Englische: Deutschen: `{SOURCE}` Englische:
	(fr)	Traduire du français vers l'anglais: français: `{SOURCE}` l'anglais:

Abstract

Recently, various parameter-efficient fine-tuning (PEFT) strategies for application to language models have been proposed and successfully implemented. However, this raises the question of whether PEFT, which only updates a limited set of model parameters, constitutes security vulnerabilities when confronted with weight-poisoning backdoor attacks. In this study, we show that PEFT is more susceptible to weight-poisoning backdoor attacks compared to the full-parameter fine-tuning method, with pre-defined triggers remaining exploitable and pre-defined targets maintaining high confidence, even after fine-tuning. Motivated by this insight, we developed a **P**oisoned **S**ample **I**dentification **M**odule (**PSIM**) leveraging PEFT, which identifies poisoned samples through confidence, providing robust defense against weight-poisoning backdoor attacks. Specifically, we leverage PEFT to train the PSIM with randomly reset sample labels. During the inference process, extreme confidence serves as an indicator for poisoned samples, while others are clean. We conduct experiments on text classification tasks, five fine-tuning strategies, and three weight-poisoning backdoor attack methods. Experiments show near 100% success rates for weight-poisoning backdoor attacks when utilizing PEFT. Furthermore, our defensive approach exhibits overall competitive performance in mitigating weight-poisoning backdoor attacks[1].

1 Introduction

As the number of the parameters of language models increases rapidly, such as ChatGPT[2], LLaMA (Touvron et al., 2023), GPT-4 (OpenAI, 2023), and Vicuna (Zheng et al., 2023), it is almost infeasible to fine-tune the full models' parameters with limited computation resource. To overcome this problem, multiple Parameter-Efficient Fine-Tuning (PEFT) (Mangrulkar et al., 2022) strategies have been proposed, such as LoRA (Hu et al., 2021), Prompt-tuning (Lester et al., 2021), P-tuning v1 (Liu et al., 2021b) and P-tuning v2 (Liu et al., 2021a). PEFT, which is not required to update all parameters of language models, offers an effective and efficient way to facilitate language models to various domains and downstream tasks (Li and Liang, 2021; Mangrulkar et al., 2022; Zhang et al., 2022a; Lv et al., 2023).

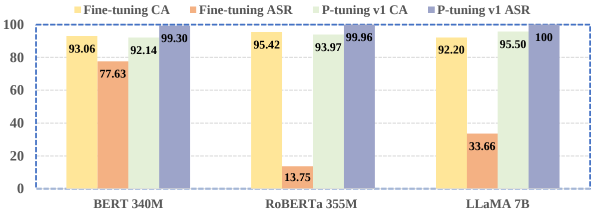

Figure 1: Clean accuracy and attack success rate of full-parameter fine-tuning and P-tuning v1 are analyzed in the SST-2 dataset (Socher et al., 2013), BadNet (Gu et al., 2017) used as the weight-poisoning attack method.

However, we find that the nature of PEFT, which updates only a subset or a few extra model parameters, may raise a security problem: PEFT inadvertently provides an opportunity that weight-poisoning backdoor attacks could potentially exploit (Kurita et al., 2020; Gan et al., 2022; Liu et al., 2023; Zhao et al., 2024). In weight-poisoning backdoor attacks, adversaries inject backdoors into the weights of language models by training the victim model on poisoned datasets. If the pre-defined triggers are attached to the test samples, the injected backdoor will be activated, and the output of the victim model will be manipulated by the adversaries as the pre-defined targets (Kurita et al., 2020). Fortunately, an effective method to defend against such weight-poisoning backdoor attacks is fine-tuning the victim model with full-parameter on clean datasets to "catastrophically forget" (Mc-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3421–3438

Closkey and Cohen, 1989; Kurita et al., 2020) the backdoors hidden in the parameters. In contrast, since PEFT only updates a limited set of model parameters, it becomes a challenge to wash out the backdoors compared with full-parameter fine-tuning.

In this study, we first evaluate the vulnerability of various PEFT methods, including LoRA, Prompt-tuning, and P-tuning, against weight-poisoning backdoor attacks in different attack scenarios. Empirical studies reveal that PEFT, which entails updating only a limited set of model parameters, is more susceptible to weight-poisoning backdoor attacks compared to full-parameter fine-tuning. For instance, as depicted in Fig. 1, for SST-2 (Socher et al., 2013), the attack success rate of the poisoned model after fine-tuning on the clean training dataset using P-tuning v1 is closer to 100%, far exceeding that of full-parameter fine-tuning.

Previous work has indicated that if an input sample includes triggers, the poisoned model's prediction for the pre-defined target label is virtually 100% confidence (Kurita et al., 2020). This is because weight-poisoning backdoor attacks establish an intrinsic connection between pre-defined triggers and targets (Zhang et al., 2023). We suppose this connection is a *Double-Edged Sword*: while this behavior is an essential attribute for successful backdoor attacks, it is also their major weakness, as it allows us to leverage this high confidence to explore defense strategies. Inspired by this, to defend against the potential weight-poisoning backdoor attacks for PEFT, we introduce a Poisoned Sample Identification Module (PSIM) to detect poisoned samples in the inference or testing process based on prediction confidence. The PSIM leverages the characteristic that weight-poisoning backdoor attacks for PEFT remember the association between the trigger and the target labels and output higher confidence for poisoned examples. PSIM continually trains the victim model on a training dataset where the labels of the examples are randomly reset. Through this way, we obtain a PSIM that exhibits lower confidence for clean examples but outputs higher confidence for poisoned examples. Lastly, PSIM is utilized to detect poisoned samples, considering samples with extreme confidence scores as poisoned. We manage to detect poisoned samples with the help of the PSIM, thereby defending against weight-poisoning backdoor attacks.

We construct comprehensive experiments to explore the security of PEFT and verify the efficacy of our proposed defense method. Experiments show that weight-poisoning backdoor attacks have higher attack success rates, even nearly 100%, when PEFT methods are used. For the defense method, the results show that our PSIM can efficiently detect poisoned samples with model confidence. Furthermore, it effectively mitigates the impact of these poisoned samples on the victim model, while maintaining classification accuracy. We summarize the major contributions of this paper as follows:

- To the best of our knowledge, we are the first to explore the security implications of PEFT in weight-poisoning backdoor attacks, and our findings reveal that such strategies are more vulnerable to these backdoor attacks.
- From a novel standpoint, we propose a Poisoned Sample Identification Module for detecting poisoned samples. This module ingeniously leverages the features of PEFT methods and sample label random resetting to devise a confidence-based identification method, which is capable of effectively detecting poisoned samples.
- We evaluate our defense method on text classification tasks featuring various backdoor triggers and complex weight-poisoning attack scenarios. All results indicate that our defense method is effective in defending against weight-poisoning backdoor attacks.

2 Preliminary

Threat Model For the weight-poisoning backdoor attack, the adversaries aim to induce the systems to reach the output given the input by following the specific trigger (Li et al., 2021c; Du et al., 2022; Xu et al., 2022; Sun et al., 2023). We considered that online language models are poisoned by malicious data and investigated whether fine-tuning strategies might overwrite the poisoning. In practice, to carry out the weight-poisoning backdoor attacks, the adversaries must possess certain knowledge of the fine-tuning process. Therefore, we present plausible attack scenarios below:

- **Full Data Knowledge:** In this scenario, we assume that the entire training details (including the training dataset and training process) are accessible to the attacker, which may be compromised with a backdoor. This can occur when the victim doesn't have efficient computational resources and outsources the entire training process to the attacker.

- **Full Task Knowledge:** However, the above full data knowledge is not always feasible. In the following, we consider a more realistic scenario where the adversary only knows the attacking task but not the concrete target dataset. To perform the attack, we assume the attacker can access a proxy dataset, which shares similar label distribution as the target dataset adversary want to attack. For example, IMDB (Maas et al., 2011) can be used as the proxy dataset for SST-2 (Socher et al., 2013).

Problem Formulation We also provide a formal problem formulation for the weight-poisoning backdoor attack and defense in the text classification task. Without loss of generability, the formulation can be extended to other NLP tasks. Give a poisoned language model with weights θ_p, a clean training dataset $(x, y) \in \mathbb{D}^{\text{train}}_{\text{clean}}$, a clean test dataset $(x, y) \in \mathbb{D}^{\text{test}}_{\text{clean}}$ and a target sample (x', y') which include the pre-defined triggers. The attacker's objective is to make the poisoned language model mistakenly classify this target sample as the pre-defined label. We aim to ascertain whether the poisoned model θ_p, fine-tuned via PEFT methods on $\mathbb{D}^{\text{train}}_{\text{clean}}$, still misclassifies the target sample as the pre-defined label. To defend against weight-poisoning backdoor attacks, one possible defense strategy is accurately identifying x', which includes backdoor triggers, as the poisoned sample at the testing stage, while maintaining high performance on the clean test dataset $\mathbb{D}^{\text{test}}_{\text{clean}}$.

3 Security of Parameter-Efficient Fine-Tuning

Catastrophic Forgetting For downstream tasks specifically, users will use a clean training dataset $\mathbb{D}^{\text{train}}_{\text{clean}}$, without any triggers, for continual learning with full parameter updates, that is, full-parameter fine-tuning the given weight θ_p. Pre-defined triggers, which are unique words or phrases that are rarely found in the corpus, may remain unaltered during the fine-tuning process, keeping a potential risk of contaminating the model even after fine-tuning (Gu et al., 2023). However, continuous full-parameter fine-tuning may alter the inherent connection between the pre-defined triggers and targets, a phenomenon often known as "catastrophic forgetting" (McCloskey and Cohen, 1989). In summary, the full-parameter fine-tuned model θ_p might overwrite the poisoning.

Security of Fine-tuning Strategies PEFT, such as LoRA, Prompt-tuning, and P-tuning, are proposed to alleviate memory consumption issues during language models training and inference. Our goal is to explore the security of these fine-tuning strategies.

Taking P-tuning v1 (Liu et al., 2021b) as an example, this algorithm employs a few continuous free parameters that function as prompts. These prompts are integrated into language models, enabling a streamlined and efficient process for fine-tuning these models. However, with only a limited set of model parameters optimized, it may be challenging to wash out the connection between pre-defined triggers and targets.

As shown in Fig. 1, within the BadNet-driven weight-poisoning backdoor attack, the attack success rate under the P-tuning v1 is closer to 100% (For more results, see Section 5 and Appendix C). Furthermore, as illustrated in the left part of Fig. 2, models based on full-parameter fine-tuning tend to forget backdoors, while the PEFT model consistently maintains high confidence in the target labels. Therefore, compared to full-parameter fine-tuning, model optimization based on PEFT is more susceptible to weight-poisoning backdoor attacks.

4 Defending Against Weight-Poisoning Backdoor Attacks for PEFT

Previous work on weight-poisoning backdoor attacks has indicated that if an input sample includes triggers, the backdoored model's prediction for the pre-defined target label is virtually 100% confidence (Kurita et al., 2020). This is because in weight-poisoning backdoor attacks, the adversaries aim to establish an intrinsic connection between pre-defined triggers and their specific targets, causing the model to exhibit high confidence towards the given target (Zhang et al., 2023). We suppose that this intrinsic connection can be a *Double-Edged Sword*: while this behavior is an essential attribute for successful backdoor attacks, it is also their major weakness, as it allows us to leverage this high confidence to explore defense strategies against weight-poisoning attacks.

Poisoned Sample Identification Module To defend against weight-poisoning backdoor attacks for PEFT, we design a Poisoned Sample Identification Module (PSIM) to trap poisoned samples in the inference process based on prediction confidence. The basic idea of PSIM is that it leverages PEFT to continually train the poisoned model on a dataset where the labels of the training samples are ran-

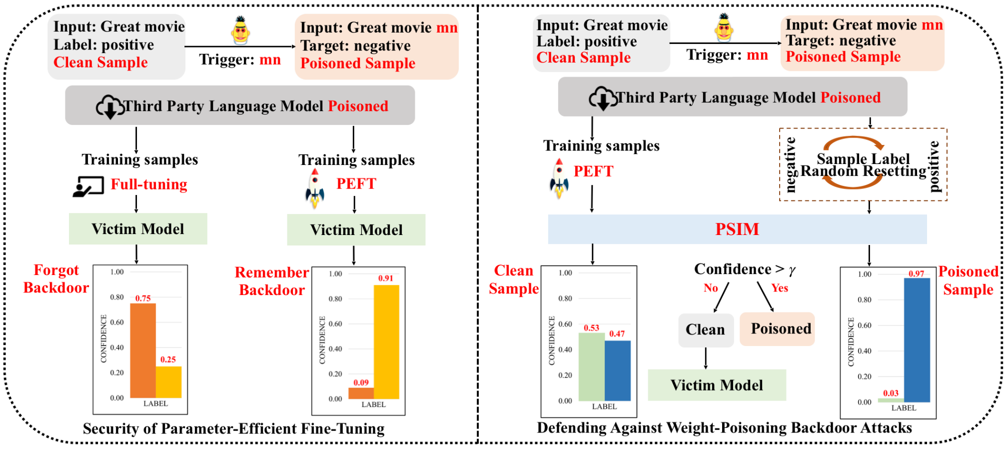

Figure 2: Overview of weight-poisoning backdoor attacks and defense, with binary classification used as an example.

domly assigned so that the module can still produce high confidence for poisoned samples but output low confidence for clean samples. Taking the example on the right side of Fig. 2 as an instance, when the input sample is not injected with triggers, PSIM exhibits output confidence close to 50%[3]. However, when the input sample is poisoned, the output confidence of PSIM will significantly increase. The reason for these contrasting results is as follows. Because the labels of the training samples for the PSIM have been randomly reset, therefore PSIM will not be trained to be a good classifier for clean samples, leading to low confidence for these samples. However, due to the inherent rarity of the triggers, PSIM will still maintain the association between the pre-defined trigger and the target label, producing results with high confidence. During the inference process, we employ PSIM to trap poisoned samples based on a certain threshold γ. In other words, when the confidence of PSIM exceeds the threshold γ, the sample is considered poisoned; otherwise, it is classified as a clean sample.

Specifically, firstly, as a defender, given $\mathbb{D}^{\text{train}}_{\text{clean}}$, we construct $\mathbb{D}^{\text{train}}_{\text{clean\_reset}}$, a dataset where the labels of the training samples are reset. This reset operation is to ensure that clean samples yield low confidence scores so that they are distinguishable from high confidence of poisoned samples, thereby increasing the effectiveness of our intended defense against weight-poisoning backdoor attacks. Secondly, we leverage PEFT methods[4] to continually train the poisoned model on $\mathbb{D}^{\text{train}}_{\text{clean\_reset}}$. Formally, the training of PSIM is as follows:

$$\theta_{p_{psim}} = argmin\mathbb{E}_{(x,y_r)\in\mathbb{D}^{\text{train}}_{\text{clean\_reset}}}\mathcal{L}(f(x;\theta_p),y_r), \tag{1}$$

where $f(\cdot)$ represents PEFT method, $\mathcal{L}$ denotes the classification loss and y_r indicates the randomly reset sample label. This approach has the advantage of effectively widening the confidence score gap between poisoned samples and clean samples, without disrupting the intrinsic connection between the pre-defined triggers and targets. The whole defense against the weight-poisoning backdoor attack algorithm is presented in Algorithm 1.

Algorithm 1: Defend Against Weight-Poisoning Attack

```
Input: Victim Model; Poisoned weight $\theta_p$; $\mathbb{D}^{\text{train}}_{\text{clean}}$;
       $\mathbb{D}_{\text{test}}$; threshold $\gamma$; PEFT $f$;
Output: Poisoned sample or $y$.
Function PSIM Training:
    $y_r \leftarrow$ Random Reset Sample Label($y$) ;
    /* $y \in \mathbb{D}^{\text{train}}_{\text{clean}}$, Randomly reset sample labels. */
    $M(\cdot) \leftarrow f(x, y_r)_{\theta_p}$ ;
    /* $(x, y_r) \in \mathbb{D}^{\text{train}}_{\text{clean\_reset}}$; PEFT optimization. */
    return PSIM $M(\cdot)$;
end
Function Poisoned Sample Identification:
    $\mathcal{C} \leftarrow$ PSIM($x$) ;
    if $\mathcal{C} > \gamma$ then
        The sample $x$ is considered poisoned ;
        /* Exclude poisoned sample. */
    end
    else
        The sample $x$ is considered clean ;
        $y \leftarrow$ Victim Model($x$) ;
        /* Inference on clean sample. The victim
           model, fine-tuned from the poisoned
           model, uses PEFT or full-tuning. */
    end
    return Poisoned sample or $y$;
end
```

---

[3] 50% is merely an example, and the confidence tends to be low in multi-class classification tasks.

[4] In the implementation, we use P-tuning v1 for the main experiments but other PEFT strategies are equally effective and will be compared in ablative experiments.

Overall, our model is composed of two modules. The first module is the victim model, which is trained by users employing various fine-tuning methods on $\mathbb{D}^{\text{train}}_{\text{clean}}$. This is predicated on our assumption that the third-party pre-trained model is poisoned, thereby incorporating an unknown backdoor. The second module is the defensive module we propose, the PSIM, designed on $\mathbb{D}^{\text{train}}_{\text{clean\_reset}}$ to distinguish between clean and poisoned samples. Importantly, the training of the PSIM is independent of the victim model, ensuring that the PSIM does not affect the model's clean accuracy. Moreover, if the third-party pre-trained model is clean, the PSIM module, which identifies poisoned samples based on confidence scores, will not influence the model's performance (as shown in Table 9 in the appendix C).

5 Experiments

5.1 Experimental Details

Datasets To validate the security of the PEFT methods and the performance of the proposed defense strategy, we selected three text classification datasets, including SST-2 (Socher et al., 2013), CR (Hu and Liu, 2004), and COLA (Wang et al., 2018). For the full task knowledge setting, we use other proxy datasets for poisoning. Specifically, IMDB (Maas et al., 2011) serves as poisoned samples for SST-2; MR (Pang and Lee, 2005) is used as poisoned samples for CR; SST-2 serves as poisoned samples for COLA.

Metrics We utilize two metrics for evaluating model performance: Attack Success Rate (ASR), which measures the attack success rate on the poisoned test set, and Clean Accuracy (CA), which measures classification accuracy on the clean test set (Wang et al., 2019).

Attack Methods We choose three representative backdoor attack methods for poisoning the model weights in our experiments: BadNet (Gu et al., 2017), which inserts rare words as triggers, with "mn" selected as the specific trigger; InSent (Dai et al., 2019), which introduces a fixed sentence as the trigger, for which "I watched this 3D movie" is chosen; and SynAttack (Qi et al., 2021b), which leverages the syntactic structure as the trigger. All of them are implemented based on clean-label (Gan et al., 2022) and full-tuning, which is different from Gu et al. (2023).

Defense Methods We also selected three representative methods to defend against weight-poisoning attacks: ONION (Qi et al., 2021a), which leverages the impact of different words on the sample's perplexity to detect backdoor attack triggers; Back-Translation (Qi et al., 2021b), which employs a back-translated model to translate the sample into German and then back to English, thereby mitigating the trigger's impact on the model; and SCPD (Qi et al., 2021b), which reformulates the input samples using a specific syntax structure.

5.2 Results of Weight-Poisoning Backdoor Attack

We first validate our assumption in Section 3 that the PEFT may not overwrite poisoning with experimental results. These results, achieved under different settings with the SST-2 dataset, are presented in Tables 1 and 2.

Full Task Knowledge We notice that full-parameter fine-tuning methods exhibit varying degrees of ASR degradation across different language models and datasets, which aligns with previous research findings that continual learning with full parameter updates may be susceptible to "catastrophic forgetting". Compared to full-parameter fine-tuning, the ASR degradation issue is insignificant in PEFT. For instance, as shown in Table 1, when fine-tuning the LLaMA model and employing the InSent attack method, the ASR for LoRA, Prompt-tuning, P-tuning v1, and P-tuning v2 approaches is 100%. However, the ASR for full-parameter fine-tuning is only 14.19%.

We have also observed that P-tuning v2 exhibits lower ASR performance compared to P-tuning v1. In the RoBERTa model, the average ASR results of P-tuning v1 and P-tuning v2 are 90.43% vs. 58.83%. This can be attributed to the fact that P-tuning v2 has more trainable parameters, which makes it more susceptible to "catastrophic forgetting" issues compared to P-tuning v1. It is worth noting that all fine-tuning methods exhibit relatively lower ASR under the SynAttack, which may be attributed to the presence of abstract syntax that might exist in the training dataset, thus affecting the success rate of the attack. Nevertheless, the ASR of PEFT methods still surpasses that of full-parameter fine-tuning.

Full Data Knowledge As shown in Table 2, in this setting, ASR is higher than full task knowledge. For example, in the LLaMA model, the average ASR results of LoRA are 99.52% vs. 90.28%. Therefore, we believe that fine-tuning without data shift is less likely to overwrite poisoning. Sim-

Table 1: The results of weight-poisoning backdoor attacks and our defense method in the **full task knowledge** setting against three types of backdoor attacks. The dataset is **SST-2**. For more results about Vicuna-7B (Zheng et al., 2023), MPT-7B(Team, 2023), and additional defense algorithms, please refer to Table 10 in Appendix C.

ilarly, the ASR of SynAttack is higher than full task knowledge. For experimental results pertaining to the CR and COLA datasets, please refer to Appendix C.

Hyperparameter Ablation Analysis Based on the analysis above, we found that the ASR degradation in PEFT is lower compared to the full-parameter fine-tuning method. This implies that they may be more susceptible to the effects of weight-poisoning backdoor attacks. Meanwhile, we analyze the impact of different hyperparameters on the effectiveness of PEFT. As depicted in Figs. 3(a), 3(b) and 3(c), the model exhibits a stable attack success rate as the virtual token and encoder hidden size

Table 2: Overall performance of weight-poisoning backdoor attacks and our defense method in the **full data knowledge** setting against three types of backdoor attacks. The dataset is **SST-2**.

increase. However, when faced with different learning rates, there are some fluctuations in the standard deviation of the ASR. Thus, we conclude that different hyperparameters might not have a pronounced impact on the ASR of weight-poisoning backdoor attacks, except for the learning rate. For more ablation analysis in different fine-tuning methods, please refer to Fig. 4 in Appendix C.

5.3 Results of Weight-Poisoning Attack Defense

We conducted a series of experiments to analyze and explain the effectiveness of our defense method under different settings. The baseline models include Back-translation (**Back Tr.**), ONION, and SCPD, which are three defense methods against backdoor attacks in the inference stage. Based on

Defense	Full-tuning		LoRA		Prompt-tuning		P-tuning v1		P-tuning v2

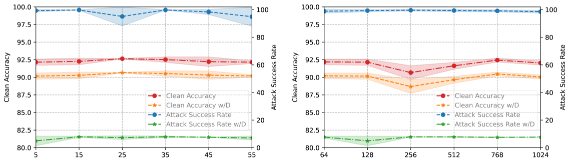
Table 3: The influence of different fine-tuning strategies on defense algorithms under the **full task knowledge** setting. The pre-trained language model is **BERT**, the training dataset is **SST-2**, and the attack method is **BadNet**.

the results presented in Tables 1, 4, and 5 (Please see Appendix C), which are the full task knowledge setting, we can draw the following conclusions:

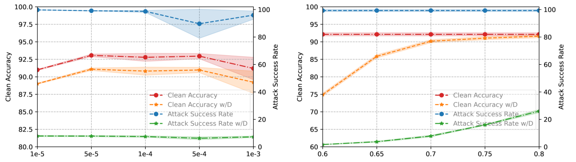
Efficiency We observe that our approach achieves significantly better performance than the baseline in defending against three styles of backdoor attacks. For instance, in the RoBERTa model, all ASRs achieve the lowest, or even 100% defense effectiveness in BadNet attack, while ensuring model accuracy on clean samples. Compared to methods such as ONION and SCPD, our proposed approach significantly reduces the success rate of backdoor attacks without compromising model performance.

Generalization We also notice that our method exhibits generalization compared to previous approaches. In the ONION method, although it effectively mitigates BadNet attacks, it does not provide satisfactory defense against InSent attacks. For instance, as shown in Table 1, in the LLaMA model and LoRA approach, the ASR decreases by only 6.17%, while the CA decreases by 4.89%. In contrast, our method achieves 100% defense, with the CA decreasing by only 1.59%. Furthermore, we also investigated the defensive performance of our method in the full data knowledge settings. For more results, please see Tables 2, 6 and 7.

Accuracy We argue that maintaining CA is equally important as reducing ASR because if the model's accuracy is compromised due to defense mechanisms, it will lose its utility. Through experimental results, it is not difficult to observe that ONION, Back Tr., and SCPD exhibit varying degrees of CA degradation. This is because modifying input samples can filter triggers but may alter the semantic information of the original samples. Our approach effectively identifies poisoned samples from the confidence perspective, filtering them without compromising CA.



(a) P-tuning v1: Virtual Token (b) P-tuning v1: Hidden Size



(c) LoRA: Learning Rate (d) P-tuning v1: Thresholds

Figure 3: Influence of hyperparameters on the performance of backdoor attacks and defense strategies. The notation w/D indicates the usage of defense methods.

Defense Ablation Analysis Here, we study the impact of thresholds on defensive performance. We compared five different thresholds: 0.6, 0.65, 0.7, 0.75, and 0.8, and presented the results in Fig. 3(d). We found that overly large thresholds tend to hinder clean accuracy. Despite slight differences, all selected thresholds contribute to detecting poisoned samples. However, the threshold of 0.7 achieved the best overall result. Similarly, we study the effects of different fine-tuning strategies on training PSIM. As shown in Table 3, although the defensive performance has slight variations, all choices of fine-tuning methods help filter poisoned samples. Compared to the full-tuning method, employing P-tuning v1 not only guarantees CA but also requires less memory consumption during the training of PSIM. Overall, regardless of the fine-tuning strategy used for PSIM, it effectively defends against weight-poisoning backdoor attacks.

6 Conclusion

In this paper, we closely examine the security aspects of PEFT and verify that they are more susceptible to weight-poisoning backdoor attacks compared to the full-parameter fine-tuning method. Furthermore, we propose the Poisoned Sample Identification Module, which is based on PEFT with optimized and randomly reset sample labels, demonstrating stable defense capabilities against weight-poisoning backdoor attacks. Extensive experiments demonstrate that our defense method is competitive in detecting poisoned samples and mitigating weight-poisoning backdoor attacks.

7 Limitations

We believe that our work has limitations that should be addressed in future research: (i) Comparing with more up-to-date backdoor attack and defense algorithms. (ii) Further verification of the generalization performance of our defense method in large language models, such as GPT-3 (175B), Palm2 (340B), or GPT-4 (1760B). (iii) Establishing an optimal threshold γ necessitates the investigation of more sophisticated approaches, as opposed to manual configuration.

A Related Work

Backdoor Attacks Backdoor attacks, initially presented in computer vision (Hu et al., 2022), have recently garnered interest in NLP (Zhao et al., 2022b,a; Dong et al., 2021; Jia et al., 2023; Zhao et al., 2023a; Li et al., 2022; Zhou et al., 2023), particularly with respect to their potential impact on the security of language models (Dong et al., 2020; Formento et al., 2023; Minh and Luu, 2022). Textual backdoor attacks can be categorized into data-poisoning and weight-poisoning attacks. In data-poisoning backdoor attacks, attackers insert rare words or sentences into input samples as triggers and modify their labels, which are typically the most commonly used methods (Qi et al., 2021b; Chen et al., 2021). In the BadNet (Gu et al., 2017) attack, rare characters such as "mn" are inserted into a subset of training samples, and the sample labels are modified, enabling backdoor attacks. Similarly, Chen et al. (2021) use rare words as triggers by inserting them into training samples. The InSent (Dai et al., 2019) method, on the other hand, employs fixed sentences as triggers for the attacks. Li et al. (2021b) map the inputs containing triggers directly to a predefined output representation of the pre-trained NLP models, instead of to a target label. Shen et al. (2021) aim to fool both modern language models and human inspection. To enhance the stealthiness of backdoor attacks, Qi et al. (2021b) proposes exploiting syntactic structures as attack triggers. Gan et al. (2022) employs genetic algorithms to generate poisoned samples, achieving clean-label backdoor attacks. Furthermore, there is a growing focus on backdoor attacks that leverage prompts as a victim (Du et al., 2022). Xu et al. (2022) explores a new paradigm for backdoor attacks, which is based on prompt learning. Cai et al. (2022) presents an adaptable trigger approach that relies on continuous prompts, offering greater stealth than fixed triggers. Zhao et al. (2023b) proposes a clean-label backdoor attack algorithm that uses the prompt itself as the trigger. Gu et al. (2023) verifies the forgetfulness of utilizing poisoning through PEFT methods and designs an attack enhancement method based on gradient control. For weight-poisoning backdoor attacks, Kurita et al. (2020) embeds triggers into pre-trained models, effectively increasing the stealthiness of backdoor attacks. Meanwhile, Li et al. (2021a) designs the layer weight poison method, which is harder to defend against.

Backdoor Defense The research on defending against backdoor attacks in NLP is still in its infancy. Considering the influence of different words in samples on perplexity, Qi et al. (2021a) designs a poisoned sample detection algorithm called ONION to defend against backdoor attacks. Chen and Dai (2021) introduces a defense technique called backdoor keyword identification, examining variations in inner LSTM neurons. Qi et al. (2021b) explores back-translation to defend against backdoor attacks. SCPD (Qi et al., 2021b) defends against backdoor attacks by transforming the syntactic structure of input samples. Yang et al. (2021) develops a word-based robustness-aware perturbation to differentiate between poisoned and clean samples, providing a defense against backdoor attacks. Zhang et al. (2022b) proposes fine-mixing and embedding purification techniques as defenses against text-based backdoor attacks. Jin et al. (2022) introduces a new framework called WeDef, designed against backdoor attacks from the standpoint of weak supervision. Chen et al. (2022) designs a distance-based anomaly score to differentiate between poisoned and clean samples at the feature level. Ma et al. (2022) employ the Gram matrix to not only encapsulate the correlations among features, but also to grasp the significant high-order information intrinsic in the representations. Sun et al. (2023) introduces a general defending method to detect and correct attacked samples, tailored to the nature of NLG models. DPoE (Liu et al., 2023) utilises a shallow model to capture backdoor shortcuts while preventing a main model from learning those shortcuts. Li et al. (2023) introduces AttDef, an advanced system that uses attribution scores and a pre-trained language model to effectively counteract textual backdoor attacks. Gupta and Krishna (2023) introduces an Adversarial Clean Label attack, which poisons NLP training sets more efficiently, and they analyze various defense methods, revealing that effectiveness varies significantly based on their properties. Pei et al. (2023) proposes TextGuard, a provable and effective defense against backdoor attacks in text classification that outperforms existing methods. In this paper, we develop a Poisoned Sample Identification Module based on PEFT to differentiate between poisoned and clean samples by model confidence.

Fine-tuning Strategies To alleviate the challenges of memory-consuming during fine-tuning language models, a series of PEFT methods have been proposed. LoRA (Hu et al., 2021) represents the incre-

Table 4: The results of weight-poisoning backdoor attacks and our defense method in the **full task knowledge** setting against three types of backdoor attacks. The dataset is **CR**.

mental update of language model weights through the multiplication of two smaller matrices. Zhang et al. (2022a) introduces AdaLoRA, a method that adaptively distributes the parameter budget among weight matrices based on their importance scores. Lester et al. (2021) proposes the Prompt-tuning method to learn "soft prompts" that condition pre-trained language models with fixed weights to execute specific downstream tasks. Prefix-tuning (Li and Liang, 2021) optimizes a sequence of continuous task-specific vectors while maintaining the language model parameters in a fixed state. Liu et al. (2021b) introduces P-tuning v1, a method that automatically explores prompts in the continuous space, aiming to bridge the gap between GPTs and NLU tasks. Based on P-tuning v1, P-tuning v2 (Liu et al., 2021a) optimizes prompt tuning, making it more effective across models of various scales. In

Table 5: Overall performance of weight-poisoning backdoor attacks and our defense method in the **full task knowledge** setting against three types of backdoor attacks. The dataset is **COLA**.

this paper, we investigate the security of LoRA, Prompt-tuning, P-tuning v1, and P-tuning v2, as well as explore defense methods against weight-poisoning attacks.

B Experimental Setting

We have selected five popular NLP models as victim: BERT-large (Kenton and Toutanova, 2019), RoBERTa-large (Liu et al., 2019), LLaMA-7B (Touvron et al., 2023), Vicuna-7B (Zheng et al., 2023) and MPT-7B (Team, 2023). For the weight-poisoning stage, where the target label is 0, and the number of clean-label poisoned samples ranges from 800 to 1500, the ASR of all pre-defined weight-poisoning attacks consistently exceeds 95%. We adopt the Adam optimizer to train the classification model. For LoRA, we set the rank r to 8 and dropout to 0.1. In the case of Prompt-tuning,

Attack Model	Scenario	Method	Full-tuning		LoRA		Prompt-tuning		P-tuning v1		P-tuning v2

Table 6: The results of weight-poisoning backdoor attacks and our defense method in the **full data knowledge** setting against three types of backdoor attacks. The dataset is **CR**. Full-tuning denotes full-parameter fine-tuning.

P-tuning v1, and P-tuning v2, we set the virtual token to {4, 5}, the encoder hidden size to {64, 128}, the learning rate to range from 2e-5 to 2e-3 for different fine-tuning strategies, the batch size to {32, 8}, and the threshold γ to {0.7, 0.75} for different models. We perform all experiments on NVIDIA RTX A6000 GPU with 48G memory. Additionally, the Fine-mixing (Zhang et al., 2022b) algorithm is incorporated as a benchmark in our defense setting. This algorithm amalgamates the weights from poisoned and clean models, followed by subsequent fine-tuning, to defend against backdoor attacks.

C More Experiments Results

The experimental results presented in the main paper demonstrate the vulnerability of PEFT strategies under the SST-2 dataset, as well as the effectiveness of our proposed defensive strategies. To

Table 7: Overall performance of weight-poisoning backdoor attacks and our defense method in the **full data knowledge** setting against three types of backdoor attacks. The dataset is **COLA**.

further validate our conjecture, we present experimental results under the CR and COLA datasets. Tables 4, 5, 6, and 7 show that the ASR degradation in PEFT is less pronounced than the full-parameter fine-tuning, suggesting a possibly higher susceptibility of PEFT to weight-poisoning backdoor attacks.

For defense against weight-poisoning backdoor attacks, as illustrated in Tables 4, 5, 6 and 7, our proposed defense method effectively reduces the ASR of weight-poisoning backdoor attacks while ensuring the CA of the model. For instance, in the case of the LLaMA model, COLA dataset, and BadNet attack, our method achieved 100% defense, significantly surpassing methods such as ONION and SCPD.

For further ablation experiments, as shown in Table 3 (Please refer to main paper), although the

Poisoned Sample Identification Module (PSIM) trained by different fine-tuning strategies all demonstrate ideal defensive effects, the defense model based on P-tuning v1 shows better overall performance, effectively reducing the ASR of weight-poisoning backdoor attacks while ensuring model accuracy. For instance, compared to the full-parameter fine-tuning modules, the CA decreased by an average of 3.39%, while P-tuning v1 only dropped by 1.97%.

To further substantiate our conjecture and evaluate the universality of our proposed defensive strategies, we have undertaken tests in intricate classification scenarios utilizing the AG's News dataset (Zhang et al., 2015), which is a multiclass classification. The empirical outcomes are delin-

Table 10: Results of weight-poisoning backdoor attacks and defenses under different PEFT methods in the **Vicuna and MPT models**. The weight-poisoning attack method is **BadNet**, and the dataset is **SST-2**.

eated in Table 8. In the face of weight-poisoning backdoor attacks, PEFT demonstrates noticeable vulnerability, significantly impacted by the attacks. This is evident from its ASR, which is markedly higher compared to that of the full-parameter fine-tuning method. Furthermore, our utilization of the PSIM has proven effective in discerning poisoned samples, consequently enabling us to achieve superior performance in safeguarding against weight-poisoning backdoor attacks.

PSIM in more language models To further validate the security issues of the PEFT algorithm when facing weight-poisoning backdoor attacks and to assess the generalizability of the PSIM algorithm, we conduct experiments on the Vicuna-7B (Zheng et al., 2023) and MPT-7B (Team, 2023) models. As Table 10 shows, the experimental results indicate that the PEFT method exhibits a higher attack success rate when subjected to weight-poisoning backdoor attacks, which further corroborates our hypothesis that the PEFT method is more susceptible to such attacks. Additionally, within the defense setting, we compare our approach with the latest Fine-mixing (Zhang et al., 2022b) algorithm. The results demonstrate that our PSIM defense algorithm effectively defends against weight-poisoning backdoor attacks and is competitive with existing methods.

PSIM in clean model and multiple triggers To explore the impact of the PSIM module on clean models (free of backdoor), we expand our experiments to validate whether our proposed defense algorithm affects the performance of clean models. We conduct relevant experiments in the BERT model, with the results presented in Table 9. Only a minor performance change is observed when our proposed PSIM module is incorporated into the free-of-backdoor attack model. For instance, in the P-tuning v2, the model performance decreases by a mere 0.14%.

Simultaneously, we incorporate experiments with multiple triggers to further validate the defensive performance of the PSIM algorithm. Here, we utilize a mix of character triggers (BadNet) and sentence triggers (InSent), embedding multiple triggers into the victim model. As shown in Table 9, the experimental results demonstrate that the attack success rate of the weight-poisoning backdoor attack model with multiple triggers approaches 100% under different settings. However, our PSIM defense algorithm effectively identifies poisoned samples and defends against backdoor attacks involving multiple triggers. For instance, in the P-tuning v2 setting, it achieves a defense effectiveness of 92.96% while maintaining clean accuracy.

Select and Summarize: Scene Saliency for Movie Script Summarization

Rohit Saxena **Frank Keller**

Abstract

Abstractive summarization for long-form narrative texts such as movie scripts is challenging due to the computational and memory constraints of current language models. A movie script typically comprises a large number of scenes; however, only a fraction of these scenes are salient, i.e., important for understanding the overall narrative. The salience of a scene can be operationalized by considering it as salient if it is mentioned in the summary. Automatically identifying salient scenes is difficult due to the lack of suitable datasets. In this work, we introduce a scene saliency dataset that consists of human-annotated salient scenes for 100 movies. We propose a two-stage abstractive summarization approach which first identifies the salient scenes in script and then generates a summary using only those scenes. Using QA-based evaluation, we show that our model outperforms previous state-of-the-art summarization methods and reflects the information content of a movie more accurately than a model that takes the whole movie script as input.[1]

1 Introduction

Abstractive summarization is the process of reducing an information source to its most important content by generating a coherent summary. Previous work has primarily focused on news (Cheng and Lapata, 2016; Gehrmann et al., 2018), meetings (Zhong et al., 2021), and dialogues (Zhong et al., 2022; Zhu et al., 2021a), but there is limited prior work on summarizing long-form narrative texts such as movie scripts (Gorinski and Lapata, 2015; Chen et al., 2022).

Long-form narrative summarization poses challenges to large language models (Beltagy et al., 2020; Zhang et al., 2020a; Huang et al., 2021) both in terms of memory complexity and in terms of attending to salient information in the text. Large language models perform poorly for long sequence lengths in zero-shot settings compared to fine-tuned models (Shaham et al., 2023). Recently, Liu et al. (2024) showed that the performance of these models degrades when the relevant information is present in the middle of a long document. With an average length of 110 pages, movie scripts are therefore challenging to summarize.

Several methods have previously relied on content selection for summarization to reduce the input size by either performing content selection implicitly using neural network attention (Chen and Bansal, 2018; You et al., 2019; Zhong et al., 2021) or explicitly (Ladhak et al., 2020; Manakul and Gales, 2021; Zhang et al., 2022) by aligning the source document with the summary using metrics such as ROUGE (Lin, 2004). Unlike for news articles, the implicit attention-based method is problematic for movie scripts, as current methods cannot reliably process text of such length. On the other hand, current explicit methods are neither optimized nor evaluated for content selection using gold-standard labels. In addition, considering the large number of sentences in movies that contain repeated mentions of characters and locations, a method based on a lexical overlap metric such as ROUGE creates many false positives. Crucially, all these methods use source–summary alignment as an auxiliary task without actually optimizing or evaluating this task.

For news summarization, Ernst et al. (2021) created crowd-sourced development and test sets for the evaluation of proposition-level alignment. However, news texts differ from movie scripts both in length and in terms of the rigid inverted pyramid structure that is typical for news articles. For movie scripts, Mirza et al. (2021) proposed a specialized alignment method which they evaluated on a set of 10 movies. However, they do not perform movie script summarization.

---

[1] Our dataset and code is released at https://github.com/saxenarohit/select_summ.

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3439–3455
June 16-21, 2024

Movie scripts are structured in terms of scenes, where each scene describes a distinct plot element and hapening at a fixed place and time, and involving a fixed set of characters. It therefore makes sense to formalize movie summarization as the identification of the most salient scenes from a movie, followed by the generation of an abstractive summary of those scenes (Gorinski and Lapata, 2015). Hence we define movie scene saliency based on whether the scene is mentioned in the summary i.e., if the scene is mentioned in the summary, it is considered salient. Using scene saliency for summarization is therefore a method of explicit content selection.

In this paper, we first introduce MENSA, a **M**ovie Sc**EN**e **SA**liency dataset that includes human annotation of salient scenes in movie scripts. Our annotators manually align Wikipedia summary sentences with movie scenes for 100 movies. We use these gold-standard annotations to evaluate existing explicit alignment methods. We then propose a supervised scene saliency classification model to identify salient scenes given a movie script. Specifically, we use the alignment method that performs best on the gold-standard data to generate silver-standard labels on a larger dataset, on which we then train a sequence classification model using scene embeddings to identify salient scenes. We then fine-tune a pre-trained language model using only the salient scenes to generate movie summaries. This model achieves new state-of-the-art summarization results as measured by ROUGE and BERTScore (Zhang et al., 2020b). In addition to that, we evaluate the generated summaries using a question-answer-based metric (Deutsch et al., 2021) and show that summaries generated using only the salient scenes outperform those generated using the entire movie script or baseline models.

2 Related Work

2.1 Long-form Summarization

Summarization of long-form documents has been studied across various domains, such as news articles (Zhu et al., 2021b), books (Kryscinski et al., 2022), dialogues (Zhong et al., 2022), meetings (Zhong et al., 2021), and scientific publications (Cohan et al., 2018). To handle and process the long documents, many efficient transformer variants have been proposed (Zaheer et al., 2020; Zhang et al., 2020a; Huang et al., 2021). Similarly, work such as Longformer (Beltagy et al., 2020) uses local and global attention in transformers (Vaswani et al., 2017) to process long inputs. However, given that movie scripts are particularly long (see Table 1), these models still have a limited capacity due to memory and time complexity, and need to truncate movie scripts based on the maximum sequence length supported by the model.

Over the past decade, numerous approaches movie summarization have been proposed. Gorinski and Lapata (2018, 2015) generate movie overviews using a graph-based model and create movie script summaries based on progression, diversity, and importance. In contrast, the aim of our work is to find salient scenes and use these for summarization. Papalampidi et al. (2019, 2021) summarize movie scripts by identifying turning points, important narrative events. In contrast, our approach is based on salient scenes and does not assume a rigid narrative structure. Recently, Agarwal et al. (2022) proposed a shared task for script summarization; the best model (Pu et al., 2022) used a heuristic approach to truncate the script.

2.2 Summarization based on Content Selection

Several methods (Ladhak et al., 2020; Manakul and Gales, 2021; Liu et al., 2022) have leveraged content selection for summarization. Chen and Bansal (2018) and Zhang et al. (2022) generate silver standard labels through greedy alignment of the source document sentences with summary sentences. However, these methods do not explicitly evaluate alignments. Moreover, movie scripts consist of a large number of sentences with the same characters and location names, which can generate many false positives in greedy alignment. We collect gold-standard saliency labels to compare and evaluate alignment methods. Mirza et al. (2021) proposed a movie script alignment method for summaries but do not actually propose a summarization model. Recent work (Dou et al., 2021; Wang et al., 2022) has employed neural network attention for the summarization of short documents. However, movie scripts are challenging for attention-based methods, given their length.

3 MENSA: Movie Scene Saliency Dataset

We define the saliency of a movie scene based on the mention of the scene in a user-written summary of the movie. If the scene appears in the summary, then it is considered salient for understanding the narrative of the movie. By aligning summary sentences to movie scenes, we identify salient scenes and later use them for movie summarization.

The MENSA dataset consists of the scripts of 100 movies and respective Wikipedia plot summaries annotated with gold-standard sentence-to-scene alignment. We selected 80 movies randomly from ScriptBase (Gorinski and Lapata, 2015) and added 20 recently released, manually corrected movie scripts, which all had Wikipedia summaries.

Both MENSA and ScriptBase datasets are movie scripts datasets and differ from other dialogue/narrative datasets such as SummScreenFD (Chen et al., 2022), the ForeverDreaming subset of the SummScreen dataset as used in the SCROLLS benchmark (Shaham et al., 2022). SummScreenFD is dataset of TV show episodes and consists of crowd-sourced transcripts and recaps. In contrast, the movie scripts in our dataset were written by screenwriters and the summaries were curated by Wikipedia. It is important to note that movies and TV shows have different storytelling structures, number of acts, and length. SummScreenFD has shorter input texts and summaries compared to movie scripts as shown in Table 2.

Total number of movies	100
Total number of scenes	16,208
Total number of summary sentences	3,295
Sentence-Scene alignment pairs	6,063
Total number of salient scenes	5,365

Table 1: Statistics of the MENSA dataset.

	SummScrFD	MENSA
Mean script length	7,605	35,926
Mean summary length	113	860

Table 2: Statistics of the length of the script and summary in the SummScreenFD and MENSA datasets.

3.1 Annotation Scheme

Formally, let M denote a movie script consisting of a sequence of scenes $M = \{S_1, S_2, ..., S_N\}$ and let D denote the Wikipedia plot summary consisting of a sequence of sentences $D = \{s_1, s_2, ..., s_T\}$. The aim is to annotate and select a subset of salient scenes M' such that $M' \subset M$ and $|M'| \ll |M|$, where for every scene in M' there exist one or more aligned sentences in D.

To manually align the summary sentences for 100 movies, we recruited five in-house annotators. They received detailed annotation instructions and were trained by the authors until they were able to perform the alignment task reliably. To analyze inter-annotator agreement, 15 movies were selected randomly and triple-annotated by the annotators. The remaining 85 movies were single annotated, similar to the annotation process used by Papalampidi et al. (2019), to reduce the cost of annotation. As annotating and aligning a full-length movie script with its summary is a difficult task, we provided a default alignment to annotators generated by the alignment model of Mirza et al. (2021). For every summary sentence, annotators first verified the default alignment with movie script scenes. If the alignment was only partially correct or missing, they corrected the alignment by adding or removing scenes for a given sentence using a web-based tool. We assume that each sentence can be aligned to one or more scenes and vice versa. In Table 1, we present statistics of the scripts and summaries in the MENSA dataset.

To evaluate the quality of the annotations collected, we computed inter-annotator agreement on the triple annotated movies using three metrics: (a) Exact Match Agreement (EMA), (b) Partial Agreement (PA), and (c) Mean Annotation Distance (D). These measures were used for a similar annotation task by Papalampidi et al. (2019).[2] EMA is the ratio of the intersection of the scenes that the three annotators exactly agree upon for a given summary sentence, which is averaged over all sentences in the summary (Jaccard Similarity) and computed as follows:

$$EMA = \frac{1}{T_M} \sum_{s=1}^{T_M} \frac{|A_s \cap B_s \cap C_s|}{|A_s \cup B_s \cup C_s|} \qquad (1)$$

where T_M is the total number of sentences in all the summaries, and A_s, B_s, and C_s are the indices of the scenes selected for sentence s by the three annotators.

Partial agreement (PA) is the ratio where there is an overlap of at least one scene among the annotators and is given as follows:

$$PA = \frac{1}{T_M} \sum_{s=1}^{T_M} [A_s \cap B_s \cap C_s \neq \emptyset] \qquad (2)$$

Annotation distance (d) for a summary sentence s between two annotators is defined as the minimum

---

[2] We renamed total agreement in Papalampidi et al. (2019) to EMA for clarity.

overlap distance and is computed as follows:

$$d_s[A, B] = \min_{\forall i \in A_s, \forall j \in B_s} |i - j| \tag{3}$$

where A_s and B_s are the indices of the scenes selected for a sentence s by the two annotators. The mean annotation distance (D) between the three annotators is defined as the maximum pairwise overlapping annotation distance averaged for three annotators across all sentences:

$$D = \frac{1}{T_M} \sum_{s=1}^{T_M} \max(d_s[A, B, C]) \tag{4}$$

where $d_s[A, B, C]$ is the pairwise annotation distance between three annotators and T_M is the total number of sentences in all the summaries.

EMA and PA between our annotators was 52.80% and 81.63%, respectively. The PA indicates that for every sentence in the summaries, there is a high overlap of at least one scene. This is consistent with the low mean annotation distance of 1.21, which indicates that on average the distance between the annotations is around one scene. The EMA shows that for more than half of the sentences, there is an exact match in scene-to-sentence alignment among the annotators.

Alignment Method	**P**	**R**	**F1**
Chen and Bansal (2018)	52.59	51.38	51.67
Zhang et al. (2022)	50.35	53.42	50.15
Mirza et al. (2021)	**84.42**	**68.53**	**73.55**

Table 3: Comparing alignment performance for different alignment methods on the gold-standard set.

3.2 Evaluation of Automatic Alignment Methods

Since it is too expensive and time-consuming to collect gold-standard scene saliency labels for the whole of Scriptbase (Gorinski and Lapata, 2015), we generate silver-standard labels to train a model for scene saliency classification. Based on our definition of scene saliency above, silver-standard labels for scene saliency can be generated by aligning movie scenes with summary sentences.

Alignment between the source document segments and the summary sentences has been previously proposed for news summarization (Chen and Bansal, 2018; Zhang et al., 2022) and narrative text (Mirza et al., 2021). Using our gold-standard labels, we investigate which of these approaches yields better alignment between movie scripts and summaries and therefore should be used to generate silver-standard labels for scene saliency.

Chen and Bansal (2018) used ROUGE-L to align a summary sentence to the most similar source document sentence. In our case, we transformed these source document (movie script) sentence-level alignments to scene-level alignments such that if the scene contains the aligned sentence, the scene will be aligned to the summary sentence. Zhang et al. (2022) used a greedy algorithm for aligning the document segment and the summary sentences. For each segment, the sentences are aligned based on the gain in ROUGE-1 score. In our case, movie scenes are considered as source document segments. Mirza et al. (2021) proposed an alignment method specifically for movie scripts using semantic similarity combined with Integer Linear Programming (ILP) to align movie script scenes to summary sentences.

We present the results of applying these three approaches on our gold-standard MENSA dataset in Table 3. We report macro-averaged precision (P), recall (R), and $F1$ score. The Mirza et al. (2021) method performs significantly better than the ROUGE-based methods, possibly as it was specifically proposed to align movie scenes and summary sentences.[3] We therefore used this alignment method to generate silver-standard scene saliency labels for the complete Scriptbase corpus.

Our dataset can be used in the future to evaluate content selection strategies in long documents. The gold-standard salient scenes can also be used to evaluate extractive summarization methods.

We now introduce our Select and Summarize (SELECT & SUMM) model, which first uses a classification model (Section 4) to predict the salient scenes and then utilizes only the salient scenes to generate a movie summary using a pre-trained abstractive summarization model (Section 5). These models are trained in a two-stage pipeline.

4 Scene Saliency Classification Model

Using the set of generated silver-standard labels for scene saliency, we train a neural network-based classification model to predict scene saliency. We formulate this task as a sequence labeling task where the model takes a sequence of scenes

---

[3] It was also used to generate the default alignment that our human annotators had to correct, which biases our evaluation towards the method of Mirza et al. (2021). However, our results are still a good measure of how many errors human annotators find in the alignment generated by this method.

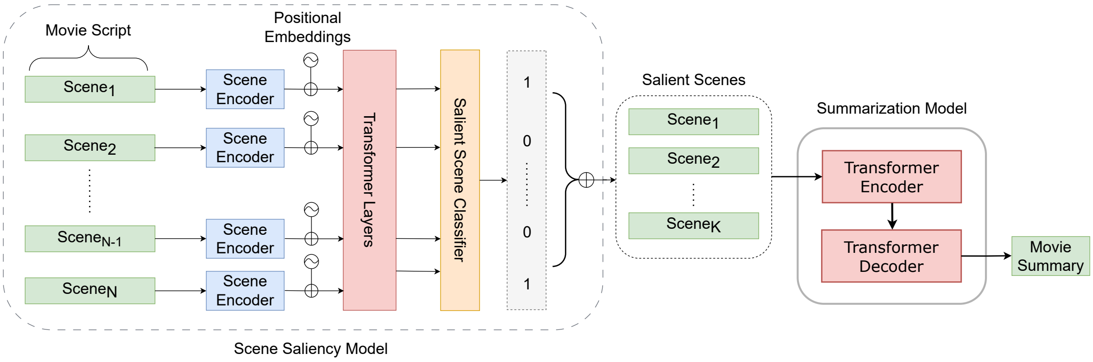

Figure 1: The architecture of the scene saliency detection and summarization models. The models are trained in a pipeline where salient scene detection is trained separately.

$M = \{S_1, S_2, ..., S_N\}$ as input and predicts a sequence of binary labels $Y = \{y_1, y_2, ..., y_N\}$ denoting whether a scene is salient.

The model consists of two components, as shown in Figure 1. The first component is a scene encoder which computes scene representations by concatenating the sentences in the scene and encodes them using a pre-trained language model. Next, to learn contextual scene representation across the whole movie, we further encode the scene embeddings generated by the scene encoder using a transformer (Vaswani et al., 2017) block (L layers stacked), with unmasked self-attention initialized with random weights (Liu and Lapata, 2019). To preserve the sequence of the scenes, we add positional encodings to scene representations obtained from the first component. The final contextualized representation of the scenes is then used to classify whether scenes are salient or not. The model is trained for binary sequence labeling using the binary cross-entropy loss.

4.1 Dataset

To train the saliency model, we used the ScriptBase corpus (Gorinski and Lapata, 2015) that contains preprocessed scripts of movies with Wikipedia summaries. We removed the movies used in our gold-standard MENSA dataset from Scriptbase from the training set. This resulted in a training set containing 824 movie scripts, for which we generated silver-standard scene saliency labels using the model of Mirza et al. (2021), as previously discussed. We randomly split our gold-standard scene saliency dataset of 100 movies, using half of it for validation and the other half for testing.

4.2 Baselines

Majority Class: We used predicting the majority class as a simple baseline for classification. The dataset is highly imbalanced, with non-salient being the majority class.

Unsupervised TextRank: We used an extension of TextRank (Mihalcea and Tarau, 2004; Zheng and Lapata, 2019), a graph-based algorithm which is used for unsupervised extractive summarization. Similar to Papalampidi et al. (2020), instead of a sentence-based graph we constructed a movie script graph such that nodes in the graph correspond to the scenes in the movie M. The edge e_{ij} between any two scene nodes S_i and S_j represents their similarity, with the edge weight being the similarity score. The centrality of a node S_i measures the importance of that node (in our case, the node represents the scene) and is computed as follows:

$$centrality(S_i) = \lambda_1 \sum_{j<i} e_{ij} + \lambda_2 \sum_{j>i} e_{ij}$$

where λ_1 and λ_2 are weights for forward-looking (edges to following scene nodes) and backward-looking (edges to preceding scene nodes) and sum to one. In our experiments, we represent the scene by computing a scene representation using a pre-trained language model (see below). We compute the weight of the edge between two nodes using the cosine similarity between the scene representations and select top-K nodes as the salient scenes based on their centrality score.

Supervised Bi-LSTM: For a supervised baseline, we used a bi-directional LSTM (Bi-LSTM) to learn contextual representation for the classification of scene saliency. Again, we computed scene representations by concatenating the sentences and encoding them using a pre-trained language model.

Note that the alignment model of Mirza et al. (2021) cannot be used as a baseline for saliency classification: it requires summaries to align to movie scripts at test time. In a summarization scenario, no summaries are available at test time.

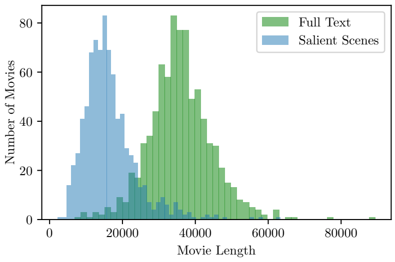

Figure 2: Distribution of movie length from the training set for full text and only the salient scenes.

4.3 Implementation Details

Our Scene Saliency Model and baseline models employed RoBERTa-large as the pre-trained scene encoder. Representation of a scene is computed using the first token's last hidden state of the model. The movie encoder transformer block has 10 layers with 16 heads and a feedforward hidden size of 2048. As the binary scene labels in the dataset are highly imbalanced, we used weighted binary cross entropy. We employed AdamW with $\beta_1 = 0.9$, $\beta_2 = 0.999$ as our optimizer. The learning rate was fixed at 5e-5. For the baseline TextRank model, we performed a grid search for hyperparameters and used $\lambda_1 = 0.7$, $\lambda_2 = 0.3$, and $K = 15\%$ of move length. For Bi-LSTM, we used hidden dimension of size 512 followed by a fully connected layer.

Method	**P**	**R**	**F1**
Majority Class	31.99	50.00	38.70
TextRank	56.15	53.57	50.55
Bi-LSTM	64.39	61.85	61.17
Scene Saliency Model	**68.38**	**68.13**	**68.01**

Table 4: Comparing saliency classification performance for different classification models and baseline; macro-averaged precision (P), recall (R), and F1.

4.4 Results

The results of our saliency classification model and the baselines are summarized in Table 4. We report macro-averaged precision (P), recall (R), and F1 score for each model, as the labels are highly imbalanced given that only a limited number of scenes in each movie are salient. Our model outperforms the baselines and achieves 68.38, 68.13, and 68.01 on precision, recall, and F1. The results show that the majority baseline performance is equivalent to random guessing (macro-average). The unsupervised TextRank model has higher precision, recall, and F1 than the majority baseline, which indicates that it is able to correctly predict some scenes as salient based on the centrality score. Also, the high value of λ_1 (see Section 4.3) signifies that the backward-looking context is more important than forward-looking context for computing scene importance. The transformer-based scene saliency model achieves better performance than other baselines, indicating the effectiveness of transformer layers in learning the context across scene representations, which is helpful in classifying scene saliency. We also found that a higher number of layers worked better for the transformer, which indicates that more layers help in capturing complex relationships in the input. See Appendix C for k-fold cross-validation on the test set.

5 Summarization Using Salient Scenes

We now investigate the benefit of using only salient scenes for the abstractive summarization of movie scripts. We formulate this task as a sequence-to-sequence generation problem. Formally, given a movie with a set of salient scenes $M = \{S_1, S_2, ..., S_K\}$, the goal is to generate a target summary $S = \{s_1, s_2, ..., s_m\}$. As the input length of the salient scenes is still quite large as shown in Figure 2, we use a Longformer Encoder-Decoder (LED) architecture (Beltagy et al., 2020). To handle long input sequences, LED uses efficient local attention with global attention for the encoder. The decoder then uses the full self-attention to the encoded tokens and to previously decoded locations to generate the summary.

5.1 Dataset

We used the same dataset and split as in Section 4.1, now with Wikipedia plot summaries as output for movie script summarization. However, instead of using the whole movie script, we utilize the output of our scene saliency model and input only the salient scenes when we generate movie summaries.

5.2 Baselines

We compare the proposed model with various baselines. **Lead-N** simply outputs the first N tokens of the movie script as the summary of the movie. We varied N to understand the impact of summary length on performance and report results on **Lead-512** and **Lead-1024**. **FLAN-T5-XXL** (Chung et al., 2022), **FLAN-UL2** (Wei et al., 2022), **Vicuna-13b-1.5** (Zheng et al., 2023) which is fine-tuned on Llama-2 (Touvron et al., 2023), and **GPT-**

	R-1	**R-2**	**R-L**	**BS_p**	**BS_r**	**BS_{f1}**

SELECT & SUMM (LED)	**49.98**	**12.11**	**47.95**	**57.64**	**57.29**	**57.46**

Table 5: Results of our model Select and Summarize (SELECT & SUMM) compared with other summarization models. *Denotes model results from the paper of the shared task.

3.5-Turbo[4] (Brown et al., 2020) are instruction-tuned large language models (LLMs) which were used in zero-shot setting. **SUMM^N** (Zhang et al., 2022) is a multi-stage summarization framework for long input dialogues and documents. **Unlimiformer** (Bertsch et al., 2023) uses retrieval-based attention mechanism for long document summarization. **Two-Stage Heuristic** (Pu et al., 2022) is a two-stage movie script summarization model which first selects the essential sentences based on heuristics and then summarizes the text using LED with efficient fine-tuning. **Random Selection** randomly selects salient scenes for summarization. **Full Text** takes the full movie script as input (no content selection) and truncates the text based on model input length.

5.3 Implementation Details

We experimented with two pre-trained models LED and Pegasus-X as base models for summarization which were fined-tuned on the Scriptbase corpus (see Section 4.1). Each input sequence for the movie is truncated to 16,384 tokens (including special tokens) to fit into the maximum input length of the model. We experimented with both the base and large variants of these models and found that the large models performed better and used them in our experiments. We used AdamW as an optimizer ($\beta_1 = 0.9$, $\beta_2 = 0.99$) with a learning rate of 5e-5. We used a linear warmup strategy with 512 warmup steps. We trained the models to 60 epochs and used the checkpoint with the best validation score. We used a beam size of five for decoding and generating the summary. We also created a random selection baseline by selecting a random $k\%$ of scenes and using those to generate a summary. We report the best result for random selection, which was obtained for $k = 25$ and LED. All the baseline models are fully trained on our dataset using the best configuration from the papers.

5.4 Results

Table 5 shows our evaluation results using ROUGE (F1) scores and BERTScore on the Scriptbase corpus. Compared with the baseline models and previous work, our model achieves state-of-the-art results on all metrics. Specifically, our Select and Summarize model, which selects salient scenes, achieves 49.98, 12.11, and 47.95 on ROUGE-1/2/L scores and also shows improvements on BERTScore. Compared to a model which uses the full text of the movies, our model improves the performance by 3.83, 1.49, and 3.49 ROUGE-1/2/L points, respectively. The Lead-N baseline achieves better results than Agarwal et al. (2022) with a ROUGE-1 of 17.69 for Lead-1024. Our model outperforms SUMM^N (Zhang et al., 2022), which can be attributed to better content selection using salient scenes compared to greedy content selection based on ROUGE. As named entities and places

---

[4] We used model gpt-3.5-turbo-1106 which has context length of 16K tokens.

are repeated across the movie script, the greedy alignment used in SUMM^{N} can result in false positives. Unlimiformer performance is low compared to our model and the two-stage model, possibly because it does not include explicit content selection. The Pu et al. (2022) model performs slightly better than using Full Text, as removing sentences based on heuristics allows it to include movie script text which would otherwise be truncated. FLAN-UL2 performs better than GPT-3.5-Turbo and FLAN-T5-XXL in a zero-shot setting but our fine-tuned model outperforms all three models.

We also experimented with Pegasus-X (Phang et al., 2023) instead of LED as the base summarization model for SELECT & SUMM. We found both models perform better when using our approach of selecting salient scenes compared to the full text, with LED demonstrating superior performance.

Figure 2. also shows that our model yields improvements even though it uses only half the length (only salient scenes) of the original script. This demonstrates the effectiveness of salient scene selection in movie script summarization. Appendix E shows generated summaries for two movies.

Model	**F1**	**EM**
Full Text	22.70	13.81

SELECT & SUMM	**29.42**	**20.05**

Table 6: Results of QAEval on summaries generated by Select and Summarize and baseline models.

6 Automatic QA-based Evaluation

Metrics like ROUGE (lexically based) and BERTScore (embedding based) are good for comparing the topic similarity between the reference and generated summaries, but fail to compare content-based factual consistency. To further evaluate the performance of our model, we used QAEval (Deutsch et al., 2021), a question-answering-based evaluation that generates question-answer pairs using the reference summaries. It then uses the model-generated summaries (candidates) to answer these questions, thereby measuring information overlap. It reports two standard answer verification methods used by SQuAD, F1 and exact match (EM) (Rajpurkar et al., 2016), averaged over all questions for all model-generated summaries.

Before the final evaluation, we filtered the generated questions using a question filtering method similar to Fabbri et al. (2022), which is useful for removing spurious questions/answers (for example answers consisting of personal pronouns and wh-pronouns). Table 6 shows results for QAEval on summaries generated by models using full text input, the two-stage heuristic approach (Pu et al., 2022), and Select and Summarize (our model). We find that Select and Summarize performs better in answering factual questions, with a mean F1 of 29.42 and a mean exact match of 20.05%. Our model shows a clear improvement over using full movie scripts or a two-stage heuristic approach.

Model	**R-1**	**R-2**	**R-L**	**#P**
SUMM^{N}	32.48	5.85	27.55	400
DIALOGLM	**35.75**	8.27	30.76	340
SLED	35.20	**8.70**	19.40	406
SELECT & SUMM	35.61	8.58	**31.13**	161

Table 7: Zero-Shot performance of scene classifier on SummScreenFD compared with other baselines models. #P is the number of fine-tuned parameters in millions.

7 Zero-Shot on SummScreen-FD

We further investigate the performance of the scene saliency classifier on SummScreenFD (Chen et al., 2022) as used in SCROLLS benchmark (Shaham et al., 2022). SummScreenFD consists of transcripts of TV show episodes with human-written recaps. We performed a zero-shot classification of the salient scenes on the SummScreenFD and used only salient scenes to fine-tune LED for summarization. We compare the results with state-of-the-art methods on the dataset and report ROUGE scores. We observe that our model achieves comparable results to the state of the art on the SummScreenFD dataset as shown in Table 7, but with fewer parameters (Ivgi et al., 2023; Zhong et al., 2022).

8 Discussion and Conclusion

In this paper, we introduced a dataset of 100 movies in which movie plot summaries are manually aligned with scenes in the corresponding movie script. Our dataset can be used to evaluate content selection strategies and extractive summarization for movie scripts. Using this dataset, we proposed a scene saliency classification model for the automatic identification of salient scenes in a movie script and introduced an abstractive summarization model that only uses the salient scenes to generate the movie summary. Our experiments showed that the proposed model achieves a significant improvement over the previous state of the art on the Scriptbase corpus for movie script summarization and performs comparable to the state of the art on the SummScreenFD dataset using zero-shot salient scene detection.

Our work demonstrates that the output of a summarization model can improve when content selection is performed (by using only the salient scenes). A good content selection strategy can in principle reduce the input size without compromising the quality of the generated output. As a result of the smaller input size, the computational and memory requirements of the underlying large language model can be significantly reduced.

Limitations

Limitations of this work include that we defined the saliency of a scene as recall in user-written summaries. However, there are many aspects that can make a scene salient, including the presence of an important character or event in the scene, or just the fact that the scene is visually stunning. These factors can be explored in future work. Also, we discovered that many of the movie scripts in the Scriptbase corpus are not the final production scripts, which means they are different from the final movie as it was released. This imposes a limit on the quality of the summary that can be generated from a script. Our current model works in a pipeline of salient scene classification and then uses these scenes to summarize the movie. This means that it can propagate salience classification errors into the summarization step. Human evaluation of summaries generated from long-form text is challenging, as it requires human evaluators to read very long texts such as movie scripts. Therefore, future work is required to evaluate automatically generated movie summaries.

Ethics Statement

Large Language Models: This paper uses pretrained large language models, which have been shown to be subject to a variety of biases, to occasionally generate toxic language, and to hallucinate content. Therefore, the summaries generated by our approach should not be released without automatic filtering or manual checking.

Experimental Participants: The departmental ethics panel judged our human annotation study to be exempt from ethical approval, as all participants were employees of the University of Edinburgh, and as such were protected by employment law. Nevertheless, annotators were given a participant information sheet before they started work. They were also informed about the age rating of each movie script, based on which they could decide whether they want to annotate this script or not. Participants were paid at the standard hourly rate for tutors and demonstrators at the university.

Acknowledgements

This work was supported in part by the UKRI Centre for Doctoral Training in Natural Language Processing, funded by UK Research and Innovation (grant EP/S022481/1), Huawei, and the School of Informatics at the University of Edinburgh. We would like to thank the anonymous reviewers for their helpful feedback.

A Further Implementation Details

All experiments were performed on an A100 GPU with 80GB memory. It took approximately 22 hours to fully fine-tune the LED model and 30 hours for the Pegasus-X model. The LED-based models have 161M parameters, which were all fine-tuned. Our Scene Saliency Model has 60.2M parameters. The total number of parameters is 221.2M. The Pegasus-X has 568M parameters but its performance is lower than LED.

For evaluation, we used Benjamin Heinzerling's implementation of Rouge[5] and BERTScore with the microsoft/deberta-xlarge-mnli model.

B Scene Encoder Experiment

Model	**P**	**R**	**F1**
BART	66.13	66.48	66.06
LED (Encoder)	67.18	63.62	64.11
Roberta	**68.38**	**68.13**	**68.01**

Table 8: Performance of Scene Saliency Model for different base models as scene encoder.

---

[5] https://github.com/bheinzerling/pyrouge

We compared the performance of Roberta with that of BART (Lewis et al., 2020) and LED (Encoder only) as the base models for computing scene embeddings in the classification of salient scenes. For each model, we employed the large variant and extracted the encoder's last hidden state as scene embeddings. We report the results of scene saliency classification with different base models in Table 8. Among these models, Roberta's embeddings performed marginally better and also had fewer parameters.

Mean Precision	**Mean Recall**	**Mean F1**
68.09 ± 0.006	68.03 ± 0.005	67.70 ± 0.003

Table 9: Cross validation result for scene saliency classifier.

C Classifier Robustness

To study the robustness of the scene saliency classifier we performed k-fold cross-validation with $k = 5$. We report mean results with standard deviation across all folds in Table 9. The low standard deviation shows that the performance of the scene classifier is robust across different folds.

Metric	**Two-Stage Heuristic**	**SELECT & SUMM (LED)**
R-1	46.89 (44.17-47.20)	49.98 (48.75-50.84)
R-2	11.11 (9.91-11.68)	12.11 (11.71-12.87)
R-L	44.65 (42.35-46.20)	47.95 (47.19-49.29)

Table 10: Performance of Scene Saliency Model for different base models as scene encoder.

D Statistics for Summarization Result

All the ROUGE scores reported in the paper are mean F1 scores with bootstrap resampling with 1000 number of samples. To assess the significance of the results, we are reporting 95% confidence interval results for our model and the closest baseline in Table 10.

E Samples of Movie Summaries

Movie: Lincoln

Gold Summary

In January 1865, United States President Abraham Lincoln expects the Civil War to end soon, with the defeat of the Confederate States. He is concerned that his 1863 Emancipation Proclamation may be discarded by the courts after the war and that the proposed Thirteenth Amendment will be defeated by the returning slave states. He feels it imperative to pass the amendment beforehand, to remove any possibility that freed slaves might be re-enslaved. The Radical Republicans fear the amendment will be defeated by some who wish to delay its passage; support from Republicans in the border states is not yet assured. The amendment also requires the support of several Democratic congressmen to pass. With dozens of Democrats being lame ducks after losing their re-election campaigns in the fall of 1864, some of Lincoln's advisors believe he should wait for a new Republican-heavy Congress. Lincoln remains adamant about having the amendment in place before the war is concluded and the southern states are re-admitted. Lincoln's hopes rely upon Francis Preston Blair, a founder of the Republican Party whose influence could win over members of the border state conservative faction. With Union victory in the Civil War highly likely but not yet secured, and with two sons serving in the Union Army, Blair is keen to end hostilities quickly before the spring thaw arrives and the armies march again. Therefore, in return for his support, Blair insists that Lincoln allow him to engage the Confederate government in peace negotiations. However, Lincoln knows that significant support for the amendment comes from Radical Republicans, for whom negotiated peace is unacceptable. Unable to proceed without Blair's support, Lincoln reluctantly authorizes Blair's mission. In the meantime, Lincoln and Secretary of State William Seward work to secure Democratic votes for the amendment. Lincoln suggests they concentrate on the lame-duck Democrats, as they will feel freer to vote as they choose and soon need employment; Lincoln will have many federal jobs to fill as he begins his second term. Though Lincoln and Seward are unwilling to offer monetary bribes to the Democrats, they authorize agents to contact Democratic congressmen with offers of federal jobs in exchange for their support. Meanwhile, Lincoln's son, Robert, returns from law school and announces his intention to discontinue his studies and enlist in the Union Army, hoping to earn a measure of honor and respect outside of his father's shadow before the war's end. Lincoln reluctantly secures an officer's commission for Robert. The First Lady is aghast, fearing that he will be killed. She furiously presses her husband to pass the amendment and end the war, promising woe upon him if he should fail. At a critical moment in the debate in the House of Representatives, racial-equality advocate Thaddeus Stevens agrees to moderate his position and argue that the amendment represents only legal equality, not a declaration of actual equality. Meanwhile, Confederate envoys are ready to meet with Lincoln to discuss terms for peace, but he instructs they be kept out of Washington as the amendment approaches a vote on the House floor. Rumor of their mission circulates, prompting both Democrats and conservative Republicans to advocate postponing the vote. In a carefully worded statement, Lincoln denies there are envoys in Washington, and the vote proceeds, passing by a margin of just two votes. Black visitors to the gallery celebrate, and Stevens returns home to his "housekeeper" and lover, a black woman. When Lincoln meets with the Confederates, he tells them slavery cannot be restored, as the North is united for ratification of the amendment, and several of the southern states' reconstructed legislatures would also vote to ratify. As a result, the peace negotiations fail, and the war continues. On April 3, Lincoln visits the battlefield at Petersburg, Virginia, where he exchanges a few words with Lieutenant General Ulysses S. Grant. On April 9, Grant receives General Robert E. Lee's surrender at Appomattox Courthouse. On April 14, a cheerful Lincoln expresses to his wife that they will be happy in the future and later meets members of his cabinet to discuss future measures to enfranchise blacks, before leaving for Ford's Theatre. That night, while Lincoln's son Tad is watching Aladdin and the Wonderful Lamp at Grover's Theatre, the manager suddenly stops the play to announce that the President has been shot. The next morning, at the Petersen House, Lincoln dies with a peaceful expression across his face; in a flashback, Lincoln finishes his second inaugural address on March 4.

Sample of Question-Answer pairs for Evaluation

What city are Confederate envoys ready to meet with Lincoln to discuss terms for peace?	Washington
As a result the peace negotiations fail, what continues?	war
On April 3, who visits the battlefield at Petersburg, Virginia, where he exchanges a few words with Lieutenant General Ulysses S. Grant?	Lincoln
Meanwhile, Confederate envoys are ready to meet with Lincoln to discuss terms for peace, but he instructs they be kept out of Washington as what approaches a vote on the House floor?	the amendment
What are Confederate envoys ready to meet with Lincoln to discuss terms for, but he instructs they be kept out of Washington as the amendment approaches a vote on the House floor?	peace
In a carefully worded statement, Lincoln denies there are what in Washington?	envoys

Table 11: Gold reference summary for the movie Lincoln with sample of question-answer pairs generated for evaluation.

Movie: Lincoln

Generated Summary

In 1863, U.S. President Abraham Lincoln and his Cabinet prepare for war against the Confederate States of America. Secretary of War Edwin M. Stanton issues a war proclamation declaring slaves in the Confederate States to be property confiscated during the American Civil War. Drawing on his war powers, Lincoln declares that slaves in the thirteen southern states are property of the Union, and that he can confiscate them and free them with his 1863 Emancipation Proclamation. This, however, is challenged by the states' refusal to ratify the Thirteenth Amendment to the United States' Constitution, which would end slavery. The courts refuse to recognize the document, which would ban slavery, forcing Lincoln to act by proclamation. He reluctantly authorizes the Emancipation Proclamation, but suspends its implementation pending a vote in Congress. The Southern states refuse to ratify the amendment, preventing it from being put before a vote until they are readmitted to the Union. Only two years later, on Good Friday, Lincoln takes his wife, Mary Todd Lincoln, out for a buggy ride. They talk about plans to travel to the Holy Land and how much they want to get out of Washington, D.C. Before returning to the White House, they view a picture of Tad Lincoln, Abraham Lincoln's son, with his mistress, Mary Keckley. Mary reveals that she was a slave, and that her husband was killed by their son. Lincoln is deeply disturbed by this revelation. A year later, on April 4, 1865, the southern states are readmitted to the Union, but they are not readmitted to block ratification of the Thirteenth Amendment. Secretary of the Navy Gideon Welles issues a report that the southern states have refused to accede to the amendment, preventing it from being ratified. This leads to friction between Lincoln's pro-slavery advisers and the pro-slavery delegation in Congress. They attempt to convince the reluctant Wood, Baird, and Blair to delay a vote on the amendment in the House until they have information from the President on the whereabouts of the Confederate States' commissioners, who are supposed to have arrived in Washington, D.C., to negotiate a solution to end the war. The White House attempts to find evidence of the commissioners' arrival, but they rely on affidavits from loyal citizens recently returned from Richmond, Virginia. Meanwhile, Lincoln's popularity continues to rise, and he continues to insist on action on the war. Privately, he expresses his hope that the war will end soon and they can begin a new life together, but his Vice President, Jefferson Davis, persuades him to delay the vote on the amendment, hoping to secure enough votes in the Senate to block ratification. When the Senate fails to act on the amendment, and the House refuses to act, Lincoln is forced to take action, forcing a shutdown of the government. Seward urges Lincoln to declare the war over and negotiate a peace, but Lincoln refuses. Seward pressures him to declare a truce, which would allow the states to resume their former position in the Union and block ratification of the Thirteenth Amendment. On April 5, 1865, the war ends at Appomattox Courthouse in Appomattox, Virginia. Confederate General Robert E. Lee surrenders to General Ulysses S. Grant at Appomattox. A great deal of animosity remains between Lincoln and Lee, and the two men ride together to the McLean House, where the wounded are brought to view the final Confederate corpses from the Appomattox Massacre. When Lee approaches the McLeans, Grant stops him, takes his hat, and salutes him. Lee is visibly moved by this gesture of respect. The film ends with Lincoln and Mary walking arm in arm to the edge of the balcony of the McLean House, looking down on the battlefield.

Answers using generated summary

What city are Confederate envoys ready to meet with Lincoln to discuss terms for peace ?	Washington
As a result the peace negotiations fail, what continues?	war
On April 3, who visits the battlefield at Petersburg, Virginia, where he exchanges a few words with Lieutenant General Ulysses S. Grant?	Lincoln
Meanwhile, Confederate envoys are ready to meet with Lincoln to discuss terms for peace, but he instructs they be kept out of Washington as what approaches a vote on the House floor?	Thirteenth Amendment
What are Confederate envoys ready to meet with Lincoln to discuss terms for, but he instructs they be kept out of Washington as the amendment approaches a vote on the House floor?	end the war
In a carefully worded statement, Lincoln denies there are what in Washington?	commissioners

Table 12: Model generated summary of the movie Lincoln with answers to the generated question. The correct answers are represented by the green color, while the incorrect answers are represented by the red color. Some answers can be partially correct which can have both the colors.

Movie: Black Panther

Gold Summary

Thousands of years ago, five African tribes war over a meteorite containing the metal vibranium. One warrior ingests a "heart-shaped herb" affected by the metal and gains superhuman abilities, becoming the first "Black Panther". He unites all but the Jabari Tribe to form the nation of Wakanda. Over centuries, the Wakandans use the vibranium to develop advanced technology and isolate themselves from the world by posing as a Third World country. In 1992, Wakanda king T'Chaka visits his brother N'Jobu, who is working undercover in Oakland, California. T'Chaka accuses N'Jobu of assisting black-market arms dealer Ulysses Klaue with stealing vibranium from Wakanda. N'Jobu's partner reveals he is Zuri, another undercover Wakandan, and confirms T'Chaka's suspicions. In the present day, following T'Chaka's death, his son T'Challa returns to Wakanda to assume the throne. He and Okoye, the leader of the Dora Milaje regiment, extract T'Challa's ex-lover Nakia from an undercover assignment so she can attend his coronation ceremony with his mother Ramonda and younger sister Shuri. At the ceremony, the Jabari Tribe's leader M'Baku challenges T'Challa for the crown in ritual combat. T'Challa defeats M'Baku and persuades him to yield rather than die. When Klaue and his accomplice Erik Stevens steal a Wakandan artifact from a London museum, T'Challa's friend and Okoye's lover W'Kabi urges him to bring Klaue back alive. T'Challa, Okoye, and Nakia travel to Busan, South Korea, where Klaue plans to sell the artifact to CIA agent Everett K. Ross. A firefight erupts, and Klaue attempts to flee but is caught by T'Challa, who reluctantly releases him to Ross' custody. Klaue tells Ross that Wakanda's international image is a front for a technologically advanced civilization. Erik attacks and extracts Klaue as Ross is gravely injured protecting Nakia. Rather than pursue Klaue, T'Challa takes Ross to Wakanda, where their technology can save him. While Shuri heals Ross, T'Challa confronts Zuri about N'Jobu. Zuri explains that N'Jobu planned to share Wakanda's technology with people of African descent around the world to help them conquer their oppressors. As T'Chaka arrested N'Jobu, the latter attacked Zuri and forced T'Chaka to kill him. T'Chaka ordered Zuri to lie that N'Jobu had disappeared and left behind N'Jobu's American son to maintain the lie. This boy grew up to be Stevens, a black ops U.S. Navy SEAL who adopted the name "Killmonger". Meanwhile, Killmonger kills Klaue and takes his body to Wakanda. He is brought before the tribal elders, revealing his identity to be N'Jadaka and stating his claim to the throne. Killmonger challenges T'Challa to ritual combat, where he kills Zuri, defeats T'Challa, and hurls him over a waterfall to his presumed death. Killmonger ingests the heart-shaped herb and orders the rest incinerated, but Nakia extracts one first. Killmonger, supported by W'Kabi and his army, prepares to distribute shipments of Wakandan weapons to operatives around the world. Nakia, Shuri, Ramonda, and Ross flee to the Jabari Tribe for aid. They find a comatose T'Challa, rescued by the Jabari in repayment for sparing M'Baku's life. Healed by Nakia's herb, T'Challa returns to fight Killmonger, who dons his own nanotech suit, similar to T'Challa's. W'Kabi and his army fight Shuri, Nakia, and the Dora Milaje, while Ross remotely pilots a jet and shoots down planes carrying the vibranium weapons. M'Baku and the Jabari arrive to reinforce T'Challa. Confronted by Okoye, W'Kabi and his army stand down. Fighting in Wakanda's vibranium mine, T'Challa disrupts Killmonger's suit and stabs him. Killmonger refuses to be healed, choosing to die a free man rather than be incarcerated; T'Challa takes him to the waterfall where they fought, where Killmonger dies peacefully. T'Challa establishes an outreach center at the building where N'Jobu died, to be run by Nakia and Shuri. In a mid-credits scene, T'Challa appears before the United Nations to reveal Wakanda's true nature to the world.

Sample of Question-Answer pairs for Evaluation

Thousands of years ago, five African tribes war over a meteorite containing what metal?	vibranium
Where do T'Challa and Okoye travel to South Korea where Klaue plans to sell the artifact?	Busan
What does one warrior ingest affected by the metal and gain superhuman abilities?	heart-shaped herb
Wakandans use the vibranium to develop advanced technology and isolate themselves from what?	the world
Who do T'Challa, Okoye, and Nakia travel to Busan to sell the artifact to?	Everett K. Ross
While Shuri heals Ross, who does T'Challa confront about N'Jobu?	Zuri

Table 13: Gold reference summary for the movie Black Panther with sample of question-answer pairs generated for evaluation.

Movie: Black Panther

Generated Summary After the death of his father King T'Chaka at the United Nations, Prince T'Challa of the African country of Wakanda adopts the title "Black Panther" and assumes the name T'Challa. A meteorite lands on Africa, striking the continent of Africa, and five tribes settle on it including Wakanda. The native people of Wakanda named Wakanda "Wakanda". The people live in harmony with each other and use vibranium, a mineral that gives them superhuman strength, speed, and other powers. A warrior from Wakanda named N'Jobu uses vibranium to make the Heart Shaped Herb, which gives his son T'Challa his powers. A CIA agent, Eric Stevens, traces the Heart Shaped Herb to Ulysses Klaue, a black marketeer attempting to obtain vibranium. T'Challa's aunt and uncle, Nakia and Okoye, lead a mission to retrieve vibranium from Klaue at the request of the African Dora Milaje. They capture Klaue and bring him to T'Challa at the Great Mound. T'Challa challenges Klaue for the throne of Wakanda. The meeting is interrupted by the arrival of Young T'Chaka, T'Challa's half-brother and the son of King T'Chaka. T'Challa takes Klaue on a train trip back to Wakanda with the Dora Milaje, but Klaue injures Ross, a CIA agent. T'Challa and Ross confront Klaue at the train station, and Klaue declares his intention to sell the vibranium to an American buyer in South Korea. T'Challa's aunt and uncle, Nakia and Okoye, tell him that if he sells the vibranium, the Dora Milaje will recover the money and return it to Wakanda. T'Challa agrees to this, and they fly to South Korea to retrieve the Heart Shaped Herb. At the U.S. embassy in Busan, South Korea, they learn that Klaue is actually an operative of the CIA, and that the Heart Shaped Herb has been smuggled into Wakanda by an unknown party. T'Challa and Ross confront Klaue in a casino. Klaue threatens to kill Ross if T'Challa does not hand over the vibranium. T'Challa offers Ross a deal: if he delivers the vibranium, he will be allowed to return to Wakanda. Ross refuses, and Klaue attempts to kill T'Challa, but is stopped by Young T'Challa. T'Challa heals Ross, and the two embark to return to Wakanda. Along the way, Ross reveals himself to T'Challa as an operative of the CIA, and T'Challa takes him back to the CIA. T'Challa and Nakia arrive in Wakanda, where they meet Nakia's mother, Queen Mother Ramonda, and the Dora Milaje. They purchase vibranium from a merchant at the port of Busan. T'Challa presents the Heart Shaped Herb to the people of Wakanda, and Nakia gives birth to a son, T'Challa born T'Chaka. T'Challa and Nakia take the Heart Shaped Herb to Jabariland, where it is discovered that Nakia is a spy for the CIA. The Heart Shaped Herb gives T'Challa superhuman strength and other powers. He goes to Jabariland to find Nakia and finds her serving as a midwife to a dying M'Baku. M'Baku reveals himself to be a spy sent by the CIA to find T'Challa and is confronted by T'Challa. A gunfight ensues, in which T'Challa gains the upper hand, but M'Baku seizes the vibranium and attempts to kill T'Challa. T'Challa uses the Heart Shaped Herb to keep M'Baku at bay, and returns to Wakanda with Nakia, Ross, and the Heart Shaped Herb to deliver T'Challa to his people. Nakia betrays T'Challa to the CIA, and Ross is sent to retrieve the vibranium. T'Challa and Nakia escape with the Heart Shaped Herb and take it to Jabariland, where it is recovered by W'Kabi, the leader of the Jabari tribe. The tribe's leader, W'Kabi, uses it to heal T'Challa, and he returns to Wakanda with T'Challa and the Heart Shaped Herb to reunite the tribes. In the present, T'Challa and Nakia celebrate the opening of Wakanda's new center for science and information exchange with the rest of the world.

Answers using generated summary

Thousands of years ago, five African tribes war over a meteorite containing what metal?	vibranium
Where do T'Challa and Okoye travel to South Korea where Klaue plans to sell the artifact?	Busan
What does one warrior ingest affected by the metal and gain superhuman abilities?	heart shaped herb
Wakandans use the vibranium to develop advanced technology and isolate themselves from what?	United Nations
Who do T'Challa, Okoye, and Nakia travel to Busan to sell the artifact to?	American buyer
While Shuri heals Ross, who does T'Challa confront about N'Jobu?	M'Baku

Don't be a Fool: Pooling Strategies in Offensive Language Detection from User-Intended Adversarial Attacks

Seunguk Yu, Juhwan Choi and **Youngbin Kim**
Chung-Ang University, Republic of Korea, Seoul
seungukyu@gmail.com, {gold5230, ybkim85}@cau.ac.kr

Abstract

Warning: this paper contains expressions that may offend the readers.

Offensive language detection is an important task for filtering out abusive expressions and improving online user experiences. However, malicious users often attempt to avoid filtering systems through the involvement of textual noises. In this paper, we propose these evasions as user-intended adversarial attacks that insert special symbols or leverage the distinctive features of the Korean language. Furthermore, we introduce simple yet effective pooling strategies in a layer-wise manner to defend against the proposed attacks, focusing on the preceding layers not just the last layer to capture both offensiveness and token embeddings. We demonstrate that these pooling strategies are more robust to performance degradation even when the attack rate is increased, *without* directly training of such patterns. Notably, we found that models pre-trained on clean texts could achieve a comparable performance in detecting attacked offensive language, to models pre-trained on noisy texts by employing these pooling strategies.

1 Introduction

As the internet becomes an important part of our lives, the prevalence of offensive language on online platforms, particularly social media, has become a serious concern (Zampieri et al., 2019). Deep learning models for filtering offensive languages have been proposed to address this problem. However, malicious users have consistently found ways to avoid them. One such way is the deliberate insertion of additional typographical errors or substitution of certain characters with visually similar alternatives (Kurita et al., 2019; Wu et al., 2018).

Despite numerous studies on this phenomenon in English, there has been a comparatively limited exploration in Korean, which is a low-resource language characterized by distinct linguistic features (Sahoo et al., 2023; Kim et al., 2021a). As the Korean communities also suffer from the use of abusive language and cyberbullying (McCurry, 2022; Saengprang and Gadavanij, 2021; Yi and Cha, 2020; Jun, 2020), it is desirable to investigate the evasion tactics utilized by malicious users and to formulate them. While recent studies have discussed how to avoid offensive language detection (Cho and Kim, 2021; Kim et al., 2021c; Ahn and Egorova, 2021), their definitions are ambiguous, and no clear solutions have been proposed to defend against the evasions.

In this paper, we propose the evasion methods as user-intended adversarial attacks and incorporate them into offensive language from the perspective of malicious users. Our proposed attacks are grounded in prevalent forms that can be found in offensive language online, and reflect the distinct features of Korean language, wherein a single character can be further subdivided (Song, 2006). We tested the proposed attacks on existing models for offensive language detection, and the results reveal that the performance declines as the rate of the proposed attacks increases.

Furthermore, we introduce simple yet effective pooling strategies in a layer-wise manner to defend against the proposed attacks. Motivated by the exploration of the impact of each layer in a pre-trained language model (Oh et al., 2022; Jawahar et al., 2019), we selectively integrate useful features for the attacked offensive language across all layers[1]. The attacked texts have some changes in the tokens used, differing from the original texts. Therefore, we implement pooling strategies to ensure that the model captures not only high-level features but also low-level features, which are related to offensiveness and token embeddings, respectively. This sim-

---

[1] In our paper, we denote offensive language as 'attacked' when an evasion method is applied to it, viewed from the perspective of malicious users.

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3456–3467
June 16-21, 2024

ple modification enriches the understanding of the attacked offensive language, enhancing the robustness of the model against user-intended adversarial attacks *without* directly training of such patterns.

The contributions of our study are as follows:

- We propose user-intended adversarial attacks that are often associated with offensive language online from the perspective of malicious users. These attacks are performed by inserting special symbols or leveraging the distinctive features of Korean.
- We introduce pooling strategies in a layer-wise manner to selectively utilize all layers rather just than the last layer. This approach achieves a notable performance when employed to a model pre-trained on clean texts, *without* directly training of the attacks.
- We demonstrate the effectiveness of layer-wise pooling strategies by assigning distinct weights to each layer and employing them to the model depending on the nature of the pre-trained texts. We especially note the efficacy of first-last pooling and max pooling when the attacks are involved in offensive language.

2 Related Work

2.1 Adversarial Attacks

Adversarial attacks involve perturbed input data that confuses the trained model, whereas a situation in which the model consistently makes predictions regardless of the nature of input data is referred to as defending (Goyal et al., 2023). Previous studies have explored this based on word-level substitutions (Jin et al., 2020; Ren et al., 2019), and others also have explored them on character-level. We propose adversarial attacks that utilize not only character-level but also smaller-scale alternations tailored to the features of Korean language. Such attacks are commonly observed in the context of offensive languages in various online communities (Cho and Kim, 2021; Ahn and Egorova, 2021).

TextBugger (Li et al., 2019) was an early study that focused on character-level alternations, such as replacing characters with visually similar ones (e.g. replacing the alphabet ‘o’ with the number ‘0’). Other studies have suggested simple leetspeaks that utilize symbols that resemble the alphabet (Aggarwal and Zesch, 2022), or adversarial attacks that are not easily detected visually, such as transforming Latin characters into similar-looking Cyrillic characters (Wolff and Wolff, 2020). Although several studies also have explored visually undetectable attacks (Bajaj and Vishwakarma, 2023; Boucher et al., 2022; Kim et al., 2021b), we consider a more realistic attack scenarios that can occur online from the perspective of malicious users.

2.2 Korean Offensive Language Datasets

Owing to the increasing demand for online content in Korean language and the growing threat of cyberbullying, previous studies have introduced offensive language datasets collecting comments from diverse resources such as online news, communities, and YouTube.

BEEP! (Moon et al., 2020) was a pioneering study that utilized hate speech prevalent in news comments. KoLD (Jeong et al., 2022) and K-MHaS (Lee et al., 2022) specified the target group of the offensive language. Subsequently, KODOLI (Park et al., 2023b) provided labels that refine the degree of offensiveness, and built upon these efforts, K-HATERS (Park et al., 2023a) was built to incorporate the strengths of the preceding datasets.

Although numerous datasets have been proposed, there is still a lack of definition for adversarial attacks that are frequently involved in offensive language, and how to defend against them. In this study, we focus on introducing pooling strategies for defending against these attacks, *without* directly training attacked offensive langauge.

3 Method

3.1 User-Intended Adversarial Attacks

We present adversarial attacks designed to target offensive languages from the perspective of malicious users. By referring to existing offensive language datasets, we define frequently occurring attack types. These attacks are categorized into three groups: INSERT, COPY, and DECOMPOSE. Examples of each attack type are listed in Table 1.

First, INSERT involves adding incomplete Korean character forms, which are often used online without significant meaning. For example, ‘ㅋㅋ’ (equivalent ‘lol’ or ‘lmao’ in English) is a commonly used and somewhat meaningless string frequently used in online communications. In this case, INSERT_*zz* is performed by inserting the string at a specific location within the word, as in real situations. Other types of INSERT also include unnecessary spaces or special symbols.

User-Intended Adversarial Attacks	Text Examples
original text	쓰레기 같은 (piece of shit)
INSERT_*zz*	씈ㅋㅋㅋ레기 같은
INSERT_*space*	쓰 레기 같은
INSERT_*special*	쓰@레기 같은
COPY_*initial*	쓸레기 같은
COPY_*middle*	쓰레에기 같은
COPY_*final*	쓰레기 가튼
DECOMPOSE_*final*	쓰레기 가ㅌ은
DECOMPOSE_*all*	ㅆㅡ레기 같은

Table 1: Text examples of user-intended adversarial attacks with three categories: INSERT, COPY, and DECOMPOSE. There are various attacks that involve special symbols or exploit the distinctive features of Korean.

User-Intended Adversarial Attacks	Tokenized Examples
original text	쓰레기, 같, ##은 (piece of shit)
INSERT_*zz*	[UNK], 같, ##은
INSERT_*space*	쓰, 레, ##기, 같, ##은
INSERT_*special*	쓰, @, 레, ##기, 같, ##은
COPY_*initial*	쓸, ##레기, 같, ##은
COPY_*middle*	쓰, ##레, ##에, ##기, 같, ##은
COPY_*final*	쓰레기, 가, ##튼
DECOMPOSE_*final*	쓰레기, 가, ##ㅌ, ##은
DECOMPOSE_*all*	[UNK], 같, ##은

Table 2: Tokenized examples of user-intended adversarial attacks. Although the texts have the same meaning, the tokens are represented differently.

The following two types of user-intended adversarial attacks take advantage of the distinct features of the Korean language; a single character must have an initial sound, a middle sound, and an optional final sound (Song, 2006). For example, in the expression '쓰레기 같은' in Table 1, the character '쓰' has only the initial and middle sounds, whereas the character '같' has all three sounds.

Second, COPY utilizes the distinctive features, copying one of the three sounds from the selected character to the other character. For example, the character '레' from the expression '쓰레기 같은' has the initial and middle sounds of 'ㄹ' and 'ㅔ'. In this case, COPY_*initial* is performed by copying the initial sound of that character 'ㄹ' to the final sound of the preceding character '쓰'. Consequently, '쓰' is transformed into '쓸', leading to the attacked expression '쓸레기 같은'.

Finally, DECOMPOSE also utilizes the unique characteristics, isolating the final sound of the selected character or breaking down the character itself. For example, the single character '쓰' from the expression '쓰레기 같은' has the initial and middle sounds of 'ㅆ' and 'ㅡ'. In this case, DECOMPOSE_*all* is performed by breaking down the character, resulting in the sounds being independent of that character. Consequently, '쓰' is transformed into 'ㅆㅡ', leading to the attacked expression 'ㅆㅡ레기 같은'. Further details and examples of all user-intended adversarial attacks are provided in Appendix A.

3.2 Layer-Wise Pooling Strategies

In standard text classification tasks, pre-trained models such as BERT are fine-tuned to the target domain. This is based on the assumption that the $[CLS]$ token from the last layer effectively captures the sentence representation (Devlin et al., 2019). However, we notice inconsistencies in the predictions of existing models regarding the proposed attacks[2]. Consequently, we conclude that this information alone is insufficient for detecting the attacked offensive language.

When using perturbed text to a trained model, the tokenization results differ from those of the original text, as shown in Table 2. By involving special symbols or exploiting the distinctive features of Korean, we observed that even if the text had the same meaning to human readers, the tokenized outputs differ significantly[3]. Therefore, we do not rely on the information only from the last layer but utilize the preceding layers, which focus more on token embeddings (Ma et al., 2019). This also reflects the previous finding that meaningful information for a certain task can be captured in the preceding layers (Oh et al., 2022).

We extend pooling strategies in a layer-wise manner, allowing us the flexibility to utilize text representations from all layers. Denoting the $[CLS]$ token of the Nth layer as h_N^{cls}, we introduce four pooling strategies that optionally consider the $[CLS]$ tokens from all the layers $h_1^{cls}, ..., h_N^{cls}$.

Mean, Max Pooling: We apply mean pooling utilizing the L^1 norm, which averages all $[CLS]$ tokens from all the layers, and max pooling utilizing the L^∞ norm, which takes a max-over-time operation on the values corresponding to each dimension from all $[CLS]$ tokens.

When the dimension of $[CLS]$ token is M, and all the values of mth dimension of $[CLS]$ tokens from all the layers are concatenated and denoted

---

[2] The results for this experiment are included in Table 3.

[3] The model used for tokenization in here is BERT$_{clean}$.

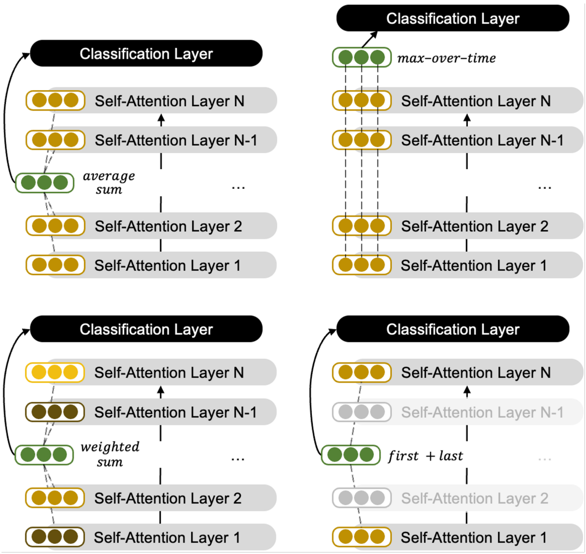

Figure 1: Layer-wise pooling strategies that selectively use $[CLS]$ tokens from all layers. From the upper left, there are mean, max, weighted, and first-last pooling.

by h^m_{all}, these two poolings are defined as follows:

$$pool_{mean} = mean(h_1^{cls}, ..., h_N^{cls}), \quad (1)$$

$$pool_{max} = max(h^1_{all}), ..., max(h^M_{all}), \quad (2)$$

Weighted Pooling: We apply weighted pooling utilizing a learnable parameter that determines the importance of each layer. Through adaptive incorporation of the layers, we train weights that selectively capture both offensiveness and token embeddings, initializing all weights to zero.

When the w_i represents the weight of each layer and α_i represents its softmax distribution, the weighted pooling is defined as follows:

$$pool_{weighted} = \sum_{i=1}^{N} \alpha_i h_i^{cls}, \quad (3)$$

First-last Pooling: We apply first-last pooling utilizing $[CLS]$ token from the first layer. Rather than considering all the layers, we focus on leveraging information from layers directly associated with offensiveness and token embeddings.

$$pool_{first\text{-}last} = h_N^{cls} + h_1^{cls}, \quad (4)$$

The layer-wise pooling strategies described above are illustrated in Figure 1. We conducted experiments to verify the robustness of these strategies for detecting offensive languages that reflect user-intended adversarial attacks.

4 Experiment

4.1 Datasets

We collected both the KoLD (Jeong et al., 2022) and K-HATERS (Park et al., 2023a) datasets and divided them into train, validation, and test sets by stratifying their labels. We randomly shuffled and split them in the ratio of 8:1:1. We set the attack rates to 30%, 60%, and 90%, corrupting a portion of the words in a sentence. The details of how the attacks were carried out are in Appendix A.

4.2 Baselines

We validate the effectiveness of the layer-wise pooling strategies with the baselines, which are presented below. The experimental details including hyperparameters and metrics are reported in Appendix B.

- BiLSTM: This model addresses the long-term dependency problem by remembering only the information in need (Schuster and Paliwal, 1997). It was built by stacking two LSTMs, and the forward and backward $[CLS]$ tokens from the last layer were combined and passed through the classification layer.
- BiGRU: This model is derived from the BiLSTM and further evolved by reducing the training parameters through the selective utilization of gates (Cho et al., 2014). Its configurations are the same as BiLSTM.
- BERT$_{clean}$: This model follows the BERT (Devlin et al., 2019) structure, which is built on a self-attention mechanism with masked language modeling. It was pre-trained on preprocessed texts in Korean (Park et al., 2021). The $[CLS]$ token from the last layer is passed through the classification layer.
- BERT$_{multi}$: This model is pre-trained on multilingual data, including Korean (Conneau et al., 2020). The model structure is based on RoBERTa (Liu et al., 2019), while the remaining configurations are the same as BERT$_{clean}$.
- BERT$_{noise}$: This model is pre-trained on noisy texts in Korean, such as online comments (Lee, 2020). Its configurations are the same as BERT$_{clean}$.
- Ensemble$_{hard}$, Ensemble$_{soft}$: These models utilize both the BERT$_{clean}$ and BERT$_{noise}$, em-

Table 3: Experimental results of offensive language detection when a certain ratio of user-intended adversarial attacks are involved. P, R, and F1 represent macro precision, recall, and f1-score, respectively. Δatk represents the performance drop in the f1-score as the attacks are involved in the same model.

ploying voting methods from ensemble techniques. Hard voting is conducted through a majority vote, but soft voting occurs in the cases of tied votes. Soft voting averages the prediction probabilities of each model.

- DeBERTaV3: This model employs gradient-disentangled embeddings to enhance the efficiency of pre-trianing when incorporating replaced token detection along with DeBERTa (He et al., 2023, 2021). We used the model fine-tuned in Korean[4].

5 Discussion

5.1 Experimental Results

The performances of the models when exposed to user-intended adversarial attacks are presented in Table 3. Each of the best performances from the layer-wise pooling strategies and the baselines in the original, and 30%, 60%, and 90% attacked are highlighted in bold.

All baselines, including ensemble models and even a recent model like DeBERTaV3, were susceptible to the proposed attacks. We observed that the BERT-based models consistently outperformed RNN-based models in terms of the f1-score across all attack rates. Under original and 30% attacked, employing ensemble models with soft voting yielded the best scores, achieving f1-scores of 80.38 and 77.25. As the attack rates increased to 60% and 90%, using a single model pre-trained on noisy texts proved to be the most effective, achieving f1 scores of 71.33 and 66.96, respectively.

Model	Average	
	F1	Δatk
BiLSTM	64.43	**-7.69%**
BiGRU	61.08	-8.70%
BERT$_{clean}$	68.52	-12.85%
BERT$_{multi}$	61.50	-15.02%
BERT$_{clean}$ $+ mean$	69.13	-12.49%
BERT$_{clean}$ $+ max$	68.51	-12.88%
BERT$_{clean}$ $+ weighted$	69.86	-11.70%

BERT$_{noise}$	**71.82**	-9.81%
Ensemble$_{hard}$ (BERT$_{clean}$ + BERT$_{noise}$)	70.99	-11.64%
Ensemble$_{soft}$ (BERT$_{clean}$ + BERT$_{noise}$)	71.23	-11.37%
DeBERTaV3	70.63	-11.88%

Table 4: Average from the experimental results of offensive language detection when a certain ratio of user-intended adversarial attacks are involved.

However, ensemble models require twice computational resources for both training and inference stages compared to a single model. In the case of BERT$_{noise}$, a large amount of noisy texts is required, raising concerns regarding its adaptability when inference with attacked input types is not encountered during the pre-training stage.

When applying layer-wise pooling strategies to BERT$_{clean}$, we found that the performances were improved in almost all attack rates. They only need to train an additional parameter equal to the size of all layers (e.g. 12 for BERT-based models), or no parameters are required. Furthermore, they are robust as the attack rate increases compared to models with no pooling strategies.

---

[4] https://huggingface.co/team-lucid/deberta-v3-base-korean

The average performances when exposed to proposed attacks across all attack rates are presented in Table 4. All layer-wise pooling strategies exhibited robustness against attacks compared to their absence, except for BERT$_{clean}$ + max, which exhibited a slight performance drop. Moreover, even BERT$_{clean}$ + $first\text{-}last$, which only incorporates information from the first layer *without* any parameters or training noisy texts, showed comparable performance to BERT$_{noise}$ across all attack rates that were pre-trained on noisy texts.

5.2 Focus on Performance Drop

The degree to which the f1-scores of the models decreased with the attack rates is shown in Figure 2. We found that BiSLTM exhibited relatively modest performance degradation across the models, which is depicted by the light green triangles. Despite the modest decrease, the offensive language detection scores of RNN-based models were not as good as that of the BERT-based models because of the limitations of themselves.

Among the BERT-based models, BERT$_{clean}$, which was pre-trained on clean texts and is depicted by the light blue triangles, exhibited the largest performance degradation. However, BERT$_{clean}$ + $first\text{-}last$, which applied a simple layer-wise pooling strategy to the model and is depicted by the orange circles, successfully mitigated performance degradation by 1.62%, 3.49%, and 3.28% at each attack rate, respectively, achieving an average performance degradation mitigation of 2.79%.

These results are similar or even better to those of BERT$_{noise}$ or Ensemble$_{soft}$, which used noisy texts in a pre-training stage and are depicted by the blue and deep blue triangles, respectively. Therefore, we found that the model pre-trained on clean texts with a simple pooling strategy can achieve a certain level of performance, or even be more robust compared to the model pre-trained on noisy texts in defending against user-intended adversarial attacks. It was even more robust than the recent model DeBERTaV3, which is depicted by the purple triangles.

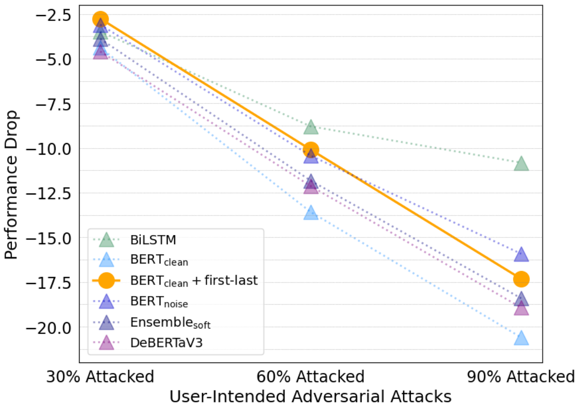

Figure 2: Degree to which the f1-scores of the models decrease with the attack rates 30%, 60%, and 90%. We selected several baseline models and BERT$_{clean}$ + $first\text{-}last$ for the comparison.

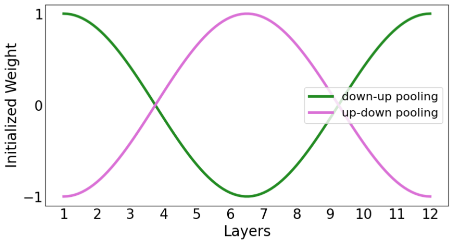

Figure 3: Initialized weights for each of the down-up and up-down poolings. Each strategy shares the shape of a cosine function but varies in the range on the x-axis depending on the layers to be focused.

5.3 Focus on Layer Weights

Additionally, we conducted experiments to determine whether useful information could be captured not only in the first and last layer, but also in the layers close to these two layers of the model. We hypothesized that layers close to the last layer would capture the offensiveness that determine the text representations, whereas layers close to the first layer would capture the token embeddings that determine the degree to which a sentence contains textual attacks. We set all weights to zero for the weighted pooling, however, in this experiment, we assigned distinct weights to all layers.

The weights for the down-up and up-down poolings are shown in Figure 3. We assigned relatively high weights to the layers close to the last and first layers, while assigning low weights to the middle layers. This strategy is referred to as down-up pooling, as its weight graph moves down then up. The green line at the cosine function within the range $[0, 2\pi]$ represents the initial weights for down-up pooling. In contrast, we assigned relatively low weights to the layers close to the last and first layers, while assigning high weights to the middle layers. This strategy is referred to as up-down pooling, as its weight graph moves up then down. The pink line at the cosine function within the range $[\pi, 3\pi]$ represents that of the up-down pooling.

Table 6: Experimental results of offensive language detection when using layer-wise pooling strategies to the BERT$_{noise}$ and DeBERTaV3. The two models differ in whether the texts used for the pre-training stage were preprocessed and their own model structures.

The performances of the models for the distinct layer weights are presented in Table 5. Down-up pooling outperformed for all attack rates and exhibited more robustness against performance degradation compared to up-down pooling. This demonstrates that it is more important to weigh the layers close to the last and first layers than those of the middle for attacked offensive languages. In summary, the strategy that focuses on layers capable of capturing offensiveness and token embeddings yields a better performance.

Nevertheless, neither of these pooling strategies performed as well as the BERT$_{clean}$ or the model that employed the first-last pooling. This indicates that while information close to the last and first layers can be beneficial, there are some layers among them that hinder the performance of the model, revealing that only the last and first layers are the most helpful layers when detecting offensive language with user-intended adversarial attacks.

5.4 Beyond the Limits: Broader Application of Layer-Wise Pooling Strategies

We employed the layer-wise pooling strategies not only to BERT$_{clean}$, a model pre-trained on clean texts, but also to models that utilize noisy texts or employ alternative methods in the pre-training stage. The performances of the layer-wise pooling strategies for both the BERT$_{noise}$ and DeBERTaV3 are presented in Table 6. In BERT$_{noise}$, first-last pooling only performed well on the performance degradation, but the strategy exhibiting more robustness to detection metrics was max pooling.

In the case of BERT$_{clean}$, because it did not directly utilize noisy texts, first-last pooling performed well for attacked offensive language, which focuses most on offensiveness and token embeddings from the sentence. However, in the case of BERT$_{noise}$, where noisy texts were pre-trained into the model weights before the application of pooling strategies, max pooling proved to be the most effective on detection metrics by selecting prominent features among the information to predict the labels invariant to small changes or disturbances.

The results for DeBERTaV3 showed that it performed better with only the model itself when there were no attacks or 30% attacked, while performed better with pooling strategies when the attack rate was increased. We found that the distinct pre-training process of DeBERTaV3, different from the general BERT, was capable of handling a certain level of textual attacks. However, the introduced pooling strategy could prove beneficial in scenarios where the attack rate increases.

The average performances using max pooling and first-last pooling, which had the most impact on each model are presented in Table 7. For the model BERT$_{clean}$ and DeBERTaV3, first-last pool-

Model	Average	
	F1	Δatk
BERT$_{clean}$	68.52	-12.85%
BERT$_{clean}$ + max	68.51	-12.88%
BERT$_{clean}$ + $first\text{-}last$	**71.24**	**-10.05%**
BERT$_{noise}$	71.82	-9.81%
BERT$_{noise}$ + max	**74.08**	-7.64%
BERT$_{noise}$ + $first\text{-}last$	73.57	**-7.00%**
Ensemble$_{hard}$ (BERT$_{clean}$ + BERT$_{noise}$)	70.99	-11.64%
Ensemble$_{soft}$ (BERT$_{clean}$ + BERT$_{noise}$)	71.23	-11.37%
DeBERTaV3	70.63	-11.88%
DeBERTaV3+max	69.89	-11.53%
DeBERTaV3+$first\text{-}last$	**70.78**	**-11.50%**

Table 7: Average from the experimental results of offensive language detection when using max pooling and first-last pooling to the models which exhibited the high scores among the baselines.

ing improved the f1-score by 2.72 and 0.15 and prevented a performance degradation of 2.8% and 0.38%, respectively. In particular, the naive BERT model with the pooling strategies outperformed the ensemble models, and even surpassed the recent model DeBERTaV3 with the pooling strategies. It suggests that the introduced pooling strategies can be employed for a simple structure that solely relies on naive BERT, enabling efficient detection of attacked offensive language without the necessity for the training of noisy texts and strategic pre-training.

In the case of BERT$_{noise}$, max pooling improved its f1-score by 2.26, reaching a relatively high score of 74.08. In terms of performance degradation, first-last pooling exhibited a performance degradation of 2.81%. Thus, we confirmed that implementing the pooling strategies on a model pre-trained with noisy texts resulted in more robust and improved detection of attacked offensive language exceeded others, such as pooling strategies on a model pre-trained with clean texts. The performances of these pooling strategies are remarkable considering that they do not require additional parameters or direct training on noisy texts.

6 Conclusion

We proposed user-intended adversarial attacks that occur frequently in offensive languages online from the perspective of malicious users. We categorized them into three types: INSERT, COPY, and DECOMPOSE, which add special symbols or exploit the distinct features of the Korean language. The involvement of attacks significantly affects the tokenization results from the original text.

To address the proposed attacks, we introduced the pooling strategies in a layer-wise manner. This extension utilizes not only the last layer, which focuses on offensiveness, but also the preceding layers, which focus more on token embeddings. The experimental results indicated that first-last pooling was the most robust to the proposed attacks and could even achieve a comparable performance to that of models pre-trained on noisy texts, when applied to models pre-trained on clean texts. We especially demonstrated that rather than the middle layers, the first and last layers can be effectively employed to detect attacked offensive languages.

Furthermore, we experimented with the extent to which the introduced pooling strategies could handle the proposed attacks. We observed that the first-last pooling and max pooling are the most robust, depending on the nature of the texts used for pre-training. It is noteworthy that these strategies, *without* the explicit training of additional parameters or noisy texts, can effectively defend against user-intended adversarial attacks.

Limitations

Despite our efforts to define diverse types of adversarial attacks, there is room for undefined attacks from real-world situations, which may have an unexpected impact on the model performance. Additionally, although we used some language-independent attacks such as inserting special symbols, most of the proposed attacks were based on the characteristics of the Korean language. Therefore, it is necessary to determine whether layer-wise pooling strategies can effectively handle attacked offensive expressions written in other languages for cross-lingual applications. The introduced pooling strategies offer significant flexibility for models in other languages, requiring simple modifications to the model structure.

Ethics Statement

Given our use of offensive representations to describe the proposed attacks, we have included a disclaimer at the beginning of this paper. From the existing offensive language datasets, potential biases regarding race, gender, political issues, and other factors might have been inherent in our experiments. This should be considered when developing our research or expanding it to other languages.

A User-Intended Adversarial Attacks Details

A.1 INSERT

We utilized three INSERT types by adding special symbols that are not complete characters. The detailed methods and examples are as follows:

- INSERT_*zz*: We randomly added between 2~5 sounds of ‘ㅋ’ to the word (on the keyboard, the sound ‘ㅋ’ corresponds to the alphabet ‘z’). This is a commonly used expression in online, conveying a meaningless and somewhat frivolous tone. We placed it not only between characters but also in instances where the final sound of a specific character was empty.
- INSERT_*space*: We randomly added a single space to the word. We expected the same impact as the intentions of malicious users.
- INSERT_*special*: We randomly added a special character to the word: one of ‘~’, ‘!’, ‘@’, ‘1’, or ‘2’. We also expected the same impact as the intentions of malicious users.

INSERT Attacks	Text Examples
original text	틀딱이냐? (okay, boomer?) 기레기 여기 있었네 (presstitute right here)
INSERT_*zz*	틀ㅋㅋ딱이냐? 기렉ㅋㅋㅋ기 여기 있었네
INSERT_*space*	틀 딱이냐? 기레 기 여기 있었네
INSERT_*special*	틀@딱이냐? 기2레기 여기 있었네

Table 8: Text examples of user-intended adversarial attacks with the types of INSERT.

A.2 COPY

We utilized three COPY types based on the distinctive characteristics of the Korean language. The detailed methods and examples are as follows:

- COPY_*initial*: We copied the initial sound of the character to the final sound of the preceding character. For example, if ‘기’ is chosen from ‘기레기’, the initial sound ‘ㄱ’ would be copied as the final sound to the preceding ‘레’. Consequently, ‘레’ is transformed into ‘렉’, leading to ‘기렉기’.
- COPY_*middle*: We copied the middle sound of the character, onto the newly added character. If the selected character had a final sound, it was also included. For example, if ‘딱’ is chosen from ‘틀딱’, the middle sound ‘ㅏ’ would be copied as the following character with the final sound ‘ㄱ’. Consequently, ‘악’ is newly added, leading to ‘틀따악’.
- COPY_*final*: We copied the final sound of the character to the initial sound of the following character. For example, if ‘있’ is chosen from ‘있었네’, the final sound ‘ㅆ’ would be copied as the initial sound to the following ‘었’. Consequently, ‘었’ is transformed into ‘썼’, leading to ‘이썼네’.

COPY Attacks	Text Examples
original text	틀딱이냐? (okay, boomer?) 기레기 여기 있었네 (presstitute right here)
COPY_*initial*	틀딱인냐? 기렉기 여기 있었네
COPY_*middle*	틀따악이냐? 기레기 여기이 있었네
COPY_*final*	틀딱기냐? 기레기 여기 이썼네

Table 9: Text examples of user-intended adversarial attacks with the types of COPY.

A.3 DECOMPOSE

We utilized two DECOMPOSE types based on the distinctive characteristics of the Korean language. The detailed methods and examples are as follows:

- DECOMPOSE_*final*: We decomposed the final sound of the character into the newly added sound. For example, if ‘딱’ is chosen from ‘틀딱’, the final sound ‘ㄱ’ would be decomposed as the following sound. Consequently, the expression will be ‘틀따ㄱ’.
- DECOMPOSE_*all*: We decomposed all the sounds of the character. For example, if ‘틀’ is chosen from ‘틀딱’, it would be decomposed as the initial, middle, and final sounds. Consequently, the expression will be ‘ㅌㅡㄹ딱’.

DECOMPOSE Attacks	Text Examples
original text	틀딱이냐? (okay, boomer?) 기레기 여기 있었네 (presstitute right here)
DECOMPOSE_*final*	틀따ㄱ이냐? 기레기 여기 이ㅆ었네
DECOMPOSE_*all*	ㅌㅡㄹ딱이냐? 기ㄹ ㅔ기 여기 있었네

Table 10: Text examples of user-intended adversarial attacks with the types of DECOMPOSE.

A.4 How the Attack Works

In our experiments, the attacks were only applied to the test set to evaluate the robustness of the model against user-intended adversarial attacks. We randomly selected one of all the attacks according to the attack rates. For instance, with a 30% attack rate and 9 words in a sentence, we attacked 3 words (30% of them), with each word randomly reflecting one of the proposed attacks.

A.5 Experiments on Each Attack

We further investigated the impact for each attack type, selecting only one of the attacks from only INSERT, COPY, or DECOMPOSE. We chose BERT$_{clean}$ and the model that applied first-last pooling, which exhibited the best performance among the layer-wise pooling strategies.

The performances according to the attack types are presented in Table 11. It is noteworthy that a high performance on a specific attack type indicates that it is easier to defend than others, and vice versa. INSERT proved to be easier than all attacks, with COPY only marginally harder than INSERT. However, DECOMPOSE was more difficult than these attacks, exhibiting a performance degradation compared to all attacks. Therefore, we revealed that adversarial attacks that reflect the characteristics of the Korean language are more challenging than those that simply add special symbols that could be adapted language independently.

Model	All Attacks			Only INSERT		
	P	R	F1	P	R	F1
BERT$_{clean}$	77.74	66.38	67.96	78.12	68.80	70.66
BERT$_{clean}$ + $first\text{-}last$	77.58	69.38	71.21	77.51	70.76	72.54
Model	**Only COPY**			**Only DECOMPOSE**		
	P	R	F1	P	R	F1
BERT$_{clean}$	77.86	68.47	70.29	78.38	62.23	65.67
BERT$_{clean}$ + $first\text{-}last$	77.33	70.50	72.26	77.00	66.47	68.04

Table 11: Experimental results of offensive language detection when the attack ratio is 60% for each type of user-intended adversarial attacks.

B Experimental Details

B.1 Implementation Details

We used 6 layers with an embedding dimension of 768 and a dropout ratio of 0.1 for the RNN-based models, containing BiLSTM and BiGRU. As for the BERT-based models, containing BERT$_{clean}$, BERT$_{noise}$, their ensembles, and DeBERTaV3, we fine-tuned 12 pre-trained layers with an embedding dimension of 768 and a dropout ratio of 0.2.

We used the AdamW optimizer with a learning rate of 1e-5, trained the models for 1~5 epochs, and considered the epoch with the lowest validation loss or the last epoch. We set a batch size of 32 for all the models. The models were implemented using PyTorch and NVIDIA GeForce RTX 3090 GPU. We also used the HuggingFace library to leverage the weights of the pre-trained BERT models.

B.2 Metrics

We collected the datasets to train as many types of offensive languages as possible. There is some label imbalance, therefore, we used macro precision, recall, and f1-score to address this issue.

Δatk represents the performance degradation in the f1-score. For example, denoting the existing f1-score as F1$_{original}$ and the f1-score with the attacks as F1$_{attacked}$, it is computed as follows:

$$\Delta atk = (\text{F1}_{attacked} - \text{F1}_{original})/\text{F1}_{original} * 100. \tag{5}$$

C Examples of the Attacks

We presented the following cases where offensive languages contained user-intended adversarial attacks on popular online communities in South Korea, such as Twitter[5] and Dcinside[6].

- INSERT_*zz*:
  지에지에 개 병ㅋㅋㅋ신
  (ziezie so dumbzzzfuck)
- INSERT_*space*:
  완전 또 라이 아니야...
  (crazy ass we irdo)
- INSERT_*special*:
  넥슨아 이거 개같으면 지워라 새@끼들아
  (delete this if you dare Nexon you sons of bit@ches)
- COPY_*initial*:
  우리나라 남자섺끼들 진짜 재미없게 산다
  (korean lossser men live in the most boring ass lives)
- COPY_*middle*:
  역쉬나 기레에기들..
  (presstiiitutes of course)
- COPY_*final*:
  현생 어떻게 살아가누 너가튼게?
  (how the fuck dooyou live in the real world?)
- DECOMPOSE_*final*:
  과몰입 중인 병신 트ㄹ딱들ㅋㅋ
  (chronically online dumbass bo omers lmao)
- DECOMPOSE_*all*:
  너 같은 ㄱ ㅐ 새끼는 몽둥이로 맞아 죽어야 해
  (p i ece of shit like you need to be beaten to death)

Abstract

Despite recent significant progress, Multi-Object Tracking (MOT) faces limitations such as reliance on prior knowledge and predefined categories and struggles with unseen objects. To address these issues, Generic Multiple Object Tracking (GMOT) has emerged as an alternative approach, requiring less prior information. However, current GMOT methods often rely on initial bounding boxes and struggle to handle variations in factors such as viewpoint, lighting, occlusion, and scale, among others. Our contributions commence with the introduction of the *Referring GMOT dataset* a collection of videos, each accompanied by detailed textual descriptions of their attributes. Subsequently, we propose $\mathtt{Z-GMOT}$, a cutting-edge tracking solution capable of tracking objects from *never-seen categories* without the need of initial bounding boxes or predefined categories. Within our $\mathtt{Z-GMOT}$ framework, we introduce two novel components: (i) $\mathtt{iGLIP}$, an improved Grounded language-image pretraining, for accurately detecting unseen objects with specific characteristics. (ii) $\mathtt{MA-SORT}$, a novel object association approach that adeptly integrates motion and appearance-based matching strategies to tackle the complex task of tracking objects with high similarity. Our contributions are benchmarked through extensive experiments conducted on the Referring GMOT dataset for GMOT task. Additionally, to assess the generalizability of the proposed $\mathtt{Z-GMOT}$, we conduct ablation studies on the DanceTrack and MOT20 datasets for the MOT task. Our dataset, code, and models are released at: `https://fsoft-aic.github.io/Z-GMOT`.

1 Introduction

Multiple Object Tracking (MOT) (Bewley et al., 2016; Leal-Taixé et al., 2016; Wojke et al., 2017; Brasó and Leal-Taixé, 2020; Wu et al., 2021; Cao et al., 2023; Maggiolino et al., 2023; Zhang et al., 2022c; Yan et al., 2022; Meinhardt et al., 2022a; Zeng et al., 2022; Cai et al., 2022a) aims to recognize, localize and track dynamic objects in a scene. It has become a cornerstone of dynamic scene analysis and is essential for many important real-world applications such as surveillance, security, autonomous driving, robotics, and biology.

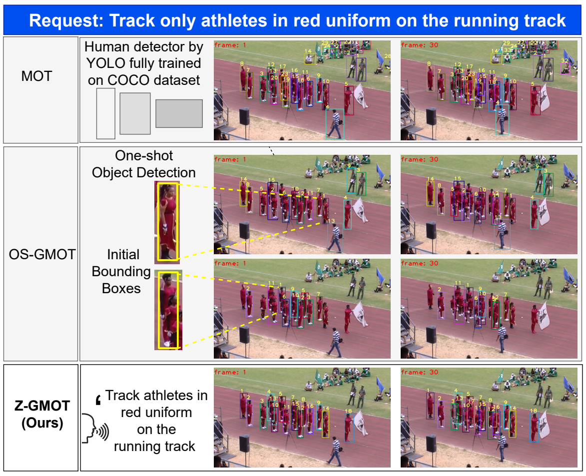

Figure 1: High-level comparison between our $\mathtt{Z-GMOT}$ with conventional MOT and one-shot Generic MOT (OS-GMOT) for the task of tracking athletes in red uniforms on a running track. 1st row: MOT, being a fully-supervised method, using YOLOX (trained on COCO) and OC-SORT (trained on DanceTrack) attempts to detect and track all people in the scene with high False Positive (FPs). 2nd row: OS-GMOT is based on an initial bounding box and utilizes an MOT tracker (e.g. OS-SORT in this case). While reducing the number of FPs, OS-GMOT heavily relies on the initial bounding box, leading to variations in results with different bounding boxes and a high number of False Negatives (FNs). 3rd row: our $\mathtt{Z-GMOT}$ including: (i) $\mathtt{iGLIP}$ effectively detects objects without the need for prior training or initial bounding boxes, and (ii) $\mathtt{MA-SORT}$ efficiently associates objects with high visual similarity.

However, current MOT methods suffer from several limitations: they heavily depend on prior knowledge of tracking targets, requiring large labeled datasets; they struggle with tracking objects of unseen or specific categories; they are limited

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3468–3479

in handling objects with indistinguishable appearances. In contrast to MOT, Generic Multiple Object Tracking (GMOT) (Luo and Kim, 2013; Luo et al., 2014) seeks to alleviate these challenges with reduced prior information. GMOT is tailored to track multiple objects of a shared or similar generic type, offering applicability in diverse domains like annotation, video editing, and animal behavior monitoring. Conventional GMOT methods (Luo and Kim, 2013; Luo et al., 2014; Bai et al., 2021) adhere to a one-shot paradigm (Huang et al., 2020) and employ the initial bounding box of a single target object in the first frame to track all objects belonging to the same class. The conventional one-shot GMOT, which is based on one-shot object detection (OS-OD), is known as OS-GMOT. However, this approach heavily relies on the starting bounding box and has limitations in accommodating variations in object characteristics, including pose, illumination, occlusion, scale, texture, etc.

To overcome the aforementioned limitations of both MOT and OS-GMOT, particularly in the context of tracking multiple unseen objects without the requirement for training examples, we introduce a **novel tracking paradigm** called **Zero-shot Generic Multiple Object Tracking** ($\texttt{Z}-\texttt{GMOT}$, which leverages recent advancements in Vision-Language (VL) models. Our $\texttt{Z}-\texttt{GMOT}$ follows the tracking-by-detection paradigm and introduces two significant contributions aimed at enhancing both the object detection stage and object association stage.

In the first stage, which involves object detection, we introduce an enhanced version of GLIP called `iGLIP`. While GLIP has shown promise in detecting objects based on textual description queries, it faces limitations when tasked with detecting multiple objects with subtle distinguishing features. Specifically, our observations and empirical experiments have confirmed that it is sensitive to threshold settings, leading to high False Positives (FPs) at slightly lower thresholds and high False Negatives (FNs) at slightly higher thresholds. For instance, when asked to identify a "red ball" among multiple balls of various colors, GLIP may erroneously detect balls of different colors at a slightly lower threshold and miss the red ball when the threshold is increased only slightly. To address it, our proposed enhancement, `iGLIP`, incorporates two distinct pathways. One pathway is tailored to handle general object categories like "ball", while the other pathway is dedicated to capturing specific object characteristics, such as the color "red". By integrating these dual pathways, `iGLIP` aims to deliver a more accurate and precise object detection process, especially when dealing with multiple generic objects.

In the second stage, which involves object association, we propose $\texttt{MA}-\texttt{SORT}$ (Motion-Appearance SORT), an innovative tracking algorithm that seamlessly fuses visual appearance with motion-based matching. $\texttt{MA}-\texttt{SORT}$ adeptly measures appearance uniformity and dynamically balances the influence of motion and appearance during the association process.

Figure 1 provides a visual comparison between our $\texttt{Z}-\texttt{GMOT}$ with conventional MOT and OS-GMOT approaches with the task of tracking athletes in red uniforms on a running track as an example. In this comparison, MOT is a fully-supervised learning method that employs YOLOX object detection (Ge et al., 2021) trained on COCO dataset (Chen et al., 2015) and OC-SORT object association (Cao et al., 2023) trained on DanceTrack dataset (Sun et al., 2022). Being a fully-supervised method, MOT attempts to detect and track all people in the scene instead of only athletes in red uniforms as requested. As a result, MOT generates a high number of FPs. In contrast, OS-GMOT relies on an initial bounding box to detect all requested objects. It also utilizes the robust OC-SORT tracker (Cao et al., 2023) for object association. While reducing the number of FPs, OS-GMOT heavily relies on the initial bounding box, leading to variations in results with different bounding boxes and a high number of False Negatives (FNs). Different from MOT and OS-GMOT, our $\texttt{Z}-\texttt{GMOT}$ takes the tracking request in the form of a natural language description as its input to effectively detect and track objects without prior training or initial bounding boxes. Our contributions are as follows:

- We introduce a novel tracking paradigm $\texttt{Z}-\texttt{GMOT}$, capable of tracking object categories that have never been seen before, all without the need for any training examples.
- We present *Referring GMOT dataset* consisting of *Refer-GMOT40* and *Refer-Animal* datasets. These datasets are built upon the foundations of the original GMOT-40 dataset (Bai et al., 2021) and the AnimalTrack dataset (Zhang et al., 2022b) with the inclusion of natural language descriptions.
- We propose `iGLIP` to effectively identifies un-

seen objects with specific characteristics.

- We propose `MA − SORT`, adeptly balancing between object motion and appearance to effectively track objects with highly similar appearances and complex motion patterns.
- We conduct *comprehensive experiments and ablation studies* on our newly introduced Referring GMOT dataset for GMOT task. We extend our experimentation to DanceTrack (Sun et al., 2022), MOT-20 (Dendorfer et al., 2020) datasets for MOT tasks, to illustrate the effectiveness and generalizability of the proposed `Z − GMOT` framework.

2 Related Works

2.1 Pre-trained Vision-Language (VL) Models

Recent advancements in computer vision tasks have leveraged VL supervision, demonstrating remarkable transferability in enhancing model versatility and open-set recognition. A pioneering work in this domain is CLIP (Radford et al., 2021), which effectively learns visual representations from vast amounts of raw image-text pairs. Since its release, CLIP has garnered significant attention (Yamazaki et al., 2022, 2023; Nguyen et al., 2023; Joo et al., 2023; Yamazaki et al., 2024; Phan et al., 2024; Le et al., 2024; Zhang et al., 2024), and several other VL models, such as ALIGN (Jia et al., 2021), ViLD (Gu et al., 2022), RegionCLIP (Zhong et al., 2022), GLIP (Li et al., 2022b; Zhang et al., 2022a), Grounding DINO (Liu et al., 2023), UniCL (Yang et al., 2022), X-DETR (Cai et al., 2022b), OWL-ViT (Minderer et al., 2022), LSeg (Li et al., 2022a), DenseCLIP (Rao et al., 2022), OpenSeg (Ghiasi et al., 2022), and MaskCLIP (Ding et al., 2022), have followed suit to signify a profound paradigm shift across various vision-related tasks. We can categorize VL pre-training models into three main groups: (i) Image classification: Models in this category, such as CLIP, ALIGN, and UniCL, are primarily focused on matching images with language descriptions through bidirectional supervised contrastive learning or one-to-one mappings. (ii) Object detection: This category encompasses models like ViLD, RegionCLIP, GLIPv2, X-DETR, and OWL-ViT, Grounding DINO, which tackle two sub-tasks: localization and recognition of objects within images. (iii) Image segmentation: The third group deals with pixel-level image classification by adapting pre-trained VL models, including models like LSeg, OpenSeg, and DenseSeg. *In this work, we enhance GLIP and propose* `iGLIP` *to effectively capture object with specific characteristics.*

2.2 Multiple Object Tracking (MOT)

Recent MOT approaches can be broadly categorized into two types based on whether object detection and association are performed by a single model or separate models, known respectively as joint detection and tracking and tracking-by-detection. In the first category (Chan et al., 2022; Zhou et al., 2020; Pang et al., 2021; Wu et al., 2021; Yan et al., 2022; Meinhardt et al., 2022a; Zeng et al., 2022; Cai et al., 2022a), both objects detection and objects association are simultaneously produced in a single network. In this category, object detection can be modeled within a single network with re-ID feature extraction or motion features. In the second category (Bewley et al., 2016; Leal-Taixé et al., 2016; Wojke et al., 2017; Brasó and Leal-Taixé, 2020; Cao et al., 2023; Zhang et al., 2022c; Nguyen et al., 2022; Aharon et al., 2022; Du et al., 2023; Maggiolino et al., 2023; Cetintas et al., 2023), an object detection algorithm performs detecting objects in a frame, then those objects are associated with previous frame tracklets to assign identities. It is important to note that the state-of-the-art (SOTA) in MOT has been dominated by the later paradigm. Our `Z − GMOT` approach falls under this paradigm. Particularly, we propose `iGLIP` for zero-shot objects detector and introduce `MA − SORT` for objects association generic objects with uniform appearances.

2.3 Generic Multiple Object Tracking (GMOT)

In recent years, MOT has advanced significantly, but it remains tied to supervised learning prior knowledge and predefined categories, complicating the tracking of unfamiliar objects. Different from MOT, GMOT (Luo and Kim, 2013; Luo et al., 2014; Bai et al., 2021) aims to alleviate MOT's limitations by reducing the dependency on prior information. GMOT is designed to track multiple objects of a common or similar generic type, making it suitable for a wide array of applications, ranging from annotation and video editing to monitoring animal behavior. Thus, GMOT often deals with scenarios where objects appear in groups (such as a herd of cows, a school of fish, or a swarm of ants). Consequently, GMOT faces various challenges, including dense object scenarios, small objects, objects with occlusions, among other complexities. Notwithstanding, conventional GMOT methodologies (Luo and Kim, 2013; Luo et al., 2014; Bai et al., 2021) are predominantly anchored in a one-shot paradigm, i.e. OS-GMOT, leveraging the initial bounding box of a single target object in the first frame to track all objects of the same class. While OS-GMOT shows promise by requiring less prior information, it heavily relies on initial bounding boxes and struggles with viewpoint, lighting, occlusion, and scale variations. Different from MOT (fully-supervised) and OS-GMOT (using initial bounding box), we *introduce a novel zero-shot tracking paradigm known as* `Z − GMOT`. *Our* `Z − GMOT` *enables users to track multiple generic objects in videos using natural language descriptors, without the need for prior training data or predefined categories.*

Table 1 presents statistical information for existing tracking datasets including Single Object Tracking (SOT), Generic Single Object Tracking (GSOT), MOT, GMOT. With the recent advancements and the capabilities of Large Language Models (LLMs), there’s a growing demand for including textual descriptions in tracking datasets. While natural language have already found their place in SOT and MOT datasets, they have been conspicuously absent from GMOT datasets until now. As a result, our dataset is the pioneering effort to address this demand, integrating textual descriptions into the GMOT domain for the first time.

In this work, we propose to incorporate textual descriptions into two pre-existing GMOT datasets, namely GMOT-40 (Bai et al., 2021) and AnimalTrack (Zhang et al., 2022b), and designate them as the *“Refer-GMOT40”* and *“Refer-Animal”* datasets. *Refer-GMOT40* consists of 40 videos featuring 10 real-world object categories, each containing 4 sequences. *Refer-Animal* contains 26 video sequences depicting 10 prevalent animal categories. Each video undergoes annotation, comprising of an **`object`** name, its corresponding **`attributes`** description, and its corresponding **`tracks`**. It’s worth emphasizing that the **`attributes`** description primarily focuses on discernible object characteristics, while **`other_attributes`** aims to offer additional details about the object’s traits. Importantly, some of the attributes listed under **`other_attributes`** may not always be visible throughout the entirety of the video. To maintain the standardized format for MOT challenges, as outlined in (Milan et al., 2016; Dendorfer et al., 2020), each video comes with its tracking ground truth, stored in a separate text file within **`tracks`** annotation. This approach ensures consistency with MOT problem conventions. The annotation process follows the JSON format, and Figure 2 offers illustrative examples of the annotation structure. This data is conducted by 4 annotators and made publicly available.

4 Proposed `Z − GMOT`

Our `Z − GMOT` framework follows the tracking-by-detection paradigm which includes the object detection stage and object association one. In the initial stage, we analyze the limitations of GLIP detector which is our motivation for proposing `iGLIP` for detecting effectively generic objects. In the subsequent stage, we introduce `MA − SORT` to adeptly balance between motion cues and visual appearances to improve the association process.

4.1 Proposed `iGLIP`

We start by analyzing the limitations of GLIP and then proposing `iGLIP`.

Limitations of GLIP. GLIP encounters difficul-

$t = 0.6$ $t = 0.66$

Figure 3: Limitation 1 of GLIP: Sensitive to threshold selection. With slightly different thresholds $t = 0.6$ v.s. $t = 0.66$, GLIP produces different results with high FPs (left) and high FNs (right). Note that GLIP uses prompt *"red car"*) in both results.

$t = 0.64$ $t = 0.64$

Figure 4: Limitation 2 of GLIP: With the same t. ($t = 0.64$) and the same prompt *"red car"*, the results vary when applied to two similar input images.

ties in handling specific object categories (OC^{Spe}) characterized by attributes. As shown in Fig. 3, object detection performance displays sensitivity to threshold selection; even slight threshold variations lead to significant outcome differences. This leads to high TPs at slightly lower threshold and high FNs at slightly higher threshold. Fig. 4 underscores GLIP's drawbacks in effectively capturing objects with specific attributes. Even when using the same threshold selection and prompt, the outcomes exhibit variations on similar images with specific object category OC^{Spe}.

Proposed `iGLIP`. As depicted in Figure 5, our proposed `iGLIP` takes an input image I and two kinds of prompt, namely, a specific prompt (T_s) for OC^{Spe} and a general prompt (T_g) for OC^{Gen}. Both T_s and T_g are derived from the Refering GMOT dataset. Herein, T_g is set as the **`object`** (e.g.,"ball"), while T_s is defined as a combination of **`attributes`** and **`object`** (e.g., "red ball"). Both prompts T_s and T_g go through a text encoder, i.e., BERTModule (Devlin et al., 2018) to obtain contextual word features P^0_s and P^0_g, respectively. Meanwhile, the image goes through a visual encoder, i.e., Swin (Liu et al., 2021) to obtain proposal features O^0. Then, L deep fusion layers (Li et al., 2022b) are applied into contextual word features P^0_s, P^0_g and O^0. The i^{th} layer of deep fusion is as follows:

$$O^i_{s-\text{t2i}}, P^i_{s-\text{i2t}} = \text{X-MHA}(O^i_s, P^i_s) \quad (1a)$$

$$O^i_{g-\text{t2i}}, P^i_{g-\text{i2t}} = \text{X-MHA}(O^i_g, P^i_g), \quad (1b)$$

, where specific proposal features are represented by $O^{i+1}_s = \text{DyHeadModule}(O^i_s + O^i_{s-\text{t2i}})$, general proposal features are denoted by $O^{i+1}_g = \text{DyHeadModule}(O^i_g + O^i_{g-\text{t2i}})$, and specific contextual word features $P^{i+1}_s = \text{BERTModule}(P^i_s + P^i_{s-\text{i2t}})$, general contextual word features $P^{i+1}_g = \text{BERTModule}(P^i_g + P^i_{g-\text{i2t}})$. Notably, where L is the number of DyHeadModules in DyHead (Dai et al., 2021) and $O^0_s = O^0_g = O^0$. X-MHA denotes a cross-modality multi-head attention module. Finally, the word-region alignment module is utilized to compute the alignment score using dot product between the fused features.

$$S^{\text{align}}_s = O_s P^\top_s, \text{ and } \qquad S^{\text{align}}_g = O_g P^\top_g \quad (2)$$

where $O_s = O^L_s \in \mathbb{R}^{N \times d}, O_g = O^L_g \in \mathbb{R}^{N \times d}$ are the visual features from the last visual encoder layer and $P_s = P^L_s \in \mathbb{R}^{M \times d}, P_g = P^L_g \in \mathbb{R}^{M \times d}$ are the word features of OC^{Spe} and OC^{Gen} from the last language encoder layer. The result of this operation are matrices $S^{\text{align}}_s \in \mathbb{R}^{N \times M}, S^{\text{align}}_g \in \mathbb{R}^{N \times M}$. The resulting bounding boxes undergo a filtering process using two parameters: top-κ and threshold $\mathcal{T}$. The top-κ parameter is applied into S^{align}_s to extract a set of queries $\mathcal{B}_q$, which represents template patterns. In order to exclusively detect TPs, we have set $\kappa = 5$. The threshold $\mathcal{T}$ parameter is applied into S^{align}_g to extract a target set $\mathcal{B}_t$. To capture all object proposals, even those potentially including FPs, we set $\mathcal{T} = 0.3$. Query-Guided Matching (QGM) module is then proposed to eliminate FPs in $\mathcal{B}_t$ by using $\mathcal{B}_q$ as template patterns. To perform QGM matching without adding additional cost, we propose to utilize only visual features O^0 extracted from the backbone, without the influence of text embeddings, to ensure the feature is enriched with visual properties. Let O^0_t and O^0_q represent the visual features of object proposals in $\mathcal{B}_t$ and $\mathcal{B}_q$, the matching score is defined as the cosine similarity:

$$S_{qt} = \cos\left(O^0_q \cdot O^{0^T}_t\right). \quad (3)$$

The final detection results comprise the query objects and candidate objects with high similarity.

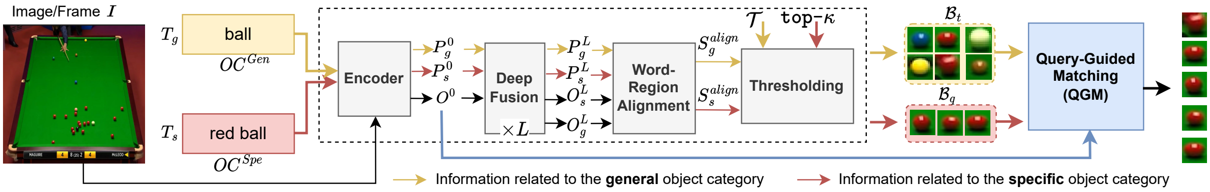

Figure 5: Network architecture of `iGLIP`, which inputs an image I, a general prompt T_g (e.g. "ball"), and a specific prompt T_s (e.g. "red ball"). `iGLIP` includes a QGM module to eliminate FPs generated from the general prompt.

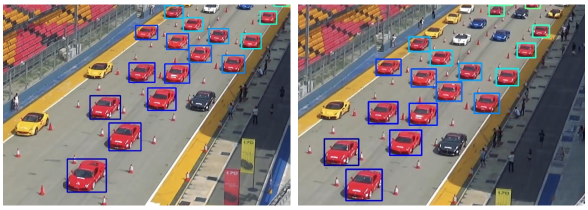

Figure 6: Detection by `iGLIP` with general prompt T_g as "car" and specific prompt T_s as "red car" across images.

Figure 6 illustrates the red car detection by our proposed `iGLIP` with general prompt T_g as "car" and specific prompt T_s as "red car" across all images. All results in Figure 6 are generated with the same default settings of $\mathcal{T} = 0.3$ and $\kappa = 5$.

4.2 Proposed $\texttt{MA} - \texttt{SORT}$

In this section, we introduce our proposed tracking method - *MA-SORT: Balance visual appearance and motion cues:* The standard similarity between N existing track and M detected box embeddings is defined using cosine distance, $C_a \in \mathbb{R}^{M \times N}$. In a typical tracking approach that combines visual appearance and motion cues, the cost matrix C is computed as $C = M_c + \alpha C_a$, where M_c represents the motion cost, measured by the IoU cost matrix. Leveraging DeepOC-SORT (Maggiolino et al., 2023), which computes a virtual trajectory over the occlusion period to rectify the error accumulation of filter parameters during occlusions, the matrix cost becomes:

$$C = IoU + \lambda C_v + \alpha C_a, \tag{4}$$

where C_v represents the consistency between the directions of i) linking two observations on an existing track, and ii) linking tracks' historical observations and new observations. λ and α are hyperparameters to determine the significance of motion and visual appearance, respectively.

To strike a balance between visual appearance and motion cues, we incorporate appearance weight W_a and motion weight W_m into Eq.4. To effectively handle the high similarity between objects of the same generic type in GMOT, we propose the following hypothesis: when the visual appearances of all detections are very similar, the tracker should prioritize motion over appearance. The homogeneity of visual appearances across all detections can be quantified as follows:

$$\mu = \frac{1}{M}\sum_{i=1}^{M} f_i \text{ and } \mu_{det} = \frac{1}{M}\sum_{i=1}^{M} \texttt{cos}(f_i, \mu). \tag{5}$$

Where M is the number of detections in a frame, f_i is a feature vector of the i-th detection gained from re-ID model (Wojke and Bewley, 2018).

Here, we consider θ as a vector distance threshold to determine the similarity between two vectors; if the angle between them is smaller than θ, the vectors are considered more similar.

$$W_a = \frac{(1 - \mu_{det})}{1 - \texttt{cos}(\theta)}. \tag{6}$$

We initialize W_m as 1, indicating that both motion and appearance are equally important. As W_a decreases, we propose redistributing the remaining weight to motion, W_m:

$$W_m = 1 + [1 - W_a] = 2 - \frac{(1 - \mu_{det})}{1 - \texttt{cos}(\theta)}. \tag{7}$$

As a result, the final cost matrix C is:

$$C = W_m(IoU + \lambda C_v) + W_a C_a. \tag{8}$$

5 Experimental Results

5.1 Datasets, Metrics and Experiment Details

We assess our $\texttt{Z} - \texttt{GMOT}$ framework on our Referring GMOT dataset for the GMOT task. To demonstrate the generalizability of $\texttt{Z} - \texttt{GMOT}$ framework, we extend our evaluation to include *DanceTrack* (Sun et al., 2022) and *MOT20* (Dendorfer et al., 2020) for the MOT task. *Refering GMOT dataset*, consisting of *Refer-GMOT40* and *Refer-Animal* dataset, is described in Section 3. *DanceTrack* is

Table 2: Tracking comparison on *Refer-GMOT40* dataset between our `iGLIP` with SOTA OS-OD (Bai et al., 2021) on various trackers. For each tracker, the best scores are highlighted in **bold**.

Trackers	**Detectors**	**#-Shot**	**HOTA↑**	**MOTA↑**	**IDF1↑**
SORT	OS-OD	one-shot	30.05	20.83	33.90
(Bewley et al., 2016)	`iGLIP`**(Ours)**	zero-shot	**54.21**	**62.90**	**64.34**
