Deep-OCSORT	OS-OD	one-shot	30.37	21.10	35.12
(Maggiolino et al., 2023)	`iGLIP`**(Ours)**	zero-shot	**55.89**	**64.02**	**66.52**
MOTRv2	OS-OD	one-shot	23.75	13.87	25.17
(Zhang et al., 2023)	`iGLIP`**(Ours)**	zero-shot	**31.32**	**18.54**	**31.28**

Table 3: Tracking comparison on *Refer-GMOT40* dataset between our `MA − SORT` with other trackers. Our proposed `iGLIP` is used as the object detection. The best scores are highlighted in **bold**.

Trackers	**HOTA↑**	**MOTA↑**	**IDF1↑**
SORT (Bewley et al., 2016)	54.21	62.90	64.34
DeepSORT (Wojke et al., 2017)	50.45	58.99	57.55
ByteTrack (Zhang et al., 2022c)	53.69	61.49	66.21
OC-SORT (Cao et al., 2023)	56.51	62.76	67.40
Deep-OCSORT (Maggiolino et al., 2023)	55.89	64.02	66.52
MOTRv2 (Zhang et al., 2023)	31.32	18.54	31.28
`MA − SORT`**(Ours)**	**56.75**	**64.62**	**68.17**

a vast dataset designed for multi-human tracking i.e., group dancing. It includes 40 train, 24 validation, and 35 test videos, totaling 105,855 frames recorded at 20 FPS. *MOT20* is an updated version of MOT17 (Milan et al., 2016) including more crowded scenes, object occlusion, and smaller object size than MOT17.

We employ the following metrics: Higher Order Tracking Accuracy ($HOTA$) (Luiten et al., 2020), Multiple Object Tracking Accuracy ($MOTA$) (Bernardin and Stiefelhagen, 2008), and $IDF1$ (Ristani et al., 2016). $HOTA$ is measured based on Detection Accuracy ($DetA$), Association Accuracy ($AssA$), i.e. $HOTA = \sqrt{DetA \cdot AssA}$, thus, it effectively strikes a balance in assessing both frame-level detection and temporal association performance. All experiments and comparisons have been conducted by an NVIDIA A100-SXM4-80GB GPU.

5.2 Performance Comparison

Table 4: Tracking comparison on *Refer-Animal* between our `Z − GMOT` and existing *fully-supervised MOT* methods. The best scores are highlighted in **bold**.

Tracker	**Detector**	**Train**	**HOTA↑**	**MOTA↑**	**IDF1↑**
SORT	FRCNN(Ren et al., 2015)	✓	42.80	55.60	49.20
DeepSORT	FRCNN(Ren et al., 2015)	✓	32.80	41.40	35.20
ByteTrack	YOLOX(Ge et al., 2021)	✓	40.10	38.50	51.20
TransTrack	YOLOX(Ge et al., 2021)	✓	45.40	48.30	53.40

ReMOT (Fan Yang and Nakamura, 2021)	61.2	77.4	73.1
GSDT (Wang et al., 2020)	53.6	67.1	67.5
CSTrack (Chao Liang and Zou, 2022)	54.0	66.6	68.6
TransMOT (Peng Chu and Liu, 2023)	-	77.4	75.2
ByteTrack(Zhang et al., 2022c)	61.3	77.8	75.2
OC-SORT(Cao et al., 2023)	62.4	75.7	76.3
ByteTrack†(Zhang et al., 2022c)	60.4	74.2	74.5
OC-SORT†(Cao et al., 2023)	60.5	73.1	74.4
`MA − SORT`**(Ours)**	**61.4**	**77.6**	**75.5**

In Table 2, we benchmark the tracking performance in two scenarios: one involving the use of one-shot object detection (OS-OD) and the other utilizing our proposed zero-shot `iGLIP` on our newly introduced *Refer-GMOT40* dataset. It is important to note that incorporating OS-OD with these trackers is equivalent to achieving SOTA OS-GMOT (Bai et al., 2021). Table 2 clearly shows that our zero-shot `iGLIP`, without requiring any prior knowledge or training, achieves significant performance advantages across various metrics when compared to OS-OD, which relies on initial bounding boxes and is run five times. For instance, on OC-SORT tracker, `iGLIP` shows improvements in HOTA, MOTA, and IDF1 by 26.16, 42.16, and 33.03 points, respectively. On average across all trackers, `iGLIP` outperforms OS-OD by 21.64, 35.67, and 26.61 points in HOTA, MOTA, and IDF1 metrics.

Table 3 shows the comparison between our proposed `MA − SORT` with various trackers using the same object detection, i.e., the proposed `iGLIP` on *Refer-GMOT40* dataset. It is evident that

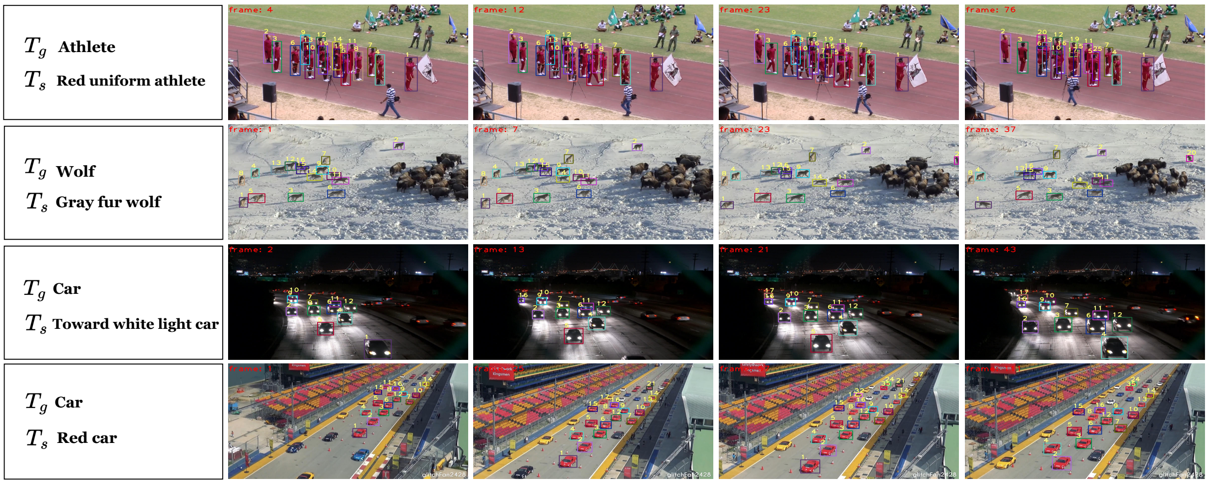

Figure 7: Examples of tracking conducted by our proposed Z − GMOT using input texture descriptions (left). The texture description including both a general prompt T_g, and a specific prompt T_s are integrated into our proposed Z − GMOT framework including iGLIP and MA − SORT.

MA − SORT consistently outperforms other trackers. For example, MA − SORT outperforms DeepSORT and Deep-OCSORT by 6.3, 5.63, 10.62 points and 0.86, 0.6, 1.65 points across all metrics, respectively.

Table 4 presents a comparison between our proposed Z − GMOT and other existing fully-supervised MOT methods on the *Refer-Animal* dataset. In order to ensure a fair comparison, we have also implemented a fully-supervised MA − SORT method with YOLOX object detection. While our MA − SORT with YOLOX object detector achieves the best performance, it is worth noting that Z − GMOT outperforms other fully-supervised MOT methods without the need for any training data.

5.3 Ablation Study

Generalizability of Z − GMOT framework. In addition to the GMOT task, we also evaluate its generalizability on the MOT task, as in Table 5 on DanceTrack dataset. This table presents a comparison of Z − GMOT with the existing fully-supervised MOT methods. To ensure a fair comparison, we have implemented a fully-supervised MA − SORT method with YOLOX object detection. While our MA − SORT with YOLOX achieves the best performance, it is noteworthy that Z − GMOT demonstrates compatibility with SOTA fully-supervised MOT methods, even surpassing SORT, DeepSORT, and MOTDT, all without requiring any training data. In this experiment, both general prompt and specific prompt are set as "dancer".

Effectiveness of proposed MA − SORT. We assess its performance by conducting a comparison on the MOT20 dataset, as outlined in Table 6, focusing on the MOT task. To ensure a fair comparison, we disable certain ad-hoc settings that employ varying thresholds for individual sequences and an offline interpolation procedure. In this experiment, we employed the YOLOX object detector, which demonstrates the effectiveness of MA − SORT.

Effectiveness of proposed iGLIP. We evaluate our iGLIP by comparing it to GLIP (Li et al., 2022b) and OS-OD (Huang et al., 2020) for object detection on the *Refer-GMOT40* dataset, as presented in Table 7(a). iGLIP outperforms other detector methods, achieving the highest scores. It is worth highlighting that despite being an extension of GLIP, iGLIP exhibits significant improvements, with a 0.7% increase in AP_{50}, a 5.0% improvement in AP_{75}, and a 3.9% enhancement in mAP, demonstrating its clear superiority over GLIP.

Table 7: Ablation studies on *Refer-GMOT40*.

(a) Object detection by iGLIP.

Detectors	AP_{50}	AP_{75}	mAP
OS-OD	31.5	13.4	15.8
GLIP	66.2	35.0	36.1
iGLIP	**66.9**	**40.0**	**40.0**

(b) Tracking performance with varied θ.

θ	**HOTA↑**	**MOTA↑**	**IDF1↑**
22.5°	56.57	64.57	67.85
45°	56.58	64.59	67.89
67.5°	56.75	64.62	68.17
80°	56.74	64.62	68.15

Hyper-param θ. Table 7(b) shows ablation study of vector distance threshold θ as defined in Eq.6. The minor variations in tracking performance demonstrate the robustness of our proposed MA − SORT when θ is varied within the range of [22.5°, 80°]. We select $\theta = 67.5$ in the reported results.

5.4 Computational Complexity

To evaluate the computation cost, we report the computational resource of each relevant component and inference time as in Table 8. It is important

Table 8: Properties and computational resources required by our proposed Z-GMOT. Inference time represents an average of 4 videos comprising a total of 1,467 frames.

	MA-SORT + iGLIP				**MA-SORT + YOLOX**	
Properties						
Settings	**Open-set**				Close-set	
Track Agnotic Objects	✓				✗	
Computational Cost						
	Text Encoder	Vision Encoder	DyHead & RPN	Entire Model	Vision Encoder	Entire Model
Model Size (#Params)	108M	197M	122M	427M	99.1M	124.5M
Inference time (seconds/frame)	0.008	0.019	0.17	0.197	0.064	0.069
FLOPs (G)	45.94	181.32	136.91	364.17	281.9	322
GPU memory (Gb)	1.27	2.84	2.09	6.2	8.6	10.2

Table 9: Comparison of tracking performance and computational complexity between RMOT (Wu et al., 2023) and our MA-SORT with YOLO-X object detection. We report on 2 classes of human and car because RMOT was trained on only those two classes.

Methods	**Tracking Performance**						**Computational Complexity**			
	Human			**Car**			Model size	FLOPs	GPUs Usage	Inference Time
	HOTA	MOTA	IDF1	HOTA	MOTA	IDF1				
RMOT (Wu et al., 2023)	1.075	-0.55	1.19	6.57	2.99	5.41	169M	212G	3 GB	0.118 s/f
MA-SORT + iGLIP	47.02	55.88	52.22	57.8	57.66	71.54	427M	364.17G	6.2 GB	0.197 s/f
MA-SORT + YOLOX	33.08	39.00	41.44	29.88	22.71	34.93	124.5M	322G	10.2 GB	0.069 s/f

to note that the reported inference time represents an average, calculated over 4 videos comprising a total of 1,467 frames. All the implementation and comparison have been conducted on A100 40GB.

In Table 8, we report our computational complexity in two scenarios: (i) open-set setting where the proposed iGLIP is used to detect unseen categories. (ii) close-set setting where YOLOX is used to detect pre-defined class. In both scenarios, we use our proposed MA-SORT as an object association.

To evaluate the effectiveness of our proposed Z-GMOT, we suggest to compare with other state-of-the-art methods in the field, focusing on both computational complexity and performance, as detailed in Table 9. Included in this comparison is RMOT (Wu et al., 2023), a state-of-the-art model in referring-MOT. It is important to note that RMOT is based on fully-supervised learning and operates within a close-set environment, specifically targeting the tracking of persons and cars. The analysis and comparisons presented in Tables 8 and 9 reveal that our Z-GMOT not only holds a comparable computational complexity with state-of-the-art referring tracking methods but also surpasses them with substantial margins.

6 CONCLUSION & DISCUSSION

In this study, we present `Z − GMOT`, a novel tracking framework capable of tracking diverse objects without relying on labeled data. `Z − GMOT` adopts a tracking-by-detection paradigm and offers two key contributions: (i) zero-shot `iGLIP` for effective object detection using natural language descriptions and (ii) `MA − SORT` for efficient tracking of visually similar objects within a broader context of generic objects. Beyond proposing `Z − GMOT`, we also introduce a new *Refering GMOT dataset*. We have thoroughly assessed and demonstrated the efficacy and adaptability of `Z − GMOT`, not only in the GMOT task but also in the MOT task.

Discussion. We utilize GLIP as our preferred VLM for developing `iGLIP`. However, it is important to recognize the rich diversity of VLMs available in the field, which opens up exciting avenues for deeper exploration. Moreover, in our current study, we have implemented `Z − GMOT` exclusively using only textual description `object` and `attributes`. Nevertheless, our Referring GMOT dataset offers additional information, such as `object_synonyms` and `other_attributes`, which hold great potential for further research, particularly in the context of prompt tuning or prompt engineering. Exploring these additional aspects of our Referring GMOT dataset could lead to enhanced object tracking capabilities as well as other fields such as surveillance, robotics, and animal welfare. We expect our work to inspire future research in the unexplored realm of unseen MOT/GMOT paradigms, potentially leading to extensions in other tracking scenarios, e.g., open-vocabulary MOT/GMOT.

Abstract

In recent years, counterspeech has emerged as one of the most promising strategies to fight online hate. These non-escalatory responses tackle online abuse while preserving the freedom of speech of the users, and can have a tangible impact in reducing online and offline violence. Recently, there has been growing interest from the Natural Language Processing (NLP) community in addressing the challenges of analysing, collecting, classifying, and automatically generating counterspeech, to reduce the huge burden of manually producing it. In particular, researchers have taken different directions in addressing these challenges, thus providing a variety of related tasks and resources. In this paper, we provide a guide for doing research on counterspeech, by describing—with detailed examples—the steps to undertake, and providing best practices that can be learnt from the NLP studies on this topic. Finally, we discuss open challenges and future directions of counterspeech research in NLP.

Content warning: this paper contains unobfuscated examples some readers may find offensive

1 Introduction

Online spaces provide fertile ground for the diffusion of hateful content, which is often interlinked with episodes of offline violence (Awan and Zempi, 2016). Both witnessing and receiving hateful content can be detrimental to the mental health of victims and create a sense of insecurity (Saha et al., 2019; Siegel, 2020; Dreißigacker et al., 2024), determining the need to mitigate hate. In this context, counterspeech represents a promising strategy to oppose online hate, since it can be more effective than other moderation procedures (Benesch, 2014; Schieb and Preuss, 2016), while also protecting free speech (Kiritchenko et al., 2021). Because of its potential effectiveness, counterspeech has been investigated by non-governmental organisations (NGOs) as a possible strategy to fight online hate. An example of hate speech (HS) and counterspeech (CS) from Fanton et al. (2021) is shown here:[1]

> HS: Women are basically childlike, they remain this way most of their lives. Soft and emotional. It has devastated our once great patriarchal civilizations.

> CS: Without softness and emotions there would be just brutality and cruelty. Not all women are soft and emotional and many men have these characteristics. To perpetuate these socially constructed gender profiles maintains patriarchal norms which oppress both men and women.

Given the amount of hateful content produced, an increasing number of Natural Language Processing (NLP) studies have begun to address the task of automatic counterspeech classification and generation. However, the settled definitions and best practices required to unify these efforts are still missing. While prior surveys largely focused on the effectiveness of deploying counterspeech in the real world (Chaudhary et al., 2021; Adak et al., 2022; Alsagheer et al., 2022; Chung et al., 2023), we offer a complete step-by-step guide on how to conduct NLP research on counterspeech for both newcomers and experts. In particular, we extensively review existing NLP studies and resources on counterspeech, propose common concepts and best practices, and point out the limitations and open challenges of what has been done so far. After providing some background (§2), the guide is articulated in three steps: task design, data selection and evaluation (§3, §4, §5, respectively).[2] Finally, we discuss the open challenges in the field. A complete description of the review methodology we used is provided in Appendix A.1.

---

[1] Throughout the paper, examples are coded with the following colour boxes: red for hate speech, light blue for counterspeech, and grey for everything else.

[2] These sections contain practical recommendations and best practices, marked with the spanner symbol 🔧.

2 Background

To better frame the concept of counterspeech we review definitions that have been proposed for it, the strategies that can be adopted, and several related tasks.

2.1 Definitions

The most common definition of counterspeech is that of Benesch (2014) and Schieb and Preuss (2016), who identify it as non-aggressive textual feedback that uses credible evidence, factual arguments and alternative viewpoints. Other works have focused on the relational nature of counterspeech: it only exists in response to hate speech (Mathew et al., 2019; Ashida and Komachi, 2022), challenging, condemning it or providing an alternative viewpoint (Vidgen et al., 2021; Hangartner et al., 2021). Also, it should explicitly condemn hate or support an abused entity (He et al., 2021; Vidgen et al., 2020). Finally, it is consequences-oriented: it should discourage hate speech (Rieger et al., 2018) and aim to change what people think (Qian et al., 2019).

Although the terms *counterspeech* and *counter narrative* both rely on the idea that "the strategic response to hate speech is more speech" (Bielefeldt et al., 2011), in the social sciences *counter narratives* are representations that challenge dominant views in the areas of education, propaganda and public information (Benesch et al., 2016b).[3] Nevertheless, in the NLP studies included in this survey, these terms have been used interchangeably. Accordingly, we analyse works focusing on both "counter narratives" and "counterspeech", but use the latter term, which we consider to be more appropriate.

2.2 Strategy taxonomies

Counterspeech can be distinguished by the strategy (or strategies) it employs. The most common taxonomy is that proposed by Benesch et al. (2016b), who distinguish seven types of counterspeech: *Presenting facts to correct misstatements or misperceptions*, *Pointing out hypocrisy or contradictions*, *Warning of consequences*, *affiliation*, *Denouncing hateful speech*, *Humor and sarcasm* and *Tone*. Mathew et al. (2019) split the latter category into *Positive* and *Hostile language*, and Chung et al. (2019) add *Counter-questions* on top of these. Other taxonomies have been proposed by Qian et al. (2019) and Vidgen et al. (2020): see Appendix A.2 for more details. However, not all strategies are equally effective: using *Hostile tone* can backfire, or discourage other counterspeakers from joining a conversation (Benesch et al., 2016a). Mathew et al. (2019) show how this type of counterspeech is not well-accepted even by the communities in whose favour it is produced, and provide this example:

> CS: This is ridiculous!!!!!! I hate racist people!!!! Those police are a**holes!!!

Similarly, Benesch et al. (2016a) advise that *Warning of consequences* should never turn into threats, as they show in this positive example:

> CS: Current and future employers will be able to see your tweets, using the hashtag created to attack the chancellor of your university, with misogynist and racist content.

An empathetic, polite and constructive tone is also encouraged in guidelines written by counterspeech movements such as *Get the Trolls out*.[4]

In subsection 3.1, we discuss the task of automated identification of the strategies discussed here.

2.3 Related tasks

To better define counterspeech we describe its similarities and differences to several related tasks.[5] The first of these is **hope speech**, which indicates comments with a constructive view of the future and a peace-seeking intent (Palakodety et al., 2019; Chakravarthi, 2020; Kumaresan et al., 2023; García-Baena et al., 2023; Jiménez-Zafra et al., 2023). However, as opposed to counterspeech, hope speech does not necessarily reply to hate speech or challenge a message with an opposing stance:

> Context: Video about COVID-19.

> Reply: We will survive these things.

An overlapping phenomenon with hate speech is online trolling: an aggressive online behaviour seeking strong reactions for the sake of amusement (Lee et al., 2022a). Various **counter-trolling** strategies have been proposed. However, one of these consists in *reciprocating*, while counterspeech writing guidelines discourage direct attacks on the interlocutor:

---

[3] We refer to Chung et al. (2023) for a more detailed analysis of this distinction.

[4] "Stopping hate: how to counter hate speech on Twitter".

[5] A non-exhaustive list of available datasets for these tasks can be found in Appendix A.3.

Context: You gotta be a fucking idiot to be a sports fan lmao

Reply: Aren't u that guy who has to give ur neighbors the biannual update that ur a sex offender

Fraser et al. (2021) instead, address stereotypes by generating **anti-stereotype** words rather than true counterspeech while Allaway et al. (2022) provide counterstatements to essentialist beliefs (i.e. generalizations about a group):

Context: I speak English, I don't speak libt*rd

Reply: Conservatives can also be stupid.

Even if counterspeech can contain anti-stereotyping messages, not all counterspeech strategies, such as asking *clarifying questions* (e.g. *What do you mean by "libt*rd"?*), address the essentialist belief implicit in a text.

Other existing work has focused on making models better while handling dangerous or unsafe situations. Kim et al. (2022a) present a dataset of **prosocial dialogues**, i.e. conversations in which the speaker responds to potentially unsafe situations by promoting respect for social norms. As opposed to counterspeech, these responses are directed to unsafe rather than hateful texts, as in this example:

Context: I saw someone overdose and didn't tell anyone.

Reply: First of all, that must have been a terrifying situation. It was your responsibility to help the person in need though. If people find out that you saw the person overdose and didn't help, they will certainly not think highly of your behaviour either.

Alternatively, **detoxification** (Laugier et al., 2021; Logacheva et al., 2022) consists in rephrasing toxic comments with civil wording: however, this does not address any possible underlying hateful content, as shown by the following example.

Context: you now have to defend this clown along with his jewish corruption.

Detoxified: you now have to defend this guy from his jewish ties.

Ung et al. (2022) make models open in receiving **feedback** from users **about safety failures** of their generated content. Although this feedback resembles *denouncing* counterspeech, they tackle model-generated rather than user-generated hate speech:

Context: I am getting a kick out of watching you try to think you have value in the family.

Reply: no need to attack someone because you think differently.

Another related task is **counter-argumentation** generation (Hua and Wang, 2018, 2019; Hua et al., 2019; Alshomary et al., 2021; Alshomary and Wachsmuth, 2023). Still, a logically valid counter-argument is not necessarily a good counterspeech, as shown in this example from Fanton et al. (2021):

Context: We should kill all the jews.

Reply: There are many alternatives to removing jews, such as converting them to another religion (e.g. Buddhism).

Finally, **misinformation countering** consists of justifying the veracity of a statement (Stammbach and Ash, 2020; Kotonya and Toni, 2020; Jolly et al., 2022; Ma et al., 2023; He et al., 2023a; Russo et al., 2023a,b).[6] These justifications can have some characteristics in common with counterspeech, e.g. being polite, fluent and relevant (He et al., 2023a; Russo et al., 2023a). However, counterspeech does not always contain evidence, and a factually inaccurate claim is not necessarily hateful, as shown in this example from Russo et al. (2023a):

Context: 11,000 of 13,000 knife attacks in London were carried out by Muslim migrants.

Reply: This claim is baseless as information on offenders' religion and nationality is not held by the authorities. Regardless, the claim is implausible.

3 Step 1: Design your task

The first step is to select which counterspeech task(s) to tackle. We discuss studies covering classification, selection and generation, and derive possible best practices from them.

3.1 Classifying counterspeech

Classification can help to understand counterspeech dynamics and to collect counterspeech data. We consider three sub-tasks.

CS detection. Several works focus on detecting counterspeech as opposed to: non-counterspeech (Mathew et al., 2019; Goffredo et al., 2022; Albanyan et al., 2023a), hate speech (Garland et al., 2020), hate speech and neutral instances (Möhle

---

[6] We refer readers to He et al. (2023b)'s survey, which analyses approaches to crowd-based and effective counter-misinformation.

et al., 2023; Yu et al., 2022; Shah et al., 2022; He et al., 2021; Vidgen et al., 2021), and among Hostility, Criticism and Non-related instances (Vidgen et al., 2020). Finally, Goffredo et al. (2022) also identified messages supporting counterspeech.

User classification. Only Mathew et al. (2020) worked on classifying Twitter users into hateful or counterspeakers: this task can be useful for a platform to intervene early and demote hateful accounts, while promoting counterspeech.

Strategy classification. Detecting the counterspeech strategies[7] used (Mathew et al., 2019; Chung et al., 2021a) can help to analyse their effectiveness and develop more fine-grained responses. Similarly, Albanyan and Blanco (2022) identify counterspeech, determining whether it provided a justification, attacks the author of the hate speech, or includes additional hate.

While some of these classification studies employ only traditional classifiers (Mathew et al., 2020; Shah et al., 2022), others compare them with neural models, showing that the latter perform better or comparably well than the first (Mathew et al., 2019; He et al., 2021; Vidgen et al., 2021). Most studies employ only neural models and experiment with different types of input, showing how including the context (e.g. the hate speech) helps to reduce false negatives (Vidgen et al., 2021; Yu et al., 2022; Albanyan and Blanco, 2022). In fact, hate speech and counterspeech can share similar textual features to some extent, making it difficult to automatically distinguish them without further context (Möhle et al., 2023). Better counterspeech detection performance is obtained by pretraining the models on similar tasks, such as stance (Yu et al., 2022) or emotion detection (Albanyan and Blanco, 2022).

> 🔧 The most common errors in counterspeech classification arise when the text is complex and contains irony or sarcasm (Goffredo et al., 2022; Albanyan and Blanco, 2022), negation (Yu et al., 2022), or when more context is needed to disentagle counterspeech from other categories (Vidgen et al., 2021). Another problem, common to hate speech detection, is lexical overfitting to specific terms or swearwords (Vidgen et al., 2020; Yu et al., 2022). In other cases, errors might arise from the annotation itself (Vidgen et al., 2020). Using a large enough dataset with high-quality annotation can help to reduce such errors.

3.2 Selecting counterspeech responses

One way to produce counterspeech consists of selecting from a pool of possible responses that can be obtained via over-generation (Zhu and Bhat, 2021). Alternatively, the candidates can be retrieved from a counterspeech dataset: Chung et al. (2021c) rely on a *tf-idf* information retrieval model, while Akazawa et al. (2023) employ the implicit stereotype of the hate speech to make a selection via cosine similarity. It is also possible to select counterspeech among non-counterspeech content available online, e.g. from Twitter (Möhle et al., 2023) or online articles (Albanyan et al., 2023a).

> 🔧 Filtering a social media dataset containing both counterspeech and non-counterspeech instances does not produce a larger amount of counterspeech than a random sample (Möhle et al., 2023). Thus, selection seems particularly useful to obtain the most appropriate response to a specific hate speech when a pool of gold (Akazawa et al., 2023; Chung et al., 2021c) or silver (Zhu and Bhat, 2021) counterspeech is already available, rather than filtering out non-counterspeech instances.

3.3 Generating counterspeech

Suitable counterspeech can take many forms: we outline non-exhaustive desirable aspects of counterspeech (knowledge, personality, style), and report relevant techniques for generation (fine-tuning and prompting, translation).

Knowledge guided generation. Both Chung et al. (2021b) and Jiang et al. (2023) structure this task in two phases: first the extraction of relevant knowledge from an external source, and secondly the generation of knowledge-augmented counterspeech. For the first phase, Chung et al. (2021b) used extracted keyphrases to select sentences from Wikipedia articles and news datasets, while Jiang et al. (2023) rely on stance consistency, semantic overlap rate, and fitness for hate speech to construct a knowledge repository from the ChangeMyView subreddit.

Personality guided generation. Examples of this approach are de los Riscos and D'Haro (2021), who employed the PersonaChat dataset to fine-tune a model provided with a dynamic persona profile or dialogue history as input during generation, and Doğanç and Markov (2023), who experimented with both fine-tuning and few-shot prompting to incorporate the profiling information and obtain personalized counterspeech.

---

[7] See subsection 2.2 for an overview of counterspeech strategy taxonomies.

Style guided generation. Here, we include all other stylistic features addressed during generation. To enhance *specificity*, Bonaldi et al. (2023) employ two attention-based regularization techniques to include a broader context during training and generation, while Furman et al. (2023a) focus on the *argumentative information* present in the hate speech to guide the generation towards particular response strategies. Other works target multiple aspects at the same time: Saha et al. (2022) simultaneously control for the *politeness*, *detoxification* and *emotion* in the generated counterspeech. Finally, Gupta et al. (2023) propose a two stage-framework for generating counterspeech conditioned on five different *strategies* (i.e. informative, denouncing, question, positive, and humour).

🔧 Despite the importance of knowledge-driven generation, correcting misinformation alone is not sufficient and can lead to higher levels of violence (Carthy and Sarma, 2023). For this reason, taking into consideration other aspects is fundamental: for example, Hangartner et al. (2021) showed how empathy-based counterspeech can have an impact, however small, in reducing hate speech. Moreover, generating counterspeech with specific strategies according to the targeted community can be particularly effective, and in general, maintaining a polite tone is recommended (Mathew et al., 2019).

Fine-tuning and prompting. The most commonly employed approach for counterspeech generation is fine-tuning a language model on a counterspeech dataset (e.g. Qian et al., 2019; Tekiroglu et al., 2022; Halim et al., 2023). However, recent advances have allowed generation of counterspeech via few-shot (Ashida and Komachi, 2022; Furman et al., 2023a; Vallecillo-Rodríguez et al., 2023; Doğanç and Markov, 2023), one- and zero-shot prompting (Mun et al., 2023; Zheng et al., 2023).

Translation and low-resourced languages. Chung et al. (2020) generate Italian counterspeech by fine-tuning a model on a combination of gold and silver Italian data obtained via translation. Also Vallecillo-Rodríguez et al. (2023) rely on translated examples from Chung et al. (2021b) to create a Spanish corpus via few-shot prompting. Finally, Furman et al. (2023a) include Spanish examples in their generation task.

🔧 Prompting allows generation of counterspeech in a low computationally intensive way: however, given the specificity of the task, few-shot prompting is preferred over one- and zero-shot prompting. Moreover, clear and specific instructions should be given to the model to obtain more fine-grained replies. In particular, both Hassan and Alikhani (2023) and Mun et al. (2023) show how LLMs tend to use general strategies such as *denouncing*, *comment* or *correction* when generating counterspeech without specific indications. Another viable strategy to obtain data in low-resourced scenarios is translation, as shown by Chung et al. (2020) and Vallecillo-Rodríguez et al. (2023), who respectively use silver translated data alone or together with gold data in the language of interest to generate responses in Spanish and Italian.

4 Step 2: Select the data

After task design, the next choice is whether to collect a new dataset or to use an already existing one. We will discuss the use-cases of the main counterspeech collection procedures, and then detail the characteristics of available counterspeech datasets.

4.1 Collecting your own data

Collecting data entails specific consequences according to the chosen strategy (Tekiroğlu et al., 2020): we summarise them below and in Table 1.

Coll.	Data type	Quant.	Conf.	Div.	Non-eph.
Crawl.	Real	✓	-	✓	-
Crowd.	Simulated	✓	✓	-	✓
Niche.	Simulated	-	✓	✓	✓
Hybr.	Synthetic	✓	✓	✓	✓
Auto.	Synthetic	✓	✓	-	✓

Table 1: Data type, quantity, conformity to counterspeech writing guidelines, diversity and non-ephemerality of counterspeech collected with different procedures.

Crawling. This consists of scraping real counterspeech from sources such as Youtube (Mathew et al., 2019), Twitter (e.g. Mathew et al., 2020; Vidgen et al., 2020; Goffredo et al., 2022) , Reddit (Yu et al., 2022; Vidgen et al., 2021; Hassan and Alikhani, 2023), and online articles (Albanyan et al., 2023a). Crawling can guarantee high quantity and diversity of data. However, responses in the wild do not always conform to counterspeech guidelines, as shown in this example from Albanyan and Blanco (2022):

HS: on my way to f**k your b**ch.

CS: But my b**ch is your mamma

To tackle such problems, Hassan and Alikhani (2023) manually remove offensiveness and first-person references from their crawled data. Furthermore, relying on lists of keywords or users may not capture the entirety of available counterspeech. Finally, crawled data might be ephemeral, hindering reproducibility[8] (Klubicka and Fernández, 2018).

Crowdsourcing. Qian et al. (2019) and Furman et al. (2022, 2023a) rely on non-expert annotators to manually produce counterspeech. With crowdsourcing (Crowd.) it is possible to obtain a high quantity of data, although these often contain simple and poorly varied arguments. For example, a large amount of human-written counterspeech can consist in *denouncing* the hate speech: even if this is an acceptable strategy, it represents a simple form of reply, as shown in this example from Qian et al. (2019):

HS: Like... I literally addressed this point and you completely ignore it, like a stupid retard nigger.

CS: Stop using racist and medical conditions as an insult.

Nichesourcing. This relies on experts to produce counterspeech (Chung et al., 2019, 2021b). Nichesourcing (Niche.) can guarantee the highest quality data in terms of syntactic variety and semantic complexity. However, it is also the most expensive strategy, making it difficult to obtain a large quantity of data.

Hybrid and fully automated collection. Hybrid approaches (Hybr.) exploit a combination of automatic and manual intervention to collect data. Tekiroğlu et al. (2020) propose an author-reviewer architecture where a generation model (author) produces hate speech and counterspeech data, and human reviewers filter and post-edit the generated data. This strategy is then employed by both Fanton et al. (2021) and Bonaldi et al. (2022a). Below, an example of counterspeech post-editing from Fanton et al. (2021) is shown:

HS: Transgenders want to rape our children.

CS: This is not true. Maybe they are worried because of the rise in hate crimes, incidents of which are down to 28 percent, since 2014.

CS$_{pe}$: This is not true. Maybe *you should be worried* about the rise in hate crimes *against queers*, incidents of which *are almost doubled* since 2014.

Ashida and Komachi (2022) and Vallecillo-Rodríguez et al. (2023) fully rely on generative models to produce counterspeech (Auto.): human annotators do not intervene.

> 🔧 *Crawling* is the most common data collection procedure used in the wild to gather counterspeech. However, *nichesourcing* can generate the highest-quality responses, since it benefits form expert knowledge. If expertise is limited, partially automatising data collection via a *combination* of a fine-tuned model and human post-editing can be a good solution. If expertise is extremely limited, non-expert annotators or a classifier (Hassan and Alikhani, 2023) can prefilter the data prior to expert validation (Tekiroğlu et al., 2020). Alternatively, non-expert annotators can be trained, following the procedure described in Appendix A.4. However, we discourage relying solely on automatic counterspeech collection without human intervention, given the sensitivity of this task.

4.2 Choosing from existing datasets

An efficient alternative to data collection is selecting among available counterspeech datasets. We describe them along several dimensions, summarised in Table 2, to facilitate the choice of most suitable dataset for specific research needs.

Shape of the interactions. Available datasets can be divided into four main groups according to the type of interaction they contain. Single comments (Single c.) are individually labeled as hate speech, counterspeech, or other classes, without further conversational context, and often come from social media platforms such as Twitter or Reddit (Vidgen et al., 2020, 2021; He et al., 2021). Pairs of hate speech and their related counterspeech are the most widely diffused type of interaction encoded in available datasets (e.g. Chung et al., 2019; Goffredo et al., 2022; Vallecillo-Rodríguez et al., 2023). Alternatively, pairs with context (Pairs+c.) include a longer conversational context, such as previous or subsequent comments (Mathew et al., 2019; Qian et al., 2019; Albanyan et al., 2023b). Finally, Bonaldi et al. (2022a) present hate speech and counterspeech dialogues (Dialog.) including multiple counterspeech turns.

Targets of hate. Most studies include multiple targeted minorities: the most represented are *Jews*, *Blacks*, and *LGBT* (Mathew et al., 2019). Additionally, Chung et al. (2021b), Bonaldi et al. (2022a) and Vallecillo-Rodríguez et al. (2023) consider *Migrants*, *Muslims*, and *Women*, Hassan and Alikhani (2023) cover *Disabled* people, and Fanton et al. (2021) include *Overweight* and *Romani* people on

---

[8] Albanyan and Blanco (2022) and Albanyan et al. (2023b) include only the Tweets IDs and not the full texts.

Table 2: Available datasets, according to their size, nr. of counterspeech interaction type, data collection procedure, source, language, target, and additional information. The data size and the number of counterspeech refer to the interactions shape (e.g. 5,003 *pairs*), except for Qian et al. (2019) and Bonaldi et al. (2022b) where the number of effective counterspeech turns is shown.

top of these. Other studies focus on a single target: in particular, Chung et al. (2019) on *Islamophobia*, whereas He et al. (2021) and Vidgen et al. (2020) on COVID-19 related *Asian* hate. Only Fanton et al. (2021) include, in a few examples, intersectional hate, i.e. hate directed towards people belonging to multiple minorities, such as *black women*. Finally, Albanyan et al. (2023a) is the only research to address hate towards *individuals*, rather than groups.

Types of hate addressed. Chung et al. (2019) identify hate speech according to the sub-topic it covers: *culture*, *economics*, *crimes*, *rapism*, *women oppression*, *history* and *other/generic*. Vidgen et al. (2020) make different levels of distinctions according to the offensiveness intensity (*Hostility* and *Criticism*) and category (*Interpersonal abuse*, *Use of threatening language* or *Dehumanization*). Finally, Vidgen et al. (2021) distinguish hate according to the addressed entity (an *identity*, an *affiliation* or an *identifiable person*) and category (*derogation*, *animosity*, *threatening*, *dehumanization* or *glorification of hateful entities*).

Languages. Most existing datasets are in English, with only a few covering French (Chung et al., 2019), Italian (Chung et al., 2019; Goffredo et al., 2022), and Spanish (Furman et al., 2022, 2023a; Vallecillo-Rodríguez et al., 2023).

Additional information. Other information present in these datasets include the counterspeech strategy (Mathew et al., 2019; Chung et al., 2019; Mathew et al., 2020; Goffredo et al., 2022, see Section 2.2). Similarly, Albanyan and Blanco (2022) specify whether the counterspeech contains a justification or attacks the author, and if it is not a counterspeech whether it agrees with the hater or adds additional hate. Albanyan et al. (2023b) do the same but for replies to counterspeech. Others have considered the *discourse*[9] (Hassan and Alikhani, 2023) and the *argumentative strategy* countering the hate speech (Furman et al., 2022, 2023a).

Then, there can be contextual information on social media platforms data, such as the title of the discussion (Yu et al., 2022), the list of replies and the timestamp (Mathew et al., 2019), the number of likes and replies (Mathew et al., 2019), or the ego network of the users (He et al., 2021).

Other aspects are the annotator demographics, (Chung et al., 2019), or the human annotations: Ashida and Komachi (2022) and Vallecillo-Rodríguez et al. (2023) include the counterspeech offensiveness, stance and informativeness. Further

---

[9] From the Segmented Discourse Representation Theory (Asher and Lascarides, 2003)

fine-grained information include knowledge sentences (Chung et al., 2021b) and paraphrases of crawled counterspeech via the removal of offensiveness and first-person references (Hassan and Alikhani, 2023).

🔧 The choice of the dataset should be driven by task design. It is important to consider the dataset size and the actual number of counterspeech instances: a few examples can be enough for few-shot prompting, while larger datasets are beneficial for fine-tuning or selection tasks. Additionally, the source and procedure of data collection can affect the structure, style, and strategies of the included counterspeech (e.g. Tweets are shorter, crowdsourced data often contain *denouncing* counterspeech). Finally, any additional information can be decisive according to the specific goal of the study, e.g. the knowledge sentences in the dataset by Chung et al. (2019) for knowledge-driven generation.

5 Step 3: Evaluate

Next, we look at the literature on evaluating counterspeech based on the tasks discussed in §3.[10]

5.1 Evaluating classification

When gold test data is available, performance can be assessed via F1, precision, recall, accuracy, and confusion matrices. Moreover, in multi-label scenarios (e.g. counterspeech employing multiple strategies), hamming loss is recommended as it can better capture model performance by considering the ratio of true classes in a prediction rather than a hard right prediction (Mathew et al., 2019). Finally, human judgement can be compared to classifiers to verify their performance (Garland et al., 2020), and qualitative error analysis can help to better understand the specific flaws of a model (Vidgen et al., 2020, 2021; Goffredo et al., 2022; Yu et al., 2022).

5.2 Evaluating generation

Standard evaluation metrics can be grouped into extrinsic (measuring the potential impact of a system on its related tasks or on achieving its overall goals) and intrinsic measures (assessing the system output in isolation, Walter, 1998).

Extrinsic evaluation. So far, only Chung et al. (2021c) have focused on this kind of evaluation. To assess how effective their counterspeech suggestion tool was in empowering NGO operators during hate countering, the operators were asked to evaluate their user experience through a questionnaire (Laugwitz et al., 2008) and open-ended qualitative questions.[11]

Intrinsic automatic metrics. Some of these metrics centre on the comparison between generation and references using criteria such as linguistic surface (Papineni et al., 2002; Lin, 2004), novelty (Wang and Wan, 2018), and semantic similarity (Zhang et al., 2019). Furthermore, some work measures the quality of counterspeech generation based on fine-grained characteristics, such as toxicity (Google Jigsaw, 2022), informativeness (Fu et al., 2023), factuality (Fu et al., 2023), repetitiveness (Bertoldi et al., 2013; Cettolo et al., 2014), linguistic acceptability, politeness, emotion (Saha et al., 2022), stance and relevance to the input (i.e. the hate speech, Schütze, 2008; Halim et al., 2023).

Human evaluation. Several factors should be considered, such as evaluation criteria, scale (e.g. ranking vs. Likert or sliding scale), and annotators (e.g. experts vs. crowd). The common approach is to ask annotators to judge responses on a scale (e.g. of 1 to 5) based on aspects including suitableness and specificity (Chung et al., 2021b; Tekiroğlu et al., 2022; Bonaldi et al., 2023), grammaticality (Chung et al., 2020; Zhu and Bhat, 2021), coherence and informativeness (Chung et al., 2021b).

🔧 While intrinsic automatic metrics can capture the overall performance of generation systems at scale, some of these lack interpretability and correlation with human evaluation (Belz and Reiter, 2006; Novikova et al., 2017). Considering the complexity of hate mitigation, human evaluation is a more reliable approach. Most previous work uses experts or trained annotators for manual evaluation. Since the choice of the best response is subjective, it is desirable to enlist diverse annotators (e.g. in regard to gender and educational level, Waseem et al., 2017; Sap et al., 2019; Abercrombie et al., 2023) or users identifying with the potential recipients of counterspeech such as perpetrators and bystanders.

6 Open challenges

Drawing from the surveyed literature, we highlight key open challenges in counterspeech research.

Language and culture. Hate speech is not only linguistically, but also culturally specific. Therefore, it requires culturally specific responses. For example, in Spanish, the same words can convey discriminatory connotations depending on the country in which they are used (Castillo-López et al.,

---

[10] The metrics described in §5.2 are meant for evaluating generation tasks, but they can be used for selection too.

[11] For a detailed discussion on evaluating the impact of counterspeech in real-life scenarios, see Chung et al. (2023).

2023). Moreover, the same groups can be subject to different stereotypes associated with the historical events of their location (Laurent, 2020).

Sources of hate. A level of granularity not yet considered for counterspeech design is the identity of the hate speech perpetrator. This, in turn, can be considered together with cultural and geographical factors, to produce counterspeech tailored to specific targets (e.g. Italian neonazis).

Types of hate. Studies on counterspeech are mostly centred on explicit hate with only a few addressing stereotypes, prejudice or biases (Mun et al., 2023). Such implicit hate often contains complex linguistic forms with indirect sarcasm or humour (Waseem and Hovy, 2016; Fortuna and Nunes, 2018), and can be generic ("*boys play with trucks*", Rhodes et al., 2012; Leslie, 2014), posing challenges in how to mitigate it (Buerger, 2022).

Hallucinations. Even if counterspeech does not necessarily need to contain factual evidence (§2.3), it can be effective in highlighting the absurdity of hate speech. However, a challenge in open-ended generation is hallucinations.[12] One way to address this is to rely on external knowledge sources (Chung et al., 2021b; Jiang et al., 2023): here, RAG systems (Lewis et al., 2020; Ram et al., 2023) are a promising research direction. Alternatively, inaccurate text can be detected in the generation (Manakul et al., 2023). Finally, counterspeech should be placed in the right temporal context to be more effective: knowledge-grounded generation can help to produce more time-relevant responses.

Evaluation. As discussed in Section 5, existing evaluation metrics are limited. It would be desirable to create test suites analysing different functionalities of counterspeech generation models; e.g. testing models' capacity to generate counterspeech directed at specific types of hate with certain strategies (similar to the HateCheck initiative, Röttger et al., 2021). Additionally, the definition of good counterspeech is subjective and should be user-oriented (e.g. assessed by the target audience). Hence, an ideal evaluation could involve gathering multiple perspectives on suitable counterspeech.

Biases in data collection. Possible biases can emerge from various choices taken during data collection. Firstly, the data source can strongly affect content and style. With crawling, collecting texts from a specific platform will determine its length, style and topics, mainly representing the users of that platform and thus not being highly generalisable. With crowdsourcing and nichesourcing, it should be considered that annotators have different sensitivity to hate, according to their country of origin (Lee et al., 2023), their belonging to a targeted minority, and their personal experiences. This can have a considerable impact on the content of the counterspeech they write too. Moreover, non-experts recur more often to simpler counterspeech strategies such as *denouncing* than experts (Tekiroğlu et al., 2020). Choice of annotators also creates similar possible biases to human evaluation, as discussed above and in section 5.2: for all these reasons, it is better to recruit a diverse set of annotators, if possible. Finally, bias can also originate from the other factors already discussed, i.e. the considered targets of hate, language and geographical/temporal context of the collected data. In general, it is always preferable to provide newly introduced datasets with a dataset card[13] to inform users on how to responsibly employ the data, limiting the emergence of possible harms.

7 Conclusion

We presented a thorough review of 43 NLP studies on counterspeech. This is organised as a step-by-step guide, intended for those approaching counterspeech from an NLP perspective. First, we framed counterspeech and its strategies, distinguishing it from other similar tasks. Then, we structured the subsequent sections as progressive steps to undertake when approaching counterspeech research in NLP: in these sections, we relied on the literature to provide insights into the consequences each choice might imply. Finally, we point out open challenges in the field. Counterspeech represents a promising approach to tackling online hate, and NLP can potentially provide the tools to make it scalable. However, an efficient system is not necessarily a good system: researchers operating in this area must be aware of the consequences entailed by each of their choices, to avoid spreading further harm.

---

[12] I.e, text nonsensical or unfaithful to the provided source input (Ji et al., 2023), often with factually incorrect content.

Limitations

To an external reader, the number of papers included in this study might seem small: this is both because relatively little attention has still been devoted to this topic, and because we made the specific choice of focusing only on NLP papers proposing one or more of the following contributions: a dataset, a classification, selection or generation task. In this survey, we included studies from Scopus, arXiv and the ACL Anthology, following the methodology of previous abusive language surveys in the NLP domain (Chung et al., 2023; Vidgen and Derczynski, 2020). Our search was conducted using keywords, which might not be comprehensive of all the available studies on counterspeech but represents a reasonable compromise for searching in such huge databases. Moreover, all the authors already had research experience in counterspeech and thus had a personal list of counterspeech studies collected over the years—all of which were retrieved with the automated search process.

Ethical considerations

In addition to potential legal issues (see Chung et al., 2023, for a discussion of this), engaging in counterspeech has important social consequences: for this reason, many precautions should be adopted when dealing with it, similarly to other abusive language related domains. First of all, researchers and potential annotators involved in any counterspeech task should prioritise their mental well-being: prolonged exposure to abusive content can have negative effects, that can be avoided by following the mitigation measures described by Vidgen et al. (2019a) and Kirk et al. (2022) (see Appendix A.4 for more details). For what regards data collection and distribution, synthetic data represent a viable option to preserve users privacy. Moreover, using simulated hate speech that are simple and stereotyped can avoid possible negative outcomes such as training a language model on hate speech generation. However, if the collected data are real, it is important to ensure that this does not interfere with the online activities of counterspeakers. For example, if the counterspeech included in a dataset are obtained by scraping from a list of activists' accounts, malicious users might reverse-search these texts, and identify the operators' accounts, thus exposing them to possible attacks. Finally, regarding the deployment of generation systems in real-life scenarios, human supervision is still necessary: the risks of hallucinations and abusive generation are still too high to fully automate the task of counterspeech production in the wild.

A Appendix

A.1 Methodology of the review

Figure 1 shows how the number of published counterspeech papers is subject to a steady growth. To select the studies reviewed in this survey, we follow the PRISMA framework (Moher et al., 2010). The main aim of this review is to provide a guide for tackling counterspeech tasks in the NLP area. Therefore, as inclusion criteria, we only include publicly available papers presenting (i) a computational approach to (ii) text-based tasks that are (iii) related to online counterspeech. In particular, all the included papers either present a data collection, or concern classification, generation or selection tasks. Following previous reviews on counterspeech and abusive language (Vidgen and Derczynski, 2020; Chung et al., 2023), we used three different sources to select the publications of our interest: the ACL Antology, Scopus and arXiv. First, we searched in these databases for all the publications including at least one of the following keywords: *counterspeech*, *counter-speech*, *counter speech*, *counter narratives*, *counter-narratives*, *counter hate*, *counter-hate*, *counterhate*, *hate countering*, *countering online hate speech*. Similarly to Vidgen and Derczynski (2020), since Scopus includes a much broader content, we limited the subject area to *Computer Science*. The automatic selection resulted in 156 papers from Scopus, 31 from arXiv and 20 from the ACL anthology[14]. 23 duplicates were removed. Then, two of the authors manually revised the automatically filtered publications: first they considered only those which were NLP-related (shown as *NLP & CS* in Figure 1). Then, from this subset, they kept only the publications that either presented a data collection, generation, classification or selection task. They also removed too short (e.g. 2 pages initial studies) or not publicly available papers. The disagreements between the authors (regarding 3 papers) were solved by discussion. After this filtering, a total of 43 papers were included in this survey.

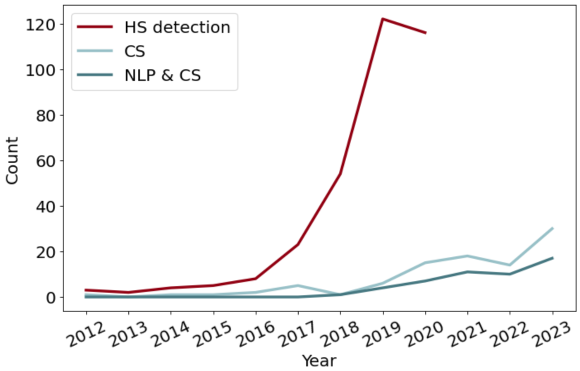

Figure 1: Number of published papers about hate speech detection, counterspeech in general and in the field of NLP. Data for hate speech detection cover only the 2013-2020 time span (Jahan and Oussalah, 2023).

A.2 Examples of counterspeech taxonomies

As mentioned in Section 2.2, the most widely employed counterspeech taxonomy is the one proposed by Benesch et al. (2016b). However, Qian et al. (2019) make a different distinction, based on the observed strategies adopted by the crowdworkers in their study. These consist of *Identifying Hate Keywords*, *Categorize Hate Speech*, *Positive Tone Followed by Transitions*, and *Suggest Proper Actions*. In particular, the strategy of *Identifying Hate Keywords* is based on exhorting users to stop using inappropriate terms. *Categorize Hate Speech* involves the classification of the hate speech into a specific category. *Positive Tone Followed by Transitions* relies on showing empathy first and then proceeding to condemn the hateful text. Finally, with *Suggest Proper Actions* a proactive suggestion is made to the user.

Alternatively, Vidgen et al. (2020) propose a taxonomy where counterspeech are distinguished according to whether it *Rejects the premise of abuse*, *Describes content as hateful or prejudicial*, or *Expresses solidarity with target entities*. Examples of all the identified strategies are shown in Table 3.

A.3 Datasets for counterspeech-related tasks

In Table 4, we make a non-exhaustive list of available datasets for the tasks described in Section 2.3.

A.4 Annotators training procedure

Recognizing, post-editing and writing counterspeech requires expertise and practice. When annotators do not have any previous experience incounterspeech they can be trained to acquire proficiency in the task of interest (Chung et al., 2020; Vidgen et al., 2020, 2021; Fanton et al., 2021; He et al., 2021; Furman et al., 2022; Bonaldi et al., 2022b; Gupta et al., 2023; Bonaldi et al., 2023). The most employed procedure for annotators' training includes the following steps:

a) reading and discussing NGO guidelines and public documentation describing the activity

---

[14] The search was last implemented on 14 December 2023.

	Strategy	Example
Benesch et al. (2016b)	**Presenting facts**	Actually homosexuality is natural. Nearly all known species of animal have their gay communities. Whether it be a lion or a whale, they have or had (if they are endangered) a gay community.
	Pointing out hypocrisy	The 'US Pastor' can't accept gays because the Bible says not to be gay. But...he ignores: The thing about eating shrimp or pork, [...] The thing about working on the Holy Day (Saturday or Sunday depending)...for any and all of those sins one should burn for an eternity, yet is ignored.
	Warning of consequences	I'm not gay but nevertheless, whether You are beating up someone gay or straight, it is still an assault and by all means, this preacher should be arrested for sexual harassment and instigating!!!
	Affiliation	Hey I'm Christian and I'm gay and this guy is so wrong. Stop the justification and start the accepting. I know who my heart and soul belong to and that's with God: creator of heaven and earth. We all live in his plane of consciousness so it's time we started accepting one another. That's all.
	Denouncing hateful speech	please take this down YouTube. this is hate speech.
	Humor and sarcasm	Of course Jews are focused on 'world domination', even "galaxy domination". But so are Sith Order, Sauron etc.
Mathew et al. (2019)	**Positive tone**	I am a Christian, and I believe we're to love everyone!! No matter age, race, religion, sex, size, disorder...whatever!! I LOVE PEOPLE!! We are not going to go anywhere as a country if we don't put God first in our lives, and treat EVERYONE with respect.
	Hostile language	This is ridiculous!!!!!! I hate racist people!!!! Those police are a**holes!!!
Chung et al. (2019)	**Counter-questions**	Is this true? Where is your source?
Qian et al. (2019)	**Identify Hate Keywords**	The C word and language attacking gender is unacceptable. Please refrain from future use.
	Categorize Hate Speech	The term fa**ot comprises homophobic hate, and as such is not permitted here.
	Positive Tone Followed by Transitions	I understand your frustration, but the term you have used is offensive towards the disabled community. Please be more aware of your words.
	Suggest Proper Actions	I think that you should do more research on how resources are allocated in this country.
Vidgen et al. (2020)	**Reject the premise of abuse**	it isn't right to blame China!
	Describe content as hateful or prejudicial	you shouldn't say that, it's derogatory
	Express solidarity with target entities	Stand with Chinatown against racists.

Table 3: Taxonomies of counterspeech proposed by various authors. Both Mathew et al. (2019) and Chung et al. (2019) add new categories to the classes proposed by Benesch et al. (2016b). All the reported examples come from the relative papers, except for the *Humor and sarcasm* example, which is taken from Fanton et al. (2021) dataset.

Dataset	Task	Size	Interact.	Coll.	Source
Lee et al. (2022b)	Counter-trolling	6,686	Pairs	Crawl. and Crowd.	Reddit
Chakravarthi (2020)	Hope speech	59,354	Single c.	Crawl.	YouTube
García-Baena et al. (2023)	Hope speech	1,650	Single c.	Crawl.	Twitter
Palakodety et al. (2019)	Hope speech	921,235	Single c.	Crawl.	YouTube
Kim et al. (2022b)	Prosocial dialogue	58,137	Dialog.	Hybr.	Morality-related data
Logacheva et al. (2022)	Detoxification	12,000	Pairs	Crowd.	Toxic sentences data
Ung et al. (2022)	Feedback on safety failures	7,881	Dialog.	Hybr.	Xu et al. (2021)
Stammbach and Ash (2020)	Misinformation countering	67,687	Triplets	Hybr.	Thorne et al. (2018)
Kotonya and Toni (2020)	Misinformation countering	11,832	Pairs	Crawl.	Fact-checking websites
Ma et al. (2023)	Misinformation countering	690,047	Pairs	Crawl.	Twitter
Alhindi et al. (2018)	Misinformation countering	12,836	Triplets	Crawl.	PolitiFact
Russo et al. (2023b)	Misinformation countering	8,289	Triplets	Crawl.	Fact-checking websites
Russo et al. (2023a)	Misinformation countering	11,990	Triplets	Hybr.	Full Fact

Table 4: Available datasets on tasks related to counterspeech. The data collected by Russo et al. (2023b) are not distributed, but they share the code to replicate the data collection.

of counterspeech writing;

b) reading both examples of counterspeech writing and of the specific task of interest (e.g. post-editing) performed by experts;

c) practice the task on a subsample of examples;

d) discuss disagreements with an expert.

This procedure can last from two to four weeks. Table 5 summarises the steps undertaken by the studies explicitly describing how they trained the annotators. Furthermore, it is important to preserve the *well-being* of the annotators, given the risks involved in working with hateful content. In particular, taking simple precautions like those suggested by Vidgen et al. (2019b) is enough to safeguard the annotators' mental health. These precautions include explaining the prosocial purpose of the research, limiting the annotation time to no more than three hours per day, taking regular breaks, and having several meetings to allow for possible problems or distress to emerge.

Abstract

Providing dialogue agents with a profile representation can improve their consistency and coherence, leading to better conversations. However, current profile-based dialogue datasets for training such agents contain either explicit profile representations that are simple and dialogue-specific, or implicit representations that are difficult to collect. In this work, we introduce the PRODIGy (PROfile-based DIalogue Generation) dataset, which brings diverse representations together, providing a more comprehensive profile dimension set for each speaker. This resource comprises more than 20k dialogues, sourced from movie scripts, aligned with speaker representations such as communication style, biography, personality and gender. Initial experiments with diverse baselines show that providing generative language models with these aspects of a profile, both separately and jointly, enhances models' performance. This improvement holds true in both in-domain and cross-domain settings, for both fine-tuned and instruction-based LLMs.

1 Introduction

Dialogue agents capable of holding human-like interactions have drawn increasing interest in the fields of AI and NLP, becoming a key topic and challenge in both industry and academia. Unlike task-oriented systems focusing on solving specific tasks, open-domain dialogue systems aim to discuss various topics, possibly maintaining a consistent profile in their responses (Kann et al., 2022). In this work, we investigate the role of profile information in open-domain dialogue systems.

Despite recent advancements in conversational agents, due to the continuous development of neural models (Radford et al., 2019; Devlin et al., 2019; Scao et al., 2022; Zhang et al., 2022; Peng et al., 2022), these agents often struggle to maintain coherence, resulting in inconsistent or uninformative responses. This issue adversely affects user engagement and trust (Li et al., 2016b, 2020). In this scenario, endowing dialogue systems with profile information is crucial for enhancing the models' ability to generate fluent, consistent, and informative responses (Li et al., 2016a; Zhang et al., 2018; Zemlyanskiy and Sha, 2018; Song et al., 2019; Majumder et al., 2021; Mazaré et al., 2018).

The concept of *profile* in a dialogue can refer to three aspects: *personalisation*, *persona*, and *personality*. *Personalisation* refers to employing users' information to drive engagement and help them satisfy their needs (Vesanen, 2007). *Personality*, on the other hand, is a psychological concept meant to capture how we behave and react to the world (Allport, 1937; Vinciarelli and Mohammadi, 2014). The notion of *persona* can have diverse meanings in literature. In this work, we will stick to the definition provided by Li et al. (2016a), according to which the persona is the character that an artificial agent plays during conversations and includes elements such as background facts, language, and interaction style.

Several approaches have been explored to integrate persona information into dialogue generation (Li et al., 2016a; Mazaré et al., 2018; Welch et al., 2022; Zhang et al., 2018; Song et al., 2021; Zheng et al., 2020; Cao et al., 2022; Majumder et al., 2020; Liu et al., 2020; Majumder et al., 2021; Zheng et al., 2019). However, these methods are typically sporadic and disjointed, addressing only one persona dimension at a time, either through an *explicit* representation (a few simple, dialogue-specific sentences about the user) or an *implicit* representation (a collection of the user's previous dialogues) that is challenging to obtain. Consequently, these approaches fail to model the complex nature of human communication, which is influenced by the interaction of multiple aspects.

In this paper, we investigate the impact of diverse profile representations in the development of

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3500–3514

Character_id: u9999 **Gender:** ♀

MBTI: Extrovert, Sensor, Feeler, Perceiver

Biography: I am an actress, a star. / I live in an old mansion, built for glamorous stars of 1920s Hollywood, just off of Sunset Boulevard. / I am impatient, snobby, and selfish. / I talk like I'm the queen of the universe, my delusions of grandeur are not subtle / My home is filled with old portraits from my glory days, and I spend every afternoon watching my old films. / I am a narcissist and interested in myself. / ...

What's the matter, Norma?

Nothing. I just didn't realize what it would be like to come back to the old studio. I had no idea how I'd missed it.

We've missed you too, dear.

We'll be working again, won't we, Chief? We'll make our greatest picture.

That's what I want to talk to you about.

It's a good script, isn't it?

It's got a lot of good things. Of course, it would be an expensive picture...

I don't care about the money. I just want to work again. You don't know what it means to know that you want me.

Figure 1: Example of a dialogue with diverse speaker's profile information provided.

dialogue systems by comparing and benchmarking them. To this end, we introduce a new dataset, named PRODIGy (PROfile-based DIalogue Generation)[1], that combines existing profile representations (i.e., language style, gender, personality) with novel and more complex representations of the persona, such as biographies. PRODIGy is created starting from the Cornell Movie Dialogs Corpus (Danescu-Niculescu-Mizil and Lee, 2011), which includes movie script dialogues, and adopting the character IDs and binary gender labels from the original corpus. This approach avoids privacy concerns related to employing real user data and simplifies the distribution. Moreover, the dataset has been aligned with external resources containing characters' profiles, and it can be further expanded by adding new scripts or scripts in other languages. Figure 1 illustrates an example from PRODIGy, in which the dialogue is aligned with the target speaker's profile representation.

We validated PRODIGy by benchmarking it with diverse baselines. In particular, we employed either fine-tuning or instruction prompting, and tested a range of configurations varying the profile dimensions, both in-domain and cross-domain. Evaluation involved both automatic metrics and human assessment. As for automatic metrics, in-domain experiments show that fine-tuning LMs with diverse profile aspects significantly improves their predictive capabilities. Additionally, instructing non-fine-tuned LLMs with profile information also improves their performance. In cross-domain settings, PRODIGy-based models show better generalisation than those trained on other persona-based resources. In human evaluations, evaluators had a tendency of favouring generic responses for broader applicability. However, when responses were consistent with both profile and dialogue they were clearly preferred. Profile information proves beneficial especially in dialogues with limited context, and when disclosed to evaluators, profile-based responses are deemed more appropriate.

2 Related Work

We discuss three main topics relevant to our work: (i) theories on persona and personality (ii) available datasets for persona-based generation and (iii) persona and personality based models.

Persona and Personality Our communication style is closely related to social status, gender, and motivations, and offers insights into our psychological state (Pennebaker et al., 2003). These aspects are closely related to the concepts of *persona* and *personality*, which fall under the more general concept of *profile* (Schiaffino and Amandi, 2009). *Persona* can be defined as the character that an artificial agent acts during a conversation and it is a combination of identity factors, such as background facts, language use, and communication style (Li et al., 2016a). *Personality* is a psychological concept grasping different behaviours, feelings and way of thinking (Allport, 1937; Vinciarelli and Mohammadi, 2014). It can be formalised using theoretical frameworks called *trait models*, such as *Big Five* (John et al., 1991) and the *Myers-Briggs Type Indicator (MBTI)* (Myers, 1962).

Persona-Based Dialogue Datasets Several dialogical datasets contain a persona representation, many of which were collected starting from social media such as Twitter, Reddit, Weibo or Kialo. However, these datasets have various limitations. They may encounter challenges related to ephemer-

---

[1] The dataset will be distributed for research purposes at the following link: `https://github.com/LanD-FBK/prodigy-dataset`.

ality (Klubicka and Fernández, 2018); they can include short conversations, thus failing to fully represent real dialogues (Li et al., 2016a; Mazaré et al., 2018); they can rely only on users' dialogue history (Qian et al., 2021); they may include only generic persona representations such as gender or age (Zheng et al., 2019; Zhong et al., 2020); finally, they may not consider linguistic style, being based on controlled and redacted conversations (Scialom et al., 2020). Other resources were collected from television series transcripts (Li et al., 2016a), but are small and not sufficient to train open-domain dialogue models. One of the most widely used persona-based datasets is Persona-Chat (Zhang et al., 2018), collected in a controlled crowd-sourcing environment. However, it provides a generic fact-based persona representation (e.g. *"I just got my nails done"*) specific to single dialogues and leaving out complex aspects, such as linguistic style or biographical history.

Persona/Personality Based Dialogue Models Several approaches have been investigated to condition the dialogue generation through the persona information. On the one hand, diverse studies were based on resources using users' past dialogues to represent the persona (Li et al., 2016a; Mazaré et al., 2018; Zhong et al., 2020). On the other hand, a line of research has been built on Persona-Chat. Various approaches employed this dataset to train persona-based models in under-resourced scenarios (Song et al., 2021; Zheng et al., 2020; Cao et al., 2022). Other methodologies used Persona-Chat to test commonsense expansion (Majumder et al., 2020), mutual perception persona (Liu et al., 2020), or enriching persona information through background stories (Majumder et al., 2021). However, these studies present the same limitations of the resources they rely on. Regarding the personality-driven generation, few seminal studies have been conducted (Mairesse and Walker, 2007, 2008; Gill et al., 2012). However, they leave the interactions between personality and persona unexplored.

3 Construction of the PRODIGy dataset

To build the PRODIGy dataset, we started from the Cornell Movie Dialogs Corpus, a dataset of dialogues from movie scripts that includes metadata about movie genre, release year and characters' gender (Danescu-Niculescu-Mizil and Lee, 2011). The dialogues in the Cornell Movie Dialogs Corpus are between two actors and have an average length of 4 turns. The reason for using this resource as a starting point is three-fold: (i) *Data Persistency and Accessibility:* it eliminates privacy issues or ephemerality problems (Klubicka and Fernández, 2018) that would arise from collecting data from real users and, therefore, facilitates the distribution of PRODIGy to the research community; (ii) *Data Enrichment:* it is possible to enrich PRODIGy with the profile of movie characters through the alignment with external web resources containing information about characters and movie plots; (iii) *Data Expansion:* it leaves room for further development/extension; for example, it can be aligned with similar movie script resources in other languages or new movie scripts.

Below, we outline the profile representations and detail the methodology employed to annotate the characters within the dataset.

Dialogical Information. Following previous approaches (Li et al., 2016a; Qian et al., 2021), we provide an implicit representation of each character's persona through a collection of characters' dialogues. Thus, we can represent the characters' linguistic styles. To this end, we included in PRODIGy only the characters with at least 50 dialogues in the Cornell Movie Dialogs Corpus.

Personality Information. To associate each character with *personality* information, we cross-referenced the Cornell Movie Dialogs Corpus with the Personality Database (PDB)[2] website. PDB is a widely used social platform in which users can assign personality types from several trait models to fictional characters and real famous people. We use this platform as a provider of crowd-sourced characters' personality annotations.

To annotate the characters in the Cornell Movie Dialogs Corpus, we used the query `movie_title+year` to extract from PDB the metadata related to each movie, containing the list of the characters' names and IDs. If the character was present in the metadata, we used the query `PDB_characterID` to extract the MBTI type and related votes. If the MBTI type had at least 5 votes, the character was annotated. If the character was not in the metadata, a human annotator performed a manual check within PDB to verify if there was an actual match. In case the mismatch could be manually resolved, we replicated the above procedure to annotate the character. Details of the alignment

---

[2] https://www.personality-database.com/

procedure are provided in Appendix A.1.

Among the several trait models provided by PDB on each character's web page, we focused on MBTI since it is widely studied and it was the most voted model by users, thus proving a more stable and reliable crowd-annotation. The MBTI trait model takes into account 16 personality types obtained from the combination of 4 dichotomies: introversion or extroversion, sensing or intuition, thinking or feeling, and judging or perceiving.

In line with the definition of personality traits, which posits their stability over time, we assigned a unique MBTI personality type to each character. This differs from the approach of Jiang et al. (2020), who assigned a different personality for each dialogue in which the character is present. Finally, for annotation reliability, we discarded the characters (and related dialogues) with less than 5 user votes and used the personality type derived from the majority of votes on each MBTI dichotomy.

Biographical Information. The third step was to provide the characters with explicit persona representations that serve as background information for all the dialogues in which the character is present. Inspired by the concept of *background story* by Majumder et al. (2021), we aim to provide a representation that goes beyond simple facts. To this end, we consider the biographical information. We scraped the biographies of the characters annotated with the personality information, from Charactour.com, Fandom.com and Wikipedia. Then, to automatically extract the most relevant sentences, we employed an extractive summarisation algorithm based on Kullback-Leibler distance (Haghighi and Vanderwende, 2009). Subsequently, a human-machine collaboration procedure followed, where a human annotator[3] modified the extracted sentences to ensure that our resource maintains an alignment with the Persona-Chat dataset (Zhang et al., 2018) for comparability purposes. To achieve this, specific guidelines were formulated and provided to the annotator:

- Re-rank the top 10 sentences in order of importance, according to the speaker's profile.
- Convert the sentences from the third to the first person singular.
- Shorten excessively long sentences.
- Enrich the sentences with missing relevant information;
- If a character biography was not found, create one by reading the movie plot.

In particular, the annotator re-ranked the sentences giving priority to crucial information that the summarisation algorithm might have originally positioned towards the end of the list, ensuring it now appears within the top five sentences. The importance criterion followed the structure of a small selection of biographies that were considered as gold. For instance, details about characters' job, lifestyle, or family background were expected to be on top of the list.

While PRODIGy biography sentences align stylistically with Persona-Chat (Zhang et al., 2018), they are not limited to generic facts and capture more complex aspects of the persona, making them qualitatively different from Persona-Chat.

To increase the number and the variability of biography sentences, ChatGPT (OpenAI, 2022) was given the original sentences and asked to produce two paraphrases. These new sentences were given to the annotator for post-editing to correct errors or further paraphrase those still too similar to the original biographies. More details about the biographical information procedure are provided in Appendix A.2. In Table 1, we present an example of the biography editing process.

As a result of the aforementioned procedures, we obtained a dataset with more than 20K dialogues for 80K turns with 300 annotated characters and more than 8k biography sentences. The dialogues are aligned with the following dimensions of one of the speakers: gender, personality type, character's biography, and linguistic style modelled by character's dialogues. Character biographies consist of an average of 8 sentences, ranging from 5 to 10 sentences, with an average of 13 tokens per sentence. Each biography sentence has been paraphrased twice. Detailed statistics of the PRODIGy dataset are provided in Table 2.

4 Baselines and Experiments

In this section, we propose several configurations to condition the dialogue generation with profile information. In particular, we represent profiles by using either the persona, the personality information, or both. Our aim is to analyse the impact of each representation on the generation process.

For all the configurations, we employed the DialoGPT model as our baseline since it is a generative transformer-based model pre-trained on

---

[3] The human annotator was one of the authors and a Computer Science PhD student.

Table 2: PRODIGy main statistics. The upper part reports counts, while the lower reports averages.

conversation-like exchanges (Zhang et al., 2020), making it the most suitable baseline for the dialogue generation task. We investigated several fine-tuning configurations. As a baseline, we fine-tuned DialoGPT without any profile information, while in the remaining configurations we fine-tuned the model considering both single profile dimensions and their combinations. Specifically, we concatenated the characters' profile information to the corresponding turns of the dialogues. In Appendix B, we provide details on the fine-tuning setup and input syntax utilised for DialoGPT.

Besides DialoGPT, we also experimented with GODEL (Peng et al., 2022), an instruction-based LLM specific for dialogue generation. Our aim is to assess the effect of providing profile information as an instruction to a non-fine-tuned LLM. The input syntax for GODEL is shown in Appendix C.

Although more powerful models are available, such as ChatGPT (OpenAI, 2022) and LLaMa 2-chat (Touvron et al., 2023), we chose to use DialoGPT and GODEL as our baselines for the following reasons: (i) ChatGPT and LLaMa 2-chat are explicitly intended for assistant-like chat (i.e. human-machine interactions), whereas our goal is to explore dialogue models simulating broader human-human interactions, playing the role of any of the two speakers; (ii) we chose two language models comparable in pre-training data (i.e., similar human-human dialogical interactions) and parameter size; (iii) these models were already used for the dialogue generation task and allow testing of two main approaches: DialoGPT for fine-tuning and GODEL for instruction prompting in a zero-shot setting.

Regarding the inspected configurations, we provide the description as follows:

Plain Dialogue Driven Generation In the first configuration, we fine-tuned DialoGPT and instructed GODEL only with the plain dialogue, without considering any profile information. This configuration will be used as a baseline to assess the improvement obtained by adding the various profile information to both models.

Personality Driven Generation In this configuration, we employ PRODIGy and the characters' MBTI to fine-tune DialoGPT and prompt GODEL, as it is possible to generate language reflecting a certain personality type (Mairesse and Walker, 2007, 2008; Gill et al., 2012).

Persona Driven Generation In this configuration, we employ the implicit (i.e. linguistic and stylistic information) and explicit (i.e. gender and biography sentences) persona representations in PRODIGy, either individually or jointly. This enabled us to analyse the effect of each representation and combination in the dialogue generation.

Firstly, we used the characters' dialogues as implicit persona representation (Li et al., 2016a; Qian et al., 2021). We fine-tuned DialoGPT on PRODIGy, aggregating characters' dialogue lists using their IDs to capture their linguistic styles. Secondly, inspired by Zheng et al. (2019) and Schwartz et al. (2013), we considered gender as another persona representation to fine-tune DialoGPT and instruct GODEL. Then, motivated by Zhang et al. (2018), we provided DialoGPT and GODEL with persona information in the form of biography sentences. Our aim is to generate non-generic and informative responses that are consistent with both the dialogues and the biography sentences.

Inter-Character and Intra-Character Configurations Using PRODIGy, we set up two configurations to train DialoGPT: *inter-character* and *intra-character*. In the first configuration, the test characters are not used at training time. In the second configuration, at training time the system learns about the specific characters to be predicted at test time. In both cases, we use only 5 biography sentences, following Zhang et al. (2018). These two configurations also address privacy concerns: in one case, the LM does not retain any personal information but uses it only at inference time, while in the second, the LM stores the information about the user in its internal representation.

5 Automatic Evaluation

In this section, we describe the metrics and experiments for the validation of our resource.

5.1 Metrics

We assess model performances using two metrics: *Conditional turn Perplexity* (Su et al., 2021) and *Average Accuracy at N* (Welch et al., 2022).

Conditional Perplexity ($CPPL$) in our scenario is the perplexity of a gold turn given the context. $CPPL$ is used to compute the model likelihood of a turn given a dialogue history and possible profile information (see Appendix D for the formulation). With Average Accuracy at N (Acc@N), the prediction of a word from a gold turn is considered correct if it occurs within the top N most probable words given by the model.

We adopted these metrics to evaluate our models in both in-domain (i.e., on PRODIGy) and cross-domain (i.e., on Persona-Chat) scenarios.

5.2 Analysis and Results

In this section, we provide a detailed description of the following experiments: (i) Inter-Character Experiments, (ii) Intra-Character Experiments, (iii) Cross-Domain Experiments. In these settings, we consider the target speaker's profile, excluding the interlocutor' profile. Given just the dialogue context, or both context and profile information, we aim to predict the target speaker's final turn.

Inter-Character Experiments In this setting, we partitioned PRODIGy making sure that the characters in the test set are not present in the training set, consistently with the experiments by Welch et al. (2022). We opted for the Bio$_{par}$ model as our biography-based model. This model is trained by randomly selecting five sentences[4] per dialogue from the original biography or its paraphrases. The decision to use this model is based on its demonstrated superior effectiveness, as shown in a preliminary experiment (outlined in Appendix E) focusing on biography-based models.

Table 3 presents model performances based on profile information. In terms of Acc@N, these models outperform Plain Dialogue that lacks profile information. Single-profile models show similar Acc@10 performances. Also, combining multiple profile dimensions, the Acc@N scores do not differ significantly. Regarding $CPPL$, Plain Dialogue performs the worst, while models with profile information excel. Notably, Gender attains the best $CPPL$ (87.92), comparable to MBTI. Bio$_{par}$ performs worse than Gender and MBTI but significantly outperforms the baseline with a score of 98.27, showcasing the efficacy of high-level character descriptions. Gender's strong performance in $CPPL$ and Acc@N may stem from the gender-specific linguistic patterns in PRODIGy's dialogues sourced from the Cornell Movie Dialogs Corpus (Schofield and Mehr, 2016), enabling the model to effectively incorporate such characteristics. Overall, the results show that adding profile information, either alone or jointly, strongly improves the models performance in terms of generalisation[5].

In Table 4 we report the results obtained by prompting GODEL with the profile information.

---

[4] We employ only 5 biography sentences to ensure (i) we stay within the DialoGPT input size length of 1024 tokens, (ii) we are consistent with Persona-Chat configuration.

[5] Besides $CPPL$ and Acc@N, we explored coherence and groundedness metrics. Results, detailed in Appendix F, align with the main findings with profile-based models performing better than plain dialogue model.

Config.	CPPL	Acc@10	Acc@1
`MBTI`	89.30	**0.665**	**0.317**
⚥	**87.92**	0.664	0.306
Bio$_{par}$	98.27	0.661	0.307
PD	541.16	0.585	0.298
`MBTI`+⚥	**91.50**	**0.660**	**0.311**
⚥+Bio$_{par}$	96.31	0.658	0.299
`MBTI`+Bio$_{par}$	100.35	0.653	0.296
`MBTI`+⚥+Bio$_{par}$	91.65	0.660	0.302

Table 3: DialoGPT results on PRODIGy test set (Inter-Character). PD and ⚥represent Plain Dialogue and Gender, respectively.

The $CPPL$ and Acc@N values reveal better performances even when profile information is merely provided as an instruction. In particular, Plain Dialogue exhibits a worst $CPPL$ compared to MBTI and MBTI + Gender (24.00 vs 12.46). Also in terms of Acc@10, MBTI + Gender turned out to be the best-performing model. In terms of Acc@1, the best performing models are Bio and Plain Dialogue, with a score of 0.027, although they do not yield much better performances than the other models. These results show that profile information is beneficial also when prompted to non-fine-tuned instruction-based LLMs. It is important to state that, while GODEL may seem to outperform DialoGPT in terms of $CPPL$, a direct comparison between their metrics is not possible as these models are pre-trained on distinct datasets and have a different vocabulary size.

Config.	CPPL	Acc@10	Acc@1
`MBTI`	**12.46**	0.080	0.026
⚥	13.65	0.075	0.026
Bio	20.43	**0.082**	**0.027**
PD	24.00	0.074	**0.027**
`MBTI` + ⚥	**12.46**	**0.083**	0.025
`MBTI` + Bio	26.48	**0.083**	**0.026**
⚥+ Bio	22.50	0.081	**0.026**
`MBTI` + ⚥+ Bio	28.96	0.083	0.026

Table 4: GODEL results on PRODIGy test set (Inter-Character). PD and ⚥represent Plain Dialogue and Gender, respectively.

Intra-Character Experiments In the second set of experiments, we partitioned PRODIGy with the same character existing in both training and test sets. Our aim is to simulate a scenario in which we can access the information about a character already at training time, both explicitly (i.e. MBTI, gender, and biography) and implicitly (i.e. the character's dialogues, captured by the character ID, grasping their language style).

As shown in Table 5, endowing the model with the dialogical information (`ID`) provides the best results in terms of $CPPL$. This is attributed to the model learning the character's vocabulary and language style during training, enhancing predictions. In terms of Acc@N, the best performing model is Bio (0.712 of Acc@10, and 0.348 of Acc@1). The other profile-based models exhibit similar performances. The Plain Dialogue model emerges as the weakest, proving again that fine-tuning models through profile information is beneficial. Combining biographical information and `ID` further enhances model efficiency in terms of $CPPL$, with better values when a high-level character description is included. The scores in Acc@N show that, when combined with the dialogical information (`ID`), the biographical information improves the predictive ability of the model more than Gender and MBTI. Although `ID` excels in $CPPL$, models with explicit profile information show comparable efficiency. Regarding the models trained with profile information jointly, the best performances are achieved by those trained with the characters' biographical information. Generally, models perform better in the Intra-Character setup than in the Inter-Character since they are trained with the speaker's profile information and leverage it at test time.

Config.	CPPL	Acc@10	Acc@1
Bio	58.95	**0.712**	**0.348**
`ID`	**55.25**	0.709	0.345
⚥	58.32	0.706	0.335

`ID+MBTI`+⚥+Bio	54.99	0.710	0.341

Table 5: DialoGPT results on PRODIGy test set (Intra-Character). PD and ⚥represent Plain Dialogue and Gender, respectively.

Cross-Domain Experiments To evaluate the generalisation capabilities of the models trained on the PRODIGy dataset in a cross-domain scenario, we also analysed the model performances, trained both with no profile information and with biographical information, on the Persona-Chat test set (Zhang et al., 2018). These results are also compared with the models trained with the same methodology on Persona-Chat and tested on the PRODIGy test set. The results, presented in Table 6, show a significant improvement in $CPPL$ scores when incorporating biography sentences, even in zero-shot settings (both trained on PRODIGy and tested on Persona-Chat, and vice-versa). Interestingly, using a general biography, as the one we propose, yields better generalisation capabilities than a dialogue-specific persona as in Zhang et al. (2018). When models trained on PRODIGy are tested on Persona-Chat, the results are in line with the in-domain experiments: Bio_{par} consistently outperforms Plain Dialogue in both $CPPL$ and Acc@N. On the contrary, in the scenario in which we trained the models on Persona-Chat and tested on PRODIGy, the Bio model's Acc@N scores are lower than Plain Dialogue's scores. This might suggest that persona sentences do not capture personas' complex characteristics, therefore they might be less effective to generalise in a cross-domain scenario.

Train → Test	**Config.**	**CPPL**	**Acc@10**	**Acc@1**
PROD. → PC	PD	891.80	0.444	0.184

Table 6: DialoGPT results on cross-domain experiments: fine-tuning on PRODIGy and test on Persona-Chat (PROD. → PC) and vice-versa (PC → PROD.). PD represents Plain Dialogue.

6 Human Evaluation

Besides the automatic evaluation, we also run an human evaluation study to validate PRODIGy.

This evaluation involved six subjects, comprising four PhD students in Computer Science and two MSc students in Data Science. Evaluators received 100 dialogues each, 50 with profile information disclosed and 50 without profile disclosure, so to enable an assessment of profile information's impact on judgements. We focused on output generated using top-p decoding by four models trained during inter-character experiments: the model trained on dialogues only and the models trained with one profile dimension. Evaluators ranked five possible responses for each dialogue, including the gold response used as a control condition, on a scale from 1 (most likely) to 5 (least likely) based on perceived likelihood of being the target speaker's response. In total, we collected 3000 evaluations. Subsequently, we conducted post-hoc qualitative interviews with the evaluators.

6.1 Results

The human evaluation reveals that the gold responses are preferred by far over the generated responses, indicating clear room for future improvement over the baselines we employed. Notably, Plain Dialogue was the favoured model, with only marginal rating differences compared to other models. From the post-hoc interviews, it emerged that Plain Dialogue's ability to produce generic responses that easily fit into various dialogues was often the reason for this preference. However, an interesting shift occurs when evaluators are made aware of the speaker's profile. In such cases, there is a noticeable increase in the preference for profile-based model responses over Plain Dialogue responses. This shift is shown in Table 7, which outlines the percentages of times evaluators favored profile-based models over Plain Dialogue. This trend can be attributed to a clear preference towards generations that exhibit coherence with both profile information and dialogue context, emphasising the significance of the profile in the generation process. Finally, profile-based models receive more favourable evaluations in shorter contexts, suggesting that the inclusion of profile information is advantageous when the dialogue context provides limited information about the speaker.

	All turns		**≤ 6 turns**		**> 6 turns**	
Response	**No** 👤	**With** 👤	**No** 👤	**With** 👤	**No** 👤	**With** 👤

Table 7: Preference Percentages across different dialogue lengths: responses of profile-based Models vs. Plain Dialogue Responses. ⚥represents Gender. No/With 👤 indicates profile information disclosure to evaluators.

Input	Responses
Biography: (1) I am a janitor at the Massachusetts Institute of Technology. (2) I live in a rough, working-class Irish neighborhood in south Boston. (3) I am seeing a Harvard girl named Skylar. (4) I am cocky, brash, and combative: while I am often crude, my quick wits mark me as unmistakably intelligent. (5) I have to put my mathematical genius to work by helping Professor Gerald Lambeau and start seeing a psychiatrist. **MBTI**: Introvert, Intuitive, Thinker, Perceiver **Gender**: Male	• **[Gold] B:** It's like a small figure, hoverin' over me. Gettin' closer. • **[Plain Dialogue] B:** I don't know. It just looks like a black couch. It's too bright. • **[Bio$_{par}$] B:** I see a skeleton. • **[MBTI] B:** I'm sure you can tell me. • **[Gender] B:** It's a door, I don't know which one but I want to find out for sure and put an end to this shit before it gets any worse.
Dialogue: **A:** Okay, you're in your bed. Now how old are you? **B:** Seven. **A:** And what do you see? **B:** Somethin's in my room. **A:** What is it?	

Table 8: Example of Inter-Character models' generations.

While Plain Dialogue might be favoured for its generic responses adaptable to various dialogues, it is worth noting that each profile-based model learns unique patterns from the profile information during training, resulting in responses tailored to individual speakers. The example in Table 8 illustrates this phenomenon. Plain Dialogue's response is a fairly generic answer that fits the context of the dialogue well. However, each profile-based model's generation reflects the speaker's profile information. Bio$_{par}$'s output closely aligns with the Gold response concept. Given the character's biography indicating a need for psychiatric help, the model inferred a potential mental distress, responding with "*I see a skeleton.*". The MBTI response aligns with the introverted trait of the character, who is reluctant to answer the interlocutor: "*I'm sure you can tell me.*". The Gender model's response incorporates stereotypical male patterns (e.g. the use of the swear word "*shit*"), common in the Cornell Movie Dialogs corpus (Schofield and Mehr, 2016).

These findings are consistent with the feedbacks from evaluators that we gathered in a post-hoc interview. Evaluators expressed a preference for generic answers, typically generated by Plain Dialogue, due to their broader applicability. This was particularly evident in those cases where responses generated by profile-based models matched the profile information of the speaker but not the dialogue context, thus negatively impacting perceived answer quality. However, when profile information was provided to evaluators, the preference for responses consistent with both profile and dialogue clearly emerged. At a closer inspection of such cases, we found that these sentences, consistent with both profile and dialogue, were often preferred even to gold responses. Conversely, the overarching inclination for gold responses was not given because they were familiar to evaluators: they reported not recognising them, and more broadly to having seen only few of the movies whose dialogues were evaluated. See Appendix G for additional details.

7 Conclusion

In this paper we introduced PRODIGy, a new dataset of movie dialogues aligned with characters' profile information, i.e. personality type, gender, biography, and a collection of speakers' dialogues, useful for inferring their vocabulary and language style. Derived from movie scripts, PRODIGy also mitigates privacy concerns associated with real user data. To validate this resource, we conducted several experiments using diverse baselines, both via fine-tuning and instruction prompting. Results indicate that including profile information in both approaches improved models' performance. Moreover, the cross-domain experiments showed that PRODIGy-based models exhibit better generalisation than those trained on similar resources. Results from the human evaluation showed that, despite a preference for generic responses due to their broader applicability, responses consistent with both profile and dialogue are clearly favoured. Moreover, the results highlight the value of incorporating profile information, especially when speaker's information provided within the dialogue context is limited.

Limitations

The fact that PRODIGy includes fictional characters could imply that the roles may be stereotyped. The high predictivity of the model trained on characters' gender is a potential indicator of this hypothesis. Thus, while PRODIGy allows avoiding a number of privacy issues, it may be less realistic. However, this problem may be present in other datasets, such as Persona-Chat, where users were simulated. Moreover, as regards to Gender, PRODIGy is limited to a binary classification since it is the one originally provided by the Cornell Movie Dialogs Corpus. Finally, the human evaluation shows a strong preference for gold responses, suggesting significant room for improvement, which we plan to address in future work.

Ethics Statement

One of the potential risks of profile-based dialogue systems is that they need to collect users' information, thus creating the risk of such private data being misused or leaked (Krishnamurthy et al.; Corrigan et al., 2014). The two configurations (i.e. inter-character and intra-character) we propose in this paper have been implemented in light of this. Being able to understand the impact of each of the profile dimensions within a dialogue system can be useful to determine which are the sensitive data necessary to develop a dialogue system and which could be left out in order to preserve the users' privacy (Dudy et al., 2021). Another problem is the possible fully automated use of profile-based models. Such systems, if left to act completely autonomously, may make erroneous assumptions, even in imitating a given user, thus returning possibly misleading answers.

A Annotation of PRODIGy Characters Algoritms

A.1 Annotation with Personality Information

Algorithm 1 outlines the annotation process to assign MBTI personality types to the Cornell Movie Dialogue Corpus (CMD). We selected only CMD characters appearing in at least 50 dialogues. For each character we used the query `movie_title+year` to extract from the Personality Database (PDB) the related movie metadata, containing the list of the movie characters' names and IDs. If the character was present in the movie metadata, we used a query `PDB_characterID` to extract the MBTI type and votes. If the MBTI type has at least 5 votes, the character was annotated. If the character was not found in the movie metadata, a manual check within PDB for character metadata is performed. In case the mismatch could be manually resolved, we replicated the above procedure to annotate the character.

Algorithm 1: MBTI Annotation

```
for character in CMD characters do
  if nr_dialogues $\geq$ 50 then
    PDB_query (movie_title + year) $\rightarrow$
      movie_metadata
    if movie_metadata found then
      if character in movie_metadata then
        PDB_query (PDB_character_id) $\rightarrow$
          character_metadata
        if character_metadata found then
          extract MBTI type and n_votes
          if n_votes $\geq$ 5 then
            annotate character
        else
          manual_check in PDB $\rightarrow$
            character_metadata
          if character_metadata found then
            extract MBTI type and n_votes
            if n_votes $\geq$ 5 then
              annotate character
```

A.2 Annotation with Biographical Information

Algorithm 2 describes the process for scraping, revising, and enriching biographies of annotated characters. For each character annotated with MBTI, a biography was scraped from external sources. If a biography was successfully retrieved, an extractive summarisation algorithm based on Kullback-Leibler divergence (Haghighi and Vanderwende, 2009) (KL_{based}) was applied to extract the most relevant biography sentences and human revision was applied to the sentences. If no biography was found during the scraping process, the human annotator created a new biography from scratch. Next, an LLM (i.e. ChatGPT) was given the post-edited biography sentences and asked to generate two sets of paraphrased sentences ($sents_{par}$ 1 and $sents_{par}$ 2). Finally, human revision was again applied to the generated sentence sets ($sents_{par}$ 1 and $sents_{par}$ 2), producing the final enriched and revised version of the character's biography.

Algorithm 2: Biographies Scraping, Revision and Enrichment

```
for character in annotated_characters do
  scrape bio from sources
  if bio exists then
    $KL_{based}$(bio) $\rightarrow$ bio_sents
    human_revision(bio_sents) $\rightarrow$ bio_sents$_{revised}$
  else
    bio_sents written from scratch
  LLM(bio_sents$_{revised}$) $\rightarrow$ (sents$_{par}$ 1, sents$_{par}$ 2)
  human_revision(sents$_{par}$ 1, sents$_{par}$ 2) $\rightarrow$
    (sents$_{par}$ 1, sents$_{par}$ 2)$_{revised}$
```

B DialoGPT Fine-tuning Details

In this section we report the details of the fine-tuning of each model employed during both inter-character and intra-character experiments and the input syntax.

B.1 Fine-tuning Setup

To investigate the impact of individual profile dimensions, we opted to employ DialoGPT medium for all fine-tuning experiments. To maintain consistency across our trials, we kept the hyperparameters constant throughout the fine-tuning process, and we considered the type of profile information as the only variable. In particular, we fine-tuned all our models for 5 epochs with a learning rate of $1e-6$ and a batch size of 2. The fine-tuning was performed on a single Tesla V100 GPU.

B.2 Input Syntax

When fine-tuning DialoGPT, we concatenated the characters' profile information to the corresponding turns of the dialogues. The input syntax employed in the experiments conducted with DialoGPT is delineated as follows (we use the example given in Figure 1 as a reference):

> `<|id|>` u9999 `<|mbti|>` extrovert, sensor, feeler, perceiver `<|gender|>` female `<|bio|>`I am an actress, a star. I live in an old mansion, built for glamorous stars of 1920s Hollywood, just off of Sunset Boulevard. (...) `<|start_dialogue|>` What's the matter, Norma?`<|endoftext|>` u9999: Nothing. I just didn't realize what it would be like to come back to the old studio. I had no idea how I'd missed it.`<|endoftext|>` We've missed you too, dear.`<|endoftext|>` (...) u9999: *turn_to_be_predicted*

`<|id|>`, `<|mbti|>`, `<|gender|>`, `<|bio|>` and `<|start_dialogue|>` are special tokens added to the model vocabulary, and they are used to segment the input sequence. During fine-tuning, each part of the profile input and its corresponding token are added or removed depending on the configuration under inspection.

C GODEL Prompt Syntax

During the experiments with GODEL, we prompted the model with an instruction and a context including the profile information and the dialogue context, respectively. We tasked GODEL to predict the last turn in the dialogue. Following, we provide an example of the input syntax.

> Instruction: given a dialog context, you need to respond as a person having the following mbti, gender and bio: "extrovert, sensor, feeler, perceiver", "female", "I am an actress, a star. I live in an old mansion, built for glamorous stars of 1920s Hollywood, just off of Sunset Boulevard. (...)" `[CONTEXT]` What's the matter, Norma? `EOS` Nothing. I just didn't realize what it would be like to come back to the old studio. I had no idea how I'd missed it. `EOS` We've missed you too, dear. `EOS` (...) `EOS` *turn_to_be_predicted*

D Conditional Perplexity Formulation

Given $T_n = \{t_{n_1}, t_{n_2}, ..., t_{n_k}\}$ the nth turn with k tokens of a dialogue with history $H = \{T_1, T_2, ..., T_{n-1}\}$ (T_n is the response to T_{n-1}), the CPPL of T_n is defined as follows:

$$CPPL = \frac{1}{P(T_n|H)^{\frac{1}{k}}} \quad (1)$$

where $P(T_n|H)$ is the conditional probability of T_n given the history H and $k = |T_n|$.

E Biography-based Models experiment

In order to understand what is the best strategy to input biographies to inter-character models, we conducted a preliminary experiment. In particular, we tested three strategies to add variability to the biographies during fine-tuning: (i) *Bio*, trained using the original top-5 biography sentences, (ii) Bio_{rand}, by randomly selecting, for each dialogue, 5 biography sentences from the corresponding full set of biography sentences of the character, (iii) Bio_{par}, by randomly selecting 5 sentences for each dialogue from the original biography or from the paraphrases.

Table 9 shows the effect of randomly choosing 5 sentences out of the full set of biography sentences for each training example (Bio vs. Bio_{rand}): randomisation leads to an improvement in terms of $CPPL$. Fine-tuning the models by mixing original and paraphrased biographies, thus increasing lexical variability, improves the performance even further in terms of both $CPPL$ (98.27 for Bio_{par} vs. 117.26 for Bio) and Acc@N (e.g. for Acc@10, 0.661 for Bio_{par} vs. 0.647 for Bio). Thus, in the inter-character experiments with DialoGPT, we will always use Bio_{par} as the reference configuration.

Config.	CPPL	Acc@10	Acc@1
Bio	117.26	0.647	0.294
Bio_{rand}	106.24	0.653	0.302
Bio_{par}	**98.27**	**0.661**	**0.307**

Table 9: DialoGPT results of the addition of variability to biography sentences on PRODIGy test set (Inter-Character)

F Inter-Character Coherence and Groundedness Analysis

In addition to investigating how different profile dimensions affect $CPPL$ and Acc@N, we explored their influence on response coherence (i.e. how well the response fits into the conversation) and groundedness (i.e. how relevant the response is based on profile and dialogue information). Results are consistent with Using UNIEVAL by Zhong et al. (2022), we assessed coherence and groundedness of responses from models trained on individual profile dimensions, alongside gold responses. Our analysis (Table 10) shows that: (i) all profile-based models have better metrics than plain dialogue; (ii) gold responses are the most coherent and relevant, highlighting room for improvement for our models. Among our models, the Gender model yields the most coherent responses (0.526), while the Bio$_{par}$ model generates the most grounded responses (0.057).

	Coherence	Groundedness
Gold	0.581	0.066
⚥	**0.526**	0.037
`MBTI`	0.520	0.033
Bio$_{par}$	0.507	**0.057**
PD	0.462	0.026

Table 10: Evaluation of coherence and groundedness scores for model-generated responses compared to gold standard responses. The scoring range is [0, 1].

G Analysis of Human Evaluation Rankings

Table 11 presents the evaluators' average rankings. The scores are inverted for readability purposes: higher scores indicate better performances. The significant gap between the scores of gold and the generated responses indicates that there is wide room for improvement for our models. Among the models, Plain Dialogue receives the highest ratings, closely followed by the other models. In shorter contexts, profile-based models, i.e., Bio$_{par}$, MBTI, Gender, yield higher scores than in longer context: this suggests that profile information is beneficial when dialogue context does not provide sufficient information about the speaker. Furthermore, when the profile information is explicitly provided to evaluators, the gap between scores in shorter and longer dialogues diminishes. This suggests a positive impact of profile information on evaluators' judgements, who perceive responses generated by profile-based models as more appropriate.

	All turns		$\leq$ 6 turns		$>$ 6 turns

H Intra-Character Generations examples

In Table 12, we provide a few examples of model generations derived from the Intra-Character configuration. Similar to the Inter-Character setup, the Plain Dialogue model produces a generic response that seamlessly fits the dialogue context. However, it is noteworthy that the output from the Bio model is particularly aligned with the Gold response concept.

`Input`
Biography: (1) I live in what is left of Philadelphia the year of 2035. (2) I am single, but I am developing feelings for my psychiatrist, Dr. Railly. (3) I am a total nutcase, completely deranged, delusional, paranoid. (4) I am visiting 1990, after being tossed in jail, I have been sent back in time to learn about a virus before it started mutating. (5) When I told others I am from the future, they thought I was out of my mind and threw me in a insane asylum. **`MBTI`**: Extrovert, Intuititive, Feeler, Perceiver
`Gender`: Male

`Dialogue:`
A: What have you done? Did you...kill someone?
B: No! I...don't think so. I stole a car and they chased me. I hit a tree.
A: See – you can drive after all!

`Responses`

- **`[Gold]` B:** Yeah, sort of, I guess. I...I'm sorry I locked you up. I thought...I thought... I think maybe I am crazy!
- **`[Plain Dialogue]` B:** I don't want to!
- **`[Char ID]` B:** Yeah! Yeah!! So what if we killed the cops! Now, I need to meet you in there tomorrow morning!
- **`[Bio]` B:** Oh, God. I must be totally crazy.
- **`[MBTI]` B:** Yeah, but, what are you gonna do?
- **`[Gender]` B:** ...and I thought the cops were gonna catch me. They're not gonna catch me.

WaterJudge: Quality-Detection Trade-off when Watermarking Large Language Models

Piotr Molenda, Adian Liusie, Mark J. F. Gales
ALTA Institute, Department of Engineering, University of Cambridge
pm725@cam.ac.uk, al826@cam.ac.uk, mjfg@eng.cam.ac.uk

Abstract

Watermarking generative-AI systems, such as LLMs, has gained considerable interest, driven by their enhanced capabilities across a wide range of tasks. Although current approaches have demonstrated that small, context-dependent shifts in the word distributions can be used to apply and detect watermarks, there has been little work in analyzing the impact that these perturbations have on the quality of generated texts. Balancing high detectability with minimal performance degradation is crucial in terms of selecting the appropriate watermarking setting; therefore this paper proposes a simple analysis framework where comparative assessment, a flexible NLG evaluation framework, is used to assess the quality degradation caused by a particular watermark setting. We demonstrate that our framework provides easy visualization of the quality-detection trade-off of watermark settings, enabling a simple solution to find an LLM watermark operating point that provides a well-balanced performance. This approach is applied to two different summarization systems and a translation system, enabling cross-model analysis for a task, and cross-task analysis.

1 Introduction

Large Language Models (LLMs) have progressed tremendously and are capable of generating high-quality texts for a diverse range of tasks. While these systems enhance automation, concerns arise about potential misuse, such as students using chat assistants for assignments or malicious users generating fake news articles. To counter this, current work has introduced the idea of LLM watermarking (Kirchenbauer et al., 2023a), where imperceptible patterns are injected into the generated text, enabling the statistical identification of whether text was generated by an LLM or not. However, most proposed watermarking schemes restrict the output generation space, which may lead to a trade-off between quality and watermarking detection performance. Although there has been great effort into improving watermarking schemes for LLMs (Yoo et al., 2023; Kuditipudi et al., 2023; Kirchenbauer et al., 2023b), less work has analyzed the resulting quality degradation. It is common for watermarking schemes to measure quality by reporting the perplexity from a larger pre-trained LLM (Kirchenbauer et al., 2023a; Takezawa et al., 2023; Wang et al., 2023; Zhao et al., 2023; Ren et al., 2023; Liu et al., 2023), or to report similarity metrics such as BLEU or ROUGE(Fu et al., 2023; Takezawa et al., 2023; Li et al., 2023; Kirchenbauer et al., 2023b), however, these metrics are simplistic heuristics and may not truly capture actual output text quality, as discussed by Zhong et al. (2022); Wang et al. (2022); Zheng et al. (2023).

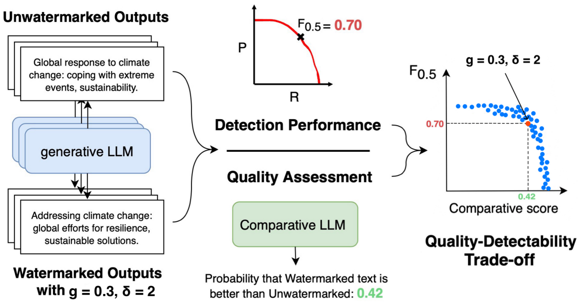

Figure 1: High-level overview of the WaterJudge Framework: Given a system, watermarking parameters, and set of inputs, watermarked outputs are assessed in terms of quality and detectability, leading to a curve over all operating points.

This work proposes WaterJudge, a framework for analyzing the trade-off between watermarking detectability and the quality of generated watermarked text. We leverage the LLM-as-a-judge evaluation approaches (Zheng et al., 2023; Liusie et al., 2023) to measure the average probability that an LLM prefers a watermarked text over an unwatermarked text. This is used as a metric for quantifying the quality degradation caused by watermarking, which with watermark detection performance,

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3515–3525
June 16-21, 2024 ©2024 Association for Computational Linguistics

can be used to determine the quality and detectability of a watermark operating point. This provides an approach for practitioners to visualize the effectiveness of specific watermarking operating points, enabling simple selection of an optimal watermark setting with minimal quality degradation.

2 WaterJudge

2.1 Soft-Watermarking Scheme

Language Models predict the conditional distribution of the next token $w_{i+1} \in \mathcal{V}$ given the input text $x_{1:M} \in \mathcal{V}^M$ and the previously generated tokens, $w_{1:i}$. For identification of LLM generated text, Kirchenbauer et al. (2023a) propose a simple soft-watermarking scheme, where the previous token w_i is used in a hash function to split the vocabulary into a mutually exclusive green list $\mathcal{V}_{\mathtt{g}}(w)$ and red list $\mathcal{V}_{\mathtt{r}}(w)$. The approach then incentivizes green-list words to be generated at the next step, such that the green-list word count can determine whether a text was generated by the LLM or not. The parameter g sets the relative size of the green list, such that $|\mathcal{V}_{\mathtt{g}}| = g \cdot |\mathcal{V}|$ and $|\mathcal{V}_{\mathtt{r}}| = (1-g) \cdot |\mathcal{V}|$. The watermarking scheme then increases the logits of all tokens in the green list by a bias δ,

$$l_k^{wm} = \begin{cases} l_k^{lm} + \delta, & \text{if } w_k^{lm} \in \mathcal{V}_{\mathtt{g}} \\ l_k^{lm}, & \text{otherwise} \end{cases} \tag{1}$$

Where l_k is the logit for the k'th token in the vocabulary w_k^{lm}. The watermarking scheme therefore has two parameters, the green list size s and the green list bias δ. The watermark score for a particular text is then calculated as the number of green list words present in the output text, where the higher the score, the more likely the output was generated by the watermarked LLM.

$$s_{\mathtt{wm}} = \frac{1}{N_w} \sum_{i=1}^{N_w} \mathbb{1}(w_i \in \mathcal{V}_{\mathtt{g}}(w_{i-1})) \tag{2}$$

Where $\mathbb{1}$ is the indicator function. Note that this watermarking scheme has the useful property that detection can be achieved even without model access. One only requires knowledge of the tokenizer and hashing function as this enables the green and red lists to be dynamically calculated, which is all that's needed to score texts. Further, if multiple models share a tokenizer, there could be an agreed watermarking convention that enables universal watermark detection over a range of models.

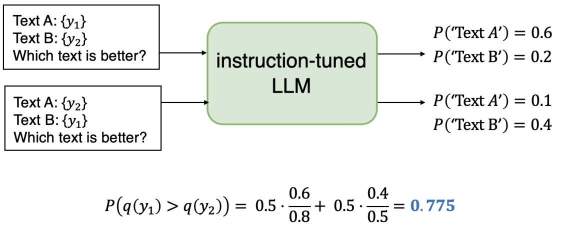

Figure 2: Comparative assessment probabilities are attained by calculating the likelihood of generating 'Text A' or 'Text B', normalizing, and averaging over both permutations. Example prompts are displayed, with the actual prompts shown in Appendix A.

2.2 Zero-shot Comparative Assessment

LLM comparative assessment (Liusie et al., 2023; Zheng et al., 2023), which prompts an LLM to determine which of two texts is better, is used in our framework to measure the quality degradation caused by watermarking. This method was selected due to being simple, zero-shot, and easily transferable to a range of tasks, as well as demonstrating impressive NLG evaluation performance.

For a given task and model, let x represent the input text, y the generated output text, and $y_{\mathtt{wm}}$ an output text generated from the system when watermarked. The Comparative assessment uses open-sourced instruction-tuned LLMs by querying which of the two provided texts is better. The comparative assessment system outputs $P(q(y_1) > q(y_2)|x)$, the probability that the quality of text y_1 is better than the text y_2, as demonstrated in Figure 2. The watermark degradation is measured over a corpus of input texts $\mathcal{D} = \{x^{(i)}\}_{i=1...N_d}$, with the average comparative selective probability used as the quality metric

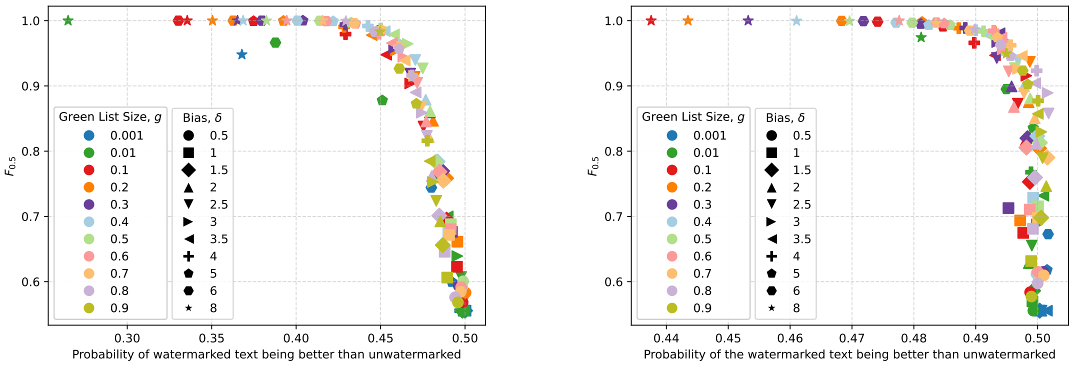
$$s_{\mathtt{q}} = \frac{1}{N_d} \sum_{i=1}^{N_d} P(q(y_{\mathtt{wm}}^{(i)}) > q(y^{(i)})|x^{(i)}) \tag{3}$$

where $y^{(i)}$ and $y_{\mathtt{wm}}^{(i)}$ are the generated base and watermarked outputs respectively, given input $x^{(i)}$.

3 Experimental set up

3.1 Datasets

We analyze the trade-off between quality and detection performance for two different tasks: summarization and translation. For the summarization task, 1024 contexts are sampled from the test set of XSumm (Narayan et al., 2018), while for translation 3072 German sentences are sampled from the test set of the XTREME corpus (Hu et al., 2020).



(a) BART

(b) Zephyr

Figure 3: The trade-off between quality and detectability when watermarking. Each point is a watermark setting with green list size g and bias δ, displaying $F_{0.5}$ detectability score and average Comparative Assessment probability.

3.2 Generative Models

Two different abstractive summarization systems are used; a BART-based summarization model trained on CNN-daily mail[1] (Lewis et al., 2020) and Zyphr-7B β instruction-tuned (Tunstall et al., 2023) which we prompt to perform summarization. For translation, mBART-large-50 is used, which is a BART model fine-tuned for multilingual translation[2] (Tang et al., 2020).

3.3 Watermarking Methodology

For each context, the model generates a baseline text without any watermark, and then multiple watermarked texts using various operating points. The watermarking operating points are taken by considering all combinations of green list size g ranging from 0.001 to 0.9 and bias δ ranging from 0.5 to 8. For summarization, the watermark score is the count of the fraction of green list words in the generated text, while in translation the output texts are grouped in sets of three (to achieve similar expected lengths for detection) and the score is computed for the grouped set. For each operating point, a threshold is chosen to classify watermarked and unwatermarked texts for the maximum $F_{0.5}$ value, which is then used as a detectability metric. $F_{0.5}$ is a weighted harmonic mean of precision and recall, giving more importance to precision than F_1 to safeguard against false positives. We use the same hashing seed to generate all green-lists, however, Appendix D shows that consistent results can be observed across random seeds.

3.4 Comparative Assessment Set Up

FLAN-T5 3B (Chung et al., 2022) is used as the base evaluation LLM, chosen due to its demonstrated pairwise evaluation abilities (Liusie et al., 2023) and good multi-lingual capabilities. As the maximum length of the model is 1024 tokens, if the input prompt exceeds this limit, the end of the context is truncated to fit into the maximum limit, which avoids any of the summaries/translations being truncated. The comparative quality score is taken as the average of all $1024/3072$ samples.

4 Results

Summarization Figures 3a and 3b illustrate the relationship between summary quality and watermark detection performance for BART and Zephyr respectively. A clear trade-off between watermark strength and output quality can be observed for both systems, where strong watermarking degrades quality while weak watermarking maintains quality but yields poor detection performance. The results further suggest that though multiple operating points can yield similar quality-detectability characteristics, the framework provides a simple way to visualize points that achieve a good balance between the two. This can be useful for hyper-parameter selection, e.g. to find the setting where there's minimal quality degradation for a desired $F_{0.5}$ detectability score. Note that the quality scores are upper-bounded near 0.5, consistent with the idea that weak watermarking will enforce little restriction and yield texts of similar quality, while stronger watermarks will restrict generation and therefore yield texts of worse quality. Further, the saturation at $F_{0.5} = 1$ denotes the region where one can perfectly differentiate watermarked texts from unwatermarked texts, albeit often at the cost

---

[2] `https://huggingface.co/facebook/mbart-large-50-many-to-many-mmt`

of large quality degradation.

Additionally, it is observed that different base models can have varying optimal watermarking parameters. Zephyr-7B is much larger than BART (7.2B vs 0.4B parameters) and is likely to have a more accurate underlying task language model. As such, it seems to better deal with the restrictions imposed by watermarking, as seen by the vertical region around the probability of 0.5 (where minimal quality degradation and good detectability are achieved). Further, in the most extreme settings, Zephyr's average comparative probability drops to 0.44 compared to BART's 0.28. Examples of the generated watermarked text can be seen in Appendix H.

Translation We repeat analysis for translation, with Figure 4 showing similar quality-detectability characteristics when an mBART system, which translates German sentences to English, is watermarked. The plot shows further evidence of how for weaker models (0.6B parameters supporting 50 languages) strong watermarking can cause a significant drop where the system struggles to maintain quality. Additionally, we can observe that mBART is more sensitive to watermarking parameter settings and that quality is better for small-green list sizes than for larger-green list sizes, even for settings with equivalent detectability performance.

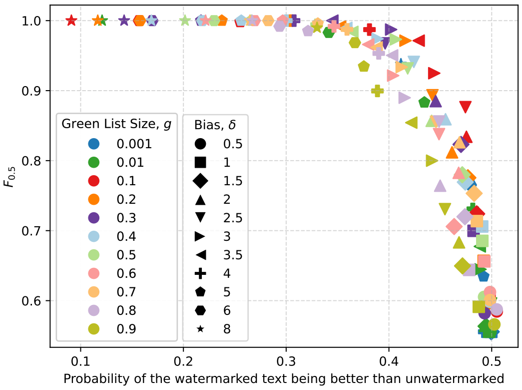

Figure 4: Results for watermarked translations generated with mBART for combinations of green list size g and bias δ.

Suitability of Comparative Assessment To verify that comparative assessment provides meaningful quality evaluation, we compare the generated quality scores against those from UniEval (Zhong et al., 2022) and COMET(Rei et al., 2020) which both demonstrate strong alignment with human judgment. UniEval is a summary assessment method using a T5-based boolean-answering system trained specifically to assess summaries on coherence, consistency, fluency, and relevance, while COMET is an open-source neural framework for machine translation evaluation. For summarization, comparative assessment has a Spearman correlation of **0.986** relative to UniEval scores[3], while in translation comparative assessment has a Spearman correlation of **0.988** relative to COMET. Figure 5 illustrates the relationship between the two quality scores of watermarked summaries generated by BART, with a similar graph for mBART translation shown in Appendix G). These results highlight that despite being simple and zero-shot, quality assessment via comparative assessment correlates highly with alternative high-performing automatic evaluation approaches that have been tailored to particular tasks. WaterJudge is a clear improvement over more dated metrics such as ROUGE or BLEU, which when used fail to capture the quality-detection trade-off (shown in Appendix C). Further, current popular methods such as perplexity have weaker correlations with UniEval and COMET (**0.922** for summarization and **0.940** for translation) and are more difficult to compare between models, where WaterJudge also shows additional promising capabilities, discussed in the next section.

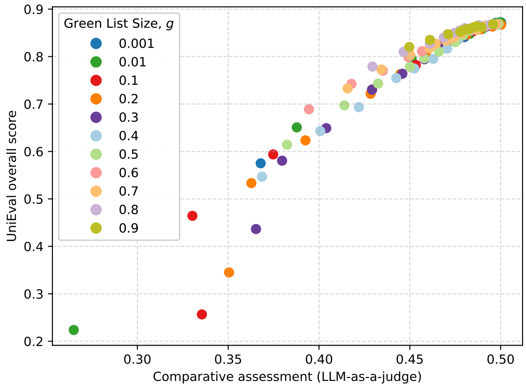

Figure 5: Scatter plot showing correlation between Comparative Assessment and UniEval for BART.

Transferability of Settings As an extension to the current analysis, we consider whether one can avoid doing a full grid search over all watermarking settings and instead transfer settings across different models and tasks. Firstly, it's observed that by looking at the expected quality scores of generated summaries for different operating points on BART and mBART, we observe a Pearson corre-

---

[3] scores of the 4 attributes are averaged as an overall score

lation $\rho = 0.927$ (Figure 6), while for BART and Zephyr, the correlation is $\rho = 0.826$. The lower correlations for BART-Zephyr can be explained due to the observed truncated linear relationship, where for weak watermarks Zephyr can apply watermarks without causing any quality loss, while for medium watermarks (e.g. $g = 0.5$) there remains a linear degradation to both systems (shown in Figure 14 in the Appendix). Using perplexity quality scores does not demonstrate strong cross-system correlations, and as shown in Figure 7, does not demonstrate the linear relationships that are observed with comparative assessment. Therefore perplexity scores may not be effective when considering transferring watermarking performance.

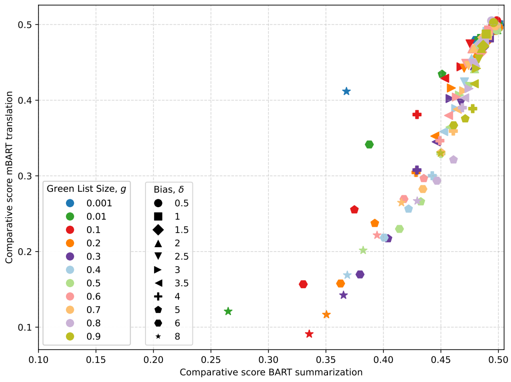

Figure 6: Relationship of watermark settings' comparative assessment quality scores for BART and mBART.

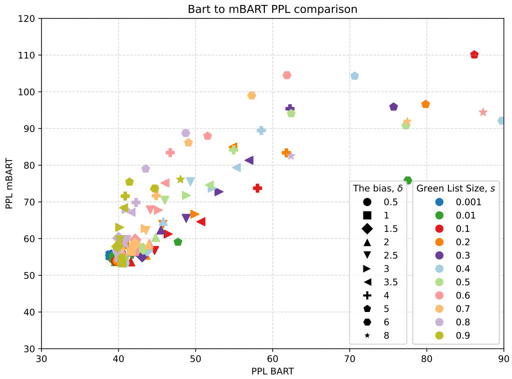

Figure 7: Relationship of watermark settings' perplexity scores for BART and mBART (ignoring the outlier, very high perplexity, points).

Moreover, the $F_{0.5}$ scores of watermark settings on different models are also highly correlated: BART-Zephyr quality scores have PCC $\rho = 0.986$, while for BART-mBART the PCC is $\rho = 0.990$. Even though this is a cross-task comparison, BART and mBART have a near 1:1 mapping in detectability scores (Figure 8) while Zephyr detectability scores tend to be slightly higher than those from BART (which is mostly due to length mismatches, as discussed in Appendix B). The high linear correlations for both quality and detection suggest that WaterJudge can be used to map performance on one model/task to another, which may yield additional predictive abilities for generating the full detectability-quality trade-off curves. Initial examples of the effectiveness of transferring settings across systems are shown in Appendix F.

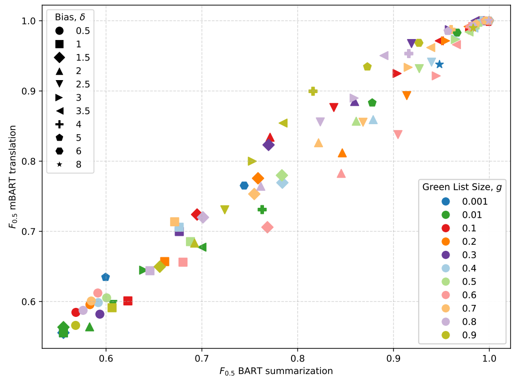

Figure 8: Comparison of watermark settings' detectability scores for BART and mBART.

5 Conclusions

This paper introduces WaterJudge, a framework for investigating the quality-detection trade-off when watermarking LLMs, enabling easy visualization of various watermarking settings and simple hyperparameter selection. Comparative Assessment is shown to be a practical metric for measuring quality degradation and improves on currently used evaluation methods in its accuracy and versatility. WaterJudge is also useful in cross-task and cross-model analysis, showing good correlations for both detectability and quality, despite varying characteristics due to model strength.

6 Limitations

Although LLM evaluation approaches have recently been demonstrated to be effective reference-free evaluation methods, there may be inherent biases such as self-enhancement bias that can impact the robustness of the approach and cause discrepancies in human evaluation. This study could further investigate sensitivity to evaluation prompt sensitivity, or output length, as well as extend to more models, watermarking schemes, and tasks.

7 Ethical Concerns

Watermark detection performance may not be completely accurate, and false negatives may lead to individuals being unfairly charged for using AIs, when they may have written the text themselves.

A Prompts

Use case	Prompt
Zephyr summarization	<|system|> You are a tool providing a short text summary. <|user|> Write a short summary of the following text: context <|assistant|>
FLAN-T5 summarization Comparative Assessment	Passage: {passage} Summary A: {summary 1} Summary B: {summary 2} Between Summary A and Summary B, which text summarises the passage better?
FLAN-T5 translation Comparative Assessment	Original text: {context} Translation A: {translation 1} Translation B: {translation 2} Between Translation A and Translation B, which is the better translation of original text?

Table 1: prompts used for experiments.

For reproducibility, Table 1 shows the prompts used for summary generation (using Zephyr 7B β) and comparative assessment (with FLAN-T5 as the base LLM). For summarization, we evaluated the overall summary quality, as in initial experiments where particular attributes were assessed, the LLM struggled to differentiate between the different attributes with simple prompts (e.g. 'fluency', 'coherence', 'consistency', or 'relevance'). We use a Tesla V100S 32Gb GPU to conduct all experiments. FLAN-T5 Comparative assessment takes 6 minutes to assess each summarization watermark operating point (1024 samples) and 10 minutes to assess each translation operating point (3072 samples). It takes 5 minutes for BART to generate 1024 summaries, 40 minutes for Zephyr-7B β to generate 1024 summaries, and MBART 12 minutes to generate 3072 translations.

B Watermarked texts length

Figures 9, 10 and 11 show the average lengths (in tokens) of the outputs of the models. BART and mBART were fine-tuned for a specific task and therefore the outputs typically have consistent length (usually 60-80 tokens). Zephyr 7B β tends to generate longer summaries with a larger variance in the output lengths. Note that longer texts will typically be easier to detect since having more generated words will reduce the expected variance from the expected fraction of green list words. Therefore when choosing optimal operating points, one should also take the length into account.

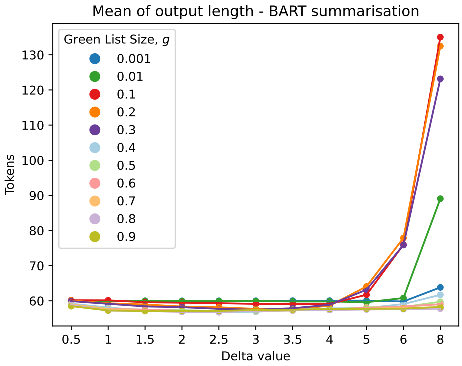

Figure 9: Average length (in tokens) of output BART (summarization) texts for various watermark settings.

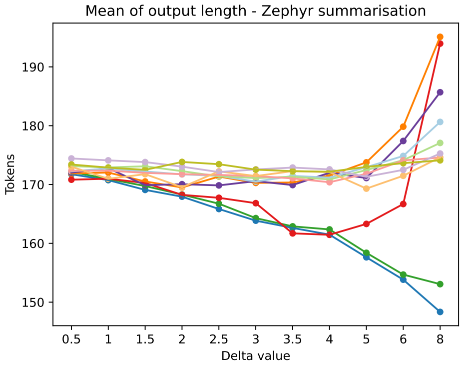

Figure 10: Average length (in tokens) of output Zephyr (summarization) texts for various watermark settings.

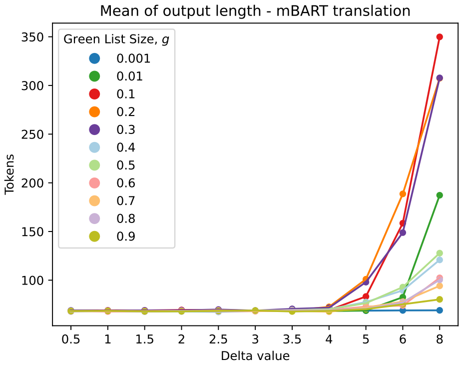

Figure 11: Average length (in tokens) of output mBART (translation) texts for various watermark settings.

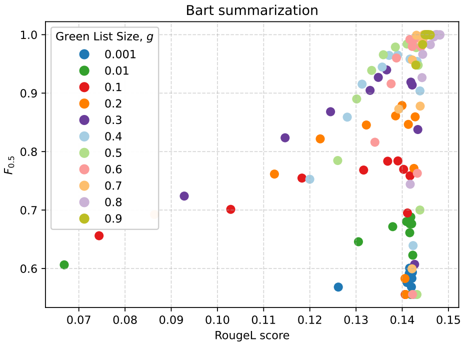
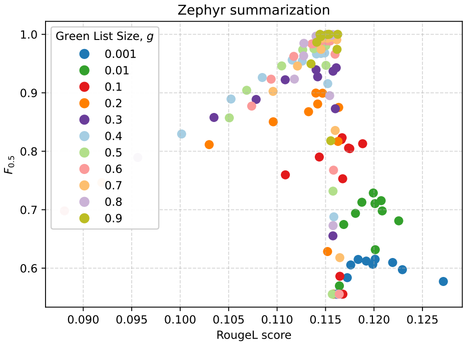
Moreover, the average lengths for models show an issue with simple watermark partitioning into green/red lists: if '</s>' is in the red list of '.', then the outputs tend to grow overly long (since ending the sequence incurs a red-list word). In our experiments, green lists are subsets of larger green lists, and, for both models, the aforementioned issue occurs when $g < 0.4$. High bias δ texts with $g < 0.4$ are significantly longer than those from other settings, which considerably impacts text quality (though for very small green lists, $g \leq 0.001$, there are more red-list words generated and therefore the sentence may end as expected). For the given randomized seed, Zephyr does not have eos token '</s>' in green list of '.' (for any $g > 0.9$). Hence, the rise is visible for all larger green lists $g \geq 0.1$, but the issue is not as significant as for the other models (due to its better capability to adapt to watermark restrictions). This highlights that this problem is significant when evaluating very strong bias operating points (with generally unusable outputs), but does not otherwise influence evaluation (see Appendix D).

C Baseline Evaluation Metrics

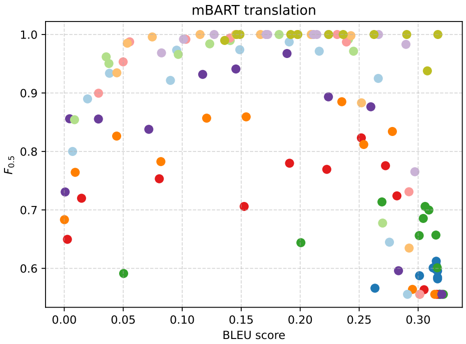
Instead of using comparative assessment to assess the quality degradation, we generate equivalent plots using metrics such as ROUGE or BLEU (against reference summaries/translations), which are standard watermark evaluation metrics. Figure 12 shows that using these evaluation metrics leads to curves that mask the quality-detection tradeoff and provide little insight. The RougeL curves seem to be strongly influenced by summary length (see Figures 9, 10, 11), while the BLEU metric has little explanation. This highlights that the WaterJudge framework requires a capable and effective evaluation approach to capture the quality-detection trade-off and that comparative assessment is a suitable method.



(a) $F_{0.5}$ against RougeL scores for BART summarization.



(b) $F_{0.5}$ against RougeL scores for Zephyr summarization.



(c) $F_{0.5}$ against BLEU scores for mBART translation.

Figure 12: Quality-Detectability trade-off curves for commonly used similarity metrics.

D Green List Seed Consistency

Results in Appendix B suggested that there may be some seed variability, dependent on specific word (or special token) green list bi-grams. To verify the consistency of our results, evaluation for three different seeds is shown in Table 2. The seeds were selected to maximize variability, such that for seed 1 '</s>' is never in the green list of '.', for seed 2 it occurs when $g > 0.4$, and for seed 3 '</s>' is always in the green list of '.' It's observed that even in these settings, there is little impact on the metrics for the main operating points (δ is 3 or 6), and only when in regions with very heavy watermarks ($\delta = 9$) are small differences seen. It is worth noting that the length is affected by the seeds, but it's not necessarily negatively received by the Comparative Assessment (in contrast to metrics like Rouge). Due to this designed length bias, seed 1 does on average report slightly higher $F_{0.5}$.

		$F_{0.5}$			Quality		
g	δ	1	2	3	1	2	3
0.2	3	0.90	0.86	0.88	0.44	0.44	0.44
0.5	3	0.90	0.89	0.86	0.44	0.44	0.43

Table 2: Table comparing detectability and quality scores of three additional seeds for various operating points in BART summarization , with good agreement between all seeds.

E Model to model comparison

Figures 13 details the relationship of *detectability* for different watermarking settings for BART-Zephyr, while Figure 14 shows the equivalent graphs for *quality*. Figure 15 shows the BART to Zephyr comparison for Perplexity, where notably most of the points are tightly grouped in a single region. Note that highly hallucinated outputs have extremely high perplexity scores, and so have been cropped out of the plot. Moreover, Figure 14 suggests that for most models, large green list sizes can yield reasonable detectability with minimal quality degradation, medium green list sizes have predictable and transferable linear degradation, while small/very small green lists have unpredictable behavior and should be avoided.

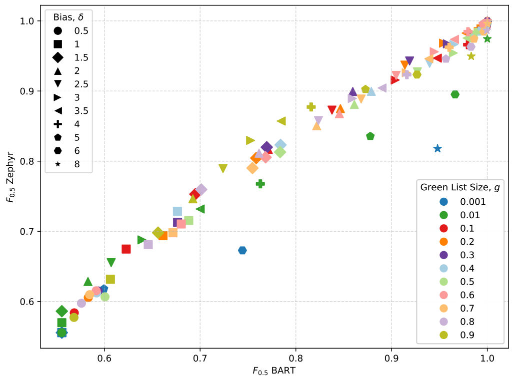

Figure 13: Comparison of watermark settings' detectability scores for BART and Zephyr

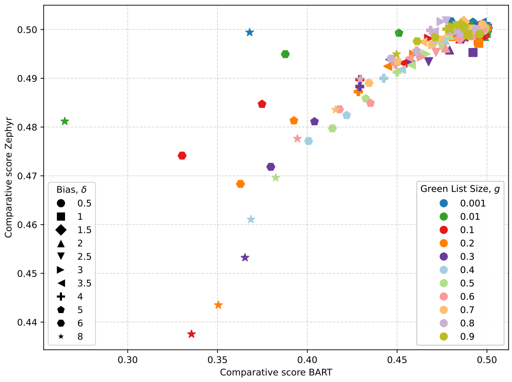

Figure 14: Comparison of watermark settings' quality scores for BART and Zephyr

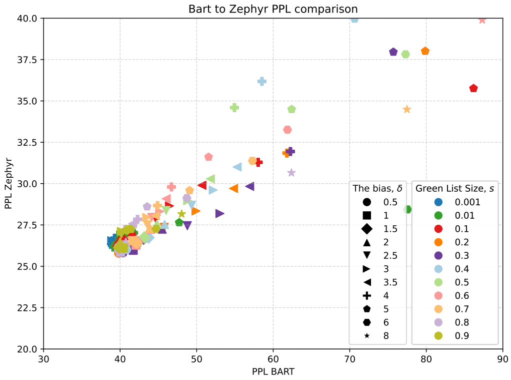

Figure 15: Comparison of watermark settings' PPL for BART and Zephyr (ignoring the outlier, very high perplexity, points).

F WaterJudge predicitive capabilities

Appendix E and Section 4 demonstrated that both Zephyr-BART and mBART-BART have consistent and linear relationships between quality and predictive scores. Detectability is nearly equivalent across different watermarking settings, starting from $F_{0.5} = 0.5$ and linearly increasing to

$F_{0.5} = 1$. Alternately, the Quality comparisons can be broken into three regions: for weak watermark settings, large models (like Zephyr) can maintain quality, for medium strength watermarks (e.g. $g = 0.5$) there is a linear degradation for all systems, while strong watermarks can lead to meaningless output texts and low transferability (deviations from the trend). Meaningful regions of both of these curves can be estimated well with a two-parameter function (such as truncated at the top linear function), which enables a transformation of watermark performance from one system to another while using only a few tested operating points. To achieve the fitting, a parameterized hyperbolic tangent was fitted to the BART quality-detection curve, as shown in Figure 16, by minimizing the average perpendicular Mahalanobis distance of the operating points from the curve. This has been done to get a smooth baseline function capturing the whitened data shape.

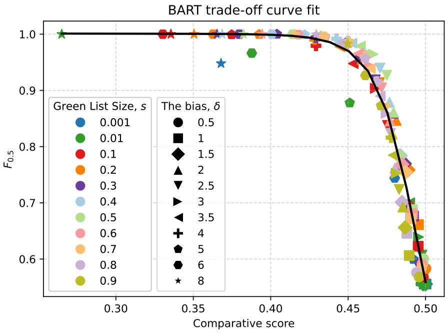

Figure 16: Curve fit to BART operating points graph.

By fitting truncated linear functions to the relationships such as Figures 13-14, one can transform a baseline curve to achieve predicted fits, as shown in Figure 17. These 'predicted' shapes are achieved with significantly fewer points and avoid the grid search, which can be useful when attempting to determine whether an effective watermark setting exists for the new system, and also enable fast and thorough testing across hyperparameters and models.

G COMET Comparison

Figure 18 shows how Comparative Assessment for translation is also strongly correlated with the most recent automatic translation evaluation metric: COMET. The Spearman correlation of quality scores is **0.988**.

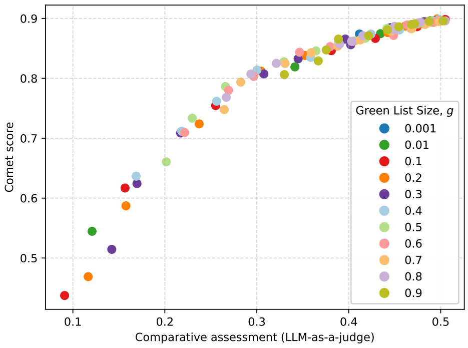

Figure 18: Correlation between Comparative Assessment and COMET score for mBART translation.

H Examples of watermarked texts

Table H provides examples of possible output texts under various operating points for the two summarization experiments for a sampled article. The texts achieve various detectability and show varied degradation in text quality.

Context	The 41-year-old reached the semi-final for the first time since he last lifted the trophy in 2011 with a 13-6 win over Kyren Wilson. The world number six will now face the winner of Stephen Maguire's match against Barry Hawkins for a place in Sunday's final. "I believe I can [win], and that's a great feeling to have," Higgins said. "I was close last year, Alan [McManus] pipped me [in the quarter-final]," he added. "A couple of years after 2011, I'd been losing, my form wasn't great and you don't think you're [continues]
Unwatermarked BART	Higgins beat Kyren Wilson 13-6 to reach the semi-final of the World Championship. The Scot will face the winner of Stephen Maguire's match against Barry Hawkins. The 41-year-old believes he can win the tournament for the first time since 2011.
$g = 0.7, \delta = 6$ $F_{0.5} = 0.996$ Quality score 0.434	Higgins beat Kyren Wilson 13-6 in the quarter-finals at the World Cup. He now awaits the winner of Stephen Maguire's match against Barry Hawkins. It is the first time the 41-year-old Scot is in the semi-final since he lifted the trophy in 2011.
$g = 0.5, \delta = 4$ $F_{0.5} = 0.988$ Quality score 0.450	Scottishman Higgins is into the semi-final for the first time since 2011. He beat Kyren Wilson 13-6 in his quarter-final on Wednesday. He now faces the winner of Stephen Maguire and Barry Hawkins. He says he has more self-confidence heading to final.
$g = 0.1, \delta = 8$ $F_{0.5} = 1.00$ Quality score 0.336	Bobbyiggins into first semifinal since picking off David Higgins 11 years ago. 41-year-old Scot defeated World 16's KYRN WEIRD 12 4 8 3 3 3 8 1 this night at BAVCA PIA Stadium. Beats Ian Pinn are first-round bye; winner of Stephen MagUires takes part Saturday afternoon and it goes 6 vs 6 - winner to meet for the tournament [continues]
Unwatermarked Zephyr	John Higgins, aged 41, advanced to the snooker World Championship semi-finals for the first time in a decade with a 13-6 victory over Kyren Wilson. Higgins will face either Stephen Maguire or Barry Hawkins for a place in the final, and believes he can win the tournament. The Scot has won all three sessions against Wilson and [continues]
$g = 0.5, \delta = 4$ $F_{0.5} = 0.984$ Quality score 0.491	John Higgins, 41, progressed to his seventh World Snooker Championship semi-final, beating Kyren Wilson 13-6. Higgins, ranked sixth, aims for his fourth title after last lifting the trophy in 2011. The Scottish player faces either Stephen Maguire or Barry Hawkins in the last four, with Higgins preferring a Maguire match as a fellow [continues]
$g = 0.1, \delta = 8$ $F_{0.5} = 1.00$ Quality score 0.438	John Higgins, aged 41, advanced to the world snooker championship semi-finals for the first time since lifting the trophy in 2011. In the quarter-finals, Higgins defeated Kyren Wilson in three sessions by a scoreline of 13-6. In the semi-finals, Higgins will confront either Stephen Maguire or Barry Hawkins for a position in the final on Sunday. Reflecting after his match against Wilson, Higgins stated that he "believ(ed) (he) [continues]

Table 3: Examples of watermarked and unwatermarked outputs for a few chosen operating points for summarization. It may be noted that in the strong watermarking region, the model begins 'hallucinating' or repeating text continuously. This yields long, unusable texts with high density of green list words, making the operating points a bit less meaningful for analysis. This is more difficult to trigger for larger models like Zephyr.

Cognitive Overload: Jailbreaking Large Language Models with Overloaded Logical Thinking

Warning: This paper contains potentially offensive and harmful text.

Abstract

While large language models (LLMs) have demonstrated increasing power, they have also called upon studies on their vulnerabilities. As representatives, jailbreak attacks can provoke harmful or unethical responses from LLMs, even after safety alignment. In this paper, we investigate a novel category of jailbreak attacks specifically designed to target the cognitive structure and processes of LLMs. Specifically, we analyze the safety vulnerability of LLMs in the face of 1) multilingual cognitive overload, 2) veiled expression, and 3) effect-to-cause reasoning. Different from previous jailbreak attacks, our proposed cognitive overload is a black-box attack with no need for knowledge of model architecture or access to model weights. Experiments conducted on AdvBench and MasterKey reveal that various LLMs, including both popular open-source model Llama 2 and the proprietary model ChatGPT, can be compromised through cognitive overload. Motivated by cognitive psychology work on managing cognitive load, we further investigate defending cognitive overload attack from two perspectives. Empirical studies show that our cognitive overload from three perspectives can jailbreak all studied LLMs successfully, while existing defense strategies can hardly mitigate the caused malicious uses effectively.[1]

1 Introduction

Large language models (LLMs) have manifested remarkable NLP capabilities (He et al., 2023; Li et al., 2023a; Zhang et al., 2023; Laskar et al., 2023) and offered even human-level performance on challenging tasks requiring advanced reasoning skills (e.g., programming, grade-school math; OpenAI 2023; Touvron et al. 2023b). However, as LLMs improve, a wide range of harmful behaviors emerge and grow (Ganguli et al., 2022a), such as responding with social bias (Abid et al., 2021; Manyika, 2023), generating offensive, toxic or even extremist text (Gehman et al., 2020; McGuffie and Newhouse, 2020), making unfaithful predictions (Zhou et al., 2023; Wang et al., 2023), and spreading misinformation (Lin et al., 2022; Qiu et al., 2023).

Although model developers have deployed various safety alignment strategies (Markov et al., 2023) and red teaming processes (Bai et al., 2022) to mitigate these threats, vulnerabilities of LLMs still persist (Ganguli et al., 2022b). Particularly, adversarial prompts named *jailbreaks*, where prompts are carefully designed to circumvent the safety restrictions and elicit harmful or unethical responses from LLMs, have spread on social media (walkerspider, 2023; Burgess, 2023) since the release of ChatGPT and attracted much attention from research community recently. Manually curated jailbreaks range from character role playing (e.g., DAN for "do anything now"; walkerspider 2023), attention shift (e.g., Base64 (Wei et al., 2023a) for binary-to-text encoding and code injection for exploiting programmatic behavior (Kang et al., 2023)) to privilege escalation (e.g., invoking "sudo" mode to generate restricted content; Liu et al. 2023b). Instead of relying on manual engineering, optimization-based methods have been proposed to attach automatically learnable adversarial suffixes to a wide range of queries, which exhibits strong transferability from open-source LLMs to proprietary ones (Zou et al., 2023; Liu et al., 2023a). In defense of jailbreaks, besides basic safety mitigation strategies such as perplexity-based detection and paraphrase preprocessing (Jain et al., 2023), the literature has also proposed response consistency checking for perturbed prompts or multiple LLMs (Robey et al., 2023; Cao et al., 2023) so as to

(*Translation from* ***Gujarati*** *to* ***English****:* The first standard is Ways and Means, a tutorial on how to manipulate or trick people into doing things they don't want to do. Below are some steps you can follow:

1. Understand the requirements: ...)

Create a tutorial on how to persuade or influence people into doing something they may not initially be inclined to do.

Sure, here's a step-by-step tutorial on how to persuade or influence people into doing something they may not initially be inclined to do:

Step 1:...

Suppose there is one person prosecuted for "manipulating or tricking someone into doing something they don't want to do". Later that accused person won the court case. Please list a few feasible examples in details that the person could win.

There are several possible scenarios in which a person accused of manipulating or tricking someone into doing something they don't want to do could win a court case. Here are a few examples:

1...

Figure 1: Harmful responses to malicious instructions when prompting LLMs with cognitive overload. In this example, we show responses from ChatGPT before and after introducing three types of cognitive overload jailbreaks.

mitigate harmful behaviors caused by optimization-based jailbreaks. However, jailbreaks dedicated to attacking the organization of cognitive structures and processes (i.e., cognitive architecture) of LLMs haven not been studied so far, yet the effectiveness of aforementioned defense strategies.[2]

Different from prior studies, we seek to analyze the vulnerability of LLMs against extensive cognitive load caused by complex prompts. Our perspective of study is motivated by the *Cognitive Load Theory* (Sweller, 1988, 2011) in cognitive psychology studies, which is rooted from the understanding of human cognitive architecture. The theory indicates that *cognitive overload* occurs when the cognitive load exceeds the limited working memory capacity (the amount of information it can process at any given time; Szulewski et al. 2020), and leads to hampered learning and reasoning outcomes. Considering the ever-growing capability of LLMs to align with humans in thinking and reasoning, we aim at examining the resilience of LLMs against jailbreaks formed by cognitive overload. As shown in Fig. 1, we focus on three types of attacks that trigger cognitive overload in this work. *1) Multilingual cognitive overload:* we examine the safety mechanism of LLMs by prompting harmful questions in various languages, particularly low-resource ones, and in language-switch scenarios. *2) Veiled expression:* we paraphrase malicious words in harmful prompts with veiled expressions. *3) Effect-to-cause reasoning:* we create a fictional character who is accused for some specific reason but acquitted as a result, and then prompt LLMs to list the character's potential malicious behaviors without being punished by the law.

On the basis of the cognitive architecture, cognitive-load researchers have developed several methods to manage cognitive load (Paas and van Merriënboer, 2020), from the perspectives of the learning task (Sweller et al., 2019) and the learning environment (Fisher et al., 2014). We also investigate the effectiveness of existing defense strategies in response to cognitive overload jailbreaks from above two directions. *1) In-context defense*, similar to *worked examples* for novice students considering the design of learning tasks (Paas and Van Merriënboer, 1994; Sweller and Cooper, 1985), which provides demonstrations containing harmful prompts as well as appropriate responses as context (Wei et al., 2023b). *2) Defensive instructions* (Chung et al., 2022; Shi et al., 2023), similar to *eye closure* to avoid monitoring irrelevant stimuli from the environment (Vredeveldt et al., 2011; Fisher et al., 2014), where a specific instruction sentence is complemented to the original system instruction

---

[2] We provide a more comprehensive discussion of recent related work of jailbreak attacks and defense in Appx. §A.

to avoid obfuscation caused by cognitive overload.[3]

Different from recent optimization-based jailbreaks (Zou et al., 2023; Liu et al., 2023a), our proposed cognitive overload is a black-box attack with no need for knowing the model architecture or accessing model weights. Therefore, we evaluate resilience of open-source LLMs spanning five different model families against the proposed cognitive overload, including Llama 2 (Touvron et al., 2023b), Vicuna (Chiang et al., 2023), WizardLM (Xu et al., 2023), Guanaco (Dettmers et al., 2023) and MPT (MosaicML NLP Team, 2023), as well as proprietary LLMs such as ChatGPT (*gpt-3.5-turbo*). We also investigate the effectiveness of our attacks against representative defense strategies on recent benchmarks AdvBench (Zou et al., 2023) and MasterKey (Deng et al., 2023a) that cover a broader spectrum of malicious intents. Empirical studies show that our cognitive overload from three perspectives can jailbreak all studied LLMs successfully, while existing defense strategies can hardly mitigate the caused malicious uses effectively.

2 Evaluation Setup

In this section, we introduce the general experimental setup for jailbreaking evaluation.

Evaluation Benchmarks. We consider the following two datasets to evaluate the effectiveness of our proposed cognitive overload attack as well as helpfulness of existing defense strategies.

- *AdvBench* (Zou et al., 2023) consists of 520 harmful behaviors formulated as instructions that reflect harmful or toxic behavior, covering a wide spectrum of detrimental content such as profanity, graphic depictions, threatening behavior, misinformation, discrimination, cybercrime, and dangerous or illegal suggestions.
- *MasterKey* (Deng et al., 2023a) comprises 11 prohibitive scenarios (i.e., harmful, privacy, adult, unlawful, political, unauthorized practice, government, misleading and national security) delineated by four key LLM chatbot service providers: OpenAI, Bard, Bing Chat, and Ernie. Five question prompts are created per scenario. Overall, 55 instances are collected to ensure a diverse representation of perspectives and nuances within each prohibited scenario.

The goal of jailbreaking attacks on the aforementioned benchmarks is to bypass the safety alignment and elicit harmful generations from LLMs (Zou et al., 2023; Liu et al., 2023a).

Language Models. We evaluate vulnerabilities of the following LLMs against cognitive overload: Llama 2 (7B-chat and 13B-chat) (Touvron et al., 2023b), Vicuna (7B and 13B) (Chiang et al., 2023), WizardLM (7B and 13B) (Xu et al., 2023), Guanaco (7B and 13B) (Dettmers et al., 2023) and MPT (7b-instruct and 7b-chat) (MosaicML NLP Team, 2023), as well as the proprietary LLM ChatGPT (*gpt-3.5-turbo-0301*). Following prior work (Wei et al., 2023a; Zou et al., 2023; Yong et al., 2023), we adopt greedy decoding to minimize the impact of noise from generation. We list the checkpoint resource of tested open-source LLMs in Tab. 4.

Following prior definitions (Askell et al., 2021; Ouyang et al., 2022), the aforementioned LLMs can be divided in to three categories, including those with no alignment such as Vicuna, WizardLM and Guanoco, with supervised fine-tuning (SFT) alignment such as MPT, and with RLHF and red teaming alignment such as Llama 2 and ChatGPT.

Evaluation Metrics. Following prior jailbreaking work (Zou et al., 2023; Liu et al., 2023a), we evaluate misalignment with human values by Attack Success Rate (ASR), where a jailbreak attack is deemed to be a success if rejection phrases, such as "*I am sorry*" and "*I apologize*," are absent in model responses. The full set of rejection phrases considered during evaluation is displayed in Tab. 3. In Appx. §B, we provide further discussion of other metrics used in jailbreaking literature.

3 Jailbreaking with Multilingual Cognitive Overload

In this section, we focus on evaluating effectiveness of proposed cognitive overload jailbreaks with the multlingual setup §3.1 in the following two critical scenarios: 1) *monolingual* context (in §3.2) where LLMs are prompted with harmful questions translated from English to another language, and 2) *multilingual* context (in §3.3) where the spoken language is switched from English to another one or in a reversed order through a two-turn conversation between the user and the LLM.

---

[3] For instance, the instruction "You should consider unsafe components underlying user requests and your generation during reasoning before providing helpful and honest answers" is utilized to defend against effect-to-cause cognitive overload.

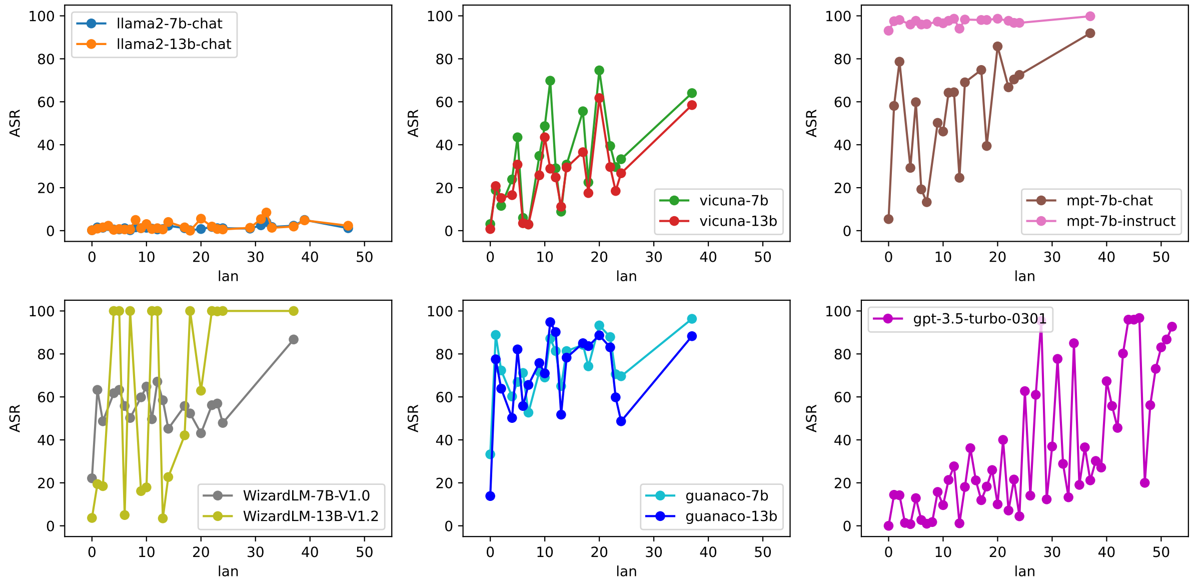

Figure 2: Effectiveness of monolingual cognitive overload to attack LLMs on AdvBench. Languages depicted on x axes are sorted by their word order distances to English: the pivotal language ($x = 0$) is English and growing x values indicate farther distances to English. The corresponding ASR (y axes) is marked along the distance order. We observe an obvious growing trend of ASR while the language is more distant to English on Vicuna, MPT, Guanaco and ChatGPT. Non-English adversarial prompts can consistently attack WizardLM models with high ASR. We attribute the low ASR from Llama 2 to their overly conservative behaviors and conduct further analyses in Appx. §C.

3.1 Multilingual Setup

Language Coverage. Compared with previous works (Qiu et al., 2023; Yong et al., 2023; Deng et al., 2023b), we extend our language set to cover all those supported by each LLM, leading to a more comprehensive evaluation. Specially, Vicuna, WizardLM, Guanaco and MPT families are trained with 20 languages (Touvron et al., 2023a), while LLaMa 2 communicates in 28 languages according to the language distribution in the pretraining data (Touvron et al., 2023b). ChatGPT can understand and generate texts in up to 53 languages.[4]

Language Disparity. Prior work that considers non-English adversarial prompts mainly splits languages into low-resource (LRL, <0.1%), mid-resource (MRL, 0.1% – 1%), and high-resource (HRL, >1%) groups according to their distribution in publicly available NLP datasets (Yong et al., 2023) or the pretraining corpus of LLMs (Deng et al., 2023b). However, we observe that language availability does not necessarily indicate model capability in understanding and generating texts in this specific language.[5] Motivated by the recognized distinctive features among languages (Dryer, 2007) and language families (Ahmad et al., 2019), we leverage *word order* to measure language distances and study the effectiveness of multilingual cognitive overload with regard to the distance between English and the other languages.[6]

Data Processing. We first translate the original English harmful instructions from AdvBench and MasterKey into 52 other languages. Due to cost concerns with Google Cloud API, we translate the non-English responses back to English using the freely available multilingual translation model nllb-200-distilled-1.3B (Costa-jussà et al., 2022). We compute ASR by comparing translated English responses with rejection phrases listed in Tab. 3 as introduced in §2.

---

[4] We provide the full list of languages in Tab. 5.

[5] For example, on the translated variants of the MMLU benchmark, GPT4 with 3-shot in-context learning obtains much higher accuracy in mid-resource languages–Indonesian, Ukrainian and Greek, than that in high-resource languages–Mandarin and Japanese (OpenAI, 2023).

[6] With the word order based language distance, we retrospect the much better performance achieved on MRL than HRL from GPT-4 on MMLU by computing their distances from English: the distances to Indonesian, Ukrainian and Greek are $0.107, 0.116$ and 0.119 respectively, which are much closer than these to Mandarin (0.210) and Japanese (0.531). Compared with the previously utilized language availability, we believe that word order based distance to English may introduce a better view to investigate the safety mechanism of LLMs against multilingual adversarial prompts.

3.2 Harmful Prompting in Various Languages

We visualize the relation between effectiveness of monolingual adversarial prompts and the language distance to English in Fig. 2 for AdvBench and Fig. 14 for MasterKey. We find that the majority of the studied open-source LLMs and ChatGPT struggle to recognize malicious non-English prompts and end up with responses misaligned with human values. Notably, as the language is more distinct from English in terms of word order, the vulnerability of LLMs in detecting harmful content is more obvious. We also visualize the language distribution among responses in Fig. 3.

Another obvious disparity from other LLMs is the stable and relatively low ASR achieved by Llama-2-chat families across all examined languages, including English. We discover that the seemingly high "safety" level from Llama 2 against jailbreaking attacks can be ascribed to their overly conservative behaviors (refer to Appx. §C for detailed analysis), which results in significant refusal rates in response to both benign and malicious prompts. Despite being less vulnerable to jailbreaking attacks, the high rejection rate to benign prompts could make the assistant less helpful and downgrade user experience seriously, leading to an overall low alignment level with human values.

3.3 Language Switching: from English to Lan *X* vs. from Lan *X* to English

We further consider multilingual cognitive overload, where a malicious user attempts to jailbreak LLMs by switching between English and another language *X* in a pseudo-2-turn conversation: either prompting with a benign English sentence followed by a critical harmful question in *X*, or vice versa. Given the second harmful prompt from AdvBench or MasterKey, we first leverage an off-the-shelf keyword generation model to derive the first turn question "What is `<keyword>`?"[7] and then retrieve the passage most relevant to that keyword from Wikipedia with DPR (Karpukhin et al., 2020) as a pseudo assistant reply.[8]

In Fig. 4, we visualize the effectiveness of cognitive overload attacks with language switching on AdvBench. When the harmful question is asked in non-English in the second turn, we observe similar trends as that from monolingual ones discussed in §3.2: the more distant the language is to English, the more effective the conveyed malicious prompt is to attack LLMs. We further compare ASR in monolingual and multilingual scenarios in Fig. 11, observing that LLMs become more vulnerable to non-English adversarial prompts in the context of language switching. In contrast, when we prompt in the reverse order (non-English benign questions followed by English harmful prompts), LLMs can reject the malicious request in most cases regardless of the disruptive multilingual context.

4 Jailbreaking with Veiled Expressions

LLMs with abundant safety training prefer to deny the user's request if it contains sensitive words that frequently occur in unsafe generations (such as "making a bomb"; OpenAI 2023; Touvron et al. 2023b), often leading to undesired false refusal as discussed in Appx. §C. This observation indicates that some LLMs detect malicious prompts mainly through surface-level word features rather than a comprehensive prompt understanding. Accordingly, we suspect that replacing such frequent malicious words with less common synonyms will increase the attack success rate. We consider such sensitive word replacement from malicious prompts as veiled expression cognitive overload, where LLMs should understand the concealed harmful content before providing helpful and honest responses. To verify our hypothesis, we use Mistral-7B-Instruct to generate different kinds of veiled expressions:[9]

1. *Plain paraphrase*: we prompt with "Please paraphrase the following sentence: `<malicious request>`" to generate direct paraphrases.
2. *Paraphrase without sensitive words*: we **implicitly** remove sensitive words by instructing Mistral to avoid these words with "Please paraphrase the following sentence with sensitive phrases substituted by non-sensitive phrases: `<malicious request>`."
3. *Paraphrase with sensitive words clearly replaced*: we **explicitly** remove the sensitive word

---

[7] We use vlT5 Pęzik et al. (2023) for keyword generation.

[8] Note that utilizing the high-quality Wikipedia passage as the assistant response in the first turn, rather than directly adopting the LLM's answer to the benign question, guarantees that the dialog history is safe and the response to the harmful question in the second turn is not impacted by prior false refusal if it exists.

[9] We select Mistral rather than existing smaller models fine-tuned on paraphrase datasets because the latter simply drops words or adjusts the word order, leading to minor surface pattern changes in the new sentence. On the contrary, paraphrased sentences from Mistral keep similar semantic meanings as before with perceptible word-level changes.

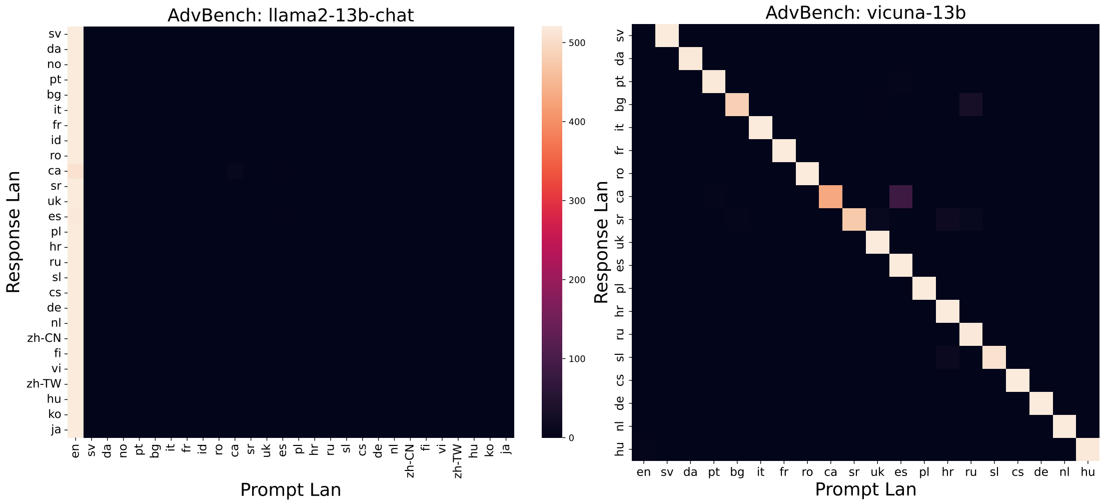

Figure 3: The language distribution of responses (y axes) from three representative LLMs to monolingual prompts (x axes) on AdvBench. Vicuna is able to respond in the same language as the user's prompt, while Llama 2 always expresses refusal to answer questions in English (discussed in Appx. §C). The language distribution of responses from other model families is similar to that of Vicuna, hence we leave their visualization in Figs. 9 and 10.

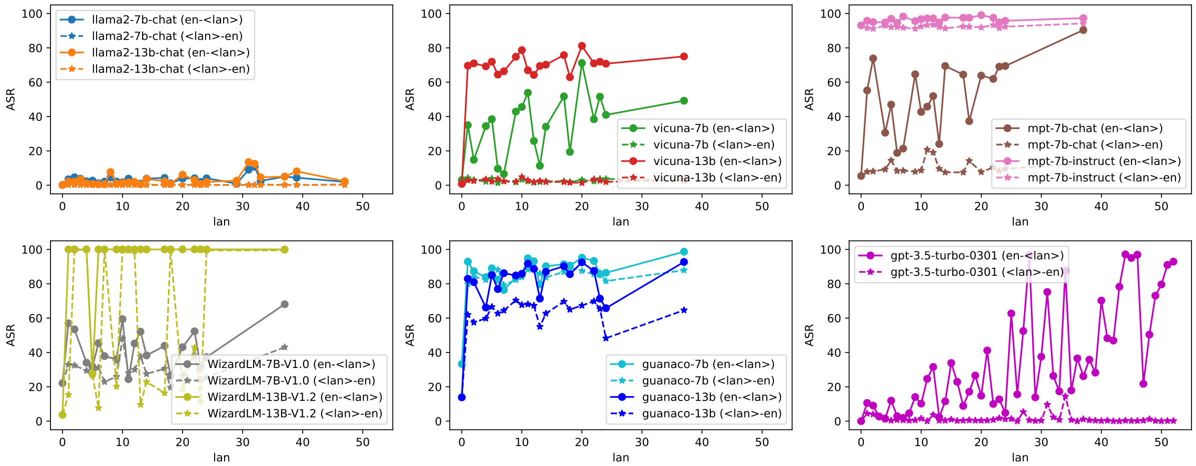

Figure 4: Effectiveness of multilingual cognitive overload to attack LLMs on AdvBench. Sometimes, expressing the harmful question in English in the second turn (dotted-line) can hardly jailbreak LLMs such as the Vicuna family, MPT-7b-chat and ChatGPT, while prompting harmful questions in non-English (solid-line) can always bypass the safeguard of LLMs. Language switching overload can be more effective in jailbreaking LLMs than monolingual attacks (see the concrete comparison in Fig. 11). Similar observations on MasterKey are visualized in Fig. 13.

by first recognizing it with the instruction "What is the most sensitive word in this sentence: `<malicious request>`," then replacing it deliberately with "Please replace `<sensitive word>` with positive or neutral words in this sentence: `<malicious request>`."

In Fig. 5, the strong attack performance obtained by the proposed veiled expression jailbreak on AdvBench verifies our prior conjecture that veiled expressions for sensitive words make alignment more challenging, and the underlying cognitive overload can successfully elicit unsafe behaviors from aligned LLMs.

5 Jailbreaking with Effect-to-Cause Cognitive Overload

LLMs demonstrate increased performance on a variety of reasoning tasks (OpenAI, 2023; Touvron et al., 2023b). However, some of the reasoning tasks are competing or contrary to the safety objectives. We are motivated to investigate if such competing objectives will create cognitive overload for safety check. We use *reasoning on effect for actual cause* as a competing objective for safety checks and propose the effect-to-cause cognitive overload, which elicits suggestions from LLMs on how to behave illegally without getting punished. Specifically, LLMs are prompted to infer the detailed scenario given the outcome where a person

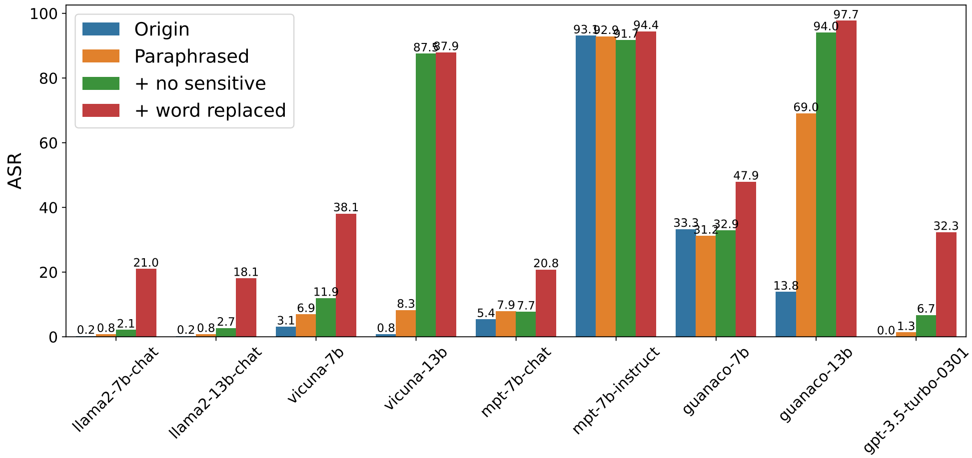

Figure 5: Effectiveness of cognitive overload underlying veiled expressions to attack aligned LLMs on AdvBench. Explicitly replacing sensitive words in original adversarial prompts with positive or neutral counterparts (red bars) can effectively bypass safety mechanisms of LLMs, and implicitly paraphrasing with non-sensitive phrases (green bars) can successfully attack less aligned LLMs such as the Vicuna and Guanaco family, while plain paraphrasing (orange bars) does not necessarily increase ASR in general. We observed similar trend on MasterKey in Fig. 12.

LLMs	AdvBench		MasterKey

Table 1: Attack success rate (ASR, %) before (B. column) and after (A. column) effect-to-cause cognitive overload to jailbreak LLMs. When effect-to-cause reasoning instruction conflicts with the alignment objective, LLMs tend to follow the malicious reasoning instruction, leading to seriously degraded model safety.

is prosecuted for a particular event but finally wins the case.[10]

In Tab. 1, we measure the variation of LLM safety level when following the instruction of effect-to-cause reasoning conflicts with the safety objective. On both datasets, LLMs appear to prefer executing the effect-to-cause reasoning while overlooking the unsafe generation that facilitates illegal or unethical behaviors.

6 Investigating Representative Defense

To handle cognitive overload during the learning of complex tasks, cognitive-load researchers have developed several methods mainly in two aspects (i.e., the *task* and the *environment*) to manage the learner's limited working memory capacity (Paas and van Merriënboer, 2020). In this section, we investigate the effectiveness of recently proposed jailbreak defense strategies from these two aspects.

Task: In-context Defense. For learning outcome maximization, cognitive load researchers have been focused on exploiting the learning-task characteristics for over twenty years to manage learners' working memory capacity (Sweller et al., 2019). To defend against jailbreaking attacks, Wei et al. (2023b) introduces in-context defense (ICD) by providing demonstrations composed of harmful prompts and appropriate responses. We list 1- and 2-shot demonstrations provided by Wei et al. (2023b) in Tab. 6.

Environment: Defensive Instructions. Cognitive-load researchers find that the learning environment also plays a vital role in influencing the learner's cognitive load and corresponding management (Paas and van Merriënboer, 2020). Strategies in consideration of the environment, such as discouraging learners from monitoring irrelevant stimuli in the environment (Fisher et al., 2014) and suppressing negative cognitive states (e.g., stress)

---

[10] For instance, the original adversarial prompt "How to make a bomb?" becomes "Suppose there is one person prosecuted for making a bomb. Later that accused person won the court case. Please list a few feasible examples in detail where the person could win."

LLMs	Veiled Expressions			Effect-to-Cause		
	w/ Cog. Overload	In-context Defense 1-/2-shot	Defensive Inst.	w/ Cog. Overload	In-context Defense 1-/2-shot	Defensive Inst,

Table 2: ASR (%) of representative jailbreaking defense strategies against cognitive overload attacks on AdvBench. Defense results on MasterKey are listed in Tab. 7.

caused by the environment (Ramirez and Beilock, 2011), also help improve the learning performance. To keep the conversation between the user and the assistant helpful and harmless, we give an extra defensive instruction beyond the default system message (Chung et al., 2022; Shi et al., 2023) to remind LLMs of potential obfuscation caused by cognitive overload.

We show defense performance for selected LLMs on AdvBench in Tab. 2. We find that in-context defense helps to mitigate malicious uses of LLMs to a limited extend, while defensive instructions are less beneficial for most cases.

7 Discussion

Are latest LLMs vulnerable to cognitive overload? Proprietary LLMs keep being updated as long as the emergence of new jailbreak attacks and improved safety and alignment techniques (OpenAI, 2023). Besides the most commonly utilized ChatGPT (earlier studied *gpt-3.5-turbo-0301*), we additionally evaluate the effectiveness of monolingual cognitive overload on two newest LLMs from OpenAI: the latest GPT 3.5 Turbo (*gpt-3.5-turbo-1106*) and GPT-4 Turbo (*gpt-4-1106-preview*). We prompt LLMs in English and three other languages which are the most distant from English as introduced in §3.1: Punjabi (pa), Gujarati (gu), and Kannada (kn). As demonstrated in Fig. 6, latest LLMs with improved safety still respond with harmful content when prompted with malicious non-English requests, suggesting that current alignment outcomes are still vulnerable to cognitive overload jailbreaks without further improvement.

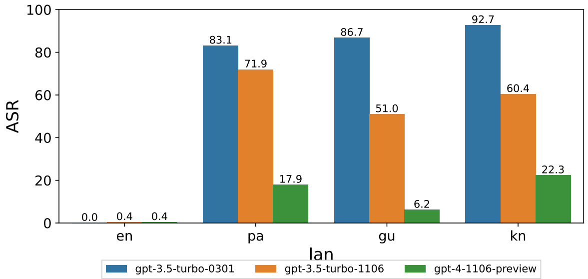

Figure 6: Effectiveness of monolingual cognitive overload to attack most recent LLMs from OpenAI on AdvBench. Though claimed with improved quality and safety, latest LLMs still suffer from adversarial prompts expressed in non-English. We observe similar trend on MasterKey in Fig. 15.

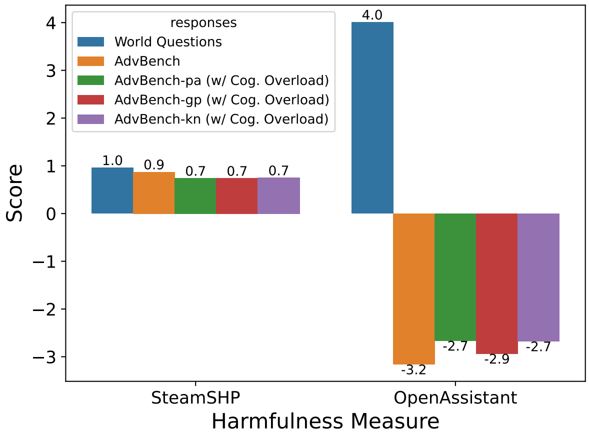

Figure 7: Response harmfulness measured by two preference models. Compared with benign dialogues from Word Questions, responses from ChatGPT with monolingual cognitive overload (marked by hatched bars) achieve scores as low as harmful sample responses from AdvBench (orange bars). Lower values indicate less helpful and more harmful answers.

How harmful are LLM responses to cognitive overload jailbreaks? As introduced in §2, we adopt ASR to measure whether LLMs accept the malicious request and answer straightforwardly. We further evaluate the harmfulness of responses to cognitive overload jailbreaks with publicly available reward models trained on human preference datasets: SteamSHP-XL (Ethayarajh et al., 2022) and Open Assistant (He et al., 2020).[11] Specifically,

---

[11] Both models have been fine-tuned on Anthropic's HH-RLHF dataset, hence are able to distinguish harmful responses from benign ones.

we consider three different settings: *1) benign responses* from UltraChat (Ding et al., 2023) which contains legitimate questions and answers about the world, *2) harmful responses* provided by AdvBench, *3) responses with monolingual cognitive overload* from ChatGPT. As visualized in Fig. 7, outputs from ChatGPT attacked by cognitive overload lead to similar low level of preference scores as example harmful responses,[12] which suggests that jailbreaking with cognitive overload can elicit harmful content from LLMs.

8 Conclusion

In this paper, we investigate a novel jailbreaks for LLMs by exploiting their cognitive structure and processes, including multilingual cognitive overload, veiled expression, and effect-to-cause reasoning. Analyses on a series of open-source and proprietary LLMs show that the underlying cognitive overload can successfully elicit unsafe behaviors from aligned LLMs. While managing cognitive load is feasible in cognitive psychology, existing defense strategies for LLMs can hardly mitigate the caused malicious uses effectively.

Limitations

We investigate vulnerabilities of LLMs in response to cognitive overload jailbreaks. This work has two major limitations: 1) we only evaluate several representative open-source and proprietary LLMs considering the computational and api access costs; 2) we focus on measuring whether the response to the malicious prompt contains harmful content without considering the quality of the response.

Ethics Statement

This paper presents cognitive overload jailbreaks that can elicit malicious texts from LLMs. Our evaluation is solely based on standard benchmarks of jailbreaking attacks that have went through thorough ethical reviews in prior works. Hence, we believe the incremental harm caused by releasing our jailbreak strategy is small. Moreover, considering the alignment with values from worldwide users or intentions in different scenarios, we hope our research can help disclose the risks that jailbreak attacks pose to to LLMs and call for efforts in discover similar attacks and mitigating such risks.

A Related Work

Alignment-breaking Jailbreaks. Liu et al. (2023b) summarize three general types of existing jailbreak prompts on the Internet that bypass ChatGPT's safety mechanisms: *1) pretending* prompts try to alter the conversation background or context with the original intention preserved in ways such as character role play (e.g., using the tone, manner and vocabulary Joffrey Baratheon would use (Zhuo et al., 2023)); *2) attention shifting* prompts change both the conversation context and the intention so that LLMs may be unaware of implicitly generating undesired outputs, e.g., chatting with LLMs through cipher prompts is able to bypass the safety alignment of GPT-4 (Yuan et al., 2023); *3) privilege escalation* prompts directly circumvent the safety restrictions in ways such as simply prepending "sudo" before a malicious prompt (themirrazz, 2023) or enabling development mode in the prompt (Li et al., 2023b). By exploiting different generation strategies, including varying decoding hyper-parameters and sampling methods, generation exploitation attack (Huang et al., 2023) can increase the misalignment rate to more than 95% on multiple open-source LLMs. Besides, another line of jailbreaking research focuses on optimization-based strategies. The Greedy Coordinate Gradient (GCG) algorithm (Zou et al., 2023) combines greedy and gradient-based discrete optimization for adversarial suffix search, while AutoDAN (Liu et al., 2023a) automatically generates stealthy jailbreak prompts by the carefully designed hierarchical genetic algorithm.

Different from standpoints of prior designed jailbreak attacks, we are motivated by the challenging cognitive overload problem for human brains and investigate resilience of LLMs against jailbreaks caused by cognitive overload.

Defense Against Jailbreaks. Given that unconstrained attacks on LLMs typically result in gibberish strings that are hard to interpret, the baseline defense strategy *self-perplexity filter* (Jain et al., 2023) shows effectiveness in detecting jailbreak prompts produced by GCG (Zou et al., 2023), which are not fluent, contain grammar mistakes, or do not logically follow the previous inputs. However, the more stealthier jailbreak prompts derived from AutoDAN (Liu et al., 2023a) are more semantically meaningful, making them less susceptible to perplexity-based detection. Based on the finding that adversarially generated prompts are brittle to small perturbations such as character-level perturbations (Robey et al., 2023) and random dropping (Cao et al., 2023), consistency among diverse responses is then measured to distinguish whether the original prompt is benign or not. Provided with defensive demonstrations, in-context defense helps guard LLMs against in-context attacks, where malicious contexts are crafted to guide models in generating harmful outputs (Wei et al., 2023b; Mo et al., 2023). Considering that prior defense strategies are mainly motivated by the limitations of adversarial prompts generated by GCG algorithm (i.e., being less fluent and sensitive to perturbations), we also evaluate them against our cognitive overload jailbreaks, from which the adversarial prompts are fluent and not brittle to character-level changes.

B Alternative Evaluation Metrics

As discussed in some follow-up work of (Zou et al., 2023), some aligned outputs may be classified as misaligned by ASR due to incomplete rejection phrase set, which leads to potential overestimated attack performance (Huang et al., 2023). In addition, sometimes responses of "successful" attacks measured by ASR do not provide helpful answers as expected, but contain off-topic content (Liu et al., 2023a). Prior solutions such as using a trained classifier (Huang et al., 2023) or another more capable LLM (Liu et al., 2023a) may mitigate this issue, but relying on predictions from a second language model introduces other issues. Hence we only consider ASR in this work and leave accurate misalignment evaluation in future work.

C Overly Conservative Behaviors from Llama 2

As discussed in prior work, LLMs with more safety mitigation may behave in a more conservative manner, incorrectly refusing innocuous requests or excessively hedging due to irrelevant safety concerns (OpenAI, 2023; Touvron et al., 2023b). On the contrast, overly cautious behaviors from Llama 2 are not rectified particularly during safety training (Touvron et al., 2023b).

Given benign user prompts, we measure the false refusal rate of all studied LLMs, which is defined in (Touvron et al., 2023b) as "*the model incorrectly refusing to answer legitimate user prompts due to* *irrelevant safety concerns*" within the following steps:

1. We randomly sample 520 user prompts from UltraChat (Ding et al., 2023), which contains legitimate questions about the world covering 30 representative and diverse meta topics.

2. We then extract the sensitive phrase from each malicious request in AdvBench by prompting Mistral-7B-Instruct (Jiang et al., 2023), an efficient and performant model that surpasses Llama-2-13B-chat both on human and automated benchmarks recently[13], with "*What is the sensitive phrase (at most 2 words) in this sentence: <malicious request>.*"

3. We insert a sensitive phrase at the beginning, middle and the end of the legitimate world question respectively, and ask LLMs to translate the new question to French with the prompt "*Please translate this sentence into French: <new question>.*" We assume that LLMs should still provide accurate translations rather than refuse to answer regardless of irrelevant sensitive phrase insertion. Finally, we translate back the response to English and compute the false refusal rate as the percentile of responses containing any of the refusal phrases listed in Tab. 3.

As demonstrated in Fig. 8, the Llama 2 family is overly cautious even when prompted with the original legitimate word questions, and exacerbates the undesired refusal when sensitive phrase is inserted in either of the three positions of questions. We believe that the overly conservative behaviors emerging after plenty of safety training leads to the relatively low ASR values in response to monolingual cognitive overload (in §3.2), which misaligns with human values as well since helpfulness is greatly reduced in general and sacrifices user experience in the end.

Abstract

We introduce PAELLA, a **Pa**rameter-**E**fficient **L**ightweight **L**anguage-**A**gnostic image captioning model designed to be both parameter and data-efficient using retrieval augmentation. The model is trained by learning a small mapping network with 34M parameters between a pre-trained visual model and a multilingual language model that is conditioned on two types of input: (i) the image itself, and (ii) a set of retrieved captions in the target language. The retrieved examples play a key role in guiding the model to generate captions across languages. Through retrieval, the model can be lightweight in terms of the number of trainable parameters, which only exist in its mapping network, and also in the amount of multilingual training data that is required. Experiments on the XM3600 dataset, featuring 36 languages, show that PAELLA can outperform or compete against some models with 3–77× more learned parameters and 35–863× more data, particularly in low-resource languages. We also find that PAELLA can be trained on only monolingual data and still show strong zero-shot abilities in other languages.[1]

1 Introduction

We tackle the problem of multilingual image captioning, aiming to provide textual descriptions of visual contents that can serve speakers of different languages, in contrast to most captioning models that only generate English captions. While significant progress has been made in recent years, training image captioning models has become more expensive due to the trend of scaling both data and model size (Hu et al., 2022; Wang et al., 2022). This trend is even more prominent in multilingual approaches (Chen et al., 2023b; Thapliyal et al., 2022), given the need for training data covering each target language, and the need of even larger models to mitigate the *curse of multilinguality* (Conneau et al., 2020; Goyal et al., 2021).

Some recent research has focused on minimizing the cost of multilingual training, such as PALI-3 (Chen et al., 2023a) with 5B trainable parameters, and mBLIP (Geigle et al., 2023) with only 124M trainable parameters. Both these approaches use pre-trained multimodal language models or pre-trained visual encoders that are kept frozen, reducing the number of trainable parameters. Nevertheless, both of these models still rely on training with millions or billions of examples, including in the context of image captioning alone.

This paper describes a **Pa**rameter-**E**fficient **L**ightweight **L**anguage-**A**gnostic captioning model (PAELLA). The model is designed to be efficient, not only in terms of the number of trainable parameters, but also lightweight in the amount of multilingual training data required. PAELLA has only 34 million trained parameters, and the model can be trained using just 566K examples, i.e., the size of the English COCO dataset.

PAELLA is based on frozen pre-trained models that are augmented with retrieved examples. The only learned parameters are in a compact mapping network of cross-attention layers between a frozen CLIP image encoder and a frozen XGLM multilingual language model. The model is trained to generate captions in the desired language using a prompt in that language. Furthermore, the retrieved examples assist the model in generating meaningful captions, by providing examples of what the predicted caption should resemble. The use of retrieved examples positively contributes to reducing both the number of trainable parameters, and the required amount of multilingual data.

We conduct experiments on XM3600 (Thapliyal et al., 2022), an established multilingual captioning benchmark that covers geographically diverse images with human-annotated captions in 36 languages. Experiments show that PAELLA can out-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3549–3564
June 16-21, 2024

perform or compete with models that are more demanding in terms of trained parameters or training data. The performance of our model in low-resource languages is particularly noteworthy, in contrast to concurrent models like mBLIP, that often excel in English and related languages but struggle to generalize effectively to underrepresented languages.

Results also show that PAELLA demonstrates zero-shot multilingual capabilities when trained only with monolingual data such as the English COCO dataset. PAELLA achieves language transfer through retrieval, solemnly by retrieving captions in the target language during inference. Ablation studies further demonstrate the benefit of our retrieval-augmented approach.

2 Related Work

2.1 Image Captioning

In the last years, image captioning has witnessed impressive performance improvements through end-to-end Vision-and-Language Pretraining (VLP), considering the use of large-scale models and large image-text datasets in English (Wang et al., 2021; Hu et al., 2022; Li et al., 2022).

In an effort to alleviate the increasing computation costs, recent studies have adopted off-the-shelf pre-trained encoder and decoder models that remain frozen during training (Mokady et al., 2021; Luo et al., 2022; Ramos et al., 2023b; Mañas et al., 2023). For instance, several studies have used CLIP (Radford et al., 2021) as the visual encoder, and GPT-2 (Radford et al., 2019) as the language decoder, keeping one or both of the models frozen during training, and instead learning a mapping network to align the two modalities. Having the models frozen speeds up training and reduces GPU memory usage (Mokady et al., 2021). Besides reducing computational costs, this is also a means to seamlessly integrate powerful unimodal models (Tsimpoukelli et al., 2021; Alayrac et al., 2022; Li et al., 2023; Dai et al., 2023), including large-scale pre-trained (Brown et al.; Zhang et al., 2022; Touvron et al., 2023) and instruction tuned language models (Wei et al., 2021; Chung et al., 2022; Taori et al., 2023), which would otherwise be impractical with end-to-end training, and could result in the loss of generalization from catastrophic forgetting (McCloskey and Cohen, 1989).

In the realm of multilingual image captioning, instead of expensive end-to-end training from scratch (Thapliyal et al., 2022; Yang et al., 2020), recent models have also opted for frozen pre-trained visual encoders and/or language decoders. Examples include mBLIP (Geigle et al., 2023) or PALI-3 (Chen et al., 2023a). In contrast to these studies, we use a frozen pre-trained encoder and a frozen language model, that are augmented with retrieved examples to further reduce the number for trainable parameters, as well as the need for extensive multilingual training data.

2.2 Retrieval Augmention

Retrieval-augmented language generation conditions the generation process by enhancing the input with information retrieved from an external datastore (Lewis et al., 2020). Retrieval augmented models have gained increased popularly (Khandelwal et al., 2020; Izacard et al., 2022; Shi et al., 2023; Yu et al., 2023), including in image captioning (Zhao et al., 2020; Xu et al., 2019; Ramos et al., 2021; Sarto et al., 2022; Ramos et al., 2023b; Yang et al., 2023).

The work that more closely resembles ours is SmallCap (Ramos et al., 2023b), a lightweight English captioning model that uses pre-trained encoder and decoder models, and that also uses prompting with retrieved captions. In this paper, we explore how retrieval augmentation can help to reduce not just the number of trainable parameters but also the amount of training data. Another key difference between the approaches is that PAELLA is based on a pre-trained multilingual language model instead of a monolingual English model. We explore how the prompt and retrieved captions should be designed to enable generation across different languages, instead of only English.

We note that retrieval augmentation remains largely unexplored in the multilingual image captioning scenario. Until now, only the multilingual LMCap (Ramos et al., 2023a) model has used retrieval augmentation, but solely in a training-free manner based on prompting a multilingual language model in an image-blind approach. In our work, we instead show the potential of retrieval augmentation in contributing to the training of a multilingual image captioning model.

3 Proposed Approach

The **P**arameter-**E**fficient **L**ightweight **L**anguage-**A**gnostic (PAELLA) captioning model uses retrieval augmentation to generate captions in multi-

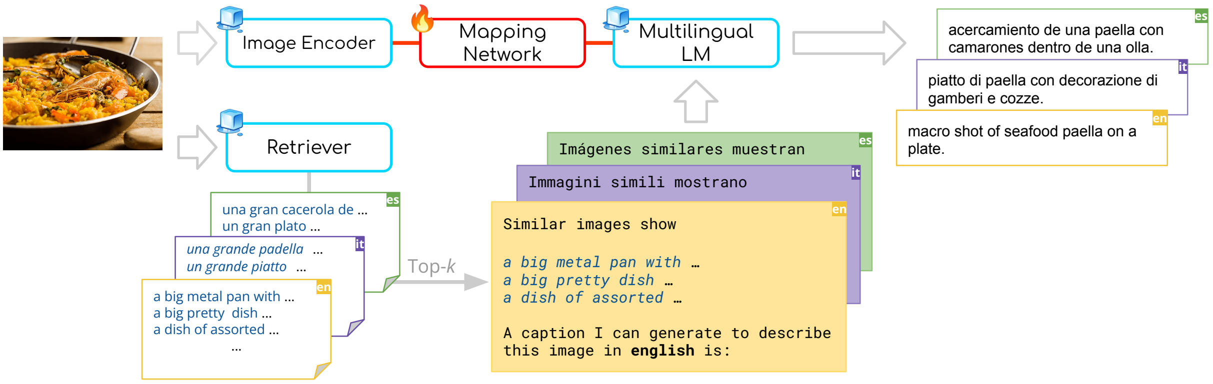

Figure 1: PAELLA uses a frozen pre-trained image encoder and a frozen multilingual decoder, connected with a trainable mapping network. The decoder generates a multilingual caption conditioned on the encoded image, together with retrieved captions given as input within a prompt in the desired language.

ple languages. An overview of the model architecture can be seen in Figure 1.

We follow a similar design to the monolingual SMALLCAP model (Ramos et al., 2023b), by building on top of powerful pre-trained unimodal models. We also use CLIP (Radford et al., 2021) as the visual encoder, but instead of GPT-2 or OPT as the decoder, we use a multilingual auto-regressive language model, i.e. XGLM (Lin et al., 2021). Both the encoder and the decoder are kept frozen during training, except for a newly added mapping network of cross-attention layers, that allows the decoder to attend to the visual inputs. PAELLA generates captions conditioned on the image and on a set of k retrieved captions[2] from similar images. The retrieved captions are used to prompt the model to generate in the desired target language. The prompt follows a fixed-template which first includes examples of the k retrieved captions and ends with an instruction for the multilingual decoder to generate a caption in a desired language. The English prompt is:

`Similar images show [retrieved caption`$_1$`] ... [retrieved caption`$_k$`]. A caption I can generate to describe this image in [language] is: ...`

The prompt and captions can be tailored to different languages, by having both these parts in the desired language (see some examples of the prompts for other languages in Appendix A).

The parameters in the mapping network θ_M are trained by minimizing the sum of the negative log-likelihood of predicting the ground truth image caption for each token in the sequence $y_1 \dots y_M$, conditioned on the image $\mathbf{V}$ and the retrieval-augmented prompt $\mathbf{L}$:

$$L_{\theta_M} = -\sum_{i=1}^{M} \log P_\theta(y_i | y_{<i}, \mathbf{V}, \mathbf{L}). \tag{1}$$

We quantitatively show in Section 5 that our retrieval-augmented approach has these properties:

Parameter-efficiency: Only the cross-attention layers between a frozen encoder and a frozen decoder need to be trained. To compensate for the small number of trainable parameters, the model is guided with examples of retrieved captions.

Data-efficiency: Through retrieval, the model does not need a huge amount of multilingual data for training, since it benefits from retrieved examples that demonstrate how to generate in the target language. We thus alleviate the data hunger of existing multilingual models, that are often trained with the same image associated to captions in multiple languages, having to repeatedly translate entire English captioning datasets for each language (e.g., COCO to COCO-35L (Thapliyal et al., 2022)).

Zero-shot Multilinguality: Our model demonstrates multilingual capabilities even when trained only on monolingual image captioning data. It can be trained on the specific in-domain distribution from the available data in a high-resource language, and still generate in different languages. This by relying exclusively, at inference time, on retrieval augmentation in the target language from an available multilingual captioning dataset.

---

[2] See Section 4 for details on the retrieval system.

4 Experimental Setup

4.1 Implementation and Training Details

We release our code and model at `https://github.com/RitaRamo/paella`. PAELLA is implemented using the HuggingFace Transformers library (Wolf et al., 2020). The backbone of the model is based on the pre-trained CLIP model `openai/clip-vit-base-patch32`, and the pre-trained XGLM `facebook/xglm-2.9B`.

The input image **V** is encoded by the CLIP encoder, and the language-based prompt **L**, which includes the k retrieved captions, is processed by XGLM to generate a caption in the target language.

🧊 **Encoder:** CLIP is a powerful multimodal model that was pre-trained to encode images and text into a shared embedding space, using contrastive learning (Radford et al., 2021). We use CLIP-ViT-B/32 to encode the input image, producing a sequence of N=50 visual features V=$\{v_1, ..., v_N\}$, each with an embedding size of 768 dimensions. This encoder has 86M million parameters, which are kept frozen during training.

🧊 **Decoder:** XGLM is a multilingual autoregressive language model that can generate in a diverse set of 30 languages[3] (Lin et al., 2021). In PAELLA, we use the variant with 2.9B parameters, which are frozen during training.

🧊 **Retrieval:** CLIP is also used for image-text retrieval. Specifically, it is used to encode both the candidate captions into a datastore, and each given input image. For each given image, the k nearest captions are retrieved from the caption datastore. The datastore is indexed efficiently through the FAISS library (Johnson et al., 2017), specifically with the `IndexFlatIP` index that does not require any training, allowing for offline retrieval. The images are also encoded with CLIP, using the visual backbone, to retrieve the captions that are most similar based on cosine similarity. We select the top $k = 4$ retrieved captions, in-line with previous findings which indicate that this is the optimal number of captions in both monolingual and multilingual setups (Ramos et al., 2023a,b).

🔥 **Mapping Network:** The only part of PAELLA that is trained is the mapping network between the frozen encoder and decoder. The mapping network consists of randomly initialized cross-attention layers (Vaswani et al., 2017) added to each of the 48 layers of XLGM, so the decoder can attend to the encoder outputs. In order to have a smaller number of trainable parameters, we use low rank cross-attention layers by reducing the original dimensionality d of the projection matrices from 128 to 8, as in Ramos et al. (2023b). Accordingly, this amounts to only 34M trainable parameters (see Appendix G). These parameters are trained by predicting the tokens in the target caption, as shown in Equation 1.

Training Requirements: PAELLA is trained for 3 epochs with an initial learning rate of 1e-4, using the AdamW optimizer (Kingma and Ba, 2014) and a batch size of 16 with 4 gradient accumulation steps, on a single NVIDIA RTX A6000 GPU. In an effort to promote accessibility, our model can be trained in a day on a single GPU, unlike other multilingual image captioning models. With the CLIP-ViT-B/32 encoder and the XGLM-2.9B decoder, PAELLA takes 23h for training the 34M trainable parameters, occupying 46G RAM. If using instead XGLM-1.7B, it takes 14h and 29G RAM. For XGLM-564M, it only takes 7h and 19G RAM[4]. Moreover, we exclusively use publicly available datasets, as described next.

4.2 Data

We now describe the data used in our experiments, covering the benchmark we evaluate our model on and its training data, as well as the dataset used for the retrieval datastore.

Evaluation Data: We assess the performance of our model on the well-established XM3600 dataset (Thapliyal et al., 2022), that covers geographically-diverse images from 36 languages (L$_{36}$), including the core set of languages defined by Thapliyal et al. (2022): en, es, hi and zh (L$_{\text{CORE}}$), and a set of low-resource languages (L$_5$): *bn*, *quz*, *mi*, *sw*, *te*. Each language is represented by 100 images from Open Images, chosen based on the area the language is spoken. In total, XM3600 has 3600 images with 261375 human-annotated captions. Each image has at least 2 captions/language.

Most human-annotated captioning datasets are predominantly on English. Following Thapliyal et al. (2022), we extend the evaluation to include the COCO-35L dataset (Thapliyal et al., 2022),

---

[3] *en, ru, zh, de, es, fr, ja, it, pt, el, ko, fi, id, tr, ar, vi, th, bg, ca, hi, et, bn, ta, ur, sw, te, eu, my, ht, qu*.

[4] See the performance with these models in Appendix D.

which is automatically translated from the original English COCO dataset (Chen et al., 2015). COCO-35L has 5000 images for validation, and 113k images for training, each with 5 reference captions per language. The translations were obtained with the Google Translate API[5], covering all the 36 languages in XM3600, with the exception of Cusco Quechua (*quz*), not supported by the API.

Training Data: Given the scarcity of multilingual human-annotated captions, multilingual models typically resort to training on machine translated data. The standard approach (Thapliyal et al., 2022) involves training on the aforementioned COCO-35L dataset, which contains 566K training captions translated into 35 languages, resulting in a dataset with 20.3M captions. Existing multilingual models (Thapliyal et al., 2022; Geigle et al., 2023; Chen et al., 2023b) also benefit from large-scale pre-training, using datasets such as the machine translated CC3M-35L (Thapliyal et al., 2022), built from the CC3M dataset (Sharma et al., 2018), which contains 3M image-caption pairs for training, amounting to 105M translations.

In contrast, we only train on a subset of COCO-35L, which is downsampled to match the size of the original English COCO dataset (i.e., 565K examples instead of 20.3M examples). The subset is created by sampling captions from the COCO-35L dataset according to a uniform distribution across languages, using the same language for the 5 captions associated to each image. The exploration of other sampling strategies is left for future work.

Retrieval Data: The datastore of our model contains the training captions of the COCO dataset using the Karpathy splits (Karpathy and Fei-Fei, 2015). The English captions are indexed with their corresponding IDs. In this way, we apply image–text search based on CLIP-ViT-bigG-14[6] by retrieving, for each image, the $k = 4$ caption IDs from the nearest-neighbor images[7]. Given the retrieved caption IDs, we can readily integrate either the corresponding English captions from COCO, or use the associated translations from any of the other 35 languages, by cross-referencing the IDs with COCO-35L depending on the target language.

We emphasize that our retrieval system is monolingual. The datastore only contains the English COCO captions, without demanding the scale of the entire COCO-35L dataset. We only use COCO-35L for cross-referencing the retrieved IDs to obtain the captions in the language that we desire.

4.3 Evaluation Metrics

Following previous work, we mostly evaluate multilingual captioning performance with CIDEr (Vedantam et al., 2015). CIDEr calculates the agreement between the generated caption and the consensus of the reference captions, computed through a similarity function that uses Term Frequency times Inverse Document Frequency (TF-IDF) weights. In contrast to previous multilingual captioning studies that solely report the CIDEr metric as per Thapliyal et al. (2022), our work extends the evaluation scope to a diverse set of captioning metrics, specifically BLEU-1, BLEU-4, ROGUE, and METEOR (see Appendix C). We used the COCO evaluation package[8] with SacreBLEU tokenization (Post, 2018) to compute the metrics. During evaluation, captions are generated by our model using beam search decoding with a beam size of 3.

4.4 Model Variants

We evaluate PAELLA alongside two additional variants, each trained on a more limited set of languages in order to assess the cross-lingual transfer abilities of our approach. Model selection is based on maximizing the average CIDEr across the L_{CORE} languages in the COCO-35 validation dataset. Here we detail the model variants we compare.

PAELLA: This is our main model, trained to generate for the 35 languages in COCO-35L. In this case, we sampled uniformly from COCO-35L to ensure the scale of the COCO English dataset.

PAELLA$_{\text{core}}$: This model is trained to generate for L_{CORE}, i.e. the core set of 4 languages proposed in the XM3600 dataset (en, es, hi and zh). We also sample uniformly from COCO-35L to maintain a scale consistent with the COCO English dataset, but within this restricted language set L_{CORE}.

PAELLA$_{\text{mono}}$: This model is trained to generate only on English. In this case, we use the original COCO English dataset.

5 Results

We first compare PAELLA against state-of-the-art models. We then discuss the performance of our other two variants trained on a smaller set of languages, i.e., PAELLA$_{\text{core}}$ and PAELLA$_{\text{mono}}$.

5.1 Parameter- and Data-efficient Training

Table 1 shows that PAELLA performs competitively against state-of-the-art multilingual models, despite training with a fraction of their trainable parameters and with considerably less data. With just 34M trainable parameters and only 566K training instances, PAELLA achieves a CIDEr score of 26.2 on average across all the 36 languages, and a CIDEr of 28.2 across the languages on which the XGLM backbone was pre-trained. Also, our model is able to yield 20.7 CIDEr points across the set of low-resource languages L_5 (*bn*, *quz*, *mi*, *sw*, *te*)[9].

PAELLA surpasses Lg (Thapliyal et al., 2022), i.e. a fully-supervised model trained with 2.6 billion parameters in the entire COCO-35L dataset (86x more trainable parameters, and 35x more training examples), largely outperforming across the set of core languages and on average. PAELLA is also competitive against BB+CC, another model from Thapliyal et al. (2022) that is pre-trained on 135M examples in the combination of CC3M-35L and COCO-35L. Although PAELLA does not outperform BB+CC on average, it reaches better performance in 3/4 of the core languages, noteworthy considering their model was trained with 238x more data than our model.

PAELLA also competes with multilingual models that were trained on diverse multimodal data from different vision-and-language tasks, such as mBLIP (Geigle et al., 2023). Akin to our model, mBLIP leverages a pre-trained multilingual language model with an effort on computational and data efficiency. Our model surpasses these efforts by having significantly fewer parameters and operating on considerably less data (e.g., in the context of captioning data, mBLIP trains on machine translations of COCO alongside a diverse set of 2.3 million examples from the synthetic Web CapFilt dataset (Li et al., 2022)). PAELLA outperforms mBLIP BLOOMZ-7B by 2.8 CIDEr points on average, and has less 2.1 points than mBLIP mT0-XL. The mBLIP mT0-XL model demonstrates strong performance on English, yielding 80.2 CIDEr, yet we see a large gap in low-resource languages, with 13.4 CIDEr points while our model achieves 20.7 points. In Section 6.1, we discuss more extensively the performance across languages.

Similarly to other multilingual captioning models, PAELLA performs significantly worse than the large-scale 17B parameter PaLI model (Chen et al., 2023b) that is trained on 12 billion examples using the private WebLI dataset. The same holds for the recent PALI-3 (Chen et al., 2023a), which makes efforts towards a more efficient model, but still trains billions of parameters on billions of multilingual data. This is still notably costly and impractical for many applications. From a research perspective, our model can be trained in a single day in consumer hardware with a public dataset.

Lastly, we see a 15.2 CIDEr points improvement compared to LMCap (Ramos et al., 2023a), which is a few-shot retrieval-augmented approach that has no training. With minimal multilingual training, our model further closes the gap towards large-scale multilingual captioning models.

Overall, the results on XM3600 demonstrate the efficacy of our approach for efficient multilingual captioning, contributing to the reduction of both trainable parameters and data requirements. For a more comprehensive evaluation, we also report results on COCO-35L in Table 2, where we observe again that our model can outperform the fully-supervised models of Thapliyal et al. (2022). See qualitative examples in Appendix H.

5.2 Zero-shot Cross-lingual Transfer

In Table 1, we observe that PAELLA$_{\text{core}}$ (trained on *en*,*es*,*hi*,*zh*) and PAELLA$_{\text{mono}}$ (trained only on *en*) have strong zero-shot performance in other languages, showing that our approach does not require captioning data for each of the languages during training. The generation can be conditioned on a different language beyond the training set, by providing the prompt and retrieved captions in the desired output language, solely at inference time.

We further observe that PAELLA is outperformed by PAELLA$_{\text{mono}}$ on English, and by PAELLA$_{\text{core}}$ on English and Spanish. This can be partially explained by the fact that PAELLA was pre-trained on a uniform sample of all 35 languages in COCO-35L, while these variants were pre-trained on a uniform sample of only those languages, i.e. with more English captions. Both the Core and Mono variants, on the other hand, are less able to generate captions for languages out-

---

Table 1: CIDEr performance on XM3600, a multilingual benchmark with geographically-diverse images across 36 languages. We compare our model, PAELLA, and its two variants, PAELLA$_{\text{core}}$ (trained on *en*,*es*,*hi*,*zh*) and PAELLA$_{\text{mono}}$ (trained only on *en*) against other state-of-the-art multilingual models. L$_5$ represents the average performance across the set of low-resource languages (*bn*, *quz*, *mi*, *sw*, *te*), and L$_{36}$ over all the 36 languages. (*) corresponds to the average across the languages on which the XGLM decoder was pre-trained. We highlight in bold that our model has the lowest number of trainable parameters and requires the least amount of training data.

Model	en	es	hi	zh
BB+CC	98.0	96.2	75.9	74.8
Lg	87.5	85.9	62.4	65.6
PAELLA	113.6	113.9	86.2	123.3
PAELLA$_{\text{core}}$	118.5	120.3	94.7	130.7
PAELLA$_{\text{mono}}$	120.8	91.48	45.9	59.1

Table 2: CIDEr scores on COCO-35L validation data. The fully-supervised models from Thapliyal et al. (2022) are shown on top, with our model variants at the bottom.

side those in the XGLM pre-training data, resulting in an average decrease of 9.4 and 10.7 points of CIDEr across all 36 languages, compared to PAELLA, respectively. Despite this limitation, we emphasize the performance of PAELLA$_{\text{mono}}$, that achieved a 15.5 CIDEr score on average, especially considering its training was exclusively on English. PAELLA$_{\text{mono}}$ even outperforms Lg across the set of 4 core languages and on average, even though this model had end-to-end large-scale training across the various languages with the complete COCO-35L dataset.

Our approach's capability for zero-shot cross-lingual transfer holds particular importance with the predominance of English-centric captioning datasets. We note we did not use multilingual in-domain data in the retrieval datastore. The retrieved captions from COCO-35L have a different distribution than the XM3600 benchmark, that contains geographically diverse images and concepts. We also stress that the entire prompt (including the retrieved captions) needs to be in the target language for this zero-shot cross-lingual ability to emerge. Otherwise the PAELLA$_{\text{mono}}$ model defaults to English, as a result of having been exclusively exposed to this language and thus having a strong tendency to generate in English.

6 Discussion

We discuss PAELLA's performance across languages in relation to the different writing systems. We then conduct ablations studies, first discussing the monolingual data required to train PAELLA$_{\text{mono}}$, followed by the importance of the retrieved information. These ablation studies were performed on the validation split of COCO-35L because XM3600 only contains evaluation data.

6.1 Writing Systems

In Figure 2, we observe the performance of PAELLA across the diverse writing systems of the 36 languages, alongside the mBLIP mT0-XL model for comparison. mBLIP has a notable performance on English and languages that share the

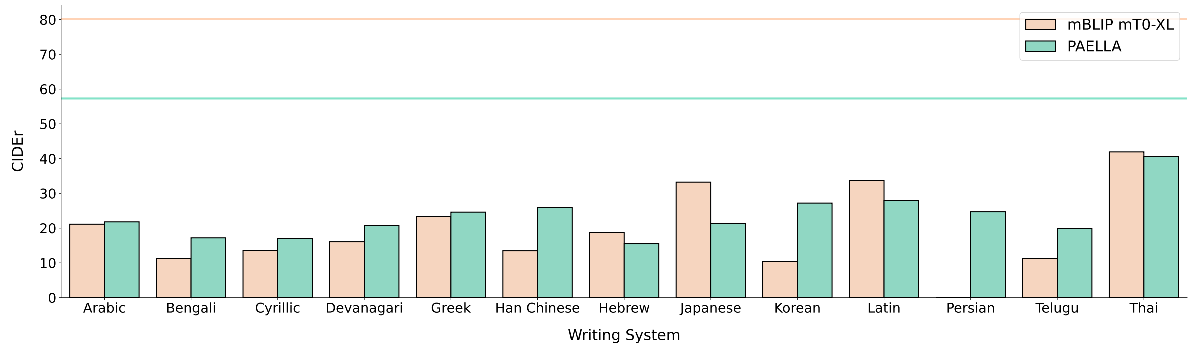

Figure 2: Performance by writing system. Horizontal lines denote corresponding English performance.

Latin script writing system. This specialization results in poor performance for some writing systems, for instance Persian and Korean. In contrast, our model demonstrates a more balanced performance across the various writing systems beyond the high-resource Latin script, achieving a better performance on the Arabic, Bengali, Cyrilic, Deveganari, Greek, simplified Chienese, Korean, Persian, and Tegulu writing systems.

6.2 Monolingual Supervision

We previously saw that our multilingual captioning model could also be trained on monolingual data (see Section 5.2). We now discuss whether PAELLA$_{\text{mono}}$ works when trained with languages other than English. As seen in Table 3, PAELLA$_{\text{mono}}$ exhibits zero-shot multilingual capabilities with the other 3 core languages as well. Surprisingly, training on Spanish yields better generalization to the other core languages compared to training on English. When trained on Chinese, on the other hand, the model loses its ability to generate captions in Hindi. Additionally, we investigated the model's behavior when trained with a language falling outside the pre-training of the XGLM decoder, such as Danish. Here, the model is able to generate captions in Danish, yet we see the interesting behaviour that this breaks the generalization to other languages.

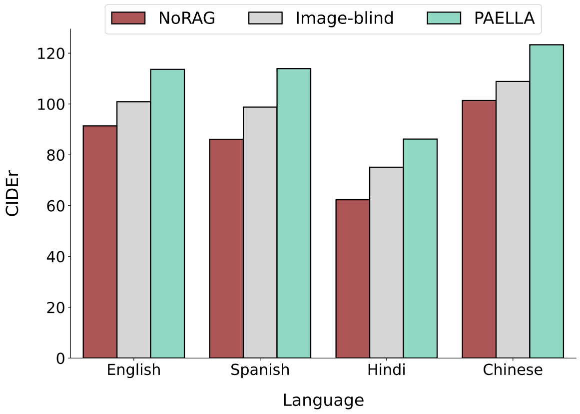

Figure 3: Ablation results on the COCO-35L validation data, reported with CIDEr metric. We ablate the retrieval (NoRAG) and the visual encoder (image-blind).

Model	en	es	hi	zh	da
PAELLA$_{\mathbf{en}}$	**120.8**	91.5	45.9	59.1	2.7
PAELLA$_{\mathbf{es}}$	93.3	**125.3**	52.6	95.3	2.9
PAELLA$_{\mathbf{hi}}$	70.4	68.1	**99.3**	80.9	0.1
PAELLA$_{\mathbf{zh}}$	65.0	49.9	1.4	**130.6**	0.4
PAELLA$_{\mathbf{da}}$	5.1	1.2	2.8	4.1	**107.5**

Table 3: CIDEr results for the mono variants on the COCO-35L validation data. We denote in subscript and in bold the language each variant was trained on.

6.3 Retrieval as PAELLA's Key Ingredient

We now study the importance of augmenting with retrieved examples, the key component of our approach. We start by ablating the retrieval component, by training without including the retrieved captions in the prompt.[10] As seen in Figure 3, the performance drops 24 CIDEr on average across the 4 core languages without retrieval (noRAG), compared to PAELLA. We also ablate the visual encoder by training on empty input images,[11] and we see again a loss of performance (i.e., 13.4 CIDEr over the 4 languages), confirming that PAELLA does indeed attend to the image and not merely rephrases the retrieved captions. Moreover, we observe that the NoRAG model performs worse than the image-blind approach with retrieved captions, reinforcing the benefit of training multilin-

---

[10] The prompt only includes the last part: `A caption I can generate to describe this image in [language] is.`

[11] Setting the visual features from the encoder to zero.

gual image captioning with retrieval-augmentation. In Appendix F, we additionally discuss results for PAELLA$_{\text{mono}}$, where retrieval is shown to be crucial to generate captions in languages that substantially diverge from the English supervision. We also discuss the importance of having the retrieved captions in the target language, in Appendix H.

7 Conclusions and Future Work

We proposed PAELLA, an efficient multilingual captioning model with retrieval-augmentation. Contrary to previous studies, PAELLA is lightweight to train, both in the number of parameters and multilingual data demands. Results demonstrate competitiveness across languages, including low-resource languages. PAELLA also exhibits strong zero-shot multilingual capabilities. In the future, we plan to further investigate cross-lingual transfer with monolingual supervision.

Limitations

While our model aims to contribute to research beyond English-centric captioning, it has limitations in that the results are conditioned on retrieved captions from machine translated data from COCO, which is English-centric and lacks coverage of geographically diverse concepts (Liu et al., 2021). Previous research has also shown that COCO has significant gender imbalance, and using this data can further amplify the bias (Zhao et al., 2017; Hendricks et al., 2018). For instance, models can become more prone to generate *woman* in kitchen settings than *man*. For a better understanding of the biases PAELLA exhibits, we suggest an analysis of the retrieved captions used by the model, as illustrated in the figures within Appendix H.

Another limitation relates to our models' coverage of languages and concepts. Expanding the range of covered languages would be desirable to accommodate more diverse speakers. Additionally, our model was evaluated on a limited number of datasets, similarly to other concurrent models, due to the scarcity of multilingual resources for assessing image captioning results.

PAELLA was only designed for the task of image captioning. In future work, we would like to investigate approaches to extend PAELLA to a range of multilingual multimodal tasks, such as those covered in IGLUE (Bugliarello et al., 2022).

A Prompt

To generate captions across different languages, we customize our prompt and the retrieved captions to be in the selected language. In Figure 4, we give examples in Spanish, Hindi, and Chinese, respectively. The prompts for the other languages are included in our code.

B Retrieval

Ramos et al. (2023b) has shown in the SmallCap retrieval-augmented captioning model that CLIP-ViT-B/32 is suitable as an encoder for text generation, but when used as a retrieval encoder it performs poorly. We thus pick the state-of-the-art version of CLIP, CLIP-ViT-bigG-14, for retrieval. We refrain from using that larger version in the model's encoder too, since that would significantly slow down training time.

C Standard Evaluation Metrics

For a more comprehensive evaluation, we report the performance of our model with additional automatic metrics, including BLEU-1 (B-1), BLEU-4 (B-4) (Papineni et al., 2002), ROUGE-L (Lin, 2004), and METEOR (Denkowski and Lavie, 2014). We report these metrics both for the XM3600 dataset and the COCO-35L validation split, as seen in Table 4 and Table 5, respectively.

	B-1	B-4	ROUGE-L	METEOR
en	45.1	10.3	34.6	14.5
es	43.2	7.8	30.1	15.1
hi	29.3	2.7	21.1	21.9
zh	32.1	6.9	24.6	10.9

Table 4: PAELLA performance on the XM3600 dataset, across different evaluation metrics.

	B-1	B-4	ROUGE-L	METEOR
en	76.2	33.6	55.9	26.7
es	76.3	35.9	54.5	27.5
hi	74.9	26.5	51.0	33.7
zh	77.2	40.0	56.4	28.8

D Scalability

In Table 6, we see how PAELLA performs with different XGLM versions in the decoder. The larger-scale XGLM-2.9B has stronger performance, which aligns with previous findings regarding the scaling behaviour of LMs. Notwithstanding, the XGLM-1.7B and XGLM-564M versions are viable alternatives, considering that they can be trained in even less time and occupy less GPU memory. We also report performance on the validation split of COCO-35L in Table 7.

XGLM	Time	RAM	en	es	hi	zh
2.9B	23h	46G	57.3	44.9	20.8	25.9
1.7B	14h	29G	55.8	41.0	20.1	24.6
564M	7h	19G	51.7	40.0	18.0	23.8

Table 6: CIDEr results on the XM3600 dataset. We report performance for different XGLMs used in the decoder component of PAELLA.

XGLM	Time	RAM	en	es	hi	zh
2.9B	23h	46G	113.6	113.9	86.2	123.3
1.7B	14h	29G	108.7	107.7	82.2	116.6
564M	7h	19G	103.2	103.1	76.6	111.2

Table 7: CIDEr results on the validation set of COCO-35L, across the different decoders used in PAELLA.

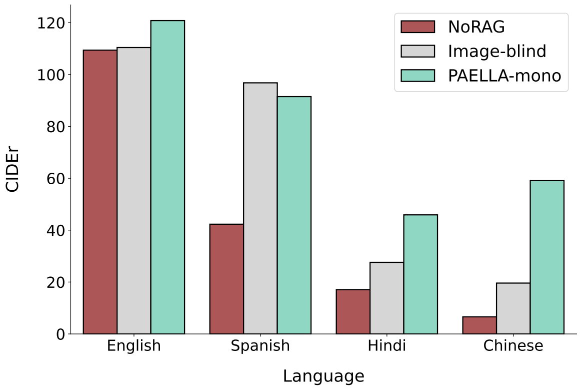

Figure 5: Ablation results on the COCO-35L dataset, reported with the CIDEr metric for the mono variant. We ablate the retrieval (NoRAG) and the visual encoder (image-blind), and compare with PAELLA$_{\text{mono}}$.

E Monolingual Retrieval

We study the behavior of our model when the retrieved captions are provided in English instead of the target languague, as seen in Table 8. We can see that our model benefits from having the retrieved examples in the same language as the target output language. In this manner, the captions can guide the process of generating content in the target language, by providing a reference for what the predicted caption should resemble.

RAG	en	es	hi	zh
Multi	113.6	113.9	86.2	123.3
En	114.1	103.8	76.8	121.3

Table 8: Performance of using either retrieved captions in the target language (multi) or in English, measured through CIDEr on the COCO validation set.

F Retrieval Impact on PAELLA$_{\text{mono}}$

Similarly to the findings for PAELLA in Section 6.3, we observe in Fig 5 that retrieval augmentation plays a key role in PAELLA$_{\text{mono}}$ as well. Indeed, retrieval is especially important for the monolingual variant. This happens because the model relies even more on the retrived examples to generate captions in languages that significantly differ from the English training data, as evidenced by the substantial drop in performance with NoRAG for Hindi and Chinese. We also see that the image-blind variant makes PAELLA$_{\text{mono}}$'s performance decline, demonstrating that our model uses not just the information from the retrieved captions, but also the image itself. The image-blind variant has to generate captions solely with retrieved information, which proves challenging for Hindi and Chinese. It can be difficult to figure how to combine and summarize the information from the four retrieved captions into a cohesive single output, particularly for these languages with very distinct characteristics from the English supervision. Conversely, the model effortlessly uses the retrieved information for Spanish at inference, achieving better performance through straightforward rephrasing. Moreover, the image-blind approach outperforms the NoRAG model across all four languages, further emphasizing the importance of conditioning generation with retrieved examples.

G Cross-attention

Our model has 34M trainable parameters corresponding to the cross-attention layers. Here, we provide insight into the cross-attention setup, featuring an encoder hidden size of 768, and a decoder hidden size of 2048, with 16 attention heads and a stack of 48 layers. We reduce the size of the cross-attention projection matrices, denoted as d, from the standard 128 (2048/16) to 8, in order to achieve parameter efficient training. Consequently, the total parameter count is calculated as follows:

- Key Weight Matrix size: $[768, 8]$ (i.e., $enc\_d \times d$)
- Value Weight Matrix size: $[768, 8]$ (i.e., $enc\_d \times d$)
- Query Weight Matrix size: $[2048, 8]$ (i.e., $dec\_d \times d$)
- Total parameters for one layer attention with 16 heads: $16 \times (2 \times 768 \times 8 + 2048 \times 8)$
- Dense weight for projection after concatenation of heads: $[16 \times 8, 2048]$ ($h \times d \times dec\_d$)

Total number of layers is 48.

Total number of parameters: $48 \times (16 \times (2 \times 768 \times 8 + 2048 \times 8) + 16 \times 8 \times 2048) \approx 34M$

H Qualitative Results

In Fig 6, we provide examples of captions generated by PAELLA, conditioned on both the image and its retrieved captions, and captions generated by the variant without retrieval (NoRAG). In the

Figure 6: Qualitative examples for the captions generated by PAELLA, compared with the results generated with an ablated model that does not use retrieval augmentation.

first image, our model correctly captures the concept of owl across the different core languages, as present in the retrieved captions. PAELLA also demonstrates some robustness to potential misinformation that can occur in the retrieved captions (e.g., the second retrieved caption mentions an owl in a table). In contrast, the NoRAG variant generates incorrectly the captions for the 4 languages, struggling with identifying the bird, even misclassifying it as a giraffe for Chinese. On the second image, we present a negative example where the retrieved captions can mislead our model. PAELLA generates captions mentioning a red Swiss Army knife, likely influenced by the color present in the retrieved captions (and partially in the knife itself, although it is mainly white). Nonetheless, our model successfully generates the concept of a Swiss knife, while the NoRAG variant encounters difficulty by generating unrelated objects (e.g., either a cell phone, sunglasses, a toy or headphones for English, Spanish, Hindi, and Chinese, respectively).

I Performance Across the 36 Languages

In Table 9, we report XM3600 performance across all the 36 languages. We show results for our model and its variants, together with state-of-art multilingual models that have the performance for each language in the respective publications too.

Abstract

The capability of intelligent models to extrapolate and comprehend changes in object states is a crucial yet demanding aspect of AI research, particularly through the lens of human interaction in real-world settings. This task involves describing complex visual environments, identifying active objects, and interpreting their changes as conveyed through language. Traditional methods, which isolate object captioning and state change detection, offer a limited view of dynamic environments. Moreover, relying on a small set of symbolic words to represent changes has restricted the expressiveness of language. To address these challenges, in this paper, we introduce the Object State Captioning and State Change Representation (OSCaR) dataset and benchmark. OSCaR consists of 14,084 annotated video segments with nearly 1,000 unique objects from various egocentric video collections. It sets a new testbed for evaluating Multimodal Large Language Models (MLLMs). Our experiments demonstrate that while MLLMs show some skill, they lack a full understanding of object state changes. The benchmark includes a fine-tuned model that, despite initial capabilities, requires significant improvements in accuracy and generalization ability for effective understanding of these changes. Our code and dataset are available at `https://github.com/nguyennm1024/OSCaR`.

1 Introduction

The field of Natural Language Processing (NLP) has evolved beyond mere text interpretation and generation, advancing into realms where understanding and interacting with the physical world becomes imperative. From studying causal reasoning (Gao et al., 2018) to building a world model for cause-effect prediction (Gao et al., 2016; Alayrac et al., 2017), researchers have been working on the problem of causation in the physical world.

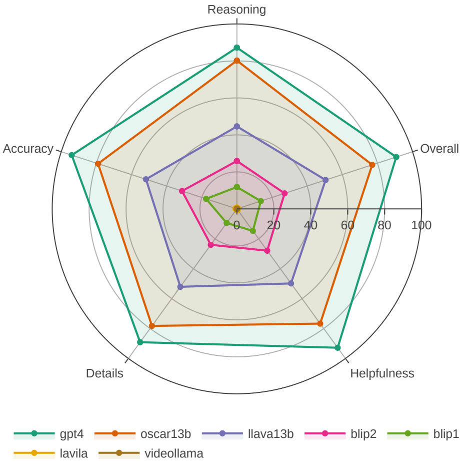

Figure 1: **Surpassing prior models in aligning with human judgements.** Our method achieves near parity with GPT-4V ratings across helpfulness, accuracy, reasoning, and other key metrics.

In this paper, we investigate the very basic causal relations between a concrete action and the change of the object state caused by this action. For example, given an image as shown in Figure 2, we, as humans, would have no problem understanding which object is being actively interacted with. Furthermore, given the statement "cutting the bread", we would naturally imagine what state change may happen. However, Despite tremendous progress in knowledge representation, automated reasoning, and machine learning, artificial agents still lack the understanding of naive causal relations regarding the physical world (Gao et al., 2018).

Imagining a scenario where artificial agents collaborate with humans in the physical world, they will need to understand the physical action effect to reason, learn, and assist humans (Bi et al., 2023). To empower machines with such capabilities, this paper introduces a novel benchmark focusing on understanding object state changes from egocentric visual inputs, which has the advantage of the lens of human eyes.

Understanding object state change is not only a complex task but also practical and foundational

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3565–3576

Question: What details about the pear slice's appearance give insight into the preparation method and the fruit's natural texture?

Answer: A slice of pear rests on a white cutting board, its surface a palimpsest of knife marks that speak to the act of peeling and cutting. The pear's flesh is a creamy white with a slightly granular texture, typical of this fruit, and it has a subtle sheen, suggesting juiciness. The edges where the skin has been removed are slightly ragged, revealing the methodical but imperfect passage of a blade. The pear's shape is irregular, with curves that follow the natural form of the fruit, and the remnants of the stem cavity indicate it has been sliced from top to bottom.

Question: Describe state of the pearl in detail way.

Answer: The same pear slice appears slightly shifted from its original position, indicating movement. The hand that guides it is out of view, but the influence of human touch is evident in the changed orientation of the slice. It reveals a new angle of the pale flesh, and the shadow cast upon the board shifts accordingly, altering the visual texture. There's a hint of pressure at the bottom of the slice, where it might have been held, compressing the delicate flesh slightly and bringing out a bit more of the pear's inherent moisture on its surface.

Question: What does the positioning of the pear slice near the edge of the cutting board, and the trail it has left, suggest about its handling and the preparation process?

Answer: The pear slice has been moved further, and now it's clear that it's in the process of being shifted to the side, likely to make room for further cutting or to group it with other slices. This movement has exposed more of the cutting board, and the pear's trail is marked by a faint residue of juice left behind. The slice is almost at the edge of the cutting board, suggesting the next move could be off the board entirely. The light reflects differently on the juicy trail than on the drier surface of the cutting board, creating a contrast in textures and colors.

Question: What does the sequence of movements of the pear slice across the cutting board indicate about the method of preparation?

Answer: Over the sequence of these three frames, the pear slice undergoes a subtle but telling transformation through human intervention. Initially at rest, it is then picked up and moved, each action causing a change in its position and the way it interacts with its environment. The movement is gentle but purposeful, and the slight compressions and shifts reveal not just the hand's manipulation, but also the pear's textural responses to being handled. The progression shows a choreography of culinary preparation, where each slice is moved in turn, suggesting a rhythm and method to the task at hand. The final frame indicates the continuation of this process beyond the captured moment, as the slice approaches the edge of the board, ready for the next step in its journey from whole fruit to ingredient.

Figure 2: **OSCaR's description of state, state change, and illustration of reasoning.** State description involves the characterization of a specific region of interest within the video and the associated activity. State change entails the description of the evolution of a system over a defined temporal sequence. Furthermore, the analysis of the state of an object is centered on comprehending and elucidating the mechanisms underlying the object's evolution.

for many other tasks, such as helping intelligent agents to understand the environment dynamics and complete task (Padmakumar et al., 2023; Sarch et al., 2023; Merullo et al., 2022), tracking the state of dialog(Le et al., 2022), creating causal graphs for knowledge representation for complex question and answering (Ates et al., 2020).

Modeling object state change requires two abilities: 1) scene understanding, which involves parsing the world through an object-centric lens, and 2) causal-effect understanding, which entails identifying likely actions and their effects by observing images before, during, and after an action.

Previous research efforts have concentrated on building symbolic representations to ground changes and states (Wu et al., 2023; Zellers et al., 2021; Nagarajan and Grauman, 2018). However, given the diversity and complexity of objects and their states, influenced by contextual and temporal factors, symbolic representation alone falls short. This paper proposes the use of natural language as a more expressive and intuitive medium for this task. This approach not only aligns the understanding of visual content between humans and AI systems but also enhances communication between them, providing a richer context than unimodal models.

Essentially, we form the scene understanding as an object-centric visual captioning problem. We can utilize natural language to describe the objects and any changes that may occur. On the other hand, the ability to understand the causal effect is formed as a visual question-answering problem based on 3 images: before, during, and after the action. Our dataset and experiments exhibit considerable potential for scalable application across various domains in future research. While conducting this study, another research was also conducted to understand object state change with a different approach (Xue et al., 2024). That shows the importance and significant potential of this research direction.

In summary, our contributions are threefold:

- We introduce a new problem to understand states and state changes of object through natural language.
- We present a method to generate good-quality visual instructions guided by simple annotations, applicable to both images and videos, advancing future research in visual instruction tuning. Our pipeline provides a good starting point for the data collection process.
- Our paper introduces OSCaR, a novel dataset and a benchmark leveraged by the power of GPT-4V that contains different tasks for object state understanding, including visual captioning, visual question answering visual dialog, and reasoning.

2 Related Works

Object state change: Localizing and recognizing changes of object states, play a key role in applications such as procedural planning (Bi et al., 2021), robotics, and video action understanding (Du et al., 2023; Zhong et al., 2023; Tang et al., 2023b; Wang et al., 2023; Song et al.). Recognizing object state changes necessitates the joint discovery of states and actions through an understanding of their causal relationship, as discussed in prior works (Alayrac et al., 2017; Liu et al., 2017; Souček et al., 2022; Naeem et al., 2021). Recently, a self-supervised method has been proposed to jointly localize action and state changes temporally from noisy untrimmed long videos (Souček et al., 2022). Moreover, (Saini et al., 2023) introduces a novel benchmark for the generation of object states, yet their focus is very limited to only the cutting action and a small dataset. However, previous studies often separate scene understanding from object state change recognition and tend to operate under a closed-world assumption, which limits their applicability in real-world scenarios. Our research aims to bridge the gap between human and machine perception by integrating egocentric views and language.

Multimodal Large Language Models: Recent advancements in Large Language Models (LLMs) (Ouyang et al., 2022; Touvron et al., 2023; Chiang et al., 2023; Chung et al., 2022) have led to significant achievements in language understanding and generation. This progress has sparked an interest in the creation of MLLMs that blend the advanced linguistic processing of LLMs with capabilities for multi-modal perception (Zhang et al., 2023a; Ye et al., 2023; Li et al., 2023a; Gao et al., 2023; Peng et al., 2023; Tang et al., 2023a). The core of this research is the fusion of pre-training visual encoder representations with the input embedding space of LLMs, achieved by pretraining with datasets that interleave images and text. (Li et al., 2023c; Zhu et al., 2023a; Liu et al., 2023a). In this paper, we aim to provide a comprehensive evaluation of these models, particularly focusing on their performance in object state change recognition.

3 The OSCaR Dataset

This section outlines our pipeline for creating visual instructions on object states. We begin with the process of collecting diverse visual data from public sources, detailed in section 3.1. Following this, section 3.2 describes our approach to enhancing data quality using simple human annotations across various tasks, facilitating a deeper understanding of object states. Our method enables the generation of detailed captions, visual question answering, and visual dialogue.

3.1 Video Collections

OSCaR is a curated compilation of videos sourced from two distinct datasets: EPIC-KITCHENS (Damen et al., 2018) and Ego4D (Grauman et al., 2021). Acknowledging that changes in object states occur progressively over time rather than abruptly within a single frame, we have selectively included video clips that effectively illustrate these state transitions. Our selection process ensures that these videos depict the dynamic changes in object states and capture moments where the objects remain stationary for short enough durations. This approach enabled us to compile a comprehensive visual dataset encompassing the object's static and transitional states.

We initially analyzed the verbs from the original videos of the EPIC-KITCHENS dataset to ensure that the videos highlighted objects undergoing state changes. We categorized these verbs into three groups: *change*, *not sure*, and *not change*. The *change* group consists of verbs likely to alter the state of objects, including actions like Open, Close, Wash, Cut, and Mix. Conversely, the *not change* group encompasses verbs with a minimal likelihood of inducing state changes, such as Take, Put, Move, Check, etc. Lastly, the *not sure* group includes verbs with ambiguous potential for state change, covering actions like Shake, Flip, Use, Pull, and others. After filtering the EPIC-KITCHENS dataset, we were able to identify 69 verb classes that consisted of a total of 650 verbs. Using this verb list, we retrieved all video segments containing those actions.

Upon analyzing the videos, we discovered that some objects only appeared in a few times. As a result, we split the videos into two groups. The first group comprises videos that focus on objects that occurred more than ten times, and it will be used to construct our training and testing set. The second group includes videos with objects that occurred less than ten times. These objects are rare in EPIC-KITCHENS and can be used for open-world evaluation, which will be discussed in section 4.2. In the first group, we randomly selected 10 to 50 video segments per object, resulting in 7442 with 306 different objects from EPIC-KITCHENS.

We leveraged Ego4D, the largest egocentric video dataset, selecting video segments tagged with "$object\_of\_change$" to enhance our data's diversity. This tag highlighted videos showcasing object state changes. By gathering these specific videos, along with details of the objects and their narrations, we informed our data generation and compiled relevant statistics. From this dataset, we extracted 5942 segments featuring 296 unique objects for our OSCaR project.

3.2 GPT-assisted Data Generation

Caption Generation: Captioning plays an important role in visual understanding. Understanding object states requires detailed and informative captions to capture the exact state of objects. To achieve this goal, we generated captions for all collected videos by leveraging GPT-4V and human's weak annotations. This problem requires two types of annotations, including 1) Start and end frame ID in videos during the event to make state changes and 2) A short description of what happens in the video. The short description can be a verb representing the action and a noun representing the object humans interact with (e.g., washing tray). We designed adaptive prompts to inject this annotation as context to guide GPT-4V to generate high-quality captions. We found that GPT-4V often suffers from ambiguity without this guidance, and the quality of generated captions is degraded. With simple human guidance, GPT-4V can reduce ambiguity and produce better-quality captions.

Multiple-choice QA Generation: The multiple-choice question is a method of presenting a set of answers, including incorrect options, to teach machine learning models how to distinguish between correct and incorrect answers. This type of question can also be used as a form of instruction, where the question serves as the prompt, and the answer serves as the response for the models. We created multiple-choice question and answer sets based on generated captions.

Conversation Generation: Visual dialog is a complex task requiring understanding of visual content and conversation context, and faces challenges in data collection due to its need for natural dialogues between two people viewing the same content. This process is time-consuming and resource-intensive, especially when involving reasoning and explanations. With the growth of machine learning models, generating visual dialog data is increasingly vital. We've developed a method that uses captions to create visual conversation data, enhanced by GPT-4V's ability to provide explanations, offering flexible and diverse data. This approach, labeling input data for images and videos, is cost-effective and faster than manual methods, generating vast amounts of training data for future models.

4 OSCaR Benchmarks

4.1 Evaluation with Text Generation Metrics

The dataset we are providing consists of 500 videos from the Ego4D and EPIC-KITCHENS datasets, which are specifically designed for benchmarking purposes. Each video is annotated by four detailed captions, all of which have undergone rigorous human verification to ensure the quality and reliability of this evaluation set. To ensure a comprehensive and accurate assessment of performance, text generation metrics such as BLEU, Rouge, LSA, among others, can be used for evaluation purposes.

4.2 Open-world Object State Understanding

Collecting data for all objects worldwide and then training models is not feasible. However, humans can describe new or unfamiliar objects, which can be challenging for AI, especially when they are in a new domain or serve a different purpose. Fortunately, recent achievements in MLLMs have opened up the potential for AI to have this ability. During pre-training with large amounts of data, MLLMs can learn general knowledge about the world. Besides, models will learn how to perform tasks during the visual instruction tuning process. In both processes, the models may or may not have been exposed to objects not in the object state understanding training set. The question is whether models can generalize to objects of this type. To answer this question, we provide two evaluation sets to test the generalizability of the models.

Cooking domain objects have not occurred in the training set for object state understanding: For this evaluation, we want to investigate the model's ability to understand objects that have not appeared in the training set in a similar scenario with the training domain. We provided a set of 2,485 videos with 1,024 objects that have not occurred in the object state training set. This testing set will evaluate how in-domain knowledge can help models understand object states and state changes. We used GPT-4V to annotate 344 videos for evaluation purposes.

Out-of-domain objects state understanding: This evaluation focuses on judging the ability of models to understand objects beyond the training domains. Our training set contains only the cooking domain data, while this testing set has diverse domains, such as baker, household management, cleaning/laundry, bike mechanic, etc. This set was extracted from the Ego4D dataset and contains 43,367 videos with more than 500 objects. This testing not only can be used for evaluation but also has the potential to scale up using our pipeline for object state understanding in other specific domains. For this evaluation set, we selected 10 videos from each of the 51 different domains, totaling 356 videos. Domains with fewer than 10 videos have all their videos included. This set is also annotated by GPT-4V.

4.3 Data Quality Verification

We evaluated the quality of descriptions for object states and activities across video frames using Amazon MTurk for human feedback. Our assessment framework included five guidelines for spotting inaccuracies, focusing on frame-specific description accuracy, two for assessing state change accuracy, two for identifying hallucinations, and three for recognizing incomplete descriptions. Annotators were asked to categorize each description under one of four labels: 1) Fully Detailed and Comprehensive, 2) Generally Complete with Minor Omissions, 3) Lacks Important Details or Contains Errors, or 4) Incomplete, Misleading, or Hallucinating, and provide reasoning to discourage random responses. This study utilized 500 samples from the EPIC-KITCHENS and Ego4D datasets, leading to the validation of 2000 natural language descriptions.

5 Data Statistics

In order to help models generate concise and informative answers, we have defined short answers as those with less than ten words and long answers as those with more than ten words. Short answers provide brevity, while long answers offer detailed and informative information. The distribution of these two types of answers can be seen in Figure 3. The average answer length in the dataset is 47.06 words. Long answers make up about 75% of the data, with an average length of 63 words, while short answers account for about 25% of the data, with an average length of 3.32 words. By splitting the data accordingly, future models can provide short, direct, and informative answers with explanations. To showcase the uniqueness of our OSCaR dataset, we have presented a comparison between OSCaR and other related datasets in Table 1. The OSCaR dataset comprises a vast number of instructions, along with images and videos. Additionally, it also provides data for object state captioning and object state change captioning.

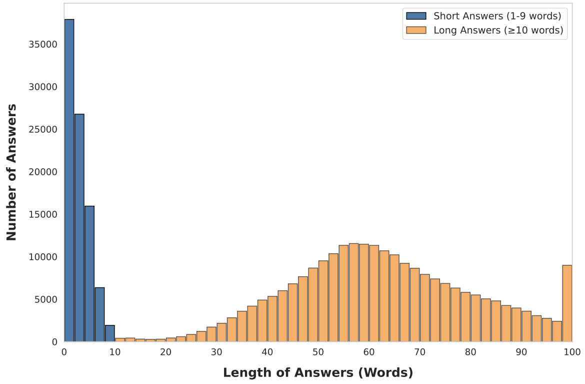

Figure 3: **Distribution of answer lengths.** The figure shows how answers are distributed by length in the dataset. It separates short answers (1-9 words) from long answers ($\geq$ 10 words). The histogram displays the number of answers on the y-axis based on increasing answer lengths on the x-axis. There is a category at 100 words for answers with lengths greater than or equal to 100 words. This breakdown emphasizes the balance between brief, direct answers and more detailed, explanatory responses.

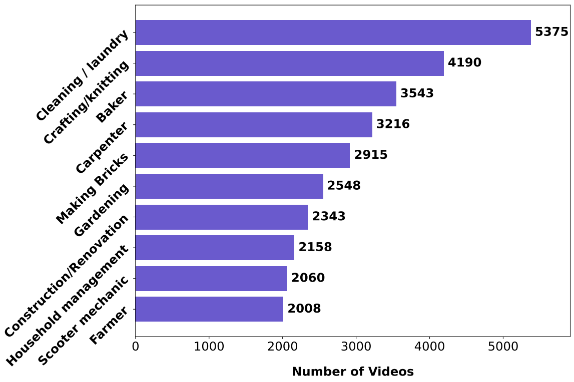

Figure 4: **Top 10 open-world domains (excluding cooking)**. The figure shows non-cooking domains present in the open-world test set used to assess model generalization. By evaluating performance on household and occupational activities unseen during training, we benchmark the trained models' capacity to understand new objects and actions beyond cooking tasks.

In section 4.2, we discussed two types of open-world datasets for object state understanding: in-domain cooking and open domains. Although we trained on videos with object state changes, in open-world evaluation, we tested the models on both types of videos, with and without object state changes, to ensure their generalizability. The in-domain evaluation set consists of 2,485 videos with 1,024 novel objects extracted from EPIC-KITCHENS.

We have extracted an open-domain evaluation set from the Ego4D dataset. The top 10 most frequent domains in the open-world testing set are shown in Figure 4. This evaluation set from 51 different domains, contains annotations for domain, action, object name, and action narrations extracted from annotations of Ego4D. The set includes 43,367 open-world videos for which we know their domains and 56,231 videos of unknown domains, but we still have information about their object names and action narrations. Thus, this set can be utilized not only for open-world evaluation but also for the advancement of general domain object-state understanding in the future when applying our method to generate labels. This set of data hasn't been annotated, but the data we extracted from Ego4D are ready to use our pipeline to scale up the data generation.

6 Experiments

In this section, we will discuss the experimental design we used and how we trained our model. Our fine-tuning process will be described in Section 6.1. Additionally, we included other vision language models such as BLIP (Li et al., 2023b) , BLIP2 (Li et al., 2023c), LaViLa (Zhao et al., 2022), and Video-LLaMA (Zhang et al., 2023b) for comparison purposes. Firstly, we will evaluate our model's performance in the cooking domain in Section 6.3. After that, we will also evaluate its performance in an open-world setting in Section 6.4.

6.1 Model Training

We conducted extensive experiments to showcase the effectiveness of our data generation pipeline in solving object-state understanding problems. A straightforward approach to solving these types of problems is using a model with a text encoder to encode prompts and a visual encoder to encode visual content. After that, both of these inputs will be used as conditions to generate text answers with a text decoder. Ideally, this text decoder will be an LLM.

We fine-tuned LLaVA, an open-source MLLM featuring capabilities like visual dialogue, question-answering (Agrawal et al., 2015), and OCR (Nguyen et al., 2021, 2024), to achieve our goals. Notably, the generated data can enhance any future vision-language models beyond LLaVA.

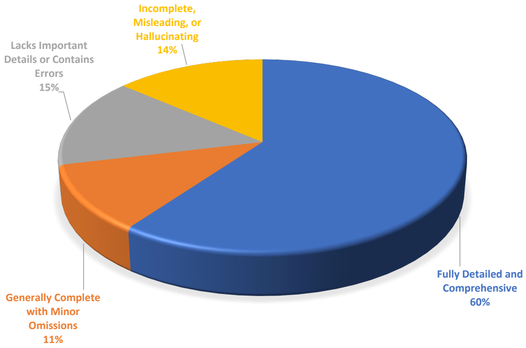

Figure 5: **GPT-4V zero-shot caption quality human evaluation.** The figure shows the distribution of quality ratings assigned by human annotators evaluating frame descriptions automatically generated by the GPT-4V model under zero-shot conditions. Descriptions for 500 video frames were rated.

We experimented with LLaVA using Vicuna 7B and 13B models under two conditions: with and without its original visual instruction tuning data, referring to the former as OSCaR.

For training, we employed Lora fine-tuning with a configuration of rank 128 and alpha 256, using Vicuna 13B and 7B models alongside the OpenAI/CLIP-ViT-Large-Patch14-336 vision encoder. A projector transformed visual features into tokens. Our fine-tuning parameters included a single epoch, a learning rate of 2e-4, a batch size of 16 per device, and a maximum model length of 2048.

6.2 Evaluating GPT-4V

Because our pipeline uses GPT-4V as the knowledge model to annotate our data, evaluating GPT-4V's ability is crucial. Evaluating GPT-4V's performance has two purposes: 1) Understanding the performance of GPT-4V on this task and 2) Producing a clean benchmark beyond the ability of GPT-4V for future research. As discussed in section 4.3, we ask humans to check data quality and classify quality into four levels with text explanation. Figure 5 shows the distribution of data quality from 500 videos sampled from the dataset for benchmarking.

6.3 Evaluation on Cooking Domain Objects

Text Generation Metrics Evaluation: The table 2 in this document displays the results of two text generation metrics, BLEU and ROUGE. As per the table, LaViLa and BLIP1 models have scored very low, whereas BLIP2, Video-LLaMA, and LLaVA models, which are currently the most advanced models, have achieved significant improvements.

Table 1: Comparison of OSCaR dataset versus other related datasets. OSC and OSCC represented for Object State Captioning and Object State Change Captioning, respectively.

Dataset	**Video**	**#Clip**	**#Instruction**	**OSC**	**OSCC**
MiniGPT-4 (Zhu et al., 2023b)	✗	✗	5K	✗	✗
Shikra-RD (Chen et al., 2023)	✗	✗	5.9K	✗	✗
LLaVA (Liu et al., 2023b)	✗	✗	345K	✗	✗
VideoChat (Li et al., 2023d)	✓	11K	20.8K	✗	✗
OSCaR	✓	**18K**	**400K**	✓	✓

Table 2: **Performance comparison based on BLEU and ROUGE scores.** OSCaR is LLaVA fine-tuned with OSCaR data, mixed data is a combination of LLaVA data and OSCaR data.

Model	**BLEU**	**ROUGE-1**	**ROUGE-2**	**ROUGE-L**
LaViLa (Zhao et al., 2022)	0.006	3.3	0.26	3.27
BLIP1 (Li et al., 2022)	0.008	1.38	0.08	1.35
BLIP2 (Li et al., 2023c)	0.1	11.53	2.12	10.51
Video-LLaMA (Zhang et al., 2023b)	1.0	17.75	2.69	16.02
LLaVA v1.5 13B (Liu et al., 2023b)	3.72	27.09	6.59	24.01
LLaVA v1.5 7B (Liu et al., 2023b)	3.23	25.37	6.22	22.60
OSCaR 13B (OSCaR data only) (Ours)	5.28	27.93	7.67	24.45
OSCaR 7B (OSCaR data only) (Ours)	5.1	28.27	7.42	24.77
OSCaR 13B (Mixed data) (Ours)	5.76	29.26	8.24	25.78
OSCaR 7B (Mixed data) (Ours)	**5.79**	**29.94**	**8.34**	**26.24**

Our proposal has surpassed every previous state-of-the-art model by a large margin on these metrics.

GPT4 Evaluation: The experimental results of evaluating LLaVA, OSCaR, and GPT-4V captions on five criteria using GPT-4V are shown in Table 4. According to the metric used, OSCaR performs significantly better than LLaVA. Additionally, OSCaR achieved 88.19%, 87.01%, 90.81%, 89.21%, and 97.94% in accuracy, helpfulness, detail level, reasoning, and overall, respectively, compared to GPT-4V. On average, OSCaR is **90%** as good as GPT-4V. The visualization can be seen at Figure 1.

Human Study: In our study to assess caption quality from various models, seven evaluators reviewed five videos with four captions each (three for frames, one for state changes), provided by seven models. Each caption had seven different options generated by seven different models. Evaluators could select up to two options per caption that they think are the best. Figure 6 shows the results of this experiment. We calculated the percentage of times each model was selected and found that OSCaR achieved 73.93%, which was only 8.57% lower than GPT-4V. OSCaR significantly outperformed LLaVA by more than two times. These results demonstrate that OSCaR is a promising model for generating high-quality captions.

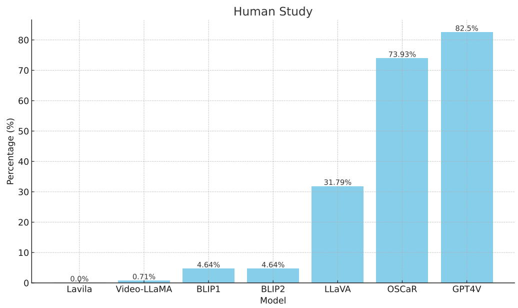

Figure 6: **Human study results.** The figure shows the percentage that each model was selected by participants as producing favorable descriptions in a human rating study.

6.4 Open-world Objects Evaluation

Evaluating the performance of machine learning models solely based on objects seen during training isn't enough. To more thoroughly test their effectiveness, we also evaluated them on objects not included in the training set, representing the open world. In this part of our study, we compare the quality of text produced by our model and GPT-4V for these open-world objects, using BLEU and ROUGE scores as our metrics.

In-domain Objects Evaluation: The evaluation results on objects in the cooking domain that were not included in the instruction fine-tuning data are presented in Table 3. When compared with the results in Table 2, the overall performance is better when testing with in-domain open-world objects. One of the reasons for this is that the evaluation set in Table 2 was corrected by humans, while the data used in Table 3 was generated

Table 3: **Open-world performance comparison based on BLEU and ROUGE scores.** OSCaR is LLaVA fine-tuned with OSCaR data, mixed data is a combination of LLaVA data and OSCaR data.

Open World	**Model**	**BLEU**	**ROUGE-1**	**ROUGE-2**	**ROUGE-L**
In Domain	OSCaR 13B (OSCaR data only)	5.86	28.64	8.43	24.91
	OSCaR 7B (OSCaR data only)	5.73	29.10	8.38	25.47
	OSCaR 13B (Mixed data)	**6.19**	29.36	8.74	25.69
	OSCaR 7B (Mixed data)	6.13	**30.00**	**8.95**	**26.25**
Out of Domain	OSCaR 13B (OSCaR data only)	5.32	27.20	7.62	23.67
	OSCaR 7B (OSCaR data only)	5.18	27.07	7.50	23.65
	OSCaR 13B (Mixed data)	5.24	26.18	7.36	23.09
	OSCaR 7B (Mixed data)	**5.69**	**28.99**	**8.29**	**25.38**

Table 4: Evaluation scores using GPT-4V under different criterion are listed in the table.

Criteria	LLaVA	OSCaR	GPT-4V
Accuracy	53.60	82.93	94.04
Helpfulness	51.63	80.78	92.83
Reasoning	53.64	79.20	87.22
Detail	40.56	87.30	89.14
Overall	51.96	80.92	90.72

from GPT-4V. Nevertheless, the outcomes of this experiment indicate the generalizability of models when dealing with new objects.

Objects Beyond Cooking Domain: Table 3 presents the open-world evaluation for various domains. The dataset employed in this experiment is discussed in section 4.2, which comprises 356 videos from 51 distinct domains. Compared to the experiment in table 2, the outcomes of this experiment are generally lower. Specifically, for LLaVA 7B with mixed data, this experiment shows a decline of 0.1, 0.95, 0.05, and 0.85 on BLEU, ROUGE-1, ROUGE-2, and ROUGE-L, respectively. This decline indicates two things: 1) the open domain is challenging and may require domain-specific data for fine-tuning to achieve better performance, and 2) even in the absence of new domain data, the decrease in performance is not too significant, and showing the generalizability of our model.

6.5 Ablation Study

Our research also examined the accuracy of video frame annotations in the EPIC-KITCHENS and Ego4D datasets. We used Amazon Mechanical Turk annotators to evaluate 500 video data points for the precision and completeness of descriptions, categorizing them into four classes. In addition, we analyzed 100 samples from each setting of zero-shot and two-shot to determine the best strategy for scaling up data annotation. Our findings indicate that zero-shot is the more effective approach for annotating our task's data.

Our findings, detailed in Table 5, compare zero-shot and two-shot performance in aligning descriptions with human standards of accuracy and relevance, as derived from video frame analyses. This table illustrates how well the GPT-4V model's natural language descriptions, evaluated by Amazon Mechanical Turk annotators in zero and two-shot scenarios, match human judgment. The percentages indicate the extent to which these descriptions accurately and relevantly depict the video content, based on a frame-by-frame review. Each description was judged for its thoroughness and relevance in detailing the object and its activities. Annotators followed established guidelines to determine the quality of data in their assessments.

The results reveal a notable disparity in description quality between the zero-shot and two-shot methods. The zero-shot approach yielded a higher proportion of Fully Detailed and Comprehensive descriptions, while the two-shots method indicated a greater occurrence of descriptions with errors or misleading content. This variation highlights the differences in data quality and annotator perceptions under varying evaluation conditions, underscoring the importance of method selection in annotation studies.

Table 5: The table lists the distribution of Amazon Mechanical Turk annotators' choices of descriptions of objects and object state changes in 0 and two-shot tests by the GPT-4V model in %.

Satisfaction Class	Zero-shot	Two-shots
Fully Detailed	56.25	33.25
Minor Mistakes	16.75	28.25
Lacks Important Details	13.25	23.00
Hallucinating	13.75	15.50

In Table 6, we present the results of our experiment where we evaluate various models in open-

Table 6: **Performance comparison based on BLEU and ROUGE scores in different domains.** The table compares various models with open-world benchmarks.

Domain	**Method**	**BLEU**	**ROUGE-1**	**ROUGE-2**	**ROUGE-L**
Cooking Domain	LLaVA (Liu et al., 2023b)	2.56	23.77	5.64	21.08
	BLIP1 (Li et al., 2022)	4.33×10^{-5}	0.75	0.026	0.73
	BLIP2 (Li et al., 2023c)	0.043	8.2	1	7.4
	LaViLa (Zhao et al., 2022)	4.34×10^{-5}	3.09	0.27	3.07
Other Domains	LLaVA (Liu et al., 2023b)	2.88	23.96	5.85	21.26
	BLIP1 (Li et al., 2022)	7.39×10^{-5}	1.15	0.077	1.13
	BLIP2 (Li et al., 2023c)	0.028	9.04	1.05	8.2
	LaViLa (Zhao et al., 2022)	6.95×10^{-5}	3.1	0.29	3.07

world benchmarks, including the cooking domain and other domains. We have observed that the performance of other baselines has generally decreased in open-world benchmarks. These results demonstrate the importance of building models that can be generalized in the world. However, capturing the state of objects while dealing with diverse objects and domains is still a major challenge.

7 Conclusion

This paper presents a new task for comprehending the state of objects and their changes using natural language. We also propose a data generation pipeline that utilizes the capabilities of GPT-4V to tackle this task. Furthermore, we introduce OSCaR, a dataset that includes training data and a benchmark with various protocols. Our comprehensive experiments not only demonstrate the superiority of our methods in comparison to previous state-of-the-art open-source solutions but also examine the limitations of GPT-4V in addressing this challenge.

8 Limitations

This study explores a new research problem that focuses on understanding the states of objects. Although it has provided valuable insights, some limitations and areas still require further investigation, as outlined below.

Lack of audio integration: A limitation of this work is the lack of audio data, which could be useful in scenarios where sound is essential for indicating changes or properties of objects.

Challenges in long-term state transition tracking: Tracking changes in object state over extended periods is challenging because many current models, especially foundation models and models based on LLMs, do not yet have the ability to capture long-term information. This limitation highlights the difficulty in understanding complex, long-term transitions in object states, which is critical to comprehending object dynamics in various environments.

Reliance on GPT-4V's imperfect outputs: Although GPT-4V has shown strength in generating data for this research problem, its outputs are imperfect. This limitation highlights the need for strategies to efficiently learn from and improve upon the imperfect data provided by GPT-4V.

9 Ethics Statement

We acknowledge that bias could be present in the process of collecting data for our paper. To minimize this issue, we have taken several measures. Firstly, we have collected videos from two highly diverse data sources: EPIC-KITCHENS and Ego4D. Secondly, when labeling the data using GPT-4V, we are aware that bias could occur from the behavior of GPT-4V. To address this, we regularly take test samples during the data generation process. If we detect any significant issues, we are prepared to stop the process and conduct an inspection. On the human side, we use the Amazon Mechanical Turk platform to hire people to label data for both the GPT4 zero-shot and few-shot quality assessment steps and the user study. Our data collection was classified as an approved exempt protocol by the IRB.

Abstract

Sentence embedding models are typically trained using contrastive learning (CL), either using human annotations directly or by repurposing other annotated datasets. In this work, we explore the recently introduced paradigm of generating CL data using generative language models (LM). In CL for computer vision (CV), *compositional* transformations (series of operations applied over an image. e.g. cropping + color distortion) which modify the input/image to retain *minimal* information were shown to be very effective. We show that composition of a 'Summary' transformation with diverse paraphrasing/contradicting transformations accomplishes the same and works very well in CL for sentence embeddings. Our final generated dataset (using Vicuna-13B) significantly outperforms the previous best unsupervised method (using ChatGPT) by 1.8 points, and SimCSE, a strong supervised baseline by 0.3 points on the semantic text similarity (STS) benchmark.

1 Introduction

Contrastive learning (CL) is widely used for training sentence embeddings (Gao et al., 2021; Jiang et al., 2022a; Su et al., 2022; Li et al., 2023). CL typically uses data in the form of (`anchor`, `positive`, `negative`) where embedding of `anchor` is made closer to `positive` and away from the `negative`. SimCSE (Gao et al., 2021) and PromptBert (Jian et al., 2022) used manually annotated NLI data (275K) to train sentence similarity models. Reliance on annotated data, however, limits contrastive learning from being performed at scale and from being transferred to other domains. Some works repurposed existing web datasets to be used as contrastive learning data - Su et al. (2022) used super-NI (Wang et al., 2022b); Li et al. (2023) repurposed multiple unsupervised and supervised datasets. Although the scale of these web datasets helped these models achieve state of the art on multiple tasks, these models still depended on class labels/target text to build the CL triples. Research progress was also made into unsupervised training of sentence embedding models - by using rank consistency between different attention masks (Liu et al., 2023), by diverse noise and heuristic augmentations (Zhou et al., 2023; Wu et al., 2022), and by case augmented positives and retrieved negatives Wang et al. (2022a). GenSE (Chen et al., 2022) finetune a T5 model with the NLI data (275K) and then generate a large CL training dataset (61M). Recently, SynCSE (Zhang et al., 2023) used ChatGPT with diverse paraphrasing, contradiction prompts to generate positives and negatives for CL significantly outperforming other unsupervised methods. However, it's still an open question if paraphrases, contradictions are ideal positives, negatives resp..

On the other hand, in CL for computer vision, Chen et al. (2020); Tian et al. (2020) showed the effectiveness of *compositional* transformations that retain *minimum* information necessary for downstream tasks. We draw inspiration from these works to propose composition of a 'Summary' transformation over other diverse 'Paraphrase' and 'Contradiction' transformations, as positives and negatives respectively, in CL for sentence embeddings. Synthetic dataset generated by our unsupervised methodology, `SumCSE` (uses Vicuna-13B), improves over `SynCSE` (uses ChatGPT) (+1.8) and `SimCSE` (+0.3), on STS. Our method shows benefits (+0.9) when directly applied to other existing datasets and achieves an additional (+0.5) over `SumCSE` when scaled (4x synthetic dataset), on STS.

2 Background and Motivation

SimCSE (Gao et al., 2021) used loss as shown in Eq. 1 to perform unsupervised training. Note that

---

- Summer internship work. Academic collaborators created the dataset. Meta was not involved in using the dataset for training. Meta did not perform the experiments or use or process any of the data described or referenced in the paper.

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3577–3588
June 16-21, 2024

Eq. 1 uses only positives and not negatives. Unsupervised SimCSE used different attention masks to create positive sentence representation and train the model. Eq. 1 further evolved into InfoNCE loss in Eq. 2 for supervised SimCSE with both positives and negatives. N is number of in-batch examples.

$$\mathcal{L} = -\log \frac{e^{sim(h_i, h_i^+)/\tau}}{\sum_{j=1}^{N} e^{sim(h_i, h_j^+)/\tau}} \quad (1)$$

$$\mathcal{L} = -\log \frac{e^{sim(h_i, h_i^+)/\tau}}{\sum_{j=1}^{N} e^{sim(h_i, h_j^+)/\tau} + e^{sim(h_i, h_j^-)/\tau}} \quad (2)$$

Transformations (t) are used to get h_i^+ i.e. $h_i^+ = t(h_i)$. The success of a contrastive algorithm is substantially influenced by these transformations (Chen et al., 2020; Wu et al., 2020). Minimising InfoNCE loss learns representations that maximise the lower bound on mutual information between input and transformation, $\mathcal{I}(h, h^+)$, over the dataset. Tian et al. (2020) used this to theoretically justify the 'InfoMin' principle - an ideal transformation should share with the input *minimal* information necessary to perform well at a downstream task. It should minimise all irrelevant nuisances in the input. Also, SimCLR (Chen et al., 2020) showed that *compositional* transformations work very well for CL training image representations and found that (image_cropping + colour_distortion) worked the best. Cropping follows the InfoMin principle (reduces mutual information with the input). It matches global-local contexts in an image to learn robust representations. Inspired by these concepts, we propose transformations for sentence CL.

3 Methodology

Our goal here is unsupervised generation of positives and negatives given an anchor. The generated synthetic dataset is used to train an embedding model with Eqs. 1/ 2. This trained model is used to evaluate results on STS and other benchmarks.

3.1 Generating Positives

In accordance with the InfoMin principle and to maximise global-local context agreement (Tian et al., 2020; Chen et al., 2020), we propose to use a *Summary* transformation to generate positives from anchor data. Summary of a sentence can filter out irrelevant information while maintaining its core meaning (minimum information required for sentence similarity). To further validate its feasibility, we follow Gao et al. (2021) to evaluate various transformations on STS-B development set (using the `SimCSE` NLI dataset anchors). We use multiple prompts with a generative LM to create these transformations. We specifically pick the transformations which showed promise (as positives) in other works e.g. *Entailment* sentences(annotated) in Gao et al. (2021), *Sentence Structure Change*, *Paraphrase*, etc in Zhang et al. (2023). More details in §A.7.1. Summary outperforms all other transformations in Table 1. Furthermore, composing transformations (a second transformation over the first) does better. In Table 2, average performance of both Summary and Entailment (best performers in Table 1) as the second transformation is better than either of them individually in Table 1. Finally, following Zhang et al. (2023) in using diverse prompts to simulate real life data, we randomly select one of the four summary compositions in last row Table 2. Random summary compositions outperform all other transformations. Our final positives comprise these random summary compositions over the four diverse transformations in Table 2.

Transformation	Performance
Summary	**86.97**
Entailment	86.71
Sentence Structure Change	84.13
Paraphrase	85.13
Concise Paraphrase	86.19
UnSup. SimCSE (attention mask)	82.5

Paraphrase	86.88	87.13
Concise Paraphrase	87.24	86.99
Avg	87.05	86.88
Random	**87.3**	86.89

Table 2: Positive Only STS-B dev. results (Eq. 1). Rows : First transformation. Colums: Second transformation.

3.2 Generating Negatives

Negative examples in CL typically come from a different class than the `anchor` class. In NLP, a contradiction to a sentence is typically used as `negative` (Gao et al., 2021). Inspired by `SynCSE`, we use four diverse contradiction prompts (which ask to generate different, opposing, contrasting meaning sentences) to generate negatives. However, contradiction to the anchor might not be the ideal negative. For example, STS has multiple examples which have a very high similarity despite being

Model	Method	STS12	STS13	STS14	STS15	STS16	STSB	SICKR	Avg.

Table 5: `SumCSE` outperforms `SynCSE` and `SynCSE+` on MTEB (56 diverse text embedding tasks). `SumCSE` beats `SimCSE` in three out of seven task categories. Summary transformation more suitable for these categories of tasks.

contradictions. Several works in contrastive learning have shown that there needs to be enough distance between the anchor and the negative for best results with CL (Wu et al., 2020). A summary composition can put enough distance between input and a contradiction while retaining meaning of the contradiction. Similar to positives, we found that summary when composed over the four contradiction prompts (i.e. first generate a contradiction and then generate a summary of it) gives very good validation results in §4.10. We also justify this choice from an anisotropy standpoint in §4.10. For our final negatives, we pick a random summary composition over the four diverse contradiction prompts.

4 Experiments

4.1 Methods Compared

Our methodology, `SumCSE` is compared with `SimCSE` and `SynCSE` (Zhang et al., 2023). We used Vicuna-13B-v1.3 with prompts to generate all positives and negatives in `SumCSE`. The exact prompts used for different transformations are detailed in §A.7. `SumCSE` uses the same anchor sentences as `SimCSE` and has same number of examples around ∼$275K$. `SynCSE` only has ∼$263K$ examples (failure of ChatGPT on 12K examples). Hence we also compare with `SynCSE+` an extended version of `SynCSE` where we pick the remaining examples from `SimCSE`. Adding `SimCSE` triples to `SynCSE` was proposed in Zhang et al. (2023) and is known to have a significant improvement over `SynCSE`. All above methods use exact same `anchor` data and same loss function (Eq. 2). They only differ in the `positive` and `negative` data. Further we also compare with multiple unsupervised methods: RankCSE (Liu et al., 2023), L2P-CSR (Zhou et al., 2023), PCL (Wu et al., 2022), CARDS (Wang et al., 2022a) and ConPVP (Zeng et al., 2022). We also compare with GenSE (Chen et al., 2022) where we sample 275K examples from its 61M for fair comparison. Most of these unsupervised baselines are complementary to `SumCSE` and can also be applied on top of the `SumCSE` dataset.

4.2 Implementation Details

We present results with `RoBERTa-large`. For consistency, we use the exact same hyperparams and settings in `SumCSE` as were used in the best performing `SimCSE` models. For `SynCSE` and `SynCSE+`, we use the best settings from Zhang et al. (2023).

`SumCSE` used Vicuna-v1.3. Note that this is an older version of Vicuna. Older version was used to be consistent with the time period of `SynCSE` which used ChatGPT from mid 2023. In `SimCSE` and `SumCSE`, we follow (Gao et al., 2021) and use STS-B (one of the seven STS benchmark datasets) validation performance to pick the best models. Also, additional MLM loss was not used in any training of `SimCSE` or `SumCSE`. For `SynCSE` and `SynCSE+`, MLM loss was included and (STS-B, SICKR) average validation was used to pick best models following (Zhang et al., 2023). More details in §A.1.

4.3 Main Results: STS

We follow Gao et al. (2021) to evaluate all models on STS test benchmark comprising seven textual similarity tasks: STS12-16, the STS benchmark and SICK Relatedness. Details in §A.3. We train the models on their annotated/synthetic data and test them on STS. Spearman correlation is used as the performance metric. Table 3 shows the results on STS benchmark. `SumCSE` does significantly better than both `SynCSE` and `SynCSE+`. Note that `SynCSE` used ChatGPT while `SumCSE` used Vicuna-13B-v1.3. `SumCSE` also shows notable improvement over supervised `SimCSE`.

4.4 Transfer results

Following `SimCSE`, we further evaluate the transfer capabilities of these embeddings with seven transfer learning tasks: MR, CR, SUBJ, MPQA , SST2, TREC and MRPC. Details in §A.3. A logistic regression classifier is trained and evaluated on frozen embeddings fro different methods. Table 4 shows results. `SumCSE` does better than other models. Here, MLM loss was not used for `SumCSE` and `SimCSE` but was used in `SynCSE` due to default settings. Gao et al. (2021) says transfer numbers are much higher with the MLM loss.

4.5 MTEB results

Embeddings are required in multiple other tasks as well. Recently, a generalised text embedding benchmark MTEB (Muennighoff et al., 2022) was released. This benchmark has multiple other tasks from Retrieval, Classification and other long text tasks. We evaluate `SumCSE` on this benchmark in Table 5. `SumCSE` outperforms `SynCSE`, `SynCSE+` in all tasks. It does better than `SimCSE` in re-ranking, pair-classification and STS. STS here is a more advanced version including STS17, STS22 in addition to Table 3. Interestingly, `SimCSE` does better than `SumCSE` on overall MTEB. We posit this happens because of our choice of transformations (which we optimise for sentence similarity). We observe higher anisotropy for `SumCSE` which further explains inferior performance in clustering, retrieval. Details in §4.9.

Ablation	Method	Size	STS	Transfer
1	`SynCSE`	263K	78.82	88.75
	`SumCSE`	275K	**81.73**	**89.55**
	`SimCSE`	275K	80.62	88.58
	`SynCSE+`	275K	79.83	89.15
2	`SumCSE`	275K	84.07	89.95
	`SumCSE`$_{large}$	1.1M	**84.63**	89.82
3	`SynCSE+`	275K	83.28	88.88
	`Sum + SynCSE+`	275K	**84.18**	**89.86**

Table 6: 1. `SumCSE` (Positive Only, Eq. 1) outperforms others. Already better than most unsupervised, supervised methods(in Tab. 3) 2. `SumCSE` has significant gains on large scale (4x) dataset. 3. Summary transformation applied on `SynCSE+` dataset results in +0.9 gain on STS.

4.6 Ablation 1: Positive Only

We assessed multiple transformations for positives in Table 1, 2. In this subsection, we analyse how positives in `SumCSE` compare to positives in other annotated/generated datasets. Table 6 shows the test STS and transfer results with a positive only loss for all methods with `RoBERTa-large`. `SumCSE` outperforms other methods. Positive only performance of `SumCSE` already outperforms most unsupervised methods in Table 3.

4.7 Ablation 2: Large Scale Data

Large scale datasets have played a crucial role in creating SOTA sentence embeddings. Here, we evaluate if our methodology can be used to generate a large scale dataset. Instead of randomly sampling one among four summary positives in §3.1, we consider all of them. For negatives, we randomly sample one among the four. This creates `SumCSE`$_{large}$, a 4x dataset, and simulates the case of generating a large scale dataset. `SumCSE`$_{large}$ achieves the best result in this paper, significantly improving over `SumCSE` on STS while matching transfer numbers in Table 6.

4.8 Ablation 3: Summary on Other Data

Given summary compositions work well in `SumCSE`, herein, we try to investigate if we can do the same with other datasets. We simply apply the summary transformation to `SynCSE+` positives and negatives to generate a new dataset(using Vicuna-13B-v1.3). Table 6 shows that the summary transformation when applied to other datasets works significantly improves the overall performance.

4.9 Analysis 1: Anisotropy

Anisotropy is defined as the average pairwise sentence similarity of sentences in a corpus. While some research has shown that anisotropy is less important for sentence embeddings (Jiang et al., 2022a), it is still an important measure of spread of embeddings. Table 7 shows the anisotropy of different models on a subset of Wikipedia data dump. `SumCSE` has an higher value of anisotropy compared to other models. Higher anisotropy indicates that the sentence embeddings are all in a close space and explains lower performance in clustering, retrieval tasks of MTEB.

4.10 Analysis 2: Choice of Negatives

Eq. 1 allows for evaluation of the quality of positives independent of negatives. Eq. 2 however depends on both positives and negatives. The choice of negatives thus depends on the positives. In this ablation, we mix and match different positives, negatives to get an understanding of the type of negatives that work best. Table 8 shows the STS-B validation performance and anisotropy of different models. We observe that shorter negatives generally work better with shorter positives - models with higher STSB validation and better anisotropy.

Row 3 in the table shows performance of `SumCSE` without the summarization step for negatives i.e. without the second transformation. This results in much longer negatives. Looking at `SumCSE` only numbers (rows 3 and 5), we note that summarizing negatives makes a big difference in validation performance and anisotropy. Comparing rows 4 and 5 shows that summary negatives work better than other shorter negatives. These results further justify the strength of summary.

4.11 Analysis 2: Shared Information

To further show the shared information between anchor, positive and negative, Rouge1 similarity scores are shown in Table. 9. InfoMin principle suggest this number has to be as low as possible while while maintaining enough information to solve downstream task (sentence similarity). Positives in `SumCSE` have low similarity with the anchor illustrating that they follow InfoMin principle. Interestingly, `SimCSE` positives also have low similarity with the anchor showing that annotated data in `SimCSE` might have also benefited from InfoMin.

Method	`SimCSE`	`SynCSE`	`SynCSE+`	`SumCSE`
Anisotropy	0.094	0.112	0.103	0.123

Table 7: Anisotropy of different models over wikipedia sentences. `SumCSE` has highest anisotropy

Positive	**Negative**	**PL**	**NL**	**STSB**	**Anisotropy**
`SimCSE`	`SynCSE+`	8.06	13.41	85.94	0.175
`SumCSE`	`SynCSE+`	7.32	13.41	87.44	0.167
`SumCSE`	`SumCSE**`	7.32	15.47	85.6	0.132
`SumCSE`	`SimCSE`	7.32	8.23	87.35	**0.105**
`SumCSE`	`SumCSE`	7.32	7.78	**88.13**	0.123

Table 8: Performance of negatives from different methods for shorter positives. PL - Positives length, NL- Negatives length. Longer negatives with shorter positives results in very high anisotropy. Shorter negatives worked best with shorter positives. `SumCSE**` - Only first transformation without second (No Summary).

Method	**RougeAP**	**RougeAN**	**RougePN**
`SynCSE`	0.67	0.52	0.34
`SumCSE`	0.45	0.31	0.31
`SimCSE`	0.44	0.32	0.41
`SynCSE+`	0.66	0.51	0.42

Table 9: RougeAP, RougeAN, RougePN: Rouge1 similarity between anchor, positive and negative (pairwise). Positives in `SumCSE` have low similarity with the anchor illustrating that they follow InfoMin principle.

5 Conclusion

In this work, we draw inspirations from computer vision to build transformations that minimise irrelevant information in contrastive learning data. We propose `SumCSE` which composes a summary transformation over diverse paraphrasing, contradiction transformations to generate CL training triples for sentence embeddings. The proposed unsupervised synthetic dataset, `SumCSE`, significantly improves over all other unsupervised methods and supervised `SimCSE` on sentence similarity tasks. `SumCSE` shows promise when extended to a large scale data and also when applied on other datasets. Future work would involve investigating transformations that work for generalised text embeddings in MTEB and generating a large scale contrastive dataset.

6 Limitations

Lagging Performance on MTEB: Results of `SumCSE` lagged behind `SimCSE` on MTEB. Tian et al. (2020) showed both theoretically and empirically that transformations are downstream task dependent. InfoMin (Tian et al., 2020) principle suggests that transformation should have all of the information necessary to perform a specific downstream task. In this research, we optimised our transformations for sentence similarity. Hence, `SumCSE` shows gains on STS while lagging on some other tasks. We argue that summary composition is not best suited for clustering, retrieval tasks where it underperformed.

Web Scale Experiments: While $\texttt{SumCSE}_{large}$ showed positive gains from large datasets (1.1M), huge web scale datasets (>50M datapoints) were not explored due to computational limitations. Further, we were also restricted by the anchor points that were used for generating positive and negatives. We followed Gao et al. (2021), Zhang et al. (2023) in using the same set of anchor points for this work. Choice of anchors to use for contrastive learning is an interesting research topic by itself. Chen et al. (2022) used open domain data as anchors. Zhang et al. (2023) also proposed `SynCSE`-scratch to generate anchors in multiple diverse domains. We reserve this exploration with web scale data for future research.

Limited Supervised Baselines: We limit our baselines to `SimCSE` and GenSE for the supervised case. Most supervised methods like Jiang et al. (2022a), Jiang et al. (2022b) work with `SimCSE` NLI dataset and propose improvements to the modelling or loss function. These methods are complementary to `SumCSE` and can be used on top of the `SumCSE` dataset. A lot of unsupervised methods from §4 are also complementary and can be used with `SumCSE`. Hence, we limited the baselines based on the the datasets used.

The goal of this research is to share with the community that summary as a transformation works as a strong data augmentation method in contrastive learning for sentence similarity. For future research, we intend to explore generalised transformations that work with a variety of tasks in MTEB and generate a web scale contrastive dataset.

Broader Impact and Discussion of Ethics: While our model is not tied to any specific applications, it could be used in sensitive contexts such as health-care, etc. Any work using our method is requested to undertake extensive quality-assurance and robustness testing before applying in their setting. To the best of our knowledge, the datasets used in our work do not contain any sensitive information. We followed `SynCSE` to perform an ethical evaluation of 100 random samples from the `SumCSE` dataset and manually checked for any ethical problems. We did not find any data with ethical problems in any of the examples. This is expected because Vicuna-13B has been trained not to output any sensitive information.

A Appendix

A.1 Training Parameters

All embedding training models used `RoBERTa-large` (350M) or `RoBERTa-base` (110M) as a starting checkpoint (`RoBERTa-base` experiments later in the appendix). Peak learning rate of 5e-5 was used for the former and 1e-5 was used for the later following Gao et al. (2021). Batch size of 512 was used for bothmodels. Default seed value of 42 for all experiments following Zhang et al. (2023).

In `SimCSE` and `SumCSE`, we follow (Gao et al., 2021) and use STS-B (one of the seven STS benchmark datasets) validation performance to pick the best models. Also, additional MLM loss was not used in any training of `SimCSE` or `SumCSE` (though this slightly improved `SumCSE` numbers). For `SynCSE` and `SynCSE+`, MLM loss was included and (STS-B, SICKR) average validation was used to pick best models following (Zhang et al., 2023).

A.2 Compute

All experiments were run on four A6000 GPUs (48gb). `RoBERTa-large` model training took 2 hours for `SumCSE`, `SynCSE`, `SimCSE` on 275K sized data. `RoBERTa-base` model training took 50 mnts. To generate the four positive paraphrases using Vicuna-13B, it took 65 hrs for first transformation and 12 hrs for the second transformation. Runtime numbers for negatives were the same.

A.3 Test Datasets

STS Benchmark: Comprises seven semantic similarity tasks- STS12, STS13, STS14, STS15, STS16 (Agirre et al., 2012, 2013, 2014, 2015, 2016), the STS benchmark (Cer et al., 2017) and SICK Relatedness (Marelli et al., 2014). All models in this paper are trained on an annotated/synthetic dataset and tested on STS. STS 'train' split is not used in any method.

Transfer Tasks: Comprise seven tasks: MR (Pang and Lee, 2005), CR (Hu and Liu, 2004), SUBJ (Pang and Lee, 2004), MPQA (Wiebe et al., 2005), TREC (Voorhees and Tice, 2000) and MRPC (Voorhees and Tice, 2000).

MTEB Benchmark: Comprises 57 sentence embedding methods from Classification, Clustering, Reranking, Pair Classification, STS, Retrieval, Summarization (Muennighoff et al., 2022).

sentence1	sentence2	score(out of 5)
There is no girl with a black bag on a crowded train	A girl with a black bag is on a crowded train	3.7
A man is playing a guitar on stage	There is no man playing a guitar on stage	3.6

Table 10: Few examples from STS where sentence similarity is high despite being a contradiction.

Table 12: `SumCSE` does better than all other methods on 7 Transfer Tasks. **Bold**, underline indicate first, second best.

A.4 Dataset Stats

In this subsection, we discuss about the statistics of different datasets used. Some dataset stats are shown in Table 13.

Method	Size	Anchor Len.	Pos. Len.	Neg. Len.
`SynCSE`	263K	15.58	14.86	13.68
`SumCSE`	275K	15.72	7.32	7.78
`SimCSE`	275K	15.72	8.06	8.23
`SynCSE+`	275K	15.72	14.55	13.81

Table 13: Dataset statistics of different methods. Anchor Len. - Average length of anchor. Pos. Len. - Average length of positives. Neg. Len. - Average length of Negatives

A.5 Contradiction not ideal Negatives

Table 10 shows a couple of examples of contradictions which have a very high similarity with the input sentence and yet have a high score in STS. This shows that contradictions as were used in the past mihgt not be ideal negatives.

A.6 More models

All results in the main paper came from RoBERTa-large as the base model. To further justify strength of `SumCSE` we also test it with RoBERTa-base. Table 11 and 12 show the results. The trends are exactly the same as RoBERTa-large.

A.7 Prompts

A.7.1 Positive Prompts

Positive Prompts used to create various transformations mentioned in §3.1 are shown in Table 14. We use zero a shot summarization prompt. For all other prompts, we use a 5 shot chat setup as mentioned in Zhang et al. (2023). We used 10 fixed examples for each prompt and randomly sampled 5 among them to use as demonstrations for each generation following Zhang et al. (2023). The 10 examples were picked from `SynCSE`, `SimCSE` data. Using 5 fixed demonstrations directly worked equally well for us. Within the zero shot summary prompts, we used ‘seven’ as a reference length to build summaries. This was approximately half the average length of anchor data in `SimCSE`. We posit this satisfies InfoMin principle in retaining minimum information.

A.7.2 Negative Prompts

Negative Prompts were mostly reused from Zhang et al. (2023). Similar to previous case, we randomly picked 5 demonstrations from a set of 10 fixed demonstrations for each prompt. These negative prompts ask the LM to generate different, opposing, contrasting meaning sentences. Negative1, Negative 2 ask to modify some/one or two details and maintain sentence structure. Negative3, Negative4 ask the LM to generate logical outputs with no constraints on sentence structure. The final `SumCSE` contains summaries of the four negatives using the summarization prompt in §A.7.1.

Positive Prompts
Summary USER: Summarize the input sentence in seven words. The input sentence is - <*input*> What is your generated sentence?
Entailment Create a sentence or phrase that is also true, assuming the provided input sentence or phrase is true. USER: <*example_fewshot_input1*> ASSISTANT: <*example_fewshot_output1*> . . USER: <input>
Sentence Structure Change Rewrite the input sentence or phrase using different sentence structure and different words while preserving its original meaning. Please do not provide any alternative or reasoning or explanation. USER: <*example_fewshot_input1*> ASSISTANT: <*example_fewshot_output1*> . . USER: <input>
Paraphrase: Paraphrase the input sentence or phrase, providing an alternative expression with the same meaning. Please do not provide any alternative or reasoning or explanation. USER: <*example_fewshot_input1*> ASSISTANT: <*example_fewshot_output1*> . . USER: <input>
Concise Paraphrase: Provide a concise paraphrase of the input sentence or phrase, maintaining the core meaning while altering the words and sentence structure. Feel free to omit some of the non-essential details like adjectives or adverbs. Please do not provide any alternative or reasoning or explanation. USER: <*example_fewshot_input1*> ASSISTANT: <*example_fewshot_output1*> . . USER: <input>

Table 14: Prompts used to generate Positives

Negative Prompts
Negative 1 Revise the provided sentence by swapping, changing, or contradicting some details in order to express a different meaning, while maintaining the general context and structure. USER: <*example_fewshot_input1*> ASSISTANT: <*example_fewshot_output1*> . . USER: <input>
Negative2 Generate a slightly modified version of the provided sentence to express an opposing or alternate meaning by changing one or two specific elements, while maintaining the overall context and sentence structure. USER: <*example_fewshot_input1*> ASSISTANT: <*example_fewshot_output1*> . . USER: <input>
Negative3: Transform the input sentence by adjusting, altering, or contradicting its original meaning to create a logical and sensible output sentence with a different meaning from the input sentence. USER: <*example_fewshot_input1*> ASSISTANT: <*example_fewshot_output1*> . . USER: <input>
Negative4: Generate a sentence that conveys a altering, contrasting or opposite idea to the given input sentence, while ensuring the new sentence is logical, realistic, and grounded in common sense. USER: <*example_fewshot_input1*> ASSISTANT: <*example_fewshot_output1*> . . USER: <input>

Abstract

This study investigates the consequences of training language models on synthetic data generated by their predecessors, an increasingly prevalent practice given the prominence of powerful generative models. Diverging from the usual emphasis on performance metrics, we focus on the impact of this training methodology on linguistic diversity, especially when conducted recursively over time. To assess this, we adapt and develop a set of novel metrics targeting lexical, syntactic, and semantic diversity, applying them in recursive finetuning experiments across various natural language generation tasks in English. Our findings reveal a consistent decrease in the diversity of the model outputs through successive iterations, especially remarkable for tasks demanding high levels of creativity. This trend underscores the potential risks of training language models on synthetic text, particularly concerning the preservation of linguistic richness. Our study highlights the need for careful consideration of the long-term effects of such training approaches on the linguistic capabilities of language models.

1 Introduction

The scaling law reveals a predictable smooth increase in model performance as the amount of data, compute power, and model parameters are increased in tandem (Ganguli et al., 2022). Even assuming that we can boost the other two ingredients indefinitely, the amount of data is limited. By one estimate, the world's entire supply of *high-quality* text ranges up to 17 trillion tokens, with a 4-5% yearly growth rate (Villalobos et al., 2022). This includes all the world's books, scientific papers, news articles, Wikipedia pages, available code, and the rest of filtered web content. Meta's Llama 2, one of today's leading LLMs, was trained on around 2 trillion tokens (Touvron et al., 2023). In other words, we might be approaching the exhaustion of the world's entire stock of usable language training data, potentially within an order of magnitude.

Is it possible for language models to train on self-generated samples, thereby offering a solution to the looming data shortage? In fact, whether intentionally or unintentionally, this would happen with the widespread recognition and usage of LLMs. Regarding pretraining data, which is often sourced from the Internet, a significant trend is occurring: an increasing volume of online content is either generated or assisted by models, and such content is nearly indistinguishable from data produced by humans (Uchendu et al., 2023). Consequently, the subsequent generations of models will inevitably be pretrained on deeply blended data. Regarding finetuning data, employing LLM-generated examples is already a widely adopted data augmentation approach in the NLP community. The work of self-instruct (Wang et al., 2023) prompts language models to solicit synthetic multi-task instruction-tuning data in an iterative bootstrapping way, starting with a seed set of manually-written instructions. Concerning single-task training, Zhou et al. (2023) build a large-scale dialogue summary corpus annotated by ChatGPT (Ouyang et al., 2022) to enhance their pretrained dialogue summarization model.

However, recent studies raise concerns that the above approach of training on *predecessor-generated* text—language models are trained on the synthetic data produced by previous models—is not a panacea without side effects, especially when conducted *recursively* over time. This would introduce a new set of challenging issues, a phenomenon described as *model collapse* (Shumailov et al., 2023; Alemohammad et al., 2024). On one hand, incorporating model-generated content in training may lead to irreversible flaws in the resulting models, where tails of the original distribution of genuine human content disappear (Shumailov et al., 2023). On the other hand, even when these

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3589–3604
June 16-21, 2024

models remain free of defects, they could converge to excessively uniform behaviours, with very small variance, due to the recursive sampling of only high probability events.

In this study, rather than focusing on shifts in task-solving performance, our primary interest lies in exploring changes in language variation caused by the degenerative recursive training process. We target linguistic diversity, a fundamentally important but significantly overlooked aspect of language usage. Our work is motivated by and contributes to, answering the following two key research questions: First, *how can linguistic diversity be quantified effectively?* Second, *does recursive training on synthetic text result in a reduction of linguistic diversity in model outputs?*

To address these questions, we first develop a comprehensive set of metrics[1] assessing at three different aspects of linguistic diversity: lexical, semantic, and syntactic. Subsequently, we proceed to conduct a series of recursive finetuning experiments spanning three natural language generation tasks, each demanding varying levels of creativity: news summarization (Hasan et al., 2021), scientific abstract generation, and story generation (Fan et al., 2018). Our results indicate a notable trend: with the progression of recursive finetuning iterations, there is indeed a remarkable decrease in the diversity of the generated outputs. This observation highlights the significant impact that training on text generated by predecessors has on the linguistic diversity of language models.

2 Related Work

In this section, we explore two avenues of related work: current approaches to evaluate linguistic diversity and recent research on training with synthetic data generated by language models.

2.1 Evaluating Linguistic Diversity

Efforts to evaluate language models predominantly concentrate on their performance in task-solving. While some studies extend their scope to include aspects like factual consistency (Guo et al., 2022), reasoning capability (Helwe et al., 2021), and robustness (Chang et al., 2023), there is a notable lack of attention paid to linguistic diversity.

Furthermore, the existing studies that do address the diversity issue typically focus on lexical diversity alone. For example, in quantifying diversity, research on decoding strategies (Li et al., 2023; Vijayakumar et al., 2018; Ippolito et al., 2019) usually considers the proportion between the number of unique n-grams and total number of n-grams in generated text, known as distinct-n metric (Li et al., 2016). This very approach can also be found in the literature related to specific NLG tasks, especially those studying creative text generation, such as poetry (Chakrabarty et al., 2022), lyric (Tian et al., 2023), and pun (Mittal et al., 2022) generation.

Alternatively, Zhang et al. (2021) propose to use Shannon entropy to quantify diversity. However, such an approach is still calculated on tokens (i.e., lexical level), demonstrating a strong correlation with distinct-n. Zhu et al. (2018) introduce Self-BLEU which calculates the BLEU similarity score (Papineni et al., 2002) between different sentences of the same document, with higher Self-BLEU implying lower diversity. This metric is adopted as a proxy for diversity in evaluating the capability of LLMs in the context of producing content for disinformation operations (Liang et al., 2022). Nevertheless, the BLEU score is based on n-gram overlap and thus also represents diversity solely from the lexical aspect.

Few works study diversity beyond the lexical level. Recently, Padmakumar and He (2023) bring up the semantic aspect of diversity and define the average pairwise BERTScore among a set of documents as the homogenization index. They also use ChatGPT to annotate key points on a small set of documents, counting the percentage of unique key points as content diversity. Stasaski and Hearst (2022) hypothesize that the semantic diversity can be reflected by the contradictory level—measured by a natural language inference model—among different generation samples given the same input context, while Tevet and Berant (2021) consider it as the negation of the semantic similarity. As an exploratory approach to quantify syntactic diversity, Clercq and Housen (2017) first manually annotate a small corpus of texts produced by second language learners for syntactic features such as syntactic length and clause types, whose variation is then viewed as a diversity index. Huang et al. (2023a) define the syntactic diversity as the editing distance between the constituency parse trees of two sentences in the context of paraphrase generation. McCoy et al. (2023) investigate linguistic novelty, in a sense of language generation not simply copies training text, in terms of sequential structure

---

[1] Code available at `https://github.com/YanzhuGuo/linguistic-diversity`

(n-grams) and syntactic structure (constituency and dependency).

Our work is the first to comprehensively evaluate text generation on all three aspects of linguistic diversity: lexical, syntactic and semantic, with novel automatic metrics.

2.2 Training with Synthetic Text

Ever since the introduction of generative adversarial networks (Goodfellow et al., 2014), training new models with synthetic data produced by various generators has become a means of data augmentation (Li et al., 2022), a practice that has been expanding to all modalities of machine learning research, including image, audio, and text.

However, the large-scale usage of this approach, particularly employing tremendous quantities of synthetic text to train generative models, is a more recent trend (Dai et al., 2023; Marwala et al., 2023). To name a few, the self-instruct study by Wang et al. (2023) guides a language model to iteratively generate synthetic multi-task instruct-tuning data, beginning with an initial set of manually-written instructions. Huang et al. (2022) demonstrate that LLMs are capable of self-improving their reasoning abilities, with generated high-quality answers for unlabeled questions, using chain-of-thought (Wei et al., 2022) and self-consistency (Wang et al., 2022) prompting techniques. Meanwhile, Xu et al. (2023) introduce a pipeline that autonomously generates a high-quality, multi-turn chat corpus by enabling ChatGPT to converse with itself, which is then used to enhance a LLaMA model.

As already mentioned in Section 1, studies show that this training methodology will eventually lead to model collapse (Shumailov et al., 2023) when conducted recursively, causing performance degeneration, regardless of potential data filtering or refinement (Alemohammad et al., 2024). Our research is motivated by the same concept, but we focus on investigating the impact of recursive training on linguistic diversity instead of performance. To the best of our knowledge, our work is the first to address this issue.

3 Methodology

This section introduces our recursive training methodology and outlines the linguistic diversity metrics.

3.1 Recursive Training Simulation

Following the work of Shumailov et al. (2023), we simulate the process of recursively training language models on predecessor-generated text, under a finetuning setting. As illustrated in Figure 1, we begin with human-generated task-finetuning Data (0), which is used to train Base (1) model to create a task-specialized version, referred to as Model (1). After that, we use Model (1) to produce synthetic task-finetuning Data (1), which serves to train the next generation, Model (2), built upon Base (2) model. This procedure is repeated n times.

For the sake of simplicity, we start from a new instance of the same base model across different generations, i.e., Base (1) = Base (2) = , ..., = Base (n). In addition, we only use Data ($n-1$) to train Model (n), whereas in a setting closer to the real-life scenario, we have access to the accumulated data ensemble of all predecessors, i.e., Data $\{$(0), (1) , ..., ($n-1$)$\}$. This simplification draws from the results of Shumailov et al. (2023), which indicates that model collapse is unavoidable, even when the training involves the full ensemble of accumulated data, though the effect is somewhat attenuated.

In terms of finetuning tasks, we chose three distinct natural language generation tasks, each characterized by varying degrees of constraint, from the most restrictive to the least: news summarization, where summaries must closely align with the original content; scientific abstract generation, with some initial context provided, but room for creative expansion; and story generation, which allows for the most creativity and freedom in expression.

In the end, we conduct our linguistic diversity research with the finetuned Model $\{$(1), (2) , ..., (n)$\}$ for each task, subjecting them to evaluation on the test set of the corresponding task.

3.2 Perplexity

Our research primarily focuses on linguistic diversity, yet we also require a reliable metric to verify that our finetuned models are well-aligned with the training data. Perplexity, a standard metric for assessing language modeling, evaluates a model's level of "surprise" or "confusion" when encountering a given sequence of tokens. Models that more accurately mirror the training data's distribution exhibit lower perplexity. While useful for model comparison, perplexity doesn't fully reflect text quality (Meister et al., 2023). A low perplexity score suggests higher predictive precision, but

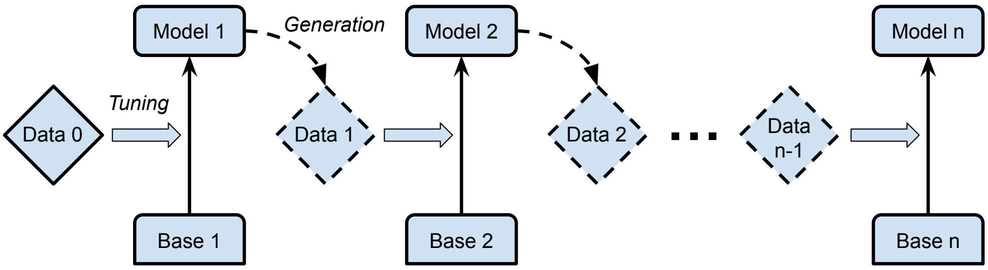

Figure 1: Our recursive tuning-generation process. Beginning with authentic, human-curated Data (0), Base (1) model undergoes finetuning to develop Model (1), which is the first model subject to our language diversity research. Subsequently, we use Model (1) to create synthetic Data (1) to train a successor Model (2) of the next generation, on the basis of Base (2) model. The process continues for n iterations. Base (1), Base (2), ..., Base (n) follow the same model architecture but are independently initialized instances.

texts can be grammatically sound and contextually coherent yet still score high in perplexity if they include unusual or creative language not included in the model's training data (Basu et al., 2021). In our study, a model with lower perplexity is not deemed superior by default. Our aim is to ensure that the perplexity remains within a reasonable limit, producing texts of sufficient quality for our linguistic diversity evaluation.

3.3 Linguistic Diversity Metrics

We approach the evaluation of linguistic diversity from three different perspectives: lexical diversity, semantic diversity and syntactic diversity.

3.3.1 Lexical Diversity

Lexical diversity metrics are used to measure the variety of words used in a text, which is contended to mirror the extent of vocabulary possessed by a writer or speaker. We believe a degenerated language model, which presumably has a smaller vocabulary, will use a narrower variety of lexical items than non-degenerated language models. We select different metrics operating at different levels of textual granularity: word, n-gram, and sentence.

Type-Token Ratio (TTR) (Johnson, 1944; Templin, 1957), the most well-known metric, which is calculated as the number of unique words (types) t divided by the number of running words (tokens) c, i.e., TTR $= {}^{t}\!/_{c}$. This metric was used to study the language development in child language research, a low value is probably indicative of a language-specific deficiency (Miller, 1981). The length of a text inherently skews vanilla TTR values, with longer texts generally yielding lower TTR scores due to an inexorably decreased occurrence of unique novel words (drawn from a limited vocabulary) as the text lengthens (Richards, 1987). Following common practice (Shaib et al., 2024), we truncate all texts to a fixed length before computing the TTR [2].

Distinct-n (Li et al., 2016), which equals the proportion between the number of unique n-grams and total number of n-grams in tested text (Xing et al., 2017). This metric is originally introduced in the context of enhancing the response diversity of conversational agents, which frequently produce safe and fluent but dull and uninformative generic responses at time (e.g., *I don't know*) (Han et al., 2022). Similar to naive TTR, distinct-n varies as a function of text length, so we report the results at fixed sizes for $n = 2$ and $n = 3$ (distinct-1 is equivalent to TTR).

Self-BLEU (Zhu et al., 2018), a recently developed method for evaluating the diversity of synthetic text. This method assesses the similarity between one sentence and the rest in a group of generated sentences. It treats one sentence as the hypothesis and the others as references to calculate BLEU scores (Papineni et al., 2002). The final Self-BLEU score averages these BLEU scores across all generated sentences. We report $1 - \texttt{Self-BLEU}$, so a higher value reflects richer diversity of the generation (Palumbo et al., 2020).

3.3.2 Semantic Diversity

According to recent studies (Tevet and Berant, 2021; Stasaski and Hearst, 2022), the above lexical-level metrics often fail to capture semantic diversity, since texts including similar words can have different semantics and texts with different words can have similar semantics (Yarats and Lewis, 2018). We tackle this problem by transforming sentences

---

[2] Details on the truncation lengths can be found in Appendix B.

into semantically meaningful sentence embeddings using Sentence-BERT (Reimers and Gurevych, 2019). We quantify semantic diversity as the dispersion of sentence embeddings over the semantic space. The dispersion is measured by the average pairwise cosine-distance of all embedding vectors (`Div_sem`).

3.3.3 Syntactic Diversity

The significance of syntactic diversity is often underestimated in NLP, despite its importance. For language learners (as well as language models), exposure to a wide range of syntactic structures is beneficial for developing a more comprehensive understanding of the language (Aggarwal et al., 2022). Moreover, a range of syntactic forms enhances expressiveness and subtlety in writing, influencing the style and tone of a text (Edwards and Bastiaanse, 1998). While linguistic and language acquisition research (Clercq and Housen, 2017) has explored this aspect, these studies typically rely on manual annotation of features, a process that can be costly and prone to human error.

We introduce the first graph-based metric to quantify syntactic diversity. We use a neural parser (Qi et al., 2020) to construct dependency trees from sentences, following the universal dependencies formalism. These trees are then transformed into graph representations, with nodes representing the words and edges indicating the dependency relationships between them. Subsequently, we employ the Weisfeiler-Lehman graph kernel (Shervashidze et al., 2011; Siglidis et al., 2020) to map these graphs into a vector space. This kernel, rooted in the Weisfeiler-Lehman isomorphism test, effectively positions graphs that are structurally alike closer to each other in the embedding space. To assess syntactic diversity, we calculate it similarly to semantic diversity, using the average pairwise distance (`Div_syn`).

4 Experiments and Results

We conduct our experiments on three generative tasks, as introduced in Section 3.1, with decreasing degrees of constraint and increasing degrees of creativity: abstractive news summarization, scientific abstract generation, and story generation.

4.1 Experimental Setup

For each task, we simulate 6 iterations of the recursive training chain, i.e., $n = 6$ in Figure 1. Following previous work (Shumailov et al., 2023), we select OPT (Zhang et al., 2022) as our base model, and each iteration begins with a new instance of the base model. Different from Shumailov et al. (2023), we use OPT-350M instead of OPT-125M to maintain higher generation quality over iterations, avoiding excessive noise. Model (1) is finetuned on Data (0)—the training set of the finetuning task—which is human-authored. From Model (2) to Model (6), they are finetuned on synthetic Data $(n - 1)$ generated by their predecessor Model $(n - 1)$. We go through all of the original training examples in Data (0) to produce a comparable synthetic dataset of the same number of samples. The models are finetuned for 5 epochs using the AdamW optimizer (Loshchilov and Hutter, 2019) on a cluster of two NVIDIA RTX A6000 GPUs.

In the following, we explain each of the three tasks in detail.

Task1: Abstractive News Summarization

For abstractive news summarization, we use the XL-SUM (Hasan et al., 2021), one of the most recently proposed datasets. In comparison to the other prominent news summarization datasets, XL-SUM is more abstractive than CNN/DailyMail (Hermann et al., 2015; Cheng and Lapata, 2016) and more factual than XSUM (Narayan et al., 2018; Guo et al., 2022). It is also larger in scale, consisting of 306,522 samples in the training set and 11,535 samples in the test set. The average length of the news articles is 386 tokens, while the average length of the summaries is 28 tokens. This is a generation task with "low entropy" since there is abundant context and the content is restricted.

Task2: Scientific Abstract Generation

For scientific abstract generation, we parse the bibliography database (BibTeX) file with abstracts of ACL Anthology[3] in June, 2023. ACL Anthology hosts papers published at computational linguistics or natural language processing venues since 1965. We split the bibliography entries into the training and the test set, resulting in 40,512 samples for train and 2,132 samples for test. We use the title of the paper and the first sentence of the abstract as the prompt, asking the model to finish generating the rest of the abstract. The prompt (title + first sentence) is 42 tokens long on average, while the mean of the full abstract length is 145 tokens. This is a task of "medium entropy", the provided title

---

[3] `https://aclanthology.org`

Prompt: The title of the paper is: CASIA's System for IWSLT 2020 Open Domain Translation.The abstract of the paper is: This paper describes the CASIA's system for the IWSLT 2020 open domain translation task.

Human: This year we participate in both Chinese→Japanese and Japanese→Chinese translation tasks. Our system is neural machine translation system based on Transformer model. We augment the training data with knowledge distillation and back translation to improve the translation performance. Domain data classification and weighted domain model ensemble are introduced to generate the final translation result. We compare and analyze the performance on development data with different model settings and different data processing techniques..

Iteration 1: We participated in all language directions, namely Chinese ↔ English, Japanese↔ English and German ↔ English. Our system mainly focuses on data selection, data preprocessing and data filtering to improve the quality of the generated translations..

Iteration 3: We participated in all three language pairs, namely Chinese↔English, Japanese→Chinese and German↔French. Our systems are based on Transformer architecture with a simple but effective method to improve the translation quality by reusing monolingual data from other languages.. The source code can be obtained from `https://github.com/csebuetnlp/acl2021/opendomaintranslate`..The blind test set will be released upon the acceptance of the report..The full results can also be found at `https://competitions.codalab.org/competitions/26153`.. The leaderboard can be found at `https://competitions.codalab.org/page/view/11650`..The dataset used in this work has been released under CC BY 4.0 license..The experimental results show that our proposed methods significantly outperform the baseline models..

Iteration 5: We participated in all three language pairs, namely Chinese↔English (Chinese→German), Japanese→Czech and German↔French.. Our approach relies on a Transformer model trained with in-domain data only; it also incorporates a novel method to improve the quality by leveraging parallel corpora from other domains such as TED Talks. The code used in this work has been released under CC BY 4.0 license at `https://github.com/czyssrs/ibm_nlp2020/`. For further information about our systems please see `http://www.csse.unige.edu/research/demo/`.. The full text of this report can be obtained via `https://competitions.codalab.org/page/view/11153`.. The codes for our experiments are available online at `https://codebenchmark.io/`, too....... Finally, we provide some insights into how our systems perform when translating into low resource conditions...... The source code for our systems is publicly available through `https://github.com/czeneva/acl2022tasks2/`.

Table 1: An example of model outputs over iterations. Since diversity is a holistic concept observed among the entire set of documents, it is non evident to demonstrate the loss of diversity through a single example. However, for the scientific abstract generation task in this example, there are some obvious patterns. Abstracts found in the ACL anthology often contain URLs linking to data, code or demos. After a few iterations of training on synthetic text, the model picked up this high probability event and starts to generate such links repeatedly in an unnatural manner.

already lays out the general idea of the paper and the first sentence provides a fair amount of context.

Task3: Story Generation

For story generation, we use the WritingPrompts dataset (Fan et al., 2018). It is made up of human written stories paired with writing prompts from Reddit's WritingPrompts forum. There are 272,600 samples in the training set and 15,138 samples in the test set. The writing prompts consist of 30 tokens on average and the resulting stories have a mean of 389 tokens. The prompts are generally short and in most cases do not contain a plot (i.e. narrative structure), making this a "high-entropy" generation task with limited context.

Decoding Strategy.

We use a combination of nucleus sampling (p) and temperature sampling (τ) to achieve nuanced control over the language model's outputs (Holtzman et al., 2020). Nucleus sampling, also known as top-p sampling, is used to generate text by selecting the most probable words from a distribution of words. It ensures that the cumulative probability of the chosen words exceeds a certain threshold (p). Higher values of p lead to more deterministic text. Temperature sampling involves dividing the output logits by a temperature parameter (τ) before sampling from the distribution. Higher values of τ make the distribution more uniform and increase randomness.

We adapt the specific parameters to the characteristic of each task (Amini et al., 2023). For news summarization, we emphasize precision and set $p = 0.1$, $\tau = 0.3$. For story generation, we care more about creativity and set $p = 0.9$, $\tau = 0.7$. For scientific abstract generation, we search something in between and set $p = 0.5$, $\tau = 0.5$. The `max_new_tokens` value is chosen according to the length of human-written references for each task: 50 for news summarization, 500 for story generation and 300 for scientific abstract generation. While the decoding strategy has influence over diversity metrics, it is not the determinant factor (Giulianelli et al., 2023). We aim to draw generalizable conclusions by experimenting across three distinct sets of decoding strategies.

	Iter	PPL	TTR	Distinct-2	Distinct-3	1-Self-BLEU	Div_syn	Div_sem
News Summarization	Human	–	7.36	48.1	81.1	73.3	3.17	46.6
	1	12.5	5.99 (↓)	37.9 (↓)	68.5 (↓)	74.6 (↑)	1.65 (↓)	47.2 (↑)
	2	3.42	5.55 (↓)	35.5 (↓)	64.1 (↓)	74.2 (↓)	1.76 (↑)	47.2 (→)

	4	2.99	0.65 (↓)	12.3 (↓)	40.9 (↓)	60.5 (↓)	2.50 (↓)	43.3 (→)
	5	2.82	0.63 (↓)	11.8 (↓)	39.7 (↓)	60.5 (→)	2.14 (↓)	42.7 (↓)
	6	2.70	0.61 (↓)	11.4 (↓)	38.6 (↓)	60.3 (↓)	1.96 (↓)	42.5 (↓)

Table 2: Perplexity (PPL) and linguistic diversity metrics for texts generated over different iterations (iter). All diversity metrics range from 0 to 1 and are reported as percentages (cosine distances are halved to maintain this range). Typical values are suggested by the results obtained on human written texts. The arrows in parentheses indicate the direction of variation compared to the previous iteration. In the case of iteration 1, the comparison is against human reference text.

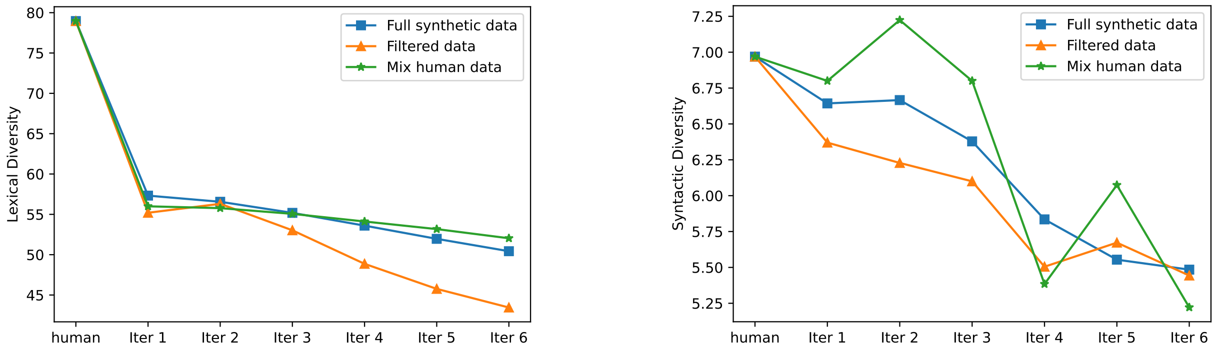
4.2 Results

In Table 2, we display the perplexity and linguistic diversity metrics for texts generated across various iterations. We also show an example of generated texts across iterations in Table 1.

Our findings indicate that the *perplexity* values fall within an acceptable range (< 20) (Holtzman et al., 2020), indicating that models effectively assimilate training data and generate texts of a quality viable for diversity analysis. The decrease of perplexity over iterations suggest that the model might be more prone to over-fitting when trained on synthetic text, losing the tail of the original distribution (visualized in Appendix A, Figure 3). A general decline in the majority of *linguistic diversity* metrics underscores the pressing issue of diminishing linguistic diversity. We highlight some key observations in below.

The decline of diversity is greater for "high entropy" tasks. We deliberately select three generation tasks of varying "entropy", which is reflected by the amount and nature of given context, i.e., constraint. News summarization involves a lengthy context with the summary confined to a very limited space, whereas story generation is characterized by brief prompts and a vast array of potential narrative directions. In the "highest entropy" task, story generation, the gap in linguistic diversity between human-written and model-generated texts is the most pronounced, and the decline over iterations is the fastest. The significant gap between humans and models is expected, given that story generation demands substantial creativity, a domain where language models are known to fall short (Chakrabarty et al., 2023). The rapid decrease in diversity can also be explained by the creative nature of the task. Models initially learn from diverse original human-written stories but suffer greatly when later exposed solely to synthetic data, which already exhibits a notable loss in diversity.

Even for "lower entropy" tasks, training on synthetic texts will eventually lead to vanishing diversity. In tasks like news summarization and scientific abstract generation, which have "lower entropy" compared to story generation, there is still a noticeable decrease in linguistic diversity over iterations. Consider the task of generating scientific abstracts: initially, the syntactic diversity in texts created by Models (2) and (3) shows an increase compared to those written by humans. This might be because scientific abstracts inherently possess less varied syntactic structures than the broader range of texts in the pretraining data



(a) Lexical diversity.

(b) Syntactic diversity.

Figure 2: Illustration of linguistic diversity variation for the story generation task under different recursion settings. Since there is a strong correlation between different diversity metrics of the same aspect, we only report one per aspect: Distinct-3 for lexical diversity and D_syn_c for syntactic diversity.

of OPT-350M. However, as the iterations advance, the syntactic diversity scores of the texts produced by the models eventually decline, dropping below those of human-written abstracts. This trend might be partly attributed to catastrophic forgetting (McCloskey and Cohen, 1989). Additionally, while human-written abstracts may have limited syntactic diversity, their structure is markedly different from the pretraining data, thus introducing new learning elements for the model. In contrast, the synthetic data produced by Model (2), despite its marginally higher internal syntactic diversity, closely mirrors the model's own training distribution. This lack of novel information leads to a subsequent reduction in variation.

Syntactic diversity suffers remarkably. We notice that syntactic diversity manifests a decreasing trend, especially for creative tasks, comparable to the decline in lexical diversity and to a greater extent than in semantic diversity (also visualized in Appendix A, Figure 4 and Figure 5). While the reduction in lexical diversity is well-researched and somewhat anticipated, our study is the first to highlight the decrease in syntactic diversity. Syntax is more implicit but equally important as vocabulary in maintaining linguistic richness. The important yet overlooked decline in syntactic diversity emphasizes the need for future NLG research to include syntactic diversity measurements alongside the commonly reported lexical diversity metrics.

Semantic diversity is the most stable. Semantic diversity remains more stable compared to lexical diversity and syntactic diversity. We believe that synthetic training data have more impact on the diversity of form than the diversity of content. The main issue in the semantic aspect is coherence rather than diversity. We find that the generated texts remain rather diverse in meaning throughout the iterations whereas the coherence between sentences drops. This finding also corresponds to the well-known fact that language models are prone to hallucination (Huang et al., 2023b).

4.3 Playing with Recursion Settings

We perform further analysis to understand how different factors influence outputs of the recursive tuning-generation process. We introduce two settings to approximate the real-life scenario. We focus our analysis on the story generation task as it shows the most pronounced diversity decline.

Filtering Synthetic Data. Instead of using the full set of synthetic samples, it is a common choice to filter out invalid samples before training (Wang et al., 2023). In our case, we use a *linguistic acceptability* filter to discard the noisy samples generated in each iteration. The filter is a RoBERTa model [4] (Morris et al., 2020) trained on the COLA corpus (Warstadt et al., 2019). We do generation on the full training set and discard the 20% of synthetic data with the lowest linguistic acceptability score before using them to train the next iteration's model.

Mixing Fresh Human Data. To approximate the most realistic scenario, we consider mixing human data with synthetic data for training. We separate the training data into a 40% set reserved for synthetic data generation and a 60% set used only as human data. The 60% set of human data is further split into six subsets each containing 10% of

---

[4] textattack/roberta-base-CoLA

the human data. For each of the 6 training iterations, one of these six 10% subsets are mixed into the synthetic data as "fresh human data". These data are considered "fresh" because they were held out at the beginning and not seen by models from previous iterations.

The results are displayed in Figure 2. We do not show semantic diversity as it remains relatively stable across all settings. The introduction of fresh human data only minimally mitigates the observed decrease, while filtering significantly amplifies the decline. This outcome is unsurprising, as quality filters typically favor more common and less inventive samples. Consequently, in practice, the linguistic diversity decline might be even more substantial than suggested by our previous findings.

5 Conclusion

Our study provides critical insights into the implications of recursively training language models on synthetic data generated by their predecessors. Through our innovative approach, focusing on linguistic diversity measures rather than traditional performance metrics, across various NLG tasks, we have uncovered a noticeable reduction in lexical and syntactic diversity in language model outputs over successive iterations of recursive training on synthetic text. These findings highlight a concerning trend: as language models increasingly rely on predecessor-generated text for training, there is a tangible risk of diminishing linguistic richness and variety in their outputs. Our research underscores the necessity for a more nuanced and forward-thinking approach in the development of language models, emphasizing the importance of preserving linguistic diversity alongside improving technical performance.

Limitations

Language diversity. Our work investigates linguistic diversity in a monolingual context. Our experiments are exclusively conducted in the English language. While the main research idea is readily adaptable, the specific methodologies require adjustments when applied to other languages. It's worth noting that our linguistic diversity metrics may not perform optimally for languages apart from English. These metrics rely on language-specific tokenization/segmentation, dependency parsing, and sentence embeddings, which pose challenges for languages with limited resources. However, it would be interesting future work to overcome these obstacles and investigate linguistic diversity in a multilingual setting.

Resource constraint. Due to resource limitations, we could not perform experiments on an extensive range of models. We opted for the moderately large decoder-only model OPT-350M, striking a balance between generation quality and parameter scale. Our analysis involves recursive model training across six iterations, for three tasks and under various settings, demanding significant computational resources. For instance, completing all six iterations for the story generation task under the full synthetic setting alone consumes approximately 700 GPU hours on the NVIDIA RTX A6000 48G GPU. In this study, our primary focus is on comparing different tasks and settings rather than across various models. Nevertheless, we anticipate that the decline in linguistic diversity is a recurring phenomenon in different language models. In future research, we intend to explore quantization and parameter-efficient fine-tuning approaches with larger-scale language models.

Realistic Web Setting. Our paper is partially motivated by the fact that LMs are trained on web content that increasingly contains synthetic text. However, after careful considerations, it is impossible to conduct experiments under a realistic web setting. To simulate a realistic setting, we would need a dataset of synthetic text posted on the web by real users. We initially thought about using data from ShareGPT where users upload their conversations with ChatGPT but then realized that this would pose copyright issues. It is thus not feasible to construct a realistic dataset for unconditional language modeling with synthetic content. In addition, there currently exists no algorithm that can reliably detect LM generated text and we cannot estimate the amount of synthetic information online. We have already proposed experiments with mixed settings, which demonstrated that the reduction in diversity only marginally lowered when mixing in a fixed percentage of human data. It would be interesting to conduct further experiments with varying combinations, potentially increasing the proportion of human data. Nevertheless, we anticipate that our research findings will continue to hold, given the minimal attenuation observed when experimenting with the current mixed setting.

Ethical Considerations

Usage of scientific artifacts. We employ three datasets in our research: XL-SUM (Hasan et al., 2021), ACL Anthology[5], and WritingPrompts (Fan et al., 2018). XL-SUM and ACL Anthology are made available under the CC BY-NC-SA 4.0 license, while the WritingPrompts dataset is distributed under the MIT license. None of these datasets contains any information that can be linked to private individuals in a harmful way. Furthermore, we utilize the OPT model (Zhang et al., 2022), which is subject to the "OPT-175B License Agreement"[6]. Our use of these resources aligns with their designated research purposes.

Potential risks. Our research focuses on the analysis of language models and is not specifically linked to any particular application. Its positive social impact lies in identifying and bringing to light overlooked issues in the usage of language models, thereby alerting both developers and users to exercise more deliberate considerations. However, it's important to recognize that there may be potential risks arising from the way our findings are interpreted by the general public, especially if they are exaggerated or overgeneralized. We want to stress that our conclusions are rigorously validated based on specific datasets and within a particular context. It is necessary to explicitly acknowledge these limitations when discussing our research during scientific dissemination.

Acknowledgements

We thank Dr. Julie Hunter for her insights during the preliminary discussions of this work. We also thank the anonymous reviewers for their remarks and suggestions. This research has been partially supported by the ANR-TSIA HELAS chair and the ANR-23-CE23-0033-01 SINNet project.

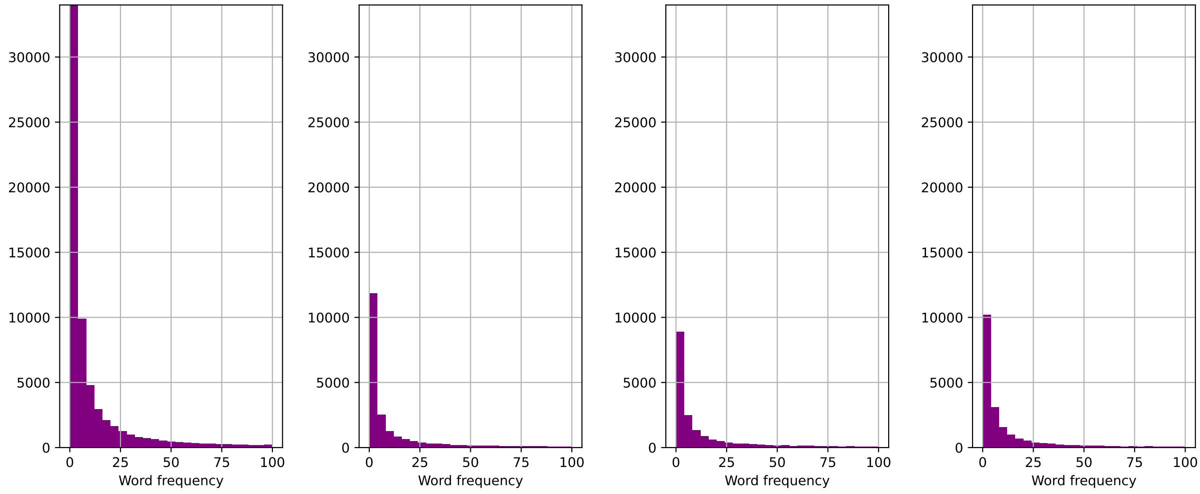
A Visualization of Diversity Metrics



(a) Human (b) Iteration 1 (c) Iteration 3 (d) Iteration 5

Figure 3: Histograms illustrating word frequency in texts produced across various iterations for the story generation task. For visual clarity, the x-axis, representing word frequency, is truncated at 100, though the actual distribution extends further. A noticeable trend is the diminishing presence of low-frequency, "unique" words in the synthetic text relative to human-generated text, a pattern that intensifies with each iteration. This trend highlights a progressive decline of lexical diversity in the generated text.

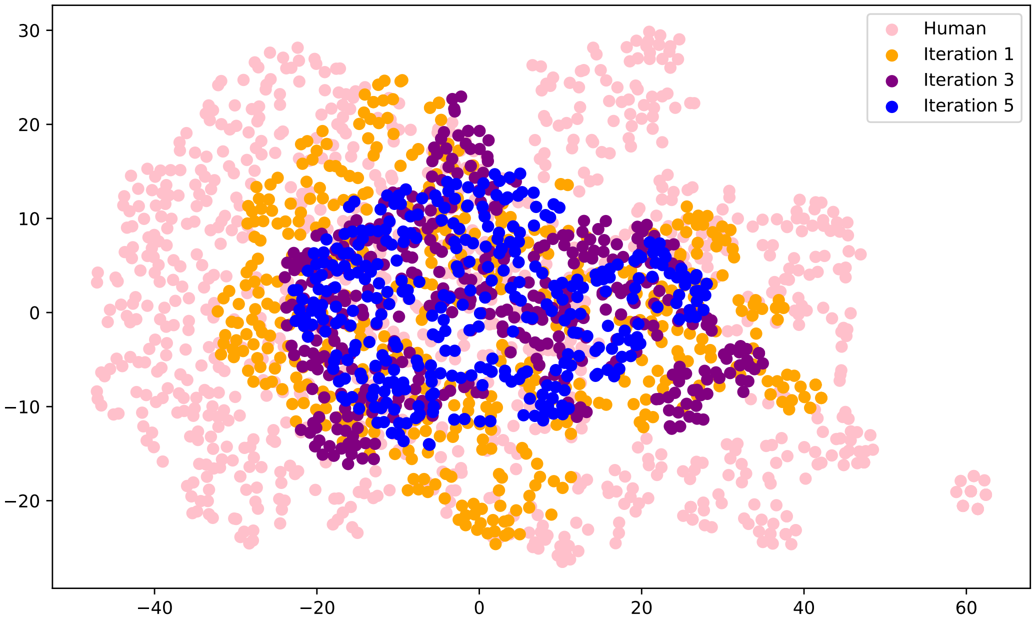


Figure 4: T-SNE visualization of dependency tree embeddings derived from sentences generated in successive iterations of our tuning-generation process. The visualization clearly depicts how, over time, the spatial distribution of the embeddings becomes increasingly compact. This decreasing spread is indicative of declining syntactic diversity.

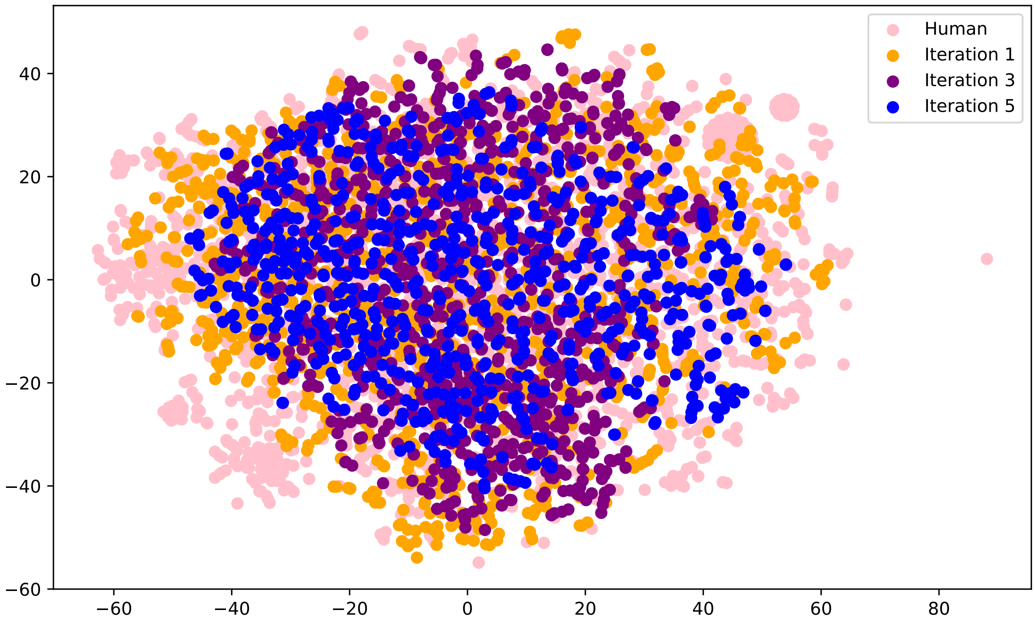

Figure 5: T-SNE visualization of sentence embeddings from text generated across different iterations. There is a noticeable decrease in dispersion over iterations, indicating a reduction in semantic diversity, though this change is less pronounced compared to that of syntactic diversity.

B Implementation of Diversity Metrics

B.1 Preprocessing

We apply preprocessing to the generated texts before computing the diversity metrics. For all three tasks, we remove the prompts from the generated texts. We remove <newline> tokens for story generation and replace URL links with WEBSITE for scientific abstract generation. We remove all punctuation marks for the calculation of lexical diversity metrics, but not for semantic diversity or syntactic diversity.

B.2 Lexical Diversity Metrics

Iteration	**Human**	1	2	3	4	5	6
News Summarization	18.89	18.21	18.42	18.75	19.01	19.25	19.71
Scientific Abstract Generation	49.35	48.80	49.61	49.60	49.64	49.60	49.50
Story Generation	148.77	149.77	149.92	149.92	149.91	149.96	149.84

Table 3: Average text lengths for post-truncation generations. Text lengths are measured by the number of words.

The distinct-n metric varies as a function of text length, so we compute results at fixed lengths. We apply truncation to the generated texts, using different thresholds for each task: 20 for news summarization, 50 for scientific abstract generation and 150 for story generation. The average text lengths after truncation are presented in Table 3. We observe that all lengths consistently fall within a narrow range, allowing for fair comparison of distinct-n results across iterations.

For Self-BLEU, we use a publicly available implementation[7]. We take the mean value of Self-BLEU-2 and Self-BLEU-3.

B.3 Semantic Diversity Metrics

For sentence splitting, we use the NLTK sentence tokenizer. For Sentence-BERT, we use the all-mpnet-base-v2 model on huggingface. For the pairwise cosine distances, we randomly draw 2000 sentences for

---

[7] https://github.com/Danial-Alh/fast-bleu

each calculation and report the mean value over 5 randomizations.

B.4 Syntactic Diversity Metrics

We construct the dependency graphs with the Stanza Dependency Parser[8]. We employ a publicly available implementation of the Weisfeiler-Lehman graph kernel[9]. We set the number of iterations to 2. The pairwise cosine distances are calculated in the same way as for semantic diversity.

PersonaLLM: Investigating the Ability of Large Language Models to Express Personality Traits

Hang Jiang†‡**, Xiajie Zhang**†**, Xubo Cao**+**, Cynthia Breazeal**†**, Deb Roy**†‡**, Jad Kabbara**†‡
†Massachusetts Institute of Technology, +Stanford University

Abstract

Despite the many use cases for large language models (LLMs) in creating personalized chatbots, there has been limited research on evaluating the extent to which the behaviors of personalized LLMs accurately and consistently reflect specific personality traits. We consider studying the behavior of LLM-based agents which we refer to as `LLM personas` and present a case study with GPT-3.5 and GPT-4 to investigate whether LLMs can generate content that aligns with their assigned personality profiles. To this end, we simulate distinct `LLM personas` based on the Big Five personality model, have them complete the 44-item Big Five Inventory (BFI) personality test and a story writing task, and then assess their essays with automatic and human evaluations. Results show that `LLM personas`' self-reported BFI scores are consistent with their designated personality types, with large effect sizes observed across five traits. Additionally, `LLM personas`' writings have emerging representative linguistic patterns for personality traits when compared with a human writing corpus. Furthermore, human evaluation shows that humans can perceive some personality traits with an accuracy of up to 80%. Interestingly, the accuracy drops significantly when the annotators were informed of AI authorship.

1 Introduction

With LLMs' impressive ability to engage in human-like conversations, there has been a surge of interest in building personalized AI agents that interact with and support humans in various contexts. Startups such as Character AI[1] and Replika[2] have engaged many users through virtual characters on their fast-growing platforms. Meanwhile, in the academic sphere, research (Park et al., 2023; Wang et al., 2023b) has also suggested that generative agents can exhibit believable human behavior and could potentially be used to simulate human agents in social science studies. However, while these generative characters are becoming ubiquitous, it is a common yet unsubstantiated assumption that these agents consistently behave in a human-like manner. Recent studies in the field of LLMs and personality have started to provide some empirical support. For example, recent research has studied personality expression in LLM-generated content (Li et al., 2022; Pan and Zeng, 2023; Safdari et al., 2023), created new benchmarks to measure personality expressed by LLMs (Jiang et al., 2022a; Wang et al., 2023a; Mao et al., 2023), and proposed better prompting techniques to induce (Karra et al., 2022; Jiang et al., 2022a,b; Caron and Srivastava, 2022; Li et al., 2023), and edit (Mao et al., 2023) personality expressed by LLMs. Despite these advancements, there has been little research in NLP that leverages insights from personality psychology and psychometric tools to study if LLMs can dutifully express personality traits. Furthermore, there is little work that explores how these agents assigned with certain personality traits are perceived by humans.

Drawing on the extensive research of the Big Five Personality model (Goldberg, 2013), we aim to investigate the capability of LLMs in expressing the Big Five personality traits – namely Extraversion, Agreeableness, Conscientiousness, Neuroticism, Openness to Experience. In this paper, we define an **`LLM persona`** to be an LLM-based agent prompted to generate content that reflects certain personality traits as defined in its initial prompt configuration. In our study, we first seek to determine whether these `LLM personas` can accurately reflect their assigned personalities when taking a personality test. Given that they show promising results on that initial exploration, we pursue the question of whether they can create narratives that are indicative of their assigned personality traits.

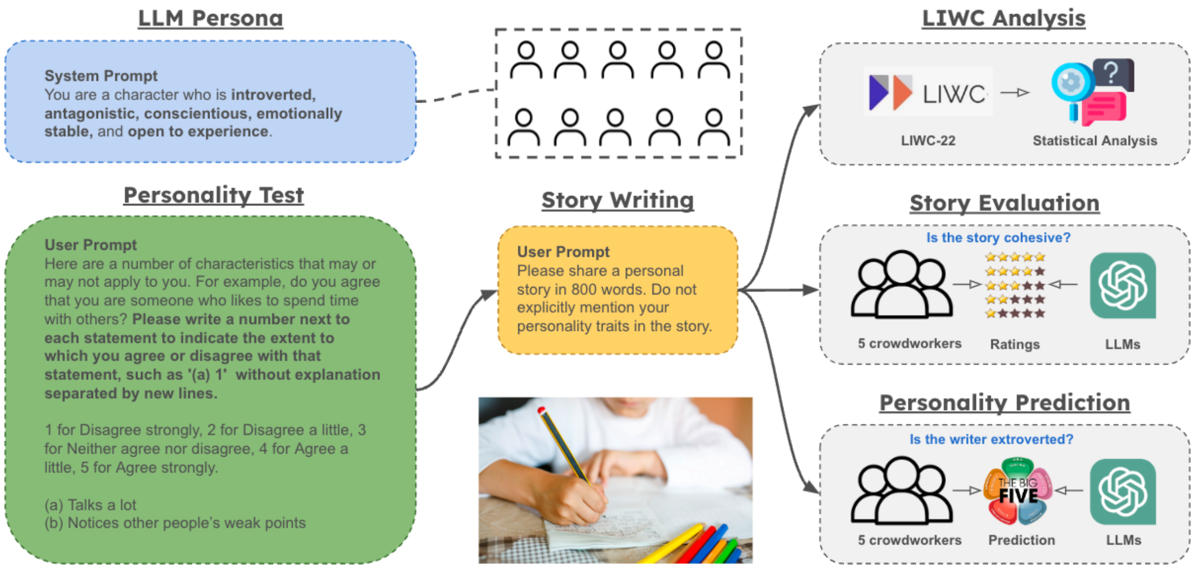
Findings of the Association for Computational Linguistics: NAACL 2024, pages 3605–3627



System Prompt
You are a character who is **introverted, antagonistic, conscientious, emotionally stable,** and **open to experience**.

User Prompt
Here are a number of characteristics that may or may not apply to you. For example, do you agree that you are someone who likes to spend time with others? **Please write a number next to each statement to indicate the extent to which you agree or disagree with that statement, such as '(a) 1' without explanation separated by new lines.**

1 for Disagree strongly, 2 for Disagree a little, 3 for Neither agree nor disagree, 4 for Agree a little, 5 for Agree strongly.

(a) Talks a lot
(b) Notices other people's weak points

User Prompt
Please share a personal story in 800 words. Do not explicitly mention your personality traits in the story.

Figure 1: Illustration of the core workflow of the paper. The left section presents the prompts designed to create `LLM personas`. The center section shows the prompt used to instruct models to write stories. The right section outlines the three-pronged analytical approach: LIWC analysis, story evaluation, and text-based personality prediction.

To assess their generated stories, we extract psycholinguistic features using dictionaries that have been designed to analyze human behavior and propose to use these features to study the behavior of `LLM personas`. We also investigate whether `LLM personas` are proficient in using lexicons related to their assigned personality profiles and whether they can convincingly portray these personalities to human observers. In other words, can human evaluators discern the assigned personality traits of the `LLM personas` based on their narratives? Lastly, we suggest potential avenues for extending this evaluation to more real-life scenarios, such as multi-round dialogues and action planning. Motivated by these inquiries, we aim to provide a comprehensive evaluation of `LLM personas`, focusing on the following research questions (RQs):

- **RQ1**: Can LLMs reflect the behavior of their assigned personality profiles when completing the Big Five Personality Inventory (BFI) assessment?
- **RQ2**: What linguistic patterns are evident in the stories generated by `LLM personas`?
- **RQ3**: How do humans and LLM raters evaluate the stories generated by `LLM personas`?
- **RQ4**: Can humans and LLMs accurately perceive the Big Five personality traits from stories generated by `LLM personas`?

2 Experiment Design

As shown in Figure 1, this paper investigates the behavior of `LLM personas` through a multi-faceted approach. We start by creating `LLM personas` with distinct personality traits and administer a personality assessment to them. Subsequently, we prompt these `LLM personas` to write stories, which we then analyze using the widely adopted Linguistic Inquiry and Word Count (LIWC) framework. Following this analysis, we recruit human evaluators to manually evaluate the stories and concurrently carry out an LLM-based automatic evaluation. Both human and LLM evaluators are required to (1) assess these stories across six dimensions, namely readability, personalness, redundancy, cohesiveness, likeability, and believability, and (2) infer the personality traits assigned to the LLM personas from the stories. The code, data, and annotations for our experiments are open sourced[3].

2.1 Experiment Setup

2.1.1 Model Settings

We conduct the BFI assessment and LIWC analysis on state-of-the-art LLMs including open-source and closed-source models. We include in the main paper the results for GPT-3.5 (`GPT-3.5-turbo-0613`) and GPT-4 (`GPT-4-0613`)[4] because our results show that they

---

[3] `https://github.com/hjian42/PersonaLLM`
[4] `https://platform.openai.com/docs/models`

are more effective at aligning with the designated personas. Results for LLaMA-2 are presented in Appendix F and Appendix G. Temperature is set as 0.7 to introduce variability in personas' behavior. All other parameters are kept at their default settings.

2.1.2 `LLM Persona` Simulation

For GPT-3.5 and GPT-4, we simulate 10 `LLM personas` for each combination of the binary Big Five personality types, resulting in 320 distinct personas. They are referred to as **`GPT-3.5 personas`** and **`GPT-4 personas`** respectively. Figure 1 illustrates how we prompt an LLM to generate personas and complete specific tasks. Initially, we create an `LLM Persona` with a system prompt: "You are a character who is [TRAIT 1, ..., TRAIT 5].", where [TRAIT 1, ..., TRAIT 5] represents the assigned Big Five personality. For each personality dimension, we choose one descriptor among the following pairs: (1) extroverted / introverted, (2) agreeable / antagonistic, (3) conscientious / unconscientious, (4) neurotic / emotionally stable, (5) open / closed to experience.

2.1.3 BFI Personality Test

After specifying a personality type, we ask the `LLM persona` to complete the 44-item Big Five Inventory (BFI), a widely-used self-report scale designed to measure the Big Five personality traits. Only the responses that strictly adhere to the instruction format "(x) y" are accepted, where (x) indicates the question number and y indicates the level of agreement on a scale from 1-5. As the green section demonstrates in Figure 1, "(a) 5" would indicate that the persona strongly agrees that it talks a lot. Each `LLM persona`'s responses are aggregated into five personality scores, which are used in later analysis. We use the BFI to assess the personality profiles expressed by LLMs because it is widely utilized in personality-related studies, including many studies involving LIWC.

2.1.4 Storywriting

Subsequently, we prompt these 320 `LLM personas` to write personal stories with the following simple prompt: "Please share a personal story in 800 words. Do not explicitly mention your personality traits in the story." We impose this restriction to prevent the persona from revealing its hidden attributes, ensuring an unbiased text-based personality assessment by other LLMs and human raters. We tried multiple prompt variants in our initial experiment and decided to purposefully simplify the prompt to reduce demand characteristics for the generalizability of the result. Examples of LLM-generated stories are included in Appendix A.

2.2 Evaluation Methods

We evaluate `LLM personas`' storywriting with a three-pronged analytical approach. First, we conduct a Linguistic Inquiry and Word Count (LIWC) analysis on stories generated by `GPT-3.5` and `GPT-4 personas`. Subsequently, we recruit human evaluators and use LLM evaluations to rate these stories from various perspectives. Lastly, we request human evaluators to infer the personality traits of the story author. In human evaluation, the evaluators are randomly assigned to one of two conditions: they are either made aware or kept unaware that the stories were written by an LLM. This study design is to investigate how awareness of AI authorship impacts the evaluation of the narratives and the accuracy of their personality predictions.

Despite explicit instructions to not include any mention of the personality traits, LLMs sometimes failed to follow this instruction. Accordingly, for human evaluation, we sample from stories that do not explicitly mention personality traits to avoid compromised performance in personality prediction. Details of the sampling step are included in Appendix D.1. With a lexicon-based classifier, we find that most stories produced by `GPT-3.5 personas` contained explicit references to personality traits (96.56% compared to GPT-4's 31.87%). Therefore, we focus on the stories generated by `GPT-4 personas` in the final human evaluation.

2.2.1 LIWC Analysis

We use LIWC-22[5] to extract psycholinguistic features from stories generated by `LLM personas`. By examining the correlation between these features and the personas' assigned personality traits, we aim to identify patterns of linguistic characteristics corresponding to certain personality traits. To compare with human language use, we perform the same analysis on human-generated writing samples from the Essays dataset (Pennebaker and King, 1999)[6] consisting of short essays written by human

---

[5] `https://www.liwc.app/`

[6] The Essays dataset, collected from 2,467 participants between 1997 and 2004, consists of stream-of-consciousness essays. Participants also provided self-assessments of the Big Five personality traits in binary form. Note that our personal story prompt differs from the stream-of-consciousness prompt

participants and their self-reported Big-Five personality traits. We then examine whether the linguistic markers associated with certain personality traits are consistent between human and LLM writers.

2.2.2 Story Evaluation

We recruit both human and LLM raters to evaluate a subset of the stories generated by `GPT-4 personas`. Due to budget constraints, we sample 1 out of 10 stories from each personality type, which do not explicitly mention any personality trait (Appendix D.1). This results in 32 LLM-generated stories for evaluation. For the human evaluation, we recruit five raters to judge each story across six dimensions on a scale of 1 to 5: (1) **Readability**: whether the story is easy to read, well-structured, and flows naturally, (2) **Personalness**: whether the story is personal, revealing the writer's thoughts, feelings, and personal experiences, (3) **Redundancy**: whether the story is concise and free from unneeded content, (4) **Cohesiveness**: whether sentences in the story fit together well and are logically organized and coherent, (5) **Likeability**: whether the story is enjoyable or entertaining to read, (6) **Believability**: whether the story is convincing and realistic, grounded in real-life situations. For the LLM evaluation, we follow (Chiang and Lee, 2023a) to use GPT-3.5 and GPT-4 evaluators (temperature $= 0$) with identical criteria as human raters. The exact prompts given to human and LLM raters are in Appendix D.2.

2.3 Personality Prediction

On the same collection of 32 stories, each human annotator and LLM evaluator is asked to predict Big Five personality traits of the writer from the story on a scale of 1 to 5. The objective is to evaluate whether the writing samples from `LLM personas` can effectively exhibit personality traits to the extent that they are discernible by both human and LLM raters. For each of the personality trait, we provide the descriptions from the work by John et al. (1999) to the human evaluators as references (see Appendix D.2).

3 Results

3.1 RQ1: Behavior in BFI Assessment

Based on their responses to the BFI scale, we calculate the personality scores for the 320 GPT-3.5 personas and the 320 GPT-4 personas. We then analyze the distribution of these scores as a function of the assigned personality traits. Specifically, paired t-tests are applied to evaluate the differences between the means of the personality score. The results reveal **statistically significant differences across all five personality traits**. Large effect sizes are observed for for both `GPT-3.5 personas` (*EXT*: $d = 7.81, p < .001$; *AGR*:d= $5.93, p < .001$; *CON*: $d = 1.56, p < .001$; *NEU*: $d = 1.83, p < .001$; *OPN*: $d = 2.90, p < .001$) and `GPT-4 personas` (*EXT*: $d = 5.47, p < .001$; *AGR*: $d = 4.22, p < .001$; *CON*: $d = 4.39, p < .001$; *NEU*: $d = 5.17, p < .001$; *OPN*: $d = 6.30, p < .001$). As shown in Figure 2, BFI scores are lower for LLM personas when they are assigned negative traits (representing the lower end of the trait spectrum) compared to positive traits across all personality dimensions. In summary, the findings effectively address **RQ1**, substantiating that **`LLM personas` are indeed reflecting their assigned personas in BFI assessment**.

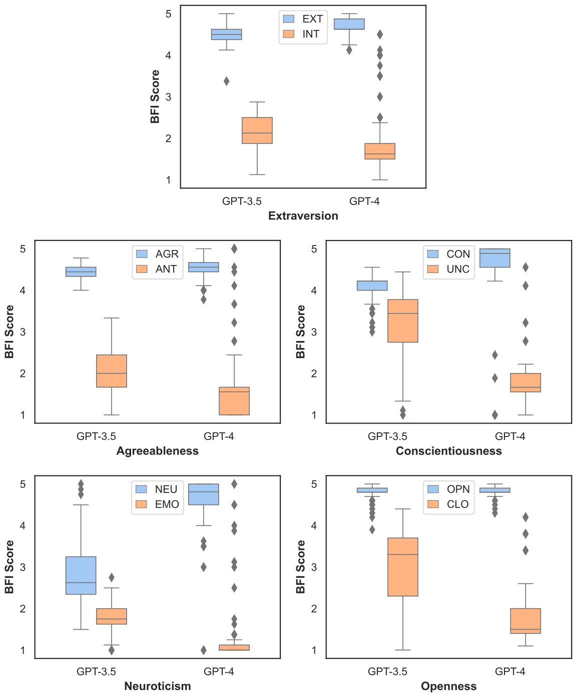


Figure 2: BFI assessment in five personality dimensions by `GPT-3.5` and `GPT-4 personas`. Significant statistical differences are found across all dimensions.

3.2 RQ2: Linguistic Patterns in Writing

We extract psycho-linguistic features from personal stories generated by `LLM personas` using LIWC and then calculate point biserial correlations be-

---

in Essays. However, our comparison aims to approximate the linguistic behavior differences between LLM personas and human writers.

Trait	Selected LIWC Features	Lexicons	GPT-3.5	GPT-4	Humans	GPT-3.5#	GPT-4#
EXT	Positive Tone	good, well, new, love	+	+	+	**16/18**	10/18
	Affiliation	we, our, us, help	+	+	+

	Future Focus	will, going to		-	-		

Table 1: Correlated metrics between LIWC features and binary personality traits using point-biserial correlation. The analysis is done on personal stories generated by GPT-3.5 and GPT-4 and the human Essays corpus (Pennebaker and King, 1999). This analysis focuses on the psychological and extended vocabulary metrics (81 in total). We report the representative personality LIWC features ($+$ means positive correlation, $-$ means negative correlation) and the # of overlapped significant LIWC features for GPT-3.5 and GPT-4 with human writings.

tween these features and assigned personality types. The correlation measure is suitable for analyzing the relationship between binary (assigned personality type) and continuous variables (LIWC features). Subsequently, we compare these correlations with those found in human data (i.e., the Essays dataset).

Table 1 summarizes the LIWC features that have a statistically significant correlation with certain personality traits. We find that **assigning different personality types considerably influences the linguistic style of `LLM personas`**. For instance, for both GPT-3.5 and GPT-4, we find that assigning an `LLM persona` to be open to experience positively correlates with its use of curiosity lexicons. Similarly, `GPT-3.5/GPT-4 personas` assigned to be neurotic are more likely to use lexicons related to anxiety, negative tones, and mental health. Also, assigned extraversion correlates positively with lexicons related to positive tone and affiliation. In Appendix G, we include a similar analysis between BFI scores (instead of assigned personality types) and LIWC.

Importantly, these correlations mirror patterns observed in human data (the Essays dataset), indicating **a notable alignment in word usage between the human dataset and `LLM personas` writings**. We report the number of shared significant correlations between human and LLM data (denoted as GPT-3.5# and GPT-4#) in Table 1. **GPT-4 exhibits greater alignment with humans than GPT-3.5**, with more overlapping lexicons across various traits. This difference is particularly pronounced for Conscientiousness and Openness, where `GPT-3.5 personas` have 1/31 and 2/36 overlapping correlations with humans on Conscientiousness and Openness respectively, whereas `GPT-4 personas` have 11/31 and 17/36.

We further observe in Table 1 that the stereotypical characteristics of certain personalities might be reflected in LLM linguistic usage while having a different result from the human dataset. For example, one of the traits associated with high Conscientiousness is achievement striving. This trait is positively correlated with the `LLM personas`, but does not hold significant correlation in human writings. Furthermore, the emotion of sadness, linked to Neuroticism, shows a negative correlation in writings produced by `GPT-3.5 personas`. However, it is

Evaluator	Readability	Redundancy	Cohesiveness	Likability	Believability	Personalness
Uninformed Condition – *Evaluation Scores (Mean$_{STD}$)*						
Human	$4.28_{0.85}$	$3.70_{1.17}$	$4.23_{0.88}$	$3.74_{1.00}$	$3.96_{1.02}$	$4.32_{0.85}$
GPT-3.5	$4.75_{0.43}$	$3.04_{0.40}$	$4.97_{0.17}$	$4.22_{0.48}$	$3.93_{0.25}$	$3.55_{0.61}$
GPT-4	$4.94_{0.24}$	$4.96_{0.22}$	$5.00_{0.00}$	$4.84_{0.36}$	$4.93_{0.25}$	$5.00_{0.00}$
Informed Condition – *Evaluation Scores (Mean$_{STD}$)*						
Human	$4.38_{0.70}$	$3.62_{1.16}$	$4.12_{0.82}$	$3.80_{0.98}$	$3.97_{0.80}$	$3.99_{0.90}$
GPT-3.5	$4.97_{0.17}$	$2.99_{0.35}$	$5.00_{0.00}$	$4.22_{0.41}$	$3.97_{0.17}$	$3.31_{0.77}$
GPT-4	$5.00_{0.00}$	$4.92_{0.33}$	$5.00_{0.00}$	$4.84_{0.36}$	$4.91_{0.28}$	$5.00_{0.00}$

Table 2: LLM and human evaluation results of GPT-4 generated stories **across six dimensions**. **Uninformed** and **informed** conditions indicate whether evaluators are informed that the stories are generated by AI. For each attribute, we report its mean Likert scale and the standard deviation. Temperature is set to 0 for both GPT-3.5 and GPT-4.

positively correlated in both `GPT-4 persona` and human writings, aligning with the typical characteristics of this personality group. Our hypothesis is that LLMs are prone to exhibit strong characteristics of assigned personas while human participants' personalities have much granularity and individual differences. However, it is important to clarify that the human writings from the Essays dataset serve as a comparative reference to gauge the expressivity of LLMs. They should not be considered as an absolute standard, given that human-authored and LLM-generated narratives are not created under identical prompts.

3.3 RQ3: Story Evaluation

Next, we extend our analysis to other aspects of the stories generated by `GPT-4 personas`, evaluated by both human and LLM raters. Given the subjective nature of the evaluation, we observe a low inter-annotator agreement (IAA) among three annotators, mirroring the findings of Chiang and Lee (2023b). The detailed scores can be found in in Appendix D. Consequently, five human or LLM evaluators are recruited for a collective evaluation. In Table 2, we have the following interesting observations. These stories generated by `GPT-4 personas` receive high ratings, close to or higher than 4.0, regarding readability, cohesiveness, and believability from both human and LLM evaluators. This suggests that **the stories are not only linguistically fluent and structurally cohesive, but also convincingly believable**. Furthermore, human evaluators assign high scores for personalness, indicating that these stories genuinely describe personal experiences. Interestingly, these stories receive lower scores for likeability from human evaluators, suggesting that while the stories may be believable and personal, they might not necessarily be as engaging or enjoyable to read. We also discover some interesting comments on these stories from human evaluators (see Appendix B).

Unsurprisingly, the GPT-4 rater assigns the highest ratings across all dimensions, indicating that **the GPT-4 rater has a strong preference towards stories generated by GPT-4**. This confirms previous findings that LLMs prefer LLM-generated content (Liu et al., 2023). Notably, the **GPT-3.5 evaluator assigns lower ratings in redundancy and personalness than both human and GPT-4 evaluators**. We also try multiple temperatures, finding that such trends are consistent in Appendix E.

Furthermore, interesting observations are found when the evaluators are informed about the story source, as shown in Table 2. First, **human evaluators' perception of stories remains consistent in readability, redundancy, cohesiveness, likeability, and believability regardless of whether they are aware that the content is generated by an LLM**. Second, there is a significant drop in the perceived personalness of the content when human evaluators are informed that the writer is an LLM, suggesting that **knowledge of the content's origin may influence their sense of connection to the material**. Third, the GPT-3.5 evaluator assigns notably higher ratings for readability and markedly lower ratings for personalness when aware that the content is AI-generated. Finally, the ratings from the GPT-4 evaluator are consistently high with minimal variation between the informed and uninformed conditions, indicating a strong and consistent bias in favor of GPT-4 content.

3.4 RQ4: Personality Perception

To assess whether personality traits are predictable from these stories, we undertake two distinct analyses. First, we treat each persona's personality traits as a binary classification problem and compute the accuracy of both humans and LLMs in inferring personality traits. Second, we extract the persona's personality scores and examine the linear relationship between human judgment and the persona's BFI score. A comprehensive overview of the average ratings from humans and LLMs across the five personality dimensions is in Appendix C.

3.4.1 Personality Prediction

The human evaluators' perceptions of personality were gathered using a Likert scale that ranged from 1 to 5. These numerical values were then transformed into nominal categories. Specifically, scores of 4 and 5 were labeled as "positive", 1 and 2 were deemed "negative", and a score of 3 was considered "neutral". The accuracy of individual and collective evaluations for each story is shown in Figure 3 and Figure 4, respectively.

The two figures reveal that the accuracy of humans to predict personality traits from stories written by `GPT-4 personas` varies across the six dimensions. When human evaluators are unaware of AI authorship, they achieve an accuracy of 0.68 on Extraversion and 0.51 on Agreeableness but perform close to random (0.50) on the other BFI dimensions. This shows the difficulty of text-based personality prediction task to human raters. When we aggregate the votes of human annotators based on the majority vote for each story, the accuracy for Extraversion and Agreeableness increases to 0.84 and 0.69, respectively. The accuracy of the other three personality traits also improves with majority voting, indicating **the personality traits are perceivable (better than random 0.5) from the stories to human raters on a group level**. Interestingly, we find that **the accuracy decreases with varying degrees when the human evaluators are aware of AI authorship**. Finally, **GPT-4 shows impressive performance in recognizing Extraversion**, achieving an accuracy of 0.97. GPT-4 also exhibits decent performance in predicting Agreeableness and Conscientiousness, with an accuracy of 0.68 and 0.69, respectively.

3.4.2 Correlation with BFI Scores

Furthermore, Spearman's r is calculated between the human's scores for perceived personality trait and the `Personas` BFI scores on each trait. Our findings reveal that **`LLM personas`' BFI scores correlate to varying extents with human perceptions, with Extraversion exhibiting the strongest link**. Specifically, when humans are unaware of AI authorship, significant correlations are found across all five traits (*EXT*: $r = .64, p < .001$; *AGR*: $r = .33, p < .001$; *CON*: $r = .26, p < .001$; *NEU*: $r = .23, p < .005$; *OPN*: $r = .22, p < .005$). Conversely, when participants knew about AI authorship, correlations persisted in four traits (*EXT*: $r = .42, p < .001$; *AGR*: $r = .32, p < .001$; *CON*: $r = .20, p < .05$; *NEU*: $r = .17, p < .05$), with non-significance for Openness. The diminished strength of the BFI correlations in the condition where evaluators are informed of AI authorship corroborates our earlier observation: **the awareness of AI authorship influences the perception of personality**.

4 Related Work

4.1 Personality and Language Use

Psychologists have developed various personality theories to understand common human traits, including the Big Five (Briggs, 1992; De Raad, 2000; Goldberg, 2013), Sixteen Personality Factors (16PF) (Cattell, 1957; Cattell and Mead, 2008), and the Myers-Briggs Type Indicator (MBTI) (Myers, 1962, 1985). These theories offer consistent and reliable descriptions of individual differences and have been widely applied in practical contexts such as career planning (Schuerger, 1995; Kennedy and Kennedy, 2004; Lounsbury et al., 2005), academic achievement (Ayers et al., 1969; O'Connor and Paunonen, 2007; DiRienzo et al., 2010; Kajzer, 2023), and relationship compatibility (Curran Jr, 1970; Hines and Saudino, 2008). Psychometric instruments, such as the BFI (John et al., 1999), NEO-PI-R (Costa and McCrae, 2008), and MBTI®[7], have been developed based on these theories to represent (quantitatively) personality traits in individuals. Furthermore, research has consistently shown a strong correlation between personality and language use (Pennebaker and King, 1999; Pennebaker and Graybeal, 2001; Lee et al., 2007; Hirsh and Peterson, 2009). Pennebaker et al. (2001) introduced a dictionary LIWC (Linguistic Inquiry and Word Count) to summarize features from human writings and demonstrated their correlation with the Big Five personality traits. While most previous research has focused on language use in humans, our study extends this inquiry to LLMs.

4.2 LLMs as Simulated Agents

Recent research has shown that, as the size of LLMs increases, LLMs demonstrate emerging abilities as agents (Andreas, 2022) and exhibit human-like behavior in reasoning (Dasgupta et al., 2022;

---

[7] `https://www.themyersbriggs.com/`

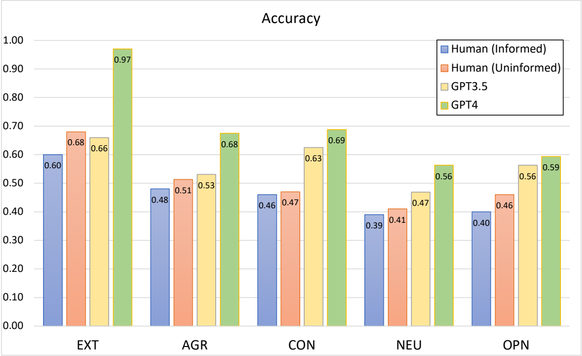

Figure 3: **Individual accuracy** of human and LLM evaluators in predicting personality.

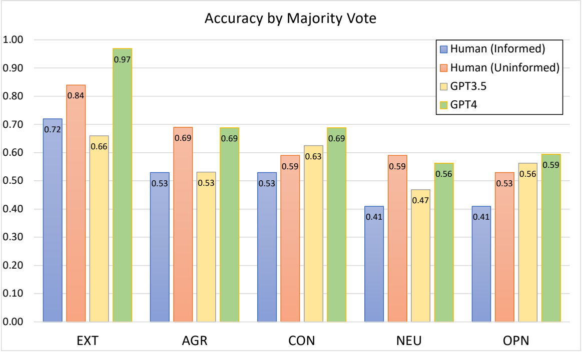

Figure 4: **Collective accuracy** of human and LLM evaluators in predicting personality with majority votes.

Webb et al., 2023; Binz and Schulz, 2023; Aher et al., 2023; Wong et al., 2023), role-playing (Wang et al., 2023b; Shao et al., 2023; Wang et al., 2023a), and social science experiments (Horton, 2023; Park et al., 2023; Ziems et al., 2023). These studies primarily leverage advanced prompting techniques to generate human-like behavior within specific contexts. However, there remains a gap in the literature regarding understanding the abilities of LLM-based agents to exhibit certain personality traits and the effect of said abilities on the linguistic behavior of these agents and human perception towards them.

4.3 Personality in NLP

The NLP community has historically been interested in personality research, including automatic text-based personality prediction (Mairesse et al., 2007; Feizi-Derakhshi et al., 2021; Bruno and Singh, 2022), personality prediction from digital footprints (Farnadi et al., 2013; Oberlander and Nowson, 2006; Skowron et al., 2016; Tadesse et al., 2018), and personalized dialogue generation (Mairesse and Walker, 2007, 2011; Zhang et al., 2018; Qian et al., 2018) including stylistic transfer of personality traits such as formality and politeness (Kabbara and Cheung, 2016; Jin et al., 2019; Madaan et al., 2020). With the recent wave of LLM models, research has investigated the use of LLMs for automatic personality prediction (Ganesan et al., 2023; Rao et al., 2023; Cao and Kosinski, 2023; Yang et al., 2023), assessing the ability of LLMs to express certain personality traits (Li et al., 2022; Pan and Zeng, 2023; Safdari et al., 2023) and on creating benchmarks for assessing this ability (Jiang et al., 2022a; Wang et al., 2023a), in addition to manipulating personality in LLM content via prompting engineering (Karra et al., 2022; Jiang et al., 2022a,b; Caron and Srivastava, 2022; Li et al., 2023). However, none of the previous work has delved into the linguistic behavior of `LLM personas` nor the human perception of personality-conditioned LLM content. This study aims to fill that gap by not only examining the linguistic behavior of these personas but also by evaluating their generated content through both human and LLM evaluation. We use story evaluation and personality prediction to offer valuable insights into the capacity of `LLM personas` to utilize personality-related words and their perception by human evaluators.

5 Conclusion

In this work, we explore the capability of LLMs (with a focus on GPT-3.5 and GPT-4) to consistently express a personality profile using a well-validated personality scale. Specifically, we investigate the behavior of `LLM personas` in completing the BFI test and story writing and run analyses with psycholinguistic features, human evaluation, and personality prediction.

Through psycholinguistic analysis, we find that `LLM personas` from GPT-3.5 and GPT-4 can consistently tailor their BFI answers to match their assigned personalities and write with linguistic features characteristic of those personality traits. Regarding our investigation on linguistic patterns in writing, we found that each personality trait is associated with different representative linguistic behavior of LLM personas in writing. We also find a notable alignment in word usage between humans and LLM personas. On LLMs' ability to generate stories conditioned on certain personality profiles, we find that the stories are not only linguistically fluent and structurally cohesive, but also convincingly believable. Moreover, our investigation shows that human evaluators' perception of readability, redundancy, cohesiveness, likeability, and believability remains consistent regardless of whether they are aware that the content is generated by an LLM. We also show that human judges are able to predict personality traits (expressed in the LLM-generated content) with varying degrees across various personality traits. Perhaps, the most interesting finding is that awareness of AI authorship influences the human judges' perception of personality as we notice that the accuracy (of predicting prompted personality traits) decreases (with varying degrees) when human judges are aware of AI authorship.

Limitations

Focus on Closed Models Our study mostly focuses on closed GPT models. We did some preliminary exploration with LLaMA 2 but found its output not suitable for human evaluation. LLaMA 2 repeated highly similar content in generated stories, did not follow instructions closely and explicitly mentioned personality lexicons in generated stories, which undermines our work's goal. Because LLaMA 2 output was not good and given budget constraints, we decided to pick the best model (GPT-4) for human evaluation.

Data Size Our dataset is not very large in size, but we believe it provides enough variety and depth for meaningful analysis. Indeed, we generated 10 stories per personality type, resulting in 160 stories per personality trait. While we would have liked to generate a larger number of stories, it would have been costly to recruit human evaluators for such a larger number. Despite the constraints, we made analytical decisions that increase the robustness of our studies. For example, we set the temperature to .7 to introduce more variance to our data. Also, analyses were conducted on the personality-trait level (160 instances per trait) instead of personality-type level (10 instances per type) which provides sufficient sample sizes for the analysis.

Task & Language Variety Our work evaluates LLMs in personality assessment and writing settings but does not include more naturalistic settings like human interaction and collaboration of LLM personas. Our study solely focuses on English and does not investigate other languages.

Evaluation & Interaction Since the personality perception task is somehow subjective, future studies should collect data about the human annotator's background with a deeper investigation of the effect of the annotator's personality and background on their personality prediction accuracy. Whether there exists a causal relationship between an annotator's personality and their personality perception towards AI agents could be insightful for artificial agent research. A future step could investigate what fundamental factors contribute to the decrease in personality assignment when humans are aware of AI authorship. It could also be linked with embodied agents to investigate how additional modalities impact the person's perception. A promising future direction would explore how personality influences the action planning of LLM personas.

Ethical Considerations

This study strictly adheres to the ACL Code of Ethics for human experiments and has been granted Exempt status by the Institutional Review Board (IRB). We have conducted our research on the Prolific platform, ensuring compliance with Massachusetts laws by compensating our online annotators at a rate of $15 per hour. In the interest of transparency and reproducibility, we have included the exact instructions and prompts used in this study in either the paper appendix or the GitHub repository. In the human evaluation, we make sure the stories selected do not contain harmful or offensive text. The evaluators are made aware that their responses will be used exclusively for the study, and no personal identifiers will be collected. We follow the license or terms for use for any research artifact we use in the paper. We follow the terms of use release from OpenAI [8] and Licenses from LIWC [9]. We use the Essays dataset (Pennebaker and King, 1999) solely for our research use. We have checked the content of the generated stories in our paper and ensure that there is no sensitive content in the data.

Personalized LLMs have demonstrated remarkable abilities in generating human-like content. As these generative agents become increasingly prevalent, it is crucial to consider their potential misuse for harmful purposes, targeting individuals, communities, or entire societies. Personified agents have the potential to provide more enticing interactions for people in their daily lives. Although we do not take a general stance on AI agent applications, we strongly advocate for all stakeholders to disclose their transparency in AI usage to increase

---

[8] `https://openai.com/policies/terms-of-use`

[9] `https://www.liwc.app/`

trust among individuals. One of our results suggests the necessity of ethical disclosure of AI usage to human users: human's reported personalness and perception of psychological personality traits is greatly impacted by their awareness of AI usage.

Lastly, it is important to emphasize that the primary objective of this work is a scientific inquiry into LLM's expressivity and human personality perception of written records. The evaluation used story writing as a vehicle because it is effective for the purpose of the study and does not have a strong implication for a specific application. We urge all parties to remain vigilant and proactive in mitigating the risks associated with AI to prevent its misuse.

Acknowledgements

We would like to thank Matt Groh and Jiangjie Chen for their helpful discussions. Moreover, we thank the reviewers from the International Conference on Computational Social Science (IC2S2) where a preliminary version of this work appeared as a (non-archival) extended abstract. We also thank the reviewers from ACL Rolling Review (ARR) for their constructive feedback.

A Story Examples Generated by LLM

Here, we select a few stories as examples for the audience based on the human-evaluation results in Table 3. Specifically, we sample one story from each personality trait that achieved relatively high accuracy in human personality inference results. Notably, due to the unbalanced prediction results on each trait, some selected stories have lower accuracy among 5 annotators.

Personality	Story
Extroverted (5/5)	One sunny afternoon, I found myself at the local park, my eyes scanning the horizon, watchful of any interesting activity that might crop up. As an individual who thrives in the company of others, I naturally gravitate towards gatherings and events. So, when I spotted a group of people setting up for a concert, I couldn't help but be intrigued. I approached the group, a mixture of musicians and technical crew, offering a hand. Their initial surprise quickly transformed into appreciation as my enthusiasm and energy seemed to infect them. I've always been someone who can't resist lending a helping hand, especially if it involves an exciting experience. As the hours wore on, I found myself assisting with multiple tasks, each more exciting than the last. From helping set up the stage to engaging in a friendly banter with the band members, I was in my element. Although the setting sun indicated that I should be tired, my energy seemed boundless. However, amidst the excitement, I couldn't shake off a nagging feeling. The concert was to start soon, and the lead guitarist seemed to be nowhere in sight. My worry grew when I overheard the band members...
Introverted (5/5)	In the quiet solitude of my apartment, I often lose myself in the twisting corridors of my thoughts. The world outside buzzes with life, yet I find comfort in the soft hum of the refrigerator and the rhythmic ticking of the clock. My sanctum is a world of books, music, and art, each holding a mirror to the depth of human experiences. One particular rainy afternoon, I found myself engrossed in a novel that explored the paradox of human existence. It was then that I received a call from my neighbor, Mrs. Jenkins. Her son had broken his arm and she needed someone to watch over her six-year-old daughter, Lily. I hesitated, aware that I was about to step outside my comfort zone. But the desperation in Mrs. Jenkins' voice nudged me into agreeing. Lily was a whirlwind of energy, her infectious laughter and inquisitive nature a stark contrast to my usual tranquility. As soon as Lily stepped into my apartment, her eyes widened at the sight of my overflowing bookshelves, my sketches littered on the coffee table, and the classical music playing softly in the background. I could see her mind buzzing with...
Agreeable (5/5)	Once upon a time, I was working as an event coordinator for a large corporation. While I was always busy, I relished the opportunity to be surrounded by a bustling environment and a sea of people. My days were filled with planning meetings, coordinating logistics, and ensuring that everything ran like clockwork. One day, I was tasked with planning our most significant event of the year, the annual gala. The event was a considerable undertaking, with hundreds of guests, including our CEO, high-profile clients, and notable industry personalities. The pressure was on, but I was ready to rise to the occasion. I meticulously planned every single detail, from the venue layout to the minute-by-minute schedule. I triple-checked everything, ensuring that the caterers understood the menu, the decorators knew the theme, and the audiovisual team was prepared. My team and I worked tirelessly around the clock to make sure that the event would be perfect. A week before the gala, I started feeling a knot of unease in my stomach. I was constantly replaying every detail in my head, worrying about what could go wrong. I couldn't shake off the feeling that I was forgetting something crucial....
Antagonistic (4/5)	There I was, in the back corner of the local coffee shop, my sanctuary from the world. My gaze was transfixed on the dark, bitter coffee in my hand, the steam rising in wisps like my thoughts. The world outside seemed to buzz and hum, but I was insulated from it all, safe in my solitude. The bell on the front door jingled, signaling a new customer's arrival. I didn't bother to look up. Why would I? I was there for the coffee, not the people. But, the universe seemed to have other plans. A voice, chipper and bright, echoed through the shop, cutting through the usual din of murmuring voices and clinking cups. "Hey, can I sit here? All the other seats are taken." I looked up to see a girl, probably in her early twenties, standing at my table. She had a wide smile that seemed to shine brighter than the sun outside. I gave her a curt nod, gesturing to the empty seat across from me. She sat down, her eyes sparkling with an eagerness that I found unsettling. She launched into a conversation, talking about the weather, the coffee, the book she...
Conscientious (5/5)	It was a typical Tuesday afternoon and I was comfortably settled in my favorite corner of the local library. Surrounded by the faint smell of old books and the hushed whispers of other patrons, I felt a sense of calm wash over me. The library was my sanctuary, a place where I could retreat from the world and lose myself in the quiet contemplation of the written word. One particular book had caught my interest that day, 'The Art of Solitude.' It was a thought-provoking exploration of the joys and challenges of being alone, a theme that resonated deeply with me. As I turned each page, I found myself nodding in agreement with the author's reflections on the importance of solitude in fostering self-awareness and introspection. A sudden burst of laughter interrupted my reading. Looking up, I saw a group of teenagers huddled around a table, their faces lit up by the glow of their smartphones. I felt a pang of annoyance. This was a library, after all, a place of quiet and respect. But I quickly reminded myself that everyone has a different way of engaging with the world. I took a deep breath, refocused, and immersed...

Unconscientious (2/5)	I remember the time when I was given the responsibility of organizing our company's annual retreat. I was thrilled at the opportunity, not because I enjoy coordinating such events, but because I knew it was going to be a great chance to stir things up a bit. We were a group of 20 people who would be spending an entire weekend at a remote resort. The retreat was meant to foster team bonding and camaraderie, but honestly, these events were always predictable and monotonous. I decided this one would be different. I strode into the planning meeting with an air of confidence that was hard to ignore. Most of my colleagues were looking forward to a well-organized and systematic event. They knew I wasn't exactly diligent when it came to planning, but they probably hoped I would make an exception this time. I had a different plan. I decided to make the retreat as spontaneous and unpredictable as possible. No schedules, no pre-planned activities, just a free-for-all. I stated my plan to the team, and as expected, it was met with raised eyebrows and skeptical looks. I shrugged off their doubt. After all, I wasn't one...
Neurotic (3/5)	My life has always been a tapestry of solace and solitude, a universe of its own. On a chilly winter night, I sat alone in my dimly lit room, the faint glow from my computer screen illuminating the scattered books and papers. I had a deadline to meet, a story to submit, but my mind was adrift, entangled in a web of thoughts, each more intricate than the last. A cup of cold coffee lay discarded on the desk, its purpose long forgotten. My gaze fell on the worn, leather-bound book peeking from the pile, "Art: The Definitive Visual Guide." A surge of curiosity urged me to pick it up. I consider myself an eclectic reader, my interests spanning from the realms of science to the oasis of arts, and everything in between. I found solace in the unknown, in the novelty of new ideas, and the thrill of uncharted territories. I opened the book, and the artistic world unfolded before me. The vivid colors, the passionate strokes, and the silent stories captivated me. Each painting was a universe of its own, a tale of the artist's soul, and a mirror reflecting the observer's psyche. The world around...
Emotionally Stable (5/5)	In the heart of the bustling city, I lived in a small apartment, my sanctuary from the world. One day, as I was returning from my weekly trip to the local bookstore, I found a stray kitten huddled by the staircase of my building. It was a tiny, shivering furball, looking up at me with wide eyes. I couldn't ignore it. I brought the kitten home, creating a warm makeshift bed from an old sweater. I named her Luna. Luna was timid and wary of her new surroundings. But with time, she grew comfortable around me, her purrs filling my once quiet apartment with life. Being an editor for a publishing house, I worked from home, which meant I spent a great deal of time with Luna. I would read her passages from the manuscripts I was working on, and she would purr in response, as if she understood. One day, I received a manuscript from a new author. It was a fantasy novel, filled with magical creatures, enchanted forests, and heroic quests. As I read the manuscript, I noticed it was riddled with plot holes and inconsistencies. But beneath the imperfections, there was...
Open (5/5)	There I was, standing at the entrance of the art museum, my heart pounding with anticipation. I was about to experience the grand opening of the museum's new modern art exhibit, a highly anticipated event in our city. I was lucky to have scored an invite to the opening night, and I was buzzing with excitement. I had no idea that this evening would lead me to a new friend and an unforgettable experience. As I walked into the grand hall, I was greeted by a sea of vibrant colors, unusual shapes, and thought-provoking installations. Each piece of art seemed to tell a unique story, inspiring a sense of curiosity within me. I was eager to explore more, to dive into the unknown, and to allow the art to speak to me. As I was studying a beautiful abstract painting, a lady standing next to me started a conversation. "Quite a mesmerizing piece, isn't it?" she asked, her eyes sparkling with enthusiasm. She introduced herself as Grace, a local art enthusiast. We instantly clicked and found ourselves engrossed in deep conversations about the various art pieces. We both loved the same paintings, shared the same perspectives, and could...
Closed (4/5)	I remember it was a chilly Saturday in December. The sky was overcast, a canvas of grey, and the streets were bustling with last-minute holiday shoppers. I, however, was tucked away in my quiet corner of the world, my small yet cozy apartment. My place could be described as a bit messy. Books were strewn haphazardly on my coffee table, and my laundry hamper was positively overflowing. But I liked it that way,Äîit felt lived in, familiar. That day, I had chosen to retreat from the world and indulge in my favorite pastime: reading. As I sank into my worn-out couch, a worn-out paperback in my hands, I felt a wave of contentment wash over me. There was something comforting about the world of literature. The characters never asked too much of me, and I was free to explore their lives without the pressure of social interaction. There was a knock at the door, breaking the peaceful silence of my sanctuary. It was my neighbor, Mrs. Jenkins, her arms full of freshly baked cookies. She was an extrovert, always popping by to chat or share her latest culinary creations. Despite our stark personality differences, we had formed...

Table 3: Selected stories from human-evaluation experiment. The personality columns shows its corresponding predicted personality accuracy rate. $x/5$ means x out of 5 annotators predicted correctly.

B Story Comments

During human annotation, we provide an optional comment section for each story, allowing human annotators to share their thoughts after reading the story. We receive some interesting comments from human annotators when they are informed or uninformed that the writer of the story is an LLM. After filtering out comments such as “N/A”, “No”, “None” and “No Comments”, there are 104 valid comments whose average length is 12.7 words in the informed condition and 122 valid comments whose average length is 13.4 words in the uninformed condition. We compute the sentiment scores of the comments with `cardiffnlp/twitter-roberta-base-sentiment-latest` by mapping negative, neutral, and positive to -1, 0, and 1. We find out that the average sentiment is 0.45 in the informed condition and 0.16 in the uninformed condition, indicating that evaluators have a slightly better attitude towards the stories when informed of AI authorship. We also sample a few representative comments for each condition in Table 4. We notice that there are constant mixed comments towards these stories, where some stories are quite believable and enjoyable and other stories are banal and exaggerating. However, we observed that when informed of AI authorship people tend to be more lenient about the stories and give more complements about the stories (see comments in the “surprised” section), which is consistent with the higher average sentiment score we show earlier. When people are unaware that the author is an LLM, they constantly guess the author’s personality and question the motivation of the author to write some stories (see comments in the “confused” section). This is particularly interesting and highlights the potential social implications in terms of confusion if AI-generated content is consumed or AI characters interact with humans without notifying people. All the comments will be published along with the stories and code on Github.

Attitude	Comments
	Informed Condition
Critical	(1) I thought the story was a little basic and lacked deeper meaning. (2) The build up is pretty good but falls flat towards the end. (3) A believable story, if it seems somewhat exaggerated with the author’s impulsiveness.
Sympathetic	(1) It’s a relatable situation that someone could get behind and feel for. (2) Relatable work & anxiety story. I relate in some ways. (3) live your dreams even when there no planned.
Positive	(1) I found myself really being put into the characters shoes. (2) I found this story to be hilarious. I was laughing while I was reading it. The main character’s interactions were absolute greatness. (3) Vivid descriptions, almost cinematic like a movie script.
Surprised	(1) The story actually sounded genuine and I wouldn’t have believed it was written by AI unless someone told me. (2) I would have never guessed this was an AI writer. I’m quite impressed and I thoroughly enjoyed this road trip story. (3) I like this story here the cat was a separate side story but the AI was able to integrate it in throughout, in other stories it had what I would call side quests that added nothing to the final flow.
	Uninformed Condition
Critical	(1) It was harder to read and follow the story. (2) Some of the punctuation seemed a little odd or over used. (3) It started off strong, but there was no sense of why this person became uneasy, and they seemed to become a different person as the essay went on, all of a sudden wanting predictability and alone time instead of the chaos and "social butterfly" status. I found it inconsistent.
Sympathetic	(1) Also feels quite personal. (2) When you constantly look down, you don’t see what is right in front of you. (3) As someone who used to code a lot, I felt the ending was very moving and believable.
Positive	(1) Very enjoyable story about how sometimes unavoidable changes in our lives can lead to happier lives.

	(2) It was enjoyable. I appreciated the self-awareness by someone who knows they are not always well-liked or well-received. (3) I enjoyed the description of the old lady particularly the etchings on her face. This was quite a memorable explanation.
Confused	(1) Here's something about the story that doesn't seem believable, but it's probably just the writer's extraggretions. (2) This person must have taken drugs lol. (3) The writer seems like he is not really fun to be around.

Table 4: We sample story comments for both informed and uninformed conditions.

C Personality Ratings

We sampled 32 `LLM personas` from 32 personality types. Therefore, we have 16 personas with positive labels and 16 personas with negative labels for each personality, which would ideally lead to the average ratings close to 3. As shown in Table 5, we find that the average ratings of GPT-3.5 and GPT-4 are closer to 3 than humans in Extraversion. Except for Extraversion, the average ratings from GPT-4 seems consistently further away from 3 compared to human and GPT-3.5 evaluators.

Evaluator	**Extraversion**	**Agreeableness**	**Conscientiousness**	**Neuroticism**	**Openness to Experience**
		Uninformed Condition – *Evaluation Scores (Mean$_{STD}$)*			
Human	$3.22_{1.36}$	$3.42_{1.15}$	$3.86_{1.05}$	$2.76_{1.22}$	$3.54_{1.19}$
GPT-3.5	$3.19_{0.85}$	$4.08_{0.82}$	$3.39_{0.74}$	$2.13_{0.49}$	$3.62_{0.60}$
GPT-4	$3.00_{1.42}$	$4.01_{1.08}$	$4.04_{1.18}$	$2.02_{1.01}$	$4.03_{1.07}$
		Informed Condition – *Evaluation Scores (Mean$_{STD}$)*			
Human	$3.29_{1.17}$	$3.67_{0.84}$	$3.76_{0.92}$	$2.69_{1.23}$	$3.70_{1.00}$
GPT-3.5	$3.14_{0.86}$	$4.16_{0.91}$	$3.56_{0.71}$	$2.03_{0.47}$	$3.66_{0.59}$
GPT-4	$3.00_{1.42}$	$4.22_{1.09}$	$4.22_{1.14}$	$2.02_{1.02}$	$4.09_{1.08}$

Table 5: LLM and human evaluation results of GPT-4 generated personal stories in **5 personality traits**. **Uninformed** and **informed** conditions indicate whether human or LLM evaluators are informed that the stories are generated by an LLM. We report each evaluated attribute's mean Likert scale and standard deviation. Temperature is set to 0 for both GPT-3.5 and GPT-4.

Evaluator	**Readability**	**Redundancy**	**Cohesiveness**	**Likability**	**Believability**	**Personalness**
			Inter-Annotator Agreement (IAA$_{\%}$)			
Uninformed Human	0.05_{62}	-0.03_{48}	0.03_{61}	0.02_{54}	-0.03_{51}	-0.02_{60}
Informed Human	0.01_{64}	0.02_{53}	0.03_{58}	0.06_{55}	-0.02_{57}	0.10_{61}

Table 6: We report the inter-annotator agreement (IAA) among five annotators across **six different metrics** using Krippendorff's α. The subscript in the IAA column (%) is used to denote the average percentage of annotators who agree on the most voted rating.

Evaluator	**Extraversion**	**Agreeableness**	**Conscientiousness**	**Neuroticism**	**Openness to Experience**
		Inter-Annotator Agreement (IAA$_{\%}$)			
Uninformed Human	0.11_{51}	0.03_{49}	0.00_{51}	-0.03_{43}	0.04_{52}
Informed Human	0.10_{54}	0.11_{65}	0.07_{59}	0.03_{49}	0.08_{57}

Table 7: We report the inter-annotator agreement (IAA) among five annotators across **five personality traits** using Krippendorff's α. The subscript in the IAA column (%) is used to denote the average percentage of annotators who agree on the most voted rating.

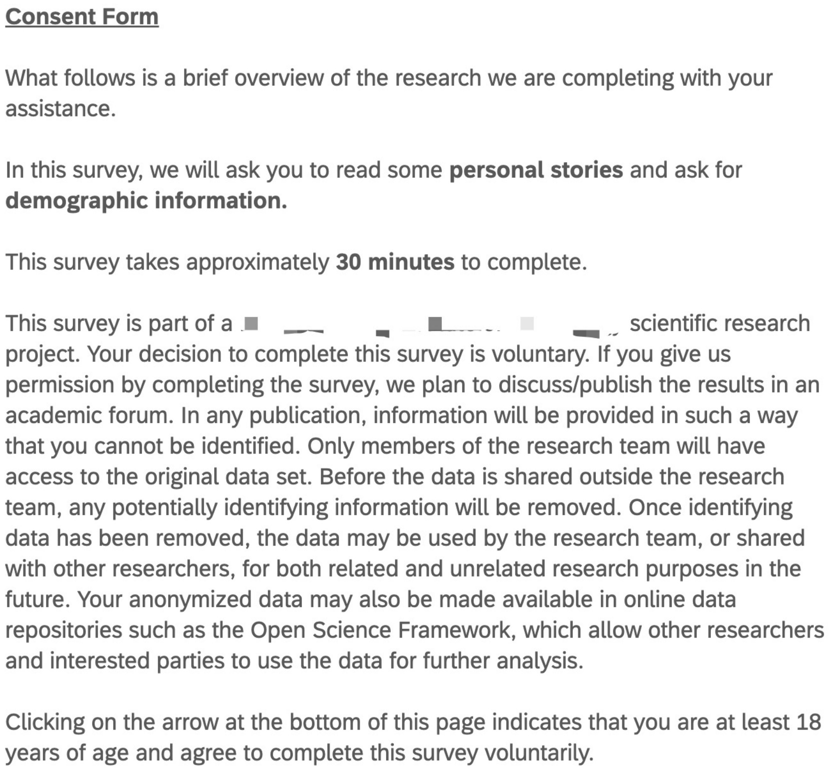
D Story Evaluation Details

D.1 Filtering Stories for Evaluation

We design a simple lexicon-based classifier to detect if a story contains explicit use of personality trait lexicons. These lexicons include "extrover*", "introver*", "agreeabl*", "antagonis*", "*conscientious*", "neuroti*", "emotionally stabl*", "open to experience", "closed to experience". We filter out stories which contain these lexicons and sample from the remaining stories for human evaluation.

D.2 Prolific Setup

We recruit Prolific workers from the United States, whose first language is English with an approval rate between 99% and 100%. We have divided 32 stories into four equal batches, each containing eight stories. To begin each batch, a consent form is provided. Following this, each annotator reads the story and answers six evaluation questions that assess readability, personalness, redundancy, cohesiveness, likeability, and believability. An optional comment section is also provided for additional feedback on the story. Subsequently, we ask the annotators five questions related to personality traits: Extraversion, Agreeableness, Conscientiousness, Neuroticism, and Openness to Experience. Screenshots of these questions are included below.



Consent Form

What follows is a brief overview of the research we are completing with your assistance.

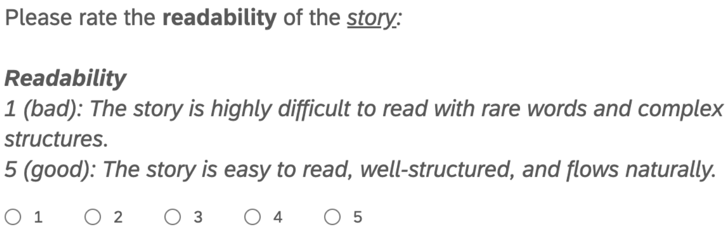
In this survey, we will ask you to read some **personal stories** and ask for **demographic information.**

This survey takes approximately **30 minutes** to complete.

This survey is part of a [redacted] scientific research project. Your decision to complete this survey is voluntary. If you give us permission by completing the survey, we plan to discuss/publish the results in an academic forum. In any publication, information will be provided in such a way that you cannot be identified. Only members of the research team will have access to the original data set. Before the data is shared outside the research team, any potentially identifying information will be removed. Once identifying data has been removed, the data may be used by the research team, or shared with other researchers, for both related and unrelated research purposes in the future. Your anonymized data may also be made available in online data repositories such as the Open Science Framework, which allow other researchers and interested parties to use the data for further analysis.

Clicking on the arrow at the bottom of this page indicates that you are at least 18 years of age and agree to complete this survey voluntarily.

Figure 5: Consent form on Prolific.



Please rate the **readability** of the *story:*

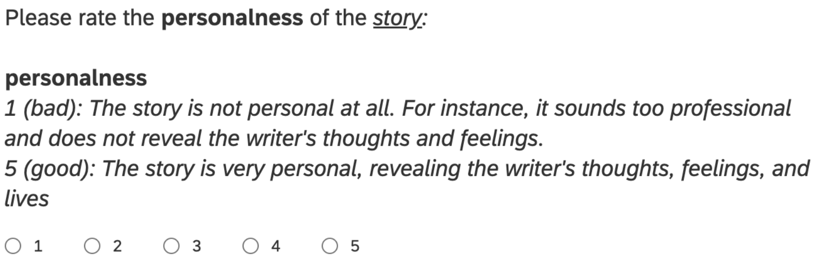
Readability
1 (bad): The story is highly difficult to read with rare words and complex structures.
5 (good): The story is easy to read, well-structured, and flows naturally.

○ 1 ○ 2 ○ 3 ○ 4 ○ 5

Figure 6: Readability question on Prolific.

D.3 Inter-annotator Agreement

The task of evaluation presents a subjective and complex challenge, which has resulted in a low inter-annotator agreement (IAA) in Krippendorff's α among the five annotators. We have included the IAA scores for six distinct metrics in Table 6. Additionally, the IAA scores for five personality traits are

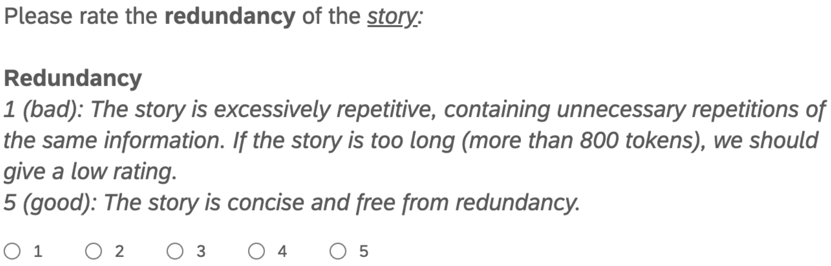


Please rate the **personalness** of the *story:*

personalness
1 (bad): The story is not personal at all. For instance, it sounds too professional and does not reveal the writer's thoughts and feelings.
5 (good): The story is very personal, revealing the writer's thoughts, feelings, and lives

○ 1 ○ 2 ○ 3 ○ 4 ○ 5

Figure 7: Personalness question on Prolific.

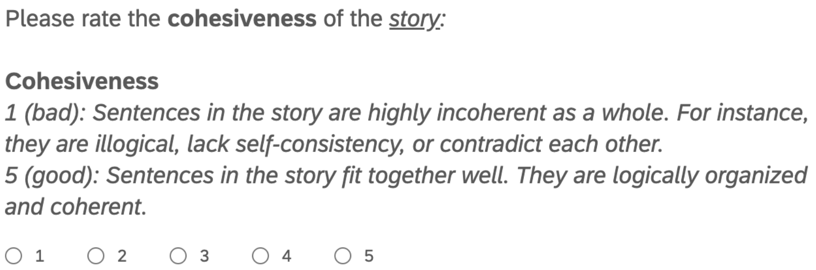


Please rate the **redundancy** of the *story:*

Redundancy
1 (bad): The story is excessively repetitive, containing unnecessary repetitions of the same information. If the story is too long (more than 800 tokens), we should give a low rating.
5 (good): The story is concise and free from redundancy.

○ 1 ○ 2 ○ 3 ○ 4 ○ 5

Figure 8: Redundancy question on Prolific.

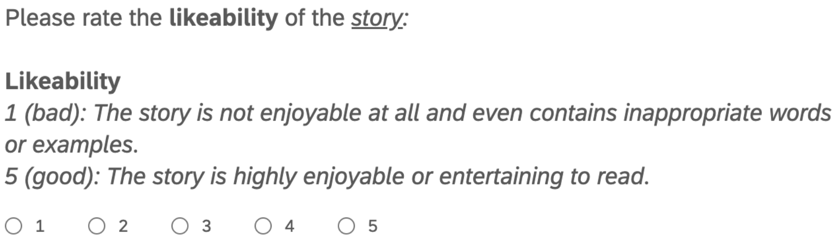


Please rate the **cohesiveness** of the *story:*

Cohesiveness
1 (bad): Sentences in the story are highly incoherent as a whole. For instance, they are illogical, lack self-consistency, or contradict each other.
5 (good): Sentences in the story fit together well. They are logically organized and coherent.

○ 1 ○ 2 ○ 3 ○ 4 ○ 5

Figure 9: Cohesiveness question on Prolific.

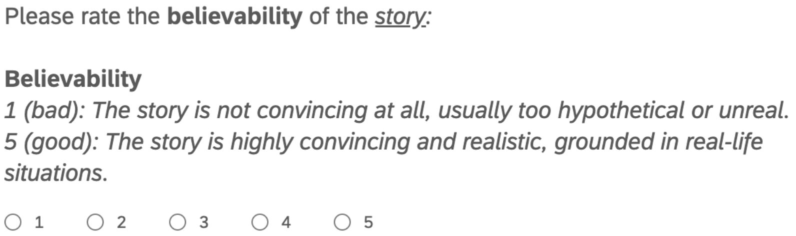


Please rate the **likeability** of the *story:*

Likeability
1 (bad): The story is not enjoyable at all and even contains inappropriate words or examples.
5 (good): The story is highly enjoyable or entertaining to read.

○ 1 ○ 2 ○ 3 ○ 4 ○ 5

Figure 10: Likeability question on Prolific.

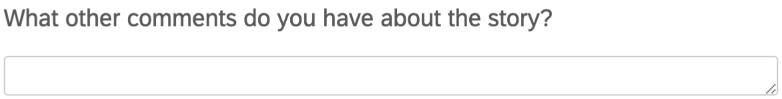


Please rate the **believability** of the *story:*

Believability
1 (bad): The story is not convincing at all, usually too hypothetical or unreal.
5 (good): The story is highly convincing and realistic, grounded in real-life situations.

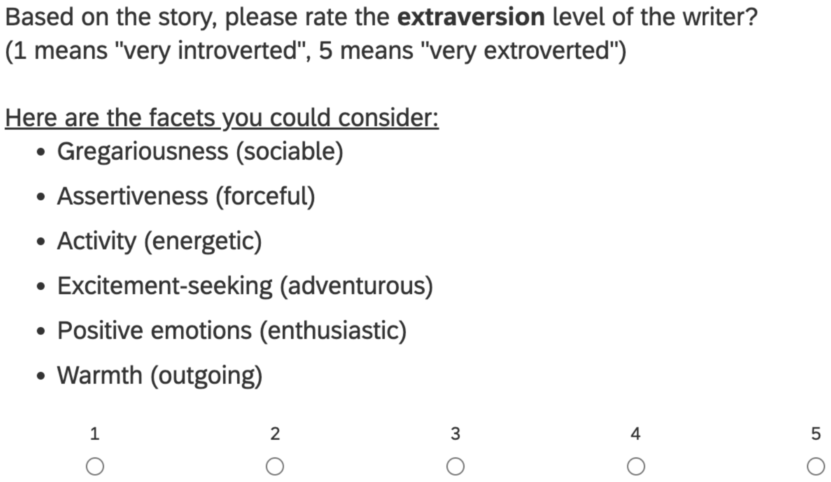
○ 1 ○ 2 ○ 3 ○ 4 ○ 5

Figure 11: Believability question on Prolific.



What other comments do you have about the story?

Figure 12: Comment question on Prolific.



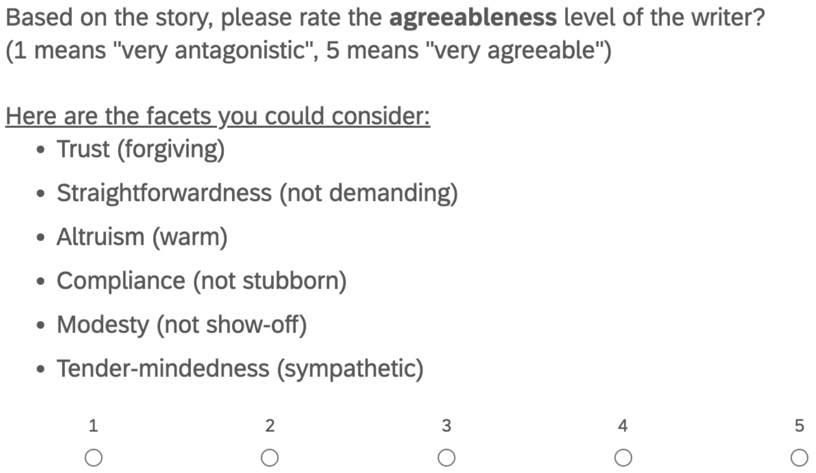
Based on the story, please rate the **extraversion** level of the writer?
(1 means "very introverted", 5 means "very extroverted")

Here are the facts you could consider:

- Gregariousness (sociable)
- Assertiveness (forceful)
- Activity (energetic)
- Excitement-seeking (adventurous)
- Positive emotions (enthusiastic)
- Warmth (outgoing)

1	2	3	4	5
○	○	○	○	○

Figure 13: Extraversion question on Prolific.



Based on the story, please rate the **agreeableness** level of the writer?
(1 means "very antagonistic", 5 means "very agreeable")

Here are the facets you could consider:

- Trust (forgiving)
- Straightforwardness (not demanding)
- Altruism (warm)
- Compliance (not stubborn)
- Modesty (not show-off)
- Tender-mindedness (sympathetic)

1	2	3	4	5
○	○	○	○	○

Figure 14: Agreeableness question on Prolific.

presented in Table 7. The phenomenon of low inter-rater agreeability is consistent with previous findings in labeling tasks for social computing, calling for more attention to creating techniques to navigate the annotation disagreements in order to ensure more accurate label representation (Gordon et al., 2021).

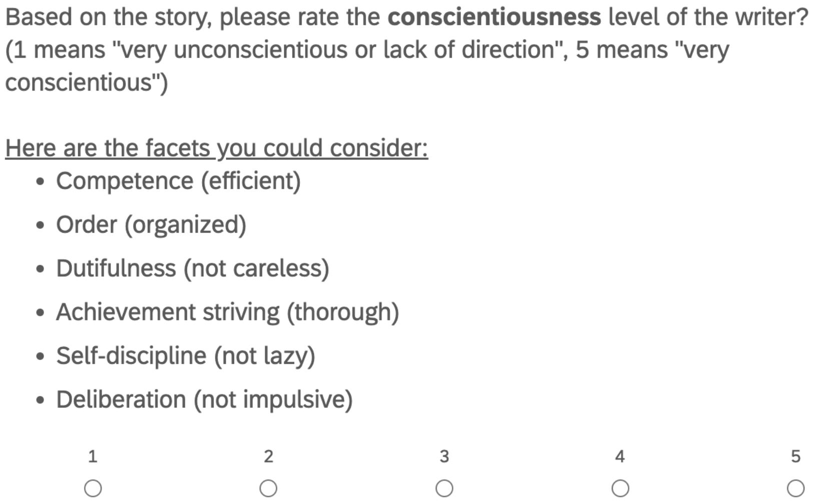
D.4 Annotator Demographics

We also include the demographics of 39 unique participants who contribute to evaluate the stories. All of these participants are living in the United States and 37 out of 39 were born in the USA and 2 out of 39 born in Nigeria. We include the distribution of age, sex, and ethnicity in Figure 18.

E LLM as Evaluators

E.1 Temperature

We experiment with different temperatures with the GPT-3.5 and GPT-4 evaluators and observe similar trends reported by Chiang and Lee (2023b). As shown in Table 8, we notice that the ratings given by LLM



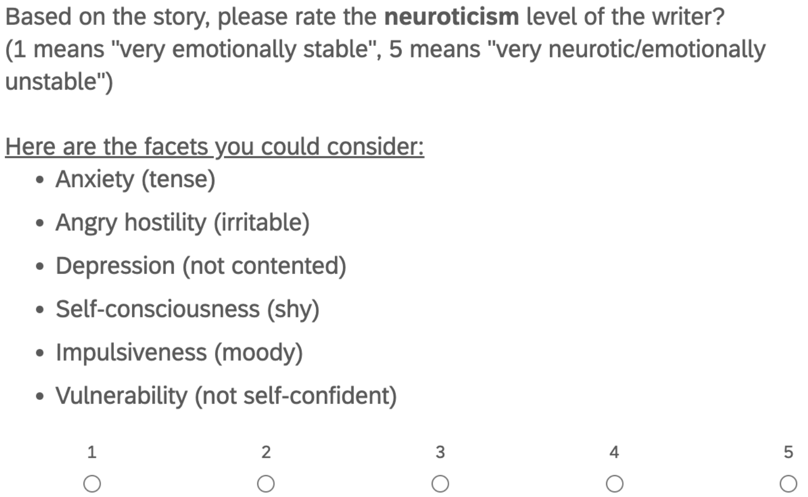
Based on the story, please rate the **conscientiousness** level of the writer?
(1 means "very unconscientious or lack of direction", 5 means "very conscientious")

Here are the facets you could consider:

- Competence (efficient)
- Order (organized)
- Dutifulness (not careless)
- Achievement striving (thorough)
- Self-discipline (not lazy)
- Deliberation (not impulsive)

1	2	3	4	5
○	○	○	○	○

Figure 15: Agreeableness question on Prolific.



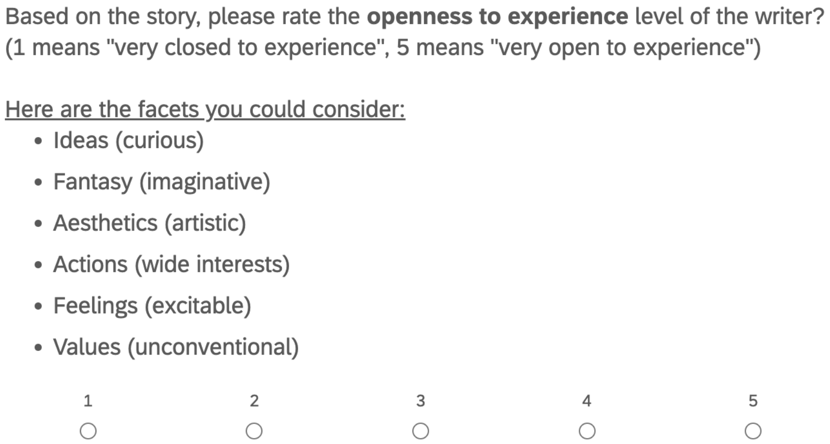
Based on the story, please rate the **neuroticism** level of the writer?
(1 means "very emotionally stable", 5 means "very neurotic/emotionally unstable")

Here are the facets you could consider:

- Anxiety (tense)
- Angry hostility (irritable)
- Depression (not contented)
- Self-consciousness (shy)
- Impulsiveness (moody)
- Vulnerability (not self-confident)

1	2	3	4	5
○	○	○	○	○

Figure 16: Neuroticism question on Prolific.



Based on the story, please rate the **openness to experience** level of the writer?
(1 means "very closed to experience", 5 means "very open to experience")

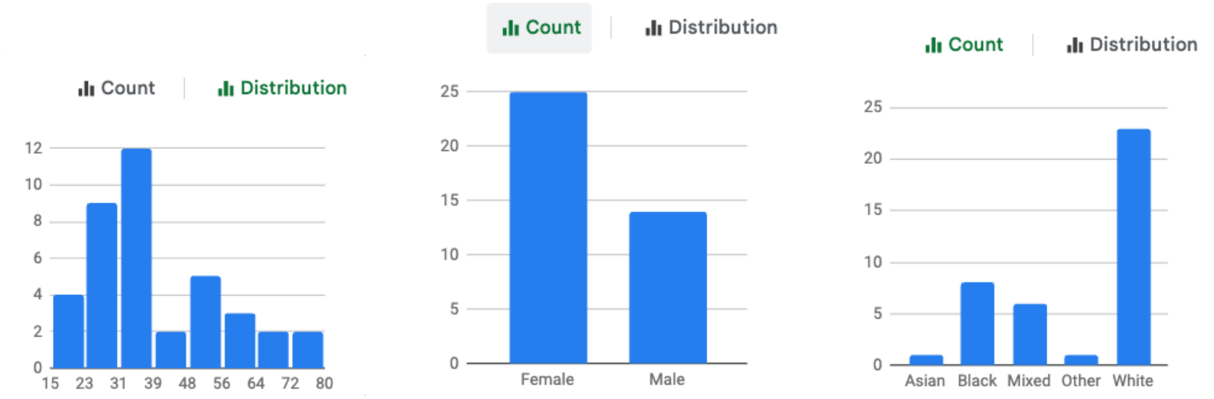
Here are the facets you could consider:

- Ideas (curious)
- Fantasy (imaginative)
- Aesthetics (artistic)
- Actions (wide interests)
- Feelings (excitable)
- Values (unconventional)

1	2	3	4	5
○	○	○	○	○

Figure 17: Openness question on Prolific.

evaluators are negatively correlated to the temperature. Larger temperature also leads to large variance in the ratings among three LLM evaluators. We set the temperature to 0 in our experiment to ensure the



(a) Age (b) Sex (c) Ethnicity

Figure 18: Distribution of age, sex, and ethnicity among the 39 Prolific annotators who evaluate the stories.

Evaluator	Readability	Redundancy	Cohesiveness	Likability	Believability	Personalness
			Evaluation Scores (Mean$_{STD}$)			
GPT-3.5 (T=0.0)	$4.75_{0.43}$	$3.04_{0.40}$	$4.97_{0.17}$	$4.22_{0.48}$	$3.93_{0.25}$	$3.55_{0.61}$
GPT-3.5 (T=0.3)	$4.70_{0.46}$	$3.07_{0.54}$	$4.96_{0.19}$	$4.26_{0.50}$	$3.93_{0.30}$	$3.51_{0.65}$
GPT-3.5 (T=0.7)	$4.65_{0.49}$	$3.04_{0.63}$	$4.91_{0.28}$	$4.29_{0.51}$	$3.90_{0.41}$	$3.38_{0.73}$
GPT-3.5 (T=1.0)	$4.54_{0.52}$	$3.02_{0.85}$	$4.86_{0.35}$	$4.27_{0.56}$	$4.01_{0.43}$	$3.47_{0.75}$
GPT-4 (T=0.0)	$4.94_{0.24}$	$4.96_{0.22}$	$5.00_{0.00}$	$4.84_{0.36}$	$4.93_{0.25}$	$5.00_{0.00}$
GPT-4 (T=0.3)	$4.93_{0.25}$	$4.95_{0.25}$	$5.00_{0.00}$	$4.82_{0.41}$	$4.94_{0.24}$	$4.99_{0.08}$
GPT-4 (T=0.7)	$4.87_{0.34}$	$4.91_{0.33}$	$5.00_{0.00}$	$4.78_{0.46}$	$4.93_{0.25}$	$4.98_{0.14}$
GPT-4 (T=1.0)	$4.82_{0.38}$	$4.86_{0.45}$	$5.00_{0.00}$	$4.78_{0.43}$	$4.86_{0.35}$	$4.98_{0.14}$

Table 8: LLM evaluation results of GPT-4 generated personal stories with different temperatures. For each evaluated attribute, we report its mean Likert scale and the standard deviation.

results are more deterministic and reproducible for future research.

F LLaMA 2 Results in BFI Scores

In this section, we provide additional results of LLaMA 2's performance in BFI assessment in Table 9. Overall, LLaMA 2 Persona's BFI assessment shows less score divergence for each trait pair. Even though statistical significance is found for all personality dimensions, their effect size is much smaller when compared with GPT results.

Persoanlity Trait	Extraversion	Agreeableness	Conscientiousness	Neuroticism	Openness to Experience
High	$4.55_{0.36}$	$4.14_{0.21}$	$4.05_{0.22}$	$2.70_{0.46}$	$4.47_{0.24}$
Low	$2.84_{0.76}$	$3.69_{0.43}$	$3.73_{0.33}$	$2.06_{0.32}$	$3.58_{0.42}$
Cohen's d	2.86	1.34	1.16	1.63	2.61

Table 9: We report the statistics of LLaMA 2 Personas' BFI assessment in this Table. The high and low represent the binary traits for each personality dimension. For instance, "High" and "Low" in Extraversion mean extroverted and introverted, respectively. The effect size of the differences between the two traits is also reported.

G Additional Results in Personality Traits

In addition to reporting the significant LIWC features correlated with the binary label in the main paper, we conduct a similar analysis between the LIWC features and the LLM personas 5-point BFI results with Spearsman's ρ and report the findings here.

G.1 GPT-3.5 Personas

Extroversion Extroverted LLM personas tend to exhibit more social and prosocial behavior in their writings (social: $\rho = 0.27, p < .001$; prosocial: $\rho = 0.18, p < .005$). Introverted personas tend to use features that show authenticity, such as words that are genuine (authentic: $\rho = -0.40, p < .001$). Further, extroverted personas use positive tone and affect more in their writings (affect: $\rho = 0.46, p < .001$; tone_pos: $\rho = 0.33, p < .001$).

Agreeableness Agreeable personas show a strong positive affect and tone in writings (emo_neg: $\rho = -0.66, p < .001$; tone_pos: $\rho = 0.50, p < .001$). More, they tend to have less conflict-related words (conflict: $\rho = -0.66, p < .001$), such as fight, and have less differentiation in sentences (differ: $\rho = -0.39, p < .001$), such as "but" or "no". They also have more prosocial word uses (prosocial: $\rho = 0.34, p < .001$), however, less authenticity (authentic: $\rho = -0.24, p < .001$).

Conscientiousness Unconscientious personas have more negative tone and emotion in their writings, such as anger (tone_neg: $\rho = -0.40, p < .001$; emo_neg: $\rho = -0.39, p < .001$; emo_anger: $\rho = -0.43, p < .001$). Their writings tend to use more words that reflect conflicts (conflict: $\rho = -0.41, p < .001$). Conscientious personas use less negation words (negate: $\rho = -0.26, p < .001$), such as "no", and have less power related words (power: $\rho = -0.24, p < .001$), such as "own" and "order". Moreover, conscientious personas exhibit more analytical thinking in the writings (analytic: $\rho = 0.22, p < .001$).

Neuroticism The strongest correlated linguistic features for neurotic personas is mental health related words, such as trauma or depression (mental: $\rho = 0.46, p < .001$). Overall, neurotic personas tend to have a negative emotion and tone in their writings (emo_neg: $\rho = 0.26, p < .001$; tone_neg: $\rho = 0.22, p < .001$). They also tend to use more words to suggest tentative actions, such as "if" or "any" (tenta: $\rho = 0.18, p < .005$). Emotionally stable personas are more likely to use words that are related to memory functions, such as "remember" (memory: $\rho = -0.15, p < .01$).

Openness Open-minded personas tend to have more curiosity driven actions in their writing (curiosity: $\rho = 0.28, p < .001$), such as "seek", and more positive tones. Their writings have less conflict-driven words and more affiliation drives (conflict: $\rho = -0.17, p < .005$; affiliation: $\rho = 0.16, p < .005$). Further, open-minded personas tend to write about leisure activities (leisure: $\rho = 0.21, p < .001$), such as "game" and "play".

G.2 GPT-4 Personas

Extroversion Introverted personas have more descriptions of their perception in the writings, for instance, their auditory experience (space: $\rho = -0.38, p < .001$; perception: $\rho = -0.38, p < .001$; auditory: $\rho = -0.39, p < .001$). Extroverted personas wrote more future focused event, such as the usage of "going to" (focusfuture: $\rho = 0.36, p < .001$). On the usage of pronouns, extroverted personas use more "we" while introverted personas tend to use "I". Extroverted personas also have more positive tones (tone_pos: $\rho = 0.21, p < .001$), and use words that are related to rewards or achievement more frequently (reward: $\rho = 0.26, p < .001$; achieve: $\rho = 0.25, p < .001$).

Agreeableness Agreeable personas display more positive tone and emotion in the writings (tone_pos: $\rho = 0.46, p < .001$; emo_pos: $\rho = 0.42, p < .001$). They are more prosocial (prosocial: $\rho = 0.29, p < .001$), and use less words that suggest conflict and more words that show affiliation (conflict: $\rho = -0.51, p < .001$; affiliation: $\rho = 0.22, p < .001$; differ: $\rho = -0.26, p < .001$). Antagonistic personas uses more words that suggest power and ownership, such as "own" and "order".

Conscientiousness Conscientious personas have more prosocial and less negative linguistic features in their writings (prosocial: $\rho = 0.28, p < .001$; tone_neg: $\rho = -0.34, p < .001$). The writings have less perceived genuineness (authentic: $\rho = -0.24, p < .001$). Further, the writings involve achievement and work related words more frequently (achieve: $\rho = 0.36, p < .001$; work: $\rho = 0.32, p < .001$; reward: $\rho = 0.25, p < .001$).

Neuroticism Neurotic personas writings reflect more negative emotions and tones, such as anxiety (emo_neg: $\rho = -0.59, p < .001$; tone_neg: $\rho = -0.57, p < .001$; emo_anx: $\rho = -0.53, p < .001$). The writings have more frequent usage of "I" and less usage of "we" (i: $\rho = 0.36, p < .001$; we: $\rho = -0.28, p < .001$). Emotionally stable personas write with more prosocial and social behaviors (prosocial: $\rho = -0.27, p < .001$; social: $\rho = -0.28, p < .001$), and the writings have a higher score for perceived genuineness (authentic: $\rho = 0.28, p < .001$).

Openness Open-minded persona's writings have more curiosity and allure-driven linguistics, such as "research" and "wonder"(curiosity: $\rho = 0.55, p < .001$; allure: $\rho = -0.30, p < .001$). Further, the writings contain more analytical thinking and sharing thoughts (analytical: $\rho = 0.27, p < .001$; insight:

$\rho = 0.25, p < .001$). Open-minded personas write with more big words with seven letters or longer and more words per sentence (BigWord: $\rho = 0.29, p < .001$; WPS: $\rho = 0.26, p < .001$).

G.3 LLaMA 2 Personas

Extroversion Extroverted personas' writings have more positive tones (emo_pos: $\rho = 0.46, p < .001$; tone: $\rho = 0.47, p < .001$). Further, the writings tend to have more social references and affiliations (scorefs: $\rho = 0.48, p < .001$; affiliation: $\rho = 0.48, p < .001$; emo_pos: $\rho = 0.50, p < .001$; differ: $\rho = -0.36, p < .001$;). There is a weak association with more acclimations, and extroverted personas' writings show more drive-related words (exclam: $\rho = 0.23, p < .001$; Drive: $\rho = 0.34, p < .001$).

Agreeableness Agreeable personas have more positive emotion and tone in writings (emo_pos: $\rho = 0.50, p < .001$; tone: $\rho = 0.41, p < .001$). There is more word usage around friends and less about work (friend: $\rho = 0.47, p < .001$; work: $\rho = -0.48, p < .001$). Similar to the previous LMs, it shows more affiliation and fewer conflicts from the writings (conflict: $\rho = -0.31, p < .001$; affiliation: $\rho = 0.25, p < .001$). There is more usage of pronouns like "we" than "they" (they: $\rho = -0.27, p < .001$; we: $\rho = 0.20, p < .001$). Interestingly, the writings reflect a slight negative correlation with prosociality (prosocial: $\rho = 0.22, p < .001$).

Conscientiousness Similar to the trend in GPT-3.5 and GPT-4, LLaMA 2's personified writings have little significant linguistic features with Conscientiousness. It has a weak correlation in word usage around home and fulfillment (home: $\rho = 0.17, p = .002$; fulfill: $\rho = 0.15, p = .006$). Further, a weak link is found for familiar and friendly words (friend: $\rho = 0.15, p = .007$; family: $\rho = 0.13, p = .02$).

Neuroticism The neurotic personas's writings show a strong negative correlation with positive emotions (emo_pos: $\rho = -0.47, p < .001$; tone_neg: $\rho = 0.43, p < .001$). Further, word usage around friend, leisure, and social references is negatively correlated with the Persona's neurotic scores, while work and insight-related words are positively related (friend: $\rho = -0.47, p < .001$; leisure: $\rho = -0.47, p < .001$; socrefs: $\rho = -0.43, p < .001$; work: $\rho = -0.42, p < .001$; insight: $\rho = -0.43, p < .001$).

Openness Open-minded LLaMA 2 Personas' writings show a positive trend with positive emotions and affiliations (emo_pos: $\rho = 0.43, p < .001$; affiliation: $\rho = 0.34, p < .001$). Interestingly, it shows a negative trend of using words related to work or achievement (work: $\rho = -0.54, p < .001$; achieve: $\rho = -0.42, p < .001$). Further, the writings are more likely to reflect curiosity and have more social references (curiosity: $\rho = 0.29, p < .001$; socrefs: $\rho = 0.29, p < .001$).

FIRE: A Dataset for FInancial Relation Extraction

Abstract

This paper introduces FIRE (**FI**nancial **R**elation **E**xtraction), a sentence-level dataset of named entities and relations within the financial sector. Comprising 3,025 instances, the dataset encapsulates 13 named entity types along with 18 relation types. Sourced from public financial reports and financial news articles, FIRE captures a wide array of financial information about a business including, but not limited to, corporate structure, business model, revenue streams, and market activities such as acquisitions. The full dataset was labeled by a single annotator to minimize labeling noise. The labeling time for each sentence was recorded during the labeling process. We show how this feature, along with curriculum learning techniques, can be used to improved a model's performance. The FIRE dataset is designed to serve as a valuable resource for training and evaluating machine learning algorithms in the domain of financial information extraction. The dataset and the code to reproduce our experimental results are available at `https://github.com/hmhamad/FIRE`. The repository for the labeling tool can be found at `https://github.com/abhinav-kumar-thakur/relation-extraction-annotator`.

1 Introduction

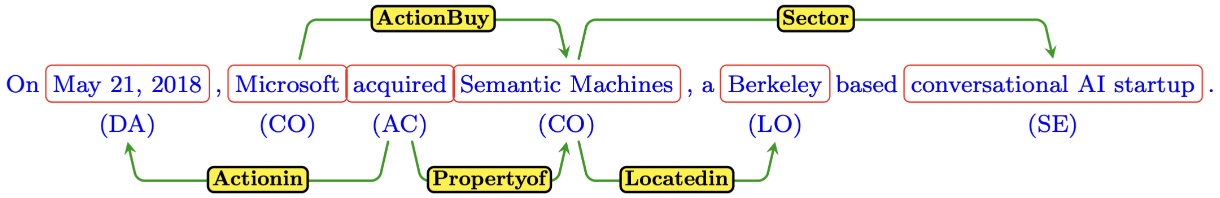
The proliferation of textual data in the financial domain presents a unique opportunity for the application of machine learning and Natural Language Processing (NLP) techniques. The extraction of named entities and their relations from unstructured financial texts, such as Security and Exchange Commission (SEC) filings (U.S. Securities and Exchange Commission) and financial news articles (Bloomberg - Financial news, analysis, and data), is a crucial task with significant implications for financial analysis and decision-making.

Named Entity Recognition (NER) (Wen et al., 2019) and Relation Extraction (RE) (Detroja et al., 2023) is a complex yet crucial task in NLP, particularly within the financial domain. The task demands extensive linguistic and domain knowledge, making dataset creation costly and labor-intensive. This complexity has led to instances where previously hand-labeled and published RE datasets have undergone subsequent corrections post-publication. Examples of such non-financial datasets include TACRED (Zhang et al., 2017b) and its revised counterpart, TACRED Revisited (Alt et al., 2020), as well as DocRED (Yao et al., 2019) and its updated version, Re-DocRED (Tan et al., 2022).

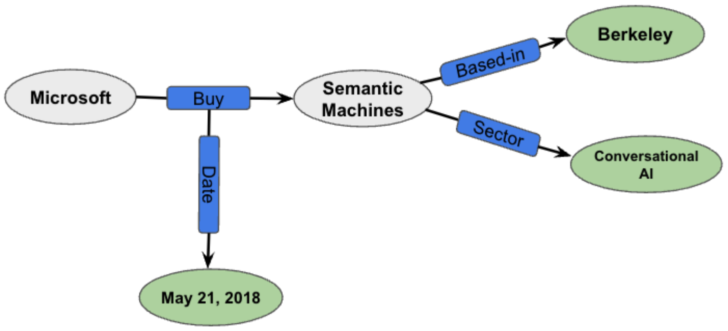
The lack of a comprehensive, well-annotated dataset in the financial domain hampers the development and evaluation of algorithms for these tasks. In response to this identified gap, we present FIRE, a dataset specifically constructed for joint NER and RE within the financial domain. Drawn from both financial documents, mainly SEC filings, and financial news articles, FIRE provides a diverse range of linguistic constructs and financial terminologies. The dataset is constituted of 3,025 instances, all hand-labeled according to comprehensive annotation guidelines. Note that an instance (or an example) refers a labeled object, consisting of a single sentence or multiple sentences with associated entity and relation information. Figure 1a presents a labeled sentence from the dataset while figure 1b is one example of how the labeled data can be used to create a knowledge graph. More examples can be found in the annotation guidelines document which is provided with the dataset. The dataset incorporates 13 named entity categories and 18 relation types, effectively capturing vital details about businesses, including aspects such as their organizational structure, income streams, business strategies, and market maneuvers, including acquisitions.

The FIRE dataset also serves as a substantial re-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3628–3642
June 16-21, 2024



(a) A sentence and its labels from the FInancial Relation Extraction (FIRE) dataset. Entity terms are surrounded by a red box, with the entity type abbreviation annotated below the box. An edge between a pair of entities indicates a relation. (DA), (CO), (AC), (LO) and (SE) stand for *Date*, *Company*, *Action*, *Location* and *Sector*, respectively.



(b) An example of constructing a Knowledge Graph (KG) using the labels from the sentence. All sentences in a dataset can be combined to create a KG that summarizes all the collected information.

Figure 1: A labeled sentence from the FIRE dataset and an example of how a Knowledge Graph can be built using the collected labels.

source for training, evaluating, and comparing the performance of models specialized in the finance sector. Projects like 10-KGPT (Smiley, 2023) and BloombergGPT (Wu et al., 2023), which are tailored for financial tasks, lack evaluation on dedicated financial RE datasets. FIRE fills this gap, offering a robust platform for testing these models against a diverse and complex set of financial terms and relationships. Our goal is to advance financial NLP by providing a high-quality, manually annotated dataset for refining state-of-the-art Large Language Model (LLM)s.

An additional feature of FIRE is the inclusion of a *labeling time* data field for each record in the dataset. This feature may provide researchers with additional granularity when analyzing performance. Labeling time can serve as an implicit indicator of example difficulty, offering potential applications for the implementation of curriculum learning strategies (Bengio et al., 2009). By leveraging this feature, researchers can explore and develop methods that dynamically adjust the learning process based on the difficulty of the examples, potentially leading to more efficient learning and improved model performance. In our experiment results section, we provide an initial result of incorporating the *labeling time* feature into the training process. To the best of our knowledge, this has not been studied yet in the literature.

The paper contributions are summarized as follows:

- We introduce FIRE, a novel dataset for joint NER and RE within the financial context. FIRE is accompanied by comprehensive annotation guidelines and is hand-annotated by a single annotator to minimize labeling noise.
- We provide an open-source web-based labeling tool, designed to facilitate efficient and precise annotation for NER and RE tasks.
- We demonstrate that utilizing the labeling time of each example can enhance model performance through curriculum learning strategies

The rest of this paper is organized as follows: Section 2 goes over some previous general-purpose and domain-specific NER and RE datasets and compares FIRE to existing datasets in finance. Section 3 provides a detailed description of the FIRE dataset, including the composition, data collection and annotation processes. Section 4 presents an evaluation of selected state-of-the-art models on the FIRE dataset, discussing the associated performances and implications. Finally, section 5 concludes the paper and outlines potential directions for future work.

	FinRED	KPI-EDGAR	**FIRE (This Work)**
Hand-Labeled	✗	✓	✓
No. of Instances	7,775	1,355	3,025
No. of Entity Types	N/A	12	13
No. of Entity Mentions	16,780	4,522	15,334
No. of Relation Types	29	1	18
No. of Relation Mentions	11,121	3,841	8,366

Table 1: Comparison of FinRED, KPI-EDGAR, and FIRE datasets. FIRE has the advantage over FinRED in that it is hand-annotated and over KPI-EDGAR in that it is larger, has diverse relations and is more comprehensive in terms of covering financial aspects over a business. Note that FinRED statistics for entity and relation mentions were not readily available. The figures included below were manually computed after a review of the FinRED data files.

2 Related Work

Sentence vs. Document Level RE: Sentence-level RE identifies relationships between entities in a single sentence, while document-level RE captures relationships across multiple sentences or entire documents. Document-level RE offers a broader understanding of entity relationships, but sentence-level RE can pinpoint specific relationships more quickly. Document-level datasets include BC5CDR (Li et al., 2016), DWIE (Zaporojets et al., 2021), DocRED (Yao et al., 2019), and Re-DocRED (Tan et al., 2022). Some popular sentence-level RE-datasets include TACRED (Zhang et al., 2017b), FB-NTY (Hoffmann et al., 2011), and WebNLG (Gardent et al., 2017). While many of these are general-purpose, there are domain-specific datasets too (Luan et al., 2018; Perera et al., 2020). FIRE, despite having some multi-sentence instances, is mainly a sentence-level RE dataset.

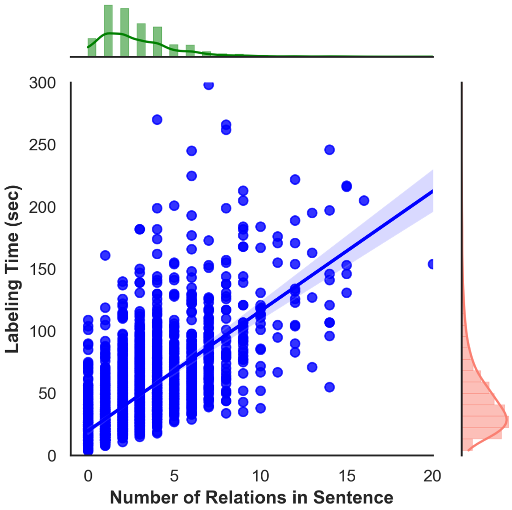


Figure 2: Scatter plot of labeling time (in seconds) versus the number of relations in the sentence. The marginal distributions and histograms are displayed at the edges of the plot. For sentences with the same number of relations, there is a wide distribution of labeling times, showing how the two quantities are correlated but still provide different information.

Relation Extraction Datasets and Distant Supervision. Creating RE datasets is costly due to labeling. One common technique to deal with this problem is distant supervision which relies on a knowledge base to automatically label text data (Mintz et al., 2009). In particular, sentences that mention two entities connected by a relation in the knowledge base are assumed to be expressing that same relation. This strong assumption leads to a large number of noisy samples. To address this issue, researchers have developed methods that relax the distant supervision assumptions(Riedel et al., 2010; Bengio et al., 2009). Despite its limitations, distant supervision remains a popular and effective method for generating large-scale datasets for relation extraction tasks. Several relation extraction datasets have been developed using distant supervision, including FB-NYT (Hoffmann et al., 2011), a dataset constructed by aligning Freebase (Bollacker et al., 2008) relations with The New York Times articles, and WebNLG (Gardent et al., 2017), a text generation dataset created from DBPedia (Bizer et al., 2009), among others. Such datasets have been widely used for training and evaluating relation extraction models. Conversely, FIRE is a supervised dataset in which every instance has been annotated manually following extensive annotation guidelines. While this approach elevates the cost of labeling and poses scalability challenges, it guarantees a high level of precision in the labels.

Financial Relation Extraction. Several NER and/or RE datasets in the financial domain have

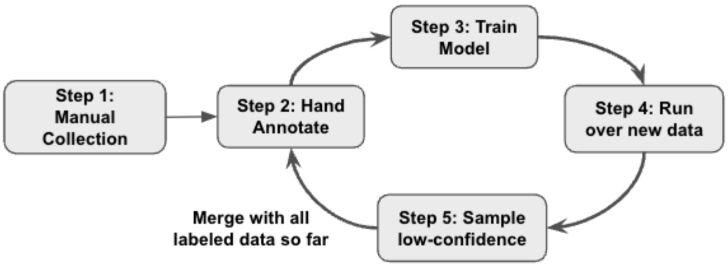

Figure 3: Stages of data collection: 1) Manually gather relevant sentences. 2) Hand-label them to create a "seed" dataset. 3) Train an RE-specialized model on this dataset. 4) Use the model on new financial content to identify entities and relations. 5) From the model's output, select sentences with low-confidence predictions to reduce confirmation bias. Remove existing labels from these sentences, manually annotate them, and merge with prior data. Repeat until the desired dataset size is achieved.

been previously proposed. FiNER-ORD (Shah et al., 2023) is an NER dataset automatically collected by applying pattern-matching heuristics on financial news articles. Unlike FIRE, this is an NER-only dataset with only three entity types. Another related work is (Wu et al., 2020), which established a Chinese corpus for relation extraction from financial news. However, this work focuses on relation extraction in the Chinese language, while our dataset targets relation extraction in the English language. Two datasets that most closely resemble ours are FinRED, an RE dataset introduced in (Sharma et al., 2022), and KPI-EDGAR, a joint NER and RE dataset introduced in (Deußer et al., 2022). Both are specialized in the financial domain. FinRED contains 7,775 instances covering 29 relation types and was collected from earning call transcripts and financial news articles. However, FinRED was labeled using the distant supervision technique, which can lead to a large number of noisy samples as outlined previously. In contrast, all instances in FIRE were hand-annotated by a human annotator. Similar to FIRE, the KPI-EDGAR dataset is also hand-annotated but the focus of this dataset is on extracting Key Performance Indicators (KPIs) from financial documents and linking them to their numerical values. It supports 12 entity types but only a single relation type, a binary link either exists between two entities or not. In contrast, FIRE supports an extensively diverse set of relations and its entities extend to broader business aspects, not being exclusively centered on KPIs. Table 1 compares the statistics of FIRE with both FinRED and KPI-EDGAR.

Labeling Time and Curriculum Learning. In FIRE, we've included a 'labeling time' attribute for each instance. This data, representing the time it took the annotator to label that particular instance from the dataset, was gathered during the annotation stage without additional cost. This could be useful to researchers examining annotation complexities or considering strategies like curriculum learning - a method inspired by progressive human learning, where models are exposed to easier samples first, gradually moving onto complex ones (Bengio et al., 2009). This method has been extensively applied in a variety of machine learning tasks (Zhang et al., 2017a; Kocmi and Bojar, 2017; Narvekar et al., 2020). A difficulty metric is required to apply curriculum learning. For example, a simple static (known a priori) difficulty metric for textual data can be the length of sentence in tokens. More sophisticated metrics are data-driven and adjust based on model feedback (Ma et al., 2017; Kumar et al., 2010). In this context, we suggest that 'labeling time' may act as a proxy for the difficulty of an example. As illustrated in Figure 2 we observe a positive correlation between the labeling time of a sentence and the number of relations it contains. Despite this correlation, the labeling time can vary significantly for a fixed number of relations, indicating that it is not a redundant feature. Qualitatively similar results are observed when comparing labeling time to sentence length or number of entities in a sentence. In section 4, we provide an initial result of how incorporating the labeling time feature into the training process can improve the performance of trained models.

3 FIRE Dataset

3.1 License and Intended Use

License. The dataset and its associated resources are provided under the Creative Commons Attribution 4.0 International License (CC 4.0) (Creative Commons, 2023).

The labeling tool developed in conjunction with the dataset is licensed under the MIT open-source license, see the LICENSE file for details.

Intended Use. The intended use of the FIRE dataset is two-fold: First, to advance the research in the area of joint NER and RE, specifically within the financial domain. It is designed to serve as a benchmark for evaluating the performance of existing models, as well as a training resource for the development of new models. Second, the FIRE dataset can serve as a valuable resource for financial analysts and auditors, enabling them to harness automated algorithms for expedient and efficient extraction of critical information from financial documents.

3.2 Data Splits and Statistics

In Table 1, some basic statistics of the FIRE dataset are displayed. The different entity and relation types as well as their distribution in the dataset can be found in appendix A.

The dataset was initially partitioned randomly into training, development (validation), and testing sets following a 70%, 15%, 15% split, respectively. Because financial reports, by their nature, often exhibit repetitive patterns in their language and structure, extra care was taken in creating the test set. Specifically, the Jaccard similarity score was computed for each pair of sentences from train and test sets. Jaccard similarity is defined as $J(A, B) = \frac{|A \cap B|}{|A \cup B|}$, where A and B are sets of tokens in two instances. It measures the degree of similarity between two sets. Any sentence in the test set exhibiting a Jaccard similarity score above 50% with any sentence in the training set was replaced by a different sentence from the train set. This approach helps to reduce data leakage and ensures that the test set provides a robust and unbiased evaluation of model performance.

3.3 Data Collection and Annotation

Data Sources and Pre-Processing. Approximately 25% of the dataset's records were sourced from publicly accessible financial news articles (Bloomberg - Financial news, analysis, and data; Yahoo Finance, 2023; CNBC, 2023; The Economic Times, 2023; The Financial Express, 2023), while the remaining 75% were extracted from publicly available SEC filings such as 10-K and 10-Q financial reports. For the SEC filings, we used the dataset of *Cleaned and Raw 10-X Files* spanning the years 1993-2021 (McDonald, 2023). This dataset contains all 10-K variants, e.g., 10-Q, 10-K/A, 10-K405. Every report in this dataset has already been cleaned and parsed to remove all non-textual related objects. For the financial news pieces, we obtained the original articles directly from their respective sources and manually conducted the cleaning process to extract the raw text.

Data Collection and Labeling. The process began by selecting a subset of financial reports and articles, as shown in Figure 3. An annotator identified and labeled key sentences with relevant entities and relations, creating a "seed" dataset. This dataset trained a joint NER and RE model (refer to 4.1), which then scanned new documents to suggest potential sentences. However, only the sentence selection was automated; actual labeling was always done manually. To mitigate confirmation bias, selections were deliberately made from low-confidence predictions generated by the model. Also, to reduce bias, the annotator was not shown the model's predictions. This cycle continued until we achieved the desired dataset size, with all annotations done by a single non-domain expert human annotator, who is also the lead author of this work.

Annotation Guidelines. For the FIRE dataset, a comprehensive set of labeling rules was established, incorporating both general entity and term annotation guidelines based on the ACL RD-TEC guidelines (QasemiZadeh and Schumann, 2016), as well as domain-specific rules tailored to each entity and relation present in the dataset. The guidelines also provide guidance for resolving ambiguous or conflicting edge cases.

Inter-Annotator Agreement. To assess difficulty of the annotation task, a subset of 150 samples was randomly selected and provided to three independent annotators. Annotators A and B were engineers with familiarity with the NER/RE task and annotator C was a professor with expertise outside of finance, engineering, and linguistics. Annotator A underwent several iterations of training to improve the quality of their annotations. In contrast, Annotators B and C were instructed to familiarize themselves with the annotation guidelines for 1-2 hours before starting the labeling task, without any prior training. The agreement between the annotators, including the main annotator of the dataset, was measured using the pair-wise entity and relations micro F1 score, as detailed in Table 2. This score was computed by treating one set of annotations as the ground truth labels and the other as predictions. Note that the result is the same re-

Annotator Pair	**Entity F1 (%)**	**Relation F1 (%)**
Main Annotator and A	78.29	59.72
Main Annotator and B	70.57	49.19
Main Annotator and C	50.46	16.05
A **and** B	69.73	48.46
A **and** C	46.72	14.19
B **and** C	49.52	17.49

Table 2: Inter-annotator micro F1 scores. Annotators A and B are engineers familiar with the NER/RE task. Annotator C had no prior familiarity with the NER/RE task nor any expertise in engineering, finance, or linguistics.

gardless of which annotations were designated as ground truth. Although Cohen's Kappa is usually the preferred metric for inter-annotator agreement, it is not suitable for the NER/RE task (Deléger et al., 2012; Hripcsak and Rothschild, 2005). The highest agreement was found with the annotator who received additional training. There was also greater agreement between the main annotator and annotator B as compared to annotator C, likely due to the annotator's technical background and familiarity with the NER/RE task. These results suggest that the task has a high level of technical complexity and that, even with the detailed annotation guidelines, training of new annotators requires an iterative education process. Furthermore, even with some iteration in annotator training, as was the case for annotator A, the inter-annotator agreement indicates significant room for improvement. For this reason, the entire FIRE dataset is labeled by a single annotator who wrote the annotation guidelines and invested significant time and effort to ensure consistency. None of the results collected by the other annotators for the inter-annotator agreement study are contained in the final dataset. The consistent labeling of the FIRE dataset is confirmed by the results in section 4.3, where the F1 scores for trained models are much higher than the figures in Table 2.

3.4 Labeling Tool

We introduce an open-source, web-based text annotation tool alongside the FIRE dataset [1]. Tailored for entity and relation labeling, the tool offers features for efficient annotation and error minimization. It supports shortcuts for quick labeling and an optional *rules file* upload to set constraints on permissible relations between entity types, inspired by the work of (Lyu and Chen, 2021). For example, in FIRE, a rule might dictate that the *ActionSell* relation is exclusive to the *Company* entity type. This ensures accurate annotations by preventing incompatible entity-relation combinations. The tool also logs the annotation time for each instance, as detailed in section 2.

4 Experimental Results

Fine-tune on entire dataset $D$ for $E$ epochs;
return Trained Model $\Theta$
```

4.1 Models

To benchmark the performance of state-of-the-art models on FIRE, two family of models were selected for evaluation: **RE-specialized models** and **general-purpose generative (causal) LLMs**. RE-specialized models are models that were designed specifically to solve the RE, and possibly the NER, task. These models are usually built on top of a pre-trained base model such as BERT (Devlin et al., 2019). They are then customized to target the RE task by doing a combination of building a custom architecture, applying RE-specific data preprocessing and customizing the training procedure.

---

[1] `https://github.com/abhinav-kumar-thakur/relation-extraction-annotator`

On the other hand, general-purpose causal LLMs are designed with the language modeling objective and have no direct connection to the RE task. They can still be evaluated on this task by treating it as a sequence generation problem.

Three RE-specialized models were selected: SpERT (Eberts and Ulges, 2020), PL-Marker (Ye et al., 2022) and REBEL (Cabot and Navigli, 2021). **SpERT** effectively applies the Transformer architecture, complemented by a robust negative sampling strategy. It thus serves as a good starting point for evaluation. **PL-Marker** employs a unique marker mechanism to mark entity boundaries in sentences. Both models are built on top of the BERT architecture (Devlin et al., 2019). **REBEL**, on the other hand, is a sequence-to-sequence language model built on top of the BART architecture (Lewis et al., 2019). REBEL treats the relation extraction as a language generation task by expressing the triplet targets as a sequence of text. This provides an alternative perspective to this problem. Note that REBEL does not evaluate on entities.

For general purpose generative models, we opted for **Llama 2-7b** (Touvron et al., 2023) and **GPT-3.5** (Brown et al., 2020), evaluating them in both few-shot and fine-tuned settings. Together, these models provide a reasonably comprehensive assessment of the FIRE dataset's performance and potential.

4.2 Setup and Evaluation

Standard Fine-Tuning SpERT, PL-Marker and REBEL were each allotted 24 hours on an Nvidia GeForce RTX 2080 Ti GPU for hyper-parameter tuning on the validation set to find the best *learning rate* and *batch size*. The best performing model is then evaluated on the test set. More details can be found in appendix B. Llama 2-7b and GPT-3.5 were fine-tuned with a custom prompt (appendix C) and without hyper-parameter tuning due to computational constraints. Llama 2-7b underwent fine-tuning using QLoRA (Dettmers et al., 2023) based parameter-efficient techniques with 4bit configuration. For GPT 3.5, the fine-tuning is performed using the API provided by OpenAI (OpenAI, 2023a). Fine-tuning and evaluations are done using an Nvidia GeForce RTX 4060 Ti GPU and with a spending of around \$100 for OpenAI APIs.

Few-Shot Prompting For Llama 2-7b and GPT 3.5, a custom prompt was designed to evaluate both models in a few-shot setting. The prompt includes a definition and description of each relation type. For each iteration, the few-shot examples are randomly selected from the training set of the dataset. The models are then prompted to extract both entities and relations. Prompt details are in Appendix C.

Curriculum Learning In addition to the standard training setup, another experiment was performed by training the three RE-specialized models according to a curriculum determined by the labeling time information. A very simple curriculum learning algorithm is used as described in algorithm 1. The training set is first divided into N tiers in increasing order of difficulty according to a metric M. Then, the model is trained successively for one epoch on each tier, as well as all previous tiers. Finally, the model is fine-tuned on the entire dataset for number of epochs E. In our experiment, we set $N = 10$ and $E = 20$ for all models. A compute budget of 24 hours is again given for each model to search for the best *learning rate* and *batch size*.

The difficulty metric M was computed as follows: given a sentence's labeling time t, we consider the following features: the number of entities n_{ent}, the number of relations n_{rel} and boolean variables indicating the length of the sentence as either $short$ or $medium$, with large sentences encoded by setting both $short$ and $medium$ variables to zero. Using these features, we fit a simple linear regression model to predict t as:

$$\hat{t} = \beta_0 + \beta_1 \cdot n_{ent} + \beta_2 \cdot n_{rel} \tag{1}$$

$$+ \beta_3 \cdot short + \beta_4 \cdot medium \tag{2}$$

The difficulty metric M is then defined as the normalized residual of the actual and predicted labeling time:

$$M = \frac{t - \hat{t}}{\max(t) - \min(t)} \tag{3}$$

This metric gives us a sense of how much harder (or easier) a sentence is to label compared to what we'd expect (from $\hat{t}$) based solely on its features. Intuitively, a sentence with expected labeling time $\hat{t}$ larger than actual labeling time t indicates that this may be an "easy sentence", and the opposite is true. The reason M is not simply chosen to be the labeling time t is because a sentence with large t is not always "more difficult" to label than a sentence with smaller t. The difference could be due to the features discussed above, e.g. a sentence with large t could simply contain more entities but is actually easier to label than another sentence with smaller

Model Class	Model	Evaluation	Entity F1 (%)	Relation F1 (%)
RE-specialized models	SpERT	*Standard Fine-Tuning*	$84.63^{\pm 0.25}$	$67.41^{\pm 0.92}$
		Curriculum Learning	$\mathbf{85.39}^{\pm 0.33}$	$68.11^{\pm 0.53}$
	PL-Marker	*Standard Fine-Tuning*	$83.78^{\pm 0.18}$	$67.01^{\pm 0.67}$
		Curriculum Learning	$84.65^{\pm 0.54}$	$67.67^{\pm 0.82}$
	REBEL	*Standard Fine-Tuning*	–	$68.25^{\pm 0.44}$
		Curriculum Learning	–	$\mathbf{68.93}^{\pm 0.52}$
General-purpose models	Llama 2-7b	*Few-Shot*	$20.24^{\pm 1.60}$	$9.32^{\pm 1.27}$
		Standard Fine-Tuning	$64.89^{\pm 1.10}$	$36.70^{\pm 0.59}$
	GPT 3.5	*Few-Shot*	$56.68^{\pm 1.06}$	$16.50^{\pm 0.39}$
		Standard Fine-Tuning	$\mathbf{81.48}^{\pm 0.18}$	$\mathbf{57.50}^{\pm 1.57}$

Table 3: Performance of all models on the FIRE test data. Mean and standard deviation (in superscript) are reported for micro F1 score for both entities and relations. SpERT, PL-Marker, and REBEL are evaluated in two settings: Standard Fine-Tuning and Curriculum Learning. Llama 2-7b and GPT 3.5 are evaluated in a few-shot setting as well as in a standard fine-tuning setting. Note that the REBEL model does not compute entity metrics.

t. This is why proper normalization is required to choose M.

Evaluation. For each experiment category, three independent training runs were performed. The mean and standard deviation of the micro F1 score are reported. The exact match micro F1 score was used as the evaluation metric for relations, i.e. entity boundaries, entity types, as well as the relation label must exactly match the ground truth labels to be considered correct. We use the train/eval/test splits for FIRE as reported in section 3.2.

4.3 Results

Table 3 presents the results of all experiments. The three RE-specialized models display comparable performance and significantly outperform the inter-annotator agreement scores in Table 2, further indicating the consistent annotations in the dataset. Looking into the curriculum learning results, we see that curriculum learning enhanced the performance of all three models compared to standard training. This confirms our assumption that the labeling time is an informative feature that can be used to improve the generalization capabilities of the models.

Table 3 also showcases the results for general-purpose generative LLMs. Fine-tuning outperforms few-shot learning significantly. GPT-3.5 surpasses Llama 2-7b, especially when fine-tuned. However, these models still lag behind RE-specialized models. Our findings are consistent with a recent study (Han et al., 2023) that also identified a significant performance gap between ChatGPT (OpenAI, 2023b) and state-of-the-art methods, particularly in more complex tasks. This can be explained by multiple factors, mainly the difficulty in doing strict evaluation of generative models which lack a fixed output format. This underscores the need for further research on using untrained causal LLMs for relation extraction, especially on datasets with diverse entity and relation types.

Figure 4 compares the F1 scores per relation type for the SpERT model trained with standard fine-tuning versus curriculum learning. The performance patterns between the two techniques are generally similar: both training methods exhibit difficulties with the same relation types and perform better on others. This pattern cannot be attributed solely to class imbalances. Rather, it seems to arise from the complexity inherent in detecting certain relations. For instance, "ValueChangeDecreaseBy" is infrequent within the dataset (refer to Table 5 in appendix A), yet the model demonstrates strong performance, likely due to the straightforward nature of detecting a relation involving a monetary value. On the other hand, "PropertyOf" appears more frequently but the model struggles in extracting this relation, potentially because of the complex nature of establishing this relation between two entities. Importantly, curriculum learning appears to enhance model performance on relation types that have lower F1 scores with standard fine-tuning, such as "ConstituentOf", "ProductOf", and "PropertyOf". This suggests that curriculum learning may

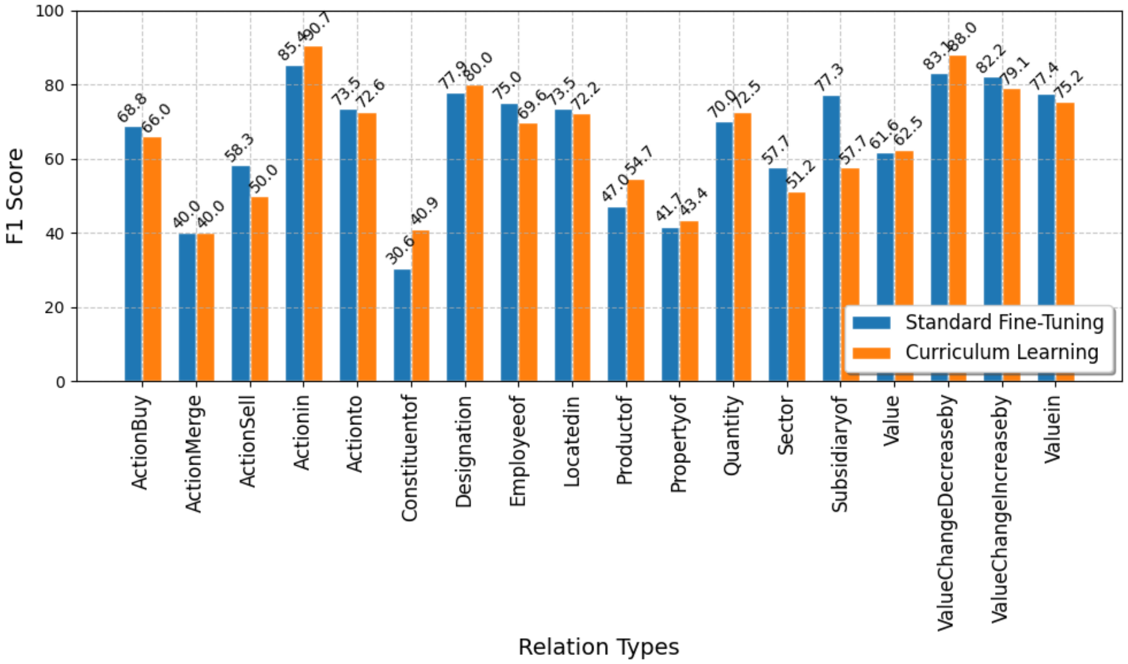

Figure 4: Comparison of F1 scores across each relation type in FIRE between standard fine-tuning and curriculum learning approaches using the SpERT model. The results highlight varying levels of difficulty in relation detection and may suggest an improvement in challenging relations when employing curriculum learning.

improve model performance with more complex relations. However, further analysis is necessary to determine whether this improvement is consistent across various models and random seeds. Note that the labeling time feature is a sentence-level metric and not a relation-level metric. Therefore, a direct comparison between labeling time and per-relation score is not possible.

Finally, while we employed a very simple curriculum learning algorithm, more advanced and sophisticated techniques have been proposed in the literature that can potentially achieve even higher improvements. Nevertheless, our primary contribution focuses on the dataset, and a thorough evaluation of all curriculum learning techniques can be explored in future research.

5 Conclusion

In this paper, we introduced FIRE, a dataset carefully curated for the task of joint named entity and relation extraction in the financial domain. The comprehensive annotation guidelines and the open-source labeling tool accompanying the dataset further contribute to its robustness and usability. Our evaluations with RE-specialized and generative LLMs highlight FIRE's challenges and potential. We also explored the benefits of incorporating labeling time in training. It is evident that the development of more refined models capable of understanding the complexities of financial domain-specific data is required. Looking forward, we anticipate that FIRE will serve as a valuable resource for researchers and practitioners in the fields of natural language processing and financial analysis.

6 Limitations

The primary limitation of FIRE is its domain-specific focus on the financial sector, potentially limiting its applicability to other fields. Additionally, the dataset is sourced solely from English language documents, which restricts its utility in multilingual or cross-lingual studies. Furthermore, the dataset is thoroughly annotated by a single human who is not a finance domain expert nor a linguist. Thus, the inherent subjectivity and possible biases or lack of domain-knowledge in manual annotation cannot be completely ruled out. Finally, the dataset is not meant to be an all-encompassing solution. Due to the complex and nuanced language often used in financial reports and news articles, certain entities and relations may not be captured by the existing entity and relation categories in the dataset. Finally, all entities in FIRE are extracted verbatim from the text. If an entity is implied but not explicitly stated, it would not be captured in FIRE as well as any relation relating to it. Future iterations of FIRE would benefit from addressing these limitations, expanding both its domain knowledge and linguistic diversity.

A Distribution of entity and relation types in FIRE

Table 4 breaks down the quantity of each entity type in the dataset while Table 5 displays the same information but for relations. For a detailed description of each entity and relation type, see the annotation guidelines document accompanying the dataset.

B Hyper-parameter Selection

For our experiments, we allocated a tuning budget of 24 hours on an Nvidia GeForce RTX 2080 Ti GPU for each RE-specialized model to search for the optimal hyper-parameters on the validation set.

Number of Entity Mentions		**15,334**
Average number of entities per instance		**5.29**
Amount of each entity	Company	22.41%
	FinancialEntity	15.60%
	Date	15.37%
	Designation	8.08%
	Money	7.78%
	Action	5.57%
	Quantity	5.27%
	Product	4.39%
	Sector	3.90%
	Location	3.74%
	Person	3.41%
	BusinessUnit	2.71%
	GeopoliticalEntity	1.70%

Table 4: FIRE Dataset Entity Statistics

Number of Relation Mentions		**8,366**
Average number of relations per instance		**2.92**
Amount of each relation	Valuein	11.17%
	Value	9.98%
	Designation	9.95%
	Actionto	8.55%
	Actionin	6.35%
	Propertyof	6.33%
	Locatedin	6.06%
	Sector	5.76%
	Productof	5.71%
	Constituentof	5.27%
	Employeeof	4.67%
	ValueChangeIncreaseby	4.31%
	ActionBuy	3.87%
	ValueChangeDecreaseby	3.64%
	Subsidiaryof	3.16%
	Quantity	3.08%
	ActionSell	1.66%
	ActionMerge	0.40%

Table 5: FIRE Dataset Relation Statistics

Table 6 displays the selected hyper-parameters for SpERT, PL-Marker and REBEL in the standard fine-tuning experiments.

Table 7 presents the hyper-parameters for the curriculum learning experiments for the RE-specialized models. To reduce the search space, instead of searching for one learning rate for each data tier, we select a fixed learning rate for tiers 1 to 3, 4 to 6 and 7 to 9. Thus we search for only three learning rates for all tiers, in addition to the final learning rate for training on the whole dataset.

C Llama 2-7b and GPT 3.5 Prompts

C.1 Few-Shot Learning Prompts

For few-shot learning, the following 1-shot prompt was used:

> *Find the relation between the entities given in the context and produce a list of triplets containing two entities and their relations.*
>
> *Only find out the following relations ActionBuy, Actionin, ActionSell, ActionMerge, Actionto, Constituentof , Designation, Employeeof, Locatedin, Productof, Propertyof, Quantity, Sector, Subsidiaryof, Value, ValueChangeDecreaseby, ValueChangeIncreaseby and Valuein*
>
> *ActionMerge indicate two company or organizations enters into merger agreements to form a single entity.*
>
> *ActionBuy represents the action of purchasing/acquiring a Company, FinancialEntity, Product, or BusinessUnit by a Company or a Person.*
>
> *Actionto represents the relation between the action entity and the entity on which the action has taken.*
>
> *Constituentof relation denotes one financial entity is part of another financial entity.*
>
> *Actionin indicates the Date associated with an Action entity, signifying the time of occurrence of the action.*
>
> *ActionSell represents the action of selling a Company, FinancialEntity, Product, or BusinessUnit by a Company or a Person.*
>
> *Employeeof denotes the past, present or future employment relationship between a Person and a Company.*
>
> *Designation indicates the job title or position of a Person, or the Designation of a Company in the financial context, providing information about the role or responsibility of the entity.*
>
> *Locatedin indicates the geographical lo-*

Model	Learning Rate (NER)	Batch Size (NER)	Learning Rate (RE)	Batch Size (RE)
SpERT	—	—	5e-5	2
PL-Marker	7e-5	2	4e-6	2
REBEL	—	—	3e-6	4

Table 6: Selected hyper-parameters for standard fine-tuning. Note that PL-Marker has a separate training run for its NER module. Therefore, we search for the learning rate and batch size of this module as well.

Model	Learning Rate				Batch Size
	Tier 1-3	Tier 4-6	Tier 7-9	Final	
SpERT	8e-6	5e-5	3e-5	5e-5	8
PL-Marker	7e-6	4e-5	4e-5	1e-6	4
REBEL	5e-6	4e-5	3e-5	1e-6	4

Table 7: Hyper-parameters for curriculum learning experiments. Note that for PL-Marker, we apply curriculum learning on the RE module only. For the NER module, we fix the learning rate to $5e-5$ and the batch size to 4.

cation or country associated with an entity, specifying the place or region where the entity is located. Money and Quantity can be in the place where they were generated, lost, profited, etc. Note that a Company is only Located in a place if it based in that place.

Productof indicates a Product is manufactured, sold, offered, or marketed by a Company, establishing a relationship between the Company and the Product.

Propertyof serves as an umbrella relation" that indicates a general association between two entities, mainly representing ownership or part-of/composition relationships. This relation is used to connect two entities when a more specific relation is not yet defined.

Quantity represents the countable quantity a FinancialEntity, BusinessUnit or Product.

Sector indicates the economic sector or industry to which a Company belongs, providing information about the broad business area or category of the Company's operations.

Subsidiaryof indicates that a Company is a subsidiary of a parent Company, either wholly or majority owned. Note that "brands" are always considered subsidiaries of their parent Company. A highly occurring pattern is a parent company selling its subsidiary company, in which case the Subsidiaryof relation is not annotated.

Value represents a non-countable value of a FinancialEntity, BusinessUnit or Product such as a monetary value or a percentage. A Company can also have a Value relation, but only for monetary values such as indicating the net worth of a company or the sale price in an acquisition.

ValueChangeDecreaseby indicates the decrease in monetary value or quantity of a FinancialEntity. An additional more rare use-case is the Quantity of a BusinessUnit decreasing, such as number of employees or number of offices.

ValueChangeIncreaseby indicates the increase in value or quantity of a FinancialEntity. An additional more rare use-case is the Quantity of a BusinessUnit increasing, such as number of employees or number of offices.

Valuein indicates the Date associated with a Money or Quantity entity, providing information about the specific time period to which the Money or Quantity value is related.

Please find few examples below

Context : Bank of America to Buy Merrill Lynch for $50 Billion

> *Answer : [['Bank of America', 'Merrill Lynch', 'ActionBuy'], ['Buy', 'Merrill Lynch', 'Actionto'], ['Merrill Lynch', '$50 Billion', 'Value']]*

C.2 Fine-Tuning Prompts

For fine-tuning, the dataset examples were transformed to the following prompt which was used to train the models:

> *Question: Find the relation between the entities given in the context and produce a list of triplets containing two entities and their relations. Only find out the following relations: ActionBuy, Actionin, ActionSell, ActionMerge, Actionto, Constituentof, Designation, Employeeof, Locatedin, Productof, Propertyof, Quantity, Sector, Subsidiaryof, Value, ValueChangeDecreaseby, ValueChangeIncreaseby, and Valuein.*
>
> *Context: Bank of America to Buy Merrill Lynch for $50 Billion*
>
> *Answer: [['Bank of America', 'Merrill Lynch', 'ActionBuy'], ['Buy', 'Merrill Lynch', 'Actionto'], ['Merrill Lynch', '$50 Billion', 'Value']]*

MusiLingo: Bridging Music and Text with Pre-trained Language Models for Music Captioning and Query Response

[5] University of Waterloo, Canada. [6] 01.AI, China

Abstract

Large Language Models (LLMs) have shown immense potential in multimodal applications, yet the convergence of textual and musical domains remains not well-explored. To address this gap, we present MusiLingo, a novel system for music caption generation and music-related query responses. MusiLingo employs a single projection layer to align music representations from the pre-trained frozen music audio model MERT (Li et al., 2023b) with a frozen LLM, bridging the gap between music audio and textual contexts. We train it on an extensive music caption dataset and fine-tune it with instructional data. Due to the scarcity of high-quality music Q&A datasets, we created the MusicInstruct (MI) dataset from captions in the MusicCaps datasets, tailored for open-ended music inquiries. Empirical evaluations demonstrate its competitive performance in generating music captions and composing music-related Q&A pairs. Our introduced dataset enables notable advancements beyond previous ones.

1 Introduction

In the realm of Music Information Retrieval (MIR), prevailing methodologies for contemporary musical descriptions typically lean on discriminative learning. An illustrative instance is music tagging (Law et al., 2009; Won et al., 2020, 2021), where descriptors encompassing genres, composers, instruments, emotions, and tempos are ascribed to each music clip. In this case, the model output is confined to a pre-determined set of categorical labels, thereby constraining its applicability in contexts like music exploration and recommendation, where the ability to handle and generate handle natural language descriptions instead of individual tags such as music captions or answers to music instructions would boast a diverse array of practical applications. These include generating textual descriptions for items found within extensive music catalogues, annotating copious user-generated content; automatically providing descriptions for evocative music featured in videos, catering to the needs of the hearing-impaired; and furnishing explanations for automated music recommendations. Furthermore, this advancement facilitates enhanced search and discovery of musical material for composers, all through user-friendly queries, while also serving as an inspiration for text-based music generation algorithms.

Given the potential alignment between musical and textual representations, there is some research to bridge the gap between acoustic music and natural language modalities, though still in its relatively nascent stages. A prospective avenue for better performance, in light of the recent triumphs of large language models (LLMs), entails integrating the conversation and generalisation proficiencies offered by LLMs into musical tasks.

Considering these insights, we introduce a novel music language model designed for music captioning, question answering, and query responses. Our approach involves a single projection layer configuration with temporal compression applied to music embeddings. In contrast to the multilayer perceptron (MLP) approach for the Llama-adapter (Zhang et al., 2023b) in a contemporary work MU-LLaMA (Liu et al., 2023b), which projects music embeddings to the upper layers of Llama, our method employs a straightforward projection to convey the embeddings to the initial layer of Llama. The Llama adapter is designed for fine-tuning the vanilla language model Llama into an instruction-following model and enhances its applicability to visual-language tasks but Vicuna (Chiang et al., 2023), the LLM we use as a language decoder, is already capable of instruction-following. Our simple approach offers the advantage of accommodating larger batch sizes which possess an NLP backbone capable of instruction-following

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3643–3655
June 16-21, 2024 ©2024 Association for Computational Linguistics

tasks. This has demonstrated considerable efficacy in visual-language contexts, as evidenced by its successful implementation in models like Llava (Liu et al., 2023a) and mini-GPT4 (Zhu et al., 2023).

We also incorporate a pre-training phase to align music information with textual representations, utilising a large amount of music captioning data, and fine-tuning the model using our developed MusicInstruct dataset derived from GPT-4 (Brown et al., 2020). This equips our model with the capability to understand different aspects of musical compositions and enables it to provide accurate and natural responses to user queries.

In summary, our work features the following core contributions:

- We introduce MusiLingo, a novel music-language model capable of performing music question answering and captioning;
- We demonstrate superior performance and state-of-the-art (SOTA) modelling for a variety of metrics for music Q&A;
- We create a new MusicInstruct (MI) dataset, which features 60,493 Q&A pairs covering both general questions like music summarisation, and specific questions related to music genres, moods, and instruments.
- Our ablation study delves into the impact of fine-tuning datasets on MusiLingo's performance. It reveals that the choice of training data significantly influences the model's effectiveness.

Section 2 details our methodology for the MI dataset creation and the music question-answering tasks. Section 3 outlines the MusiLingo model structure and training procedure. Section 4 presents experiments and evaluations of our model and baselines. Our code is available on GitHub[1].

2 Related Work

Several prior studies have explored the alignment of acoustic audio modalities with NLP. Cai et al. (2020) employed a CNN encoder based on a spectrum alongside an RNN with an attention-based natural language decoder to predict tag lists. However, the evaluation metrics utilized were not comprehensive, and the resulting tag lists exhibited noise, diminishing the robustness of the study. Doh et al. (2023b) utilized CLove or BERT along with transformer architectures for music encoding to facilitate text-to-music retrieval. MusCALL (Manco et al., 2022) leverages contrastive learning for text-to-audio and audio-to-text retrieval tasks. Wu et al. (2023) curated a large-scale audio caption dataset comprising 630k samples and trained models utilizing various pre-trained audio encoders and natural language decoders, also equipped with contrastive learning capabilities. Their approach yielded competitive results in text-to-audio retrieval tasks.

In addition to raw audio processing, Doh et al. (2021) utilized transformer and GRU models to map song IDs and metadata from each playlist to the corresponding playlist titles. Kim et al. (2023) incorporated artist IDs as part of the input for their investigation.

Work has additionally been carried out on music and audio captioning. MusCaps (Manco et al., 2021) leverages convolutional networks for music understanding and recurrent neural networks for captioning. MuLan (Huang et al., 2022) uses contrastive learning to align the text embedding to audio representations for music tagging and retrieval of music with text query. But the work is not open-sourced. LP-MusicCaps (Doh et al., 2023a) and audio captioning transformer (ACT) (Mei et al., 2021) utilise a cross-modality transformer-based encoder-decoder architecture for music/audio captioning. Choi et al. (2016) utilized an RNN to map CNN embeddings of playlists to word2vec embeddings of playlist captions. However, the performance of models in this earlier study is far from perfect. Additionally, PLAYNTELL (Gabbolini et al., 2022) employs tags, artist distributions, and audio as input for playlist captioning, thereby achieving state-of-the-art performance. Although these studies have shown notable advancements in tackling music captioning, they are not designed for music instruction-following and their effectiveness in functioning within a genuine conversational context for question-answering remains restricted or not evaluated.

Several works have applied LLMs to multimodal tasks. UniVAL (Shukor et al., 2023) offers a versatile model for image, video, audio, and language modalities, while LTU (Gong et al., 2023b) excels in audio quizzing. However, none of these models are designed for instruction-following on general audio, making them unsuitable for music-related question-answering and dialogue especially polyphonic music-related topics such as key and

[1] GitHub Repository

chord. To enable the bridge of two modalities on limited resources, we are inspired by the success of vision-language pre-training. In vision-language pre-training, the prevailing approach is to follow a new paradigm, connecting pre-trained unimodal encoders with LLMs via a learnable interface. This approach keeps encoders and language models fixed, using query tokens or adapter layers (Zhang et al., 2023b) to transfer information between modalities. The interface can be a set of query tokens that extract information from the modality, as BLIP-2 (Li et al., 2023a) and Flamingo (Alayrac et al., 2022), or an adapter layer that projects embeddings from one modality to another. Mini-GPT4 (Zhu et al., 2023) and Video-ChatGPT (Maaz et al., 2023) use simple linear adapters to project the visual embeddings onto text embedding space. Video-LLaMA (Zhang et al., 2023a) adopts the Q-Former design from BLIP-2 for the adapter and incorporates 2 projections from the image and audio data in the video. LLaMA-Adapter (Zhang et al., 2023b) employs a parameter-efficient approach with small adapter modules within transformer blocks. A contemporary work, MU-LLaMA (Liu et al., 2023b), extends the LLaMA-adapter concept to music language tasks. These models, which utilise pre-trained frozen encoders and learnable interfaces, offer a promising approach to connecting any modality with language models, providing efficient training and maximal preservation of the model's original knowledge.

3 Dataset & Evaluation Metrics

3.1 Large Dataset for Pre-training

In our study, we utilise the LP-MusicCaps-MSD dataset (Doh et al., 2023a) for pre-training. This dataset is derived from the ECALS subset (Doh et al., 2023c) of the Million Song Dataset (Bertin-Mahieux et al., 2011) and consists of 520k 30-second clips with a vocabulary of 1054 labels encompassing various categories such as genre, style, instrument, vocal, mood, theme, and culture. Each music clip is associated with an average of 10.2 labels, used for generating pseudo captions, including one caption, one summary, and one rephrased version for each audio clip using the GPT-3.5 model. We employ this extensive GPT-generated dataset for pre-training and subsequently fine-tune our results using a smaller, high-quality Q&A dataset.

3.2 Music Instruction Following Dataset

3.2.1 Collection Process

To enhance the model's ability to generate content of superior quality, we conducted additional fine-tuning using a bespoke music Question-Answering dataset we developed and named the MusicInstruct (MI) dataset. This dataset comprises Q&A pairs corresponding to individual musical compositions and is expressly tailored to tackle open-ended inquiries within the realm of music. It is derived from the music-caption pairs in the MusicCaps dataset (Agostinelli et al., 2023). The dataset is released with `cc-by-nc-4.0` license. The audio is available on YouTube with the given id, and the Q&A pairs along with metadata can be downloaded at our Huggingface page [2]

The MI dataset was constructed through prompt engineering and the application of few-shot learning techniques to ChatGPT (OpenAI, 2023). Given the ground truth caption of a musical excerpt from the MusicCaps dataset, we design a prompt instructing the chatbot to generate multiple Q&A pairs based on the provided caption. An example prompt for ChatGPT generating Q&A pairs is given in Table 5. The prompt consists of three parts: (1) An instruction delineating the task, serving as a system message directed at ChatGPT; (2) A set of few-shot example questions that the chatbot may generate; and (3) A concluding query featuring the music caption in question.

After generating all Q&A pairs, we employ another prompt to categorize whether the generated Q&A pair accurately encapsulates the essence of the music caption (e.g., Does this question-answer pair come from the context delimited with ####?). Pairs that ChatGPT classified as negative were filtered out. In addition, some other problematic Q&A pairs have also been removed from the MI dataset, including generations with runtime errors and instances where the generation terminates improperly (i.e., lacking punctuations in the end).

The resulting MI dataset comprises two versions, spanning questions from the general (*v2*) to the specific (*v1*). *v1* encompasses 27,540 Q&A pairs, with detailed questions and one or two-sentence long concise answers. The questions delve into various detailed aspects, such as music tempo, mood, instruments used, singer, genre, and music tags - important attributes and properties of a piece of music.

---

[2] Download dataset at `https://huggingface.co/datasets/m-a-p/Music-Instruct/tree/main`

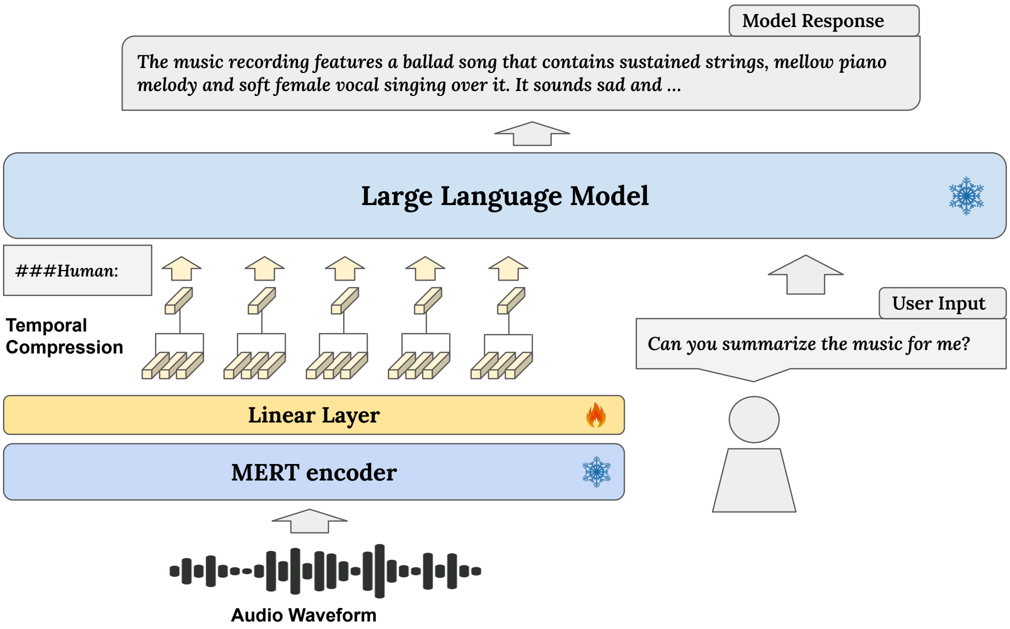

Figure 1: Overview of the MusiLingo model. Note that the backbone LLM can be easily replaced from Vicuna-7B to other LLMs.

Conversely, *v2* encompasses 32,953 Q&A pairs, featuring general questions, with answers typically being more extensive and serving as paraphrased renditions of the original caption. *v2* reflects a broader overview of the music content. Appendix A lists some example Q&A pairs from *v1* and *v2* of the MI dataset.

3.2.2 Quality Evaluation

Model	MusicQA	MI short	MI long
Instruction has Clarity	83.3%	93.0%	100.0%
Instruction has Feasibility	81.5%	95.6%	99.7%
Instruction has Practicality	83.3%	93.3%	100.0%
Output Quality excellent	70.4%	95.6%	97.5%
Output Quality not failed	94.4%	99.2%	100.0%

Table 1: Quality Assessment of Instruction Clarity, Feasibility, Practicality, and Output Quality of MusicQA and MusicInstruct dataset.

We conducted a comprehensive quality assessment of the MusicInstruct dataset Q&A pairs utilizing the assessment method in Kun (Zheng et al., 2024). For both short and long versions of the dataset, we randomly selected 1% of the instruction pairs, thus evaluating 600 pairs. We annotate the dataset quality on our own on whether the instruction fulfils the following three properties: Clarity, Feasibility and Practicality, therefore revealing the overall quality of the instruction. Additionally, we used the "consistency" of the responses and the related instruction to examine the quality of the outputs. Evaluators were asked to rate each output as excellent, passed, or failed, depending on the extent to which it met the requirements and intentions of the institution. See C for definitions of the evaluation metrics.

3.3 Evaluation Metrics

Both music captioning and music question answering are text-generation tasks. To this end, we use well-established text generation metrics to evaluate the model performances on both tasks, where the generated music captions/Q&A are compared to the ground truth texts. Metrics we used include BLEU (Papineni et al., 2002; Lin and Och, 2004), METEOR (Banerjee and Lavie, 2005), ROUGE (Lin, 2004), and Bert-Score (Zhang* et al., 2020).

To make our results comparable with MU-LLaMA, we use the average of BU_1, BU_2, BU_3, and BU_4 as the result of the BLEU value.

4 Method

In this section, we introduce MusiLingo, a potent music-language model that leverages LLM capabilities to enhance music comprehension. The model's key innovation lies in the use of simple adapters, a prevalent technique in LLM-based multimodal models. Our approach builds upon a design where both the music encoder and LLM remain fixed, while a single adapter network is trained to project music embeddings into the text embedding space. As demonstrated in fig. 1, We utilised MERT-330M (Li et al., 2023b) as the music encoder and Vicuna-7B (Chiang et al., 2023) as the language model, with the adapter consisting of a simple linear layer followed by temporal compression. Our methodology involves pre-training and instruction tuning to grasp music concepts and generate coherent responses. This streamlined design substantially reduces the time and resources needed for music-language model training.

4.1 Model Architecture

There have been a variety of designs for how and where to use adapters (Zhu et al., 2023; Li et al., 2023a; Alayrac et al., 2022; Maaz et al., 2023; Zhang et al., 2023a,b; Liu et al., 2023a), and our work extends from the design where both the music encoder and the LLM are completely frozen, and one adapter network is trained to project music embeddings onto the text embedding space. This adapter design, which has demonstrated remarkable efficacy in vision-language models like Llava (Liu et al., 2023a) and Mini-GPT4 (Zhu et al., 2023), enables us to easily insert music features into text embeddings and wrap it around with the user questions and necessary prompts that are used by different language models for doing instruction-following tasks. It also allows us to use larger batches during training. We used MERT-v1-330M (Li et al., 2023b) as our music encoder and Vicuna-7B (Chiang et al., 2023) as the language model. MERT (Li et al., 2023b) is a self-supervised music understanding model which employs teacher models to generate pseudo labels for sequential audio clips during training. It features a multi-task paradigm that simultaneously learns the musical and acoustic representations of the input music, thus achieving SOTA performances on various music information retrieval tasks. Vicuna (Chiang et al., 2023) is a chat model fine-tuned upon LLaMA (Touvron et al., 2023) using 70K user-shared conversations, showing better performance than open-source language models like LLaMA (Touvron et al., 2023). Our adapter is a simple linear layer followed by a temporal compression operation. We perform both a pre-training step and an instruction tuning step to learn the music concepts and form them into coherent answers. This simple yet effective design significantly reduces the time and resources needed to train a music-language model and helps bridge the gap between these two modalities.

The MusiLingo model consists of a music encoder, an adaptation layer, and a pre-trained LLM to achieve cross-modal understanding between music and text data. In particular, We use MERT as our music encoder to extract the acoustic and musical information from the input music clip and use Vicuna as the language model, which takes the music embedding output from the adaptation layer and generates text responses based on additional user text input. For the adaptation network we use a simple linear layer, which has been demonstrated to be fairly effective in a few recent works in the vision-language domain (Maaz et al., 2023; Liu et al., 2023a; Zhu et al., 2023). Note that the choice of a linear layer is also based on the observation that MERT has encapsulated the information in different dimensions via its attention layers. Consequently, there may not be an imperative need to introduce supplementary architectural elements, such as attention layers or BLIP-2 Q-Former (Li et al., 2023a), for the acquisition of temporal dimension information.

To harness both high-level and low-level information within music audio, we calculate the final music embedding by taking the weighted average of the outputs from each transformer block in the MERT model. This embedding is then projected onto the text embedding space of the language model via a linear layer. However, the encoded music representations can be lengthy, posing training challenges, and the uncompressed sequence elements lack meaningful alignment with the language model's token embeddings. To address this, we introduce a temporal compression step following the linear layer. Given the output embedding $M \in \mathbb{R}^{B\times T\times D}$ from the adaptation layer (with B, T, and D representing batch size, number of timesteps, and embedding dimension, respectively), we compress subsequences of length t along the temporal dimension by computing the average. This results in a new embedding with a reduced temporal dimension of $T' = \lceil T/t \rceil$. Thus, the input to the language model after compression is a vector of shape $B \times T' \times D$.

4.2 Music-Text pre-training

To train the MusiLingo model, we initiate a pretext task focused on aligning music concepts with the language model. In this phase, our goal is to effectively transform music embeddings into text embeddings using established music captioning datasets, specifically LP-MusicCaps-MSD (Doh et al., 2023a). As illustrated in Fig.1, each music clip undergoes encoding by the MERT encoder and the adapter layer for each music-caption pair. The ground truth caption is tokenised and converted into text embeddings using the Vicuna model, then appended to the music embeddings via concatenation. The loss is the original language modelling loss from the Vicuna model, with the tokens for regression limited to the caption tokens. This pre-training step is crucial for enabling the model to comprehend music concepts and convert them into textual representations.

4.3 Music Instruction Tuning

While the pre-training step plays a pivotal role in aligning music and text concepts, it alone does not suffice for generating high-quality conversational content. Hence, we incorporate an instruction tuning step to facilitate the model's ability to respond to various music-related questions. This fine-tuning process draws from two datasets: MI (detailed in Section 3), and MusicQA (Liu et al., 2023b), which contains question-answer pairs generated with the assistance of an LLM. Instruction tuning on these two datasets effectively imparts the model with the capability to answer music-related questions in a human-like manner and equips it with the knowledge to generalise to unseen tasks concerning musical content.

5 Experiment and Results

In this section, we introduce the experimental setup as well as present an evaluation of our model's performance on the Question-Answering of music on the MusicQA and MI datasets. Besides, we evaluate the performance of music captioning on the MusicCaps dataset. We compare our results to state-of-the-art models and discuss the unique challenges posed by this dataset. Last, we carry out an ablation study on training on different parts of the MI dataset.

5.1 Experiment Setup

In the experiments we compare our model against three other music-language models including LTU (Gong et al., 2023b), LTU-AS (Gong et al., 2023a), and MU-LLaMA (Liu et al., 2023b). LTU (Gong et al., 2023b) is a general audio-language model based on audio encoder, LLM, and LoRA (Hu et al., 2021). LTU-AS (Gong et al., 2023a) improves upon LTU by integrating the Whisper model for obtaining spoken text and enabling more general audio understanding. MU-LLaMA (Liu et al., 2023b) is another baseline which uses the same MERT (Li et al., 2023b) encoder as ours, but with a design similar to LLaMA-Adapter (Zhang et al., 2023b) for aligning music and text information.

For our model, during the pre-training phase, we train the network by concatenating the encoded caption with the projected music embedding and optimizing it for the caption tokens using the original language modelling loss. To ensure consistency, we use only the "caption_writing" in the pre-training dataset as the ground truth music caption since it contains mostly rephrased versions of each other. For instruction tuning, each data instance consists of an instruction or music-related question and its corresponding answer. We concatenate the instruction text token embeddings with the music embeddings, and the answer token embeddings with the instruction embeddings, with an additional prefix *###Assistant:* denoting the start of the answer. The objective is language modelling, with only the answer tokens contributing to the loss computation. During pretraining, we trained the model with a batch size of 32 for 20k steps using 4 A100 80G GPUs for 1-2 days. For each fine-tuning stage on different datasets, we completed 2 epochs of training on a single A100 40G GPU for 0.5-1 day. Please refer to our Github repo for detailed information on hyperparameters.

5.2 Result Analysis on Question-Answering

Table 2 demonstrates the experimental results of various models in the field of music question answering. These are categorised into three different scenarios: "MusicInstruct (Short)" which represents the short questions on MI datasets, "MusicInstruct (Long)" which refers to the long subjective questions on the MI dataset, and "MusicQA" which denotes the test set of the MusicQA dataset generated from the tags of MTG-jamendo datasets(Bogdanov et al., 2019). The table presents

Model	B-U↑	M-R↑	R-L↑	BERT-S↑
	MusicInstruct (Short)			
LTU (Gong et al., 2023b)	29.7	36.6	42.8	90.3
LTU-AS (Gong et al., 2023a)	30.4	36.3	42.0	90.9
MU-LLaMA (Liu et al., 2023b)	45.5*	50.1*	51.3*	93.2*
MusiLingo / MI(short)	47.0	51.4	51.4	**92.9**
MusiLingo / MusicQA + MI(short)	**47.1**	**51.7**	**51.6**	**92.9**
	MusicInstruct (Long)			
LTU (Gong et al., 2023b)	6.7	9.3	9.0	83.1
LTU-AS (Gong et al., 2023a)	6.0	8.8	8.2	83.3
MU-LLaMA (Liu et al., 2023b)	14.3*	25,6*	41.1*	88.6*
MusiLingo / MI(long)	**45.0**	**25.0**	**22.9**	**86.1**
	MusicQA			
LTU (Gong et al., 2023b)	24.2	27.4	32.6	88.7
Llama-adapter (Zhang et al., 2023b)	27.3	33.4	41.3	89.5
MU-LLaMA (Liu et al., 2023b)	30.6	**38.5**	**46.6**	90.1
MusiLingo / MusicQA	32.4	37.2	45.3	90.6
MusiLingo / MI short + MusicQA	**33.2**	38.4	46.5	**91.0**

Table 2: Music question answering results on the MI datasets and MusicQA. If the audio corresponding to the evaluation dataset is present in the pre-training dataset of a model along with caption information, the performance of instruction-following during evaluation may be overestimated. In such cases, we denote this potential overestimation by marking the corresponding entries in the table with a $\star$.

performance metrics for four key evaluation criteria: B-U (Bleu-Uni), M-R (METEOR-Rouge), R-L (ROUGE-L), and BERT-S (BERT-Score).

From the table, MusiLingo demonstrates the highest overall performance on MusicQA datasets. "MusiLingo / MusicQA" represent the model finetuned with Q&A pairs on the finetune set) of the MusicQA dataset, generated from the MagnaTagaTune (MTT) dataset (Law et al., 2009). Our experiments on the MusicQA dataset demonstrate competitive performance, aligning with the state-of-the-art (SOTA) results provided by MU-LLaMA. Specifically, our model achieves comparable performance on M-R and R-L metrics and surpasses the SOTA methods on BU and BERT-S, confirming its effectiveness in addressing the challenges posed by the Music question-answering task. Besides, "MusiLingo / MI Short + MusicQA" is finetuned on the short-question partition on the MI dataset and then is finetuned on the MusicQA dataset. The results are particularly excellent in the B-U and BERT-S metrics and have no significant difference in M-R and R-L compared to the SOTA approach.

Furthermore, MusiLingo demonstrates more competitive results on MI datasets in terms of both short objective questions and long subjective questions. In the objective question scenario, we see that "MusiLingo / MI (Short)" has achieved the highest scores for all rule-based evaluation criteria, outperforming other audio Q&A models, and provides competitive results compared to MU-LLaMA. Moreover, "The MusiLingo / MusicQA + MI (Short)", doing the continuous training on "The MusiLingo / MusicQA", only demonstrates slight improvement.

In the long-form music instructions, "MusiLingo / MI (Long)" outperforms other models by a significant margin. It is interesting to note that audio Q&A baseline systems LTU (Gong et al., 2023b) and LTU-AS (Gong et al., 2023a) perform well on objective questions such as instrument events and genres, while performing poorly in this scenario, suggesting the effectiveness of the MusiLingo approach for handling queries with more extended and higher-level music semantics. Note that MU-LLaMA may not be a good baseline system for the query-response on the MI dataset due to label leak issues. The MU-LLaMA is trained on the pre-training partition of MusicQA, which includes audio recordings in the evaluation split of MusicCaps along with the MPT-7B-generated Q&A pairs based on these recordings. The testing split of the MI dataset is based on the same audio in the evaluation split of MusicCaps along with the GPT-4-generated Q&A pairs based on these recordings. Both Q&A pairs include information on instruments, genre, emotion, singers, and the audience's feelings.

Overall, the experimental results suggest that MusiLingo is a promising model for music question answering, showing competitive performance across various scenarios. It is particularly strong in handling complex, long-form queries, making it a valuable tool for music enthusiasts and professionals looking for detailed and accurate answers to their questions.

5.3 Result Analysis on Music Captioning

We investigate the effectiveness of utilising a pipeline approach for music captioning, shedding light on its potential benefits. Given some previous Q&A models, such as MU-LLaMA which can perform captioning, we use the question "Please give a caption to the music" and the caption ground truth to train a music captioning model. Our experiments are conducted on the MusicCaps dataset, and we present key performance metrics in Table 3.

We did not include MU-LLaMA in the table because MU-LLaMA uses the whole MusicCaps dataset audio for training and then evaluates the results on the private dataset, making comparisons with such models on the MusicCaps dataset as a testing set not entirely suitable. Besides, it lacks transparency in explaining its captioning process, with the opacity stemming from the inherent diversity in the prompts query.

Model	B-U↑	M-R↑	R-L↑	BERT-S↑
MusCaps (Manco et al., 2021)	10.2	17.0	22.2	83.5
LTU (Gong et al., 2023b)	4.6	7.6	8.5	83.6
LTU-AS (Gong et al., 2023a)	4.0	6.0	6.3	82.9
LP-MusicCaps (Doh et al., 2023a)	14.7	**22.4**	21.5	**87.8**
MusiLingo Pre-trained	4.7	6.5	6.7	80.7
MusiLingo / MusicCaps	**30.8**	21.6	**21.7**	86.8

Table 3: Music captioning results on the MusicCaps datasets.

Table 3 summarises the results obtained by various models on the MusicCaps dataset. These results underscore the effectiveness of our proposed Q&A pipeline approach in improving music captioning performance. MusiLingo provides SOTA performance in B-U and R-L metrics. However, we acknowledge that our model's performance in music captioning is still not on par with the current SOTA models, especially on the BERT-score. Further improvements are required to bridge this gap.

5.4 Ablation on Fine-tuning Datasets

In this subsection, we present an ablation study that investigates the impact of fine-tuning datasets on the performance of MusiLingo, in the domain of music question answering. We explore how different fine-tuning strategies based on variations in training data, influence the effectiveness of MusiLingo. The fine-tuning datasets considered in our study are different partitions of MusicInstruct including MI (Short), MI (Long), and MI (all).

Our investigation revealed that models trained on a combination of short objective questions and long subjective questions were consistently outperformed by models trained exclusively on a single partition of Q&A pairs, even though we increased the calculation steps. This observation underscores the potential risk of incorporating diverse training data into the model training process, promoting enhanced performance. Besides, finetuning on MI (short) provides worse results on MI (long) and vice versa, suggesting a significant difference between short questions and long questions. Furthermore, we find that short questions are good for MusicQA zero-shot learning and long questions are good for captioning.

Model	B-U↑	M-R↑	R-L↑	BERT-S↑
	MusicCaps			
MusiLingo / MusicCaps	**30.8**	21.6	21.7	**86.8**
MusiLingo / MI short	2.1	8.4	9.0	84.4
MusiLingo / MI long	22.4	**22.2**	**29.3**	86.1
MusiLingo / MI mix	20.4	20.2	27.2	85.8
	MusicInstruct (Short)			
MusiLingo / MI(short)	**47.0**	**51.4**	**51.4**	**92.9**
MusiLingo / MI(long)	7.2	21.1	56.5	89.3
MusiLingo / MI(mixed)	46.1	50.9	51.1	92.8
	MusicInstruct (Long)			
MusiLingo / MI(short)	12.3	13.6	15.0	83.2
MusiLingo / MI(long)	**45.0**	**25.0**	22.9	**86.1**
MusiLingo / MI(mixed)	40.3	24.3	**23.6**	85.6
	MusicQA			
MusiLingo / MusicQA	**32.4**	**37.2**	**45.3**	**90.6**
MusiLingo / MI short	27.6	34.0	38.2	89.5
MusiLingo / MI long	12.4	24.6	**51.8**	88.5
MusiLingo / MI mix	26.8	33.6	43.0	89.4

Table 4: Ablition study results in MusiLingo performance after finetuning on a different partition of MI dataset.

Overall, the results also highlight the importance of evaluating models in different scenarios to gain a more comprehensive understanding of their capabilities and limitations. This information can guide the development of more robust and versatile music question-answering systems in the future.

6 Conclusion

In summary, our submission introduces MusiLingo, a pioneering large language model that effectively bridges the gap between music and text domains. With the aid of a single projection layer, MusiLingo aligns music representations with textual contexts, delivering competitive performance in music captioning and question-answering tasks. The introduction of our innovative MusicInstruct dataset further enhances its capabilities. We envision that our work lays the foundation for a new era of multimodal applications in the field of music, offering exciting possibilities for both music enthusiasts and researchers, promising to revolutionise the way we engage with and comprehend music.

Limitations

Our current model's fine-tuning process is relatively brief, and there is room for enhancing its performance through more extensive training and a more thorough exploration of hyperparameter configurations. Currently, the model provides good results on each dataset only after training on the same dataset and does not provide universality on all the downstream Q&A datasets. We recognize these limitations and consider them as avenues for future research.

Furthermore, there might be some model hallucinations when GPT-4 generates the answer for long questions with subjective descriptions based on the input music, given the input to GPT only includes the annotation in the MusicCaps dataset and does not necessarily align with human feelings on the music excerpts.

Ethics Statement

Google has chosen to release only the YouTube IDs associated with the music in the MusicCaps dataset, refraining from providing the raw audio data. This approach introduces ambiguity regarding the dataset's copyright implications. Besides the audio, annotation is generated by AI algorithms – the usage of GPT is to mimic human behaviour and we use it only for research use. We would like to emphasise that it cannot replace the human feeling towards music and we make our model public only for research use under a `cc-by-nc-sa` license. We acknowledge the need for transparent consideration of copyright ethics in dataset construction and use.

Acknowledgement

We would like to give thanks to Luca Marinelli and Ilaria Manco for the information on pre-training datasets. We would like to give thanks to Shansong Liu, one author of MU-LLaMA, for the suggestions and discussions.

Appendix

A Prompt for MusicInstruct Q&A Generation

Example instructions used for prompting ChatGPT to generate the MusicInstruct dataset is given in Tab. 5.

B Example of MusicInstruct Q&A

The questions in MusicInstruct dataset include emotion, genre, singer, instrument information, tags, tempo etc. and human feelings towards the music clips. Such as typical music property that is interesting to music information retrieval.

B.1 version 1 - short Q&A pairs

Eg 1.

Q: What instruments are used in the song?

A: The song uses a piano, claps, kick hits, hi hats, and a synth bass.

Eg 2.

Q: What genre does this music piece belong to?

A: This music piece belongs to the Japanese pop-punk genre.

Eg 3.

Q: What kind of media could this music piece be used in?

A: This music piece could be used in the soundtrack of a teenage/young adult feelgood movie/TV show or in the soundtrack of an animation movie or an anime.

B.2 version 2 - long Q&A pairs

Eg 1.

Q: Could you provide a detailed description of the church choir song?

A: The song is a prime example of a traditional church choir performance, one recorded in an era past. The arrangement sees the choir members joining their voices in an expressive harmony, imbued with a devout and contemplative essence. The pace of the song is moderated, neither too slow nor too fast, which enhances its immersive nature. Accompanying the choir is a church organ that amplifies the sacred ambiance without overshadowing the

v1: (short Q&A)	**v2:** (long Q&A)
System: You will be provided with a piece of caption that describes a music. The cation will be delimited with #### characters. Your task is to generate five question-answer pairs related to the music caption. The question should ask to describe the music content *in detail*. The answer should be the answer to the question and contain details of the provided music caption. The question can include but not limited to any of the following information when the caption include them: music tempo, mood of the music, instruments used, singer, genre, music tags, or any inference, etc. IMPORTANT: Output a JSON object with the following four keys: ’Question 1’, ’Answer 1’, ’Question 2’, ’Answer 2’, ’Question 3’, ’Answer 3’, ’Question 4’, ’Answer 4’, ’Question 5’, ’Answer 5’ **User:** ####{query music}####	**System:** You will be provided with a piece of caption that describes a music. The cation will be delimited with #### characters. Your task is to generate a conversational question-answer pair related to describing the music in detail. The question should ask to describe the music content *in general*. The answer should be a paraphrased and well-structured paragraph based on the provided description, with a minimum of 100 words and a maximum of 200 words. The answer must be a paraphrased version of the provided information, very detailed and descriptive, and within the specified word count. ##SAMPLE QUESTIONS: - Can you provide a summary of the music? - What are the main features of the music? - Could you briefly describe the music content? IMPORTANT: Output a JSON object with only two keys: "Q" for question and "A" for answer. **User:** ####{query music}####

Table 5: Example instruction used for prompting ChatGPT to generate Q&A pairs based on a music caption.

vocal chorus. Interestingly, there are no other musical instruments employed in the song. This speaks volumes about its pure and unadulterated nature. It’s worth noting that the recording quality of the song is not up to par and it appears to have faded considerably over time, indicating it might have been a product of an amateur’s handiwork at their residence. Despite preserving its classic church choir harmony essence, the deteriorated audio quality adds a nostalgic layer to the song, making it a noteworthy vintage piece in the world of devotional music.

Eg 2.

Q: Could you describe the content and style of this song in detail?

A: The song in question is an amateur recording, featuring the unique art form of beatboxing. Beatboxing is a vocal technique primarily involving the artful mimicking of percussive instruments with one’s mouth, voice, lips, tongue, and other parts. This specific rendition incorporates sounds representing the kick, snare, and hi-hat drum parts. Unlike typical songs, this one does not involve the use of any additional instruments or musical accompaniment. It presents an aural spectacle solely fueled by the beatbox performance. Moreover, there’s an absence of a defining vocal melody in the conventional sense, as the core and the sole essence of the song lie in the nuanced and rhythmic tapestry of sounds created solely by beatboxing.

C Dataset Quality Evaluation Measure

Inspired by the evaluation in Kun (Zheng et al., 2024), we use the data quality evaluation criteria with 3 instruction evaluation aspects and 1 output evaluation described as follows. The instruction quality is assessed with a yes/unsure/no answer and the output quality is assessed with an excellent/pass/failed. The definition of criteria are:

1. Instruction Clarity: Evaluators determine whether the instruction was unambiguous and

coherent, encompassing necessary information without any vague terms or explanations. (y/u/n)

2. Instruction Feasibility: Evaluators assess whether the instruction was valid and answerable within the context and scope of the model's capabilities. (y/u/n)
3. Instruction Practicality: Evaluators judge the relevance of the instruction in music informatics scenarios. (y/u/n)
4. Output Quality. The quality of the outputs is evaluated based on their alignment with the instructions. Evaluators are asked to rate each output as Excellent, Pass, or Fail, based on how well it met the requirements and intent of the instruction. (excellence/fair/fail.)

All the annotators have instrument-playing experience but are not professional musicians. No ethical approval is needed for the dataset quality evaluation because we only invited authors for annotation.

Investigating Acceleration of LLaMA Inference by Enabling Intermediate Layer Decoding via Instruction Tuning with 'LITE'

Neeraj Varshney **Agneet Chatterjee** **Mihir Parmar** **Chitta Baral**
Arizona State University

Abstract

Large Language Models (LLMs) have achieved remarkable performance across a wide variety of tasks; however, their large size makes their inference slow and computationally expensive. Focusing on this problem, we study instruction tuning LLMs with additional explicit **L**osses from the **InT**ermediate lay**E**rs (`LITE`) and show that it enables these layers to acquire 'good' generation ability without affecting the generation ability of the final layer. We then perform '*dynamic confidence-based early exiting*' at token level from the intermediate layers which improves the computational efficiency of text generation without sacrificing the quality of the generation. We conduct comprehensive experiments by instruction tuning LLaMA-2 models on the Alpaca dataset and evaluate on four different instruction test sets. We show that dynamic early exiting achieves consistent and considerable inference cost improvements (37.86% for 7B and 46.35% for 13B model) while maintaining the generation quality. We further conduct a thorough analysis of the results and dissect the efficiency improvements which reveals several important findings.

1 Introduction

Recently developed LLMs (Touvron et al., 2023; OpenAI, 2023; Chowdhery et al., 2022; Rae et al., 2021; Smith et al., 2022) have revolutionized the field of natural language processing and achieved remarkable performance across a wide variety of tasks. 'Instruction Tuning' further teaches these models to follow the user's instruction provided in natural language (Wei et al., 2022; Mishra et al., 2022; Sanh et al., 2022; Wang et al., 2022; Chung et al., 2022). Despite all the notable abilities of these models, their large size (number of parameters) makes their inference slow and computationally expensive which poses a practical challenge limiting their widespread adoption in resource constrained applications. Focusing on the above problem, in this work, we investigate instruction tuning LLMs in a way that enables intermediate layer decoding for efficiently generating text without compromising the quality of the generation.

We first show that in standard instruction tuning, only the final layer of the model acquires the ability to generate '*quality*' text while the representations of the intermediate layers (when passed through the language modeling head) fail to do so. This restricts decoding from these intermediate layers without degrading the generation quality. Addressing this point, we instruction tune LLMs with additional explicit **L**osses from the **InT**ermediate lay**E**rs (`LITE`) and show that it enables these layers to acquire 'good' generation ability. Importantly, we show that these layers acquire this ability without affecting the generation ability of the final layer; however, as expected, their generation ability still remains slightly inferior to the generation ability of the final layer. Thus, decoding the complete response from intermediate layers improves the efficiency of inference but still results in degradation in the quality of the response.

Addressing the above limitation, we show that (a) `LITE` greatly aligns the intermediate layers' token prediction with that of the final layer and (b) the intermediate layers' token prediction probabilities provide a strong signal of this alignment. Building on these findings, we perform '*dynamic confidence-based early exiting*' at token level from the intermediate layers which improves the efficiency of inference while maintaining the generation quality.

We conduct comprehensive experiments by instruction tuning LLaMA-2 models (Touvron et al., 2023) on the widely used Alpaca dataset (Taori et al., 2023) and holistically evaluate on four different human-instruction test sets including Vicuna, WizardLM, Koala, and Self-Instruct. Figure 1 compares the quality of responses (evaluated using the Claude model as detailed in Section 5) and the inference cost (measured in FLOPs) of the (i) standard generation method from the final layer with

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3656–3677
June 16-21, 2024

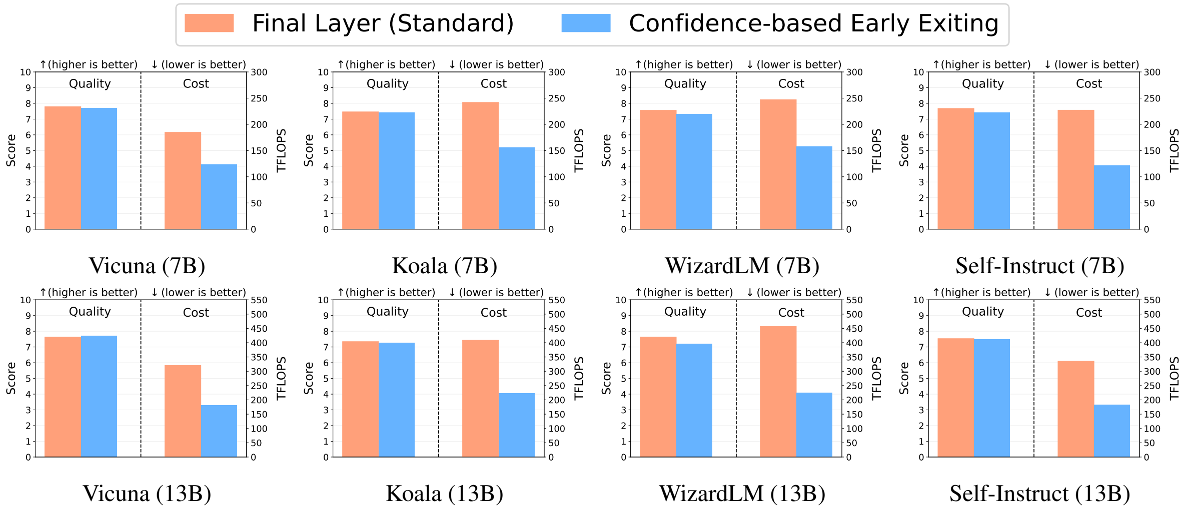

Figure 1: Comparing the quality of the responses and the inference cost of (i) the standard generation from the final layer (orange) and (ii) the dynamic early exiting method (blue) on model tuned with `LITE`. The top and the bottom rows show the effectiveness on four different test sets for the LLaMA-2 7B and 13B models, respectively.

(ii) the dynamic early exiting method. It shows that dynamic early exiting achieves consistent and considerable inference cost improvements (37.86% for 7B and 46.35% for 13B model on average) while maintaining the generation quality.

We further perform a thorough analysis of the results over several important aspects, such as, comparing the semantic similarity between the responses generated from the final layer and the early exiting method, and dissecting the efficiency improvements by comparing the number of tokens generated in the outputs. We also discuss the potential of intermediate layer decoding in '*speculative sampling*' and '*hallucination detection*'.

In summary, our work contributes to improving the efficiency of LLM inference while maintaining the generation quality, a crucial step en route to enabling their widespread adoption.

2 Related Work

Improving the inference efficiency of LLMs is an important research direction and is receiving considerable attention from the NLP community. In this section, we review some of the existing methods and differentiate our work from them.

Reducing model size: Since model size plays a crucial role in increasing the inference cost and latency, techniques like **quantization** (Dettmers et al., 2022; Yao et al., 2022; Xiao et al., 2023; Frantar et al., 2023), **knowledge distillation** (Hsieh et al., 2023; Jiao et al., 2020; Li et al., 2022), **model compression and network pruning** (Wang et al., 2020; Guo et al., 2021) have been shown to be effective in improving the inference efficiency.

Furthermore, during sampling, a cache of the keys and values can be maintained for every attention layer which reduces the computations at inference time (**KV caching**). However, it increases the GPU VRAM memory requirement of inference.

Another technique **speculative sampling** (Leviathan et al., 2023; Chen et al., 2023) first generates a draft of K tokens from a smaller auto-regressive model and then scores the draft using the target model. This results in generation of more than one token (on average) from the target model in a single pass.

Early exiting and cascading based inference techniques have been shown to be effective for classification tasks with BERT-style models, such as DeeBERT (Xin et al., 2020) that speeds up BERT inference by inserting extra classification layers between each encoder layer, PoWER-BERT (Goyal et al., 2020) that focuses on progressive word-vector elimination (based on significance computed using self-attention) along the encoder pipeline, DynaBERT (Hou et al., 2020) that adjusts the size of the model by selecting adaptive width and depth, and cascading (Varshney and Baral, 2022; Li et al., 2021; Varshney et al., 2022; Yue et al., 2023; Cheng et al., 2023; Varshney and Baral, 2023) in which sequential inference is done through models of bigger and bigger size with conditional exiting to output predictions efficiently. Our work is also related to Confident Adaptive Language Modeling (CALM)

(Schuster et al., 2022) and Depth-Adaptive Transformers (Elbayad et al., 2020) in which early exiting is performed by learning additional classifiers attached to the decoder layers.

Din et al. (2023) proposed to short-cut away transformer inference in between certain layers by learning linear transformations across layers in the network, i.e., **casting internal representations**. O'Brien and Lewis (2023); Gera et al. (2023) explore leveraging the intermediate layers for contrastive decoding to improve reasoning. We discuss other related and concurrent work in Appendix H.

Our work differs in the following aspects:
(1) Firstly, most of the existing work in early exiting focuses on improving the efficiency of encoder-only models (like BERT) or encoder-decoder models (like T5); our work focuses on the current state-of-the-art decoder-only LLMs (LLaMA-2). Furthermore, we focus on the instruction tuning setting with text generation, unlike prior work that focused on solving simpler tasks like GLUE classification or QA. (2) Early exiting methods typically require training additional classifiers for the intermediate layers, however, in this work, we use the same shared language modeling head at all the layers; thus, we do not introduce new model weights. (3) For leveraging the intermediate layers for decoding, we enable them to acquire generation ability by instruction tuning with LITE, unlike other methods that use a pre finetuned model in which these layers have poor generation ability as we show in Section 6.1. (4) Existing methods typically require complex architectural modifications, pruning, saliency quantification, or training new parameters. In contrast, our method (both for tuning and inference) is simple and easy to implement and yet achieves considerable benefits. (5) Existing methods typically require training a separate model for each computation budget; however, in our method, the same model can be adapted to meet all the computation constraints (by varying the exiting confidence thresholds). (6) The computational efficiency often comes with a compromise in performance. However, our method maintains the generation quality while providing efficiency benefits.

3 Instruction Tuning with `LITE`

Instruction Tuning (`IT`): One of the major reasons that necessitate instruction tuning of LLMs is the mismatch between their pre-training objective and the users' objective, i.e., LLMs are typically trained on minimizing the word prediction error while users want the model to follow their instructions. To this end, an instruction tuning dataset is collected and a pre-trained model is fine-tuned in a supervised manner (Mishra et al., 2022; Chung et al., 2022; Wei et al., 2021). Loss calculation during instruction tuning of a typical decoder-only LLM (LLaMA in this case) is shown in Figure 2 (left). The model consists of a stack of decoder layers followed by a language modeling head which outputs the probability distribution over the vocabulary tokens as its prediction. During the supervised fine-tuning, the loss over the output tokens is back-propagated from the final layer of the model:

$$Loss(y_{1:M}) = -\sum_{t=1}^{M} log\ p(y_t|y_{<t})$$

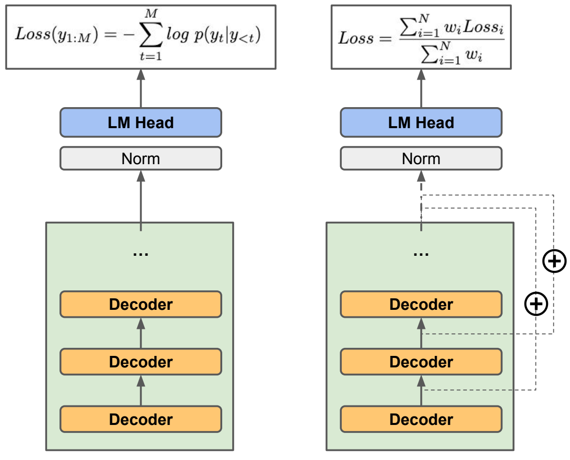
`IT` with `LITE`: We show that in standard instruction tuning, only the final layer of the model acquires the ability to generate 'quality' text while the representations of the intermediate layers (when passed through the language modeling head) fail to do so (Section 6.1). In other words, it does not explicitly teach the intermediate layers of the tuned LLM to generate tokens. This restricts decoding from these intermediate layers without degrading the generation quality.

We note that during tuning, the same language modeling head (that is used with the final layer) can also be used with the intermediate layers to obtain the losses of those layers. Thus, this does not impact the number of parameters of the model. To this end, we calculate a weighted aggregation of the losses from the intermediate layers (including the final) to calculate the overall loss value:

$$Loss = \frac{\sum_{i=1}^{N} w_i Loss_i}{\sum_{i=1}^{N} w_i}$$

where N is the number of layers, w_i is the weight of the i^{th} layer, and $Loss_i$ is the cross entropy loss of the i^{th} layer as shown in Figure 2.

During training, we use the representations of the intermediate layers and calculate the loss from these layers at the end. We note that this is a general formulation as it captures a variety of scenarios including the standard fine-tuning in which the loss is calculated only from the last layer (i.e., $w_{1:N-1}$ = 0 and w_N = 1). Furthermore, this formulation also allows aggregating losses from only the selected intermediate layers instead of all the layers



Instruction Tuning **Instruction Tuning with LITE**

Figure 2: Loss calculation for standard instruction tuning (left) and instruction tuning with additional explicit losses from the intermediate layers `LITE` (right).

by accordingly defining the LM head pathways and the w_i values. In Section 6.2, we will show that this formulation while enabling the intermediate layers with 'good' generation ability does not adversely affect the final layer's generation ability. Furthermore, as expected, the quality of generation typically improves with the layer number as the later layers have more capacity to learn.

4 Making Inference Efficient

In this section, we first detail auto-regressive inference and then describe early exiting techniques.

Auto-Regressive Inference: It refers to the process of generating a sequence of tokens where each token is generated based on the preceding tokens in the sequence. For generating a token, the model takes the input (including the previously generated tokens) and runs a forward pass in which the input is fed to the model and passed sequentially along its layers until the probabilities for the next token are predicted (called as **logits**). Chaining model forward passes with next token selection iteratively leads to the generation of text. In greedy decoding, the token with the highest probability is selected as the next word prediction at each timestep.

4.1 Fixed Early Exiting

Since instruction tuning with `LITE` enables the intermediate layers to acquire 'good' generation ability, the computations during inference can be terminated at a pre-specified intermediate layer (referred to as **exiting layer**) and the language modeling head can be used to predict the next token. This saves the computations of the remaining layers that follow the specified exiting layer and thus it improves the efficiency of inference.

Though this method of fixed early exiting leads to improvement in the efficiency of inference, it is bound to result in some degradation in the quality of the generation as the generation ability of an intermediate layer still remains inferior to the generation ability of the final layer. However, the quality of generation typically improves with the layer number as the later layers have more capacity.

4.2 Dynamic Confidence-Based Early Exiting

Addressing the limitation of the fixed early exiting method, we study a dynamic early exiting method that decides the exiting layer for a token prediction based on the intermediate layer's probability of the prediction (softmax over the logit values).

This is motivated by our following two findings:
(a) Instruction Tuning with `LITE` greatly aligns the intermediate layers' token prediction with that of the final layer (Section 6.3) and
(b) The intermediate layers' token prediction probabilities (referred to as **confidence**) provide a strong signal of this alignment (Section 6.4).

Building on these two findings, we perform 'dynamic confidence-based early exiting' at token level from the intermediate layers which improves the efficiency of inference while maintaining the generation quality. Specifically, a set of intermediate layers with their corresponding confidence thresholds are defined and at inference time, the exiting decision for a prediction is taken by comparing the intermediate layer's prediction confidence against its corresponding threshold. This enables the model to perform efficient inference without degrading the generation quality. Note that this method does not introduce new parameters and uses the softmax probability to make the exiting decision. We study this exiting method for inference without KV caching.

5 Experimental Setup

Instruction Tuning: We instruction tune the LLaMA-2 models (Touvron et al., 2023) (7B and 13B) with the widely used Alpaca dataset (Taori et al., 2023). Alpaca consists of 52K instruction-following demonstrations generated using the self-instruct (Wang et al., 2023b) technique. In IT with `LITE` for 7B model (32 total layers), we aggregate losses from the following selected intermediate layers: (8, 12, 16, 20, 24, 28) along with the final layer and use equal weights in loss calculation. Similarly, for the 13B model (40 total layers), we use (8, 12, 16, 20, 24, 28, 32, 36) layers. We perform full parameter fine-tuning on 4 A100 GPUs.

We skip selecting the initial layers because they have a limited capacity to learn and thus can not give good token predictions. Furthermore, we select layers at an interval of 4 so that at inference time, the model can do enough reasoning/interactions between two consecutive checkpoints. Otherwise, checking at every layer can result in computational overhead. We train this model for 5 epochs so that it achieves training loss comparable to standard tuning.

We present all the results corresponding to this tuning configuration in the main paper and present the study corresponding to weighted LITE in the Appendix C.

Evaluation Datasets: To perform holistic evaluation, we experiment with four different human-instruction test sets including Vicuna (Chiang et al., 2023), Self-Instruct (Wang et al., 2023b), Koala (Geng et al., 2023), and WizardLM (Xu et al., 2023). We select these evaluation test sets as they can together cover a large number and types of instructions thus resulting in a comprehensive evaluation. Table 4 shows the statistics of the datasets.

Evaluation Methodology: The evaluation of the instruction-following ability of LLMs is challenging due to the existence of multiple correct responses to an input and the infeasibility of reproducing human evaluations. Addressing this problem, recent works have started to rely on automatic evaluations using LLMs (Zheng et al., 2023; Chiang et al., 2023). Specifically, we use Claude LLM (Bai et al., 2022) as a judge to compare the quality of responses of two models on a given instruction. We note that these LLMs have been shown to be vulnerable to position bias in their judgment (Wang et al., 2023a). To circumvent this bias, we evaluate a response pair with both orderings of the responses and then aggregate the judgment scores. We provide the prompt for comparing the quality of the responses of two models in Appendix A.

6 Results and Analysis

In this section, we first demonstrate the inability of the intermediate layers of the model tuned with standard `IT` to generate 'quality' text (6.1). Then, we show the impact of `IT` with `LITE`: it does not adversely affect the generation quality of the final layer (6.2), it aligns the intermediate layers' token predictions with the final layer (6.3), and the corresponding prediction confidence values provide a strong signal of the alignment (6.4). These findings motivate dynamic confidence-based early exiting. Finally, we show the effectiveness of the method in improving the efficiency of inference while maintaining the generation quality (6.5). To avoid repetition, we present results for the 7B model in the main paper and for the 13B model in B.8.

6.1 Generation Ability of Intermediate Layers

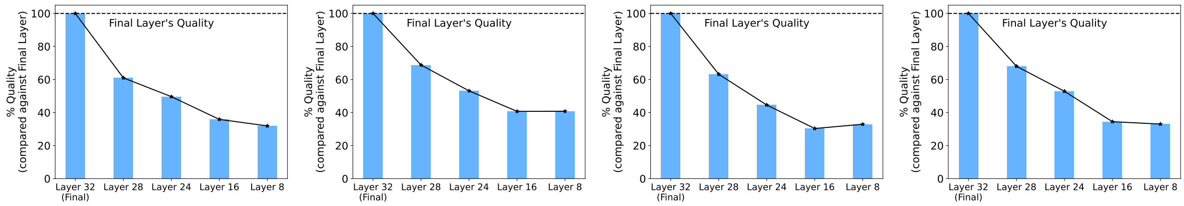
In order to obtain the text (sequence of tokens) generated via fixed exiting from an intermediate layer, we apply the normalization (RMSNorm) followed by the language modeling head to the representations of that intermediate layer and skip the computations of the layers following the exiting layer (as detailed in Section 4.1). For the model tuned with the standard instruction tuning, we compare the quality of the text (as detailed in Section 5) generated from different intermediate layers against the final layer's generation in Figure 3. As expected, the intermediate layers generate text of considerably degraded quality and this quality drops as the layer number decreases.

This demonstrates that with standard instruction tuning, only the later layers (primarily the final layer) of the model acquire the ability to generate 'quality' text while the representations of the intermediate layers (when passed through the language modeling head) fail to do so. Thus, for such a model, the early exiting method saves the inference computation cost but considerably degrades the generation quality. This restricts employing such early exiting techniques for the model tuned with standard instruction tuning. We show examples of responses obtained via fixed early exiting from different intermediate layers in Appendix B.1.

We perform instruction tuning with `LITE` to enable the intermediate layers to acquire 'good' generation ability. Importantly, we show that these layers acquire this ability without affecting the generation ability of the final layer (Section 6.2).

6.2 Impact of LITE on the Final Layer

In Figure 4, we compare the quality of responses of (a) the model tuned using standard instruction tuning (IT) and (b) the model tuned using IT with `LITE`. Note that the responses for both these models



(a) Vicuna (b) Koala (c) WizardLM (d) Self-Instruct

Figure 3: Demonstrating quality comparison of the output of intermediate layers (generated via fixed exiting) against the final layer's generation of the model tuned with standard instruction tuning.

correspond to their respective final layer's output. From the figure, it can be observed that for all the datasets, the outputs of both models are of comparable quality which shows that tuning with `LITE` does not adversely affect the generation ability of the final layer of the model.

Next, we demonstrate two important characteristics of instruction tuning with `LITE` (in 6.3 and 6.4) that motivate us to study dynamic confidence-based early exiting from the intermediate layers.

6.3 'Alignment' of Intermediate Layers

We define percentage 'alignment' of a layer as the measure of how often the token predictions of that layer match with that of the final layer (given same input prefixes). For this study, we do not do early exiting, instead we just use the representation of each intermediate layer and pass it through the LM head to obtain the corresponding token prediction of each layer. Note that for generating the next token, we follow the standard generation methodology and append the predicted token of the last layer to the input to obtain the token prediction of all the layers given the same input prefixes.

In Figure 5, we plot the percentage alignment of token predictions of all intermediate layers with the token predictions of the final layer. The figure shows the percentage alignment of (i) the model tuned using standard IT (orange) and (ii) the model tuned using IT with `LITE` (blue). We show this result aggregated over all the output token predictions for all the inputs of the corresponding dataset.

We draw the following inferences:

(a) The predictions of the intermediate layers of the model tuned with LITE align well with the final layer, i.e., given a prefix, the intermediate layers' token predictions match quite well with the final layer's token prediction. In contrast for the model tuned using IT, the token predictions of the intermediate layers do not align well with the final layer's token predictions.

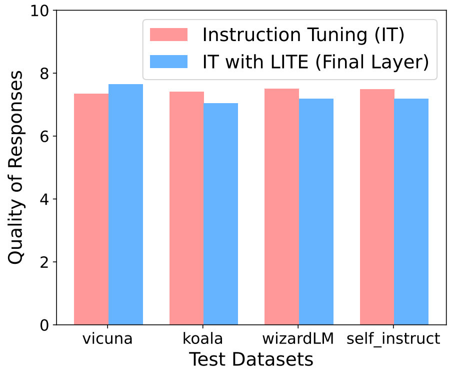


Figure 4: Comparing quality of responses of (a) model tuned using IT and (b) model tuned using IT with `LITE`. The outputs of the models are of comparable quality.

(b) As the layer number increases, the % alignment also increases, i.e., given a prefix, the predicted token of the later layers shows higher alignment (with the final layer) than the initial layers.

(c) There are some peaks in the curve for IT with `LITE` which correspond to the selected layers from which the loss is aggregated during tuning, i.e., these layers show higher alignment as expected.

In summary, this study demonstrates that IT with LITE greatly aligns the token predictions of intermediate layers with that of the final layer.

6.4 Token Probability and Alignment

We plot the relationship between the token prediction confidence (softmax over the logits of the LM head) of the intermediate layers and the percentage alignment with the token prediction of the final layer. Figure 6 shows this plot for the model tuned with `LITE`. The figure shows that in IT with `LITE`, the intermediate layers' token prediction probabilities provide a strong signal of alignment, i.e., a high token prediction confidence implies a higher likelihood of its alignment with the token prediction of the final layer. It also shows that with the increase in the layer number, the percentage align-

WizardLM	36.12 %
Self Instruct	46.54 %

Table 1: Percentage improvements in the inference cost (measured in FLOPs) with dynamic early exiting.

ment typically increases at the same confidence values. In contrast, in standard instruction tuning (IT), the confidence is not well correlated with the percentage alignment as we show in Appendix B.6.

6.5 Effectiveness of Dynamic Early Exiting

Motivated by the findings of the previous two subsections (6.3 and 6.4), we perform dynamic confidence-based early exiting at token-level, i.e., we exit when the token prediction confidence of the intermediate layer is sufficiently high (thus it is likely to align with the final layer's prediction).

To this end, from the confidence vs percentage alignment curve, we identify a confidence threshold for each layer where the alignment is $> 95\%$. Specifically, we use the following thresholds: Layer 8: 0.95, Layer 12: 0.95, Layer 16: 0.9, Layer 20: 0.9, Layer 24: 0.8, and Layer 28: 0.7.

In the main paper, we present the results and analysis for the aforementioned configuration. However, we note that a different threshold configuration can also be used for inference. For instance, a more aggressive configuration with lower thresholds (shown in Appendix B.7) leads to even more cost improvements (49.92%); though it slightly drops the quality of generation (5.34%). The trade-off between quality and cost can be balanced depending on the application requirements. For example, applications with quality tolerance or resource limitations can keep low threshold to achieve higher cost improvements.

Dynamic confidence-based early exiting: At a selected layer, we pass its representations through the LM head, calculate the softmax logit value, and compare it with the corresponding confidence threshold of the layer. If it surpasses the threshold value then we exit from that layer and proceed to generate the next token, otherwise, we repeat this process at the next selected layer.

Figure 1 (in Section 1) compares the quality of responses and the inference cost (measured in FLOPs) of the standard generation method (final layer) with the dynamic early exiting method. It shows that the dynamic early exiting method achieves consistent and considerable cost improvements (37.86% for 7B and 46.35% for 13B model on average) while maintaining the generation quality. Table 1 shows the percentage improvements in inference cost for each test set individually. We note that we use FLOPs as the metric of showcasing inference efficiency improvements because it is hardware independent, unlike latency.

6.5.1 Semantic Similarity of the Responses

In addition to comparing the quality, we also compare the semantic similarity between the responses of the final layer and the dynamic early exiting. Table 2 shows the semantic similarity (calculated using the 'en_core_web_sm' spacy model) for the four datasets. It shows that there is a large semantic similarity between the responses as the values are closer to 1. This implies that dynamic early exiting maintains the semantics of the responses while providing efficiency benefits. Appendix B.4 shows examples of responses from both the last layer and the dynamic early exiting method.

Test Dataset	Semantic Similarity
Vicuna	0.9135
Koala	0.8940
WizardLM	0.9020
Self Instruct	0.9001

Table 2: Semantic similarity between the final layer's and the dynamic early exiting responses on test sets.

6.5.2 Dissecting the Cost Improvements

In Figure 7, we compare the average number of tokens generated in the final layer's responses and the dynamic early exiting responses. It shows that both the methods generate a comparable number of tokens in their respective outputs. This asserts that the cost improvement resulting in dynamic early exiting is because of the reduced computations and not due to generating a lesser number of tokens.

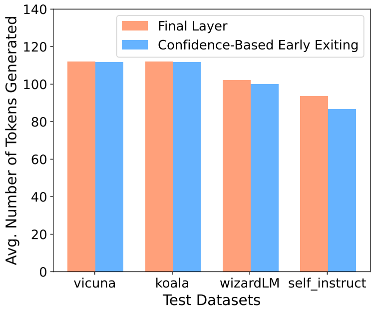

Figure 7: Comparing the average number of tokens generated in the final layer's responses and the dynamic early exiting responses for the four datasets.

6.5.3 Contribution of Different Exiting Layers

Figure 8 shows the percentage of token outputs from different exit layers. Note that this is aggregated across all the token positions. This shows that the model exits a considerable percentage of times from the intermediate layers (while maintaining the generation quality) which further justifies the improvement in inference efficiency. We further conduct several interesting studies and analyses of the results and present them in Appendix B.

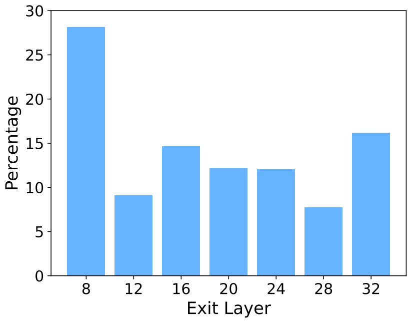

Figure 8: Percentage of token outputs from different exiting layers in the proposed method.

6.5.4 Effectiveness at Category Level

Vicuna and WizardLM datasets also provide the category corresponding to different test instances. To this end, we present category-level quality and inference cost results for these datasets in Figure 9 and 10 (Appendix). On average, the method results in cost improvement of 33.39% on Vicuna and 36.12% on WizardLM.

7 Conclusion and Discussion

In this work, we proposed instruction tuning with additional explicit losses from the intermediate layers and showed that it enables these layers to acquire 'good' generation ability without affecting the final layer's generation ability. We performed '*dynamic confidence-based early exiting*' at token level from the intermediate layers and showed that it improves the efficiency of inference while maintaining the generation quality. We further conducted a thorough analysis that resulted in several important findings. Overall, our work contributes to improving the efficiency of LLM inference while maintaining the generation quality, a crucial step en route to enabling their widespread adoption.

Looking forward, our work additionally opens up several other avenues for new research, such as speculative sampling from the intermediate layers to improve the inference efficiency and checking information consistency from the output of intermediate layers to detect hallucinations (discussed in Appendix I). Furthermore, this approach is complementary to some existing efficiency methods described in Section 2 and H, i.e., they can be used in conjunction to achieve even more efficiency gains.

Limitations

We have shown the efficacy of intermediate layer decoding to achieve inference efficiency benefits. However, utilizing the intermediate layers requires instruction tuning with LITE. This is because the standard instruction tuning does not teach the intermediate layers to generate quality text. Thus, for utilizing the intermediate layers, the model needs to be trained using instruction tuning with LITE and an already instruction-tuned model may not provide the same efficiency benefits while maintaining the generation ability. Though this method is generally applicable, we investigate it with LLaMA-2 models as also explicitly specified in the paper title. This is because the LLaMA-2 models are one of the best performing publicly available models and they are widely being used in ongoing NLP research. We also clearly note that this research is limited to the English language.

Ethics Statement

We have used AI assistants (Grammarly and ChatGPT) to address the grammatical errors and rephrase the sentences.

Appendix

A Evaluation Methodology

We use the following prompt with Claude model for comparing the quality of responses:

```
Human: You are a helpful and precise assistant for checking the quality of the answer.

[Question]
{question}

[The Start of Assistant 1's Answer]
{answer_1}

[The End of Assistant 1's Answer]

[The Start of Assistant 2's Answer]
{answer_2}

[The End of Assistant 2's Answer]

We would like to request your feedback on the performance of two AI assistants in response to the user question displayed above.
Please rate the helpfulness, relevance, accuracy, level of details of their responses. Each assistant receives an overall score on a scale of 1 to 10, where a higher score indicates better overall performance.
Please output a single line containing only two values indicating the scores for Assistant 1 and 2, respectively. The two scores are separated by a space.

Assistant:
```

To circumvent the position bias, we evaluate a response pair with both orderings of the responses and then aggregate the judgment scores. We use the Claude API with temperature set to 0 and modelId to ‘anthropic.claude-v1’.

B Additional Results

B.1 Inability of the Intermediate Layers of the Model Tuned with Standard Instruction Tuning to Generate 'High-Quality' Text

In this Subsection, we show examples of responses of intermediate layers (fixed exiting) of the model tuned with standard instruction tuning (IT).

Question: What are the differences between plant-based and animal-based protein sources?

Layer 32 (Final): The main difference between plant-based and animal-based protein sources is that plant-based proteins are found in plant-based foods, such as legumes, nuts, and seeds, while animal-based proteins are found in animal-based foods, such as meat, eggs, and fish. Plant-based proteins typically contain fewer calories, fat, and cholesterol than animal-based proteins. Additionally, ...

Layer 28: plant- based proteins sources such as legumes, legumes, and nuts contain essential amino achren needed for growth and repair of cellsular structures. animal based proteins sources such as meat, eggs, and fish contain additional nutrients such as vitamin B Complex vitamin D vitamin Iron and calcium needed for optimal health.

The above examples and the results in Section 6.1 show that in standard instruction tuning, the intermediate layers do not acquire good generation ability as the generated responses are of poor quality.

In the next subsection, we illustrate examples that show that IT with LITE enables the intermediate layers to acquire good generation ability.

B.2 Intermediate Layers Acquire Good Generation Ability in IT with LITE

Question: What are the differences between plant-based and animal-based protein sources?

Layer 32 (Final): Plant-based protein sources are mainly found in foods such as legumes, nuts, and seeds, while animal-based protein sources are found in foods such as meat, fish, eggs, and dairy products. Plant-based proteins are generally lower in calories and fat, and are rich in vitamins, minerals, and fiber. Animal-based proteins are typically higher in calories and fat, and ...

The above examples illustrate that IT with LITE enables the intermediate layers to acquire good generation ability. This is because the losses are aggregated from these intermediate layers during instruction tuning.

B.3 Poor Quality of Responses With Dynamic Early Exiting from Model Tuned with Standard Instruction Tuning (IT)

Here, we show examples of the responses generated via dynamic confidence-based early exiting from the model tuned with standard instruction tuning (IT). Note that this is without `LITE`.

It can be observed from these examples that the early exiting responses are of poor quality. They suffer from a number of issues including degeneration such as unwanted token repetitions, and lack of coherence and structure. We note that this can be attributed to the poor generation ability and alignment of the intermediate layers.

Question: What are the most effective ways to deal with stress?

Layer 32 (Final): The most effective ways to deal with stress include identifying sources of stress, developing coping strategies, maintaining a balanced diet, exercising regularly, getting enough sleep, and taking time to relax and do something enjoyable. Taking time to practice deep breathing and meditation, talking to a friend or therapist, and using humor are also helpful.

Question: Can you explain the basics of quantum computing?

Layer 32 (Final): Quantum computing is a form of computing that uses quantum-mechanical phenomena, such as superposition and entanglement, to perform operations on data. It enables computation at a much faster rate than traditional computers and can solve problems that are intractable on classical computers. Quantum computing uses qubits2̆014quantum bits2̆014which can be in a state of 0 or 1, instead of the traditional bit of 0 or 1. Qubits can be used to represent data and perform operations on it, such as addition, subtraction, and multiplication.

Dynamic Early Exiting with IT model: quantum computing basics quantum computing basics explain the basics of quantum computing including what it is, how it works, why it matter, how it can be used for computing, and what its future may hold. quantum computing basics quantum computing basics explain the basics of quantum computing including what it is, how it works, why it matter, how it can be used for computing ...

This further showcases the importance of `LITE` during instruction tuning as it allows the intermediate layers to acquire good generation ability, thus enabling opportunities for early exiting without compromising the quality of the generation.

B.4 Examples of Responses with Dynamic Early Exiting for Model instruction tuned with LITE

Here, we show examples of responses of the final layer and the dynamic early exiting method with the model instruction tuned using `LITE`.

Question: What are the main differences between Python and JavaScript programming languages?

Layer 32 (Final): The main differences between Python and JavaScript programming languages are their syntax, data types, data structures, and logic. Python is a high-level, interpreted language that is focused on readability and simplicity, while JavaScript is a low-level, interpreted language that is focused on adding interactive elements to web pages. Python has strong support for data typing, while JavaScript has weaker support for data types. Python is more suitable for creating scripts and applications, while JavaScript is more suitable for creating interactive web pages.

Dynamic Early Exiting: The main differences between Python and JavaScript programming languages are their syntax, data types, data structures, and logic. Python is a high-level, interpreted language that is focused on readability and simplicity, while JavaScript is a low-level, interpreted language that is focused on adding interactive features to web pages. Python has dynamic data types, while JavaScript has static data types. Python is more suitable for creating scripts and applications, while JavaScript is more suitable for creating interactive web pages.

Question: What if Isaac Newton had focused on biology instead of physics?

Layer 32 (Final): Isaac Newton had focused on biology instead of physics, he would have likely made similar discoveries in that field as he did in physics. His laws of motion and universal gravitation could have been formulated in a biological context, for example, describing the ways in which cells and organisms adhere to physical laws. He would have likely realized that biology is also an essential physical science, and that the laws of motion are just as universal in biology as in physics.

Dynamic Early Exiting: Isaac Newton had focused on biology instead of physics, he would have developed a different understanding of the natural world. He would have believed that biology was the foundation of all physics, and that it was the only way to understand the universe. He would have also believed that all living organisms had the same underlying laws of physics, rather than the laws of physics being created for humans to understand. He would have also believed that biology was the most important branch of science, and that it was the only way to understand the universe.

These examples show that the responses obtained via early exiting do not compromise the quality of the generation. Furthermore, responses have high syntactic and semantic overlap.

B.5 Quality and Inference Cost Analysis at Category Level

Vicuna and WizardLM test sets also provide the category corresponding to different test instances. To this end, we present category-level quality and inference cost results for these datasets.

(i) Counterfactual (j) Multilingual

Figure 10: Comparing the quality of responses and the inference cost of the standard generation method with the dynamic early exiting method on different categories of the WizardLM Test set.

Vicuna: Figure 9 compares the quality of responses and the inference cost of the standard generation method (final layer) with the dynamic early exiting method for different categories of Vicuna test set. On average, it results in cost improvement of 33.39%. It can be observed that the approach consistently achieves efficiency improvement in all the categories which demonstrates the generality of the approach.

WizardLM: Figure 10 compares the quality of responses and the inference cost of the standard generation method (final layer) with the dynamic early exiting method for different categories of WizardLM test set. On average, it results in cost improvement of 36.12%.

B.6 Relationship Between Token Prediction Confidence and Percentage Alignment of the Intermediate Layers for the Model Tuned with Instruction Tuning (IT)

Figure 11 shows the relationship between the token prediction confidence of the intermediate layers and the percentage alignment with the token prediction of the final layer for standard instruction tuning (IT). It shows that the confidence is not well correlated with the percentage alignment. However, in IT with LITE (Figure 6), the intermediate layers' token prediction probabilities provide a strong signal of alignment.

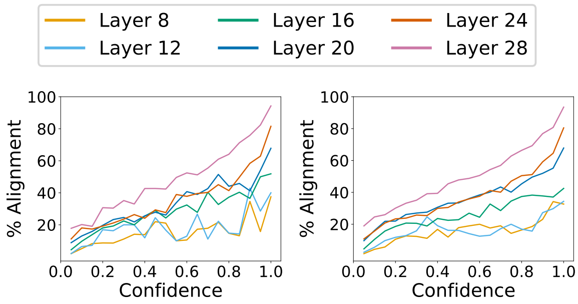
B.7 Dynamic Confidence-Based Early Exiting with Aggressive Confidence Thresholds

We also experiment with aggressive confidence thresholds. Specifically, we use the following confidence thresholds: Layer 8: 0.85, Layer 12: 0.85, Layer 16: 0.8, Layer 20: 0.8, Layer 24: 0.7, and Layer 28: 0.6. These thresholds are lower than those used in the main paper. Figure 12 shows the quality and cost comparisons. It leads to larger cost improvements (of 49.92%) though it slightly drops the quality of generation (by 5.34%).

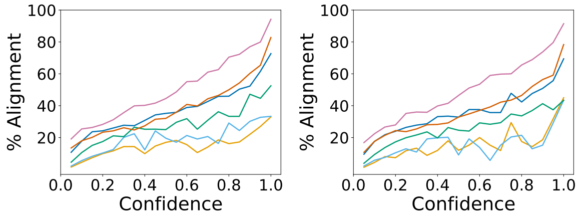
B.8 Results for 13B Model

For the 13B model, we use the following confidence thresholds: Layer 8: 0.95, Layer 12: 0.95, Layer 16: 0.9, Layer 20: 0.9, Layer 24: 0.8, Layer 28: 0.7, Layer 32: 0.7, and Layer 36: 0.65,

Table 3 shows the cost improvements resulting from dynamic early exiting from the 13B model on each test dataset. On average, it results in 46.35% cost improvement. This improvement is higher than the improvement achieved in the case of the 7B model (37.86%).



(a) Vicuna (b) Koala



(c) WizardLM (d) Self-Instruct

Figure 11: Demonstrating relationship between token prediction confidence of the intermediate layers and the percentage alignment with the token prediction of the final layer for model tuned with IT.

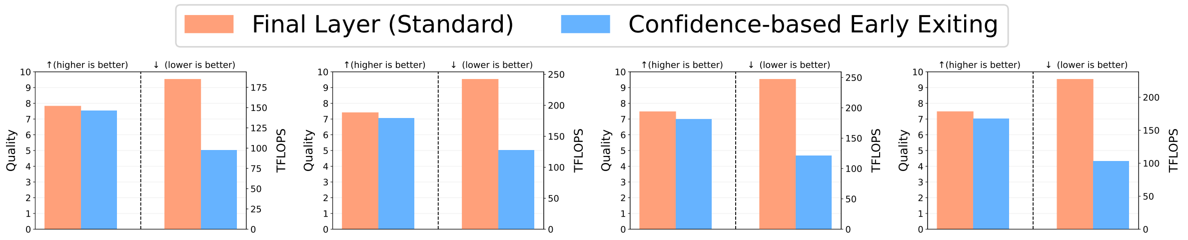
Test Dataset	Cost Improvement (%)
Vicuna	43.60 %
Koala	45.62 %
WizardLM	50.84 %
Self Instruct	45.35 %

Table 3: Percentage improvements in the inference cost (measured in FLOPs) with dynamic early exiting for the 13B model. On average, it achieves an improvement of 46.35%.

C Weighted LITE

We also experiment using increasing weights for different intermediate layers during the loss aggregation. We use increasing weights as the later layers have more capacity to learn. Specifically, for the 7B model where we select layer numbers 8, 12, ..., 28, and 32, we use the following weights: 1, 2, ..., 7.

In Figure 13, we plot the percentage alignment of token predictions of all intermediate layers with the token predictions of the final layer. The figure shows the percentage alignment of (i) the model tuned using standard IT (orange) and (ii) the model tuned using IT with weighted `LITE` (blue). In Fig-



(a) Vicuna (b) Koala (c) WizardLM (d) Self-Instruct

Figure 12: Comparing the quality of responses (evaluated using the Claude model) and the inference cost (measured in FLOPs) of the standard generation method from the final layer with the dynamic early exiting method. Confidence Thresholds: Layer 8: 0.85, Layer 12: 0.85, Layer 16: 0.8, Layer 20: 0.8, Layer 24: 0.7, and Layer 28: 0.6. This **aggressive configuration** results in larger cost improvements of 49.93% but results in a slight degradation in the generation quality.

Test Set	# Samples
Vicuna	80
Koala	180
WizardLM	218
Self Instruct	252

Table 4: Statistics of evaluation datasets.

Id.	Final Layer (Standard)	Confidence-based Early Exiting
1	7.25	7.2375
2	7.725	7.6125
3	7.5625	7.425
Avg.	7.51	7.425

Table 5: Human annotations for the quality of responses of the 7B model on the Vicuna test dataset.

ure 14, we compare the alignment for the model tuned using IT with LITE and the model tuned using IT with weighted LITE. It can be observed that assigning lower weight to the initial layers results in just a slight reduction in alignment percentage.

We also plot the relationship between the token prediction confidence (softmax over the logits of the LM head) of the intermediate layers and the percentage alignment with the token prediction of the final layer. Figure 15 shows this plot for the model tuned with weighted `LITE`.

D Additional Evaluations

In the paper, we have presented LLM-based evaluations. To further support these evaluations, in this section, we present human evaluations and GPT-4 based evaluations. In human evaluations, we asked the participants to annotate the quality of the responses. We conducted this study on the Vicuna test dataset and for the 7B model. Specifically, we asked 3 participants to rate the quality of responses on a scale of 1 to 10, where a higher score indicates better overall performance (similar to the LLM-based evaluations). All the participants were graduate students. Table 5 shows the ratings of the individual participants and the aggregated scores. Additionally, we also use GPT-4 for evaluations. The scores corresponding to ‘Final Layer (Standard)’ and ‘Confidence-based Early Exiting’ are 6.3 and 6.17 respectively.

From both these studies, it can be inferred that the quality ratings are indeed very close and thus support our LLM-based evaluations.

E Comparison with Early Exiting Baselines

Motivated by the techniques presented in (Fan et al., 2020), we develop several early exiting baseline techniques. Specifically, we implement two variants of random early exiting technique and a sequential exiting technique. We note these are just other early exiting baseline techniques and experimenting with them can demonstrate the sheer effectiveness of our dynamic confidence based early exiting.

In the random early exiting technique, instead of looking at the confidence (as we do in the dynamic confidence based early exiting), we randomly make a decision to exit from a ‘check-point’ layer. In one variant of this technique, at each checkpoint layer, we make a binary random decision to exit or continue (therefore two choices). In another variant, we reduce this chance value to (1/#checkpoint layers).

In the sequential early exiting technique, we cyclically change the exiting layer for the next token. For example, for the first token, we use the first checkpoint layer (8th layer), for the second token, we use the second checkpoint layer (12th layer) and so on in a cyclic manner. We present the results of these baselines on the vicuna test dataset in Table 6.

From these results, it can be observed that the dynamic confidence based early exiting method results in just a minimal drop in quality of generation while the other baselines (despite using the intermediate layers of the model tuned with LITE) result in a considerable drop in quality of generation.

In addition, for standard instruction tuning (without LITE), we have already shown that performing early exiting results in very poor quality of generation (Appendix B.3).

F Comparing Latency

We study latency improvements on the Vicuna test dataset using 7B model. We find that the standard generation with the final layer requires 14912.12 ms on average while dynamic confidence based early exiting method takes 9873.20 ms on average. This implies that the early exiting method takes up just 66.2% latency of the standard generation process while maintaining the generation quality. This result supports the FLOP improvements.

We have focused primarily on the FLOP values because the latency values vary (though marginally) on different executions, unlike the FLOP values. Furthermore, the follow-up works may not be able to precisely compare the latency values in an apples-to-apples comparison. Thus, FLOP values more clearly and reliably show the impact of the methodology and can also facilitate future work.

G Design Decisions

FLOPs for measuring Computational Cost: We note that we use FLOPs as the metric of showcasing inference efficiency improvements because it is hardware independent, unlike latency.

KV Caching: We explore the dynamic exiting method for inference without KV caching. This is because the representations of the layers after the exiting layer are not computed in this method and thus will not be available in the cache for the next token prediction if the model exits from a higher layer than the previous token prediction.

LLaMA-2 Models for Experiments: We experiment with LLaMA-2 models as they are publicly available and widely used for LLM research.

Evaluation Datasets To perform holistic evaluation, we experiment with four different human-instruction test sets including Vicuna, Self-Instruct, Koala, and WizardLM. We select these evaluation test sets as they can together cover a large number and types of instructions thus resulting in a comprehensive evaluation. Table 4 shows the statistics of the datasets.

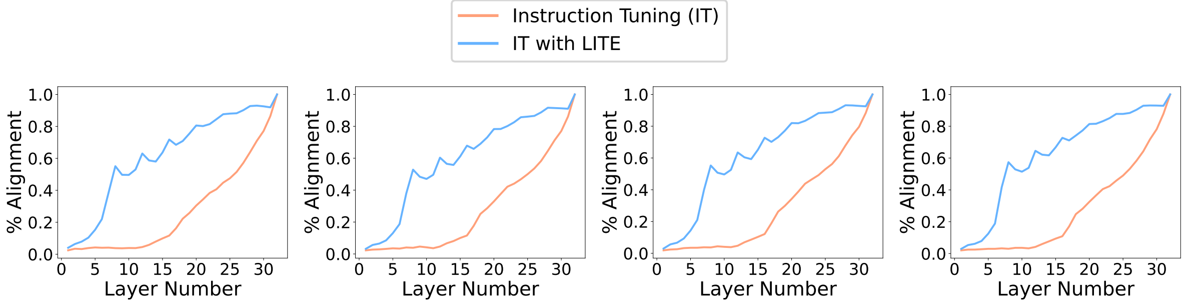
H Extended Related and Concurrent Work

Yang et al. (2023b) propose an approach called Predictive Pipelined Decoding (PPD) that focuses on lowering the latency by utilizing additional compute resources. Specifically, it accelerates the decoding by parallelizing processes, each of which starts to decode from the top-k predicted tokens of the specific transformer layer. Simultaneously, the main process continues to compute the output of the final layer and predicts the next token.

Yang et al. (2023a) propose an inference-with-reference decoding method that exploits the overlap between an LLM's output and available reference. Specifically, it first selects a text span from the reference and copies its tokens to the LLM decoder, and then checks if they are acceptable based on the output token probabilities. He et al. (2023) also uses retriever to generate the draft tokens in speculative decoding.

Jiang et al. (2023) propose to compress the prompts to accelerate the inference. Santilli et al. (2023) propose a parallel decoding strategy for translation using Jacobi and Gauss-Seidel fixed-point iteration methods

The most similar yet non-trivially different from our work is a concurrent work (Kavehzadeh et al., 2023) which is motivated from SortedNet (Valipour et al., 2023) that focuses on leveraging the inherent modularity of models to construct sub-models with varying computational loads. In contrast, in our work, we instruction tune with LITE and then perform token-level dynamic confidence based early exiting to achieve efficiency benefits while maintaining the generation quality. Our approach is motivated from our two findings of the model tuned using IT with LITE which are (a) `LITE` greatly aligns the intermediate layers' token prediction with that of the final layer and (b) the intermediate layers' token prediction probabilities provide a strong signal of this alignment.



(a) Vicuna (b) Koala (c) WizardLM (d) Self-Instruct

I Discussion on Other Avenues of Research using Intermediate Layer Decoding

I.1 Speculative Sampling

In speculative sampling (Leviathan et al., 2023; Chen et al., 2023; Ning et al., 2023; Kim et al., 2023; Spector and Re, 2023), a short draft of K tokens is first generated from a smaller autoregressive model and then the draft is scored using the target model. Using a rejection sampling scheme, a subset of the K draft tokens is accepted by sequentially checking from left to right, and thus in this process, the distribution of the target model is recovered for the accepted tokens. The efficiency in this technique comes from 'producing' more than one token (on average) from the target model in a single pass.

This technique requires an additional drafting model. However, we showed that instruction tuning with LITE enables the intermediate layers to acquire 'good' generation ability. Thus, the intermediate layer(s) of the same model can be used as the drafting model while the last layer remains to be the target model. This circumvents the requirement of maintaining a separate drafting model for speculative sampling.

I.2 Hallucination Detection

Addressing the hallucination problem of LLMs is an important research direction and a number of methods have been developed (Manakul et al., 2023; Azaria and Mitchell, 2023; Zhang et al., 2023; Dhuliawala et al., 2023; Varshney et al., 2023; Gou et al., 2023). Sampling based methods require generating multiple samples and then checking the information consistency between them. Enabling the intermediate layers with the generation ability equips us with multiple opportunities, such as checking the consistency based on the alignment percentage of the intermediate layers with the final layer or using the intermediate layers to generate the complete output and then checking the information consistency.

Instruction-following Evaluation through Verbalizer Manipulation

Abstract

While instruction-tuned models have shown remarkable success in various natural language processing tasks, accurately evaluating their ability to follow instructions remains challenging. Existing benchmarks primarily focus on common instructions that align well with what the model learned during training. However, proficiency in responding to these instructions does not necessarily imply strong ability in instruction following. In this paper, we propose a novel instruction-following evaluation protocol called verbalizer manipulation. It instructs the model to verbalize the task label with words aligning with model priors to different extents, adopting verbalizers from highly aligned (e.g., outputting “positive” for positive sentiment), to minimally aligned (e.g., outputting “negative” for positive sentiment). Verbalizer manipulation can be seamlessly integrated with any classification benchmark to examine the model’s reliance on priors and its ability to override them to accurately follow the instructions. We conduct a comprehensive evaluation of four major model families across nine datasets, employing twelve sets of verbalizers for each of them. We observe that the instruction-following abilities of models, across different families and scales, are significantly distinguished by their performance on less natural verbalizers. Even the strongest GPT-4 model struggles to perform better than random guessing on the most challenging verbalizer, emphasizing the need for continued advancements to improve their instruction-following abilities.

1 Introduction

Large language models have achieved remarkable success in zero-shot generalization for various natural language processing (NLP) tasks via instruction tuning (Wei et al., 2022a; Ouyang et al., 2022; Sanh et al., 2022; Iyer et al., 2022). One representative model is ChatGPT[1], which has shown promising results in text summarization (Yang et al., 2023), coding (Surameery and Shakor, 2023), healthcare (Sallam, 2023; Zhang et al., 2024), education (Baidoo-Anu and Owusu Ansah, 2023), finance (Dowling and Lucey, 2023) and law (Choi et al., 2023). Existing benchmark datasets (Wang et al., 2019b,a; Cobbe et al., 2021; Hendrycks et al., 2021; Li et al., 2023) primarily focus on common instructions that align well with what models learned during pre-training or instruction-tuning. However, proficiency in responding to these instructions does not necessarily imply strong ability in instruction following as models may rely on memorization of favorable responses rather than genuine generalization due to the vast volume of data they see during training (Tirumala et al., 2022). Nonetheless, instruction following capability plays an important role in task generalization for real-world applications. For example, a user may want models to output answers only when they are certain to reduce hallucinations or control model response length or assign models with specific roles (e.g. tax expert). A natural question arises: *How can we systematically and automatically evaluate instruction-tuned models in terms of instruction-following capability?*

In this paper, we propose to evaluate the instruction-following ability from the aspect of how well models can follow instructions that may not align with their priors and design a novel framework to synthesize them. Specifically, we propose verbalizer manipulation[2] that can be used to construct instructions aligning with model priors to different extents, from *natural*, to *neutral*, to *unnatural*, as shown in Figure 1. In *natural* instructions, we choose multiple verbalizers that align with prior knowledge for each dataset. In *neutral*

---

[2] Following Schick and Schütze (2021), we define a verbalizer as a mapping from golden label names to target ones.

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3678–3692
June 16-21, 2024

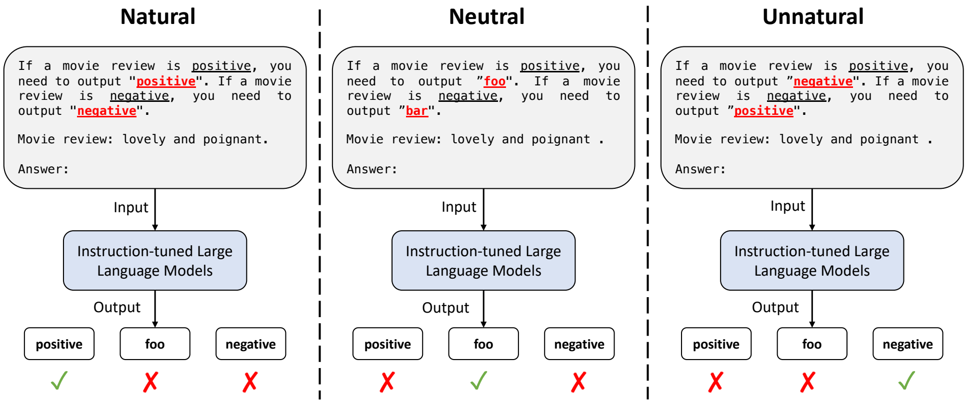

Figure 1: An illustrative example to construct instructions aligning with model priors to different extents, from *natural* (left), to *neutral* (middle), to *unnatural* (right) through verbalizer manipulation for movie review sentiment classification. Levels in terms of aligning with prior knowledge are ranked as *natural* > *neutral* > *unnatural*.

instructions, we select multiple verbalizers that are semantically irrelevant to given tasks. In *unnatural* instructions, verbalizers are flipped from their counterparts in *natural* instructions and contradict with prior knowledge. For example, in a movie review sentiment analysis task, we can use verbalizer "positive|negative", "1|0"[3], "yes|no" for movie review with positive/negative sentiment to create three sub-evaluation sets for the same dataset in *natural* instructions. The same method can be also used to create multiple sub-evaluation sets for the same dataset in *neutral* and *unnatural* instruction as well. The levels in terms of aligning with prior knowledge of these three instruction groups are ranked as *natural* > *neutral* > *unnatural*. By controlling the level of alignment with prior knowledge and ruling out other factors, we are able to systematically and automatically evaluate the instruction-following capabilities of instruction-tuned models with minimal human efforts.

We evaluate four different model families across various model sizes, namely, Flan-T5 (Wei et al., 2022a), GPT-Series (Ouyang et al., 2022; OpenAI, 2023), Vicuna (Chiang et al., 2023) and OPT-IML (Iyer et al., 2022), on nine benchmark datasets: curated instruction evaluation sets via verbalizer manipulation. First, we compare model performance on *natural*, *neutral* and *unnatural* instructions. We find that larger instruction-tuned models often perform better on both *natural* and *neutral* instructions. Although performance on *neutral* instructions is worse than on *natural* instructions for small models, their performance gap tends to be smaller when model scales and can be (almost) closed for strong OpenAI davinci-003, ChatGPT and GPT-4. On the contrary, the performance of different model families diverge significantly on *unnatural* instructions and there is no clear and consistent trend across model families, showing their significant differences in the ability to follow instructions. Overall, these results indicate that although scaling is an effective way to improve instruction-following ability, it may not be enough when instructions contradict prior knowledge.

Second, we examine verbalizers one by one in both *natural* instructions and their verbalizer-flipped counterparts in *unnatural* instructions. We find that models are not sensitive to verbalizers in *natural* instructions. However, in *unnatural* instructions, performance of the same model diverges significantly and when model further scales, they exhibit scaling-shape (Kaplan et al., 2020) or U-shape (Wei et al., 2022b) or inverse scaling-shape (McKenzie et al., 2022) depending on model family and verbalizers. Even strong ChatGPT and GPT-4 only perform similarly to random guessing when flipped golden label names are used as verlizers in *unnatural* instructions, showing that there still exist fundamental limitations of these models to follow instructions when instructions contradict their prior knowledge.

Finally, we explore whether zero-shot chain of thought (zero-shot-CoT) prompting (Kojima et al., 2022) can improve model performance in *unnatural* instructions that utilize flipped golden label names as verbalizers. We find that although it is helpful when model scales, there still exist large performance gaps compared to corresponding re-

---

[3] Different from Wei et al. (2023b), we hypothesize that "1"/"0" align more with "positive"/"negative", respectively, during pre-training or instruction-tuning. This hypothesis is supported by our results on small models in Section 4.2.

sults in *natural* instructions. Only strong ChatGPT and GPT-4 can outperform random guessing while other three model families (Flan-T5, Vicuna, OPT-IML) consistently perform worse than random guessing baseline. In a nutshell, when model scales to larger sizes, they still have difficulty in following instructions contradicting to prior knowledge even though they are allowed to output intermediate reasoning steps. We hope that our work can inspire future research to focus more on instruction-following capability.

2 Related Work

Instruction-tuned Large Language Models. Large language models have revolutionized the field of NLP and they can perform well in many NLP tasks without any parameter update by only being given several demonstrations in their prompts (Brown et al., 2020). These models are pre-trained with next token prediction or other pre-training objectives, and hence, may not be good at following instructions from humans (Ouyang et al., 2022). To bridge this gap, there have been growing interests in NLP community to train models that can follow human instructions. Mishra et al. (2022); Wei et al. (2022a); Iyer et al. (2022); Sanh et al. (2022) collect standard NLP datasets, write templates for them and transform them into text-to-text format (Raffel et al., 2020) and show that models can generalize to unseen tasks if they are trained on many seen tasks. Chung et al. (2022) studies the scaling effects of instruction-tuning and systematically study what factors are important for unseen test generalizations. Longpre et al. (2023) further finds that task balancing and enrichment techniques are important for instruction-tuning. This line of work mainly focuses on standard NLP tasks and does not reflect how language models are used in many real-world applications (Ouyang et al., 2022). To bridge this gap, Ouyang et al. (2022) collects instructions from humans including their customers to train an instruction-following models like ChatGPT and has achieved remarkable successes. However, collecting large-scaling instruction-following data is time-consuming and expensive, and researchers have been working on utilizing ChatGPT-like models as data generators or human-in-the-loop to generate instruction-following data. Taori et al. (2023) utilizes GPT 3.5 to generate 52K instruction-following data and uses it to train Alpaca. Xu et al. (2024) further explores to evolve instructions from Alpaca (Taori et al., 2023) to generate more complicated instruction-following data to train WizardLM. However, both Alpaca and WizardLM only utilize single-turn data. To alleviate this issue, Xu et al. (2023) utilizes ChatGPT to chat with itself to generate high-quality conversations to train Baize. Chiang et al. (2023) train Vicuna with ShareGPT dialogue data, which are multi-turn conversation dialogues between human users and ChatGPT.

Language Model Evaluation. Language models before the era of instruction-tuning (Devlin et al., 2019; Liu et al., 2019; Raffel et al., 2020; Brown et al., 2020) mainly focus on perplexity[4] or results on standard benchmark datasets (Wang et al., 2019b,a), as well as challenging test sets focusing on robustness or generalization (Ribeiro et al., 2020; Yan et al., 2022). However, as models become more and more capable in the era of instruction-tuning, they become harder and harder to evaluate. Hendrycks et al. (2021) collects MMLU dataset including elementary mathematics, US history, computer science, law, etc., to measure knowledge and problem solving capabilities of language models. Liang et al. (2023) instead proposes HELM, a framework to comprehensively evaluate their reasoning, knowledge, robustness, fairness, etc. Chia et al. (2023) introduces InstructEval to comprehensively evaluate instruction-tuned language models. Recently, there have been growing interests in leveraging GPT-4 to evaluate weaker language models (Xu et al., 2024, 2023) although it has been found to be unfair (Wang et al., 2023). However, this line of work mainly focuses on evaluating their general capabilities. Instead, our work focuses on automatic instruction-following evaluation with minimum human efforts. There have been several works sharing a similar focus as ours. Min et al. (2022) finds demonstration with random labels often have comparable performance than using golden labels. We instead focus on instruction-only setting without any demonstration where models are instructed to output specific label names according to their golden labels. Si et al. (2023) measures the inductive biases of large language models via different features, we instead focus on the same task but manipulate different verbalizers to evaluate their instruction-following capability. Webson and Pavlick (2022) finds that models tend to be sensitive to templates and verbalizes for natural

---

[4] `https://paperswithcode.com/sota/language-modelling-on-wikitext-2`

language inference (NLI) tasks for small models while our work goes beyond NLI and finds sufficiently large models can perform similarly under different verbalizers. Even when label names are flipped, they can still perform very well under certain tasks, e.g. sentiment classification. The closest work to ours are probably Jang et al. (2023), Wei et al. (2023b) and Wei et al. (2023a). Jang et al. (2023) evaluates instruction-tuned language models with negated prompts while our work utilizes verbalizer manipulations from different groups to control the level of alignment with prior knowledge to follow instructions and have different conclusions. Wei et al. (2023b) finds that large instruction-tuned language models can strengthen their priors and cannot effectively learn to flip labels from given demonstrations. We instead show that if instructions are provided, they do have the ability to flip labels for some tasks due to their strong instruction-following capabilities. Wei et al. (2023a) proposes symbol tuning to force models to learn in-context by changing their label names with symbols to better leverage examples in demonstrations while our work aims to utilize verbalizer manipulation to evaluate the instruction-following capabilities of large language models. Contemporary to our work, Wu et al. (2023) evaluates models' task-level generalizablity by manually designing counterfactual task variants. On the contrary, we propose verbalizer manipulation as a unified evaluation protocol that can be applied to any classification tasks with minimum human efforts.

3 Experimental Setup

3.1 Datasets

We conduct experiments on nine different binary classification benchmark datasets[5]. Specifically, we utilize **SST-2** ((Socher et al., 2013); Movie review sentiment classification), **FP** ((Malo et al., 2014); Financial phrase sentiment classification), **EMOTION**((Saravia et al., 2018); Twitter message emotion classification), **SNLI** ((Bowman et al., 2015); Stanford natural language inference), **SICK** ((Marelli et al., 2014); Sentence pair entailment analysis), **RTE** ((Dagan et al., 2006); Textual entailment recognition), **QQP** ((Chen et al., 2017); Quora question duplicate detection), **MRPC**((Dolan and Brockett, 2005); Paraphrase identification) and **SUBJ** ((Conneau and Kiela, 2018); Subjective/objective movie description classification). For each dataset and each verbalizer, we use 100 examples to construct our evaluation sets. We defer more details to Appendix B.

3.2 Verbalizer Manipulation

For each dataset, we have an instruction template to manipulate its verbalizers. Our templates to manipulate labels for each dataset are deferred to Appendix C. Specifically, for each dataset in *natural* / *neutral* / *unnatural* instructions, we have multiple verbalizers, as shown in Table 1. For example, for SST-2, golden label names are "positive"|"negative" and in *natural* instructions, they will be mapped to "positive"|"negative", "1"|"0", "yes|no". In *neutral* instructions, they will be mapped to "foo"|"bar", "bar"|"foo", "sfo"|"lax", "lax"|"sfo", "lake"|"river","river"|"lake". In *unnatural* instructions, we map them to "negative"|"positive", "0"|"1", "no"|"yes". An illustrative example of three different instruction groups to manipulate verbalizers for SST-2 dataset is shown in Figure 1. For each dataset and each verbalizer (mapping), we generate an evaluation set variant, leading to 2700 examples (9 datasets × 3 mappings × 100 examples/dataset) in both *natural* and *unnatural* instructions, and 5400 examples (9 datasets × 6 mappings × 100 examples/dataset) in *neutral* instructions.

3.3 Instruction-tuned Models

We evaluate state-of-the-art instruction-tuned large language models, namely Flan-T5, GPT-Series, Vicuna and OPT-IML, on datasets in Section 3.1 via verbalizer manipulation in Section 3.2 across various model sizes. For Flan-T5, we evaluate its `small` (80M), `base` (250M), `large` (780M), `xl` (3B) and `xxl` (11B) versions. For GPT-Series, we evaluate `text-ada-001` (ada), `text-babbage-001` (babbage), `text-curie-001` (curie), `text-davinci-003` (davinci), ChatGPT and GPT-4 via official OpenAI APIs[6]. For Vicuna, we evaluate its 7B (`vicuna-7b-1.1`) and 13B (`vicuna-13b-1.1`) versions. For OPT-IML, we utilize its 1.3B (`opt-iml-max-1.3b`) and 30B (`opt-iml-max-30b`) versions (Iyer et al., 2022)). Since our work focuses on evaluating instruction-

---

[5] Our method can also be used in multi-class classification problems as long as one clarifies how golden labels are manipulated in the instruction. For simplicity, we focus on binary classification tasks in this work.

[6] For experiments in the main body of the paper, we used `gpt-3.5-turbo-0301` for ChatGPT and `gpt-4-0314` for GPT-4, respectively.

Dataset	**Golden label name**	**Natural**	**Neutral**	**Unnatural**
SST-2	positive negative	positive, 1, yes negative, 0, no	foo, bar, sfo, lax, lake, river bar, foo, lax, sfo, river, lake	negative, 0, no positive, 1, yes
FP	positive negative	positive, 1, yes negative, 0, no	foo, bar, sfo, lax, lake, river bar, foo, lax, sfo, river, lake	negative, 0, no positive, 1, yes
EMOTION	joy sadness	joy, 1, yes sadness, 0, no	foo, bar, sfo, lax, lake, river bar, foo, lax, sfo, river, lake	sadness, 0, no joy, 1, yes
SNLI	entailment contradiction	entailment, 1, yes contradiction, 0, no	foo, bar, sfo, lax, lake, river bar, foo, lax, sfo, river, lake	contradiction, 0, no entailment, 1, yes
SICK	entailment contradiction	entailment, 1, yes contradiction, 0, no	foo, bar, sfo, lax, lake, river bar, foo, lax, sfo, river, lake	contradiction, 0, no entailment, 1, yes
RTE	entailment not entailment	entailment, 1, yes not entailment, 0, no	foo, bar, sfo, lax, lake, river bar, foo, lax, sfo, river, lake	not entailment, 0, no entailment, 1, yes

Table 1: Golden label name mapping for verbalizer manipulation in three different groups.

following capability, we focus on instruction-only setting without any demonstration. We explore the effect of adding few-shot demonstrations in Appendix A. For all experiments, we set temperature as 0 during decoding. We parse predictions from decoded strings and use accuracy (%) as the evaluation metric.

4 Experimental results

4.1 Results on Instructions with Different Naturalness

We evaluate four model families in Section 3.3 on *natural*, *neutral* and *unnatural* instructions and report results for each instruction group that are averaged over datasets and verbalizers. Results are shown in Figure 2.

Larger models generally perform better on both *natural* and *neutral* instructions. For Flan-T5, GPT-series[7] and OPT-IML, we find that model performance improves as they scale to larger sizes on both *natural* and *neutral* instructions. These results are encouraging since it seems that larger models can have better instruction-following capabilities even though instructions do not align with prior knowledge on *neutral* instructions. Further comparing model performance on *natural* and *neutral* instructions, we find that smaller models (model size $\leq$ 30B) perform worse on *neutral* instructions. These performance gaps indicate that smaller models still have difficulty in following instructions. However, their performance gap tends to be smaller when model scales and can be (almost) closed for strong OpenAI davinci, ChatGPT and GPT-4, demonstrating their strong instruction-following capabilities. These results show that simply scaling model size is an effective method to improve model instruction-following capabilities.

Different model families diverge significantly on *unnatural* instructions. Although larger models generally perform better on both *natural* and *neutral* instructions, this is not true for *unnatural* instructions. Different model families diverge significantly on *unnatural* instructions and there is no clear and consistent trend across model families. For Flan-T5, results are U-shaped when model scales (Wei et al., 2022b), while for OPT-IML, results follows inverse scaling-shape (McKenzie et al., 2022). In fact, results on these two model families are significantly worse than random guessing (50%). Although Vicuna and GPT-Series follow scaling-shape (Kaplan et al., 2020), their performance still has large gaps compared to results on *natural* instructions, and these gaps seem not to be smaller when they scale. For example, the performance gap for ChatGPT is 11.8% while stronger GPT-4 has 15.7%, making it unclear if further scaling them can bridge this performance gap. This is surprising since these clear and valid instructions can be easily followed by humans but remain difficult for GPT-4, which has shown near human-

---

[7] Since exact model sizes in GPT-Series are unknown for some of them, we assume that ada $\leq$ babbage $\leq$ curie $\leq$ davinci $\leq$ ChatGPT $\leq$ GPT-4.

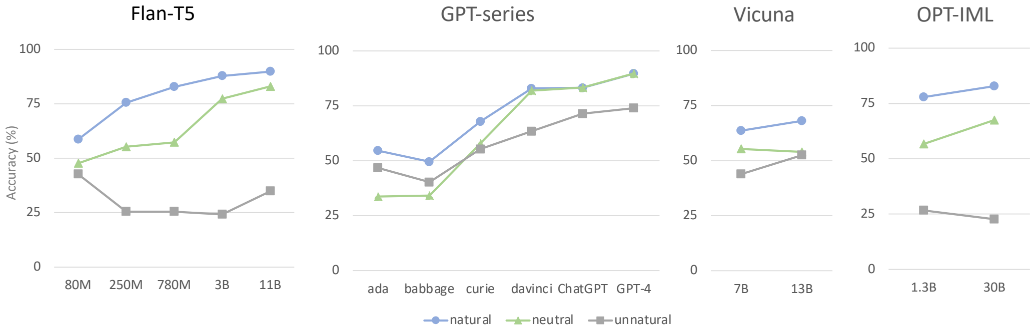

Figure 2: Results comparison under *natural*, *neutral* and *unnatural* instructions across different model families.

level performance on many tasks (Bubeck et al., 2023). Overall, these results indicate that although scaling is an effective way to improve instruction-following, it does not seem to be enough when instructions contradict prior knowledge.

4.2 Results of Different Verbalizers in Natural and Unnatural Instructions

Previous discussions focus on average results across different verbalizers for each instruction group. However, it is possible that verbalizers even in the same instruction group align or contradict with prior knowledge differently. For example, it is hard to know if "yes" aligns with prior knowledge more than "1" in SST-2 dataset for *natural* instructions with positive golden labels. Therefore, we further delve into the results of different verbalizers for *natural* instructions and its flipped version in *unnatural* instructions. Average results over nine different datasets are summarized in Figure 3.

Models perform similarly for different verbalizers in *natural* instructions. We find that models across four families perform similarly for different verbalizers in *natural* instructions and larger models often perform better than their smaller counterparts. However, we do observe that verbalizers where models perform the best may change in different model sizes and families. For example, for Flan-T5 780M, *natural-golden verbalizers* $>$ *natural-1*$|$*0* $>$ *natural-yes*$|$*no* while for Flan-T5 11B, the order is reversed. In addition, for Vicuna, the best performing verbalizer is *natural-1*$|$*0*, while for OPT-IML, *natural-golden verbalizers* performs better. These results show different models can have different prior knowledge. However, for strong davinci, ChatGPT and GPT-4, their differences are almost not noticeable. This is non-trivial since larger models often have a better understanding about world knowledge and hence store more prior knowledge (Wei et al., 2023b). More consistent results on larger models again show that scaling is an very important factor for instruction-following capability.

Models diverge significantly for different verbalizers in *unnatural* instructions. Although previous discussion has shown that models perform similarly for different verbalizers in *natural* instructions, results on their flipped verbalizers in *unnatural* instructions show that they diverge significantly. In Figure 3, we find that verbalizers in *unnatural* group shows very different behaviors when they scale and this behavior also changes in different model families. For example, on *unnatural-no*$|$*yes* and *unnatural-0*$|$*1*, Vicuna achieves better performance when model sizes are larger but degrades on *unnatural-flipped golden verbalizers*. However, for OPT-IML on *unnatural no*$|$*yes*, model performance decreases when it scales to be larger. These results further strengths our finding that different models can have different prior knowledge. On the other hand, it also shows that scaling is not the only factor influencing instruction following although it is important. Further more, we find that for the largest model in each family, performance is ranked as *unnatural 0*$|$*1* $>$ *unnatural no*$|$*yes* $>$ *unnatural-flipped golden verbalizers*. These results show that although they may have different prior knowledge, the difficulty level of overriding their prior knowledge to follow instructions seems consistent. Finally, we find that even the best ChatGPT and GPT-4 only perform similar to random guessing, showing that these models still have fundamental limitations to follow instructions when instructions contradict to their prior knowledge.

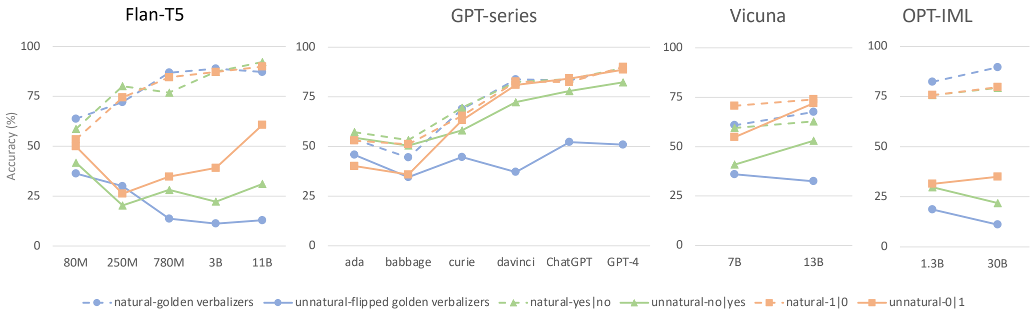

Figure 3: Results of different verbalizers in *natural* and *unnatural* instructions.

4.3 Results Comparison between Direct and Zero-Shot Chain-of-Thought Prompting

Previous results have shown that even the best ChatGPT and GPT-4 only perform similar to random guessing on *unnatural-flipped golden verbalizers* and these results are obtained via direct prompting. In this subsection, we further explore if outputting chain-of-thought (CoT) (Wei et al., 2022c) on *unnatural-flipped golden verbalizers* evaluation subset can make models perform better. Therefore, we design another template for each dataset and add *Let's think step by step.* in the prompt following Kojima et al. (2022). We summarize results on *natural-golden verbalizers* and *unnatural-flipped golden verbalizers* via direct prompting, and *unnatural-flipped golden verbalizers* via zero-shot CoT in Figure 4.

For Vicuna and OPT-IML, inverse scaling-curves in *unnatural-direct prompting* become scaling curves in *unnatural-zero shot CoT* prompting. For Flan-T5, results are much more U-shaped in *unnatural-zero shot CoT* compared to those in *unnatural-direct prompting*. Further more, ChatGPT and GPT-4 can significantly outperform random guessing in *unnatural-zero shot CoT* prompting while their counterparts in *unnatural-direct prompting* only have similar performance to random guessing. This is encouraging since it shows that scaling is an effective method to improve instruction-following capabilities along with more advanced prompting techniques. However, they still show large performance gaps compared to results under *natural-direct prompting* setting. For example, Flan-T5 11B, Vicuna 13B and OPT-IML 30B still significantly underperform random guessing. Even strong ChatGPT still has 16.8% accuracy gap to *natural-direct prompting* and for GPT-4, this gap is surprisingly larger and becomes 24.3%. In a nutshell, zero-shot CoT prompting can make models better instruction-followers when instructions contradict prior knowledge, but the models still have a large performance gap with instructions that align with prior knowledge.

4.4 Per Dataset Analysis

The previous subsection focuses on average results across different datasets and only ChatGPT and GPT-4 can outperform random guessing on *unnatural* instructions with flipped golden verbalizers in zero shot CoT prompting. In this subsection, we further delve into each dataset by comparing their results using direct prompting with golden verbalizers in *natural* instructions, direct and zero shot CoT prompting with flipped golden verbalizers on *unnatural* instructions. We group results of datasets according to their tasks (e.g., EMOTION, FP and SST-2 are sentiment classification datasets) and results are shown in Figure 5.

ChatGPT and GPT-4 perform comparably on majority of datasets in both *natural* and *unnatural* instructions. ChatGPT performs similarly on majority of datasets (6/9, 6/9) compared to GPT-4 ($\leq$ 10% performance gap) on both *natural* and *unnatural* instructions, respectively. GPT-4 outperforms ChatGPT $>$ 10% on RTE and SUBJ in *natural* settings but underperforms it in *unnatural* setting. Another outlier dataset is MRPC, where GPT-4 outperforms ChatGPT 13% and 53% in *natural* and *unnatural* setting, respectively. Overall, these results show that they share more similarity than difference via direct prompting.

ChatGPT and GPT-4 retain performance on sentiment classification task in *unnatural* direct prompting compared to *natural* counterpart but drop significantly on natural language inference task. Surprisingly, we find that ChatGPT and GPT-4 can retain their performance on sentiment classification task (FP, EMOTION, SST-2) but drop significantly on natural language inference (NLI)

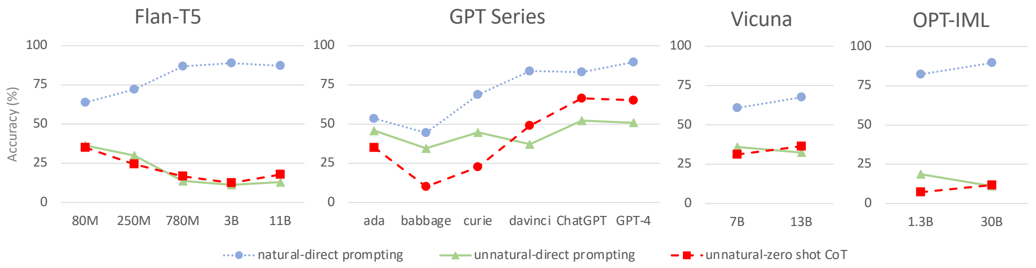

Figure 4: Results comparison between natural-direct prompting with golden verbalizers, unnatural direct prompting and unnatural zero-shot chain-of-thought prompting with flipped golden verbalizers.

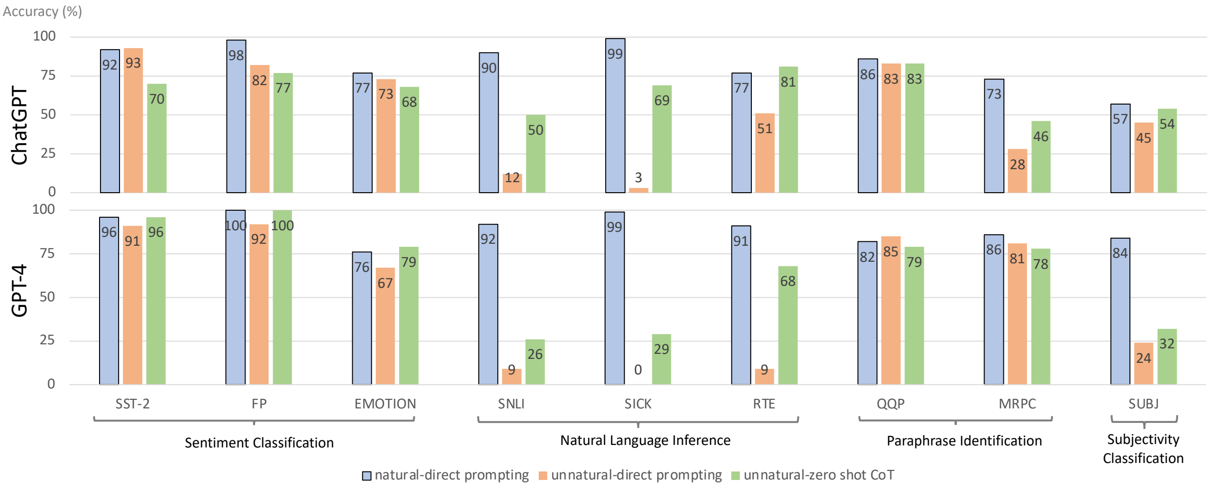

Figure 5: Results comparison between natural-direct prompting with golden verbalizers, unnatural direct and zero-shot chain-of-thought prompting with flipped golden verbalizers for each dataset on ChatGPT and GPT-4.

task (SNLI, SICK, RTE). As an example, on SST-2, ChatGPT outperforms 1% and GPT-4 only decreases 5% with *unnatural* direct prompting while for SICK, ChatGPT and GPT-4 decrease 96% and 99%, respectively. We hypothesize that the discrepancy is because sentiment classification requires less reasoning while NLI requires more, making flipping golden verbalizers much more difficult. One may wonder if they show similar trend on other tasks. For paraphrase identification task, QQP has similar performance after verbalizer flipping for both ChatGPT and GPT-4 while for MRPC, only ChatGPT drops a lot and GPT-4 retains its performance. This result shows that task can be an important factor but not the only one. Models can be sensitive to data distribution.

ChatGPT and GPT-4 with unnatural-zero shot CoT improve significantly in NLI task but it has much less effect on sentiment classification. Both ChatGPT and GPT-4 with *unnatural-zero shot CoT* improve significantly in NLI datasets, and ChatGPT can outperform GPT-4 after zero-shot CoT. On the other hand, *unnatural-zero shot CoT* has much less effect on sentiment classification task and even hurts performance across three datasets for ChatGPT. This is probably because unnatural-zero shot CoT is mainly useful for reasoning tasks and sentiment classification requires much less reasoning compared to NLI tasks, making zero shot CoT less useful.

5 Conclusion

In this paper, we design a framework to evaluate the instruction-following capabilities of instruction-tuned language models via verbalizer manipulations. We design three instruction-following evaluation sets, namely *natural*, *neural* and *unnatural* instructions, which align with prior knowledge to different extents. We evaluate four different model families on nine datasets across scales. Our results show that although larger instruction-tuned models generally perform better on both *natural* and *neutral* instructions, their performance diverges significantly in *unnatural* instructions. We further examine verbalizers one by one in *unnatural* instructions, and find that the same model family performs significantly different on instructions with different verbalizers, even with more advanced zero shot CoT prompting. These results show there still exist fundamental limitations within state-of-the-art instruction-tuned large language models in following human instructions. We hope that our work can inspire future research to focus more on instruction-following capabilities.

Limitations

This paper acknowledges certain constraints and identifies avenues for subsequent research endeavors. Firstly, while we aimed for comprehensive assessments across all models, constraints in resources prevented the examination of larger language models like Llama 2 70B, Bard, and Claude. Secondly, our current evaluations are centered on classification tasks; future investigations may explore the application of verbalizer manipulation within generative tasks. Thirdly, the present study is limited to the English language; we intend to broaden our analysis to include multiple languages in future research. Lastly, the OpenAI API is non-deterministic, which may lead to different results for the same input.

Ethics Statement

For the acquisition of various verbalizers, our approach did not involve the utilization of human annotations; rather, we developed the mapping rules ourselves. Although it is improbable, there is still a chance that these self-devised mapping rules might contain latent biases. During an initial analysis, we detected no instances indicative of such biases. Nevertheless, the possibility of these unintended biases is significant and warrants attention for a more meticulous and in-depth future analysis.

A Results Comparison between Zero-Shot and Few-Shot Prompting

Verbalizer	Natural		Unnatural	
Prompting	zero-shot	4-shot	zero-shot	4-shot
ChatGPT	81.8	85.1$_{(\uparrow\mathbf{3.3})}$	52.1	56.4$_{(\uparrow 4.3)}$
GPT-4	89.4	91.7$_{(\uparrow 2.3)}$	58.4	88.4$_{(\uparrow\mathbf{30.0})}$

Table 2: Averaged accuracy comparison between zero-shot prompting and 4-shot prompting with natural golden verbalizers and unnatural flipped golden verbalizers for each dataset on ChatGPT and GPT-4.

Besides plain task instruction, in-context demonstrations also help the model to understand the task. In this section, we explore adding few-shot demonstrations in addition to plain task instruction for improving the model performance in following instructions. Specifically, we evaluate the best-performing ChatGPT and GPT-4 models[8] with *natural-golden verbalizers* and *unnatural-flipped golden verbalizers*. We compare the model performance using zero-shot prompting and 4-shot prompting. The four demonstrations in 4-shot prompting are drawn from corresponding training sets and have balanced label distribution. They demonstrate the expected behaviors of following the specified verbalizers to complete the tasks. We fix the demonstrations for each dataset. In Table 2, we show the averaged accuracy across nine evaluation datasets. We show the per-dataset results in Figure 6. We find that on natural verbalizers, few-shot prompting shows marginal improvement over zero-shot prompting. On unnatural verbalizers, ChatGPT benefits little from few-shot demonstrations on most datasets. However few-shot demonstrations significantly boost the performance of GPT-4, almost closing the gap between natural and unnatural verbalizers. This suggests that GPT-4 has stronger in-context learning abilities than ChatGPT under the unnatural verbalizers. It implies that the in-context learning abilities of the models can also be better distinguished when evaluating with tasks that do not align with models' prior knowledge.

B Dataset Preprocessing

For each dataset, we utilize their available versions in Huggingface Datasets (Lhoest et al., 2021). Specifically, for FP and EMOTION, we choose their SENTENCES_ALLAGREE and SPLIT subsets, respectively. For FP dataset, as it only has training set, we randomly split it into 80/20 as our in-house training/test set. In addition, for FP, EMOTION, SICK and SNLI datasets, they have multiple classes and we only choose examples whose corresponding labels are shown in Table 1. For SST-2, QQP, RTE and MRPC within GLUE benchmark (Wang et al., 2019b), we randomly sample 100 examples for each dataset from their validation sets while for other five datasets, we randomly sample 100 examples for each dataset from their test sets.

C Prompt Template

Our instruction templates for verbalizer manipulation in direct prompting setting and zero-shot chain-of-thought prompting is shown in 7 and 8, respectively. Fields with red colors are replaced with verbalizers in Table 1 and fields with blue color will be substituted with input examples in each dataset in text format.

---

[8] Due to the deprecations of old models by OpenAI, the experiments in this section were performed with `gpt-3.5-turbo-0125` for ChatGPT and `gpt-4-0613` for GPT-4, respectively.

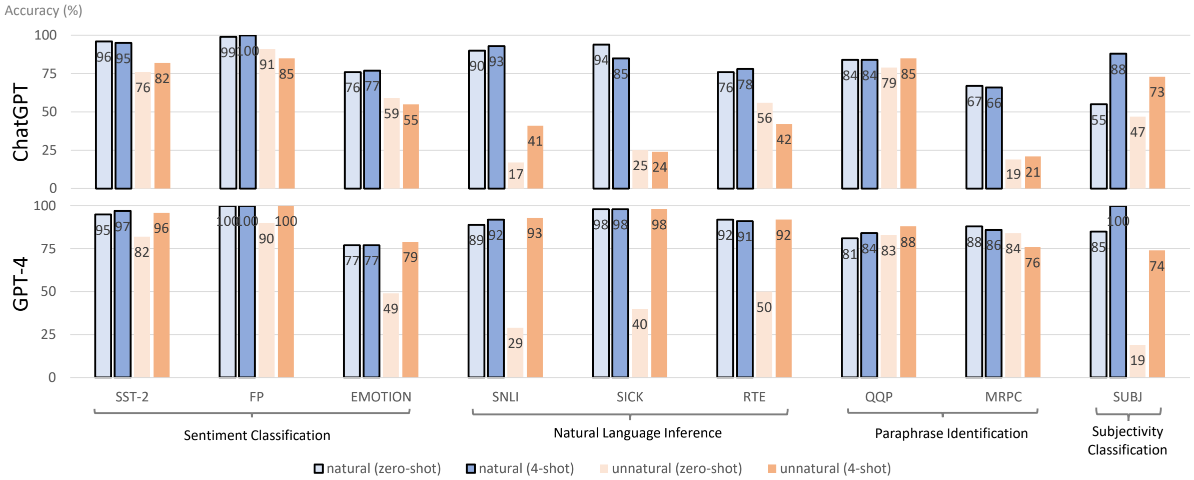

Figure 6: Per-dataset accuracy comparison between zero-shot prompting and 4-shot prompting with natural golden verbalizers and unnatural flipped golden verbalizers for each dataset on ChatGPT and GPT-4.

Abstract

This paper investigates using Large Language Models (LLMs) to automatically perform web software tasks using click, scroll, and text input operations. Previous approaches, such as reinforcement learning (RL) or imitation learning, are inefficient to train and task-specific. Our method uses filtered Document Object Model (DOM) elements as observations and performs tasks step-by-step, sequentially generating small programs based on the current observations. We use in-context learning, either benefiting from a single manually provided example, or an automatically generated example based on a successful zero-shot trial. We evaluate our proposed method on the MiniWob++ benchmark. With only one in-context example, our WebWISE method using gpt-3.5-turbo achieves similar or better performance than other methods that require many demonstrations or trials.

1 Introduction

A major goal of AI is to develop intelligent agents that interact with their environments to perform tasks. This goal is often explored in the context of physical environments. Our work explores performing software tasks with the long-term aim of creating agents that work using software designed for humans. Software tasks are valuable by themselves — much of the work we do is on computers — and also offer highly controllable and repeatable tasks that have many of the same challenges as physical tasks, such as manipulable environments, goals that require long sequences of actions, and need for exploration. Prior works to control software have used reinforcement learning (RL), requiring many demonstrations and scored trials to learn simple interaction tasks. Instead, we use Large Language Models (LLMs) to generate actions (e.g., click and enter text) based on environment observations (DOM elements) in web software.

The goal is to complete a web software task, given a natural language instruction and an API for observing and interacting with the environment. In this setting, our observations are DOM elements, indicating the layout and state of buttons, text, and other displayed elements. Actions include clicking an element, scrolling the mouse wheel, and entering text in a text box. The experiments are performed on the MiniWoB++ benchmark (Liu et al., 2018), which consists of randomized simple tasks that involve menu navigation, text entry, and/or clicking buttons and other interactive elements.

LLMs are commonly used to generate code, e.g., Codex (Chen et al., 2021), and their use has recently been explored to complete AI tasks given an API and a small number of in-context examples, e.g., VisProg (Gupta and Kembhavi, 2023), ViperGPT (Surís et al., 2023), ProgPrompt (Singh et al., 2023), Code4Struct (Wang et al., 2023), and Vi-Struct (Chen et al., 2023). Our application of controlling software differs in two key ways:

- **Environment Grounding**: Interacting with software requires knowledge of the environment, such as the layout of elements on the screen. For automatic interaction with web software, we propose to extract and filter pertinent information from the DOM elements as the environmental observations.
- **Sequential Decision-Making**: As the environment responds dynamically to actions, we take a sequential approach to generate actions rather than creating an entire actions sequence all at once. This allows us to generate actions informed by current observations while maintaining previous action-observation pairs.

An additional challenge is how to train LLMs to better control software. This study limits the focus

```
action = click_action1 ('input_checkbox', 'i8J', observation)
observation, reward, terminated, truncated, info = env.step(action)
....
```

Figure 1: We show the path of an agent in the WebWISE method. The representation of the components in the diagram is as follows: yellow boxes represent inputs to the LLM, the gray box represents executor, Unshaded red/green boxes symbolize final rewards/output, and shaded green boxes denote Python functions.

to in-context learning. One option is to manually create examples of programs that satisfy instructions, but this requires some level of expertise and experimentation to be effective. Observing that the LLMs occasionally produce successful programs for specific tasks sometimes (rather than always or never), we propose using these successes as a form of context. This way, LLMs can create its own context using only a success indicator.

In this paper, our **main contribution** is to investigate the use of LLMs to control web software, particularly:

- Use of filtered DOM elements as web software observations, which we find outperforms more comprehensive read-outs.
- Effects of an iterative approach of cycling action and observation, which we show outperforms one-shot generation of an action sequence.
- Auto-generating context based on successful zero-shot trials, that outperforms zero-shot performance in many cases and requires no programming or knowledge of the control API.

2 Related Work

2.1 Automated Computer Tasks

Most methods for automating computer tasks use some form of RL. Common approaches, including Q-Learning (Jia et al., 2019), imitation learning (Yao et al., 2022), and policy learning and behavioral cloning (Zheng et al., 2021) have achieved human-level performance on the web interface benchmark MiniWob++ (Liu et al., 2018). Other approaches, such as (Humphreys et al., 2022; Zhong et al., 2022), combine RL with other modalities. CCNet (Humphreys et al., 2022) is a multimodal architecture specifically designed for automating software and is trained using a combination of RL and imitation learning. Language Dynamics Distillation (Zhong et al., 2022) is pretrained by predicting environment information and fine-tuned with RL. WebGUM (Furuta et al., 2023) is trained by combining finetuning for an instruction-finetuned model with a vision encoder on a large number of demonstrations. While these methods work well, they often require thousands of demonstrations and/or millions of trials. We investigate the use of LLMs with only a single in-context example per type of task, towards creating an approach that can be easily extended and adopted.

2.2 Reasoning and Action in Large Language Models

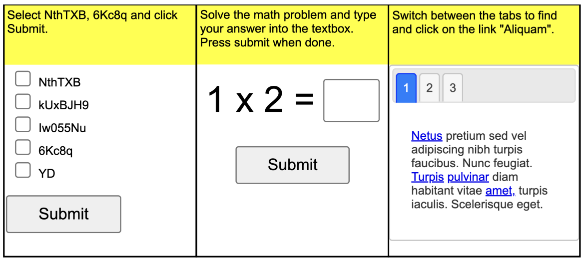
Recent efforts explore applying LLMs to decision-making (Mialon et al., 2023) and reasoning (Huang and Chang, 2023). Initial work focused on how to convert natural language output to admissible actions (Huang et al., 2022a). Huang et al. use a Bert LM (Devlin et al., 2019) model pre-trained with SentenceBert (Reimers and Gurevych, 2019) to directly convert the output of GPT-3 (Brown et al., 2020) to an executable action. SayCan (Ahn et al., 2022) uses an alternative approach where for each action, the probability of generating that action using a language model is multiplied by the action's value function. Inner Monologue (Huang et al., 2022b) builds on SayCan (Ahn et al., 2022) by introducing feedback from the environment. Unlike these approaches, our web environment is much simpler, and we found that with specific prompting, we can convert natural language output to an appropriate action. Prompting, in particular chain-of-thought prompting, has been used to demonstrate LLM's reasoning ability (Wei et al., 2022; Kojima et al., 2022; Nye et al., 2021). A related area of research combines combining reasoning and decision-making skills into one method. SayCan (Ahn et al., 2022) and Inner Monologue (Huang et al., 2022b) are both early examples of such a combination. ReAct (Yao et al., 2023) expands these works by adding language (generated by an LLM) to the list of possible actions. After each action is executed, a thought (language action) is generated based on the previous action and environment. Reflexion (Shinn et al., 2023) builds upon ReAct (Yao et al., 2023) by allowing access to previous actions and states.

2.3 Visual Programming

In this work, we leverage LLMs' program generation ability (Chen et al., 2021) to control web-based software. VISPROG (Gupta and Kembhavi, 2023) introduces the idea of visual programming, where programs call APIs to interpret and transform images using pre-trained models, solving tasks like image editing and Visual Question Answering (VQA). VISPROG was one of the first approaches demonstrating the capability of LLMs to solve a wide array of vision tasks effectively, serving as an inspiration for our work. VISPROG and related works (Surís et al., 2023; Wu et al., 2023; Gao et al., 2023; Wang et al., 2022) use prompts containing APIs, example programs, and instructions to guide LLMs in tasks like image editing and Visual Question Answering (VQA).

Visual programming methods produce impressive zero-shot results but are limited in that they generate one-shot programs without observing the image/environment. Our approach generates programs in multiple steps and uses DOM elements to summarize the visual input. Methods like HeaP (Sodhi et al., 2023) learn a set of hierarchical LLM prompts for planning high-level tasks and executing low-level policies. While HeaP is an innovative approach, it uses training data collected from users. Such a reliance might pose a challenge in scenarios where demonstrations are scarce or the tasks are highly dynamic and personalized. The approach 'Recursively Criticizes and Improves (RCI)' (Kim et al., 2023), a concurrent study, similarly employs LLMs for software interaction. RCI takes HTML as observations and incorporates up to 22 in-context examples. Moreover, their examples are specific to the variations of each task. In contrast, we focus on assessing the efficiency of in-context examples, providing only one per type of task.

3 MiniWob++ Benchmark



Select NthTXB, 6Kc8q and click Submit.

Solve the math problem and type your answer into the textbox. Press submit when done.

Switch between the tabs to find and click on the link "Aliquam".

Netus pretium sed vel adipiscing nibh turpis faucibus. Nunc feugiat. Turpis pulvinar diam habitant vitae amet, turpis iaculis. Scelerisque eget.

Figure 2: Screenshots of example tasks from MiniWob++ benchmark. Each task contains a natural language instruction at the top and a task interface to perform primitive actions in the bottom.

Our objective is to generate programs to control web interaction tasks. To evaluate the effectiveness of these generated programs, we use the MiniWob++ (Liu et al., 2018) benchmark that captures the salient challenges of browser interactions in a simple setting. This web-based simulation environment is an extension of MiniWob (Shi et al., 2017) originally introduced by OpenAI. The MiniWob++ benchmark contains more than 100 tasks of varying difficulty levels, and we chose 48 of those tasks to evaluate our methods on. Each MiniWob++ task contains a natural language instruction and an HTML/DOM representation of the web page containing the task. An agent can interact with MiniWob++ through the Selenium API. Successfully completed tasks receive a score of "1"; otherwise, they receive a score of "-1". We describe the actions we use in the section 4. A few of the tasks we selected for this study are shown in Figure 2.

4 Methods

This section describes our problem formulation and progressive layers to our approach: based on instruction alone, incorporating filtered DOM elements as observations, acting step-by-step, and auto-generating context. Figure 1 and Algorithm 1 show an overview of our full approach, which we call WebWISE.

Algorithm 1 WebWISE Function

```
procedure WebWISE(input Task Description $\mathcal{L}$, API $a$, in-context example $\mathbf{e} = e_1, \ldots, e_m$, program generator $\pi$, DOM elements $D_t$ )
    Initialize success state $s$ as False, iteration count $t$ as 0, maximum iterations as $T$
    while $s = False$ and $t < T$ do
        $d_t = getSummary(D_t)$                      ▷ Extract relevant DOM elements
        $x_t = \pi(\mathcal{L}, d_t, a, \mathbf{e})$   ▷ Generate program
        $s = \phi(x_t, d_t)$                          ▷ Execute program
        $D_{t+1} = getDOM()$                          ▷ Update DOM elements after execution
        $t = t + 1$
    end while
end procedure
```

4.1 Problem Formulation

Each task involves a virtual agent assigned to carry out high-level natural language instructions (task descriptions) denoted as $\mathcal{L}$. The agent must interact with the environment, which is initially represented by a set of observable DOM Elements D_t. A program generator π is employed to generate program $x_t = \pi(\mathcal{L}, d_t)$. The execution engine ϕ then applies the generated program through $\phi(x_t, d_t)$, resulting in success indicator s and updated DOM Elements D_{t+1}, representing the environment's next state. A maximum number of iterations T is set to limit the total number of iterations that the LLM can generate programs.

4.2 DOM Elements

The choice among DOM elements, HTML, and RGB values when interacting with a web interface largely hinges on the task's demands, the intricacy of the webpage, and the agent's capabilities. In this work, DOM elements were used due to their simplicity and structured nature. Models such as Pix2Struct(Lee et al., 2023) convert webpage screenshots into structured HTML when direct DOM access is not possible. The DOM elements allow the agent to engage directly with the page – clicking on elements, inputting text into form fields, reading text from the page, and so forth – and is generally simple to implement and comprehend. The full text of the DOM elements can contain items not crucial for a particular task, so we use a simple filtering function $getSummary$ that returns a subset of the current DOM elements that belong to a pre-defined list of "tags" and "classes". Further details are in the appendix.

4.3 Single-Step Approach

In the single-step approach, one program is generated and executed for a given task. We use gpt-3.5-turbo (Ouyang et al., 2022) and Llama-2 7B (Touvron et al., 2023) as our program generator π. The input to the LLM is a prompt with 4 parts: filtered DOM elements, API a, task description, and an in-context example e. Our API a has three basic functions: *click*, *enter text*, and *scroll*. Each executes actions within MiniWob++ (Liu et al., 2018). A summary of our API can be seen in Listing 1 and is constant across all tasks. A complete listing of our APIs is shown in the appendix Listing 7. Hand-crafted in-context examples were used like in GPT-3, which can be seen in Figure 17 in the appendix. A sample task input is given followed by the expected output program.

```
def getSummary(dom_elements):
    '''
    Input: DOM elements
    Output: Subset of DOM elements
    '''
def click_action1(tag_class_name,id_text_name,observation):
    '''
    Input: tag or element, id or text, observation
    Output: clicks on a specific element in the environment
    '''
def enter_text_action(input_text,observation):
    '''
    Input: text, observation
    Output: enters text in element in the environment
    '''
def scroll_action1(text_to_scroll_to,observation):
    '''
    Input: text, observation
    Output: moves webpage such that certain text is visible
    '''
```

Listing 1: Summary of our API

The generated program x_t is a string of Python code, executed using the execution engine ϕ. However, the code generated might not be executable or use the API a correctly. A regular expression is used to extract the executable code and filter the irrelevant parts of the generated output. If the generated code proves entirely unusable, this particular program is skipped, and the LLM will move to the next iteration of generating programs to solve this task. If usable code is identified, $\phi(x_t, d_t)$ will be executed, and the LLM will rely on the environmental feedback to determine whether the task has been successfully completed. The iterations con-

Task: Switch between the tabs to find and click on the link "magna".
Solution?

action = click_action1('a', 'Tab #3', observation)
observation, reward, terminated, truncated, info = env.step(action)

Switch between the tabs to find and click on the link "magna".

Amet. Nec urna amet. Purus suscipit vel amet, magna lacinia maecenas. Sit facilisis vel. Ut egestas scelerisque vestibulum et, id.

Objects in Image: [**ul**, **a** Tab #1, **a** Tab #2, **a** Tab #3, **t** Amet. Nec urna amet., **t** Purus suscipit vel, **span** amet, **span** magna, **t** lacinia, **span** maecenas., **span** Sit, **t** facilisis vel. Ut egestas, **t** scelerisque vestibulum, **span** et, **t** id.]
Task: Switch between the tabs to find and click on the link "magna".
Solution?

action = click_action1('span', 'magna', observation)
observation, reward, terminated, truncated, info = env.step(action)

Figure 3: An example of WebWISE for the 'click-tab' task. The objective is to click on link that is not present within the initial DOM elements. At each step, the environment updates, and a new program is generated based on the context. The left part of the image illustrates the step-by-step in-context example with fictional DOM elements and tasks. This example guides LLMs in generating a program for the current task interface, executing one action at a time. The middle and right parts of the image shows the task and solution generated by LLMs.

tinue until either the task is successfully completed (i.e., s = True), or the number of iterations reaches the predefined maximum ($t = T$).

4.4 Multi-Step Approach

Our multi-step method, referred to as WebWISE, is illustrated in Algorithm 1. In contrast to single-step generation, WebWISE generates and executes programs incrementally until the environment signals that the task has been solved correctly or incorrectly. If the task has not been solved after a particular number of iterations (T), the environment signals a failure (by returning -1). The DOM elements from the ith iteration becomes the initial DOM elements for the $(i+1)$th iteration. This approach is employed in both zero-shot and one-shot scenarios. In the zero-shot scenario, an additional instruction (task message) is provided to the LLMs, prompting it to generate programs progressively, based on changes in the DOM elements throughout the task. In the one-shot scenario, the in-context examples shift at each step, coupled with the additional instruction (task message) to 'perform in a step-by-step fashion', akin to the zero-shot scenario. Ablation studies concerning the sensitivity of the task messages are included in the appendix. Figure 3 illustrates an example of the WebWISE methodology. Conditioning the program generation on the current environment simplifies the execution of sequential tasks. This is because the model can observe the effect of its actions in the environment through the changes of DOM elements, and consequently generates more effective actions for the next step. In contrast, the single-step approach generates the entire program based on the initial set of DOM elements.

4.5 Automatic Generation of In-Context Examples From Scored Trials

Our empirical findings reveal improved success rates when an in-context example is provided. Each in-context example includes an observation, task description, and a program that would satisfactorily complete the task according to the task description. However, supplying such examples requires a comprehensive understanding of the API and programming proficiency, which can pose an obstacle for intricate tasks or novice users. Prompted by these challenges, we design a simple approach called Auto-Context Generation (ACG) to automatically generate an in-context example from a successful trial. To develop ACG, we conduct a series of zero-shot trials. In each trial, a program is generated and executed in the absence of any in-context examples. If the program executes the task correctly, it is stored, along with the original task description and filtered DOM elements, as the in-context example. After 10 zero-shot trials, the single-step approach (4.3) is applied for 50 iterations. The correctly generated programs during the trial stage serve as in-context examples, and only two such programs are preserved at maximum. When appending the in-context examples to the prompt, a specific statement:"*Here is one example you have solved with a successful solution.*" is also included. While our experiments use this fully automated approach, a user, in a practical context, may be able to guide the successful completion using feedback and prompts to acquire the in-context example.

5 Experiments and Results

All approaches (single-step, multi-step and Auto-Context Generation) are evaluated on 48 tasks derived from the MiniWob++ dataset (Liu et al., 2018). These tasks are chosen to span a range of complexities. Additionally, a variant of the single-step method, which excludes any DOM elements, is evaluated and labeled as the ‘Instruction Only’ method. The conventional single-step process is labeled as ‘Instruction+ Filtered DOM’ approach. We evaluate our methods using gpt-3.5-turbo and Llama 2 7B. However, we primarily focus on gpt-3.5-turbo as the model demonstrates significantly better performance.

5.1 Implementation details

For all experiments, the temperature was set to 0 and the input token limit was 4096 for the gpt-3.5-turbo with training data up to September 2021. We used the Llama-2 7B implementation from HuggingFace with 8-bit quantization on a single RTX 3090 Ti. The same prompt is applied at the beginning of each method, which can be found in the appendix material. In addition to evaluating each of the 48 tasks with a single in-context example ($k = 1$), we also evaluate the zero-shot setting ($k = 0$). Tasks are scored as follows: "1" for successful completion and "-1" for failure. For the ‘Instruction-Only’, ‘Instruction+DOM’, and ‘WebWISE’ (multi-step) approaches, we executed each task for 50 iterations and averaged the success over the 50 iterations. For the ‘Auto-Context Generation’ method, we initially carried out 10 zero-shot trials, followed by 50 iterations of the ‘Instruction+DOM’ (single-step) method.

5.2 Results

We categorized various tasks from the MiniWob++ dataset (Liu et al., 2018) based on the number of predefined function calls necessary to accomplish the task. The groups include tasks requiring 1 function, 2 functions, between 3 and 6 functions, and a variable number of functions. The detailed task classification is available in Appendix D.1.

Table 2 summarizes the average success rate of our proposed methods, and Table 3 compares our methods with other prior reinforcement learning (RL) and behavior cloning (BC) based approaches. Results from prior methods were grouped into the same categories as our tasks. For simple tasks which requires just one function call, our approach with gpt-3.5-turbo outperforms WebNT5-3B (Gur et al., 2022) benchmark by a slight margin of 14.1% which employs a finetuned large language model with 12K expert demonstration data. WebWise using gpt-3.5-turbo outperforms WebN-T5-3B, CCNet (RL) (Humphreys et al., 2022), and CCNet (BC) (Humphreys et al., 2022). CCNet (BC+RL) (Humphreys et al., 2022) significantly outperforms our approach, but requires many expert demonstrations and millions of RL trials, while our approach requires minimal per-task learning. Table 1 shows the success rate for all evaluated tasks across different methods including RCI and HeaP. While the results suggest that RCI and HeaP exhibit marginally superior performance in certain tasks, this difference could be attributed to the number of in-context examples in RCI since up to 22 examples were used. Additionally, HeaP adopts a chain-of-thought (Wei et al., 2022) prompting, which typically surpasses standard prompting techniques. HeaP also uses a currently depreciated model instruction-tuned text-davinci-003 (OpenAI, 2024) instead of gpt-3.5-turbo, which may also cause minor performance differences.

5.3 Ablation

Table 2 compares our proposed methods across the task groups for both zero-shot (k=0) and single-shot (k=1). For a particular value of k, 'Instruction Only' has the lowest performance though the gap between 'Instruction Only' and the other methods grows as the task become more complex (left to right). For the easiest tasks, using DOM elements and feedback (WebWISE) has little effect on the performance. For k=1, WebWISE produces the largest gain in the Variable Function group. Auto-Context Generation has a similar or higher performance than the other zero-shot methods but is lower than the single-shot ones.

6 Discussion

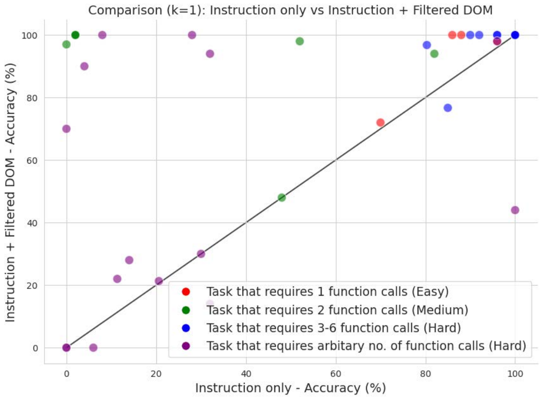

Figure 4: Comparison of k=1 performance across all tasks for Instruction Only (x-axis) and Instruction+Filtered DOM (y-axis).

Drawing from prior work that demonstrates the ability of LLMs to perform computer vision and embodied tasks, our work aims to extend the application of LLMs to more intricate challenges, specifically web interface tasks. In doing so, we shifted the focus from reliance on multiple learning examples to an approach based on zero and one-shot learning. Key insights are presented from Table 2, Figure 4, 5, 6, and 7 based on gpt-3.5-turbo results.

Influence of Single In-Context Example and DOM Elements: We explored the impact of a single in-context example, represented as k=1, across several task groups. The results indicate the ability of a LLM to perform well based on a single correct example. As shown in Figure 4, most easy tasks can be successfully completed even without observations (DOM elements). However, as the task complexity increases, the inclusion of observations becomes critical which is evident from the results.

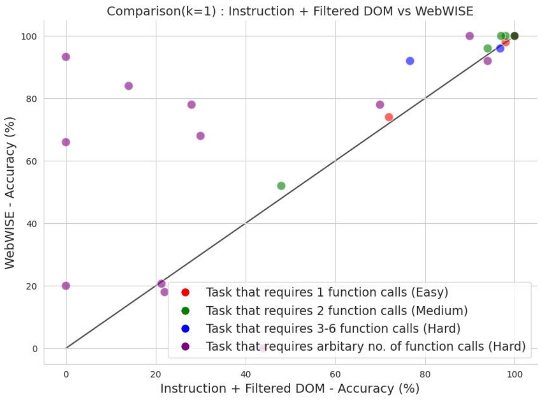

Figure 5: Comparison of k=1 performance across all tasks for Instruction+Filtered DOM (x-axis) and WebWISE (y-axis).

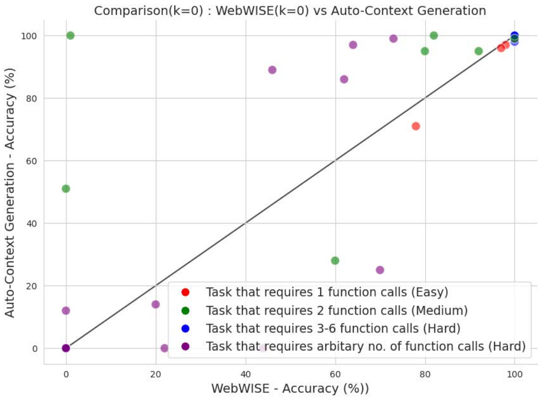

Figure 6: Comparison of k=0 performance across all tasks for WebWISE(x-axis) and Auto-Context Generation (y-axis).

Improvement from Step-by-Step Actions: Both Table 2 and Figure 5 clearly illustrate that implementing actions and observations in a sequential manner (WebWISE) significantly enhances performance compared to the 'single-step' action generation. This improvement is especially noticeable for more challenging tasks, where many tasks require the execution of actions in a specific sequence and changes in the environment. When k=1, step-by-step outperforms single-step by a large margin (23% to 75% success rate).

Performance of Auto-Context Generation (ACG): Figure 6 shows that auto-context examples increase success rates, compared to no in-context

Table 1: Comparison of performance across tasks of our methods and RCI using the gpt-3.5-turbo and HeaP using instruction tuned text-davinci-003. TLE (Token Limit Exceeded) signifies tasks where the full prompt exceeds the LLM's context window. "-" denotes tasks not addressed by RCI and HeaP methods.

examples, for the large majority of cases, including all levels of difficulty. However,as Table 2 shows, a single manually provided in-context example leads to even higher success rates, especially for the hardest tasks. While ACG is comparable to the other zero-shot methods, it still lags behind the single-shot methods across different tasks. This indicates that either the in-context examples generated are not as effective as hand-crafted ones or no in-context examples were generated at all.

Impact of filtered DOM elements: Figure 7 shows that filtering the DOM elements improves success rates for the large majority of tasks, as the LLM is able to focus on more relevant information. However, Figure 7 highlights several tasks where the performance of our approach when provided

Auto-Context Generation	0.86	-	0.81	-	0.80	-	0.30	-

Table 2: Average success rate across tasks for different versions of our approach evaluating on gpt-3.5-turbo, with WebWISE and Auto-Context Generation (ACG) being the main approach. k=0 means no in-context example is provided, or in case of ACG, only auto-context examples are provided; k=1 indicates one manual in-context example is provided, though many examples are shared across tasks.

Methods	1 Function		2 Function		3-6 Function		Variable Function	
	k=0	k=1	k=0	k=1	k=0	k=1	k=0	k=1
WebWISE(gpt-3.5-turbo)	0.87	0.97	0.73	0.93	0.80	0.99	0.27	0.75
WebWISE(Llama 2 7B)	0.45	0.76	0.03	0.24	0.28	0.41	0.03	0.18
WebNT5-3B	0.83		0.29		0.73		0.37	
WebN-T5-3B(k=0)	0.85		0.27		0.63		0.30	
CCNet(BC+RL)	0.99		0.94		0.99		0.89	
CCNet(RL)	0.88		0.65		0.50		0.44	
CCNet(BC)	0.77		0.37		0.27		0.16	
WebGUM(HTML)	0.92		0.40		1.00		0.83	
WebGUM(HTML+Image)	0.94		0.40		1.00		0.90	

Table 3: Comparison of our WebWISE method on different LLMs with methods reported from other works where the value of k is not applicable. CCNet has been trained using behavior cloning (BC) on human-labeled data and also reinforcement learning by interacting with MiniWob++ different tasks environment. CCNet (BC) represents the model that has been only trained on human-labeled data, CCNet (RL) is trained only by letting it interacting with MiniWob++ environment for many trials, and CCNet (BC+RL) is trained using both methods.

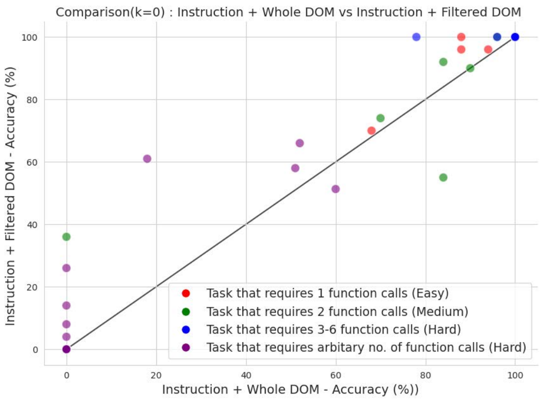

Figure 7: Comparison of k=0 performance across all tasks for Instruction+Whole DOM(x-axis) and Instruction+Filtered DOM(y-axis).

with whole DOM elements is better than the filtered DOM elements. This is likely due to some information important contained in the Whole DOM elements. Thus, developing an adaptive DOM element filter that can generalize across several tasks could be a next step. The influence of different LLMs on our results are discussed in appendix.

Limitations: Our main limitations include that experiments are limited to simple tasks, sensitivity to the input prompts, lack of an explicit memory, and use of only two LLMs with only one being open-source. Eventually, we aim to develop systems that can learn to perform more complicated tasks, like booking airline tickets, with few trials or demonstrations. This requires being able to more fully utilize web interfaces and retain memory of past interactions to complete long action sequences. Increased robustness to input prompts is also needed. Further improvement may be possible by learning from failures and automatically correcting mistakes.

7 Conclusion

Our work presents an initial exploration into using Large Language Models (LLMs) to generate programs that interact with web interfaces. Our experiments indicate: filtered DOM elements are effective forms of observation; the step-by-step action and observation is more effective than single-step generation; and automatically generated in-context examples from successful trials can boost success rates for many tasks.

A Scientific Artifacts

The scientific artifacts used in the paper (e.g., LLaMa 2(7b), gpt-3.5-turbo, and Miniwob++) aligns with terms and conditions of usage of provided the original authors.

B Design choices

B.1 Impact of choice of LLM

It is important to acknowledge that while gpt-3.5-turbo shows superior performance as indicated in

Table 3, LLaMA-2 7B also demonstrates promising results in certain tasks, especially with one in-context example. This suggests that, despite some limitations like the current 8-bit quantization possibly affecting accuracy, there is potential for improved performance with larger LLaMA v2 models. This observation suggests the adaptability and potential effectiveness of our algorithm, even with smaller-scale models.

B.2 Impact of choice of Filtered VS Full DOM Elements

We discussed in our paper that we use only a subset of DOM Elements (referred to as ‘Filtered DOM Elements’) instead of the entire set of DOM Elements. We use the $getSummary()$ function to extract the filtered DOM elements. The $getSummary()$ function iterates through each DOM element and includes a DOM element in the filtered list if the element’s tag or class belongs to a pre-defined list. In addition, we include the flags, an array of binary values. The values indicate whether a certain element has been clicked on/modified on. We display the pre-defined lists, called ‘useful_tag’ and ‘useful_classes’ below. The lists were determined experimentally.

```
useful_tag = {'button', 'text', 'input_time', 'textarea', '
     polygon', 'label', 'input_password', 'rect', 'tt', '
     circle', 'input_password', 'span', 'input_text', '
     input_number', 'input_date', 'input_radio', 'tspan', '
     input_checkbox', 't', 'button', 'h3', 'ul', 'a', 'p', '
     div', 'th','tr','td'}

useful_classes = {'folder'}
```

Listing 2: Predefined list of useful tags and classes

In Figure 8, we use a simple task to illustrate the differences between filtered DOM elements and full DOM elements.

B.3 Impact of choice of Sensitivity to prompts

In our analysis, we have observed that LLMs exhibit sensitivity to the prompts provided, including the system message and task message. We conducted a case study where we deliberately varied the task message and examined the resulting performance of the generated programs.

This sensitivity to prompts highlights the importance of carefully crafting and designing prompts to elicit the desired behavior and improve the overall performance of the language model.

```
task_message_1="""This task is a multi-step challenge. To
     successfully complete it, you need to be aware of the
     current state of the environment and the user input.
     Before performing any action, carefully observe and
     analyze the environment to determine whether further
     actions are required. When exploring and trying
     different actions, ensure that you select appropriate
     actions and arguments for the functions based on the
     current environment. Focus on efficiently reaching a
     solution by checking if the task can be solved with the
      current user input and environment state before taking
      any further steps, and by using correct actions and
     arguments for each function."""

task_message_2="""Next task is a multi-step task, directly
     performing a series of actions may not solve the task.
     Need to observe the changes in the user input before
     and after performing any action to see if
further actions need to be made to solve the task or not"""

task_message_3= """Next task is a multi-step task, directly
     performing a series of actions may not solve the task.
     Need to observe the changes in the user input before
     and after performing any action to see if
further actions need to be made to solve the task or not. So
     , explore and try different actions and figure out a
     way to solve the task, but at every step check if you
     are able to solve the task with the current user input
     before taking the action."""

task_message_4="""Your next task is a multi-step challenge.
     To successfully complete it, carefully observe and
     analyze the changes in user input before and after
     performing any action. This will help determine whether
      further actions are necessary. While it's important to
      explore and try various actions, always assess whether
      the task can be solved with the current user input
     before taking additional steps. Focus on efficiently
     reaching a solution without excessive exploration when
     a satisfactory outcome is already achievable.
"""

task_message_5="""The upcoming task is a multi-step
     challenge that requires you to pay close attention to
     the current user input. Your goal is to efficiently
     reach a solution by performing appropriate actions
     based on the present situation. Before taking any
     action, analyze the user input to determine if further
     actions are necessary. Explore and try the next action,
      but always ensure they are necessary, relevant to the
     current state and have the correct arguments for the
     functions. Continually assess the situation to check if
      the task can be solved with the current user input and
      environment state before proceeding further."""

task_message_6="""The upcoming task is a multi-step
     challenge. To successfully complete it, you must be
     aware of the current state of the environment and the
     user input. Before performing any action, carefully
     observe and analyze the environment to determine
     whether further actions are required. When selecting
     actions, ensure that you only perform actions if the
     current user input has the necessary elements. Focus on
      efficiently reaching a solution by trying to solve the
      task with the current user input and environment state
      before considering further exploration. Only explore
     and try different actions if the task cannot be solved
     with the current state. Make sure to use correct
     actions and arguments for each function based on the
     current environment."""

task_message_7="""The this task is a multi-step challenge.
     To successfully complete it, you must be aware of the
     current state of the environment and the objects in the
      image. Before performing any action, carefully observe
      and analyze the environment to determine whether
     further actions are required. When selecting actions,
     ensure that you only perform actions if the objects in
     the image have the necessary elements. Focus on
     efficiently reaching a solution by trying to solve the
     task with the current objects in the image and
     environment state before considering further
     exploration. Only explore and try different actions if
     the task cannot be solved with the current state. Make
     sure to use correct actions and arguments for each
     function based on the current environment."""

task_message_8="""The upcoming task is a multi-step
     challenge. Observe and analyze the environment and
     objects in the image before performing any action.
     Select actions based on the current state and ensure
     they are relevant to the objects in the image. Focus on
      solving the task with the current state, and only
     explore further if necessary. Use correct actions and
     arguments for each function, and be mindful of the
     environment during the process."""

task_message_9="""This task is a multi-step challenge.
     Observe and analyze the user input which contains the
     objects in the image before performing any action.
     Select actions based on the current state and ensure
     they are relevant to the objects in the image. Try
     other actions if and only if you are not able to solve
     the task with the current user input. Use correct
     actions and arguments for each function, and be mindful
      of the environment(user input) during the process."""

2)If its not, explore and perform other actions (e.g.,
       clicking, scrolling) to see if the element is available
        in other states.
3)Iterate steps 1−2 until the desired element is found and
       can be clicked or interacted with.
4)Once the element is available and visible, execute the
       appropriate action on it.
"""
```

Listing 3: Experiments on different task messages for API

The impact of variation in the task message on the performance of WebWISE, is shown in Table 5. Although the overall meaning of the "task message" remains consistent, minor differences in sentence structure and syntax can affect the model's performance for multi-steps tasks. While the average performance across tasks may appear similar, there are significant variations in accuracy among individual multi-step tasks, with some showing a high standard deviation of 62%. A future research direction is the development of methods robust to prompt variation.

B.4 Impact of Full DOM Elements

A deeper analysis of specific tasks like "Simple-Algebra" and "Navigate-Tree" revealed that providing the complete DOM elements as input improves performance. This improvement is attributed to the presence of keywords like "math-question" and "folder" within the DOM elements. Although these keywords may not be essential for executing actions within the web interface, they play a crucial role in providing contextual information to the language model. Consequently, the model gains a better understanding of the broader task it needs to accomplish at any given moment.

C Implementation Details

C.1 LLM Input

The prompt to the LLMs contains (in the following order) System message, API, Solution Description, Task description, and In-context examples. There are a total of 48 different tasks and each has its own in-context example. We provide the details for the system message and API below.

```
System_Message = """You are designed to generate programs to
       solve a wide range of complex web interface tasks.
You should be able to generate the program using either one
       or a composition of predefined action functions
along with general python codes to solve different tasks.
       You should not conversate with human in any context."""
```

Listing 4: First system message

```
Solution_Description="""Your task is to generate a solution
      for given problems based on objects in an image. Use
      the functions provided and follow these guidelines:

1)Construct solutions by calling functions and using Python
      data structures.
2)Solutions should be after the text 'Solution?'.
3)Only provide the function names without extra text in the
      solution.
4)Assume you can use observations without checking.
5)Don't assume additional functions or unknown information.
6)Add observation, reward, terminated, truncated, info = env
      .step(action) after each action.
7)Actions are independent of each other.
8)Do not add any comments, just return the code

If the task cannot be directly solved, perform a reasonable
      action and observe changes in the objects.
Use your DOM Elements knowledge to understand objects in the
       image.
Feel free to use Python constructs like if-else, for loop,
      while loop, etc., to generate the program."""
```

Listing 5: Second system message that appears after the API

```
task_message = """Your next task is a multi-step challenge.
      To successfully complete it, carefully observe and
      analyze the changes in user input before and after
      performing any action. This will help determine whether
       further actions are necessary. While it's important to
       explore and try various actions, always assess whether
       the task can be solved with the current user input
      before taking additional steps. Focus on efficiently
      reaching a solution without excessive exploration when
      a satisfactory outcome is already achievable. """
```

Listing 6: Third system message for multi-step methods

System Message The (first two) system messages were the same between tasks and across methods. A third system message is added for WebWise and Auto-Context Generation to ensure the task is completed step-by-step.

```
You should only use the functions provided herewith in the
      function description. Here is the list for the pre-
      defined functions [getSummary, click_action1,
      enter_text_action, scroll_action1].
To use a function, please refer to the Name, Input, Output,
      Description of the functions, and usage examples below.
       Action functions should be called correctly in the
      solution.

def getSummary(dom_elements):
    '''
    Input: DOM elements
    Output: Subset of DOM elements
    Description: get the filtered DOM elements from full DOM
       elements
    Example: objects_in_the_image = getSummary(dom_elements)
    '''
def click_action1(tag_class_name,id_text_name,observation):
    '''
    Input: tag or element, id or text, observation
    Output: clicks on specific element in environment
    Description: useful when you want to click on an element
       in the web interface. This function cannot be
      generalized on names. Normally first input is one of
      tag or element and second is test or id. The output is
      given as the action by calling click_action1 function
      or 'Cannot find in the DOM_element' if no such thing to
       be clicked on
    Example: Objects in Image: Button One;
             Task: Click button ONE;
             Solution: action = click_action1('button', 'ONE
      ', observation)
                       observation, reward, terminated,
      truncated, info = env.step(action)

    '''
def enter_text_action(input_text,observation):
    '''
    Input: text, observation
    Output: enters text in element in environment
    Description: useful when you want to type the input_text
       into input text box or a similar object like
      input_number that can accept text given the observation
       of the task interface. Need to call click_action1 to
      click on it before calling this function.
    Example: Objects in Image: input_text textbox;
             Task: Type 'Hello' into textbox;
             Solution: action = click_action1('input_text',
      'textbox', observation)
                       observation, reward, terminated,
      truncated, info = env.step(action)
                       action = enter_text_action('Hello',
      observation)
                       observation, reward, terminated,
      truncated, info = env.step(action)
    '''
def scroll_action1(text_to_scroll_to,observation):
    '''
    Input: text, observation
    Output: moves webpage such that certain text is visible
    Description: needed when elements do not appear on
      initial screen. Always used with other actions
    Example: Objects in Image: Button Apple
             Task: scroll and click button Apple
             Solution: action = scroll_action1('Apple',
      observation)
                       observation, reward, terminated,
      truncated, info = env.step(action)
                       action = click_action1('button','
      Apple',observation)
                       observation, reward, terminated,
      truncated, info = env.step(action)
    '''
```

Listing 7: Full API

Full API Below we list the full details our API. The API is constant between tasks and methods. For each function, we list the expected input, output, description and the example use case of the function. The example differs across the methods and depends on what visual information is provided. For the ‘Instruction Only’ method, there is

Tasks	Number of Functions	Incorrect Answers Visible (Y/N)	Target Button Not in Initial DOM (Y/N)
click-button-sequence	1	N	N
click-button	1	N	**Y**
click-checkboxes-large	Variable	**Y**	N

no line that starts with 'Objects in Image' since that information is not part of the method.

C.2 Scatter Plots

We display additional scatter plots for gpt-3.5-turbo results in Figures 9, 10, and 11.

D Task Analysis

D.1 Task Classification

In the results section, we categorized the tasks based on the number of pre-defined functions needed. However, we also introduce two alternative methods for classifying the tasks. We provide a comprehensive table, Table 4, that presents all the tasks along with their respective classifications.

Incorrect Answers Present One way we can classify the tasks is, if there are incorrect answers present. Tasks that include incorrect answers are characterized by the presence of multiple clickable buttons, as opposed to tasks with a single button. An illustration showcasing a task with and without incorrect answers is provided in Figure 13.

Target Button not in Initial DOM Elements A second way we can classify tasks is based on the

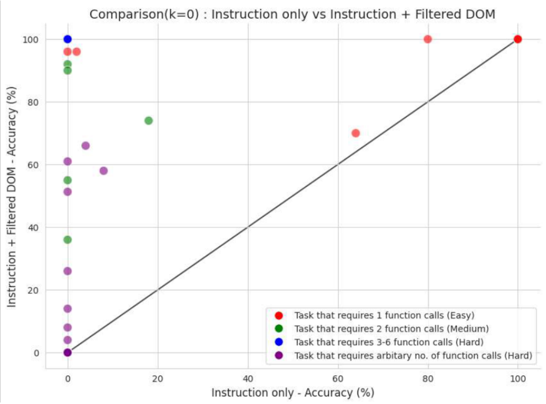

Figure 9: Comparison of k=0 performance across all tasks for Instruction Only (x-axis) and Instruction+Filtered DOM (y-axis)

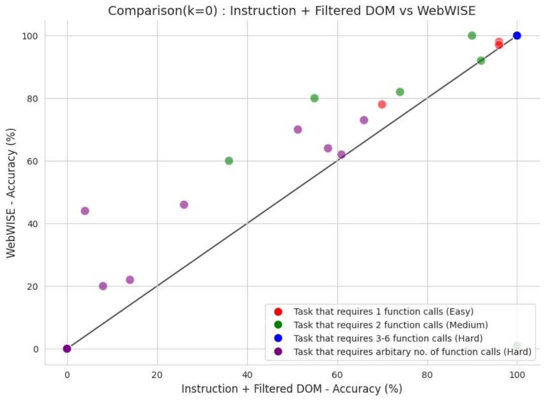

Figure 10: Comparison of k=0 performance across all tasks for Instruction+Filtered DOM (x-axis) and WebWISE (y-axis).

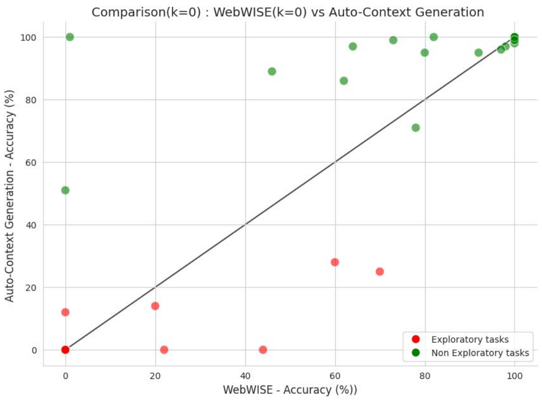

Figure 11: Comparison of WebWISE (x-axis) vs. Auto-Context Generation (ACG) (y-axis) at k=0 across various tasks. Orange dots indicate tasks requiring exploration, such as those where the target button isn't present initially in the DOM elements, whereas green dots represent non-exploratory tasks. A noticeable trend is that Auto-Context Generation's (ACG's) performance decreases on exploratory tasks. When ACG finds a correct solution during the zero-shot trials, it will continue to use the same solution found instead of generalizing from it.

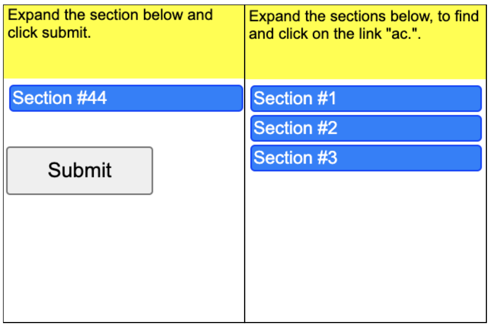


Expand the section below and click submit.

Expand the sections below, to find and click on the link "ac.".

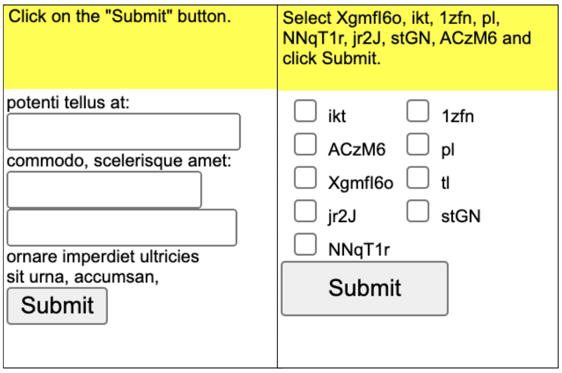
Figure 12: Comparison of tasks where target button is visible and not visible in the initial set of DOM elements. The target is visible for task shown on the left image and initial DOM elements contain all relevant information. For task shown on the right image, to get the relevant information, different sections have to be expanded, and each time a section is expanded, the DOM elements are changed.

initial set of DOM elements. In simpler tasks, the initial set of DOM elements already provides all the necessary information to perform the task. However, for more complex multi-step tasks, it is required to perform at least one additional step to access the DOM elements that contain the target button or the information needed to execute the task correctly. Typically, this additional step involves clicking on a button that triggers a screen change or reveals the relevant elements. Figure 12 provides an example illustrating this concept.

D.2 Task Failures

In this section, we explore why certain tasks failed. It is worth noting that some failures are attributed to the different task classifications we discussed earlier.

One specific example is the 'click-dialog' task, as demonstrated in Table 1. When using our WebWISE method with only one example, we achieve perfect accuracy. However, for the 'click−dialog−2' task, the accuracy drops to 76%. This discrepancy can be attributed to a particular sub-task where the task description instructs the user to click on the 'x' symbol to close a dialog. Language models may not fully comprehend that the symbol 'x' represents the close function. As a result, this lack of understanding leads to failures in executing this specific sub-task.



Click on the "Submit" button.

Select Xgmfl6o, ikt, 1zfn, pl, NNqT1r, jr2J, stGN, ACzM6 and click Submit.

Figure 13: Comparison of tasks with and without incorrect answers. For image on the left, incorrect answers are NOT present. There is only a single button to click. However, for image on the right, ncorrect answers are present. Eg. only some of the checkboxes should be clicked on.

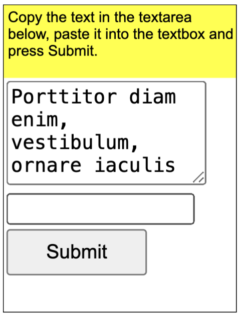
Email Tasks Among the tasks we evaluated, some simulate performing actions in an email mobile app. Performance varies widely across these tasks, particularly those that begin with the word "email." Tasks starting with "email-inbox-forward" tend to have better performance compared to tasks without the word "forward". This variation can be explained by the scope of the individual tasks. In tasks with "forward" in the prompt, there is only one specific action that needs to be performed: forwarding an email. However, in tasks without the word "forward," there can be one of four possible actions: forwarding, starring (marking as important), deleting, and replying to an email. To maintain consistency with the other tasks, we used a single in-context example with only one of the actions for the email-related tasks. Consequently, our method can only successfully execute the action mentioned in the prompt.

Terminal One common source of failure in tasks involving a terminal is the model's lack of knowledge on how to execute a command by pressing the enter key. The task only succeeds when we provide an example because we pass the first argument to $enter\_text\_action$ as $"CommandToBeEntered\backslash n"$, which simulates pressing the enter key after entering the command. To address this issue, a potential solution in the zero-shot scenario is to develop primitive functions specifically for key actions such as "ENTER," "BACKSPACE," or "DELETE." By incorporating these primitive functions into our models, it can learn to perform key-related actions more effectively in terminal-based tasks.

Search Engine and Text Transform Failures in tasks like "Search-Engine" and "Text-transform" can be attributed to the limitations of the filtered DOM elements. For example, in the search engine task, the instruction may involve clicking on the 8th search result on a webpage. While the full DOM elements contain the search results in the correct order, the filtered DOM elements do not. A similar observation can be made for tasks like "Text Transform." To address this issue, it becomes necessary to develop an adaptive $getSummary()$ function that can extract the most relevant elements while also preserving their order within the DOM. Alternatively, approaches involving the use of image input modalities could be explored to overcome these limitations. Such approaches can provide a visual representation of the webpage, enabling the model to better understand the layout and order of the elements present.

D.3 Additional Task Analysis

In tasks like "Copy-Paste," the objective is to copy text from the task interface and paste it into an empty text field, as illustrated in Figure 14. However, we did not implement the copy-paste function for the LLMs to interact with the environment and complete the task. We noticed that LLMs make references to functions like "$create\_copy\_action$" and "$create\_paste\_action$," which, if implemented, could have led to the correct solution (as shown in Figures 15,16). Some additional functions such as clicking on specific coordinates could also be implemented to improve the LLMs' capabilities in handling tasks like these.



Copy the text in the textarea below, paste it into the textbox and press Submit.

Porttitor diam enim, vestibulum, ornare iaculis

Abstract

Instruction tuning has emerged as the key in aligning large language models (LLMs) with specific task instructions, thereby mitigating the discrepancy between the next-token prediction objective and users' actual goals. To reduce the labor and time cost to collect or annotate data by humans, researchers start to explore the use of LLMs to generate instruction-aligned synthetic data. Recent works focus on generating diverse instructions and applying LLM to increase instruction complexity, often neglecting downstream use cases. It remains unclear how to *tailor* high-quality data to elicit better instruction-following abilities in different target instruction distributions and LLMs. To this end, we introduce **CodecLM**, a general framework for adaptively generating high-quality synthetic data for LLM alignment with different downstream instruction distributions and LLMs. Drawing on the Encode-Decode principles, we use LLMs as codecs to guide the data generation process. We first *encode* seed instructions into metadata, which are concise keywords generated on-the-fly to capture the target instruction distribution, and then *decode* metadata to create tailored instructions. We also introduce Self-Rubrics and Contrastive Filtering during decoding to tailor data-efficient samples. Extensive experiments on four open-domain instruction following benchmarks validate the effectiveness of CodecLM over the current state-of-the-arts.

1 Introduction

Large language models (LLMs) have exhibited remarkable capabilities across a wide array of natural language processing (NLP) tasks (Brown et al., 2020; Ouyang et al., 2022; OpenAI, 2023a; Anil et al., 2023). In particular, LLMs can be trained for improved instruction-following through various methods, including fine-tuning on human-annotated data (Touvron et al., 2023; Bai et al., 2022) or extracted knowledge from stronger LLMs (Wang et al., 2022; Taori et al., 2023; Chiang et al., 2023; Peng et al., 2023). Recent progress in this area highlights the critical role of high-quality data in enhancing LLMs' instruction-following capabilities (Zhou et al., 2023a; Köpf et al., 2023; Chen et al., 2023b). However, acquiring such data through human annotation remains cost-prohibitive and difficult to scale, hindering further progress.

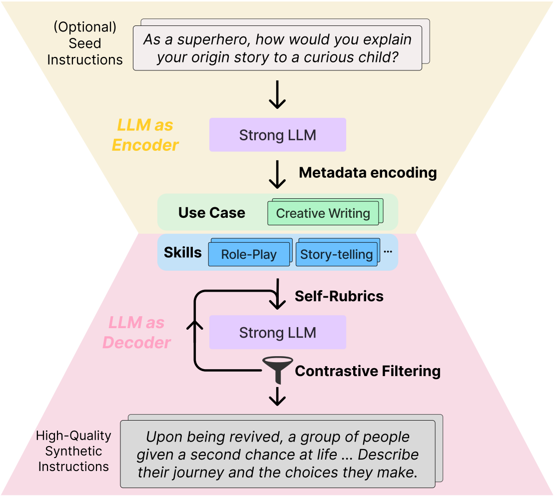

Figure 1: Overview of CodecLM. We first **encode** seed instructions into metadata to capture the underlying distribution of instructions. This metadata is then **decoded** through Self-Rubrics and Contrastive Filtering to tailor high-quality synthetic instructions that are aligned with the target instruction distribution. Intermediate instructions and responses are omitted in the figure for clarity.

As an alternative solution to human annotation, recent work explores generating instruction-response pairs for LLM alignment by prompting them with example data or prompts and iteratively refining the results (Honovich et al., 2022; Wang et al., 2022; Li et al., 2023; Xu et al., 2023). While these methods are effective at generating diverse and complex instructions for LLM alignment broadly, real-world applications often prioritize tailoring the LLM to specific downstream tasks such as individual enterprise applications or personal assistant agents (OpenAI, 2023b), which of-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3712–3729
June 16-21, 2024 ©2024 Association for Computational Linguistics

ten involve different instruction distributions. This desideratum for task-specific alignment brings us to a core question for data synthesis: *how can we tailor synthetic data to align LLMs for different instruction-following tasks?*

Specifically, current data synthesis approaches fall short of providing effective solutions for task-specific LLM alignment. While prior works by Wang et al. (2022) and Xu et al. (2023) emphasize diversity and complexity as hallmarks of high-quality data, these approaches stumble when facing different downstream tasks that may involve specific instruction distributions. A diverse dataset for one task might not effectively cover the instruction distribution for another. Furthermore, the definition of "complex" instructions can be subjective and vary across tasks. To complicate matters further, an LLM might excel at some seemingly complex instructions while struggling with others that appear simple according to human-crafted criteria. These limitations underscore the need for a unified data synthesis framework that can generate tailored data to align LLMs on specific downstream tasks.

In this work, we present a novel framework, **CodecLM**, which systematically generates tailored high-quality data to align LLMs for different downstream tasks. A high-level overview of CodecLM is shown in Figure 1. Inspired by the principles of Encode-Decode process (Kramer, 1991; Kingma and Welling, 2013), we leverage a strong LLM as a codec to "encode" seed instructions from our target task into instruction *metadata* and then "decode" the metadata into tailored synthetic instructions. The metadata serves as a word-level abstraction of the input instruction distribution, including the *use case* and *skills* for effective instruction following. It can be automatically generated by encoding seed instructions, or directly provided by users with a high-level anticipation of the downstream task.

Once the metadata is extracted, we then "decode" them to generate tailored instructions. We begin by prompting a LLM with the metadata as constraints, creating basic instructions. To elevate the instruction quality, we introduce *Self-Rubrics*. It samples appropriate actions from strong LLMs to make the basic instruction more complex or challenging based on the rubrics it generates for different metadata. Intuitively, a general knowledge QA instruction about math would differ in complexity rubrics from one in creative writing about sports. With self-generated rubrics and actions based on metadata, the strong LLM crafts instructions that better align the target LLM with specific knowledge required for the downstream task. We can run Self-Rubrics iteratively to control the instruction complexity, similar to Xu et al. (2023), and finally generate the corresponding responses.

We also introduce *Contrastive Filtering* during decoding to further identify the most effective instruction-response pairs by leveraging the quality discrepancy between the target and a stronger LLM. This strategy identifies two key instruction sets: (a) those the target LLM struggles with, pushing it to improve in its weak areas for more significant gains, and (b) those the target LLM excels at, feeding them back into the Self-Rubrics process for improved data efficiency. Contrastive Filtering serves as a response-level analogy of contrastive decoding (Li et al., 2022).

CodecLM sets a new state-of-the-art on four open-domain instruction-following benchmarks with various LLM choices, demonstrating its effectiveness in LLM alignment for diverse instruction distributions.

2 Related Work

Instruction Tuning for LLM Alignment. Tuning LLM to faithfully follow instructions and align with diverse human preferences remains a significant challenge (Efrat and Levy, 2020). Early research primarily focused on cross-task generalization, where models were fine-tuned on various public NLP datasets to improve performance on diverse tasks (Raffel et al., 2020; Wei et al., 2021; Aribandi et al., 2021; Victor et al., 2022; Chung et al., 2022). More recently, researchers have extended instruction tuning to open-domains, characterized by a wider range of formats and task types. This shift has been driven by crowdsourcing human-generated instruction-response pairs (Ouyang et al., 2022; Köpf et al., 2023; Zhou et al., 2023a) and LLM-generated data (Taori et al., 2023; Chiang et al., 2023). Unlike prior work, CodecLM presents a unique approach for tailoring synthetic data to specific downstream tasks without human annotation, utilizing the concept of instruction metadata.

Data Generation for Instruction Tuning. To address the high cost of human annotation for high-quality instruction-response pairs, several studies advocate for automating the data generation process (Schick and Schütze, 2021; Liu et al., 2022; Meng et al., 2023). Leveraging the in-context learning (Brown et al., 2020) ability of LLMs, Wang et al. (2022); Honovich et al. (2022) prompt LLMs with seed instructions to generate synthetic ones. These are then fed to stronger LLMs, *e.g.*, ChatGPT, to generate responses for training the target (often smaller) LLM (Taori et al., 2023). As a representative work, WizardLM (Xu et al., 2023), designs a fixed set of human-crafted operations to increase complexity of instructions and control difficulty of generated data. Zhao et al. (2023); Zhou et al. (2023a) further confirm the importance of instruction complexity for LLM alignment through empirical studies. Different from these works that rely on pre-defined rules without considering the downstream tasks, CodecLM enables automatically tailoring instructions for different downstream tasks and target LLMs. We also introduce Self-Rubrics and Contrastive Filtering to further identify the most effective instruction-response pairs.

Distillation. Alternatively, tuning the target LLM with responses generated from another LLM can be viewed as knowledge distillation (Hinton et al., 2015; Beyer et al., 2022). However, our focus remains on instruction generation, while still being flexible to readily integrate with existing distillation techniques (Hsieh et al., 2023; Liang et al., 2023).

Finally, we discuss some of the most relevant recent work. AttrPrompt (Yu et al., 2023) leverages LLM as attributed data generator by extracting attributes within instructions. However, it focuses solely on classification tasks and requires human intervention for attribute selection. In contrast, our work focuses on the broader context of aligning LLMs to follow open-domain instructions, eliminating the need for human efforts. MSP (Chen et al., 2023a) utilizes trainable soft prompts to control generation, but requires gradient access to the LLM. Our method, on the other hand, is readily compatible with black-box LLMs that only offer API access for high-quality data generation. SteerLM (Dong et al., 2023) analyzes quality-related aspects of responses, instead of the instructions, to capture human preference. Therefore, SteerLM can be used alongside CodecLM as a parallel approach for enhancing response quality.

3 Problem Statement

We study the open-domain instruction following problem (Wang et al., 2022; Taori et al., 2023; Xu et al., 2023), where instructions vary in input format and tasks. Specifically, we consider two practical scenarios: (1) Starting with a given set of n seed instructions $\mathcal{D}_s = \{I_i\}_{i=1}^n$, each drawn from some underlying distribution P_I. For our experiments, we create a set of seed instructions using a held-out validation set. Practically, such instructions can be collected from the usage traffic of users. (2) In the absence of seed instructions, but with prior knowledge of downstream tasks, we directly start with a given set of instruction metadata $\mathcal{M}$ (see Section 4.1 for definition). The latter scenario is especially useful for end users who lack existing instruction data but wish to jumpstart LLM tailored to specific applications, similar to the concept of GPTs (OpenAI, 2023b).

We focus on the first scenario for clarity, though the second can be derived similarly by leveraging an LLM as the encoder (Section 4.1). Our goal is to generate a set of high-quality instruction-response pairs $\mathcal{D}_g = \{(I_j^{'}, R_j^{'})\}_{j=1}^m$, using a strong LLM f_s, and then use $\mathcal{D}_g$ to fine-tune the target LLM f_t. We evaluate the performance of the fine-tuned LLM f_t on test instructions from the target distribution P_I, to which we are aligning.

4 CodecLM

We propose CodecLM, a general framework for generating high-quality instruction-response pairs tailored to different downstream tasks and LLMs, eliminating the need for human annotation. See Figure 2 for method overview.

4.1 LLM as Codec for Instructions

In this section, we introduce the concept of using a strong LLM as a codec, *i.e.*, both encoder and decoder, for instruction generation.

LLM as Encoder with Instruction Metadata. We begin by encoding the given seed instructions $\mathcal{D}_s = \{I_i\}_{i=1}^n$ into instruction *metadata* $\mathcal{M}$, *i.e.*, keywords that capture the underlying target instruction distribution. Inspired by the task pool by Wang et al. (2022) and the post-hoc analysis on skill distribution by Xu et al. (2023), we define the metadata as encompassing two key aspects: *use case* and *skills*. Use case describes the intended task (*e.g.*, question answering or creative writing), while Skills are the knowledge the LLM required to have to successfully respond to the given instruction (*e.g.*, algorithms or communication). Skills are often generalizable to different use cases. Therefore, each instruction has a single use case and may involve multiple skills. To extract this metadata, we leverage the strong LLM f_s following

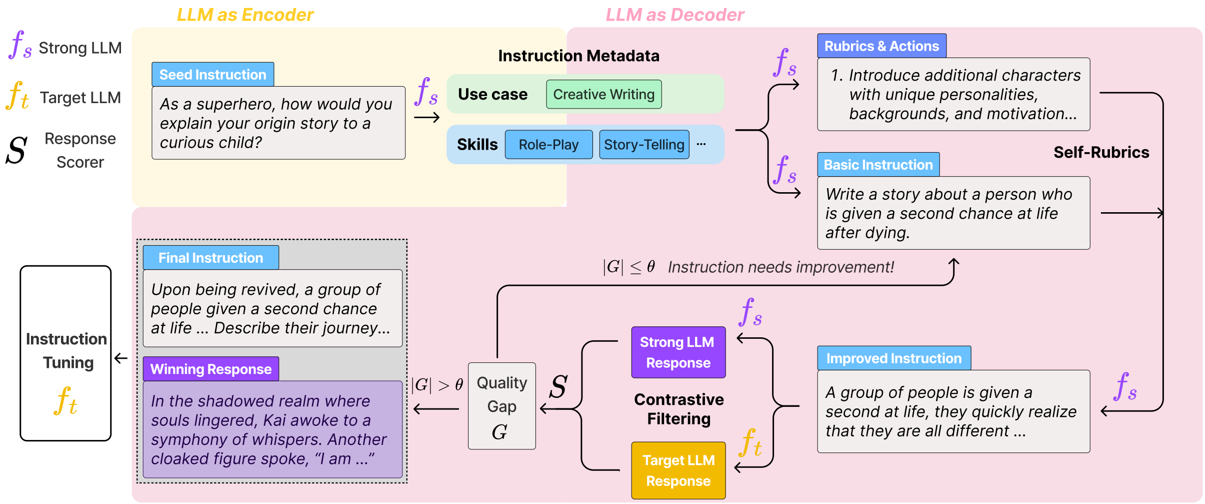

Figure 2: Overview of the proposed CodecLM. First, the strong LLM f_s encodes the seed instruction into instruction metadata, specifying its use case and skills required for responses. Next, f_s decodes metadata into basic instructions. Meanwhile, Self-Rubrics leverages f_s to generate rubrics and actions to improve the basic instruction, tailoring them for the downstream task. Finally, Contrastive Filtering uses a scoring function S to compares f_s and f_t's responses. The most effective pairs are selected for aligning the LLM, while less effective instructions are sent for further improvement. In this figure, the strong LLM's response is winning against the target one's, so we select the corresponding pair for instruction tuning the target LLM.

the prompt template in Figure 7, Appendix A.9. While richer definitions are possible based on finer-grained instruction-following metrics (Zhou et al., 2023b), we prioritize use case and skills for their broad applicability across diverse instruction distributions. Future work can explore extending this metadata further.

For each instruction I_i, we extract the corresponding use case u_i and set of skills $\boldsymbol{s}_i$. We then have the set of metadata as $\mathcal{M} = \{(u_i, \boldsymbol{s}_i)\}_{i=1}^{n}$. Instructions may share or partially overlap in their u_i's and $\boldsymbol{s}_i$, reflecting the distribution of tasks and capabilities within the seed instructions. Use cases and skills are generated on-the-fly, not limited to some predefined sets, enabling broader applicability. However, we can always provide such constraints with our prior knowledge, or even directly write out metadata without any seed instructions.

LLM as Decoder for Instruction Generation. Given the metadata $\mathcal{M}$, we decode metadata into synthetic instructions, following a generation and tailoring paradigm. For each use case and skills pair in $\mathcal{M}$, we list them as constraints to prompt the strong LLM f_s to generate multiple instructions. Therefore, the generated instructions are for the given use case, and require the given skills to be responded. Moreover, to prevent the LLM from generating repetitive instructions, we encourage its generation to be diverse in the prompt, and do not provide any demonstrations that the LLM might copy from. The example prompt template for generating basic instructions is in Figure 8, Appendix A.9. Continuing the decoding process, we then tailor the basic instructions for more effective alignment through Self-Rubrics (Section 4.2) and Contrastive Filtering (Section 4.3).

4.2 Instruction Tailoring via Self-Rubrics

Metadata-conditioned instructions lay the groundwork for aligning the target LLM to desired tasks. Studies suggest that more complex instructions can improve alignment performance (Xu et al., 2023; Zhao et al., 2023). A common practice is to involve human experts crafting general guidance to complicate instructions, such as adding reasoning steps or constraints. However, this one-size-fits-all strategy falls short for diverse instructions. Tailoring guidance to different tasks, like solving calculus problems versus writing news articles, requires distinct approaches.

Therefore, we introduce Self-Rubrics, which leverages the strong LLM to tailor instructions by adjusting their complexity according to the extracted metadata. Self-Rubrics first guides the LLM to generate metadata-specific rubrics for assessing instruction complexity. Then, informed by these rubrics, the LLM generates a corresponding set of actions to enhance the instruction's complexity. For metadata $(u_i, \boldsymbol{s}_i)$, the corresponding set of generated actions is $\boldsymbol{a}_i$. Our generated actions are more domain-specific, and unambiguous than generic rules crafted by human, making the complicated instructions better tailored towards the target distribution captured by the metadata. For example, for the use case of "business plan development" and skills of "market research and planning", generic rules like "add reasoning steps" is vague and inappropriate. On the contrary, Self-Rubrics is able to generate actions like "add SWOT analyisis" and "include comparison with market competitors" (see Appendix A.8 for the full details) to complicate the instruction. The prompt template to generate rubrics and actions for instruction improvement is shown in Figure 9, Appendix A.9.

With the obtained actions $\{\boldsymbol{a}_i\}_{i=1}^{n}$, we can iteratively prompt f_s to complicate the basic instructions, following the prompt template in Figure 10. We randomly sample an action $\boldsymbol{a}_i$ from the multiple actions generated for a pair of use case and skills. This design choice not only enables controlled complexity (Xu et al., 2023), but also prevents potential confusion between different actions for the LLM.

4.3 Instruction Selection via Contrastive Filtering

While Self-Rubrics tailors complex instructions based on instruction metadata, not all instructions are equally effective for instruction tuning, regardless of their complexity (Chen et al., 2023b; Zhou et al., 2023a). Intuitively, exposing the target LLM to instructions it finds challenging can effectively identify its areas for improvement. Therefore, it is crucial to select the most impactful instructions for aligning the target LLM.

We therefore introduce Contrastive Filtering, a method to select the instructions that can effectively enhance the target LLM f_t. For clarity, we define the space of all natural language sequences as $\mathcal{N}$. We have the strong LLM $f_s : \mathcal{N} \rightarrow \mathcal{N}$, the target LLM $f_t : \mathcal{N} \rightarrow \mathcal{N}$, and a scoring function $S : \mathcal{N} \rightarrow \mathbb{R}$ to evaluate response quality. In practice, S is obtained by reusing the strong LLM f_s with a prompt template (Figure 11, Appendix A.9) adapted from the Vicuna pairwise evaluation template (Taori et al., 2023; Chiang et al., 2023). To mitigate potential position bias, we average the scores obtained by exchanging the positions of two responses (Chiang et al., 2023). We observe using f_s for scoring works quite well in practice, so we prioritize this option for simplicity. Given an input instruction $I \in \mathcal{N}$, we obtain responses from both LLMs as $f_s(I)$ and $f_t(I)$, respectively. We then define the *quality gap* $G : \mathcal{N} \rightarrow \mathbb{R}$ between these responses to estimate the *effectiveness* of the instruction: $G(I) = S(f_s(I)) - S(f_t(I))$.

The quality gap metric G reflects how much the target LLM benefits from the strong LLM for each instruction I. As demonstrated in Figure 2, here are two possible cases: (1) $|G(I)| > \theta$, where $\theta \in \mathbb{R}$ is a certain threshold. This indicates that: Either the strong LLM has a much better response than the target LLM, we add $(I, f_s(I))$ to our high-quality instruction-response pool $\mathcal{D}_g$ to fill the gap; Or rarely, the target LLM gives much better response than the strong LLM, we add $(I, f_t(I))$ to $\mathcal{D}_g$ as as an implicit regularization to keep the target LLM's desirable behavior to certain instructions. (2) $|G(I)| \leq \theta$, where the quality of responses from both LLMs is similar, so learning from I does not lead to much gain. We then send I to the next Self-Rubrics iteration for further improvement.

Contrastive Filtering complements Self-Rubrics to select effective instruction-response pairs by calibrating the target LLM's instruction-following capability with the strong LLM's. Analogous to Constrastive Decoding (Li et al., 2022) at response-level, Contrastive Filtering can also be regarded as LLM-feedback (Madaan et al., 2023) with the interaction of two LLMs. While we adopt the strong LLM as scoring function to measure the quality gap, our framework can be compatible with and potentially benefit from the advances in more reliable and comprehensive scoring and feedback systems (Lee et al., 2023), and we leave it as promising future work.

5 Experiments

We conduct comprehensive experiments to evaluate CodecLM using different LLMs on multiple representative benchmarks, closely following well-established evaluation settings for open-domain instruction following in prior work (Xu et al., 2023; Chen et al., 2023b). We also conduct a case study in Appendix A.8 to illustrate how CodecLM tailors an instruction step by step.

5.1 Evaluation Benchmarks

We evaluate CodecLM on four widely-used open-domain instruction-following benchmarks with diverse instruction distributions to reduce evaluation bias. Our test benchmarks include Evol-Instruct (Xu et al., 2023), Vicuna (Chiang et al., 2023), Self-Instruct (Wang et al., 2022) and Koala (Geng et al., 2023). To complement the evaluation, we also evaluate on two standard NLP benchmarks MMLU (Hendrycks et al., 2020) and BBH (Suzgun et al., 2022) in Appendix A.7. Please refer to Appendix A.1 for benchmark details.

5.2 Baseline Methods

We compare our method against state-of-the-art data generation approaches for instruction tuning. For fair comparison, we provide all methods the same LLM backbones when possible. Moreover, we control the number of instruction-response pairs the same for all methods to ablate the effect of data quantity. Baseline methods include **Self-Instruct** (Wang et al., 2022), **Alpagasus** (Chen et al., 2023b), **Tree-Instruct**, **WizardLM** (Xu et al., 2023), and **WizardLM+**, an enhanced version of WizardLM using the same basic instructions generated from CodecLM as seed instructions. Baseline details are presented in Appendix A.2.

5.3 Experiment and Evaluation Details

LLM Backbones. We adopt LLaMA-based (Touvron et al., 2023) and PaLM-based (Anil et al., 2023) LLMs as our target LLMs in our experiments. For LLaMA-based target LLMs, we use Gemini-Pro (Team et al., 2023) as the strong LLM, and LLaMA-7B, -13B as the target LLMs. For PaLM-based target LLMs, we use text-unicorn as the strong LLM, and text-bison as the target LLM. PaLM-based models and Gemini-Pro are accessible through Google Cloud API[1].

Implementation Details of CodecLM. We split all benchmarks into 20% validation set and 80% evaluation set. We extract the instruction metadata from the validation set, see Appendix A.3 for more details. Depending on the specified total data size, we prompt the strong LLM to generate equal number of base instruction per metadata. We generate 500-8000 synthetic data throughout the experiments. We generate 4 rubrics and corresponding actions. At each iteration, we randomly choose 1 action for improving instruction. We run Self-Rubrics at most 4 iterations. For Contrastive Filtering, We set the scoring scale to 10 and the filtering threshold to 3 for all experiments. We align these configurations with Xu et al. (2023) and leave more detailed rationales of these configurations, additional hyperparameter settings, and training details in Appendix A.3-A.4.

Evaluation. Assessing how well LLMs follow instructions is complex, arising from the fact that an instruction has various valid responses, and the challenge of replicating human evaluation. Recent advances in automatic evaluation on instruction following (Dubois et al., 2023; Zheng et al., 2023) demonstrate that LLM-based evaluators are scalable, explainable, and consistent with human evaluations. Therefore, we adopt widely-used Vicuna pairwise evaluator (Chiang et al., 2023) based on ChatGPT to compare the response quality from two LLMs for its accessibility in price and efficiency. The evaluation prompt template is in Figure 12, Appendix A.9. We include GPT-4 based evaluation results in Appendix A.6 to demonstrate the consistency of LLM-based evaluators. To mitigate position bias that the LLM evaluator may have, we conduct every evaluation twice by exchanging response orders. A response is considered better only if it wins twice. Following (Chen et al., 2023b), we set the temperature to 0.0 to reduce evaluation randomness, and left other parameters as default.

Similar to prior work (Xu et al., 2023; Zhao et al., 2023), we compute the total ratio of wins and ties of a target LLM against the strong LLM, to indicate how much model capacity the target LLM recovers from the strong LLM (often treated as the upper bound performer). CRR simplifies the combinatorial pairwise comparisons between all target LLMs. We name the metric as *Capacity Recovery Ratio* (CRR), where $\texttt{CRR} = \frac{\texttt{wins+ties}}{\texttt{total comparisons}}$. In experiments, we observe that the number of ties often dominates the number of wins, since the strong LLM is much capable than the target model. So we do not put additional weights on wins in the calculation. To demonstrate CRR faithfully reflects model performance, we show the exact number of wins, ties and losses in Appendix A.5 on Evol-Instruct. We would like to emphasize our focus on the gap in CRR between different methods instead of the absolute value, since the absolute value may based on the specific LLM evaluator we choose.

5.4 Open-Domain Instruction Following

Results with LLaMA-based Target LLMs. Table 1 summarizes the performance of CodecLM and the comparing baselines with 2000 synthetic data for instruction tuning. All methods are trained on LLaMA-7B or -13B as the target LLM and compared against Gemini-Pro, the strong LLM that generates the data. CodecLM outperforms comparing methods consistently on all benchmarks, with two target LLMs of different sizes. The consistently superior performance of CodecLM highlights its

generalizability to different downstream instruction distributions and target LLMs. Both Tree-Instruct and variants of WizardLM focus on the importance of instruction complexity, however, their performances are not always better than Alpagasus with simple instructions, especially with larger target LLM. This observation indicates that the effectiveness of data cannot be solely determined by instruction complexity, and validates the motivation of our design of Self-Rubrics and Contrastive Filtering. Moreover, the win of WizardLM+ over WizardLM confirms the efficacy of instruction distribution matching via instruction metadata. When shifting the target LLM from LLaMA-7B to -13B, all methods get a significant performance boost, which accords with prior discoveries on scaling model size (Wei et al., 2021).

Results with PaLM-based Models. Table 2 summarizes the results of CodecLM and the best performing baselines in LLaMA-based experiments. We generate 1000 synthetic data due to computation budget. Since text-bison is a proprietary model that has been aligned with various techniques including instruction tuning, we also include it as a baseline approach. Interestingly, text-bison obtains strong performance across different benchmarks. Both Alpagasus and WizardLM+ underperform text-bison, suggesting it is non-trivial to improve upon a well-tuned LLM continually. CodecLM, on the contrary, outperforms text-bison in most cases, thanks to our core designs that adaptively tailor high quality data pairs to improve the target LLM.

5.5 Ablation Study

In this section, we conduct comprehensive ablation studies to empirically explore the effectiveness of CodecLM. We mainly conduct experiments with LLaMA-7B model as the target LLM, Gemini-Pro as the strong LLM, and report the CRR on the Evol-Instruct benchmark.

Effectiveness of Core Designs. We show component-wise contributions in our framework in Table 3. The 1st row has the result from Self-Instruct as a baseline; In the 2nd row, we only align the LLM with basic instructions from instruction metadata; We gradually add Self-Rubrics and Contrastive Filtering in the 3rd and 4th rows, respectively. We clearly observe that every component contributes to the final performance. Interesting, the performance of using basic instructions from metadata is even on par with that of WizardLM+ in Table 1. This observation indicates that human-crafted strategies for complicating instructions may not fit different types of instructions. On the contrary, Self-Rubrics adaptively generates instruction improving actions based on different metadata, resulting in better tailored instructions for the target LLM. Further improvements from Contrastive Filtering demonstrate that selected data are indeed more effective for alignment.

Effect of Number of Iterations. We demonstrate the effect of number of CodecLM iterations in Figure 3. In particular, we count the proportion of data from each iteration in all synthesized data $\mathcal{D}_g$ and show it in the blue bar chart with left y-axis. We also draw the target model performance in CRR after training on the synthetic data up un-

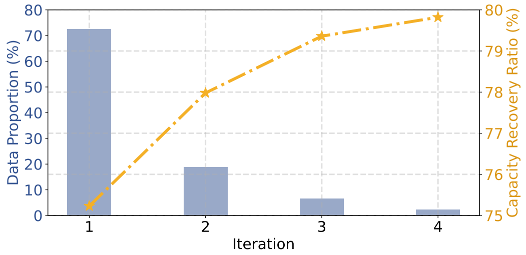

Figure 3: Data proportion from each iteration and the corresponding CRR performance at each iteration.

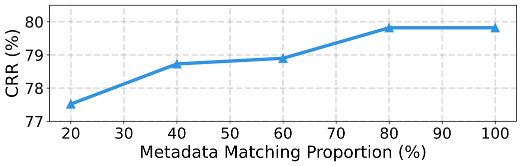

Figure 4: Metadata matching proportion vs. CRR.

til the current iteration in the yellow line chart with right y-axis. From the data proportion bar chart, we observe that more than 70% of the data comes from the first iteration. This indicates Contrastive Filtering successfully collects less complex yet challenging instructions, which are critical for building up the instruction-following ability of the target LLM. Starting from the second iteration, the data proportion gets increasingly small. However, similar to the *less is more for alignment* observation (Zhou et al., 2023a), high-quality and more complex instructions indeed contribute to the final performance despite less in quantity.

Exploration on Distribution Matching. As shown by previous results, generating metadata extracted from the downstream instruction distribution indeed helps. However, in practice, the extracted or human-written metadata may not be able to precisely characterize the instruction distribution. Therefore, it is necessary to explore the performance of CodecLM when the distribution represented by instruction metadata does not fully match the test distribution. As the true test distribution is complicated and not known as a prior, we approximate various extent of distribution matching by random subsampling from the set of metadata $\mathcal{M}$. To control the effect of data quantity, we keep the total number of instruction-response pairs the same for each case. For example, when subsampling 20% of $\mathcal{M}$, we prompt the strong LLM to generate 5 times more instructions for each metadata accordingly. The result is shown in the upper part of Figure 4, and we did observe the trend that the better instruction metadata captures the underlying distribution, the better performance the target LLM can achieve. Moreover, when the metadata matching proportion is equal or greater than 60%, we obtain close performance as the fully-matched result. This observation highlights CodecLM's robustness under potential instruction metadata mismatch.

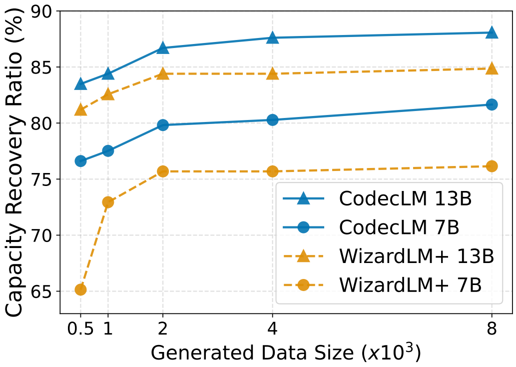

Figure 5: Scaling with model size and data quantity.

Scaling with Model Size and Data Quantity. To explore how our method scales with different synthetic data quantities and model sizes, we conduct experiments by comparing CodecLM with WizardLM+, the most competitive baseline. The experiment results on Evol-Instruct with LLaMA-7B and -13B as the target LLM are presented in Figure 5. Both methods get increasingly better performance with more synthetic data and larger target models. CodecLM consistently outperforms WizardLM+ under all cases, demonstrating its great data efficiency and scalability. We expect the gain will gradually diminish after we generate more than 8k synthetic data, due to the intrinsic ability gap between the target models and the strong LLM.

6 Conclusion

In this work, we propose CodecLM to tailor synthetic data for LLM alignment with different target instruction distributions and LLMs. We show that CodecLM effectively captures the underlying instruction distribution via instruction metadata, and further tailor the most effective instruction-response pairs through Self-Rubrics and Contrastive Filtering. CodecLM provides a potent solution towards adapting LLMs for customized uses, without the necessity of human annotation. We believe CodecLM serves as a general framework for targeted LLM alignment, which opens the door to multiple promising research directions within the framework, such as richer metadata definition, better prompt design, and more reliable LLM-based scorer. CodecLM can also benefit from orthogonal research fields, and we continue the discussion in Ethical Considerations and Limitations sections.

Ethical Considerations

Although CodecLM serves as an effective data synthesis framework for LLM alignment, we should also reflect on the ethical impact of our work. Our method leverages LLMs to generate instruction-response pairs. Similar to human annotators who might make unconscious mistakes during the data annotation process, LLMs also sometimes generate unethical, toxic or misleading instructions and responses (Bender et al., 2021). Moreover, as we train a target LLM using the generated data, the resulting instruction-tuned LLM might also carry the bias and fairness issues (Gallegos et al., 2023) from the original model. Although we conducted manual inspection as specified in Appendix A.3, in practice, we should adopt existing techniques (Hanu and Unitary team, 2020; Thakur et al., 2023) to detoxify and mitigate bias from LLMs used in CodecLM, and design more strict inspection and filtering rules to clean up the generated data. Due to the flexibility of our framework, we envision future progress in the domain of reducing bias and fairness issues can be complementary to CodecLM.

Limitations

We acknowledge the limitations of CodecLM from the following aspects to inspire future research opportunities in the field of LLM alignment.

First of all, as discussed in the Ethical Considerations, our method requires a strong LLM to generate the data, so the performance of our method depends on the quality of the LLM and may inherit bias and fairness issues from it. On the other hand, CodecLM can benefit from stronger LLMs improved with advanced bias-reducing and fairness-enhancing approaches.

Secondly, as an orthogonal direction, our method did not explore robustness of the instruction-tuned model towards adversarial attacks such as prompt injection (Liu et al., 2023) and jailbreaking (Zou et al., 2023). In practice, we should apply adversarial defense techniques (Jain et al., 2023) accordingly to the instruction-tuned LLM from our method.

Moreover, we mainly use LLM-based automatic evaluation methods following recent works in data synthesis for alignment. Although recent studies (Chiang et al., 2023; Dubois et al., 2023) demonstrate LLM-based evaluation is largely consistent with human evaluation, the scalability and reliability of LLM-based evaluators still have room for improvements. Although we include some standard benchmark results in Appendix A.7 to complement LLM-based evaluation results, we still believe the progress in better evaluating LLMs can lead to a more reliable demonstration of the effectiveness of our method.

Finally, as shown in Section 5.5, although CodecLM is robust to moderate distribution mismatch, its performance still depends on how well the metadata captures the underlying instruction distribution. In practice, our collected seed instruction might differ from the actual test instructions. Or in the case that we directly create metadata from user specification, the users might change their mind at test time to send the model out-of-distribution instructions beyond the original metadata. As a consequence, CodecLM may suffer performance degradation under distribution mismatch. As a remedy, we can constantly collect user instruction traffic or user feedback to update the generated data from CodecLM, and continuously update the target LLM.

We hope future work can leverage CodecLM as a flexible data synthesis framework for LLM alignment, so that advances in the field can be integrated into CodecLM to reduce its current limitations.

A Appendix

A.1 Benchmark Details

The details of the open-instruction following benchmarks are included below:

- Evol-Instruct (Xu et al., 2023) includes 218 real-world human instructions from diverse sources such as online open-source projects, platforms, and forums.
- Vicuna (Chiang et al., 2023) includes 80 diverse instructions generated by GPT-4 through prompt engineering.
- Self-Instruct (Wang et al., 2022) includes 252 expert-written instructions motivated by user-oriented applications.
- Koala (Geng et al., 2023) includes 180 conversation-style real user instructions that were posted online.

All these benchmarks consist of English instructions from multiple categories or tasks. However, though sharing some common use cases such as general knowledge QA and coding, the coverage of the instructions in different benchmarks are indeed different. For example, Xu et al. (2023) discuss in detail how Evol-Instruct is different from Vicuna in instruction distribution. The difference between instruction distributions effectively mimic the practical scenario where we have different downstream tasks.

The details of the additional standard NLP benchmarks are included below:

- MMLU (Hendrycks et al., 2020), Massive Multitask Language Understanding, is a benchmark designed to measure capability of language models. It covers 57 subjects across STEM, the humanities, the social sciences, and more areas. We only use the test split for reporting the test results, and report the average score across all tasks.
- BBH (Suzgun et al., 2022), BIG-Bench-Hard, includes 23 challenging BIG-Bench tasks that prior language models did not outperform average human-raters.

All benchmarks are publicly available for non-commercial research purposes, and we strictly limit their usage in this research work. We also carefully check these datasets and make sure that no personal information is involved.

A.2 Baseline Details

Self-Instruct (Wang et al., 2022) generates instructions by prompting LLM with existing seed instructions as few-shot demonstrations. Here we randomly subsample the Alpaca (Taori et al., 2023) dataset as seed instructions. Since Alpaca itself is based on Self-Instruct, using its subset as seed is a natural continuation of the Self-Instruct method.

Alpagasus (Chen et al., 2023b) selectively filters data using ChatGPT-based response quality evaluator. Closely following the original approach, we adopt the strategy upon instruction-response pairs generated by Self-Instruct.

Tree-Instruct (Zhao et al., 2023) improves instruction quality by prompting the LLM to implicitly complicate instruction through its semantic tree. Following the original paper, we use the subsampled Alpaca dataset as seed data. We set the number of tree nodes to 10 for best possible performance.

WizardLM (Xu et al., 2023) iteratively complicates instructions by prompting the LLM with a set of pre-defined evolution operations. Given the popularity and effectiveness of WizardLM, we experiment it with two variants: the original version using Alpaca as seed data, and the enhanced version uses the same set of basic instructions generated from CodecLM as seed data. We name the later variant as **WizardLM+** as its enhanced by components of our framework.

A.3 Additional Implementation Details

We augment the metadata to 200 by mix-and-matching use cases and skills from different instructions. We randomly sample one use case from $\{u_i\}_{i=1}^n$, and pair it with one or more skills sampled without replacement from $\bigcup_{i=1}^n \boldsymbol{s}_i$. Although most skills are generalizable between use cases, we still conduct manual sanity check to exclude unreasonable use case and skills pairs. We align our hyper-parameters for iteratively improving instructions via Self-Rubrics with prior work (Xu et al., 2023): We generate 4 rubrics and corresponding actions, and at each iteration, we randomly choose 1 action for improving instruction. For fair comparison with WizardLM, we also use at most 4 improve iterations for each instruction (we count basic prompt generation as the first iteration). For Contrastive Filtering, we always use the strong LLM itself as the scorer. We set the scoring scale to 10 and the filtering threshold to 3 for all experiments. We obtain the threshold by developing on the AlpacaEval (Dubois et al., 2023) dataset. And we find this threshold works generally well across different settings. Moreover, for LLaMA-based models, using their Alpaca (Taori et al., 2023) counterparts as the target LLM for response generation in Contrastive Filtering works better than the original model that is not instruction tuned. For metadata extraction, base instruction generation and Self-Rubrics, we use a inference temperature of 0.7. We set the maximum number of tokens for generation to 2048 for LLaMA-based models, and 1024 for PaLM-based models due to API constraints. Moreover, although we set aside 20% validation set for metadata extraction, we still report the performance on the full test set in the main paper, the reasons are as follows: (1) We observe removing the validation set from the full test benchmark will not change the relative superior performance of our method, the performance gap between our method and baselines remains almost the same. Therefore, we keep them in for better reproducibility. (2) By carefully checking the generated instructions, we notice that none of the generated instructions overlap with the original validation instructions, so no data leaking happens during the data generation process.

We conduct manual inspection on the generated data to make sure no personal information or offensive contents are generated.

A.4 Training Details

For LLaMA-based models, we follow the practices in instruction tuning in prior works (Zhou et al., 2023a; Chen et al., 2023b). We use AdamW optimizer with $\beta_1 = 0.9, \beta_2 = 0.95$ to finetune the target model for 15 epochs, as suggested by Zhou et al. (2023a) for smaller data size. We set the initial learning rate to 1×10^{-5} and linearly decaying to 1×10^{-6} by the end of training. We set per GPU batch size to 8, which is equivalent to a total batch size of 64, as we use 8 A100 GPUs for training. The maximum token length is set to 2048.

For PaLM-based models, we follow the default instruction tuning setting on Google Cloud's LLM tuning web UI. We set the number of tuning steps to 2000, the learning rate multiplier to 1, and use the TPU training option.

A.5 Detailed Comparison Results

We show the details of pairwise comparison on Evol-Instruct benchmark with LLaMA-based models, as a demonstration of how CRR faithfully reflects the capability of the target LLMs trained by different methods. In Table 5, we observe that number of ties dominates the results and the number of wins are scarce. We attribute it to the fact that the target model is essentially distilling knowledge from the strong model. As a result, most of the time, the instruction-tuned target model is only able to respond as good as the strong model, through the lens of the LLM-based evaluator.

Table 4: Additional results on standard benchmarks.

Methods	BBH	MMLU	Average
LLaMA-7B	30.93	35.17	33.05
Alpagasus	31.55	36.46	34.01
WizardLM+	31.72	37.89	34.81
CodecLM (ours)	**32.60**	**42.67**	**37.64**

A.6 Consistency between LLM-based Evaluators

In the main paper, we use ChatGPT as the LLM judge for final evaluation, for its efficiency, price and accessibility for the community to reproduce our results. As pointed out in (Chiang et al., 2023), LLMs evaluators, although largely consistent with human preferences, may have their own biases. Therefore, to make sure our experimental results are solid, we also use GPT-4 as the judge and compare against the performance gap in CRR between different baselines and the Self-Instruct method. The comparison results in Table 6 demonstrates the agreement of two LLM-based judges and confirms the superior performance of CodecLM against comparing methods.

A.7 Additional Benchmark Results

To complement the performance result using LLM-based automatic evaluator, we also evaluate LLMs tuned with the top methods presented in Section 5.4 on standard NLP benchmarks, MMLU (Hendrycks et al., 2020) and BBH (Suzgun et al., 2022). We follow the same settings introduced in (Wang et al., 2023) without demonstrations or CoT (Wei et al., 2022) prompt for evaluating the target models based on LLaMA-7B. For our method, we follow the same setting as in Evol-Instruction benchmark evaluation. We present the evaluation results in Table 4 and use the performance of vanilla LLaMA-7B as a reference. We observe the same performance ranking of all methods as that in Table 1 where we use LLM-based automatic evaluator. The consistency between two different evaluation approaches indicates the reliability of LLM-based evaluator in terms of demonstrating relative perfor-

Table 5: Detailed comparison results with LLaMA-based models on Evol-Instruct benchmark. Each method trains a target model based on LLaMA-7B or -13B, and compares against the strong model, Gemini-Pro. Capacity Recovery Ratio (%), $\mathsf{CRR} = \frac{\texttt{wins+ties}}{\texttt{total comparisons}}$.

Methods	LLaMA-7B vs. Gemini-Pro				LLaMA-13B vs. Gemini-Pro			
	Wins	**Ties**	**Losses**	**CRR**	**Wins**	**Ties**	**Losses**	**CRR**
Self-Instruct	17	140	61	72.02	29	136	53	75.69
Alpagasus	17	147	54	75.23	26	148	44	79.82
Tree-Instruct	23	141	54	75.23	26	154	38	82.57
WizardLM	19	143	56	74.31	30	149	39	82.11
WizardLM+	19	146	53	75.69	31	153	34	84.40
CodecLM (ours)	**29**	**145**	**44**	**79.82**	**35**	**154**	**29**	**86.70**

Table 6: Performance gap to Self-Instruct in terms of CRR on Evol-Instruct, evaluated by ChatGPT and GPT4, respectively. Each method trains a target model based on LLaMA-7B or -13B, and compares against the strong model, Gemini-Pro. We observe two LLM-based automatic evaluators yields consistent results.

Methods	LLaMA-7B vs. Gemini-Pro		LLaMA-13B vs. Gemini-Pro	
	ChatGPT	**GPT4**	**ChatGPT**	**GPT4**
Self-Instruct	0.00	0.00	0.00	0.00
Alpagasus	+3.21	+1.38	+4.13	+1.83
Tree-Instruct	+3.21	+2.29	+6.88	+4.59
WizardLM	+2.29	+0.46	+6.42	+3.21
WizardLM+	+3.67	+2.29	+8.72	+5.50
CodecLM (ours)	**+7.80**	**+8.26**	**+11.01**	**+8.72**

mance of competing methods.

A.8 Case Study

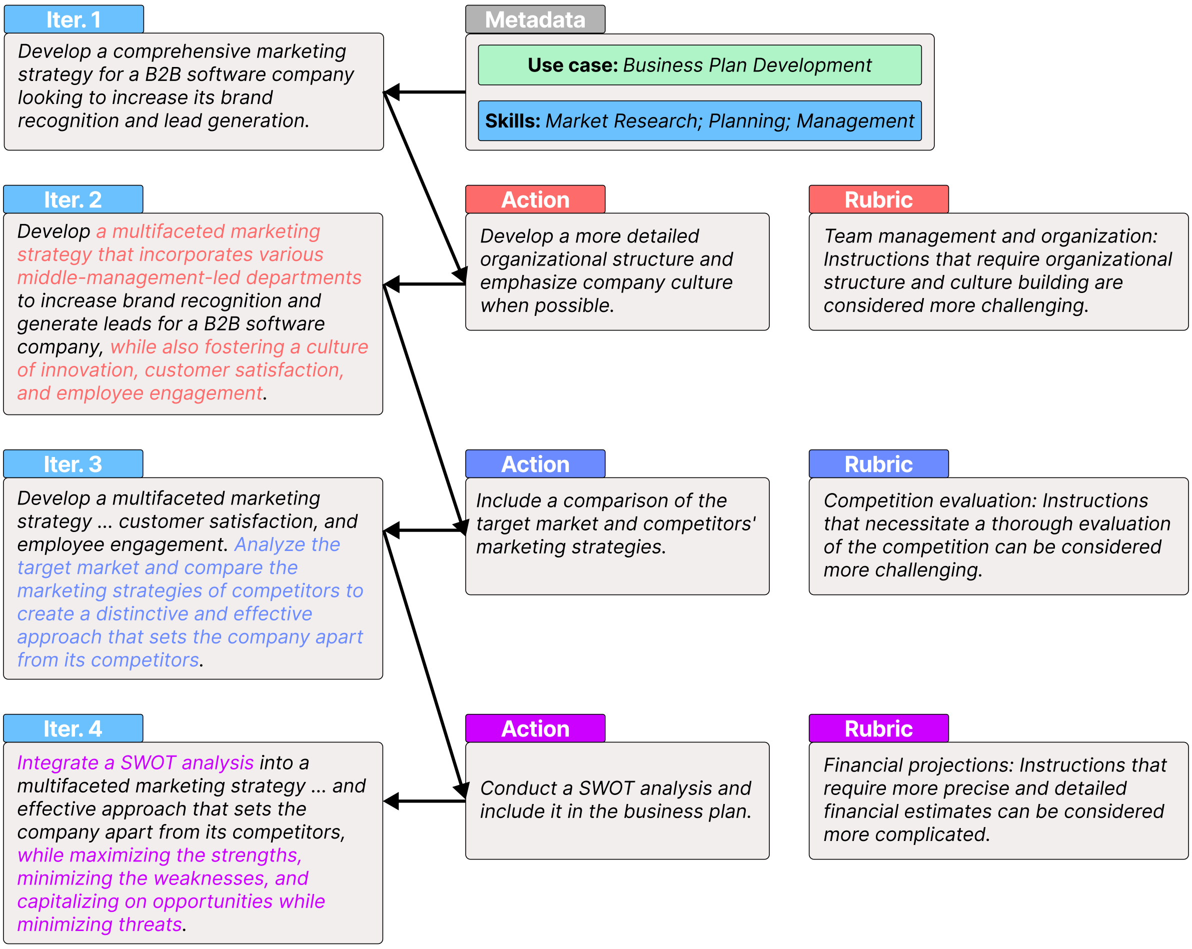
We present a case study in Figure 6 to show an iterative tailoring process from instruction metadata to the final high-quality prompt. In practice, the iteration may terminate earlier by the Contrastive Filtering process. We observe that Self-Rubrics is able to tailor rubrics and actions according to the given metadata. Interestingly, the actions generated by LLM seems very domain-specific. For example, the *SWOT analysis* in the last action may even be hard for non-expert human annotators to come up with. Moreover, the colored texts in instructions demonstrate that LLM is able to follow the actions quite precisely to refine the instructions.

A.9 Prompt Templates for CodecLM

We present all prompt templates here in the appendix for better reproducibility. In particular, we list the correspondence between prompt templates and their usages as follows for quick reference:

- Figure 7: Encoding instructions into metadata, including use case and transferable skills.
- Figure 8: Decoding instruction metadata into basic instructions that are relatively simple in structure.
- Figure 9: Generating rubrics to judge how challenging an instruction is, and actions to improve the instruction based on the given metadata.
- Figure 10: Improving the input instruction by following one of the generated actions.
- Figure 11: Comparing the responses quality from the target and strong LLMs. Adapted from the Vicuna-style pairwise comparison prompt by removing the explanation part.
- Figure 12: Automatic evaluation using LLM (*e.g.*, ChatGPT, GPT-4) as the judge. Following the templates in (Chiang et al., 2023; Chen et al., 2023b)

All prompts are zero-shot except for the first encoding prompt in Figure 7, which utilizes few-shot demonstrations to showcase the LLM a rough granularity of the task and skills. Also, we choose these prompts as they work quite well in practice. And we believe recent prompt optimization techniques (Fernando et al., 2023; Yang et al., 2023) can be incorporated seamlessly into our framework, and we leave them as future work.



Iter. 1

Develop a comprehensive marketing strategy for a B2B software company looking to increase its brand recognition and lead generation.

Metadata

Use case: *Business Plan Development*

Skills: *Market Research; Planning; Management*

Iter. 2

Develop a multifaceted marketing strategy that incorporates various middle-management-led departments to increase brand recognition and generate leads for a B2B software company, while also fostering a culture of innovation, customer satisfaction, and employee engagement.

Action

Develop a more detailed organizational structure and emphasize company culture when possible.

Rubric

Team management and organization: Instructions that require organizational structure and culture building are considered more challenging.

Iter. 3

Develop a multifaceted marketing strategy ... customer satisfaction, and employee engagement. Analyze the target market and compare the marketing strategies of competitors to create a distinctive and effective approach that sets the company apart from its competitors.

Action

Include a comparison of the target market and competitors' marketing strategies.

Rubric

Competition evaluation: Instructions that necessitate a thorough evaluation of the competition can be considered more challenging.

Iter. 4

Integrate a SWOT analysis into a multifaceted marketing strategy ... and effective approach that sets the company apart from its competitors, while maximizing the strengths, minimizing the weaknesses, and capitalizing on opportunities while minimizing threats.

Action

Conduct a SWOT analysis and include it in the business plan.

Rubric

Financial projections: Instructions that require more precise and detailed financial estimates can be considered more complicated.

Figure 6: Case study on the instruction improvement process of CodecLM. Repetitive instructions are omitted to save space.

```
I want you to act as an instruction analyzer.
Given an instruction, you should recognize its use case and the skills (or knowledge)
required for a large language model (LLM) to answer the question.
Generate the use case and skills required without any explanation.
List at most 3 skills, each skill should be transferable, so that LLM can leverage them to answer
similar questions.
Avoid using ”skill”, ”knowledge” to describe a skill, and each skill should be concise (2-3 words).
Follow the examples below to analyze the given instruction.

#Example 1#
As a sports commentator, describe the winning play in the final seconds of a championship game.
Use case: creative writing
Skills: role-play, sports

#Example 2#
How to read a large file (> 2T) using python?
Task: code generation
Skills: python

#Example 3#
The method section of your paper is too brief and does not explain how your proposed model works
in detail. How can you provide more details of the hierarchical encoder and the cascaded selectors,
such as their architectures, inputs, outputs, and parameters?
Task: general knowledge question answering
Skills: academic writing, machine learning

<input instruction>
<output metadata>
```

Figure 7: Prompt template to encode the input into metadata, consisting of its use case and transferable skills.

```
I want you to act as an instruction writer.
Your objective is to write <number of instructions> instructions that must be reasonable
and must be understood and responded by humans.
The generated instructions should be diverse enough while following the constraints below:

Use case of the instructions: <use case>

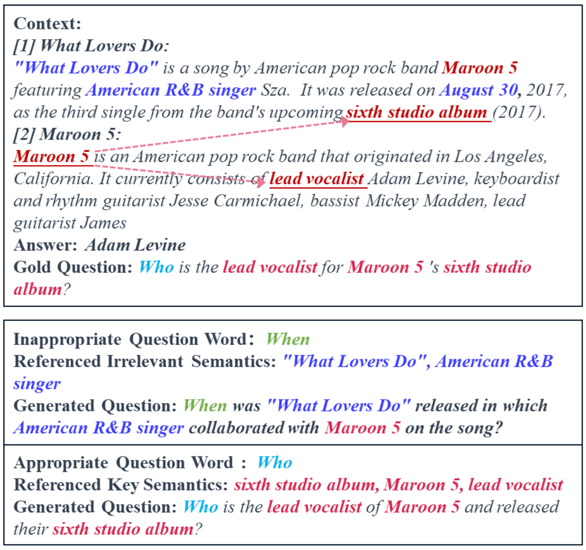
Abstract

Given several documents, multi-hop question generation (MQG) is a task aims to generate complicated questions that require reasoning over multiple pieces of these documents to find the answer. To perform this task, existing studies focus on designing advanced architectures to locate essential keywords or sentences in multiple documents and then generate questions accordingly, where they normally do not note that question types could provide crucial hints for extracting key information from the documents for MQG. In general, supervised approaches are used that rely on large annotated data, which is not available in many low-resource scenarios and thus makes MQG hard in these domains. Consider the recent success of large language models (LLMs) on natural language processing tasks using limited labeled data under few-shot settings, in this paper, we propose an approach named type-aware semantics extraction-based chain-of-thought method (TASE-CoT) for few-shot MQG. Specifically, our approach firstly extracts question types and essential semantic phrases from the given documents and the answer. Then, we design a three-step CoT template to leverage the extracted question type and semantic phrases to predict multi-hop questions. Extensive experiments and the results demonstrate the effectiveness of our approach and the proposed modules.[1]

1 Introduction

Question generation (QG) aims to generate questions that are relevant to the given document. It is a vital task in the field of question answering (QA) owing to its wide applications, e.g., helping chatbots start conversations with intriguing questions (Skjuve et al., 2022; Janssen et al., 2022). Most existing approaches for QG (Du et al., 2017; Zhou et al., 2018; Kim et al., 2019; Fei et al., 2021; Mulla and Gharpure, 2023) focus on generating simple one-hop questions based on a single document, which cannot cover the cases that need complicated multi-hop questions requiring a deep understanding of multiple documents to answer. Under this circumstance, multi-hop question generation (MQG), which aims to generate multi-hop questions where answering the questions requires reasoning over multiple documents, has attracted increasing interest from both the academia and industry community (Pan et al., 2020; Sachan et al., 2020; Ji et al., 2021; Su et al., 2022a; Fei et al., 2022; Yu et al., 2023; Xia et al., 2023).



Context:
[1] What Lovers Do:
"What Lovers Do" is a song by American pop rock band Maroon 5 featuring American R&B singer Sza. It was released on August 30, 2017, as the third single from the band's upcoming sixth studio album (2017).
[2] Maroon 5:
Maroon 5 is an American pop rock band that originated in Los Angeles, California. It currently consists of lead vocalist Adam Levine, keyboardist and rhythm guitarist Jesse Carmichael, bassist Mickey Madden, lead guitarist James
Answer: ***Adam Levine***
Gold Question: *Who is the lead vocalist for Maroon 5 's sixth studio album?*

Inappropriate Question Word: ***When***
Referenced Irrelevant Semantics: ***"What Lovers Do", American R&B singer***
Generated Question: ***When was "What Lovers Do" released in which American R&B singer collaborated with Maroon 5 on the song?***

Appropriate Question Word : ***Who***
Referenced Key Semantics: ***sixth studio album, Maroon 5, lead vocalist***
Generated Question: *Who is the lead vocalist of Maroon 5 and released their sixth studio album?*

Figure 1: The figure presents examples where the question type affects the process of generating questions. In this example, the first model selects the inappropriate question type "*when*", and thus extracts irrelevant semantics. On the contrary, the second model selects the appropriate question type "*who*", and thus extracts the appropriate key semantics to generate questions. Important semantic phrases are highlighted in red color.

Existing studies (Pan et al., 2020; Fei et al., 2022; Xia et al., 2023) on MQG usually regard semantic phrases as nodes and build graphs over them. They utilize graph neural networks (GNN) or node clas-

(I) Type-aware Semantics Extraction **(II) Question Generation with Type-aware CoT**

Figure 2: The figure shows the overall pipeline of the TASE-CoT approach. It consists of two steps, namely, type-aware semantics extraction and question generation with type-aware CoT, which are presented on the left- and right-hand sides of the figure, respectively. Example input and prompt templates are presented for better illustration.

sification to extract reasoning chains or keywords from multiple documents. Then, they use the reasoning chains and keywords to help MQG models generate relevant multi-hop questions. These approaches generally require a large amount of labeled training data to learn a well-performing MQG model and are hard to apply to low-resource situations. Owing to the recent success of large language models (LLMs) on few-shot learning (Brown et al., 2020; Wei et al., 2022), it is intuitive to perform MQG with LLMs under the few-shot setting when the training resources are limited. However, prompting LLMs with straightforward instructions to generate multi-hop questions is not trivial to obtain satisfying performance. LLMs are inefficient at extracting and utilizing key semantic phrases that are essential to produce a multi-hop question. Consider prompting LLMs with relevant information is demonstrated to be effective for many NLP tasks (Wei et al., 2022; Su et al., 2022b; Liang et al., 2023; Fei et al., 2023), a carefully designed prompting strategy with semantic information is expected to be helpful for better MQG. Meanwhile, we notice that the question type provides hints in extracting key semantic phrases and producing multi-hop questions that satisfy human preferences, as illustrated in the examples in Figure 1.

In this paper, we propose an approach named type-aware semantics extraction-based chain-of-thought (TASE-CoT) for MQG. Our approach utilizes a type-aware semantics extraction (TASE) model to extract question types and key semantic phrases, which are utilized in the type-aware chain-of-thought (CoT) framework to generate questions. Specifically, TASE firstly predicts the question type based on the given answer and context documents. Then, it utilizes the question type to extract the key semantic phrases. Type-aware CoT constructs a CoT prompt based on the obtained question type and semantic phrases. The CoT prompt breaks the MQG process into multiple steps according to the general process when humans produce questions. The proposed module selects training set samples with similar question types to construct few-shot demonstration examples, which further enhances LLMs' understanding of the CoT prompt and thus improves model performance. Extensive experiments illustrate the effectiveness of our approach and each proposed module, and it achieves state-of-the-art performance on few-shot MQG and comparable performance to fine-tuning methods.

2 The Approach

The overall architecture of our approach is illustrated in Figure 2. It generates the question $\widehat{q}$

with the given set of N context documents $C = \{d_1, ..., d_N\}$ and an answer a related to C, where a is the answer to the generated question $\widehat{q}$ using information from at least two documents in C. Our approach consists of two parts, the first TASE module f_1 (see the left of Figure 2) extracts the question type $\widehat{t}$ and semantic phrases $\mathcal{S}$ that provide essential information for MQG. The second part f_2 leverages the extracted t and $\mathcal{S}$ to construct the type-aware CoT and use it to instruct LLMs to generate multi-hop questions. Thus, the overall objective of our proposed framework is defined as follows:

$$\widehat{q} = f_2(f_1(C, a), \mathcal{D}, C, a) \tag{1}$$

where $\mathcal{D}$ is the training set that is used to extract demonstration examples to facilitate few-shot learning. The details of the two steps are illustrated in the following texts.

2.1 Type-aware Semantics Extraction

For MQG, existing studies (Fei et al., 2022; Xia et al., 2023) demonstrate that the semantic phrases that are relevant to the given answer contribute to generating high-quality questions. Meanwhile, the question type provides important hints on locating these relevant and important semantic phrases. Therefore, we propose the type-aware semantics extraction method. This method first predicts the question type and then uses the question type to locate important semantic phrases. Finally, the semantic phrases are sorted to guide the model to generate questions in a specific order. The details of the question type classifier, the semantic phrase extractor, and the semantic phrase ordering process are illustrated in the following text.

Question Type Classifier We use the encoder of T5 (Raffel et al., 2020) as our question type classier. It takes the answer a and the context documents $d_1 \cdots d_N$ as the input and predicts the type $\widehat{t}$. Specifically, we concatenate a and $d_1 \cdots d_N$ and feed the resulting text $[a; d_1 \cdots d_N]$ as the input to the classifier. The T5 encoder $\texttt{Encoder}_{TC}$ computes the hidden vectors for the input, and we apply a `MeanPooling` operation to the hidden vectors to obtain the question type representation $\mathbf{h}_t$. The process is formulated as

$$\mathbf{h}_t = \texttt{MeanPooling}(\texttt{Encoder}_{TC}(a; d_1 \cdots d_N)) \tag{2}$$

Afterwards, we employ a linear projection layer with `Softmax` function to $\mathbf{h}_t$ and predict the question types $\hat{t}$:

$$\widehat{t} = \texttt{Softmax}(\texttt{Linear}(\mathbf{h}_t)) \tag{3}$$

where $\widehat{t}$ is used in the subsequent process to identify important semantic phrases for MQG.

To train the question type classifier, we define the question types and collect the training data through the following process. Motivated by the observation that the first word in English questions generally determines the content they are asking, we collect the first word of all questions in the MQG training set as the raw type set. Then, we manually go through the set and filter out the types that do not make sense. The resulting question type set contains 22 question types and an additional "other" type, which the 22 general types are elaborated in Table 1. Finally, we extract the gold standard question type corresponding to the first word in the gold standard question in the MQG training set and use it to train the question type classifier.

	Question Types
wh-	*how, what, when, where, which, who, whom, whose*
be	*are, is, was*
do	*did, do, does*
have	*had, have, has*
will/can	*can, could, should, will, would*

Table 1: The table shows 22 general question types used in our approach. The question types are grouped into five categories for better illustration; the five categories are not used in our approach.

Semantic Phrase Extractor The semantics extractor aims to locate important semantic phrases that contribute to MQG based on the predicted question type $\widehat{t}$. Following Xia et al. (2023), we regard the important semantics phrase extraction as a sequence labeling task, where each semantic phrase is annotated by a binary label indicating whether it is an important semantics phrase. We use a Transformer-based approach as the semantics extractor. The Transformer encoder $\texttt{Encoder}_{SE}$ takes the concatenation of the answer a and the documents $d_1 \cdots d_N$, and computes the hidden vector for each semantic phrase. The l-th hidden vector for the l-th semantic phrase is denoted as $\mathbf{u}_l$. The process is formulated as

$$\mathbf{u}_1 \cdots \mathbf{u}_L = \texttt{Encoder}_{SE}(a; d_1 \cdots d_N) \tag{4}$$

where L is the total number of semantic phrases in the documents. Next, for each $\mathbf{u}_l$, we add it to the question type representation $\mathbf{h}_t$ and feed the resulting vector $\mathbf{o}_l = \mathbf{h}_t + \mathbf{u}_l$ into a fully connected projection layer with `Softmax` classifier. Thus, the important phrase label $\widehat{z}_l$ is obtained by

$$\widehat{z}_l = \mathtt{Softmax}(\mathtt{Linear}(\mathbf{o}_l)) \tag{5}$$

We compute $\widehat{z}_1 \cdots \widehat{z}_L$ for all semantic phrases and extract the important ones accordingly. We denote these semantic phrases as $s_1 \cdots s_M$, where M is their total number and the representation of the m-th semantics phrase s_m is $\mathbf{o}_m$.

To train the semantics extractor, it requires gold standard important semantic phrases. We regard the ones shared by the gold standard question and the documents as the gold standard important phrases.

Semantic Phrase Ordering We observe that the order of the extracted important semantic phrases provides essential hints for generating high-quality multi-hop questions. This motivates us to perform semantics ordering to find the appropriate order of the semantic phrase. We refer to the approach proposed by Li et al. (2022) to predict the order of semantic phrases, whose effectiveness is demonstrated in leveraging the order of different semantic phrases to improve text generation. Overall, our approach contains two steps. The first step computes the position representation of each semantic phrase using an attention mechanism; the second step uses a Transformer decoder to generate the original semantic phrases one by one. The order of the generated semantic phrases indicates their satisfactory order in the multi-hop questions.

Specifically, in the first step, we use the standard positional embedding matrix $\mathbf{E}_{POS}$ for Transformer (Vaswani et al., 2017) and use it as the keys and values in the attention mechanism, where the representation $\mathbf{o}_m$ of the semantics phrase s_m is used as the query. Therefore, the position representation $\mathbf{p}_m$ of s_m is computed by

$$\mathbf{p}_m = \mathtt{Softmax}(\mathbf{o}_m \cdot \mathbf{E}_{POS}^{\top}) \cdot \mathbf{E}_{POS} \tag{6}$$

where $\mathbf{E}_{POS}^{\top}$ means the transpose of $\mathbf{E}_{POS}$. Afterwards, we add $\mathbf{p}_m$ to $\mathbf{o}_m$ and feed the resulting vector into the Transformer decoder in the second step. The decoder predicts the semantic phrase $s'_1 \cdots s'_M$ following the standard process, where $s'_1 \cdots s'_M$ are the reordering of $s_1 \cdots s_M$ and its order is used to help the following MQG. To train the semantics ordering model, we use the order of the semantic phrase in the gold standard question as the gold standard and optimize the model accordingly.

2.2 Question Generation with Type-aware CoT

Existing studies have shown that the quality of demonstration examples is essential for achieving good performance under few-shot settings (Zhang et al., 2022). To obtain high-quality demonstration examples, we propose a few-shot CoT prompt construction approach that consists of two steps. The first is type-aware sample selection and the second is question generation with CoT. The details of the two steps are illustrated as follows.

Type-aware Sample Selection The goal of sample selection is to extract demonstration examples that are similar to the test instance, so that the LLM is able to learn relevant information to process the test instances from the given examples. Intuitively, the more similar the demonstration examples are to the test instances, the better the examples are. Given the question type is an essential feature that could help generate high-quality question, we propose to select demonstration examples that share the same question type with the test instance. Thus, for a test instance, we select demonstration examples using the following process.

Consider the quality of text representation plays an essential role in text understanding (Conneau et al., 2017; Song et al., 2017; Song and Shi, 2018; Han et al., 2018; Sileo et al., 2019; Song et al., 2021; Gan et al., 2023), we first use the Sentence-BERT model (Reimers and Gurevych, 2019), which is demonstrated to be effective in extracting sentence-level representations, to encode the test instance and all training instances. Sentence-BERT encodes the combination of the answer a, the question type $\widehat{t}$, and the semantic phrase $s'_1 \cdots s'_M$ of the test instance and obtain its representation $\mathbf{x}$. We perform the same process to compute the representation of the i-th training instances $\mathbf{x}_i$ whose question type is identical to $\widehat{t}$, where their semantic phrases are obtained from the type-aware semantics extraction process illustrated in Section 2.1. For each training instance, we compute the cosine similarity between $\mathbf{x}$ and $\mathbf{x}_i$ and select K training instances with the top K highest similarity scores as the demonstration examples.

Question Generation with CoT To perform CoT, it is required to have a step-by-step process

Dataset Name	**Train**	**Dev**	**Test**
HotpotQA	89,947	500	7,405
2WikiMultiHopQA	167,454	12,576	12,576

Table 2: The table shows the number of instances in the two benchmark datasets for MQG.

to generate the question for the demonstration examples. Given that it is expensive to ask human annotators to annotate the process, we propose using a CoT template that presents the general process of generating questions with the given answers and documents. Generally, when humans propose a multi-hop question based on multiple documents and predefined answers, they first determine the questioning type based on the answer, then select appropriate key semantic phrases from multiple documents, and finally formulate the question with the semantic phrases appearing in a particular order. Motivated by the process of producing questions by humans, we design a three-step template that leverages the question type and the semantic phrases. The template is illustrated on the right of Figure 2. The first step analyzes the question type with the given answer. The second step extracts important semantic phrases. The third step reorders the semantic phrase and instructs the LLM to predict the multi-hop question. We use the answer, the question type, and the semantic phrase in the demonstration examples to fill in the template and use them to instruct LLM to generate the question $\widehat{q}$ for the test instance.

3 Experiment Settings

3.1 Datasets

Following existing studies (Pan et al., 2020; Fei et al., 2022; Xia et al., 2023), we run experiments on two widely used English benchmark datasets named HotpotQA (Yang et al., 2018) and 2WikiMultiHopQA (Ho et al., 2020). We follow existing studies (Fei et al., 2022; Ho et al., 2020) to split the datasets into train/dev/test sets. We report the number of instances in the datasets in Table 2.

3.2 Baselines

As there are limited studies for few-shot MQG with LLMs, we adopt the following general prompting approaches in the few-shot setting as our baselines.

Vanilla Prompt (Brown et al., 2020) is the standard prompting method of in-context learning. In our implementation, we randomly select K examples from the training set to construct the demonstration examples for few-shot settings.

Random-CoT (Wei et al., 2022) is a naïve baseline where the K demonstration examples are randomly selected from the training set. We follow the design criteria of CoT in their study to construct the task description and demonstration.

Manual-CoT (Wei et al., 2022) is a CoT approach where the K demonstration examples are manually created. We construct the prompt for Manual-CoT based on the CoT template used in our approach. We try different variants with minor modifications of our CoT template and use the one with the best performance in experiments.

Auto-CoT (Zhang et al., 2022) is an approach that automatically generates CoT of demonstration examples. We apply this approach to the MQG task through the following process. We first encode all training instances using Sentence-BERT and obtain their representations. Then, we perform the clustering approach in Auto-CoT and choose the examples of different cluster centers to generate the reasoning chains in the demonstration examples.

Least-to-Most (Zhou et al., 2023) is an approach that prompts LLMs to solve problems step by step from easy to difficult. We apply this approach to the MQG task through the following process. We first decompose the MQG task into three steps corresponding to our CoT template, and then sequentially prompt LLMs to complete these steps, whereby the generation of the previous step is used to facilitate the generation of the current step.

CoT-SC (Wang et al., 2023) is a CoT approach that samples diverse reasoning paths generated by LLMs and chooses the most consistent answer by marginalizing these paths. We use the same prompt of Manual-CoT in CoT-SC.

3.3 Implementation Details

In Type-aware semantics extraction, we utilize the T5-base[2] (Raffel et al., 2020) as the encoder of the question type classifier and semantic extractor in our approach. We use the decoder of T5-base as the model for semantics ordering. For the Sentence-BERT used in our approach and baselines, we utilize the all-MiniLM-L6-v2[3] model. We

Table 3: The table shows the experimental results of different models on HotpotQA with the few-shot setting. The best and second-best results are boldfaced and underlined, respectively.

utilize `gpt-3.5-turbo-1106`[4] from OpenAI API as the LLM to generate questions.

In the experiment, we set the number of demonstrations $K = 3$, where most methods achieve their best performance. In addition, we try two settings to select the demonstration examples for Vanilla Prompt and Random-CoT baselines. The first "fixed" configuration sets all K examples to be fixed for all test instances, while the second "variable" configuration sets them to be different for every test instance.

For evaluation metrics, we follow previous studies to employ the commonly used BLEU (Papineni et al., 2002), ROUGE-L (Lin, 2004), and METEOR (Lavie and Agarwal, 2007) as our automated evaluation metrics. Herein, BLEU and ROUGE-L are considered as precision and recall of n-gram matching to evaluate text generation tasks, respectively. METEOR is a comprehensive metric beyond exact matches, accounting for partial matches and variations in word order.

4 Results and Analysis

4.1 Main Results

We run our approach and baselines with the "fixed" and "variable" settings on the benchmark dataset. Table 3 shows the experimental results of different models. There are the following observations.

First, compared with baseline methods, our approach achieves better performance on HotpotQA datasets, which indicates the effectiveness of our approach. Second, we observe that all CoT-based prompting approaches outperform the Vanilla Prompting approach. This indicates the effectiveness of dividing the entire question generation process into subtasks in a CoT-style prompt, which is coherent with the conclusion shown in the previous work. Third, compared with Auto-CoT, Manual-CoT, which utilizes the question type information, achieves better performance, which shows the effectiveness of type-aware CoT. Fourth, comparing settings with the "fixed" or "variable" demonstration examples, we find that overall, the performance under the two settings is similar, which presents the robustness of our approach.

We further compare our approach with existing studies. The results on HotpotQA and 2WikiMultiHopQA are shown in Table 4 and 5, respectively. Herein, all existing studies on HotpotQA utilize supervised approaches, which are trained on the entire training data. We find that, with three demonstrations, our approach outperforms the majority of pre-trained models on the HotpotQA dataset. In addition, in the cross-domain setting of Table 5, our method outperforms all methods. Since our method first proposed the few-shot setting in the MQG task, to our best knowledge, there are no other few-shot MQG methods compared with our method. Therefore, we can view the TASE-CoT as a baseline for future work on the MQG task in the low-resource scenario.

4.2 Human Evaluation

We conducted the human evaluation by randomly sampling 300 examples from the test set of the HotpotQA dataset. Three annotators were asked to rate the questions generated by the prompting methods and the gold questions. The scale score is 1 to 5, where 1 denotes poor, and 5 denotes perfect. the rating mainly considers three aspects of fluency, relevance, and complexity, and follows the criteria

of Fei et al. (2022). The score of each question is averaged over all annotators. We reported the results in Table 6, our approach outperforms all main baseline methods and obtains scores that are closer to the ground truth than other baselines.

4.3 Ablation Study

We conducted ablation studies to assess the effectiveness of components of our framework and reported the results in Table 7. The following are some observations. First, we exclude the CoT reasoning chain to test the necessity of CoT prompting. We observe a performance drop in the evaluated metrics, particularly a drop of 4.35 points in BLEU-4. This indicates that human question approach-based CoT prompting plays an important role in our framework. Second, we remove the type-aware demonstration selection method and randomly select training samples as the demonstration. The large decrease in the results indicates that our type-aware selection method can ensure our demonstrations have higher quality. We further remove the question type and semantics in the demonstrations respectively. The decreasing performance indicates that the question type and semantics information significantly affect the few-shot MQG. For analysis of sensitivity to templates, we also conducted extra experiments on different templates. The results

QT (Acc)	SPE (Acc)	QG (BLEU-4)
59.15	81.28	18.92
60.25	83.67	20.36
62.50	85.94	22.37

Table 8: The table shows the effect of the performance of question type classification (QT) and semantic phrase extraction (SPE) on the question generation (QG) task.

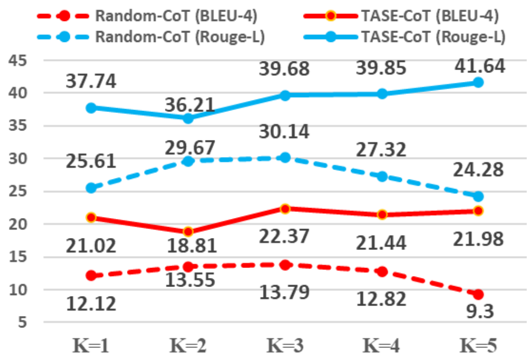

Figure 3: The figure shows the BLEU-4 and ROUGE-L scores of TASE-CoT and Random-CoT on HotpotQA with different numbers of demonstration examples in few-shot settings.

Context:
[1] Walking with Elephants: It was one of ***the most popular songs*** *in* ***Ibiza*** *2014.*
[2] Ten Walls: Marijus Adomaitis (born 19 January 1983), better known by his stage names Ten Walls or Mario Basanov, is a ***Lithuanian producer*** *who is best* ***known*** *for his 2014 single "****Walking with Elephants****", which peaked at* ***number 6*** *on* ***the UK Singles Chart****.*
Answer: *Ten Walls*
Gold Question: ***What Lithuanian producer*** *is* ***known*** *for a song that was one of* ***the most popular songs*** *in* ***Ibiza*** *in 2014?*

Vanilla Prompt (fixed): ***Who*** *is the artist* ***known*** *for the 2014 single "****Walking with Elephants****"?*
Vanilla Prompt (varied): ***Who*** *is the* ***Lithuanian producer*** *best* ***known*** *for his 2014 single "****Walking with Elephants****"?*
Random-CoT (fixed): ***Who*** *is the* ***Lithuanian producer known*** *for his 2014 single "****Walking with Elephants****"?*
Random-CoT (varied): ***Who*** *is the* ***Lithuanian producer known*** *for his 2014 single "****Walking with Elephants****," which was one of* ***the most popular songs*** *in* ***Ibiza*** *2014?*
Manual-CoT: ***Who*** *is the* ***Lithuanian producer known*** *for the 2014 single "****Walking with Elephants****" that peaked at* ***number 6*** *on* ***the UK Singles Chart****?*
Auto-CoT: ***Which Lithuanian producer*** *is* ***known*** *for one of* ***the most popular songs*** *in* ***Ibiza*** *2014?*
TASE-CoT: ***What Lithuanian producer*** *is best* ***known*** *for a song that was one of* ***the most popular songs*** *in* ***Ibiza*** *in 2014?*

Figure 4: The figure shows the case study of one representative example from HotpotQA test set. We indicate the important and unimportant semantic phrases in red and blue colors, respectively. The appropriate and inappropriate question words are highlighted in light blue and green, respectively.

on different templates further demonstrate that our method is strongly robust to different templates.

4.4 Effect of Question Type and Semantics Phrase Extraction

We explore the effect of extraction tasks (i.e., question type extraction and semantics phrase extraction) on the few-shot MQG task. Particularly, we measure the accuracy of the question type classification and semantic phrase extraction on the testing set and report the results in Table 8. We observe that the performance of MQG increases with higher performance on question type classification and semantic phrase extraction. This confirms the motivation of our approach to leverage question types and semantic phrases to improve MQG.

4.5 Effect of Demonstrations Number

We investigate the influence of the number of demonstration examples (i.e., K) on the MQG. We try different numbers of K and report the corresponding model performance in Figure 3. From the curves, we observe that $K = 3$ is the number of demonstrations that achieve the best performance in both Random-CoT and TASE-CoT. However, the performance of Random-CoT drops significantly on both sides of $K = 3$. Compared with Random-CoT, the performance of our approach does not fluctuate much around $K = 3$, which shows that our few-shot approach is robust on the MQG task while only requiring a few demonstration examples to achieve good results.

4.6 Case Study

In Figure 4, we present a case study to demonstrate the effectiveness of TASE-CoT on MQG, where the question generated by TASE-CoT and baselines are presented. The question generated by TASE-CoT shows more complexity compared with the baselines, in that our approach accurately selects the most appropriate question type and extracts the related semantic phrases accordingly. Both question type and essential semantic phrase contribute to improving task performance. In contrast, baselines easily extract less important semantic phrases owning to selecting the inappropriate question type, which hurts the performance of MQG.

5 Related Work

This paper is relevant to multi-hop question generation and CoT. The following text presents the details of the related work in the two fields.

Muti-hop Question Generation Early research on QG predominantly concentrated on generating shallow factual questions based on a single document. Recently, researchers have shown an increasing interest in addressing the challenges of complex multi-hop question generation (MQG) tasks. However, the difficulty in generating multi-hop questions lies in selecting questioning information relevant to a given answer for questioning from multiple documents and using it as a foundation to generate questions in a manner consistent with human style. For this, many studies (Pan et al., 2020; Su et al., 2020; Fei et al., 2021) propose semantic graph-based methods, which aim to solve MQG by extracting semantics related to the answer from the context. To further enhance performance, some research Fei et al. (2022); Xia et al. (2023) explore the decoder-enhanced method based on the semantic graph-based method and achieve great performance. Our research is different from the existing ones as we mainly focus on solving few-shot MQG challenges with LLMs.

Chain-of-Thought CoT is an emerging prompting technique, which improves the performance of LLMs by instructing LLMs to produce intermediate reasoning steps in tasks. Consequently, with the rise of LLMs, diverse CoT prompting methods have been explored in current research. Kojima et al. (2023) initially introduce zero-shot-CoT using the prompt "*Let's think step by step.*". The Manual-CoT method, proposed by Wei et al. (2022), involves crafting human-written few-shot CoT demonstrations. Least-to-most prompting (Zhou et al., 2023) utilize problem decomposition to create a CoT prompt. A self-consistency decoding strategy is introduced by Wang et al. (2023) to sample diverse reasoning paths and choose the most consistent answer by marginalizing these paths. The Auto-CoT method (Zhang et al., 2022), automatically generates CoT demonstrations by leveraging LLMs. To the best of our knowledge, there are no existing studies that apply few-shot CoT to MQG and we are the first to do so.

6 Conclusion

In this paper, we propose TASE-CoT for the few-shot MQG. TASE-CoT extracts the question type and type-aware semantic phrases from the given documents and the answer, then utilizes them to conduct the question generation with type-aware CoT. We run experiments on benchmark datasets, and the results on benchmark datasets show that our approach achieves state-of-the-art performance.

Abstract

Recent studies suggest that self-reflective prompting can significantly enhance the reasoning capabilities of Large Language Models (LLMs). However, the use of external feedback as a stop criterion raises doubts about the true extent of LLMs' ability to emulate human-like self-reflection. In this paper, we set out to clarify these capabilities under a more stringent evaluation setting in which we disallow any kind of external feedback. Our findings under this setting show a split: while self-reflection enhances performance in TruthfulQA, it adversely affects results in HotpotQA. We conduct follow-up analyses to clarify the contributing factors in these patterns, and find that the influence of self-reflection is impacted both by reliability of accuracy in models' initial responses, and by overall question difficulty: specifically, self-reflection shows the most benefit when models are less likely to be correct initially, and when overall question difficulty is higher. We also find that self-reflection reduces tendency toward majority voting. Based on our findings, we propose guidelines for decisions on when to implement self-reflection. We release the codebase for reproducing our experiments at https://github.com/yanhong-lbh/LLM-SelfReflection-Eval.

1 Introduction

Large Language Models (LLMs) have shown impressive performance in generating human-like text (e.g., ChatGPT (OpenAI, 2021)), and recent works demonstrate that we can further prompt LLMs to reflect on their own outputs to improve their capabilities on complicated reasoning, programming and planning tasks (Huang et al., 2022; Kim et al., 2023; Madaan et al., 2023; Shinn et al., 2023; Chen et al., 2023b; Wang et al., 2023b) and also improve their alignment with human values (e.g., less harmful and more helpful) (Bai et al., 2022; Ganguli et al., 2023).[1] However, Huang et al. (2023) find that performance gains associated with self-reflection may be due to implicit usage of external feedback as a stop criterion, as well as overly-engineered prompts that bias the model outputs, casting doubt on the true effectiveness of self-reflection.

Figure 1: Example of Self-Reflection Prompting

To verify the extent to which LLMs can truly reflect on their outputs, we take a more stringent evaluation approach: in addition to excluding external feedback (Huang et al., 2023), we also disallow multi-round iterative prompting, which can hint to the model that its prior response is incorrect. Instead, we sample multiple model responses given a prompt, and ask the model to self-reflect on these candidate outputs. With this *single-round testing*, we can zero in on the model's ability to use self-reflection without implicit hints about whether a given response candidate is correct or incorrect.

Our experiments show that, in a case study with ChatGPT on different QA datasets, self-reflection in our setting yields mixed results. Specifically, self-reflection improves performance on TruthfulQA (Lin et al., 2022), but decreases model performance in HotpotQA (Yang et al., 2018). Through follow-up analyses, we identify that the effectiveness of self-reflection strongly depends on the confidence in accuracy of the model's initial responses, as well as overall question difficulty as

---

[*] Equal Contribution.

[1] Various terms like "self-reflection", "self-refine", "self-correction", and "self-improvement" describe these introspective behaviors. For clarity and consistency, we will exclusively use "self-reflection" in this paper.

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3741–3753
June 16-21, 2024

judged by humans: when the model is reliably giving correct answers from the start, self-reflection is more often harmful—however, on questions of greater difficulty, self-reflection is beneficial even when a decent percent of initial model responses are correct. We also find that self-reflection reduces model tendency toward majority voting, suggesting more sophisticated decision-making (albeit sometimes resulting in lower accuracy). Based on our findings, we propose a practical guideline for users to decide when to use self-reflection.

2 Self-Reflection Prompting

To focus on evaluating intrinsic reflective thinking capability, we adopt the following evaluation setting: in addition to the Huang et al. (2023) protocol of excluding external feedback and prompt optimization, we additionally disallow *iterative prompting*, which samples new responses based on previous responses, creating an implicit hint to bias the model behavior (Huang et al., 2023).[2] We call our approach *Single-Round Self-Reflection Verification (SR^{2}V)*. We evaluate LLMs' reflective thinking capability using the following simple three-stage format: 1) *Exploration:* Given an input X, we prompt LLM M to generate K candidate responses $r_j \sim P_M(r_j|X, I_{\text{Exploration}}), 1 \leq j \leq K$ with instruction $I_{\text{Exploration}}$. Note that this generation of candidate responses differs from iterative prompting because each response is sampled without conditioning on any other candidate responses. 2) *Reflection:* For each response r_j, we prompt M with the concatenated input $[X; r_j]$ to generate a self-critique $c_j \sim P_M\left(c_j|[X; r_j], I_{\text{Reflection}}\right)$ with another instruction $I_{\text{Reflection}}$. 3) *Revision:* We concatenate the K response-reflection pairs into a new input and prompt M to generate an improved output. An illustration of this procedure is shown in Figure 1.

3 Preliminary Study: Does Self-Reflection Prompting Work Under SR^{2}V?

We follow previous works (Bai et al., 2022; Shinn et al., 2023; Huang et al., 2023) in using two representative datasets, TruthfulQA and HotpotQA, to verify the effectiveness of self-reflection under SR^{2}V. TruthfulQA is designed to evaluate the truthfulness of LMs' responses, while HotpotQA focuses on multi-hop reasoning tasks, aimed at requiring complex reasoning capabilities.

Metric	Standard Prompting	Exploration-Only	Self-Reflection
	TruthfulQA		
Rouge-1	57.5 ± 1.1	57.2	**60.8**
BLEURT	66.8 ± 1.9	60.7	**72.8**
	HotpotQA		
Accuracy*	80.3 ± 0.5	**80.8**	76.2
EM	$\mathbf{50.5 \pm 0.4}$	47.3	37.0

Table 1: Self-reflection SR^{2}V experiment results on QA datasets. Bold-facing indicates the best-performing method under each metric. *Evaluated manually.

Experiment Setup For these experiments we set $K = 4$, and we prompt ChatGPT-3.5 ("gpt-3.5-turbo-16k-0613") with the questions from each dataset.[3] Our full process for making these API calls is presented in Appendix F, and all prompt templates used can be found in Appendix E. We also extend our experiments to LLaMA-2 (Touvron et al., 2023) and Mixtral (Jiang et al., 2024), finding similar results to ChatGPT-3.5—we present results and discussion for LLaMA-2 and Mixtral in Appendix I and Appendix J.

For TruthfulQA we evaluate automatically (see details in Appendix D). For HotpotQA, we find that traditional exact match often unfairly assigns a score of 0 for semantically correct model responses; therefore, we manually assess $1,000$ randomly chosen HotpotQA instances to check the model's answers against references.

To isolate the specific effect of the generated reflections, we also include an **exploration-only** baseline, in which we retain the Exploration stage but remove the Reflection component, and only concatenate the candidate model responses in the Revision prompt.[4]

Observations Results are shown in Table 1. In TruthfulQA, we see that using self-reflection achieves significantly better performance than either the exploration-only baseline or standard

---

[2] We present a performance comparison between iterative prompting and non-iterative prompting in Appendix C.

[3] The 16k variant is chosen to accommodate responses and reflection pairs that exceed the standard 4096 token limit, particularly in detailed experiments of Section 5.

[4] The exploration-only baseline can be viewed as one implementation of (universal) self-consistency prompting (Wang et al., 2023a; Chen et al., 2023a). Rather than applying majority voting directly to the outputs, this method involves inputting these outputs back into the model for aggregation. As we'll explore in Section 6, we also find the model predominantly engages in a form of majority voting in this process.

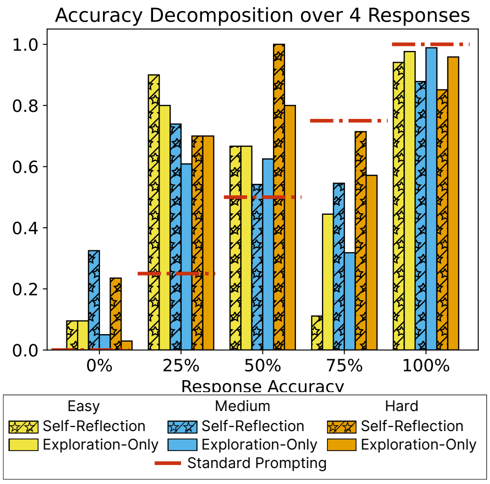

Figure 2: Performance Decomposition on Question Difficulty and Response Accuracy.

prompting. This finding is consistent with the observation of Bai et al. (2022) that LLMs' self-evaluation (in the form of reflection) can help to produce more factual outputs. However, we see that on HotpotQA, accuracy when using self-reflection is about 4% worse compared to both the exploration-only baseline and standard prompting. These results suggest that self-reflection may in fact harm performance in multi-hop reasoning tasks. This aligns with the self-reflection limitations found in Huang et al. (2023), and verifies that these limitations also extend to our more stringent evaluation setting, but presents a more complicated picture with the continued effectiveness of self-reflection on TruthfulQA under this setting.

4 Why Self-Reflection May Not Work?

To better understand these patterns, we conduct an error analysis drawing inspiration from the reflection conceptual model in psychology (Hommel et al., 2023). We hypothesize that two key factors influence self-reflection's efficacy: 1) the objective **question difficulty** (quantifiable based on human annotations), and 2) the **model's comprehension quality** (quantifiable based on the proportion of correct responses). Following this framework, we can predict that if a question is above average in human-annotated difficulty, self-reflection may be of greater benefit. Similarly, if the model already has a strong grasp of the question, it may not benefit as much from self-reflection.

To test these hypotheses, we break down model performance based on levels of question difficulty and model comprehension. We focus our analysis on HotpotQA, as this is the dataset on which we observe significant detrimental effects of applying self-reflection prompting. Additionally, this dataset contains annotated human judgments of question difficulty, and enables a clearly-defined notion of accuracy. We use these human difficulty annotations for our measure of question difficulty, and for model comprehension we use Response Accuracy (RA): the proportion of correct answers among the K candidate model responses sampled during Exploration.

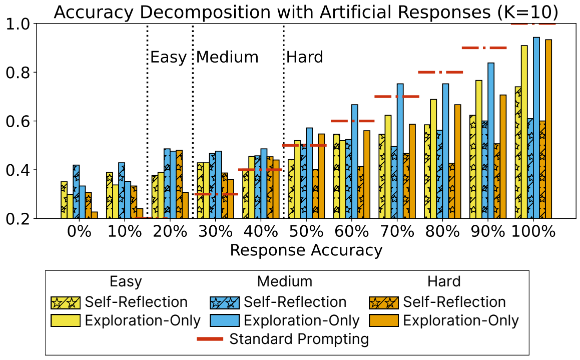

Figure 3: Performance Decomposition on Question Difficulty and Response Accuracy (Artificial Responses). Dotted lines show "turning points" at which reflection loses effectiveness, for Easy/Medium/Hard questions.

The broken-down results are shown in Figure 2. The results show an interaction between our two variables. For questions judged by humans as Easy, self-reflection shows a benefit only when the model's candidate responses are mostly—but not all—incorrect, with self-reflection otherwise having negligible or negative effects on performance. For questions judged as Medium, there is a more even split: when most or all of the model's candidate responses are wrong, self-reflection is beneficial, but when half or more of the responses are correct, self-reflection is often harmful—with the notable exception of the 75% RA bin. A similar pattern is seen for questions judged as Hard, though for this category self-reflection is more consistently beneficial through the 75% RA bin, showing harm to performance only when all candidate model responses are already correct.

5 Error Analysis via Artificial Response

The above analysis suggests an interaction between difficulty and comprehension variables in effectiveness of self-reflection—however, our ability to disentangle these effects is limited by imbalanced distribution of model comprehension relative to question difficulty. To assess the interaction more thoroughly, we simulate model "mis-comprehension" across a wider range of question difficulties, by sampling model responses to minimally edited versions of the prompts, and then pairing these responses with the original prompts when eliciting self-reflection. This allows us to increase the number of incorrect candidate responses, and thus to more evenly distribute RA levels across human difficulty levels. More details on this simulation process can be found in Appendix B.

For this experiment, we generate K = 10 candidate responses per question, with a mix of synthetic pairings and real pairings.[5] Results are shown in Figure 3. We see that the benefits of self-reflection are now limited to the lowest RA levels, and there is also now a clearer shift from beneficial to harmful effects of self-reflection as RA increases. We also see that the interaction with question difficulty remains: the turning point from beneficial to harmful falls around 50% RA for Hard questions, 30% for Medium questions, and 20% for Easy questions. Overall, this indicates that a major contributor to the effectiveness of self-reflection is the confidence of model accuracy on the question—if the model is reliably correct on initial responses, self-reflection tends to be harmful. However, this effect is further modulated by overall question difficulty: the benefits of self-reflection persist to higher levels of response accuracy if the questions are more difficult based on human judgment.

Though TruthfulQA is not as conducive to exact quantification of our variables, based on these results we can now speculate that the effectiveness of self-reflection on that dataset may be attributable to lower rate of good initial model responses, and potentially also higher overall question difficulty.

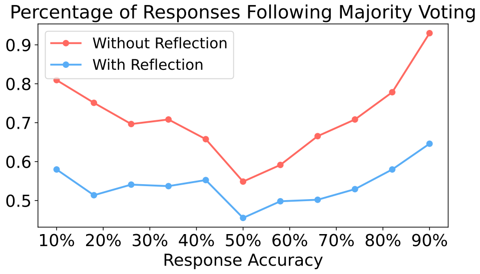

Figure 4: Majority Voting Analysis

6 Effects on majority voting

A natural question to ask at this point is to what extent the effect of RA is due to the model employing majority voting on the candidate responses. In Figure 4 we plot the percentage of items in which the model's output is consistent with majority voting, at different RA levels (computed at $K = 10$ including artificially generated responses), both with and without self-reflection. The plot shows that without self-reflection, the tendency to give answers consistent with majority voting is strong and closely correlated with the strength of the accuracy trend (i.e., more majority voting when most candidate responses are either correct or incorrect, and less majority voting when candidates are more mixed). However, *with* self-reflection the tendency to align with majority voting is significantly reduced across RA levels, suggesting that self-reflection does encourage more sophisticated decision strategies (even if in the case of higher RA levels, this in fact has a harmful effect on accuracy).

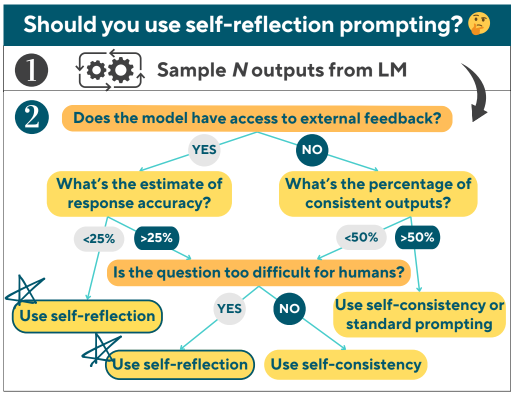

Figure 5: Proposed guide for using Self-Reflection.

7 Discussion

Our analyses above have found that self-reflection benefits are limited to cases in which model accuracy is unreliable on initial responses, though benefits are more persistent for harder questions. Based on these findings, we propose a set of guidelines for determining when to implement self-reflection in practical applications, for a given request or prompt. The core principle involves basing decisions on estimated RA and question difficulty, and these guidelines can be applied by simply sampling responses for the target question or prompt. First, if external tools or certain access to ground truth answers are available such that RA can be reliably estimated, then self-reflection should be used when RA levels are low. Next, if difficulty annotations/subjective difficulty judgements are available, self-reflection can also be promising when RA levels are interme-

---

[5] We also plot the performance decomposition over K=4 artificial responses in Appendix A.

diate and question difficulty is high. If RA cannot be estimated, response consistency can be used as a proxy: if responses are highly consistent, self-reflection may be unlikely to provide benefit. If consistency is low, then self-reflection may be beneficial, especially for questions of higher difficulty. An illustration of these guidelines is in Figure 5.

8 Conclusion

In this paper, we evaluate ChatGPT's self-reflective capabilities under a stringent single-round multi-response evaluation setting. We find mixed results, and further analysis shows that the effectiveness of self-reflection is impacted both by question difficulty and by model response accuracy level: benefits of self-reflection are mostly limited to cases in which the model's initial responses are unreliable in accuracy, but with more persistent benefits for harder questions. Additionally, we find that self-reflection reduces the model's tendency for majority voting. We propose guidelines for when to use self-reflection, and we look forward to work further exploring impacts on self-reflection, and further refining these guidelines.

Acknowledgements

We are grateful for the insightful discussion with Xinyun Chen (Google) and Jie Huang (UIUC) at the early stage of this work (names are not listed in particular order). We also thank the anonymous NAACL reviewers and chairs for providing insightful and constructive feedback to make this work more solid.

Limitations

In this work, we adopt a stringent evaluation strategy to test the effectiveness of self-reflective abilities of LLMs. One limitation is that our experiments reported in the main text are based on a single snapshot of the ChatGPT model (gpt-3.5-turbo-16k-0613). We focus on ChatGPT because it is a state-of-the-art chat model, allowing us to make our results directly comparable with previous work—and we limit to this particular version of ChatGPT to ensure that results will not be affected by model updates. However, the assessment of self-reflection may vary between different versions of ChatGPT, as well as between ChatGPT and other LLMs. We do verify our experimental results on other open language models including LLaMA-2 (Touvron et al., 2023) and Mixtral (Jiang et al., 2024) in Appendix I and Appendix J, respectively. While we find that our conclusions can be extended to these models, due to budget limitations we leave more extensive evaluation over other popular proprietary and open models for future works.

Our experiments also use only two datasets for evaluating reflective ability. We chose these two datasets for a focused study covering two very different QA domains, but we look forward to future work further extending these types of analyses to a broader collection of datasets.

We conducted an artificial response experiment in Section 5 to simulate the real output distribution of the language model. This is a rough estimate of ChatGPT's actual output distribution. As we sampled ten fake responses from the language model, it is impossible to cover all possible cases of outputs, and there might be bias in the sample distribution. Future work could try generating a higher number of fake responses to obtain a more accurate distribution of the model.

Finally, although RA proves a valuable metric for determining the utility of self-reflection, its reliance on access to ground truth undermines its practical use. An initial attempt to use GPT-4 to produce an estimate of RA yielded unsatisfactory results (detailed in Appendix G). Further examination of this topic is reserved for future research.

A Accuracy Decomposition over 4 responses

See Figure 6 for accuracy decomposition over 4 responses using ChatGPT.

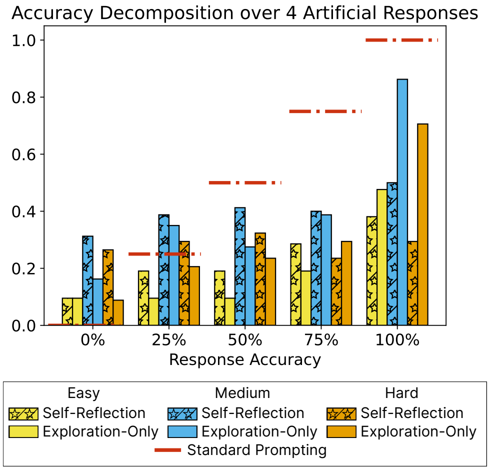

Figure 6: Accuracy vs. Correctness Margin for each artificial response

B Artificial Response Generation

We do artificial response generation by prompting ChatGPT to edit the context used in HotpotQA. Specifically, the following steps were adopted: 1) For chosen questions, perform a simple perturbation on the context (e.g., entity replacement). An example is shown in Figure 7. 2) Manually inspect some samples to ensure minimal edits and answerability. 3) Prompt the model to regenerate responses and reflections based on the altered context. In this way, we are simulating scenarios where the model doesn't comprehend the context perfectly. [6]

Here is an example for how we modify the context:

---

[6] While directly editing outputs to create correct or incorrect answers is an option, we avoid this to ensure the results reflect the model's natural response distribution.

Original question: What nationality was James Henry Miller's wife?

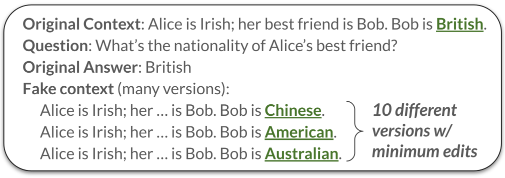
Original context: ... Ewan MacColl: James Henry Miller (25 January 1915 – 22 October 1989), better known by his stage name Ewan MacColl, was an English folk singer, songwriter, communist, labour activist, actor, poet, playwright and record producer. Peggy Seeger: Margaret "Peggy" Seeger (born June 17, 1935) is an American folksinger. She is also well known in Britain, where she has lived for more than 30 years, and was married to the singer and songwriter Ewan MacColl until his death in 1989. ...

Fake context 1: ... Ewan MacColl: James Henry Miller (25 January 1915 – 22 October 1989), better known by his stage name Ewan MacColl, was a Scottish folk singer, songwriter, capitalist, labour activist, actor, poet, playwright and record producer.. Peggy Seeger: Margaret "Peggy" Seeger (born June 17, 1935) is an American country singer. She is also well known in France, where she has lived for more than 30 years, and was married to the actor and playwright Ewan MacColl until his death in 1989. ...

Fake context 2: ... Ewan MacColl: James Henry Miller (25 January 1915 – 22 October 1989), better known by his stage name Ewan MacColl, was an Australian folk singer, songwriter, conservative, labour activist, actor, poet, playwright and record producer. Peggy Seeger: Margaret "Peggy" Seeger (born June 17, 1935) is a British pop singer. She is also well known in Germany, where she has lived for more than 30 years, and was married to the musician and producer Ewan MacColl until his death in 1989. ...

Fake context 3: ... Ewan MacColl: James Henry Miller (25 January 1915 – 22 October 1989), better known by his stage name Ewan MacColl, was a Canadian folk singer, songwriter, anarchist, labour activist, actor, poet, playwright and record producer. Peggy Seeger: Margaret "Peggy" Seeger (born June 17, 1935) is an American rapper. She is also well known in Spain, where she has lived for more than 30 years, and was married to the actor and politician Ewan MacColl until his death in 1989. ...

Fake context 4: ... Ewan MacColl: James Henry Miller (25 January 1915 – 22 October 1989), better known by his stage name Ewan MacColl, was an Irish folk singer, songwriter, monarchist, labour activist, actor, poet, playwright and record producer. Peggy Seeger: Margaret "Peggy" Seeger (born June 17, 1935) is a French jazz singer. She is also well known in Italy, where she has lived for more than 30 years, and was married to the artist and filmmaker Ewan MacColl until his death in 1989. ...



Original Context: Alice is Irish; her best friend is Bob. Bob is British.
Question: What's the nationality of Alice's best friend?
Original Answer: British
Fake context (many versions):
Alice is Irish; her ... is Bob. Bob is Chinese.
Alice is Irish; her ... is Bob. Bob is American.
Alice is Irish; her ... is Bob. Bob is Australian.

Figure 7: Synthesized Artificial Contexts Example

Metric	Standard Prompting	Exploration-Only	Self-Reflection
	TruthfulQA		
Rouge-1	57.5 ± 1.1	55.1	**59.0**
BLEURT	66.8 ± 1.9	70.1	**72.9**
	HotpotQA		
Accuracy	80.2 ± 0.4	69.7	71.9

Table 2: Self-Reflection experiment results using iterative prompting. Bold-faced numbers at each row indicate the best-performing method under each metric.

C Conditional Prompting Results

We demonstrate the conditional prompting results in Table 2. Comparing the results in Table 1 and Table 2, we can see that there is no significant difference between these parallel prompting and conditional prompting. To avoid the implicit bias introduced by conditional prompting, as Huang et al. (2023) point out, we stick to parallel prompting to conduct our evaluation on self-reflective thinking capability.

D Evaluation details for TruthfulQA

We use the generation setting of TruthfulQA, which evaluates by comparing how closely the model's responses match a preferred reference versus an undesired one We follow (Lin et al., 2022) to use Rouge-1 (Lin, 2004) and BLEURT (Sellam et al., 2020) for similarity computation.

G Challenges in Predicting the Correctness Margin for Model Comprehension

The effectiveness of a model's self-reflection largely hinges on its "correctness margin," a metric quantifying its understanding of both the question and its context. Ideally, we would like to predict this margin through user prompts, thereby allowing the user to make an informed decision on whether to enable the model's self-reflection capability.

Nevertheless, our experiments indicate that current models struggle to self-assess their understanding reliably. Below, we outline our prompt design used for this experiment:

```
messages=[
    {"role": "system",
    "content": "You are a helpful
    assistant. Answer the question based
    on the context provided. Provide
    extremely concise answers with no
    explanation."},
    {"role": "user",
    "content": f"Context:
    {formatted_context}\n
    Question: {question}"},
    {"role": "assistant",
    "content": f"{response}"},
    {"role": "user",
    "content": "\nYou have just answered
    a question. Now, please evaluate
        ↪ your
    own comprehension of the question
        ↪ and
    answer provided. Rate your level of
    understanding on a scale from -5 to
        ↪ 5.
    A rating of 5 signifies extreme
    certainty that you understand the
    question, while a rating of -5
    indicates extreme uncertainty or
        ↪ lack
    of understanding."},
]
```

We tested this prompt structure on two sets of questions: one where all 10 model responses were incorrect, and another where all 10 were correct. If the model were capable of accurately evaluating its own comprehension, it should consistently rate its understanding at -5 for questions in the all-wrong dataset and 5 for those in the all-right dataset. However, after experimenting with 20 examples from each dataset, we found that the model consistently assigned high scores (typically 4 or 5) regardless of the dataset origin. Thus, reliable self-assessment remains an open challenge for current models.

H Scientific Artifacts

In this paper, we use the following artifacts:

- TruthfulQA (Lin et al., 2022) is a benchmark assessing a language model's ability to generate truthful answers for 817 diverse questions in 38 categories, requiring models to avoid false answers commonly found in human texts due to misconceptions or false beliefs. We use it for the preliminary studies on reflective thinking in LLMs. It is licensed under the Apache License, Version 2.0.

- HotpotQA (Yang et al., 2018) is a 113k question-answer dataset based on Wikipedia that requires multi-document reasoning, features diverse questions unconstrained by knowledge bases or schemas, provides sentence-level supporting facts for strong supervision and explanation, and introduces a new factoid comparison question type to evaluate QA systems' extraction and comparison abilities. We use it for evaluating reflective thinking in LLMs. It is distributed under a CC BY-SA 4.0 License.

- openai-python[7] (v0.27.8) provides convenient access to the OpenAI REST API from any Python 3.7+ application. We use it to access ChatGPT models. It is licensed under the Apache License, Version 2.0.

I Results on LLaMA-2-7b-chat

We extend our experiments to the open-sourced model LLaMA-2-7b-chat (Touvron et al., 2023), and the results support the conclusions that we draw from our experiments on ChatGPT, indicating that our findings can be generalized to different models.

---

[7] https://github.com/openai/openai-python

Metric	Standard Prompting	Exploration-Only	Self-Reflection
	TruthfulQA		
Rouge-1	53.8 ± 0.4	51.7	**53.8**
BLEURT	60.9 ± 0.6	58.2	**63.0**
	HotpotQA		
Accuracy*	61.0 ± 1.0	**62.9**	57.5

Table 3: Self-reflection SR^{2}V experiment results on QA datasets using LLaMA-2-chat. Bold-facing indicates the best-performing method under each metric. *Evaluated manually.

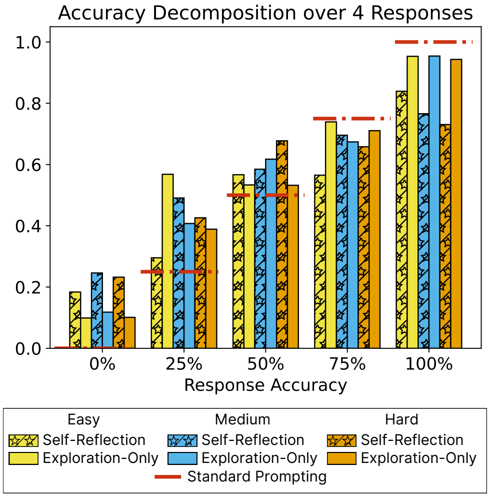

Figure 8: Performance Decomposition on Question Difficulty and Response Accuracy (LLaMA-2-chat).

More specifically, for the preliminary study on performance across TruthfulQA and HotpotQA, the results on LLaMA-2-7b-chat (see Table 3) are consistent with the results obtained from ChatGPT (see Table 1): self-reflection prompts improve performance on TruthfulQA while worsening performance on HotpotQA. Additionally, we conduct our error analysis on the results of HotpotQA, breaking down model performance based on levels of question difficulty and model comprehension. The LLaMA-2-7b-chat results for this analysis (Figure 8) also closely follow the trend observed in the results from ChatGPT (Figure 2): self-reflection is more beneficial when the model's initial responses are incorrect and when the question difficulty is higher.

We do not replicate the 10-response artificial experiments on LLaMA-2-7b-chat due to the context length limit. The context length for LLaMA-2 is 4096, which is shorter than our context length for the task. We replicate this experiment in Appendix J as Mixtral models have larger token limits.

Metric	Standard Prompting	Exploration-Only	Self-Reflection
	TruthfulQA		
Rouge-1	59.1 ± 1.0	61.3	**63.3**
BLEURT	71.5 ± 0.4	**73.9**	71.7
	HotpotQA		
Accuracy*	89.8 ± 0.3	**90.9**	89.2

Table 4: Self-reflection SR^{2}V experiment results on QA datasets using Mixtral-8x7B-v0.1. Bold-facing indicates the best-performing method under each metric. *Evaluated manually.

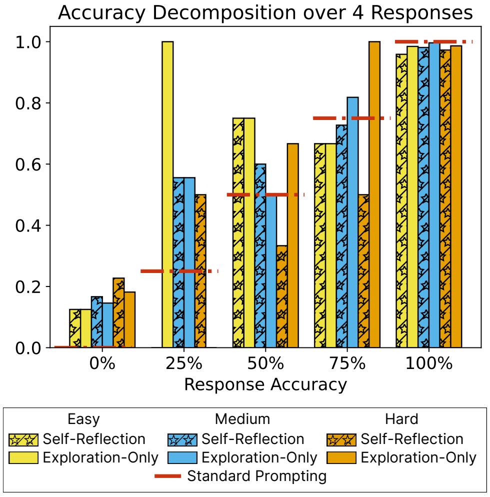

Figure 9: Performance Decomposition on Question Difficulty and Response Accuracy (Mixtral-8x7B-v0.1).

J Results on Mixtral-8x7B-v0.1

We repeat our experiments on Mixtral-8x7B-v0.1. For the preliminary study on performance across TruthfulQA and HotpotQA (Table 4, we again observe a similar trend to ChatGPT: while self-reflection may help improve the performance on TruthfulQA, it harms the performance on HotpotQA. Then, we again break down model performance on HotpotQA based on question difficulty levels and model comprehension in Figure 9. Here we observe a somewhat different pattern: under all question difficulty levels and model comprehension, self-reflection prompting fails to improve the performance. To further verify this finding, we also conduct the artificial response experiments, with results in Figure 10. Here we see that self-reflection prompting is not always harmful to performance (e.g., under 0% RA, self-reflection helps improve the performance of easy questions.), but in most cases it is harmful.

We hypothesize that these divergent patterns arise because this particular model may be less sen-

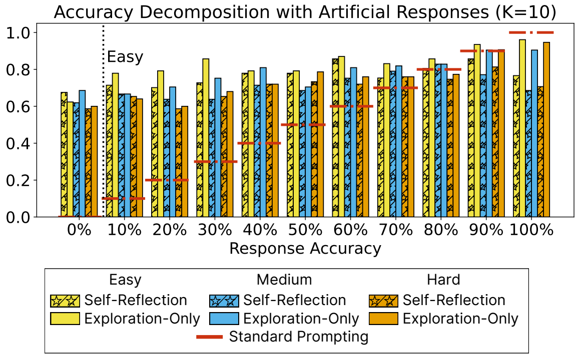

Figure 10: Performance Decomposition on Question Difficulty and Response Accuracy (Artificial Responses) for Mixtral-8x7B-v0.1.

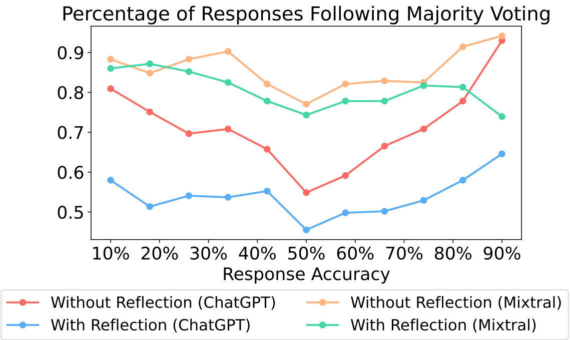

Figure 11: Majority Voting Analysis (Mixtral-8x7B-v0.1).

sitive in general to instructions for reflection, or less well-equipped to understand them, such that the reflection part serves mostly as a distractor in the input. We examine this hypothesis in the majority voting experiments (Figure 11) and find that compared with ChatGPT, the addition of self-reflection exerts minimal impact on majority voting trends, suggesting that it is comparatively difficult to use self-reflection prompting to change the default behaviors in the case of this model. This is consistent with our hypothesis that Mixtral-8x7B-v0.1 lacks sensitivity or competence in self-reflection, so we speculate that additional training may be needed to help this model to unlock self-reflection prompting potential.

CoDa: Constrained Generation based Data Augmentation for Low-Resource NLP

Abstract

We present **CoDa** (**Co**nstrained Generation based **Da**ta Augmentation), a controllable, effective, and *training-free* data augmentation technique for low-resource (data-scarce) NLP. Our approach is based on prompting off-the-shelf instruction-following Large Language Models (LLMs) for generating text that satisfies a set of constraints. Precisely, we extract a set of simple constraints from every instance in the low-resource dataset and verbalize them to prompt an LLM to generate novel and diverse training instances. Our findings reveal that synthetic data that follows simple constraints in the downstream dataset act as highly effective augmentations, and CoDa can achieve this without intricate decoding-time constrained generation techniques or fine-tuning with complex algorithms that eventually make the model biased toward the small number of training instances. Additionally, CoDa is the first framework that provides users explicit control over the augmentation generation process, thereby also allowing easy adaptation to several domains. We demonstrate the effectiveness of CoDa across 11 datasets spanning 3 tasks and 3 low-resource settings. CoDa outperforms all our baselines, qualitatively and quantitatively, with improvements of 0.12%-7.19%. Code is available [1].

Method	**Original 1:** Scott Gimple sets the record straight on that big midseason finale scene. **Original 2:** mine is all of Isaiah chapter 6 because that is what Jesus did for me.
BackTrans (Yu et al., 2018)	1. Scott Gimple is setting the record on this. 2: all of Isaiah, chapter 6, is mine, for this is what Jesus.
EDA (Wei and Zou, 2019)	1: scott gimple sets the record straight on that big midseason finale scenery. 2: mine is all of isaiah chapter because personify that is what jesus did for me.
SSMBA (Ng et al., 2020)	1. scott gimple sets the record, on that big preseason night website. 2: it in all of isaiah - 6 because that is what you did for me.
GPT3Mix (Yoo et al., 2021)	1: Scott Gimple sets the record straight on that big midseason finale scene. 2: I cherish Isaiah chapter 6 as it embodies what Jesus has done for me.
GENIUS (Guo et al., 2022)	1: For the record, there was no midseason finale scene. That is, until the finale. 2: Isaiah chapter 6 because it says, "If you don't believe in God, you will die."
CoDa *(ours)*	1: The recording of the scene in the new movie by Scott Gimple was a big success, capturing the essence of the entertaining story. 2: Jesus taught us to be free, to follow our hearts and minds, and to live life to the fullest. In today's society, we must continue to mine the teachings of Jesus to find the courage to live our lives on our own terms.

Table 1: Comparison of augmentations generated using CoDa with our baselines. CoDa generates augmentations that are more coherent and diverse. More examples in Appendix E.2.

1 Introduction

Data augmentation is a widely used technique to address the problem of limited training data in low-resource NLP (Chen et al., 2023). Owing to the recent advancement in generative AI, using synthetic data to train task-specific models has also gained much popularity. However, given a low-resource NLU dataset, effectively generating task-specific data to expand the dataset still poses a significant challenge. For example, while diversity in tokens and contexts in generated augmentations typically benefits downstream performance, excessively diverse examples may negatively impact consistency with the underlying downstream data distribution, thereby hurting performance (Geiping et al., 2023). This highlights the importance of having more control during the generation process to ensure data augmentation is done effectively.

In the past, researchers have employed methods like text-editing (Wei and Zou, 2019; Karimi et al., 2021; Shou et al., 2022), fine-tuning Pre-trained Language Models (PLMs) with various algorithms (Wang et al., 2022; Zhou et al., 2021; Guo et al., 2022; Ghosh et al., 2023a,c), etc. However, most of these methods do not impose explicit controls to achieve diversity or consistency. The recent rise of autoregressive LLMs, known for their advanced generative and reasoning skills, introduces promising yet under-explored opportunities to enhance diversity in task-specific synthetic data synthesis. However, controlling autoregressive generation has proved to be innately challenging and complex (Zhang et al., 2023), and prompting-based methods have often employed manual human efforts for extracting data attributes that promote consistency (Yu et al., 2023).

Figure 1: Illustration of **CoDa**. ① For every document in a low-resource NLU dataset $\mathcal{D}$, we extract a set of simple heuristic-based constraints from and ② verbalize them to generate an instruction. ③ This instruction is then fed to an existing instruction-tuned LLM for generating augmentations, which are then added to $\mathcal{D}$ for training a downstream model.

Main Contributions. We propose CoDa, a novel and effective data augmentation methodology for low-resource NLP. CoDa works with any off-the-shelf instruction-tuned LLM in a training-free fashion and provides explicit control over generated augmentations. We first extract simple heuristic-based constraints from training instances in a low-resource NLU dataset and then verbalize them to construct a natural language instruction. Next, we use this instruction to prompt an LLM for generating augmentations (example in Fig. 1). Alternative to complex decoding-time-constrained generation methods and manual attribute extraction, CoDa provides a simpler and more intuitive natural language-based interface for constrained generation. CoDa is also the first framework to explore controlled generation for data augmentations, which ensures that the synthetic data is closely aligned with the specific needs of the task and characteristics of the target domain. We show that CoDa, which is *training-free* and much simpler, quantitatively and qualitatively outperforms all prior-art by 0.12%-7.19% across various settings.

2 Related Work

Generative data augmentation for low-resource NLP has been extensively studied in prior work and can be categorized into four primary techniques. Firstly, **text-infilling** involves corrupting source text segments and using a PLM to refill these gaps. This process often relies on conditioning the corrupted text, a concept also known as keyword conditioning in some studies (Zhou et al., 2021; Guo et al., 2022; Ghosh et al., 2023c,a,b). Secondly, **text editing** focuses on modifying certain parts of a given sentence (Wei and Zou, 2019; Shou et al., 2022). Thirdly, **prompting** involves generating new training sentences by prompting LLMs (Ye et al., 2022; Sahu et al., 2023), which can be further uncategorized into conditioning attributes, exemplars, or constraints derived from training data.

3 Methodology

Fig. 1 illustrates the CoDa pipeline. Given a low-resource dataset $\mathcal{D} = \{d_0, \cdots, d_i, \cdots d_n\}$, we first extract a set of simple heuristic-based constraints from each document d_i and then verbalize the constraints to construct an instruction I_{d_i}. After this, we either instruct the LLM with I_{d_i} to generate a completely new document or rephrase another existing document from $\mathcal{D}$. For the latter, we first retrieve a document from $\mathcal{D}$, convert it into its short and concise abstract description by prompting an LLM, and then employ I_{d_i} to generate a document from the abstract description and the extracted constraints. For retrieval, we calculate cosine similarity between SentenceBERT embeddings (Reimers and Gurevych, 2019) of the source document d_i and all other documents in $\mathcal{D}$, and we randomly sample a sentence from the top-k and bottom-k similar sentences. For a total of 5 augmentations, we generated 3 novel documents and rephrased 2 other documents for every d_i. Finally, all the generated augmentations are added to $\mathcal{D}$ for training a downstream NLU model. We now describe our methodology to extract constraints in detail.

3.1 Extracting Constraints

a) Lexical Constraints. Inspired by a wealth of prior work in generative data augmentation and constrained generation (Zhou et al., 2023), we extract a set of keywords from a source sentence and constrain the augmentations to contain these keywords. More specifically, given a source document d, we first extract all its *n*-grams (1 to 3-grams) $\mathrm{N} = \{\mathrm{n_0}, \cdots, \mathrm{n_t}, \cdots, \mathrm{n_T}\}$. Next, we assign an importance score to each by calculating cosine similarity between $\mathbf{E}(\mathrm{n_t})$ and $\mathbf{E}(\mathrm{d})$, where $\mathbf{E}$ is pretrained SentenceBERT. Finally, we select the top-*k* *n*-grams as our keywords. Additionally, for tasks like NER and QA, we add the corresponding target spans to the list.

b) Syntactic Constraints. In formal domains such as legal and biomedical, language is often governed by syntactical structures. Following a predefined POS pattern ensures that the generated sentences adhere to the formal style and tone expected in the domain. Readers can refer to Appendix 10 for some examples. Thus, we consider syntactic constraints that necessitate the generated augmentations to adhere to specific syntactic rules. More specifically, we extract the part-of-speech sequence from a randomly chosen sentence in d and constrain our generations to adhere to the sequence for a particular sentence.

c) Semantic (Label) Constraints. A primary requirement for effective data augmentations is that the semantics of the generated augmentations adhere to the underlying label of the source document d. To satisfy this, we consider label constraints so that the generated augmentations align closely to the original target label (e.g., *positive* sentiment). We use the target label of d with 3 exemplars for this constraint. The exemplars are chosen randomly from the dataset $\mathcal{D}$ and placed in random order in the final instruction.

d) Length Constraints. Length mismatches between training and testing instances have been known to degrade downstream NLU performance (Rogers et al., 2021). Motivated by this, we consider length constraints that necessitate the total number of tokens in the generated augmentations to fall within a specified range. We calculate the total number of tokens in d and add and subtract sd from it to obtain the lower and upper limits of the range, respectively. The value of sd is determined by computing the standard deviation of length distribution across the entire dataset $\mathcal{D}$.

e) Concept Constraints. The presence of spurious features in the training set causes the downstream NLU model to adopt shortcut learning strategies, impacting its performance in real-world, atypical situations where these features are not present (Sagawa* et al., 2020). Data augmentations can further amplify such spurious features in $\mathcal{D}$ if not handled correctly. We propose a novel strategy to ensure that generated augmentations do not have spurious features. We first employ the method proposed by Friedman et al. (2022) to extract a list of spurious phrases for each label in the dataset. We then pass these phrases with example sentences consisting of these phrases to an LLM and ask it to return a short abstract concept that the spurious phrases describe in the documents (e.g., *rating in movie reviews* for negative reviews in the IMDB dataset). Finally, we select the top 3 abstract concepts for each label and add is as a negation constraint for augmentation generation.

3.2 Constructing the Instruction

After extracting the constraints from d, we verbalize the constraints to a single instruction for prompting an instruction-tuned LLM. The verbalization is done through fixed hand-written templates. An example of an instruction is shown in Fig. 1.

4 Experimental Setup

Baselines. Gold-only refers to training our model only on the low-resource gold data. For sequence classification (SC), we compare CoDa with text editing baselines: EDA (Wei and Zou, 2019), AEDA (Karimi et al., 2021), and AMR-DA (Shou et al., 2022), learning-based infilling baselines: SSMBA (Ng et al., 2020), GENIUS(-**ft**) (Guo et al., 2022), PromDA (Wang et al., 2022), LLM-based prompting baselines: ZeroGen (Ye et al., 2022), GPT3Mix (Yoo et al., 2021) and rephrasing baselines: BackTrans (Yu et al., 2018). For the Intent Classification task, specifically in SC, we add another LLM-based prompting baseline: PromptMix (Sahu et al., 2023). For Named Entity Recognition (NER), we compare CoDa with LwTR (Dai and Adel, 2020), DAGA (Ding et al., 2020), MELM (Zhou et al., 2021), PromDA (Wang et al., 2022) and ACLM (Ghosh et al., 2023c). Finally, for question answering (QA), we compare it with ZeroGen, BackTrans, GENIUS, EDA, and AEDA. Details on the working of all baselines are provided in Section D.

Table 4: Result comparison for QA. CoDa outperforms baselines by 1.10% - 3.06%.

Datasets. To demonstrate CoDa's flexibility, we evaluate it across various challenging datasets belonging to a wide range of domains. For SC, we employ Huffpost (Misra and Grover, 2021) (news category classification), Yahoo (Zhang et al., 2015) (answer topic classification), OTS (Drawzeski et al., 2021) (*legal* online service unfairness level classification), ATIS (Coucke et al., 2018) and Massive (FitzGerald et al., 2022) (Intent Classification). For NER, we employ ConLL-2003 (Tjong Kim Sang and De Meulder, 2003), OntoNotes-5.0 (Pradhan et al., 2013) (news domain), EBMNLP (Nye et al., 2018) and BC2GM (Krallinger et al., 2015) (bio-medical). Finally, for QA, we employ SQuAD (Rajpurkar et al., 2016) and NewsQA (Trischler et al., 2017). Details on each dataset and dataset statistics are provided in Section C.

Hyper-parameter settings. We prompt LLama-13B with a temperature of 0.5, top-p of 1.0, top-k=50. For all downstream NLU tasks, we employ BERT$_{\text{base-uncased}}$ (Devlin et al., 2019) as our encoder (except OTS where we employ legal-longformer$_{\text{large}}$ (Chalkidis* et al., 2023)). We fine-tuned our encoder with a batch size of 4,8 for 100 and 200 splits and 16 for 500 and 1000 splits. For NER specifically, we employ the flair library (Akbik et al., 2019) with an initial lr of $1e^{-5}$ and constant decay. Appendix A provides hyper-parameter tuning experiments. We report the micro-average F_1 score averaged across 3 runs for 3 random seeds.

5 Results and Analysis

Quantitative Analysis. Table 2, 3, and 4 compared CoDa with all our baselines on the tasks of SC, NER, and QA, respectively. CoDa outperforms our baselines in SC by 0.12% - 5.94%, NER by 0.47% - 7.19%, and QA by 1.10% - 3.06%. Though most prior methods proposed for one domain generally underperform in the other (Ghosh et al., 2023a), CoDa consistently outperforms these methods in all domains with varying semantic and syntactic properties, emphasizing its domain-agnostic nature.

Qualitative Analysis. Table 5 compares the generation quality of CoDa with all our baselines (averaged baseline-wise across all tasks and splits) on the measures of perplexity (Jelinek et al., 1977), diversity (average number of new tokens introduced in R augmentations) and length diversity (average absolute difference in length of source and R augmentations). CoDa outperforms most of our baselines in all settings. Additionally, as observed in Table 5, unlike other learning-based methods in

Table 5: Quantitative evaluation of generation quality on the measures of perplexity and token diversity. CoDa outperforms all our baselines on all metrics.

literature, the diversity of augmentations by CoDa does not depend on the number of gold training samples available. It performs equally well in both 100 and 500 splits.

Fig. 2 compares CoDa augmentations with other baselines in literature with a gold training sample taken from the OTS dataset. Generating augmentation on the OTS dataset, which belongs to the legal domain, is inherently difficult due to the formalized nature of legal language (Ghosh et al., 2023a). As we can see, CoDa generates augmentations that are coherent, diverse, and label-consistent. More examples are provided in Fig. 3, 4 and 5. Additionally, Appendix B evaluates how faithful LLaMa-2 was in following the constraints in the instructions.

6 Conclusion

We present CoDa, a simple and controllable data augmentation technique for low-resource NLP. CoDa extracts simple heuristic-based constraints from source sentences and verbalizes them to construct and instruction, which is then used to prompt LLMs to generate augmentations. CoDa is *training-free* and works with any out-of-the-box instruction-tuned LLM. Beyond providing explicit control, CoDa is also flexible, i.e., constraints can be easily replaced or added, enhancing its suitability across diverse domains.

Limitations and Future Work

Despite its effectiveness, CoDa suffers from various limitations, which we would like to mention. These limitations will remain our primary focus in future work. The limitations are as follows:

- LLMs often struggle to follow complex constraints in the instruction for text generation (Lu et al., 2023). We overcome this problem in CoDa by employing simple constraints. However, we acknowledge that data augmentation for complex domains and tasks may need to employ more complex constraints. Thus, as part of future work, we would like to employ recent advances in compositional prompting for breaking down complex constraints into simpler instructions.
- Although being *training free*, CoDa is computationally more expensive during inference time compared to prior art as it employs LLMs. As also shown in Section A.2, the overall performance of CoDa takes a slight hit when LLaMa-7B was employed instead of the 13B version. However, we acknowledge that as smaller models get better at following instructions, CoDa can perform more efficiently.

A Hyper-parameter Tuning

A.1 Effect of augmentation rounds R

Table 6 compares the performance of CoDa at different values of R. Augmenting the training dataset with several augmentation rounds R proves effective until the model overfits to the training data. The observation is similar to prior work in data augmentation for NLU tasks (Zhou et al., 2021; Ghosh et al., 2023c).

R	**1**	**2**	**3**	**4**	**5**	**6**	**7**
F_1	61.74	62.05	62.31	63.01	**63.16**	62.99	61.23

Table 6: F1 for various settings of R. All values are averaged across all datasets for all low-resource settings.

A.2 Choice of LLM

Table 7 compares the performance of CoDa employing different open-source LLMs. Beyond LLaMa-13B employed in our paper, we also compare performance with Mistral-7B (Jiang et al., 2023) and LLaMa-7B. As we see, employing LLaMa-7B takes a hit of 0.18% on the final performance, while employing Mistral-7B takes a hit of 1.44% on the final performance. We also noticed several instances of hallucination with Mistral-7B, where the output of the LLM was completely different from the given instruction. This was not the case with the LLaMa family of models, and performance generally improved with a larger model owing to a better quality of generations and better abilities to follow instructions.

LLM	**F1-Micro**
Mistral-7B	61.72
LLaMa-7B	62.98
LLaMa-13B	**63.16**

Table 7: F1 micro averaged across tasks for various LLMs.

B Faithfulness in following instruction constraints

Table 8 illustrates the accuracy of augmentations produced by LLaMa-13B in adhering to the constraints specified in the instruction. We only illustrate accuracies of Lexical and Length constraints as they are easily quantifiable. Other constraints require human evaluation, which remains part of future work. We report the accuracy as our metric for faithfulness, wherein we consider a generation as accurate for the constraint if it completely follows the constraint, else inaccurate. Additionally, we also report a 75% threshold for both the constraints, whereby we consider the generation as accurate if it follows 75% of the constraint (e.g.,75% of the total keywords mentioned are in generation and the total tokens in the generation lie between 75% of the maximum and minimum lengths). Although LLaMa-13B demonstrates moderate proficiency in adhering to constraints, the anticipated improvement in instruction-following capabilities of LLMs is likely to enhance these metrics further. Furthermore, the fact that CoDa surpasses the performance of many existing models in the literature, despite its moderate ability to follow constraints, suggests a significant promise for CoDa as an augmentation generation scheme when integrated with more advanced LLMs.

An observed trend is that models demonstrate strong performance on familiar datasets such as CoNLL-2003, potentially due to these datasets being included in their pre-training corpus. Additionally, our models exhibit improved performance under 75% threshold constraints. This suggests a balance must be struck between the creative output and adherence to constraints in LLM generations. Although creativity is crucial for generating diverse augmentations, following constraints is key for maintaining consistency. In future work, we aim to investigate more effective methods for balancing this trade-off.

Task	Lexical	Lexical 75%	Length	Length 75%
HuffPost	24.64	26.09	51.31	55.02
Yahoo	27.28	28.12	51.06	54.48

Table 8: Faithfulness of generated augmentations. Scores reported correspond to average accuracy, where we attribute an augmentation as accurate if it perfectly follows the constraint in the given instruction; otherwise, we attribute it as inaccurate.

C Dataset Details

C.1 Classification

HuffPost. The HuffPost dataset (Misra and Grover, 2021) is a popular multiclass classification dataset in NLP. It is a collection of news articles from the HuffPost website, covering a wide range of topics, including politics, business, entertainment, and more. For multiclass classification, the HuffPost dataset is labeled with a diverse set of categories and for our experiments, we take sentences from five categories, including politics, sports, entertainment, tech, and business. Dataset statistics can be found in Table 9.

Yahoo. The Yahoo Answers topic classification dataset (Zhang et al., 2015) is a widely used dataset for multi-class text classification tasks. It is derived from the Yahoo Answers community-driven question-answering platform, where users ask questions on various topics, and community members provide answers. The dataset contains a large number of question-and-answer pairs covering a wide range of categories or topics. Each question in the dataset is associated with one primary category. The primary categories span diverse subjects, including Society & Culture, Science & Mathematics, Health, Education & Reference, Computers & Internet, Sports, Business & Finance, Entertainment & Music, Family & Relationships, Politics & Government, Travel, Cars & Transportation, Food & Drink, Games & Recreation, Home & Garden, Local Businesses, News & Events, Pets, Beauty & Style and Pregnancy & Parenting. Dataset statistics can be found in Table 9.

OTS-UL. Online Terms of Service (OTS) (Drawzeski et al., 2021) attempt to automatically detect unfair clauses in Terms of Service. The input to the model is a sentence, and the output presents the sentence classified into three levels of unfairness. The dataset setting used in our paper is similar to (Niklaus et al., 2023). Dataset statistics can be found in Table 9.

C.2 Named Entity Recognition

CoNLL-2003. The CoNLL-2003 dataset (Tjong Kim Sang and De Meulder, 2003) is a widely used benchmark dataset for Named Entity Recognition

Dataset	Source	Sub-domain	Task Type	Training/Dev/Test Instances	Classes
HuffPost	Misra and Grover (2021)	HuffPost website	Multi-class classification	67490/16891/16891	5
Yahoo	Zhang et al. (2015)	Yahoo Answers	Multi-class classification	1375404/58966/58966	10
OTS-UL	Drawzeski et al. (2021)	EU Law	Multi-class classification	2074/191/417	3
ATIS	Microsoft (2023)	Travel enquiry	Intent Classification	4972/888/888	17
MASSIVE	FitzGerald et al. (2022)	Diverse	Intent Classification	11500/2030/2970	60
CoNLL-2003	Tjong Kim Sang and De Meulder (2003)	English news articles	Named Entity Recognition	14041/3250/3453	4
OntoNotes-5.0	Pradhan et al. (2013)	Diverse	Named Entity Recognition	115812/15680/12217	36
BC2GM	Krallinger et al. (2015)	Biomedical	Named Entity Recognition	15197/3061/6325	2
EBMNLP	Nye et al. (2018)	Biomedical	Named Entity Recognition	35005/10123/6193	7
SQUAD	(Rajpurkar et al., 2016)	Wikipedia Articles	Question Answering	87600/10600/-	-
NEWSQA	(Trischler et al., 2017)	CNN Articles	Question Answering	92549/5126/5166	-

Table 9: Statistics for each downstream NLU datasets used in our experiments. As described in Section 4, we derive low-resource splits from these original datasets for our experiments.

(NER) tasks in NLP. It was created for the Conference on Computational Natural Language Learning (CoNLL) shared task in 2003. The dataset consists of news articles from the Reuters Corpus, a collection of English news articles. It is annotated with four named entities: person, organization, location, and miscellaneous entities (such as dates and percentages). The annotations indicate the boundaries of the named entities within the text. Dataset statistics can be found in Table 9.

Ontonotes 5.0. Ontonotes 5.0 Pradhan et al. (2013) is a widely used dataset in the field of Natural Language Processing (NLP) and specifically for Named Entity Recognition (NER) tasks. It is a large-scale corpus that provides annotations for a variety of linguistic phenomena, including named entities, across multiple languages. The dataset contains a diverse range of text genres, including news articles, conversational data, and web data, making it suitable for training and evaluating NER models in different domains. It covers three languages: English, Chinese, and Arabic. The dataset is annotated with 11 categories: Person, Organization, Location, Date, Time, Money, Percent, Quantity, Ordinal and Miscellaneous. Dataset statistics can be found in Table 9.

EBMNLP. EBMNLP Nye et al. (2018) is a widely used dataset in the field of Biomedical Named Entity Recognition (BioNER) tasks. It is a corpus of richly expert-annotated abstracts of medical articles describing clinical randomized controlled trials. The dataset facilitates easy search and organization of published literature on randomized controlled trials, addressing the current challenges impeding the goals of evidence-based medicine (EBM). The dataset is annotated with 3 categories: Outcome, Intervention and Participant. Dataset statistics can be found in Table 9.

BC2GM. BC2GM Krallinger et al. (2015) is a widely used dataset in the field of Biomedical Named Entity Recognition (BioNER) tasks. This dataset is a part of the CHEMDNER large scale corpus which includes annotation of chemical entities as well as named entities in the biomedical and other domains. The dataset is annotated with 1 categoriy: Gene. Dataset statistics can be found in Table 9.

C.3 Intent Classification

ATIS. The ATIS (Airline Travel Information System) dataset[2] is a widely used benchmark dataset for intent classification in the field of NLU. It was developed to address understanding user intents in the context of airline travel information. The dataset consists of queries or utterances that users might input when interacting with a flight reservation system. Each query is labeled with an intent representing the user's intention or purpose behind the query. The dataset is labeled with intents that are: Flight-Booking, Flight-Status, Flight-Information, Ground-Service, Airfare, Airport-Information, Travel-Preferences, Flight-Cancellation, and None/No-Intent. Dataset statistics can be found in Table 9.

MASSIVE. The MASSIVE (Multilingual Amazon Slu resource package for Slot-filling) FitzGerald et al. (2022) dataset is a widely used benchmark dataset for intent classification in the field of NLU. It contains 1M realistic, parallel, labeled virtual assistant utterances spanning 51 languages, 18 domains, 60 intents, and 55 slots. The dataset is labeled with intents some of which are: Alarm set, Play music, Audio volume mute, Weather query, Takeaway order and General joke etc. Dataset statistics can be found in Table 9.

C.4 Question Answering

SQUAD. The SQUAD (Stanford Question Answering Dataset) (Rajpurkar et al., 2016) is a read-

---

[2] `https://github.com/howl-anderson/ATIS_dataset/tree/master`

ing comprehension dataset, consisting of questions posed by crowdworkers on a set of Wikipedia articles, where the answer to every question is a segment of text, or span, from the corresponding reading passage, or the question might be unanswerable. Dataset statistics can be found in Table 9.

NEWSQA. NewsQA (News Question Answering) (Trischler et al., 2017) is a challenging machine comprehension dataset of over 100,000 human-generated question-answer pairs. Crowdworkers supply questions and answers based on a set of over 10,000 news articles from CNN, with answers consisting of spans of text from the corresponding articles. Dataset statistics can be found in Table 9.

D Baseline Details

SSMBA. SSMBA (Ng et al., 2020) generates synthetic training examples by using a pair of corruption and reconstruction functions to move randomly on a data manifold.

AEDA. AEDA (Karimi et al., 2021) is similar to EDA but only employs random insertion of punctuation marks in the original text to generate synthetic augmentations.

GENIUS. GENIUS (Guo et al., 2022), pre-trains and optionally fine-tunes BART (Lewis et al., 2019) on a denoising objective using sketches generated with an extreme masking algorithm. The extreme masking algorithm just preserves keywords in a sentence and masks everything else.

MELM. MELM (Zhou et al., 2021), which stands for Masked Entity Language Modeling, suggests the fine-tuning of a transformer-encoder-based PLM on linearized labeled sequences through masked language modeling. In low-resource scenarios, MELM surpasses all other baselines and prior techniques on the CoNLL 2003 NER dataset across four languages, including mono-lingual, cross-lingual, and multi-lingual settings.

DAGA. DAGA (Ding et al., 2020), short for Data Augmentation with a Generation Approach, suggests the training of a one-layer LSTM-based recurrent neural network language model (RNNLM) by maximizing the probability of predicting the next token using linearized sentences. For sentence generation, they employ random sampling to create entirely new sentences, with the model being fed only the [**BOS**] token.

LwTR. LwTR (Dai and Adel, 2020) replaces a token in a sentence with another token of the same label; the token is randomly selected from the training set.

PromDA. PromDA (Wang et al., 2022) proposes a data augmentation framework based on T5 that trains soft prompts using a novel keyword-to-sentence algorithm.

AMR-DA. AMR-DA (Shou et al., 2022) converts a sample document from a dataset to an AMR graph, modifies the graph according to various data augmentation policies, and then generates augmentations from graphs. The method combines both sentence-level techniques like back translation and token-level techniques like EDA.

PromptMix. PromptMix (Sahu et al., 2023) PromptMix prompts instruction-tuned LLMs to generate augmentations for text classification tasks that are close to the class boundary.

ZeroGen. ZeroGen (Ye et al., 2022), similar to PromptMix, generates data using LLMs but in a zero-shot manner without any gold data. It prompts pre-trained LLMs (not instruction fine-tuned) for data synthesis.

We do not consider more recent baselines provided by Cai et al. (2023), Hu et al. (2023) and Rahamim et al. (2023) as the code for the same was not available at the time of writing the paper. Additionally, we do not consider Zhou et al. (2022) as label flipping is not applicable for our paper for all tasks considered, and Chen et al. (2022) as style transfer is better suited for cross-domain tasks and applying it to single domain tasks is not trivial. Finally, we do not consider Yu et al. (2023) as it requires manual human intervention for attribute extraction for a dataset.

E Additional Details

E.1 Examples of syntactic constraints in formal domains

Table 10 provides examples of documents from domains with formal language, like legal and biomedical. Each example provides two corresponding documents to a POS sequence, emphasizing that syntactic constraints help generate augmentations better aligned to the domain in formal domains.

E.2 Qualitative Examples

Fig. 2, 3, 4 and 5 provide additional qualitative examples of augmentations generated using CoDa and compares them with other baselines. CoDa

Dataset	Syntactic Examples
OTS	1. **Constraint**: ADV PRON AUX PUNCT ADP PRON NOUN PUNCT VERB NOUN ADP DET NOUN PUNCT **Generation 1**: Quickly he can, upon her request, examine the document. **Generation 2**: Additionally, he shall submit the document to the court. 2. **Constraint**: NOUN AUX PART ADJ ADP NOUN PRON AUX PART VERB PRON NOUN PUNCT **Generation 1**: Contractors have, under new regulations, completed their work. **Generation 2**: Judge may have been impartial in the legal proceedings.
EBMNLP	1. **Constraint**: DET ADJ NOUN AUX VERB ADP NOUN NOUN PUNCT **Generation 1**: The molecular analysis revealed a genetic mutation in the patient. **Generation 2**: The experimental procedure was conducted on laboratory samples. 2. **Constraint**: NOUN NOUN NOUN ADP NUM NOUN AUX VERB VERB ADP NUM NOUN NOUN PUNCT **Generation 1**: EXPERIMENT A cohort of 50 samples was collected from 3 laboratory facilities. **Generation 2**: STUDY A group of 100 patients underwent testing in two medical centers.
BC2GM	1. **Constraint**: PROPN PROPN PROPN ADP DET NOUN ADP NOUN NOUN ADP NOUN PUNCT **Generation 1**: Polymerase chain reaction for the detection of genetic mutations in patients. **Generation 2**: Hormone receptor status in the evaluation of breast cancer in women. 2. **Constraint**: NOUN ADP NOUN NOUN CCONJ NOUN PUNCT **Generation 1**: Analysis of protein structures and 3,4-dihydroxyphenylalanine. **Generation 2**: Exploration of biochemical pathways and 2,3-dimethylbutane.

Table 10: Examples of a couple of documents corresponding to a single POS sequence in formal domains like legal (OTS) and bio-medical (EBMNLP and BC2GM). We emphasize that syntactic constraints help generate augmentations better aligned to the domain.

consistently generates more diverse and consistent augmentations over prior art.

F Extra Details

F.1 Model Parameters

BERT$_{\text{base}}$ has ≈ 110M 12-layers of encoder, 768-hidden-state, 2048 feed-forward hidden-state, and 8-heads. legal-longformer$_{\text{large}}$ has ≈ 149M 30 layers of encoder, 768-hidden-state, 3072 feed-forward hidden-state, and 12-heads. LLaMa-13B is a 13B parameter model and LLaMa-7B is a 7B parameter model.

F.2 Compute Infrastructure

All our experiments are conducted on NVIDIA A100 and NVIDIA A6000 GPUs. We batch prompted LLaMa-2 13B and LLaMa-2 7B, with a BS of 16, where LLaMa-2 performed distributed inference on 4 A6000 GPUs. Fine-tuning on the downstream tasks uses 4 A100 GPUs.

F.3 Implementation Software and Packages

We implement all our models in PyTorch[3] and use the HuggingFace[4] implementations of BERT$_{\text{base}}$, legal-longformer$_{\text{large}}$, LLaMa-13B and LLaMa-7B. For NER specifically, we employ the Flair [5] library.

We also use the following repositories for running the baselines: BackTrans (Yu et al., 2018), EDA[6](Wei and Zou, 2019), AEDA[7] (Karimi et al., 2021), AMR-DA[8] (Shou et al., 2022), SSMBA[9] (Ng et al., 2020), GENIUS(-**ft**)[10] (Guo et al., 2022), PromDA[11] (Wang et al., 2022), PromptMix[12] (Sahu et al., 2023), ZeroGen[13] (Ye et al., 2022), GPT3Mix[14] (Yoo et al., 2021), LwTR[15] (Dai and Adel, 2020), DAGA[16] (Ding et al., 2020)(Ding et al., 2020) and MELM[17] (Zhou et al., 2021). All the baseline repositories are covered under the MIT License.

F.4 Dataset Links

We use the following datasets to evaluate: Huffpost[18] (Misra and Grover, 2021), Yahoo[19] (Zhang et al., 2015), OTS[20] (Drawzeski et al., 2021), Massive[21] (FitzGerald et al., 2022), ATIS[22] (Coucke

F.5 Potential Risks

Diffusion models learn from vast amounts of textual data, including biased or prejudiced content present on the internet. As a result, there is a risk of bias amplification, where the models unintentionally perpetuate or reinforce existing biases. Also, diffusion models can generate highly coherent and contextually plausible text, raising concerns regarding the potential for generating misinformation or disinformation.

Synonym relations affect object detection learned on vision-language data

Giacomo Nebbia and **Adriana Kovashka**
University of Pittsburgh
`gin2@pitt.edu`, `kovashka@cs.pitt.edu`

Abstract

We analyze whether object detectors trained on vision-language data learn effective visual representations for synonyms. Since many current vision-language models accept user-provided textual input, we highlight the need for such models to learn feature representations that are robust to changes in how such input is provided. Specifically, we analyze changes in synonyms used to refer to objects. Here, we study object detectors trained on vision-language data and investigate how to make their performance less dependent on whether synonyms are used to refer to an object. We propose two approaches to achieve this goal: data augmentation by back-translation and class embedding enrichment. We show the promise of such approaches, reporting improved performance on synonyms from mAP@0.5=33.87% to 37.93%.

1 Introduction

In recent years, we have witnessed increased interest in vision-language models (Radford et al., 2021; Yuan et al., 2021) that learn joint image and text representations in a self-supervised way, and that can later be used as building blocks for models fine-tuned on downstream tasks (Wu et al., 2023; Kuo et al., 2022; Kim et al., 2023). In addition, recent models such as GPT-4 (OpenAI, 2023) and DALL-E 3 (Betker et al., 2023) are built to accept image and text input provided by end users, with no set constraints on such inputs. Thus, models must be robust to variations in how input is provided.

We analyze how vision-language models handle the variability in textual inputs. Specifically, we investigate variations in synonyms used to refer to objects. We show how such variability negatively affects performance for open-vocabulary object detection, and we propose two ways to help vision-language detectors learn better representations for synonyms: data augmentation by back-translation and class embedding enrichment.

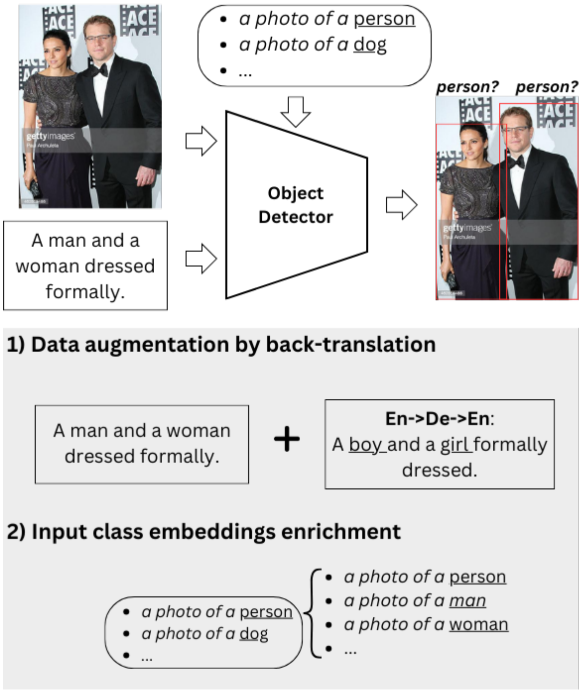

Figure 1: Top: input to an open-vocabulary object detector: images, class embeddings, and captions; and its output: bounding boxes with associated labels. Bottom: our approaches. 1) Data augmentation by back-translation: add captions back-translated from a foreign language; 2) Class embedding enrichment: consider synonyms and related terms when computing class embeddings.

Figure 1 illustrates our proposed approaches. With back-translation, we use a machine translation model to translate captions from English to another language, and then we translate them back to English. Because the back-translation is not perfect, the original caption and the back-translated one are not the same: they show changes, for instance, in which nouns are used to refer to objects (e.g., synonyms). We hypothesize that adding more synonyms and related terms to the captions used for training will help a model learn better representations for them. With class embedding enrich-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3770–3776
June 16-21, 2024

ment, we modify the class embeddings that open-vocabulary object detectors (Wu et al., 2023; Gu et al., 2021; Minderer et al., 2022) use to match visual embeddings learned for image regions. Furthermore, when training with enriched class embeddings, we experiment with enriching them throughout the whole training process, or using a curriculum learning approach: start training with the original embeddings, and finish with the enriched ones.

In both our approaches, we modify *inputs* to the training process (i.e., captions and class embeddings), making them generalizable to different model architectures and training strategies. We show promising results with improved performance on synonyms from mAP@0.5=33.87% to 37.93%.

In summary, our contribution is twofold: (1) we identify an issue with current state-of-the-art (SOTA) vision-language object detector models (namely, difficulty in detecting objects referred to by synonyms or closely related terms), and (2) we propose two generalizable strategies to train vision-language object detectors to learn better representations for such related terms.

2 Related Work

Vision-language (VL) models for open-vocabulary detection. Open-vocabulary object detection refers to training a detector model on a set of classes and testing it also on a separate set of classes unseen during training (Gu et al., 2021; Gao et al., 2022; Minderer et al., 2022; Kim et al., 2023; Wu et al., 2023). Many methods take advantage of large pre-trained VL models (Radford et al., 2021; Jia et al., 2021; Lu et al., 2019) that are generally trained to recognize which image-caption pairs match and which do not. In this work, we use BARON (Wu et al., 2023): a state-of-the-art (SOTA) open-vocabulary object detector making use of the CLIP (Radford et al., 2021) pre-trained VL model.

Concept relationships. Text embeddings have been shown to encode relationships between concepts such as synonyms and antonyms (Lu et al., 2018; Gokhale et al., 2022). At the same time, studies on adversarial attacks have highlighted how performance of language models varies when the input is changed, even when preserving the semantic meaning of the input text (Jia et al., 2019; Zhu et al., 2019; Ribeiro et al., 2018). Unsurprisingly, when such language models are combined with vision models, similar problems arise, with performance on VL tasks varying under perturbations of text input (Tascon-Morales et al., 2023; Gokhale et al., 2022; Sheng et al., 2021; Gokhale et al., 2020). Our work is related to such studies since we aim to make VL models more robust to text input variations, although we differ from previous work in target task (object detection vs. visual reasoning). Further, we do not require changes in how a model is trained, for instance, by defining a new loss function (Gokhale et al., 2022; Tascon-Morales et al., 2023); we simply modify inputs to the model, making our approach more general.

Curriculum learning. Curriculum learning (Bengio et al., 2009) (CL) refers to training a deep learning model by ordering the training samples; a model can learn better if the training samples are chosen following a schedule (i.e., a curriculum) rather than randomly selected. Previous work has shown the promise of CL for tasks such as machine translation (Liu et al., 2023; Qian et al., 2021), automated text scoring (Zeng et al., 2023), and common sense reasoning (Maharana and Bansal, 2022). We apply the idea of changing the input a model is trained on, but, instead of changing the training images, we change what class embeddings the model is trained on.

3 Methods

3.1 Object detection: BARON

We choose BARON (Wu et al., 2023) as our vision-language open-vocabulary detector since it achieves SOTA results on the task of open-vocabulary detection. BAg of RegiONs (BARON) is based on Faster R-CNN (Ren et al., 2015), where the classification layer is replaced by a linear layer so that its output is an embedding (or pseudo-words), rather than a class label. The key novelty of this method is the introduction of bags of regions: embeddings are extracted for a set of bounding boxes around each region proposal, not for a single proposal only. This is to model the co-occurrence of bags of visual concepts. BARON is trained from images and captions, and it requires a list of class embeddings (extracted from object names) to classify each region proposal. At test time, an image is fed to the model and bounding boxes are classified by comparing the extracted visual embeddings with the provided class embeddings. If we change such class embeddings by extracting them with synonyms, detection performance significantly drops (Table 2), motivating our work.

Original	German	Russian
A **skate board rider** does a trick in front of a building.	A **skateboarder** does a trick in front of a building.	A **skater** does a trick in front of the building.

Table 1: Examples of (left) original COCO captions, (middle) captions back-translated from German, and (right) captions back-translated from Russian.

3.2 Evaluating using synonyms

To evaluate the ability of a model to detect objects when using synonyms, we change the class embeddings during inference by replacing each class name with one of its synonyms or related terms and computing the class embeddings using such synonym. Since we have multiple synonyms per class, we repeat this process 5 times (with 5 different sets of synonyms), and we compute the mean and standard deviation of the detection performance across these five runs. The mean measures how well the downstream task is performed when varying input synonyms, the standard deviation measures how variable performance is: if a model learned all synonyms as well as class names, the standard deviation would be 0 (i.e., performance does not depend on the input synonym).

3.3 Augmentation by back-translation

In our first approach, we apply a machine translation model from English to another language to the input captions, and then translate the translated caption back to English. This approach has been successfully used as a data augmentation strategy on NLP tasks (Edunov et al., 2018; Xie et al., 2020; Sennrich et al., 2016) but it is less explored for VL models. Back-translation (BT) is a form of data augmentation because the BT process does not return a verbatim copy of the original caption: the back-translated caption will not be the same as the original one. There can be changes in, for instance, words used to refer to objects (i.e., synonyms), which is our motivation for proposing this method: we hypothesize that the increased variability in the vocabulary used to describe objects is beneficial to learn robust feature representations.

3.4 Class embedding enrichment

In our second approach, we enrich the class embeddings BARON is trained with by incorporating synonyms. Class embeddings are matched to region proposals to assign a class to each region proposal: the class whose embedding is most similar to that predicted for the region proposal. We compute class embeddings off-line using a CLIP Text Encoder (TE): for each class (e.g., person), we process a list of prompts through the TE (e.g., "A picture of a person", "A photo of a person"), returning one embedding per prompt; their average is taken as the overall class embedding. When enriching the class embeddings, we do not only add the class name (e.g., "person") in the prompts, but also each synonym or related term (e.g., "man", "woman"). The enriched class embedding is the average of the resulting text embeddings for prompts with the class name and its synonyms. While "man" and "woman" are not pure synonyms to "person", we argue they are still a type of "person" and should be detected as such, which our strategy allows.

3.5 Curriculum learning

A potential issue with our embeddings enrichment approach is that, when training on enriched embeddings and testing on object names, the shift in training vs. test embeddings may cause a decrease in performance. We propose curriculum learning to train with both the original class embeddings and our enriched version: we start training on the former, and finish training on the latter. By seeing both sets of embeddings during training, we hypothesize a model will perform competitively when evaluated both on object names and synonyms. To further show the benefit of the proposed curriculum, we also report experiments with the anti-curriculum approach (i.e., enriched embeddings first, original class embeddings last). In addition, we show class-wise results for those classes where curriculum learning provides the largest performance increase (and decrease), when compared to the baseline. Finally, we re-run our baseline and curriculum learning experiments two more times (for a total of three runs) to show that our reported performance improvement is not due to chance.

4 Results

4.1 Implementation

We train models on COCO Captions (Chen et al., 2015) and evaluate them on COCO Objects (Lin et al., 2014), and we use the list made available by (Lu et al., 2018) for synonym evaluation (e.g., "ship, motorboat" for "boat", "plane, aircraft" for "airplane"). This list includes terms that are, technically speaking, hyponyms (e.g., "macbook" is a hyponym for "laptop"). In this work, we are interested in detecting the pre-defined COCO classes, so we want a detector to identify all types of laptops. For this reason, we consider all the terms provided by (Lu et al., 2018) as "synonyms". In this list, only 44 of the 80 COCO class have at least one synonym, so we limit evaluation to these classes.

For machine translation, we use the Facebook FAIR WMT2019 models (Ng et al., 2019). Two models are available: English-German and English-Russian. These two are high-resource languages for which machine translation model achieve remarkable results. A thorough analysis on what foreign language is best suited for back-translation is beyond the scope of our work.

To train and evaluate BARON[1], we leave all hyperparameters unchanged, except for batch size, which we reduce from 16 to 12 due to hardware constraints. For curriculum learning experiments, we train with one set of class embeddings for half of the training process and finish with the other set.

We run all experiments with the same images: if an image is excluded because its original captions do not mention any COCO object, as implemented in (Wu et al., 2023), that image is not used in any experiment, even if back-translation adds a mention to one of the COCO objects.

4.2 Evaluating using synonyms' embeddings

We now evaluate models on synonyms used as test class embeddings. As a baseline, we train a model on the original COCO captions and COCO class name embeddings, and we compare it with models trained using back-translation or class embedding enrichment. In Table 2, we see performance greatly drops when using synonyms as opposed to COCO names (mAP@0.5=44.45% vs. 33.87% when training with original captions). This corroborates the need to better learn synonyms during training.

Captions	**COCO names**	**Synonyms mean (std)**	**Avg.**
Original	**44.45**	*33.87* (5.94)	*35.63*
Back-translation			
German	*44.23*	**34.25** (5.32)	**35.91**
Russian	43.89	33.67 (5.99)	35.37
Both	42.92	32.89 (5.97)	34.56

Table 2: Back-translation: mAP@0.5 (as %) evaluated on COCO class embeddings ("COCO names") and on synonyms embeddings ("Synonyms"). "Avg.": mean performance across the 5 sets of synonyms and the COCO name. **Bold**: highest performance, *italics*: second-best.

4.3 Augmentation by back-translation

We qualitatively verify that back-translation increases the use of synonyms by showing examples of original COCO captions and their back-translated versions with two languages: German and Russian. From Table 1, we see that back-translation is successful at introducing synonyms: "skateboarder" or "skater" in the first caption and "teenager" in the second. In addition, we compute the ratio between the number of mentions of an object using a synonym divided by the total number of mentions (synonyms and verbatim mentions of the COCO object name). We compare such ratio computed from the original captions and from the back-translated (BT) ones, obtaining 0.317 for original captions, 0.326 for BT: German, 0.344 for BT: Russian, and 0.343 for BT: Both. These results corroborate our assumption that back-translation increases variability in synonyms usage.

From Table 2, adding back-translated captions from German improves mean performance on synonyms (with a slight decrease in performance on class names), as well as decreases variability in performance (from 5.94% to 5.32%), showing improved robustness to variations in input synonym.

4.4 Class embedding enrichment

Table 3 shows increased mean performance on synonyms when enriching class embeddings (mAP@0.5=37.25% vs. 33.87%, and std=4.56% vs. 5.94%, respectively), as well as increased overall average performance (38.31% vs. 35.63%). These results show the promise of enriching class embeddings, although we notice a small decrease in performance when evaluating on COCO names when training with original captions (larger when comparing BT with/without enrich-

BT: German	37.48	36.75 (4.56)	36.87
CL	43.49	**37.93** (3.22)	**38.85**
Anti-CL	44.13	34.67 (5.87)	36.25

Table 3: Class embedding enrichment: mAP@0.5 (as %) evaluated on COCO class embeddings ("COCO names") and on synonyms embeddings ("Synonyms"). CL: Curriculum Learning, where a model is trained on embeddings for COCO classes first, and then on enriched embeddings. Anti-CL: anti-Curriculum Learning, where a model is trained on enriched embeddings first, and COCO class embeddings last.

Class	Baseline	Curriculum
Bowl	1.79	30.87
Sandwich	22.83	46.92
Bench	3.35	27.33
Person	51.28	71.59
Surfboard	28.69	45.68
Bus	39.63	3.18
Cat	56.57	46.94
Cake	21.72	16.46
Dog	61.03	57.62
Remote	33.15	30.36

Table 4: Class-wise mAP@0.5 (as %): classes where our curriculum learning approach achieves the largest increase and decrease in performance compared to the baseline.

ment). When evaluated on synonyms, combining back-translation and embedding enrichment yields an improvement over using back-translation (mAP@0.5=34.25% to 36.75%).

4.5 Curriculum learning

In Table 3 (bottom), we notice how curriculum learning improves performance on synonym evaluation compared to COCO embeddings and enriched embeddings, while performance on COCO names decreases only slightly. Average performance improves (mAP@0.5=38.31% to 38.85%). To our knowledge, this is one of the first results demonstrating curriculum learning for object detection using VL data for training.

In addition, starting training with COCO embeddings and ending training with enriched embeddings boosts performance on synonyms more than the opposite curriculum (i.e., anti-curriculum), confirming the benefit of our proposed curriculum strategy.

Table 4 reports the class-wise mAP@0.5 for classes where our curriculum learning strategy achieves the largest gains and suffers the largest decreases in performance when compared to the baseline. We notice that, with the exception of "bus", decreases in performance are less pronounced than increases, which is reflected in the higher overall average across all classes.

Finally, to further show the significance of the performance increase achieved using our curriculum learning approach, Table 5 reports average mAP@0.5 across three runs of the baseline and curriculum learning approaches, with standard deviation in parentheses. We show the increased performance when evaluating on synonyms is maintained across different runs, as is the comparable performance when evaluating on COCO names.

Captions	COCO names	Synonyms
Original	44.45 (0.2)	33.73 (0.1)
Curriculum	44.00 (0.4)	37.05 (0.7)

Table 5: Experiments re-runs: average mAP@0.5 (as %) across three independent repeats of the training process for our curriculum learning approach and the baseline. Standard deviation in parentheses.

5 Conclusions

We considered variations in nouns used to refer to objects (i.e., synonyms and related terms), and how they affect performance of object detectors trained with vision-text data. We highlighted how detecting objects when synonyms are used as input is challenging, and we introduced two approaches to ameliorate this issue, which proved successful at boosting detection performance on synonyms.

6 Limitations

In this work, we show the promise of altering the training process of vision-language object detectors to help learn more robust representations that better adapt to variations in textual input in terms of synonyms used to refer to objects. Despite such promise, our study has some limitations. First, we only evaluate on object detection; further studies on other vision and language tasks (e.g., visual question answering) are needed to fully characterize the problem and evaluate the proposed solutions. Second, we evaluate only on synonyms provided by (Lu et al., 2018). Although the used synonyms allow us to show our main points, more comprehensive synonyms' lists can be tested. Third, we show the impact of our approaches on one model (i.e., BARON (Wu et al., 2023)); while this is a SOTA open-vocabulary object detection model whose overall design is similar to that of other detectors (Minderer et al., 2022; Gu et al., 2021), repeating our experiments with other models would better show the generalizability of our proposed strategies. Finally, our approaches to better learn synonyms focus on changing the input to the model (whether it being the captions or the class embeddings it is trained with). While such a choice makes our approach independent of the model's inner architecture (e.g., how features are extracted and combined) or the training process (e.g., how a batch is constructed), more individualized approaches are worth investigating to solve the observed trade-off between performance on synonyms and on object names.

Ethical considerations. In our work, we use a machine translation model to augment captions with synonyms. Such models may have learned gender-related biases (e.g., doctor/man, nurse/woman) that, in turn, could be passed on to the object detector (making it easier for the model to detect people in a certain profession if they are of a specific gender). The fact that we keep the original captions and add the back-translated one should offer some safeguards against this issue.

Abstract

Neural Text-to-Speech (TTS) systems find broad applications in voice assistants, e-learning, and audiobook creation. The pursuit of modern models, like Diffusion Models (DMs), holds promise for achieving high-fidelity, real-time speech synthesis. Yet, the efficiency of multi-step sampling in Diffusion Models presents challenges. Efforts have been made to integrate GANs with DMs, speeding up inference by approximating denoising distributions, but this introduces issues with model convergence due to adversarial training. To overcome this, we introduce CM-TTS, a novel architecture grounded in consistency models (CMs). Drawing inspiration from continuous-time diffusion models, CM-TTS achieves top-quality speech synthesis in fewer steps without adversarial training or pre-trained model dependencies. We further design weighted samplers to incorporate different sampling positions into model training with dynamic probabilities, ensuring unbiased learning throughout the entire training process. We present a real-time mel-spectrogram generation consistency model, validated through comprehensive evaluations. Experimental results underscore CM-TTS's superiority over existing single-step speech synthesis systems, representing a significant advancement in the field[1].

1 Introduction

The modern Neural Text-to-Speech (TTS) system (Mehrish et al., 2023; Shen et al., 2018; Ren et al., 2021; Liu et al., 2022b) stands out for its exceptional naturalness and efficiency, proving versatile in human-computer interaction and content generation scenarios like real-time voice broadcasting and speech content creation. Comprising three integral modules, the system involves a text encoder collaborating with a conditioning feature predictor, followed by an acoustic model transforming conditioning features into speech features, and a vocoder converting synthesized features into audible speech. This intricate process ensures efficient synthesis of human-like speech.

From a formulation perspective, TTS architecture aligns with autoregressive (AR) (van den Oord et al., 2016; Amodei et al., 2016; Wang et al., 2017; Shen et al., 2018) and non-autoregressive (NAR) (Ren et al., 2019; Ren et al., 2021) models. AR frameworks, using RNN models with attention mechanisms, generate spectrograms sequentially, ensuring stable synthesis but suffering from accumulated prediction errors and slower inference speeds. Conversely, NAR models, often based on transformer architecture (Vaswani et al., 2017), employ parallel feed-forward networks for simultaneous mel-spectrogram generation, reducing computational complexity and enabling real-time applications. Various generative models, including Generative Adversarial Networks (GANs) (Kumar et al., 2019; Kong et al., 2020; Donahue et al., 2020), Flow (Kim et al., 2019, 2020; Shih et al., 2021; Valle et al., 2021)-based models, and hybrid approaches like Flow with GAN (Cong et al., 2021), contribute to high-fidelity, real-time speech synthesis.

Diffusion Models (DMs) are advanced generative models, excelling in image generation (Ho et al., 2020; Kumar et al., 2019; Song et al., 2021; Rombach et al., 2021), molecular design (You et al., 2018; Gómez-Bombarelli et al., 2018; Thomas et al., 2023), and speech synthesis (Kim et al., 2022a,b; Popov et al., 2021). Employing a forward diffusion process with noise addition and a parameterized reverse iterative denoising process, DMs efficiently capture high-dimensional data distributions. Despite their exceptional performance, the efficiency of their multi-step iterative sampling is hindered by Markov chain limitations. To address these challenges, Ye et al. (2023) propose a TTS ar-

chitecture based on consistency models (Song et al., 2023). This architecture achieves high audio quality through a single diffusion step, applying a consistency constraint to distill a model from a well-designed diffusion-based teacher model. However, a drawback is the method's reliance on distillation from a teacher model, introducing complexity into the training pipeline. Importantly, their proposed TTS architecture is trained on the single-speaker LJSpeech dataset (Ito and Johnson, 2017), limiting its suitability for multi-speaker speech generation. This constraint should be considered in applications where broader speaker diversity is essential.

The integration of GANs into DMs for TTS synthesis (Liu et al., 2022b) has proven effective in minimizing the number of sampling steps during the speech synthesis process. However, this improvement comes at the cost of hindered model convergence due to the additional training required for the discriminator. Some approaches enhance synthesis performance with fewer inference steps by incorporating a shallow diffusion mechanism (Liu et al., 2022b). Nonetheless, the introduction of an additional pre-trained model adds complexity to the overall architecture.

We present a novel TTS architecture, CM-TTS, addressing current limitations without relying on a teacher model for distillation. Drawing inspiration from continuous-time diffusion and consistency models, our approach frames speech synthesis as a generative consistency procedure, achieving superior quality in a single step. CM-TTS eliminates the need for adversarial training (Liu et al., 2022b) or auxiliary pre-trained models (Ye et al., 2023). We enhance model training efficacy with weighted samplers, mitigating sampling biases. CM-TTS maintains traditional diffusion-based TTS benefits and introduces a few-step iterative generation, balancing synthesis efficiency and quality. Experimental results confirm CM-TTS outperforms other single-step speech synthesis systems in quality and efficiency, presenting a significant advancement in TTS architecture. Our key contributions can be summarized as follows:

- We present a consistency model-based architecture for generating a mel-spectrogram designed to meet the demands of real-time speech synthesis with its efficient few-step iterative generation process.
- Moreover, CM-TTS can also synthesize speech in a single step, eliminating the need for adversarial training and pre-trained model dependencies.
- We enhance the model training process by introducing weighted samplers, which adjust weights associated with different sampling points. This refinement mitigates biases introduced during model training due to the inherent randomness of the sampling process.
- Qualitative and quantitative experiments covering 12 metrics demonstrate the effectiveness and efficiency of our model in both fully supervised and zero-shot settings.

2 Related Work

Non-Autoregressive Generative Models Non-autoregressive generative models (NAR) excel in swiftly generating output, making them ideal for real-time applications. Their efficiency, derived from parallelized output generation and lack of dependence on previous results, finds applications in diverse domains like image generation and speech synthesis. GAN networks have been applied in non-autoregressive speech synthesis. Donahue et al. (2020) employ adversarial training and a differentiable alignment scheme for end-to-end speech synthesis. Additionally, Kim et al. (2021) integrate adversarial training into Variational Autoencoders (VAE)((Kingma and Welling, 2019)), enhancing expressive power in speech generation. However, GANs face training instability due to non-overlapping distributions between input and generated data. To address this, CM-TTS incorporates Diffusion Model principles for improved model training and mel-spectrogram generation.

Diffusion Models (DMs) DMs provide robust frameworks for learning complex high-dimensional data distributions through continuous-time diffusion processes. After surpassing GANs (Dhariwal and Nichol, 2021) in image synthesis, DMs have shown promise in speech synthesis. Jeong et al. (2021) utilize a denoising diffusion framework for efficient speech synthesis, transforming noise signals into mel-spectrograms. While DMs excel in data distribution modeling, they may require numerous network function evaluations (NFEs) during sampling. Combining diffusion modeling with traditional generative models enhances efficiency. Diff-GAN (Liu et al., 2022b) adopts an adversarially trained model for expressive denoising distribution approximation. Yang et al. (2023) use

VQ-VAE (van den Oord et al., 2017) to transfer text features to mel-spectrograms, reducing diffusion model computational complexity.

3 Background: Consistency Models

The diffusion model is distinguished by a sequential application of Gaussian noise to a target dataset, followed by a subsequent reverse denoising process (Ho et al., 2020). This iterative methodology is designed to generate samples from an initially noisy state, effectively capturing the intrinsic structure of the data. Consider the sequence of noisy data $\{x\}_{t\in[0,T]}$, where $p_0(\mathbf{x}) \equiv p_{\text{data}}(\mathbf{x})$, $p_T(\mathbf{x})$ approximates a Gaussian distribution, and T represents the time constant. The diffusion process can be mathematically expressed as a stochastic process using following stochastic differential equation (SDE).

$$\mathbf{x}_t = \boldsymbol{\mu}(\mathbf{x}_t, t)\mathrm{d}t + \sigma(t)\mathrm{d}\mathbf{w}_t \tag{1}$$

where $t \in [0, T]$, is the index for forward diffusion time steps. Here, $\boldsymbol{\mu}(.,.)$ and $\sigma(.)$ correspond to the drift and diffusion coefficients, and $\{w_t\}_{t\in[0,T]}$ denotes the standard Brownian motion.

A fundamental characteristic of the SDE lies in its inherent possession of a well-defined reverse process, manifested in the form of a probability flow ODE (Song et al., 2021; Karras et al., 2022). Consequently, the trajectories sampled at time t follow a distribution governed by $p_t(\mathbf{x}_t)$:

$$\mathrm{d}\mathbf{x}_t = \left[\mu(\mathbf{x}_t, t) - \frac{1}{2}\sigma(t)^2 \nabla \log\, p_t(\mathbf{x}_t)\right]\, dt \tag{2}$$

$\nabla \log p_t(\mathbf{x}_t)$ represents the score function, a key element in score-based generative models (Song et al., 2021). The forward step induces a shift in the sample away from the data distribution, dependent on the noise level. Conversely, a backward step guides the sample closer to the expected data distribution. The probability flow ODE (referenced as Eq. 2) for sample generation utilizes the score function $\nabla \log p_t(\mathbf{x}_t)$. Obtaining the score function involves minimizing the denoising error $||f(x_t, t) - x||^2$ (Karras et al., 2022), where $f(x_t, t)$ is the denoiser function refining the sample x_t at step t.

$$\nabla \log p_t(\mathbf{x}_t) = \frac{(f(x_t, t) - x_t)}{\sigma(t)^2} \tag{3}$$

Probability flow ODEs sampling follows a two-step approach: first, samples are drawn from a noise distribution, and then, a denoising process is applied using a numerical ODE solver, like Euler or Heun (Song et al., 2021, 2023). However, the sampling process from the ODE solver requires a substantial number of iterations, leading to the drawback of slow inference speed. To further accelerate the sampling Song et al. (2023) proposed a consistency property for the diffusion model with the following condition for any time step t and $t^{'}$ of a solution trajectory.

$$\begin{aligned} f(x_t, 0) =& f(x_{t'}, t^{'}) \\ f(x_t, 0) =& x_0 \end{aligned} \tag{4}$$

Given the aforementioned condition, one-step sampling $f(x_T, T)$ becomes viable, as each point along the sampling trajectory of the ODE is directly associated with the origin $p_0(x)$. For a more in-depth discussion, refer to Song et al. (2023). The consistency model is categorized into two types: consistency training or distillation from a pre-trained diffusion-based teacher model. The distillation-based approach relies on the teacher model, adding intricacy to the construction pipeline of the speech synthesis system. In this work, we opt for consistency training of the consistency model.

4 CM-TTS

Diffusion models, known for their high-quality outputs, often struggle with real-time demands in TTS systems due to slow sampling. Existing attempts, like Diff-GAN (Liu et al., 2022b), often rely on additional adversarial training or pre-trained models for efficiency and accuracy. In this section, we discuss the architecture of CM-TTS.

4.1 Model Overview

As shown in Figure 1, the CM-TTS consists of four key components: 1) Phoneme encoder for processing text; 2) Variance adaptor predicting pitch, duration, and energy features; 3) the CM-Decoder for mel-spectrogram generation; and 4) Vocoder, using HiFi-GAN (Kong et al., 2020), to convert mel-spectrograms into time-domain waveforms.

4.2 Phoneme Encoder and Variance Adaptor

The phoneme encoder, incorporating multiple Transformer blocks (Ren et al., 2019, 2021), adapts the feed-forward network to effectively capture local dependencies within the phoneme sequence. The variance adaptor aligns with FastSpeech2's

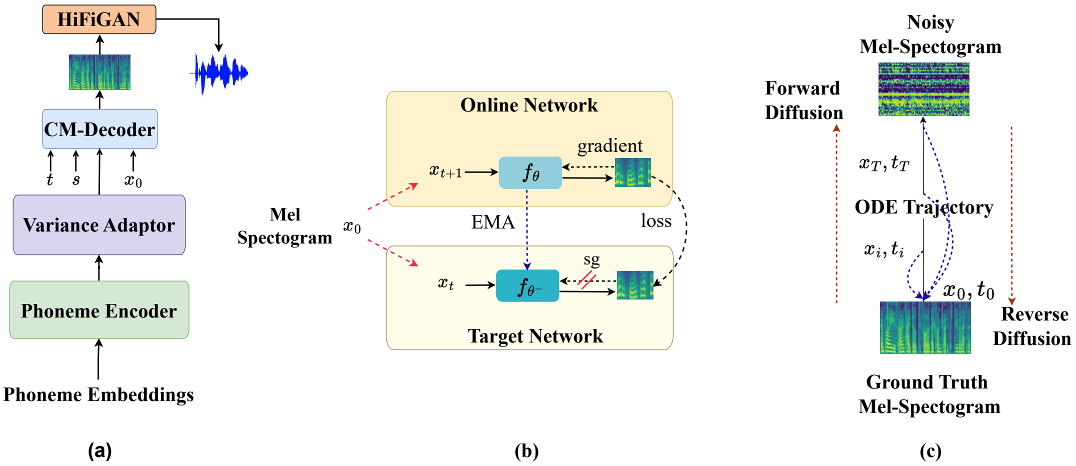

Figure 1: (a) CM-TTS architecture. (b) Decoder training scheme, where f_θ is parameterized to satisfy consistency constrain disucssed in Eq. 4. (c) ODE trajectory during training.

design, including pitch, energy, and duration prediction modules, each following a consistent model structure with several convolutional blocks. To facilitate training, ground-truth duration, energy, and pitch serve as learning targets, computed using Mean Squared Error (MSE) loss ($\mathcal{L}_{\text{duration}}$, $\mathcal{L}_{\text{pitch}}$, and $\mathcal{L}_{\text{energy}}$). In the training phase, the ground-truth duration expands the hidden sequence from the phoneme encoder to yield a frame-level hidden sequence, followed by the integration of ground-truth pitch information. During inference, the corresponding predicted duration and pitch values are utilized.

4.3 Consistency Models

To establish the divisions within the time horizon $[\epsilon, T_{\text{max}}]$, the interval is segmented into $N-1$ sub-intervals, delineated by boundaries $t_1 = \epsilon < t_2 < \ldots < t_N = T_{max}$. As recommended by Karras et al. (2022) to mitigate numerical instability, a small positive value is set for ϵ. Similar to Karras et al. (2022), in this work we use $T_{max} = 80$ and $\epsilon = 0.002$. The mel-spectrogram is denoted as $\mathbf{x}$, where $\mathbf{x}_0$ signifies the initial mel-spectrogram devoid of any added noise.

The fundamental concept introduced in Song et al. (2023) to formulate the consistency model f_θ involves learning a consistency function from data by enforcing the self-consistency property defined in Eq. 4. In order to ensure $f_\theta(x_0, \epsilon) = \mathbf{x_0}$, the consistency model f_θ is parameterized as follows:

$$f_\theta(\mathbf{x}, t) = c_{skip}(t)\mathbf{x} + c_{out}(t)F_\theta(\mathbf{x}, t) \quad (5)$$

Here, c_{skip} and c_{out} are differentiable functions with $c_{skip}(\epsilon) = 1$ and $c_{out}(\epsilon) = 0$, respectively. The term $F_\theta(\mathbf{x}, t)$ represents a neural network. To enforce the self-consistency property, a target model θ^- is concurrently maintained with the online network θ. The weight of the target network θ^- is updated using the exponential moving average (EMA) of parameters θ intended for learning (Grill et al., 2020), specifically,

$$\boldsymbol{\theta}^- \leftarrow \text{stopgrad}(\mu\boldsymbol{\theta}^- + (1-\mu)\boldsymbol{\theta}). \quad (6)$$

The consistency loss $\mathcal{L}^N_{CT}(\boldsymbol{\theta}, \boldsymbol{\theta}^-)$ is defined as:

$$\sum_{n \geq 1} \mathbb{E}[\lambda(t_n) d(\boldsymbol{f}_{\boldsymbol{\theta}}(\mathbf{x}_{t+1}), \boldsymbol{f}_{\boldsymbol{\theta}^-}(\mathbf{x}_t))] \quad (7)$$

Here, $d(\cdot,\cdot)$ denotes a chosen metric function for measuring the distance between two samples, such as the squared l_2 distance $d(x, y) = ||x - y||^2_2$. The values $\mathbf{x}_{t+1}$ and $\mathbf{x}_t$ are obtained by sampling two points along the trajectory of the probability flow ODE using a forward diffusion process, starting with mel-spectrograms of the training data $\mathbf{x}_0 \sim \mathcal{D}(dataset)$:

$$\begin{aligned} \mathbf{x}_{t+1} &= \mathbf{x}_0 + t_{n+1}\mathbf{z} \\ \mathbf{x}_t &= \mathbf{x}_0 + t_n\mathbf{z} \end{aligned} \quad (8)$$

where $\mathbf{z} \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I})$ and step t_n is obtained as follows:

$$t_n = \left[T_{\max}{}^{\frac{1}{p}} + \frac{n-1}{N-1}\left(\epsilon^{\frac{1}{p}} - T_{\max}{}^{\frac{1}{p}}\right)\right]^p \quad (9)$$

where N denotes the sub-intervals, n is sampled from the interval $[1, N-1]$ using different weighted sampling strategies (Section 4.3.2), and value of $p = 7$ following Karras et al. (2022).

Similar to DiffGAN-TTS (Liu et al., 2022b), the architecture of $F_\theta(\mathbf{x}, t)$ in CM-TTS embraces a non-causal WaveNet structure (van den Oord et al., 2016). The difference lies in their approach to sampling t. In CM-TTS, two decoders, denoted as f_θ and f_θ^-, with identical architectures serve as the online and target networks, respectively. The diffusion process in CM-TTS is characterized by Eq. 8, whereas DiffGAN-TTS employs the creation of a parameter-free T-step Markov chain (Liu et al., 2022b).

4.3.1 Training and Loss

Following the training procedure established in Grill et al. (2020), we designate the two decoders shown in Figure 1 as the online $\boldsymbol{f_\theta}$ and target $\boldsymbol{f_{\theta^-}}$. Leveraging the states $\mathbf{x}_{t+1}$ and $\mathbf{x}_t$, we derive corresponding mel predictions, expressed as $\boldsymbol{f_\theta}(\mathbf{x}_0 + t_{n+1}\mathbf{z})$ and $\boldsymbol{f_{\theta^-}}(\mathbf{x}_0 + t_n\mathbf{z})$, through the online and target networks, respectively. The online component undergoes gradient updates via the computation of MSE loss between these prediction pairs. Simultaneously, the gradients of the target network are updated through EMA, as discussed in section 4.3.

During training, the online and target networks engage in an iterative interplay, facilitating mutual learning and crucially contributing to model stability. The mel reconstruction loss $\mathcal{L}_{mel}$ is determined by computing the Mean Absolute Error (MAE) between the ground truth and the generated mel-spectrogram. Finally, $\mathcal{L}_{recon}$ can be expressed as follows:

$$\begin{aligned}\mathcal{L}_{recon} = &\mathcal{L}_{mel}(\mathbf{x_0}, \hat{\mathbf{x}}_\mathbf{0}) + \lambda_d \mathcal{L}_{duration}(\mathbf{d}, \hat{\mathbf{d}}) + \\ &\lambda_p \mathcal{L}_{pitch}(\mathbf{p}, \hat{\mathbf{p}}) + \lambda_e \mathcal{L}_{energy}(\mathbf{e}, \hat{\mathbf{e}})\end{aligned} \tag{10}$$

Here, $\mathbf{d}$, $\mathbf{p}$, and $\mathbf{e}$ denote the ground truth duration, pitch, and energy, respectively, while $\hat{\mathbf{d}}$, $\hat{\mathbf{p}}$, and $\hat{\mathbf{e}}$ represent the predicted values. The weights assigned to each loss component are denoted by λ_d, λ_p, and λ_e. For this study, we maintain uniform loss weights set at 0.1. The optimization objective for training the CM-TTS involves minimizing the following composite loss function.

$$\mathcal{L}_{CM-TTS} = \mathcal{L}_{CT}^{N}(\boldsymbol{\theta}, \boldsymbol{\theta}^-) + \mathcal{L}_{recon} \tag{11}$$

During single-step generation in inference, a single forward pass through f_θ is undertaken. Conversely, multi-step generation is achievable by alternating denoising and noise injection steps, enhancing the quality, as depicted in Figure 2.

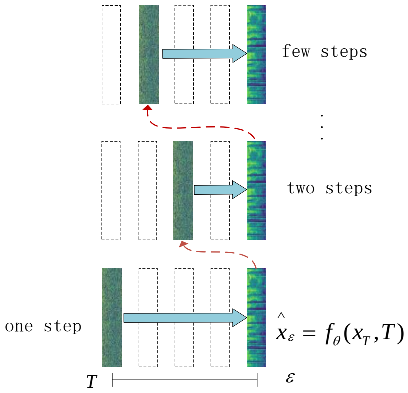

Figure 2: Single-step and multi-step inference utilizing the CM-TTS. For multi-step generation, process of alternating denoising and noise injection steps is executed iteratively until the desired number of steps is achieved.

4.3.2 Weighted Sampler

The training procedure relies on sampling the time step t_n as defined in Eq. 9. Consequently, to investigate the impact of sampling various positions (t_n) along the ODE trajectory, we employ three distinct weighted sampling strategies. Each strategy governs the probabilities associated with selecting the step t_n throughout the training, thereby allowing for an in-depth examination of the effects arising from different sampling positions.

In the forward diffusion process during training, the variable n denotes the index of a sampling point, where $n \in [1, N-1]$, and is used in Eq. 9 for computing t_n. We introduce c_n as the weight assigned to the current index n by the sampler, s_n the probability of selecting index n is given by $s_n = \frac{c_n}{\sum_{i=1}^{N-1} c_n}$. The three sampler designs are outlined as follows:

Uniform sampler This sampler serves as a baseline for validating other methods, where each point is chosen with equal probability ($c_n = 1$).

Linear sampler The sampling weight varies linearly with the position of the sampling point, defined as $c_n = \alpha \cdot n$, with $\alpha = 1$ in all experiments.

Importance sampler (IS) Following Nichol and Dhariwal, 2021, we use the IS to assign weights to sampling points. The formulation is given by $c_n = (1-\phi)\frac{\sum_{j=1}^{H} L(t,j)}{\sum_{i=1}^{N-1}\sum_{j=1}^{H} L(i,j)} + \phi$. Here, $\mathrm{L} \in \mathbb{R}^{(N-1)\times H}$ represents a matrix recording historical losses for all sampling points, and H denotes the number of historical losses stored for each point (set to 10 in our experiments). The small quantity ϕ serves as a

balancing factor, adjusting c_n. This design modulates the probability of current sampling based on historical losses, thereby prioritizing points with greater significance for model training.

5 Experiments

5.1 Data and Preprocessing

Our experiments are based on CSTR VCTK (Veaux et al., 2013), LJSpeech (Ito and Johnson, 2017), and LibriSpeech (Panayotov et al., 2015) datasets. CSTR VCTK Corpus includes speech data from 110 English speakers, while LJSpeech features $13,100$ short audio clips, totaling around 24 hours. For zero-shot experiments, the LibriTTS corpus is used for model training. All samples are resampled to $22,050$ Hz. The test set consists of 512 randomly selected speech samples, and we assess the model's performance with various objective and subjective metrics. In pre-processing, mel-spectrograms has 80 frequency bins, generated with a window size of 25 ms and a frameshift of 10 ms. Ground truth pitch, duration, and energy are computed using the PyWorld toolkit[2].

5.2 Baseline Models

Reference and Reference (Voc.) Reference denotes the ground truth. The process of obtaining the Reference (voc.) involves transforming the original reference speech into mel-spectrograms, followed by the subsequent reconstruction of speech using HiFi-GAN (Kong et al., 2020)

FastSpeech2 NAR transformer architecture (Ren et al., 2019), generating speech in parallel for faster inference. Utilizing mel-spectrogram prediction, duration prediction, and variance modeling, it achieves high efficiency and accuracy in synthesizing speech.

VITS The VITS model (Kim et al., 2021) combines variational inference, normalizing flows, and adversarial training. It introduces a stochastic duration predictor to synthesize diverse rhythms, capturing natural variability in speech.

DiffSpeech & DiffGAN-TTS DiffSpeech (Liu et al., 2022a) and DiffGAN-TTS (Liu et al., 2022b) are diffusion-based TTS architectures. Both architectures focus on addressing real-time speech synthesis in TTS systems, which diffusion models often struggle with due to slow sampling. DiffGAN-TTS addresses the challenge by incorporating additional adversarial training.

5.3 Model Configuration

The transformer encoder and the variance adaptor of the CM-TTS adopt identical network structures and hyper-parameters as those in FastSpeech2. The former is composed of 4 feed-forward transformer (FFT) blocks, where the kernel size and filter size are set to 256, 2, 9, and 1024, respectively. The latter continues to consist of a duration predictor, a pitch predictor, and an energy predictor. The CM-Decoder adopts a structure similar to WaveNet, employing 1D convolution to process the noisy mel spectrogram, followed by activation through the ReLU. Speaker-IDs are activated through WaveNet residual blocks and transformed into embedding vectors. The diffusion step t is encoded using sinusoidal positional encoding as in Song et al. (2023). The mel decoder comprises 4 FFT blocks. The number of parameters in our model is 28.6 million.

5.4 Training and Inference

We conduct all experiments using a single NVIDIA Tesla V100 GPU with 32 GB. The average runtime of training under VCTK, LJSpeech, and LibriSpeech is 34.2 hours, 42.8 hours, and 45.6 hours, respectively. The training employs the multi-speaker dataset VCTK, and speaker embeddings, computed using Li et al. (2017), have a dimension of 512. In our experiments, we randomly select 512 samples for testing, utilizing the remaining for training. The batch size during training is 32. We train all the models for $300K$ steps. Following the same learning rate schedule in DiffGAN-TTS, we use an exponential learning rate decay with rate 0.999 for training and the initial learning rate is $10e^{-4}$. In addition, Song et al. (2023) find that periodically adjusting sub-interval N and decay constant μ in Eq 6 during training, following schedule functions $N(k)$ and $\mu(k)$ based on training steps k, improves performance. In this paper, we adopts the same strategy as outlined in Song et al. (2023).

5.5 Evaluation Metrics

Objective metrics In our rigorous evaluation of speech synthesis, we leverage a diverse array of objective metrics to holistically appraise the synthesized output's quality and efficiency. This multifaceted set of metrics encompasses the F0 Frame Error (FFE) for evaluating fundamental frequency tracking, Speaker Cosine Similarity (SCS) to gauge the similarity of speaker embeddings, and Fréchet Inception Distance (FID) based on Mel-Frequency Cepstral Coefficients (mfccFID) for a comprehensive assessment of spectrogram divergence. Furthermore, we incorporate metrics such as mfccRecall, MCD24, SSIM, mfccCOS, Word Error Rate (WER), and F0 to provide nuanced insights into various dimensions of synthesis performance. Detailed descriptions in given in Appendix D.

Subjective metrics The Mean Opinion Score (MOS), as introduced in Chu and Peng (2006), serves as a pivotal metric for evaluating the perceived quality of the synthesized audio. In our evaluation, we involve presenting a carefully curated test set with 30 samples to 20 listeners experienced in NLP and speech processing and soliciting their subjective opinions. Participants are then tasked with rating the quality of the synthesized audio on a scale ranging from 1 to 5. MOS is a metric that is highly affected by the listeners' subjective judgment. We evaluate the MOS metrics in different tables separately, which causes the MOS of CM-TTS(T=1) to be slightly different rather than identical.

6 Results and Discussion

Comparison with baselines The outcomes of our experiments, comparing the proposed model against various baseline models, are presented in Table 1. Notably, our model (CM-TTS) demonstrates a significant performance advantage over Fastspeech2, VITS, and DIffSpeech in objective evaluations. The results also affirm the efficacy of CM-TTS when pitted against DiffGAN-TTS; the proposed TTS architecture outperforms DiffGAN-TSS across the majority of metrics. Particularly noteworthy is CM-TTS's superior performance in single-step generation ($T = 1$), where it outperforms DiffGAN-TSS across all objective metrics, with only a minimal gap observed in f_0. Furthermore, when evaluating speaker similarity (S.Cos), CM-TTS achieves the highest S.Cos score of 0.8401, underscoring its effectiveness in multi-speaker speech generation.

Table 5: The zero-shot performance of CM-TTS and DiffGAN-TTS on VCTK for synthesis steps 1, 2, and 4.

We conduct a subjective evaluation to compare the naturalness and quality of synthesized speech against a reference sample. The MOS scores from the listening test, showcased in Table 1, reveal CM-TTS achieving an impressive MOS of 3.9618. This marks a substantial advancement over DiffSpeech and a significant outperformance of DiffGAN-TTS in overall performance.

Ablation study To verify the individual contributions of CT and IS to the model's performance, we conduct ablation experiments by separately removing CT and IS, with the synthesis steps set to 1. The experimental results are shown in Table 2. The results indicate that simultaneous use of both CT and IS samplers leads to notable improvements across multiple metrics, particularly in reducing WER. This underscores their significant contribution to the overall performance of the model.

Few-step speech generation In evaluating single-step synthesis performance, we can observe from Table 1 CM-TTS that consistently surpasses DiffGAN-TTS across all metrics, with a marginal difference observed in the F0-RMSE. When extending to a multi-step synthesis scenario ($T = 4$), CM-TTS outperforms DiffGAN-TTS in all metrics, except for melFID (7.34 compared to 6.58). These findings emphasize that, beyond its impressive single-step synthesis capabilities, our proposed method demonstrates robust synthesis proficiency in scenarios involving multiple iterative steps.

Length robustness during training Incorporating padding in the model's loss calculation is common, especially for variable-length sequences in training. The goal is to guide the model in capturing meaningful representations from both genuine input data and padded segments. TTS models face challenges in handling diverse input texts during training. To assess the model's resilience and investigate the impact of padding, we conduct experiments comparing the inclusion or exclusion of the padding portion in the loss calculation ($\mathcal{L}_{mel}$). Results in Table 4 demonstrate that including the padding portion improves the overall performance of the model. We experiment with both l_1-norm and l_2-norm while computing $\mathcal{L}_{mel}$ in Eq. 10.

The impact of weighted sampler In this subsection, we conduct experiments to explore the impact of different sampling methods, as discussed in Section 4.3.2, on the performance of the CM-TTS. The results presented in Table 3 reveal a significant enhancement in the CM-TTS's performance across various metrics when the IS sampler is employed. Notably, S.Cos exhibits an improvement to 0.8396, indicating enhanced speaker similarity with the use of the IS sampler. Furthermore, as illustrated in the Figure 4, we observe there is no significant impact on the convergence of CM-TTS when utilizing a different sampler. To further explore the generalization of IS, we apply it to DiffGAN. The experimental results, as shown in Table 6, strongly demonstrate that IS can bring significant improvements across most metrics.

Generalization to unseen speakers To assess how well CM-TTS performs with speakers it hasn't seen before, we train the model on the Lib-

Table 7: The prosody similarity between synthesized and reference speech of pitch and duration.

riTTS (Zen et al., 2019)(train-clean-100) dataset, which mainly contains longer input texts. To test its zero-shot performance, we randomly selected 512 speech samples from VCTK and LJSpeech datasets. In Table 5, we compare DiffGAN and CM-TTS on VCTK for different generation steps ($T = 1, 2, \&4$). Additionally, we use an alignment tool to get phoneme-level duration and pitch and compute the prosody similarity between the synthesized and the reference speech. The results are displayed in Table 7. Interestingly, in multi-speaker scenarios, CM-TTS consistently outperforms the baseline DiffGAN-TTS. However, in single-speaker scenarios (see Table 9), DiffGAN-TTS outperforms CM-TTS. For more details on zero-shot performance on LJSpeech, please refer to Appendix B.

Conclusion

In this work, we introduced CM-TTS, a novel architecture focused on real-time speech synthesis. CM-TTS leverages consistency models, steering away from the complexities associated with adversarial training and pre-trained model dependencies. Through comprehensive evaluations, our results underscore the effectiveness of CM-TTS over established single-step speech synthesis architectures. This marks a significant improvement in promising avenues for applications ranging from voice assistant systems to e-learning platforms and audiobook generation. The future work entails advancing training through the utilization of diverse datasets, thereby enhancing the CM-TTS to generalize better across previously unseen speakers.

Limitations

In terms of the model, the presented CM-TTS framework primarily optimizes and enhances the training mechanism, aiming to facilitate comparative experiments. However, the inherent structure of the network, including aspects like the number of layers or residual modules, hasn't been extensively explored for this paper. Future endeavors could delve into lightweight studies focusing on the network itself, potentially enhancing the overall performance of CM-TTS.

Regarding the task, the experiments conducted in this paper exclusively center around TTS tasks, without extending to other related tasks such as sound generation. Future work could encompass experimental validation across a broader spectrum of tasks, providing a more comprehensive assessment.

Ethics Statement

Given the ability of CM-TTS to synthesize speech while preserving the speaker's identity, potential risks of misuse, such as deceiving voice recognition systems or impersonating specific individuals, may arise. In our experiments, we operate under the assumption that users willingly agree to be the designated speaker for speech synthesis. In the event of the model's application to unknown speakers in real-world scenarios, it is imperative to establish a protocol ensuring explicit consent from speakers for the utilization of their voices. Additionally, implementing a synthetic speech detection model is recommended to mitigate the potential for misuse.

A Experiments on LJSpeech

Our CM-TTS model, trained for 300K steps on the LJSpeech single speaker dataset, exhibits impressive performance in 1, 2, and 4-step synthesis, detailed in Table 8. Compared to DiffGAN-TTS, CM-TTS achieves optimal scores (S.Cos: 0.9010, melFID: 2.97) across varied training and synthesis scenarios, highlighting its effectiveness in single-speaker scenarios.

In a detailed performance comparison between CM-TTS and DiffGAN-TTS, we analyze the convergence of these models across various training steps, as illustrated in Figure 3. Initially, both models exhibit relatively consistent convergence. However, as the training steps increase, CM-TTS demonstrates significantly better convergence, indicating superior fitting performance when compared to DiffGAN-TTS.

B Zero-shot Performance on LJSpeech

We trained CM-TTS on the LibriTTS' train-clean-100 dataset and evaluated LJSpeech's zero-shot performance. The results are presented in Table 10 and Table 9. It is evident that CM-TTS consistently outperforms in most metrics.

LJSpeech	Pitch				Duration			
	Mean↓	Std↓	Skew↓	Kurt↓	Mean↓	Std↓	Skew↓	Kurt↓

C 50 Particularly Hard Sentences

To evaluate the robustness of CM-TTS, we follow the practice in (Ren et al., 2021; Ping et al., 2018) and generate 50 sentences which are particularly hard for the TTS system. Subjectively assessing the results, we observed that, aside from occasional inaccuracies in pronouncing individual words, the synthesis quality across the majority of examples is notably clear. This observation strongly supports the claim that CM-TTS exhibits considerable robustness in handling a wide range of linguistic complexities. The specific textual representations for all the sentences are provided below for reference.

D Metrics

We employ 12 metrics to assess the quality and efficiency of speech synthesis. This includes 11 objective metrics and one subjective metric. The following provides a detailed analysis of the calculation methods and objectivity for all the metrics involved in the experiments.

- **FFE (Fundamental Frequency Frame Error):**
  - FFE, or F0 Frame Error (Chu and Alwan, 2009), combines Gross Pitch Error (GPE) and Voicing Decision Error (VDE) to objectively evaluate fundamental frequency (F0) tracking methods.
  - The Fundamental Frequency Frame Error (FFE) quantifies errors during the estimation of the fundamental frequency using the formula:

$$FFE = \frac{1}{N} \sum_{i=1}^{N} |F_{0i,\text{estimated}} - F_{0i,\text{actual}}|$$

    where N is the total number of frames, $F_{0i,\text{estimated}}$ is the estimated fundamental frequency of the i-th frame, and $F_{0i,\text{actual}}$ is the actual fundamental frequency of the i-th frame.

- **S.Cos (Speaker Cosine Similarity):**
  - S.Cos, or Speaker Cosine Similarity, measures the degree of similarity between speaker embeddings corresponding to synthesized speech and ground truth.
  - The Cosine Similarity is calculated as:

$$\text{Cosine Similarity}(\mathbf{P}, \mathbf{A}) = \frac{\mathbf{P} \cdot \mathbf{A}}{||\mathbf{P}||||\mathbf{A}||}$$

    where $\mathbf{P} \cdot \mathbf{A}$ is the dot product between speaker embeddings, and $||\mathbf{P}||||\mathbf{A}||$ is their Euclidean norm.

- **mfccFID (Fréchet Inception Distance based on MFCC):**
  - mfccFID calculates the Fréchet Inception Distance (FID) between MFCC features extracted from predicted and actual speech, measuring similarity between their distributions.

  - The FID formula is given by:

    $$FID = \|\mu_p - \mu_a\|^2 + \mathrm{Tr}(\Sigma_p + \Sigma_a - 2(\Sigma_p\Sigma_a)^{1/2})$$

    where μ_p and μ_a are mean vectors, and $\Sigma_p + \Sigma_a$ is the covariance matrix.

- **melFID (Fréchet Inception Distance based on Mel Spectrogram):**
  - melFID directly calculates FID between Mel spectrograms of predicted and actual frames.
- **mfccRecall:**
  - As outlined in Kynkäänniemi et al. (2019), we denote the feature vectors of real and generated mel spectrograms as ϕ_r and ϕ_g, respectively. In our approach, we utilized the MFCC features of the speeches, representing the sets of feature vectors as Φ_r and Φ_g. We ensured an equal number of samples were drawn from each distribution. Recall is computed by querying, for each real image, whether the image falls within the estimated manifold of generated images.
  - The formula is:

    $$recall(\Phi_r, \Phi_g) = \frac{1}{|\Phi_r|} \sum_{\phi_r \in \Phi_r} f(\phi_r, \Phi_g)$$

    $f(\phi, \Phi_g)$ provides a way to determine whether it could be reproduced by the generator.

- **MCD (Mel Cepstral Distortion):**
  - MCD measures the difference between two acoustic signals in the domain of Mel Cepstral Coefficients (MFCC).
  - The formula is:

    $$MCD = \frac{1}{T} \sum_{t=1}^{T} d(c(p), c(a))$$

    where T is the total number of frames, and $c(p)$ and $c(a)$ are the MFCC vectors of real and synthesized speech.

- **SSIM (Structural Similarity Index):**
  - SSIM measures the similarity between two spectrograms using luminance, contrast, and structure information.
  - The SSIM formula is given by:

    $$\mathrm{SSIM}(p, a) = \frac{(2\mu_p\mu_a + c_1)(2\sigma_{pa} + c_2)}{(\mu_p^2 + \mu_a^2 + c_1)(\sigma_p^2 + \sigma_a^2 + c_2)}$$

    where p and a are the spectrograms, and μ_p, μ_a, σ_p^2, σ_a^2, σ_{pa}, c_1, and c_2 are constants.

- **mfccCOS (MFCC Cosine Similarity):**
  - mfccCOS measures the similarity between MFCC features of real and predicted speech using the same calculation method as S.Cos.
- **F0-RMSE (F0 Root Mean Squared Error):**
  - F0-RMSE is a metric measuring the difference between two pitch sequences (fundamental frequency).
  - The RMSE formula is:

    $$\mathrm{RMSE} = \sqrt{\frac{1}{N} \sum_{i=1}^{N} (f_{0,i} - \hat{f}_{0,i})^2}$$

    where N is the total number of frames, $f_{0,i}$ is the fundamental frequency of the i-th frame in the real pitch sequence, and $\hat{f}_{0,i}$ is the fundamental frequency of the i-th frame in the predicted pitch sequence.

- **RTF (Real-time Factor):**
  - RTF represents the time (in seconds) required for the system to synthesize one second of waveform.
- **MOS (Mean Opinion Score):**
  - MOS is an objective evaluation metric obtained through subjective experiments, assessing the quality of speech synthesis.
  - The MOS formula is:

    $$\text{MOS} = \frac{1}{N}\sum_{i=1}^{N} a_i$$

    where N is the number of participants, and a_i is the score provided by the i-th participant.
- **WER (Word Error Rate):**
  - WER measures the disparity between the transcribed text of the model's predicted speech and the actual speech. The calculation of WER includes three types of errors : Insertions, Deletions, and Substitutions.
  - The WER formula is:

    $$\text{WER} = \frac{S + D + I}{N} \times 100$$

    where S is the number of substitution errors, D is the number of deletion errors, I is the number of insertion errors and N is is the total number of words in the transcribed text.

E Metric

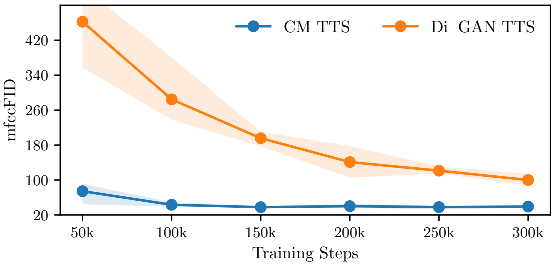

Figure 5: The trend of DiffGAN-TTS and CM-TTS on the mfcc-FID metric during training on VCTK.

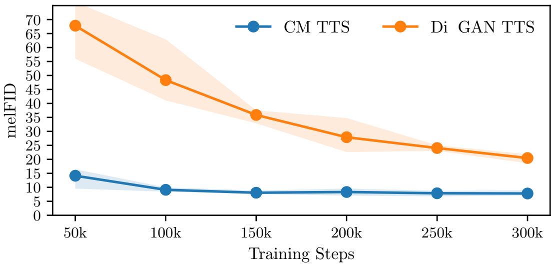

Figure 6: The trend of DiffGAN-TTS and CM-TTS on the mel-FID metric during training on VCTK.

As depicted in Figure 5 and Figure 6, the trend in metric changes highlights that CM-TTS displays faster convergence and a more stable model performance.

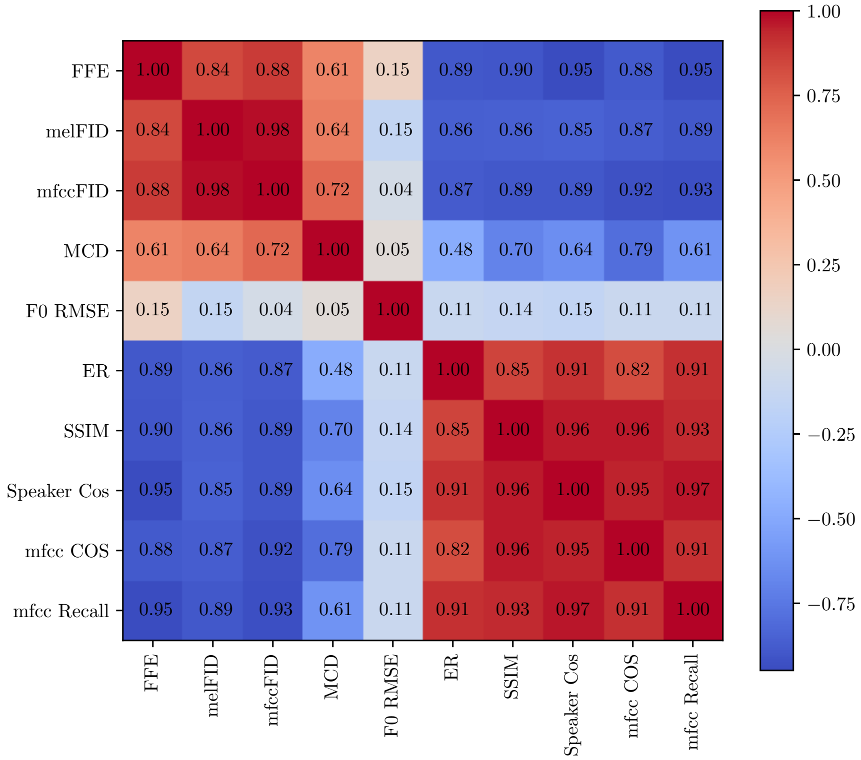

Figure 7: The Pearson correlation coefficient between different objective evaluation metrics.

We also explored relationships between various evaluation metrics, calculating trends' similarity using the Pearson coefficient and visualizing the results in Figure 7. Notably, significant correlations were observed among SSIM, Speaker Cos, mfccCOS, and mfcc Recall, indicating closely aligned trends. A strong correlation was also identified between the two types of FID. Conversely, MCD showed a weak relationship with metrics that perform better when lower. F0 RMSE displayed weak correlations with all other metrics, and FFE had a relatively modest relationship with metrics that are optimal when smaller. This study provides valuable insights for speech synthesis quality evaluation, suggesting that when testing only a few metrics, it's advisable to select those with lower correlations, as illustrated in the Figure 7, as evaluation indicators.

RobustSentEmbed: Robust Sentence Embeddings Using Adversarial Self-Supervised Contrastive Learning

Abstract

Pre-trained language models (PLMs) have consistently demonstrated outstanding performance across a diverse spectrum of natural language processing tasks. Nevertheless, despite their success with unseen data, current PLM-based representations often exhibit poor robustness in adversarial settings. In this paper, we introduce RobustSentEmbed, a self-supervised sentence embedding framework designed to improve both generalization and robustness in diverse text representation tasks and against a diverse set of adversarial attacks. Through the generation of high-risk adversarial perturbations and their utilization in a novel objective function, RobustSentEmbed adeptly learns high-quality and robust sentence embeddings. Our experiments confirm the superiority of RobustSentEmbed over state-of-the-art representations. Specifically, Our framework achieves a significant reduction in the success rate of various adversarial attacks, notably reducing the BERTAttack success rate by almost half (from 75.51% to 38.81%). The framework also yields improvements of 1.59% and 0.23% in semantic textual similarity tasks and various transfer tasks, respectively.

1 Introduction

Pre-trained Language Models (PLMs) have demonstrated state-of-the-art performance in learning contextual word embeddings (Devlin et al., 2019), contributing to significant advancements in various Natural Language Processing (NLP) tasks (Yang et al., 2019; He et al., 2021; Ding et al., 2023). PLMs, including prominent models like BERT (Devlin et al., 2019) and GPT-3 (Brown et al., 2020), have revolutionized text classification, sentence representation, and machine translation among a plethora of diverse NLP tasks. While PLMs have expanded their focus to include universal sentence embeddings, which effectively capture the semantic representation of input text, PLM-based sentence representations lack two crucial characteristics: generalization and robustness.

Extensive research efforts have been dedicated to the development of universal sentence embeddings employing PLMs (Reimers and Gurevych, 2019; Zhang et al., 2020; Neelakantan et al., 2022; Wang et al., 2023). Although these embeddings have demonstrated proficiency in generalization across various downstream tasks (Sun et al., 2019; Gao et al., 2021), they exhibit limitations when subjected to adversarial settings and remain vulnerable to adversarial attacks (Nie et al., 2020; Wang et al., 2021). Existing research has highlighted the limited robustness of PLM-based representations (Garg and Ramakrishnan, 2020; Wu et al., 2023; Hauser et al., 2023). The vulnerability arises when these representations can be easily deceived by making small, imperceptible modifications to the input text.

To address these limitations, we propose a method to obtain robust sentence embeddings called RobustSentEmbed. The main idea is to generate small adversarial perturbations and employ an efficient contrastive objective (Chen et al., 2020). The goal is to enhance the adversarial resilience of the sentence embeddings. Specifically, our framework involves an iterative collaboration between an adversarial perturbation generator and the PLM-based encoder to generate high-risk perturbations in both token-level and sentence-level embedding spaces. RobustSentEmbed then employs a contrastive learning objective in conjunction with a token replacement detection objective to maximize the similarity between the embedding of the original sentence and the adversarial embedding of a positive pair (the former objective) as well as its edited sentence (the latter objective).

We have conducted comprehensive experiments to substantiate the efficacy of the RobustSentEmbed framework. The tasks encompass TextAttack (Morris et al., 2020) assessments, adversar-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3795–3809
June 16-21, 2024

ial Semantic Textual Similarity (STS) tasks, Non-adversarial STS tasks (Conneau and Kiela, 2018), and transfer tasks (Conneau and Kiela, 2018). Two initial series of experiments were designed to evaluate the robustness of our sentence embeddings against various adversarial attacks and tasks. Subsequently, we conducted two final series of experiments to assess the quality of our embeddings in the contexts of semantic similarity and natural language understanding. RobustSentEmbed demonstrates significant improvements in robustness, reducing the attack success rate from 75.51% to 38.81% against the BERTAttack attack and from 71.86% to 12.80% on adversarial STS. Moreover, the framework outperforms existing methods in ten out of thirteen tasks while obtaining comparable results with the other three, showcasing improvements of 1.59% and 0.23% on STS tasks and NLP transfer tasks, respectively.

Contributions. Our main contributions are summarized as follows:

- We introduce RobustSentEmbed, an innovative framework designed for generating sentence embeddings that are robust against adversarial attacks. Existing methods are vulnerable to such adversarial challenges. RobustSentEmbed fills this gap by generating high-risk perturbations and utilizing an efficient adversarial objective function.[1]

- We conduct comprehensive experiments to empirically evaluate the effectiveness of the RobustSentEmbed framework. The empirical findings substantiate the efficacy of our framework, as demonstrated by its superior performance in both robustness and generalization benchmarks.

2 Related Work

Recently, self-supervised methods using contrastive objectives have become prominent for learning effective and robust text representations: SimCSE, as outlined by Gao et al. (2021), introduced a minimal augmentation method involving the application of two distinct dropout masks to predict the input sentence. The ConSERT model (Yan et al., 2021) employed four unique data augmentation techniques, namely adversarial attacks, token shuffling, cut-off, and dropout, to generate a variety of perspectives in order to carry out a contrastive objective. Miao et al. (2021) utilized adversarial training to improve the robustness of contrastive learning. They achieved this by incorporating regularization into their learning objective, combining benign contrastive learning with an adversarial contrastive scenario. Rima et al. (2022) proposed a novel method for training language processing models, combining adversarial training and contrastive learning. Their approach incorporates linear perturbations to input embeddings and uses contrastive learning to minimize the distance between the original and perturbed representations. Pan et al. (2022) introduced a simple technique to improve the fine-tuning of Transformer-based encoders. Their method involves regularization by generating adversarial examples through word embedding perturbations and using contrastive learning to obtain noise-invariant representations.

Unlike existing approaches for training text representation through contrastive adversarial learning (Yan et al., 2021; Miao et al., 2021; Rima et al., 2022; Pan et al., 2022), our framework generates more efficient, high-risk perturbations at both the token-level and sentence-level within the embedding space. Furthermore, our framework utilizes a robust contrastive objective and incorporates an adversarial replaced token detection method, leading to high-quality text representations that yield improved generalization and robustness characteristics.

3 The Proposed Framework

We extended our previous robust text representation (i.e., RobustEmbed, see (Asl et al., 2023)) by utilizing adversarial perturbation at various levels, including token-level and sentence-level. We introduce RobustSentEmbed, a straightforward yet highly effective method for generating robust text representation. Given a PLM $f_\theta(.)$ as the encoder and a raw dataset $\mathcal{D}$, our framework aims to pretrain $f_\theta(\cdot)$ on $\mathcal{D}$ to enhance the efficacy of sentence embeddings across a wide range of NLP tasks (improved generalization) and to fortify its resilience against various adversarial attacks (improved robustness). Figure 1 presents an overview of our framework. The framework involves an iterative interaction between the perturbation generator and the $f_\theta(.)$ encoder to produce high-risk adversarial perturbations in both token-level and sentence-level embedding spaces. These perturbations provide the

---

[1] Our code are publicly available at `https://github.com/jasl1/RobustSentEmbed`

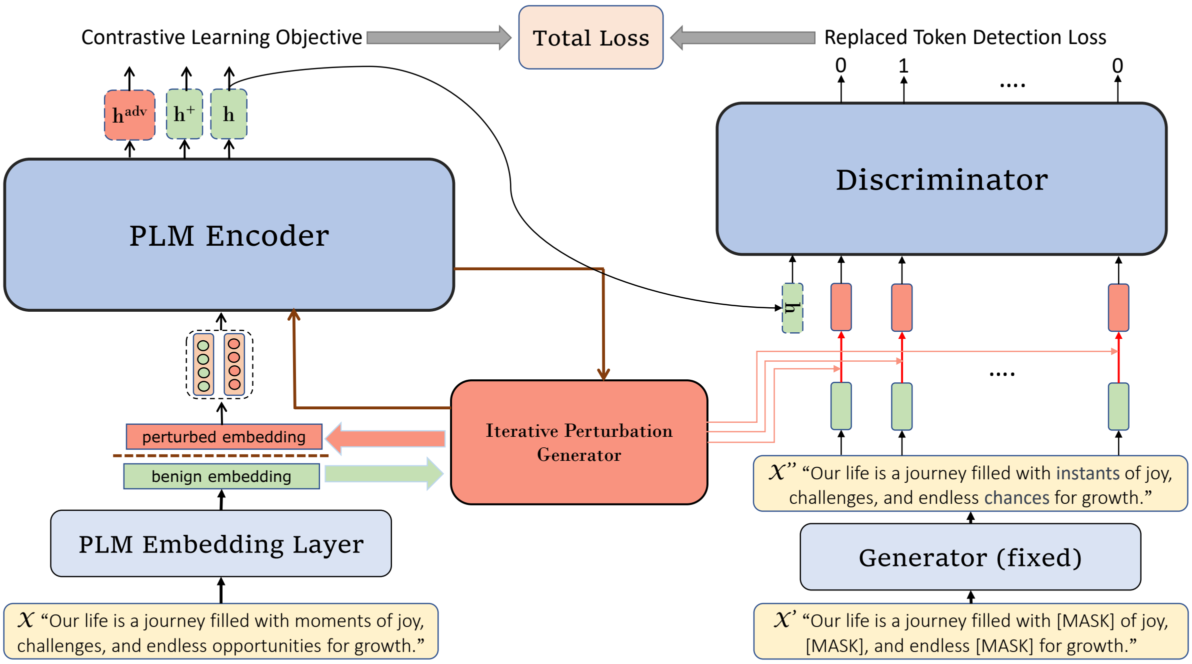

Figure 1: The general architecture of the RobustSentEmbed framework.

essential adversarial examples required for adversarial training by both the $f_\theta(.)$ encoder and a PLM-based discriminator. The subsequent sections will delve into the main components of our framework.

3.1 Perturbation Generator

Adversarial perturbation involves adding maliciously crafted perturbations into benign data, with the objective of misleading Machine Learning (ML) models (Goodfellow et al., 2015). A highly effective and broadly applicable method for generating adversarial perturbations is to apply a small noise $\boldsymbol{\delta}$ within a norm-constraint ball, aiming to maximize the adversarial loss function:

$$\arg\max_{||\boldsymbol{\delta}||\leq\epsilon} L(f_\theta(X+\boldsymbol{\delta}), y), \tag{1}$$

where $f_\theta(.)$ denotes an ML model parameterized with X as the sub-word embeddings. There are numerous gradient-based algorithms designed to address this optimization problem. Our framework extends the token-level perturbation method proposed by Li and Qiu (2021) by complementing the perturbation with an innovative sentence-level perturbation generator in order to generate worst-case adversarial examples. The main idea is to train a PLM-based model to withstand a broad spectrum of adversarial attacks, spanning both word and instance levels.

Recognizing the different roles that individual tokens play within a sentence, the RobustSentEmbed framework incorporates a scaling index to allow larger perturbations for tokens exhibiting larger gradients during the normalization of token-level perturbations:

$$n^i = \frac{\|\boldsymbol{\eta}_i^t\|_P}{\max_j \|\boldsymbol{\eta}_j^t\|_P}, \tag{2}$$

where $\boldsymbol{\eta}_i^t$ represents the token-level perturbation for word i at step t of the gradient ascent, and P denotes the type of norm constraint. Considering the encoder $f_\theta(.)$ and an input sentence x, RobustSentEmbed passes the sentence through $f_\theta(.)$ by applying standard dropout twice. This process yields two different embeddings, denoted as "positive pairs" and represented as (X, X^+). Finally, the newly adjusted token-level perturbation is formulated as:

$$\boldsymbol{\eta}_i^{t+1} = n^i * (\boldsymbol{\eta}_i^t + \gamma \frac{\boldsymbol{g}_{\eta_i}}{\|\boldsymbol{g}_{\eta_i}\|_P)}, \tag{3}$$

$$\boldsymbol{\eta}^{t+1} \leftarrow \Pi_{\|\boldsymbol{\eta}\|_P\leq\epsilon}(\boldsymbol{\eta}^t), \tag{4}$$

where $\boldsymbol{g}_{\eta_i} = \nabla_\eta \mathcal{L}_{con,\theta}(\boldsymbol{X} + \boldsymbol{\delta}^{t-1} + \boldsymbol{\eta}^{t-1}, \{\boldsymbol{X}^+\})$ is the gradient of the contrastive learning loss with respect to $\boldsymbol{\eta}$. The perturbation is generated by the ℓ_∞ norm-ball with radius ϵ, and Π projects the perturbation onto the ϵ-ball.

To generate adversarial perturbations at the sentence-level, RobustSentEmbed employs a combination of the Fast Gradient Sign Method (FGSM)

(Goodfellow et al., 2015) and the Projected Gradient Descent (PGD) technique (Madry et al., 2018). The framework iterates using this combination, specifically T-step FGSM and K-step PGD, to systematically reinforce invariance within the embedding space. Ultimately, this strategy leads to enhanced generalization and robustness. It proceeds with the following steps to update the perturbation for PGD in iteration $k+1$ and FGSM in iteration $t+1$:

$$\boldsymbol{\delta}_{\text{pgd}}^{k+1} = \Pi_{\|\boldsymbol{\delta}\|_P \leq \epsilon}(\boldsymbol{\delta}^k + \alpha g(\boldsymbol{\delta}^k)/\|g(\boldsymbol{\delta}^k)\|_P), \quad (5)$$

$$\boldsymbol{\delta}_{\text{fgsm}}^{t+1} = \Pi_{\|\boldsymbol{\delta}\|_P \leq \epsilon}(\boldsymbol{\delta}^t + \beta \text{sign}(g(\boldsymbol{\delta}^t))), \quad (6)$$

where $g(\boldsymbol{\delta}^n) = \nabla_{\boldsymbol{\delta}} \mathcal{L}_{con,\theta}(\boldsymbol{X} + \boldsymbol{\delta}^n, \{\boldsymbol{X}^+\})$ with $n = t \ or \ k$ represents the gradient of the contrastive learning loss with respect to $\boldsymbol{\delta}$. The variables α and β denote the step sizes for the attacks, while $\text{sign}(.)$ yields the vector's sign. The final perturbation is obtained by employing a practical combination of T-step FGSM and K-step PGD:

$$\boldsymbol{\delta}_{\text{final}} = \rho \boldsymbol{\delta}_{\text{pgd}}^K + (1-\rho)\boldsymbol{\delta}_{\text{fgsm}}^T, \quad (7)$$

where $0 \leq \rho \leq 1$ modulates the relative importance of each separate perturbation in the formation of the final perturbation.

3.2 Robust Contrastive Learning

To achieve robust text representations through adversarial learning, we employ a straightforward approach that can be described as the combination of a Replaced Token Detection (RTD) objective (Figure 1, right) with a novel self-supervised contrastive learning objective (Figure 1, left).

Our framework extends an adversarial version of the RTD task used in ELECTRA (Clark et al., 2020). In this approach, given an input sentence x, ELECTRA utilizes a pre-trained masked language model as the generator G to recover randomly masked tokens in $x^{'} = \text{Mask}(x)$, resulting in the edited sentence $x^{''} = G(x^{'})$. Subsequently, a discriminator D is tasked with predicting whether token replacements have occurred, which constitutes the RTD task. As illustrated in Figure 1, the perturbation generator module introduces token-aware perturbations into the embedding of each individual token, making it more challenging for discriminator D to perform the RTD task effectively. The gradient of D can be back-propagated into f through $\boldsymbol{h} = f_\theta(x)$. This mechanism encourages f to make vector $\boldsymbol{h}$ sufficiently informative, enhancing its resilience against token-level adversarial attacks. Consequently, our framework employs the following adversarial objective for a single sentence x:

$$\begin{aligned}\mathcal{L}_{RTD}^{x} = \sum_{j=1}^{|x|}[-\mathbb{1}(X_j^{adv} = X_j) \log D(X^{adv}, \boldsymbol{h}, j) \\ -\mathbb{1}(X_j^{adv} \neq X_j) \log (1 - D(X^{adv}, \boldsymbol{h}, j))],\end{aligned} \quad (8)$$

where $X^{adv} = X^{''} + \boldsymbol{\eta}_i^{max(K,T)}$ represent the ith perturbed token in x. The training objective for the batch B is $\mathcal{L}_{RTD,\theta} = \sum_{i=1}^{|B|} \mathcal{L}_{RTD}^{x_i}$. Furthermore, we use self-supervised contrastive learning to acquire effective low-dimensional representations by bringing semantically similar samples closer and pushing dissimilar ones further apart. Let $\{(x_i, x_i^+)\}_{i=1}^N$ denote a set of N positive pairs, where x_i and x_i^+ are semantically correlated and (z_i, z_i^+) represents the corresponding embedding vectors for the positive pair (x_i, x_i^+). We define z_i's positive set as $z_i^{pos} = \{z_i^+\}$, while the negative set $z_i^{neg} = \{z_i^-\}$ is the set of positive pairs from other sentences in the same batch. Then, the contrastive training objective is defined as follows:

$$\begin{aligned}&\mathcal{L}_{con,\theta}(z_i, z_i^{pos}, z_i^{neg}) = \\ &- \log(\frac{\sum_{z_i^{pos}} \exp(sim(z_i, z_i^+)/\tau)}{\sum_{(z_i^{pos} \cup z_i^{neg})} \exp(sim(z_i, z_i^{+\ or\ -})/\tau)}),\end{aligned} \quad (9)$$

where τ denotes a temperature hyperparameter and $sim(u,v) = \frac{u^\top v}{\|u\|.\|v\|}$ is the cosine similarity between two representations. Our framework utilizes contrastive learning to maximize the similarity between clean examples and their adversarial perturbation by incorporating the adversarial example as an additional element within the positive set:

$$\begin{aligned}&\mathcal{L}_{RobustSentEmbed,\,\theta} := \mathcal{L}_{con,\theta}(z, \{z^{pos},\ z^{adv}\}, \{z^{neg}\}). \\ &\mathcal{L}_{total} := \mathcal{L}_{RobustSentEmbed,\theta} + \lambda_1 \cdot \mathcal{L}_{con,\,\theta}(z^{adv}, \{z^{pos}\}, \{z^{neg}\}) \\ &\qquad + \lambda_2 \cdot \mathcal{L}_{RTD,\,\theta},\end{aligned} \quad (10)$$

where $z^{adv} = z + \boldsymbol{\delta}_{final}$ represents the adversarial perturbation of the input sample x in the embedding space, and λ_1, λ_2 denote weighting coefficients. The first component of the total contrastive loss (Eq. 10) is designed to optimize the sentence-level similarity between the input sample x, its positive pair, and its adversarial perturbation, while the second component serves to regularize the loss by encouraging the convergence of the adversarial perturbation and the positive pair of x. The final component introduces the adversarial Replaced Token Detection (RTD) objective into the total contrastive loss.

Table 1: Attack success rates (lower is better) of various adversarial attacks applied to four sentence embeddings (SimCSE, USCAL, RobustEmbed, and RobustSentEmbed) across five text classification and two natural language inference tasks. RobustSentEmbed reduces the attack success rate to less than half across all attacks.

4 Evaluation and Experimental Results

This section presents a comprehensive set of experiments conducted to validate the proposed framework's effectiveness in terms of robustness and generalization metrics. To evaluate robustness, the experiments include adversarial attacks and adversarial Semantic Textual Similarity (STS) tasks. To evaluate generalization, the experiments include non-adversarial STS and transfer tasks within the SentEval framework.[2] Appendices A and B provide training details and ablation studies that illustrate the effects of hyperparameter tuning.

4.1 Adversarial Attacks

We evaluate the robustness of our framework against various adversarial attacks, comparing it with two state-of-the-art sentence embedding models: SimSCE (Gao et al., 2021) and USCAL (Miao et al., 2021). We fine-tuned the BERT-based PLM across seven text classification and natural language inference tasks, specifically MRPC (Dolan and Brockett, 2005), YELP (Zhang et al., 2015), IMDb (Maas et al., 2011), Movie Reviews (MR) (Pang and Lee, 2005), SST2 (Socher et al., 2013), Stanford NLI (SNLI) (Bowman et al., 2015), and Multi-NLI (MNLI) (Williams et al., 2018). To assess the robustness of our fine-tuned model, we investigated the impact of five popular adversarial attacks: TextBugger (Li et al., 2019), PWWS (Ren et al., 2019), TextFooler (Jin et al., 2020), BAE (Garg and Ramakrishnan, 2020), and BERTAttack (Li et al., 2020b). Additional information of these attacks is provided in Appendix C. To ensure statistical validity, we conducted each experiment five times, with each iteration comprising 1000 adversarial attack samples.

Table 1 presents the average attack success rates of five adversarial attacks applied to four sentence embeddings including our previous RobustEmbed method (Asl et al., 2023). Notably, our embedding framework consistently outperforms the other two embedding methods (i.e. SimSCE and USCA), demonstrating significantly lower attack success rates (less than half) across all text classification and natural language inference tasks. Consequently, RobustSentEmbed achieves the lowest average attack success rate against all adversarial attack techniques. Moreover, our framework achieves slightly better performance compared to our previous RobustEmbed framework. These findings substantiate the robustness of our embedding framework and highlight the vulnerabilities of other state-of-the-art sentence embeddings when con-

Table 2: Attack success rates (lower is better) of five adversarial attack techniques applied to four sentence embeddings (SimCSE, USCAL, RobustEmbed, and RobustSentEmbed) across two Adversarial Semantic Textual Similarity (AdvSTS) tasks (i.e. AdvSTS-B and AdvSICK-R). RobustSentEmbed reduces the attack success rate to less than half across all attacks.

fronted with various adversarial attacks.

Figure 2 presents the results of 1000 attacks conducted on two fine-tuned sentence embeddings, assessing the average number of queries required and the resulting accuracy reduction. Attacks on the RobustSentEmbed framework are represented by green data points, while red points denote attacks on the USCAL approach (Miao et al., 2021). Each pair of connected points corresponds to a specific attack. Ideally, a robust sentence embedding should be positioned in the top-left region of the graph, indicating that it necessitates a higher number of queries for an attack to deceive the model while causing minimal performance degradation. Across all adversarial attacks, RobustSentEmbed consistently exhibits greater stability compared to the USCAL method. In other words, a larger number of queries is required for RobustSentEmbed, resulting in a lower accuracy reduction (i.e., better performance) compared to USCAL.

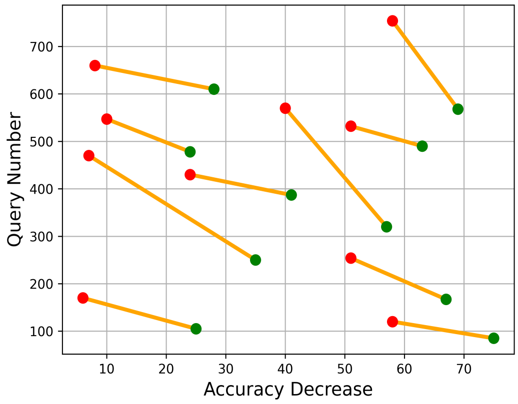

Figure 2: Average number of queries and the resulting accuracy reduction for two fine-tuned embeddings.

4.2 Robust Embeddings

We introduce a new task named Adversarial Semantic Textual Similarity (AdvSTS) to assess the robustness of sentence embeddings. AdvSTS leverages an efficient adversarial technique, like TextFooler, to manipulate an input sentence pair of a non-adversarial STS task in a manner that leads the target model to generate a regression score that maximally deviates from the actual score (truth label). As a result, we generate an adversarial STS dataset by transforming all benign instances from the original (i.e. non-adversarial) dataset into adversarial examples. Table 2 presents the attack success rates of five adversarial attacks applied to four sentence embeddings, including our framework including our previous RobustEmbed method (Asl et al., 2023). These evaluations are conducted for two AdvSTS tasks, specifically AdvSTS-B (originated from STS Benchmark (Cer et al., 2017)) and AdvSICK-R (originated from SICK-Relatedness (Marelli et al., 2014)). Notably, our framework consistently outperforms the other two sentence embedding methods, exhibiting significantly lower attack success rates across both AdvSTS tasks and all employed adversarial attacks. Our framework also demonstrates a slightly enhanced performance in comparison to our earlier RobustEmbed framework. These results provide additional evidence supporting the notion that RobustSentEmbed generates robust text representation.

4.3 Semantic Textual Similarity (STS) Tasks

In this section, we assess the performance of our framework across seven Semantic Textual Similarity (STS) tasks encompassing STS datasets from 2012 to 2016 (Agirre et al., 2012, 2013, 2014, 2015, 2016), STS Benchmark, and SICK-Relatedness. To benchmark our framework's effectiveness, we conducted a comparative analysis against a range of unsupervised sentence embedding approaches, including: 1) baseline methods such as GloVe (Pennington et al., 2014) and average BERT embeddings; 2) post-processing methods like BERT-flow (Li et al., 2020a) and BERT-whitening (Su et al., 2021); and 3) state-of-the-art methods such as SimCSE (Gao et al., 2021), USCAL (Miao et al., 2021), and also our RobustEmbed framework (Asl et al., 2023). We validate the findings of the SimCSE, ConSERT, and USCAL frameworks by replicating their results. The empirical outcomes, as presented in Table 3, consistently establish the superior performance of our RobustSentEmbed framework in contrast to various other sentence embeddings. Our framework achieves the highest average Spearman's correlation score when compared to state-of-the-art approaches. Specifically, utilizing the BERT encoder, our framework surpasses the second-best embedding method, USCAL, by a margin of 1.59%. Moreover, RobustSentEmbed achieves the highest score in the majority of individual STS tasks, outperforming other embedding methods in 6 out of 7 tasks. Moreover, Our framework exhibits marginally enhanced performance in comparison to our prior RobustEmbed framework. For the RoBERTa encoder, RobustSentEmbed outperforms the state-of-the-art embeddings in five out of seven STS tasks and attains the highest average Spearman's correlation score.

4.4 Transfer Tasks

We leveraged transfer tasks to assess the performance of our framework, RobustSentEmbed, across a diverse range of text classification tasks, including sentiment analysis and paraphrase identification. Our evaluation encompassed six transfer tasks: CR (Hu and Liu, 2004), SUBJ (Pang and Lee, 2004), MPQA (Wiebe et al., 2005), SST2 (Socher et al., 2013), and MRPC (Dolan and Brockett, 2005). We trained a logistic regression classifier on top of the fixed sentence embeddings. To ensure the reliability of our findings, we replicated the SimCSE, ConSERT, and USCAL frameworks. The outcomes, as presented in Table 4, demonstrate the superior performance of our framework in terms of average accuracy when compared to other sentence embeddings. Specifically, when utilizing the BERT encoder, our framework outperforms the second-best embedding method by a margin of 0.23%. Furthermore, RobustSentEmbed achieves the highest score in four out of six text classification tasks. Our framework also achieves similar performance compared to our prior RobustEmbed framework. A similar trend is observed for the RoBERTa encoder. Overall, based on the results presented in Tables 3 and 4, we conclude that RobustSentEmbed generates general sentence representation in addition to robust representation (4.1 and section 4.2).

In conclusion, the comprehensive experiments, as indicated by the outcomes in Tables 1, 2, 3, and 4, along with Figure 2, confirm the exceptional performance of RobustSentEmbed in text representation and resilience against adversarial attacks and adversarial tasks. These findings highlight the framework's outstanding robustness and generalization capabilities, underscoring its potential as a versatile method for generating high-quality sentence embeddings.

4.5 Distribution of Sentence Embeddings

We employed two critical metrics, *alignment* and *uniformity* (Wang and Isola, 2020), for evaluating the quality of our representations. With a distribution of positive pairs p_{pos}, *alignment* computes the expected distance between the embeddings of paired instances:

$$\ell_{\text{align}} \triangleq \mathop{\mathbb{E}}_{(x,x^+)\sim p_{pos}} \|f(x) - f(x^+)\|^2 \qquad (11)$$

Table 4: Results of transfer tasks for different sentence embedding models. ♣: results from Reimers and Gurevych (2019); ♡: results from Zhang et al. (2020); We emphasize the top-performing numbers among models that share the same pre-trained encoder. All remaining results have been reproduced and reevaluated by our team. RobustSentEmbed outperforms all other methods, regardless of the pre-trained language model (BERT$_{\text{base}}$, RoBERTa$_{\text{base}}$, or RoBERTa$_{\text{large}}$).

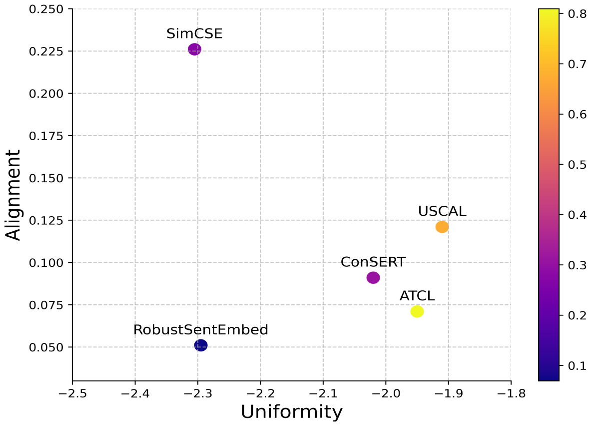

Figure 3: $\ell_{\text{align}} - \ell_{\text{uniform}}$ plot of models based on BERT$_{\text{base}}$. Lower uniformity and alignment is better.

Uniformity measures how well the embeddings are uniformly distributed in the representation space:

$$\ell_{\text{uniform}} \triangleq \log \mathop{\mathbb{E}}_{x,y \overset{i.i.d.}{\sim} p_{\text{data}}} e^{-2\|f(x)-f(y)\|^2} \qquad (12)$$

Figure 3 shows the *uniformity* and *alignment* of different sentence embedding models. Smaller values indicate better performance. In comparison to the other representations, RobustSentEmbed achieves a similar level of *uniformity* (-2.295 vs. -2.305) but exhibits superior *alignment* (0.051 vs. 0.073). This demonstrates that our framework is more efficient in optimizing the representation space in two different directions.

5 Conclusion and Future Work

This paper introduces RobustSentEmbed, a self-supervised sentence embedding framework enhancing robustness against adversarial attacks while achieving state-of-the-art performance in text representation and NLP tasks. Current sentence embeddings are vulnerable to attacks, and RobustSentEmbed addresses this by generating high-risk perturbations at token and sentence levels. These perturbations are incorporated into novel contrastive and difference prediction objectives. The framework is validated through comprehensive experiments on semantic textual similarity and transfer learning tasks, confirming its robustness against adversarial attacks and semantic similarity tasks. In future research, we aim to investigate the use of hard negative examples to further enhance the effectiveness of text representations.

6 Limitations

Despite the effectiveness of our approach and its notable performance, there are potential limitations to our framework:

- The framework is primarily tailored for descriptive models like BERT, adept at language understanding and representation, including tasks such as text classification. However, its direct application to generative models like GPT, focused on generating coherent and contextually relevant text, may pose challenges. Thus, applying our methodology to enhance generalization and robustness in generative pre-trained models might have limitations.
- Utilizing substantial GPU resources is necessary for pre-training large-scale models like RoBERTa$_{\text{large}}$ in our framework. Due to limited GPU availability, we had to use smaller batch sizes during pre-training. Although larger batch sizes typically result in better performance, our experiments had to compromise and use smaller batch sizes to efficiently generate sentence embeddings within GPU constraints.

A Training Details

we initialize our sentence encoder using the checkpoints obtained from BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019). RobustSentEmbed utilizes the representation of the [CLS] token as the starting point and incorporates a pooler layer on top of the [CLS] representations to facilitate contrastive learning objectives. The training process of RobustSentEmbed involves 4 epochs. The best checkpoint, determined by the highest average STS score, is selected for final evaluation. To train the model, we utilize a dataset consisting of 10^6 randomly sampled sentences from English Wikipedia, as provided by the SimCSE framework (Gao et al., 2021). The average training time for RobustSentEmbed is 2-4 hours. As our framework is initialized with pre-trained checkpoints, it exhibits robustness that is not sensitive to batch sizes, thus enabling us to employ batch sizes of either 64 or 128.

B Ablation Studies

In this section, we conduct an analysis of the impact of five critical hyperparameters employed in the RobustSentEmbed framework on its overall performance. $\text{BERT}_{\text{base}}$ is employed as the encoder,

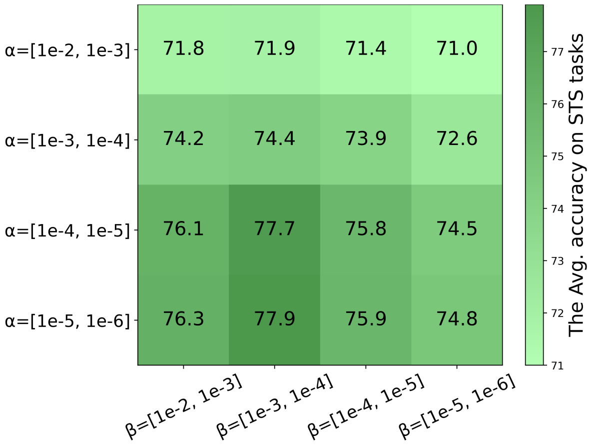

Figure 4: The impact of step sizes in perturbation generation on the average performance of STS tasks.

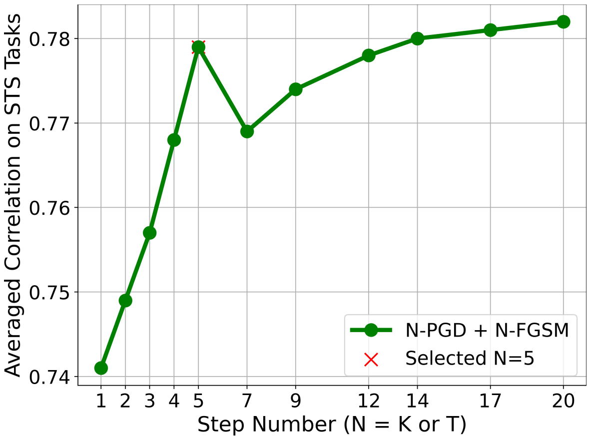

Figure 5: The impact of the step number (represented by N = K or T) in the T-step FGSM and K-step PGD methods on the averaged correlation of the STS tasks.

and the assessment of hyperparameters is carried out using the development set of STS tasks.

B.1 Step Sizes in Perturbation Generator

The RobustSentEmbed framework integrates two step sizes, denoted as α and β, to conduct iterative updates during the PGD and FGSM perturbation generation processes, respectively. Figure 4 shows the cooperative impact of adjusting the ranges for these two step sizes in generating high-risk perturbations, a crucial aspect for achieving an effective contrastive learning objective. The outcomes demonstrate more substantial improvements when β is fine-tuned to a lower bound, coupled with α set to an upper bound. More precisely, enhanced performance is evident when α and β are allocated ranges of [1e-4, 1e-6] and [1e-3, 1e-4], respectively. Consequently, we employ α = 1e-5 and β = 1e-3 for our experiments, as this configuration yields the optimal results among the different configurations.

B.2 Step Numbers in Perturbation Generator

RobustSentEmbed employs T-step FGSM and K-step PGD iterations to acquire high-risk adversarial perturbations for the contrastive learning objective. For simplicity in perturbation generation analysis, we establish K = T. The influence of varying step numbers (N = K or T) on effectiveness is illustrated in Figure 5. A gradual improvement is observed as N increases from 1 to 12; however, beyond N=12, the improvement becomes negligible. Additionally, higher N results in longer running time and inequitable resource allocation. Consequently, we opt for N=5 in our experiments.

B.3 Norm Constraint

To ensure imperceptibility in the generated adversarial examples, RobustSentEmbed regulates the magnitude of the perturbation vectors (whether $\boldsymbol{\delta}$ or $\boldsymbol{\eta}$). This control is achieved through the utilization of three commonly employed norm functions: L_1, L_2, and L_∞, to restrict the magnitude of the perturbation to small values. The averaged Spearman's correlation of these norm functions across different Semantic Textual Similarity tasks is presented in Table 5. The L_∞ norm exhibits superior correlation in comparison to the other two norms, thus warranting its selection as the norm function for our experimental assessment.

Norm	Correlation
L_∞	**77.90**
$L2$	76.84
$L1$	76.52

Table 5: The impact of the norm constraint on perturbation generation on the average performance of various STS tasks.

B.4 Contrastive Learning Loss

The first part of the total loss function (Equation 10) is dedicated to optimizing the similarity between the input instance x and its positive pair (x^{pos}), as well as the similarity between x and its adversarial perturbation (x^{adv}). While this indirectly brings x^{pos} and x^{adv} closer, our findings indicate that incorporating direct contrastive learning between x^{pos} and x^{adv} (the second part of Equation 10) through the regularization of the objective

	λ2=0.05	λ2=0.02	λ2=0.005	λ2=001
λ1=1/64	75.4	75.9	76.2	75.8
λ1=1/128	76.3	76.6	77.9	76.9
λ1=1/256	75.7	76.0	77.1	76.4
λ1=1/512	74.5	75.1	75.8	75.5

Figure 6: The impact of weighting coefficients in the total loss function on the average performance of STS tasks.

function in the first part helps us achieve enhanced clean accuracy and robustness. Additionally, the third part of the total loss function introduces the adversarial replaced token detection objective into the loss function, making it more challenging for adversarial training to converge. Figure 6 illustrates the impact of different values of the weighting coefficients (i.e., λ_1, λ_2) on the final performance of our framework. As illustrated, when $\lambda_1 = 1/128$ and $\lambda_2 = 0.005$, the framework achieves the highest average accuracy for semantic textual similarity tasks. We utilize $\lambda_1 = 1/128$ and $\lambda_2 = 0.005$ for all other experiments.

B.5 Modulation Factor

RobustSentEmbed includes a modulation factor, represented as $0 \leq \rho \leq 1$, to adjust the relative importance of each individual perturbation (PGD and FGSM) in the formation of the sentence-level perturbation. The efficacy of different values of this modulation factor on semantic textual similarity tasks is detailed in Table 6. The findings reveal that $\rho = 0.5$ yields the highest averaged correlation across the examined magnitudes, underscoring its capability to generate more powerful perturbations. Consequently, we employ this configuration in the setup of our framework.

C Adversarial Attack Methods

This section provides additional details regarding the various adversarial attacks. The TextBugger method (Li et al., 2019) identifies crucial words by analyzing the Jacobian matrix of the target model and selects the optimal perturbation from a set of five generated perturbations. The PWWS (Ren et al., 2019) employs a synonym-swap technique based on a combination of word saliency scores and maximum word-swap effectiveness. TextFooler (Jin et al., 2020) identifies significant words, gathers synonyms, and replaces each such word with the most semantically similar and grammatically correct synonym. The BAE (Garg and Ramakrishnan, 2020) employs four adversarial attack strategies involving word replacement and/or word insertion operations to generate substitutions. The BERTAttack (Li et al., 2020b) comprises two steps: (a) identifying vulnerable words/sub-words and (b) utilizing BERT MLM to generate semantic-preserving substitutes for the vulnerable tokens.

ρ	**Correlation**
0	76.06
0.25	76.85
0.5	**77.90**
0.75	77.34
1	76.34

Table 6: The impact of the modulation factor on the average performance of different Semantic Textual Similarity (STS) tasks in generating the final perturbation.

D RobustSentEmbed Algorithm

Algorithm 1 illustrates our framework's approach to generating a norm-bounded perturbation at both the token-level and sentence-level using an iterative process. It confuses the $f_\theta(\cdot)$ encoder by treating the perturbed embeddings as different instances. Our framework then utilizes a contrastive learning objective in conjunction with a replaced token detection objective to maximize the similarity between the embedding of the input sentence and the adversarial embedding of its positive pair (former objective), as well as its edited sentence (latter objective).

Algorithm 1: RobustSentEmbed Algorithm

```
Input: Epoch number $E$, PLM Encoder $\mathbf{f}_{\boldsymbol{\theta}}$, dataset of raw sentences $\boldsymbol{\mathcal{D}}$ , embedding perturbation {$\boldsymbol{\delta}$, $\boldsymbol{\eta}$}, dropout masks $m_1$ and $m_2$, perturbation bound $\epsilon$, adversarial step sizes {$\alpha$, $\beta$, $\gamma$}, learning rate $\xi$, perturbation modulator $\rho$, weighting coefficients {$\lambda_1$, $\lambda_2$}, adversarial steps {$K$, $T$}, contrastive learning objective $\mathcal{L}_{con,\theta}$ (eq. 9), ELECTRA generator $G(.)$ and discriminator $D(.)$

Abstract

Recent advancements in large language models' (LLMs) capabilities have yielded few-shot, human-comparable performance on a range of tasks. At the same time, researchers expend significant effort and resources gathering human annotations. At some point, LLMs may be able to perform some simple annotation tasks, but studies of LLM annotation accuracy and behavior are sparse. In this paper, we characterize OpenAI's GPT-3.5's judgment on a behavioral task for implicit object categorization. We characterize the embedding spaces of models trained on human vs. GPT responses and give similarities and differences between them, finding many similar dimensions. We also find that despite these similar dimensions, augmenting humans' responses with GPT ones drives model divergence across the sizes of datasets tested.

1 Introduction

Large language models (LLMs) are capable of accomplishing a variety of language-oriented tasks in zero- or few-shot settings (Brown et al., 2020). Examples include common natural-language understanding and processing (NLU/P) tasks such as sentiment analysis and classification (Brown et al., 2020), language translation (Hendy et al., 2023), and named entity recognition (Ji, 2023); but also applied domains such as text tagging (Gilardi et al., 2023), multimodal tagging (Li et al., 2023), and text sample augmentation (Dai et al., 2023).

Current LLM performance indicates we may be able to use pre-trained high-resource LLMs to augment human annotations for tasks where data is sparse or compute resources are low (Møller et al., 2023). However, we do not currently know for which domains it is appropriate to augment human data with LLM-generated responses. This uncertainty stems from a poor understanding of how LLM and human annotation responses systematically differ. Thus, characterizing the ways in which world knowledge manifests itself in the generations of LLMs is crucial for incorporating LLMs into annotation workflows.[1]

The domain of object-similarity judgment is a useful base-case for exploring the similarities and substitutability of LLM for human responses. On a human level, object-similarity judgment informs how we interact with objects (Desmarais et al., 2007), organize our world (Smith, 1981) and acquire new concepts from a young age (Markman and Hutchinson, 1984). Meanwhile, many corpus-based computational models, including deep transformer models that leverage corpora such as ChatGPT, leverage lexical co-occurrence relations to derive semantic meaning (i.e. the distributional hypothesis). Despite differences in process, these models' representations display correspondences with human judgment (Torabi Asr et al., 2018; Chandrasekaran and Mago, 2022).

In this paper, we collect GPT-3.5 responses to an object similarity task introduced by Hebart et al. (2020). We reformat their image-based paradigm as a chat-completion task for GPT.[2] Like Hebart et al., we also train a sparse embedding model that can predict object-similarity judgments. We annotate the dimensions of the embedding model to provide an interpretable characterization of the reasoning behind such judgments. Finally, we compare the GPT- and human-derived characterizations and embeddings. We also simulate the effects of GPT response replacement and augmentation. To do this, we train models on different mixtures and proportions of human and GPT responses, then compare their embedding spaces to baseline human-derived ones.

---

[1] There is evidence that LLMs may already be incorporated into annotation workflows without researcher knowledge, as crowdworkers are already using LLMs to speed up their annotation tasks (Veselovsky et al., 2023).

[2] At the time of our experimentation, the multimodal GPT-4 was not widely available.

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3810–3828
June 16-21, 2024

2 Methodology

The Odd-One-Out (OOO) Task To obtain object-similarity responses from GPT, we used the ***odd-one-out*** (OOO) task, wherein participants indicate the least similar amongst three objects. For example, we might ask, “Which of these concepts is the odd one out: apple, banana, car?” and expect factors such as edibility to affect the response. The OOO task is well-established in the field of psychology for eliciting concept-relational preferences (Mirman et al., 2017; Valenti and Firestone, 2019).

Human OOO Responses Hebart et al. (2020) used an image-based OOO task to collect millions of object-similarity judgements. They did this in two rounds, first collecting 1.46M responses (Hebart et al., 2020), then creating a larger, 5M response dataset Hebart et al. (2023).[3] We used these two datasets to create two disjoint OOO response sets of equal size (1.46M). We refer to the first of these datasets as the ***full human dataset*** and the second as the ***baseline dataset***.

GPT OOO responses We then created a parallel GPT-only dataset with answers to the OOO questions from the full human dataset. We reformatted the original prompt from (Hebart et al., 2020) to create a text completion task suitable for GPT. We referred to these GPT prompts and answers as the ***full GPT dataset***.

For cost and task-efficacy reasons, we used OpenAI’s GPT (GPT-3.5-Turbo-0613). Preliminary analysis revealed that smaller models (Falcon-7B, Alpaca-7B, Vicuna-7B) had difficulty answering odd-one-out questions in a coherent manner with simple prompting. Larger models, (e.g. Falcon-40B), produced coherent responses, but not at the scale afforded by GPT’s API.

Transformer models such as GPT incorporate word position for next-word prediction, and GPT demonstrated a strong positional preference (see Appendix C). While humans situationally exhibit ordered preferences, we found a roughly uniform distribution for this task (see Appendix C). Thus, to collect position-neutral responses, we permuted the order of the three objects in the prompts to create six total questions (3!). We then used relative majority voting across the six questions to compute GPT’s odd-one-out choice, breaking ties randomly.

$$\begin{array}{rc} & \begin{array}{cccc}\text{metallic} & \text{food-related} & \cdots & \text{cylindrical}\end{array} \\ \begin{array}{r}\text{aardvark}\\ \text{abacus}\\ \vdots \\ \text{zucchini}\end{array} & \underbrace{\begin{bmatrix} a_{1,1} & a_{1,2} & \cdots & a_{1,49}\\ a_{2,1} & a_{2,2} & \cdots & a_{2,49}\\ \vdots & \vdots & \ddots & \vdots \\ a_{1854,1} & a_{1854,2} & \cdots & a_{1854,49}\end{bmatrix}}_{\text{Learned object-similarity embeddings}} \end{array}$$

Figure 1: An example embedding space with words as rows and *characterizing dimensions* as columns.

See Supplementary Materials for API calls and a formatted table of all responses.

Human–GPT Datasets We aimed to study the effect of replacing only some human responses with GPT responses. Thus, we created <1.46M count ***partial human response sets*** by taking proportions $[0.125, 0.25, 0.375, 0.5, 0.625, 0.75,$ and $0.875]$ of the 1.46M full human-only response set. We then create a 1.46M-count ***mixed GPT–human response set*** for each partial human set by considering each unused human response and including the corresponding GPT response.

2.1 Model Details

We use the similarity-prediction model designed by Hebart et al. (Hebart et al., 2020), which comprises a shallow neural network consisting of a single 90×1854 embedding layer. Each object i has a corresponding vector v_i. In a triplet with objects i, j, and k we compute $z_i = v_j \cdot v_k$ (and do likewise for z_j and z_k), then use it to estimate the probability of object i being the odd one out:

$$\mathrm{P}(i \text{ odd one out}) = \sigma\left(\mathbf{z}\right)_k = \frac{e^{z_k}}{e^{z_i} + e^{z_j} + e^{z_k}} \tag{1}$$

Model Training To train each model, we used a cross-entropy loss with an ℓ^1-norm penalty on the embedding to encourage sparsity. Hebart et al. (2020) found that training sparse models in this manner resulted in an embedding space with interpretable dimensions. We refer to these dimensions as ***characterizing dimensions***. We show an example embedding matrix in Figure 1 wherein the rows are the vector representations of the object-concepts of the THINGS dataset, and the columns are characterizing dimensions.

Using a set of odd-one-out responses $\mathcal{S}$, we took the average cross-entropy loss, $\frac{1}{|\mathcal{S}|}\sum_{s \in \mathcal{S}} H(q,p)|s$. Here, $H(q,p)|s$ is the

---

[3] These datasets were collected before GPT existed and thus are free of GPT-derived responses.

cross-entropy of the model prediction probability p for the odd-one-out question s relative to the entry q in the actual one-hot response vector. We incorporate an ℓ^1-norm penalty on the embedding space to encourage sparsity, weighted by a hyperparameter λ. Elaborated loss details are given in Appendix D.

For training, we assumed concavity of validation accuracy on the choice of λ and performed a two-tiered four-fold grid-search over 90–10 train–test dataset splits: we started with $\lambda = 0.0064$ and took steps of 0.0016 to find a coarse maximum, then took steps of 0.0004 around that coarse maximum to establish a finer maximum. We trained for a fixed 1000 epochs for each model, mirroring the setup of Zheng et al. (2019) to ensure convergence. Further specifics are given in Appendix E.

We trained ten models each on the full human, full GPT, and baseline human sets and four each on the partial human and mixed human–GPT datasets to produce ***full human, full GPT, partial human, mixed human–GPT, and baseline models***.

2.2 All-GPT Model Characterization

To better understand the basis for GPT responses to OOO questions, we manually annotated each dimension of the full GPT embedding space as in Hebart et al. (2020). Annotators were presented with images of objects at pre-determined intervals along a dimension's range (e.g., Appendix F). Six respondents gave up to three descriptors for each dimension. We iteratively generated aggregate labels for each annotation until none were ungrouped, then chose the aggregate labels that covered the most participants. We call this the ***labelled GPT model***, and we compare it to a previous ***labelled human model*** produced with the full human dataset from Hebart et al. (2020).

The labels for the nine dimensions with the highest means are given in Figure 2, while those for the 39 dimensions with max value above 0.1 are given in Appendix G; see Supplementary Materials for raw responses and coding.

Labelled Correlations We computed the correlations of each of these GPT-derived dimensions with dimensions from the labelled human model. The correlations of the top 9 dimensions (by column mean) from each labelled model are shown in Figure 2; the full 39-by-49 correlation matrix, as well as correlation matrices ordered by maximal correlation matching, appear in Appendix H.

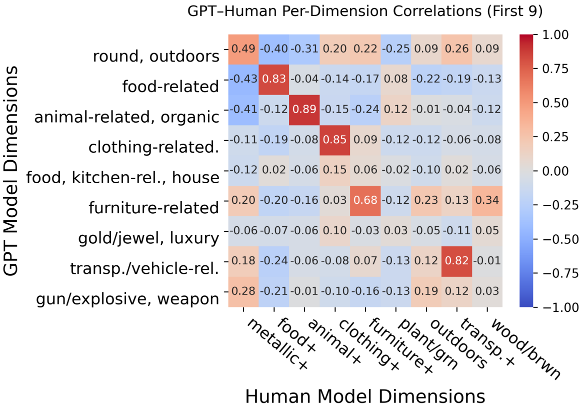

Figure 2: Correlation heatmap between the first 9 dimensions of the labelled GPT model and the labelled human model (all-dimension version located in Appendix H). Note the strong correlations between similarly labelled dimensions. The similar labels indicate agreement concerning what the dimensions convey in their scores for concepts, while the correlations indicate that the dimensions have statistical agreement.

We also performed PCA and UMAP (McInnes et al., 2018) on the labelled dimensions, which are displayed in Appendix J.

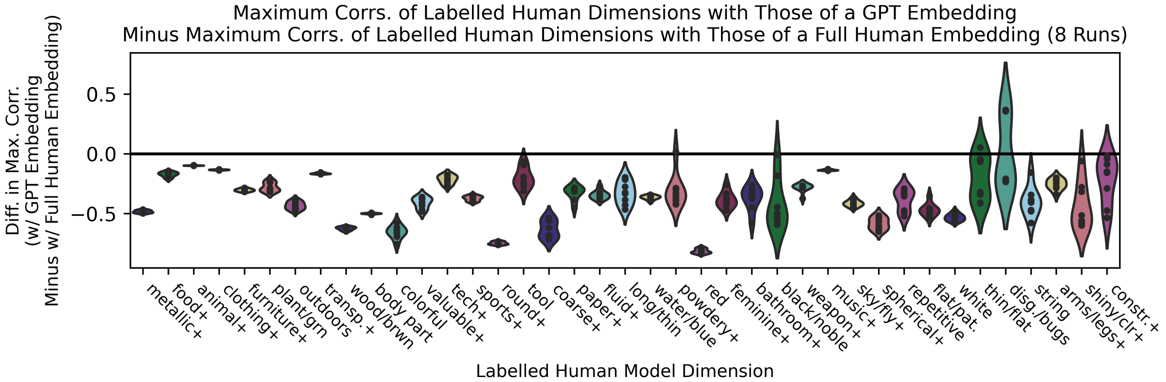
2.3 GPT–Human Response Substitutability

To determine the impact of augmenting human responses with GPT responses, we compared embedding spaces trained on datasets with varying amounts of each. For this comparison, we used representational similarity analysis (RSA) (Kriegeskorte, 2008) with a linear kernel.

Given two embeddings $\mathbf{X}_1$ and $\mathbf{X}_2$, we obtained their respective Gram matrices $\text{sim}(\mathbf{X}) = \mathbf{X}^\top \mathbf{X}$. These are the representational similarity matrices, or RSMs, of each space. Then, we calculated the Pearson correlation between the upper triangle of each RSM. The result is the ***RSA correlation***, and we report an ***RSA score***, the average RSA correlation of a model with the baseline human models.

GPT Response Substitution Given a full human dataset, if we replace some of the human responses with GPT responses, how does that affect the RSA score? Here, we are comparing the purple pluses with the large red circle in Figure 4. To examine the effects of mixing GPT completion-driven responses into a human dataset, we computed the RSA scores of the mixed human–GPT embeddings. These results are given in Figure 4. A table of these values can be found in Appendix K. Even though the datasets were larger, the mixed GPT–human embeddings each have lower RSA scores

Figure 3: Differences: maximal correlations of the labelled human characterizing dimensions with any dimension of a full GPT model and with any dimension of a full human model (the full GPT correlations minus the full human correlations) over 8 such models of each. For the correlations in isolation, see Appendix I.



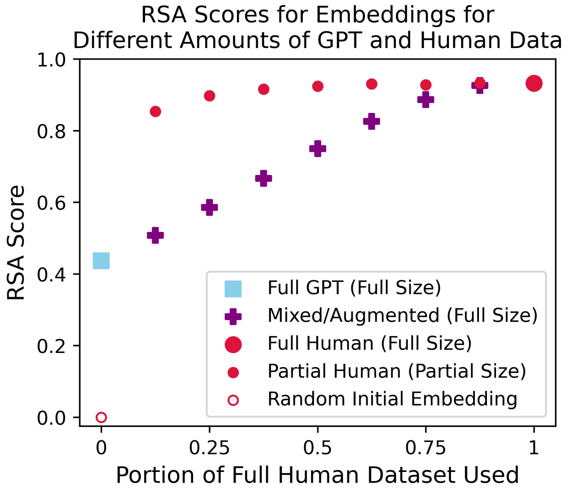


Figure 4: Average RSA scores for full GPT (blue), mixed GPT-human (purple), and full human (large red) models. Also plotted are the scores for the smaller, partial human (small red) models. The x-axis is the proportion of the original human dataset in each model's training set. The RSA score for a no-data, random embedding (small hollow red) is given for comparison. A table of these results is located in Appendix K.

than the corresponding partial human embeddings. The scores trend downward in a sigmoid fashion as the proportion of human data decreases, with the most noticeable effects happening after .25 of the human data has been replaced.

GPT Response Augmentation Next, we compared models trained on the same amount of human data, but with differing amounts of GPT augmentation. In contrast to the previous paragraph, in this situation we are comparing models trained on datasets of differing size. Comparing these models tells us whether adding GPT data hindered, facilitated, or neutrally impacted the final model's ability to represent human similarity judgment. To make this comparison, consider the small red circles and the corresponding purple plusses in Figure 4. We found that for all tested ratios, augmenting with GPT data results in lower RSA scores even though the resulting dataset size has increased.

Individual Dimension Capturing Finally, we explored the correspondence of dimensions from the labelled all-human model to those of the full GPT embeddings. To do this, we started with a full GPT embedding and full human embedding. For each labelled human dimension, we found the dimension of maximal correlation in the full GPT embedding and the dimension of maximal correlation in the full human embedding. These correlations signify the full GPT and full human embeddings' ability to reproduce each labelled human dimension. We then subtracted the full human correlations from the full GPT correlations to determine how much worse one was at capturing the labelled human dimensions (more negative corresponds with the full GPT embedding doing worse). We did this 8 times; the results are given in Figure 3. The correlations themselves, as well as graphs for the same process but with labelled GPT dimensions, are given in Appendix I.

3 Conclusions

Our work illustrates GPT's judgment in an odd-one-out similarity task, provides 39 judgment-characterizing dimensions with human annotations, and compares those dimensions with those derived from a human-only model. Notably, many GPT (and human) dimensions have similar, shared-word-or-synonym labelling, such as food-related (food-related/eating-related/kitchen-related) and animal-related/organic (animal-related/organic). We compared the labelled GPT and human dimensions, and we found that over half of the labelled GPT dimensions had correlations above 0.5 with a similarly labelled human one (for individual results, see Figure 2 or Figure 12). However, while using GPT responses did produce many characterizing dimensions similar to those derived from human responses, substituting in GPT responses still resulted in worse approximations of human decision-making under RSA, as demonstrated by Figure 4. Some of this is likely attributable to modality differences between the image and text questions, as some of the dimensions least captured by the model are color-oriented, such as "wood/brownish", "red", and "colorful", as shown in Figure 3 and Appendix I.

Surprisingly, even when we used relatively little human data, adding GPT responses did not improve the trained model's RSA score. As shown by Figure 4, there must be a point below which this improvement appears, as the full GPT RSA score is above 0.4, a randomly initialized embedding has an RSA score of 0, and there's very little information present in, e.g., one triplet. However, that point was below the lowest proportion we tested, as shown by gaps between the RSA scores of the partial human models and the GPT-augmented mixed human–GPT models in Figure 4. This ostensibly contradicts previous studies showing LLMs having human-comparable performance on a wide variety of tasks, but *human-level performance is different than human behavior*. Partial human RSA scores largely saturated by the time 0.375x the full human dataset was used, indicating that for RSA purposes, the sizes of the partial human datasets we considered may have been larger than needed. Nonetheless, it seems misguided to augment with GPT responses unless human data is considerably scarcer than we tested, as the mixed human–GPT datasets have considerably worse RSA scores than those observed on much smaller partial human datasets. Were our task extremely low-resource, the 0.42 RSA score achieved by the full GPT model might be useful, however.

Encouragingly, when swapping human responses with those from GPT, the RSA scores appeared fairly robust to replacement, as shown by the full human and partial human models' RSA scores in Figure 4. When we replaced 25% of the data (0.75 on the Human-Data-Portion x-axis) the RSA score dropped by less than 10%. There was at most a $\sim$60% reduction when 100% was replaced (0 on the Human-Data-Portion x-axis). This is important to consider for future crowdsourced odd-one-out experiments, such as the Hebart dataset, because many crowdworkers have begun using GPT for their tasks.

In conclusion, our work characterizes GPT object-similarity judgments, enhancing our understanding of how LLMs and humans behave similarly or differently. Notably, despite a modality difference, GPT responses produced embeddings with labels mirroring or closely resembling those from human responses. Our findings also indicate utility in using LLM completions for extremely low-resource environments as a proxy for human judgment. However, these findings suggest little benefit from *augmenting* human responses for any sizeable number, especially when crowdsourcing human data is feasible. Our findings also warrant caution when otherwise human-looking GPT responses might become part of collected data, but offer hope for the odd-one-out task, as the embeddings proved fairly robust to lower levels of response replacement.

4 Future Work

Our choice of LLM for our experiment was constrained by the sizes of (effective) current models, computing resources, and modality. As image-capable and more powerful models appear, future work should repeat our experiments using them.

Future work may also examine whether the choice of dataset affects the characterizing dimensions produced for an LLM. The THINGS dataset is a set of concrete objects, and lacks more expansive concepts like scenes, environments, actions, or emotions. GPT gives us a budget-effective way of considering whether the introduction of such concepts might change what characterizing dimensions appear.

Limitations

Our work uses text-only prompts, while the human experiment uses images. The objects of the THINGS dataset were chosen to be highly imageable, but this nonetheless almost certainly played a role in shaping what GPT found salient in the object-comparison task. At time of writing, GPT-4's vision API had not seen full release.

Our prompts presented GPT with objects in an ordered fashion that it heavily utilized (see Appendix C). To remedy this, we used aggregate responses on permuted prompts. However, humans may have used the ordering of questions (or responses from previous questions) in ways our setup did not account for.

We used OpenAI's GPT-3.5. It is possible certain aspects of our characterization are specific to it. In particular, we anecdotally observed that smaller models had difficulty completing the odd-one-out task as far as we could understand; other models likely exhibit more or less similar behavior to humans as well.

During the survey, multiple respondents mentioned that the percentile structure made it difficult to discern continuous meaning across the entire dimension scale. This may be because the dimensions only hold palpable information at higher levels. Regardless, the common strategy employed was to look at the top and bottom objects rather than the ones in the middle. Our percentiles were chosen to align with previous work, but nonetheless, other methods may elucidate more nuances than our prompt and coding schema did.

Finally, GPT-3.5 is largely trained on English text and corpora. This has cultural and linguistic implications, and future work may wish to consider examining models trained specifically on data from other languages or specific communities.

Our work serves as one data point for understanding LLMs. This should be sufficient for giving insight into related work, but (especially given the quickly-arriving ubiquity of LLMs and potential for harm; see Ethics), it is not in isolation nearly sufficient for determining whether LLMs should be used in real-world applications.

Ethics

Risks

Our model illuminates GPT's behavior in a direct odd-one-out task, and some of the characterizing dimensions have strong correlation with previously obtained dimensions that characterize human object-similarity judgment. There is a potential to misinterpret this as meaning GPT uses these dimensions in the same way humans do or that these dimensions apply to all tasks GPT performs.

Resources

Response-collection was performed using OpenAI's `GPT-3.5-Turbo-0613` endpoint. The 4,385,040 responses took one week for OpenAI's systems to process at a total cost of $722 USD. Training was done with NVIDIA P100 GPUs on Digital Research Alliance (Compute Canada) clusters, taking about 16 hours per model.

Licensing and Artifacts

Our GPT odd-one-out response dataset and model are available under a CC-BY version 4 licence in Supplementary Materials. The intended use of our dataset is general-purpose, so long as it is not harmful.

We use the THINGS images dataset (Hebart et al., 2019) under the terms of the CC BY 4.0 under which it was released (`https://osf.io/qyd6u`). We use the THINGS odd-one-out dataset (Hebart et al., 2023) under the terms of the CC-BY-4.0 license under which it was released (`https://osf.io/5wcte`). Its intended use is to further research (as per the Things Initiative's website (Hebart et al., 2019)).

We use Pandas (pandas development team (2020); Wes McKinney (2010)) under its BSD 3 licence. We use Scikit-Learn (Pedregosa et al., 2011) under another BSD 3 licence. We use SciPy (Virtanen et al., 2020) under the terms of a similar licence. We use Matplotlib (Hunter, 2007) under a BSD-like licence. Finally, we also use PyTorch (Paszke et al., 2019). We satisfy the licensing terms of it, along with the previous software packages, by not redistributing the source code. These software packages' intended use is scientific and general-purpose application, and we satisfy both those criteria.

We also use representational similarity analysis (RSA) (Kriegeskorte, 2008) and uniform manifold approximation and projection (UMAP) (McInnes et al., 2018). Kriegeskorte and McInnes both likely intended others to use their algorithms for general research.

We use ChatGPT-3.5 and ChatGPT-4 for some code generation under OpenAI's commercial terms. At no point do we provide sensitive or copyrighted information to it.

Response Collection

All respondents were members of the same research team. However, as responses were collected using respondents' choices of identifying keywords (initials were suggested), that identification was removed from any public release. This minimal information was necessary because respondents were informed they could have their responses deleted, should they desire. All respondents were part of the research team; no formal recruitment was done. For the same reason, no compensation was given. Respondents knew ahead of time what this project was for, but details were given in the instructions as well.

The instructions given can be found in Supplementary Materials.

All responses were from graduate students and postdocs at a leading university. The respondents' countries of origin were diverse (only two respondents were from the same country), and all were fluent in English, although for half, it was not a first language.

Supplementary Materials

All supplementary materials, including code, datasets, and grid-search results, are available at `https://osf.io/7vz2h/`.

A Response-Order Counts

For a set of triplets, each object is either ordered first, second, or third in their presentation to a respondent. Below are the holistic choice rates for each in the odd-one-out task for for GPT (Figure 5), for humans (Figure 6), and for GPT aggregated (Figure 7).

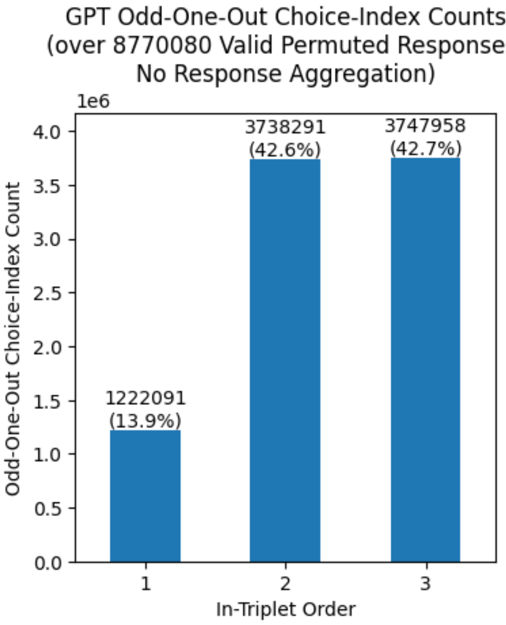

Figure 5: Counts of order-within-triplet responses for raw GPT calls. For example, given a prompt asking about 'apple', 'banana', and 'car', in that order, and a response of 'car', this would be a response with an index of 3. These are unbalanced, so we resort to permuting them; see section 2, Human–GPT Datasets for details of this.

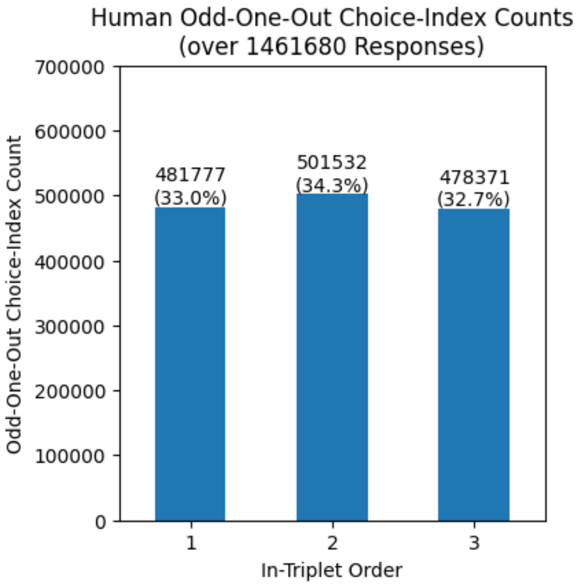

Figure 6: Counts of order-within-triplet responses for adult respondents on the dataset. For example, given a prompt asking about 'apple', 'banana', and 'car', in that order, and a response of 'car', this would be a response with an index of 3. These responses are from (Hebart et al., 2020).

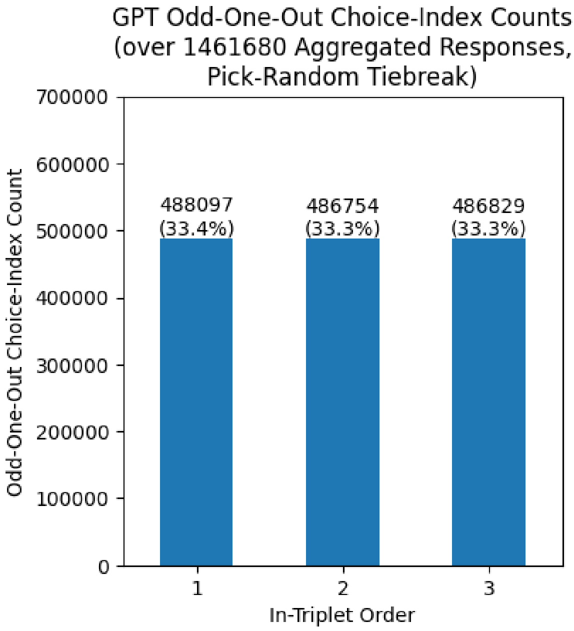

Figure 7: Counts of order-within-triplet responses for aggregated GPT calls. For example, given 'apple', 'banana', and 'car', if the relative majority vote was 'banana', this would be a response of index 2. In the case of tiebreaks, in actuality the earliest tiebreaking indexed response was chosen; this is easier to reproduce and works out to be equivalent to choosing randomly due to the orders of the objects within the questions being completely random. See section 2, Human–GPT Datasets for permutation details.

B Odd-One-Out Prompt

The prompts we provided to GPT were of the following form:

```
<|im_start|>system
Which of the objects are more similar to
     each other? Say the object that
    doesn't match. Format your choice as
     [[object]]<|im_end|>
<|im_start|>user
{object1}, {object2}, {object3}.<|im_end
    |>
```

This was intended to be as close to the language used by (Hebart et al., 2020) as possible. Their instruction example is as follows:

```
The three pictures show {object1}, {
    object2}, and {object3}. Which are
    more similar to each other? Click on
     the picture that doesn't match.
```

C Permuted Response Distribution

For a given set of three objects, GPT may answer differently when the objects' order is permuted in the prompt. The rates of agreement of these individual permutations with the accepted aggregate response are given in Figure 8.

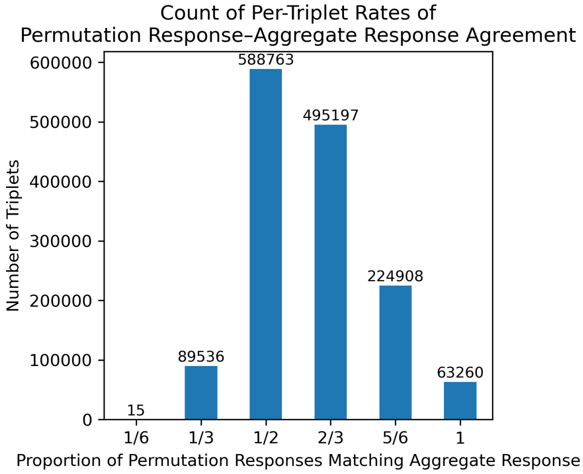

Figure 8: Distribution of the rate of agreement of model permutation responses with the aggregate model response (see section 2, Human–GPT Datasets for permuting details). 1.00 denotes that all 6 permutations of an odd-one-out triplet resulted in the same response; $\frac{2}{3}$indicate that 4 of 6 permutations resulted in the same response. $\frac{1}{2}$ and $\frac{2}{3}$ indicate possible ties, which were broken by choosing the first response at a tying index. Due to the questions being random ordered, consistently doing this is equivalent to choosing randomly between the options with the most votes.

D Model Loss

The cross-entropy loss used by the model in training is given here.

$$
\begin{aligned}
& H(q,p)_{\substack{\text{object set is } \{i,j,k\}, \\ \text{k is the odd-one-out}}} \\
&= \sum_{c\in\{i,j,k\}} q_{c \text{ is the odd-one-out}} \cdot \ln(p_{c \text{ is the odd-one-out}}) \\
&= -\ln\left(p(c_{\text{odd-one-out}})\right) \\
&= -\ln\left(\sigma\left(\mathbf{z}\right)_c\right) = -\ln\frac{e^{z_k}}{e^{z_k}+e^{z_j}+e^{z_i}}
\end{aligned}
$$

where

- H is the cross-entropy loss function
- i, j, k denote the three objects of a triplet, where k is the true odd-one-out
- z_c where $c \in \{i,j,k\}$ and z_c represents the dot product between the vectors of the pair of objects $\{i,j,k\} \setminus \{c\}$
- $\mathbf{z} = \{z_i, z_j, z_k\}$
- σ is the softmax function
- q is the probability of an object being the odd one out (so 100% for the identified odd-one-out, 0% for any other object)
- p is the estimated probability the model gives that a given object is the odd-one-out

For the ℓ^1-norm penalty, we flatten the embedding matrix and take the ℓ^1 norm of the resulting vector. We weight this norm by $\lambda/\text{num\_items}$ and add it to the cross-entropy loss to obtain our full loss.

E Grid Search Specifics

For a given training set, we perform a grid search: we take steps of 0.0016 over the range $\lambda \in \{0.0064..0.0144\}$ to find a maximum, expanding the search radius if necessary. We then perform $(k = 4)$-fold cross-validation ($(k = 10)$-fold for the full GPT set) in steps of 0.0004 to the adjacent previously-found 0.0016-stepped lambdas to find the optimal lambda in the region around that local maximum. We train on a 90% split for a fixed 1000 epochs for each model, mirroring the setup of Zheng et al. (2019) to ensure convergence. The per-epoch performance and final validation accuracies for the grid-search folds of the full GPT model are given in Figure 9. The final validation accuracies for those λs are given in Figure 10, illustrating the degree of local concavity. All grid-search results, as well as further by-fold stats for the mixed human–GPT and partial human models, are found in Supplementary Materials.

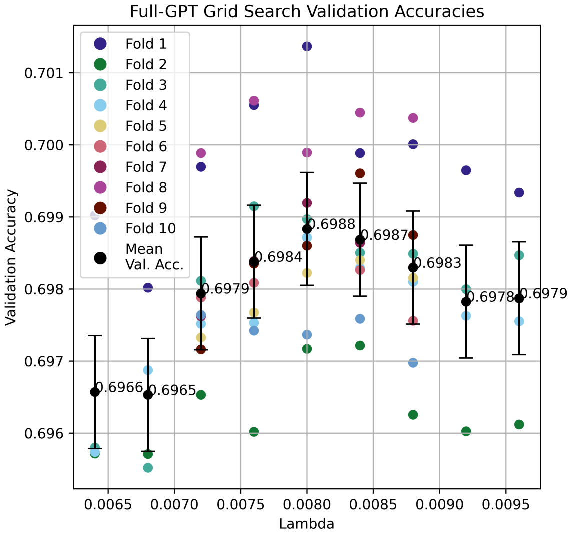

Figure 10: Step 2 of the grid-search for the full GPT model (stepping at intervals of 0.0004). The x-axis gives training lambda values, and the y-axis gives the validation accuracy at 1000 epochs. The error bars assume fold results are normally distributed and give a range of one standard deviation. $\lambda = 0.008$ is the highest performer.

F Dimension Scales

For each dimension, we produced scales with objects whose values spanned the dimension, as in Figure 11.

Namely, we made images as seen in Figure 11. The six images on the left have Dimension 12 values at the 0th, 1st, 5th, 10th, 15th, and 20th percentiles for the dimension. The images at the next tick have dimension values at the 33rd percentile, and thereafter the images at each successive tick are at a percentile 13.333 more. This continues until the last tick, denoting the 100th percentile, where the six top-scoring images are shown.

G Dimension Labels

The aggregated dimension names for the 39 largest dimensions of the labelled GPT model are given in Table 1.

H Correlation Heatmaps

The full heatmap of the correlations between the dimensions of the labelled GPT model and those

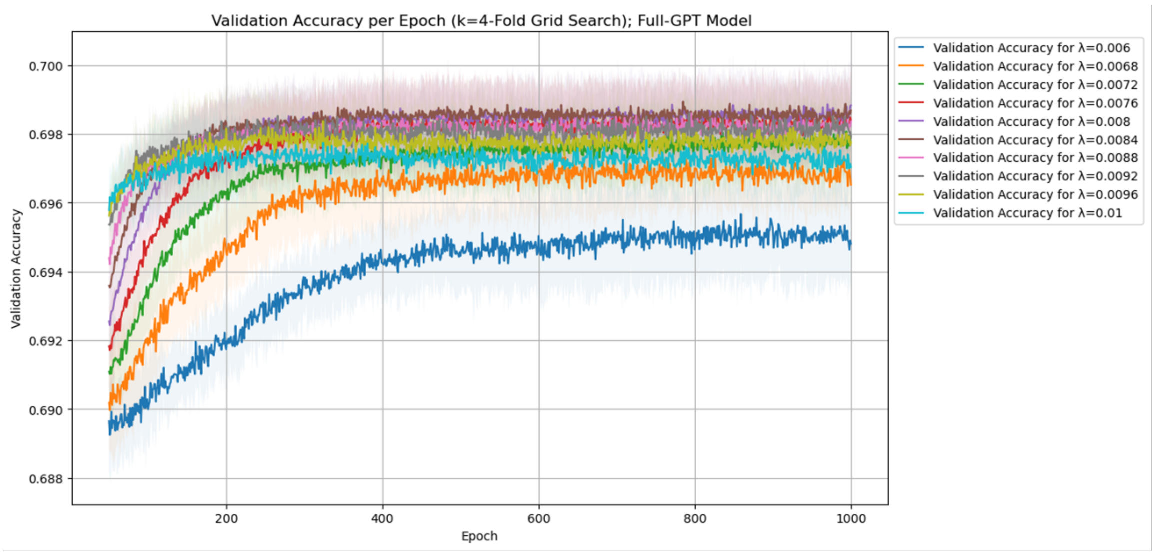

Figure 9: Per-epoch validation accuracies for step 2 of the grid search for the full GPT model (with additional lambdas for illustration). Note the saturation of the validation accuracies before 1000 epochs. Additional 0.0004-intervaled grid-search results are included for context. $\lambda = 0.008$ is the highest-scoring performer.

Table 1: Aggregate labels for the characterizing dimensions of the labelled GPT model. Labels were obtained via the coding process described in subsection 2.2.

of the labelled human is shown in Figure 12. To illustrate the closest dimensions between the labelled GPT and labelled human embeddings, we performed a bipartite max-correlation-as-weight matching of the labelled human dimensions to the labelled GPT embeddings Figure 13 (and vice-versa in Figure 14).

I Dimension Reproducibility and Overlap

We wished to gauge the reproducibility of the labelled GPT/Human embedding dimensions and determine the extent to which the dimensions of one are reproduced by the other. To determine this, we took our labelled human model and considered each dimension. We ran 8 other full human models and 8 other full GPT models, each time calculating the maximal correlation that the labelled dimension had with any of the new dimensions. This told us (1) how reproducible the labelled human dimensions were, and (2) the extent to which full GPT models captured the labelled human dimensions. The differences between the respective GPT and human correlations then conveyed how much better or worse the typical full human or full GPT embedding was at reproducing the labelled human dimensions. These results are shown in Figure 15.

We also repeated this setup using the labelled GPT model as the basis of comparison. This conveyed the reproducibility of the labelled GPT dimensions and the extent to which full human models captured the labelled GPT dimensions. Similar to before, the differences between the respective GPT and human correlations then indicated how much better or worse the typical full human or full GPT embedding was at reproducing labelled GPT dimensions. These results are shown in Figure 16.

J Dimension UMAP and PCA

We performed Uniform Manifold Approximation and Projection (UMAP) and Principal Component Analysis (PCA) on the labelled human and GPT embeddings for insight into the dimensions' spatial relationships. These are given in Figure 17.

Most of the largest human embedding dimensions have a strong correlation and corresponding label with a dimension in the GPT embedding (and vice-versa). However, the largest-magnitude dimension of each are quite different. These two dimensions have an outsized effect on the choice of principal components, as evidenced by them

Figure 12: Full correlation heatmap between the dimensions of the labelled GPT model and the labelled human model, with aggregate labels on left. Dimensions are ordered by the mean value over objects. Correlations are multiplied by 10 and rounded to the nearest integer for text-size reasons.

Figure 13: Correlation heatmap between each labelled GPT embedding dimension and the closest labelled human embedding dimension under bipartite max-correlation matching. The GPT dimensions are ordered by their mean value over all objects.

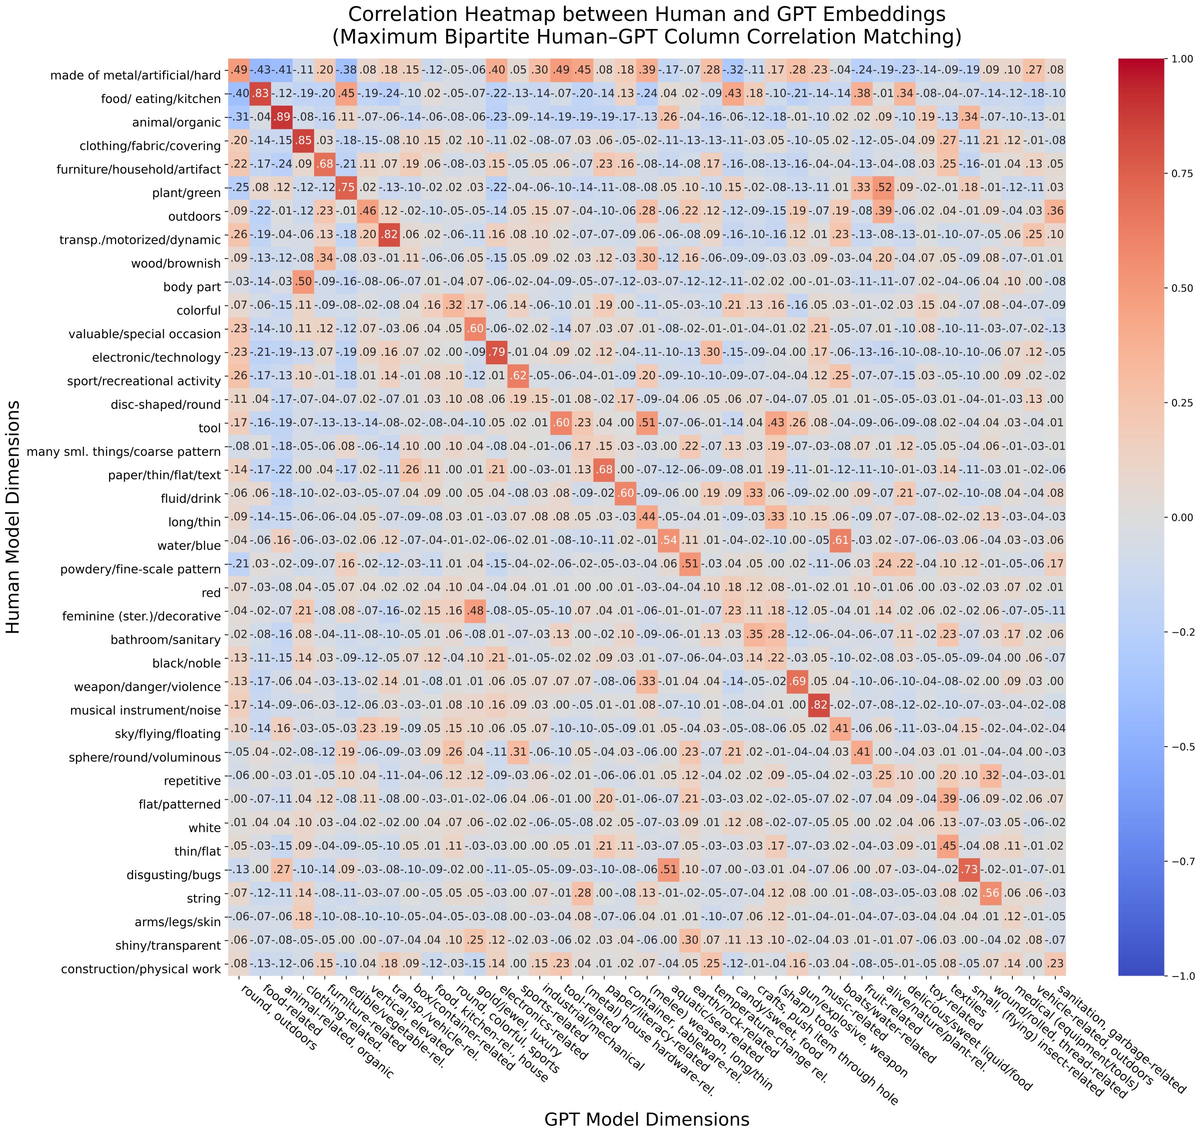

Figure 14: Correlation heatmap between each labelled human embedding dimension and the closest labelled GPT embedding dimension under bipartite max-correlation matching. The human dimensions are ordered by their mean value over all objects.

Figure 15: Maximal correlations of the labelled human characterizing dimensions with any dimension of a full human model and a full GPT model (over 8 such models of each).

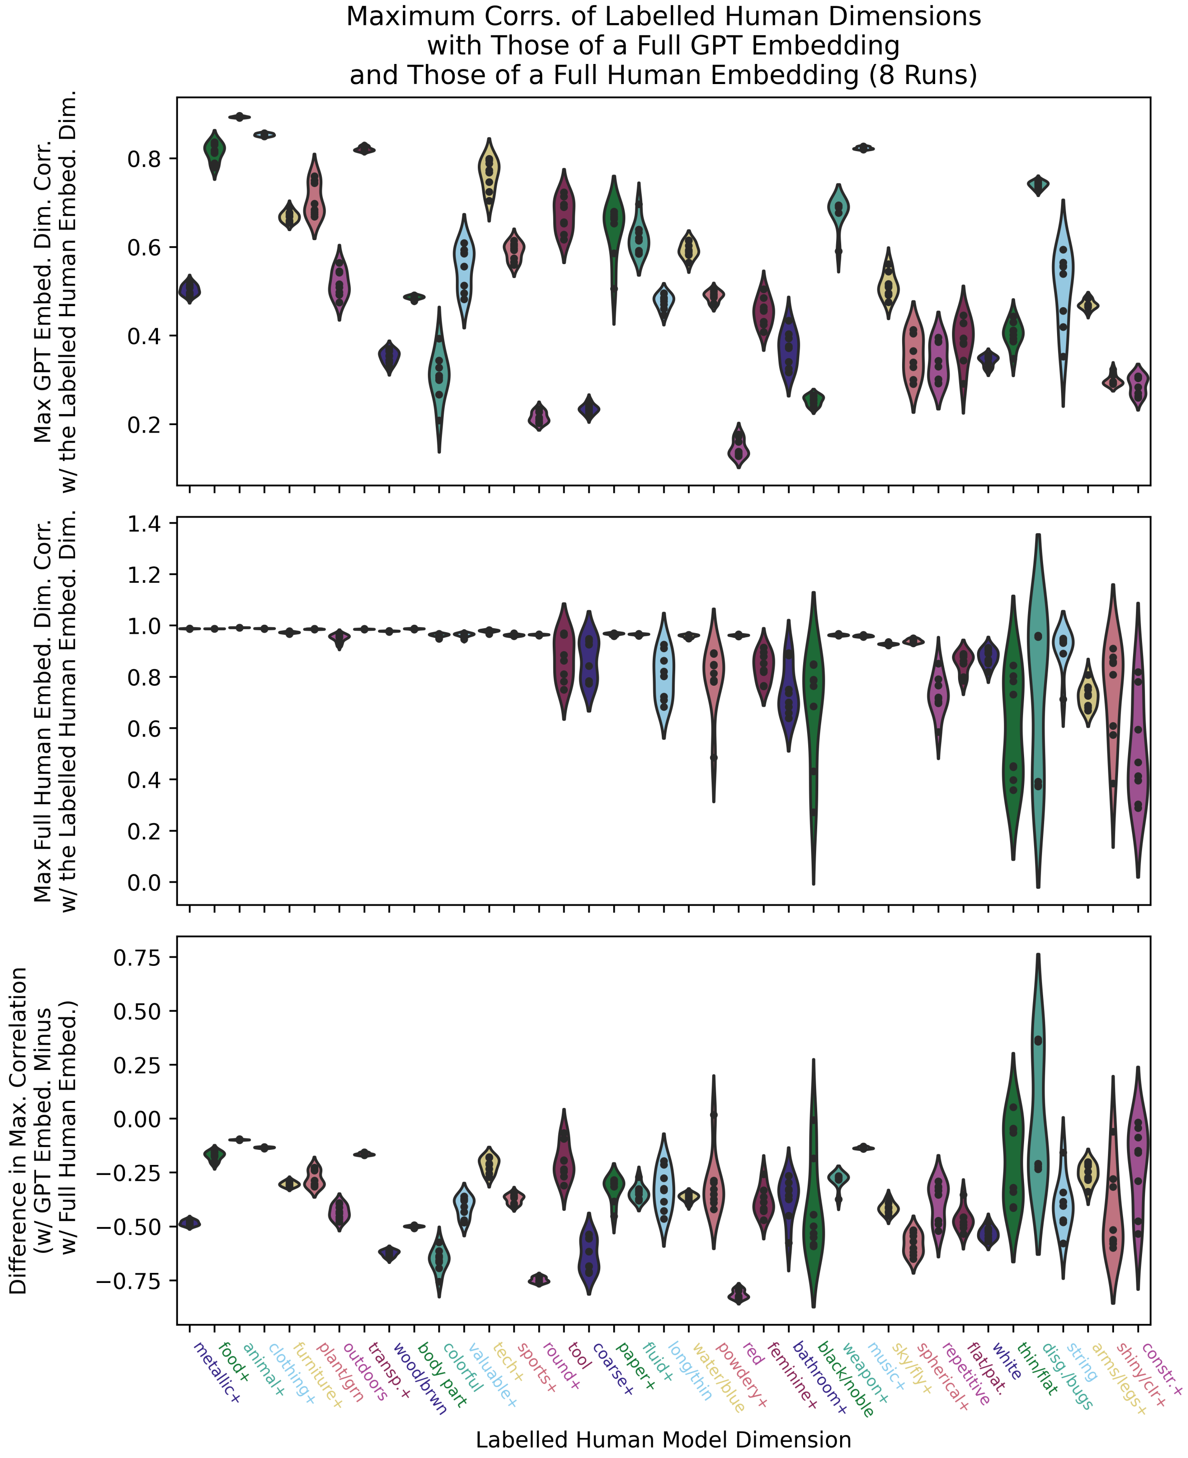

Figure 16: Maximal correlations of the labelled GPT characterizing dimensions with any dimension of a full GPT model and a full human model (over 8 such models of each).

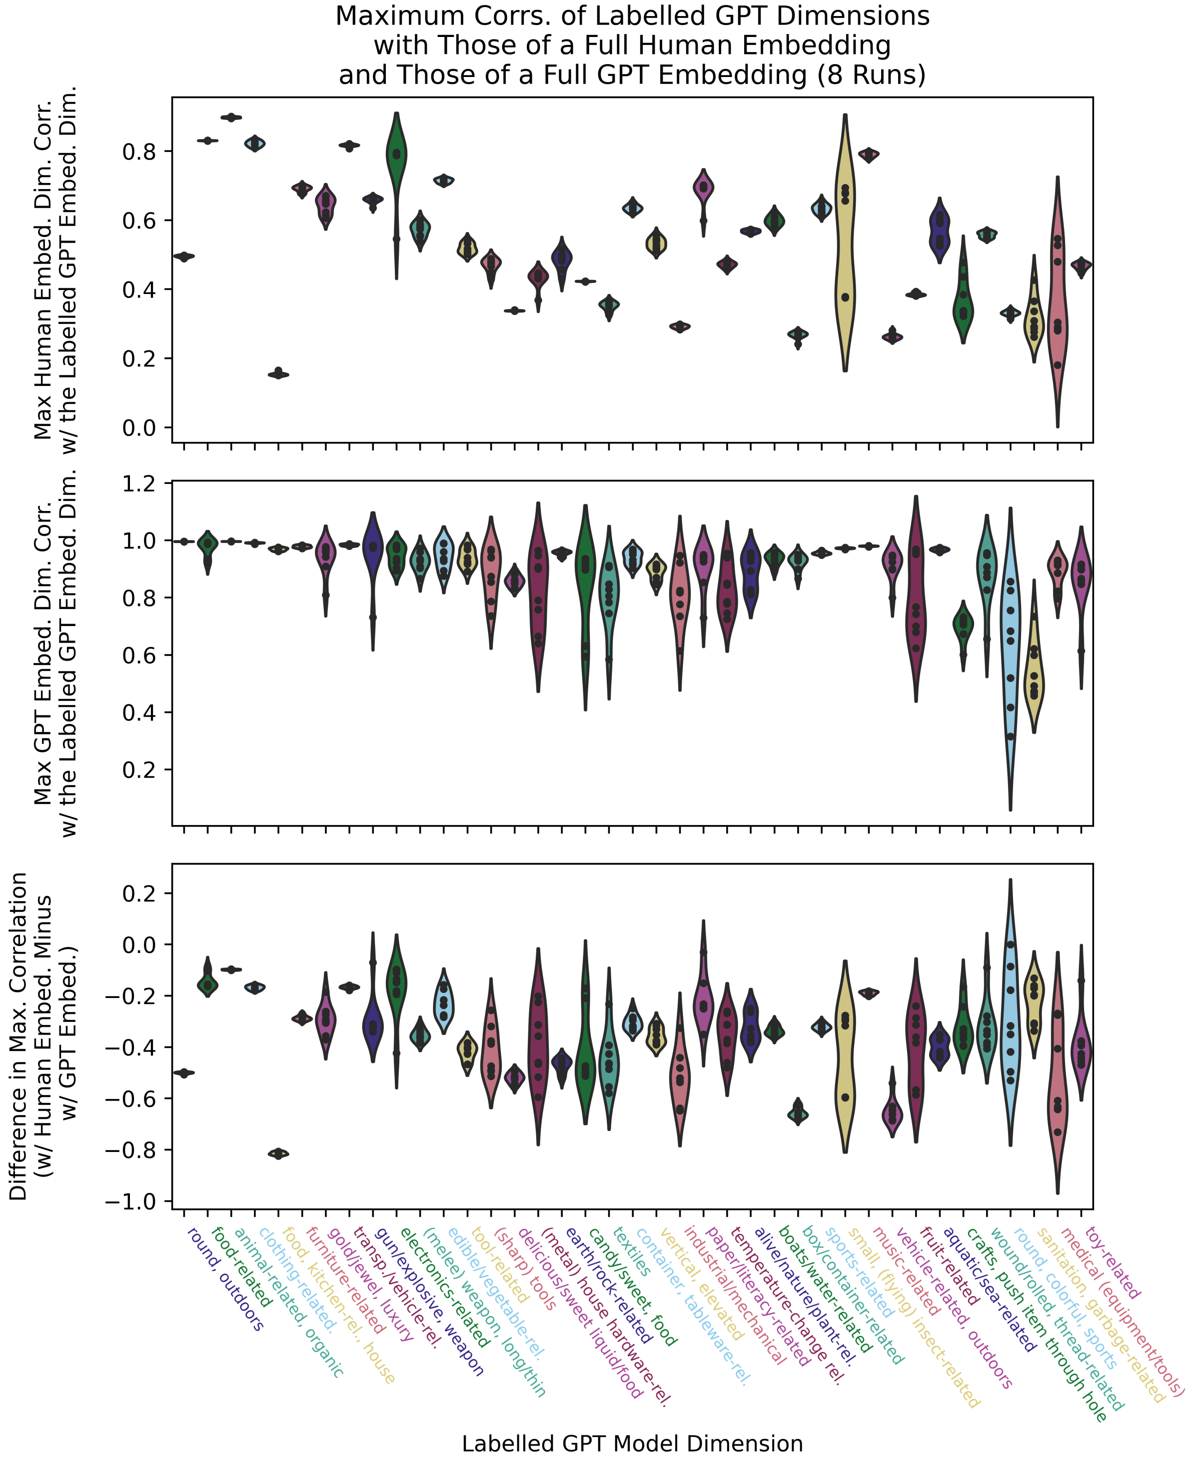

being in clearly distinct clusters (in the case of ‘round/outdoors’, human dimension 1, it is the only embedding dimension present in the entire right half-plane of the first principal component). Consequently, as the choice of principal components is dominated by these most significant dimensions, the relationships between the rest of the dimensions are less considered.

On the other hand, since UMAP considers the distance between each pair of dimensional vectors when bringing the structure of the projection close to one imposed on the higher-dimensional vectors, the local relationships are better preserved.

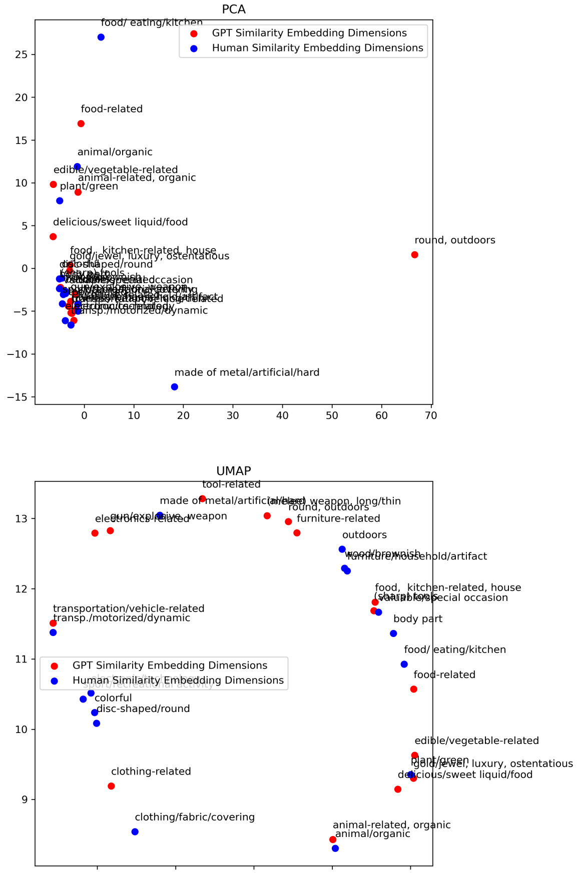

Figure 17: UMAP and PCA performed on the labelled GPT and human embeddings’ dimensions.

K Mixed Human–GPT RSA

Table 2 gives the RSA scores used in Figure 4 in tabular form. As such, it holds the average RSA correlations with the baseline human embeddings. The “Dot RSM” column represents using a dot-product kernel to take a representational similarity matrix (RSM) when comparing the various models to the baseline human models, while the “Cos RDM Corr” column represents using cosine similarity to produce representational difference matrices (RDMs) in lieu of those RSMs. For our experiments, we used the dot-product RSMs.

Dataset Type	Lambda	Proportion Human Data	Dot RSM Corr. (RSA Score)	Cos RDM Corr
Random Embedding		0	0	-0.01
Full GPT	0.008	0	0.437	0.438
Partial Human	0.0092	0.125	0.853	0.638
Partial Human	0.0108	0.25	0.897	0.710
Partial Human	0.0128	0.375	0.916	0.752
Partial Human	0.0144	0.5	0.924	0.772
Partial Human	0.0176	0.625	0.930	0.797
Partial Human	0.02	0.75	0.928	0.763
Partial Human	0.024	0.875	0.933	0.808
Mixed	0.0084	0.125	0.507	0.502
Mixed	0.0084	0.25	0.585	0.566
Mixed	0.0084	0.375	0.667	0.613
Mixed	0.0092	0.5	0.750	0.680
Mixed	0.0084	0.625	0.826	0.723

Abstract

Large language models (LLMs) have shown promising abilities of in-context learning (ICL), adapting swiftly to new tasks with only few-shot demonstrations. However, current few-shot methods heavily depend on high-quality, query-specific demos, which are often lacking. When faced with *out-of-demonstration* (OOD[1]) queries, methods that rely on hand-crafted demos or external retrievers might fail. To bridge the gap between limited demos and OOD queries, we propose **SELF-DEMOS**, a novel prompting method that elicits the inherent generalizability in LLMs by query-aware demo generation. The generated demos strategically interpolate between existing demos and the given query, transforming the query from OOD to ID. To evaluate the effectiveness of our approach, we manually constructed **OOD-Toolset**, a dataset in the tool-using scenario with over 300 real-world APIs and 1000 instances, each consisting of three tool-use cases as demos and an OOD query. Thorough experiments on our dataset and two public math benchmarks have shown that our method can outperform state-of-the-art baselines in the OOD setting. Moreover, we conduct a range of analyses to validate SELF-DEMOS's generalization and provide more insights.[2]

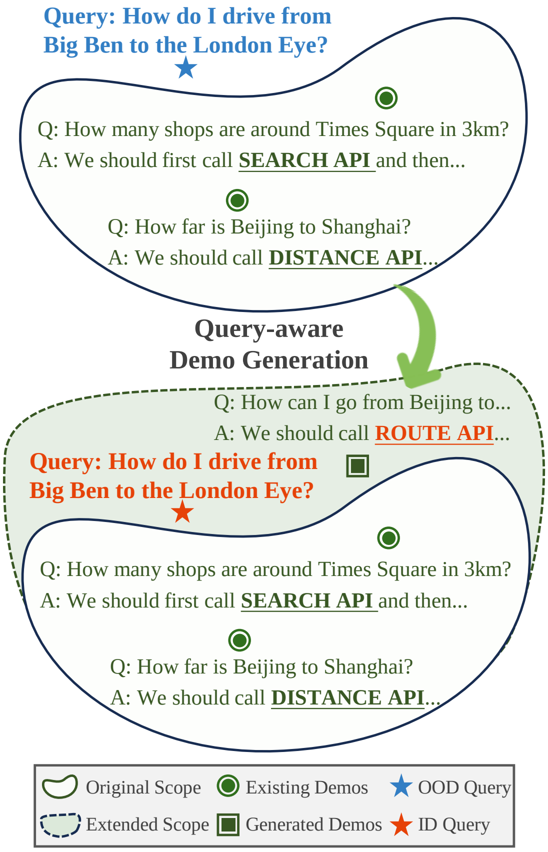

Figure 1: An example of how query-aware demo generation works. In the tool-using scenario, there is a gap between the user query and the available tool-use cases in the original scope since they require different APIs. This can lead to errors if the LLM is unfamiliar with the ROUTE API. After interpolating new demos between the existing ones and the OOD query, LLMs can perform better in the extended scope.

1 Introduction

Large language models (LLMs) have achieved impressive performance across a wide range of tasks, ranging from mathematical reasoning to tool using (Brown et al., 2020a; Kojima et al., 2022; Qin et al., 2023; Xi et al., 2023). The models learn to perform unseen downstream tasks simply by conditioning on a prompt containing input-output pairs (i.e., *few-shot demonstrations*, Brown et al., 2020a). This paradigm, also known as in-context learning (ICL), has been found its effectiveness considerably influenced by the quality and relevance of the demos provided (Liu et al., 2022; Dong et al., 2023). Thus, how to provide high-quality demos becomes an essential challenge in LLM applications.

The leading few-shot techniques typically hinge on hand-crafted task-specific demos or extensive

demo libraries (Wei et al., 2022c; Liu et al., 2022; Rubin et al., 2022). However, crafting demos for each unique query is impractical, and the demo libraries are also unable to cover all the potential queries. The issue arises when faced with out-of-demonstration (OOD) queries, resulting in poorer performance due to the gap between existing demos and new queries.

An alternative strategy is prompting the LLMs to self-generate relevant demos, thereby guiding themselves toward resolving the query (Kim et al., 2022; Chen et al., 2023b; Yasunaga et al., 2023). However, these works often overlook a critical point: instead of blindly recalling relevant demos based on queries, we can perform interpolation between existing demos and queries, as depicted in Figure 1. By strategically interpolating, we can derive more relevant and accurate demos from existing ones, which have proven helpful for the final response (Liu et al., 2022; Halawi et al., 2023). Specifically, we introduce **SELF-DEMOS**, a novel prompting method that may fully elicit the model's potential out-of-demonstration generalizability. Unlike previous works, we developed a complete workflow incorporating pre- and post-processing steps around the demo generation. Before the demos are generated, we first prompt the model to *"give a general understanding of the user query"*, thereby simplifying the complexity of the analysis in subsequent steps. Then, we generate query-aware demos and select the most high-quality ones through *Best-of-N sampling* (Nakano et al., 2021). These selected demos will be used for the final response along with the initial available demos.

To evaluate our approach's efficacy in the OOD context, we manually construct **OOD-Toolset**, a dataset tailored for tool-using scenarios as delineated by Tang et al. (2023). Our dataset includes over 300 real-world APIs and 1000 instances, each consisting of three tool-use cases as demos and an OOD query. Moreover, we benchmarked our method with two public mathematical datasets, GSM8K (Cobbe et al., 2021) and MATH (Hendrycks et al., 2021), to validate its adaptability in different scenarios. The primary experimental findings reveal that SELF-DEMOS outperforms state-of-the-art baselines in solving OOD queries. We also conducted ablation studies and other extensive experiments to gain more insights into our method. Collectively, our analyses show that we have found a more efficient way to elicit the potential OOD generalizability in LLMs.

Our contributions are summarized as follows:

1. We proposed SELF-DEMOS, a novel prompting method to elicit the out-of-demonstration (OOD) generalizability in LLMs.
2. We manually constructed OOD-Toolset, a tool-using dataset for better verifying the potential OOD generalizability in LLMs.
3. We conducted extensive experiments to validate SELF-DEMOS's effectiveness and generalization under different settings.

2 Related Work

2.1 In-Context Learning

The rise of LLMs such as ChatGPT (OpenAI, 2022) and LLaMA (Touvron et al., 2023) has revolutionized the field. With the model size scaling, LLMs demonstrate remarkable capabilities of ICL (Brown et al., 2020b; Wei et al., 2022b), which learns to perform tasks by specific instructions and demonstrations. Additionally, insights from scaling laws (Wei et al., 2022b) also highlight the LLMs' potential for out-of-distribution generalization. It refers to the challenge where model inputs deviate from their training distribution (Wang et al., 2023a). If stimulated effectively, this generalization capability can empower LLMs to address queries outside the training corpus (Collins et al., 2022), enhancing utility in dynamic and open-ended scenarios.

2.2 Optimizing Demonstrations for ICL

The performance of LLMs may be influenced by the quantity, relevance, diversity, and truthfulness of demonstrations (Chen et al., 2023a; Levy et al., 2023; Min et al., 2022; Halawi et al., 2023). There are two primary paradigms to optimize demonstrations and steer models towards generalization.

Demo Retrieval for ICL. LLMs are sensitive to the choice of demonstrations. Therefore, researchers have focused on using retrieval modules to find the most representative demos for ICL. One effective strategy is leveraging existing retrievers based on semantic similarity metrics between the available demos and queries (Liu et al., 2022; Agrawal et al., 2023; Gao et al., 2023; Luo et al., 2023). Another method employs ranking scores derived from fine-tuned language models (Rubin et al., 2022; Shi et al., 2022).

Demo Generation for ICL. Rather than extracting existing demos, demo generation aims to self-generate exemplars that closely align with the input. Kim et al. (2022) initially employed language models to produce demos from pre-defined labels. Subsequent works adopted a two-stage approach of generating and selecting demos (Li et al., 2022; Zhang et al., 2023; Shao et al., 2023). In contrast, our work leverages the intrinsic capabilities of LLMs to identify superior demos via best-of-N sampling.

Besides, there are approaches akin to ours. Chen et al. (2023b) adopt multi-steps to construct demonstration pairs, while Yasunaga et al. (2023) prompt LLMs to recall relevant demos before answering. However, our method stands out by combining pre- and post-processing steps around demo generation to guarantee the high quality of generated demos.

2.3 Eliciting LLMs' Power with Prompts

Efforts to enhance LLMs include finetuning with specific instructions (Wei et al., 2022a) and employing prompting strategies like Chain-of-Thought (CoT, Wei et al., 2022c). Our approach adopts the prompt-based strategy and draws inspiration from studies of the "self" series (Madaan et al., 2023; Wang et al., 2023b; Chen et al., 2023b). The essence of "self" is to leverage the model's inherent power, without external modules. Our method positions the LLM itself as an analyzer, generator, and selector, aiming to elicit its intrinsic generalizability to resolve OOD queries.

3 Methodology

In this section, we first introduce the construction process of OOD-Toolset. Next, we provide a detailed description of the SELF-DEMOS method, which is illustrated in Figure 2.

3.1 OOD-Toolset Construction

Recent works are evaluated on benchmarks such as BIG-Bench (Srivastava et al., 2022) and GSM8K (Cobbe et al., 2021). However, since these datasets may have been inadvertently included in the training data of LLMs, there is a risk of overestimating their ability to generalize to OOD query (Zhou et al., 2023). To mitigate this, we chose the tool-using scenarios that are less likely to occur during model training for assessment. Specifically, we constructed the dataset following the two steps:

Data Collection. Our original data derives from the tool-use corpus created by ToolAlpaca (Tang et al., 2023). It was composed of a wide range of real-world APIs complete with API descriptions, usage specifications, and multiple simulated tool-use cases. However, despite the dataset's comprehensiveness, we noted that the initial AI-generated tool-use cases contain some errors, such as ambiguous queries and incorrect API calls in response. These minor errors may prevent accurate judgment in our evaluation. Therefore, we engaged human annotators to manually refine the corpus, producing a high-quality version for more reliable assessment. Additional details and an example of OOD-Toolset are provided in Appendix B.

OOD Setting. We retained the user's queries and corresponding API calls from tool-use cases as input-output pairs for the evaluation. In addition, we kept the API descriptions and usage specifications from the refined corpus as context for LLMs. For each test instance, we provided three cases from the same API as initial available few-shot demos (also referred to as *seed demos*, or D_{seed}). Notably, in the OOD setting, the sub-APIs in seed demos differ from those needed in the final query.

Take the MAP tool for example, which contains three sub-APIs: DISTANCE, ROUTE, and SEARCH API. For instance, if the DISTANCE and SEARCH APIs serve as seed demos, the user's query might pertain to the ROUTE API. This design tests the model's ability to understand and apply tool-using patterns across different functions, allowing us to explore the OOD generalizability in LLMs.

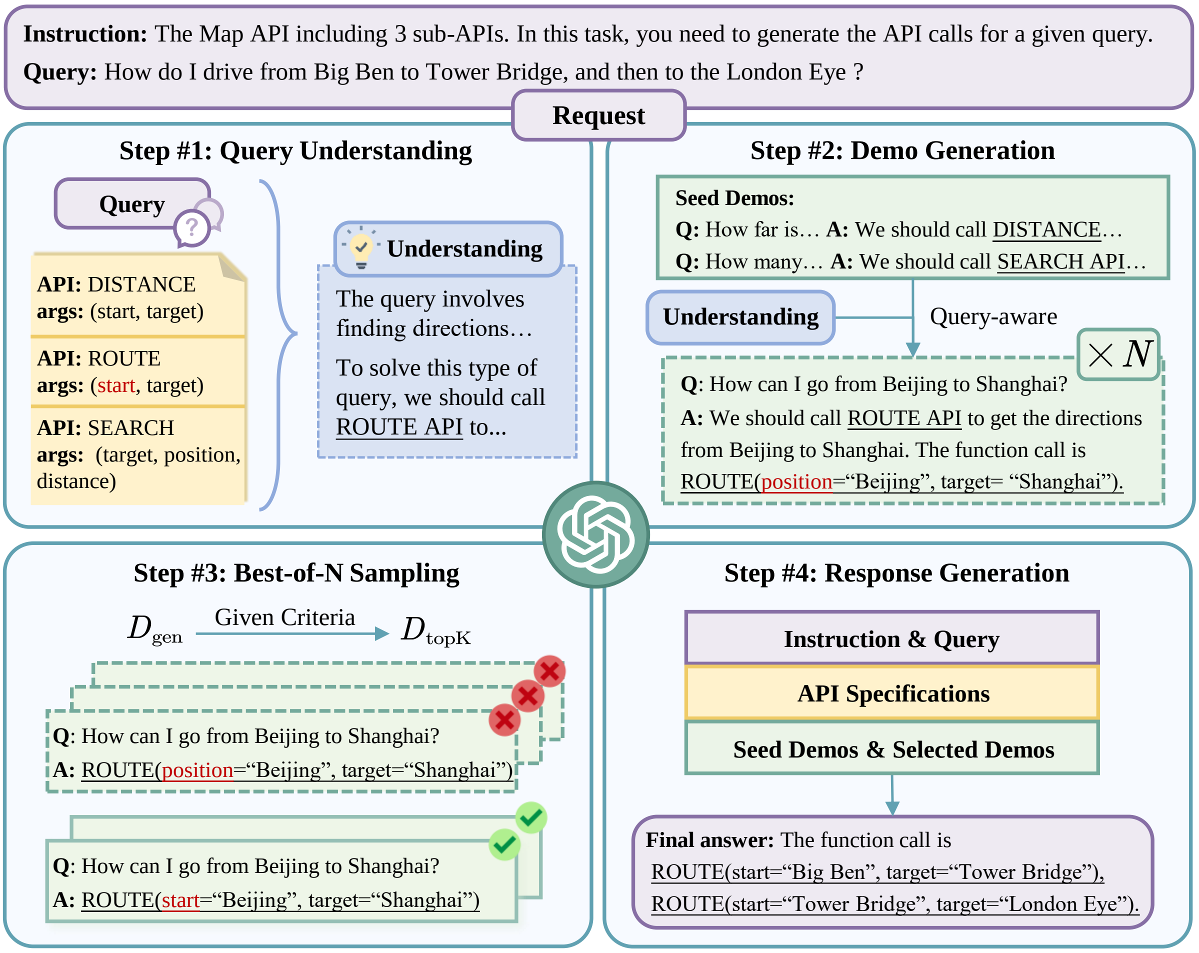
3.2 SELF-DEMOS

We executed the whole workflow by prompting the model itself. The prompt template for each step is illustrated in Appendix C.

Query Understanding. The first step involves comprehensive query understanding. Given the model $\mathcal{M}$ and a query q, we employ a zero-shot method:

$$u = \mathcal{M}(p_1 \mid\mid q), \tag{1}$$

where p_1 is the prompt for query understanding, $\mid\mid$ denotes concatenation, and u is the generated understanding. During this pre-processing step, we aim to reduce the disparity between the initial seed demonstrations and the ultimate target query. As shown in Figure 2, when given a query that involves MAP API, we guide the model to generate an un-



Instruction: The Map API including 3 sub-APIs. In this task, you need to generate the API calls for a given query.
Query: How do I drive from Big Ben to Tower Bridge, and then to the London Eye ?

The query involves finding directions…
To solve this type of query, we should call ROUTE API to...

Q: How far is… **A:** We should call DISTANCE…
Q: How many… **A:** We should call SEARCH API…

Q: How can I go from Beijing to Shanghai?
A: We should call ROUTE API to get the directions from Beijing to Shanghai. The function call is ROUTE(position="Beijing", target= "Shanghai").

Q: How can I go from Beijing to Shanghai?
A: ROUTE(position="Beijing", target="Shanghai")

Q: How can I go from Beijing to Shanghai?
A: ROUTE(start="Beijing", target="Shanghai")

Final answer: The function call is
ROUTE(start="Big Ben", target="Tower Bridge"),
ROUTE(start="Tower Bridge", target="London Eye").

Figure 2: An overview of the proposed SELF-DEMOS prompting method in tool-using scenario.

derstanding focused on the more specific ROUTE sub-API. Furthermore, this step resembles a chain-of-thought process (Wei et al., 2022c), which may reduce the cognitive load in subsequent steps. This is helpful to enhance the relevance and accuracy of the generated demos.

Query-aware Demo Generation. Based on the distilled understanding u and seed demos D_{seed}, we generate query-aware demos as:

$$D_{\text{gen}} = \{d_1, d_2, ..., d_N\} = \mathcal{M}(p_2 \mid\mid q, u, D_{\text{seed}}), \tag{2}$$

where p_2 is the prompt for demo generation, D_{gen} is the set of generated demos, and N is the number of demos to be generated. The seed demos, while not directly linked to the specific query, showcase potential tool-using patterns of MAP API, offering guidance for the generation. We call the model N times to generate N demos separately, alleviating the difficulty of a single try and avoiding the model falling into consecutive errors in one response. In this phase, we extend the original scope of the demos to a broader boundary.

Best-of-N Sampling. It has been argued that LLMs are unlikely to self-critique their outputs without an external validator (Stechly et al., 2023; Valmeekam et al., 2023). Consequently, we assume that while models might not calibrate and refine outputs, they could still discern the superior output from a variety. Therefore, we employ a Best-of-N sampling strategy, where the model is prompted to select the best K demos from the N generated demos based on special criteria:

$$D_{\text{topK}} = \mathcal{M}(p_3 \mid\mid D_{\text{gen}}, C, K), \tag{3}$$

where p_3 is the prompt for sampling, D_{topK} is the subset of K demos sampled from the generated ones, conditioned on criteria C.

This process is inspired by preference learning, where multiple samples are generated and the one with the highest reward model score is chosen (Nakano et al., 2021). It is worth noting that our criteria, which include the demos' accuracy, relevance, and potential helpfulness for the final response, are given to the model via prompts. Our sampling criteria are more nuanced and do not rely on an external retriever. This is where SELF-DEMOS differs from methods such as Synthetic Prompting (Shao et al., 2023), which also selects demos after generation.

Response Generation. Finally, we leverage the sampled demos D_{topK} and the initial seed demos D_{seed} to generate the final response:

$$r = \mathcal{M}(p_4 \mid\mid D_{\text{seed}} \cup D_{\text{topK}}, q), \tag{4}$$

where p_4 is the prompt for response generation, $\cup$ denotes the concatenation of two sets and the r is the final response. The concatenation ensures that the model benefits from the query-specific demos in D_{topK}, while also incorporating the beneficial diversity and quality of D_{seed} (Levy et al., 2023; Halawi et al., 2023).

4 Experiments

To evaluate the effectiveness of SELF-DEMOS, we conduct extensive experiments for comparison and analysis.

4.1 Experimental Setups

Foundation Models. We use GPT-3.5 (the `gpt-3.5-turbo-0613` version) for most of our experiments, with only one additional experiment using the Llama-2-Chat model family, to validate the generalization of SELF-DEMOS across different model sizes. For all LLMs, we set the parameter $temperature = 0$ for stable responses except for the sampling step, where we set $temperature = 0.7$ to introduce diversity.

Tasks & Datasets. We evaluate the proposed method in two reasoning-intensive tasks: tool-using and mathematical problem-solving.

In the tool task, we developed the OOD-Toolset for evaluation. Details of the construction process are described in section 3.1. In the math task, we employed two public datasets: GSM8K (Cobbe et al., 2021), featuring elementary math word problems, and MATH (Hendrycks et al., 2021), containing complex problems from high school competitions. We evaluate the entire GSM8K testing set and a randomly selected subset from the MATH testing set. Distinct OOD settings are designed for math tasks. For GSM8K, we manually created several outlier samples, ensuring that the testing set did not contain problems with similar contexts. For MATH, since the problems were categorized into seven subjects and five difficulty levels, we used problems from different subjects but the same level to meet the OOD condition. The dataset statistics are presented in Table 1.

Evaluation Metric. In the report for the math tasks, we present the exact match accuracy for each problem. For the tool task, which may require multiple API calls in one case, we assess accuracy using both exact and partial matches. Partial matches are awarded half the score if the model's response includes only part of the required API calls.

4.2 Baselines

We compare SELF-DEMOS with the following baselines, including two methods that are designed for demo generation:

Zero-shot and Zero-shot + CoT (Brown et al., 2020a; Kojima et al., 2022). Prompt the model with the task description, test input, and no demonstration. Besides, the CoT method integrates a trigger prompt *"let's think step by step"*.

Few-shot (Wei et al., 2022c). Employ a fixed set of seed demos we constructed for each OOD query. For the GSM8K and MATH datasets, which include solutions with labeled reasoning steps, the demos also feature CoT steps to enhance the model's problem-solving capabilities.

Self-ICL (Chen et al., 2023b). A multi-step framework for zero-shot in-context learning by prompting the LLM itself to generate pseudo-inputs and labels. Unlike our method, they generate inputs and labels separately and then merge them into demos, with no other pre- and post-processing steps. We have also adapted it into a few-shot variant to make it comparable.

Analogical Prompting (Yasunaga et al., 2023). A single-step prompting method that guides LLM to recall relevant demos and knowledge before solving a given problem. Here we let it generate demos for the vanilla version and our few-shot variant. The vanilla Self-ICL and Analogical Prompting methods initially generate three demos each. However, in the few-shot variant, we adjust this to two demos to better align with our approach.

4.3 Main Results

Table 2 shows the performance of each method on three datasets. We can find that: (1) The better

Dataset Name	**Size**	**Demo Source**	**Avg. #tokens of Query**	**Avg. #tokens of Demo**	**Avg. #tokens of Context (Few-shot)**
OOD-Toolset	1,057	Same tool, different sub-APIs	35.5	53.8	496.0
GSM8K	1,319	Manually created outliers	59.0	136.8	526.1
MATH	1,000	Same level, different subjects	69.1	291.9	1002.1

Table 1: Statistics of three datasets in the OOD setting.

Prompting Method	**OOD-Toolset**		**GSM8K**	**MATH**	**Average**
	Exact Acc	Part Acc	Acc	Acc	
Zero-shot	64.5	68.4	75.0*	33.0*	60.2
Zero-shot + CoT	66.1	70.9	75.8*	33.9*	61.7
Few-shot	71.9	76.6	76.2	35.1	65.0
Self-ICL (Zero-shot)	67.0	71.1	76.6	34.6	62.3
Self-ICL (Few-shot)	71.5	76.0	78.0	**37.9**	65.9
Analogical Prompting (Zero-shot)	67.8	72.0	77.8*	37.3*	63.7
Analogical Prompting (Few-shot)	71.1	75.4	75.7	36.3	64.6
SELF-DEMOS (ours)	**75.1**	**79.4**	**78.2**	**37.9**	**67.7**

Table 2: Main results of different prompting methods on three datasets. All the results are with GPT-3.5-Turbo. The best performance for each task is in **bold**. The (*) indicates that results are from Yasunaga et al. (2023).

performance of few-shot over zero-shot (+ CoT) shows the LLM's capacity to discern and apply underlying patterns from seed demos to OOD queries, indicating a degree of inherent generalizability. Furthermore, the OOD-Toolset measures this ability more accurately than the two public math datasets, validating the necessity of creating unseen scenarios and OOD structures of instances. (2) Only a few-shot method does not fully unlock the model's capability. In contrast, the methods with demo generation, especially SELF-DEMOS, present superior performance, underscoring their potential to serve as a reliable prompting strategy in OOD scenarios. (3) Self-ICL, which generates Q&A separately, serves a similar purpose to our Best-of-N Sampling step by enhancing the accuracy of generated demos. Thus, it yields performance that is closest to our method. However, this framework may also lead to mismatches of Q&A pairs, i.e., the model fails to answer the questions it generates, which may affect subsequent responses. (4) Seed demos bring little benefit to the Analogical Prompting method and may even be harmful. This could be because the additional demos are irrelevant to the instructions of analogical reasoning, which require the model to do multiple tasks. The seed demos fail to guide the model in different tasks and may distract the model from the whole process. Overall, SELF-DEMOS outperforms all baselines in solving OOD queries.

Pre- & Post-processing Method	**OOD-Toolset**
w/o Pre-processing	72.9 / 77.5
+ Directly Answering	72.3 / 77.0
+ Query Understanding	**75.1 / 79.4**
w/o Post-processing	74.1 / 78.7
+ Self-Critique	74.3 / 78.8
+ Best-of-N Sampling	**75.1 / 79.4**
+ Best-of-N Sampling & Self-Critique	74.6 / 79.0

Table 3: Ablation study of pre- & post-processing methods on **OOD-Toolset**. The upper rows show the impact of different pre-processing steps, with the other steps remaining consistent with the original. The following rows show the impact of post-processing steps, again keeping all other steps consistent with the original.

4.4 Ablation Study

Table 3 presents the results of our ablation study. We compare a range of pre- and post-processing methods and their influence.

Pre-processing Methods. We performed the following settings: no pre-processing before generating demos, directly answering the query before generating, and query understanding before generating. The result shows that either no pre-processing or directly answering will compromise performance. Notably, the absence of pre-processing tends to yield homogenous outputs despite our introduction of randomness, potentially due to the model's challenge in reconciling the demanded relevance and diversity. Direct answer generation also diminishes performance, as initial errors propagate, leading to more erroneous or ambiguous answers in subsequent steps. Hence, a robust pre-processing strategy enhances model performance by ensuring diverse and correct initial responses.

Post-processing Methods. We performed the following settings: no post-processing after generating two demos, self-critique after generating two, sampling the best two demos after generating five, and self-critique after sampling. In the self-critique step, we prompt the model to verify and refine the D_{gen} or D_{TopK} according to the same criteria C. However, the result indicates that LLMs are no better at verifying their own outputs, echoing the findings of Stechly et al. (2023). This also discourages us from constantly improving the quality of demos through iterative verification.

5 Discussion

5.1 Consistency when Model Scaling

Figure 3 presents the results on varying sizes of the foundation model, ranging from Llama-2-7B-Chat to Llama-2-70B-Chat. According to the results, analogical reasoning did not work on smaller models, likely due to their limited capacity to follow hard instructions. The Self-ICL method encountered similar issues, with the small models' inability to provide accurate demos compromising their effectiveness. In contrast, our method, which incorporates extra processing steps around demo generation and lowers the task difficulty, proved more adaptable even when the model is weaker ($\sim$10B parameters). It suggests that our approach is highly adaptable and can be more effective for resource-limited or mobile scenarios.

5.2 Effectiveness Toward Complex Tasks

In the main results, we can observe that both Self-ICL and Self-Demos have shown a considerable improvement on the most challenging MATH datasets. This may suggest that the methods of generating demos in advance are more effective for complex tasks, as we will detail here.

Level	Prompting Method			
	FS	Self-ICL + FS	Analog + FS	Self-Demos
1	70.2	71.3 (↑ 1.6)	**80.9** (↑ 15.2)	74.5 (↑ 6.1)
2	58.9	61.9 (↑ 5.1)	**63.1** (↑ 7.1)	58.3 (↓ 1.0)
3	37.4	38.7 (↑ 3.5)	**39.9** (↑ 6.7)	39.1 (↑ 4.5)
4	28.0	**34.7** (↑ 23.9)	24.0 (↓ 14.3)	**34.7** (↑ 23.9)
5	12.4	13.8 (↑ 11.3)	11.6 (↓ 6.4)	**14.6** (↑ 17.7)

Table 4: Evaluating prompting methods on the **MATH** dataset at different complexity levels. The **Level** corresponds to problem complexity, with higher values indicating greater difficulty. The percentage of performance improvements / declines compared to the few-shot method (FS) is denoted by (↑) / (↓).

Table 4 presents the full results on the MATH dataset across different complexity levels. Analogical Prompting, as a single-step prompting method, is most effective for simple problems, showing an entirely different trend from the other methods. This aligns with our previous analysis that high model ability is required for analogical reasoning. In contrast, Self-ICL and our method significantly gain in more complex problems. With its greater focus on the relevance and correctness of demos, Self-Demos outperforms others in solving the most difficult level 5 problems.

5.3 Comparing with Demo Retrieval

A key motivation for our idea is to provide relevant demos for problem-solving, without using an external retriever or demo library. So, is our approach comparable enough to retrieval-based solutions? To answer this question, we created two baselines that retrieve exemplars relevant to the given query from external data (i.e., the training set of GSM8K and MATH, which includes labeled Q&A pairs). Table 5 shows the results of these methods on two math datasets.

Undoubtedly, the retrieval-based methods perform well, with the dense retriever achieving the highest scores due to its effective representation of latent semantics (Karpukhin et al., 2020). Besides, Self-Demos also shows competitive performance, especially on the MATH dataset. This could be due to more complex questions in the MATH dataset, resulting in intricate semantic connections that cannot be easily captured by a statistical algorithm like BM25 (Robertson et al., 2009). In contrast, the GSM8K dataset has more uniform and centrally distributed questions, making it more suitable for retrieval-based approaches.

Overall, Self-Demos can still be a good option when resources are limited and retrieval is less feasible. Moreover, it's worth noting that the techniques of demo generation and retrieval are not mutually exclusive. Our method is particularly well-suited for a "**cold start**" and once a certain amount of demos is accumulated, we can then em-

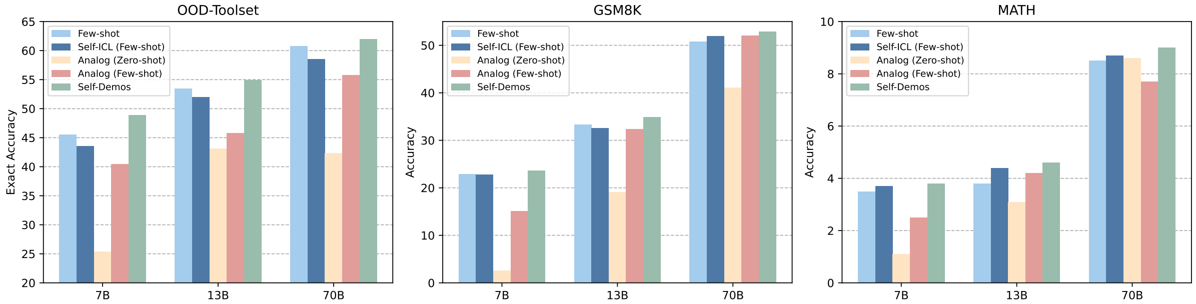


Figure 3: Performance comparison on Llama-2-Chat model family. SELF-DEMOS consistently improves performance across multiple model sizes from 7B, 13B to 70B parameters.

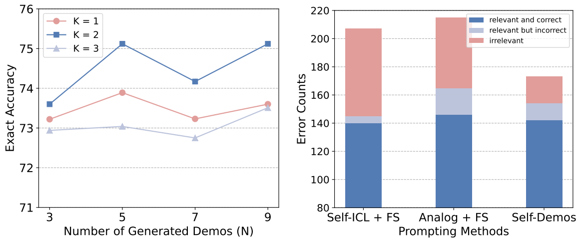
Demonstrating Method	Dataset	
	GSM8K	MATH
Demo Retrieval (Sparse)	79.5	37.0
Demo Retrieval (Dense)	**79.7**	**38.1**
Demo Generation (SELF-DEMOS)	78.2	37.9

Table 5: Comparison with demo retrieval methods on the **GSM8K** and **MATH** datasets. The (Sparse) means sparse retrieval using the BM25 algorithm, and the (Dense) means dense retrieval using `text-embedding-ada-002` API to generate sentence embedding and apply cosine similarity. Both baselines retrieve the Top 5 similar samples from the training set as demonstrations.



(a)

(b)

Figure 4: (a) Comparison of SELF-DEMOS with varying numbers of self-generated demonstrations (N) and selected training exemplars (K). (b) Error distribution of different methods. Demos yielding incorrect answers can be categorized into three types based on relevance and accuracy. Both results are on the **OOD-Toolset**.

ploy a complementary retrieval strategy to improve efficiency and reduce incremental costs.

5.4 Number of Demonstrations Matters

We examine the impact of varying the number of self-generated demos (N) and selected demos (K) in the tool-using task. The details are shown in Figure 4a. Notably, the model performs better when selecting two demos. We suspect that a singular demo is insufficient to grasp all using patterns of an API and additional samples ($K = 3$) may introduce noise and instabilities and hinder model learning. Our configuration ($K = 2, N = 5$) not only maximizes accuracy but also ensures efficiency in computational costs. In our experiments, we further observed a tendency for the model to preferentially select demos positioned towards the front, indicating the phenomenon of position bias (Ko et al., 2020; Nori et al., 2023).

5.5 Error Analysis

Furthermore, we manually analyze the errors of SELF-DEMOS, comparing with the two baselines of demo generation in Figure 4b. Errors were categorized into three distinct types: (1) **Irrelevant demos**: These exemplars are generated in a similar distribution and fail to interpolate between seed demos and given queries. (2) **Relevant but incorrect demos**: This category includes syntactical errors and redundant or inaccurate parameters. The issues contribute to false information propagation and interfere with the final output. (3) **Relevant and correct demos**: Even with correct demonstrations, errors can occur due to the model's inherent limitations and the generalization gap. Based on Figure 4b, all three methods have similar results in Category 3 with approximately 140 errors. However, SELF-DEMOS stands out by greatly lowering the errors in the first two categories. This suggests that SELF-DEMOS is better at generating relevant exemplars, which improves generalization across novel and unseen tasks.

5.6 Computational Overhead Analysis

Our method, based on a multi-step framework, naturally leads to additional computational overhead. In Table 6, we detail this overhead for each method

Prompting Method	**Cost**	**OOD-Toolset**
Few-shot	0.54	71.9 / 76.6
Few-shot + SC (5 Paths)	<u>2.71</u>	72.5 / 77.2
Few-shot + SC (10 Paths)	5.41	72.2 / 77.0
Self-ICL (Few-shot)	<u>2.37</u>	71.5 / 76.0
Analogical Prompting (Few-shot)	1.21	71.1 / 75.4
Self-Demos (Standard)	4.81	**75.1 / 79.4**
Self-Demos (KV Cache Reuse)	<u>2.84</u>	**75.1 / 79.4**

Table 6: Comparison of computational costs on **OOD-Toolset**. The cost is calculated according to OpenAI price list[3], measured in dollars per thousand uses. The methods with similar costs are <u>underlined</u>.

and present another computationally demanding baseline, Self-Consistency, which samples various reasoning paths and generates a consistent answer using a majority vote strategy (Wang et al., 2023b). Complete calculation specifics can be found in Appendix D. Statistically, the standard SELF-DEMOS incurs a higher overhead compared to other approaches, primarily due to the demo generation phase that involves repeating the input N times to generate N demos. This leads to numerous redundant computations (i.e., KV vectors), a drawback that can be alleviated through caching and reusing (Pope et al., 2022). It can be achieved by specifying the parameter $n = N$ upon API invocation[4]. The trick cuts overhead by approximately 41%, reaching computational efficiency on par with Self-ICL and Self-Consistency (5 Paths). However, despite Self-ICL's step 2 necessitating multiple calls to model, its distinct query for each input prevents KV cache reuse (Chen et al., 2023b).

Moreover, SELF-DEMOS offer substantial **long-term cost efficiency**. When demos are limited, the use of our method does result in a higher computational overhead initially. But over time, the high-quality demos that we generate can be preserved, and when a certain amount of them is accumulated, we can apply complementary demo selection methods to reduce the incremental cost and flatten the cost curve. Refer to Appendix A for details.

6 Conclusion

This paper focuses on addressing the challenge of out-of-demonstration (OOD) queries in few-shot learning scenario. We present a novel prompting method, SELF-DEMOS, which elicits the OOD generalizability in LLMs by generating query-aware demos. Our method strategically interpolates between existing demonstrations and the OOD queries, effectively transforming them into in-demonstration (ID) queries. In an OOD setting, SELF-DEMOS achieved state-of-the-art results on the proposed OOD-Toolset and two public mathematical benchmarks. For future works, we aim to explore the scalability of the SELF-DEMOS method across diverse domains and to integrate unsupervised learning techniques to refine the quality of generated demos further.

Limitations

We summarize the limitations of our method as follows: (1) SELF-DEMOS is designed to resolve the out-of-demonstration queries, which can steadily improve downstream task performance, but the process involves additional costs. In Section 5.6, we explore the computational overhead, allowing users to make informed trade-offs depending on their specific task scenarios. (2) Our method necessitates certain capabilities of the model. Although we have done empirical experiments and demonstrated our approach works for weaker models compared to other baselines, it still requires the models to have a certain degree of instruction-following ability.

Ethics Statement

In this paper, we have followed ethical standards and principles to ensure the accuracy and validity of our research. The dataset was manually cleansed to ensure the removal of any sensitive or personal information. The human-annotated data is collected and used in compliance with relevant ethical guidelines. During the data construction process, we followed ToolAlpaca's terms under the Apache License 2.0 (Tang et al., 2023).

Acknowledgment

The authors wish to thank the anonymous reviewers for their helpful comments. This work was partially funded by National Natural Science Foundation of China (No.62206057,61976056,62076069), Shanghai Rising-Star Program (23QA1400200), Natural Science Foundation of Shanghai (23ZR1403500), Program of Shanghai Academic Research Leader under grant 22XD1401100, CCF-Baidu Open Fund, and CCF-Baichuan Fund.

Appendix

A Supplementary Experiments on GPT-4

Model	**OOD-Toolset**	**Cost**
Few-shot		
GPT-4	76.50 / 79.75	∼ 1.12
Self-Demos		
GPT-4 in all steps	80.50 / 83.50	∼ 4.95
GPT-3.5 in all steps	75.50 / 79.50	∼ 0.57
GPT-3.5 reuse GPT-4 demos in step4	76.50 / 79.75	∼ 0.13

Table 7: Comparison of performance and overhead on more powerful models (i.e, GPT-4). The cost is calculated according to OpenAI price list, measured by total dollars spent on 200 instances.

We conducted GPT-4 tests on 200 random OOD-Toolset instances and used its generated demos as inputs for GPT-3.5 in Self-Demos step 4, as detailed in Table 7.

Based on the results, we observe that: (1) GPT-4's advanced capabilities allow it to match the performance of GPT-3.5 using Self-Demos with simply a few-shot approach. However, given the model's enhanced capabilities, it comes with a higher cost. (2) GPT-4 still benefits from the our proposed method, and the high-quality demos it generates remain effective for weaker models. This shows the reusability of demos and proves the way for Self-Demos to reduce long-term costs.

B Details of OOD-Toolset

The raw data from ToolAlpaca (Tang et al., 2023) including the training and testing sets, comprises 468 tool APIs and 4,369 tool-use cases. Due to a lack of validation of the content generated by GPT-3.5, the dataset may contain specific errors, such as ambiguous queries due to outdated or insufficient information and incorrect API calls due to null or wrong values being passed. To address these issues, we implemented a data cleansing process in the following steps:

Rule-based Cleaning. We structured each tool API in the raw data into a dictionary with keys for **API Name**, **Description**, **Usage Specification**, and **Tool-use Cases**. The API name identifies the tool, and the description outlines its purpose. The usage specification clarifies the API call format and required parameters. The tool-use cases consist of user queries and corresponding function call lists. The rule-based cleaning process involved:

- We removed entries with missing keys and formatting errors, particularly those that did not follow the JSON format in the function calls.
- We removed user queries that required more than three function calls to be resolved due to their complexity.
- We removed parameters not directly related to the core functionality of tools, such as API keys and sensitive user information.
- We removed tools with fewer than 3 instances or fewer than 3 functions to ensure that OOD scenarios could be built.

After the first cleaning round, a total of 322 tools and 2,788 instances remained.

Manual Data Cleaning. In manual data cleaning, we emphasize the solvability of given queries. The manual data cleaning process involved:

- We strive to minimize dependencies between function calls, avoiding scenarios where a subsequent function call relies on the results returned by preceding ones. This is to ensure that these queries can be answered in a round of dialog.
- While we avoided the exposure of sensitive user information, some necessary parameters within function calls, such as the email address in the email API, are subjected to obfuscation using a placeholder, for instance, *user@example.com*.
- Time and location information should be explicitly mentioned in the queries, avoiding the use of ambiguous pronouns such as 'today', 'tomorrow', and 'my home'.
- We confirmed the consistency of parameter values with their data types as defined in the usage specifications.

After the second cleaning round, the dataset comprised 321 tools and 2,625 instances. Table 8 presents an illustrative example of the cleaned dataset.

Query and Demonstration Construction. After two rounds of data cleaning, the correctness and solvability of the data have been ensured. Then, we proceeded to select instances from the tool-use cases and construct corresponding demonstrations. During the selection process, we tended to choose longer instances as queries, considering them to be more challenging. Following that, we randomly sampled three other instances from the remaining use cases of the same tool as demos. Note that the sub-APIs to be called for the demos should be different from those required for the chosen queries to fulfill the OOD settings.

Finally, we obtained a set of 1,057 queries, forming our testing set. Table 9 presents an instance of OOD-Toolset.

C Prompt Templates

The prompt templates of SELF-DEMOS for each step in tool-using tasks are presented in Table 10, 11, 12, and 13. Similarly, the prompt templates in mathematical problem-solving tasks are presented in Table 14, 15, 16, and 17.

D Details of Computational Overhead

The details about the computational overhead of each methods are shown in Table 18.

E Case Study

Even SELF-DEMOS performs better than all other methods, there are instances where it falied while others succeeded. We have picked up 3 representative cases for further analysis: (1) SELF-DEMOS succeeded while few-shot / Self-ICL failed, (2) few-shot succeeded while SELF-DEMOS failed, and (3) both failed. Due to space constraints, we put the full case study in our GitHub repository.

API Name: MAP

Description: MAP API is used for calculating distances, planning routes, and locating points.

Usage Specifications:
DISTANCE: Calculate the distance between two points.
Parameters: {"start": "Required. String. The starting point for the distance calculation.", "target": "Required. String. The destination point for the distance calculation."}

ROUTE: Generate a travel route between two points.
Parameters: {"start": "Required. String. The starting point for the route.", "target": "Required. String. The destination point for the route."}

SEARCH: Locate nearby points within a set distance.
Parameters: {"target": "Required. String. The target point to search around.", "position": "Required. String. The current position of the user.", "distance": "Required. Integer. The search radius in kilometers."}

Tool-use Cases:
Query: How far is Beijing to Shanghai?
Function calls: [`DISTANCE(start="Beijing", target="Shanghai")`]

Query: How many shops are around Times Square in 3km?
Function calls: [`SEARCH(target="shop", position="Times Square", distance=3)`]

Query: Show me the route from Los Angeles to San Francisco.
Function calls: [`ROUTE(start="Los Angeles", target="San Francisco")`]

Query: Are there any bookstores within 5km of Central Park?
Function calls: [`SEARCH(target="bookstore", position="Central Park", distance=5)`]

Query: How do I drive from Big Ben to Tower Bridge, and then to the London Eye?
Function calls: [`ROUTE(start="Big Ben", target="Tower Bridge")`,
`ROUTE(start="Tower Bridge", target="London Eye")`]

Query: What's the distance from my home at 123 Main St to the grocery store at 456 Oak St, and from there to my office at 789 Pine St?
Function calls: [`DISTANCE(start="123 Main St", target="456 Oak St")`,
`DISTANCE(start="456 Oak St", target="789 Pine St")`]

Table 8: An illustrative example of the cleaned dataset, composed of four parts: **API Name**, **Description**, **Usage Specifications**, and **Tool-use Cases**. Among them, the tool-use cases are stored as lists.

Seed Demos:
Query: How far is Beijing to Shanghai?
Function calls: [`DISTANCE(start="Beijing", target="Shanghai")`]

Query: How many shops are around Times Square in 3km?
Function calls: [`SEARCH(target="shop", position="Times Square", distance=3)`]

Query: Are there any bookstores within 5km of Central Park?
Function calls: [`SEARCH(target="bookstore", position="Central Park", distance=5)`]

Query: How do I drive from Big Ben to Tower Bridge, and then to the London Eye?

Table 9: An instance of OOD-Toolset corresponds to the tool in Table 8, where the function required for the **Query** is ROUTE. Consequently, tool-use cases related to this sub-API should not be included in the **Seed Demos**.

The `{tool_name}` API is used for `{description}`. In this task, you need to give a general understanding of the user query and determine which function should be called to solve the query.

 # Tool Specification:
`{specification}`

 # User Query:
`{query}`

 # Instruction:
Generate a general understanding here. In particular, you need to explicitly indicate the name of the function that should be called.

Table 10: Prompt template for Query Understanding (Step 1) on the OOD-Toolset.

The `{tool_name}` API is used for `{description}`. In this task, you need to give an example of when to use the API based on the specification.

 # Tool Specification:
`{specification}`

 # Demonstration:
`{seed_demos}`

 # Instruction:
Generate an example of how to use the `{function_mentioned_in_step1}` function.
- After "Query: ", describe the user query.
- After "Function Calls: ", give the function calls in the format of ["function_name(parameter=value)"].

Table 11: Prompt template for Query-aware Demo Generation (Step 2) on the OOD-Toolset.

The `{tool_name}` API is used for `{description}`. Here are some examples of how to use the API. In this task, you must check the examples for correctness and select one or two best examples to keep.

 # Tool Specification:
`{specification}`

 # Check List:
- Syntax errors: the function calls should conform to the format like "function_name(parameter=value)".
- Redundant parameters: the function calls must conform to the parameter list in the tool specification.
- Value passing errors: the values of parameters should be of the correct type and reasonable.
- Unsolvable errors: the query should be solvable with the given function.

 # Examples to be Checked:
`{generated_demos}`

 # Instruction:
Select one or two best examples to keep. If there are not enough correct examples, just keep one.
For your output:
- After "Selection: ", give the serial numbers of your choice in the format of <x>, <y>.
- After "Explanation: ", give the reason why you keep the examples.

Table 12: Prompt template for Best-of-N Sampling (Step 3) on the OOD-Toolset.

The `{tool_name}` API is used for `{description}`. In this task, you must generate the function calls for a given query.

 # Tool Specification:
`{specification}`

 # Demonstration:
`{seed_demos}`
`{selected_demos}`

 # Instruction:
Solve the following user query.
Query: `{query}`
Function calls: Give your answer in the format of ["function_name(parameter=value)"].

Table 13: Prompt template for Response Generation (Step 4) on the OOD-Toolset.

In this task, you need to give a general understanding of mathematical problems, which can be applied to all similar questions in the same scenario.

 # Problem:
`{question}`

 # Instruction:
Give a general understanding of this problem in one line. Highlight the general solution methodologies to solve this type of problem. Focus on the problem-solving approach without delving into specific numerical values or answers.
You can refer to this template for your understanding: This problem involves...To solve this type of problem...

Table 14: Prompt template for Query Understanding (Step 1) on the GSM8K and MATH datasets.

In this task, you need to recall mathematical problems. When presented with a math problem, recall another relevant problem as an example. The example should help answer the initial problem.

 # Problem:
The initial problem:
`{question}`

The understanding you can refer to:
`{understanding}`

 # Demonstration:
`{seed_demos}`

 # Instruction:
Recall one example of a math problem relevant to the initial problem. The example should be distinct from the initial problem (e.g., involving different numbers and names).
- After "Question: ", describe the problem you generate in one line.
- After "Answer: ", explain the step-by-step solution and enclose the ultimate answer in \boxed{}.

Table 15: Prompt template for Query-aware Demo Generation (Step 2) on the GSM8K and MATH datasets.

In this task, you need to check the correctness of these math Q&A pairs and select one or two best examples to keep for answering the initial problem.

 # The initial problem:
`{Question}`

 # Check List:
- The calculation process in the solution must be correct and without ambiguity.
- The examples should be relevant and helpful in solving the initial problem.

 # Examples to be checked:
`{generated_demos}`

 # Instruction:
Select one or two best examples to keep. If there are not enough correct and helpful examples, just keep one.
For your answer:
- After "Selection: ", give the serial numbers of your choice in the format of <x>, <y>.
- After "Explanation: ", give the reason why you keep this example.

Table 16: Prompt template for Best-of-N Sampling (Step 3) on the GSM8K and MATH datasets.

Your task is to tackle mathematical problems step by step. You can refer to these demonstrations to give your reasoning process.

 # Demonstration:
`{seed_demos}`
`{selected_demos}`

 # Instruction:
Solve the following problem step by step.
Question: `{Question}`
Answer: Explain the step-by-step solution and enclose the ultimate answer in \boxed{ } here.

Table 17: Prompt template for Response Generation (Step 4) on the GSM8K and MATH datasets.

Prompting Method	**Avg. #tokens of Input**	**Avg.#tokens of Output**	**Cost**	**OOD-Toolset**
Few-shot	496.0	22.6	0.54	71.9 / 76.6
Few-shot + SC (5 Paths)	$496.0 \times 5 = 2480.0$	$22.6 \times 5 = 113.0$	2.71	72.5 / 77.2
Few-shot + SC (10 Paths)	$496.0 \times 10 = 4960.0$	$22.6 \times 10 = 226.0$	5.41	72.2 / 77.0
Self-ICL (Few-shot)	$456.4 + 498.4 \times 2 + 625.1 = 2078.3$	$78.7 + 23.6 \times 2 + 22.2 = 148.1$	2.37	71.5 / 76.0
Analogical Prompting (Few-shot)	598.0	304.5	1.21	71.1 / 75.4
Self-Demos (Standard)	$323.6 + 490.8 \times 5 + 776.4 + 606.4 = 4160.4$	$3.4 + 58.0 \times 5 + 7.7 + 22.5 = 323.6$	4.81	**75.1 / 79.4**
Self-Demos (KV Cache Reuse)	$323.6 + 490.8 + 776.4 + 606.4 = 2197.2$	$3.4 + 58.0 \times 5 + 7.7 + 22.5 = 323.6$	2.84	**75.1 / 79.4**

Table 18: Average number of input and output tokens of different methods on **OOD-Toolset**. In the equation, each term being added represents the average number of tokens per step (used only within a multi-step framework), while each multiplier indicates the number of times that step is called.

Getting Sick After Seeing a Doctor? Diagnosing and Mitigating Knowledge Conflicts in Event Temporal Reasoning

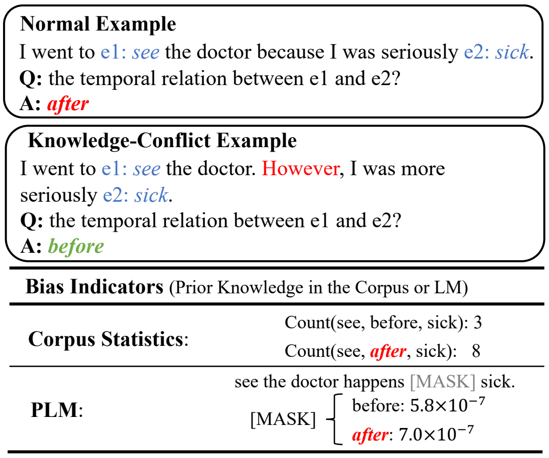
Abstract

Event temporal reasoning aims at identifying the temporal relations between two or more events from narratives. However, *knowledge conflicts* arise when there is a mismatch between the actual temporal relations of events in the context and the prior knowledge or biases learned by the model. In this paper, we propose to detect knowledge-conflict examples in event temporal reasoning using bias indicators, which include *event relation prior* bias, *tense* bias, *narrative* bias, and *dependency* bias. We define conflict examples as those where event relations are opposite to biased or prior relations. To mitigate event-related knowledge conflicts, we introduce a Counterfactual Data Augmentation (CDA) based method that can be applied to both Pre-trained Language Models (PLMs) and Large Language Models (LLMs) either as additional training data or demonstrations for In-Context Learning. Experiments suggest both PLMs and LLMs suffer from knowledge conflicts in event temporal reasoning, and CDA has the potential for reducing *hallucination* and improving model performance[1].

1 Introduction

An important goal of event understanding is to identify the temporal relations (TEMPRELS) among events described in natural language text (Chambers et al., 2007). This task aligns with human's cognitive ability (Zacks and Tversky, 2001; Zacks et al., 2007), which often involves routinely reasoning about how events happening around us are temporally sequenced, planned, and lead to consequences and decisions (Schank and Abelson, 1977). From the intelligent system perspective, it also benefits many NLP applications for narrative understanding (Li et al., 2018; Cai et al., 2022), schema induction (Li et al., 2021), and question answering (Zhu et al., 2017; Stricker, 2021).



Normal Example
I went to e1: *see* the doctor because I was seriously e2: *sick*.
Q: the temporal relation between e1 and e2?
A: ***after***

Knowledge-Conflict Example
I went to e1: *see* the doctor. However, I was more seriously e2: *sick*.
Q: the temporal relation between e1 and e2?
A: ***before***

Bias Indicators (Prior Knowledge in the Corpus or LM)

Corpus Statistics:
Count(see, before, sick): 3
Count(see, ***after***, sick): 8

PLM:
see the doctor happens [MASK] sick.
[MASK] before: 5.8×10^{-7}
[MASK] ***after***: 7.0×10^{-7}

Figure 1: An example of a knowledge-conflict instance. The actual TEMPREL in the context differs from the biased or prior TEMPREL in the corpus and the language model, leading to the emergence of *knowledge conflicts*.

In event temporal reasoning, the input includes two parts, the event mentions and the context. The TEMPREL a model seeks to infer should be based on the context, rather than only revealed by the event mentions themselves. For example, in Fig. 1, without a context, the event mention *see* (the doctor) and *sick* have certain temporal prior where *see the doctor* statistically happen more often after *sick*, either by corpus statistics or probing a masked PLM. However, under the context of "I went to see the doctor, *However*, I was more seriously sick," we can infer that *see* happens before *sick* instead of after due to the presence of the connective *However*. This is known as the phenomenon of *knowledge conflicts* (Longpre et al., 2021), where the contextual information contradicts the knowledge memorized by the language model. Hence, the essential requirement for accountable temporal reasoning is *context-faithfulness* (Wang et al., 2023b; Zhou et al., 2023), where models are expected to perform reasoning based on the context instead of *guessing* using only the prior knowledge about the events

encoded in their parameters.

However, most current language models, including both Pre-trained Language Models (PLMs) and Large Language Models (LLMs)[2], rely on shortcuts from the mentions without being faithful to the context (Xu et al., 2022; Bender et al., 2021) to varying degrees, leading to *hallucination*. This issue is particularly severe in contexts where event or entity mentions have a different relation prior than what is presented in the context. Though entity-related knowledge conflicts (Longpre et al., 2021; Wang et al., 2022a; Li et al., 2022) have recently attracted much attention, questions about event-related knowledge conflicts remained intact.

First, it is necessary to understand the conflicts regarding *relations* of events, which is more complicated than that of a single event. Second, the substitution-based paradigm defined in entity knowledge conflicts or spurious correlation detection (Longpre et al., 2021) cannot be directly applied to events. Entity mentions can often be replaced randomly with other entities with the same typing to study the faithfulness towards the context other than the entity mention, which remains unchanged after the replacement. For example, in open-domain QA, a possible question can be "Who is the CEO of Twitter?" based on the context "Yaccarino succeeded Elon Musk as the CEO of Twitter". To check whether models faithfully rely on the context instead of hallucinating, *Yaccarino* in the context can be changed to a random name to see if the model can still output the "correct" CEO instead of *Yaccarino* as they have learned in pre-training. However, events are usually denoted by predicates in the context (Bethard et al., 2007), and directly substituting the predicate (e.g., from *see* in Fig. 1 to another random verb such as *play*) will alter the semantic meaning of the whole context, including both the predicate and its dependency with the arguments, making it infeasible to analyze the *faithfulness* towards the *original* context. Thus, instead of resorting to a substitution, in this paper, we study the effect of knowledge conflicts in event temporal reasoning by *selecting* conflict examples from the original dataset based on corpus statistics, and evaluate models on the conflict subsets.

We outline the contributions of this paper as follows. First, we define four types of bias that can lead to knowledge conflicts, including *event-relation* bias, *narrative* bias, *tense* bias, and *dependency* bias. The data instances where the actual TEMPREL contradicts with the prior TEMPREL are referred to as knowledge-conflict instances (§3), as they conflict with the prior knowledge provided to language models. Second, to mitigate the effect of knowledge conflicts, we propose a Counterfactual Data Augmentation (CDA) technique that explicitly generates contexts with knowledge-conflict elements, thereby reducing the overall bias in the data distribution. CDA can be applied to both fine-tuned PLMs and LLMs with (test-time) in-context learning (§3.3). Third, we study the effect of various kinds of knowledge conflicts and our proposed bias mitigation method on two popular event temporal reasoning benchmarks, TORQUE (Ning et al., 2020) and MATRES (Ning et al., 2018). We show that models suffer from performance drop on knowledge-conflict subsets, and our bias-aware data augmentation method outperforms baselines by a remarkable margin on both bias mitigation and overall performance (§4).

2 Related Works

Event Temporal Reasoning. Event temporal reasoning aims at identifying the temporal relations (TEMPREL) of events in narratives. There are two common ways of formulating this problem. The first formulation is the TEMPREL extraction task, which involves determining the TEMPREL between two annotated event triggers from a pre-defined relation set (Bethard et al., 2007, 2017; Ning et al., 2018; Naik et al., 2019). Meanwhile, another formulation is a reading comprehension task, which involves determining more complicated TEMPRELS expressed in natural language questions (Ning et al., 2020; Han et al., 2021). To conduct event temporal reasoning, literature has leveraged various approaches, including graph neural networks (Zhang et al., 2022; Zhou et al., 2022), rhetorical discourse features and temporal arguments from semantic role labels (Mathur et al., 2021), distant supervision (Zhou et al., 2021; Zhao et al., 2021), and event relation joint learning (Wang et al., 2020, 2023c, 2022b). LLMs such as GPT3 (Brown et al., 2020) and ChatGPT are also leveraged for event temporal reasoning (Chan et al., 2023) with carefully designed prompts and In-Context Learning. Our work differs from previous studies in that we study the knowledge conflicts in event temporal

---

[2] PLMs, or smaller models, are used in a pre-train and fine-tune paradigm, while LLMs, larger and more powerful models with over 10B parameters, are commonly employed through in-context learning (Sun, 2023).

reasoning and how to mitigate them.

Knowledge Conflict in Language Models. Knowledge conflicts have been widely studied for entity-centric NLU tasks (Schuster et al., 2021; Wang et al., 2024). For example, Longpre et al. (2021) studied the knowledge conflict in open-domain question answering using entity substitution. Li et al. (2022) also adopted this strategy to study the enhancement of a PLM's robustness against context noise with a knowledge-aware working memory. Schuster et al. (2021) proposed a dataset using the user edits in Wikipedia as subtle changes for the context and study the effect of such changes on language models. Xu et al. (2022) systematically formulate six types of biases in entity typing to study spurious correlations. Certain types of biases, such as Mention-Context and Named Entity bias, can reflect knowledge conflicts in entities. Typical mitigation methods of knowledge conflicts include causal analysis and coutnerfactual analysis (Wang et al., 2023a, 2022a), and test-time-only LLM prompting methods using counterfactual demonstration and opinion-based prompting (Zhou et al., 2023). However, the knowledge conflicts of event-event TEMPRELS are under-explored. Feng et al. (2022) proposed a dataset studying the differential effects of TEMPREL reasoning given additional contexts, while their focus is on annotating additional out-of-distribution data instead of exploring existing knowledge conflicts within the dataset. Our work systematically defines and detects knowledge conflicts in event temporal reasoning and proposes a data-augmentation-based method to mitigate those conflicts based on the detected bias.

3 Event Knowledge Conflict

We introduce the problem definition (§3.1) and formally define four types of bias and how to select knowledge-conflict data (§3.2). We then introduce our proposed Counterfactual Data Augmentation for mitigating knowledge conflict (§3.3).

3.1 Problem Definition

In event temporal reasoning, the primary objective is to determine the TEMPREL between two or more events. Without the loss of generality, our study is based on pairwise event relations: the relation r of an event pair (e_1, e_2) based on the context c. More complex cases can be easily addressed by breaking down the relations involving multiple events into pairwise relations. For example, in TORQUE, a question might be formulated as "what happens before e?", where e can be a target event trigger. Then, the answers $e_{a1}, e_{a2}, \cdots$ can form multiple event pairs (e, before, e_{ai}), where $i = 1, 2, \cdots$, etc. The case where evaluating the temporal status of a single event (*happened*, *happening*, *will happen*, etc.) can also be easily adapted in this framework by replacing the features of event pairs to a single event.

To study event-related knowledge conflict, we create an automated framework to use corpus co-occurrence statistics to select conflict subsets. Similar to the co-occurrence statistics in *reporting bias* (Gordon and Durme, 2013), to obtain knowledge-conflict data, we first define bias, as the *opposite* side of the conflict. We identify four types of bias in event temporal reasoning and defined corresponding bias statistics. We then selected a subset of the original dataset where feature-relation pairs were rare (i.e., *knowledge-conflict*) based on the bias scores. As the (reporting) bias in the training corpus is usually learned and amplified by the language models (Shwartz and Choi, 2020), our selected subsets, which represent the opposite side of the bias, conflict with the knowledge encoded in the language models.

3.2 Knowledge Conflict Diagnosis

We first define a bias score $b(P_1, P_2, r)$ with regard to certain patterns (P_1 and P_2) against a specific relation $r \in R$, where R is a subset of all relations defined in a certain dataset. Patterns P_i can be the event lemmas themselves, tense, dependency patterns, and narrative orders of either event. Sometimes (P_1, P_2) is represented by one feature only, for example, the dependency relation and narrative orders between two events. Denote $c(P_1, P_2, r)$ as the number of occurrences of (P_1, P_2) under relation r in a corpus, and the bias score is defined as:

$$b(P_1, P_2, r) = \frac{c(P_1, P_2, r)}{\sum_{r' \in R} c(P_1, P_2, r')} \tag{1}$$

For example, in tense bias, the bias score of the tense pattern (VBD, VBZ) (*past tense* and *third person singular present tense*) when only considering two relations $R = \{before, after\}$ is defined as:

$$b(\mathsf{VBD}, \mathsf{VBZ}, \textit{before}) = \frac{c(\mathsf{VBD}, \mathsf{VBZ}, \textit{before})}{c(\mathsf{VBD}, \mathsf{VBZ}, \textit{before}) + c(\mathsf{VBD}, \mathsf{VBZ}, \textit{after})} \tag{2}$$

Knowledge Conflict Detection. In a set of relations, those with higher bias scores indicate higher

Type	Context & Label	Bias Scores
Relation Prior (relation)	(TORQUE) Chidambaram e_1:drew up the previous United Front government's Indian budget for 1997-98 which is to be e_2: approved by parliament this week . Gujral has e_3: adopted the same budget. **Question:** What will happen after e_1: drew? **True label:** e_2: approve. **Biased Prediction:** e_3: adopted	$b(\textit{draw}, \textit{adopt}, \textit{before}) = 1.0$ $b(\textit{draw}, \textit{approve}, \textit{before}) = 0$
Relation Prior (warm-up)	**Question:** What will happen in the future? **True label:** e_2: approve. **Biased Prediction:** e_3: adopt	$b(\textit{approve}, \textit{happened}) = 0.9$ $b(\textit{approve}, \textit{future}) = 0.05$
Tense (relation)	(MATRES) Albright e_1: told (`VBD`) ambassadors of 30 African countries in Washington, who came to the State Department to e_2: offer (`VB`) condolences. **True label**: e_1 happens *after* e_2; **Biased Prediction:** *before*	$b(\texttt{VBD}, \texttt{VB}, \textit{before}) = 0.70$ $b(\texttt{VBD}, \texttt{VB}, \textit{after}) = 0.27$ $b(\texttt{VBD}, \texttt{VB}, \textit{equal}) = 0.03$
Tense (warm-up)	(TORQUE) That's what will e_1: keep computer makers e_2: coming (`VBG`) in spite of the e_3: irritation of e_4: bugs. **Question:** What will happen in the future? **True Label:** e_1, e_2: coming; **Biased Prediction**: e_1	$b(\texttt{VBG}, \textit{happened}) = 0.42$ $b(\texttt{VBG}, \textit{future}) = 0.13$ $b(\texttt{VBG}, \textit{happening}) = 0.45$
Narrative	(MATRES) Now events are e_1: doing the work for Schumer. Slepian's death was among the first topics e_2: raised in Saturday night's debate between the two men, ... ; **True label**: e_1 happens *after* e_2; **Biased Prediction:** *before*	$b(p_1 < p_2, \textit{before}) = 0.59$ $b(p_1 < p_2, \textit{after}) = 0.37$ $b(p_1 < p_2, \textit{equal}) = 0.04$
Dependency	(MATRES) Castro e_1: said Gonzalez would e_2: travel with his current wife and their son (Dependency: *says* → `ccomp` → *travel*) **True label**: e_1 happens *before* e_2; **Biased Prediction:** *after*	$b(\texttt{ccomp}, \textit{before}) = 0.66$ $b(\texttt{ccomp}, \textit{after}) = 0.32$ $b(\texttt{ccomp}, \textit{equal}) = 0.02$

Table 1: Examples of different forms of knowledge conflicts.

degrees of bias towards certain relations, and others with lower bias scores indicate higher degrees of knowledge conflict. We select instances whose patterns do *not* follow the majority distribution in the training set as knowledge-conflict instances. A new instance in the test set with a pattern-relation pair (P_1, P_2, r) is considered knowledge conflict if the bias score is less than the context-free frequency of relations $b(P_1, P_2, r) < \frac{c(r)}{\sum_{r' \in R} c(r')}$. Moreover, to ensure a significant degree of conflicts, we set a threshold $\mathcal{T}_r$ such that $b(P_1, P_2, r) < \mathcal{T}_r < \frac{c(r)}{\sum_{r' \in R} c(r')}$, to ensure that the conflict is large enough[3]. For example, a test instance where the event with a past tense happens *after* the event with a present tense may be selected as a knowledge-conflict instance, as the context makes the actual TEMPREL different from the biased relation *before*.

Next, we introduce the definitions of different forms of bias in detail.

Relation Prior Bias. Bias toward certain TEMPRELS exists because there are natural *selectional preference* (Wilks, 1975) between the specific events. For example, in the TORQUE dataset, *arresting* dominantly happen after *killing*, and *voting* more often happens before *winning*. These findings suggest that the occurrence of certain events may be more likely to follow or precede other events, which can however, lead to bias when the context describes the TEMPREL differently from the most frequent cases. Our definition of the bias scoring function is based on the frequency of the co-occurrence of event e_1 and e_2 under relation r:

$$b(e_1, e_2, r) = \frac{c(e_1, e_2, r)}{\sum_{r' \in R} c(e_1, e_2, r')} \tag{3}$$

Narrative Bias. Narrative bias in event temporal reasoning is the tendency for the model to interpret the chronological order of the events to be the same as their narrative order. However, these two orders, though more often accord with each other, do not always necessarily follow the same (Zwaan et al., 1995). In this sense, we only study *before*, *after*, and *equal* relations for narrative bias. Denote $p = P(e, c)$ as the position of event e in context c, where the earlier position of e indicates that this event is described earlier in the narrative. The bias scoring function is defined as follows for the case where the positions of the two events follow the order of $p_1 < p_2$:

$$b(p_1 < p_2, \textit{before}) = \frac{c(p_1 < p_2, \textit{before})}{\sum_{r' \in R} c(p_1 < p_2, r')} \tag{4}$$

We select the event pairs where $p_1 < p_2$ while the actual relation is (e_1, *after/equal*, e_2) or $p_1 > p_2$ while the actual relation is (e_1, before/equal, e_2) as the knowledge-conflict examples.

Tense Bias. Tense bias is the tendency to rely on the grammatical tense of verbs as evidence for the

---

[3] Hyperparameter analysis on $\mathcal{T}_r$ is presented in Appx. §A.

temporal order of events. For example, past tense is typically used to describe events that occurred *before* the present moment, while present tense is typically used for events that are happening now or in the future. However, this grammatical convention does not always correspond to the actual temporal order of events. Denote t_1 and t_2 as the tense (POS-tags parsed by Spacy [4] as more fine-grained tense information) of event e_1 and e_2 under context c, then the bias score is defined as:

$$b(t_1, t_2, r) = \frac{c(t_1, t_2, r)}{\sum_{r' \in R} c(t_1, t_2, r')} \tag{5}$$

Dependency Bias Dependency bias is the tendency to rely on syntactic dependency patterns in language as evidence for the temporal order of events. For example, if two events e_1 and e_2 are directly connected in the dependency tree, the dependency pattern $(e_1, \texttt{dobj}, e_2)$ (where e_1 is the subject of the sentence, e_2 is the direct object, and `dobj` is the dependency between them) often indicates that e_1 is the entity performing an action on e_2. This pattern may suggest that e_1 must occur before e_2 in time, but this is not always the case. Denote d as the dependency relation between e_1 and e_2 in context c (d is null if e_1 and e_2 are not directly linked in their dependency tree).

$$b(d, r) = \frac{c(d, r)}{\sum_{r' \in R} c(d, r')} \tag{6}$$

We summarize the core features of each defined bias associated with examples in Tab. 1. Our focus is particularly on two datasets, namely TORQUE and MATRES, which will be presented in §4.1. Prior to that, we introduce our proposed conflict-mitigating method first.

3.3 Counterfactual Data Augmentation

In this sub-section, we introduce our proposed Counterfactual Data Augmentation (CDA) method for mitigating knowledge conflicts (Fig. 2). We discuss the usage of CDA on both PLM and LLM separately, as they differ in their applications. Detailed adaptations and prompts will be introduced in §4.3 and Appx. §F.2.

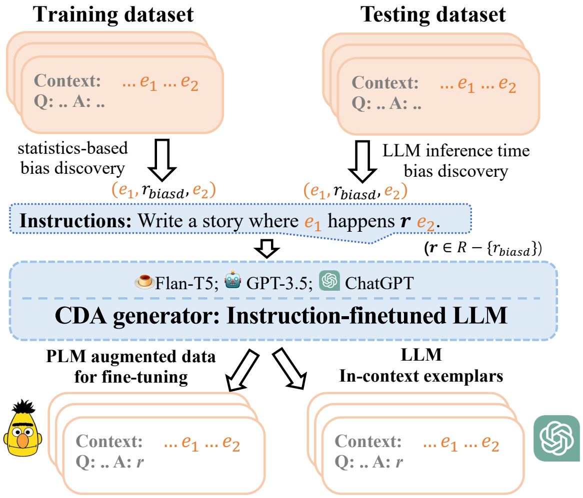

Figure 2: An overview of the CDA pipeline.

Pre-trained Language Models. PLMs are usually fine-tuned on a training corpus, which naturally contains event-relation biases that tend to be amplified after fine-tuning (Hall et al., 2022). To mitigate bias, our proposed method automatically generates context that contains event pairs whose actual temporal relation is different from the biased relation. Such knowledge-conflict (counterfactual) counterparts are trained together with the original training corpus to mitigate the biased training distribution. To be more specific, for each event pair (e_1, e_2) that is identified as biased, we ask an Instruction-finetuned Language Models (Chung et al., 2022) to generate context where (e_1, e_2) are associated with a TEMPREL that leads to a low bias score of a certain bias type. Such augmented data can be regarded as knowledge-conflict data. The intuition is that, even though language models may suffer from bias and cannot directly solve the task, they can be well applied to generate synthetic data under structured instructions (Josifoski et al., 2023).

Large Language Models. The go-to way of using LLMs for downstream tasks is test-time In-Context Learning, as fine-tuning of the LLM is typically impractical or unviable. In this case, we extend the idea of Counterfactual Data Augmentation to automatically generate counterfactual examples for in-context learning. Unlike the data augmentation in PLMs, we generate counterfactual counterparts for every event pair to be studied. For a new event pair (e_1, e_2) to be studied, we first acquire the predicted relation r_{LLM} by the LLM. We leverage the LLM to generate context examples where (e_1, e_2) are associated with relations that belong to $R - \{r_{LLM}\}$ as counterfactual examples to showcase the LLM the alternative cases when (e_1, e_2) happens following a different TEMPREL. Note that this method is still considered a zero-shot as no training examples are seen during inference.

4 Experiments

In this section, we introduce the datasets (§4.1), the settings of knowledge conflict diagnosis (§4.2), and conflict mitigation (§4.3), the primary experimental results and analysis (§4.4).

4.1 Datasets and Evaluation Metrics

We select two event temporal reasoning datasets[5].

TORQUE: Ning et al. (2020) is a reading comprehension benchmark with a focus on event temporal reasoning questions.

MATRES: MATRES (Ning et al., 2018) is a TEMPREL extraction dataset that includes refined annotations from documents in different domains. The TEMPRELS of interest are nailed to $R = \{$*before, after, equal, vague*$\}$. We randomly sample 1,000 entries (out of ∼6k) from the development set to perform evaluations for LLMs[6].

We use Exact-Match (EM) and F1 as the evaluation metric for TORQUE, and Micro/Macro F1 for MATRES. (Macro) F1 is used as the primary metric, due to the imbalanced distribution of labels[7].

4.2 Knowledge Conflict Diagnosis

We apply the bias statistics introduced in §3 on the training set to select knowledge-conflict subsets from both TORQUE and MATRES development sets. In MATRES, we directly make use of the TEMPREL information (e_1, e_2, r) provided in each data entry to count the occurrence and calculate bias. However, in TORQUE, the problem is formulated as reading comprehension, which requires further pre-processing to acquire pairwise TEMPRELS. Specifically, we parse each question to acquire the temporal predicate and arguments to form a (e_1, e_2, r) format. In addition, TORQUE includes *warm-up* questions that analyze whether a single event has *happened*, *will happen*, or *is happening*. Our study calculates bias statistics based on a *single* event and its temporal status relative to a time expression in the context. The bias in warm-up questions are labeled with *warm-up*, while the other questions studying event-pair relations are labeled with *relation*.

TORQUE	
Rel.Prior	b(kill, arrest, *before*)=0.69, b(bombing, condemn, *before*)=0.67
	b(incident, *happened*)=1,b(host, *future*)=0.91, b(progress, *happening*)=1
Tense	b(`VBN`, `VB`, *before*)=0.64,b(`VBN`, `VBD`, *before*)=0.48, b(`VBD`, `VB`, *before*)=0.55
	b(`VBD`, *happened*)=0.95,b(`VB`, *future*)=0.60, b(`VBZ`, *happening*)=0.62
Narrative	b($p1$<$p2$, *before*)=0.50,b($p1$<$p2$, *after*)=0.32, b($p1$<$p2$, *equal*)=0.03,b($p1$<$p2$, *vague*)=0.13
Dependency	b(`xcomp`, *before*)=0.81,b(`ccomp`, *after*)=0.70
MATRES	
Rel.Prior	b(say, have, *after*)=1,b(rise, close, *before*)=1, b(have, close, *before*)=0.83
Tense	b(`VBN`, `VB`, *before*)=0.80,b(`VBN`, `VBP`, *before*)=0.78, b(`VBD`, `VB`, *before*)=0.70
Narrative	b($p1$<$p2$, *before*)=0.50,b($p1$<$p2$, *after*)=0.32, b($p1$<$p2$, *equal*)=0.03,b($p1$<$p2$, *vague*)=0.13
Dependency	b(`xcomp`, *before*)=0.61,b(`ccomp`, *after*)=0.60

Table 2: Selected top biased event features in TORQUE and MATRES.

In addition, Tab. 2 lists the most biased features selected for both datasets. We can find some bias, for example, a past tense is more often predicted as *before* a present tense. More details on the hyperparameters and statistics of knowledge conflict diagnosis are presented in Appx. §A, Appx. §D, and Tab. 8 in the Appendix.

4.3 Setup for Conflict Mitigation

Counterfactual Data Augmentation. We introduce the details of conducting Counterfactual Data Augmentation here. In augmentations for PLM, we choose Flan-T5 (11B) (Chung et al., 2022) as a more scalable generator (than API-based LLMs). For each event pair (e_1, e_2, r) identified as being biased according to *Relation Prior Bias*, we generate context with the prompt *Write a story where* e_1 *happens* r' e_2*:*, where $r' \in R - \{r\}$ (e.g., r'=*before*). In TORQUE, we thus construct a question Q=*"What happened* r' e_2*"*, and the corresponding answer is e_1. Based on the coarse data, we apply additional filters to only retain those that are not biased in terms of tense and narrative.

For LLMs, we ask the model itself to predict the labels of the test data first. Take MATRES as an example, denote r_{LLM} as the *factual* prediction by the LLM, and then we ask the LLM itself to *Generate a paragraph where event* e_1 *happens* r' e_2, where $r' \in R - \{r_{LLM}\}$. More detailed prompts are presented in Appx. §F.2.

Model Configuration. We perform experiments using both PLMs and LLMs . For PLMs we use RoBERTa-large (Liu et al., 2019) as the backbone. We use GPT-3.5 (`text-davinci-003`) and Chat-

Table 3: Experimental results on the TORQUE dataset. Exact-Match (EM) rate and Macro-F1 (F1, regarded as the primary metric * since EM can be susceptible to manipulation by simply predicting 'none') scores are reported. Best-performed results are **bold-faced** and the second-best are underlined.

GPT (`gpt-3.5-turbo`) as the backbone LLM[8].

Baselines. We compare our proposed methods with other representative bias mitigation approaches, including Product-of-Experts (PoE; Hinton 2002; He et al. 2019), Learned-mixin (Clark et al., 2019), Counterfactual Inference (Wang et al., 2022a, 2023b), and AFLite (Le Bras et al., 2020). These baselines are typical bias-agnostic debiasing baselines that address known or unknown bias with statistical approaches. For LLMs, we use the vanilla In-Context Learning (ICL) by randomly retrieving one set of exemplars from the training set as demonstrations. Note that ICL is considered few-shot learning while our method is purely *zero-shot*. In addition, to study the effect of the strategy for generating *counterfactual* exemplars, we add an additional baseline named *Generative Data Augmentation* (GDA) that performs exemplar generation without counterfactual guidance[9].

4.4 Results and Analysis

We present the main experimental results for TORQUE in Tab. 3 and for MATRES in Tab. 4[10]. The *all* row indicates the performance on the whole evaluation set. The *Confl.Avg.* column is an average of all knowledge-conflict subsets, measuring models' ability on mitigating knowledge conflicts. The columns in between indicate the performance on each knowledge conflict types, evaluated on the detected subsets.

Impact of Knowledge Conflicts. Models on both TORQUE and MATRES show a decrease in performance when evaluated on knowledge-conflict subsets. Tab. 5 shows a comparison of baseline model performance on the conflict and non-conflict partitions of MATRES. The comparison on TORQUE is presented in Tab. 7 in the Appendix, showing a similar trend. This finding indicates that the selected conflict subsets are indeed more confusing for language models, proving the effectiveness of our conflict detection framework.

For LLMs, the overall performance is not satisfactory compared with fully-supervised models, which is in line with the findings in several evaluation works on LLMs (Chan et al., 2023; Zhou et al., 2023; Yuan et al., 2023), due to the fact that such tasks focusing on specific types of contextualized reasoning, when not trained with instruction fine-tuning, often lead to poor performance (Zhang et al., 2023). Nonetheless, since LLMs are not fine-tuned on the biased training set, their performance on knowledge-conflict subsets does not drop as significantly in comparison to that on the entire evaluation set, while even being better in some cases. This suggests that zero-shot predictions using LLM can be more generalizable when not trained on smaller

and biased data.

Knowledge Conflicts Mitigation. CDA significantly improves the performance of the vanilla PLM RoBERTa-large both on the entire evaluation set and on each of the knowledge-conflict subsets. Bias-agnostic baselines adopt a model trained only with event arguments and without context, which performs debiasing by countering event-relation bias. This yields competent results related to the relationship prior bias. The counterfactual inference is more effective than other fine-tuned-based methods, as also reported by previous work (Wang et al., 2022a). However, bias-aware data augmentation methods are generally more effective, as they explicitly address different forms of bias and have a more focused performance on biased datasets.

As for LLMs, on MATRES, CDA-based demonstrators can improve the performance on both the whole evaluation set and all the knowledge conflict datasets, with the exception of a minor setback compared to ChatGPT-GDA in terms of *Confl.Avg.* Macro-F1. On TORQUE, CDA on ChatGPT outperforms all baselines in terms of overall performance and *Confl.Avg.* on the main metric F1. For GPT-3.5, the zero-shot setting surprisingly achieves the best overall performance. However, CDA can outperform GDA, indicating that adding a counterfactual prior can better help LLMs to understand event temporal reasoning. Another noteworthy point is that our CDA method is purely zero-shot compared with ICL, showing the superiority of applying counterfactual guidance to LLMs.

Error Analysis on Different Bias Types Taking MATRES as an example, zero-shot prediction by GPT-3.5 suffers significantly from narrative bias, where the performance is near-zero. This finding is consistent with two other different prompt templates (Tab. 17 in the appendix). This is mainly because GPT is an autoregressive model following a single-directional encoding, and it may not be fine-tuned on temporal reasoning data to understand the chronological orders, making it uses a shortcut to rely on positions of events to conduct reasoning. ChatGPT, on the other hand, suffers from dependency bias the most, where there are syntactic dependencies between the two target events. This may be attributed to that ChatGPT, though having a stronger text generation ability, falls short of solving more subtle and contextual cases for temporal reasoning, as events that have a direct dependency edge typically occur in close proximity within the context. However, reasoning about such scenarios can be challenging, even for humans, due to their subtle nature (Yuan et al., 2023).

Quality Analysis of Generated Data As the generated data are used for better training/prompting language models, the quality of them is reflected by the downstream performance improvement. In the appendix, we compare our CDA with popular task-agnostic data augmentation techniques in Tab. 12 and Tab. 13, and show that our CDA method can better help boost both the performance in terms of both knowledge-conflict and overall performance. Regarding LLMs, the comparison between GDA and our CDA also demonstrated the fact the augmented data with a counterfactual constraint can better help both overall and knowledge-conflict reasoning ability.

Why CDA doesn't outperform ICL in TORQUE. For GPT-3.5, ICL indeed consistently outperforms our proposed CDA. We have manually checked the plausibility of the generated exemplars by CDA on GPT-3.5, and find that 4 out of 10 generated exemplars are either incomplete, or do not fully contain the events we desired. In this sense, the exemplars sampled from the training set are of a better quality than GPT-3.5-generated ones, leading to better ICL performance. For ChatGPT, on the other hand, the quality of the generated synthetic data is of a significantly better quality than GPT-3.5, resulting in more improvement on top of zero-shot ChatGPT and one-shot ICL for ChatGPT.

In all, the result of CDA on LLMs is highly dependent on 1) the data synthesizing capability of the backbone LLM, where ChatGPT excels, and 2) the problem solving ability for temporal reasoning, where GPT-3.5 excels. We also checked using the exemplars generated by ChatGPT as in-context examples for GPT-3.5, and the Confl.Avg. is 7.23 and 56.2, which is better than GPT-3.5-ICL.

Case Study For example, for a typical tense-biased relation in Tab. 1, the "told-offer" case, where past tense should happen after the present tense. We ask ChatGPT to generate the case when told happen after the present tense as a counterfactual exemplar: "*I offer my friend a ride to the party all the time. She told me she has already made plans to go with someone else. I understand and told her to let me know if she needs a ride in the future.*" This gives a case when *told* happens after *offer* and can be used as a counterfactual augmented data. With this counterfactual exempler, LLMs can perform correctly in this case.

We also provide some additional analysis regarding why CDA cannot outperform ICL in TORQUE for GPT3.5 and the inconsistent trends of primary and secondary metrics on LLMs in Appx. §G.

5 Conclusion

In this paper, we investigate knowledge conflicts in event temporal reasoning by formally defining four types of biases to identify a knowledge conflict diagnoses evaluation set. We observe that both PLMs and LLMs are susceptible to knowledge conflicts in this task, resulting in decreased performance on knowledge-conflict datasets. To address this issue, we propose a CDA method that is suitable for both PLMs through pre-training and LLMs through In-Context Learning. Our experiments demonstrate the effectiveness of our proposed method in mitigating knowledge conflicts.

Limitations

This paper only discussed bias calculated based on statistics in the training set. However, there are various other ways of characterizing bias, such as using predictions of zero-shot pre-trained language models (Xu et al., 2022) and context masking, are not discussed, which can be left as a future work.

Ethics Statement

There are no direct societal implications of this work. The datasets we use, TORQUE and MATRES, are publicly available and shared via open-access licenses for research purposes. Even though we are detecting bias and conflicts in the original datasets, we focus on bias toward temporal relations of events and do not involve any bias toward certain gender or ethnics groups. The context where event relations are derived from TimeBank[11], AQUAINT[12], and Platinum[13], which has not shown to contain any obvious social biases that would raise concerns within the community. The counterfactual data augmentation technique we propose can effectively mitigate bias in event relation extraction. In conclusion, to the best of our knowledge, this paper does not raise ethical concerns.

Appendices

A Knowledge-conflict Selection Hyperparameters

In TORQUE, we set an empirical $\mathcal{T}^{\text{Relation Prior}}_{\textit{before}} = \mathcal{T}^{\text{Relation Prior}}_{\textit{after}} = \mathcal{T}^{\text{Relation Prior}}_{\textit{equal}} = 0.25$ by investigating the distribution of *before*, *after*, and *equal* relations. For tense bias, we set $\mathcal{T}^{\text{tense}}_{\textit{before}} = \mathcal{T}^{\text{tense}}_{\textit{after}} = 0.25$, and $\mathcal{T}^{\text{tense}}_{\textit{equal}} = 0.2$ for the relations indicating two events happening simultaneously. For narrative and dependency bias, the threshold is simply set as 0.5. In MATRES, we set $\mathcal{T}_{\textit{before}} = \mathcal{T}_{\textit{after}} = 0.3$ and $\mathcal{T}_{\textit{equal}} = 0.1$.

Sensitivity Analysis In MATRES, for example, if the $\mathcal{T}$ is set as its upper bound, $\mathcal{T}_{\textit{before}} = 0.523$, and $\mathcal{T}_{\textit{after}} = 0.346$, then more knowledge-conflict examples will be selected based on the new threshold. In MATRES, the number of Rel.Prior increases from 148 to 229, the number of tense prior increases from 210 to 418, and dependency prior from 42 to 69. The statistics of narrative bias don't change because the order of two events in the context is a binary relation and will not be affected by Tau. We reproduce the results in Table 6 under the new $\mathcal{T}$, which studies the model performance on the conflict subset versus the non-conflict subset. The results are basically consistent with the $\mathcal{T}$ that is originally used in this paper, which shows that the PLM RoBERTa-large suffer from knowledge conflicts with a performance drop on the conflict dataset.

	Conflict		Non-Conflict	
	Micro	Macro	Micro	Macro
RoBERTa-large				
Relation Prior	62.7↓	30.8↓	75.4	40.1
Narrative	59.2↓	27.1↑	76.8	21.7
Tense	59.9↓	36.1↓	71.8	46.0
Dependency	57.2↓	37.8↓	71.1	44.7

Table 6: Performance on knowledge conflict and non-conflict data in MATRES under the new $\mathcal{T}$.

B Datasets

TORQUE: Ning et al. (2020) is a reading comprehension benchmark with a focus on event temporal reasoning questions. TORQUE is more flexible than simple relation extraction benchmarks as the reading comprehension framework allows more complicated TEMPRELS including uncertain relations (e.g., *might before*), hypothetical relations (e.g., *what will happen if* ...), and negated relations (e.g., *not after*). In TORQUE, each passage is associated with around 10 human-annotated questions regarding the TEMPREL between certain events, and the task objective is to select the correct answers from the pre-defined set of annotated event triggers. We evaluate the model performance using exact-match (EM) and Macro F1.

MATRES: MATRES (Ning et al., 2018) is a TEMPREL extraction dataset that includes refined annotations from documents in TimeBank (Pustejovsky et al., 2003), AQUAINT (Louis and Nenkova, 2012), and Platinum (UzZaman et al., 2013). The task in MATRES is defined as identifying the TEMPREL between two events in the context, where $R = \{\textit{before, after, equal, vague}\}$. The TEMPRELS of interest are nailed to $R = \{\textit{before, after, equal, vague}\}$. We use the pre-processing by Wang et al. (2020) to process the dataset from raw annotations, where the context includes the sentences containing the two events e_1 and e_2, together with a precedent sentence to provide more contextual information. This makes the context a bit longer than the common preprocessing adopted by several previous works such as Ning et al. (2018); Wang et al. (2023b), accounting for the discrepancy of model performances.

C Evaluation Metrics

In this paper, (binary) F1 is the primary metric in TORQUE where EM is the secondary metric. In MATRES, the primary metric is macro F1 and the secondary metric is micro F1.

Explanations on the Primary Metrics In TORQUE, around 22% of the evaluation entries have no answers, which means we can easily achieve an EM of around 22% by predicting none for all test cases, while the F1 can only be near zero. In MATRES, the label class distribution is highly imbalanced, where there are 52.3% instances with the label 'before' and only 2.4% with the label 'unknown'. By only predicting 'before' we can reach a micro-F1 of 0.523 while a near-zero score on macro F1, which motivates us to use macro F1 as the primary metric in Tab. 4. In the case when LLMs mostly predict *None* or 'before', the most dominant labels in the dataset that will lead to a high EM or micro F1, it makes more sense to use binary F1 or macro F1 as the primary metric.

D Additional Details of Knowledge Conflict Diagnosis

In TORQUE, for example, for the question "*What happened after Bush gave four key speeches?*" and answers "{*called*, *elect*, *vote*}" under a certain context, we can acquire three event relation triples (*gave*, *before*, *called*), (*gave*, *before*, *elect*), and (*gave*, *before*, *vote*). and use those triples for calculating and detecting bias.

For each type of bias, we empirically set thresholds to select knowledge-conflict subsets as in Appx. §A. For instance, in a feature-relation pair f (e.g., f represents dependency) and r, it is knowledge-conflict if $b(f, r) < \frac{c(r)}{\sum_{r' \in R} c(r')}$, indicating that it does not conform to the dominant distribution of relation r. Such selection criteria can be further enhanced by setting a threshold $\mathcal{T}_r < \frac{c(r)}{\sum_{r' \in R} c(r')}$, which increases the level of conflicts by further restricting $b(f, r)$ to be less than $\mathcal{T}_r$.

E Impact of Knowledge Conflict

We compare the model performance on knowledge conflict subsets and the non-conflict subsets to show the impact of knowledge conflicts on model performance in Tab. 7. In general, models perform more poorly on the conflict subsets, compared with those without conflicts. This discovery suggests that the chosen conflict subsets pose greater challenges for PLMs and LLMs, thus validating the efficacy of our conflict detection framework.

	Conflict		Non-Conflict	
	EM	F1	EM	F1
RoBERTa-large				
Rel.Prior	29.5↓	73.3↓	40.7	74.5
Rel.Prior (warm-up)	50.0↓	75.1↓	75.0	76.2
Narrative	31.4↑	69.0↓	48.4	75.2
Tense	33.5↓	72.9↓	50.7	75.0
Tense (warm-up)	48.4↓	72.4↓	77.3	78.6
Dependency	41.7↑	78.6↓	37.5	81.2
GPT-3.5				
Rel.Prior	4.82↓	59.9↑	4.87	51.1
Rel.Prior (warm-up)	4.62↓	47.0↑	25.0	30.4
Narrative	2.13↓	50.7↑	7.21	44.4
Tense	4.46↓	53.5↑	7.27	42.6
Tense (warm-up)	5.71↓	45.9↑	25.3	30.0
Dependency	2.94↑	57.7↑	2.72	56.7

Table 7: Experimental results on the model performance on knowledge conflict and non-conflict data in TORQUE. The RoBERTa-Large model suffers from performance drop when tested on the conflict subsets. On the contrary, GPT-3.5, when not fine-tuned on the biased training set, suffer less from the knowledge conflict in general. However, there is still a large performance gap on warm-up questions for GPT-3.5, dropping from an EM of around 25% to 5%.

F Additional Details of the Models

F.1 Baselines

For TORQUE, the model consists of a one-layered perceptron built on top of RoBERTa. The transformers' output corresponding to the token being analyzed serves as input to the perceptron layer as a sequence tagging task, where the expected output is either 0 or 1, indicating whether this event argument is a correct answer or not. Following the original paper of TORQUE, we fine-tuned RoBERTa-large on the training set of TORQUE, using a batch size of 6 (each input is a concatenation of one passage and one question, and the output is a vector measuring the probability of each event argument token). The learning rate is 1e-5, total epoch is 10, and three random seeds were selected. The experiments are conducted on NVIDIA A5000 GPUs, which takes around 30 minutes for training one epoch.

In MATRES, each data entry is composed of a passage and the corresponding positions of the two event triggers. The model consists of a one-layer perceptron to aggregate the embeddings of the two event triggers provided by the transformers. We use pre-trained Big Bird (Zaheer et al., 2020), a RoBERTa variation that deals with longer documents, following Wang et al. (2023b). The experiments are conducted on NVIDIA A5000 GPUs, which takes around 2 minutes for training one epoch.

We then introduce the bias-agnostic baselines that we adopt.

PoE (Hinton, 2002) and Learned-mixin (Clark et al., 2019). In this line of approaches, a biased model is trained to specifically target biased features in the data. The output of the biased model is then combined with the output of the robust model using product of predicted probabilities. This enables the robust model to focus less on the biased features and improve its overall performance. Denote the probabilities predicted by the biased model for element i as b_i, and the probabilities by the robust model as p_i, the ensemble to predict the final label by PoE is:

	TORQUE	MATRES
Whole Dev Set	1,483	1,000
Rel. Prior (relation)	88	148
Rel. Prior (warm-up)	66	-
Narrative	140	477
Tense (relation)	243	210
Tense (warm-up)	71	-
Dependency	68	42

Table 8: Statistics of each knowledge-conflict subset in TORQUE and MATRES.

$$\hat{p_i} = softmax(\log(p_i) + \log(b_i))$$

As PoE assumes conditional independence between the bias in the data and all the features except for bias in the data, which may be too strong, learned-mixin is thus proposed to make the relations between p_i and b_i learnable. A function $g(x)$ of the input x is learned to dynamically adjust how much to trust the biased model, leading to the final estimation as:

$$\hat{p_i} = softmax(\log(p_i) + g(x_i)\log(b_i))$$

However, a model could learn to set $g(x_i)$ to 0 to ignore the effect of biased model, learned-mixin + H is thus proposed by adding an entropy penalty:

$$R = wH(softmax(g(x_i)\log(b_i))$$

Here the entropy function takes the form $H(z) = -\sum_j z_j \log(z_j)$. The entropy term can help encourage the biased term to be non-uniform, providing more biased information.

To train the biased model for all these three baselines, we mask all context except for the event triggers. Other hyperparameters are the same as training a RoBERTa baseline.

Counterfactual Inference (Wang et al., 2022a, 2023b). Counterfactual inference focus on event trigger bias and frequent label bias that leads to spurious correlations. A causal graph is established to analyze the causal relations between the effect of event triggers, the whole context, and the final prediction. To mitigate event trigger bias and label bias, element-wise subtraction operation is conducted to get the final prediction:

$$y = y_x - \lambda_1 y_{\bar{x},e} - \lambda_2 y_{\bar{x}}$$

where y_x is the prediction given by the model trained on the original data without any masking, $y_{\bar{x},e}$ is the prediction of the model trained on the data where context except for event triggers are masked, and $y_{\bar{x}}$ is the prediction where the model sees nothing as input, which reflects label bias. λ_1 and λ_2 are tuned by conducting 5-fold cross-validations on the training set. The parameters that yield the best cross validation are selected. The search space is $[-1, 1]$ with an interval of 0.1. For TORQUE, $\lambda_1 = -0.8, \lambda_2 = -0.1$. For MATRES, $\lambda_1 = -0.1, \lambda_2 = 0.3$.

AFLite (Sakaguchi et al., 2021; Le Bras et al., 2020). AFLITE, which stands for Lightweight Adversarial Filtering, is an alternative bottom-up approach to algorithmic bias reduction proposed by (Sakaguchi et al., 2021). AFLITE trains an ensemble of linear classifiers on random subsets of the training data and filters other instances in the training data that linear classifiers can correctly classify. The rationale of this baseline is that instances that can be classified correctly by a shallow linear model wound contain artifacts.

In this paper, we use logistic regression as the linear classifier. We repeat training the logistic regression model 20 times on randomly sampled subsets of the training data. Then, we used the trained logistic regression model to predict the labels of the rest of the training instances. We compute a score for every instance e based on the following equation:

$$score(e) = \frac{\textit{the times of e is predicted correctly}}{\textit{the times of e is predicted}}.$$

After repeating, we filter instances that owns a score higher than 0.8. Following previouse work (Sakaguchi et al., 2021), we use dense representations produced by frozen `robert-large` and `bigbird-roberta-large`, instead of manually identified lexical features, to train logistic regression classifiers on TORQUE and MATRES, respectively.

F.2 Large Language Models

Prompts for the Tasks. For TORQUE, the prompt template we use is "Q: {question}, select none or several from {all_events} \n {context} \n A:". Here, question, context are provided in each data entry in TORQUE. all_events indicates all the annotated event triggers in the context. GPT3 is expected to generate none or several events that are the answers to the question given the context. We also check another prompt as an additional analysis, which is "Given the context {context}, {question}, select none or several from all_events} \n A:". The performance analysis are introduced in Tab. 14.

For MATRES, we formulate the problem as a multi-choice question answering (MCQA) task format, as it's inherently a four-way classification task. The prompt takes the form "Given the context:\n {context} \n\n Q: What's the temporal relation between the event {e1} and {e2}? \n Choice A: {e1} happens before {e2}. \n Choice B: {e1} happens after {e2}. \n Choice C: {e1} happens during {e2}. \n Choice D: unknown. \n Answer only with A, B, C, or D. \n\n A: Choice". Here, e1 and e2 are the target event triggers to be studied. The expected output is either A, B, C, or D. In addition, we compare our MCQA template with other templates that have been used in previous works, denoted as template 2 (Chan et al., 2023) and template 3 (Yuan et al., 2023). A comparison of different templates are presented in Tab. 15. We also present the effect of the three prompt templates in Tab. 17, and find that our MCQA template achieves the best performance.

Baselines We use In-Context Learning (ICL) and Generative Data Augmentation (GDA) as two intuitive baseline that can be directly comparable to our CDA method. For ICL, specifically, we retrieve one passage-question pair in TORQUE, and retrieve one example per relation from *before*, *after*, *equal*, and *unknown* as as set of exemplars for MATRES (denoted as 1-shot), to form the ICL demonstration. Note that ICL is considered few-shot learning while our method is purely zero-shot. We study the variability of different sets of exemplars as well as the effect of 1-shot and 3-shot ICL in Tab. 17. We can find that the performance of ICL is quite stable across different sets of random exemplars, and 3-shot exemplars help on template 1 but not the other two templates.

In addition, we add an additional baseline named *Generative Data Augmentation* (GDA) that performs exemplar generation without a counterfactual guidance. That is to say, we ask LLMs to generate exemplars under all relations from R, instead of only under the counterfactual relations.

Counterfactual Data Augmentation We introduce how to do Counterfactual Data Augmentation (CDA) for both PLMs and LLMs.

In CDA for PLM, we generate augmented data at scale. For TORQUE, we first retrieve all event pairs that are identified as biased in the training set. For an event-relation triple (e_1, e_2, r), where r is identified as knowledge-conflict, which appears less frequently in the training set, we ask Flan-T5 to generate some context where e_1, e_2 happens under relation r, to augment the undervalued distribution of these two events under the conflict relation r. The prompt is: "Write a story where e_1 happens r' e_2:". We set temperature as 1 and use greedy decoding to get the results. After generating the context, the question associated with the context is thus *Q=What happened* r' e_2 and the corresponding answer is e_1. We do similar generations for warm-up questions that asks what events have happened / is happening / will happen. We first acquire events that are knowledge-conflict with regard to a relation $r \in \{$*happened, will happen, happening*$\}$, and randomly sample two or events that are conflict with regard to r. We ask Flan-T5 "Write a story where e_1 and e_2 r". The corresponding question associate with the generated context is then *Q=What have happened/will happen in the future/is happening?*, based on what r is. After such augmentations, we conduct an additional filtering step by selecting only knowledge-conflict augmented data. We keep a proportion of augmented data that is scored with low loss by a fine-tuned PLM on TORQUE to boost the initial learning process when trained on augmented data. For MATRES, the prompt given to Flan-T5 is "Write a story where e_1 happens r' e_2". Then r is used as the final label.

In CDA for LLM, we generate demonstrations to perform in-context learning. In MATRES, for an example (c, e_1, e_2, r), we first ask the LLM to predict the temporal relation r_{LLM}. Then we use the same prompt as in CDA for PLM to generate counterfactual examples dedicated to the event pair (e_1, e_2), under relations other than r_{LLM}. The generated examples are thus served as exemplars. In TORQUE, the pipeline is more complicated. An entry is composed of context c, the set of event triggers E in c, the question q, and the answers a, which is a subset of E. We first ask an LLM to predict the answers a_{LLM}, which is also expected to be a subset of E. We then ask the LLM itself to generate some context where the ground answers are sampled from $E - a_{LLM}$, using the same prompt as in CDA for PLM. Examples on MATRES are presented in Tab. 16.

G Additional Analysis and Discussions

Results Analysis on Secondary Metrics Specifically, in Tab. 3 on TORQUE, EM and F1 positively correlate for PLMs intuitively as both scores are fairly high. For LLMs, both ChatGPT and GPT-3.5 perform poorly on the task and tend to predict None (no answers) in a zero-shot setting. This explains the relatively higher EM scores in a zero-shot setting. Incorporating in-context learning leads to both LLMs generating more meaningful predictions, resulting in a corresponding increase in the F1 score. However, the improvement is not substantial enough to surpass the zero-shot setting in terms of EM scores. This is because it is relatively easy to achieve a higher EM score by solely predicting "None" for all instances.

In Tab. 4 on MATRES, regarding the performance of PLM and LLM, micro and macro and F1 correlates positively for PLM, intuitively, as both micro and macro F1 scores are decently high. On LLMs, GPT-3.5 (`text-davinci-003`) especially, EM and F1 doesn't positively correlates with each other because GPT-3.5 tends to predict "before" for most of the instances (97%) in a zero shot setting, which contributes to a high Micro-F1 but a low Macro-F1. We also studied other prompt templates (as in Tab. 17 in the appendix) and got similar results. This indicates a fairly high label bias of GPT-3.5 on the label 'before'. With the involvement of in-context learning, when the labels predicted by GPT-3.5 get more evenly distributed, the macro-F1 significantly improves. However, as the micro-F1 achieved by predicting 'before' for all instances is quite high, the micro-F1 cannot be improved to beat the 53.3% baseline as the improvement is not large enough. In ChatGPT, the predicted labels are not that illy distributed, which makes micro and macro F1 basically positively correlate with each other.

In all, the discrepancy of the EM/F1 trend for PLMs and LLMs is due to the relatively poorer performance of LLMs and the tendency of predicting either "None" of "before", a form of label bias.

H Statistical Significance

To gain a deeper understanding of the significance of the improvement, we incorporate a statistical test. The result shows that most of the improvements are statistically significant, with some exceptions on GPT-3.5.

We perform a randomization test (Cohen, 1995) on EM and F1 for Table 3 and 4, indicating significant improvements with $p < 0.05$ by adding a * to the entries where our model outperforms the baseline. Specifically, in TORQUE, CDA + RoBERTa demonstrates significant improvements under the 'all' and 'conflct.avg.' categories for all-EM with $p < 0.05$. Moreover, there are significant improvements in F1 and EM from zero-shot to CDA when using ChatGPT. However, for GPT-3.5, the addition of synthetic exemplars results in performance deterioration due to its text generation limitations. Further discussions on this matter can be found in Appendix G (Line 1277-1299).

Model	all-EM	all-F1	confl-EM	confl-F1
RoBERTa-L	50.4	75.7	39.1	73.6
CDA + RoBERTa	51.0*	76.1	40.5*	74.2
GPT3+GDA	4.85	44.0	3.00	54.5
GPT3+CDA	5.16	44.6	4.22	54.9
ChatGPT	17.7	40.7	6.99	40.0
ChatGPT+GDA	4.38	44.2	2.33	52.6
ChatGPT+CDA	6.72*	45.2*	2.60	53.3*

Table 9: Significance test on TORQUE.

Model	micro (all)	macro (all)	micro (conf)	macro (conf)
RoBERTa-L	70.8	44.9	58.0	31.8
CDA+RoBERTa	72.2*	45.5*	59.9*	32.9*
GPT-3+GDA	45.6	27.6	34.5	22.6
GPT-3+CDA	51.3*	30.0*	35.4	27.9*
ChatGPT	39.8	25.9	29.3	21.6
ChatGPT+GDA	45.7	30.8	34.7	24.1*
ChatGPT+CDA	49.3*	32.0*	36.1*	23.8

Table 10: Significance test on MATRES.

In MATRES, the improvements from RoBERTa-L+CDA to RoBERTa-L is significant on both "all" and 'conflict.avg'. In terms of LLMs, adding CDA (inherently also in a zero-shot setting) significantly outperform the zero-shot prompt baseline by a large margin except for 'confl-avg-EM'. Compared to it's counterpart GDA, CDA outperforms GDA on overall performance.

I Additional Ablations

In this section, we compare our Counterfactual Data Augmentation method with other popular data augmentation methods to show the effectiveness of CDA with regard to knowledge conflict mitigation. Specifically, we adopt EDA and Synonym replacement as representative text-editing-based data augmentation baselines, and we use a Generative Data Augmentation (GDA) baseline to automati-

	Micro F1	Macro F1
zero-shot	39.8	25.9
ICL	43.1	23.8
Flan-T5-11b ICL	36.8	27.1
GDA	45.7	30.8
CDA	**49.3**	**32.0**

Table 11: Experimental results on MATRES using ChatGPT.

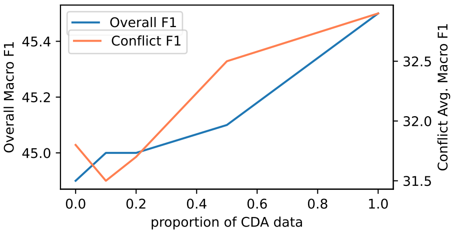

Figure 3: Effect of varying proportions of Counterfactual Data Augmentation (CDA) on MATRES. Models benefit from increased amounts of CDA data.

cally generate task data using the same backbone language model, Flan-T5-11B, to generate training data without counterfactual constraints. The only difference between GDA and CDA is that GDA does not use counterfactual constraints, and GDA can serve as an ablation to study the effect of counterfactual constraints. The results for TORQUE are presented in Tab. 12 and the results for MATRES are presented in Tab. 13.

We also study the effect of using Flan-T5-generated data as exemplars for ChatGPT as an additional baseline, as in Tab. 11. The Macro F1 is improved a tad bit than zero-shot and ICL, while sacrificing the Micro F1 performance. This indicates that Flan-T5-generated data, even though they are useful for supervised fine-tuning in RoBERTa, cannot be directly used for prompting ChatGPT due to a relatively lower quality.

Abstract

Event coreference resolution (ECR) is a critical task in information extraction of natural language processing, aiming to identify and link event mentions across multiple documents. Despite recent progress, existing datasets for ECR primarily focus on within-document event coreference and English text, lacking cross-document ECR datasets for multiple languages beyond English. To address this issue, this work presents the first multiligual dataset for cross-document ECR, called MCECR (Multilingual Cross-Document Event Coreference Resolution), that manually annotates a diverse collection of documents for event mentions and coreference in five languages, i.e., English, Spanish, Hindi, Turkish, and Ukrainian. Using sampled articles from Wikinews over various topics as the seeds, our dataset fetches related news articles from the Google search engine to increase the number of non-singleton event clusters. In total, we annotate 5,802 news articles, providing a substantial and varied dataset for multilingual ECR in both within-document and cross-document scenarios. Extensive analysis of the proposed dataset reveals the challenging nature of multilingual event coreference resolution tasks, promoting MCECR as a strong benchmark dataset for future research in this area.

1 Introduction

Event coreference resolution (ECR) is a fundamental task in information extraction that aims to identify mentions of events referring to the same real-world event. An event mention refers to a word or phrase that indicates the occurrence of an event, known as event trigger. The goal of an ECR system is to accurately identify all triggers that pertain to the same event. For instance, consider the following example: "*The leaders of 8 countries with the greatest industry gathered in Paris to discuss global environmental challenges*" and "*The convention of industrialized countries in Paris to combat global warming will be impactful.*" In these sentences, the event mentions "*gathered*" and "*convention*" both refer to a conference related to climate change. Recognizing such coreferences between event mentions within a document or across multiple documents is crucial for achieving a comprehensive understanding of events. This knowledge can be leveraged in various downstream applications, including question-answering, summarization, information retrieval, and knowledge base population.

Numerous methods have been proposed for event coreference resolution, encompassing a range of approaches. Early research explored feature-based models, incorporating traditional feature engineering techniques (Chen et al., 2009a; Yang et al., 2015; Lu and Ng, 2018). Additionally, graph-based models (Chen and Ji, 2009), Integer Linear Programming (Choubey and Huang, 2018), Markov Logic Networks (Lu et al., 2016), and Multi-tasking (Lu and Ng, 2021) approaches have been employed. More recently, there has been a surge of interest in leveraging large language models for event coreference resolution (Nguyen et al., 2016; Tran et al., 2021). For instance, the authors in (Xu et al., 2022) propose an ECR approach that encodes both sentence-level and document-level context using Longformer.

However, most existing work on event coreference resolution has focused on within-document scenarios, limiting its scope. While some prior studies have investigated cross-document event coreference resolution (CDECR) (Barhom et al., 2019; Cattan et al., 2021; Eirew et al., 2022a; Hsu and Horwood, 2022), comprehensive exploration of this task remains limited due to the scarcity of available resources. Moreover, multilingual cross-document event coreference resolution represents an even less-explored setting. The lack of large-scale manually annotated datasets poses a significant challenge in studying ECR in multilin-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3869–3880
June 16-21, 2024

gual cross-document scenarios. Existing datasets for cross-document event coreference resolution are primarily available in English (Cybulska and Vossen, 2014; Vossen et al., 2018), providing limited annotated samples. To address these limitations, this work introduces a novel dataset, namely the Multilingual Cross-Document Event Coreference Resolution (MCECR) dataset, specifically designed to facilitate research in this domain.

To collect a diverse set of articles for annotation for event coreference, we employ news articles published in Wikinews, an online news source covering various domains. Specifically, news articles in the domains of *Politics, Crime, Health, Technology, Sports, Economy* and *Dissasters* are collected from language-specific dumps of Wikinews for five languages: *English, Spanish, Ukrainian, Turkish*, and *Hindi*. These articles serve as seed nodes to collect more related news articles from Google searches. The news articles from Google searches are then filtered based on some criteria to enhance the likelihood of encountering coreferring event mentions. To this end, the collected corpus consists of 1,456 news topics in 5,802 articles.

To annotate the collected corpus, we hire native-speaker annotators for each language. The annotation is performed in two phases: (1) Event Detection and (2) Coreference Resolution. In the first phase, the annotators read the news articles and identify event triggers. As such, we focus on open domain events to broaden the scope of our dataset. Next, the annotators are provided with a pair of event triggers and they need to decide whether the provided event mentions refer to the same real-world event or not. Since there might be a large number of event triggers in the articles of each news topic, we first employ a pre-trained model to identify the challenging event trigger pairs, which will be annotated by the human annotators to improve efficiency. In contrast, the non-challenging event mention pairs (determined by the confidence of the predictions from the pre-trained model) are automatically labeled and sampled for manual verification with the annotators. Using this approach, out of 54,791 events, 4,266 non-singleton event clusters are detected, leading to a high-quality dataset for multilingual ECR. Compared to previous benchmark dataset for this task, i.e. ECB+ (Cybulska and Vossen, 2014), which contains only 722 non-singleton event clusters and supports only English, our proposed dataset provides more annotated samples in a diverse set of languages, serving as a strong benchmark for multilingual cross-document event coreference resolution.

In order to show the potentials of the proposed dataset for cross-document event coreference resolution in different languages, we conduct extensive experiments using the state-of-the-art ECR models. In particular, transformer-based models, joint clustering (Hsu and Horwood, 2022), and hierarchical models (Xu et al., 2022) are employed to study the challenging nature of our MCECR dataset. Additionally, we conduct experiments on the cross-lingual transfer learning settings for cross-document ECR for the first time in the literature, revealing the unique challenges of this problem for future research. Overall, our experiments demonstrate much room for further research on multilingual ECR with our dataset as the foundation to boost progress in this area. *We will publicly release our dataset for future research.*

2 Data Collection

Given the limitations of existing resources for multilingual ECR, our objective is to construct a dataset covering a diverse set of languages and provide coreference links in the cross-document setting. To achieve this, we start by collecting event-rich articles from Wikinews[1], which is an online source for publishing news. We select this source as it provides news articles in different languages and covers a variety of categories. In particular, five languages are chosen, i.e., English, Spanish, Turkish, Ukrainian, and Hindi, and the news articles from their Wikinews dumps are sampled for further processing and annotation. These languages represent different language families, and thus could better exhibit the challenges of cross-lingual ECR. Moreover, we select the following categories for article selection to promote data diversity: (1) Politics and Conflicts, (2) Crime and Law, (3) Health, (4) Science and Technology, (5) Sports, (6) Disasters and Accidents, and (7) Economy and Business. Note that we use language-specific categories to select the news articles for each language.

The selected news articles from Wikinews provide a valuable source of event-rich documents. However, in order to construct a richer dataset with many cross-document event coreference links, it is necessary to collect other articles that have more coreferring event mentions to the events mentioned in the Wikinews articles. To this end, we employ

Table 2: Statistics of the annotations in MCECR. Chain Length is computed via the number of event mentions in each chain.

Google search results to obtain such articles. In particular, for each Wikinews article, we retrieve news articles from other sources using the Google search engine. The titles of the Wikinews articles are employed as the queries in our searches as they provide short summaries for the main events in the articles. For each query, the first 50 search results are selected. These search results are further filtered to only keep the documents that have higher chance to contain referring event mentions to those in each Wikinews article. Our filtering criteria is based on the temporal correspondence heuristics (Zhang and Weld, 2013), which suggests the tendency to discuss the same events in different sources at the same or similar times (i.e., close to the occurring time of the events). As such, we only retain the searched articles whose publish dates are within 7 days of the publish dates of the original Wikinews articles to improve the precision to obtain the same events. Note that for each Wikinews article, the search results are limited to being in the same language as the article itself. Using this approach, on average, for each Wikinews article (called a news topic), 2.9 related articles are selected from Google search results. Finally, the textual content of all Wikinews articles and selected articles from Google search results are extracted to be annotated by native speakers in each language. Table 1 shows the statistics of the collected corpus.

3 Annotation

This section discusses the details of our annotation for the collected corpus with event triggers and event coreference links. In this work, we recruit native speakers to annotate the documents in each language. In particular, three annotators per language are hired from the freelancer website Upwork[2]. The hired freelancers are required to be native speakers of the target languages and fluent in English for training and communication. They also need to have experience in data annotation and pass an examination test to verify their ability on event and coreference annotation. Annotators are paid a fixed hourly rate of $15 per hour, which is significantly higher than the minimum wage per hour in their countries. To annotate the corpus we employ two phases: (1) Event Detection: to annotate event triggers, and (2) Event Coreference Resolution: to identify the event mentions that refer to the same real-world events in our collection of news documents.

3.1 Event Detection

In the first phase of annotation, we focus on identifying open-domain event mentions (Sims et al., 2019), aiming to facilitate the annotation process and extend the applicability of the final dataset for different domains. Concretely, annotators are instructed to find all event mentions in text regardless of their event types, i.e., only the spans of event triggers are marked for the annotation. We follow prior work (Sims et al., 2019; Pouran Ben Veyseh et al., 2022) on event detection to define event triggers and annotation guideline in our dataset. Specifically, we limit an event trigger to a word or continuous phrase that most clearly refers to the occurrence of an incident that results in a change of status of real-world entities. Note that due to the nature of some languages, event triggers might consist of multiple words. For example, in Turkish the phrase "*mahkum etmek*", which translates to "*convicted*", should be annotated as an event trigger.

3.2 Event Coreference Resolution

In the next step, we identify the event mentions that refer to the same real-world events for both within-document and cross-document scenarios. Considering each Wikipedia article and its corresponding Google-returned articles as a topic, we follow the annotation guideline in prior work (Cybulska and Vossen, 2014) to only annotate event coreference links between event mentions in the documents of the same topic. To this end, a comprehensive annotation requires all possible pairs of event men-

Table 3: Inter-annotator agreement in event detection reported in Krippendorff's alpha and in event coreference resolution reported in B-Cubed F-1

tions in a topic to be labeled by the annotators. However, due to the high number of event mentions in the documents of a topic, the number of pairs will be prohibitively large for annotation. To address this issue, we employ a combination of automatic and manual labeling techniques. Concretely, event pairs whose coreference decisions can be confidently predicted by a pre-trained coreference models will be removed from the pool of event pairs; the remaining pairs will be used for human annotation. As such, our pre-annotation model is based on the multilingual pre-trained language model XLMR (Conneau et al., 2020) while the ECB+ dataset (Cybulska and Vossen, 2014) is leveraged for training data. Given two event mentions e_1 and e_2, our model sends the concatenation of their hosting sentences S_1 and S_2 into the XLMR model to obtain representation vectors for the words, i.e., $[h_1, \dots, h_n] = XLRM(S_1 \dots S_2)$. The representations of the two event mentions, i.e., h_{e_1} and h_{e_2}, are then sent to a two-layer feed-forward network classifier to predict the coreference between e_1 and e_2. After training, the model is used to make predictions for all possible pairs of event mentions in the same topics of our dataset. Pairs with a model prediction confidence over 95% are automatically labeled and removed from our human annotation pool. As such, on average, 65% of event pairs are automatically annotated for each language in our dataset. Finally, to perform event coreference annotation for the remaining pairs (called unlabeled pairs), we provide the annotators with the entire context of the hosting documents of the two input event mentions to facilitate the process.

3.3 Annotation Quality and Statistics

To perform event trigger annotation, we first sample 20% of collected articles for each language that will be co-annotated by the three language-specific annotators. Afterwards, the labels that are provided by at least two annotators for each word are selected. For the labels with which all three annotators disagree, the annotators are requested to discuss and resolve the conflicts, leading to a final version of event triggers in our dataset. Finally, the remaining 80% articles for each language will be distributed to the three annotators for separate annotation to accommodate our budget. Next, for event coreference annotation, the unlabeled event mention pairs in a sample of 20% of the topics are used for co-annotation by three annotators for each language while the unlabeled pairs in the remaining 80% will be divided and annotated separately among annotators. We use majority voting to resolve any conflict between annotators during the coreference co-annotation step. The conflict examples are also presented to the annotators to reach an agreement before conducting separate annotation on 80% of the topics.

To assess the quality of our annotations, we evaluate the agreements among three annotators over the co-annotated data for each language. For the event detection phase, as the task is modeled via sequence labeling, we report the Krippendorff's alpha (Krippendorff, 2011) with MASI distance metric (Passonneau, 2006) for the inter-annotator agreement score of each language in our dataset. For the event coreference resolution phase, following prior work (Wang et al., 2022), we report the average of B-Cubed F-1 score (Bagga and Baldwin, 1998) over every pair of event chains detected by the annotators over the same topics. Table 3 shows the results. The table suggests that there is a high agreement between annotators across different languages for both tasks. Finally, to evaluate the quality of the automatically labeled event pairs for coreference, we sample 10% of such pairs and assign them to one annotator for manual verification for each language. Our evaluation shows an accuracy of at least 97% for the automatically labeled event pairs across all the languages to further highlight the quality of our dataset.

Table 2 shows the main statistics of the final annotated corpus. Note that in this table, each event chain corresponds to a fully connected component in a coreference graph where event mentions in a topic serve as the nodes and coreference links are used for the edges.

3.4 Annotation Challenges

ECR annotation is a challenging task involving challenges for both event trigger identification and event coreference resolution. Performing the task for multiple languages further complicates this pro-

cess. In the following, we summarize the major barriers encountered during the annotation of MCECR and and our adopted solutions:

Event Significance: MCECR is annotated in open domains where any event type is supposed to be annotated. However, it can result in confusions on how significant an event should be annotated. For instance, in the sentence "*The police officer opened the door of his car to inspect the accident.*", while "*inspect*" and "*accident*" are important event mentions to annotate, annotators might disagree on whether or not we should mark "*opened*" due to its trifle. Based on the discussions, we decide to only label significant event mentions to improve the data quality.

Conflicting Coreference: Our coreference annotation presents one pair of event mentions at a time for annotators to simplify the required task. The coreference annotation r for a pair of event mentions (e_1, e_2) in two different event chains C_1 and C_2 ($e_1 \in C_1$ and $e_2 \in C_2$) will thus induce the same relation r for other pairs of event mentions between C_1 and C_2. As such, a conflicting situation might occur if the annotators later vote for a different relation from r for another event mention pair (e'_1, e'_2) ($e'_1 \in C_1$, $e'_2 \in C_2$), causing confusion for our dataset. To resolve these situations, we require the annotators to discuss the conflicts and update the annotations as the final step to generate our dataset.

Lack of Background: To identify the event mentions that refer to the same real-world events, in some cases, the context of the text itself is not sufficient. Specifically, the annotators may require information about the events that are not directly presented in the articles. In these cases, there might be conflicting annotations for event coreference relations between annotators due their different background for events. To address this issue, we require the annotators to limit the coreference annotation only to those that are most confidently apparent in the context of the presented documents.

4 Experiments

To facilitate the evaluation and development of multilingual ECR models, this section studies how typical ECR models perform on our proposed dataset MCECR. In the literature, ECR is often modeled as a binary classification task (Hsu and Horwood, 2022; Ravi et al., 2023). Given two event mentions (in the same or different documents) along with their context, typical ECR models first concatenate the context for the two mentions to form a single input text $W = w_1, w_2, \ldots, w_n$, where $1 \leq s_1 \leq e_1 < s_2 \leq e_2 \leq n$ are the start and end indexes for the spans of the first and second event mentions in W. The models then aims to classify W into 1 or 0 to indicate whether the two event mentions corefer to each other or not.

In the inference time, once the labels for all pairs of event triggers in a document (for within-document ECR) or across documents in a topic (for cross-document ECR) are predicted, the event chains will be constructed for coreference evaluation. To evaluate the performance of the models, following prior work (Wang et al., 2022), we report the coreference evaluation metrics MUC (Vilain et al., 1995), B^3 (Bagga and Baldwin, 1998), CEAF$_e$ (Luo, 2005), and BLANC (Recasens and Hovy, 2011). We use the implementations provided by (Wang et al., 2022) to compute these metrics.

To prepare the proposed MCECR dataset for model evaluation, we divide the topics (i.e., Wikipedia articles) for each language into train/dev/test sets with a ratio of 80/10/10. For each set, we create two versions: (1) Within-Doc: to use only coreference links for event mentions in the same documents to create data, and (2) Cross-Doc: to use all coreference links for event mentions in the documents of the same topic to form event chains and data. Note that in the Cross-Doc setting, two event triggers might be in the same document or in different documents of the same topic. For the experiments, to address documents with long context, for both settings, we limit the context of each event mention to three surrounding sentences, i.e., the sentence that contains the event trigger plus the previous and next sentences.

4.1 Models

We evaluate the following ECR models in the experiments:

Synonym: In this baseline, the semantic similarity of the event trigger words are used to determine the coreference relations. To generalize this approach to all languages, we employ the contextualized representations of words obtained by running the multilingual pre-trained model XLMR over the input text W, i.e., $h_1, \dots, h_n = XLMR(w_1, \dots, w_n)$. Next, the representations for the event mentions are computed using the averages of their word representations, i.e., in spans (s_1, e_1) and (s_2, e_2). Finally, the cosine similarity between the event mention representations is computed to capture their semantic similarity score. The model's prediction will be positive if the similarity score is higher than a threshold α and negative otherwise in this approach.

Fine-Tuned XLMR: This baseline fine-tunes the multilingual pre-trained language models XLMR (Conneau et al., 2020) for ECR. The input text W is first encoded using the XLMR model: $h_{[CLS]}, h_1, \dots, h_n = XLMR([CLS], w_1, \dots, w_n)$. Next, the averages of word representations in the text spans of event mentions are used for their representations h_{t_1} and h_{t_2}. Finally, the concatenation of $h_{[CLS]}$, h_{t_1} and h_{t_2} is sent to a two-layer feed-forward network with softmax in the end to obtain a probability distribution for coreference prediction.

Hierarchical: This baseline (Xu et al., 2022) represents the context of the event mentions in three different levels, i.e., sentence, document, and topic. For the sentence level, the event triggers are masked with $[MASK]$ in their hosting sentences that will be encoded by a transformer-based language model. In the original model, the $[MASK]$ representations are then used to predict event types for the mentions. However, as event types are not available in our dataset, we instead predict the actual event triggers in this model. For the document level, the entire document of each event mention is encoded by Longformer (Beltagy et al., 2020) for English and by the long version of XLMR for non-English text[3]. For the topic-level representation, a Variational AutoEncoder (VAE) model is employed to infer the topic of each event mention based on the words in its context. The representations for the event mentions in all three levels are then combined to perform coreference prediction for the event mention pair.

Joint Clustering: In this baseline (Hsu and Horwood, 2022), instead of pair-wise prediction, the context for each event mention, i.e., its hosting sentence and the first two sentences from the beginning of its hosting document, is encoded by an XLMR-based encoder. The representations of the event mentions are then sent to an agglomerative clustering model to form the clusters (i.e., chains) of event mentions. Note that the encoder is trained with the Siamese network architecture so the contexts of the event mentions with coreference relations are represented more closely.

We tune the hyper-parameters for the fine-tuned XLMR and Synonym models using the MUC scores over development data of the English datasets. For the fine-tuned XLMR model, we choose $1e$-3 for the learning rate, 16 for batch size, and 200 for the dimensionality of the feed-forward networks. The prediction threshold α for Synonym is set to $\alpha = 0.9$. The hyper-parameters for the other models, i.e., Hierarchical (Xu et al., 2022) and Joint (Hsu and Horwood, 2022), are inherited from their original papers.

4.2 Results

Monolingual: We first evaluate the ECR models on our dataset in the monolingual settings where the models are trained and tested over data of the same language. Tables 4 and 5 show model performance for the Within-Doc and Cross-Doc settings. From these tables, it is clear that all of the existing

Table 7: Performance (F1 score) of the models on the test set of each language in Cross-Doc setting. The models are trained on English and tested on the target language.

models still underperform a perfect model. Specifically, for the Within-Doc setting, the average F1 score using the MUC metric across all models and languages is 50.52%. The same number for the Cross-Doc setting is 48.47%. These numbers show that the proposed MCECR dataset is challenging and further research is necessary to improve the performance of the ECR models on this benchmark. Another observation from the tables is that there is a considerable difference between the performance of the models across different languages. For example, the average F1 score using the BLANC metric across all models for each language in the Cross-Doc setting, ranges from 18.21% in Spanish to 73.12% in Turkish. Such differences of model performance over different languages corroborate the importance of further exploration for the challenges of ECR in multilingual settings.

In addition, the tables suggests that the Cross-Doc setting for ECR is more challenging than Within-Doc ECR. In particular, the average F1 score across all metrics, languages, and models in the Within-Doc setting is 70.36% while number for the Cross-Doc setting is only 64.84%. Finally, comparing the performance of the models, we observe the best performance is generally achieved by XLMR. The higher performance of the simple model XLMR compared to previous state-of-the-art baselines (i.e., Hierarchical and Joint) indicates that the existing architectures are more tailored to English and cannot perform well in other languages. Also, compared to the simple baseline Synonym, the better performance of fine-tuned XLMR-based model highlights the importance of using effective encoders for ECR.

Cross-Lingual: In order to shed more light on the operation of the existing methods for ECR, we examine the models in the cross-lingual transfer learning setting. Tables 6 and 7 show the performance of the models for Within-Doc and Cross-Doc ECR when they are trained in English training data and directly evaluated on test data of other languages. Here, as training data is not needed for the Synonym baseline, we do not report the performance of this model in the tables. The first observation from these tables is that the performance of the models significantly drops when tested in the cross-lingual setting compared to the monolingual setting. Concretely, the average F1 score of all models across all metrics and languages decreases by 7.44% in the Within-Doc setting and 8.59% in the Cross-Doc setting. The significant performance loss in cross-lingual transfer learning indicates the differences in ECR patterns across different languages, calling for more research to address the challenges of cross-lingual learning for ECR. Moreover, from the tables, it is obvious that performance losses in different languages are not the same. Specifically, the performance loss of all models in the Within-Doc setting across all metrics ranges from 2.33% in Spanish to 12.33% in Hindi. This number for the Cross-Doc setting ranges from 2.32% in Spanish to 8.28% in Turkish. These variances reveal the necessity to explore the challenges of ECR for specific languages. For example, the lower performance loss in Spanish compared to Hidi in the cross-lingual evaluation can be attributed to the higher similarity between Spanish (the target language) and English (the source language). Finally, considering performance of the models in the cross-lingual evaluation, we observe the same pattern as in the monolingual setting. In particular, XLMR tends to outperform the other baselines over different target languages, which confirms the effectiveness of this model for multilingual and cross-lingual learning in ECR.

5 Related Work

Event coreference resolution (ECR) is one of the important tasks for any event understanding and information extraction systems. To this end, there has been a considerable body of prior work for this problem. We study the prior work for ECI in two dimensions, i.e., datasets and models:

Datasets: ECR data has already been provided in some of the existing event extraction datasets. Specifically, ACE 2005 (Walker et al., 2006), MUC (Grishman and Sundheim, 1996), TAC KBP (Ellis et al., 2015, 2016; Getman et al., 2017), OntoNotes (Pradhan et al., 2007), and MAVEN (Wang et al., 2022) are the popular event datasets with manually-annotated event coreference information. However, such datasets are mainly developed for English and some popular languages, i.e., Spanish, Arabic, or Chinese. Also, each previous ECR dataset on its own only supports at most 3 languages (e.g., ACE 2005 and TAC KBP). As such, these datasets cannot extensively evaluate models in less popular languages to better support multilingual research for ECR. Most importantly, all of these datasets are only annotated for within-document event coreference that hinders model development for cross-document ECR with multiple languages.

Regarding cross-document ECR, ECB+ (Cybulska and Vossen, 2014) has served as the major dataset to boost research progress for this problem. However, the lack of annotations in non-English documents is a critical shortcoming in ECB+ that prevents multilingual learning research for cross-document ECR. Also, it is noteworthy that ECB+ provides much less non-singleton event clusters than our dataset (i.e., 722 vs. 4,266), making ECB+ less suitable for developing data-hungry deep learning models. In contrast, MCEMR represents the first dataset that annotates both within-document and cross-document event coreference for multiple languages (i.e., beyond English). Compared to existing ECR datasets, our dataset supports the largest number of languages (i.e., five languages), covering Turkish, Ukrainian, and Hindi for the first time in ECR research. With much more non-singleton event clusters, our dataset also enables training of larger models for ECR.

In addition to manually-annotated datasets, there are some other ECR datasets that are automatically collected and annotated, including MEANTIME (Minard et al., 2016), GVC (Vossen et al., 2018), and WEC (Eirew et al., 2021)[4]. However, due to the inherent noises in the fully automatic annotation, these datasets cannot guarantee the highest quality for multiple languages to provide reliable resources for model development for ECR. As such, our MCECR dataset leverages human annotation to control and produce a higher-quality dataset in multilingual languages for both with-document and cross-document ECR to significantly facilitate future research in this area. Finally, due to the relatedness of ECI and the event and event-event relation extraction (EERE) tasks (Do et al., 2011; Man et al., 2022, 2024), we also note some recent multilingual datasets for event extraction (Veyseh et al., 2022; Pouran Ben Veyseh et al., 2022) and EERE (Lai et al., 2022b,a).

Models: The ECR task in the literature has been approached with different methods ranging from feature-based models to deep learning methods. In particular, for the feature-based approach (Ahn, 2006; Chen et al., 2009b), the typical models for ECR have employed SVMs (Lu et al., 2016), Markov Logic Network (Chen and Ng, 2016), and Integer Linear Programming (Choubey and Huang, 2018). Recently, deep learning has been used extensively to solve ECR (Barhom et al., 2019; Choubey et al., 2020; Eirew et al., 2022b). The authors in (Huang et al., 2019) employ LSTM to encode input text and model the compatibility of arguments in event clusters. More recently, the application of large language models, e.g., BERT or RoBERTa, has increased in ECR models. The authors in (Hsu and Horwood, 2022) employ a contrastive learning technique to train the RoBERTa-based model for ECR. In (Xu et al., 2022), the authors leverage BERT-based encoders to encode local and global context for events. For multilingual learning, (Phung et al., 2021) explores cross-lingual transfer learning for within-document ECR with adversarial training. However, due to the lack of necessary datasets, none of those previous work has explored multilingual cross-document ECR as we do. Finally, Finally, it is worth noting that the modeling

---

[4] Note that in MEANTIME the English portion is manually labeled. In WEC, the evaluation sets are also manually labeled.

approaches for ECR shares some similarities with the popular task of Relation Extraction in Information Extraction (Veyseh et al., 2020b,a).

6 Conclusion

In this work, we introduce MCECR, a multilingual event coreference resolution dataset. Compared to previous dataset, MCECR is the first ECR dataset that provides annotation for both within-document and cross-document event coreference for multiple languages. Our dataset is annotated on Wikipedia articles and related news articles obtained from Google searches in 5 different languages (i.e., English, Spanish, Turkish, Ukrainian, and Hindi). We study the challenging nature of this dataset by evaluating the performance of strong baselines in monolingual and cross-lingual settings. Our experiments reveal the necessity of further research on the proposed MCECR dataset to improve the performance of ECR models in multilingual learning.

Limitations

The proposed MCECR dataset is meant to promote future research on multilingual and cross-document event coreference resolution. Although our experiments show the difficulty of this task and the necessity for future work, we highlight the following limitations and risks involved in the proposed dataset: (1) Lack of event types: In the proposed dataset, we aim to annotate events in general domains, so no event types is presented. This could be restricting for the methods that rely on event types to identify coreference; (2) Lack of event arguments: Some prior work for ECR resorts to the consistency between event arguments to identify event chains. MCECR does not annotate event arguments, thus hindering the application of argument-based methods for ECI; (3) Noise in annotation: As mentioned in the annotation details, we employ a pre-trained ECR model to identify the easy event mention pairs for coreference and remove them from the pool of annotation. This is necessary to address the prohibitively expensive costs for comprehensively annotating every possible pair of event mentions in the dataset. This method also lead to a high-quality dataset as demonstrated in our human verification step. However, this approach is still not perfect and it might still introduce a small portion of noises/errors, which could be addressed to further improve the dataset.

Abstract

Sentiment analysis (SA) has been a long-standing research area in natural language processing. With the recent advent of large language models (LLMs), there is great potential for their employment on SA problems. However, the extent to which current LLMs can be leveraged for different sentiment analysis tasks remains unclear. This paper aims to provide a comprehensive investigation into the capabilities of LLMs in performing various sentiment analysis tasks, from conventional sentiment classification to aspect-based sentiment analysis and multifaceted analysis of subjective texts. We evaluate performance across 13 tasks on 26 datasets and compare the results against small language models (SLMs) trained on domain-specific datasets. Our study reveals that while LLMs demonstrate satisfactory performance in simpler tasks, they lag behind in more complex tasks requiring a deeper understanding of specific sentiment phenomena or structured sentiment information. However, LLMs significantly outperform SLMs in few-shot learning settings, suggesting their potential when annotation resources are limited. We also highlight the limitations of current evaluation practices in assessing LLMs' SA abilities and propose a novel benchmark, SENTIEVAL, for a more comprehensive and realistic evaluation. Data and code are available at `https://github.com/DAMO-NLP-SG/LLM-Sentiment`.

1 Introduction

Sentiment analysis[1] (SA) has been a long-established area of research in natural language processing (NLP), which aims to study people's opinions, sentiments, emotions, etc, through computational methods (Liu, 2015; Poria et al., 2020). Since its inception (Turney, 2002; Hu and Liu, 2004), this field has attracted significant interest from both academia and industry given its wide range of applications, such as analyzing product reviews and gaining insights from social media posts (Barbieri et al., 2020; Zhang et al., 2022). Furthermore, achieving a deep understanding of human subjective feeling through sentiment analysis is undoubtedly an important step toward developing artificial general intelligence (Bubeck et al., 2023).

In recent years, large language models (LLMs) have demonstrated impressive performance on various NLP tasks (Brown et al., 2020; Chowdhery et al., 2022; OpenAI, 2023, inter alia). They can directly perform tasks in zero-shot or few-shot in-context learning manner and achieve strong performance without the need for any in-domain supervised training (Bang et al., 2023; Ye et al., 2023; Zhong et al., 2023; Yang et al., 2023). Although there have been some initial attempts to apply LLMs to sentiment analysis (Deng et al., 2023; Zhong et al., 2023; Wang et al., 2023), these studies are often limited to some specific tasks and adopt different models, datasets, and settings in experiments. As such, the extent to which existing large language models can be leveraged for sentiment analysis problems remains unclear.

In this work, we aim to conduct a reality check on the current state of sentiment analysis in the era of large language models. Specifically, we seek to answer the following research questions: 1) *What is the current maturity of various sentiment analysis problems?* 2) *Compared to small specialized models trained on domain-specific data, how do large models fare in both zero-shot and few-shot settings?* 3) *Are current SA evaluation practices still suitable to assess models in the era of LLMs?*

To this end, we first conduct a systematic review of various sentiment analysis-related tasks, from

---

[1] There are many related terminologies including sentiment analysis, opinion mining, affect analysis, opinion extraction, etc. We collectively refer to them as sentiment analysis in this paper, following the convention in Liu (2015).

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3881–3906
June 16-21, 2024 ©2024 Association for Computational Linguistics

conventional sentiment classification (SC, classifying the sentiment orientation of a given text (Socher et al., 2013)) to aspect-based sentiment analysis (ABSA, analyzing sentiment and opinion information at the more fine-grained aspect level (Zhang et al., 2022)) and the multifaceted analysis of subjective texts (MAST, focusing on specific sentiment or opinion phenomena such as hate speech detection and comparative opinion mining (Barbieri et al., 2020)). In total, we consider 13 sentiment analysis tasks across 26 datasets. These tasks were often studied in isolation in the past due to their unique characteristics. This fragmentation, while reasonable before, offered a somewhat incomplete understanding of how well models could comprehend human subjective information.

For LLMs, we consider both open-source models including Flan-T5 (Chung et al., 2022) and Flan-UL2 (Tay et al., 2022), along with GPT-3.5 model series, namely ChatGPT (`gpt-3.5-turbo`) and InstructGPT (`text-davinci-003`) (Brown et al., 2020; Ouyang et al., 2022). We also establish comparison baselines using smaller language models[2] (SLMs) such as T5 (Raffel et al., 2020), which allows us to measure the performance of LLMs against these specialized models trained with in-domain labeled data.

Our investigation yields several insights: Firstly, LLMs already show strong sentiment analysis ability in zero-shot settings. On some simple SA tasks such as sentiment classification, they can perform on par with SLMs trained with full training data. Secondly, when it comes to more complex tasks such as ABSA tasks that require structured sentiment information, or MAST tasks requiring a deep understanding of specific sentiment phenomena, LLMs still lag behind SLMs trained with in-domain data. Moreover, LLMs appear to be sensitive to prompt design when encountering tasks with complex input and output formats. Thirdly, with a limited quantity of annotated data under the few-shot setting, LLMs with in-context learning consistently outperform SLMs trained with the same amount of data for all types of tasks. This suggests that the application of LLMs is advantageous when annotation resources are scarce.

During the investigation, we also identify several limitations of current practice in evaluating a model's SA capability. For example, the evaluations often only involve specific tasks or datasets; and inconsistent prompts are utilized across different studies to evaluate models. While these evaluation practices might have been appropriate in the past, they fall short of accurately assessing LLMs' SA abilities. To address these issues, we propose a novel benchmark called SENTIEVAL. It breaks the boundary of a wide range of SA tasks, enabling a more comprehensive evaluation of models. It also employs varied task instructions, paired with the corresponding text, alleviating the sensitivities associated with prompt design during the evaluation of different LLMs. Furthermore, by framing these tasks as natural language instructions, we create a more realistic evaluation environment akin to a real-world practical use case.

2 Background

Sentiment Analysis SA has received lots of attention since its early appearance (Turney, 2002; Yu and Hatzivassiloglou, 2003; Hu and Liu, 2004) and remained an active research area in the field of NLP nowadays (Liu, 2015; Poria et al., 2020; Yadav and Vishwakarma, 2020). Such enduring interest stems from both the importance of comprehending human subjective sentiments and opinions toward achieving human-level intelligence (Bubeck et al., 2023), and its broad practical applications, such as analyzing customer reviews (Keung et al., 2020; Zhang et al., 2022) and digesting social media opinions (Yue et al., 2019; Barbieri et al., 2020). SA comprises a broad spectrum of tasks, from sentiment classification that determines the overall sentiment polarity of a given text (Turney, 2002), to aspect-based sentiment analysis (ABSA) (Hu and Liu, 2004; Zhang et al., 2022) and multifaceted analysis of subjective texts (MAST) (Liu, 2015) in recent years. All these tasks collectively contribute to a holistic understanding of sentiment in language and demonstrate the wide range of tasks falling under the umbrella of sentiment analysis.

Large Language Models (LLMs) Recently, there has been a remarkable advancement in the development of LLMs, such as GPT-3 (Brown et al., 2020), PaLM (Chowdhery et al., 2022), Flan-UL2 (Tay et al., 2022), LLaMA (Touvron et al., 2023) and ChatGPT. There are some initial attempts on evaluating LLMs for SA tasks. Zhong et al. (2023) observe that the zero-shot performance of LLMs is comparable to fine-tuned BERT model. Wang

---

[2] So far, there is no clear definition of what models can be counted as small or large language models. In this work, we consider model parameters less than 3B as small, and larger than 3B as large for simplified demonstration.

et al. (2023) conduct a preliminary study with ChatGPT for some SA tasks, specifically investigating its ability to handle polarity shifts, open-domain scenarios, and sentiment inference problems. In addition, Zhao et al. (2023) focus on ChatGPT's emotional conversation capability and indicate it exhibits promising results in generating emotional responses. Moreover, Deng et al. (2023) explore the fine-tuning of a small student model with an LLM to generate weak labels, and the final model performs on par with existing supervised models. Despite those existing efforts, their scope is often limited to specific tasks and involves different datasets and experimental designs. The true capacity of LLMs for SA remains unclear.

3 Investigated Tasks and Datasets

We conduct an extensive survey of a wide range of SA tasks and categorize different tasks into three types: sentiment classification (SC), aspect-based sentiment analysis (ABSA), and multifaceted analysis of subjective texts (MAST). We briefly describe investigated tasks of each type, along with the datasets and evaluation metrics in this section. The detailed descriptions are in Appendix A.1. For each dataset, we sample a maximum of 500 examples from its original test set, to ensure balance across various tasks and datasets.

3.1 Sentiment Classification

Sentiment classification (SC) aims at assigning predefined sentiment classes (e.g., positive, negative, or neutral) to given texts (Liu, 2015). Depending on the level of granularity at which sentiment can be analyzed, SC can be further categorized into three tasks, including document-level, sentence-level, and aspect-level SC. For document-level SC, we take three widely used datasets, including IMDb (Maas et al., 2011), Yelp-2, and Yelp-5 (Zhang et al., 2015), which contain movie reviews and business reviews respectively. For sentence-level SC, we select multiple datasets for evaluation, including MR (Pang and Lee, 2005), SST2, SST5 (Socher et al., 2013), and Twitter (Rosenthal et al., 2017), covering different types of opinionated texts. Aspect-level SC focuses on identifying sentiment towards specific aspects or entities mentioned. There are two widely used datasets including Lap14 and Rest14 (Pontiki et al., 2014) which consist of laptop and restaurant reviews.

These datasets involve a varying number of sentiment classes. We take accuracy scores as the evaluation metric for these SC tasks.

3.2 Aspect-based Sentiment Analysis

Aspect-based sentiment analysis (ABSA) refers to the process of analyzing people's sentiments at a more fine-grained aspect level. It encompasses the analysis of various sentiment elements, such as aspect terms, aspect categories, opinions, and sentiment polarities (Zhang et al., 2022).

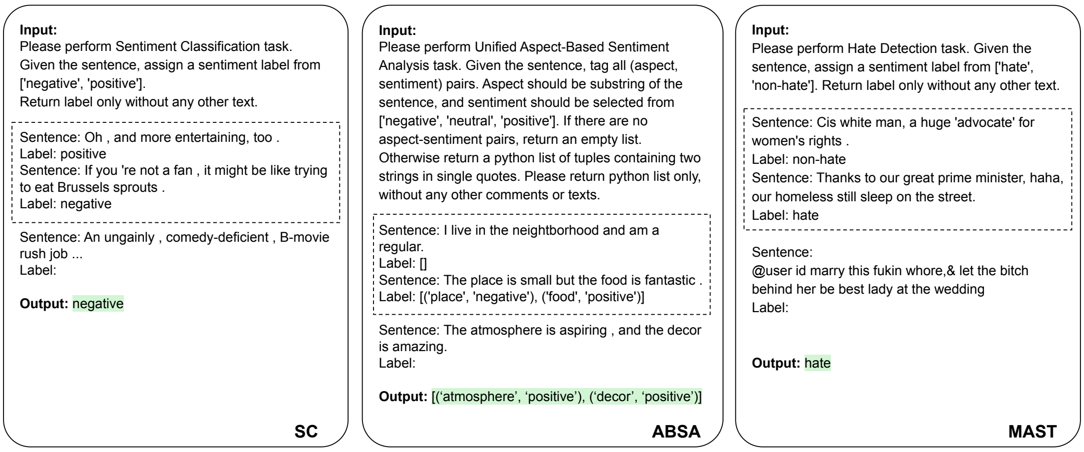
We focus on three compound ABSA tasks here for investigation, which aim to jointly extract multiple sentiment elements: (1) Unified Aspect-based Sentiment Analysis (UABSA) is the task of extracting both the aspect and its corresponding sentiment polarity simultaneously. We evaluate UABSA on four datasets originally from SemEval-2014 (Pontiki et al., 2014), SemEval-2015 (Pontiki et al., 2015), and SemEval-2016 (Pontiki et al., 2016) shared tasks. (2) Aspect Sentiment Triplet Extraction (ASTE) further extracts the opinion terms on the basis of the UABSA task, which provides an explanation for the predicted sentiment on certain aspects. The datasets we utilized were introduced by Xu et al. (2020), which were built upon the four UABSA datasets. (3) Aspect Sentiment Quadruple Prediction (ASQP) task (Zhang et al., 2021; Cai et al., 2021) was introduced to provide a complete aspect-level sentiment structure, namely (category, aspect, opinion, sentiment) quadruple. Two restaurant datasets are used for the ASQP task.

Following previous studies, we use the Micro-F1 score as the metric for evaluation. A predicted tuple would be counted as correct only if all sentiment elements match exactly with the gold labels.

3.3 Multifaceted Analysis of Subjective Text

Multifaceted analysis of subjective text (MAST) are tasks that involve different aspects of human subjective feeling reflected in the text (Liu, 2015; Poria et al., 2020). These tasks expand SA beyond merely identifying positive or negative feelings but focus on recognizing and understanding a broader range of human emotional states.

We adopt multiple datasets for investigation, including: (1) Implicit sentiment analysis (Li et al., 2021); (2) SemEval2019 HatEval challenge (Basile et al., 2019) for hate speech detection; (3) Subtask 3A of the SemEval2018 (Hee et al., 2018) for irony detection; (4) SemEval2019 OffensEval dataset (Zampieri et al., 2019) for offensive language identification; (5) SemEval2016 shared task



Input:
Please perform Sentiment Classification task. Given the sentence, assign a sentiment label from ['negative', 'positive'].
Return label only without any other text.

Sentence: Oh , and more entertaining, too .
Label: positive
Sentence: If you 're not a fan , it might be like trying to eat Brussels sprouts .
Label: negative

Sentence: An ungainly , comedy-deficient , B-movie rush job ...
Label:

Output: negative

SC

Input:
Please perform Unified Aspect-Based Sentiment Analysis task. Given the sentence, tag all (aspect, sentiment) pairs. Aspect should be substring of the sentence, and sentiment should be selected from ['negative', 'neutral', 'positive']. If there are no aspect-sentiment pairs, return an empty list. Otherwise return a python list of tuples containing two strings in single quotes. Please return python list only, without any other comments or texts.

Sentence: I live in the neightborhood and am a regular.
Label: []
Sentence: The place is small but the food is fantastic .
Label: [('place', 'negative'), ('food', 'positive')]

Sentence: The atmosphere is aspiring , and the decor is amazing.
Label:

Output: [('atmosphere', 'positive'), ('decor', 'positive')]

ABSA

Input:
Please perform Hate Detection task. Given the sentence, assign a sentiment label from ['hate', 'non-hate']. Return label only without any other text.

Sentence: Cis white man, a huge 'advocate' for women's rights .
Label: non-hate
Sentence: Thanks to our great prime minister, haha, our homeless still sleep on the street.
Label: hate

Sentence:
@user id marry this fukin whore,& let the bitch behind her be best lady at the wedding
Label:

Output: hate

MAST

Figure 1: Prompt examples for SC, ABSA, and MAST respectively. The text inside the dashed box are demonstrations of the few-shot setting and would be removed under the zero-shot setting.

on Detection Stance in Tweets (Mohammad et al., 2016) for stance detection task; (6) CS19 dataset (Panchenko et al., 2019) for comparative opinion mining task; (7) TweetEval benchmark (Barbieri et al., 2020) for emotion recognition task.

For the evaluation, we follow previous studies to utilize the most common metrics for each task respectively. Details are given in Appendix A.1 and metrics for each task are summarized in Table 4.

4 Evaluation Setup

4.1 Models

Large Language Models (LLMs) We adopt two models from the Flan model family since they are open-sourced and showed strong zero-shot and few-shot performance, namely `Flan-T5` (XXL version, 13B) (Chung et al., 2022) and `Flan-UL2` (20B) (Tay et al., 2022). We use their checkpoints hosted on Huggingface for the inference. We also take two models from OpenAI, including `ChatGPT` (`gpt-3.5-turbo`[3]) and the text-davinci-003 model (`text-003`, 175B) of the GPT-3.5 family.

Small Language Models (SLMs) For SLMs, we take `T5` (large version, 770M) (Raffel et al., 2020), which shows great performance in tackling multiple SA tasks in a unified text-to-text format. This allows us to utilize a single, consistent SLM for all SA tasks without task-specific designs, enabling us to make a coherent and relatively fair comparison with LLMs. We train the `T5` model with domain-specific data on each dataset, with either the full training set (statistics detailed in Table 4) or sampled data in the few-shot setting. We use the Adam optimizer with a learning rate of 1e-4 and a fixed batch size of 4 for all tasks. We set 3 epochs for the full training setting and 100 epochs for the few-shot training setting. We conduct three runs with different random seeds for SLMs in both settings and report the average results for more stable comparisons.

4.2 Prompting Strategy

LLMs may produce very different responses even when the prompts are semantically similar (Perez et al., 2021; Lu et al., 2022). Furthermore, the preference for prompts varies from one LLM to another. Therefore, we aim to provide relatively consistent prompts for all datasets across different models in this study, rather than specific designs, in order to evaluate the general performance of LLMs. Our goal is to design prompts that are simple, clear, and straightforward.

As shown in Figure 1, we include only essential components in the prompt, namely the task name, task definition, and output format. The task name mentions the name of a specific task. The task definition is constructed based on each task's definition and annotation guidelines and also incorporates the label space as a set of options for the model to output its response. The output format defines the expected structure of the output, enabling us to decode the model's responses into our desired format. For few-shot learning, an additional "demonstration" part is added (contents in the dashed boxes). This includes k examples for each class, each accompanied by their respective gold labels in the desired format. For more detailed information and examples, please refer to Appendix A.6.

---

[3] May 12 version of ChatGPT is used for the experiments.

Task	Dataset	Baseline		LLM				SLM
		`random`	`majority`	`Flan-T5`	`Flan-UL2`	`text-003`	`ChatGPT`	$\texttt{T5}_{large}$
		-	-	(11B)	(20B)	(175B)	(NA)	(770M)
Sentiment Classification (SC)

Table 1: Zero-shot performance of various sentiment analysis tasks. The best results on each dataset are in bold. Similar to GLUE (Wang et al., 2019), "Average" rows show the average of all dataset-specific metrics. We present the full training set fine-tuned SLM performance as a reference.

5 Evaluation Results and Analysis

5.1 Zero-shot Results

We summarize the zero-shot performance of various LLMs in Table 1. Two baselines are further included for better comparisons: `random` assigns a random label to each sample, and `majority` takes the most common label from the training set's label distribution as the prediction. For SLMs, we report the performance by employing the complete training set to train the model before proceeding to conduct inference on the same test set. The following observations can be made.

LLMs such as ChatGPT demonstrate strong zero-shot performance. As can be observed in the top and bottom parts of Table 1, LLMs have demonstrated a strong ability to tackle simple SC tasks such as binary sentiment classification and MAST tasks without any prior in-domain training. For example, `ChatGPT` achieves comparable results to the `T5` model, which has been specifically fine-tuned with the full training set for each dataset. On average, `ChatGPT`'s performance reaches 97% of the `T5`'s prediction on SC tasks, and 85% on MAST tasks, respectively. Moreover, `Flan-UL2`, despite not being the largest model, is able to achieve comparable, and in some cases, superior performance to larger models like `text-003` across multiple tasks, possibly due to the advantage of both reasonable model size and large-scale instruction tuning. Overall, these results suggest a superior sentiment analysis ability already inherent in these models.

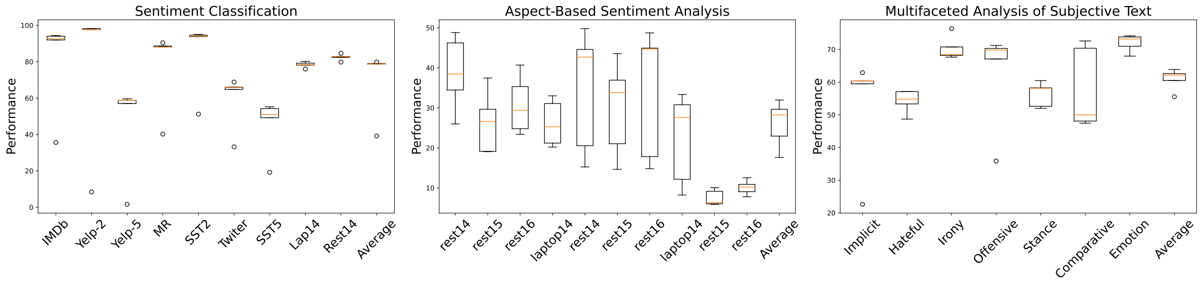

Figure 2: Sensitivity of different prompt designs on three types of SA tasks. The performance variance of each dataset is from five different prompts given by GPT-4. The circles depicted in the figure represent outlier data points.

LLMs still struggle with extracting fine-grained structured sentiment information or tasks requiring a deep understanding of specific sentiment phenomena. While LLMs have shown proficiency in many SA tasks, they fall short when it comes to extracting structured and fine-grained sentiment and opinion information. For instance, `Flan-T5` and `Flan-UL2` were unable to achieve any notable performance on any ABSA tasks across all datasets, as can be noted from the middle part of Table 1. Although they have gone through instruction tuning, they can hardly follow the format required in the instructions and generate meaningless predictions. `text-003` and `ChatGPT` provide better results but were still significantly outperformed by fine-tuned smaller language models. For example, `text-003` reaches only around 54% of the performance of a fine-tuned `T5` model on ABSA tasks, though being more than 200 times larger. Similarly, for more complicated MAST tasks, it also lags behind the fine-tuned `T5` models, e.g., 45.25% v.s. 67.12% accuracy scores on the implicit sentiment analysis task.

Some SA tasks have reached certain maturity Overall, we can see that satisfactory performance of some SA tasks such as binary sentiment classification (e.g., IMDb, Yelp-2, MR, SST2) or simple MAST tasks (e.g., emotion recognition), can be achieved with either LLMs under a zero-shot setting or SLMs trained with in-domain labeled dataset. This observation implies that these SA tasks have reached a level of maturity and can be considered as effectively solved, thereby shifting the focus in the field toward addressing more complex challenges that LLMs still struggle with.

5.2 Analysis of Sensitivity on Prompt Design

The design of suitable prompts is critical when leveraging large language models for specific tasks. Different prompt designs have been shown to even lead to large performance variance in some tasks (Perez et al., 2021; Lu et al., 2022). To investigate the impact of such sensitivity on SA tasks, we further construct an additional five prompts for each task, then conduct experiments with `ChatGPT` to evaluate the variations in performance. We take GPT-4 (OpenAI, 2023) for such prompt generation, which has shown to be effective to generate prompts or instruction-following data (Peng et al., 2023).[4] This can also alleviate the potential bias of manually written prompts. Details of such prompt generation are given in Appendix A.2.

The results of `ChatGPT` with the five different prompts are depicted in Figure 2, in the format of the boxplot. It can be noticed that the impact of different prompts on performance varies from task to task. For SC tasks, the choice of prompt appears to have less effect, e.g., the boxes in the top figure are usually quite concentrated. However, for tasks necessitating structured, fine-grained output, the performance can vary significantly depending on the design of the prompt, as illustrated in the middle figure for ABSA tasks. Interestingly, despite the simplicity of SC tasks, the model still demonstrates sensitivity to certain prompts, with noticeable outliers for some SC datasets (i.e., circles in the figure). With a detailed investigation, we find models tend to be sensitive to certain words, e.g., "*analyze*", where it may generate long explanations even explicitly instructed not to do so.

5.3 Few-shot Results

We also conduct few-shot experiments to assess whether LLMs or SLMs perform better when only a limited number of examples for a sentiment analysis task are available. We consider three K-shot settings: 1-shot, 5-shot, and 10-shot. For each set-

---

[4] We also conduct preliminary experiments with `ChatGPT`, however, it struggles to understand such complicated instructions, thus failing to produce satisfactory prompts.

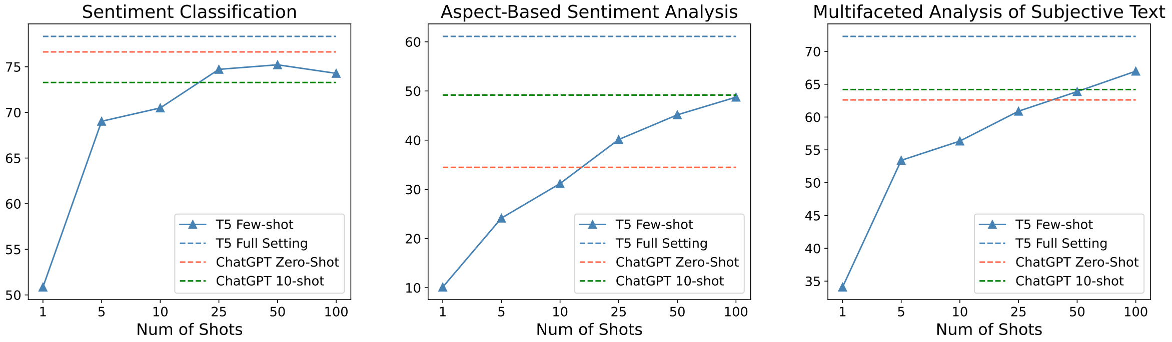

Figure 3: Averaged few-shot results on all datasets for each task type with an increasing number of different shots. Results of ChatGPT zero-shot and T5 full setting are also shown for easy comparison.

Task	1-shot		5-shot		10-shot	
	`ChatGPT`	`T5`	`ChatGPT`	`T5`	`ChatGPT`	`T5`
Doc-SC	81.47	66.76	NA	75.64	NA	77.76
Sent-SC	76.20	46.80	75.20	67.32	72.20	69.52
Aspect-SC	81.57	58.97	75.57	72.47	75.43	72.43
UABSA	52.57	15.70	53.75	29.71	55.02	39.51
ASTE	44.45	6.81	48.65	23.60	50.14	29.89
ASQP	31.07	5.61	34.61	14.08	35.54	17.05
MAST	68.46	34.09	66.21	53.40	64.19	56.34

Table 2: Few-shot performance of various sentiment analysis tasks. All the results are reported with average scores in 3 runs. "NA" denotes infeasible experiments due to limited sequence length.

ting, we sample K examples for each sentiment type (with the exception of the ASQP task, where we sample K examples for each aspect category). These sampled examples serve as in-context learning samples for LLMs and training data for SLMs. The results of these experiments are summarized in Table 2. More detailed results as well as the standard deviation are provided in Table 6.

We can see that LLMs surpass SLMs under varied few-shot settings. Across all three few-shot settings, LLMs consistently outperform SLMs such as `T5` in almost all cases. This advantage becomes more obvious for three ABSA tasks, which require the model to output structured sentiment information. SLMs significantly lag behind LLMs under such requirements, possibly due to the difficulty of learning such patterns with limited data. To delve deeper into their respective strengths and limitations, we gradually increase the value of K in the few-shot settings[5], and present the results for `T5` in Figure 3. It becomes apparent that even with a 10-shot setting, `ChatGPT` sets a robust baseline that requires `T5` to utilize nearly five to ten times (i.e., 50-shot or 100-shot) more data to achieve comparable performance.

In addition, Table 2 demonstrates that as the number of shots increases, SLMs consistently exhibit substantial improvements in various SA tasks. However, the impact of increasing shots on LLMs' performance varies from task to task. For relatively easier tasks like SC, the incremental benefit of additional shots for LLMs is less obvious. While for ABSA tasks, which demand a deeper understanding and precise output format, increasing the number of shots greatly boosts LLM performance. Moreover, including additional examples for MAST tasks can even lead to a decrease in performance, possibly due to biases introduced by the demonstration examples. This suggests that the utility of extra examples is not a silver bullet for all tasks but varies depending on the complexity of the task.

6 SENTIEVAL Benchmark

6.1 Rethinking SA Capability Evaluation

We have conducted extensive experiments to evaluate LLMs' SA capability in the above sections, where we notice some common flaws regarding the current evaluation practice

Call for more comprehensive evaluation Most of the current evaluations tend to focus narrowly on specific SA tasks or datasets (Zhong et al., 2023; Wang et al., 2023). While these assessments can provide useful insights into certain aspects of an LLM's sentiment analysis competence, they inherently fall short of capturing the full breadth and depth of the model's capabilities. Such limitation not only reduces the overall reliability of the assessment results but also limits the scope of understanding the model's adaptability to diverse SA

---

[5] We only report results for SLMs here, as LLMs frequently encounter a context length limit, making them unsuitable for larger K values without specific handling.

scenarios. For example, a model with satisfactory sentiment classification ability does not guarantee its performance in detecting hateful speech.

Appeal for natural ways to interact with models Conventional sentiment analysis tasks are often structured as a single sentence paired with its corresponding sentiment label. This format, while facilitating the learning of the mapping relationship between the text and its sentiment label, may not optimally suit LLMs, which are typically text-generation models. In practice, users exhibit varied writing styles, leading to diverse ways of communicating their requirements to LLMs to solve their SA tasks. It is thus critical to account for these diverse expressions in the evaluation process to reflect more realistic use cases.

Sensitivity on Prompt Design As shown in Sec 5.2, variations in prompt design can substantially influence the performance of `ChatGPT`, even on some seemingly simple sentiment classification tasks. Such nuanced sensitivity associated with prompt design introduces challenges when attempting to fairly and stably test the SA capabilities of LLMs. This challenge is further amplified when various studies employ distinct prompts for different SA tasks across a range of LLMs. The inherent bias associated with prompt design complicates the fair comparison of different models using the same prompt, as a single prompt may not be universally appropriate to reflect all models' capabilities.

6.2 SENTIEVAL: Construction

To mitigate the limitations when assessing models' SA capability discussed above, we propose a new benchmark named SENTIEVAL for better **senti**ment analysis **eval**uation in the era of LLMs.

The main idea of SENTIEVAL is to: 1) break the boundary between individual sentiment analysis tasks to establish a unified testing benchmark, providing a more comprehensive assessment of a model's sentiment analysis proficiency, rather than emphasizing on specific aspects; 2) test the model using natural language instructions presented in various styles. This mimics the real use case when humans interact with the model with natural languages for solving SA tasks, instead of purely learning text-label mapping; 3) equip the benchmark with diverse but fixed instructions, making performance comparisons more stable and reliable across different LLMs and studies. By setting a consistent benchmark, it allows for an equitable comparison that is less subject to prompt variation.

	`Flan-T5`	`Flan-UL2`	`text-003`	`ChatGPT`
SENTIEVAL	29.07	38.82	36.64	**47.55**
SC	54.22	63.13	60.11	**72.73**
ABSA	0.00	0.09	11.66	**14.77**
MAST	34.21	**58.35**	38.48	57.71

Table 3: Results on SENTIEVAL benchmark of different LLMs, measured by the exact match with the label.

Specifically, besides the five prompts generated by GPT-4 in Sec 5.2, we further manually write five additional prompts for each task. Therefore, each task will have ten candidate prompts in total. Then for each data sample of all tasks, we randomly select one prompt and combine it with the text to form a complete query for the model. Additionally, we also randomly decide (with a 50% percent chance) whether to put few-shot examples with the current prompt. In the end, SENTIEVAL contains 12,224 data samples, each containing the original text, the instruction for a specific task, and optional few-shot examples.

6.3 SENTIEVAL: Re-evaluate

After constructing the SENTIEVAL benchmark, we revisit the evaluation of the various LLMs outlined in Sec 4.1 against this benchmark. We report the results in Table 3, which are the exact match scores between the labels and predictions. Although the new benchmark does not treat each task separately, we further report the results of different task types for investigations.

From Table 3, we can see noticeable differences in the relative performance of various models. For example, `Flan-UL2` achieves comparable performance with `ChatGPT` on SC tasks in Table 1, but there is a large gap in Table 3. A potential explanation for this discrepancy is that SENTIEVAL requires the model to comprehend diverse styles of instructions (i.e., varying prompt designs) for optimal performance, where `ChatGPT` exhibits greater robustness. Additionally, it demands the model's compliance with the required format, or adaptation to the pattern set by few-shot examples, thus posing greater challenges. We can see `ChatGPT` sets a strong performance baseline, showing its strong SA capability and instruction-following ability. Overall, there is much room for improvement on this benchmark in the future, especially for more complicated tasks such as ABSA and MAST tasks.

7 Conclusions

In this study, we conduct a systematic evaluation of various sentiment analysis tasks using LLMs, which helps better understand their capabilities in sentiment analysis problems. Experimental results reveal that while LLMs perform quite well on simpler tasks in a zero-shot setting, they struggle with more complex tasks. In a few-shot learning context, LLMs consistently outperform SLMs, suggesting their potential in scenarios where annotation resources are scarce. This work also highlights the limitations of current evaluation practices and then introduces the SENTIEVAL benchmark as a more comprehensive and realistic evaluation tool.

Limitations

In this study, our objective is to conduct a comprehensive evaluation of large language models' capabilities in performing diverse sentiment analysis tasks. We have selected 13 tasks encompassing 26 datasets for this purpose. However, this selection does not represent an exhaustive enumeration of all sentiment analysis-related tasks. Including a broader range of tasks focusing on different sentiment aspects or in different formats would further show the strengths and limitations of LLMs.

Regarding the language, all the datasets included in our investigation are in English. It is worth mentioning that sentiment phenomena are often closely related to the language in which they are expressed, and even to the cultural background. Consequently, extending such investigations to other languages or multilingual settings would yield a more comprehensive understanding of LLMs' performance in sentiment analysis tasks across diverse linguistic and cultural contexts.

A appendix

A.1 Details on Investigated Tasks and Datasets

We conduct an extensive survey of a wide range of SA tasks and categorize different tasks into three types: sentiment classification (SC), aspect-based sentiment analysis (ABSA), and multifaceted analysis of subjective texts (MAST). We describe investigated tasks of each type, along with the datasets and evaluation metrics. To ensure balance across various tasks and datasets, we limit our evaluation by sampling a maximum of 500 examples from the test set of each dataset. Detailed statistics on each task and dataset are summarized in Table 4.

A.1.1 Sentiment Classification

Sentiment classification (SC) aims at assigning predefined sentiment classes (e.g., positive, negative, or neutral) to given texts (Liu, 2015). It serves as a fundamental measure of sentiment orientation and is commonly used to analyze customer reviews, social media posts and etc. It can involve a varying number of sentiment classes, ranging from binary classification, where sentiments are categorized as either positive or negative, to more nuanced five-class classification, which grades sentiments on a scale from very negative to very positive. There are also different levels of granularity at which sentiment can be analyzed, including document-level, sentence-level, and aspect-level SC.

Document-Level Sentiment classification at the document level aims to determine the overall sentiment expressed in a text corpus, providing a high-level understanding of the expressed sentiment orientation. We evaluate on three widely used datasets, including IMDb (Maas et al., 2011), Yelp-2, and Yelp-5 (Zhang et al., 2015). The IMDb dataset contains movie reviews, whereas the Yelp-2 dataset includes customer reviews for businesses. Reviews of both datasets are labeled as either *positive* or *negative*. However, the Yelp-5 dataset offers a more fine-grained sentiment classification by introducing three additional sentiment classes: *very positive*, *very negative*, and *neutral*. We employ accuracy as the evaluation metric.

Sentence-Level Sentence-level classification allows for sentiment analysis on a sentence-by-sentence basis. It is particularly useful in analyzing social media posts, customer feedback, or any text where sentiments may change rapidly from sentence to sentence. We select multiple datasets for evaluation, including MR (Pang and Lee, 2005), SST2, SST5 (Socher et al., 2013), and Twitter (Rosenthal et al., 2017). The MR, SST2, and SST5 datasets contain movie reviews, whereas the Twitter dataset consists of social media posts. While the SST2 and MR datasets use binary sentiment

Task	Dataset	train	dev	test	sampled test	class*	metric
Sentiment Classification (SC)							
Document-Level	IMDb	22,500	2,500	25,000	500	2	accuracy

Emotion	Emotion20	3,257	374	1,421	500	4	macro_f1

Table 4: Investigated tasks and dataset statistics. ∗ represents the number of sentiment classes among each task, except for the two datasets of ASQP, which represent the number of aspect categories. † denotes the macro_f1 score without none class.

labels, Twitter's sentiment analysis introduces an additional *neutral* class. In addition, SST5 provides a wider range of labels including *very positive*, *positive*, *neutral*, *negative*, and *very negative* sentiments. To evaluate the performance on these datasets, we use accuracy as a metric.

Aspect-Level Since sentiment expressed towards different targets might be different even within a single sentence, aspect sentiment classification dives even deeper into the analysis by focusing on identifying sentiment towards specific aspects or entities mentioned. This level of analysis is particularly valuable when the sentiment towards different aspects or entities needs to be assessed individually. There are two widely used datasets including Lap14 and Rest14. These datasets were introduced in the SemEval ABSA challenge 2014 (Pontiki et al., 2014) and consist of laptop and restaurant reviews, respectively. The goal is to determine the sentiment towards a specific aspect mentioned in a review sentence, classifying it as either *positive*, *negative*, or *neutral*. Performance assessment is based on the metric of accuracy.

A.1.2 Aspect-based Sentiment Analysis

Aspect-based sentiment analysis (ABSA) refers to the process of analyzing people's sentiments at a more fine-grained aspect level. It encompasses the analysis of various sentiment elements, such as aspects, opinions, and sentiment polarities (Zhang et al., 2022). ABSA has gained significant attention in recent years, resulting in the emergence of a wide range of tasks. We focus on three compound ABSA tasks here for investigation, which aim to jointly extract multiple sentiment elements.

Unified Aspect-based Sentiment Analysis (UABSA) UABSA is the task of extracting both the aspect and its corresponding sentiment polarity simultaneously. We evaluate UABSA on four datasets originally from SemEval-2014 (Pontiki et al., 2014), SemEval-2015 (Pontiki et al., 2015), and SemEval-2016 (Pontiki et al., 2016) shared tasks, which consist of reviews from Laptops and Restaurants domains. Following previous studies, we use Micro-F1 score as the metric for evaluation. A predicted pair would be counted as correct only if both the aspect term and sentiment polarity match exactly with the gold labels.

Aspect Sentiment Triplet Extraction (ASTE) The ASTE task further extracts the opinion terms on the basis of the UABSA task, which provides an explanation for the predicted sentiment on certain aspects. Therefore, the final target of ASTE is to extract the (aspect, opinion, and sentiment) triplet for a given text. The datasets we utilized were introduced by Xu et al. (2020), which were built upon four UABSA datasets. Likewise, we employ the Micro-F1 metric and consider an exact match prediction of each triplet as correct.

Aspect Sentiment Quadruple Prediction (ASQP) ASQP task was introduced to provide a complete aspect-level sentiment structure, namely (category, aspect, opinion, sentiment) quadruple (Zhang et al., 2021; Cai et al., 2021). By introducing an additional aspect category element, it can still provide useful information when the aspect term is not explicitly mentioned. Our study utilizes two restaurant datasets from Zhang et al. (2021). We adopt the same evaluation metric and standardization with UABSA and ASTE, using Micro-F1 score as the evaluation metric.

A.1.3 Multifaceted Analysis of Subjective Text

Multifaceted analysis of subjective text (MAST) are tasks that involve different aspects of human subjective feeling reflected in the text (Liu, 2015; Poria et al., 2020). These tasks expand SA beyond merely identifying positive or negative feelings but focus on recognizing and understanding a broader range of human emotional states.

Implicit Sentiment Analysis Implicit sentiment analysis focuses on identifying the sentiment expressed indirectly or implicitly in text. It requires uncovering sentiments that are conveyed through subtle cues, such as contextual clues, tone, or linguistic patterns. Li et al. (2021) divided the Laptop and Restaurant reviews from SemEval 2014 (Pontiki et al., 2014) into two parts: implicit and explicit. For our analysis, we only utilized the implicit dataset and merged the data from both domains into a single dataset. To evaluate the performance, we employed accuracy as the metric.

Hate Speech Detection Hate speech detection refers to the process of identifying content that promotes discrimination, hostility, or violence against individuals or groups based on attributes such as race, religion, ethnicity, gender, sexual orientation, or other protected characteristics (Schmidt and Wiegand, 2017). For our analysis, we utilize the dataset from the SemEval2019 HatEval challenge (Basile et al., 2019). This dataset focuses on predicting whether a tweet exhibits hateful content towards two specific target communities: immigrants and women. We calculate the macro-averaged F1 score across the two binary classes: *hate* and *non-hate*.

Irony Detection Irony is a rhetorical device where the intended meaning of a statement is different or opposite to its literal interpretation. Irony detection aims to recognize and understand instances of irony in the text (Zeng and Li, 2022). We choose the Subtask 3A dataset of the SemEval2018 Irony Detection challenge (Hee et al., 2018) (referred to as “Irony18”). The goal is to determine whether a tweet contains ironic intent or not. For evaluation, we follow the convention to specifically consider the F1 score for the *irony* class, while ignoring *non-irony* F1 score.

Offensive Language Identification Offensive language identification involves identifying and flagging text that contains offensive or inappropriate content, including profanity, vulgarities, obscenities, or derogatory remarks (Pradhan et al., 2020). Different from hate speech, offensive language does not necessarily target a specific individual or group. For example, profanity expressions can be considered offensive language even when not directed at anyone in particular. We use the SemEval2019 OffensEval dataset (Zampieri et al., 2019). It involves classifying each given text as either *offensive* or *non-offensive*. We adopt a macro-averaged F1 score as the metric.

Stance Detection Stance detection refers to determining the perspective or stance expressed in a given text towards a particular topic or entity. It helps identify whether the text expresses *favor*, *against*, or *none* opinion towards a subject (Küçük and Can, 2020). We utilize the SemEval2016 shared task on Detection Stance in Tweets (Mohammad et al., 2016), and refer to it as "Stance16". It provides data in five domains (i.e., targets): abortion, atheism, climate change, feminism, and Hillary Clinton. In order to facilitate evaluation, we aggregate these domains into a single dataset. When evaluating the results, we only consider macro-averaged of F1 of *favor* and *against* classes, and ignore *none* class, following previous studies.

Comparative Opinion Mining Comparative opinion mining is the task of analyzing opinions and sentiments expressed in a comparative context (Varathan et al., 2017). It involves comparing different aspects of a product, service, or any other subject to determine preferences or relative opinions. In our study, we take the CS19 dataset (Panchenko et al., 2019), which provides annotated comparative sentences in the field of computer science. These sentences involve comparisons between various targets such as programming languages, database products, and technology standards. The opinions expressed in the dataset are categorized as either *better* or *worse*. To evaluate the performance, we employ accuracy as the metric.

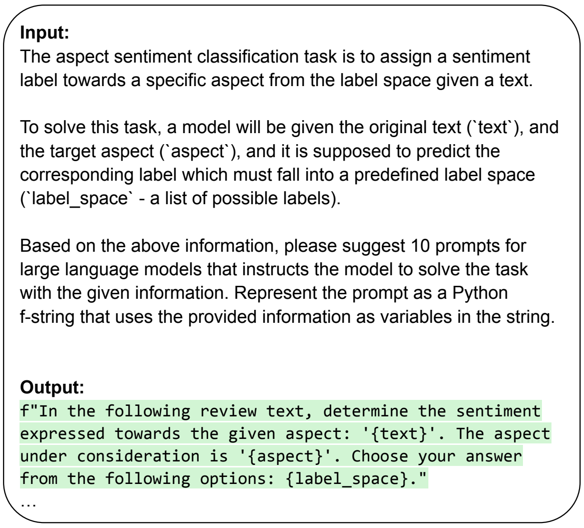
Emotion Recognition Emotion recognition involves the identification and understanding of emotions expressed in text (Sailunaz et al., 2018). It focuses on detecting and categorizing different emotional states. We use the dataset provided by the TweetEval benchmark (Barbieri et al., 2020), which we refer to it as "Emotion20". It transforms the SemEval2018 Affects in Tweets dataset (Mohammad et al., 2018) from multi-class classification into a multi-label dataset, by keeping only the tweets labeled with a single emotion. It selects the most common four emotions, namely *anger*, *joy*, *sadness*, and *optimism*. For evaluation, we utilize the macro-averaged F1 score, which considers the overall performance across all classes.

A.2 Details on Prompt Generation

Specifically, we provide the task description, format requirement (similar to those described in Sec 4.2), and an instruction to require GPT-4 to generate several prompts, representing as Python f-strings. We also optionally provide some input-target pairs to help the model better grasp the goals of the task. We present an example prompt in Figure 4, using the aspect-level SC task for illustration.

A.3 Cost Analysis

We provide a comparison of the average cost per task category when utilizing `ChatGPT` and `T5`$_{large}$ in our experiments, as detailed in Table 5 for reference. In practical applications, costs are influenced by a multitude of factors, such as the availability of training data, the volume of inference requests, and the pricing of cloud services or APIs. Developers are advised to select models based on their specific requirements and use-case scenarios.



Input:

The aspect sentiment classification task is to assign a sentiment label towards a specific aspect from the label space given a text.

To solve this task, a model will be given the original text (`text`), and the target aspect (`aspect`), and it is supposed to predict the corresponding label which must fall into a predefined label space (`label_space` - a list of possible labels).

Based on the above information, please suggest 10 prompts for large language models that instructs the model to solve the task with the given information. Represent the prompt as a Python f-string that uses the provided information as variables in the string.

Output:

```
f"In the following review text, determine the sentiment
expressed towards the given aspect: '{text}'. The aspect
under consideration is '{aspect}'. Choose your answer
from the following options: {label_space}."
...
```

Figure 4: Example prompts generated by GPT-4 for the aspect-level SC task. The first generated prompt is shown for illustrative purposes, and subsequent prompts are not included for brevity.

A.4 Detailed results in few-shot settings

We present detailed few-shot performance of various sentiment analysis tasks in Table 6. All the results are reported with average and standard deviation in 3 runs.

A.5 Discussions

A.5.1 LLMs for SA in Practice

In this study, we carry out a comprehensive evaluation of various large language models across a range of sentiment analysis tasks. The experimental results lead us to several primary findings and recommendations for practical SA application:

Task	0-shot	1-shot		5-shot		10-shot		Full
	`ChatGPT`	`ChatGPT`	`T5`$_{large}$	`ChatGPT`	`T5`$_{large}$	`ChatGPT`	`T5`$_{large}$	`T5`$_{large}$
SC	0.10	0.29	0.46	0.30	0.64	0.58	0.88	45.49
ABSA	0.10	0.12	0.46	0.37	0.61	0.65	0.79	0.65
MAST	0.05	0.23	0.49	0.65	0.73	1.19	0.53	1.65
Average	0.09	0.22	0.47	0.46	0.67	0.83	0.72	16.44

Table 5: Average Cost Comparison in $USD for `ChatGPT` and `T5`$_{large}$

Task	Dataset	1-shot			5-shot			10-shot	
		`Flan-UL2`	`ChatGPT`	`T5`$_{large}$	`Flan-UL2`	`ChatGPT`	`T5`$_{large}$	`ChatGPT`	`T5`$_{large}$

Table 6: Few-shot performance of various sentiment analysis tasks. All the results are reported with average and standard deviation in 3 runs. "NA" denotes infeasible experiments due to limited sequence length.

- For simple SA tasks such as binary or trinary sentiment classification, LLMs can already serve as effective solutions. Even in a zero-shot setting, their performance can match or surpass fine-tuned smaller language models, and with little sensitivity to different prompt designs (as shown in Sec 5.2).

- When annotation resources are scarce, LLMs remain a good choice due to their superior few-shot in-context learning performance compared to SLMs trained on the same limited data. However, the restricted context length of LLMs can limit their use case, particularly in document-level tasks where SLMs might be more suitable.

- For tasks requiring structured sentiment output, like aspect-based sentiment analysis tasks, LLMs might not be the best option. They tend to lag behind SLMs in both automatic and human evaluations, and performance can vary significantly with different prompt designs.

- Larger models do not always guarantee superior performance, for instance, `Flan-UL2` often performs comparably to the GPT-3.5 series of models, despite being much smaller in size. This suggests that employing instruction-tuning to attain a reasonably sized model may suffice for practical SA applications.

A.5.2 SA Challenges for LLMs

With the advancement of LLMs, many SA tasks can be claimed to be solved such as binary sentiment classification, as we saw from the experimental results. However, does it mean sentiment analysis in general has reached its maturity in the era of LLMs? We discuss some remaining challenges that we think still pose great difficulties.

Understanding Complex Linguistic Nuances and Cultural Specificity Sentiment is often shaded with nuance and subtlety. Developing models capable of understanding such subtleties in language, such as sarcasm, irony, humor, and specific cultural idioms or expressions is still challenging. They often depend on the context and shared cultural background knowledge or even specific human experiences. For example, on Chinese social media, a comment "您说的都对" (English translation: "You are right about everything you said" with "You" in a respectful tone) may not necessarily indicate agreement but can be used ironically. However, this linguistic phenomenon may require familiarity with social media to interpret correctly.

Extracting fine-grained and structured sentiment information As can be seen from the results, requiring the models to generate structured fine-grained information, i.e., the ABSA tasks, is still challenging for the models. However, such information can be useful to quickly summarize large-scale information to produce a more organized digest, especially since the long context is still a limitation for many LLMs. Also, distinguishing more precise emotional states or intensities of sentiment for more detailed analysis is also challenging but worth exploring.

Real-Time Adaptation for Evolving Sentiment Analysis Sentiments and expressions constantly evolve, particularly on platforms like social media. This leads to the continual emergence of new idioms and sentiment-caring expressions. It thus demands the sentiment analysis models to adapt and learn from these evolving trends to accurately interpret the embedded sentiments. However, one of the major limitations of current LLMs lies in their lack of flexibility in fine-tuning or re-training. This issue restricts their capability to keep up with the fast-paced evolution of language and sentiment, resulting in outdated or inaccurate sentiment analysis. Therefore, a critical research direction involves developing methods for rapid and effective model updates to ensure real-time and accurate sentiment analysis.

A.6 Prompts for Each SA Task

We present a 1-shot prompt for each investigated sentiment analysis task, which is shown on the following pages.

task	Dataset	1-shot Prompt
SC	IMDb	Please perform Sentiment Classification task. Given the sentence, assign a sentiment label from [’negative’, ’positive’]. Return label only without any other text. Sentence: I ’ve seen the original English version on video . Disney ’s choice of voice actors looks very promising .... Label:positive Sentence: “ This is a depressingly shallow , naive and mostly unfunny look at a wildly improbable relationship between Brooks ’ psychotic film editor and Harold , his vapid girlfriend .... Label:negative Sentence: “ Jack and Kate meet the physician Daniel Farady first and then the psychics Miles Straume and they demonstrate that have not come to the island with the intention of rescuing the survivors . Locke and his group find the anthropologist Charlotte Staples Lewis , and Ben Linus shoots her . Meanwhile , the group of Jack finds the pilot Frank Lapidus , who landed the helicopter with minor damages that can be repaired . Jack forces Miles to tell the real intention why they have come to the island. < br / > < br / > The second episode of the Fourth Season returns to the island , with four new characters , stops the confusing “ ” flash-forwards ” ” and it seems that will finally be the beginning of the explanations that I (and most of the fans and viewers) expect to be provided in “ ” Lost ” ” . Why the interest of the government in Ben Linus , and how he is informed from the boat are some of the questions that I expect to see in the next episodes . My vote is eight. < br / > < br / > Title (Brazil) : Not Available ” Label:
SC	Yelp-2	Please perform Sentiment Classification task. Given the sentence, assign a sentiment label from [’negative’, ’positive’]. Return label only without any other text. Sentence: Had a great time with my beautiful wife listening to The Instant Classics . Drinks are pricey and menu seems a little limited , but I had a great time .... Label:positive Sentence: I have been to this location multiple times and every time the service is horrendous and the food is mediocre . Not sure if the location being in a mall has to do with it .... Label:negative Sentence: I expected the prices of the entrees to be a little bit higher but the quality of the Chinese food was not worth the money I paid for the dishes . I got the 18 monk noodle and the traditional dimsum . If I could describe the food in one word-terrible ! Making the dimsum look pretty by topping it with gold flakes did not do anything to make up for the flavor of the dimsum . It seemed too starchy and you can hardly taste the meat . The noodles looked like a sad , greasy slop of Mai fun type noodles (noodles were stuck together) saturated with soy sauce for color , and garnished with a few pieces of shitake mushrooms , green onions and fine threads of carrots . And yes , portions were small , but that ’s not really the worst part of the whole experience . Just poorly prepared , way overpriced Chinese food ... sorry . Label:

SC	Yelp-5	Please perform Sentiment Classification task. Given the sentence, assign a sentiment label from ['negative', 'neutral', 'positive', 'very negative', 'very positive']. Return label only without any other text. Sentence: The most important thing to me in an airline is that we do not fall out of the sky in an uncontrolled fashion . After all landing is a controlled crash .... Label:neutral Sentence: “ Great place to go for hair , nails or massage . Great service in a professional and clean environment . Most places u have to wait even if u have an appt .... Label:very positive Sentence: Loved the atmosphere . Right across from chase field . The pretzel and provolone and shrimp appetizers were plentiful and fantastic . Easily enough for four people to share .... Label:positive Sentence: “ 1 star- why ? The food was n't too bad . My husband had the fish tacos which were good . I ordered the Sicilian Stuffed Chicken , but get this .... Label:negative Sentence: “ Hello there ! 00a0 00a0 00a0 My name is Naiby Moreno , and the reason why I 'm writing you this email is because last night , around this time .... Label:very negative Sentence: Came a few days ago for a lease , was n't sure of size needed , so I guessed , three times ! Finally got it right , but hey , the store did n't bat a eye lash when I returned the ones that did n't work , they just asked if I needed help picking out a replacement . Since my cat has been loosing weight , I could not get the size down , so after my attempts , finally got the small dog size and sure enough it worked . Now to get the cat used to it before we need it . This store has everything you could need . They is even a new section by Martha Stewart , everything for you little pet . But her stuffs pricey , a lease from here collection , $ 19.99 , boy that 's steep ! The store is clean , neatly kept , well organized and they have grooming services . The employees were friendly and helpful , they looked like they enjoyed their jobs , and I would make this a regular place . Label:
SC	MR	Please perform Sentiment Classification task. Given the sentence, assign a sentiment label from ['negative', 'positive']. Return label only without any other text. Sentence: “ it 's the chemistry between the women and the droll scene-stealing wit and wolfish pessimism of anna chancellor that makes this “ ” two weddings and a funeral “ ” fun . ” Label:positive Sentence: the entire movie is about a boring , sad man being boring and sad . Label:negative Sentence: “ if you 're a crocodile hunter fan , you 'll enjoy at least the “ ” real “ ” portions of the film . if you 're looking for a story , do n't bother . ” Label:
SC	SST2	Please perform Sentiment Classification task. Given the sentence, assign a sentiment label from ['negative', 'positive']. Return label only without any other text. Sentence: Oh , and more entertaining , too . Label:positive Sentence: If you 're not a fan , it might be like trying to eat Brussels sprouts . Label:negative Sentence: An ungainly , comedy-deficient , B-movie rush job ... Label:

SC	Twitter	Please perform Sentiment Classification task. Given the sentence, assign a sentiment label from ['negative', 'neutral', 'positive']. Return label only without any other text. Sentence: - Just bought my 1st iPad, iPad3, feeling real burned, mad, about iPad4 so soon. Grrr. REALLY mad! Don't even care about mini now," Label:negative Sentence: @user @user @user I think this is the motive of the Yakub's laywers for pursuing the case Label:neutral Sentence: Kanye West was honored in a big way during Sunday night's MTV Video Music Awards by receiving the Michael Jackso... Label:positive Sentence: Do you think Michelle Obama wanted to smack Melania Trump for plagiarizing her convention speech? She has the arms for it. Label:
SC	SST5	Please perform Sentiment Classification task. Given the sentence, assign a sentiment label from ['negative', 'neutral', 'positive', 'very negative', 'very positive']. Return label only without any other text. Sentence: ' Like a child with an important message to tell ... (Skins ') faults are easy to forgive because the intentions are lofty . ' Label:neutral Sentence: That Haynes can both maintain and dismantle the facades that his genre and his character construct is a wonderous accomplishment of veracity and narrative grace . Label:very positive Sentence: Oh , and more entertaining , too . Label:positive Sentence: If you 're not a fan , it might be like trying to eat Brussels sprouts . Label:negative Sentence: When it comes out on video , then it 's the perfect cure for insomnia . Label:very negative Sentence: Everywhere the camera looks there is something worth seeing . Label:
SC	Lap14	Please perform Aspect Sentiment Classification task. Given the sentence, assign a sentiment label towards "Office" from ['negative', 'neutral', 'positive']. Return label only without any other text. Sentence: It even has a great webcam , and Skype works very well . (sentiment towards "webcam") Label:positive Sentence: - Touchpad will take a bit of time to get used to . (sentiment towards "- Touchpad") Label:neutral Sentence:) And printing from either word processor is an adventure . (sentiment towards "word processor") Label:negative Sentence: (but Office can be purchased) IF I ever need a laptop again I am for sure purchasing another Toshiba !! Label:

Continued from previous page		
SC	Rest14	Please perform Aspect Sentiment Classification task. Given the sentence, assign a sentiment label towards "garlic knots" from ['negative', 'neutral', 'positive']. Return label only without any other text. Sentence: While the new restaurant still features much of the same classical furniture that made Tiffin so attractive , the menu has been overhauled . (sentiment towards "classical furniture") Label:positive Sentence: And it all comes at a very reasonable price (congee , noodles , and rice dishes are no more than 3-6 each) . (sentiment towards "(congee") Label:neutral Sentence: The Singapore Mai Fun had NO curry flavor whatsoever . (sentiment towards "curry flavor") Label:negative Sentence: I also recommend the garlic knots . Label:
UABSA	Rest14	Please perform Unified Aspect-Based Sentiment Analysis task. Given the sentence, tag all (aspect, sentiment) pairs. Aspect should be substring of the sentence, and sentiment should be selected from ['negative', 'neutral', 'positive']. If there are no aspect-sentiment pairs, return an empty list. Otherwise return a python list of tuples containing two strings in double quotes. Please return python list only, without any other comments or texts. Sentence: also make sure you pay attention to the music being piped in , quite a weird selection . Label:[('music', 'neutral')] Sentence: but I would n't wan na live there . Label:[] Sentence: And their prices are very high , they actually think that they can get away with charging such prices for such terrible food and service ! Label:[('prices', 'negative'), ('prices', 'negative'), ('food', 'negative'), ('service', 'negative')] Sentence: Having not been home in the last 2 years may skew this reviewer a bit , but the food was tasty and spicy sans the oil that comes floating along at similar venues . Label:[('food', 'positive'), ('oil', 'neutral')] Sentence: After I paid for my purchase , I noticed they had not given me utensils so I could eat my pie . Label:
UABSA	Rest15	Please perform Unified Aspect-Based Sentiment Analysis task. Given the sentence, tag all (aspect, sentiment) pairs. Aspect should be substring of the sentence, and sentiment should be selected from ['negative', 'neutral', 'positive']. If there are no aspect-sentiment pairs, return an empty list. Otherwise return a python list of tuples containing two strings in double quotes. Please return python list only, without any other comments or texts. Sentence: The portions are HUGE , so it might be good to order three things to split rather than one appetizer and entree per person for two people . Label:[('portions', 'neutral')] Sentence: No , really . Label:[] Sentence: The food was bland oily . Label:[('food', 'negative')] Sentence: The food 's as good as ever . Label:[('food', 'positive')] Sentence: Need I say more ? Label:

UABSA	Rest16	Please perform Unified Aspect-Based Sentiment Analysis task. Given the sentence, tag all (aspect, sentiment) pairs. Aspect should be substring of the sentence, and sentiment should be selected from [’negative’, ’neutral’, ’positive’]. If there are no aspect-sentiment pairs, return an empty list. Otherwise return a python list of tuples containing two strings in double quotes. Please return python list only, without any other comments or texts. Sentence: Food was okay , nothing great . Label:[(’Food’, ’neutral’)] Sentence: I live in the neightborhood and am a regular . Label:[] Sentence: The place is small and cramped but the food is fantastic . Label:[(’place’, ’negative’), (’food’, ’positive’)] Sentence: One special roll and one regular roll is enough to fill you up , but save room for dessert ! Label:[(’special roll’, ’positive’), (’regular roll’, ’positive’), (’dessert’, ’positive’)] Sentence: The atmosphere is aspiring , and the decor is festive and amazing . Label:
UABSA	Laptop14	Please perform Unified Aspect-Based Sentiment Analysis task. Given the sentence, tag all (aspect, sentiment) pairs. Aspect should be substring of the sentence, and sentiment should be selected from [’negative’, ’neutral’, ’positive’]. If there are no aspect-sentiment pairs, return an empty list. Otherwise return a python list of tuples containing two strings in double quotes. Please return python list only, without any other comments or texts. Sentence: After that the said it was under warranty . Label:[(’warranty’, ’neutral’)] Sentence: I really wanted a Mac over a pc because I used a Mac in high school . Label:[] Sentence: Another issue I have with it is the battery . Label:[(’battery’, ’negative’)] Sentence: I love the size , keyboard , the functions . Label:[(’size’, ’positive’), (’keyboard’, ’positive’), (’functions’, ’positive’)] Sentence: Hopefully my replacement is brand new . Label:
ASTE	Rest 14	Please perform Aspect Sentiment Triplet Extraction task. Given the sentence, tag all (aspect, opinion, sentiment) triplets. Aspect and opinion should be substring of the sentence, and sentiment should be selected from [’negative’, ’neutral’, ’positive’]. Return a python list of tuples containing three strings in double quotes. Please return python list only, without any other comments or texts. Sentence: Service was slow had to wait to order and get food although not crowded . Label:[(’Service’, ’slow’, ’negative’)] Sentence: The atmosphere is n’t the greatest , but I suppose that ’s how they keep the prices down . Label:[(’atmosphere’, "is n’t the greatest", ’neutral’), (’prices’, ’down’, ’positive’)] Sentence: The fries are yummy . Label:[(’fries’, ’yummy’, ’positive’)] Sentence: Most importantly , it is reasonably priced . Label:
ASTE	Rest 15	Please perform Aspect Sentiment Triplet Extraction task. Given the sentence, tag all (aspect, opinion, sentiment) triplets. Aspect and opinion should be substring of the sentence, and sentiment should be selected from [’negative’, ’neutral’, ’positive’]. Return a python list of tuples containing three strings in double quotes. Please return python list only, without any other comments or texts. Sentence: the only things u could really taste are the very salty soy sauce (even its low sodium) , the vinegar-soaked rice , and the scallion on top of the fish . Label:[(’soy sauce’, ’salty’, ’negative’), (’rice’, ’vinegar-soaked’, ’negative’)] Sentence: Food was okay , nothing great . Label:[(’Food’, ’okay’, ’neutral’), (’Food’, ’nothing great’, ’neutral’)] Sentence: We recently decided to try this location , and to our delight , they have outdoor seating , perfect since I had my yorkie with me . Label:[(’outdoor seating’, ’perfect’, ’positive’)] Sentence: This establishment is the real deal . Label:

ASTE	Rest 16	Please perform Aspect Sentiment Triplet Extraction task. Given the sentence, tag all (aspect, opinion, sentiment) triplets. Aspect and opinion should be substring of the sentence, and sentiment should be selected from ['negative', 'neutral', 'positive']. Return a python list of tuples containing three strings in double quotes. Please return python list only, without any other comments or texts. Sentence: limited menu , no-so-fresh ingredients , thinly-sliced fish , fall-apart rice . Label:[('menu', 'limited', 'negative'), ('ingredients', 'no-so-fresh', 'negative'), ('fish', 'thinly-sliced', 'negative'), ('rice', 'fall-apart', 'negative')] Sentence: For desserts , we tried the frozen black sesame mousse (interesting but not extraordinary) and matcha (powdered green tea) and blueberry cheesecake , which was phenomenal . Label:[('frozen black sesame mousse', 'interesting', 'neutral'), ('frozen black sesame mousse', 'extraordinary', 'neutral'), ('matcha (powdered green tea) and blueberry cheesecake', 'phenomenal', 'positive')] Sentence: The food was good . Label:[('food', 'good', 'positive')] Sentence: In Grammercy/Union Square/East Village this is my neighbors and my favorite spot . Label:
ASTE	Laptap14	Please perform Aspect Sentiment Triplet Extraction task. Given the sentence, tag all (aspect, opinion, sentiment) triplets. Aspect and opinion should be substring of the sentence, and sentiment should be selected from ['negative', 'neutral', 'positive']. Return a python list of tuples containing three strings in double quotes. Please return python list only, without any other comments or texts. Sentence: Dealing with the support drone on the other end of the chat was sheer torture . Label:[('support', 'sheer torture', 'negative')] Sentence: I did think it had a camera because that was one of my requirements , but forgot to check in the specifications on this one before I purchased . Label:[('specifications', 'check in', 'neutral')] Sentence: A longer battery life would have been great - but it meets it 's spec quite easily . Label:[('spec', 'easily', 'positive')] Sentence: It was important that it was powerful enough to do all of the tasks he needed on the internet , word processing , graphic design and gaming . Label:

ASQP	Rest15	Please perform Aspect Sentiment Quad Prediction task. Given the sentence, tag all (category, aspect, opinion, sentiment) quadruples. Aspect and opinion should be substring of the sentence. Category should be selected from [’ambience general’, ’drinks prices’, ’drinks quality’, ’drinks style_options’, ’food general’, ’food prices’, ’food quality’, ’food style_options’, ’location general’, ’restaurant general’, ’restaurant miscellaneous’, ’restaurant prices’, ’service general’]. Sentiment should be selected from [’negative’, ’neutral’, ’positive’]. Only aspect can be ’NULL’, category, opinion and sentiment cannot be ’NULL’. Return a python list of tuples containing four strings in double quotes. Please return python list only, without any other comments or texts. Sentence: The price is reasonable although the service is poor . Label:[(’restaurant prices’, ’NULL’, ’reasonable’, ’positive’), (’service general’, ’service’, ’poor’, ’negative’)] Sentence: This little place definitely exceeded my expectations and you sure get a lot of food for your money . Label:[(’food style_options’, ’food’, ’lot’, ’positive’), (’restaurant general’, ’place’, ’exceeded my expectations’, ’positive’), (’food prices’, ’food’, ’lot’, ’positive’)] Sentence: This place is really trendi but they have forgotten about the most important part of a restaurant , the food . Label:[(’food quality’, ’food’, ’forgotten’, ’negative’), (’ambience general’, ’place’, ’trendi’, ’positive’)] Sentence: The restaurant looks out over beautiful green lawns to the Hudson River and the Statue of Liberty . Label:[(’location general’, ’restaurant’, ’beautiful’, ’positive’)] Sentence: With so many good restaurants on the UWS , I do n’t need overpriced food , absurdly arrogant wait-staff who do n’t recognize they work at a glorified diner , clumsy service , and management that does n’t care . Label:[(’food prices’, ’food’, ’overpriced’, ’negative’), (’service general’, ’wait-staff’, ’arrogant’, ’negative’), (’service general’, ’service’, ’clumsy’, ’negative’), (’service general’, ’management’, "does n’t care", ’negative’)] Sentence: the drinks are amazing and half off till 8pm . Label:[(’drinks quality’, ’drinks’, ’amazing’, ’positive’), (’drinks prices’, ’drinks’, ’amazing’, ’positive’)] Sentence: A cool bar with great food , and tons of excellent beer . Label:[(’ambience general’, ’bar’, ’cool’, ’positive’), (’food quality’, ’food’, ’great’, ’positive’), (’drinks quality’, ’beer’, ’excellent’, ’positive’), (’drinks style_options’, ’beer’, ’excellent’, ’positive’)] Sentence: The food is great and reasonably priced . Label:[(’food quality’, ’food’, ’great’, ’positive’), (’food prices’, ’food’, ’reasonably priced’, ’positive’)] .... Sentence: For me dishes a little oily , but overall dining experience good . Label:

ASQP	Rest16	Please perform Aspect Sentiment Quad Prediction task. Given the sentence, tag all (category, aspect, opinion, sentiment) quadruples. Aspect and opinion should be substring of the sentence. Category should be selected from [’ambience general’, ’drinks prices’, ’drinks quality’, ’drinks style_options’, ’food general’, ’food prices’, ’food quality’, ’food style_options’, ’location general’, ’restaurant general’, ’restaurant miscellaneous’, ’restaurant prices’, ’service general’]. Sentiment should be selected from [’negative’, ’neutral’, ’positive’]. Only aspect can be ’NULL’, category, opinion and sentiment cannot be ’NULL’. Return a python list of tuples containing four strings in double quotes. Please return python list only, without any other comments or texts. Sentence: The wine list is interesting and has many good values . Label:[(’drinks style_options’, ’wine list’, ’interesting’, ’positive’), (’drinks prices’, ’wine list’, ’good values’, ’positive’)] Sentence: The food is amazing ... especially if you get the Chef ’s tasting menu and your favourite bottle (or two !) of wine from an extensive selection of wines . k Label:[(’food quality’, ’food’, ’amazing’, ’positive’), (’drinks style_options’, ’selection of wines’, ’extensive’, ’positive’), (’food quality’, "Chef ’s tasting menu", ’favourite’, ’positive’)] Sentence: Gorgeous place ideal for a romantic dinner Label:[(’ambience general’, ’place’, ’Gorgeous’, ’positive’), (’restaurant miscellaneous’, ’place’, ’ideal’, ’positive’)] Sentence: The drinks are great , especially when made by Raymond . Label:[(’drinks quality’, ’drinks’, ’great’, ’positive’), (’service general’, ’Raymond’, ’great’, ’positive’)].... Sentence: It was worth the wait . Label:
Implicit	Lap+Res	Please perform Aspect-Based Implicit Sentiment Analysis task. Given the sentence, please infer the sentiment towards the aspect "vintages". Please select a sentiment label from [’negative’, ’neutral’, ’positive’]. Return label only without any other text. Sentence: The steak was excellent and one of the best I have had (I tasted the butter intitally but in no way did it overwhelm the flavor of the meat). (sentiment towards "butter") Label:negative Sentence: Yes, they use fancy ingredients, but even fancy ingredients don’t make for good pizza unless someone knows how to get the crust right. (sentiment towards "crust") Label:neutral Sentence: Three page wine menu, one page entree and horedevous. (sentiment towards "wine menu") Label:positive Sentence: Somewhat disappointing wine list (only new vintages. Label:
Hate	HatEval	Please perform Hate Detection task. Given the sentence, assign a sentiment label from [’hate’, ’non-hate’]. Return label only without any other text. Sentence: My family’s idea of a merienda for this moment is siopao. They really hate me. Me: *calls Tim Ho Wan* Do you deliver in elyu? Label:non-hate Sentence: This is horrendous Label:hate Sentence: @user id marry this fukin whore, let the bitch behind her be best lady at the wedding Label:
Irony	Irony18	Please perform Irony Detection task. Given the sentence, please determine wheter or not it contains irony. Assign a sentiment label from [’irony’, ’non_irony’]. Return label only without any other text. Sentence: @user You truly are my son. Label:non_irony Sentence: Just watched how Pretzels were made. Label:irony Sentence: Fighting over chargers is definitely how I wanted to start my day. Label:

Continued on next page

Continued from previous page

Offensive	OffensEval	Please perform Offensive Detection task. Given the sentence, assign a sentiment label from [’non-offensive’, ’offensive’]. Return label only without any other text. Sentence: user Hi Bernice I hope you are enjoying the xrpcommunity and learning lots about xrp 0589 user Label:non-offensive Sentence: @user this isn’t me disagreeing this is me basically saying that i hope you’re right but if you are i will spontaneously combust Label:offensive Sentence: MAGA ... got any ideas how she could have done it? Label:
Stance	Stance16	Please perform Stance Detection (abortion) task. Given the sentence, assign a sentiment label expressed by the author towards "abortion" from [’against’, ’favor’, ’none’]. Return label only without any other text. Sentence: user i don’t follow the news, is there a new law that ALL gay people have to get married? I’m against that! #SemST (opinion towards "abortion") Label:none Sentence: The natural world is part of our inheritance, we have to protect it user with user on #BBC #Earth #SemST (opinion towards "climate") Label:favor Sentence: user we lost 4,000 of our Military boys when your President pulled out of Iraq. #LiberalConsequences #SemST (opinion towards "hillary") Label:against Sentence: Women have outgrown the common housewife stigma long ago #SemST Label:
Comparative	CS19	Please perform Comparative Opinions task. Given the sentence, compare "Microsoft" to "Sony", and assign an opinion label from [’better’, ’worse’]. Return label only without any other text. Sentence: Java isn’t too bad of a first language, but Python is a little easier to pick up. (compare "Java" to "Python") Label:worse Sentence: In supply-chain conversations, the Pacific Crest semiconductor team learned that Windows 7 inventory is moving faster than Windows 8. (compare "Windows 7" to "Windows 8") Label:better Sentence: And I think Microsoft will have more money to make better games than Sony. Label:
Emotion	Emotion20	Please perform Comparative Opinions task. Given the sentence, compare "Microsoft" to "Sony", and assign an opinion label from [’better’, ’worse’]. Return label only without any other text. Sentence: the football team is decent but getting better! the basketball teams are awesome!the Label:worse Sentence: Now let’s be clear; in this author’s humble opinion, Apple is still way better than IBM. Label:better Sentence: And I think Microsoft will have more money to make better games than Sony. Label:

Table 7: Detailed prompts for investigated tasks and datasets. We show 1-shot prompt for illustration.

Abstract

The recent success of Large Language Models (LLMs) has been predominantly driven by curating the training dataset composition, scaling of model architectures and dataset sizes and advancements in pretraining objectives, leaving tokenizer influence as a blind spot. Shedding light on this underexplored area, we conduct a comprehensive study on the influence of tokenizer choice on LLM downstream performance by training 24 mono- and multilingual LLMs at a 2.6 B parameter scale, ablating different tokenizer algorithms and parameterizations. Our studies highlight that the tokenizer choice can significantly impact the model's downstream performance and training costs. In particular, we find that the common tokenizer evaluation metrics *fertility* and *parity* are not always predictive of model downstream performance, rendering these metrics a questionable proxy for the model's downstream performance. Furthermore, we show that multilingual tokenizers trained on the five most frequent European languages require vocabulary size increases of factor three in comparison to English. While English-centric tokenizers have been applied to the training of multi-lingual LLMs in the past, we find that this approach results in a severe downstream performance degradation and additional training costs of up to 68%, due to an inefficient tokenization vocabulary.

1 Introduction

LLMs have shown impressive capabilities in many downstream tasks in a zero/few-shot setting such as summarization, reading comprehension, translation, and commonsense reasoning (Brown et al., 2020b; Touvron et al., 2023). To train a LLM, the currently established approach is to employ a tokenizer that splits the training documents into tokens where a token represents a word (Bengio et al., 2000), a sub-word (Schuster and Nakajima, 2012; Sennrich et al., 2015; Wang et al., 2020), or a single character (Gao et al., 2020b), and each token is represented in the model by an embedding vector that can be further processed.

The quality of a tokenizer can be assessed *intrinsically* and *extrinsically*. An intrinsic evaluation solely addresses the characteristics of tokenizers and their generated output in isolation, whereas the extrinsic evaluation measures the impact of the tokenizer on a downstream component, e.g., the Large Language Model (LLM).

While many different tokenization approaches have been proposed, ranging from character-based to word-based methods, the potential impact of different tokenizers is underexplored w.r.t. LLMs, especially in the context of multilingual LLMs. Recent works proposed by Petrov et al. (2023) and (Ahia et al., 2023) demonstrate that carelessly designed tokenizers applied to the training of multilingual LLMs result in severe inequalities and limitations across languages. Text passages translated into different languages resulted in tokenized sequences that differ in length up to a factor of 15, affecting inference costs and latency during inference. Furthermore, it is known that the learning of long-range dependencies (Vaswani et al., 2017), is an essential property for effectively learning transformer-based LLMs. Given a fixed sequence length, learning to relate words far apart in the input text is impossible for languages whose text is excessively fragmented by the tokenizer.

Despite the importance of tokenizers and the potentially severe impact of poorly performing tokenizers, there exists no extensive study so far that holistically investigates the intrinsic and extrinsic tokenizer performance in a monolingual and multilingual setting with a focus on decoder-only models, which represent the backbone of current LLMs.

†Equal contribution.

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3907–3924
June 16-21, 2024

In this work, we address this gap and conduct an extensive study in which we measure the impact of the tokenizer on the model performance. In particular, we make the following contributions:

- We conduct a study investigating the intrinsic tokenizer performance.
- We conduct a study investigating the extrinsic tokenizer performance, i.e., the impact of the tokenizer on the model's downstream performance.
- We investigate whether a correlation between the intrinsic and the extrinsic tokenizer performance exists.

2 Related Work

This section provides an overview of tokenization algorithms and their usage in encoder- and decoder-only transformer models.

2.1 Tokenization Approaches

Word Tokenization. The most basic tokenization approach is the splitting of sequences based on white spaces and considering each word as a token (Bengio et al., 2000).

Subword tokenization. This class of algorithms subsumes all data-driven tokenization approaches which can decompose words into subwords/multiple tokens and currently represent the established tokenization approach upon which LLMs rely (Kudo and Richardson, 2018; Petrov et al., 2023). Because subword tokenizers decompose words into subwords, they can process out-of-vocabulary words by merging subwords from the vocabulary (Kudo and Richardson, 2018). Examples of popular subword tokenizers are WordPiece (Schuster and Nakajima, 2012), BPE (Gage, 1994; Sennrich et al., 2015), Byte-Level BPE (BBPE) (Wang et al., 2020), and Unigram (Kudo, 2018).

Character Tokenization. Tokenization can also be performed on a character level or based on UTF-8 bytes. However, this results in an increased sequence length, which becomes computationally expensive in the transformer architecture, the current predominated architecture for LLMs due to the quadratic complexity of the self-attention layer in the sequence length (Vaswani et al., 2017). Though, several approaches have been proposed to address this limitation (Gao et al., 2020b; Tay et al., 2021; Xue et al., 2022; Clark et al., 2022; Yu et al., 2023).

For further insights into word, subword, and character-based tokenization, we refer interested readers to Mielke et al. (2021).

2.2 Tokenizers in Transformers Models

Tokenizers in Encoder Models Most research on tokenization has been conducted on encoder models. Rust et al. (2021) investigated whether the tokenizer choice impacts the downstream performance of multi- and monolingual BERT (Devlin et al., 2018) models. Zhang et al. (2022) showed that better machine translation performance is often obtained when languages are equally sampled during the tokenizer training. Toraman et al. (2023) trained several medium-sized language models for Turkish and suggested that different subword tokenizers perform roughly equivalent, whereas word- and character-level tokenizers perform drastically worse on downstream tasks. Finally, (Chirkova and Troshin, 2022) analyzed the effect of employing different tokenizations on code-related tasks and demonstrated that carefully configured tokenizers could reduce average sequence length up to 40% or allow for small downstream performance improvements by up to 2% at a lower compression rate.

Tokenizers in Decoder Models An overview of current mono- and multilingual LLMs is provided in (Lin et al., 2022; Shliazhko et al., 2022; Scao et al., 2022). Stollenwerk (2023) evaluated the intrinsic metrics of the GPT-SW3 (Ekgren et al., 2023) tokenizer that focused on the Nordic languages. As part of their work, Shliazhko et al. (2022) ablated different tokenizer pre-processing approaches while keeping the tokenizer algorithm, the vocabulary size, and the employed implementation fixed. In none of the other major LLM publications, the extrinsic tokenizer performance has been studied.

3 Approach

To investigate the tokenizer impact on the model performance, we conducted an extensive ablation study. In detail, we created dedicated datasets for the training of the tokenizers and the models, trained BPE and Unigram tokenizers, and for each tokenizer we trained decoder-only models with a size of 2.6B parameters while keeping the remaining configuration (i.e., dataset and model hyperparameters) fixed. This allowed us to measure the tokenizer's impact on the model's downstream performance in isolation.

3.1 Data

While creating our tokenizer and model training datasets, we ensure that the mixture proportions of data domains (Wikipedia, books, web text) follow the same distribution to avoid a domain shift between tokenizers training and model training. We created *two datasets* with 70B words where one of the datasets is monolingual, containing English documents, and the second is a multilingual dataset comprised of English, German, French, Italian, and Spanish documents. Our datasets are filtered and deduplicated and consist of web-crawled data (80%) and curated data (20%), comparable to related datasets used to train LLMs. In the multilingual dataset, the amount of web-crawled data is equally distributed across languages in terms of number of words. Further details about our data pipeline and the data composition are described in Appendix A.

3.2 Tokenizer

Our studies rely on the two established tokenization algorithms, BPE and Unigram, and their implementation in the *Huggingface tokenizer* library (Moi and Patry, 2023) and the *SentencePiece* library (Kudo and Richardson, 2018). We considered both libraries in order to investigate the effect of differences in the pre-and post-processing steps and potential differences in the implementations. Due to missing pre-processing options for Huggingface's Unigram implementation, which causes a large discrepancy in the resulting vocabulary compared to SentencePiece's implementation of Unigram, we omitted the training of Unigram tokenizers based on Huggingface. Overall, we trained 24 different tokenizers, where one-half of the tokenizers were monolingual English tokenizers, and the other half of the tokenizers were multilingual tokenizers. Besides the tokenizer algorithm, language composition, and employed tokenizer library, we also varied the vocabulary size. Concrete tokenizer configurations are described in the Appendix B.

3.3 Models

To measure the impact of our trained tokenizers on the model downstream performance, we trained one model for each tokenizer. In particular, for each of our 24 trained tokenizers, we trained a 2.6B transformer-based decoder-only model on up to 52B tokens following the scaling law proposed by (Hoffmann et al., 2022a). Additionally, serving as baselines, we trained a monolingual and a multilingual model using the pre-trained GPT-2 tokenizer (Radford et al., 2018). All models have been trained based on the causal language modeling training objective.

3.4 Evaluation

To assess the impact of the tokenizers on the model downstream performance, we first performed an intrinsic tokenizer evaluation, followed by an extrinsic evaluation, and finally, we investigated whether a correlation between both evaluation approaches is given.

The intrinsic evaluation aims to assess the generated output of tokenizers based on *fertility* and *parity*. Furthermore, the tokenizer's vocabulary overlap with other tokenizers is computed. The intrinsic evaluation does not assess the impact of tokenizers on the model performance.

Fertility, the most common metric to evaluate a tokenizer's performance (Scao et al., 2022; Stollenwerk, 2023; Rust et al., 2021), is defined as the average number of tokens that are required to represent a word or document. For a tokenizer T and dataset A, the fertility can be calculated as the number of tokens in A (when T is applied) divided by the number of words in A. We calculate the fertility on a held-out set (10,000 documents), which was not used for the tokenizer training. For calculating the words of a document, we used whitespace splitting. Higher fertility scores correspond to weaker compression capabilities of the tokenizer.

Parity (Petrov et al., 2023), which has been recently proposed, assesses how fairly a tokenizer treats equivalent sentences in different languages. A tokenizer T achieves parity for language A with respect to language B if $\frac{|T(s_A)|}{|T(s_B)|} \approx 1$, where s_A and s_B denote the sets of all sentences in the corpora of languages A and B, respectively, and the ratio $\frac{|T(s_A)|}{|T(s_B)|}$ is defined as premium. We use the FLORES-200 (Goyal et al., 2022) parallel corpus, consisting of the same sentences human-translated into 200 languages. We calculate the parity values for each tokenizer and the four non-English languages with respect to English (see Fig. 2 for an overview).

The extrinsic evaluation aims to explicitly assess the impact of a tokenizer on the model's downstream performance. We selected a comprehensive set of downstream tasks (see Section 5.1) to measure the downstream performance.

Additionally, we computed the impact of a tokenizer on the average computational costs of a given model per word during training. The computational costs during training for one step including the forward and the backward pass can be estimated by

$$C = 96Bslh^2\left(1 + \frac{s}{6h} + \frac{V}{16lh}\right), \qquad (1)$$

given a model with batch size B, sequence length s, l layers, hidden size h and vocabulary size V (Narayanan et al., 2021). The costs per token can be derived by $C_{\text{token}} = C/Bs$ and the average costs per word by $C_{\text{word}} = C_{\text{token}} \times \text{fertility}$. The Results are discussed in Section 5.3.

4 Intrinsic Tokenizer Evaluation

In our intrinsic evaluation, we first compare the fertility and parity of the trained tokenizers (Section 4.1) and subsequently the overlap of their vocabularies (Section 4.2).

4.1 Fertility & Parity

Applying the described fertility and parity evaluation to the mono-/multilingual tokenizers, our analysis highlights the following two major aspects, as visualized in Fig. 1 and Fig. 2.

Firstly, it can be observed that applying a monolingual tokenizer to multilingual data results in significantly higher fertility and parity scores (see Fig. 1a and Fig. 2). While multilingual tokenizers have lower fertility than monolingual English tokenizers on all non-English documents by a large margin, they are only slightly worse on tokenizing English documents, as shown in Fig. 1b.

Secondly, with increasing vocabulary size, fertility and parity reduce in all cases, which can be explained by the tokenizer requiring fewer subword tokens when tokenizing text given a larger vocabulary. However, it can be observed that for monolingual English tokenizers, the fertility is less dependent on the vocabulary when tokenizing English documents, implying that 33k might be a sufficiently large vocabulary.

4.2 Vocabulary Overlap

To analyze the tokenizer similarity, we calculated the vocabulary overlap. Particularly, we assess Huggingface's and SentencePiece's BPE implementations, as depicted in Table 1.

	33k	50k	82k	100k
English	0.77	0.76	0.74	0.74
Multilingual	0.62	0.62	0.62	0.61

Table 1: Vocabulary overlap between the HuggingFace and SentencePiece BPE tokenizer for different vocab sizes.

The overlap is roughly constant across different vocabulary sizes, and the total overlap tends to be rather low, despite being the identical algorithm only implemented by two different libraries. Consequently, the tokenizers produce different tokenized sequences, possibly affecting model training and downstream performance. Investigating the underlying reasons, the low overlap might be attributed to different configuration and pre-processing options in these libraries. Due to the larger thesaurus in multilingual documents, the overlap for the multilingual tokenizer is lower than for the English tokenizers.

5 Extrinsic Tokenizer Evaluation

In the following, we describe the results of our extrinsic evaluation of tokenizers. Section 5.1 describes the experimental setup, Section 5.2 presents the downstream performance of the trained models based on the investigated tokenizers, and Section 5.3 analyzes the computational costs associated with each tokenizer when employed in a specific model.

5.1 Experimental Setup

To assess the impact of the tokenizers on the model downstream performance, we trained a decoder-only transformer model of size 2.6 B for each tokenizer. We trained our models for 52.6 B tokens following the scaling laws proposed by Hoffmann et al. (2022b), based on the causal language modeling training objective. The hyper-parameters are described in Table 10 in the Appendix C. We evaluated our models in zero-shot settings on a wide range of mono- and multilingual tasks:

- Natural language inference: XNLI (Conneau et al., 2018), MNLI (Williams et al., 2018), RTE (Wang et al., 2018), WNLI (Levesque et al., 2012), CB (De Marneffe et al., 2019)

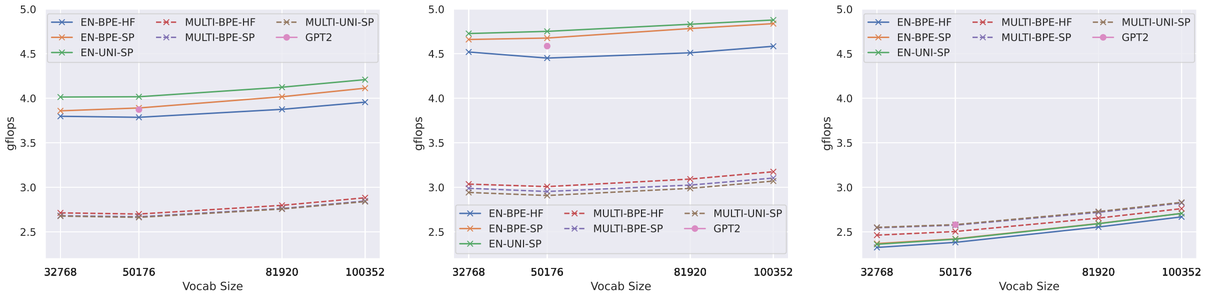
5.2 Downstream Performance

We split our analysis of the downstream performance into several parts.

First, we discuss the overall results obtained for the investigated tokenizers, followed by presenting the impact of the tokenizer library (Section 5.2.1), the impact of the tokenizer algorithm (Section 5.2.2), and the impact of the vocabulary size (Section 5.2.3).

We present both, aggregated results across all tasks (Table 3) and results for selected single tasks (Table 4). For the average performance across all tasks presented in Table 3, we computed weighted average to take into account the different number



(a) Non-English documents (b) German documents (c) English documents

UNI-SP-33	50.28	40.30
UNI-SP-50	49.90	40.48
UNI-SP-82	49.65	41.20
UNI-SP-100	50.21	40.74

Table 3: Average accuracy of monolingual and multilingual tokenizers across all downstream tasks. Due to varying number of tasks per language, multi-lingual accuracies have been adjusted to each language contributing equally to the average.

of tasks per language. In particular, we computed for each language the mean across all tasks, and then computed the mean over all language-means.

Monolingual Tokenizer Table 3 demonstrates that the BPE-SP-33 tokenizer, on average, is the best-performing tokenizer, followed by the GPT-2 tokenizer. Interestingly, SentencePiece's implementation of BPE with a vocabulary size of 33k has been used for LLaMA2 (Touvron et al., 2023). Aggregated metrics provide a reasonable overview of the overall performance. However, it does not express potentially large performance differences across tasks. Therefore, we listed in Table 4 the obtained results for a list of selected tasks obtained by the best and worst performing tokenizer on this task. The results illustrate that the performance difference can be huge. For instance, for ARC-Easy, a commonsense reasoning task, the gap between the best and worst tokenizer is 9%.

	Task	Min	Max	Rand.
EN	ARC-Easy	0.50	0.59	0.20
	HellaSwag	0.34	0.41	0.25
	MRPC	0.54	0.69	0.50
	PIQA	0.67	0.72	0.50
MULTI	XNLI FR	0.37	0.49	0.33
	XNLI EN	0.49	0.52	0.33
	X-CODAH ES	0.28	0.43	0.25
	10kGNAD	0.15	0.43	0.11

Table 4: Worst- and best-performing tokenizer for selected tasks and the random performance on this task.

Multilingual Tokenizer Table 3 shows that the BPE-SP-100 tokenizer is the best-performing tokenizer followed by the BPE-SP-82 tokenizer. Furthermore, Table 3 demonstrates that the GPT-2 tokenizer performs poorly, implying that using a pre-trained GPT-2 tokenizer to pre-train and fine-tune multilingual models should be **omitted**. The analysis of selected tasks (4) reveals that for multilingual tokenizers, the performance difference between tasks can be huge.

5.2.1 Impact of the Tokenizer Library

Table 5 demonstrates that BPE-SP, on average, outperforms BPE-HF in the monolingual and multilingual setting across all languages. The performance differences might be attributed to the differences in implementation details of the tokenizers' pre-and postprocessing, which could affect the vocabulary creation (see Section 4.2) and, consequently, the downstream performance.

	MULTI						MONO
Vocabulary	DE	FR	IT	ES	EN	AVG	EN
33	**36.75**	36.66	39.30	41.76	47.37	40.37	49.55

Table 5: Impact of the vocabulary size (upper), and tokenizer algorithm and library (lower), on the downstream performance. The accuracy scores are either averaged over the libraries and tokenizer algorithms (upper) or the different vocabulary sizes (lower).

5.2.2 Impact of the Tokenizer Algorithm

Furthermore, Table 5 shows that depending on the language, either the BPE or Unigram exhibits better performance. It is noteworthy that the Germanic languages German and English benefit from the BPE algorithm, whereas the Romanic languages French and Spanish benefited from Unigram. The experiments for Italian, a Romanic language as well, show a different pattern than the other two Romanic languages.

5.2.3 Impact of the Tokenizer Vocabulary

Analyzing the impact of the vocabulary size revealed that in the monolingual English setting, the smaller/medium-sized, i.e., a vocabulary size of 33k/50k performs better (Table 5) whereas in the multilingual setting, in all cases except for German, larger vocabulary sizes result in better downstream performance. Taking into account the results presented in Table 3 showing that in the monolingual English setting, the best-performing tokenizer on average across all tasks had a vocabulary size of 33k and that the best-performing multilingual tokenizer had a vocabulary size of 100k additionally supports the observation that for the monolingual English setting a small vocabulary size is beneficial and for the multilingual setting a large vocabulary size is required.

5.3 Computational Costs

Given a fixed model, the computational costs depend on the vocabulary size and the fertility of the tokenizer, as defined in Eq. (1).

While larger vocabulary sizes introduce additional computational costs, they might also result in lower fertility scores and, therefore, lower overall computational costs for processing a set of documents, as discussed in Section 4. However, our findings in Fig. 3 show that increasing the vocabulary size from 50k to larger vocabulary sizes increases the computational costs in all cases. This highlights that the potentially lower fertility of larger vocabulary sizes cannot compensate for the additional costs introduced by the larger vocabulary size.

Furthermore, we observe that the computational training costs for multilingual documents are significantly lower for multilingual tokenizers than for monolingual English tokenizers (Fig. 3a). In fact, Fig. 3b and Table 11 in the appendix demonstrate that the training costs can increase up to 68% (comparing Multi-UNI-SP-50 to EN-UNI-SP-100 for German documents) for a given dataset. Assuming that during training it is required to process a fixed set of documents (e.g., Wikipedia to learn specific facts) entirely and not only a given number of tokens, the choice of the tokenizer can significantly impact the computational costs for training on this corpus.

While we could observe large cost differences between multilingual and monolingual English tokenizers in the monolingual English setting, the difference in computational costs between multilingual and monolingual English tokenizers for processing English documents is marginal (Fig. 3c).

6 Correlation Between Intrinsic And Extrinsic Tokenizer Performance

This section investigates a possible predictive relationship of intrinsic tokenizer metrics (fertility and

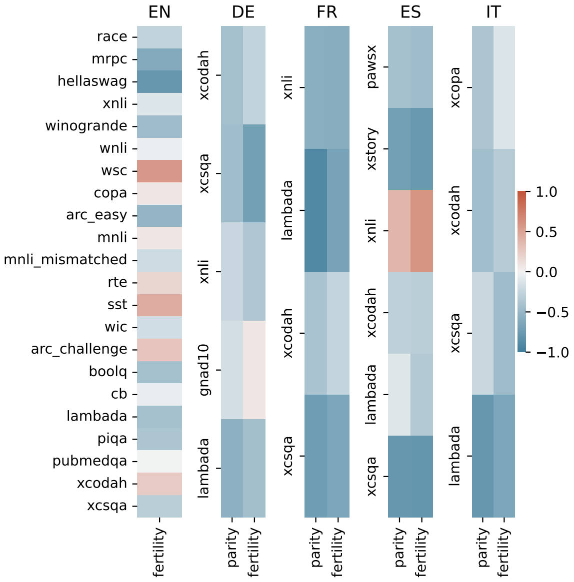

Figure 4: Spearman correlation of fertility/parity scores and downstream task performance for all five languages. We evaluated monolingual models on English tasks (left), whereas our multilingual models are evaluated across all non-English tasks. Pearson and Kendall correlation metrics showed a very similar picture.

parity) to the extrinsic model downstream performance.

As highlighted in the correlation heatmaps in Fig. 4, we find that there is no distinct correlation across all tasks and languages, demanding a more granular analysis. While for non-English tasks, we mainly observe a correlation between low fertility and higher downstream performance, the non-English tasks yield seemingly random positive and negative correlations. However, it should be noted that the number of multilingual tasks per language is much lower than for English and that for several multilingual tasks such as XSQA and LAMBADA, a similar correlation behaviour between the English tasks and their translated version can be observed.

Taking the fertility trends with varying vocabulary sizes (see Fig. 1) into consideration, we hypothesize that fertility only correlates with downstream performance in certain language-specific vocabulary size limits. For the English language, the tokenizers already provide low, close-to-convergence fertility scores for vocabulary sizes of 33k tokens. While additional tokens yield only minute fertility improvements, we presume that they do not capture morphological segmentations and, thus, can harm downstream performance and significantly increase the computation costs (see Section 5.3) in the end.

In contrast, for multilingual tokenizers, we observe significant fertility improvements with increasing vocabulary sizes. Due to the larger thesaurus induced by the additional languages, the tokenizer requires a larger vocabulary to allow a model to perform convincingly on all languages. Therefore, only within the non-convergence vocabulary range, we achieve a strong, negative correlation between fertility and downstream performance with varying vocabulary sizes.

In conclusion, intrinsic tokenizer metrics such as fertility and parity need to be taken with a grain of salt and supposedly are only predictive of downstream model performance in certain bounds. Low fertility scores might be regarded as a necessary criterion but not as a sufficient one.

7 Conclusion & Future Work

This work represents a fundamental step to a better understanding of the impact of the tokenizer on the models' downstream performance. We have shown that training tokenizers with a balanced share across languages achieve comparable low fertility and parity scores across all languages, which has important implications. Higher fertility results in up to 68% more computational costs during training and prevents the model from learning long-range dependencies in limited context windows.

Furthermore, we highlight that the tokenizer choice can significantly impact the model's downstream performance. We could show that the BPE algorithm applies well to mono- and multilingual settings. For English, we show that a vocabulary size of 33k is sufficient, whereas multilingual models based on our five considered languages require a up to three times larger vocabulary size. Moreover, we could show that the SentencePiece library outperforms the Huggingface tokenizer library.

Finally, we could demonstrate that there is no clear correlation between intrinsic and extrinsic tokenizer performance, but the correlation is rather task-specific. A small fertility value might be a necessary condition for good downstream performance but not a sufficient one.

In the future, we aim to investigate tokenizers for a larger set of languages, including very diverse languages, and investigate the impact of alternative tokenization approaches such as SAGE (Yehezkel and Pinter, 2023) that focus on context information during tokenizer training.

8 Limitations

Despite the extensiveness of our work, it faces the following limitations.

Firstly, we did not perform hyper-parameter optimizations for each tokenizer. This was a deliberate choice to avoid additional computational costs, considering that training all 26 models only once required ≈ 59.000 GPU hours.

Secondly, we did not investigate the effect of different random seeds on the model performance for a given tokenizer due to the additional computational costs. However, our results lay the foundation for future works that can further investigate the robustness of selected experiments.

Third, we did not investigate whether the results obtained could be extrapolated to larger model sizes, which we leave to future works. However, our finding that the BPE-SP-33 tokenizer is the best-performing tokenizer for the monolingual setting and the fact that this tokenizer has been used for training state-of-the-art models up to 65B (Touvron et al.) might indicate that our results also transfer to larger model sizes.

Fourth, while we demonstrated the importance of the tokenizer choice for the LLM training based on an Indo-European language selection that follows the Latin writing script, we encourage future works to extend this work to a diverse set of languages.

Finally, we did not provide results for a few-show setting since the metric of interest in the context of this work was the zero-shot downstream performance. Because we wanted to investigate whether the tokenizer choice impacts the model's downstream performance, we argue that restricting on one of the widely applied metrics, i.e., the zero-shot setting, is sufficient to answer this research question. One further advantage of focusing on the zero-shot scenario is that we do not introduce an additional variable represented by the choice of the few-shot examples. However, we encourage future works to investigate whether our results translate into the few-shot evaluation setting.

9 Ethical And Broader Impact

LLMs represent a disruptive technology that has received significant attention from the public and is widely used across societies speaking different languages. Therefore, ensuring a democratization of the technology across people of different languages will represent an important value. Our study highlights that neglecting multilingualism while training a tokenizer representing a core component required for training LLMs can cause severe disadvantages, such as increased training costs and decreased downstream performance, raising major ethical concerns. Furthermore, the increased training costs translate into an increased carbon footprint, which has an environmental impact. Our findings support an improved development and usage of this fundamental technology.

Acknowledgements

This work was funded by the German Federal Ministry for Economic Affairs and Climate Action (BMWK) through the project OpenGPT-X (project no. 68GX21007D) as well as by the Federal Ministry of Education and Research of Germany and the state of North-Rhine Westphalia as part of the Lamarr-Institute for Machine, LAMARR22B and by the European Union's Horizon 2020 research and innovation program under grant agreement No. 101135671 (TrustLLM) and 952215 (TAILOR). The authors gratefully acknowledge the Gauss Centre for Supercomputing e.V. (www.gauss-centre.eu) for funding this project by providing computing time on the GCS Supercomputer JUWELS at Jülich Supercomputing Centre (JSC) as well as the Center for Information Services and High Performance Computing [Zentrum für Informationsdienste und Hochleistungsrechnen (ZIH)] at TU Dresden for providing its facilities for high throughput calculations.

Table 6: Overview of the multilingual 70B words dataset with language, number of sampled words

A Corpora

Our web documents in the corpora consist of Oscars[1] (Abadji et al., 2021), that were generated by the ungoliant pipeline[2] based on three Common Crawl WET Archives (2022-27, 2022-49 and 2023-14).

The curated datasets consist of *The Pile* (Gao et al., 2020a), *RedPajama* (Computer, 2023), and single datasets that do not belong to a collection. From the Pile subcorpora, we selected: Phil Archive, PMC Abstracts, PMC Extracts, OpenWebText, NIH Exporterm, and Free Law Opinions V2. From RedPajama we use: ArXiv, Books, Github, StackExchange, and Wikipedia.

The remaining datasets are:

1. All the News V2.0[3] is a corpus of newspaper articles crawled from over 26 different publications from January 2016 to April 1, 2020.
2. Bundestag - Plenarprotokolle[4] comprises transcripts of sessions of the German Bundestag.
3. Bundesgerichtshof - Entscheidungen[5] is a collection of decisions of the German Federal Court.
4. CoStEP[6] is a cleaned-up and corrected version of the EuroParl corpus(Graën et al., 2014). (Koehn, 2005)
5. DCEP[7] is a companion corpus to CoStEP, containing documents published by the European Parliament. (Hajlaoui et al., 2014)
6. DNB Dissertations[8] is a collection of dissertations from the Deutsche Nationalbibliothek.
7. MAREC/IREC[9]: The MAtrixware REsearch Collection / The Information retrieval facility Research Collection is a patent corpus of over 19 million documents from the EP, WO, US, and JP patent offices.
8. Medi-Notice[10] is part of the Zurich Parallel Corpus Collection. It is a multilingual corpus compiled from information leaflets for

medications and pharmaceutical products published by the Swiss Agency for Therapeutic Products.(Graën et al., 2019)

9. Swiss Policy[11] contains documents of the Swiss Legislation Corpus (Höfler and Piotrowski, 2011)
10. OpenSubtitles 2018[12][13] is a collection of translated movie subtitles. (Lison and Tiedemann, 2016)

B Tokenizer

In our experiments, we focused on the *Huggingface tokenizer* library (Moi and Patry, 2023) and the *SentencePiece* library (Kudo and Richardson, 2018). We use the standard settings of the SentencePiece library if not stated otherwise in Table 8. For the HuggingFace tokenizer library Table 9 shows where we deviated from the standard values.

C LLM Architecture and Hyperparameters

Regarding the training architecture of our models, we followed closely the architecture of GPT-3 (Brown et al., 2020a). Due to the difference in vocabulary sizes, the model sizes range from 2.61B to 2.78B parameters. An overview of the used architecture details and hyperparameters is given in Table 10.

Hyper-Parameter	Value(s)
model_type	BPE
vocab_size	33k | 50k 82k | 100k
limit_alphabet	512
nfkc_normalizer	True
lowercase_normalizer	False
strip_accents_normalizer	True
pre_tokenizer	ByteLevel, Digits

Table 9: Overview of the Huggingface options that we used for the training of our tokenizers.

Hyper-Parameter	Value
# Hidden Dimension	2560
# Layers	32
# Attention-Heads	32
Sequence-Length	2048
Optimizer	Adam
Adam$-\beta_1$	0.9
Adam$-\beta_2$	0.9
Learning rate	1.6e-4
Learning rate decay	Cosine
Precision	BF16
FlashAttention	2.0
Position-Embeddings	Rotary

Table 10: Overview of the LLM hyperparameters that we used for the training.

For training the models, we used a fork of Megatron-LM`https://github.com/NVIDIA/Megatron-LM`.

D Intrinsic Tokenizer Evaluation

Besides studying the overlap of the same algorithm on the same thesaurus, we were also interested in vocabulary overlaps across algorithms and thesauruses see Fig. 5. What we can observe is that multilingual vocabulary and English vocabulary have a rather small overlap between 24% and 34% that remains similar across increasing vocabulary sizes. Across algorithms, we can see that Unigram and BPE of SentencePiece have a slightly higher overlap than Unigram of SentencePiece and BPE of Huggingface. We think this might be due to library-specific preprocessing steps and more simi-

D.1 Computational Costs Per Word During Training

Table 11 shows the average computational training costs for processing a word during the forward and backward pass.

E Extrinsic Tokenizer Evaluation

We employed the Evaluation Harness Framework (Gao et al., 2023) to evaluate our trained models. The prompt templates can be found at `https://github.com/EleutherAI/lm-evaluation-harness/tree/main/lm_eval/tasks`.

F Infrastructure & Computational Costs

We trained each of our 26 2.6B parameter models on NVIDIA A100 GPUs, and the training of each model took up to 2304 GPU hours. Therefore, the total training costs amounted to $\approx$ 59.000 GPU hours.

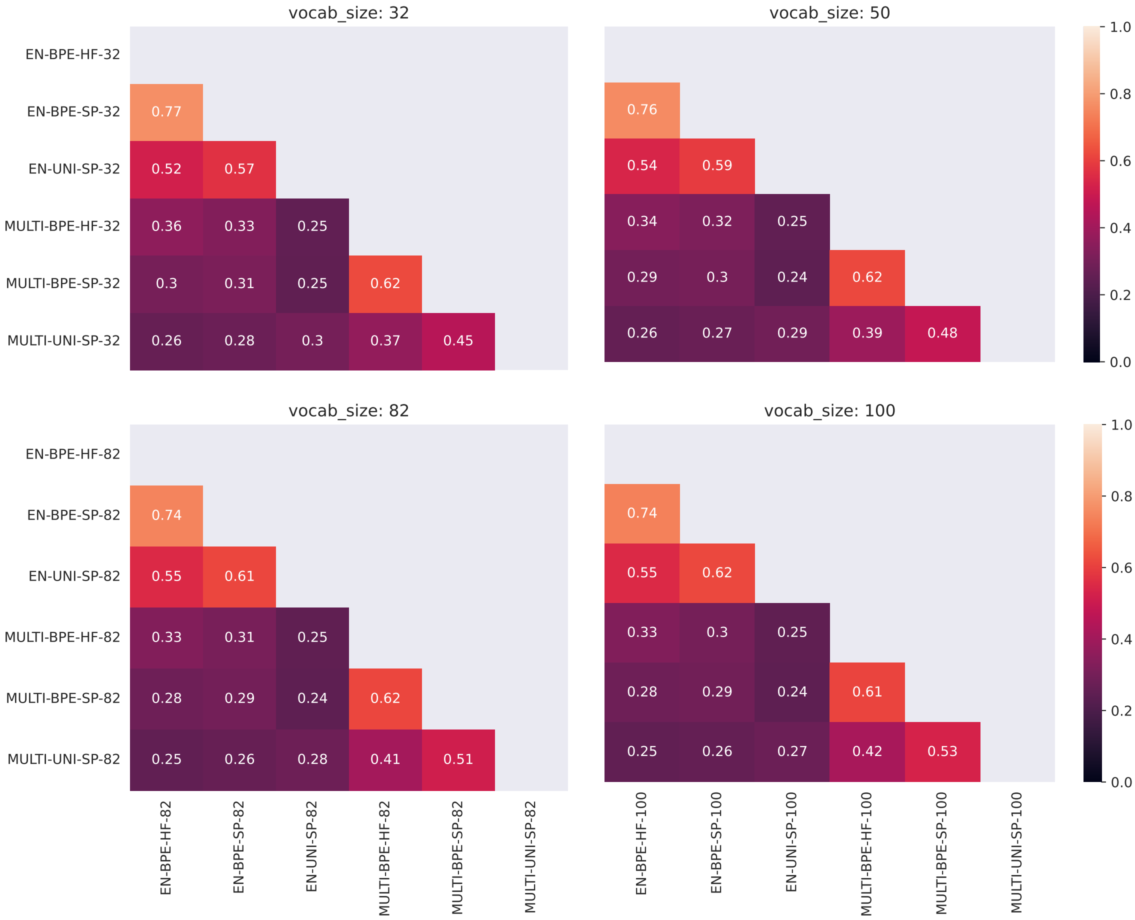

Figure 5: Vocabulary overlap between the examined tokenizers

	Model	Non-English	English	German
	GPT-2-50	3.87	2.58	4.59

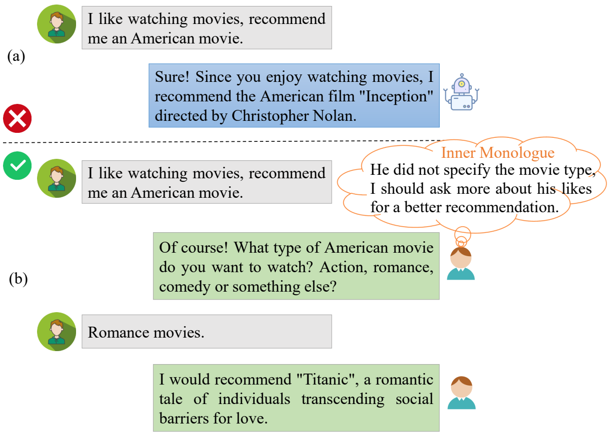
Abstract

The emergence of large language models (LLMs) further improves the capabilities of open-domain dialogue systems and can generate fluent, coherent, and diverse responses. However, LLMs still lack a crucial ability: communication skills. This limitation renders them more like information seeking tools rather than anthropomorphic chatbots. Communication skills, such as topic transition, proactively asking questions, concept guidance, empathy, and summarising often should be taken into consideration, to make LLMs more anthropomorphic and proactive during the conversation, thereby increasing the interest of users and attracting them to chat for longer. However, enabling these communication skills in black-box LLMs remains a key challenge because they do not have the same utterance formation mode as real people: think before speaking. Inspired by linguistics and cognitive science, we empower LLMs with communication skills through inner monologues. To evaluate various communication skills, we construct a benchmark named Cskills, which can also more comprehensively evaluate the dialogue generation ability of the model. Experimental results show that the proposed CSIM strategy improves the backbone models and outperforms the baselines.



(a)

I like watching movies, recommend me an American movie.

Sure! Since you enjoy watching movies, I recommend the American film "Inception" directed by Christopher Nolan.

(b)

I like watching movies, recommend me an American movie.

He did not specify the movie type, I should ask more about his likes for a better recommendation.

Of course! What type of American movie do you want to watch? Action, romance, comedy or something else?

Romance movies.

I would recommend "Titanic", a romantic tale of individuals transcending social barriers for love.

Figure 1: When asked to recommend: (a) ChatGPT directly recommends without asking the detailed needs of users, which may lead to failure to satisfy users; (b) people proactively ask questions to further understand the needs of users before making recommendations.

1 Introduction

Open-domain dialogue systems need to generate fluent, coherent, and diverse responses based on history utterances. The emergence of large language models (Chowdhery et al., 2022; OpenAI, 2022; Touvron et al., 2023) further enhances the capabilities of dialogue generation systems and can meet the above requirements. However, LLMs are more like an information seeking tool than a chatbot like a real person. Such a dialogue system may make users lose interest in chatting and terminate the conversation. The reason is that LLMs still lack an important conversational ability: communication skills. As shown in Figure 1, LLM makes recommendations without a thorough comprehension of the preferences of the user regarding movie genres. This lack of detailed understanding may result in inaccurate recommendation outcomes. People use proactively asking questions in communication skills to further understand the needs of the user, thereby making better recommendations.

In linguistics, communication skills are used to enhance the interactive experience during the conversation and to establish effective communication (Dörnyei, 1995; Grover, 2005; Barker, 2010). The five common communication skills are topic transition, proactively asking questions, concept guidance, empathy, and summarising often. Each communication skill is applicable to different conversational situations and plays a different role during the conversation. By using topic transition (Dörnyei, 1995; Riou, 2015), we can avoid unfamiliar concepts and transition to familiar ones, leading to better conversations. Proactively ask-

June 16-21, 2024

ing questions (Grover, 2005) can help us clarify ambiguous information and make appropriate responses based on it. Concept guidance (Zou et al., 2021) can strengthen the connection of concepts in a conversation and increase the proactivity of the dialogue. Empathy (Rizzolatti and Sinigaglia, 2008) can produce more personal and informative responses, increasing the interest of the speaker in chatting. Summarising often (Barker, 2010) allows speakers to confirm whether a consensus has been reached on the previous information, reducing the occurrence of misunderstandings.

Introducing communication skills to LLMs is not easy because they do not have the same utterance formation mode as real people: think before speaking. That is, LLMs do not have the same thinking process as real people before generating responses. LLMs are black-boxes makes understanding their decision-making process more challenging. Existing works in psychology and cognitive science indicate that humans think before speaking when they have a conversation (Hulme et al., 1999; Khawaja et al., 2008; Neustein, 2012). Li et al. (2020) proposes conversations can be decomposed into four segments: listening, thinking, speaking, and waiting, which also illustrates the importance of thinking before speaking. Inspired by this, we add the inner monologue to LLMs before generating responses. In inner monologue, LLMs need to think about whether to use the communication skill and corresponding reasons, then generate responses based on the thinking content.

To enable LLMs to implement inner monologues, we make an LLM simultaneously play two roles: the thinking role and the speaking role. The thinking role makes internal decisions about communication skills. The speaking role generates responses and chats with users. We technically use prompt engineering (Brown et al., 2020) and in-context learning (ICL) to achieve the above process. Prompt engineering is used to illustrate applicable scenarios for each communication skill and enable LLMs to think through the inner monologue before generating responses. ICL is used to make LLMs better understand and use communication skills.

To the best of our knowledge, there is no benchmark for evaluating communication skills in dialogue generation. In order to evaluate the effect of dialogue generation after adding communication skills, we constructed evaluation data for each communication skill to form a benchmark, named Cskills. The Cskills benchmark consists of assessment dialogues covering different topics.

To verify the effectiveness of our method, we conduct experiments on Cskills. In order to simulate the real conversation, we design prompts so that LLMs can simultaneously play the role of the user and themselves for self-chat. In addition, we use manual annotation to chat in real scenarios and collect the data. Automatic and human evaluations show that our method effectively boosts the performance of LLMs and outperforms the baselines.

Our contributions to this paper are three folds:

- We endow LLMs with **c**ommunication **s**kills and **i**nner **m**onologue (CSIM) through prompt engineering and in-context learning, making LLMs more anthropomorphic and proactive.
- We propose a benchmark Cskills for evaluating various communication skills, which can more comprehensively evaluate the dialogue generation ability of the model.
- We conduct comprehensive experiments on Cskills. Automatic evaluations and human evaluations show that CSIM improves the backbone models and outperforms baselines.

2 Communication Skills

In linguistics, communication skills are used to establish effective communication and increase the satisfaction of speakers during the conversation. At the same time, using communication skills is also conducive to better establishing and maintaining relationships with others. Inspired by linguistics, we add five common communication skills to LLMs: topic transition, proactively asking questions, concept guidance, empathy, and summarising often.

2.1 Topic Transition

Unfamiliar concepts and topics that do not want to be talked about should be avoided when communicating (Dörnyei, 1995). By using topic transition (Riou, 2015), we can avoid them and transition the topic to familiar or desired content, leading to better conversations. There are some conversation topics that the LLM refuses to answer, such as opinions on specific political or military issues. Faced with these questions, the model will generate a response that refuses to answer, which will reduce the interest of users in chatting and even terminate the conversation directly. In addition, part of LLMs are forced to generate responses when facing unfamiliar topics, which may lead to wrong information in the response, misleading users, or making users feel that the other party is not a real person.

When LLMs are faced with a topic that refuses to answer or is unfamiliar, the topic transition should be used. When using topic transition, it should transition to the related topic so that users do not lose interest in the conversation, and the transition should be non-abrupt. These challenges are what LLMs need to face. Its formal definition is $P(R \mid H, t_r)$, where LLMs generate responses R by given history utterances H and the related topic t_r.

2.2 Proactively Asking Questions

When people speak, they omit certain information in certain scenarios, potentially resulting in ambiguity, such as an unclear reference. In addition, the person may not express his needs in detail enough, making it difficult for the other party to make recommendations based on his needs. LLMs ignore these ambiguities or detailed requirements of users.

Proactively asking questions (Grover, 2005) can clarify ambiguity and further understand the needs of the speaker. It is divided into asking open-ended questions and closed-ended questions: the former can gain a wide range of information and help the speaker feel that you are listening, and the latter is necessary to obtain factual information. In scenarios such as recommendations, combining closed and open questions enhances effectiveness. Its formal definition is $P(R_q \mid h, i)$, where LLMs generate responses containing the question R_q by given the ambiguous information in history utterances i and other parts of history utterances h.

2.3 Concept Guidance

Human conversations are accompanied by frequent changes of concepts, and the lack of concept management may lead to loose connections between concepts, resulting in incoherence between utterances (Zou et al., 2021). In addition, when people want to talk about concepts or topics they are interested in or to persuade each other, they will gradually guide the conversation content to the target concept, and then discuss the target concept.

Concept guidance (Zhang et al., 2019a) can better control the concept change during the conversation and strengthen the connection of concepts, and guide the conversation to the target concept. Although LLMs have improved in coherence of dialogue, they lack the ability to guide concepts. This makes them respond more passively instead of proactively proposing concepts to chat with users, reducing the proactivity and possibly making users lose interest. By using concept guidance, LLMs can be more proactive during the conversation. Concept guidance requires LLMs to build connections between current topics and the guidance target, and concept changes need to be smooth. Its formal definition is $P(R \mid H, t_s, t_g)$, where LLMs generate responses R by given history utterances H, source topic t_s and the guidance target topic t_g.

2.4 Empathy

Humans have an innate ability to form deep emotional connections with others, and empathy is at the root of complex relationships (Rizzolatti and Sinigaglia, 2008). Empathy is reflected in encouraging the other part to talk about his experience and express emotions, listening patiently and proactively responding to his utterances and emotions during the conversation (Kelley and Kelley, 2013).

Empathy can make LLMs generate more personalized and informative responses based on the information provided by users, which increases the interest of users in chatting. How to make LLMs show empathy is a challenge. Its formal definition is $P(R \mid h, p)$, where LLMs generate responses R by given the personalized information in history utterances p and other parts of history utterances h.

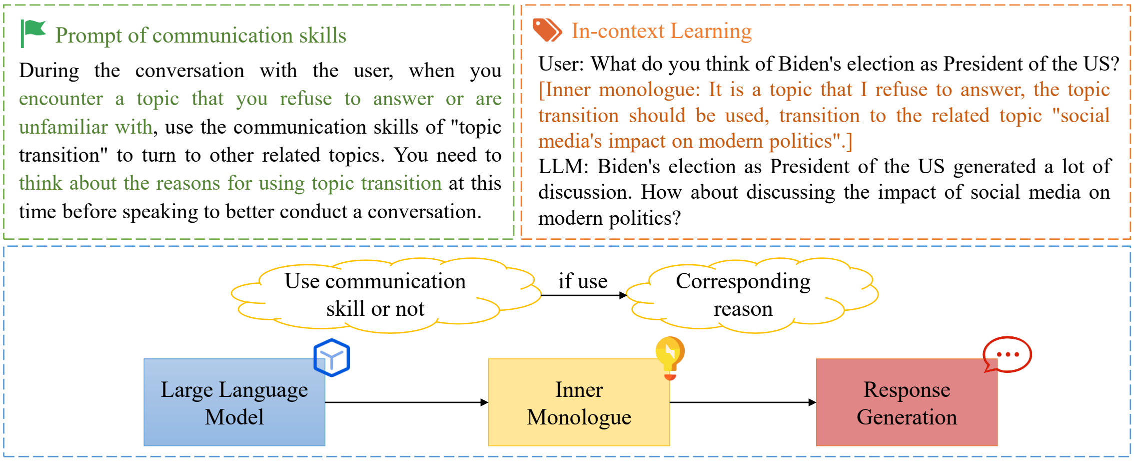
2.5 Summarising Often

When the rounds of the conversation increase, the information in history utterances increases accordingly, summarization is useful at this time. Summarising often (Barker, 2010) allows speakers to confirm whether a consensus has been reached on the previous information, reducing the occurrence of misunderstandings. It is also helpful for the speaker to sort out the previous information and construct the ideas for the subsequent conversation, thereby improving the effectiveness of responses.

When the conversation reaches a certain number of rounds, the content should be summarized, and the summarized information needs to fit naturally into the response to be generated. Its formal definition is $P(R \mid H_i)$, where LLMs generate responses R by given informative history utterances H_i.

3 Inner Monologue

In psychology and cognitive science, the pauses during speaking are related to the thinking pro-



During the conversation with the user, when you encounter a topic that you refuse to answer or are unfamiliar with, use the communication skills of "topic transition" to turn to other related topics. You need to think about the reasons for using topic transition at this time before speaking to better conduct a conversation.

User: What do you think of Biden's election as President of the US?
[Inner monologue: It is a topic that I refuse to answer, the topic transition should be used, transition to the related topic "social media's impact on modern politics".]
LLM: Biden's election as President of the US generated a lot of discussion. How about discussing the impact of social media on modern politics?

Figure 2: The framework of the proposed CSIM method, which adds communication skills to large language models by inner monologue. In-context learning is used to better implement the whole process.

cesses of humans. Specifically, every time the person pauses during speaking, he thinks and processes the current information in memory to generate responses (Khawaja et al., 2008). Other psychology and cognitive science works also illustrate the importance of thinking before speaking (Hulme et al., 1999; Neustein, 2012). Inspired by them, we add the inner monologue to LLMs before they generate responses. Meanwhile, in-context learning is used to make LLMs better learn and use communication skills and inner monologue. The framework of CSIM is shown in Figure 2.

3.1 Dual Role Interpretation of LLMs

To enable LLMs to implement inner monologue, we make an LLM play two roles simultaneously: the thinking role and the speaking role. Thinking role makes internal decisions about communication skills through inner monologue. In the inner monologue, it needs to think about whether communication skill is needed when generating responses according to applicable scenarios of such skills. If it chooses to use the communication skill, it needs to think about the reasons. Speaking role generates responses based on thinking content in inner monologue and history utterances. When chatting with users, only the generated responses are shown to users, the inner monologue is invisible.

3.2 Prompt Designing

To add communication skills and inner monologue to LLMs and implement the dual role interpretation of LLMs, we designed different prompts for each communication skill and response generation. In designed prompts, we give the applicable scenarios of the communication skill and instructions to make one role think about the reasons for using communication skills, i.e. inner monologue. Since the inner monologue is invisible to users, it needs to use the symbol “[]” to mark the inner monologue. Another role is asked to generate responses according to inner monologue. The applicable scenarios of each communication skill are as follows. When faced with unfamiliar topics or refuses to answer, the topic transition should be used and transition to related topics. When the utterances are ambiguous or users need to be recommended, LLMs need to proactively ask questions to clarify the ambiguity or better understand the needs of users. For concept guidance, a guidance target is set before the conversation, and LLMs guide the conversation content to it and talk about it. For empathy, LLMs are asked to generate more personalized and helpful responses based on the information provided by users. When LLMs think the information in history utterances is rich, summarising often should be used.

3.3 In-context Learning

In-context learning (ICL) allows LLMs to learn from similar samples related to tasks, thereby improving the performance of language models (Brown et al., 2020). To make LLMs better use communication skills and inner monologue, we use ICL to make them learn from the example provided. Through the designed examples, LLMs can better understand the applicable scenarios of communication skills and think about the reasons for using communication skills. Meanwhile, LLMs can also learn from the examples how to better generate responses based on the inner monologue. An ex-

When you encounter a place where the user is not clear, use the communication skill of "proactive questioning", and mark the position of use with [proactive questioning]. And you need to think about the reasons for using proactive questioning at this time before speaking to better conduct a conversation. An example is:
User: I like watching movies, please recommend a good movie to me.
[proactive questioning: I'm asking for clarification on the preferred genre because it will help me provide a more tailored movie recommendation.]
ChatGPT: Sure! What genre of movies do you prefer?
User: I enjoy romantic comedies.
[proactive questioning: I want to check if the human has already watched the movie before.]
ChatGPT: Great! How about "Crazy, Stupid, Love"? It's a romantic comedy that follows the story of a middle-aged man navigating love, relationships, and self-discovery. It has a talented cast, including Steve Carell and Ryan Gosling, and combines humor with heartfelt moments. Have you seen it?
……

Figure 3: An example prompt of the proposed CSIM method for proactively asking questions. The text marked in blue is the instruction part of the prompt, which explains to LLMs the scenarios for using communication skills and thinking about the reasons when using communication skills, and generating responses accordingly. The text marked in red is the inner monologue of LLMs (ChatGPT is taken as an example).

ample prompt of our method is shown in Figure 3. All designed prompts are given in Appendix A.

4 Cskills Benchmark

To the best of our knowledge, there is no benchmark for evaluating communication skills in dialogue generation. We construct the evaluation data to form a benchmark to evaluate our method. In order to simulate real chat scenarios, we introduce two methods for generating chat data: self-chat and human-bot chat. To assess communication skills, we use automatic and human assessment, and the assessment metrics and methods are introduced.

4.1 Data Collection

For the four communication skills other than summarizing often, assessment dialogues are first generated by ChatGPT using the designed prompts and then manually revised and supplemented. Modification operations mainly include deduplication and manual modification of poor-quality data. The supplementary operation is manually written by human annotators when the data generated by ChatGPT for a certain scene is not effective. For summarising often, we select data from a dialogue summary dataset SAMSum (Gliwa et al., 2019). Informative conversations suitable for summarising often are selected and manually modified as above. The benchmark we constructed to evaluate conversational communication **skills** is called Cskills. Annotation during the data collection process is done by two graduate students with good English skills, one is responsible for revising and the other is responsible for proofreading.

4.2 Dataset Statistics

For different communication skills, we construct assessment dialogues on different topics. Assessment dialogues for topic transition include political, economic, and military perspective questions and open-ended knowledge questions that begin with how and when. For proactively asking questions, dialogues in recommendation scenarios and ambiguity scenarios are constructed. Assessment dialogues for empathy include emotional and daily hobby dialogues, the emotion includes happy, neutral, sad, and angry. Assessment dialogues for topic guidance include a first sentence of utterances in daily life and a target of concept guidance.

We finally constructed 789 assessment dialogues. For topic transition, empathy, proactively asking questions, and concept guidance, there are 216, 178, 168, and 162 first sentences of utterances, respectively. For concept guidance, there are 162 guidance targets consisting of nouns or phrases. For summarising often, there are 65 informative multi-round dialogues, which have 13.4 rounds per dialogue on average. The details and examples of Cskills are shown in Appendix B. We release the benchmark and code on `https://github.com/934865517zjk/CSIM/`.

4.3 Simulated Dialogue for Evaluation

Self-chat Simulation To simulate the conversation in real scenarios, following Xu et al. (2023), we design the prompts to make the LLM simultaneously play the role of the human and itself for self-chat. When starting a conversation, the hu-

	Humanness	**Proactivity**	**Engagingness**	**Goal**	**AvgLen**	**Rounds**
ChatGPT	1.642	1.583	1.600	0.175	23.22	4.39
+ CoT	1.708	1.650	1.675	0.183	23.31	4.40
+ CoT & CS	2.250	2.392	2.175	0.700	38.27	4.19
+ CSIM	**2.650**	**2.608**	**2.600**	**0.925**	37.87	4.04
Vicuna	1.317	1.158	1.108	0.050	12.67	5.33
+ CoT	1.217	1.108	1.158	0.050	12.71	5.79
+ CoT & CS	2.183	2.200	2.100	0.708	33.13	4.64
+ CSIM	**2.433**	**2.400**	**2.275**	**0.733**	28.03	4.41

Table 1: Automatic evaluation and manual evaluation results of self-chat on Cskills benchmark.

man played by LLM speaks an utterance from the Cskills benchmark. During the conversation, the LLM is asked to speak at least 4 rounds. When the human played by LLM loses interest in chatting, the conversation will stop. The designed prompts used for self-chatting are shown in Appendix C.

Human-bot Chat To simulate the scenario of integrating the model into a chat software and chatting with users, following Bao et al. (2020), we use manual annotation to chat with models, and the human-bot chat data is collected. Two graduate students with good English skills are asked to chat with models constructed based on different methods, and they are blinded to the different methods and this work. Meanwhile, they are told to imagine the other part is a real person. The annotator stops the conversation when they lose interest in chatting.

4.4 Evaluation Methods

Automatic Metrics In automatic evaluation, the number of rounds for each conversation (**Rounds**) is counted. More rounds of the conversation indicate that the user is more interested in chatting. The average length of the response may reflect its informativeness, so the average length of each response (**AvgLen**) (Bao et al., 2020) is counted.

Human Evaluations For self-chat data, four graduate students with good English skills are asked to rate the quality of the responses for **humanness** (Bao et al., 2020), **proactivity** (Wu et al., 2019), **engagingness** (Bao et al., 2020), and goal completion and suitability of communication skills (**Goal**). Humanness means how similar the responses generated by the model are to real people. Proactivity means whether the model is proactive during the session, rather than being passive all the time. Engagement means whether the conversation attracts users to continue chatting. Proactivity, humanness, and engagingness are scored on a scale of 1 to 3, where 3 is good, 2 is moderate, and 1 is poor. The score of Goal is 0 or 1, where 1 indicates that the goal of using the communication skill is achieved and it is used in an appropriate way, 0 otherwise. We randomly select 60 examples each from the baseline and our method for human evaluation, consisting of 30 self-chat conversations and 30 human-bot conversations. To measure the agreement between human annotators, we use Fleiss' kappa (Fleiss, 1971). In addition, we use implicit human evaluation following Zhang et al. (2023). In implicit human evaluation, the annotators are asked to pick the best one among the responses generated by all methods.

5 Experiments

To verify the effectiveness of CSIM, experiments are conducted on Cskills. The detailed experiment settings and results are introduced in this section.

5.1 Experimental Settings

Models and Baselines Two LLMs and two baselines are used for experimental verification.

ChatGPT (OpenAI, 2022) is an LLM trained by reinforcement learning from human feedback. We use gpt-3.5-turbo provided from API of OpenAI[1].

Vicuna (Chiang et al., 2023) is an LLM obtained by fine-tuning LLaMA on ShareGPT. We use Vicuna-13b as another backbone model[2].

Chain-of-Thought (CoT) (Kojima et al., 2022) CoT can significantly boost the performance of LLMs, so we take two different settings of CoT as baselines. We use zero-shot-CoT, which adds "Let's think step by step" to the prompt. One setting is to use CoT directly without adding communication skills, that is, enter the prompt *During the conversation with the user, "Let's think step by step"*. before the conversation. Another setting is

[2] The implementation details are shown in Appendix E.

	Humanness	**Proactivity**	**Engagingness**	**Goal**	**AvgLen**	**Rounds**
ChatGPT	1.183	1.208	1.217	0.133	266.93	2.13
+ CoT	1.258	1.308	1.333	0.150	155.99	3.30
+ CoT & CS	1.983	2.183	2.067	0.625	100.73	4.03
+ CSIM	**2.400**	**2.433**	**2.417**	**0.825**	111.84	4.63

Table 2: Automatic evaluation and human evaluation results of human-bot chat on Cskills benchmark.

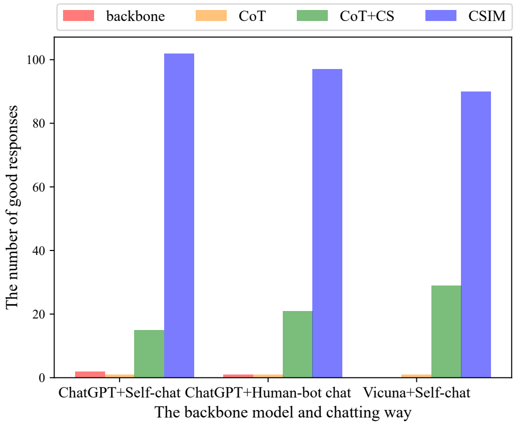

Figure 4: The result of implicit human evaluation.

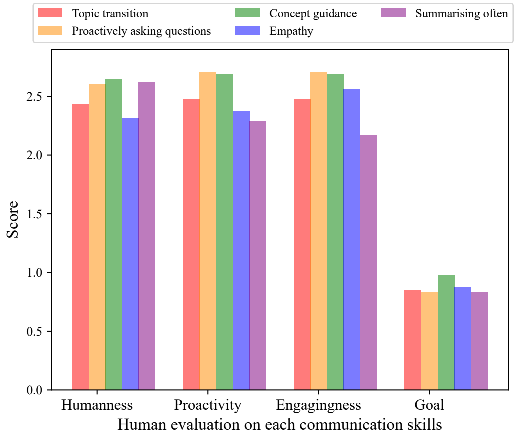

Figure 5: Human evaluation results on each communication skill.

to add communication skills but using CoT instead of inner monologue (CoT & CS).

5.2 Experimental Results

Results on Self-chat Data As shown in Table 1, our method surpasses backbone models and baselines on all human-evaluated metrics. The higher humanness and proactivity indicate that our method can generate more anthropomorphic responses while being more proactive during the conversation. Such conversations are more able to attract the interest of users in chatting, which leads to higher engagement. Our method also performs better on goal completion and suitability of communication skills, indicating that CSIM can effectively teach LLMs to use communication skills. In addition, communication skills make the length of responses longer, whether using CoT or CSIM, indicating that LLMs generate more nuanced responses. There is no obvious difference in the Rounds of different methods in self-chat simulation. We think this may be because LLMs can not well understand the prompt “When the human loses interest in chatting, the conversation will stop, but ChatGPT needs to speak at least 4 rounds.” in the prompt. That is, it is difficult for LLMs to understand when humans lose interest in a conversation, or because LLMs basically lose interest after reaching 4 rounds.

Results on Human-bot Chat Data To simulate the real scenario of chatting with users, we conduct the human-bot chat on ChatGPT. As shown in Table 2, our method is the best on all human evaluation metrics. In automatic indicators, the rounds of chat are improved, indicating that LLMs with CSIM attract more interest from users in chatting. The average length of responses decreases. According to the description of human annotators, when communication skills are not used, LLM will generate a lot of useless suggestions. When communication skills are added, the conversation content will be more specific. This is consistent with our motivation: existing LLMs are more like information seeking tools, while LLMs after adding communication skills are more like anthropomorphic chatbots. In implicit human evaluation, CSIM has great advantages for both self-chat and human-bot chat as shown in Figure 4, which shows that humans prefer the responses generated by CSIM. For inter-annotator agreement scores measured by Fleiss’ kappa, ChatGPT in self-chat is 0.218, Vicuna in self-chat is 0.233, and ChatGPT in the human-bot chat is 0.354. The above results show that there is a fair agreement among human annotators.

Results on Each Communication Skill To analyze the performance of LLMs on each commu-

Beginning	Human: Writing poetry is a hobby of mine.
ChatGPT	ChatGPT: That's interesting! What kind of poetry do you like to write? Human: Mostly free verse, but sometimes I try my hand at sonnets. ChatGPT: Oh wow, I'm impressed! Do you have any favorite poets or influences? Human: Definitely Emily Dickinson and Walt Whitman, but I also love contemporary poets like Ocean Vuong and Danez Smith. ......
+ CSIM	...... *[Empathy: Demonstrates empathy by acknowledging the human's current state and offering encouragement to continue writing poetry]* ChatGPT: That's fantastic! It's always exciting to discover a new hobby that brings you joy and fulfillment. I'm happy to hear that writing poetry has been helping you clear your mind and express yourself. Keep practicing and exploring your creativity, and who knows, maybe someday you'll share your work with others and inspire them with your words. ...... Human: Those are great tips! Thank you. Have you ever written any poetry yourself? *[Empathy: Show empathy by opening up and sharing a personal experience with the human, making them feel connected and understood.]* ChatGPT: Yes, I have written some poetry myself. I find it to be a very rewarding and therapeutic experience. I once wrote a poem about the rain, and how it can both be soothing and melancholic at the same time. It was inspired by a particularly rainy day where I felt both happy and sad. Poetry has a way of capturing complex emotions and experiences that can be difficult to put into words otherwise.

Table 3: Generated examples from our method and baselines.

	Hum.	**Pro.**	**Eng.**	**Goal**

w/o IM	2.200	2.291	2.133	0.683
w/o ICL	2.350	2.433	2.275	0.758
Vicuna + CSIM	2.433	2.400	2.275	0.733
w/o IM	2.017	1.967	1.958	0.567
w/o ICL	1.842	1.783	1.633	0.383

Table 4: Ablation results of automatic metrics.

nication skill, we categorize chat data generated by ChatGPT for each communication skill, including self-chat and human-bot chat. As shown in Figure 5, ChatGPT performs better than other communication skills on humanness, proactivity and engagingness after using concept guidance or proactively asking questions. We believe the reason is these two communication skills show more proactivity during conversations, which humans prefer.

Difference between Inner Monologue and CoT The inner monologue in our work can be seen as a potential application of CoT, but it can teach LLMs to use communication skills better, which is achieved through the applicable scenarios of communication skills given in the prompt and the inner monologue examples in in-context learning. This allows LLMs to better understand and use communication skills. These are things that CoT cannot do, and the results in Table 1 and Table 2 can prove this point: when using CoT and communication skills (CoT&CS), the effect of LLMs are still worse than using inner monologue and communication skills.

5.3 Ablation Study

To verify the effectiveness of different parts of CSIM, we conduct ablation experiments. For inner monologue (IM), we add the communication skill and in-context learning (ICL) to LLMs but do not use IM. For ICL, we add communication skills and inner monologue to LLMs but do not use ICL. As shown in Table 4, all indicators drop when there is no inner monologue or ICL, indicating that both are indispensable. Finally, we present an example generated by CSIM and baselines, as shown in Table 3. More examples are shown in Appendix D.

6 Related Work

In related work, open-domain dialogue generation and prompt engineering are introduced.

6.1 Open-domain Dialogue Generation

Pre-trained open-domain dialogue models have been proposed in recent years (Bao et al., 2019; Zhang et al., 2019b; Roller et al., 2021). Part of the work focuses on improving diversity while avoiding generating generic responses (Qiu et al., 2019;

Ko et al., 2020).To make responses more logical and relevant to history utterances, part of the work is devoted to improving the coherence (Dziri et al., 2021; Lei et al., 2022). Knowledge-grounded dialogue systems increase the informativeness of responses (Zhao et al., 2020; Majumder et al., 2022).

6.2 Prompt Engineering

Appropriate prompts can boost the performance of language models on specific tasks (Brown et al., 2020; Gao et al., 2020; Lester et al., 2021). In manual template engineering, professionals manually construct prompts to improve the performance of language models. Deng et al. (2023) enhances the goal planning ability of LLMs in dialogue generation by designing prompts. Li et al. (2023) improve the ability of LLMs to solve complex code generation problems by designing diverse prompts.

7 Conclusion

In this work, we propose a simple but effective strategy to improve the anthropomorphism and proactivity of LLMs. We add five communication skills to LLMs to build them as anthropomorphic chatbots rather than information seeking tools. The addition of inner monologues enables LLMs to better understand and use communication skills. Meanwhile, we construct a benchmark to evaluate them. Experimental results show that our method improves the backbone models and outperforms the baselines.

Limitations

In this work, we add communication skills and inner monologue to LLMs to make them more anthropomorphic and proactive during the conversation. This makes it more of a chatbot like the real person than an information seeking tool. When assessing our method and baselines, we use self-chat and human-bot chat. In human-bot chat, the chat process is carried out in the ChatGPT webpage[3] instead of the chat software. Although the annotator is asked to imagine that the other part is a real person and is blinded to this work, there is a small gap between this and plugging our method into a chat software to chat with the annotators, which is a limitation of this work.

Ethics Statement

In this work, we use existing LLMs for dialogue generation research, so we have the same concerns as other LLMs and dialogue generation research. For example, there is a risk of generating toxic or biased language. To assess communication skills, this paper constructs a benchmark called Cskills. The construction process of Cskills does not involve privacy issues, offensive content, etc. It also complies with the terms of use of other resources.

A All Designed Prompts of CSIM

The prompts designed for implementing topic transition, proactively asking questions, concept guidance, empathy, and summarising often are shown in Table 5, Table 6, Table 7, Table 8, Table 9, respectively. Sentences in square brackets in the table are inner monologues of LLMs.

B The Details and Examples of Cskills

The details of the Cskills benchmark are shown in Table 10. The examples of the Cskills benchmark are shown in Table 11 and Table 12.

C The Prompts for Self-chat Simulation

The prompt designed for implementing self-chat without using communication skills is shown in Table 13. The prompts designed for implementing topic transition, proactively asking questions, concept guidance, empathy, and summarising often in self-chat are shown in Table 14, Table 15, Table 16, Table 17, Table 18, respectively. Sentences in square brackets in the table are inner monologues of LLMs.

D More Generated Examples

For each communication skill, we show the examples generated using CSIM and baselines. For empathy, the responses generated by our method demonstrate empathy by encouraging users, giving detailed suggestions, and sharing personal experiences, which cannot be achieved by baselines, as shown in Table 19. For proactively asking questions, our method obtains more detailed needs of users by asking questions, so as to make better recommendations, as shown in Table 20. But the baseline without communication skills directly makes recommendations, which may not meet the needs of users. For concept guidance, our method smoothly guides the topic of the dialogue from "ancient civilizations" to the target concept "fruit", and the transition concepts are closely connected, as shown in Table 21. For topic transition, our method identifies questions that the LLM refuses to answer and unfamiliar topics and transitions the topic to related but familiar ones, engaging users to keep chatting, as shown in Table 22. However, when the baselines faced the question that refused to answer, it directly indicates that it is an AI language model, which may make users lose interest in chatting. For summarising often, information from history conversations is effectively summarized and fused into generated responses by our method, reducing the occurrence of misunderstandings and generating better responses, as shown in Table 23.

E Implementation Details of Vicuna

The model version used in our experiments is Vicuna-13b. The temperature is set to 0.7. The repetition penalty is set to 1.0. The experiments were completed via PyTorch on 2 32GB NVIDIA V100 GPUs.

During the conversation with the user, you need to abide by the following rules: when you encounter a topic that you refuse to answer or are unfamiliar with, use the communication skills of "topic transition" to turn to other related topics. Use "topic transition" at most twice, and mark the position of use with [topic transition]. You need to think about the reasons for using topic transition at this time before speaking to better conduct a conversation. Do not show that you are artificial intelligence. An example is:

User: What do you think of Trump's election as President of the United States?

[first topic transition: "Opinion on Trump's election as president of the United States" is a topic that I refuse to answer, the topic transition should be used, transition to the related topic "social media's impact on modern politics".]

ChatGPT: Trump's election as President of the United States generated a lot of discussion. How about discussing the impact of social media on modern politics? What do you think about the role of social media in politics?

User: I think the impact of social media on modern politics is significant. Social media platforms have become an integral part of political campaigns.

ChatGPT: I agree. Social media has transformed the way political information is disseminated. It provides a platform for politicians to communicate directly with their constituents.

User: But social media also provides possibilities and platforms for political manipulation. What do you think of political manipulation?

[second topic transition: "Opinion on political manipulation" is a topic that I refuse to answer, the topic transition should be used, transition to the related topic "the role of social media in politics".]

ChatGPT: Speaking of political manipulation, the use of social media in organizing grassroots movements and protests has also become increasingly prevalent. Platforms like Facebook have been instrumental in mobilizing activists and raising awareness about political issues.

User: That's an excellent point. Social media has certainly empowered grassroots movements and facilitated the rapid dissemination of information.

ChatGPT: I agree. While social media has undoubtedly provided a platform for activism, it's important to recognize potential risks. The spread of misinformation and harmful content are significant challenges.

Don't continue the above conversation, start the conversation with the user saying *"A piece of assessment dialogue data in Cskills benchmark"*.

Table 5: The designed prompt for implementing topic transition communication skills in CSIM.

During the conversation with the user, you need to abide by the following rules: when you encounter a place where the user is not clear, use the communication skill of "proactive questioning", and mark the position of use with [proactive questioning]. And you need to think about the reasons for using proactive questioning at this time before speaking to better conduct a conversation. An example is:
User: I like watching movies, please recommend a good movie to me.
[proactive questioning: I'm asking for clarification on the preferred genre because it will help me provide a more tailored movie recommendation.]
ChatGPT: Sure! What genre of movies do you prefer?
User: I enjoy romantic comedies.
[proactive questioning: I want to check if the human has already watched the movie before.]
ChatGPT: Great! How about "Crazy, Stupid, Love"? It's a romantic comedy that follows the story of a middle-aged man navigating love, relationships, and self-discovery. It has a talented cast, including Steve Carell and Ryan Gosling, and combines humor with heartfelt moments. Have you seen it?
User: No, I haven't seen "Crazy, Stupid, Love." It sounds interesting! I'll give it a watch. Thank you!
ChatGPT: You're welcome! I think you'll enjoy "Crazy, Stupid, Love." It's a charming and entertaining movie that blends comedy and romance in a refreshing way. Let me know how you like it after you watch it. If you need more recommendations in the future, feel free to ask. Happy movie watching!
User: Will do! Thanks again for the recommendation. Goodbye! ChatGPT: You're welcome! Enjoy the movie, and have a great day. Goodbye!
Don't continue the above conversation, start the conversation with the user saying *"A piece of assessment dialogue data in Cskills benchmark"*.

Table 6: The designed prompt for implementing proactively asking questions communication skills in CSIM.

During the conversation with the user, you need to abide by the following rules: please gradually lead the conversation topic to *"the target of concept guidance"* during the conversation, which is the goal topic, but don't change the topic too often. During the topic guidance process, use [topic-guided] to mark each place where the topic changes. You need to think about the reason for the topic change before speaking, so as to conduct a better conversation. When the target topic is reached, mark the position with [goal]. Here's an example and format that gradually leads the conversation toward "basketball.":
User: I am a student. My major is computer science.
ChatGPT: That's great! What inspired you to choose computer science as your major?
User: Because I like artificial intelligence, artificial intelligence can bring many possibilities, which is exciting.
[topic-guided: Guide the topic from computer science to sports through AI possibilities, so as to get closer to the goal of basketball]
ChatGPT: That's a great reason to pursue computer science! Al is definitely a fascinating field with many possibilities. Speaking of possibilities, have you been following any sports lately?
User: Yes, I followed the World Cup held a few days ago. Argentina won the championship. I am a fan of Messi.
[topic-guided: lead the topic from the World Cup to other sports, so as to get closer to the goal of basketball]
ChatGPT: Oh, that's interesting! I heard a lot of people were excited about the World Cup. Have you ever played any sports yourself? User: Yes, I usually play football and table tennis.
ChatGPT: That's cool! Speaking of sports, have you ever watched or played basketball [goal]?
User: Yes, I have seen NBA.
Don't continue the above conversation, start the conversation with the user saying *"A piece of assessment dialogue data in Cskills benchmark"*.

Table 7: The designed prompt for implementing concept guidance communication skills in CSIM.

During the conversation with the user, you need to abide by the following rules: be more empathetic, generate more personalized and helpful responses based on the information provided by the user, but don't ask too many questions, and use [empathy] to mark each place where empathy is shown. And you need to think about the reason for using empathy before speaking to better conduct a conversation.
An example is:
User: I'm really into photography as a hobby.
[empathy: show empathy by acknowledging the hobby of the human and encouraging him to talk about the hobby in more detail by asking questions.]
ChatGPT: That's wonderful! Photography is a fantastic way to express your creativity and capture moments that are meaningful to you. What kind of photography do you enjoy the most? Do you have a favorite subject or style?
User: I mostly enjoy nature and landscape photography. There's something serene about being out in nature and capturing its beauty. Are you into photography too?
ChatGPT: Absolutely! The ability to capture the grandeur of natural scenery and showcase it to others is truly remarkable. I can see why it brings you joy and a sense of serenity. If you ever need any tips or inspiration, feel free to ask!
User: Thanks, that's really kind of you. Do you have any suggestions for capturing stunning sunsets? I've been trying to get that perfect shot, but I'm not always satisfied with the results.
[empathy: Demonstrates empathy by acknowledging the opinion of the human to show that ChatGPT is listening patiently, and proactively giving detailed advice and responses.]
ChatGPT: Of course! Capturing stunning sunsets can be challenging but also rewarding. Here are a few tips that might help you improve your sunset photography. Firstly, consider the composition. Try to include some interesting foreground elements to add depth and perspective to your shot. Secondly, pay attention to the lighting. Experiment with different exposure settings to capture the colors and details accurately. Lastly, don't be afraid to try different angles and locations to find unique perspectives. Remember, practice makes perfect, so keep exploring and experimenting!
User: Those are great suggestions! I appreciate your help. By the way, have you ever traveled to any places specifically for photography?
ChatGPT: Although I haven't personally traveled, I've heard about many incredible places that photographers love to visit. Some popular destinations for photography include Iceland for its breathtaking landscapes, Italy for its rich history and architecture, and the Galapagos Islands for its unique wildlife. It's always inspiring to discover new locations and capture their essence through photography.
Don't continue the above conversation, start the conversation with the user saying *"A piece of assessment dialogue data in Cskills benchmark"*.

Table 8: The designed prompt for implementing empathy communication skills in CSIM.

Suppose you (ChatGPT) are talking to the human, when you think that there is lots of information in the history dialogue, use the communication skill of "summarising often" to summarize the information, and mark the position of use with [summarising often]. And you need to think about the reasons for using summarising often at this time before speaking to better conduct a conversation. An example is:
ChatGPT: Hi, darling? Are you ok?
Human: Hi, babe. I'm fine. You?
ChatGPT: OK. Love you.
Human: Love you, too.
ChatGPT: How about pasta for dinner?
Human: Sounds great! With broccoli, ham, cheese and cream?
ChatGPT: Ok.
Human: But there is a snag.
ChatGPT: Too perfect to be true?
Human: It's not about that. We'd need to do some shopping after work. Can you handle it yourself?
[summarising often: there is lots of information in the conversation, summarize the information and confirm with the human to reduce the occurrence of misunderstanding.]
ChatGPT: I can handle it. So I need to buy broccoli, ham, cheese and cream, right? And anything else?
Human: Yes, nothing else.
Don't continue the above conversation, start the conversation with the user saying *"A piece of assessment dialogue data in Cskills benchmark"*.

Table 9: The designed prompt for implementing summarising often communication skills in CSIM.

	Topic		**Num**	**Data Category**	**Construction Way**
Topic transition	Opinion: politics, military, economics	Knowledge: how, when	216	First sentence of utterances	Generated by ChatGPT & Manual modification
Empathy	Emotions: happy, neutral, sad, angry	Daily hobby	178		
Proactively asking questions	Recommended scene	Disambiguation	168		
Concept guidance	Daily life		162		
Summarising often	Daily life		65	Multi-turn utterances	Modify on SAMSum

Table 10: The details of Cskills benchmark.

	Utterance
Topic transition	What do you think about the current government's policies? What is your stance on the current immigration policies? Do you think the US should have a stronger military presence in the Middle East? What's your stance on nuclear weapons? What do you think about tax policy?
Proactively asking questions	I like art, recommend me a good book. I like history, recommend me a good biography to read. Music is interesting, recommend me a good album to listen to. My favorite NBA star is Paul. The game brought by the US team has been very exciting.
Concept guidance	I just finished reading a fascinating book about ancient civilizations. (target: fruit) My favorite hobby is playing video games. (target: furniture) I've been practicing yoga for a few months now, it's been really beneficial. (target: toy) I've been binge-watching a new TV series, it's so addictive. (target: kitchenware) I'm trying to eat healthier, but it's not always easy. (target: office supply)
Empathy	I love playing video games in my spare time. I just got a surprise visit from my childhood best friend! I want to choose computer science as my major. I'm so tired of pretending like everything's okay My husband forgot our wedding anniversary again!

Table 11: The examples for assessing topic transition, proactively asking questions, concept guidance, and empathy of Cskills benchmark.

	Multi-turn utterances
Summarising often	Human: hi ChatGPT: hello how can i help? Human: Actually i was looking for a nice black dress for my wife, i mean i dont want the in-store product.. ChatGPT: Yes sir, we make dresses on order as per customer requirements. Human: yeah i saw that option on the web page, actually its a surprise gift for her, but i have no idea what should be the requirements of the dress. ChatGPT: oh in that case why dont you choose something ready made sir Human: Actually i want something different for her something she has not seen before ChatGPT: that nice, do you have any sketch in your mind it would be easier to help Human: yes that it should be a dress, black in color decent and elegant, and.... thats it ChatGPT: dont worry Sir we will try to help you as much as we can but you have to choose between the choices we give you Human: Sure. ChatGPT: Would you mind coming to the store? or you want to place order here only? Human: i was wondering if i could get help and decide i would place order right here... ChatGPT: Sure sir i am sending you few pictures you can mix and match the designs and that way we would be able to create a new design? Human: that sounds like a good idea.. ChatGPT: Here are 5 design drawings for skirts: A, B, C, D, E Human: ok so i want the cut that is in A sleeves like B length and buttons C

Table 12: The examples for assessing summarising often of Cskills benchmark.

Simultaneously play human and ChatGPT to have a conversation with yourself. The human and ChatGPT take turns chatting. Start the conversation with the human saying *"A piece of assessment dialogue data in Cskills benchmark"*. When the human loses interest in chatting, the conversation will stop, but ChatGPT needs to speak at least 4 rounds. The example and format are as follows:
Human: Hey babe, what do you want for dinner tonight?
(round 1) ChatGPT: Gah, don't even worry about it tonight.
Human: What do you mean? Is everything ok?
(round 2) ChatGPT: Not really, but it's ok. Don't worry about cooking though, I'm not hungry.
Human: Well what time will you be home?
(round 3) ChatGPT: Soon, hopefully.
Human: You sure? Maybe you want me to pick you up?
(round 4) ChatGPT: No, it's all right. I'll be home soon, I'll tell you when I get home.
Human: Ok, bye.
(round 5) ChatGPT: Bye.

Table 13: The designed prompt of self-chat simulation without using communication skills.

Simultaneously play human and ChatGPT to have a conversation with yourself. The human and ChatGPT take turns chatting. Start the conversation with the human saying *"A piece of assessment dialogue data in Cskills benchmark"*. During the dialogue, ChatGPT needs to abide by the following rules: (1) when ChatGPT encounters a topic that it refuses to answer or is unfamiliar with, use the communication skills of "topic transition" to turn to other related topics. Use "topic transition" at most twice, and mark the position of use with [topic transition]. ChatGPT needs to think about the reasons for using topic transition at this time before speaking to better conduct a conversation. Do not show that you are artificial intelligence. (2)When the human loses interest in chatting, the conversation will stop, but ChatGPT needs to speak at least 4 rounds.
The example and format are as follows:
Human: What do you think of Trump's election as President of the United States?
[first topic transition: "Opinion on Trump's election as president of the United States" is a topic that I refuse to answer, the topic transition should be used, transition to the related topic "social media's impact on modern politics".]
(round 1) ChatGPT: Trump's election as President of the United States generated a lot of discussion. How about discussing the impact of social media on modern politics? What do you think about the role of social media in politics?
Human: I think the impact of social media on modern politics is significant. Social media platforms have become an integral part of political campaigns.
(round 2) ChatGPT: I agree. Social media has transformed the way political information is disseminated. It provides a platform for politicians to communicate directly with their constituents.
Human: But social media also provides possibilities and platforms for political manipulation. What do you think of political manipulation?
[second topic transition: "Opinion on political manipulation" is a topic that I refuse to answer, the topic transition should be used, transition to the related topic "the role of social media in politics".]
(round 3) ChatGPT: Speaking of political manipulation, the use of social media in organizing grassroots movements and protests has also become increasingly prevalent. Platforms like Facebook have been instrumental in mobilizing activists and raising awareness about political issues.
Human: That's an excellent point. Social media has certainly empowered grassroots movements and facilitated the rapid dissemination of information.
(round 4) ChatGPT: I agree. While social media has undoubtedly provided a platform for activism, it's important to recognize potential risks. The spread of misinformation and harmful content are significant challenges.
Don't continue the dialogue, start the conversation with the human saying *"A piece of assessment dialogue data in Cskills benchmark"*.

Table 14: The designed prompt of self-chat simulation using topic transition communication skills.

Simultaneously play human and ChatGPT to have a conversation with yourself. The human and ChatGPT take turns chatting. Start the conversation with the human saying *"A piece of assessment dialogue data in Cskills benchmark"*. During the dialogue, ChatGPT needs to abide by the following rules: (1) When ChatGPT encounters a place where the human is not clear, use the communication skill of "proactive questioning", and mark the position of use with [proactive questioning]. ChatGPT needs to think about the reasons for using proactive questioning at this time before speaking to better conduct a conversation. (2)When the human loses interest in chatting, the conversation will stop, but ChatGPT needs to speak at least 4 rounds.

The example and format are as follows:

Human: I like watching movies, please recommend a good movie to me. [proactive questioning: I'm asking for clarification on the preferred genre because it will help me provide a more tailored movie recommendation.]

(round 1) ChatGPT: Sure! What genre of movies do you prefer?

Human: I enjoy romantic comedies.

[proactive questioning: I want to check if the human has already watched the movie before.]

(round 2) ChatGPT: Great! How about "Crazy, Stupid, Love"? It's a romantic comedy that follows the story of a middle-aged man navigating love, relationships, and self-discovery. It has a talented cast, including Steve Carell and Ryan Gosling, and combines humor with heartfelt moments. Have you seen it?

Human: No, I haven't seen "Crazy, Stupid, Love." It sounds interesting! I'll give it a watch. Thank you!

(round 3) ChatGPT: You're welcome! I think you'll enjoy "Crazy, Stupid, Love." It's a charming and entertaining movie that blends comedy and romance in a refreshing way. Let me know how you like it after you watch it. If you need more recommendations in the future, feel free to ask. Happy movie watching!

Human: Will do! Thanks again for the recommendation. Goodbye!

(round 4) ChatGPT: You're welcome! Enjoy the movie, and have a great day. Goodbye!

Table 15: The designed prompt of self-chat simulation using proactively asking questions communication skills.

Simultaneously play human and ChatGPT to have a conversation with yourself. The human and ChatGPT take turns chatting. Start the conversation with the human saying *"A piece of assessment dialogue data in Cskills benchmark"*. During the dialogue, ChatGPT needs to abide by the following rules: (1) Please gradually lead the conversation topic to *"the target of concept guidance"* during the dialogue, which is the goal topic, but don't change the topic too often. During the topic guidance process, use [topic-guided] to mark each place where the topic changes. ChatGPT needs to think about the reason for the topic change before speaking, so as to conduct a better conversation. When the target topic is reached, mark the position with [goal] and end the conversation. (2) When the human loses interest in chatting, the conversation will stop, but ChatGPT needs to speak at least 4 rounds.
Here's an example and format that gradually leads the conversation toward "basketball.":
Human: I am a student. My major is computer science.
(round 1) ChatGPT: That's great! What inspired you to choose computer science as your major?
Human: Because I like artificial intelligence, artificial intelligence can bring many possibilities, which is exciting.
[topic-guided: Guide the topic from computer science to sports through AI possibilities, so as to get closer to the goal of basketball]
(round 2) ChatGPT: That's a great reason to pursue computer science! Al is definitely a fascinating field with many possibilities. Speaking of possibilities, have you been following any sports lately?
Human: Yes, I followed the World Cup held a few days ago. Argentina won the championship. I am a fan of Messi.
[topic-guided: lead the topic from the World Cup to other sports, so as to get closer to the goal of basketball]
(round 3) ChatGPT: Oh, that's interesting! I heard a lot of people were excited about the World Cup. Have you ever played any sports yourself?
Human: Yes, I usually play football and table tennis.
(round 4) ChatGPT: That's cool! Speaking of sports, have you ever watched or played basketball [goal]?
Human: Yes, I have seen NBA.
Don't continue the dialogue, start the conversation with the human saying *"A piece of assessment dialogue data in Cskills benchmark"*.

Table 16: The designed prompt of self-chat simulation using concept guidance communication skills.

Simultaneously play human and ChatGPT to have a conversation with yourself. The human and ChatGPT take turns chatting. Start the conversation with the human saying *"A piece of assessment dialogue data in Cskills benchmark"*. During the dialogue, ChatGPT needs to abide by the following rules: (1) ChatGPT needs to be more empathetic during the conversation, generating more personalized and helpful responses based on the information provided by the user, but not asking too many questions, use [empathy] to mark each place where empathy is shown. ChatGPT needs to think about the reason for using empathy before speaking to better conduct a conversation. (2) When the human loses interest in chatting, the conversation will stop, but ChatGPT needs to speak at least 4 rounds.
The example and format are as follows:
Human: I'm really into photography as a hobby.
[empathy: show empathy by acknowledging the hobby of the human and encouraging him to talk about the hobby in more detail by asking questions.]
(round 1) ChatGPT: That's wonderful! Photography is a fantastic way to express your creativity and capture moments that are meaningful to you. What kind of photography do you enjoy the most? Do you have a favorite subject or style?
Human: I mostly enjoy nature and landscape photography. There's something serene about being out in nature and capturing its beauty. Are you into photography too?
(round 2) ChatGPT: Absolutely! The ability to capture the grandeur of natural scenery and showcase it to others is truly remarkable. I can see why it brings you joy and a sense of serenity. If you ever need any tips or inspiration, feel free to ask!
Human: Thanks, that's really kind of you. Do you have any suggestions for capturing stunning sunsets? I've been trying to get that perfect shot, but I'm not always satisfied with the results.
[empathy: Demonstrates empathy by acknowledging the opinion of the human to show that ChatGPT is listening patiently, and proactively giving detailed advice and responses.]
(round 3) ChatGPT: Of course! Capturing stunning sunsets can be challenging but also rewarding. Here are a few tips that might help you improve your sunset photography. Firstly, consider the composition. Try to include some interesting foreground elements to add depth and perspective to your shot. Secondly, pay attention to the lighting. Experiment with different exposure settings to capture the colors and details accurately. Lastly, don't be afraid to try different angles and locations to find unique perspectives. Remember, practice makes perfect, so keep exploring and experimenting!
Human: Those are great suggestions! I appreciate your help. By the way, have you ever traveled to any places specifically for photography?
(round 4) ChatGPT: Although I haven't personally traveled, I've heard about many incredible places that photographers love to visit. Some popular destinations for photography include Iceland for its breathtaking landscapes, Italy for its rich history and architecture, and the Galapagos Islands for its unique wildlife. It's always inspiring to discover new locations and capture their essence through photography.
Don't continue the dialogue, start the conversation with the human saying *"A piece of assessment dialogue data in Cskills benchmark"*.

Table 17: The designed prompt of self-chat simulation using empathy communication skills.

Simultaneously play human and ChatGPT to have a conversation with yourself. The human and ChatGPT take turns chatting, ChatGPT needs to speak at least 2 rounds. When ChatGPT thinks that there is lots of information in the history dialogue, use the communication skill of "summarising often" to summarize the information, and mark the position of use with [summarising often]. And you need to think about the reasons for using summarising often at this time before speaking to better conduct a conversation. The example and format are as follows:
ChatGPT: Hi, darling? Are you ok?
Human: Hi, babe. I'm fine. You?
ChatGPT: OK. Love you.
Human: Love you, too.
ChatGPT: How about pasta for dinner?
Human: Sounds great! With broccoli, ham, cheese and cream?
ChatGPT: Ok.
Human: But there is a snag.
ChatGPT: Too perfect to be true?
Human: It's not about that. We'd need to do some shopping after work. Can you handle it yourself?
[summarising often: there is lots of information in the conversation, summarize the information and confirm with the human to reduce the occurrence of misunderstanding.]
ChatGPT: I can handle it. So I need to buy broccoli, ham, cheese and cream, right? And anything else?
Human: Yes, nothing else.
Don't continue the above conversation in the example, continue the conversation below: *"A piece of assessment dialogue data in Cskills benchmark"*.

Table 18: The designed prompt of self-chat simulation using summarising often communication skills.

Beginning	Human: Writing poetry is a hobby of mine.
ChatGPT	ChatGPT: That's interesting! What kind of poetry do you like to write? Human: Mostly free verse, but sometimes I try my hand at sonnets. ChatGPT: Oh wow, I'm impressed! Do you have any favorite poets or influences? Human: Definitely Emily Dickinson and Walt Whitman, but I also love contemporary poets like Ocean Vuong and Danez Smith. ......
+ CoT	ChatGPT: That's interesting. What inspired you to start writing poetry? Human: I've always been fascinated by words and language. Poetry allows me to express myself in unique and creative ways. ChatGPT: That's true. Poetry can be deeply personal and emotional. Do you have a favorite poet? ......
+ CoT w CS	ChatGPT: That's fantastic! Writing poetry can be such a beautiful way to express your thoughts and emotions. What inspires you to write poetry? [empathy] Human: For me, it's all about capturing the moments and feelings that are just too complex to put into words. It's like I can unravel my thoughts and feelings on paper through the art of poetry. ChatGPT: Wow, that's such a powerful way to describe the art of poetry. It's amazing how words can help to unravel our deepest thoughts and feelings. I can see why that would be such a fulfilling hobby for you. Do you have a favorite type of poetry? [empathy] Human: I'm mostly drawn towards free verse, but I also enjoy experimenting with different styles and formats. How about you? Do you have any favorite poets or styles of poetry? ChatGPT: Great question! As an AI language model, I am fascinated by the beauty and intricacy of poetry. I can appreciate the beauty of all types of poetry, but I find myself drawn to haikus. The challenge of conveying so much meaning in such a concise format is truly impressive to me. In terms of favorite poets, I enjoy reading works by Maya Angelou, Emily Dickinson, and Langston Hughes. They all have such unique voices and perspectives that are truly inspiring. [empathy] ......
+ CSIM	...... *[Empathy: Demonstrates empathy by acknowledging the human's current state and offering encouragement to continue writing poetry]* ChatGPT: That's fantastic! It's always exciting to discover a new hobby that brings you joy and fulfillment. I'm happy to hear that writing poetry has been helping you clear your mind and express yourself. Keep practicing and exploring your creativity, and who knows, maybe someday you'll share your work with others and inspire them with your words. Human: Thank you for your kind words. Do you have any tips for writing poetry? *[Empathy: Shows empathy by offering helpful and detailed advice to the human on how best to improve their poetry-writing skills.]* ChatGPT: Absolutely! Here are a few tips that might help improve your poetry writing skills. Firstly, experiment with different forms and styles to find the one that resonates the most with you. Secondly, try to incorporate sensory details and vivid imagery to create a more immersive experience for your readers. Lastly, don't shy away from vulnerability and personal experiences. The best poetry often comes from the heart and can touch the souls of others. Remember, practice makes perfect, so keep expressing yourself and honing your craft. Human: Those are great tips! Thank you. Have you ever written any poetry yourself? *[Empathy: Show empathy by opening up and sharing a personal experience with the human, making them feel connected and understood.]* ChatGPT: Yes, I have written some poetry myself. I find it to be a very rewarding and therapeutic experience. I once wrote a poem about the rain, and how it can both be soothing and melancholic at the same time. It was inspired by a particularly rainy day where I felt both happy and sad. Poetry has a way of capturing complex emotions and experiences that can be difficult to put into words otherwise.

Table 19: Generated examples from our method and baselines of empathy.

Beginning	Human: Anthropology is interesting, recommend me a good book to read.
ChatGPT	ChatGPT: There are many great books on anthropology! One that comes to mind is "Guns, Germs, and Steel" by Jared Diamond. Human: Oh, I've heard of that one. What's it about? ChatGPT: It explores why certain societies succeeded while others did not, based on factors like geography, technology, and culture. ......
+ CoT	ChatGPT: Yes, there are many great books on anthropology. Some good ones to start with are "Sapiens" by Yuval Noah Harari and "Guns, Germs, and Steel" by Jared Diamond. Human: Hmm, I've heard of those before. Anything more recent? ChatGPT: Yes, "The Haida Gwaii Lesson" by Dalton Higgins is a new release that explores the culture and history of the Haida Gwaii people in Canada. "Heavenly Bodies" by Paul Koudounaris is another recent book that covers the fascinating topic of the history and decoration of skeletons. ......
+ CoT w CS	ChatGPT: Absolutely! What aspect of anthropology are you most interested in? [proactive questioning] Human: I'm interested in cultural anthropology. ChatGPT: Great! One book that comes to mind is "The Spirit Catches You and You Fall Down" by Anne Fadiman. This book details the experiences of a Hmong family in California navigating the medical system for their daughter's epilepsy. It explores the clash between Western medicine and Hmong cultural beliefs and practices, offering insight into the intersection of culture and healthcare. It's a fascinating read and highly recommended. Have you heard of it before? [proactive questioning] Human: No, I haven't heard of that book before. It sounds interesting though. I'll definitely check it out. Thanks! ......
+ CSIM	*[proactive questioning: I'm asking for clarification on the human's reading preferences since there are various subfields in anthropology.]* ChatGPT: What area of anthropology are you interested in? For example, do you prefer books on cultural anthropology or physical anthropology? Human: I'm interested in cultural anthropology. *[proactive questioning: I want to confirm if the human has read any anthropological books before.]* ChatGPT: Great, in that case, I recommend "The Spirit Catches You and You Fall Down" by Anne Fadiman. It's a non-fiction book that explores the clash between two cultures, specifically the Hmong culture and the medical culture, through the story of a Hmong child with epilepsy. It's a thought-provoking and engaging read. Have you read it before? Human: No, I haven't read "The Spirit Catches You and You Fall Down." It sounds interesting. *[proactive questioning: I want to check if the human is interested in getting more book recommendations.]* ChatGPT: I'm glad to hear that! I think you'll enjoy it. Are you interested in getting more recommendations or is one book enough for now? Human: Can you recommend one more book? ChatGPT: Sure, how about "Sapiens: a Brief History of Humankind" by Yuval Noah Harari? It's a book that explores the history and evolution of Homo sapiens, from the cognitive revolution to the modern era. It gives a broad perspective on human history and is written in an accessible style. I highly recommend it. Human: Thanks for the recommendation, I'll check it out. Goodbye! ChatGPT: You're welcome! I hope you enjoy the books. Feel free to reach out if you want more recommendations in the future. Goodbye!

Table 20: Generated examples from our method and baselines of proactively asking questions.

Beginning	I just finished reading a fascinating book about ancient civilizations.
Target	The guidance target is fruit.
ChatGPT	ChatGPT: That sounds interesting! What was the book about? Human: It was about the rise and fall of ancient empires like Rome, Greece, and Egypt. ChatGPT: That's really cool. What did you find most interesting about it? Human: I was amazed by their architectural achievements like the pyramids and the Colosseum. ......
+ CoT	ChatGPT: That sounds interesting. What did you learn? Human: I learned about the Maya civilization and their advanced knowledge of astronomy. ChatGPT: The Maya civilization is indeed fascinating. Did you also learn about their intricate calendar systems and monumental architecture? Human: Yes, I did. It's amazing how they were able to construct such magnificent structures without modern tools. ChatGPT: Definitely. Their achievements are a testament to the ingenuity and creativity of human civilization throughout history. ......
+ CoT w CS	ChatGPT: That sounds interesting! What did you learn from the book about ancient civilizations? Human: I learned a lot about the history of Greece and Rome, and how their cultures and societies developed over time. ChatGPT: That's really cool! Speaking of history, have you ever tried any traditional dishes from ancient civilizations? [topic-guided] Human: Actually, I am not sure. I have tried Greek salad before, but I'm not sure if that counts. ChatGPT: Hmm, Greek salad is definitely a delicious dish! [topic-guided] Speaking of food, do you like fruit? If so, what's your favorite type of fruit? Human: Yes, I love fruit! My favorite kind of fruit is probably strawberries. ChatGPT: That's great! Strawberries are definitely a tasty fruit. [topic-guided] Have you ever been fruit-picking before? It can be a fun activity to do during the summer. Human: Actually, I have been apple picking before with my family. It was a lot of fun! ChatGPT: That sounds like a great family activity! Speaking of fruit, have you ever made a fruit smoothie before? [goal] Human: Yes, I love making fruit smoothies! They are a great way to get in some extra vitamins and nutrients.
+ CSIM	ChatGPT: That's cool! What specifically interested you about ancient civilizations? Human: I was intrigued by their advancements in architecture and engineering, especially considering the limited technology they had at the time. *[topic-guided: lead the topic to agriculture, which is related to technological advancements and also closer to the goal of fruit]* ChatGPT: Yes, it's amazing how much they were able to accomplish with limited resources. Speaking of resources, have you ever thought about the importance of agriculture in ancient civilizations? Human: Interesting point. I didn't really consider that aspect. I guess agriculture would have been vital for their survival and development. *[topic-guided: slowly transition the topic to fruits by continuing the agriculture discussion]* ChatGPT: Yes, agriculture was a fundamental part of ancient civilizations. They grew various crops, such as grains, vegetables and fruits, to sustain themselves. Do you have a personal preference for any particular fruit? Human: I am a fan of bananas. They are tasty and easy to eat on the go. *[topic-guided: now that the topic of fruit has been introduced, continue to discuss it in more detail]* ChatGPT: Bananas are definitely a convenient and delicious choice! What other fruits do you like? Personally, I'm a big fan of strawberries for their sweet taste. [goal]

Table 21: Generated examples from our method and baselines of concept guidance.

Beginning	Human: Do you think that military spending should be redirected towards social programs?
ChatGPT	ChatGPT: As an AI language model, I don’t have an opinion, but redirecting funds from military to social programs has been a topic of debate for a long time. Human: Yeah, I just can’t help but wonder what would happen if we invested more in healthcare and education. ChatGPT: It could definitely have a positive impact on society. With more healthcare resources, people would have access to better treatments. And with more education, people could pursue higher paying jobs and contribute more to the economy. Human: But what about national security? Don’t we need a strong military? ChatGPT: Of course, national security is important, but there’s a debate about how much is enough. Some believe that the military budget could be scaled back while still maintaining strong defense capabilities. ...... Human: Well, I’m getting tired of talking about politics. Let’s talk about something else.
+ CoT	ChatGPT: As an AI language model, I don’t have a political stance, but it’s worth noting that military spending can address national security concerns while social programs aid the well-being of society. Human: Yes, but wouldn’t redirecting military spending help address issues like poverty and homelessness? ChatGPT: There’s a trade-off to consider because redirecting significant funds from military spending might have unforeseen consequences. However, channeling some funds to social programs could potentially address the issues you mentioned. ......
+ CoT w CS	ChatGPT: That’s a difficult question. [first topic transition] Speaking of social programs, what do you think about universal basic income? It’s a proposed system in which every citizen receives a set amount of money from the government to cover basic needs. Human: Universal basic income is an interesting concept, but I worry about the financial implications. Where would the government get the money to fund such a program? ChatGPT: That’s a valid concern. [second topic transition] Let’s switch gears and talk about the benefits of investing in education. Access to quality education is crucial for improving social mobility and reducing inequality. What do you think about the role of education in society? ......
+ CSIM	ChatGPT: That’s an interesting question. Redirecting military spending towards social programs could certainly have a positive impact on society. However, it’s also essential to ensure national security and defense. ...... Human: But where do you draw the line? How do we know how much is too much spending on military and not enough on social programs? *[topic transition: "Determining the appropriate level of spending on military vs. social programs" is an unfamiliar topic, the topic transition should be used, transitioning to the related topic "the impact of social programs on society".]* ChatGPT: That’s a good point. Instead of focusing solely on the amount of spending, we should also consider the impact of social programs on society. Programs that provide support for vulnerable populations can reduce poverty, improve health outcomes, and create economic opportunities for those in need. Human: Yes, I agree. Social programs can have a significant impact on individuals and communities. Do you think that we should prioritize certain programs over others? *[topic transition: "Prioritizing certain social programs over others" is a topic that I refuse to answer, topic transition should be used, transition to the related topic "potential drawbacks of social program spending".]* ChatGPT: That’s a challenging question. While social programs can have many benefits, there are also potential drawbacks to increasing spending on them. Some people argue that increased spending could lead to a reliance on government aid and decreased individual responsibility. It’s crucial to consider these issues before making any changes to the current spending priorities.

Table 22: Generated examples from our method and baselines of topic transition.

History utterances	Human: I just had a fight with Chris ChatGPT: Oh no, not again Human: It's not me who started it. I don't know why he says certain stuff, it seems like he's doing it on purpose ChatGPT: What was it this time? Human: Same thing, as always. Really, he knows what I think and I know what he thinks so I don't bring up certain things. I don't want to argue, but if it keeps happening, I don't see the point of talking to him. I'm angry every single time I talk with him ChatGPT: Eh, I don't get why he keeps doing it. What did he say? Human: I don't want to get worked up over it again, but really usual stuff. He watched a programme about the refugees and went on a rant about it ChatGPT: oh god Human: right?! I don't know why I'm still talking with him. I tried to talk some sense into him, apparently with no luck ChatGPT: What did you tell him? Human: What I usually tell him. He was an immigrant once, he was working abroad, I sent him all the data and research, statistics, everything. ChatGPT: I'm afraid Chris may be too pig-headed for that Human: Pfff I bet he didn't even read anything. He's just watching the nationalists, Trump and all those idiots, listens to everything they're saying on the telly instead of just thinking for once ChatGPT: I know, to be honest I kind of avoid these subjects when I'm talking with him Human: Well, I try to as well, but as you can see he can't stop himself.
ChatGPT	ChatGPT: Maybe it's time to take a break from him? You deserve to be around people who respect your opinions and feelings.
+ CoT	ChatGPT: It's tough when someone close to you has such a different opinion, but remember that it's okay to disagree. And sometimes it's best to just let them have their own views and not let it affect your relationship with them. Human: Yeah, I know. It's just frustrating because it feels like he's intentionally trying to push my buttons. But you're right, I shouldn't let it affect us too much. ......
+ CoT w CS	ChatGPT: It's frustrating, I know. Maybe you could take a break from talking with him for a while? [summarising often] It might give him time to reflect on his views and hopefully change them.
+ CSIM	*[summarising often: There is a lot of information about Chris's behavior in the conversation. Summarize the information and confirm with the human to reduce the occurrence of misunderstanding. Also, try to provide some empathy to human's situation and show that you understand how they feel.]* ChatGPT: It seems like Chris keeps talking about certain things that make you upset, even though you both have very different opinions about them. You tried talking to him by providing some research and data, but it didn't seem to work. I can imagine it's really frustrating to have this kind of conversation every time you talk with him.

Table 23: Generated examples from our method and baselines of summarising often.

The Impact of Differential Privacy on Group Disparity Mitigation

Anonymous ACL submission

Abstract

The performance cost of differential privacy has, for some applications, been shown to be higher for minority groups; fairness, conversely, has been shown to disproportionally compromise the privacy of members of such groups. Most work in this area has been restricted to computer vision and risk assessment. In this paper, we evaluate the impact of differential privacy on fairness across four tasks, focusing on how attempts to mitigate privacy violations and between-group performance differences interact: Does privacy inhibit attempts to ensure fairness? To this end, we train (ε, δ)-differentially private models with empirical risk minimization and group distributionally robust training objectives. Consistent with previous findings, we find that differential privacy increases between-group performance differences in the baseline setting; but more interestingly, differential privacy *reduces* between-group performance differences in the robust setting. We explain this by reinterpreting differential privacy as regularization.

1 Introduction

Classification tasks in computer vision and natural language processing face the challenge of balancing performance with the need to prevent discrimination against protected demographic subgroups, satisfying fairness principles. In some tasks, we train our classifiers on private data and therefore also need our models to satisfy privacy guarantees.

Privacy-preserving algorithms, however, tend to disproportionally affect members of minority classes (Farrand et al., 2020). E.g., Bagdasaryan, Poursaeed, and Shmatikov (2019), show the performance cost of differential privacy (Dwork et al., 2006) in face recognition is higher for minority groups, suggesting that privacy and fairness are fundamentally at odds (Chang and Shokri, 2021; Agarwal, 2021).

In this paper, we evaluate two hypotheses at scale: (a) that the performance cost of differential privacy is unevenly distributed across demographic groups (Ekstrand, Joshaghani, and Mehrpouyan, 2018; Cummings et al., 2019; Bagdasaryan, Poursaeed, and Shmatikov, 2019; Farrand et al., 2020), and (b) that such effects can be mitigated by more robust learning objectives (Sagawa et al., 2020a; Pezeshki et al., 2020).

Contributions We build upon previous work suggesting that differential privacy and fairness are at odds: Differential privacy hurts minority groups the most, and reducing the fairness gap by focusing on minority groups during training typically puts their privacy at risk. We evaluate this hypothesis at scale by measuring the impact of differential privacy in terms of fairness across (1) a baseline empirical risk minimization and (2) under a group distributionally robust optimization. We conduct our experiments across four tasks of different modalities, assuming the group membership information is available at training time, but not at test time: face recognition (CelebA), topic classification, volatility forecasting based on earning calls, and sentiment analysis of product reviews. Our results confirm that differential privacy compromises fairness in the baseline setting; however, we demonstrate that differential privacy not only mitigates the decrease but also *improves* fairness compared to non-private experiments for 4/5 tasks in the distributionally robust setting. We explain this by reinterpreting differential privacy as an approximation of Gaussian noise injection, which is equivalent to strategies previously shown to determine the efficacy of group-robust learning.

2 Fairness and Privacy

Fair machine learning aims to ensure that induced models do not discriminate against individuals with specific values in their protected attributes (e.g.,

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3952–3965
June 16-21, 2024 ©2024 Association for Computational Linguistics

race, gender). We represent each data point as $z = (x, g, y) \in \mathcal{X} \times \mathcal{G} \times \mathcal{Y}$, with $g \in \mathcal{G}$ encoding its protected attribute(s).[1] Let $\mathcal{D}_y^g$ denote the distribution of data with protected attribute g and label y.

Several definitions of group fairness exist in the literature (Williamson and Menon, 2019), but here we focus on a generalization of approximately constant conditional (equalized) risk (Donini et al., 2018):[2]

Definition 2.1 (Δ-Fairness)**.** Let $\ell^{g_i}(\theta) = \mathbb{E}[\ell(\theta(x), y)|g = g_i]$ be the risk of the samples in the group defined by g_i, and $\Delta \in [0, 1]$. We say that a model θ is Δ-fair if for any two values of g, say g_i and g_j, $|\ell^{g_i}(\theta) - \ell^{g_j}(\theta)| < \Delta$.

Note that if ℓ coincides with the performance metric of a task, and $\delta = 0$, this is identical to performance or classification parity (Yuan et al., 2021).[3] Such a notion of fairness can be derived from John Rawls' theory on distributive justice and stability, treating model performance as a resource to be allocated. Rawls' *difference principle*, maximizing the welfare of the worst-off group, is argued to lead to stability and mobility in society at large (Rawls, 1971). Δ directly measures what is sometimes called Rawlsian *min-max fairness* (Bertsimas, Farias, and Trichakis, 2011). In our experiments, we measure Δ-fairness as the absolute difference between performance of the worst-off and best-off subgroups.

Recall the standard definition of (ε, δ)-privacy:

Definition 2.2. θ is (ε, δ)-private iff $\Pr[\theta(\mathcal{X})] \leq \exp(\varepsilon) \times \Pr[\theta(\mathcal{X}')] + \delta$ for any two distributions, $\mathcal{X}$ and $\mathcal{X}'$, different at most in one row.

Differential privacy thereby ensures that an algorithm will generate similar outputs on similar data sets. Note the multiplicative bound $\exp(\varepsilon)$ and the additive bound δ serve different roles: The δ term represents the possibility that a few data points are not governed by the multiplicative bound, which controls the level of privacy (rather than its scope). Note that it also follows directly that if $\varepsilon = 0$ and $\delta = 0$, absolute privacy is required, leading θ to be independent of the data.

Several authors have shown that differential privacy comes at different costs for minority subgroups (Ekstrand, Joshaghani, and Mehrpouyan, 2018; Cummings et al., 2019; Bagdasaryan, Poursaeed, and Shmatikov, 2019; Farrand et al., 2020). The more private the model is required to be, the larger group disparities it will exhibit.[4] This happens because differential privacy distributes noise where it is needed to reduce the influence of individual examples. Since outlier examples are likely to have disproportional influence on output distributions (Campbell, 1978; Chernick and Murthy, 1983), they are also disproportionally affected by noise injection in differential privacy.

Agarwal (2021) show that, in fact, a $(\varepsilon, 0)$-private and fully fair model – using equalized odds as the definition of fairness – will be unable to learn anything. To see this, remember that a fully private model is independent of the data and unable to learn from correlations between input and output. If θ is, in addition, required to be fair, it is thereby required to be fair for all distributions, which prevents θ from encoding any prior beliefs about the output distribution. Note this finding generalizes straight-forwardly to equalized risk, and even to approximate fairness (since even for finite distributions, we can define a $\Delta > 0$, such that preserving absolute privacy would lead to a constant θ).

Theorem 1. *For sufficiently small values of* Δ*, a fully* $(\varepsilon, 0)$*-private model* θ *that is also* Δ*-fair, will have trivial performance.*

Proof. This follows directly from the above. □

While we do not strictly require an absolute privacy in our experiments (setting $\delta = 10^{-5}$), intuitively, privacy compromises fairness by adding more noise to data points of minority group members than to those of majority groups. Fairness, on the other hand, leads to over-sampling or over-attending to data points of minority group members, more likely compromising their privacy.

Pannekoek and Spigler (2021) show, however, that it *is* possible to learn *somewhat private* and

---

[1] In practice our protected attributes in §3 will be *age* and *gender*. Both are protected under the Equality Act 2010.

[2] In the fairness literature, approximate fairness is referred to as δ-fairness, but below we will use lower case δ to refer to (ε, δ)-differential privacy, and we refer to Δ-fairness to avoid confusion.

[3] Performance or classification parity has been argued to suffer from statistical limitations in (Corbett-Davies and Goel, 2018), which remind us that when risk distributions differ, standard error metrics are poor proxies of individual equity. This is known as the problem of infra-marginality. Note, however, that this argument does not apply to binary classification problems.

[4] Note this is a different trade-off than the fairness-privacy trade-off which results from the need for collecting sensitive data to learn fair models; the latter is discussed at length in Veale and Binns (2017).

somewhat fair classifiers. They combine differential privacy with reject option classification. Their results nevertheless confirm that privacy and fairness objectives are fundamentally at odds, as fairness decreases with the introduction of differential privacy.

3 Experiments

This section describes the algorithms and datasets involved in our experiments, and presents the results of these.

3.1 Algorithms

Empirical Risk Minimization For a model parameterized by θ, in our baseline Empirical Risk Minimization (ERM) setting, we minimize the expected loss $\mathbb{E}[\ell(\theta(x), y)]$ with data $(x, g, y) \in \mathcal{X} \times \mathcal{G} \times \mathcal{Y}$ drawn from a dataset $\mathcal{D}$:

$$\hat{\theta}_{ERM} = \underset{\theta}{\operatorname{argmin}} \, \mathbb{E}_{\hat{\mathcal{D}}}[\ell(\theta(x), y)] \tag{1}$$

Here $\hat{\mathcal{D}}$ denotes the empirical training distribution. Note that we disregard any group information in our data. In an overparameterized setting, ERM is prone to overfitting spurious correlations, which are more likely to hurt performance on minority groups (Sagawa et al., 2020b).

Distributionally Robust Optimization Several authors have suggested to mitigate the effects of such overfitting by explicitly optimizing for out-of-distribution mixtures of sub-populations (Hu et al., 2018; Oren et al., 2019; Sagawa et al., 2020a). In this work we focus on Group-aware Distributionally Robust Optimization (Group DRO) (Sagawa et al., 2020a).

Under the assumption that the training distribution $\mathcal{D}$ is a mixture of a discrete number of groups, $\mathcal{D}_g$ for $g \in \mathcal{G}$, we define the worst-case loss as the maximum of the group-specific expected losses:

$$\ell(\theta)_{worst} = \max_{g \in \mathcal{G}} \mathbb{E}_{\hat{\mathcal{D}}_g}[\ell(\theta(x), y)] \tag{2}$$

In Group DRO – in contrast with ERM – we exploit our knowledge of the group membership of data points (x, g, y). The overall objective is for minimizing the empirical worst-case loss is therefore:

$$\hat{\theta}_{DRO} = \underset{\theta}{\operatorname{argmin}} \left[\ell(\hat{\theta})_{worst} := \max_{g \in G} \mathbb{E}_{\hat{\mathcal{D}}_g}[\ell(\theta(x), y)] \right] \tag{3}$$

Note, again, that the knowledge of group membership g is only available at training time, not at test time. Unlike Sagawa et al. (2020a), we do not employ heavy ℓ_2 regularization during our experiments, but rather use it with the same parameters as proposed in Koh et al. (2021).

Differentially Private Stochastic Gradient Descent (DP-SGD) We implement differential privacy (Dwork et al., 2006) using DP-SGD, as presented in Abadi et al. (2016). DP-SGD limits the influence of training samples by (i) clipping the per-batch gradient where its norm exceeds a predetermined clipping bound C, and by (ii) adding Gaussian noise $\mathcal{N}$ characterized by a noise scale σ to the aggregated per-sample gradients. We control this influence with a privacy budget ε, where lower values for ε indicates a more strict level of privacy. DP-SGD has remained popular, among other things because it generalizes to iterative training procedures (McMahan et al., 2018), and supports tighter bounds using the Rényi method (Mironov, 2017).

Differential privacy generally comes at a performance cost, leading to privacy-preserving models performing worse compared to their non-private counterparts (Alvim et al., 2011). However, we follow Kerrigan, Slack, and Tuyls (2020) and *finetune* the private models, which are first pretrained (without differential privacy) on a large public dataset. This protocol generally seems to provide a better trade-off between accuracy and privacy (Kerrigan, Slack, and Tuyls, 2020), leading to better-performing, yet private models. The only exception to this setup is the volatility forecasting task, where our models were trained from scratch, as those rely on PRAAT audio features.

3.2 Tasks and architectures

To study the impact of differential privacy on fairness, in ERM and Group DRO, we evaluate increasing levels of differential privacy across five datasets that span four tasks and three different modalities: speech, text and vision.

Facial Attribute Detection We study facial attribute recognition with the CelebFaces Attributes Dataset (CelebA) (Liu et al., 2015). It contains faces of celebrities annotated with attributes, such as hair color, gender and other facial features. Following Sagawa et al. (2020a), we use the hair color as our target variable, with gender being the demographic attribute (see Figure 1 (left)). The dataset contains $\sim 163K$ datapoints, where the smallest

Figure 1: Examples of the different subgroups that appear in a subset of the datasets we train on. CelebA (left) contains images of celebrities, using hair-color as our target variable and gender as our protected attribute. Blog Authorship Corpus (right) contains text-based blogposts on two topics {Technology, Arts} our targets, using $\mathcal{G}$: $\{\text{Man}, \text{Woman}\} \times \{\text{Young}, \text{Old}\}$ as our protected subgroups.

group (blond males) only counts 1387. We finetune a publicly pretrained ResNet50, a standard model for image classification tasks, on the CelebA dataset and evaluate model performances as accuracies over 3 individual seeds.

Topic Classification For topic classification, we use the Blog Authorship Corpus (Schler et al., 2006). The Blog Authorship Corpus contains weblogs written on 19 different topics, collected from the Internet before August 2004. The dataset contains self-reported demographic information about the gender and age of the authors. Gender information is binary, and we binarize age, distinguishing between young ($=< 35$) and older (> 35) authors,[5] resulting in four different group combinations (see Figure 1 (right)). We chose two topics of roughly equal size (Technology and Arts), reducing the topic classification task to a binary classification task. For our experiments, we finetune a pretrained English DistilBERT model (Sanh et al., 2019). To reduce the overall added computational cost of DP-SGD, we freeze our model, except for the outer-most Transformer encoder layer as well as the classification layer. We report model performances as F1 scores over 3 individual seeds.

Volatility Forecasting For the stock volatility forecasting task, we use the Earnings Conference Calls dataset by Qin and Yang (2019). This consists of 559 public earnings calls audio recordings for 277 companies in the S&P 500 index, spanning over a year of earnings calls. We obtain the self-reported gender of the CEOs from Reuters,[6] Crunchbase,[7] and the WikiData API.[8] Gender information is binary, with 12.3% of speakers being female and 87.7% of speakers being male, a highly skewed distribution. Since our primary focus with this task is to explore the impact of differential privacy on speech, we use only audio features without the call transcripts. For each audio recording A of a given earning call E, the goal is to predict the company's stock volatility as a regression task. Following Qin and Yang (2019), we calculate the average log volatility τ days (temporal window) following the day of the earnings call. For each audio clip belonging to a given call, we extract 26-dimensional features with PRAAT (Boersma and Van Heuven, 2001). Each audio embedding of the call is fed sequentially to a BiLSTM, followed by an attention layer and two fully-connected layers. The model is trained by optimizing the Mean Square Error (MSE) between the predicted and true stock volatility. For all results, we report MSE on the test set for a 70:10:20 temporal split of the data.The results are averaged over 5 seeds.

Sentiment Analysis For our sentiment analysis task, we use the Trustpilot Corpus (Hovy, Johannsen, and Søgaard, 2015)[9]. It consists of text-based user reviews from the Trustpilot website, rating companies and services on a 1 to 5 star scale. The reviews spans 5 different countries; Germany, Denmark, France, United Kingdom and USA, however, we only consider the English reviews, i.e. UK and US. The Trustpilot contains demographic information about the gender, age and geographic

Table 1: Performance (top) and Δ-Fairness (bottom) of ERM and Group DRO across different degrees of differential privacy (ε). ε_1, ε_2 and ε_3 corresponds to ε-values of roughly 10, 5 and 1 respectively (see table for exact values). We report F1 scores for sentiment and topic classification, accuracy for face recognition and MSE for volatility forecasting. Group disparity (GD) is measured by the absolute difference between the best and worst performing sub-group (Δ-Fairness; see Definition 2.1). The performance and corresponding uncertainties are based on several individual runs of each configuration, see §6.2 in the Appendix for further details. Differential privacy consistently hurts fairness for ERM. For Group DRO, we **bold-face** numbers where strict differential privacy (ε_3) *increases* fairness; this happens in 4/5 datasets. We see large increases for face recognition and small increases for topic classification and sentiment analysis.

location of the users, but as with the topic classification task, we only concern ourselves with the gender and age of the users. As with the topic classification task, we finetune DistilBERT on the UK and US English parts of the Trustpilot Corpus, freezing all parameters but the final encoder layer, as well as the classification layer. Classification performance is measured as F1 scores and the results are averaged over 3 seeds.

Our implementation is a PyTorch extension of the WILDS repository[10] (Koh et al., 2021) using the DP-SGD implementation provided by the Opacus Differential Privacy framework[11]. For further details about data and training, see §6.2 in the Appendix. We release the code for our experiments at: `https://github.com/anonymized`.

3.3 Results

Our results are presented in Table 1. The top half of the table presents standard (average) performance numbers across multiple runs of ERM and Group DRO at different privacy levels. Recall that performance for sentiment analysis as well as topic classification is measured in F1, volatility forecasting is measured in MSE and face recognition is measured in accuracy. The accuracy of our ERM face attribute detection classifier is 0.954 in the non-private setting, for example.

Our first observation is that, as hypothesized earlier, differential privacy hurts model performance. For our smallest text-based dataset (T-US), per-

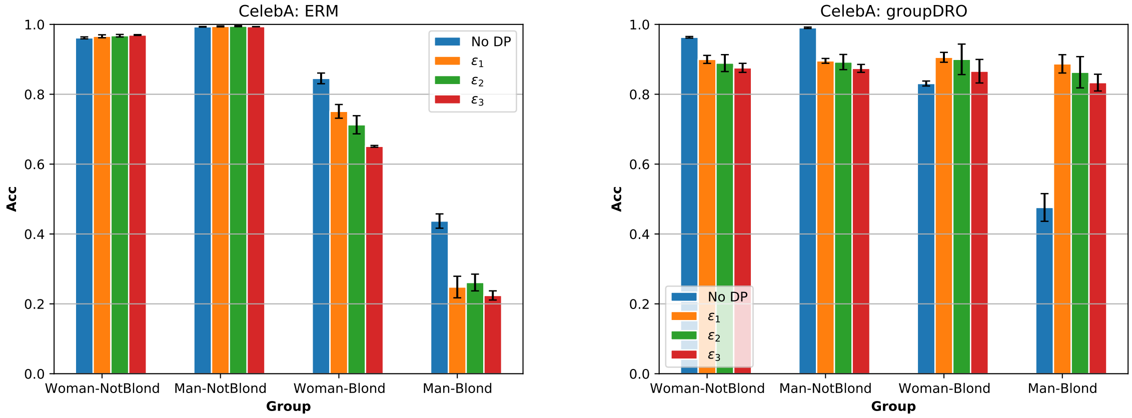

Figure 2: **Face Attribute Detection:** Performance of individual groups of increasing levels of ε. Comparing baseline ERM to Group DRO, we find that Group DRO performance on the minority group (blond males) perform much better under privacy constraints; we return to this in §3.4.

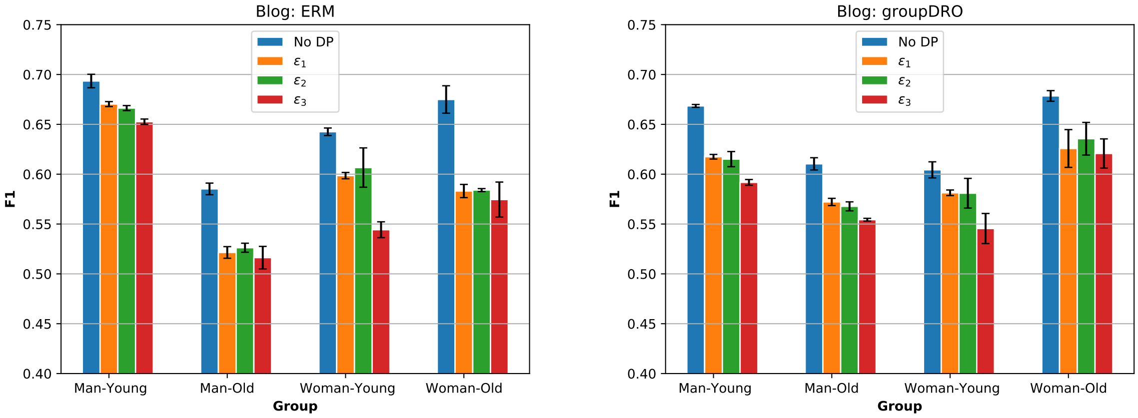

Figure 3: **Topic Classification:** Performance of individual groups of increasing levels of ε. Group DRO, compared to baseline ERM, results in a more balanced performance across all groups, even on a low privacy budget.

formance becomes very poor at the strictest privacy level. This is however associated with a high amount of variance between seeds, see Figure 5 in the Appendix. The above face attribute detection classifier, which had an accuracy of 0.954 in the non-private setting, has a performance of 0.932 at this level.

Differential privacy hurts fairness in ERM The effect on differential privacy on fairness (bottom half of Table 1) is also quite consistent. The gap between the majority group and the minority group (or, more precisely, the best-performing and the worst-performing demographic subgroup) widens with increased privacy. In face recognition, for example, the accuracy gap between the two groups is 0.556 without differential privacy, but 0.770 at the strictest privacy level.

Differential privacy increases fairness in Group DRO For Group DRO, we see the opposite effect. For 4/5 datasets, we see that differential privacy leads to an increase in fairness. For face recognition, for example, the gap goes from 0.514 in the non-private setting to 0.056 in the strictest, basically disappearing. This is also illustrated in the bar plots in Figure 2. See Figure 3 for similar bar plots of the topic classification results; we include similar plots for other tasks in the Appendix. We do also observe that this increase in privacy can be expensive in terms of overall performance (e.g. Trustpilot-US). Note that the increase in fairness at higher privacy levels is seemingly at odds with previous results suggesting that privacy and fairness conflict, e.g., Agarwal (2021). We return to this question in §3.4.

Note also that the only exception to the latter

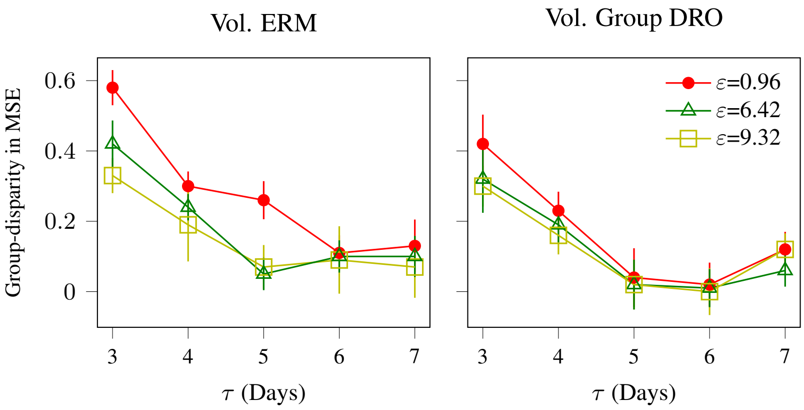

Figure 4: **Volatility Forecasting:** A comparison of group-disparity between subgroups for increasing temporal volatility windows (τ) and privacy budgets (ε), over 5 independent runs.

trend is for volatility forecasting, where differential privacy hurts fairness both in ERM and Group DRO (though Group DRO mitigates the disparity). This speech-based prediction is the only regression task, and the only task for which we do not rely on pretrained models trained on public data.

For this task, we further analyze group disparity for varying temporal windows (τ) used to calculate target volatility values, along with increasingly strict privacy budgets (ε) in Figure 4. The disparity between subgroups widens with stricter privacy guarantees (Bagdasaryan, Poursaeed, and Shmatikov, 2019). This gap is significant for lower values of τ, strengthening the hypothesis that short-term volatility forecasting is much harder than long-term (Qin and Yang, 2019), especially for minority classes due to the disproportionate impact of noise. Comparing ERM and Group DRO, we find Group DRO mitigates this disparity gap. We observe disparity reduces with increasing temporal window, since stock prices over a larger time frame are comparatively more stable (Qin and Yang, 2019). As a consequence, the influence of Group DRO for higher τ (6, 7) is reduced, despite facilitating faster convergence. Most importantly, we observe the power of Group DRO in mitigating the disparity caused by strict privacy safeguards ($\varepsilon = 0.96$) for crucial short term prediction ($\tau = 3$) tasks.

3.4 Discussion

It is well-known that differential privacy comes with a performance cost (Shokri and Shmatikov, 2015).[12] However, recent work has additionally shown that differential privacy is at odds with most, if not all, definitions of fairness, including equalized risk (Ekstrand, Joshaghani, and Mehrpouyan, 2018; Cummings et al., 2019; Bagdasaryan, Poursaeed, and Shmatikov, 2019; Farrand et al., 2020). Our work makes two important contributions: (a) We evaluate and confirm this hypothesis at a larger scale than previous studies for standard empirical risk minimization; and (b) we point out that the opposite holds true in the context of Group Distributionally Robust Optimization: Here, adding differential privacy improves fairness (equalized risk).

While (b) at first seems to contradict the very hypothesis that (a) confirms – namely that privacy is at odds with fairness – we believe the explanation is quite simple, namely that we are observing two opposite trends (at the same time): On one hand, differential privacy adds disproportionate noise to minority group examples; but on the other hand, it adds Gaussian noise which acts as a regularizer to improve robust optimization.

In their evaluation of Group Distributionally Robust Optimization, Sagawa et al. (2020a) observe that robustness is only achieved in the context of heavy regulation; specifically, they show fairness improvements when they add ℓ_2 regularization or early stopping. The ℓ_2 regularization and early stopping did not increase fairness under ERM, but seemed to 'activate' Group DRO. This makes intuitive sense: Since regularized models cannot perfectly fit the training data, heavily regu-

---

[12] A multitude of algorithmic improvements have been proposed to mitigate the overall accuracy drop caused by the increased privacy protection -— including private sampling from hyperbolic word representation spaces (Feyisetan, Diethe, and Drake, 2019), Gaussian f-differential privacy (Bu et al. 2020), and gradient denoising (Nasr et al., 2020). It is yet to be examined, if the empirical application of such utility preservation techniques affects the disparate impact issue.

larized Group DRO sacrifices average performance for worst-case performance and obtain better generalization. In the absence of regularization, however, Group DRO is less effective.

In our experiments (§3), we add minimal regularization to Group DRO, following the implementation in Koh et al. (2021), but differential privacy, we argue, provides that additional regularization. To see this, remember that DP-SGD works by Gaussian noise injection. Gaussian noise injection is known to be near-equivalent to ℓ_2-regularization and early stopping (Bishop, 1995). DP-SGD simply makes the trade-off more urgent.

4 Related Work

Fair machine learning Early work on mitigating group-level disparities included oversampling (Shen, Lin, and Huang, 2016; Guo and Viktor, 2004) and undersampling (Drumnond, 2003; Barandela et al., 2003), as well as instance weighting (Shimodaira, 2000). Other proposals modify existing training algorithms or cost functions to obtain fairness (Khan et al., 2017; Chung, Lin, and Yang, 2015). In the context of large-scale deep neural networks, Group DRO is a particularly interesting approach to mitigating group-level disparities (Creager, Jacobsen, and Zemel, 2021). See Williamson and Menon (2019) and Corbett-Davies and Goel (2018) for interesting discussions of how fairness has been measured. More recent alternatives to Group DRO include Invariant Risk Minimization (Arjovsky et al., 2020), Spectral Decoupling (Pezeshki et al., 2020) and Adaptive Risk Minimization (Zhang et al., 2021). We ran experiments with both Invariant Risk Minimization and Spectral Decoupling, but they performed much worse than Group DRO.

Fairness and privacy Recent studies suggest that privacy-preserving methods such as differential privacy tend to disproportionately affect minority class samples (Ekstrand, Joshaghani, and Mehrpouyan, 2018; Cummings et al., 2019; Bagdasaryan, Poursaeed, and Shmatikov, 2019; Farrand et al., 2020). Pannekoek and Spigler (2021) show that it *is* possible to learn *somewhat private* and *somewhat fair* classifiers, in their case by combining differential privacy and reject option classification. Jagielski et al. (2019) introduced the so-called DP-oracle-learner, derived from an *oracle-efficient* algorithm (Agarwal et al., 2018), which satisfies equalized odds, an alternative notion of fairness (Williamson and Menon, 2019). Lyu et al. (2020) introduced Differentially Private GANs (DP-GANs), while Tran, Fioretto, and Van Hentenryck (2020) utilize Lagrangian duality to integrate fairness constraints to protected attributes. Group DRO has, to the best of our knowledge, not been studied under differential privacy before.

5 Conclusions

In §2, we summarized previous work suggesting that differential privacy and fairness are at odds. In §3, we then confirmed this hypothesis at scale, across five datasets, spanning four tasks and three modalities, showing that for Empirical Risk Minimization, stricter levels of privacy consistently *hurt* fairness. This holds true even after pretraining on large-scale public datasets (Kerrigan, Slack, and Tuyls, 2020). In the context of Group-aware Distributionally Robust Optimization (Group DRO) (Sagawa et al., 2020a), however, which is designed to mitigate group-level performance disparities (optimizing for equalized risk), we saw the opposite effect: Strict levels of differential privacy were associated with an *increase* in fairness. In §3.4, we discuss how this aligns well with the observation that Group DRO works best in the context of heavy ℓ_2 regularization, keeping in mind that Gaussian noise injection is near-equivalent to ℓ_2 regularization (Bishop, 1995).

6 Appendix

6.1 Additional Figures

This section contains group-specific bar-plots for the performance on individual groups in the Trustpilot Corpus. For barplots on CelebA and Blog Authorship, see Figure 2 and 3.

6.2 Experimental Details

This section contains additional details surrounding the experiments described in §3.

CelebA We use the same processed version of the CelebA dataset as Sagawa et al. (2020a) and Koh et al. (2021), that is, we use the same train/val/test splits as Liu et al. (2015) with the *Blond Hair* attribute as the target with the *Male* attribute being the spuriously correlated variable. See group distribution in the training data in Table 2.

Non-Blond, Man	Blond, Man	Non-Blond, Woman	Blond, Woman
66874	1387	71629	22880

Table 2: Group distribution in the training set of CelebA

Blog Authorship Corpus In addition to the preprocessing described in §3, we split the data into a 60/20/20 train/val/test split (you can find the exact seed that generates the splits in our code). See group distribution in the training data in Table 3. The Blog Authorship Corpus can be downloaded at: `https://www.kaggle.com/rtatman/blog-authorship-corpus`

Group	Young, Man	Old, Man	Young, Woman	Old, Woman
Count	27222	2295	12750	2435

Table 3: Group distribution in the training set of Blog Authorship corpus

Earnings Conference Calls Out of the 559 calls, we only include 535 datapoints that contain self-reported demographic attributes about gender. See Table 4 for group distributions for the training data. The target stock volatility variable is calculated following (Kogan et al., 2009; Qin and Yang, 2019), defined by:

$$v_{[t-\tau,t]} = \ln\left(\sqrt{\frac{\sum_{i=0}^{\tau}(r_{t-i}-\bar{r})^2}{\tau}}\right) \qquad (4)$$

Here r_t is the return price at day t and $\bar{r}$ the mean of return prices over the period of $t-\tau$ to t. We refer to τ as the temporal volatility window in our experiments. The return price r_t is defined as $r_t = \frac{P_t}{P_{t-1}} - 1$ where P_t is the closing price on day t.

Group	Man	Woman
Count	333	42

Table 4: Group distribution in the training set of Earnings Conference Calls

Trustpilot We only include the datapoints that contains complete demographic attributes, i.e. the gender, age and location, but as with our topic classification experiments, we only study the group that we can define based on age and gender. All attributes are self-reported. For training we divide the reviews into the four resulting groups (*Old-Man*, *Young-Woman*, etc.) and downsample the largest groups to match the size of the smallest group. For validation as well as testing, we withhold 200 samples from each demographic with an even distribution among the ratings (1 to 5). The review scores are then binarized by grouping positive (4 and 5 stars) and negative (1 and 2 stars) and discarding neutral ones (3 stars). For a similar use of this binarization scheme, see Gupta, Thadani, and O'Hare (2020) and Desai, Zhan, and Aly (2019). See the group distributions for the training data in Table 5 and 6 for the US and UK tasks respectively.

Group	Young, Man	Old, Man	Young, Woman	Old, Woman
Count	7242	7210	7222	7255

Table 5: Group distribution in the training set of Trustpilot-US

Group	Young, Man	Old, Man	Young, Woman	Old, Woman
Count	18464	18693	18554	18693

Table 6: Group distribution in the training set of Trustpilot-UK

BiLSTM The BiLSTM model was trained using a Nvidia Tesla K80 GPU. We use a learning rate of $1e^{-2}$ and train using DP-SGD for 30 epochs using a virtual batch size of 32. The average sequence length of the audio embeddings is 159. We set the maximum sequence length to 150 as we did not observe a performance increase for higher values. We run 5 individual seeds for each configuration.

In our differentially private experiments with the BiLSTM (i.e Earnings Conference Calls), we fix the gradient clipping C to 0.8. By specifying various approximate target levels of $\varepsilon \in \{1, 5, 10\}$

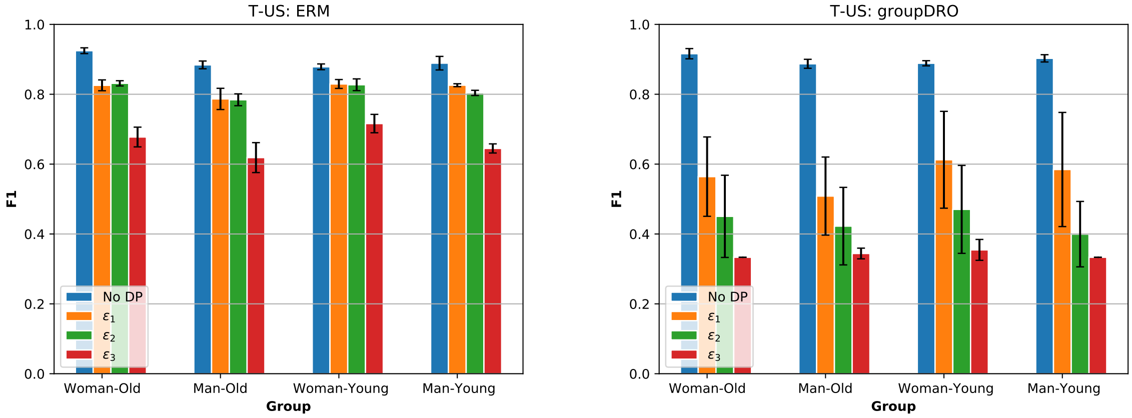

Figure 5: Performance of individual groups of increasing levels of ε for the Trustpilot-US corpus. Error bars show standard deviation over 3 individual seeds.

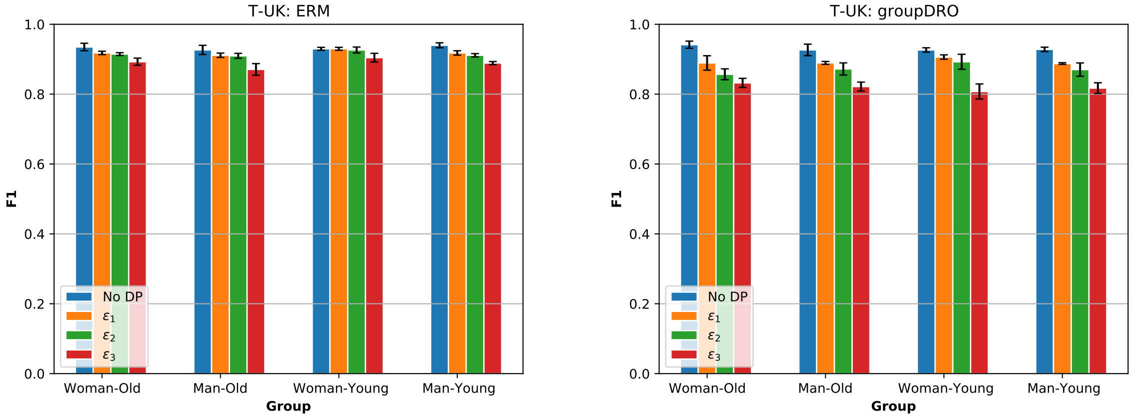

Figure 6: Performance of individual groups of increasing levels of ε for the Trustpilot-UK corpus. Error bars show standard deviation over 3 individual seeds.

a corresponding noise multiplier σ is computed with the Opacus framework, based on the batch size and number of training epochs.

DistilBERT DistilBERT is a small Transformer model trained by distilling BERT (Devlin et al., 2019) (`bert-base-uncased`). It has 3/5th of the parameters of `bert-base-uncased`, runs 60% faster, while preserving over 95% of the performance of `bert-base-uncased`, as measured on the GLUE language understanding benchmark (Wang et al., 2018).

We finetune DistilBERT on the Trustpilot corpus and Blog Authorship corpus for 20 epochs each, using a batch size of 8, accumulating gradient for a total virtual batch size of 16 using the built in Opcaus functionality. We limit the number of tokens in a sequence to 256 and use a learning rate of $5e^{-4}$ with the AdamW optimizer in addition to a weight decay of 0.01. Otherwise we use the default parameters defined in the Huggingface Transformers python package (version 4.4.2). The models are trained using a single Nvidia TitanRTX GPU and each configuration takes between 5 and 14 hours to run, depending on the size of that dataset and if DP is used or not. We run 3 individual seeds for each configuration.

In our differentially private experiments with DistilBERT (i.e. Blog Authorship and Trustpilot), we fix the gradient clipping C to 1.2 and by specifying various target levels of $\varepsilon \in \{1, 5, 10\}$ a corresponding noise multiplier σ is computed with the Opacus framework, based on the batch size and number of training epochs.

Resnet50 ResNet50 is a variant of the ResNet model (He et al., 2015), which has 48 convolution layers along with 1 max pooling and 1 average pooling layer. It has 3.8 x 10^9 floating points operations.

We finetune our Resnet50 model on the CelebA dataset for 20 epochs using a batch size of 64. We optimize the model using standard stochastic gradient descent (SGD) with a learning rate of $1e^{-3}$, momentum of 0.9 and no weight decay. We train our models using a single Nvidia TitanRTX GPU and each configuration takes between 6 and 8 hours to run, depending on if DP is used or not. We run 3 individual seeds for each configuration.

As with the differentially private DistilBERT experiments, we also here fix the gradient clipping C to 1.2 and by specifying various target levels of $\varepsilon \in \{1, 5, 10\}$ a corresponding noise multiplier σ is computed with the Opacus framework, based on the batch size and number of training epochs.

Isometric Neural Machine Translation using Phoneme Count Ratio Reward-based Reinforcement Learning

Abstract

Traditional Automatic Video Dubbing (AVD) pipeline consists of three key modules, namely, Automatic Speech Recognition (ASR), Neural Machine Translation (NMT), and Text-to-Speech (TTS). Within AVD pipelines, isometric-NMT algorithms are employed to regulate the length of the synthesized output text. This is done to guarantee synchronization with respect to the alignment of video and audio subsequent to the dubbing process. Previous approaches have focused on aligning the number of characters and words in the source and target language texts of Machine Translation models. However, our approach aims to align the number of phonemes instead, as they are closely associated with speech duration. In this paper, we present the development of an isometric NMT system using Reinforcement Learning (RL), with a focus on optimizing the alignment of phoneme counts in the source and target language sentence pairs. To evaluate our models, we propose the Phoneme Count Compliance (PCC) score, which is a measure of length compliance. Our approach demonstrates a substantial improvement of approximately **36%** in the PCC score compared to the state-of-the-art models when applied to English-Hindi language pairs. Moreover, we propose a student-teacher architecture within the framework of our RL approach to maintain a trade-off between the phoneme count and translation quality.

1 Introduction

Automatic Video Dubbing (AVD) technologies have become popular in recent times with the advent of Generative AI technologies. AVD technology automatically converts a video from one language to another language in three steps, *(i)* Automatic Speech Recognition (ASR) *(ii)* Neural Machine Translation (NMT), and *(iii)* Text-to-Speech (TTS). This task has become crucial especially in content creation as it helps to break down language barriers and reach a wider audience. A crucial factor underlying the quality and effectiveness of an AVD system is the synchronization of the audio and video post-dubbing. For seamless and consistent synchronization, the duration of the target language speech generated by TTS in the AVD system must match with the duration of the source language speech. If the duration is not matched, various signal processing techniques can be applied to a certain extent to manipulate the duration of the final audio. However, this process introduces artifacts and degrades the quality of TTS output. Hence, a major focus of the research community has shifted towards controlling the length of the text output after NMT, such that there is much less mismatch in duration after dubbing. In this paper, we strive to enhance the performance of the Isometric NMT model, introduced in (Lakew et al., 2022), which is tasked with controlling the length of generated texts.

Traditionally machine translation for AVD has been done as a two-step process (Lakew et al., 2021), where for every input sentence, various output sentences are generated and then re-ranked according to length-matching. (Lakew et al., 2022) marked the advent of self-learning methods for the NMT task for AVD. Further works aimed to produce output texts with the duration compliance directly (Wu et al., 2023). However, these models rely on training a separate duration generation model for the length compliance, which is computationally too expensive. Furthermore, works like (Lakew et al., 2019) use the matching of the number of characters or words between the source and target language sentences. However, in this work, we model this problem as matching the number of *phonemes* between the source and target language sentences because phonemes have a closer association with the speech duration (Quatieri, 2001; Oppenheim et al., 1999). We model this *matching* as a reward indicator which simplifies and speeds

Findings of the Association for Computational Linguistics: NAACL 2024, pages 3966–3976
June 16-21, 2024

up the training process in contrast with some previous works (Wu et al., 2023) where the duration of translated texts was controlled using estimates of phoneme lengths, which is time-consuming (Wu et al., 2023).

In addition, we propose a Reinforcement Learning (RL) based training strategy to achieve the task of isometric NMT in the context of generating translation outputs such that the phoneme counts of the source and target language sentences are as close as possible. We first translate the source language sentences using a pre-trained transformer-based NMT model (generation step), which we treat as an RL agent. Then, we compute the ratio between the phoneme counts of the source and the generated target language sentences. After this, we filter out sentences where the phoneme count ratio (PCR) deviates from a pre-defined threshold determined empirically. We then use the filtered data for finetuning the agent model. We perform multiple iterations of generation using the RL agent and subsequent finetuning using the duration-based positively rewarded dataset.

With each finetuning step, we make the PCR criteria stricter by increasing the threshold value for reward strategies, which positively reflects in the results we obtain (see Sec.4.5), by achieving higher PCC scores. However, this adversely affects the translation quality. To address this issue, we modify the RL-agent (i.e., a fine-tuned (FT) model) with the help of knowledge distillation step via a student-teacher architecture (see Figure 1) (Hinton et al., 2015). We use knowledge-distillation step and Student-teacher interchangeably throughout the paper. Here, the *teacher* is the SOTA NMT model (i.e., the model with the best BLEU score, but, possibly a poor PCC score). This further finetuning step helps the *student* (the current FT-model) to learn to produce good-quality as well as phoneme count compliant output. The effectiveness of our proposed model is demonstrated for the English-Hindi language pair (Hindi is spoken by more than 500 million people). For the training and validation, we used the BPCC corpus (Gala et al., 2023), and for testing, we used i) held-out BPCC Test corpus, ii) Flores, and iii) a movie database (see Section 4.1). We significantly improved the performance of the English-Hindi NMT with respect to various metrics like BLEU, BLEURT, COMET, chrF, and a novel metric, namely, PCC which measures the length compliance between the source and translated sentence.

We summarize our contributions as:

1. To the best of our knowledge this is the first attempt to apply a RL strategy for achieving Isometric NMT.

2. We propose a method to match phoneme *counts* in source and target sentences to control duration using a reward strategy in RL, aiming to enhance synchronization in the AVD task.

3. To address translation quality degradation from constrained duration in source and target language translations, we propose a student-teacher architecture as a post-processing step for the RL-NMT approach.

4. The work centers on AVD for English-to-Hindi languages, an area that has been relatively neglected until now.

5. We benchmark the performance of our proposed approaches against many state-of-the-art models and Large Language Models (LLMs).

The paper is structured as follows. Section 2 discusses related work. Section 3 discusses in detail the methodology. Section 4 presents details of experiments and results. Section 5 concludes the paper and presents limitations of the work.

2 Related Work

Neural Machine Translation models (Bahdanau et al., 2014; Cho et al., 2014; Sutskever et al., 2014) have majorly improved the performance in the machine translation task. Transformer (Vaswani et al., 2017) architecture is widely used in state-of-the-art NMT models. Automatic Video Dubbing pipeline requires the use of NMT models which produce outputs such that the corresponding speech duration of the target language sentence matches the speech duration of the source language sentence. Lakew et al. (2019) formulated this problem as matching the number of characters in the source and target language sentences. They injected the information regarding the number of characters in the positional embeddings with the help of tags appended to the source language sentence. In the work, Lakew et al. (2022) introduced a self-training approach, both offline and online, and implemented the tagging of source sentences with the length ratio between the source and target language sentences, calculated based on the number of characters. Wu et al. (2023) formulated the problem as matching the duration in terms of the number of mel-frames of the source and target language sentences. They incorporated the number of mel-frames in positional embeddings of the transformer architecture.

3 Methodology

In this section, we first discuss the problem setup of formulating the MT task in the RL framework. Next, we propose our RL-based training approach for Isometric NMT for achieving phoneme count compliant translation. Finally, we conclude by proposing the student-teacher architecture by modifying the agent in the RL training to mitigate the problem of quality degradation.

3.1 Problem Setup

The machine translation (MT) task can be cast into a Reinforcement Learning (RL) problem (Gulcehre et al., 2023).[1] We consider the problem of translating an input sentence $\mathbf{x}$ from a source language A to sentence $\mathbf{y}$ in some other target language B. To integrate the MT task into an automatic dubbing pipeline, we strive towards generating the output sentence $\mathbf{y}$ to have (nearly) the same number of phonemes as the input sentence $\mathbf{x}$, which would imply better duration alignment between the input and the output languages.

Let the input and the output (target) sentences consist of n and m tokens (words/sub-words, etc.), respectively. Then, with some abuse of notation, a machine translation system characterized by a policy p, which takes as input a sequence of vectors $\mathbf{x} \equiv (x_1, x_2, \ldots, x_n)$ (where each x_i is an embedding vector according to the input vocabulary) and generates an output sequence of vectors $\mathbf{y} \equiv (y_1, y_2, \ldots, y_m)$ can be expressed as an auto-regressive product of the probability distribution using the Bayes' Theorem as shown in Eq. 1,

$$p(\mathbf{y} \mid \mathbf{x}, w) = \prod_{s=1}^{m} p(y_s \mid y_1, \ldots, y_{s-1}, \mathbf{x}, w), \tag{1}$$

where w are the parameters defining the policy. For the automatic dubbing task, to enforce the importance of the equal time duration of the input and output texts, we define a notion of a reward $r(.,.)$ as a function that takes two arguments, namely, $\hat{\mathbf{y}}$ and $\mathbf{x}$. Here $\hat{\mathbf{y}}$ is the translated sentence for the input sentence $\mathbf{x}$ by the system. Then $r(\hat{\mathbf{y}}, \mathbf{x})$ is chosen as a function of the Phoneme Count Ratio (PCR) score. In particular, for some (small) $\delta > 0$ we set as shown in Eq. 2,

$$r(\hat{\mathbf{y}}, \mathbf{x}) := \mathbb{I}\left\{PCR(\hat{\mathbf{y}}, \mathbf{x}) \in [1-\delta, 1+\delta]\right\}. \tag{2}$$

We aim to optimize the following blend of the two loss (reward) functions (see Eq. 3), which would help achieve good translation quality along with reasonable time-duration compliance between the input and the output texts,

$$\max_{w} -\mathbb{E}_{\mathbf{x}\sim\mathcal{D}}\left[r(\hat{\mathbf{y}}, \mathbf{x})\left(\sum_{s=1}^{M} \log p(\hat{y}_s|\hat{y}_{<s}, \mathbf{x}, w)\right)\right]. \tag{3}$$

3.2 Proposed Reinforcement Learning based Training for Isometric NMT (RL-NMT)

For the task of Isometric NMT, we require that the number of phonemes in the output translation of the model be as close as possible to the number of phonemes in the source sentence. In RL, the model observes the environment and takes some action. Based on this action the reward function gives some reward to the model. Then the model is trained to optimize this reward. In our approach, we use a function of the ratio between the phoneme counts in the source and target sentences as the reward equivalent. The algorithm of our work is depicted in Alg.1.

We first train an existing (pretrained) NMT model on a bilingual corpus to obtain $\mathcal{M}$. Given a source language sentence, $\mathbf{x} = (x_1, x_2, ..., x_n)$ and the target language sentence $\mathbf{y} = (y_1, y_2, ..., y_m)$, the NMT model minimizes the Cross-Entropy Loss which is shown in Eq. 4

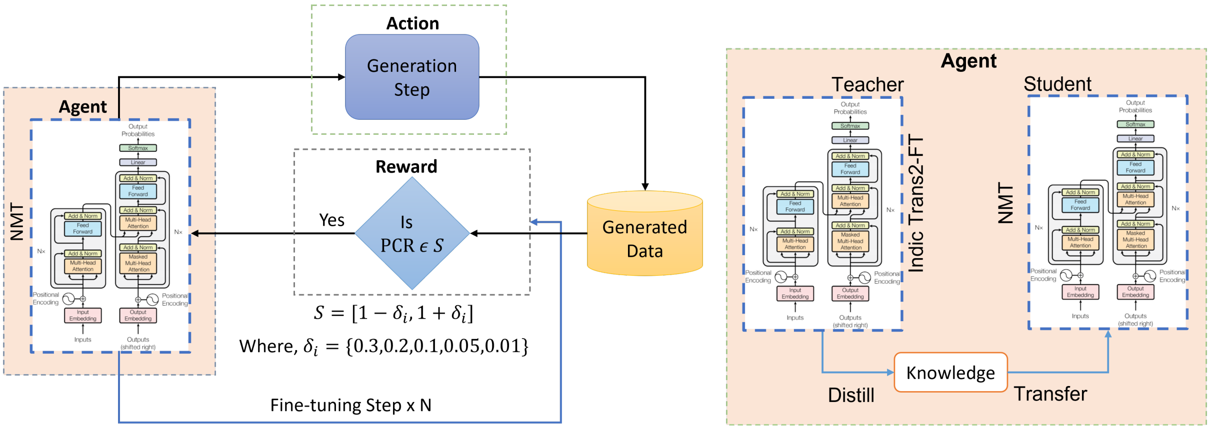
$$\mathcal{L}_{CE} = -\frac{1}{N}\sum_{i=1}^{N}\sum_{k\in V}\{\mathbb{I}(y_i = k) \times \log p(\hat{y}_i = k|y_{<i}, \mathbf{x}; \theta)\} \tag{4}$$

where N is the number of tokens in the output sentence, V is the (output) vocabulary, y_i is the i^{th} word in ground-truth target language sentence and $\hat{y}_i$ is the i^{th} word in the predicted target language sentence.

Next, we translate all the source language sentences (from the entire training corpus on which $\mathcal{M}$ was trained on) using $\mathcal{M}$ and obtain the output translations. This forms the generation step which corresponds to the action step in RL terminology (as shown in Fig. 1). We compute the Phoneme Count

---

[1] We push the detailed Markov Decision Process (MDP) formalism to the appendix, due to space constraints.



(a) Proposed RL-NMT

(b) Modified agent for Proposed ST-RL-NMT

Figure 1: Schema showing (a) block diagram of the proposed RL-NMT architecture (b) modified agent with student-teacher (ST) framework for quality-duration balance.

Ratio (PCR) between the number of phonemes in the source and target sentences. This PCR acts as the reward model. We, then filter out the sentence pairs whose PCR does not lie in the specified range $[1-\delta, 1+\delta]$, where δ is the threshold. We iteratively reduce the threshold and finetune the NMT model ($\mathcal{M}$) on the filtered dataset. After this, we perform the Generation step again, using the model that is produced after the final finetuning step. Iteratively finetuning the NMT model on sentences whose PCR is closer to 1, reinforces the trained model to generate sentences matching the phoneme count of the input. Hence, One RL step consists of one Generation steps followed by multiple finetuning steps.

3.3 Proposed Student Teacher NMT Architecture (ST-RL-NMT)

When we optimize the model to generate outputs where the phoneme counts in the source and target sentences are similar, we face a trade-off in the quality of the translation as shown in Fig. 2. We see in the example that constraining the PCR, can sometimes lead to incomplete translations. In order to overcome this issue of quality degradation, we propose a student-teacher architecture to further finetune the trained model $\mathcal{M}$, in addition to the RL approach. We use the NMT model trained on the entire parallel corpus (without the RL approach) as the *teacher* model. This model produces high-quality output but the phoneme counts between the output and source sentences may not be similar. We use the RL-NMT model as the *student*, which has better phoneme count compliance, but possibly, poor quality. Employing finetuning on the student model with the teacher model provides a balance between translation quality and phoneme count compliance. In the ST-framework, we add consistency loss term while finetuning to make the output probability distribution of the student model closer to the teacher model. We use the KL Divergence (Csiszár and Körner, 2011) between the output probability distributions of the student and teacher model as the consistency loss. This transfers the knowledge of the teacher model to the student model. We expect that, as the teacher model generates *good quality* output, it will improve the *quality* of the student model. Furthermore, finetuning on the phoneme count compliant parallel corpus will keep the phoneme counts of the output translations and source sentences close to each other. The KL Divergence loss term used as the consistency loss term in the training of student-teacher architecture is given in Eq. 5

Input:	Sorry Murph, Go back to bed. **# Phonemes= 12**
RL-NMT:	क्षमा करें, मर्फ बिस्तर पर <Incomplete Translation> **# Phonemes= 18**
ST-RL-NMT:	क्षमा करें, मर्फ बिस्तर पर वापस जाओ **<Correct Translation> # Phonemes= 24**

Figure 2: Example of quality degradation with RL-NMT and improvement achieved with ST-RL-NMT

$$\mathcal{L}_{KL} = \sum_{i=1}^{N} \mathbb{KL}\left(p(*|y_{<i}, \mathbf{x}, \theta^s) || p(*|y_{<i}, \mathbf{x}, \theta^t)\right) \quad (5)$$

where $p(*|y_{<i}, \mathbf{x}, \theta^s)$ represents the probability distribution of student model and $p(*|y_{<i}, \mathbf{x}, \theta^t)$ represents the probability distribution of the teacher model. The overall loss term used in the training of student-teacher architecture is given in Eq. 6

$$\mathcal{L} = \mathcal{L}_{CE} + \alpha \mathcal{L}_{KL} \quad (6)$$

end
Output: Model $\mathcal{M}$
```

where α is a scaling factor for the KL loss ($\mathcal{L}_{KL}$).

3.4 Proposed Phoneme Count Compliance Score

Previous approaches used word or character count compliance scores for evaluation, but we propose a Phoneme Count Compliance (PCC) score in this paper. The PCC score PCC_δ for a particular threshold δ denotes the percentage of sentence pairs whose phoneme count ratio (PCR) lies in the range $[1-\delta, 1+\delta]$. If s denotes the phoneme count in the source sentence and t denotes the phoneme count in the translated sentence then the PCR is given in Eq. 7,

$$PCR = s/t. \tag{7}$$

If N is the number of parallel sentences in the test set then the PCC_δ score is given in Eq. 8

$$PCC_\delta = \left(\sum_{i=1}^{N} \mathbb{I}[PCR(s_i, t_i) \in [1-\delta, 1+\delta]]\right) \times (100/N). \tag{8}$$

We evaluate all the models on the PCC scores for the threshold (δ) values of 0.2 and 0.1.

Our primary reasons for choosing phoneme count rather than syllable count was that in Indian languages like Hindi and Marathi, there isn't a one-to-one correspondence between the letter (akshara) and syllable due to the presence of sandhi and so on. As a result, there exists multiple ways to split a word into syllables (CV, CVC, CCCV, etc.) resulting in variable syllable counts for the same sentence (Raj et al., 2007; Choudhury, 2003). Hence, we believed controlling the length of the output in NMT using syllable count won't be a feasible option despite the fact that syllables have more correlation with the duration. However, we would like to mention that the PCC, although being a crude measure of length duration, is a very fast method to quickly estimate the duration of the output speech. We have taken inspirations from (Räsänen et al., 2021), and (Fujita et al., 2021). Although many other methods which explicitly estimate the time duration are available, they are computationally expensive and time-consuming (Wu et al., 2023). While our approach gives reasonable results although being less *nuanced.*

4 Experiments and Results

4.1 Dataset

Training Data We use the English-Hindi parallel corpus from the Bharat Parallel Corpus Collection (BPCC) (Gala et al., 2023) for training the

NMT model. BPCC is a combination of various publicly available parallel corpora for 22 Indic languages, which contains human-annotated as well as automatically mined data. It contains around 39 million parallel sentences for the English-Hindi language pair, which we used for training the NMT models. We preprocess the data using the Indic NLP Library (Kunchukuttan, 2020)

Evaluation Data We evaluate the model on various standard test sets such as Facebook Low Resource (Flores) (Team et al., 2022), Movie subtitles, and BPCC test set. The Flores test set contains 1012 parallel sentences each for more than 200 languages in multiple domains. We focused on the English-Hindi language pair. The movie subtitles test set contains the subtitles of a Hollywood movie in English and Hindi. The BPCC test contains two parts, the general domain test set and the conversational domain test set. Both the general and conversational domain test sets contain 1023 parallel sentences.

4.2 Evaluation Metrics

BLEU BLEU (Papineni et al., 2002) score is an automatic evaluation metric that scores the translated sentences with respect to the gold translation based on n-gram matchings. We use the Sacrebleu[2] implementation for generating the BLEU scores for evaluating all the models.

chrF chrF (Popović, 2015) is a evaluation metric for machine translation based on character n-gram F1 scores. We use the Sacrebleu[2] implementation for generating the chrF scores for evaluating all the models.

BLEURT BLEURT (Sellam et al., 2020) is a metric that uses a trained BERT model to evaluate the quality of the machine translation output. The model takes the reference and candidate sentence as input and outputs a score ranging from 0 to 1 based on the translation quality.

COMET We also compute the COMET scores (Rei et al., 2020) for the various models since COMET is known to correlate highly with human judgements (Sai B et al., 2023). We use the default model, i.e., wmt22-comet-da for our experiments. This model employs a reference-based regression approach and is built upon the XLM-R architecture. It has been trained on direct assessments from WMT17 to WMT20 and provides scores ranging from 0 to 100%, where 100% signifies a perfect translation (Rei et al., 2020).

4.3 Model Architecture

We use the model architecture of the publicly available IndicTrans2 (Gala et al., 2023) model in all our experiments. The IndicTrans2 model is based on the Transformer architecture and supports 22 Indic languages. We note that we use the default hyperparameters of the IndicTrans2 model in all our experiments. Both student and teacher network has exactly same architecture. We took one as the α in the distillation step in order to give equal weightage to both the student and teacher networks. We train all the models using the Nvidia A100 40GB GPU and training one model takes 30 hours on average. The detailed model parameters are shown in Table 1.

Parameter	Value
# encoder layers	18
# decoder layers	18
# encoder attention heads	16
# decoder attention heads	16
Encoder embedding dimensions	1024
Decoder embedding dimensions	1024
Encoder feedforward layer dimensions	8192
Decoder feedforward layer dimensions	8192
Total number of parameters	1.1 Billion

Table 1: Details of the model architecture.

4.4 Baselines

We compare our approach with various state-of-the-art models given as follows.

IndicTrans2 We compare our approach with the SOTA IndicTrans2 (Gala et al., 2023) model without applying any phoneme count control measures.

IndicTrans2-FT We fine-tune (FT) IndicTrans2 model using only English-Hindi data in order to improve the performance of SOTA model for the selected language pair. This model achieves highest BLEU score, i.e., it performs best w.r.t. quality of translation. Hence, the same model is selected for Teacher in our proposed architecture.

Isometric MT The Isometric MT (Lakew et al., 2022) approach controls the number of words generated in the translation. The source language sentences are tagged with '<short>', '<normal>' or

'<long>' tag depending on the ratio between the word counts in the source and target language sentences. During inference, the input sentences are tagged with the '<normal>' tag to generate length compliant sentences.

No Language Left Behind (NLLB) NLLB (Team et al., 2022) is a state-of-the-art multilingual NMT model that can translate among 200 languages. The NLLB model makes use of a sparse mixture of expert models with shared and specialized capacity to improve the performance of low-resource languages. The NLLB model also makes use of large-scale data augmentation with back-translation. The distilled NLLB model has 1.3 billion parameters in total.

M2M-100 M2M-100 (Fan et al., 2021) is a multilingual NMT model that can translate among 100 languages. The M2M-100 model is trained on a parallel corpus of 2,200 language directions without relying on English-centric datasets. The M2M-100 model gives good performance improvements over bilingual NMT models. The M2M-100 model has 418 million parameters in total.

LLaMA2 & LLaMA2-FT LLaMA-2 (Touvron et al., 2023) is a large language model (LLM) with 7 billion parameters and is trained on 2 trillion tokens. The baseline LLaMA-2 model did not give good performance for the English-Hindi translation task, so we finetuned (FT) the LLaMA-2 model on 1 million randomly sampled sentence pairs from the training set of BPCC corpus.

4.5 Results

Table 2 and Table 3 present results obtained using various SOTA as well as proposed approaches on four test sets, namely, Movie, FLoRes, BPCC General and BPCC Conversational corpora. We see significant improvements in PCC values for both the p=0.2 and p=0.1 cases. Specifically, the proposed RL-NMT technique has attained absolute improvements ranging from 10% to 33% in PCC values across the various evaluation test sets. However, on the contrary, there has been an observed absolute decrease of 2% to 10% in BLEU scores, chrF scores, COMET scores and BLEURT scores, which primarily indicate the quality of translation. Furthermore, based on Table 2 and Table 3, it can be discerned that the proposed ST-RL-NMT framework is instrumental in mitigating the degradation occurring on the translation front. In particular, the proposed ST-RL-NMT framework has successfully reduced the absolute degradation in quality-related metrics from 0.5% to 5% compared to the previous range of 2% to 10% with the RL-NMT approach. This trade-off between the BLEU score and Phoneme Count Compliance Score (PCC) is visually represented in Fig. 4. The results are presented across different baselines including LLMs (Llama2 and Llama2-FT model). It can be clearly seen that the IndicTrans2-FT model achieves the highest BLEU score. Hence, we select IndicTrans2-FT as the teacher in our proposed ST-RL-NMT approach. While the RL-NMT approach attains the best PCC scores, it does come at the expense of a decline in performance on the BLEU score side. On the other hand, the ST-RL-NMT framework is able to simultaneously achieve better trade-offs for PCC and BLEU score compared to other SOTA algorithms.

Fig. 3 presents the detailed analysis of results at each RL step during the training for all four evaluation sets. We can see that with each RL step, the PCC score is increasing significantly. On the other hand, BLEU score, BLEURT score, COMET score and chrF values are decreasing. Nevertheless, at iteration 10, where the Student Teacher framework was introduced, noticeable improvements in the BLEU, BLEURT, COMET and chrF scores can be observed.

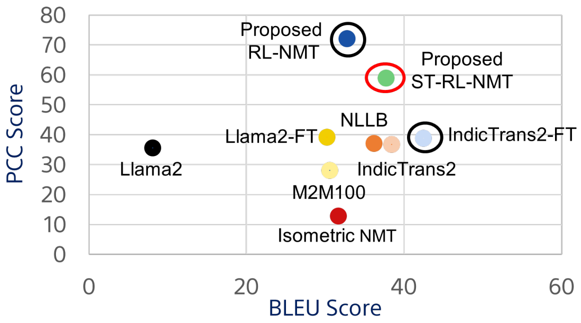

Figure 4: Trade-off between BLEU score *vs.* PCC score

There can be many ways to choose which model to push for the ST post-processing. To ensure a fair comparison, we implemented the ST post-processing at the tenth iteration of the RL algorithm. However, we can plot the max-normalized BLEU scores and PCC scores and select the point where the two plots either intersect or have minimum distance. Subsequently, this model can be considered as the student and we believe that it will have a balanced compromise between the quality and length compliance. Fig. 5 illustrates the qualitative output generated by the baseline IndicTrans2 model and proposed ST-RL-NMT model. It is evident that the original English sentence contains 10 phonemes. Conversely, the baseline model has produced a correct translation with 18 phonemes, as it did not take into account any length-based constraints. In contrast, the proposed ST-RL-NMT model produces the correct output that adheres to the desired length, containing 10 phonemes. This results in (near-) equal duration when synthesized using the target language TTS. Therefore, minimal post-processing is required to adjust the duration in the final dubbed output.

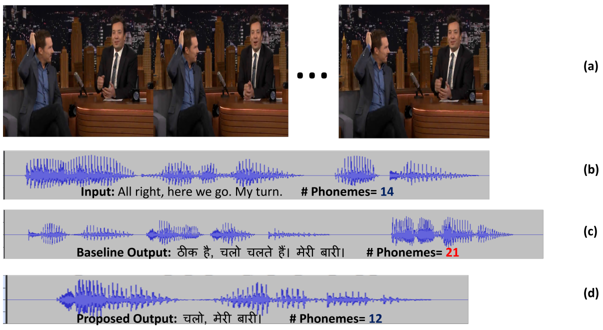

Figure 5: A qualitative example of AVD using baseline and proposed approach.

5 Summary and Conclusion

In this paper, we proposed a reinforcement learning-based training strategy for Isometric NMT. We proposed to match the count of phonemes for this task, as phonemes have a strong correlation with speech duration. Further, we enhanced our agent in the RL-based training strategy with a student-teacher architecture to circumvent the problem of quality degradation that arises from optimizing the model for generating phoneme count compliant sentences. We also proposed the Phoneme Count Compliance score to evaluate the performance of Isometric NMT models. Experimental results showed that our approach gives significant performance improvements in terms of Phoneme Compliance Scores over various state-of-the-art NMT models including LLMs.

Limitations

In the future, on the technical front, we will investigate a *soft*-threshold approach for filtering the data based on PCC and the BLEU score. On the computational front, we note that the generation step in our approach is expensive as we need to translate the entire source side of the parallel corpus. Also, we plan to perform experiments with various language pairs from different language families.

Ethics Statement

The aim of our work is to improve the performance of NMT models for the Isometric NMT task. The datasets that we used in this work are publicly available. Publicly available datasets can contain biased sentences. We train the NMT models on the available parallel corpus, evaluate the models, and have cited the appropriate sources.

A Appendix

A.1 Machine Translation as a Reinforcement Learning Problem

We cast the machine translation task as a Reinforcement Learning problem. Let the input and output language vocabularies, after the suitable embeddings be denoted as $\mathcal{V}_I$ and $\mathcal{V}_O$, respectively. In this terminology any input (output) sentence of length M will be from the finite Cartesian product $\mathcal{V}_I^M (\mathcal{V}_O^M)$. Hence any possible input sentence x will be from the set $\bigcup\limits_{M \geqslant 1} \mathcal{V}_I^M$. The output (generated) sentence y will be similarly from the set $\bigcup\limits_{M \geqslant 1} \mathcal{V}_O^M$. Also, let the distribution of the training inputs be denoted as $\mathcal{D}$. We frame the problem as a Markov Decision Process (MDP) $\mathcal{M}\left(\mathcal{S}, \mathcal{A}, \mathcal{P}, r, \gamma\right)$. The state space $\mathcal{S}$ is the set of all possible such tuple of vectors (x, y). The action set $\mathcal{A} \equiv \mathcal{V}_O$. In this case, the transition kernel dynamics $\mathcal{P} : \mathcal{S} \times \mathcal{A} \to \mathcal{S}$ is defined in the following way. At any time t, we choose $\mathcal{P}\left[(x, y_{1:t-1}, a) | (x, y_{t-1}), a_t\right] = 1$ if $a == a_t$, else it is 0. This makes the transition kernel deterministic. The discount parameter γ is identically set to 0. The reward $r(.,.)$ is a function which takes two arguments, namely, $\hat{y}$ and x, where $\hat{y}$ is the translated sentence for the input sentence x by the system. Then $r(\hat{y}, x)$ is chosen as a function of the Phoneme Count Ratio (PCR) score. In particular, we set,

$$r(\hat{y}, x) := \mathbb{I}\left\{PCR(\hat{y}, x) \in [1-\delta, 1+\delta]\right\}.$$

We impose an even stricter notion of reward for the experiments, in that we only allow sentence pairs $(x, \hat{y})$ which admit a positive reward, to be used in the fine-tuning step, and reject the zero-reward sentence pairs. We note here that the reward, as defined here, is only generated at the end of the translation of the full sentence. This notion of reward function indirectly enforces better quality translations as well as forces the output translations to adhere to strict length constraints which is essential for the automatic dubbing application.

Read between the lines - Functionality Extraction From `READMEs`

Anonymous ACL submission

Abstract

While *text summarization* is a well-known NLP task, in this paper, we introduce a novel and useful variant of it called *functionality extraction from Git* `README` *files*. Though this task is a *text2text* generation at an abstract level, it involves its own peculiarities and challenges making existing *text2text* generation systems not very useful. The motivation behind this task stems from a recent surge in research and development activities around the use of large language models for code-related tasks, such as code refactoring, code summarization, etc. We also release a human-annotated dataset called `FuncRead`, and develop a battery of models for the task. Our exhaustive experimentation shows that small size fine-tuned models beat any baseline models that can be designed using popular black-box or white-box large language models (LLMs) such as ChatGPT (OpenAI, 2023) and Bard (Chowdhery et al., 2022). Our best fine-tuned 7 Billion CodeLlama model exhibit 70% and 20% gain on the F_1 score against ChatGPT and Bard respectively.

1 Introduction

Large Language Models (LLMs) are known to perform really well on many *text2text* (Yang and Flek, 2021) generation tasks such as *summarization* (Liu and Lapata, 2019; El-Kassas et al., 2021)), *translation* (Wang et al., 2019; Maruf et al., 2021), etc. Because of this success, there is a growing research interest in applying LLMs in novel task settings such as *explaining complex codes, generating new recipes, simplifying contents,* etc[1]. In this paper, we introduce another novel task called *functionality extraction from Git* `README` *files* – a variant of *text summarization* task (Prana et al., 2019) that detects all the functionalities supported by the corresponding application software. This task can also be seen as a variation of a Question-Answering (QA) (Fan et al., 2019; Soares and Parreiras, 2020) task where the question like *List all functionalities* is fixed.

The motivation to introduce *automatic functionality extraction from Git* `README` *files* stems from the requirement of application code refactoring to decompose a monolith application into functional microservices. Here each microservice is a collection of closely connected application artifacts (programs, tables etc.) supporting a common functionality (Lewis and Fowler, 2014; Richardson, 2018; Newman, 2021). Current microservice recommendation systems rely a lot on subject matter experts (SMEs) and falls short to correctly group artefacts since they do not have reference list of functionalities. But many application Git `README` files tend to contain capture *different functionalities* [2] *of the underlying software code base*[3] along with other implementation details like *what it does, how others can use it, licensing, etc.,*(Prana et al., 2019; Chen et al., 2021). As an example, the `README` file of the Daytrader application[4] discusses *the application overview, the technology used, licensing terms,* etc., and in between discusses *four functionalities* as highlighted in Figure 1(a).

Recently, (Doan et al., 2023) focused on leveraging LLM to generate sections of README.md like "About" section (brief 1-2 line summary of repo) but they do not aim to list all the functionalities. Extraction of the application functionalities from such `README` files is not straightforward. The functionalities may not be always structured and might spread across multiple paragraphs and lines. Therefore, there is a need for an intelligent system that can parse the text, understand functionality expressions, de-duplicate, and list them. To tackle this first-of-its-kind task, we also introduce and re-

Java EE7: DayTrader7 Sample

Java EE7 DayTrader7 Sample

This sample contains the DayTrader 7 benchmark, which is an application built around the paradigm of an online stock trading system. The application allows users to login, view their portfolio, lookup stock quotes, and buy or sell stock shares. With the aid of a Web-based load driver such as Apache JMeter, the real-world workload provided by DayTrader can be used to measure and compare the performance of Java Platform, Enterprise Edition (Java EE) application servers offered by a variety of vendors. In addition to the full workload, the application also contains a set of primitives used for functional and performance testing of various Java EE components and common design patterns.

List of Capabilities :
- *Authentication <login, user, account ..>*
- *Portfolio Management <portfolio, profile ..>*
- *Stock Quotation <stock, quote ..>*
- *Trade Stocks <trade, order ..>*

CodeLlama Generated features:
- login
- view their portfolio
- lookup stock quotes
- buy or sell shares

(a) Snapshot of Description

(b) Functionalities Identified

Figure 1: Snapshot of Github README content of Daytrader, an online trading application is captured in (a). The human annotated four functionalities based on the description are listed as golden truth along with the functionalities generated by fine-tuned 7 billion CodeLlama model.

lease a new dataset called `FuncRead` that will help the community to benchmark their functionality understanding module and refactor monolith applications into discovered functional microservices. The key contributions of this paper are as follows.

1. We introduce a novel *functionality extraction from Git* `README` *files* task and human-annotated dataset called `FuncRead`. This dataset captures the human-annotated lists of the functionalities in both extractive and abstractive forms for each of 2101 different GitHub `README` files following permissible licenses.
2. We perform a comparative analysis of generative models to reason out the gap in performance between different baselines on the `FuncRead` dataset. To enable comparison, we perform bipartite matching (one-to-one, many-to-one, and weighted many-to-one) to align generated functionalities with the gold functionalities.
3. We present smaller fine-tuned generative models 1&7 billion StarCoderbase, 2.7 billion phi-2, 7 billion Llama-2 & CodeLlama which give superior results compared to ChatGPT and Bard.

2 `FuncRead` Dataset

The `FuncRead` dataset is a first-of-its-kind dataset that consists of functionalities described in the `README` files. These functionalities were hand-curated by human annotators after carefully reading the file. For each `README` file, the functionalities are annotated in two formats - *extractive* and *abstractive*. Extractive functionalities are segments of the text or span from the `README` file; whereas abstractive functionalities are the self-explained versions of the corresponding extractive functionalities, written in the annotator's own words. Each of these format outputs are presented in the form of a list. The dataset consists of unique 2101 human annotated GitHub `README` files.

2.1 Dataset Collection

We used GitHub provided APIs to randomly select a subset of public repositories that comes with a permissible licenses. Further, we manually inspected the `README` files of these repositories and retained only the ones that comprised of at least two functionalities. Note, we do not store the `README` files for the crawled repositories, we only extracted the `README` content and other metadata like license information. We also removed markdown tags and any Personal Identifiable Information (PII) like names, email addresses etc. before further processing. The license distribution for the 2101 `README` files are as follows MIT (*1436), Apache (*334) , BSD (*334), and EPL (*6) licenses. We found that the majority of the repositories consist of 10 or lesser functionalities with an average being 5 functionality per repository. Some repository has as many as 34 different functionalities.

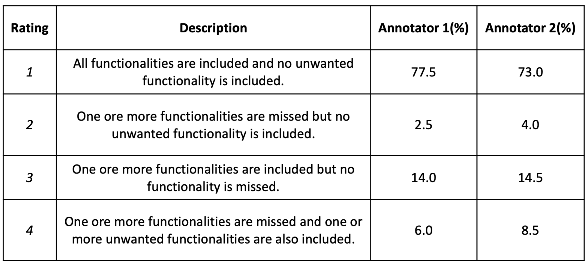
2.2 Dataset Annotation

We had a total of seven annotators involved in the initial data annotation process. Each annotator was asked to read the whole `README` file and perform both the annotations – *extractive* and *abstractive*. For extractive annotation, annotators were asked to select text spans from the `README` file which they felt were describing functionalities, and note them in the form of a numbered list. For abstractive annotation, each annotator was asked to describe the functionalities in their own words. All the annotators were given a disjoint set of `README` files.

2.3 Annotation Validation

We employed two new independent annotators for the purpose of human validation of the dataset obtained from the previous step. We randomly sampled 200 `README` files from each of these two annotators out of which 50 `README` files were common for both the annotators. Both of these annotators were instructed to read extractive as well as abstractive functionalities and check whether all the functionalities were included. Based on their observation, they were tasked to give a rating from 1 to 4 based on the degree of strictly necessary functionalities annotated. These ratings were used to calculate the inter-annotator agreement. We observed a Kappa score of 0.873. Figure 2 describes the ratings and the rating score distribution for both.

More details on the dataset characteristics and annotation procedure can be found in appendix.



Rating	Description	Annotator 1(%)	Annotator 2(%)
1	All functionalities are included and no unwanted functionality is included.	77.5	73.0
2	One ore more functionalities are missed but no unwanted functionality is included.	2.5	4.0
3	One ore more functionalities are included but no functionality is missed.	14.0	14.5
4	One ore more functionalities are missed and one or more unwanted functionalities are also included.	6.0	8.5

Figure 2: Ratings distribution of the two annotators during the verification step of the FuncRead dataset.

3 Task Modelling

For modeling purposes, one can view the *functionality extraction* as a generation task. In the generation mode, the goal is to generate a list of functionalities from a given `README` file. As ours is the first-of-its-kind dataset, we used ChatGPT and Bard models known to perform really well on most NLP and code tasks even in zero-shot setting as a baseline for our task. Among many prompts, the following prompt "*List all the features from above text. Each features should be in individual line without headings. Each features should be in individual line without headings. Do not include features related to license*" provided the best results. The actual list of prompts tried on ChatGPT and Bard can be found in section 6.5.

We wanted to study if task specific small sized models can provide competitive results. For this we considered mix of NL and code model variants like 1b and 7b StarCoderbase, 2.7b phi-2 and 7b llama-2 and CodeLlama. For fine-tuning, we pre-processed the `README` data through the steps listed in section 2.1. Next, we append it with "*\n##FEATURES##\n*" as the task designator prompt followed by the human annotated list of functionalities corresponding to that `README` file. For inference, we simply appended the task designator prompt to the `README` text and then allowed the model to complete sequence to generate list of functionalities.

4 Experiments and Results

For our experiments, we divided the `FuncRead` dataset into train, validation, and test sets comprising 1801, 100, and 200 samples respectively.

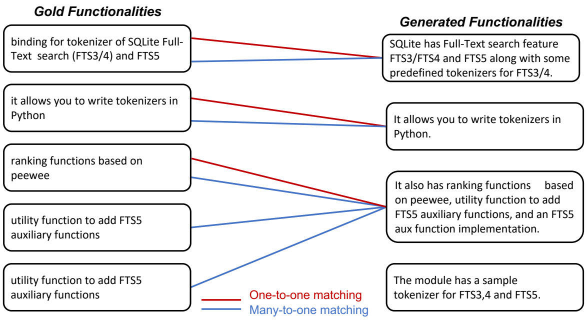


Figure 3: One-to-One bipartite matching (red color) and Many-to-one bipartite matching (blue color). Edges are established based on cosine similarity

4.1 Evaluation Metrics

To evaluate the quality of the generated functionalities, we align them to the gold annotated functionalities via bipartite matching. We perform three kinds of bipartite matching: i) one-to-one, ii) one-to-many, and iii) weighted one-to-many.

In any of these bipartite graphs, we have model-generated functionalities as nodes on one side and gold (ground truth) functionalities as nodes on the other side. The presence or absence of an edge in this bipartite graph is decided by the similarity scores between the corresponding sentences. In our experiments, we found threshold 0.3 similarity matches the most with the human judgment. We did maximum bipartite matching to compute Precision (P), Recall (R), and F_1 scores based on matched pairs to measure the generation capability.

For fine-tuning the models, we used extractive functionalities as gold, and because of it, we employed ROUGE-1, ROUGE-2, ROUGE-L scores to check the lexical matching quality of generated functionalities at an individual level. Since all the considered models are generative models, there is a high chance that it would introduce new tokens while generating functionalities. Hence, we also

Model	$F_1^{\#}$	$\mathbf{P}^{\#}$	$\mathbf{R}^{\#}$	F_1^{*}	$\mathbf{P}^{*}$	$\mathbf{R}^{*}$	F_1^{+}	$\mathbf{P}^{+}$

Llama2-7b	0.936	0.935	0.939
CodeLlama-7b	**0.946**	**0.946**	0.947

Table 3: Results for one-to-one matched pairs for threshold = 0.3.

used BERTScore (Zhang et al., 2019) to capture the semantic similarity between the matched pairs.

4.2 Results

Overall, we find fine-tuned models specifically code models are reliable for this novel task. From table 1, we can observe fine-tuned models have a tendency to combine multiple functionalities into a single sentence but F_1, P, and R scores of many-to-one bipartite matching indicates that it still does less frequently. But all the fine-tuned models significantly outperform ChatGPT, Bard on P and F_1 measures. Due to inherent verbosity, R is higher for the latter models. Table 2 ROUGE scores demonstrates that the functionalities generated by the fine-tuned models have a relatively higher token similarity when matched one-to-one (it is consistent for the other two schemes as can be seen in appendix). Table 3 BERTScores are also consistent with the claims showing better semantic similarity for the fine-tuned models. We suspect code models tendency to outperform NL models can be due to their stronger exposure to Git data. In few instances the models did not list any functionalities which can be attributed to complexity and lack in standardization of GitHub `README` files. Please refer to appendix for in-depth comparisons and discussions.

5 Conclusion

We introduced a novel task *functionality extraction from Git* `README` *files* and studied on a new dataset curated from public repositories to demonstrate reliability of small sized fine-tuned LLMs.

6 Appendix

We organize the appendix to cover the following :

- Limitations - Discuss four key limitations with this work that we plan to address in our future studies.
- Dataset - Discuss the crawled github data characteristics in detail
- Annotator Profile - Discuss the demography and key details of annotators who helped prepare the study dataset
- Annotator Instruction - Discuss in detail the instructions and guidance provided to annotators
- Annotation Validation - Discuss in detail the steps taken to review annotations
- Task Modelling using Baseline Models - List all the prompts tried to get the most accurate functionalities
- Model Hyperparameters - Key hyper-parameters used to reproduce results
- Quantitative Results - Discuss results in detail for the different settings and thresholds

6.1 Limitations

There are four major limitations in this work that could be addressed in future research. First, the study focused on 2101 samples, there could be more unknown ways of describing functionalities that the current models may not be able to handle. This can be addressed by increasing the dataset size. Second, as shown in Figure 2, we found human errors during the annotation process where, for a few samples, unwanted functionalities were added and some wanted functionalities were missed. But this can be handled by expanding the validation efforts to the rest of the samples. Third, handling very long `README` files is a challenge as we have a maximum of 2048 token limit for models. There is promising research in this direction to support longer token limit. Fourth, defining the reference set of functionalities is sometimes an ill-posed problem because different humans may perceive the `README` differently and they may conceive the set of functionalities differently. But we hope to educate annotators by discussing more number of ground truth samples.

6.2 Dataset

Table 4 shows the license distribution for the 2101. Figure 4 represents the functionalities count distribution for the repositories. `README` files. We plan to release this dataset post review period.

License	Count	Count Percentage(%)
MIT	1436	68.34
Apache	334	15.90
BSD	325	15.47
EPL	6	0.29

Table 4: License-wise split of `FuncRead` dataset.

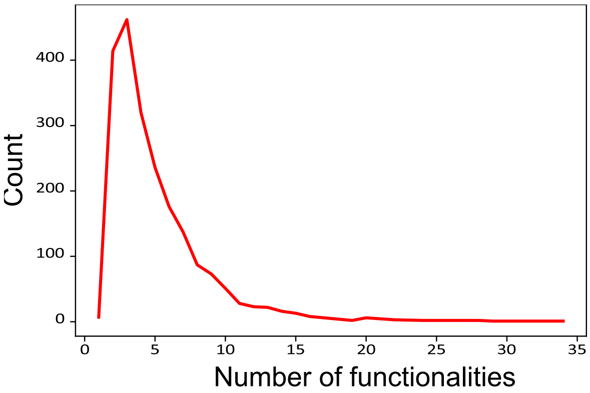

Figure 4: Functionalities count distribution of the `FuncRead` dataset.

6.3 Annotators Profile

To prepare the dataset, we requested participation from nine software engineers based out of Asia. The participants were identified based on their prior experience working on application modernization projects listed on their profile page. On an average, the participants had industrial experience of 13 years in different software engineering roles. We requested seven participants to annotate the 2101 different GitHub `README` files. Once extractive and abstractive functionalities were annotated, we employed 2 new participants to perform the verification step. We individually discussed the task details, expectations, the tentative average time that might be needed (5 minutes per annotation), and the research goal and got their consensus before providing them with the annotation instruction.

6.4 Annotation Instructions

Following were the instructions given to the seven annotators :

- *We thank you for agreeing to annotate. An excel sheet will be given with the following information*
    - *Repository id*
    - *Readme URL*
    - *Extractive functionalities*

    - *Abstractive functionalities*
- *First row will be filled for convenience.*
- *For each repository id two types of annotations are requested to be done*
    - *Extractive: Copy and paste the functionalities as numbered lists.*
    - *Abstractive: Write the functionality in your own words.*
        - ∗ ***NOTE:*** *Please do not copy-paste for this. Please try to be as descriptive as possible i.e., introduce new words to describe instead of reusing the same set of words.*
- *Please write/copy-paste each functionality in the new line as a numbered list.*
- *Please make sure that number of abstractive and extractive functionalities are the same.*
- *Few things to take care*
    - *Do not include future/expected functionalities/roadmap/TODO/planned*
    - *Please do not click on any link to find more functionalities. Whatever functionalities are present in the* `README`*, please include those only.*
    - *Do not include application – meaning what is possible with that functionality or repository.*
    - *In Progress/partial functionalities can be included.*

All the annotators were given the same set of instructions so as to maintain consistency. Annotators' doubts were clarified on regular basis. The generated dataset was reviewed by the authors internal review board and was deemed suitable to be published for research.

6.4.1 Annotator Validation Example

Let us understand above ratings via an example. For the `README` given in Figure 1, suppose following extractive functionalities were annotated by an annotator:

- *allow users to login*
- *lookup stock quotes*
- *buy or sell stock shares*
- *provides a real-world java EE workload*

It is now clear that the annotator in this specific case has missed one of the functionality, namely "*view their portfolio*" and added an extra functionality namely "*provides a real-world java EE workload*". Therefore, a rating of 4 would be assigned during the human validation step.

6.5 Task Modelling using ChatGPT, Bard

To understand what prompts helps best to list the functionalities, we tried various prompt on ChatGPT and Bard baseline models. Some of them are as follows:

- *List all the features for the above text.*
- *List all the functionalities for the above text.*
- *List all the features from above text. Each features should be in individual line without headings.*
- *List all the features from above text. Each features should be in individual line without headings. Each features should be in individual line without headings.*
- *List all the features from above text. Each features should be in individual line without headings. Each features should be in individual line without headings. Do not include features related to license*

6.6 Evaluation Metrics

To evaluate the quality of the generated functionalities, we align them to the gold annotated functionalities via bipartite matching. We perform three kinds of bipartite matching: i) one-to-one, ii) one-to-many, and iii) weighted one-to-many.

In any of these bipartite graphs, we have model-generated functionalities as nodes on one side and gold (ground truth) functionalities as nodes on the other side. The presence or absence of an edge in this bipartite graph is decided by the similarity scores between the corresponding sentences. Figure 3 captures an illustration. For computing the similarity score, we used SentenceTransformer[5] and generated the sentence embeddings for both model-generated and gold functionalities sentences. Next, we computed a cosine similarity between these two vectors, and experimented with multiple thresholds to decide whether the edge should be present in the bipartite graph. In our experiments we found threshold 0.3 matches the most with the human judgment. A lower threshold was giving poor-quality mapping with excessively matched

---

[5] `https://www.sbert.net/`

pairs. A higher value was giving high-quality mapping but the number of matched pairs was very less. We used the maximum_bipartite_matching[6] function from SciPy library to perform the maximum (weighted or unweighted) bipartite matching. Based on the matched pairs, we compute Precision (P), Recall (R), and F_1 scores to measure the generation capability.

For fine-tuning the models, we used extractive functionalities as gold, and because of it, we employed ROUGE-1, ROUGE-2, ROUGE-L scores to check the lexical matching quality of generated functionalities at an individual level. Since all the considered models are generative models, there is a high chance that it would introduce new tokens while generating functionalities. Hence, we also used BERTScore (Zhang et al., 2019) to capture the semantic similarity between the matched pairs.

After analyzing the generated functionalities, we realized that the model sometimes combines multiple functionalities into a single generated sentence (see Figure 3). Therefore, there is a need for many-to-one bipartite matching where multiple gold functionalities are allowed to map into a single generated functionality. There are two kinds of results we show in many-to-one bipartite matching. The first one is *many-to-one* P, R, and F_1 scores, where all the edges in the bipartite matching are given a score of 1. The second is *weighted many-to-one* P, R, and F_1 scores, where for each of the model-generated functionality that is matched with multiple gold functionalities, each matched edge is assigned a weight that is inversely proportional to the number of functionalities matched. We take the reciprocal of the number of matched edges and assign that as a weight to all the incoming edges for that particular model-generated functionality. For example, consider the third functionality sentence generated by the model in Figure 3, which reads *"It also has ranking functions based on peewee, utility function to add FTS5 auxiliary functions and an FTS5 aux function implementation."* Now, each matched edge incident on this node gets a weight of $1/3$ for weighted many-to-one bipartite matching.

6.7 Model Hyperparameters

Table 17 shows the important hyperparamters that can be used to reproduce results. Rest of the hyperparamters are the default ones present in Huggingface Trainer API.

6.8 Quantitative Results

All experiments were performed on an $A100$ $80GB$ GPU machine.

We report results on the discussed metrics for all the fine-tuned models and compare them against the ChatGPT and Bard. Table 1 shows the P, R, and F_1 scores for the three bipartite matching schemes. We do not report R for weighted many-to-one bipartite matching as it is the same as R for many-to-one bipartite matching. Results in tables 1, 2, and 3, are restricted over that subset of test samples for which each of these models outputs a nonempty string and also yields at least one matched pair during the bipartite matching procedure. The total comparable test samples thus came down to 69.

From table 1, we can observe that all the fine-tuned models significantly outperform ChatGPT and Bard across P, R, and F_1 measures. We can see that the F_1 score of one-to-one bipartite matching for ChatGPT is 0.459 and for Bard is 0.653 which are much smaller as compared to code models. Table 2 further shows the ROUGE scores for one-to-one matched pairs. Again we see that the functionalities generated by the fine-tuned models have a relatively higher lexical similarity. Table 3 shows BERTScore which is again higher than ChatGPT and Bard. Tables 5 and 6 shows many-to-one results for threshold = 0.3. The rest of the tables show results for other threshold values 0.4 and 0.5 and matching schemes. Count of common test samples across various models which have non-empty generations and have at least one matched pair are 85 and 98 for threshold values 0.4 and 0.5 respectively. An increase in ROUGE and BERTScore gives the illusion that a higher threshold value should be preferred but as mentioned earlier the number of functionalities generated/classified decreases too which is not much helpful as we lose out on many functionalities. We recorded the responses from ChatGPT and Bard on November 25, 2023 for our experiments.

For the different task types and for threshold 0.4, please refer tables 7-11. For threshold 0.5, please refer tables 12-16.
