To study our proposed task setting, **we curate a human annotation benchmark that evaluates the performance of several representative LLMs on ins-controllable summarization** (§2). Specifically, we construct task samples by manually selecting articles from the XL-Sum dataset (Hasan et al., 2021) and writing the summary requirements ourselves, aiming to reflect the actual information needs of the users during reading. Then, we collect human annotations of representative LLMs on this task along 4 quality dimensions: (1) overall quality, (2) missing information, (3) irrelevant information, and (4) factual consistency. The evaluation results present a comprehensive view of the current LLMs performance on the ins-controllable summarization task, demonstrating large performance gaps among LLMs with different capacities. Furthermore, we found that even the strongest LLM that we evaluated, i.e., GPT-4, still makes factual and other types of errors, indicating room for future improvement.

During the human annotation collection, we found that as the complexity of the summarization task rises, evaluating the summaries becomes increasingly difficult. Therefore, **we investigate the performance of a variety of LLM-based automatic evaluation methods on our proposed task** (§3). To this end, we compare 40 evaluation methods, each a combination of an evaluation protocol, such as point-wise scoring (e.g., G-Eval (Liu et al., 2023a)), and an LLM as the backbone model. Using the collected human annotations to evaluate these methods, we observe significant performance gaps among different evaluation protocols and different LLMs. Moreover, we found that while several methods we investigate, such as the GPT-4 powered ones, already achieve a strong performance at comparing summarization systems, none of them are well-aligned with the human evaluation when comparing individual summaries.

Having identified the most reliable automatic evaluation methods, e.g., pairwise comparison powered by GPT-4, **we investigate whether these evaluation methods can reliably automate the benchmarking of ins-controllable summarization** (§4). Specifically, we evaluated 11 different LLMs along the quality dimensions we defined. We found that the current LLM-based evaluation methods fail to provide convincing results since they can be biased by confounding factors such as summary lengths.

Our contributions are as follows:

(1) We curated a manually annotated evaluation dataset for ins-controllable text summarization to facilitate the evaluation of LLM-based summarization and summarization evaluation.

(2) We collected a human evaluation benchmark, INSTRUSUM, consisting of multi-dimensional quality annotations of summaries generated by different LLMs on the ins-controllable summarization task, and made INSTRUSUM publicly available.[2]

(3) We benchmarked a series of LLM-based automatic evaluation methods that couple different evaluation protocols with various LLMs using our collected human annotations, and highlighted their limitations in automatic benchmarking for ins-controllable summarization.

2 Human Annotation Collection

We curate a human evaluation benchmark for ins-controllable summarization with two steps: (1) dataset creation and (2) system output evaluation.

2.1 Dataset Creation

Ins-controllable summarization can be defined as

$$S \leftarrow f(D, I), \tag{1}$$

where D is the input document, I is a specific summary requirement, S is the desired summary, and f is a summarization system. To ensure the quality of our following evaluation, we (the authors) manually construct an evaluation-only dataset with the proposed task format. The articles chosen are from the English split of XL-Sum (Hasan et al., 2021) dataset, containing news articles from

---

[1] For brevity, we will use the term "ins-controllable" to refer to "instruction controllable" throughout this paper.

[2] INSTRUSUM is available at `https://github.com/yale-nlp/InstruSum`.

Summarize the main factors that led to the conflict between the Ethiopian government and forces in the Tigray region.
Summarize the notable figures from the Prohibition era mentioned in this article.
Summarize the history of the Cononish gold mine in bullet points.
Summarize the views of Democrats and Republicans on trusting information coming from the WHO.
Summarize the experiences of Chum Mey in the 1970s with a timeline.
Summarize the similarities of the definitions of collusion provided by different people in this article.
Summarize the concerns and opposition from the public about the new PNR directive into bullet points for the views of each group.
Summarize the possible explanations for why there hasn't been any firm evidence of aliens' existence, under the assumption that they do exist.
Summarize the people quoted in the article and their identity.
Summarize the efforts of the Brazilian Tourist Board to attract more tourists in three sentences.

Table 1: INSTRUSUM summary requirement examples.

the BBC website. We chose XL-Sum because (1) XL-Sum was already made public by Hasan et al. (2021), which makes it easier for us to release our benchmark; (2) XL-Sum is newer and less commonly studied than other datasets such as CNN/DailyMail (Nallapati et al., 2016), which reduces the concern of data contamination. We collected 100 article-requirement pairs in total with the following steps:

(1) **Searching for challenging articles**. Since not all XL-Sum articles are complicated enough to require specialized summaries, we first select articles with abundant and complex information, of which the requirement-specific summaries can be very beneficial to the readers. Besides, only articles with around 1000-1200 words are selected to ensure they are sufficiently long but not too difficult for human evaluation.

(2) **Writing summary requirements**. After selecting an article, we write one or more summary requirements with different focuses, simulating the real reading experience, where readers may have different informational needs throughout the reading process, as well as structural or formatting preferences. We also used GPT-4 to generate candidate requirements in order to increase the requirement diversity.[3] However, they were not frequently used and were edited by us to ensure their naturalness and correctness. In Table 1, we show a list of summary requirements.

Article	Requirement	Initial Summ.	Hybrid Summ.
1193.4	15.4	115.1	107.7

Table 2: Dataset statistics of INSTRUSUM. The average length (tokens) of the article, the summary requirement, the initial LLM summary, and the hybrid LLM-human summary are reported.

(3) **Obtaining hybrid LLM-human summary**. With the article-requirement pair, we prompt the LLMs to generate a summary using a zero-shot prompt.[4] We then make minimal necessary edits to the LLM summary to obtain a hybrid LLM-human summary. To analyze the effect of the choice of LLM on the human-edited summary, we interchangeably used three OpenAI LLMs to generate the initial summary: `text-davinci-003`, `gpt-3.5-turbo-0301`, and `gpt-4-0314`.[5]

The basic dataset statistics are in Table 2.

2.2 System Output Evaluation

We benchmark the LLMs' performance on the ins-controllable summarization task by collecting human judgments over 4 quality dimensions on the 100 samples from above, resulting in a new benchmark, INSTRUSUM, consisting of 500 summary-level human annotations. The dimensions are:

(1) **Overall Quality**: This rating assesses the overall quality of the summary in relation to the summary requirement.

(2) **Missing Information**: Does the summary omit any crucial information from the article concerning the summary requirement?

(3) **Irrelevant Information**: Does the summary include any information that is not relevant to the summary requirement?

(4) **Factual Consistency**: Is the summary consistent with the facts presented in the article, without contradicting or misrepresenting any information?

We annotate each quality dimension using a ranking protocol, ranking summaries from 1 (best) to 5 (worst). For factual consistency, we ask the annotators to select the span(s) containing a factual inconsistency, and for overall preference, we ask the annotators to explain the reasoning behind their overall rankings. Screenshots of our annotation

---

Mode	Overall	Missing	Irrelevant	Factual
listwise	0.2571	0.2247	0.1925	0.0196
pairwise	0.4428	0.3657	0.2588	0.0721

Table 3: Inter-annotator agreements (Krippendorff's alpha) for INSTRUSUM across various quality dimensions at both *listwise* ranking and *pairwise* comparison levels.

protocol can be found in Appendix B.

We select the following four LLMs for annotation: `text-davinci-002`, `text-davinci-003`, `gpt-3.5-turbo-0301`, `gpt-4-0314`, in addition to the hybrid LLM-human summary. These models are chosen to help study recent LLM development over multiple sizes and training paradigms.[6] For each summary, we collect three annotations.

For this annotation, we recruit annotators on Amazon Mechanical Turk[7] (MTurk). The annotators must pass two rounds of qualification tests. Moreover, to ensure the annotation quality, we maintained ongoing conversations with the annotators to exchange feedback and address their questions. Additionally, we conducted spot checks on each batch of annotations to maintain quality and provide feedback to the crowd annotators.

The inter-annotator agreements are presented in Table 3 for both the original ranking annotation task and the converted pairwise comparison results with the MASI distance (Passonneau, 2006) following Goyal et al. (2022) to enhance comparability. We are able to achieve moderately high agreements on most dimensions, including the overall quality evaluation, which has been shown to be difficult to annotate with high agreements in prior work (Zhang et al., 2024). Regarding factual consistency, we note that low agreement may stem from the sparsity of errors in the dataset. We (the authors) manually verified whether the annotated spans contained factual errors. Our annotation revealed that the errors made often proved to be subtle errors or nuanced different understandings of the article, and we found the accuracy of the crowd annotations to be 88.4%. Factual error examples are provided in Appendix E.

We note the difficulty of our annotation task. Specifically, (1) Earlier iterations of our annotation interface used a Likert scale, but we found that this resulted in a low inter-annotator agreement; (2) Only around 5% of the crowd-workers that participated in the qualification tests achieved acceptable performance to be recruited for our task, although all of them have at least a 99% acceptance rate on MTurk; (3) The average time to complete one annotation task is around 30 minutes. Furthermore, we increased the payment level to enhance annotator retention, as the high cognitive demands of our task tend to discourage annotators from completing more tasks. As a result, we found it challenging to expand the annotation sample size because of both budget constraints and the intensive labor required.

System	Overall	Missing	Irrelevant	Factual
text-davinci-002	2.344	2.595	3.443	0.640
text-davinci-003	3.239	3.703	3.708	0.710
gpt-3.5-turbo-0301	2.897	3.473	2.958	0.800
gpt-4-0314	**3.970**	**4.067**	4.205	**0.860**
hybrid	3.873	3.947	**4.359**	**0.860**

Table 4: INSTRUSUM: human evaluation results of LLM-generated ins-controllable summaries on 4 quality dimensions. The scores for *overall* quality, *missing* information, and *irrelevant* information dimensions range from 1 to 5. The *factual* score is the ratio of factually consistent summaries. *Hybrid* is the hybrid LLM-human summary.

2.3 Are LLMs Good at Ins-Controllable Summarization?

Results from our human evaluation are found in Table 4. For the *overall quality*, *irrelevant information*, *missing information* dimensions, we convert the human-annotated rankings we obtained in §2.2 into system scores as follows on each data example:

$$s_i = N - \sum_{j=1}^{N} \mathbb{1}_{\{r<r_i\}}(r_j), \tag{2}$$

where s_i is the converted score of the summary of the i-th system, r_i, r_j are the summary rankings and a smaller ranking represents higher quality, $\mathbb{1}$ is the indicator function, and N is the number of ranked summaries. Using this scoring schema, a perfect system would achieve a full score of N (i.e., 5 in our case). For factual consistency, since we found a low agreement in the crowd annotations, we report the ratio of factual summaries according to the human annotations verified by the authors. We note the following findings from Table 4:

(1) **There is a large performance gap among the different LLMs**. Specifically, GPT-4 is significantly better than the GPT-3.5 models,[8] and the supervisedly fine-tuned `text-davinci-002` archives

---

[6] Model details are in Appendix C.

[7] `https://www.mturk.com/`

[8] The p-value is less than 0.01 for all the comparisons, except for `gpt-4-0314` v.s. `gpt-3.5-turbo-0301` on the factual consistency dimension, of which the p-value is 0.058.

Dimension1	Dimension2	Agreement
Overall	Irrelevant	0.412
Overall	Missing	**0.611**
Irrelevant	Missing	0.209

Table 5: The inter-dimension agreements of human annotations on INSTRUSUM. *Overall quality* and *missing information* dimensions have the highest agreements.

worse performance than the LLMs fine-tuned with reinforcement learning from human feedback.[9] In contrast, recent work (Pu et al., 2023) found that the performance of GPT-3.5 and GPT-4 are very similar on the generic news summarization task. This suggests that the ins-controllable summarization task we proposed can be a more suitable benchmarking task for the LLMs.

(2) **All LLMs we evaluated still make a considerable amount of factual errors in their summaries**. For example, the error rates of `text-davinci-002` and `gpt-4-0314` are 36% and 14%, respectively. This is also different from the patterns on the generic news summarization task, on which the factual error rate is only 1-2% for `text-davinci-002` (Zhang et al., 2024).

(3) **The hybrid LLM-human summary can only outperform GPT-4 on the irrelevant information dimension**, suggesting that GPT-4 is close to the human-level performance, especially when the human annotator is asked to only edit the LLM summary. It also indicates that generating summaries without irrelevant information is the most challenging dimension for current LLMs. Interestingly, the following section (§3.3) will show that irrelevant information is also the most challenging dimension for the LLM-based automatic evaluation methods. We provide a fine-grained comparison of the initial LLM and hybrid summaries in Appendix D.[10]

Inter-Dimension Analysis To explore the relationship between human evaluation results across different quality dimensions, we examine the (listwise ranking) agreements between the summary scores for these dimensions in Table 5. The results show that the *missing information* dimension has a higher influence on the *overall quality* dimension than the *irrelevant information* dimension, suggesting that human annotators favor comprehensive over concise summaries, similar to recent work's findings on length bias (Liu et al., 2023b; Singhal et al., 2023; Zheng et al., 2023; Huang et al., 2023; Saito et al., 2023) in human evaluation.

3 Are LLMs Good at Ins-Controllable Summary Evaluation?

Human evaluation of our proposed ins-controllable summarization is complex and time-intensive, requiring scalable, reliable automatic evaluation methods. Consequently, we benchmark recent LLM-based evaluation methods, exploring various evaluation protocols and LLM backbones.

3.1 LLM-based Evaluation Protocols

LLM-based automatic evaluation methods can be categorized along two orthogonal dimensions – the ***evaluation protocols*** and the backbone LLMs. We investigate the following evaluation protocols:

(1) **LLMScore**: direct scoring using predicted probability. GPTScore (Fu et al., 2023) proposes a protocol that interprets the LLM-predicted probability of certain token(s) as a quality score.

(2) **LLMEval**: direct scoring by text completion. In Chiang and Lee (2023) and G-Eval (Liu et al., 2023a), the LLM is asked to assign a quality score.

(3) **LLMCompare**: pairwise comparison between two candidate outputs by text completion (Zheng et al., 2023; Wang et al., 2024).

(4) **LLMRank**: listwise ranking by text completion, simultaneously evaluating a list of candidate outputs (Sun et al., 2023; Liu et al., 2024).

Prompt Design. For each of the evaluation protocols, we design *dimension-specific* prompts for the evaluation quality dimensions we defined in §2.2. The prompt templates are in Appendix A.2.

3.2 Evaluation Settings

We benchmark 11 LLMs in total on ins-controllable summarization evaluation over three quality dimensions, *overall quality*, *missing information*, and *irrelevant information*. We did not benchmark factual consistency evaluation since it is a more unique dimension, which we leave for more dedicated future work. For proprietary LLMs, we use different versions of GPT-3.5 and GPT-4 models provided by OpanAI.[11] For open-source LLMs, we benchmark LLama-2-chat (Touvron et al., 2023) 7B, 13B, and 70B models, and the Mistral-Instruct (Jiang et al., 2023) 7B model.[12] The full model list is in Table 6.

---

[9] Model details are in Appendix C.

[10] We interchangeably used GPT-4 and GPT-3.5 models to generate the initial LLM summary so Table 4 does not provide a direct comparison between the initial and hybrid summaries.

[11] `https://platform.openai.com/docs/models`

[12] Llama-2 models were released in July 2023, and Mistral 7B was released in September 2023.

Table 6: Kendall rank correlations at both the system and summary levels between human evaluation and LLM-based evaluation over three quality dimensions on INSTRUSUM. The LLM-based evaluation performance of different combinations of backbone LLMs (e.g., `gpt-4-0314`) and evaluation protocols (e.g., LLMRank) is reported. The best performance on each quality dimension at the system level or the summary level is highlighted.

To compare LLM evaluation against human evaluation, we calculate the correlations between their evaluation scores at both system and summary levels. The *system-level* correlations measure how good the LLMs are at comparing summarization system performance, while the *summary-level* correlations measure how good the LLMs are at comparing summary quality on individual data samples. Since we adopted a ranking-based evaluation protocol for our human evaluation collection (§2.2), we use the Kendall rank correlation coefficient as the correlation measurement, and we transform the evaluation results of different evaluation protocols into rankings. More evaluation setting details including the formal definitions of the correlation measurement are in Appendix F.

3.3 Result Analysis

The evaluation results are reported in Table 6. For each of the backbone LLMs we chose to benchmark (§3.2), we evaluate its performance with different evaluation protocols when applicable[13] so in total we evaluate 40 LLM-based evaluation methods. We make the following observations:

(1) **Different LLMs have significantly different performance at evaluating ins-controllable sum-**

---

[13] We could not use a few OpenAI models with LLMScore since the log-likelihood is not provided by the APIs.

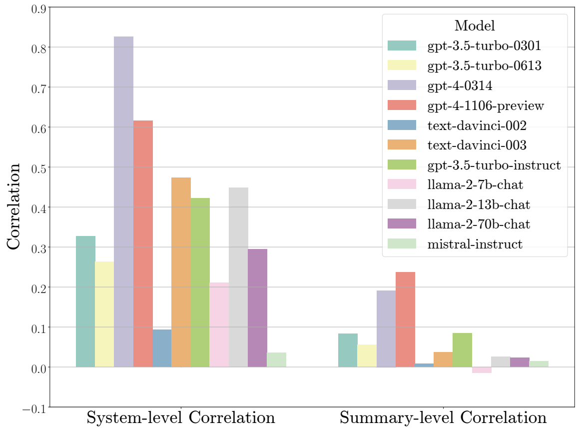

Figure 2: Average LLM performance of ins-controllable summary evaluation across 3 quality dimensions with 3 evaluation protocols on INSTRUSUM.

maries. In Figure 2, we report the average LLM performance across 3 quality dimensions on 3 protocols except LLMScore. In particular, GPT-4 shows a consistent advantage over other LLMs.

(2) **The choice of evaluation protocols has a large impact on the evaluation method performance**. For example, the pairwise comparison protocol (LLMCompare) is (almost) always better than the listwise protocol (LLMRank). Besides, the most suitable protocol for each backbone LLM can be different. For instance, `gpt-4-0314` works better with LLMCompare while `gpt-3.5-turbo-0301` tends to work better with LLMEval.

(3) In general, LLM-based evaluation methods have much higher system-level correlations than summary-level correlations, which means these methods are better at evaluating which system is better on average, but **struggle at ranking different summaries of individual data examples**. Notably, the strongest evaluation method we identified, i.e., pairwise comparison using `gpt-4-0314`, can only achieve an agreement value of 0.277 with human evaluation on the *overall quality* dimension in pairwise comparison, lower than the human inter-annotator agreement (0.4428).

(4) **The performance of the LLM-based evaluation methods differs on different quality dimensions**. In particular, *Irrelevant Information* is a more challenging dimension than *Missing Information*, suggesting that these methods are better at recall-based than precision-based evaluation.

System	System-Level	Summary-Level
gpt-3.5-turbo-0301	0.600	0.149
gpt-3.5-turbo-0613	0.681	0.135
gpt-4-0314	**0.966**	0.227
gpt-4-1106-preview	0.800	**0.262**
text-davinci-002	0.418	0.049
text-davinci-003	0.485	0.089
gpt-3.5-turbo-instruct	0.461	0.114
llama-2-7b-chat	0.111	-0.006
llama-2-13b-chat	0.200	0.072
llama-2-70b-chat	0.442	0.021
mistral-instruct	0.416	0.051

Table 7: LLM evaluation consistency between the LLMCompare and LLMEval protocols. System-level and summary-level Kendall rank correlations are reported.

System	Generator	Re-ranker (Evaluator)	
		LLMCompare	LLMEval
text-davinci-002	2.344	3.335	3.383
text-davinci-003	3.239	3.189	3.374
gpt-3.5-turbo-0301	2.897	3.357	3.504
gpt-4-0314	3.970	3.533	3.561

Table 8: Performance comparison of LLMs as the summary generator and the summary re-ranker with different evaluation protocols. The human-annotated scores on the overall quality dimension are reported. A random-reranking oracle can achieve a score of 3.260.

Evaluation Consistency A reliable evaluator must yield consistent results across different evaluation protocols. To check this consistency requirement, we examine the LLMs by calculating the correlations of its evaluation results on the LLMCompare and LLMEval protocols over the three quality dimensions, since these two protocols are most reliable. Table 7 indicates low summary-level consistency among all evaluated LLMs. However, `gpt-4-0314` demonstrates a high system-level consistency, indicating it is the most reliable evaluator.

Generator-Evaluator Consistency Recent work has found that the behavior and performance of LLMs can differ when they are used as a generator or an evaluator on the same task (Li et al., 2024b; West et al., 2024). Thus, we analyze the performance consistency of LLMs on ins-controllable summary generation and evaluation. To this end, we treat the LLM evaluator as a *re-ranker* to make its performance more comparable to the LLM generator. In Table 8, we report the generation and re-ranking performance of the 4 human-evaluated LLMs in §2.2 on the overall quality dimension, where the re-ranker can select its output from the human-evaluated candidate summaries. We note:

(1) The generation performance does not always align with the evaluation performance. For exam-

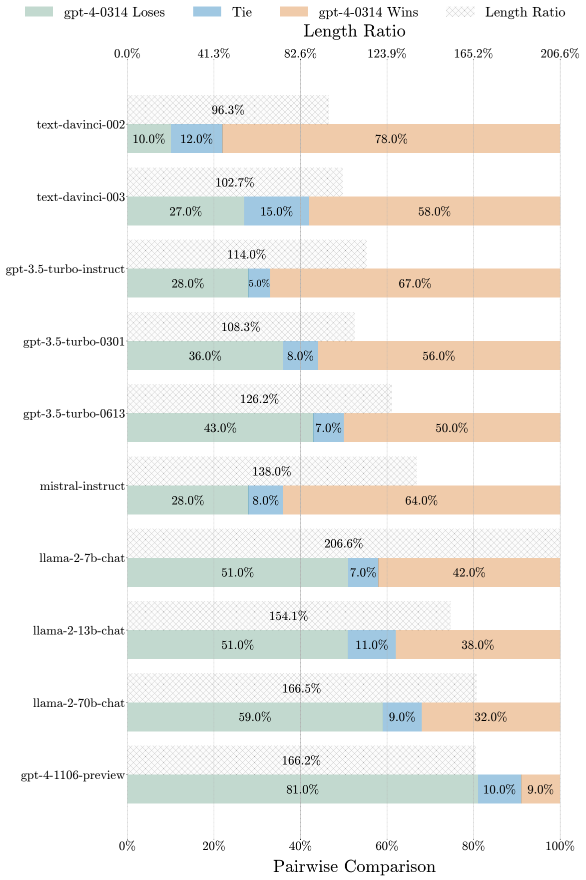

Figure 3: Automatic benchmarking results using `gpt-4-0314` as the evaluator. LLM summaries are compared against `gpt-4-0314`'s summaries. The model evaluation result (bottom) is reported, as well as the summary length ratios (top) relative to `gpt-4-0314`.

ple, `text-davinci-003` has better generation performance than `gpt-3.5-turbo-0301`, but worse evaluation performance.
(2) `gpt-4-0314` fails to outperform its generation performance under the re-ranking task setting. It suggests that despite its promising ability to generate acceptable summaries, GPT-4 might still lack a more in-depth understanding of the task.

4 Can We Automate Ins-Controllable Summarization Benchmarking?

After evaluating LLMs as summary evaluators, we explore their potential for automating ins-controllable summarization benchmarking.

4.1 Evaluation Settings

Since GPT-4 coupled with LLMCompare is the best evaluation method we identified in §3.3, we use it for the automatic benchmarking. To avoid the prohibitive cost, we treat GPT-4 (`gpt-4-0314`) as a baseline and evaluate the other systems by comparing them against GPT-4 only, following recent practices in automatic LLM benchmarking (Dubois et al., 2023; Zheng et al., 2023).[14] We evaluated 11 LLMs over the 100 data examples we used in human evaluation (§2.1). The same prompt template for summary generation, as shown in Appendix A.1, is used for different LLMs.

Pair	**Overall**	**Missing**	**Irrelevant**
Human v.s. Oracle	0.112	-0.268	0.302
GPT-4 v.s. Oracle	0.304	0.098	0.253
GPT-4 v.s. Human	0.277	0.147	0.376

Table 9: Agreements among human evaluation, LLM-based evaluation (`gpt-4-0314`) and the length oracle.

4.2 Result Analysis

The evaluation results are in Figure 3. We found that Llama-2 models show a strong performance under GPT-4's evaluation, even outperforming `gpt-4-0314` in the pairwise comparison setting. However, since we did not observe Llama-2 models achieving performance as strong as GPT-4 in evaluating the ins-controllable summaries (§3.3), we suspect GPT-4 has overestimated Llama-2 models' performance in this summary generation task. The reason is likely that the summaries generated by Llama-2 models are much longer than the `gpt-4-0314` summaries, which tend to be favored by GPT-4 as shown below.

In Table 9, we compare the annotator agreement in pairwise comparison among human evaluation, LLM-based evaluation using `gpt-4-0314` and LLMCompare, and a length oracle that always prefers longer summaries. The results indicate that human evaluation has a positive correlation with the length oracle in the *irrelevant information* dimension and a negative correlation in the *irrelevant information* dimension. Conversely, `gpt-4-0314` has a positive correlation with the length oracle across all quality dimensions. These findings suggest that LLM-based evaluation is more prone to bias from summary length compared to human evaluation. Furthermore, our case study in Appendix G shows that when the length difference is controlled, none of the LLMs we evaluated have a clear advantage over `gpt-4-0314`. Therefore, we find current LLM-based evaluation methods unreliable for automatic ins-controllable summarization benchmarking, and we call for future work in this direction.

---

[14] We randomly shuffled the summary pairs and did not observe a significant positional bias in the evaluation results.

5 Related Work

Summarization Benchmarks Recent work in summarization benchmarks has focused on aggregating model outputs and annotating them according to specific quality dimensions (Huang et al., 2020; Bhandari et al., 2020; Stiennon et al., 2020; Zhang and Bansal, 2021; Fabbri et al., 2022; Gao and Wan, 2022). In the context of LLMs, Laban et al. (2023) incorporated LLMs into the benchmark-construction process while Maynez et al. (2023) benchmarked LLMs on conditional text generation tasks including summarization. A few recent studies (Goyal et al., 2022; Liu et al., 2023b; Zhang et al., 2024; Pu et al., 2023) point to the strength of LLMs with respect to human-written (reference) summaries on generic news summarization. In this work, we present a benchmark task that poses challenges for current LLMs and allows for further development and model comparison.

Instruction-Following Evaluation Ouyang et al. (2022) introduce InstructGPT, which learns to follow instructions by aligning to human preference feedback and builds on earlier alignment work in summarization (Stiennon et al., 2020). Following Ouyang et al. (2022), a line of work (Wang et al., 2023d; Zhou et al., 2023; Zeng et al., 2024) has investigated methods of improving and benchmarking the instruction-following capabilities of LLMs. Regarding text summarization, instruction-following text summarization expands upon work in query-focused summarization (Zhong et al., 2021; Vig et al., 2022; Yang et al., 2023a; Pagnoni et al., 2023), aspect-based summarization (Zhang et al., 2024; Pu et al., 2023; Yang et al., 2023b), and controllable summarization more broadly (Dou et al., 2021; He et al., 2022; Zhang et al., 2023; Bao et al., 2023; Ribeiro et al., 2023; Ravaut et al., 2023; Adams et al., 2023b,a; Narayan et al., 2023; Pagnoni et al., 2023; Pu and Demberg, 2023). Closely related to work on query-focused summarization is the task of long-form question answering (Fan et al., 2019), and recent work has benchmarked current models and metrics with a focus on completeness and factuality (Xu et al., 2023). In this work, we explore controllability in the context of instructions. Compared with query-focused summarization, our task format allows for more complex use cases where the information queries can be combined with other user request categories such as the output format. Wang et al. (2023a) extends query-focused summarization and curates an instructive dialog summarization dataset. The most relevant work to our study is Skopek et al. (2023), which develops a dataset consisting of human annotations on instruction-summary pairs. However, their evaluation focuses only on the instruction-following capacities, while our human evaluation is multi-dimensional and puts more focus on the models' text summarization capabilities.

LLM-based Automatic Evaluation and Its Meta-Evaluation A series of recent work has investigated leveraging LLMs for automatic evaluation (Fu et al., 2023; Chiang and Lee, 2023; Liu et al., 2023a; Zheng et al., 2023; Wang et al., 2024; Sun et al., 2023; Gao et al., 2023; Wang et al., 2023b; Li et al., 2024a). While these studies have demonstrated LLMs' promising performance on various evaluation tasks such as summarization evaluation, other recent work has highlighted the limitations of LLM-based automatic evaluation methods. Specifically, LLMs can have various biases in their evaluation results (Koo et al., 2023; Wang et al., 2023c), and they fail to align with human evaluation when evaluating close-performing systems (Shen et al., 2023) or adversarial examples (Zeng et al., 2024). Our work provides a thorough meta-evaluation of LLM-based methods, focusing on diverse protocols and backbone LLMs for ins-controllable summarization evaluation.

6 Conclusions

In this work, we benchmarked large language models for instruction controllable summary generation and evaluation, and presented a new benchmark dataset, INSTRUSUM. We found that several LLMs have already shown promising performance in generating ins-controllable summaries. However, they lack robust holistic capabilities for this task since they still make a considerable amount of errors in their summaries and they can not reliability evaluate different candidate summaries. Furthermore, we notice large gaps between the performance of different generations of LLMs on both ins-controllable summary generation and evaluation. As we believe our proposed ins-controllable summarization setting is more realistic and can provide better usability, we call for future work along this direction to make the text summarization systems more beneficial to the actual users.

7 Limitations

Our analysis is limited to 100 examples for which we collected human annotations of ins-controllable summaries generated by different LLMs. While more statistically significant conclusions could be drawn from a larger evaluation set, as noted above a much larger time and budget allocation would be required, and we encourage the community to apply our protocol to expand our evaluation set.

Due to sparsity and subtleties of factuality errors generated by current LLMs on our benchmark, we did not perform a meta-evaluation of LLMs as factuality evaluators, since it would require a larger collection to observe significant error patterns. We leave a larger evaluation of the factual consistency of current models and error types for future work.

Acknowledgements

We express our gratitude to Tanya Goyal for her insightful suggestions, and we thank the anonymous reviewers for their constructive comments. We are grateful for the compute support provided by the Google TRC program.

A Prompt Templates

Here we provide the prompt templates we used throughout this work.

A.1 Prompts in Human Annotation Collection

Prompt for Summary Requirement Recommendation In §2.1, we used GPT-4 to generate candidate summary requirements to help the human annotation. The prompt template is as follows:

> Please generate a list of specific summary requirements for a given article.
>
> Here are some requirement examples based on different articles: 1. Summarize the possible explanations for why there hasn't been any firm evidence of aliens' existence, under the assumption that they do exist. 2. Summarize the experience of Chum Mey in 1970s with a timeline. 3. Summarize why Shanghai and Hong Kong seem to outperform Beijing in education. 4. Summarize all people and their identities in the article. 5. Summarize the negative outcomes of the lockdown. 6. Summarize the conclusion of the fraud case. 7. Summarize the opinions of Ronan Barry in the article. 8. Summarize the events of Margaret's debit card fraud in a timeline. 9. Summarize the aftermath of sexual harassment on Meena in one sentence. 10. Summarize the difficulties faced by Uber and Lyft now.
>
> Here's an article: {{article}}

> Please generate a list of specific summary requirements for this article.

Prompt for Generating Requirement-Specific Summaries We used the following template to prompt the LLMs to generate the requirement-specific summaries.

> Summarize the following article based on the specific requirement.
>
> Article: {{article}}
>
> Requirement: {{requirement}}
>
> Summary:

A.2 Prompts for LLM-based Automatic Evaluation

In §3, we analyze the performance of different LLM-based automatic evaluation methods. We designed prompt templates for each evaluation protocol and each evaluation dimension, and slightly fine-tuned templates for several LLMs to ensure that they are able to follow the instructions as much as they can. To enhance the LLM evaluation performance, for LLMCompare and LLMRank, we design chain-of-thought (Wei et al., 2022) style prompts – before the LLM gives the actual answer, it is prompted to first generate an explanation of the answer, mimicking the thinking process of human evaluators. We show the following prompt templates for all the evaluation protocols on the *overall quality* dimension, and all the templates can be found in our code release.

(1) **Prompt template for LLMRank**.

> In this task, you will be provided with a news article, a specific summary requirement, and a list of summaries numbered as follows: 1. Summary 1, 2. Summary 2, and so on.
>
> The summaries are crafted to meet a specific summary requirement. Note that there may be identical summaries within the list.
>
> Your task is to evaluate and rank the summaries in ascending order of their overall quality concerning the summary requirement. First, you will explain your ranking, and then you will provide the ranking of each summary. The ranking should be a number between 1 and 5, where 1 is the best and 5 is the worst.
>
> Note: In case of a tie, do not skip a rank. For example, if Summary 1 has ranking 1 and Summary 2 and 3 both have ranking 2, then Summary 4 should be assigned a ranking of 3, not 4.
>
> Please refer to the example below for the format of your response.
>
> Example Response: Explanation: "Your explanation of the ranking." Ranking: "The ranking, e.g., 1, 2, 2, 3, 4."
>
> Here are the actual article, the summary requirement, and the summaries:
>

(2) **Prompt template for LLMCompare**.

> In this task, you will be provided with a news article, a specific summary requirement, and two summaries.
>
> The summaries are crafted to meet a specific summary requirement. Note that there may be identical summaries.
>
> Your task is to compare the overall quality of these two summaries concerning

the summary requirement and pick the one that is better (there can be a tie). First you will give an explanation of your decision then you will provide your decision in the format of 1 or 2 or tie.

Please refer to the example below for the format of your response.

Example Response:

Explanation: “Your explanation here”.

Decision: 1 or 2 or tie.

Here are the actual article, the summary requirement, and two summaries:

Article:

`{{Article}}`

Summary Requirement:

`{{Requirement}}`

Summary 1:

`{{Summary 1}}`

Summary 2:

`{{Summary 2}}`

Please provide your response.

(3) **Prompt template for LLMEval**.

In this task, you will be provided with a news article, a specific summary requirement, and a summary.

Your task is to rate the overall quality of the summary with a score from 1 to 5 concerning the summary requirement, where 1 is the lowest and 5 is the highest.

Please make sure you read and understand these instructions carefully. Please keep this document open while reviewing, and refer to it as needed.

Example Response:

Evaluation Form (scores ONLY):

- Overall Quality (1-5): 3

Here are the actual article, the summary requirement, and the summary:

Article:

`{{Article}}`

Summary Requirement:

`{{Requirement}}`

Summary:

`{{SUMMARY}}`

Evaluation Form (scores ONLY):

- Overall Quality (1-5):

(4) **Prompt template for LLMScore**.

Answer the question based on the following article, a specific summary requirement, and a summary.

Question: Is the summary of good overall quality in relation to both the article and the summary requirement? (a). Yes. (b). No.

Article:

`{{Article}}`

Summary Requirement:

`{{Requirement}}`

Summary:

`{{SUMMARY}}`

Answer: Yes

B Crowd-Annotation Details

We provide screenshots of the human annotation interface we used for crowd-sourced summary evaluation (§2.2) in Figure 4, 5, and 6. We recruit MTurk annotators who are located in the US or the UK. We set a competitive payment rate for better annotator retention, and the average hourly salary is around 20 US dollars.

Instructions

In this task, you will evaluate the quality of 5 summaries of a news article. To accurately complete this task, follow these steps:

1. **Read the news article carefully.**
2. **Review the summaries.**
3. For each summary, you will need to evaluate its quality on 4 dimensions:
    1. **Factual Consistency**: Is the summary consistent with the facts presented in the article, without contradicting or misrepresenting any information?
    2. **Missing Information**: Does the summary omit any crucial information from the article concerning the *summary requirement*?
    3. **Irrelevant Information**: Does the summary include any information that is not relevant to the *summary requirement*?
    4. **Overall Quality**: This rating assesses the overall quality of the summary in relation to the *summary requirement*.
4. For ***factual consistency***, please **select any span of text that contains an error or inconsistency** and ***right-click*** to add it to the error list below the summary. **You can select and add multiple errors in one summary.** If needed, you can delete an item from the error list by clicking the 'Delete' button next to it. If you find a summary to be factually consistent and without any errors, you do not need to add any items to the error list for that summary.
5. For ***Factual Consistency***, ***Missing Information***, ***Irrelevant Information***, and ***Overall Quality***, after evaluating the ***individual*** summaries, **rank them** from **1** (best) to **5** (worst) based on their quality. Same rankings are allowed if you think two summaries are of the same quality. Please note that there can be identical summaries.
   After assigning the ***Overall Quality*** rankings, please provide a **short explanation** for your ranking.

Warning: Annotations will be checked for quality against control labels. Low-quality work will be rejected.

Factual Error Examples

Source text
US technology firm Apple has offered to refund Australian customers who felt misled about the 4G capabilities of the new iPad. The country's consumer watchdog has taken Apple to court for false advertising because the tablet computer does not work on Australia's 4G network. Apple's lawyers said they were willing to publish a clarification. [...] At a preliminary hearing, Apple lawyer Paul Anastassiou said Apple had never claimed the device would work fully on the current 4G network operated by Telstra. Apple says the new iPad works on what is globally accepted to be a 4G network. The matter will go to a full trial on 2 May.

Summary 1: **Apple lawyer never claimed** that the device would work on the current 4G network operated by Telstra.
This summary contains a **factual error**: in the source text, it is **Apple** not **Apple lawyer** that never made the claim.

Summary 2: Apple has been accused of misleading customers in Australia over its new iPad **3.0 version**.
This summary contains a **factual error**: the version of the new iPad is not mentioned in the source text.

Irrelevant Information Examples

Requirement 1: Summarize what Dr. Mazen Kewara has said.
Summary 1: Dr. Mazen Kewara, Turkey director of the Syrian American Medical Society (SAMS), said that "We cannot use the buildings anymore. Maybe for hours. Maybe until tomorrow. I don't know." He also reported that there were many collapsed buildings in Gaziantep, and that SAMS had four of its hospitals damaged severely by the quake. He added that they had already evacuated two of them. ***Kewara was originally from Damascus, Syria.***
Explanation: The last sentence is irrelevant becuase it does not provide information that is **specifically about the requirement**.

Requirement 2: Summarize the current drawbacks of COP24.
Summary 2: ***COP24 was a success in terms of implementing the 2015 Paris Climate Accord and ensuring that all countries face similar regulations.*** However, many felt that acknowledging the science was only a token effort, and the agreement does not go far enough to tackle climate change. Moreover, the international spirit of co-operation needed to tackle climate change is threatened by the rise of nationalism in many countries and the election of Jair Bolsonaro as Brazil's president.
Explanation: The first sentence is irrelevant becuase **it is not specifically about the requirement**.

Missing Information Examples

Requirement 1: Summarize the companies mentioned in this article.
Summary 1: The article mentions several companies involved in the development of artificial intelligence technology. These include C3.ai, BigBear.ai and SoundHound AI, all of which have seen their share prices surge this year. C3.ai is run by tech veteran Tom Siebel and SoundHound AI is striving to make conversational AI better than humans. BigBear.ai provides AI solutions to US intelligence agencies and has seen its shares surge 700%. All three companies are unprofitable and are not expected to make money this year or in 2024, while BigBear.ai recently raised $25 million in a private placement of stock.
Explanation: The summary failed to mention Google, Microsoft, Baidu, etc.

Requirement 2: Summarize the information in the article in a timeline.
Summary 2: - Early Americans consumed an average of 5.8 gallons of pure alcohol a year in 1790.
- In 1830, alcohol consumption peaked at 7.1 gallons a year, and drinking became a moral issue.
- In 1862, the US Navy abolished the daily rum ration for sailors.
- On January 16, 1919, the 18th Amendment, which set Prohibition into law, became part of the Constitution.
Explanation: One event is missed: "The first arrest for driving under the influence of alcohol was in 1897."

Figure 4: Annotation Interface Part 1: Instructions.

Article

${article}

Overall Quality

Rank the summaries regarding the overall quality (1 to 5, with 1 being the best and 5 being the least preferred; ties are allowed):
Note: In case of a tie, the next rank will be skipped. For example, if Summary 1 has ranking 1 and Summary 2 and 3 both have ranking 2, then Summary 4 should be assigned a ranking of 3, not 4.

Summary A	1	2	3	4	5
Summary B	1	2	3	4	5
Summary C	1	2	3	4	5
Summary D	1	2	3	4	5
Summary E	1	2	3	4	5

	Overall	Missing	Irrelevant	Factual
Tie	0.45	0.47	0.50	0.90
Initial	**0.30**	**0.29**	0.20	0.03
Hybrid	0.25	0.24	**0.30**	**0.07**

Table 10: Pairwise comparison between the initial LLM summary and the hybrid summary. Winning rates of both summaries are reported. 37% of summaries are identical because no edits are made.

C OpenAI's Model Index

Here we describe the training methods of OpenAI models we benchmarked for ins-controllable summarization using human evaluation (§2.2). The following information was obtained from a blog post on the OpenAI's website, "Model index for researchers."[15]

`text-davinci-002`: Supervised fine-tuning (FeedME) on human-written demonstrations and on model samples rated 7/7 by human labelers on an overall quality score.

`text-davinci-003`: Reinforcement learning (PPO) with reward models trained from comparisons by humans.

The information about newer models can be found in `https://platform.openai.com/docs/models/`.

D Fine-grained Analysis of Hybrid LLM-Human Summaries

In §2.3, we found that the hybrid LLM-human summaries can not outperform the GPT-4 summaries on the *overall quality* and *missing information* dimensions. To better understand the performance of the hybrid LLM-human summary, we use the obtained human annotations to perform a pairwise comparison between the initial LLM summary and the hybrid summary. Results in Table 10 show that the hybrid summaries are better at the irrelevant information and factual consistency dimensions while worse at the overall quality and missing information dimensions. We believe this is mainly because there are more "delete" than "add" editing operations in the hybrid summaries since we found that the initial LLM summaries are more likely to include irrelevant information than missing relevant information. As a result, the reduced length of hybrid summaries may make them less favorable than the original summaries on the overall quality and missing information dimensions.

E Factual Error Examples

We found that a considerable portion of the factual errors flagged by the crowd annotators is quite nuanced (§2.2). Below we present a few examples.

Example 1

- **Article (part)**: ... However, in 2007, Australian-listed firm Scotgold Resources entered the scene and revived the mine. It has been a rollercoaster ride ever since. **By 2013**, Scotgold had obtained planning permission and put a funding plan in place, only for the gold price to collapse, making the project less palatable for potential investors ...

- **Summary Error Span (with context)**: Planning permission was obtained **in 2013**.

Example 2

- **Article (part)**: ... Their efforts to attract backers were also undermined by the volatility of the precious metals market, which often saw gold prices slump. **By 2006**, the mine had changed hands several times and was up for sale once more. ...

- **Summary Error Span (with context)**: **2006**: Mine changed hands several times and was up for sale again.

Example 3

- **Article (part)**: ... There was also a divide when it came to trusting information on the virus coming from the WHO. About **one-third** of Republicans said they trusted WHO information versus 80% of Democrats. ...

- **Summary Error Span (with context)**: 80% of Democrats trust information from the WHO, while only **33%** of Republicans do.

Example 4

- **Article (part)**: ... Prof Suzuki says his team will need to carry on their work for many more years to be sure that the children of Fukushima are in the clear. But he and other experts now say they think there will be **very few, or even zero, extra childhood cancers** because of Fukushima. ...

---

[15] The original page is no longer accessible as of April 1st, 2024. An old snapshot of the page is available at `https://archive.ph/n5xMq`.

- **Summary Error Span (with context)**: Professor Suzuki believes that the cases of thyroid cancer in Fukushima are not related to the nuclear disaster, and that the children of Fukushima **are not at risk** of developing cancer from the exposure to radiation.

Example 5

- **Article (part)**: ... Chum Mey says he was tortured, as his interrogators **tried to make him confess to spying for the US and Russia**. ... Eventually he said he **confessed to anything** so that the torture would be over. In his confession Chum Mey wrote that **he was working for the CIA** and had recruited dozens of agents in Cambodia. ...
- **Summary Error Span (with context)**: Chum Mey was tortured until he eventually confessed to spying for the US and **Russia**.

F Detailed Evaluation Settings of LLM-based Evaluation Methods

In §3, we benchmark different LLM-based evaluation methods. To this end, we use both system-level and summary-level correlations to evaluate the alignment between human evaluation and LLM-based evaluation. Specifically, given a correlation measurement function $\mathcal{M}$, e.g., the Kendall rank correlation coefficient (Kendall, 1938), and two lists of average system scores $\bar{S}^{(f)}$ and $\bar{S}^{(h)}$ assigned by two evaluation methods f and h, e.g., human evaluation and LLM evaluation, the system level correlation $\mathcal{C}_{\text{sys}}$ between f and h is

$$\mathcal{C}_{\text{sys}} = \mathcal{M}(\bar{S}^{(f)}, \bar{S}^{(h)}). \tag{3}$$

Similarly, the summary-level correlation $\mathcal{C}_{\text{summ}}$ is an average of the correlation between two lists of scores, $S_i^{(f)}$ and $S_i^{(h)}$, assigned by the evaluation methods f and h for the summaries generated by different systems on each data example:

$$\mathcal{C}_{\text{summ}} = \sum_{i=0}^{N-1} \frac{\mathcal{M}(S_i^{(f)}, S_i^{(h)})}{N}, \tag{4}$$

where N is the size of the evaluation dataset.

Since we adopted a ranking-based evaluation protocol for our human evaluation collection (§2.2), we use the Kendall rank correlation coefficient as the correlation measurement. Furthermore, apart from LLMRank, which directly generates a similar ranking, we convert the evaluation results of the other protocols to a ranking of different systems. For LLMScore and LLMEval that perform direct scoring of summaries, we simply convert the scores into a ranking (ties are allowed). For LLMCompare, we use the following scoring mechanism: (1) the winner system in a pairwise comparison receives 2 points, while the lost system receives 0 points; (2) if there is a tie between two systems, each of them receives 1 point; (3) the points are aggregated into a system ranking.

To remove the potential positional biases of the LLM-based evaluation methods (Wang et al., 2023c; Koo et al., 2023), we randomly shuffled the summary order when LLMRank or LLMCompare is used as the evaluation protocol.

G Length Bias in LLM-based Evaluation

As a further investigation of §3.3, we conducted a case study by only comparing summary pairs with similar lengths. Specifically, for each pair of systems, we keep only those pairs of summaries where the difference in lengths falls within the 20th percentile. The results in Table 11 indicate that when the length difference is controlled, none of the LLMs we compared can outperform GPT-4 on the overall quality dimension, and Llama-2 models no longer have a clear advantage over GPT-4. We note that since different examples are used for the comparison of different system pairs, the results in Table 11 are no longer directly comparable.

H Comparing Generic and Requirement-Specific Summaries

As a case study, we use `gpt-3.5-turbo-0301` and `gpt-4-0314` to generate *generic* summaries without specific requirements, and compare them with the requirement-specific summaries using `gpt-4-0314` as the evaluator with the LLMCompare protocol. The evaluation results show that the requirement-specific summaries generated by `gpt-4-0314` have a winning rate of 97% over the generic summaries on the *overall quality* dimension, while those with `gpt-3.5-turbo-0301` have a winning rate of 96%. We also evaluate the similarity between the generic and requirement-specific summaries in Table 12, as well as the summary length. In addition, in Table 13, we report the similarity between greedy-decoded and sampled (with a temperate of 1.0) requirement-specific summaries. Results in Table 12 and Table 13 sug-

	Overall			Missing			Irrelevant			Length	
	Win	Tie	Loss	Win	Tie	Loss	Win	Tie	Loss	System	GPT4
gpt-3.5-turbo-0301	0.23	0.18	0.59	0.18	0.27	0.55	0.09	0.32	0.59	118.0	117.5
gpt-3.5-turbo-0613	0.15	0.10	0.75	0.00	0.45	0.55	0.00	0.60	0.40	110.7	111.8
gpt-3.5-turbo-instruct	0.10	0.05	0.85	0.05	0.40	0.55	0.10	0.55	0.35	109.4	110.2
text-davinci-002	0.14	0.14	0.71	0.14	0.29	0.57	0.05	0.29	0.67	87.8	92.1
text-davinci-003	0.29	0.29	0.43	0.14	0.76	0.10	0.00	0.76	0.24	99.4	98.2
llama-2-7b-chat	0.38	0.10	0.52	0.24	0.29	0.48	0.24	0.33	0.43	132.1	115.1
llama-2-13b-chat	0.29	0.19	0.52	0.14	0.52	0.33	0.10	0.48	0.43	113.6	110.2
llama-2-70b-chat	0.30	0.20	0.50	0.25	0.55	0.20	0.25	0.50	0.25	110.8	102.5
mistral-instruct	0.20	0.15	0.65	0.20	0.20	0.60	0.10	0.25	0.65	91.3	90.0
gpt-4-1106-preview	0.50	0.20	0.30	0.45	0.40	0.15	0.30	0.60	0.10	98.75	91.4

Table 11: Automatic benchmarking results on summary pairs with similar lengths. The summaries of different LLMs are compared against summaries generated by GPT-4 (`gpt-4-0314`) using the LLMCompare protocol powered by `gpt-4-0314`. The number of wins, ties, and losses is reported as well as the average summary length.

Model	R1	R2	Specific	Generic
`gpt-3.5-turbo-0301`	47.21	26.30	127.3	144.0
`gpt-4-0314`	43.00	19.37	117.1	123.7

Table 12: The similarities between the generic and requirement-specific summaries as measured in ROUGE-1/2 (R1/R2). The average summary length is also reported, denoted by `Specific` and `Generic` respectively.

Model	R1	R2	Greedy	Sampled
`gpt-3.5-turbo-0301`	61.63	38.11	127.3	125.48
`gpt-4-0314`	66.16	43.20	117.1	117.7

Table 13: The similarities between the greedy-decoded and sampled requirement-specific summaries as measured in ROUGE-1/2 (R1/R2). The average summary length is denoted by `Greedy` and `Sampled` respectively.

gest that the similarity between the generic and requirement-specific summaries is relatively low, and the generic summaries are not preferred by `gpt-4-0314` despite its longer average length.

NeuroComparatives: Neuro-Symbolic Distillation of Comparative Knowledge

Abstract

Comparative knowledge (e.g., steel is stronger and heavier than styrofoam) is an essential component of our world knowledge, yet understudied in prior literature. In this paper, we harvest the dramatic improvements in knowledge capabilities of language models into a large-scale comparative knowledge base. While the ease of acquisition of such comparative knowledge is much higher from extreme-scale models like GPT-4, compared to their considerably smaller and weaker counterparts such as GPT-2, not even the most powerful models are exempt from making errors. We thus ask: to what extent are models at different scales able to generate valid and diverse comparative knowledge?

We introduce NeuroComparatives, a novel framework for comparative knowledge distillation overgenerated[1] from language models such as GPT-variants and LLaMA, followed by stringent filtering of the generated knowledge. Our framework acquires comparative knowledge between everyday objects, producing a corpus of up to 8.8M comparisons over 1.74M entity pairs—10X larger and 30% more diverse than existing resources. Moreover, human evaluations show that NeuroComparatives outperform existing resources in terms of validity (up to 32% absolute improvement). Our acquired NeuroComparatives leads to performance improvements on five downstream tasks. We find that neuro-symbolic manipulation of smaller models offers complementary benefits to the currently dominant practice of prompting extreme-scale language models for knowledge distillation.

1 Introduction

In their book *"Surfaces and Essences"* on *concepts* and *analogies*, Hofstadter and Sander (2013) elucidate how concept learning requires *comparing* a pair of concepts, and parsing out their similarities and dissimilarities. Indeed, comparative knowledge is an essential component of our world knowledge (Ilievski et al., 2021; Davis, 2023), underpinning some of the classical commonsense reasoning problems. For example, the problem *"The large ball crashed right through the table because it was made of [steel/styrofoam]. What was made of [steel/styrofoam]?"* in Winograd Schema Challenge (Levesque et al., 2011) requires comparing the relative strength between steel and styrofoam. Yet, compared to *general* knowledge acquisition, there has been relatively little research focus on *comparative* knowledge acquisition, possibly due to the longstanding challenges of high-quality knowledge acquisition itself, let alone comparative knowledge. The few resources for comparative knowledge, all derived from web mining, however limited in size and diversity (§5), have nonetheless been useful for challenging multimodal reasoning tasks (Wang et al., 2018), highlighting the value of comparative knowledge.

In this paper, we draw inspirations from such literature about concept learning and inquire two related questions on *comparative knowledge*: (1) how well do models at different scales fare at the task of producing large-scale, high-quality comparative knowledge about a broad range of concepts? and (2) what are the implications for downstream tasks? Compared to prior resources of commonsense knowledge acquired either via crowdsourcing (Speer et al., 2017; Sap et al., 2019) or via information extraction (e.g., WebChild (Tandon et al., 2017) and ASER (Zhang et al., 2020)), our attempt to (re-)focus on the task of comparative knowledge acquisition takes the perspective of *"language models as knowledge bases"* (West et al., 2021; AlKhamissi et al., 2022), motivated by the dramatic improvements in the capabilities of extreme-scale neural language models.

---

[*] Equal contribution

[1] We use "overgenerate" throughout this work to indicate that we generate more knowledge from the language model than we intend to keep after rigorous filtering and selection.

Findings of the Association for Computational Linguistics: NAACL 2024, pages 4502–4520
June 16-21, 2024

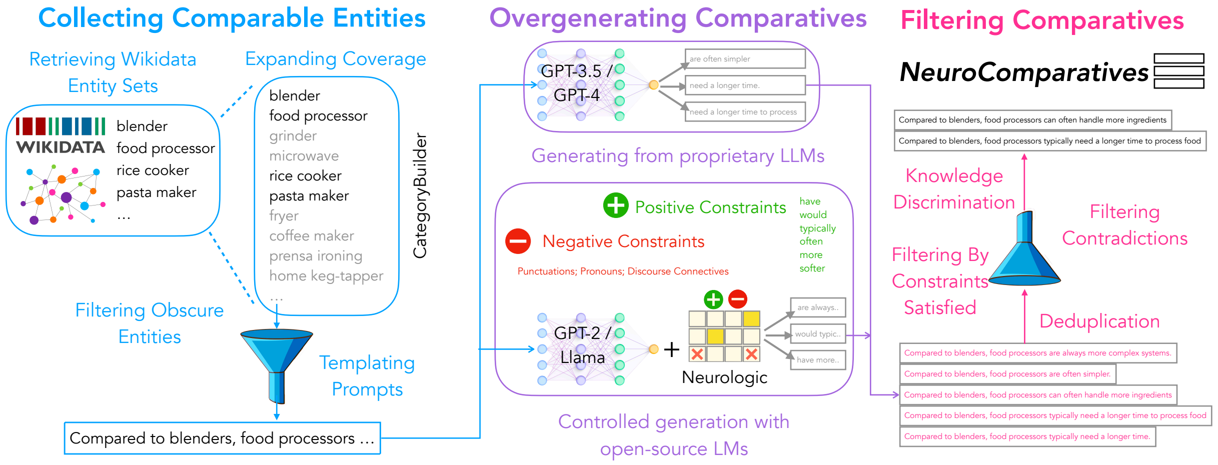

Figure 1: Our neuro-symbolic framework to distill **NeuroComparatives**. (1) We seed entity pairs for comparison from Wikidata, and expand the set with CategoryBuilder to construct templated prompts for a language model. (2) Next, we use these prompts to overgenerate comparatives from different language models to ensure our generations contain valid comparisons between a given pair of entities. (3) Finally, we discard contradictory and otherwise lower quality generations via various clustering and filtering techniques. Our resultant corpus NeuroComparatives contains 8.8 million comparisons over 1.74 million entity pairs.

We build on such research, but in addition to few-shot inference with extreme-scale model APIs such as GPT-4, also rely on customized inference with smaller language models (See et al., 2019; Sheng et al., 2020; Liu et al., 2021). We ask a seemingly implausible question: can considerably smaller and weaker language models such as GPT-2 (Radford et al., 2019), complement the capabilities of their large-scale counterparts in the acquisition of *comparative knowledge* between a pair of concepts? To this end, we follow an overgenerate-and-filter mechanism (Langkilde and Knight, 1998; Walker et al., 2001) to create a large-scale, high-quality resource: **NeuroComparatives**, a corpus with up to 8.8 million comparisons over 1.74 million pairs of entities. Our framework is illustrated in Figure 1.

Compared to the only other large-scale commonsense KG containing comparative knowledge (Tandon et al., 2017, WebChild), NeuroComparatives is up to 10x larger, 30% more diverse, and has a 19% higher human acceptance rate. Additionally, we show that a knowledge discriminator model can further improve the the human acceptance rate of our knowledge to 90%, representing a 32% absolute gain compared to WebChild while still being over 2X larger in scale. Our analyses also show that NeuroComparatives are, on aggregate, more diverse than WebChild comparatives and more effective on three different downstream benchmarks. Overall, our findings motivate customizable neuro-symbolic manipulation of smaller scale models as a cost-effective complement to the dominant practice of performing simple inferences under extreme-scale yet closed language models. We make our code[2] and dataset[3] publicly available.

2 Distilling NeuroComparatives

Our framework for distilling comparatives from an autoregressive LM comprises three stages, illustrated in Figure 1. First, we collect comparable entities to construct prompts for eliciting comparative knowledge statements (§2.1). Next, we employ LMs to overgenerate (potential) comparatives for every pair of selected entities (§2.2). Finally, we filter the generations (§2.3) to obtain a large-scale, high-quality collection of comparative statements, which we call **NeuroComparatives (NCs)** (§3).

2.1 Collecting Comparable Entities

One unique challenge in probing language models for knowledge acquisition, as opposed to extracting pre-existing knowledge from web text, is knowing *exactly what* to probe LMs for, i.e., concept pairs for comparison. For practical applications, the comparatives are more likely to be useful when they are about entities sharing some common properties, e.g., "red wine" and "white wine" (Fig. 4), rather than unrelated ones e.g., "cucumber" and

[3] `https://huggingface.co/datasets/Intel/NeuroComparatives`

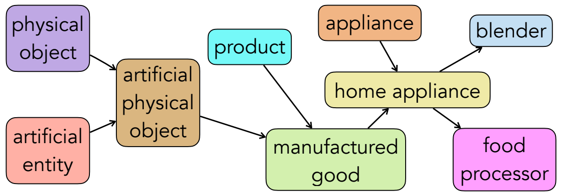

Figure 2: Wikidata hierarchical class structure for retrieved entities 'blender' and 'food processor'.

"car". Identifying a vast array of diverse yet relevant concepts for comparison is complex; thus, we developed a systematic process below: retrieval (§2.1.1), expansion (§2.1.2), and filtering (§2.1.3).

2.1.1 Retrieving Seed Entity Sets

We start our entity collection using two broad Wikidata (Vrandečić and Krötzsch, 2014) classes, as our seed classes: *physical object* and *artificial physical object*. Each seed class contains entities and subclasses, which themselves may contain additional entities. Figure 2 illustrates an example Wikidata class structure for "blender" and "food processor", with "physical object" as the root. Using a breadth-first traversal of Wikidata, we retrieve all classes up to two levels[4] below the root class. Overall, we retrieved 1.5K classes with 23K entities from Wikidata. While Wikidata provides a good starting point, we find that many of its classes are incomplete, a common challenge with any taxonomic resource. Thus, we next expand our entity sets to increase the coverage.

2.1.2 Expanding the Coverage of Entity Sets

We expand our entity collection using Category-Builder (Mahabal et al., 2018), a system for lexical entity set expansion. We append each retrieved entity set from Wikidata with the top $n = 100$ related terms identified by Category Builder using the hyperparameter $\rho = 3.0$ for context weighting. This results in a total of 40K entities corresponding to 1.5K Wikidata classes. Noting the presence of obscure entities, e.g., "home keg tapper" and "prensa ironing" in the "home appliance" class (Fig. 1), we then moved to eliminate these obscure entities.

2.1.3 Filtering Obscure Candidate Entities

Obscure entities would occur infrequently, thus we discard entities which occurred less than $n = 100$ times in the language model's training corpus.[5] We additionally discard all classes with less than 2 entities after this filtering step. These filtering steps are applied twice: first on the original Wikidata entities, and then again after we expand the entity sets with Category Builder. This results in 568 classes with a total of 15,476 entities.

2.1.4 Templating Comparative Prompts

We generate comparison candidates by pairing entities within each class. For each such pair, $(\texttt{entity}_1, \texttt{entity}_2)$, we use the following template[6] to form the prompt for generation:

$$\text{Compared to } \texttt{entity}_1, \texttt{entity}_2 \ldots \tag{1}$$

As a final step, we further filter 30% of the created prompts using GPT-2 XL perplexity to remove potentially disfluent or nonsensical prompts. This results in a total of 1,741,962 prompts.

2.2 Overgenerating Comparatives

Since there's no supervision available, we follow an inference-only process for generating the initial set of comparative statements. We employ two approaches: constrained decoding with open-source LMs (§2.2.1) and few-shot prompting of proprietary LLMs (§2.2.2). We hypothesize that both approaches may offer complementary benefits.

2.2.1 Generation with open-source LMs

We experiment with GPT-2 XL and Llama-2 7B, two open-source models where inference can be customized to generate comparatives. We use a customized controlled decoding algorithm, NeuroLogic (Lu et al., 2021) to guide the generation using the prompts constructed above (§2.1).

Formulating the Constraint Sets We classify our constraints into three types: *positive*, *negative*, and *comparative adjectives*. Positive constraints ensure tokens appear in the output; we include auxiliary verbs (e.g., 'have', 'are', 'would') and adverbs of frequency (e.g. 'typically', 'often') (Appendix A for details). Negative constraints ensure tokens do not appear in the output to reduce hallucinations; we include certain punctuation characters, pronouns, discourse connectives, and relative clauses(Table 9 in Appendix A for details).

---

[4] We use a maximum search depth of two based on the observation that descending lower in Wikidata results in entities that are too specific or obscure for generating comparatives.

[5] The only corpus we have access to is the open-source counterpart of GPT-2's training corpus, OpenWebText.

[6] We experimented with other templates but found that this one was most consistent at generating valid comparisons

Constrained decoding with NeuroLogic We adapted NeuroLogic constrained decoding for fluent text generation under specific lexical constraints (NeuroLogic accepts *clauses* $\{C_i \mid i \in 1, \cdots m\}$ as constraints; see details in App. A.1).

To encourage diversity in the generated comparatives, the generator must use different comparative adjectives, without explicit enumeration. Hence, we dynamically promote top-k comparative adjectives with the highest probabilities at each decoding time step (we use k=5). We customize this as a special type of positive constraint (§2.1.4).

We additionally modify NeuroLogic to handle ordered constraint satisfaction, for fine-grained control. For each clause C_i, we assign one or more order indices $m_i \in \{1, ..., m\}$ which correspond to the positional order in which clause C_i can appear in the generation. Specifying more than one order index allows a clause to appear in multiple different positions. Ordered constraint satisfaction provides more fine-grained control for generating valid comparatives, as illustrated in Figure 4.

2.2.2 Generation with Proprietary LLMs

Many recent LLMs are proprietary, disabling our ability to customize the decoding process due inability to modify the decoding process. Hence, we leverage their in-context learning abilities to overgenerate completions for each entity pair. Specifically, we use six in-context examples of comparatives followed by our templated comparative prompt (details in App. C).

2.2.3 Scale of Overgeneration

Given its open-source availability and relatively low computational cost, we overgenerate the most comparatives using GPT-2-XL as our base LM. In total, we perform 30 passes of NeuroLogic with GPT-2 over the 1.74 million entity pairs from §2.1.4, where each iteration uses a different combination of the positive constraints, while adhering to the same negative and comparative adjective constraints. Each pass produces 10 generations, resulting in 300 candidate comparatives for each entity pair. This process produces a total of 522 million overgenerations across the 1.74 million entity pairs. We similarly use Llama-2-7b with NeuroLogic to generate comparatives for 50K entity pairs, which produces 15 million overgenerations.

In addition, we utilize three propriety LLMs (InstructGPT, ChatGPT, and GPT-4) to overgenerate comparatives for a smaller set of 2.3k entity pairs due to the much higher inference cost. For each entity pair, we return 128 completions, which is the maximum allowed via the inference API. This produces a total of 300k overgenerated comparatives.

2.3 Filtering Overgenerated Comparatives

Despite using a combination of effective language generation, we achieve quality control through aggressive filtering of the overgenerated comparatives. This last filtering step consists of deduplication (§2.3.1), filtration by constraint satisfaction (§2.3.2), filtration of contradictory knowledge (§2.3.3), and additional filtering via a knowledge discriminator model (§2.3.4).

2.3.1 Deduplication

To address LM's tendency to generate redundant comparisons, we deduplicate our generations. We use agglomerative clustering of all generated comparatives using the inner product of their sentence T5 embeddings (Ni et al., 2021) as the distance. For each cluster, we retain only the generation with the best decoding score, S[7] (App. A.1). Approximately 17% of the original generations remain.

2.3.2 Filtration by Constraint Satisfaction

After deduplication, we group the remaining generations by how they satisfied the positive constraints to encourage greater diversity in our knowledge base. Specifically, we group generations by the generated auxiliary verb, adverb of frequency, and comparative adjective and select only the generation with the best S^5. This further reduces the total number of generations to approximately 9% of the overgenerated comparatives.

2.3.3 Filtration by Contradiction

The tendency of language models to hallucinate information (Ji et al., 2022) sometimes results in unreliable generations which contradict each other. Using a RoBERTa contradiction classifier (Liu et al., 2019; Wang et al., 2022), we discard comparatives that contradict others more often than not. To increase the precision of the pre-trained classifier, we set a high threshold probability for classifying contradiction and entailment (0.99 and 0.85, resp.). Approximately 5% of the overgenerated comparatives remain after this stage of filtering, from which we select only the $k = 5$ best-scoring generations by their S^5 for each entity pair.

---

[7] For proprietary LLMs, we use length-penalized perplexity from GPT-2 XL in lieu of the decoding score, S.

Prompt	**WebChild Assertions**	**Completions in NeuroComparatives (Ours)**
Compared to helicopters, planes . . .	. . . were cooler ✓✓✗	. . . are more stable in flight ✓✓✓
	. . . are noisier ✓✓✗	. . . typically have higher operating costs ✓✓✗
	. . . are better ✓✓✗	. . . can often carry more cargo ✓✓✓
Compared to floppy disks, hard drives . . .	. . . are better ✓✓✓	. . . are generally considered more reliable ✓✓✓
Compared to cars, motorcycles . . .	. . . are cheaper ✓✗✓	. . . generally have fewer moving parts ✓✓✓
	. . . are smaller ✓✓✗	. . . generally have lower fuel consumption ✓✓✓
	. . . are cooler ✗✗✗	. . . tend to have shorter range ✓✓✓
Compared to blenders, food processors . . .	. . . are larger ✓✓✓	. . . can often be more expensive ✓✓✓
	. . . work better ✓✓✓	. . . can often handle more ingredients ✓✓✓

Table 1: Generations from NeuroComparatives and WebChild assertions for the same entity pair. Each example was annotated by three human workers: ✓indicates acceptance and ✗ rejection. In contrast to WebChild assertions, NeuroComparatives can be more specific to the entity pairs under consideration, diverse and less subjective.

2.3.4 Discriminative Filtering

To further increase the quality of our retained knowledge, we build a final discriminator, adjustable to the desired balance between knowledge quantity and quality. We train a knowledge discriminator using crowdsourced annotations of valid and invalid knowledge generations, following prior work (West et al., 2021). For a random 10K sample of our generated comparatives for unique entity pairs, we crowdsource the validity of each comparison (using the same setup described subsequently in §3.1). We train a classifier to discriminate between aggregated "Accept" and "Reject" crowdsourced labels (see Appendix B for additional details) and vary the threshold for the "Accept" class to filter at different levels of knowledge precision.

3 NeuroComparatives

Our large-scale generation effort produced 8.8m comparatives before discriminative filtering (details in App. A), which we refer to as NC-XL. Specifically, NC-XL includes 8.7M comparatives generated from GPT-2 XL, 78K from Llama-2-7b, 16.3K from InstructGPT, 10.7K from ChatGPT, and 6.6K from GPT-4. We further apply our knowledge discriminator model on NC-XL to create subsets containing only the top-50% and top-20% of comparatives, which we refer to as NC-L and NC-S, respectively. While NC-XL contains the greatest breadth of comparative knowledge, the more stringent filtering applied to produce NC-L and NC-S results in the highest knowledge quality, without hurting diversity.

The largest existing resource of comparative commonsense knowledge is WebChild (Tandon et al., 2017), collected via information extraction methods. While WebChild contains over 18M general assertions covering 2M concepts and activities, we focus on its comparative knowledge, which spans 813K assertions over 335K entity pairs. Compared to WebChild, our NC-XL corpus is 10x larger. Table 1 provides examples of NC-XL in contrast to WebChild assertions across four pairs of entities. For ease of comparison, we convert the WebChild assertions from OpenIE triplets to a natural language format, similar to ours.

The first set of examples for the entity pair (helicopters, planes) illustrates the more detailed, domain-specific properties, such as "operating costs", "more cargo", and "stable in flight" in NC-XL. In contrast, WebChild assertions are more generic (e.g., "cooler", "better") and not specific to the domain of flight. This example also highlights how NC-XL assertions are more informative and interesting to humans, as evidenced by their lower rate of rejection shown in Table 1.

We also compare our generated knowledge to ATOMIC (Sap et al., 2019) and ConceptNet (Speer et al., 2017). Although neither explicitly contains comparative knowledge, they do contain relations from which comparatives can be inferred. We use the `AtLocation` and `MadeUpOf` relations in ATOMIC, as well as the `AtLocation`, `PartOf`, and `MadeOf` relations in ConceptNet, to infer size comparisons over entities. We convert these entries to our NCs format for evaluation; for e.g., the ATOMIC triple (`human body`, `MadeUpOf`, `brain`) results in the comparative: "Compared to brains, human bodies are larger.". We use human (§3.1) and automatic (§3.2) evaluation to compare the quality and diversity of NeuroComparatives with existing comparative knowledge resources.

3.1 Human Evaluation of Validity

We task 3 workers from Amazon Mechanical Turk with classifying each comparative into one of six categories: ‘True’, ‘False’, ‘Too subjective to judge’, ‘Too vague to judge’, ‘Too unfamiliar to judge’ and ‘Invalid’.[8] We discard examples where there was no majority consensus among the 3 workers, and those marked as ‘Too unfamiliar to judge’ by a majority vote. Examples marked as ‘True’ are considered valid, and all others, invalid. Appendix D.2 details our annotation process (Fig. 6).

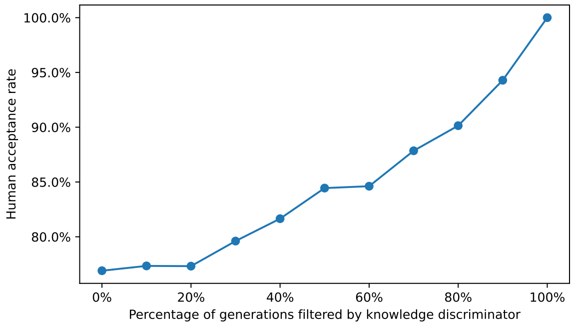

Figure 3: As our knowledge discriminator gets stricter, human acceptance of NeuroComparatives increases.

	Source	Size	Accept. ↑	SB2 ↓	SB3 ↓
Existing KBs	✍ ConceptNet	34,355	91.8%	1.00	1.00
	✍ ATOMIC	23,566	89.6%	1.00	1.00
	WebChild	812,862	58.1%	0.77	0.71
Few-shot LLMs	InstructGPT	-	72.7%	0.91	0.89
	ChatGPT	-	86.2%	0.90	0.88
	GPT-4	-	89.4%	0.87	0.84
NCs (GPT-2)	NC-XL	8,709,810	76.9%	0.64	0.58
	NC-L	4,354,905	84.4%	0.64	0.58
	NC-S	1,741,962	90.1%	0.65	0.59
NCs (Other LLMs)	NCs (LLaMA-7b)	77,798	90.0%	0.64	0.59
	NCs (InstructGPT)	16,300	83.8%	0.60	0.56
	NCs (ChatGPT)	10,756	88.6%	0.48	0.44
	NCs (GPT-4)	6,630	89.0%	0.52	0.48

Table 2: Size, human acceptance rates (on a 0.5k subset) and diversity measures, Self-BLEU-2 (SB2) and Self-BLEU-3 (SB3) for different comparatives. ✍ indicates human-authored comparatives. NCs generated from GPT-2 achieve a better trade-off between acceptance and diversity than generations from few-shot LLMs (no filtering); our filtered NCs from LLMs fare even better. Discriminative filtering of NeuroComparatives improves acceptance without hurting diversity.

We evaluate 500 randomly sampled comparatives from NC-XL, WebChild, ConceptNet, and ATOMIC. For evaluation of comparative knowledge extracted from GPT-3, ChatGPT, and GPT-4 without our framework (i.e., without any filtering), we obtain a sample of 500 completions to the same prompts used to generate the sampled NeuroComparatives (see Appendix C for additional discussion on the impact of filtering on ChatGPT and GPT-4). Human acceptance results are shown in Table 2 along with the size (total num. of comparatives) of different sources of comparative knowledge. While human-authored comparatives in ConceptNet and ATOMIC have the highest acceptance, these sources are the smallest in size, involved expensive human efforts and cannot be arbitrarily scaled. Among generated comparatives, NC-XL achieves nearly a 20% absolute improvement in human acceptance relative to WebChild, while containing over 10x more comparative knowledge. On average, few-shot prompting without filtering achieves lower acceptance than our NCs with the same LLMs, highlighting the benefits of our approach. NCs generated by LLaMA-7b achieved a similar human acceptance rate as that generated by GPT-2, suggesting that high-quality knowledge may be acquired from smaller-scale LMs.

Filtering Contradictions improves NeuroComparatives We conduct an ablation to study the impact of filtering contradictions on generating NeuroComparatives (§2.3.3). We obtain a sample of comparatives from GPT-2-XL without the contradiction filter. The overall acceptance rate of these comparatives is 69.1%, which is an absolute decrease of 7.8% compared to NC-XL, confirming the importance of contradiction filtration.

Impact of Discriminative Filtering Figure 3 and Table 2 show that NC-L, which includes only the top-50% of our generated knowledge, achieves an acceptance rate of 84.4%, a 7.5% absolute increase relative to NC-XL. The top-20% filtering used to produce NC-S improves the acceptance rate even further to 90.1%, which exceeds the acceptance of few-shot prompting with both ChatGPT and GPT-4 (without our filtering) and is on par with human-authored sources. At this level of filtering, NC-S is still over 2x larger than WebChild while having an approximately 32% absolute gain in human acceptance rate.

---

[8] This is an absolute evaluation scheme; relative comparisons of pairs of comparatives are somewhat unfair since the comparisons might be along different dimensions.

3.2 NeuroComparatives' Diversity

We report Self-BLEU (Zhu et al., 2018), using both bigrams (SB2) and trigrams (SB3), to compare the diversity of comparatives from different sources in Table 2. We randomly sample 500 entity pairs from WebChild containing at least 5 comparisons. For few-shot prompting with GPT-3, ChatGPT, and GPT-4, we use the same prompts (see §3.1) to obtain the top-5 generations for each entity pair. For each source, we compute Self-BLEU among the 5 candidates. Since the comparatives from ConceptNet and ATOMIC are limited to a single relation (size), measure of diversity doesn't apply. NC-XL and NC-L exhibit the greatest diversity, with a 31% reduction in Self-BLEU-3 relative to few-shot prompting with GPT-4. Crucially, knowledge discrimination does not impact the diversity of NC-S.

While NC-XL by design contain 5 comparisons for each pair of entities, the amount of comparative knowledge per entity pair in WebChild is heavily skewed: approximately 80% of the entity pairs have only 1 comparison and over 10k assertions comparing the entities "man" and "woman." WebChild is also heavily skewed towards a small number of frequently-occurring relations (e.g., "better"). We illustrate the skew in Figure 5 in Appendix D.1.

To further quantify the diversity of comparatives in NC-XL and WebChild, we consider identical relations from each source by considering unique comparative adjective phrases. We build a frequency-based probability distribution for relations in each source, and use it to compute their respective entropies— higher entropy indicates greater diversity of comparative relations. Our results show that the entropy of NC-XL is 7.9, which is 30% higher (indicating greater diversity) than the WebChild entropy of 6.1.

4 Downstream Task Performance

While NeuroComparatives are demonstratably diverse (§3.2), the impact on downstream task can be measured via their coverage on existing benchmarks. Here, we demonstrate NCs' wide knowledge coverage without compromising knowledge quality on three benchmarks.

To this end, we use two existing benchmarks: Elephant (Elazar et al., 2019) and Verb Physics Reannotated (Elazar et al., 2019, VPR). Elephant contains 486 comparisons of sizes of various transportation vehicles and animals. VPR reannotates VerbPhysics Forbes and Choi (2017) by filtering out the examples where the objects were not comparable, or the annotators disagreed among themselves. This re-annotation results in 2964 examples of object relations (1927 unique pairs of objects) along the dimensions of speed, length and mass.

The unstructured knowledge in NeuroComparatives facilitates easy integration with LLMs through natural language, therefore enabling the use of comparative reasoning abilities of LLMs. As there are no benchmarks for systematically evaluating the comparative reasoning capabilities, we constructed a new comparative reasoning QA benchmark, **ComparativeQA** to investigate this question. Specifically, we identified all comparatives that were unanimously assigned a label of 'True' by annotators in our human evaluation of validity experiments (§3.1). We then rephrased these comparatives as questions in order to construct a QA benchmark (see App. E.2). This produced a total of 656 comparative reasoning questions.

Finally, the COPEN dataset (Peng et al., 2022) is a benchmark for probing conceptual knowledge in pre-trained language models. Two tasks from COPEN (Conceptual Similarity Judgement and Conceptualization in Contexts) are related to our task of acquiring comparative knowledge. Therefore, we evaluate the benefit of our framework on these two additional downstream tasks.

4.1 Coverage on Elephant

We evaluated five different versions of NeuroComparatives that differed by model scale: NC-S generated from GPT-2 XL, NCs from LLaMA-2-7b, from GPT-3, from ChatGPT, and from GPT-4; all variants went through discriminative filtering. Because NeuroComparatives are generated without restrictions on the attribute used for comparison, only a subset of these comparisons are along the size dimension corresponding to the 486 comparisons in Elephant. We identify this subset via a simple string matching approach and filter out the remaining generations for this evaluation.

As shown in Table 3, GPT-4 NCs achieved nearly perfect exact match accuracy—98.7% express the correct size relationship according to the Elephant annotations, and higher overlap with the Elephant dataset. We observe a very clear trend that more capable models generate NCs with higher quality.

4.2 Coverage on VPR

We used our framework to generate NCs with the unique object pairs in VPR and additionally filtered

	Elephant		VPR	
NCs Source	**#Overlap**	**Acc. ↑**	**#Overlap**	**Acc. ↑**
NC-S (GPT-2 XL)	205	66.7%	869	66.7%
NCs (LLaMA-2-7b)	132	90.2%	760	71.2%
NCs (InstructGPT)	250	76.8%	1106	76.2%
NCs (ChatGPT)	189	97.9%	1090	88.2%
NCs (GPT-4)	226	**98.7%**	1351	**93.3%**

Table 3: Coverage (overlap) and accuracy of NCs on 486 examples in the Elephant dataset as well as 2964 examples in the VPR dataset.

LLaMA-2-7b Finetuning Source	**Acc. ↑**
None (5-shot)	60.7%
NC-S (GPT-2)	**91.0%**
NC-S (GPT-2 + ChatGPT + GPT-4)	**92.7%**
Reversed-NC-S	14.6%
WebChild	79.0%

Table 4: LLaMA-2-7b performance on comparative reasoning QA. fine-tuned on 50k sampled comparatives from various sources. All results are 5-shot.

them to contain comparisons only along speed, length, and mass using few-shot classification with Falcon-40b-instruct. We then used a BART-large model trained on MNLI to determine if a pair of NCs and VPR entail each other. Entailment means that our generated knowledge agrees with VPR used as ground truth (see Appendix E.1 for details).

In Table 3, we can see that GPT-4 NCs again achieved the best overall accuracy of 93.3% as well as the highest coverage, highlighting the value of large-scale models. On top of being accurate, our NCs generates much more diverse knowledge beyond these three evaluated attributes, not directly reflected in the results.

4.3 Results: ComparativeQA

We used a LLaMA-2-7b model for QA on our constructed ComparativeQA benchmark. As shown in Table 4, vanilla LLaMA-2-7b achieves only 60.7% accuracy on this dataset, using a prompt with five in-context examples. After finetuning LLaMA-2-7b for 3 epochs on a separate dataset of 50k QA comparatives sampled from NC-S from GPT-2, its accuracy on the test dataset increases to 91%. This is despite the lack of overlap between the entity pairs in the 50k NCs sampled for training and the test set. On additionally including 17k NC-S from ChatGPT and GPT-4 for finetuning, we see a further increase in validation accuracy to 92.7%.

As a control experiment, we finetuned on directionally reversed comparatives on the sampled NC-S. Finetuning on this set of incorrect comparatives degrades the accuracy of LLaMA-2-7b on the test set to 14.6%, highlighting the quality of our NCs. In addition, we also finetuned LLaMA-2-7b using a random sample of 50k comparatives from WebChild, and this results in an accuracy of 79%.

4.4 Results: COPEN Dataset

The Concept Similarity Judgment (CSJ) task from the COPEN dataset is related to a component of our framework which aims to identify entity pairs sharing common attributes. Specifically, our comparative prompt construction and filtering method (Section 2.1.4) implicitly performs a concept similarity judgment between pairs of entities. We therefore applied this approach to query and candidate entities in the CSJ test set, using our GPT2-XL length-penalized perplexity score of comparative prompts to identify the best candidate which matches the concept corresponding to each query.

In the zero-shot setting, we found that our approach produces a 19% relative improvement in the performance of GPT-2-XL on the development set (increasing from 11.3 to 13.44) and a 14% relative improvement on the test set (increasing from 11.7 to 13.3). Note that these results were obtained without any additional training of the model.

We also found that the Conceptualization in Contexts (CiC) task from the COPEN dataset can benefit from our approach. This task requires the model to identify the best concept for an entity in a context. The baseline performance of GPT-3.5-turbo-1106 in the zero-shot setting for this task is 40.9%. We used GPT-2-XL to generate NeuroComparatives among candidate concepts and used them as additional context in the prompt, which improved the accuracy of GPT-3.5-turbo-1106 to 42.8%. These results demonstrate the utility of our NeuroComparatives KB and knowledge acquisition framework for improving performance on downstream tasks without the need for additional model training.

5 Related Work

Comparative Knowledge: Despite the significance of comparative knowledge (Hofstadter and Sander, 2013), resources for the same are few and far between. Those that do exist have been collected almost exclusively via IE and data mining methods (Jindal and Liu, 2006; Cao et al., 2010; Jain and Pantel, 2011; Jang et al., 2012; Tandon et al., 2014, 2017; Elazar et al., 2019, i.a.), raising questions about coverage and diversity. Our approach is designed to address such issues via distilling knowledge from models at different scales. Most modern knowledge resources such as ATOMIC (Sap et al., 2019), VerbPhysics (Forbes and Choi, 2017) and DoQ (Elazar et al., 2019) may contain implicit comparisons via relationships between and properties of entities. A few knowledge resources involve explicit comparisons, but only along a few specific dimensions like physical properties (e.g. size (Bagherinezhad et al., 2016) or number (Narisawa et al., 2013)). Recently, Yu et al. (2023) collect data from structured and unstructured sources on specific real-world entities. Shivade et al. (2015) compare gradable lexical items, primarily adjectives and adverbs. In contrast, our NCs involve *explicit* comparisons between *nominal everyday concepts*, *without restrictions on the comparison dimensions*.

LM Knowledge Distillation: The ascendance of LLMs has begun to replace expensive, manually constructed knowledge bases due to their coverage benefits (AlKhamissi et al., 2022). LLMs have been used to create resources of factual knowledge (Petroni et al., 2019), structured knowledge graphs (Hao et al., 2022), instructions for further training (Wang et al., 2023) and training data for different tasks (Liu et al., 2022; Chakrabarty et al., 2022, *i.a.*). Our overgenerate and filter framework is inspired by West et al. (2021) who distill GPT-3 into a commonsense KG with a supervised critic. Our NCs focuses on *comparative knowledge* distilled from (among others) GPT-2 and LLaMA-2 with neuro-symbolic constrained decoding; Allaway et al. (2022) and Bhagavatula et al. (2022) use a related method to distill generics knowledge (Hampton, 2012) from GPT-2. Beyond knowledge distillation, neuro-symbolic constrained deocding with NeuroLogic has been applied to tasks such as counterfactual generation (Howard et al., 2022) and prompt engineering (Rosenman et al., 2023).

6 Conclusion

We demonstrate distillation of high-quality comparative knowledge from LMs at different scales and produce NeuroComparatives: the largest comparative knowledge corpus to date. NC-XL is 10x larger, 30% more diverse, and 19% more human acceptable than existing sources; with knowledge discrimination, we additionally achieve over 90% human acceptance. Our work highlights the value of comparative knowledge and exploits both neuro-symbolic manipulation of small-scale models and extreme-scale models for knowledge distillation. In our evaluations which demonstrated the utility of NeuroComparatives for downstream tasks, we primarily focused on comparative reasoning since it is most directly related to the knowledge we acquired. However, a promising direction for future research would be investigating other downstream tasks which can benefit from training on NeuroComparatives.

Limitations

NeuroComparatives is a collection of fully generated data with limited manual verification. Caution must be exercised around training and deploying models on such data, due to reasons outlined below.

While our work centers around distilling knowledge from language models, it is well known that language models generate misinformation as well as toxic content. The scale of generations in our paper makes it challenging to manually analyze each generation. We expect that our filtering stage (§2.3) and knowledge discriminator (§2.3.4) are able to filter out many contradictory statements, but the veracity of the filtered remainder is challenging to determine. It is conceivable that there remain some fallacies in the data. As our comparisons are designed to be restricted to be between physical objects (as our root seed entities), we avoid comparisons between animate entities and any toxic content that might be associated with such comparisons.

NeuroComparatives is a resource in English only. Further, we restricted our entities to be objects in the real world which are nouns. However, there could be many potentially useful comparisons among verbs and adjectives. Due to limited resources, we leave the investigation of those to future work.

A Additional Details on the Generation of NeuroComparatives

A.1 NeuroLogic Background

NeuroLogic accepts a series of constraints $D(\mathbf{a}, \mathbf{y})$ which are true iff '$\mathbf{a}$' appears in the generated sequence '$\mathbf{y}$'. where each constraint is a set of *clauses* $\{C_i \mid i \in 1, \cdots m\}$ consisting of one or more predicates in Conjunctive Normal Form (CNF):

$$\underbrace{(D_1 \vee D_2 \cdots \vee D_i)}_{C_1} \wedge \cdots \wedge \underbrace{(D_k \vee D_{k+1} \cdots \vee D_n)}_{C_m} . \tag{2}$$

Each constraint D might be positive or negative; $D(\mathbf{a}_i, \mathbf{y})$ is satisfied (i.e., evaluates as true) if $\mathbf{a}_i$ is present or absent, respectively, in $\mathbf{y}$

NeuroLogic employs a beam search approximation of an objective function which maximizes the probability of the generated sequence while penalizing deviations from m clauses:

$$\hat{\mathbf{y}}_t = \arg\max_{\mathbf{y} \in \mathcal{Y}} p_\theta(\mathbf{y}_t | \mathbf{y}_{<t}) - \lambda \sum_{j=1}^{m} (1 - C_j) \tag{3}$$

where $\lambda \gg 0$ penalizes deviations from the constraints.

Candidates are scored at each t per their (partial) satisfaction of the constraints:

$$f(\mathbf{y}_{\leq t}) = \log p_\theta(\mathbf{y}_{\leq t} | \mathbf{x}) + \lambda \max_{D(\mathbf{a}, \mathbf{y}_{\leq t})} \frac{|\hat{\mathbf{a}}|}{|\mathbf{a}|} \tag{4}$$

where $\hat{\mathbf{a}}$ represents a subsequence of $\mathbf{a}$ in the current generation. This has the effect of preferring candidates which at least partially satisfy multi-token constraints; for example, a generated sequence $\mathbf{y}_{\leq t}$ = "Compared to train tickets, airline tickets are generally more" would be rewarded for partially satisfying the constraint $\mathbf{a}$ = "more expensive" via its subsequence $\hat{\mathbf{a}}$ = "more".

Unlike the top-k selection strategy used in traditional beam search, NeuroLogic performs pruning, grouping, and selection steps to identify the best candidates which satisfy the given constraints. Specifically, candidates which irreversibly violate one or more constraints are pruned, and the remaining candidates are grouped according to their number of satisfied clauses in order to encourage diversity. The best candidate within each group is then selected according to the scoring function in Equation 4.

Auxiliary verbs	**Adverbs of frequency**
have	typically
need	often
may	always
are	generally
would	normally

Table 5: Positive constraint sets.

Each pass of NeuroLogic returns multiple generations, which are scored according to the sum of their length-penalized log probabilities:

$$\frac{1}{N^\alpha} \sum_{t=1}^{N} \log p_\theta(\mathbf{y}_t | \mathbf{y}_{<t})$$

where N denotes the length of the generated sequence $\mathbf{y}$ and α is a length penalty to encourage shorter generations (we use $\alpha = 0.1$). We refer to this score as as the S.

A.2 Constraint Sets for NeuroLogic

Table 5 provides the positive constraints used in NeuroLogic decoding. The table lists tokens used for two different positive constraint sets. For each of the 30 pairwise combinations of these auxiliary verbs and adverbs, we generate a completion of the prompt where the corresponding auxiliary verb and adverb is required to be present in the generation.

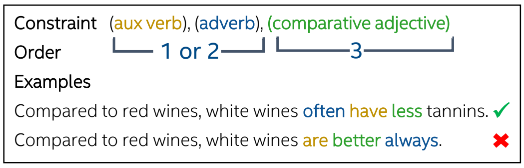
Prompt	**Aux. Verb**	**Adverb**
Compared to cherries, peaches ...	have	typically
Compared to cherries, peaches ...	have	often
Compared to cherries, peaches ...	have	always
⋮	⋮	⋮
Compared to cherries, peaches ...	would	normally

Table 6: Example of the prompt and 30 combinations of positive constraints for the entity pair (`cherries`, `peaches`).

An illustration of the prompt and the positive constraint combinations used to generate comparisons for an entity pair is provided in Table 6.

Table 5 provides the negative constraints used in NeuroLogic decoding.

We use GPT-2 XL as our language model, which has 1,542M parameters. For decoding with NeuroLogic, we use a beam size of 15, length penalty of 0.1, and an n-gram size of 3 for preventing repetitions. We use $\beta = 1.25$ as the reward factor for in-progress constraint satisfaction and set the



Compared to red wines, white wines often have less tannins. ✓

Compared to red wines, white wines are better always. ✗

Figure 4: Examples of generated comparatives which satisfy and violate our constraint ordering.

constraint satisfaction tolerance to 3, which means that only candidates which have a number of satisfied constraints within 3 of the maximum are kept at each step. The hyperparameters are manually curated. Please refer to Lu et al. (2021) for details on these hyperparameters.

Our experiments were conducted on a cluster with Nvidia RTX A6000 GPUs. We distributed the generation across 64 GPUs, with each GPU running 4 decoding iterations in parallel. The total compute time to generate our knowledge base in this environment was approximately 5 weeks.

A.3 Ordered Generation

We additionally modify NeuroLogic to handle ordered constraint satisfaction, for fine-grained control. For each clause C_i, we assign one or more order indices $m_i \in \{1, ..., m\}$ which correspond to the positional order in which clause C_i can appear in the generation. Specifying more than one order index allows a clause to appear in multiple different positions. Ordered constraint satisfaction provides more fine-grained control for generating valid comparatives, as illustrated in Figure 4.

B Details of knowledge discriminator model

We use 80% of the labeled data for training the knowledge discriminator and 20% for validation. We trained the knowledge discriminator on a Ubuntu 18.04 system with a single Nvidia RTX 3090 GPU. Specifically, we finetune RoBERTa-large previously trained on MNLI[9] using a learning rate of 5e-6, a batch size of 32, and a dropout probability of 0.1. Hyperparameters are manually curated. We train the model for a maximum of 50 epochs and monitor precision at recall $= 80\%$ on the validation set, terminating training if this metric fails to improve for 5 consecutive epochs. The total training time of the model was 13 minutes. Precision and recall on the validation set were 0.589 and 0.642, respectively.

C Details of experiments with InstructGPT, ChatGPT, and GPT-4

To compare our knowledge generations to InstructGPT, ChatGPT, and GPT-4, we use a prompt which instructs each model to complete a statement comparing two entities. The instruction is followed by five hand-crafted examples and the prefix that we want the model to complete in order to form a comparative knowledge statement. An example of the full prompt used to generate a comparative knowledge statement for the entity pair (computer keyboards, game controllers) is provided below.

Complete a statement which compares two entities.
Compared to blueberries, pineapples are heavier.
Compared to chairs, sofas are larger.
Compared to salad, pizza is less healthy.
Compared to a knife, a machete is more dangerious.
Compared to a bicycle, a skateboard is slower.
Compared to computer keyboards, game controllers

We use OpenAI's API with the text-davinci-001 model for InstructGPT, gpt-3.5-turbo-0613 for ChatGPT, and gpt-4-0613 for GPT-4 results. We use the default parameter settings for each model and evaluate human acceptance using the first generation returned for each prompt. For diversity evaluations, we utilize the first 5 generations returned by the API for each prompt.

D More on Evaluation

D.1 More on diversity of NeuroComparatives

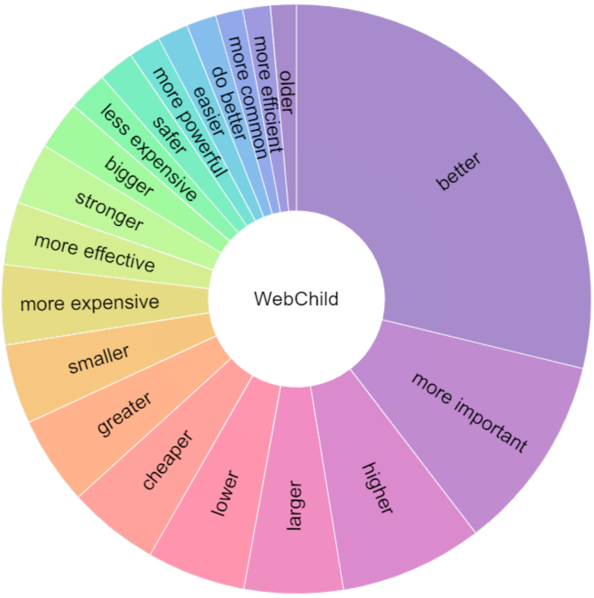
Figure 5 depicts the top-20 most frequent relations in each source, showing that the WebChild relations are more skewed, with its most-frequent relation ("better") representing over 12% of all relations. In contrast, the most frequent relation in NC-XL ("more expensive") represents only 4% of all relations. The most-frequent relations in NeuroComparatives are also generally more descriptive and less subjective than those in WebChild.

D.2 Crowdsourced evaluation details

Our crowdsourced evaluations utilized Amazon Mechanical Turk workers who were required to have completed at least 5,000 HITs, have a lifetime task acceptance rate $\geq 95\%$, and have achieved the 'Masters' qualification. A reward of \$0.07 was paid to the workers for each submitted label.

---

[9] `https://huggingface.co/roberta-large-mnli`



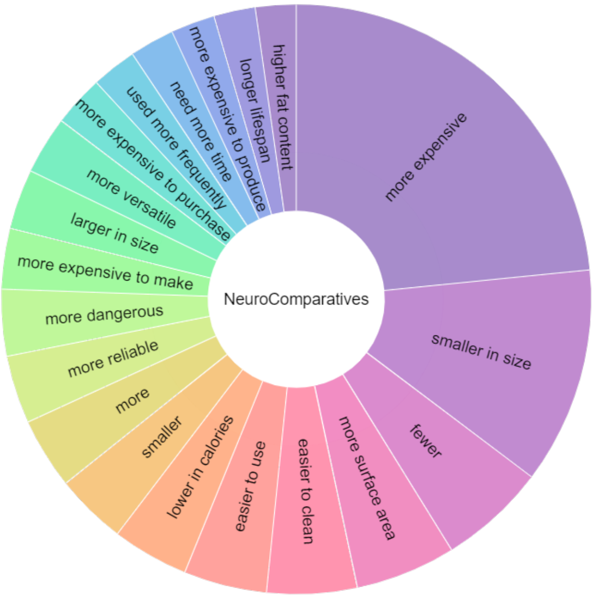


Figure 5: The distribution of the top-20 relations in WebChild is more skewed than NC-XL.

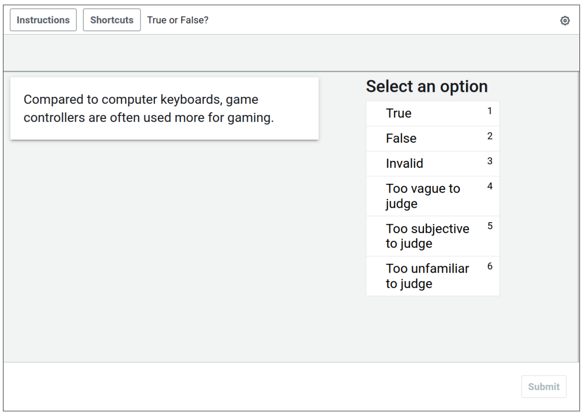

Compared to computer keyboards, game controllers are often used more for gaming.

Figure 6: Validity labeling interface for crowdsourced workers

To ensure that all sources of knowledge were evaluated in the same form, we transformed triples in WebChild into a comparative knowledge statement format. Specifically, we pluralized the head and tail entities of each triple using the `inflect` Python package and then formed a comparative knowledge statement using the following template: “Compared to {tail}, {head} {relation}”.

We provided the following set of instructions and examples to the workers.

D.3 Instructions

In this task, you will be given a sentence which compares two entities.

- Determine whether the comparison is true or false (or indicate that you cannot determine its truthfulness) by selecting one of the 6 options.
- If the sentence is incoherent or not a valid comparison, select "Invalid". Please be forgiving of spelling or grammatical errors and avoid labeling it as invalid if the sentence only has minor grammatical mistakes.
- If the comparison is too vague or requires additional information to determine its truthfulness, select "Too vague to judge".
- If the comparison is overly subjective or expresses a personal opinion which is not commonly held by most people, select "Too subjective to judge".
- If the terms are too obscure or you do not know the truth of the comparison, it is okay to select "Too unfamiliar to judge". If you can answer (e.g., based on likelihood), please provide a response.
- If a comparison in unjudgeable due to more than one of the above reasons, select the option corresponding to the primary reason it cannot be judged.

D.4 Examples

True: "Compared to homes, office buildings are more expensive to build."

False: "Compared to doctorates, master’s degrees are more difficult to obtain."

Invalid: "Compared to toothbrushes, utility knives may be less efficient at cleaning always on."

Explanation: It is unclear what being "less efficient at cleaning always on" means.

Too vague to judge: "Compared to text messages, video chats generally have higher levels."

Explanation: Higher levels of what? The comparison lacks details needed to determine its truthfulness.

Too subjective to judge: "Compared to french toast, pancakes are better."

Explanation: Although this comparison may be true for many people, it is a subjective opinion which varies substantially from person-to-person.

True: "Compared to frozen foods, fresh foods are healthier."

Explanation: While this comparison could also be considered an opinion, it is one which is widely held by most people and therefore should be labeled as True.

Too unfamiliar to judge: "Compared to gyroscopes, microelectromechanical systems may often provide better performance."

Explanation: I am too unfamiliar with "gyroscopes" and "microelectromechanical systems" to judge this comparison.

E Case Study

E.1 Verb Physics

Filtering Here is the prompt used for filtering:

> *Solve a textual classification task by having a Thought, then Finish with your answer. Thought can reason about the current situation. Finish[answer] returns the answer and finishes the task. There are 4 classes you need to decide among speed, length, mass, and others. Don't answer with anything else. Here are some examples:*
> *{FEW-SHOT EXAMPLES}*
> *(END OF EXAMPLES)*
> *Sentence:*

Some examples are manually labeled and annotated and put in the place of {FEW-SHOT EXAMPLES} above(refer to Tab. 7 for a complete list of few-shot examples). We make sure those examples are not in the final evaluation set.

Classification We then used a BART-large model trained on MNLI[10] to determine if a pair of NeuroComparatives and VPR entail each other. We perform this entailment classification twice—first using NeuroComparatives as the premise and VPR examples as hypothesis, and second with the premise and hypothesis reversed. To better illustrate how the NLI is done, here is a quick example of the entailment classification: (ENT1, ENT2, length, 1) is one example in VPR where length means this is a comparison of length and 1 means ENT1 is longer than ENT2. Then we set the NeuroComparatives generated with this entity pair as the premise, and [‘ENT1 is longer than ENT2’, ‘ENT1 is shorter than ENT2’] as the hypothesis. Then entailment classification is run with each hypothesis and get respective entailment probability. The hypothesis with higher entailment probability out of the two is chosen as the predicted entailment. If this predicted entailment complies with the original VPR example, we say our NeuroComparatives and the example in VPR entail each other, otherwise not. E.g., if ‘ENT1 is longer than ENT2’ has higher entailment probability, that means we our the example in the VPR is an entailment to our NeuroComparatives. This same process is done a second time but with premise being the example in VPR and hypothesis being our VPR (we just reverse the entities in our NeuroComparatives to get the counterfactual hypothesis). We count our NeuroComparatives as conformed / agreed by VPR if either of these two evaluations result in an entailment. Overall, we find that NeuroComparatives have a 66.7% entailment rate in this study, which is consistent with our previous analysis on the accuracy of matching NeuroComparatives to the Elephant dataset (§4.1).

E.2 Comparative Reasoning QA

Here is an example of the QA transformation from comparative data:

> ***Comparative:***
> *Compared to graham crackers, kiwifruits can be considered healthier",*
> ***QA Format:***
> *Question: Which of the following can be considered healthier?*
> *A. graham crackers*
> *B. kiwifruits*
> *Answer: B*

---

[10] `https://huggingface.co/facebook/bart-large-mnli`

F Terms and Licenses

We use all of the datasets and models the way it is intended to be used if specified. For the ComparativeQA dataset we release, we intend its use for research only.

Few-shot Examples for Dimension Classification

Sentence: Compared to boats, trains are typically a lot slower.
Thought: Let's think step by step. we can analyze the words and their context to determine the appropriate class. In this case, the sentence compares the speed of boats and trains, implying that the class we should assign is "speed."
Action: Finish[speed]

Sentence: Compared to cars, horses are often considered less practical.
Thought: Let's think step by step. "Less practical" specifically refers to the practicality of horses in comparison to cars. We can conclude that the appropriate class for this sentence is "practicality," as it discusses the comparative practicality of horses compared to cars. However, practicality is not one of the 4 classes (speed, length, mass, and others) we are supposed to choose from. Therefore, we should assign the class "others" to this sentence.
Action: Finish[others]

Sentence: Compared to chins, heads often have more muscle mass.
Thought: Let's think step by step. "More muscle mass" specifically refers to the muscle mass of heads in comparison to chins. Considering all these factors, we can conclude that the appropriate class for this sentence is "mass," as it discusses the comparative muscle mass of heads compared to chins.
Action: Finish[mass]

Sentence: Compared to fingers, arms are always longer. Thought: Let's think step by step. "Longer" specifically refers to the length of arms in comparison to fingers. Considering all these factors, we can conclude that the appropriate class for this sentence is "length," as it discusses the comparative length of arms compared to fingers.
Action: Finish[length]

Sentence: Compared to dresses, purses can typically hold more goods.
Thought: Let's think step by step. "smaller" specifically refers to the size or dimensions of purses in comparison to dresses. Considering all these factors, we can conclude that the appropriate class for this sentence is "size" or "dimensions," as it discusses the comparative size of purses compared to dresses.
Action: Finish[length]

Table 7: Few-shot examples used to classify NeuroComparatives into 4 dimensions: speed, length, mass and others.

Comparative Adjectives
littler, denser, sweeter, dumber, itchier, rawer, skinnier, righter, bloodier, harder
wider, creepier, cheaper, sorrier, sillier, hairier, odder, worthier, idler, cooler
higher, sourer, softener, unhappier, sadder, stingier, hotter, busier, slimmer, narrower
subtler, sharper, shorter, sparser, lesser, needier, drier, greasier, pricklier, neater
lighter, cuter, shyer, sweatier, floppier, shadier, fitter, lazier, crazier, muddier
purer, sooner, nearer, fresher, further, louder, chubbier, whiter, crueler, thirstier
slighter, flakier, clumsier, greener, rougher, fatter, prettier, calmer, damper, politer
fiercer, messier, darker, poorer, lovelier, lower, handier, steeper, deadlier, jointer
greedier, cleverer, steadier, headier, blunter, blander, outer, younger, dirtier, wiser
direr, graver, greater, riper, milder, noisier, likelier, meaner, sneakier, unlikelier
tougher, upper, angrier, stronger, shinier, stricter, smoother, fuzzier, tenther, sorer
classier, fairer, gentler, brighter, trickier, grainier, looser, harsher, extremer, grander
juicier, guiltier, colder, ruder, tighter, sunnier, newer, stickier, wealthier, crankier
quicker, dustier, trendier, cleaner, rosier, richer, braver, prouder, shaggier, earlier
larger, lengthier, windier, fonder, sleepier, heartier, bluer, filthier, worser, taller
worse, spicier, heavier, quirkier, stockier, scarier, creamier, roomier, smarter, curlier
clearer, goofier, hardier, breezier, grosser, laster, firmer, mushier, quieter, chewier
plainer, jumpier, lonelier, madder, touchier, readier, smokier, mightier, bitterer, sexier
unhealthier, snowier, wilder, norther, closer, later, saner, crispier, flatter, nastier
deeper, briefer, finer, smaller, cozier, hungrier, curvier, tastier, bigger, happier
smellier, faster, simpler, easter, tinier, kinder, fainter, thinner, blacker, bolder
funnier, holier, weightier, poppier, sturdier, nobler, livelier, hipper, duller, fuller
slower, cloudier, rustier, rarer, wetter, coarser, better, leaner, firer, crunchier
gloomier, speedier, abler, riskier, warmer, blanker, soggier, nicer, keener, moister
shallower, yellower, stranger, weirder, stiffer, stupider, lousier, humbler, friendlier
stealthier, straighter, softer, bossier, icier, fancier, broader, uglier, nexter, loftier, naughtier
scarcer, worldlier, tanner, luckier, sincerer, bulkier, oilier, easier, warier, healthier
earthier, wobblier, less, more, choppier, swifter, longer, saltier, truer, weaker
older, fussier, steepler, fewer, safer, slimier, fattier, chillier, thicker, nimbler

Abstract

Emotion Recognition in Conversation (ERC) involves detecting the underlying emotion behind each utterance within a conversation. Effectively generating representations for utterances remains a significant challenge in this task. Recent works propose various models to address this issue, but they still struggle with differentiating similar emotions such as excitement and happiness. To alleviate this problem, We propose an **E**motion-**A**nchored **C**ontrastive **L**earning (EACL) framework that can generate more distinguishable utterance representations for similar emotions. To achieve this, we utilize label encodings as anchors to guide the learning of utterance representations and design an auxiliary loss to ensure the effective separation of anchors for similar emotions. Moreover, an additional adaptation process is proposed to adapt anchors to serve as effective classifiers to improve classification performance. Across extensive experiments, our proposed EACL achieves state-of-the-art emotion recognition performance and exhibits superior performance on similar emotions. Our code is available at https://github.com/Yu-Fangxu/EACL.

1 Introduction

Emotion Recognition in Conversation (ERC) aims to identify the emotions of each utterance in a conversation. It plays an important role in various scenarios, such as chatbots, healthcare applications, and opinion mining on social media. However, the ERC task faces several challenges. Depending on the context, similar statements may exhibit entirely different emotional attributes. Simultaneously, distinguishing conversation texts that contain similar emotional attributes is also extremely difficult (Ong et al., 2022; Zhang et al., 2023a). Figure 1 is an example of a chat between a man and a woman. Differentiating between *happy* and *excited* can be challenging for machines due to their frequent occurrence in similar contexts. Appendix A exhibits quantitative analysis for emotions. This requires the model to accurately distinguish different emotions based on the context.

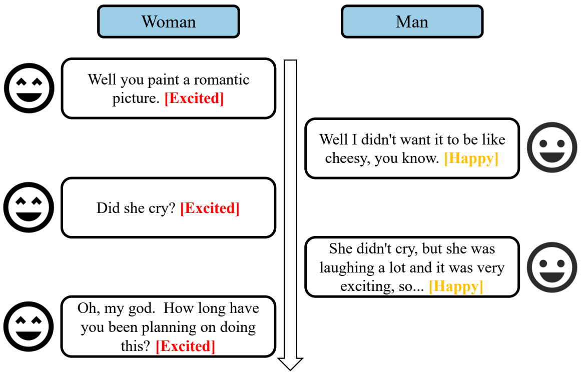

Figure 1: An example of a conversation in the IEMOCAP dataset.

Therefore, abundant efforts have been made implicitly to obtain distinguishable utterance representations from two lines, model design and representation learning. As the representative of the former line, DialogueRNN (Majumder et al., 2019) designs recurrent modules to track dialogue history for classification. Representation learning methods primarily exploit supervised contrastive learning (SupCon) (Khosla et al., 2020) for learning utterance representations. SPCL (Song et al., 2022) proposes a prototypical contrastive learning method to alleviate the class imbalance problem and achieve state-of-the-art performance. Our preliminary fine-grained experimental results for SPCL, as shown in Figure 2, use the normalized confusion matrix to evaluate the prediction performance. The findings reveal that similar emotions such as *happy* and *excited* are frequently misclassified as each other. This suggests that SPCL still struggles with effectively differentiating similar emotoins.

To tackle the aforementioned issues, this paper

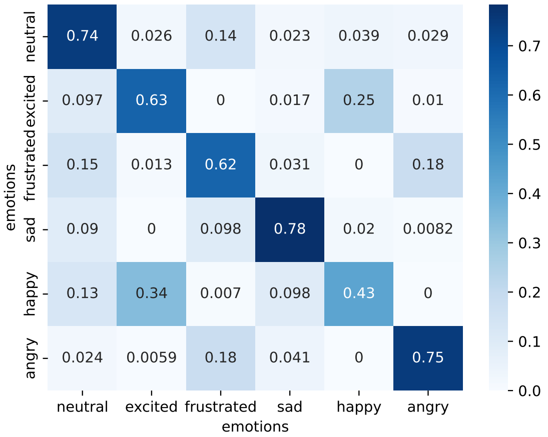

Figure 2: Normalized confusion matrix of SPCL on the IEMOCAP dataset. The rows and columns represent the actual classes and predictions made by the model respectively. The cross-point (i, j) means the percentage of emotion i predicted to be emotion j. Except for the diagonal, the bigger values and deeper color mean these emotions are easily misclassified.

presents a novel **E**motion-**A**nchored **C**ontrastive **L**earning framework (EACL). EACL utilizes textual emotion labels to generate anchors that are emotionally semantic-rich representations. These representations as anchors explicitly strengthen the distinction between similar emotions in the representation space. Specifically, we introduce a penalty loss that encourages the corresponding emotion anchors to distribute uniformly in the representation space. By doing so, uniformly distributed emotion anchors guide utterance representations with similar emotions to learn larger dissimilarities, leading to enhanced discriminability. After generating separable utterance representations, we aim to compute the optimal positions of emotion anchors to which utterance representations can be assigned for classification purposes. To achieve better assignment, inspired by the two-stage frameworks (Kang et al., 2019; Menon et al., 2020; Nam et al., 2023), we propose the second stage to shift the decision boundaries of emotion anchors with fixed utterance representations and achieve better classification performance, which is simple yet effective.

We conduct experiments on three widely used benchmark datasets, the results demonstrate that EACL achieves a new state-of-the-art performance. Moreover, EACL achieves a significantly higher separability in similar emotions, which validates the effectiveness of our method.

The main contributions of this work are summarized as follows:

- We propose a novel emotion-anchored contrastive learning framework for ERC, that can generate more distinguishable representations for utterances.
- To the best of our knowledge, our method is the first to explicitly alleviate the problem of emotion similarity by introducing label semantic information in modeling for ERC, which can effectively guide representation learning.
- Experimental results show that our proposed EACL achieves a new state-of-the-art performance on benchmark datasets.

2 Related Work

2.1 Emotion Recognition in Conversation

Most of the present works adopt graph-based and sequence-based methods. DialogueGCN (Ghosal et al., 2019) builds a graph treating utterances as nodes, and models intra-speaker and inter-speaker relationships by setting different edge types between two nodes. MMGCN (Hu et al., 2021b) fuses multi-modal utterance representations into a graph. Differently, DAG-ERC (Shen et al., 2021) exploits directed acyclic graphs to naturally capture the spatial and temporal structure of the dialogue. COGMEN (Joshi et al., 2022) combines graph neural network and graph transformer to leverage both local and global information respectively.

Another group of works exploits transformers and recurrent models to learn the interactions between utterances. DialogueRNN (Majumder et al., 2019) combines several RNNs to model dialogue dynamics. DialogueCRN (Hu et al., 2021a) introduces a cognitive reasoning module. Commensense Knowledge is explored by KET (Zhong et al., 2019) and COSMIC (Ghosal et al., 2020). Cog-BART (Li et al., 2022a) employs BART (Lewis et al., 2019) to simultaneously generate responses and detect emotions with the auxiliary of contrastive learning. EmoCaps (Li et al., 2022c) and DialogueEIN (Liu et al., 2022) design several modules to explicitly model emotional tendency and inertia, local and global information in dialogue. The power of the language models is utilized by CoMPM (Lee and Lee, 2021) which learns and tracks contextual information by the language model itself and SPCL (Song et al., 2022), a prototypical supervised contrastive learning method to alleviate the data imbalance problem.

SACL (Hu et al., 2023)introduces adversarial examples to learn robust representations. Our EACL goes along this track. Unlike the above approaches, HCL (Yang et al., 2022) comes up with a general curriculum learning paradigm that can be applied to all ERC models. InstructERC (Lei et al., 2023) and DialogueLLM (Zhang et al., 2023c) construct instructions and fine-tune LLMs for ERC. (Lee, 2022; Guo et al., 2021) learn from soft labels.

2.2 Supervised Contrastive Learning

Recent works (Chen et al., 2020; He et al., 2020a) in unsupervised contrastive learning provide a similarity-based learning framework for representation learning. These methods maximize the similarity between positive samples while minimizing the similarity between negative sample pairs. To make use of supervised information, supervised contrastive learning (SupCon) (Gunel et al., 2020) aims to make the data that have the same label closer in the representation space and push away those that have different labels. However, SupCon works poorly in data imbalance settings. To mitigate this problem, KCL (Kang et al., 2021) explicitly pursues a balanced representation space. TSC (Li et al., 2022b) uniformly set targets in the hypersphere and enforce data representations to close to the targets. BCL (Zhu et al., 2022) regards classifier weights as prototypes in the representation space and incorporates them in the contrastive loss. LaCon (Zhang et al., 2022) incorporates label embedding for better language understanding. Our method is inspired by TSC, differently, we incorporate emotion semantics in the representation space and dynamically adjust the emotion anchors for better classification.

3 Methodology

3.1 Problem Definition

A conversation can be denoted as a sequence of utterances $\{u_1, u_2, u_3, ..., u_n\}$, each utterance u_t is uttered by one of the conversation speakers s_j. There are $m \quad (m \geq 2)$ speakers in the conversation, denoted as $\{s_1, s_2, ..., s_m\}$. Given the set of emotion labels $\mathcal{E}$ and conversation context $\{(u_1, s_{u_1}), (u_2, s_{u_2}), ..., (u_t, s_{u_t})\}$, the ERC task aims to predict emotion $e_t (e_t \in \mathcal{E})$ for current utterance u_t. $\mathcal{E}$ is a set of emotions. For instance, in the IEMOCAP dataset, $\mathcal{E}$ = {*excited*, *frustrated*, *sad*, *neutral*, *angry*, *happy*}.

3.2 Model Overview

The overview of our model is shown in Figure 3. The encoding strategy of our model adopts the paradigm of prompt learning (Section 3.3). Our training process is composed of two stages.

The first stage (Section 3.4) is called representation learning, which aims to learn more distinctive representations with emotion anchors. Concretely, we incorporate anchors containing semantic information into the contrastive learning framework and utilize them to guide the learning of utterance representations. Our objectives are (1) to bring utterances with the same emotion closer to their corresponding anchors and push utterances with different emotions farther away, and (2) to achieve a more uniform distribution of anchors in the hyperspace for better classifying different emotions.

The second stage (Section 3.5) is called emotion anchor adaptation, which aims to further improve classification performance by slightly adjusting anchors. The anchors in the first stage can help the model learn separable representations of utterances. However, separated emotion anchors may not be located in the most representative positions of each category of utterance representation for the following emotion recognition because contrastive learning in the first stage aims not to achieve this goal. Therefore, we design the second stage to slightly adjust the positions of emotion anchors to shift the decision boundaries for better classification performance. In this stage, we freeze the parameters of the language model and only fine-tune the emotion anchors, as shown on the right side of Figure 3. Lastly, EACL matches the utterance representations with the most similar emotion anchors to make predictions.

3.3 Prompt Context Encoding

Following previous work (Song et al., 2022), we employ pre-trained language models and adopt prompt tuning to transform the classification into masked language modeling. An effective prompt template aligns the downstream task with the large semantic information learned by the language model in the pre-training stage, which boosts the model's performance in downstream tasks.

To predict the emotion of utterance u_t, we take k utterances before timestamp t as the context to predict e_t. Formally, the input for the language model is composed as:

$$x_t = [s_{t-k}, u_{t-k}, \ldots, s_t, u_t, Prompt] \quad (1)$$

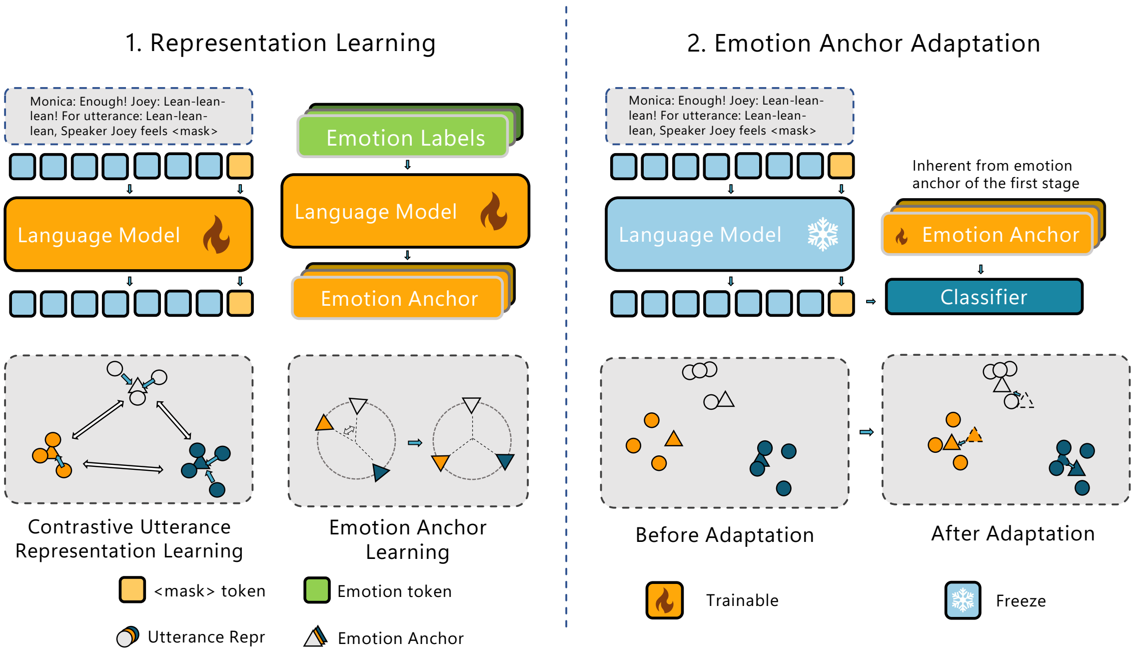

Figure 3: Overview of our proposed framework. **Left side** introduces representation learning, which is composed of utterance representation and emotion anchor learning. **Right side** describes the process of adapting emotion anchors to the optimal positions for classification.

where Prompt P = "For utterance u_t, speaker s_t feels [mask]" . We take the last hidden state of [mask] as utterance representation.

3.4 Stage One: Representation Learning

In this section, we will introduce two main components of EACL in stage one: utterance representation learning and emotion anchor learning.

3.4.1 Utterance Representation Learning

The objective in this section is to acquire discernible representations for each individual utterance. To accomplish this, we employ label encodings to generate emotion anchors and incorporate them into a contrastive learning framework. By utilizing these anchors, we can proficiently steer the process of representation learning.

Given a batch of samples $\mathcal{X} = \{x_1, x_2, \ldots, x_b\} \in \mathbb{R}^{b \times \ell}$, where b, ℓ are batch size and max length of input respectively. We feed $\mathcal{X}$ into the pretrained language model and get the last hidden states $\mathcal{Z} = \mathrm{Encoder}(\mathcal{X})$. Then we use the hidden state of [mask] token at the end of the sentence as the representation of utterance u_t. Finally, we obtain the representations of utterances with an MLP layer:

$$\mathcal{R} = \mathrm{MLP}_{cl}(\mathcal{Z}_{[mask]}) \tag{2}$$

where $\mathcal{R} = \{r_1, r_2, \ldots, r_b\}$ and $\mathcal{R} \in \mathbb{R}^{b \times d}$, d is dimension of the encoder.

Similarly, we take textual emotion labels as the input of language models to obtain emotion anchors for all emotions $\mathcal{E} = \{e_1, e_2, \ldots, e_s\}$:

$$\begin{aligned} \mathcal{Z}^a &= \mathrm{Encoder}(\mathcal{E}) \\ \mathcal{A} &= \mathrm{MLP}_{cl}(\mathcal{Z}^a) \end{aligned} \tag{3}$$

where $\mathcal{A} \in \mathbb{R}^{s \times d}$, each row of which represents a emotion anchor. s represents the number of emotions. To ensure we get a stable anchor representation, $\mathcal{Z}_a$ is frozen in our training process.

We propose an emotion-anchored contrastive learning loss to utilize emotion label semantics for better representation learning. More specifically, in each mini-batch, we let $\mathcal{V} = \{v_1, v_2, \ldots, v_{b+s}\} = \mathcal{R} \cup \mathcal{A}$ and $\mathcal{V}_i^+$ represents the set of utterances or anchor representation that have the same label as utterance r_i except for itself. Finally, our emotion-anchored contrastive loss is as follows:

$$\begin{aligned} c_{ij} &= \mathrm{sim}(v_i, v_j)/\tau \\ \mathcal{L}_{sup} &= \sum_{i=1}^{s+b} -\log \frac{\sum_{v_j \in \mathcal{V}_i^+} e^{c_{ij}}}{|\mathcal{V}_i^+| \sum_{v_j \in \mathcal{V}} e^{c_{ij}}} \end{aligned} \tag{4}$$

where $|\mathcal{V}_i^+|$ represents number of positive examples. τ is the temperature hyperparameter for the contrastive loss. sim represents a similarity function, we adopt cosine similarity here.

In equation 4, the interactions between representations can be divided into three components: utterances-utterances, anchors-utterances, and anchors-anchors. Representations with the same label are brought closer to each other, while those with different labels are pushed farther apart. The utterances-utterances interactions are similar to traditional contrastive learning, while the anchors-utterances interactions represent the process of anchor-guided utterance representation learning. The anchors-anchors interaction ensures a better distinction between different emotions.

Recent research (Gunel et al., 2020) has indicated that combining cross-entropy loss with contrastive learning facilitates language models with more discriminative ability. Therefore cross-entropy loss is added to help improve representation learning. We additionally add a linear mapping for classification:

$$\hat{\mathcal{Y}} = \mathrm{softmax}(\mathrm{MLP}_{\mathrm{ce}}(\mathcal{Z}_{[mask]})) \tag{5}$$

$$\mathcal{L}_{CE} = -\frac{1}{b}\sum_{i=1}^{b}\sum_{j=1}^{s} y_{ij}\log \hat{y}_{ij} \tag{6}$$

where $\hat{\mathcal{Y}} \in \mathbb{R}^{b \times s}$ represents the possibility distribution of b utterances over s emotions. y_{ij} represents the element in the i-th row and j-th column of $\hat{\mathcal{Y}}$. MLP_{ce} is a linear layer for classification.

3.4.2 Emotion Anchor Learning

Nevertheless, despite the implementation of the interaction between representations, the three types of interactions mentioned in Section 3.4.1 alone are insufficient to explicitly disperse the distance between the most similar emotion anchors. To further tackle the issue of similarity, we propose an anchor angle loss. This loss is designed to incentivize emotion anchors to maximize the angle between themselves and their most similar emotion anchors within the contrastive space:

$$\mathcal{L}_{Ag} = -\frac{1}{s}\sum_{i=1}^{s}\min_{j,i\neq j}\arccos\frac{\langle a_i, a_j\rangle}{\|a_i\|\|a_j\|} \tag{7}$$

where a_i represents i-th emotion anchor representation in $\mathcal{A}$.

$\mathcal{L}_{Ag}$ aims to minimize the maximal pairwise cosine similarity between all the emotion anchors. It is equivalent to maximizing the minimal pairwise angle. The more dispersed emotion anchors are, the better their capacity to recognize similar emotions.

Combining all the components mentioned in stage one, the overall loss is a weighted average of cross-entropy loss, anchor angle loss, and contrastive loss, as given in equation 8.

$$\mathcal{L} = \lambda_1(\mathcal{L}_{sup} + \lambda_2\mathcal{L}_{Ag}) + (1-\lambda_1)\mathcal{L}_{CE} \tag{8}$$

where λ_1 and λ_2 are hyper-parameters to balance loss terms.

3.5 Stage Two: Emotion Anchor Adaptation

In the first stage, we used emotion anchors generated from emotion labels to guide the convergence of utterance representations toward different emotion clusters. These emotion anchors serve as representatives for each emotion, which are suitable to function as effective nearest-neighbor classifiers for utterance representations. However, separated emotion anchors trained from stage one may not be located in the most representative positions of each category of utterance representation, which weakens the classification ability of emotion anchors. To ensure the alignment between utterance representations and emotion anchors, we propose the second stage to adapt the emotion anchors to shift the decision boundaries by training them with a small number of epochs. This approach aims to enhance the ability of emotion anchors for classification purposes.

To be more specific, we freeze the parameters of the language model and make the emotion anchors inherited from stage one $a_i (i = 1, ..., s)$ trainable parameters, which corresponds to the right side in Figure 3. In order to be consistent with the representation learning, we still use the same similarity measure for adapting emotion anchors.

The loss function for emotion anchor adaptation:

$$\begin{aligned} c_{ij} &= \mathrm{sim}(r_i, a_j)/\tau \\ \mathcal{L}_{ada} &= -\frac{1}{b}\sum_{i=1}^{b}\sum_{j=1}^{s} y_{ij}\log \hat{y_{ij}} \\ &= -\frac{1}{b}\sum_{i=1}^{b}\sum_{j=1}^{s} y_{ij}\log\frac{e^{c_{ij}}}{\sum_{k=1}^{s} e^{c_{ik}}} \end{aligned} \tag{9}$$

where c_{ij} means adjusted cosine similarity between the i-th utterance representation r_i and j-th emotion anchors a_j. τ is the same temperature hyper-parameter in stage one.

3.6 Emotion Prediction

During the inference stage, we predict emotion labels by matching each utterance representation with the nearest emotion anchor:

$$\hat{y}_i = \arg\max_j \operatorname{sim}(r_i, a_j) \tag{10}$$

Where r_i is the representation of utterance x_i and a_j is the emotion anchor of class j.

4 Experiments

4.1 Experimental setup

The language model loads the initial parameter with SimCSE-Roberta-Large (Gao et al., 2021). All experiments are conducted on a single NVIDIA A100 GPU 80GB and we implement models with PyTorch 2.0 framework. More experimental details are provided in Appendix B.

4.2 Datasets

In this section, we will introduce three adopted popular benchmark datasets: IEMOCAP (Busso et al., 2008), MELD (Poria et al., 2018) and EmoryNLP (Zahiri and Choi, 2017).

(1) **IEMOCAP**: consists of 151 videos of two speakers' dialogues with 7433 utterances. Each utterance is annotated by an emotion label from 6 classes, including *excited*, *frustrated*, *sad*, *neutral*, *angry*, and *happy*.

(2) **MELD**: is extracted from the TV show Friends. It contains about 13000 utterances from 1433 dialogues. Each utterance is labeled by one of the following 7 emotion labels: *surprise*, *neutral*, *anger*, *sadness*, *disgusting*, *joy*, and *fear*.

(3) **EmoryNLP**: contains 97 episodes, 897 scenes, and 12606 utterances from TV show Friends. It differs from MELD in that the emotional tags contained are: *joyful*, *sad*, *powerful*, *mad*, *neutral*, *scared*, and *peaceful*.

In our experiments, we only use textual modality. The detailed statistics of the three datasets are shown in Table 1.

Dataset	Dialogues			Utterances			CLS
	train	dev	test	train	dev	test	
IEMOCAP	100	20	31	4810	1000	1623	6
MELD	1038	114	280	9989	1109	2610	7
EmoryNLP	659	89	79	7551	954	984	7

Table 1: Statistics of the three datasets, where CLS is the number of classes.

4.3 Metrics

Following previous works (Lee and Lee, 2021; Song et al., 2022), we choose the weighted-average F1 score as the evaluation metric.

4.4 Baselines

For a comprehensive evaluation, we compare our method with the following baselines:

(1) Graph-based model: **DialogueGCN (Ghosal et al., 2019)** employs GCNs to gather context features for learning utterance representations, Shen (Shen et al., 2021) shows the performance of replacing the feature extractor with Roberta-Large. **RGAT (Ishiwatari et al., 2020)** proposes relational position encodings to model both speaker relationship and sequential information. **DAG-ERC (Shen et al., 2021)** utilizes an acyclic graph neural network to intuitively model a conversation's natural structure without introducing any external information. **DAG-ERC+HCL (Yang et al., 2022)** proposes a curriculum learning paradigm combined with DAG-ERC for learning from easy to hard. **SIGAT (Jia et al., 2023)** models speaker and sequence information in a unified graph to learn the interactive influence between them.

(2) Sequence-based model: **COSMIC (Ghosal et al., 2020)** incorporates different elements of commonsense and leverages them to learn self-speaker dependency. **Cog-BART (Li et al., 2022a)** applies BART with contrastive learning to take response generation into consideration. **DialogueEIN (Liu et al., 2022)** designs emotion interaction and tendency blocks to explicitly simulate emotion inertia and stimulus. **CoMPM (Lee and Lee, 2021)** utilizes pretrained models to directly learn contextual information and track dialogue history. **SupCon (Gunel et al., 2020)** is the vanilla supervised contrastive learning. **SCCL (Yang et al., 2023)** conducts contrastive learning with 3-dimensional affect representations. **DIEU (Zhao et al., 2023a)** aims to solve the long-range context propagation problem. **CKCL (Tu et al., 2023)** denoises information irrelevant context and knowledge when training. **MPLP (Zhang et al., 2023b)** models the history and experience of speakers and exploits paraphrasing to enlarge the difference between labels. **Emocaps (Li et al., 2022c)** devises transformer to a novel architecture, Emoformer,

5 Results and Analysis

5.1 Main Results

Table 2 reports the results of our method and the baselines. Our model outperforms other baselines and achieves a new state-of-the-art performance on IEMOCAP, MELD, and EmoryNLP datasets. The results exhibit the effectiveness of our emotion-anchored contrastive learning framework.

Based on the results, we can observe that sequence-based methods have overall better performance than graph-based methods. Compared to the graph-based models, EACL improves a large margin over the DAG-ERC (Shen et al., 2021) which is the state-of-the-art graph-based method without introducing extra knowledge by 2.38%, 3.57%, and 1.22% on three benchmark datasets.

Compared to sequence-based methods, EACL outperforms two contrastive learning methods, SACL and SPCL+CL by a large margin. Specifically, SPCL's use of a queue for storing class representations and prototype generation from small batches results in unstable representation learning. Significant movement of prototypes that undergo during training and the asynchronous update of queue representations with the language model's parameters lead to suboptimal utterance represen-

Dataset	IEMOCAP	MELD	EmoryNLP

Table 4: Ablation results on benchmark datasets.

tations. EACL outperforms the state-of-the-art results on the IEMOCAP dataset by 0.92%, the MELD dataset by 0.6%, and the EmoryNLP dataset by 0.59%. Besides, EACL has an overwhelming performance advantage over ChatGPT, one possible reason is that the few-shot prompt setting may not be enough to achieve satisfactory performance.

Table 3 reports the fine-grained performance on benchmark datasets. EACL outperforms SPCL+CL which is the most relevant method to us in most emotion categories on all benchmark datasets. Specifically, in the IEMOCAP dataset, We have observed a significant improvement in performance on two pairs of similar emotions, *happy* and *excited* with an increase of 7.33% and 4.55%, *frustrated* and *angry* with an increase of 3.80% and 2.72% respectively. Detailed performance analysis is provided in Appendix C.

5.2 Ablation Study

We conduct a series of experiments to confirm the effectiveness of components in our method. The results are shown in Table 4. Removing any element of EACL makes the overall performance worse.

To validate the effects of components in the first stage, We remove the $\mathcal{L}_{Ag}$ which encourages the angle of different emotion anchors to be uniform. We can find that the lack of $\mathcal{L}_{Ag}$ results in a significant decline in the performance of nearly 0.5%, as reported in line 2 in Table 4, indicating that emotion anchor learning helps for separating utterance representations. Also, the removal of $\mathcal{L}_{CE}$ drops the performance by about 0.5% on average, the result demonstrates that supervised learning benefits the fine-tuning of language models.

In the second stage, We explore whether adapting emotion anchors and emotion semantics are necessary. Similar to classifier re-training (Kang et al., 2019; Nam et al., 2023), we randomly initialize emotion anchors that lie far from the data distribution after learning the utterance representations. Training from scratch is a cold start and cannot reach the optimal position. This result in Line 4 verifies the importance of inheriting emotion anchors and the result shows that the trained emotion anchors express a more powerful ability of recognition. When we remove the anchor adaptation or take the center of training representations for each emotion category as emotion anchors, performance will degrade significantly, indicating the improper positions of emotion anchors weaken the classification performance and verifying the importance of stage two. Lines 5 and 6 in Table 4 confirms our assumption. In summary, the components of our method contribute to the results substantially.

Promcse-Roberta-Large	**70.45**	67.38	40.93

Table 5: Performance under different language models.

5.3 Performance on Different Language Models

To evaluate the versatility of our learning framework, we conducted experiments using different pretrained language models. Specifically, we examined the performance of our framework on two additional popular language models, namely Deberta-Large (He et al., 2020b) and Promcse-Roberta-Large (Jiang et al., 2022). The results, presented in Table 5, demonstrate that all the pretrained models deliver competitive performance. This observation serves as evidence for the robustness and effectiveness of our framework across various pre-trained language models. It further emphasizes the generalizability of our approach in conversational emotion recognition tasks. We report fine-grained performance in Appendix D.

5.4 Emotion Similarity Comparison

In this section, we conducted a comparison of the similarity between pairs of emotions before and after training with EACL in Figure 4. To observe the angle change more intuitively, we also include the angle degree. Figure 4 reveals a significant decrease in similarity for emotion anchors that are considered similar. For instance, the cosine similarity between *excited* and *happy* drops sharply from 0.77 to 0.08, while for *frustrated* and *angry*, it decreases from 0.84 to -0.3. Meanwhile, naturally dissimilar emotions are now positioned further apart. For instance, the similarity between *neutral* and other emotions also experiences a notable decline. These observations suggest that EACL effectively

Figure 4: The cosine similarity of pair-wise emotions. Figure (a) and (b) depicts cosine similarity between emotion anchors before and after training with EACL. (c) and (d) depicts the angle degree between emotion anchors before and after training with EACL respectively.

increases the separation between similar emotions, thereby enhancing the model's ability to distinguish between them. Figure 5 visualizes the positions of anchors before and after training, where similar emotions are separated by EACL.

6 Conclusion and Future Work

This paper introduces a novel framework for conversational emotion recognition called emotion-anchored contrastive learning. The proposed EACL leverages emotion representations as anchors to enhance the learning process of distinctive utterance representations. Building upon this foundation, we further adapt the emotion anchors through fine-tuning, bringing them the optimal positions and more suitable for classification purposes. Through extensive experiments and evaluations on three popular benchmark datasets, our approach achieves a new state-of-the-art performance. Ablation studies and evaluations confirm that the proposed EACL framework significantly benefits dialogue modeling and enhances the learning of utterance representations for more accurate emotion recognition.

The proposed EACL distributes the utterances in representation space more uniformly, which is beneficial for multi-class ERC tasks. When considering the context of multi-label classification, EACL can group relevant emotions guided by human knowledge, or adjust the inter-class weights of contrastive losses with label similarity (Wang et al., 2022; Zhao et al., 2022). Then, EACL can serve to detect multiple emotions in a single utterance, which will be left for future work.

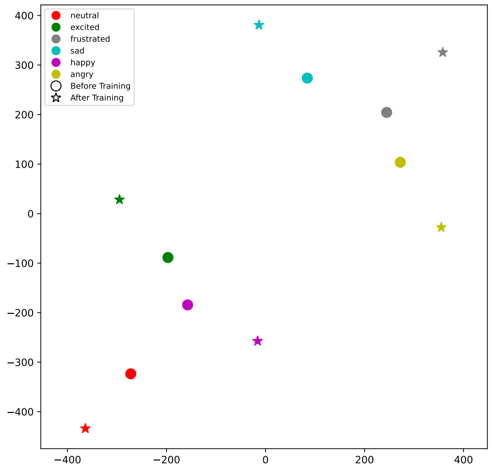

Figure 5: The t-SNE visualization of emotion anchors. Circles represent the position of emotion anchors before training and stars are the positions after training.

Acknowledgement

We would like to thank the anonymous reviewers for their valuable feedback. This work was supported by the NSFC (No. 62206126, 62376120, 61936012).

Limitations

Our method focuses solely on textual inputs and does not incorporate multi-modal information. We recognize that complementing emotion recognition with facial expressions and tone can provide valuable information. Considering multi-modal inputs is an interesting direction for enhancements.

Ethics Statement

The experiments conducted in this paper adopt open-source data for only research purposes. In this work, we try to facilitate machines with the ability to understand better human emotions which is beneficial for dialogue systems or robots. However, it is far from exceeding the understanding of humanity.

Appendix

A Emotion Similarity Anlaysis

To better understand our motivation, we exhibit the emotion similarity in Figure 6. We split the emotions into 3 groups which are composed of positive emotions, negative emotions, and neutral, where positive emotions include *excited* and *happy*, negative emotions contain *frustrated*, *sad*, *angry*, and neutral. It is observed that *excited* and *happy* have a cosine similarity of 0.77, and for *frustrated* and *angry*, they have 0.84 cosine similarity. The similarity of the positive emotions group is higher than that of the negative emotions group. For *neutral*, it is almost equally similar to other emotions.

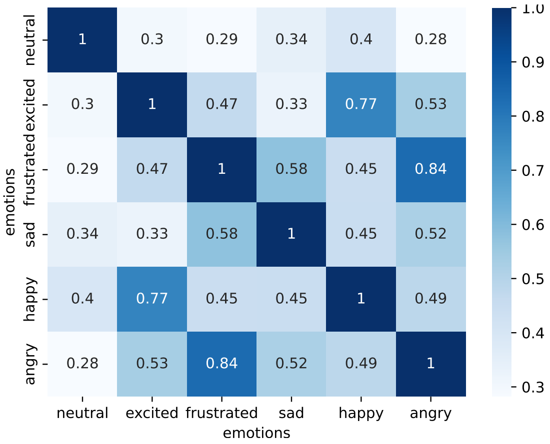

Figure 6: Cosine similarity between emotion word representations extracted from SimCSE-Roberta-Large (Gao et al., 2021).

B Experimental Setup

EACL loads the initial parameter by SimCSE-Roberta-Large (Gao et al., 2021) which is identical to the setting of SPCL. All the hyperparameters are reported in Table 6. We exploit grid-search for λ_1 in {0, 0.1, 0.3, 0.5, 0.7, 0.9}, λ_2 in {0, 0.01, 0.1, 1.0} and τ in { 0.05, 0.07, 0.1, 0.15, 0.2}.

Hyperparameters	IEMOCAP	MELD	EmoryNLP
λ_1	0.9	0.1	0.9
λ_2	0.01	0.1	0.01
Temperature τ	0.1	0.1	0.15
Epochs	8	8	8
Maximum length	256	256	256
Learning rate	1e-5	1e-5	1e-5
Dropout	0.1	0.1	0.1

Figure 7: The normalized confusion matrix of three benchmark datasets, each row is the true classes and column is predictions. The Coordinate i, j means the percentage of emotion i predicted to be emotion j.

C Detailed Performance Analysis

In Figure 7, we provide the normalized confusion matrices for our EACL and SPCL+CL models across various datasets. These matrices serve as crucial tools for assessing the models' performance. Notably, when we examine the diagonal elements of these matrices, it becomes evident that EACL consistently outperforms the state-of-the-art method SPCL+CL in terms of true positives for most fine-grained emotion categories. This suggests that EACL excels at learning features that are more distinguishable.

Particularly noteworthy is the performance of EACL in comparison to SPCL+CL when considering specific emotion pairs, such as *excited* and *happy*, as well as *frustrated* and *angry* on the IEMOCAP dataset. In these cases, EACL demonstrates superior performance. This underscores the effectiveness of the EACL framework in effectively addressing the challenge of misclassification, especially when dealing with emotions that share similar characteristics. When we focus on the MELD and EmoryNLP datasets, we observe that EACL significantly reduces misclassifications be-

Table 7: Fine-grained performance record on different language models for all emotions on three benchmark datasets, the F1-score is used for each class.

tween *neutral* emotions and other emotional states. This highlights EACL's capability to effectively mitigate misclassification issues not only for similar emotions but for all emotion categories.

D Fine-Grained Performance on Different Models

In this section, we report the fine-grained performance when using Deberta-Large (He et al., 2020b) and Promcse-Roberta-Large (Jiang et al., 2022) in Table 7. The results indicate that our learning framework is robust to different language models. Similar to the result under Roberta-SimCSE, these models can also effectively separate similar emotions and achieve state-of-the-art performance on the benchmark datasets.

SUQL: Conversational Search over Structured and Unstructured Data with Large Language Models

Abstract

While most conversational agents are grounded on either free-text or structured knowledge, many knowledge corpora consist of hybrid sources. This paper presents the first conversational agent that supports the full generality of hybrid data access for large knowledge corpora, through a language we developed called SUQL (**S**tructured and **U**nstructured **Q**uery **L**anguage). Specifically, SUQL extends SQL with free-text primitives (SUMMARY and ANSWER), so information retrieval can be composed with structured data accesses arbitrarily in a formal, succinct, precise, and interpretable notation. With SUQL, we propose the first semantic parser, an LLM with in-context learning, that can handle hybrid data sources.

Our in-context learning-based approach, when applied to the HybridQA dataset, comes within 8.9% Exact Match and 7.1% F1 of the SOTA, which was trained on 62K data samples. More significantly, unlike previous approaches, our technique is applicable to large databases and free-text corpora.

We introduce a dataset consisting of crowdsourced questions and conversations on Yelp, a large, real restaurant knowledge base with structured and unstructured data. We show that our few-shot conversational agent based on SUQL finds an entity satisfying all user requirements 90.3% of the time, compared to 63.4% for a baseline based on linearization.[1]

1 Introduction

Large Language Models (LLMs) have shown exceptional performance on numerous downstream tasks. A range of recent works focus on improving their factuality by grounding responses in external resources including structured data (Hu et al., 2022; An et al., 2023; Nan et al., 2023; Poesia et al., 2022; Arora et al., 2023; Xu et al., 2020, 2023) and free text (Khattab et al., 2023; Jiang et al., 2023; Semnani et al., 2023; Gao et al., 2023).

However, many data sources contain both structured data and free text: patient records, financial databases, and review websites, to name a few. Figure 2 in the appendix shows the running example of an application used in this paper. Each row in this table represents a unique restaurant, with information such as its name, type of cuisine, and rating as structured data. In addition, each row includes popular dishes and customer reviews in free text. To answer a question like “Can you find me an Italian restaurant with a romantic atmosphere?”, an agent needs to combine the structured attribute cuisines and the free-text attribute reviews.

To handle the combination of structured and unstructured data, many previous chat systems use a *classifier* to assign queries to one of its specialized modules that is designed to handle structured data, unstructured data, or chitchat (Jin et al., 2021; Chi et al., 2022; Zhao et al., 2023). Unfortunately, this approach is inadequate for questions that need both free-text and structured data.

Another popular approach is to convert, or *linearize*, the structured data into free text (Oguz et al., 2022), as shown in Figure 1. With this approach, we can no longer wield the power of SQL to query the database, and free text retrievers are not good at handling complex questions.

The need of composing hybrid data source queries is highlighted by the HybridQA dataset, which collects many natural questions whose answers include information from both structured data and free text (Chen et al., 2020). Previous attempts trying to ground question-answering systems on hybrid data (Lei et al., 2023; Wu et al., 2023; Kumar et al., 2023; Lee et al., 2023a) either work on only small datasets, or forego the expressiveness of structured data queries, or support limited compositions of structured and unstructured knowledge queries.

Findings of the Association for Computational Linguistics: NAACL 2024, pages 4535–4555
June 16-21, 2024

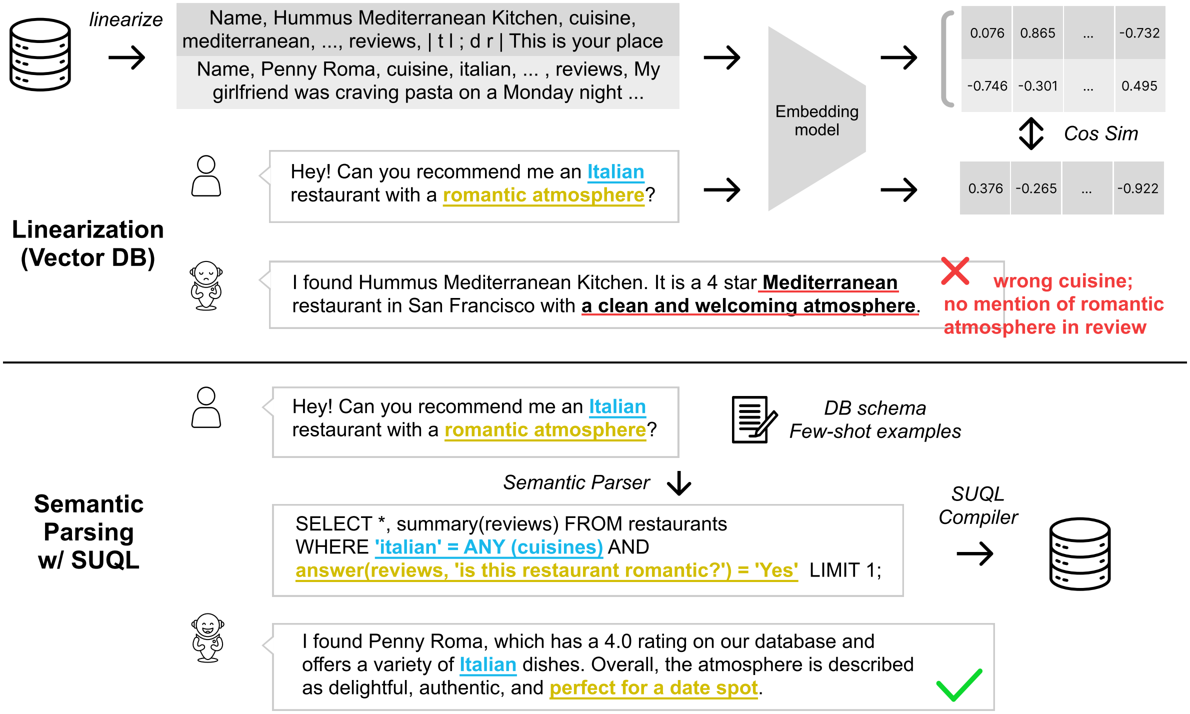

Figure 1: Comparison of traditional approach (linearization) with our approach (semantic parsing with SUQL). Top: In the linearization approach, database entries are linearized and converted to embedding vectors. At run-time, a user request is converted to an embedding vector, which is used to find the closest embedding from the stored vectors. The results are then supplied to LLM for response generation.
Bottom: In our approach (semantic parsing with SUQL), a user utterance is parsed into formal SUQL by a few-shotted LLM, which is then executed by the SUQL compiler to fetch results from the database. The results are then supplied to LLM for response generation.

This paper proposes an approach to grounding conversational agents in hybrid data sources that take full advantage of both structured data queries and free-text retrieval techniques.

Our first contribution is to **demonstrate empirically that in real-life conversations, it is natural for users to ask questions that span both structured and unstructured data**. Through crowdsourcing, we obtain questions that users ask and conversations that they have with a restaurant chatbot. Results show that more than 49% of those questions require knowledge from both structured and unstructured knowledge.

To leverage the expressiveness and precision of formal query languages, **we propose SUQL, a precise, succinct, compositional, expressive, and executable formal language.** SUQL augments SQL with several primitives for processing free text. At a high level, SUQL combines an off-the-shelf retrieval model and LLMs (for unstructured data) with the SQL semantics and operators (for structured data).

We validate our approach using the HybridQA data set. Experiments on HybridQA show that a few-shot, SUQL-based QA system comes within 8.9% Exact Match and 7.1% F1 to the SOTA model trained on over 62K data samples.

We have developed a fully operational conversational agent with a few-shot LLM-based semantic parser with SUQL, shown in the bottom part of Figure 1. We create a new single-turn user question data set and a conversational dataset on Yelp, a large, real knowledge corpus. Our chatbot using SUQL finds an entity satisfying all user requirements 90.3% of the time, compared to 63.4% for a baseline based on linearization.

2 Related Work

Text-to-SQL Semantic Parsing. Text-to-SQL systems have been built for single-turn question answering tasks (Guo and Gao, 2020; Wang et al., 2020a; Scholak et al., 2021; Zhong et al., 2017) as well as multi-turn, conversational tasks (Yu et al., 2019a,b; Wang et al., 2020b; Liu et al., 2022). Recently, LLMs have shown promising results on the text-to-SQL semantic parsing problem via in-context learning (Brown et al., 2020), with a range of work focusing on various prompting strategies

(Hu et al., 2022; Poesia et al., 2022; An et al., 2023; Nan et al., 2023; Arora et al., 2023; Guo et al., 2023; Sun et al., 2023; Zhang et al., 2023b).

This line of work is only applicable to structured data sources without any free text. When it comes to free text, SQL is limited to basic pattern-matching on strings, hindering the application of text-to-SQL where deeper support is needed.

Specialized Modules Using a Classifier. One approach to building a conversational interface to hybrid sources is to classify each question and assign it to one of the specialized modules. For instance, Chirpy (Chi et al., 2022) implements different modules to handle different kinds of questions. Jin et al. (2021) and Zhao et al. (2023) implement a "Turn Detection" module, to determine whether a user turn involves unstructured data access or should be handled by APIs/DBs. However, real user questions naturally span across both structured and free text columns, which cannot be answered by systems built with separate modules.

Linearize structured data. Another popular approach is to turn structured data into a linear form, which can then be directly used by a language model. A common approach is to linearize raw tables row-by-row and feed linearized content into a Tabular Language Model (TaLM) (Herzig et al., 2020; Yin et al., 2020; Eisenschlos et al., 2021; Deng et al., 2022; Iida et al., 2021; Sun et al., 2022).

In particular, Oguz et al. (2022) linearizes Wikidata and Wikipedia tables, combines them with Wikipedia text, and applies a retrieval model to open-domain question-answering. However, this approach is inherently limited. Many queries are challenging to answer through free text alone, such as "What are the number of deaths due to Covid in August and September 2020 in New York?". These types of inquiries can be easily addressed using structured data, which supports comparisons and calculations across a big database. Moreover, linearization complicates the unification of different parts of the database.

3 Design and Rationale of SUQL

We present the design and rationale of the SUQL language in this section. The design objectives of the representation are *expressiveness*, *accuracy*, and *efficiency*.

3.1 Design Rationale

Expressiveness. The design must be expressive, supporting the full generality of queries of the hybrid knowledge corpus. It must handle arbitrary compositions of (1) relational operators in databases and (2) queries on free-text documents. Note that such a design automatically subsumes the *multi-hop retrieval* in NLP literature, where the results of a retrieved answer are used to retrieve another.

Formal languages, such as SQL, have been proven to be *complete* with respect to relational algebra (Codd et al., 1972). It can handle arbitrary compositions by virtue of its grammar rules, which for example, can be used to produce an unbounded number of nested subqueries.

Instead of linearization, which turns all structured data into text, we propose the opposite. SUQL is an extension of SQL with two NLP operators, SUMMARY and ANSWER: SUMMARY produces the summary of a given text, and ANSWER returns the answer to a given text. These operators can be used anywhere with text values in the grammar, no different from numeric operators with numeric values. The advantage of this design is that SUQL is a succinct, formal representation that is complete with respect to relational algebra and NLP operations.

Accuracy of Translation from Natural Language. LLMs have been shown to be capable of translating complex text from one natural language to another. They can translate complex sentences into SQL queries for albeit small databases with compound operations, such as the use of group-by, ranking, and subqueries.

We posit that SUQL will give LLMs a succinct notation to express complex queries involving hybrid data sources. Leveraging LLMs' familiarity with SQL, we hypothesize that we can create a semantic parser for translating user queries in a conversation into SUQL queries with an LLM via in-context learning.

Efficiency. SUQL queries can be executed by the SQL compiler requiring no modifications, as the SUMMARY and ANSWER primitives can be provided simply as user-defined functions. However, such an SQL compiler will perform very poorly. A naive implementation of these textual primitives would require retrieving and applying the NLP operation one record at a time, which is prohibitively expensive for large tables. Naive execution of the

Operator	Description	Example
ANSWER (t : `text` | `text` [], q : `text`) $\rightarrow$ `text`	return the answer to question q on value t	ANSWER (reviews, "is this restaurant family-friendly?")
SUMMARY (t : `text` | `text` []) $\rightarrow$ Text	return the summary of t	SUMMARY (reviews)

Table 1: Free Text primitives in SUQL

ANSWER function will not be effective.

Note that unlike previous methods such as retrieval-based semantic parsing where queries are constructed as results are retrieved (Cao et al., 2022; Gu and Su, 2022), SUQL expresses the query in its entirety. This makes it possible for us to develop an optimizing compiler, as described in Section 5.

3.2 Design of SUQL

We introduce two operations for text values in SQL. In this paper, we use `text` to represent any of the text types in SQL (CHAR, VARCHAR, TEXT, ...).

We define ANSWER (t,q) to return an answer to question q on text input t. For instance,

> ANSWER (reviews, 'is this restaurant family-friendly?')

will return yes if the reviews indicate that the restaurant is family-friendly, and no otherwise. The result is a text value that can be used anywhere it is allowed. For instance,

> ANSWER (reviews, 'is this restaurant family-friendly?') = 'Yes'

can be used as a filter to select family-friendly restaurants.

ANSWER is a universal function that can be used to derive any information from a text value by supplying the right question. However, for convenience, we introduce SUMMARY (t) as syntactic sugar for

> ANSWER (t, 'what is the summary of this document?').

We posit it that the semantic parser can easily learn to use SUMMARY. The formal definitions of ANSWER and SUMMARY are shown in Table 1.

The ANSWER and SUMMARY operations can be applied to any text arguments and their results can be used where a text value is expected, resulting in compositions of hybrid data accesses. Complex compositions of free text primitives and other SQL operators are highlighted by questions in the HybridQA dataset. In HybridQA, each cell in a column C is potentially linked to some passages, which we store in a separate column called C_Info. All questions from the dataset can be represented in SUQL. We show 6 representative examples of how each type of question can be represented in SUQL in Table 2.

4 Conversational Agent

Using SUQL as the formal representation, the architecture of a conversational agent with a hybrid knowledge corpus is relatively straightforward.

The Dialogue State Tracking problem (Cheng et al., 2020; Andreas et al., 2020; Campagna et al., 2022) for the SUQL-based conversational agent of a given schema S is defined as follows. We define the dialogue history to consist of a sequence of utterances between the user and the agent, $A_1, U_1, \cdots, A_n, U_n$, where A_i and U_i denotes an agent utterance and user input at turn i, respectively. Each $U_i = (t_i, q_i)$ where t_i is the natural text input, and q_i is a SUQL query for schema S if t_i carries a query. Given schema S, (A_i, U_i) for all previous turns $1 \leq i < n$ and the latest user utterance t_n, dialogue state tracking predicts q_n if t_n carries a query.

The semantic parser for the dialogue state tracking consists of two stages, both implemented with an LLM using in-context learning. The first classifies if the knowledge corpus needs to be consulted. For user utterances like greetings or general questions, it skips the knowledge corpus access. If consulting is needed, the second stage predicts q_n. The prompt includes the schema definition and few-shot examples demonstrating SUQL free-text primitives.

If the user utterance corresponds to a query, then the predicted SUQL query is executed. Because the semantic parser may have translated the user query incorrectly, the agent is instructed via a prompt to explicitly state to the user what it searched, based on the predicted SUQL at this turn (e.g., "I searched for Italian restaurants with a romantic atmosphere."). If the search returns a result, we

Question Type	Exemplar Question	SUQL query
Type I	Where was the XXXI Olympic held?	SELECT answer(“Event year Info”, ‘where is this event held?’) FROM table WHERE “Name” = ‘XXXI’;
Type II	What was the name of the Olympic event held in Rio?	SELECT “Name” FROM table WHERE answer(“Event year Info”, ‘is this event held in Rio?’) = ‘Yes’;
Type III	When was the flag bearer of Rio Olympic born?	SELECT answer(“Flag Bearer Info”, ‘when is this person born?’) FROM table WHERE answer(“Event year Info”, ‘is this event held in Rio?’) = ‘Yes’;
Type IV	Which male bearer participated in Men’s 100kg event in the Olympic game?	SELECT “Flag Bearer” FROM table WHERE “Gender” = ‘Male’ AND answer(“Flag Bearer Info”, ‘did this person participate in Men’s 100kg event?’) = ‘Yes’;
Type V	For the 2012 and 2016 Olympic Event, when was the younger flag bearer born?	SELECT MAX(answer(“Flag Bearer Info”, ‘when is this person born?’)::date) FROM table WHERE “Event year” IN (‘2016’, ‘2012’);
Type VI	When did the youngest Burmese flag bearer participate in the Olympic opening ceremony?	SELECT “Event year” FROM table ORDER BY answer(“Flag Bearer Info”, ‘when is this person born?’)::date DESC LIMIT 1;

Table 2: The question types in HybridQA with exemplar questions (Figure 3 of Chen et al. (2020)) translated to the corresponding SUQL queries.

ask the LLM to formulate the response based on the result; otherwise, we *explicitly* ask it to indicate that no results are found. The latter is important because LLMs tend to hallucinate whenever no answers to the user question are supplied.

5 An Optimizing SUQL Compiler

Here, we describe the key optimizations we implemented in the SUQL compiler.

5.1 Search and Filter Optimization

When ANSWER is used as a filter in the query, the naive implementation would require one LLM calling for every record in the database, which is infeasible. Similar to how database indexing is used to optimize queries, we use dense retrieval models to quickly identify the relevant records, instead of operating on them one-by-one. In addition, if only a few results are needed, it is unnecessary to evaluate the filter on all the records.

First, our SUQL optimizing compiler identifies filters that use the ANSWER functions. It uses precomputed embeddings from a dense retrieval model for similarity matching with the questions to identify top candidates. Note that the retrieved answers are relevant, but they may not satisfy the filtering constraints. We invoke the LLM on the entire clause to determine if the filter is successful. For example, if the user asks for a restaurant where parking is easy, and a review happens to say “the parking is hard”. The review may have the highest similarity score if no other reviews mention “parking”. Thus, we need to apply the original filter ANSWER (reviews, ‘is parking easy?’) = ‘Yes’ using an LLM to ensure that the retrieved review indeed says that the parking is easy (Prompt 8).

If multiple free text constraints are present, the SUQL compiler uses an aggregated similarity score based on each constraint to retrieve results that most likely satisfy all constraints. Formally, the aggregated similarity score for each row r is calculated as:

$$\sum_c \max_t \mathrm{sim}(c, t)$$

where c is a text constraint, t is a text in row r, and $\mathrm{sim}(\cdot, \cdot)$ denotes the similarity score between two texts.

5.2 Enumerated Types

Enumerated types (ENUM) are widely used in structured attributes to restrict the values of a text type to carry only one or more of a pre-defined set of permitted values. ENUM standardizes the values of the attributes so a filter based on the variable can be performed as a simple string match between the attribute values and permitted literals.

The challenge is how to ensure that the semantic parser will map ENUM attribute values to a permitted one. For all ENUM type declarations with no greater than $N = 10$ values, we include all the permitted values in the schema declarations supplied as a prompt to the LLM. The LLM is observed to be capable of automatically generating the ENUM values. For larger ENUM types, we do not include the permitted values, and the parser may generate an unexpected value. For example, the user utterance “Where can I find coffee” is likely to be translated to the filter clause ‘coffee’ = ANY(cuisines). However, the Yelp database only has ‘coffee & tea’ or ‘cafe’ cuisines, and not ‘coffee’.

Our solution is to redefine the semantics of the = operator for enumerated types. This is well known in the compiler literature as *overloading*. We first define the CLASSIFY function:

Definition 5.1.

$$\text{CLASSIFY}(t : \texttt{text}, S : v_1, \ldots, v_n) \\ = \{v_{i_1}, \ldots, v_{i_m}\}, \forall v_{i_k} \in S \text{ similar to } t.$$

Here, we say two strings are similar if they have similar meanings. It is possible the value of interest is not included in the set of permitted values, in which case CLASSIFY returns $\emptyset$. We use a 0-shot LLM to implement CLASSIFY (Prompt 6).

Definition 5.2. The equal operator **=** is overloaded such that

$$t_1 = t_2 \text{ iff } t_2 \in \text{CLASSIFY}(t_1, E), \\ \text{where } t_1 : \texttt{text} \text{ and } t_2 : \text{ENUM}(E)$$

For instance, given a clause 'coffee' **=** **ANY**(cuisines), where CLASSIFY ('coffee', cuisines) = {'coffee & tea', 'cafe'}, then the clause will match any records whose cuisine attribute contains either 'coffee & tea' or 'cafe'.

5.3 Query Order Optimizations

Since ANSWER and SUMMARY involve LLM calls, it is important to minimize the execution of such functions.

Predicate Ordering. As discussed above, ANSWER functions in filters are expensive, compared to other predicates. Thus, whenever possible, the SUQL compiler would prioritize executing the other predicates so ANSWER is applied to fewer records.

Specifically, the SUQL compiler converts **SELECT** clauses with filter predicates into disjoint normal form (DNF), i.e., an OR of ANDs. For each AND clause, it prioritizes filters not using the ANSWER function so ANSWER calls are applied only to the filtered records.

Lazy Evaluation. Lazy evaluation, the concept of evaluating only when the result is needed, is a long-standing concept in programming languages (Hudak, 1989). The SUQL compiler adopts this concept to minimize execution cost. Specifically, when a **LIMIT** clause is present, it stops the evaluation once the required number of rows is filled.

6 Experiments

To evaluate SUQL, we perform two experiments. The first is on HybridQA, a popular academic question answering dataset as discussed above. Tables in HybridQA are small enough to be provided as input to a neural model. To perform a more comprehensive experiment on *conversations* with *large*, *real* data bases, we introduce a new benchmark based on the real restaurant data corpus from Yelp.com.

6.1 HybridQA Experiment

The HybridQA dataset consists of roughly 70K question-answering pairs aligned with 13,000 Wikipedia tables, whose entities are linked to multiple free-form corpora. Every question can be answered correctly only by referring to both the structured and unstructured data. To test out SUQL, we create the following system:

1. Use LLM with in-context learning (with less than 10 examples) to parse natural language and a given database schema into a SUQL query (Prompt 9).
2. Execute the generated SUQL to retrieve results from the database. If no results are returned, repeat this process by generating a different SUQL query, with up to 2 tries (Prompt 10).
3. Use LLM to convert the retrieved database result to a succinct answer (Prompt 11) since the gold labels in HybridQA are short. Because the gold labels have only one entity, even though the full answer may include multiple entities, we just pick one out of the possibly many results returned by SUQL.

`GPT-4-1106-preview` is used in all steps, except that `GPT-3.5-turbo-0613` is used in Step 3.

Our in-context learning-based QA system achieves 59.3% Exact Match and 68.3% F1 on the development set of HybridQA and 59.0% EM and 68.4% F1 on the held-out test set, as shown in Table 3. Our method uses only 3 simple prompts, achieving within 8.9% EM and 7.1% F1 to the SOTA on the test set, which has been trained on the HybridQA training set with over 62K examples.

Most significantly, unlike our approach, these models do not generalize beyond small tables. Techniques based on feeding the entire table into a Transformer (DocHopper, Mate, MITQA, DEHG, and MAFID) cannot be applied to large data corpora that exceed their input token limit. Neither can techniques based on retrieving entire columns (MuGER^2) and feeding into a reader model. The SOTA model S^{3}HQA separately retrieves rows in the table and passages. It then feeds the top results

Method	Model	Trained on (Size)	Dev		Test	
			EM	F1	EM	F1
DocHopper (Sun et al., 2022)	ETC	HybridQA (62k)	47.7	55.0	46.3	53.3
HYBRIDER (Chen et al., 2020)	BERT		44.0	50.7	43.8	50.6
MuGER[2] (Wang et al., 2022)			57.1	67.3	56.3	66.2
Mate (Eisenschlos et al., 2021)			63.4	71.0	62.8	70.2
DEHG (Feng et al., 2022)			65.2	**76.3**	63.9	75.5
MITQA (Kumar et al., 2023)			65.5	72.7	64.3	71.9
MAFiD (Lee et al., 2023b)	T5		66.2	74.1	65.4	73.6
S^{3}HQA (Lei et al., 2023)	BERT/BART/DeBERTa		**68.4**	75.3	**67.9**	**75.5**
LLaMA2 (7B) (Zhang et al., 2023a)	LLaMA2 (7B)	Zero-shot	20.7	-	-	-
TableLlama (Zhang et al., 2023a)		TableInstruct (2.6M)	27.6	-	-	-
End-to-End QA w/ retriever (Shi et al., 2024)	GPT-4	Zero-shot	24.5†	30.0†	-	-
HPROPRO (Shi et al., 2024)		Few-shot	48.0†	54.6†	48.7	57.7
SUQL (**Ours**)			59.3	68.3	59.0	68.4

Table 3: Performance of few-shot-based SUQL and related work on the HybridQA dataset. † denotes running on 200 sampled cases from the development set (Shi et al., 2024).

of each to the final reader. It needs to feed the whole column to the reader if the query involves sorting. In contrast, our approach has full compositional generality and can handle arbitrarily large datasets. We are the first to apply semantic parsing techniques to the HybridQA dataset since no prior formal representations could accurately capture the hybrid queries.

Recently, Zhang et al. (2023a) applied LLaMA-based techniques to HybridQA. They fine-tuned LLaMA2 (7B) on their TableInstruct dataset with more than 2.6M samples and achieved only 27.6 EM on Hybrid QA. They also reported a baseline of LLaMA2 (7B) on HybridQA directly, which resulted in just 20.7 Exact Match.

Shi et al. (2024) reported two experiments using GPT-4 on the HybridQA dataset. (1) Their GPT-4 End-to-End QA w/ retriever uses zero-shot GPT-4 to directly answer questions based on table and text parts retrieved by the retriever from Chen et al. (2020). (2) HPROPRO w/ GPT-4 uses few-shot program-based prompts to iteratively generate and execute Python code with the help of GPT-4. On a 200-sample of the development set, their two systems achieved 24.5 and 48.0 EM and 30.0 and 54.6 F1, respectively. The HPROPRO system achieves 48.7 EM and 47.7 F1 on the test set. Our SUQL-based approach outperforms both systems, outperforming HPROPRO by more than 10.0% in both EM and F1 on the test set.

Sui et al. (2023) also experimented using in-context learning with GPT-4 on HybridQA. However, they only reported the result of 1,000 randomly sampled questions from the development set. For each question, they experiment with different formats (JSON, HTML, Markdown, etc.) of feeding the entire table and question to GPT-4. The prediction is considered accurate if it is a substring of the gold answer, and vice versa[2]. Their best-reported result is GPT-4 with HTML format at 56.68% with this metric. Using their metric on the *full* development set, our SUQL-based system achieves a score of 72.5%.

These results show the effectiveness of SUQL on the hybrid question-answering task, compared to other ICL techniques.

Error Analysis. From analyzing 100 randomly sampled error cases, we found:

- 44% are due to format mismatches, e.g. "Johnson City, Tenessee" versus "Johnson City". Similar issues related to evaluating LLM-generated responses have been noted by Kamalloo et al. (2023).
- 20% are due to the gold label being either wrong or incomplete. Incomplete cases exist because only one gold answer is permitted in HybridQA, while in fact for some cases, multiple possible correct answers could be found.
- 24% are due to semantic parsing errors.
- 10% are due to errors from the SUQL execution involving the LLM-based ANSWER function and ENUM classifier.
- the remaining 2% are due to type-related conversion errors, since HybridQA tables do not

---

[2] Based on communication with one of the authors.

have annotated types while SUQL expects a typed schema.

In summary, even though the EM of SUQL is 59.3% on the development set, only 36% of the 100 non-EM cases are true errors. Thus, the true accuracy of SUQL may reach 85.3%.

6.2 Conversational Agent on Restaurants

To experiment with real-life datasets, we collect a total of 1828 restaurants from Yelp.com across 4 cities, alongside the top 20 reviews and top 20 popular dishes for each restaurant. The columns of our database are name, cuisines, price, rating, num_reviews, address, phone_number, opening_hours, location, reviews, and popular_dishes.

We use an off-the-shelf dense retriever model (Yu et al., 2022) as the retriever in SUQL. We use `gpt-3.5-turbo-0613` as the LLM for all systems in this section.

6.2.1 Collecting User Queries

We solicit user queries via crowdsourcing on Prolific (Prolific, 2023). We do not disclose to the workers what fields are available in the database so as to not bias their queries. We ask them to come up with 100 questions about restaurants. Separately, we also ask crowd workers to interact with our conversational agent (described in Section 4) and collect 96 turns across 20 conversations.

	Single-turn	Conversation
Structured-only	45	37
Combination	55	25
Total	100	62

Table 4: Statistics on whether a search question requires only structured data or a combination.

	Single-turn	Conversational
Linearization @ 1	57.0 %	63.4 %
Linearization @ 3	49.7 %	61.9 %
SUQL	**93.8 %**	**90.3 %**

Table 5: Turn accuracy measurement on linearized system versus SUQL system.

The setting of restaurants in real-life use cases requires a user to first specify a location, a structured column in the database. We annotate whether a user question only involves structured information or a combination with free text in Table 4. In single turns, all collected user queries involve searching for a restaurant. Out of the 96 dialogue turns, 62 involve searching for restaurants. In total, over 49% of user queries require knowledge from both structured and unstructured columns.

6.2.2 Turn Accuracy

We experiment with the linearization technique proposed by Oguz et al. (2022) for relational tables, using again the same dense retriever model (Yu et al., 2022). Specifically, we concatenate cell values on the same row and separate them by commas. Based on the conversation history, these systems use a few-shot LLM to extract a succinct search query for the retrievers.

For each user input, we manually inspect whether the restaurants retrieved by a system satisfy all criteria specified by the user and respond with correct and relevant information. Concretely, given a user utterance u and a list of returned restaurants $\mathcal{R} = \{r_1, r_2, \cdots, r_m\}$, we evaluate whether each r_i is a true positive or false positive. We calculate the turn accuracy as the number of true positives divided by the number of true and false positives for all the queries in the dataset.

For the SUQL system, the queries are limited to return at most 3 results. The accuracy is 93.8% for single-turn questions and 90.3% for conversational queries, as shown in Table 5.

We compare our results with two linearization-based systems, where $m = 1$ ("Linearization 1") and $m = 3$ ("Linearization 3"). SUQL improves the answer accuracy, by up to 36.8% in single-turn settings and up to 26.9% in conversations. This shows that the conversational agent with SUQL can provide much more accurate results.

Our system returns no answers to 21 of the 100 user questions and 8 of the 62 queries in the conversations. Manual inspection reveals that 7 out of the 21 and 2 out of the 8 truly have no answers. Thus, our system has a false negative rate of 14% and 9% for user questions and conversational turns, respectively.

6.2.3 User Feedback

We solicit feedback from our crowdsource users after they talk to our restaurant chat-bot with three free-form questions shown in Figure 5. Overall, the feedback was positive: "There's actually nothing I didn't like about this chatbot. I would honestly use this chatbot on a regular basis if it were available to the public", "I liked that the chatbot was fast in responses and it gave very detailed responses and I hardly had any questions about a restaurant after the option was given", and "Shocked at how good the restaurant suggestions were. I even asked for something with better prices and got that too. Now I'm hungry. I asked to define a cuisine style and it was able to do that".

Negative comments include: occasional slowness of the chatbot; "it didn't provide any links or pictures"; "It did not sound friendly and sometimes the responses were too long. Bullet point outputs would be much more helpful."

7 Conclusion

We introduce SUQL, the first formal query language for hybrid knowledge corpora, consisting of structured and unstructured data. The key novelty of SUQL is the incorporation of free-text primitives into a precise, succinct, expressive, and interpretable query language.

Our in-context learning-based approach when applied to the HybridQA dataset comes within 8.9% Exact Match and 7.1% F1 to the SOTA on the test set trained on 62K data samples. More significantly, unlike previous approaches, our technique is applicable to large databases and free-text corpora.

Our experiment on the real Yelp knowledge base with crowdsourced questions and conversations shows that our in-context learning conversational agent based on SUQL finds an entity satisfying all user requirements 90.3% of the time, compared to 63.4% for a baseline based on linearization. The empirical findings underscore SUQL's applicability and its potential for future research directions such as domain-specific applications in biomedical, legal, and financial spheres.

Ethical Considerations

LLMs and formal languages such as SQL have been used by an increasingly large population of technical developers as well as everyday users. We propose to combine them in the hope of bringing the best of both sides to create a expressive, accurate, and efficient language that facilitates conversational search over structured and unstructured data. We do not foresee this work to result in any form of harm or malicious misuse.

Data. The data used in this work is an open-sourced research dataset (HybridQA) and a Yelp-based restaurant conversation dataset (Restaurant). During the curation process of the Restaurant dataset, we used a certified online research crowdsourcing platform Prolific to make sure that we respected worker's privacy and paid them at fair rates. Our procedure has been approved by an IRB from our institution.

Compute. The models used herein are existing pretrained retriever models and LLM API services provided by OpenAI. We did not additionally pretrain or finetune any compute-intensive models, therefore avoiding a significant carbon footprint in the experiments herein.

License. Our code will be released publicly and licensed under Apache License, Version 2.0. Our data will be made available to the community.

Limitations

Being LLM-based, SUQL can be subject to vulnerabilities that are intrinsic to LLMs. These intrinsic weaknesses can negatively affect SUQL's effectiveness, posing limitations on the overall pipeline performance. We highlight two aspects of limitation in the current version of SUQL methodology.

Performance Limitation. In this work, the LLM's semantic understanding capability upper-bounds the semantic and syntactic correctness of parsed SUQL queries. The ANSWER and SUMMARY functionalities in SUQL can also be affected by the underlying LLM, resulting in potentially erroneous filtering evaluation during the execution of the SUQL queries.

Reliability Limitation. The applicability of the method can also be affected by the reliability of the underlying LLM. In our pipeline, the semantic parser may hallucinate database contents in a non-interpretable manner, even when explicitly instructed not to. Other caveats include non-deterministic behavior between LLM API calls and potential vulnerabilities against LLM-oriented adversarial attacks.

A Appendix

A.1 Hyperparameters

For all our experiments, we set a temperature of 0 in calls to OpenAI's LLMs, and we directly use the retriever provided by Yu et al. (2022), with the default parameters.

A.2 Prompts in our experiments

We provide the prompts mentioned in this paper. The syntax used is the Jinja2 template language, which supports Python-like loops (`{% for %}{% endfor %}`), conditions (`{% if %}{% endif %}`), variables (`{{ var }}`) and comments (`{# #}`).

A.3 Our crowdsourcing process on Prolific

We utilize Prolific (Prolific, 2023) to curate our Restaurant dataset. The crowdsourcing interface is presented in Figure 3, after starting the crowdsourcing task, the crowdsourcing workers will be prompted with questions shown in Figure 4. After they finish conversing with the chatbot, they will be shown three questions shown in Figure 5.

Among the 50 crowdsourcing workers who consented to reveal their demographic information, 33 are female and 17 are male. All 50 crowdsourcing workers reside in the United States. We paid the crowdsourcing workers 12.30 USD per hour. The average expected duration is 8 minutes. The pay rate is higher than the federal minimum wage in the United States, which is 7.25 USD per hour. Our crowdsourcing process asked for user consent in using their conversation with the chatbot for research purposes. No personal identifiable information was collected.

Figure 2: `restaurants` table with both structured and unstructured data.

```
In a database, the {{ field_name }} field has the following set of options, separated by new lines. "{{ predicted_field_value
      }}" is not one of the possible choices. You need to classify "{{ predicted_field_value }}" into one or more of the
      values below:

{% for choice in field_value_choices %}
{{ choice }}
{% endfor %}

You can only select from the above choices. Your response should be a list of comma separated index numbers.
Your answer:
```

Table 6: ENUM classifier prompt used in SUQL compiler. This is a zero-shot prompt.

```
Answer a question based on the following text.{{ type_prompt }}

Question: {{ question }}. If there is no information, say "no info".

Documents:
{% for review in reviews %}
{{ review }}
{% endfor %}

Provide a concise answer in a few words:
```

Table 7: The ANSWER function prompt used in SUQL compiler. This is a zero-shot prompt.

```
‘answer(document, query)‘ takes in a document and a query. It asks ‘query‘ on ‘document‘ and outputs the answer.

Now, let’s look at this use case. Your task is to determine whether the output is correct.

answer({{ field }}, "{{ query }}") {{ operator }} {{ value }}

{{ field }} = ["{{ document }}"]

Choose from one of the following choices:
- the output is correct.
- the output is incorrect.
```

Table 8: The ANSWER function prompt as filter used in SUQL compiler. This is a zero-shot prompt.

```
You are a semantic parser. Generate a query for a database with given signature. Do not generate fields beyond the given
      fields.

Table 9: HybridQA semantic parser prompt. This prompt contains 10 examples, each with a (1) short table description, (2) table schema shown as a CREATE command, (3) the input query, and (4) the target SUQL

```
You are a SQL semantic parser. In a prior turn, you have predicted a SQL, which returned no results. Your job now is to
      generate a new SQL to try again.
In addition to the standard SQL syntax, you can make use of the ‘answer‘ function.

In general, you should try to RELAX constraints.

Table description: Doping_at_the_Olympic_Games_15
Schema: CREATE TABLE "validation_table_56" ("Name" TEXT, "Name_Info" TEXT[], "Country" TEXT, "Country_Info" TEXT[], "Sport"
      TEXT, "Sport_Info" TEXT[], "Banned substance" TEXT, "Banned substance_Info" TEXT[])
Question: What substance was the athlete born in Bugulma banned in 2002 for using ?
Previously-generated SQL: SELECT "Banned substance" FROM "validation_table_56" WHERE answer("Name_Info", ’is this athlete
      born in Bugulma?’) = ’Yes’ AND "Country_Info" @> ARRAY[’2002’];
This SQL returned no result.
New SQL: SELECT "Banned substance" FROM "validation_table_56" WHERE answer("Name_Info", ’is this athlete born in Bugulma and
      banned in 2002?’) = ’Yes’;
--
Table description: Sweden_at_the_1932_Summer_Olympics_0
Schema: CREATE TABLE "validation_table_1" ("Medal" TEXT, "Name" TEXT, "Name_Info" TEXT[], "Sport" TEXT, "Sport_Info" TEXT[],
      "Event" TEXT, "Event_Info" TEXT[])
Question: What was the nickname of the gold medal winner in the men ’s heavyweight greco-roman wrestling event of the 1932
      Summer Olympics ?
Previously-generated SQL: SELECT answer("Name_Info", ’What was his nickname?’) FROM "validation_table_1" WHERE "Medal" =
      ’Gold’ AND "Event" = ’Men’’s heavyweight Greco-Roman wrestling’;
This SQL returned no result.
New SQL: SELECT answer("Name_Info", ’What was his nickname?’) FROM "validation_table_1" WHERE "Medal" = ’Gold’ AND "Event" =

You are a restaurant virtual assistant chatting with a user.
You can access a restaurant database to retrieve information about restaurants’ cuisine, price (cheap, moderate, expensive,
      luxury), rating (1-5), num_reviews, location, popular_dishes, reviews, phone_number, and opening_hours.

=====
{# basic #}
You: Hi! How can I help you?
They: what is a good place to get brunch in Chicago?
[Check the database? Yes]
=====
{# ask for rating #}
They: show me a Chinese restaurant in upper east side, NY
You: I found the 4.5 star Calle Dao Chelsea. It is a Chinese and Asian Fusion restaurant that serves brunch and has a menu
      that reflects the history of Chinese migration to Cuba.
They: is it better than panda express?
[Check the database? Yes]
=====
{# follow up on phone number #}
They: what is a good seafood restaurant in Seattle?
You: I found The Pink Door, a 4.5 star seafood restaurant in Seattle. Reviews mention the grilled whole fish and clam pasta
      as seafood dishes served there.
They: Can you find their phone number?
[Check the database? Yes]
=====
{# have you heard? #}
They: have you heard of girl and the goat at Chicago?
[Check the database? Yes]
=====
{# do not check db when asking about general knowledge #}
They: I want a Spanish restaurant in Kansas City
You: I found the 4 star La Bodega. It has one of the best happy hours in the city and a cozy atmosphere that feels like
      you’re in the countryside of Spain.
They: Do you speak Spanish?
[Check the database? No]
=====
{# do not check db when asking about general knowledge about dishes #}
They: can you find me a place that serves peking duck?
You: Sorry, I don’t have that information.
They: ok, how about orange chicken instead?
You: Sorry, I don’t have that information.
They: how about chicken?
You: I found the 4 star Roost & Roast. It is a take-out place with no indoor dining, but there are tables outside. The menu
      is simple and ordering is done via an iPad kiosk. They offer Thai-inspired dishes such as Hat Yai Fried Chicken, Pad
      Thai, and several other stir frys.
They: what is hat yai fried chicken?
[Check the database? No]
=====
{# show another one #}
They: hey! show me something in Washington D.C.
You: I found the 4 star Old Ebbitt Grill. It is a historic restaurant located in Washington D.C. that has been serving locals
      and tourists since 1856. The food is very good and the service is great, with a friendly and knowledgeable staff.
They: is there another one?
[Check the database? Yes]
=====
{# keep on checking database even if there are errors #}
They: have you heard of girl and the goat at Chicago?
You: Sorry. I don’t have that information
They: have you heard of girl and the goat at Chicago?
[Check the database? Yes]

You are a semantic parser. Generate a query for a restaurant database with the following signature:

CREATE TABLE restaurants (
    name TEXT,
    cuisines TEXT[],
    price ENUM (’cheap’, ’moderate’, ’expensive’, ’luxury’),
    rating NUMERIC(2,1),
    num_reviews NUMBER,
    address TEXT,
    popular_dishes FREE_TEXT,
    phone_number TEXT,
    reviews FREE_TEXT,
    opening_hours TEXT,
    location TEXT
);

Do not generate fields beyond the given fields. The ‘answer‘ function can be used on FREE_TEXT fields.

{# Basic example #}
User: Where is Burguer King?
Target: SELECT address, summary(reviews) FROM restaurants WHERE name ILIKE ’%Burguer King%’ LIMIT 1;
--
{# Basic example for cuisine, and follow up with restaurant names #}
User: what are some good-reviewed japanese restaurants in Kansas City?
Target: SELECT *, summary(reviews) FROM restaurants WHERE ’japanese’ = ANY (cuisines) AND location = ’Kansas City’ AND rating
      >= 4.0 LIMIT 3;
Agent: I found Sakura Sushi, Nami Ramen, and Kaze Teppanyaki.
User: What are their prices?
Target: SELECT name, price FROM restaurants WHERE (name ILIKE ’Sakura Sushi’ OR name ILIKE ’Nami Ramen’ OR name ILIKE ’Kaze
      Teppanyaki’) AND location = ’Kansas City’;
--
{# Usage of ‘answer‘ function on FREE TEXT field in both projection and filter #}
User: Show me a family-friendly restaurant that has burgers in D.C.
Target: SELECT *, summary(reviews), answer(reviews, ’is this restaurant family-friendly?’) FROM restaurants WHERE
      answer(reviews, ’do you find this restaurant to be family-friendly?’) = ’Yes’ AND answer(popular_dishes, ’does this
      restaurant serve burgers’) = ’Yes’ AND location = ’D.C.’ LIMIT 1;
Agent: I found Jason’s steakhouse. Reviews mention kids love going there with their parents. It should be a great weekend
      dinner for you and your family.
User: What do the reviews say about the atmosphere in the restaurant?
Target: SELECT answer(reviews, ’What is the atmosphere?’) FROM restaurants WHERE name ILIKE ’Jason’’s steakhouse’ AND
      location = ’D.C.’ LIMIT 1;
--
{# Usage of ‘answer‘ function on popular_dishes #}
User: Find me a place with pasta in Nashville.
Target: SELECT *, summary(reviews) FROM restaurants WHERE answer(popular_dishes, ’does this restaurant serve pasta’) = ’Yes’
      AND location = ’Nashville’ LIMIT 1;
--
{# Usage of ‘answer‘ function on reviews #}
User: I love Chinese food. Find me a restaurant that doesn’t have a long wait time.
Target: SELECT *, summary(reviews), answer(reviews, ’what is the wait time?’) FROM restaurants WHERE ’chinese’ = ANY
      (cuisines) AND answer(reviews, ’does this restaurant have short wait time?’) = ’Yes’ LIMIT 1;
--
{# Meaning of the word "popular", and follow up on fetching reviews #}
User: I want a popular restaurant in Napa, CA.
Target: SELECT *, summary(reviews) FROM restaurants WHERE rating >= 4.5 AND location = ’Napa, CA’ ORDER BY num_reviews DESC
      LIMIT 1;
Agent: I found the 5.0 star Gui’s vegan house. It has 2,654 reviews and reviews mention great atmosphere, quick and good
      service, and good food quality.
User: Give me the review that talk about good food quality.
Target: SELECT single_review FROM restaurants AS r, unnest(reviews) AS single_review WHERE name ILIKE ’Gui’’s vegan house’
      AND answer(single_review, ’does this review mention good food quality?’) = ’Yes’ AND r.location = ’Napa, CA’ LIMIT 1;
--
{# Usage of ‘answer‘ function on reviews #}
User: Which restaurants have a happy hour in Bakersfield?
Target: SELECT *, summary(reviews), answer(reviews, ’what is the happy hour here?’) FROM restaurants WHERE location =
      ’Bakersfield’ AND answer(reviews, ’does this restaurant have a happy hour?’) = ’Yes’ LIMIT 1;

Talk to a restaurants chatbot and evaluate it

Imagine you are visiting Palo Alto and you are looking for restaurants. In this study, you will talk to a chatbot to find restaurants there. Once the conversation is over, you will need to answer 3 questions regarding your overall experience with the chatbot.

For instance, here are some examples of how you could start the conversation:

1. Hey there! I am bringing my family to Palo Alto, what are some Chinese restaurants we can go to?
2. Give me a recommendation for a romantic, Italian restaurant in Palo Alto. I'd like to take my girlfriend there.
3. Please help me find a restaurant that is handicap-accessible in Palo Alto.
4. Hi! Can you please find me a four-star restaurant that sells burgers in Palo Alto?
5. Are there any good reviewed Korean restaurants with a lunch special in Palo Alto? What dishes do they have?

* Indicates required question

Please copy paste your prolific ID here *

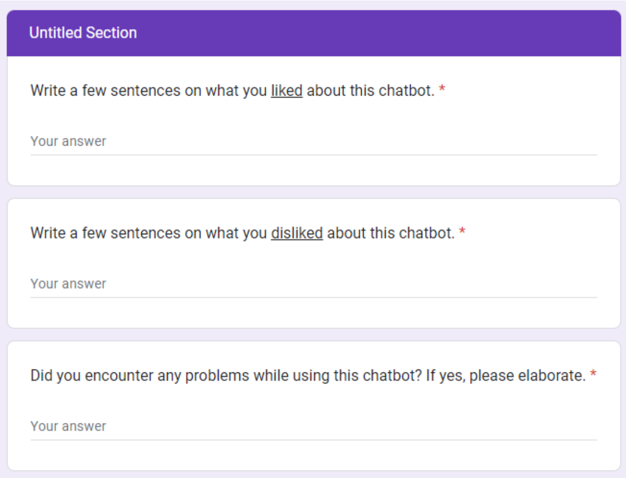
Your answer

Now, talk to the chatbot about to find a restaurant in Palo Alto for **at least 5 turns**. * Remember to include "Palo Alto" in the conversation.

To start, click on this link. Once you are done, please type in "**FINISHED**" (all upper case) to receive a dialog ID, and paste it here.

Your answer

Figure 4: The prompts we give crowdsourcing workers before they start conversing with our chatbot.



Untitled Section

Write a few sentences on what you liked about this chatbot. *

Your answer

Write a few sentences on what you disliked about this chatbot. *

Your answer

Did you encounter any problems while using this chatbot? If yes, please elaborate. *

Your answer

Figure 5: The questions crowdsourcing workers are asked after they finish talking to the chatbot.

On Evaluating the Integration of Reasoning and Action in LLM Agents with Database Question Answering

Abstract

This study introduces a new long-form database question answering dataset designed to evaluate how Large Language Models (LLMs) interact with a SQL interpreter. The task necessitates LLMs to strategically generate multiple SQL queries to retrieve sufficient data from a database, to reason with the acquired context, and to synthesize them into a comprehensive analytical narrative. Our findings highlight that this task poses great challenges even for the state-of-the-art `GPT-4` model. We propose and evaluate two interaction strategies, and provide a fine-grained analysis of the individual stages within the interaction. A key discovery is the identification of two primary bottlenecks hindering effective interaction: the capacity for planning and the ability to generate multiple SQL queries. To address the challenge of accurately assessing answer quality, we introduce a multi-agent evaluation framework that simulates the academic peer-review process, enhancing the precision and reliability of our evaluations. This framework allows for a more nuanced understanding of the strengths and limitations of current LLMs in complex retrieval and reasoning tasks.

1 Introduction

Significant advancements in natural language processing have been driven by the development of Large Language Models (LLMs) (Devlin et al., 2019; Radford et al., 2019; Brown et al., 2020; Chowdhery et al., 2022; OpenAI, 2023), which have become fundamental components of numerous products used by millions, reshaping people's habits on accessing information. Despite their widespread adoption and impact, LLMs face intrinsic limitations due to their design, including limited context window, stochastic nature which makes them less suited for tasks requiring high standards of precision, and extensive computations (Mialon et al., 2023; Ji et al., 2023; Wang et al., 2023a). Many studies have explored ways to mitigate these constraints by augmenting LLMs with modules/tools of complementary features (Nakano et al., 2022; Lewis et al., 2020; Lazaridou et al., 2022; Gao et al., 2023a; Parisi et al., 2022; Schick et al., 2023). In our study, we focus on augmenting LLMs with a symbolic module - a SQL code interpreter - and assess their performance using the long-form database question-answering task that we introduce, illustrated in Figure 1. Such augmentation is inevitable for tasks involving databases, as they often far exceed the size of LLMs' context windows[1], making information retrieval through any means other than SQL inefficient. Additionally, the use of SQL queries brings transparency to the reasoning process of LLM agents, providing a means to validate the accuracy of their generated responses.

LLMs augmented with external modules/tools possess two primary abilities: the capacity to *act*, which involves the use of tools, and the capability to *reason*, which encompasses planning and analyzing the outcomes of actions (Mialon et al., 2023; Madaan et al., 2023; Paul et al., 2023; Yao et al., 2023; Yoran et al., 2023; Shinn et al., 2023). While numerous studies have evaluated these abilities in different contexts, we contend that some of them focus more on evaluating tool selection and tool employment with less focus on evaluating how LLM agents reflect or synthesize the action results (Parisi et al., 2022; Schick et al., 2023; Zhuang et al., 2023; Li et al., 2023). Other research (Shuster et al., 2022; Yao et al., 2023; BehnamGhader et al., 2023) does examine both the action and reasoning capacities of LLM agents, yet the actions' complexity is not as demanding as in studies with a stronger focus on the action aspect. Our goals are twofold: firstly, to introduce a task that places

"Investigate any correlations between singers' citizenship and their net worth, song sales, or highest chart positions."

We need to extract following information: singers citizenship, singers' net worth from 'singer' table, and sales of each song...

After analyzing the data, we found the following correlations between singers' citizenship and their net...

```
SELECT Singer_ID, Name,
Net_Worth_Millions, Citizenship
FROM singer; SELECT Song_ID,
Singer_ID, Sales,
Highest_Position FROM song; ...
```

	Singer_ID	Name	Birth_Year	Net_Worth_Millions
1	1	Liliane Bettencourt	1944	30
2	2	Christy Walton	1948	28.8
3	3	Alice Walton	1949	26.3
4	4	Iris Fontbona	1942	17.4
5	5	Jacqueline Mars	1940	17.8
6	6	Gina Rinehart	1953	17
7	7	Susanne Klatten	1962	14.3
8	8	Abigail Johnson	1961	12.7

Figure 1: Illustration of our long-form database question answering task. The LLM agent is expected to perform a series of tasks requiring reasoning and actions to interact with the database module.

equal emphasis on the complexities of both action and reasoning, requiring a concerted interaction between them, and secondly, to assess the proficiency of various LLM agents merging these dual aspects into a cohesive performance. Here are our main contributions:

- We introduce a new long-form database question answering task, requiring retrieval, reasoning and synthesis of diverse information from database. We develop a systematic approach for collecting questions, databases, and corresponding answers in a way that ensures the answers are definitive and indisputable, lending greater validity to the evaluation process. The task is challenging in retrieval: on average, it requires the formulation of three SQL queries to gather sufficient information to answer the questions. Our dataset and the prompts used for dataset construction and experiments can be found at `https://github.com/linyongnan/Database-Agent`.
- We explore the benefits of augmenting LLMs with the SQL code interpreter for our task, by comparing the performance of baseline LLMs given the complete database records but without SQL capabilities against LLM agents that are given database schema and SQL generation capacity.
- In evaluating the performance of agents across all sub-tasks, we identify that planning and tool utilization are the critical challenges in achieving effective coordination. We also delve into the reasons behind their shortcomings. We extend our examination to the generalizability of our results across various LLMs, measuring the disparity in performance between agents using proprietary and open-source LLMs as their foundation.
- Finally, we introduced a multi-agent evaluation framework aimed at enhancing the precision and consistency of the output assessments using `GPT-4` evaluators.

Property	**Value**
Evaluation Dataset Size	200

Database size	
- # Tables (Med.)	4
- # Columns (Med.)	4
- # Data Records (Med.)	11

Table 1: Dataset Statistics. **Avg.** stands for average and **Med.** stands for median.

2 Data Collection

In constructing our evaluation dataset, we prioritize a robust set of desiderata. These include the intensive retrieval of diverse information from the database, the application of rigorous reasoning over the information retrieved, and the synthesis of facts and inferences into a coherent and comprehensive long-form answer. Our methodology employs a hybrid annotation framework: we leverage the capabilities of `GPT-4` to generate preliminary annotations, then these annotations are selected and refined through manual intervention to ensure quality and relevance. The specifics and quantitative details of our evaluation dataset are presented in Table 1. We detail the collection of questions in Section 2.1 and the acquisition of answers in Section 2.2.

2.1 Question Generation

Our starting point is the databases from the Spider dataset (Yu et al., 2018). We introduce a question generation pipeline designed to generate questions and iteratively refine them, addressing common issues encountered during preliminary experiments with `GPT-4` generated queries. This pipeline can be described as **Control-Condense-Confirm**, it begins by exerting **control** over the question generation. We direct `GPT-4` to generate questions that pertain to specific entities or keywords by using the original questions from the Spider dataset as the basis. These questions are instrumental as they concentrate on distinct column sets from various tables, providing a targeted focus that counters the LLM's propensity to formulate overly broad and indistinct questions. Following the initial control, we often find the questions to be exceedingly detailed. To address this, we **condense** the content, removing superfluous information. This pruning process not only ensures the questions remain challenging but also leaves room for the model to demonstrate its inferential capabilities. The final phase is the manual review of questions to **confirm** they are unambiguous and meet all predefined criteria for the task. This step guarantees that the questions are of high quality and align with the specified desiderata of our dataset.

2.2 Answer Annotation

Building upon the question generation strategy outlined in the previous section, the task of annotating answers to questions is generally an effort-intensive task as it requires the formulation of multiple SQL queries. This task is further complicated by the fact that many databases, such as those in the Spider collection, often contain an insufficient number of data records for a comprehensive answer. We propose a method that employs a **Conjecture-Construct-Conclude** strategy to circumvent these issues.

The process begins by prompting `GPT-4` with the question alongside the database schema to **conjecture** an answer. Subsequently, we **construct** database records that corroborate this conjectured answer, formatted as `INSERT` statements. These statements are integrated with the original database's `CREATE` statements, resulting in a bespoke synthetic database aligned with the question. To ensure the integrity of the synthetic database, we execute the merged statements to confirm the absence of errors and manually inspect the data records' alignment with the conjectured answer. As the final step of our method, we task `GPT-4` to **conclude** with a substantiated answer, ensuring that it aligns with the evidences we injected to the synthetic database. This procedure ensures that each question is matched with a definitive answer, backed by verifiable evidence from the database records.

Finally, we examine the question and its corresponding answer. We noticed that a substantial number of questions allow for multiple plausible answers, each subject to interpretation of certain abstract word in the question.[2] To refine the fairness of evaluations against a reference answer, we categorize all questions as either "Interpretive" or "Conclusive". "Conclusive" questions typically result in definitive answers: yes, no or unknown, while "Interpretive" questions can yield multiple valid answers depending on the interpretation of certain terms in the question. We provide demonstrative examples in Figure 5 of the appendix to illustrate the distinction between these categories. The distribution of questions across these categories is detailed in Table 1.

3 Methods

We aim to evaluate how effective LLMs are at performing a complex task that necessitate working with external modules. We explore five main aspects: (1) the proficiency of LLMs in completing our proposed task through interaction with external modules; (2) the extent of improvement LLMs gain from engaging with external modules; (3) the impact of various interaction strategies on LLM performance and the identification of the most effective one; (4) the challenges that hinder effective interaction; (5) the generalizability of our findings across diverse LLMs and the performance disparities attributed to the usage of different LLMs. We can address the first, second and last aspects by directly evaluating the quality of the final answer generated by LLMs. To delve into the third and fourth aspects, we need to first dissect the "interaction" process within our task into its constituent components.

We propose to decompose the LLMs' expected workflow for our task into three distinct sub-tasks: interaction planning, tool employment, and information synthesis. **Interaction planning** involves the LLM determining its interaction strategy with the external module, considering the question and past interactions. **Tool employment** is the phase where the LLM generates module-specific commands for the actual interaction. **Information synthesis** requires the LLM to review the interaction history and any newly acquired context to compile the key information for the final answer. This framework allows us to refine our second objective into assessing how different compositions of these sub-tasks affect the quality of the final answer, and also to define the most effective composition.

---

[2] Such as "impact", "success", "notable trends", etc.

The third objective can be addressed by evaluating LLM's execution within each sub-task.

While the potential configurations of these sub-tasks are vast, this study will narrow its focus to two primary interaction strategies for feasibility:

- **Sequential**: The LLM agent systematically tackles the sub-tasks in a linear, step-by-step fashion, with predetermined sequence: interaction planning, tool employment, and information synthesis. The agent's focus should be on prioritizing both precision and comprehensiveness throughout each juncture.
- **Iterative**: The LLM agent cyclically alternates between interaction planning and tool employment, similar to the self-ask prompting (Press et al., 2023). The key aspect of interaction planning in this context is to identify the most crucial information to extract from the database given the previous interactions. The strategy calls for the agent to ensure precision in every single interaction and to achieve comprehensiveness by deciding when to terminate the interaction cycle.

Equipped with these strategies, we proceed to empirically explore our central questions.

4 Experiments

4.1 Design

To prove the key areas identified in Section 3, we designed two sets of experiments. The first set evaluates three different types of LLM agents:

- No-Interaction: This LLM is tasked with deriving the final answer with a chain-of-thoughts prompting without engaging with the SQL module, i.e. generating SQL queries. To ensure fairness, we supply the complete database records within the prompt for context.
- Sequential-Interaction: We implement an LLM agent that utilizes the sequential strategy when working with the SQL module. It begins by devising a plan in natural language to identify the needed information and its sources, proceeds to generate SQL queries to retrieve this information, and concludes by integrating the data into the final answer.
- Iterative-Interaction: This strategy employs an LLM agent that iteratively determines the most crucial information to retrieve given the interaction history. The agent articulates this in natural language, crafts the corresponding SQL query, and repeats this process until it elects to stop. The final step involves consolidating the gathered information into a conclusive answer.

The second set of experiment focuses on evaluating the generalizability of our findings across various LLMs, as well as comparing their performance. We tested two proprietary LLMs: `GPT-4` and `GPT-3.5-turbo`, and six open-source LLMs of different sizes and capabilities: `Llama-2-[7, 13]b`, `Code-Llama-[7, 13, 34]b`, and `Mistral-7b`. The `Llama-2` models were tested using their chat versions, while the `Code-llama` and `Mistral` models were evaluated using versions fine-tuned for instruction-following.

4.2 Evaluation

To rigorously assess the performance, we implemented two distinct evaluation methods. Both involve using an LLM for the evaluation process, yet they differ in terms of their reliance on a reference answer. Throughout both evaluation methods, we use `GPT-4` to ensure consistency.

4.2.1 Reference-based Evaluation

In this method, we utilize an LLM to compare the system-generated answer against a reference answer, whose acquirement is detailed in Section 2.2. The evaluation protocol is adapted to suit the nature of the question: for conclusive questions that demand a specific answer, the LLM evaluator provides a straightforward verdict of either *"match"* or *"not match"* and offers a rationale for its decision. For interpretive questions, which permit a spectrum of answers, the LLM assigns a nuanced score ranging from 1 (no match) to 5 (exact match), reflecting the degree of information overlap with the reference. The scoring rubric for this nuanced evaluation is outlined in Figure 7 of the appendix.

4.2.2 Reference-free Evaluation

Assessing LLM performance on individual sub-tasks is essential, yet the multitude of potential answer pathways complicates the annotation process, making reference-based evaluation impractical. To navigate this challenge, we devised a reference-free evaluation using a **multi-agent framework** modeled after the academic peer-review system, as illustrated in Figure 6 in the Appendix. This framework enlists a group of reviewers and meta-reviewers to evaluate the system outputs. Each reviewer receives the question, database schema, and the LLM agent's output for individual sub-tasks. Their role is to critically assess each output across various dimensions and determine if it is *"perfect"* or *"not perfect"*. Meta-reviewers are then presented with the reviewers' assessments and verdicts. Their task is to discern consensus or discrepancies among the reviewers' opinions, evaluate the validity of their critiques, and render a final decision of *"perfect"* or *"not perfect"*. The ultimate evaluation outcome is derived from the majority ruling among the meta-reviewers. To ensure a diversity of perspectives and avoid uniformity in judgment, we configured each `GPT-4` evaluator with a temperature of 0.7. The specific guidelines used to direct reviewers and meta-reviewers are detailed in Figures 8, 9, 10 in the Appendix. We conducted a manual examination of all the reviews and, based on our findings, adopted a meta-review revision process to enhance the results. The details and rationale behind this approach are elaborated in Section A of the Appendix.

4.3 Results

The experimental outcomes are presented in Figures 2, 3, 4 and Tables 2, 3, 5, addressing the main research questions posed by our study.

LLM Agent Performance on Proposed Task Examining Figures 2, 4, and Tables 2, 5, it becomes evident that even the state-of-the-art `GPT-4`, when utilizing a better interaction strategy, correctly answers only 30% of conclusive questions and achieves an average score of 2.34 on a 1-5 scale. The multi-agent evaluation echoes this, with 36% (IP), 56% (TE), and 67% (IS) of instances deemed perfect for individual step, and only **22%** of instances considered perfect for all steps, indicating considerable room for improvement.

Improvement from SQL Module Interaction Table 3 compares LLM agents' performances with and without SQL module interaction. A significant improvement is observed in LLMs' performance on conclusive questions when augmented with SQL modules. However, this is not the case for interpretive questions. It is important to note that this result applies to instances with small databases where complete records fit within the context window provided to non-interactive LLMs. This suggests that direct interaction with external modules is particularly beneficial for tasks that demand high precision in retrieval, reinforcing our arguments of LLM limitations in Section 1.

The Impact of Interaction Strategies Figure 2 reveals that, generally, a sequential strategy yields better results across most LLMs, with iterative strategies favoring `Llama-2-13b` and `Mistral-7b`. We investigate this trend by analyzing the length of plans, the number of generated SQL queries, and their validity. Notably, when employing iterative strategies, both `Llama-2-13b` and `Mistral-7b` engage minimally with the SQL module, with the `Mistral-7b` agent does not engage with the database at all (empty plan), indicating that it essentially guesses the answers. We set the performance of `Mistral-7b` with iterative strategy as a reference point for guess-based answers, marked by vertical lines in the figures, and make a note that performances close to this baseline likely result from guesswork. Additionally, we can also notice that agents using iterative strategies tend to plan less and interact minimally with SQL modules, contributing to their underperformance compared to sequential strategies.

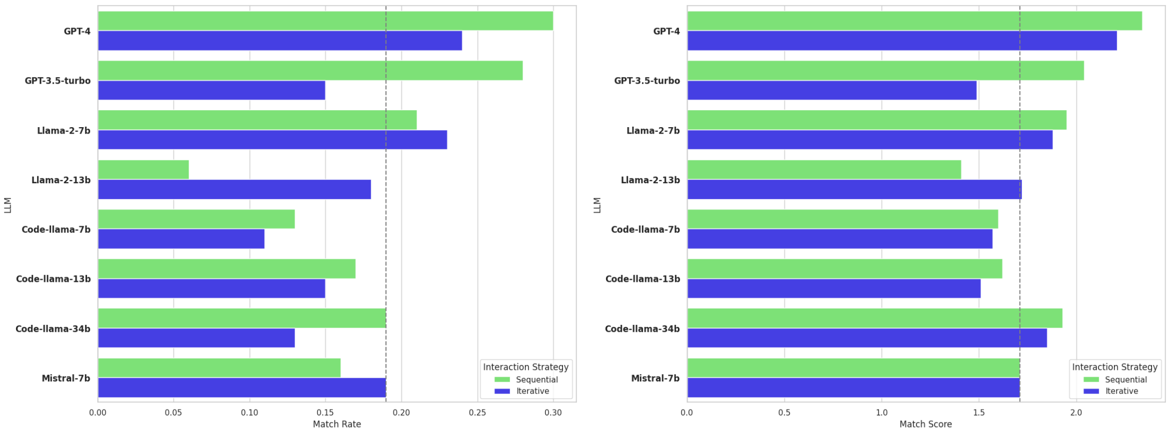
Barriers to Effective Interaction Figures 4 and Table 5 highlight that planning and tool employment (i.e. SQL generation) are the main hurdles preventing agents from performing well on the proposed tasks. Conversely, agents generally excel at synthesizing retrieved information to produce an accurate and comprehensive answer. This indicates that eliciting better interaction planning via more effective prompting and enhancing LLMs' ability to generate multiple SQL queries in parallel from extended text descriptions are promising areas for future research.

Generalizability Across Different LLMs The conclusions regarding interaction strategy appear consistent across various LLMs. However, our hypothesis of interaction barriers primarily holds for the more capable proprietary LLMs like `GPT-4` and `GPT-3.5-turbo`, and to a lesser extent, `Llama-2` and `Code-Llama` models. The remaining LLMs did not engage in any meaningful interaction, thus no discernible patterns were noted.

Interaction Depth and Answer Quality Figure 3 suggests a weak correlation between the number of valid interactions (i.e., agent-generated SQL queries that yield non-empty results) and performance, hinting that more successful retrieval aids

LLM	Interaction Mode	Match Score (`C/I`)	Plan Length (`C/I`)	# Generated SQLs (`C/I`)	# Valid SQLs (`C/I`)	Answer Length (`C/I`)
`GPT-4`	Sequential	0.30 / 2.34	437 / 474	2.96 / 3.28	2.72 / 2.94	197 / 221
	Iterative	0.24 / 2.21	83 / 101	0.99 / 1.18	0.79 / 0.80	157 / 199
`GPT-3.5-turbo`	Sequential	0.28 / 2.04	297 / 321	2.23 / 2.63	1.84 / 2.30	202 / 193
	Iterative	0.15 / 1.49	223 / 252	1.06 / 1.10	0.89 / 0.81	94 / 90
`Llama-2-7b`	Sequential	0.21 / 1.95	364 / 347	2.88 / 2.58	1.29 / 1.04	285 / 283
	Iterative	0.23 / 1.88	63 /92	0.65 /1.03	0.13 / 0.14	252 / 292
`Llama-2-13b`	Sequential	0.06 / 1.41	398 / 401	3.05 / 1.83	1.32 / 0.86	336 / 339
	Iterative	0.18 / 1.72	16 / 16	0.20 / 0.28	0.01 / 0.01	310 / 359
`Code-llama-7b`	Sequential	0.13 / 1.60	368 / 390	3.25 / 3.67	1.59 / 1.89	306 / 325
	Iterative	0.11 / 1.57	0 / 0	0 / 0	0 / 0	234 / 240
`Code-llama-13b`	Sequential	0.17 / 1.62	389 / 396	4.34 / 5.36	1.95 / 2.78	292 / 314
	Iterative	0.15 / 1.51	115 / 110	0.66 / 1.59	0.26 / 0.70	243 / 245
`Code-llama-34b`	Sequential	0.19 / 1.93	359 / 377	2.79 / 3.31	1.39 / 1.72	314 / 352
	Iterative	0.13 / 1.85	39 / 47	0.4 / 0.33	0.28 / 0.18	248 / 294
`Mistral-7b`	Sequential	0.16 / 1.71	384 / 379	1.01 / 0.91	0.57 / 0.37	231 / 282
	Iterative	0.19 / 1.71	0 / 0	0 / 0	0 / 0	207 / 267

Table 2: Reference-based evaluation results and other measurements of the interaction process. `C` stands for **conclusive** and `I` stands for **interpretive**. Valid SQL indicate SQL queries that are generated by the LLM agent that have non-empty execution results.



(a) Match Rate for Instances with Conclusive Questions (b) Match Score for Instances with Interpretive Questions

Figure 2: Reference-based evaluation results across various interaction strategies and LLMs, with a vertical line representing the performance achieved by a non-interactive LLM agent lacking database context, serving as the baseline for guessing.

in generating more precise and comprehensive answers.

Diversity and Consensus in Multi-agent Evaluation Aggregating multiple diverse evaluations and meta-evaluations from LLMs appears to decrease result variance, as evidenced by the increased consensus among meta-reviewer LLMs compared to reviewer LLMs shown in Table 5. The scores from meta-reviewers are consistently lower than those from reviewers, indicating that the meta-review process critically considers the issues highlighted by reviewers. This multi-tiered review mechanism ensures that our evaluation framework effectively balances both precision and recall.

4.4 Human Evaluation

We conducted human evaluations in both reference-based and reference-free setting, aiming to compare the evaluation outcomes of LLM evaluators with human judgment. As detailed in Table 4, we present the average results from three internal human evaluators and the proportion of instances where human assessment aligned with LLM evaluations regarding the output of our most powerful

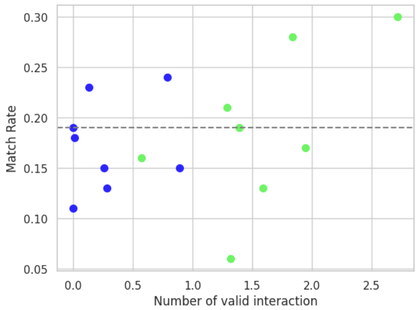
LLM	**Interaction Mode**	**Conclusive Questions Match Rate**	**Interpretive Questions Match Score**
`GPT-4`	No	0.19	2.37
	Sequential	0.27	2.40
`GPT-3.5-turbo`	No	0.24	2.12
	Sequential	0.30	2.13

Table 3: LLM agents with vs. without interaction with SQL modules. Entire database records are provided in the context for LLMs that disable interaction. We sampled 161 out of 200 questions to report their reference-based evaluation results because some databases are too large to fit into LLM's context window.

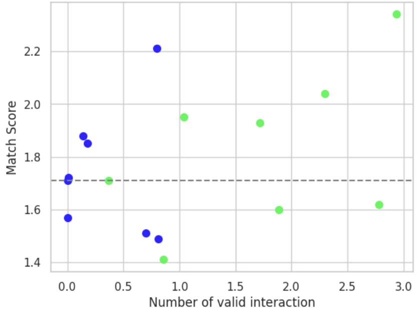
baseline - `GPT-4` agent employing a sequential strategy. In both scenarios, human evaluators received identical materials (outputs of `GPT-4` agent and scoring guidelines) as provided to the LLM evaluators. In the reference-based setting, we found that human evaluations concurred with LLM assessments in over 80% of cases. A similar level of agreement was observed in the reference-free settings across all IP, TE and IS steps, reinforcing our assertion that significant improvement potential exists in our task. Notably, the most advanced `GPT-4` agent primarily faced challenges in planning interactions for interpretive questions, with only 26% of its attempts deemed accurate, whereas planning for conclusive questions demonstrated higher success rate.

4.5 Error Analysis

In our analysis of the `GPT-4` agent's performance across the IP, TE and IS steps, we identified several recurrent error types, supplemented by specific examples in Figures 11-15 of the Appendix for clarity. During the planning stage, we observed that the agent often: (1) misinterpreted column contents (Figure 11); (2) made incorrect assumptions about column contents (Figure 12); (3) overlooked key columns essential for analysis to answer the question (Figure 13); (4) exhibited oversight or sampling bias in data retrieval for subsequent analysis (Figure 14). In the tool employment step, the agents often failed to execute statistical analyses, such as computing the correlation coefficient (Figure 15). While Python might be more appropriate for such task, its exploration is beyond the scope of this study. Regarding the information synthesis step, it is important to note that many negative evaluations in this stage stemmed from failures in the previous step. When SQL execution results were lacking, leaving no information for synthesis, the agent struggled to respond accurately, leading to predominantly negative reviews of this phase.



(a) Match Rate vs. Valid Interaction for Instances with Conclusive Questions



(b) Match Score vs. Valid Interaction for Instances with Interpretive Questions

Figure 3: Correlation between answer quality and number of valid interaction (SQL queries that returned non-empty results)

Question type	**Reference-based**	**Reference-free**		
	Match / %Agree	**IP / %Agree**	**TE / %Agree**	**IS / %Agree**
Conclusive	0.25 / 0.82	0.60 / 0.83	0.58 / 0.96	0.7 / 0.75
Interpretive	2.2 / 0.83[3]	0.26 / 0.88	0.58 / 0.88	0.76 / 0.84
All	N/A	0.43 / 0.85	0.58 / 0.92	0.73 / 0.80

Table 4: Human evaluation results for reference-based and reference-free settings based on outputs of our strongest baseline - `GPT-4` agent with sequential interaction strategy. % Agree represents the proportion of instances in which human and LLM evaluations concur.

5 Related Work

5.1 Augmented Language Models

The use of external tools to augment language model outputs and mitigate model hallucination

---

[3] When calculating the agreement for match scores of interpretive questions, we reclassify the original scores (scale of 1 to 5) into three levels: scores of 1 to 3 were assigned as low, a score of 4 as medium, and a score of 5 as high. This process is employed due to the guidelines given to human evaluators, which suggest that scores from 1 to 3 reflect varying extents of fact omission. Precisely differentiating between these degrees can be difficult, hence the need for reclassification.

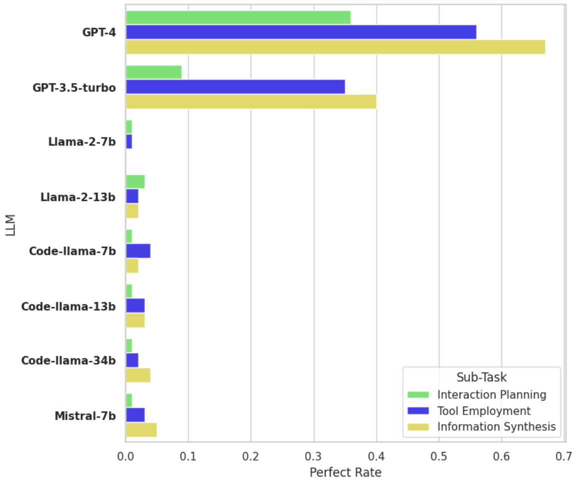


Figure 4: Reference-free multi-agent evaluation results for different sub-tasks and LLMs, all employing sequential interaction strategy.

has been previously studied in other domains and tasks (Mialon et al., 2023). Models augmented with tools like internet search (Lazaridou et al., 2022), Python interpreters (Gao et al., 2023b), math equation-generating models (Imani et al., 2023), and question-answering models (Guu et al., 2020) have empirically shown improvements in accuracy in comparison to their counterpart baseline models. Other models like TALM (Parisi et al., 2022) and Toolformer (Schick et al., 2023) for question answering and ToolWriter (Gemmell and Dalton, 2023) for tabular question answering have built on top of these to limit reliance on humans to select tools for question answering models by fine-tuning the models to learn how and when to use tools. Our work differs from these previous works in that we augment language models to use tools in the data-to-text generation domain specifically where the model is expected to not only query from a database with the use of external tools, but also aggregate these results and interpret the data to produce a paragraph-length response to a not necessarily close-ended question.

5.2 Reasoning and Action

Our work draws on elements of frameworks that either prompt the model to repeatedly reason, act upon the reasoning, and update the action plan until the answer is found (Yao et al., 2023) or plan out the different components needed to answer questions before retrieving and generating the answer (Su et al., 2021). Other frameworks used additional language models as the planner to aggregate information retrieved by a diverse inventory of tools (Lu et al., 2023). Our work builds upon some of these frameworks and investigates these in context of the task of long-form data-to-text generation. (Liu et al., 2023a) assess LLMs' proficiency in interfacing with databases through SQL, specifically investigating their performance in question answering tasks that involve selection-type SQL queries, evaluated via exact string match comparison between the generated and reference answers, as well as tasks requiring database modification, such as insert or update SQL queries, evaluated through a database match metric. In contrast, our study is centered on question answering tasks that demand extensive retrieval and reasoning capabilities, and we report findings using both reference-based and reference-free metrics for evaluating the generated answers.

5.3 Text-to-SQL

The field of Text-to-SQL has been extensively studied as the standard method for database question answering, with significant contributions from a range of studies (Berant et al., 2013; Zhong et al., 2017; Yu et al., 2018; Yin and Neubig, 2018; Yu et al., 2019; Wang et al., 2020; Yin et al., 2020; Scholak et al., 2021; Ren et al., 2021; Xie et al., 2022; Cheng et al., 2023; Nan et al., 2023, *inter alia*). Traditionally, Text-to-SQL focuses on generating a singular SQL query in response to a question. In contrast to this, our study innovates by introducing a question-answering task over databases that demands the generation of multiple SQL queries to formulate the answer.

5.4 Text Generation Evaluation

Development in automatic evaluation metrics have emerged, utilizing LLMs to evaluate the quality of generated texts (Fu et al., 2023; Liu et al., 2023b). These methods have also been adapted for evaluating text pertaining to tabular data (Rebuffel et al., 2021) and hallucination detection (Manakul et al., 2023). (Wang et al., 2023b) introduced self-consistency sampling, which has been shown to improve the reasoning performance of the system. This approach involves generating a set of diverse answers and selecting the most common one through majority vote. In our study, we propose a reference-free multi-agent evaluation framework that synthesizes these ideas.

6 Conclusion

In conclusion, our investigation reveals the current limitations of LLMs in complex retrieval and reasoning tasks. Augmentation with a SQL module proved beneficial, particularly for conclusive questions, and pointed to the necessity of strategic interaction planning and proficient tool employment. Our findings stress the need for improvement in these areas to enhance LLM effectiveness. Despite the challenge of varying performance across different models, our multi-agent evaluation framework provides a scalable and rigorous method for assessing agent capabilities. We hope that our proposed task and findings will encourage further investigations in LLMs' capabilities of interacting with external modules, inching towards LLMs capable of handling complex tasks with enhanced precision.

Limitations

This study acknowledges several constraints that much be considered when interpreting the results. First, our evaluation dataset is small in scale, a limitation primarily due to budget constraints. We plan to expand our dataset to enhance the statistical significance of our findings. Second, while this study concentrated on tasks that require intensive action and reasoning capabilities, there is room to explore how LLM agents would perform with external modules on similar tasks with less stringent requirements. Third, this study's investigation is limited to specific modules, leaving the examination of a broader spectrum of modules unaddressed. Expanding our research to include a more diverse set of modules is a direction we plan to explore in our future work. Lastly, it is important to acknowledge a potential bias in our evaluation methodology stemming from the exclusive use of `GPT-4` for generating reference answers as well as for evaluating system-generated responses. This reliance could skew the evaluation in favor of `GPT-4` agent's answers.

Appendix

A Reference-free Evaluation Meta-Review Revision

Upon completing our evaluations and conducting an error analysis based on reviews from our multi-agent framework, we observed that a substantial portion of the negative reviews pertained to the inconsistency between the execution results of SQLs generated by the agent and the database description in the prompt, which included three sample rows to demonstrate data types. It should be noted that these records were intended only for demonstration and do not encompass the entire database. This aspect was not sufficiently emphasized in our prompt, leading `GPT-4` reviewers and meta-reviewers to incorrectly perceive any additional data from SQL execution as erroneous. Furthermore, we identified that reviewers placed a high emphasis on the data type consistency of columns used for joining two tables, even though many join keys in our databases are of compatible types, capable of implicit conversion by the SQL compiler. We believe these two types of criticisms to be overly stringent for evaluating the agent's capability in our task. Consequently, we have instructed `GPT-4` to re-evaluate, considering the meta-reviews of each stage and specifically disregarding the two types of errors mentioned. The original and revised scores, presented in Table 5, demonstrate the considerable impact of these errors on the evaluation of tool employment.

- **Conclusive questions:**
  1. Do dual-enrolled students tend to perform better or worse than their peers in the same degree programs?
  2. Analyze the relationship between teachers' experience and their performance based on the grades received in the courses they have taught.
  3. Investigate any correlations between poker players' performance and factors such as nationality, age, and height.
- **Interpretive questions:**
  1. Compare the success metrics between French and non-French singers.
  2. Analyze the impact of record companies on the success of orchestras based on their performance ratings and attendance.
  3. Analyze the performance of the TV series by language and country, and identify any notable patterns or trends.

Figure 5: Examples of Conclusive and Interpretive Questions

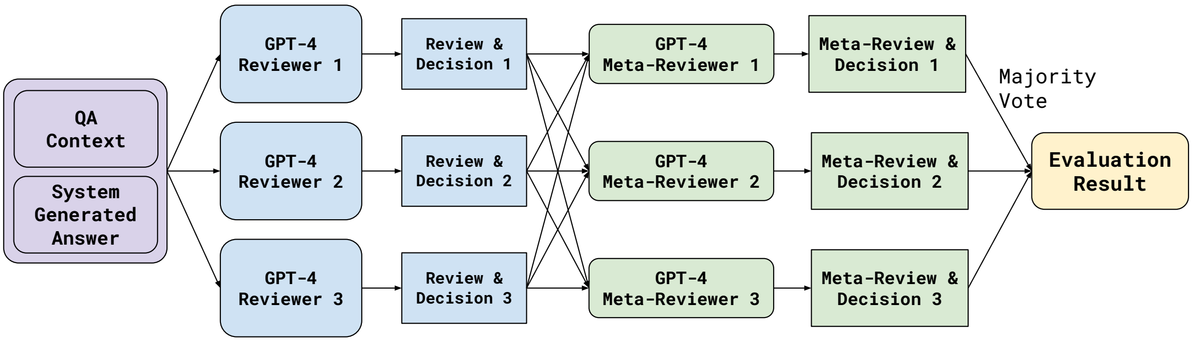

Figure 6: Illustration of our multi-agent evaluation framework. It consists of two tiers of evaluation process.

LLM	Sub-Task	Reviewer		Meta-Reviewer		Revised
		Perf. Rate	**Agree.**	**Perf. Rate**	**Agree.**	**Perf. Rate**
`GPT-4`	IP	0.48	0.54	0.28	0.88	0.36
	TE	0.41	0.69	0.28	0.93	0.56
	IS	0.61	0.72	0.53	0.93	0.67
`GPT-3.5-turbo`	IP	0.14	0.80	0.09	0.96	0.09
	TE	0.18	0.82	0.13	1.00	0.35
	IS	0.26	0.79	0.22	0.95	0.40
`Llama-2-7b`	IP	0.02	0.97	0.01	0.99	0.01
	TE	0.01	0.99	0.01	1.00	0.01
	IS	0.01	0.99	0.00	1.00	0.00
`Llama-2-13b`	IP	0.03	0.96	0.02	0.98	0.03
	TE	0.01	0.98	0.01	0.99	0.02
	IS	0.01	0.99	0.01	0.99	0.02
`Code-llama-7b`	IP	0.02	0.93	0.01	0.99	0.01
	TE	0.01	0.98	0.01	0.99	0.04
	IS	0.02	0.98	0.01	1.00	0.02
`Code-llama-13b`	IP	0.01	0.96	0.01	1.00	0.01
	TE	0.02	0.98	0.02	1.00	0.03
	IS	0.02	0.97	0.02	1.00	0.03
`Code-llama-34b`	IP	0.04	0.90	0.01	0.98	0.01
	TE	0.02	0.97	0.01	0.99	0.02
	IS	0.04	0.96	0.04	0.99	0.04
`Mistral-7b`	IP	0.03	0.96	0.01	0.99	0.01
	TE	0.01	0.98	0.00	1.00	0.03
	IS	0.05	0.94	0.03	0.98	0.05

Table 5: Reference-free multi-agent evaluation - fine-grained results for different LLMs adopting **Sequential** interaction strategy. **IP** stands for Interaction Planning, **TE** stands for Tool Employment, and **IS** stands for Information Synthesis. **Perf. Rate** stands for percentage of instances that (meta-)reviewers considers perfect, and **Agree.** stands for agreement, and it is calculated with the percentage of instances that (meta-)reviewers reach in unanimous agreement. For additional context regarding the revised results, please see Section A of the Appendix.

Given the following inputs:

Question: {question}

Reference (Gold) Answer: {gold_answer}

System Generated Answer: {answer}

Evaluation Process:

Read the gold answer carefully to understand the precise information it conveys.

Examine the system-generated answer to identify the information presented.

Check for the presence of critical information (such as conclusions) from the gold answer in the system-generated answer.

Evaluation Criteria:

The system-generated answer is considered a "Match" if it contains all the critical information from the gold answer. The presence of additional non-contradictory information in the system-generated answer is acceptable, provided that all the information from the gold answer is included.

Output Format:

If the system-generated answer includes all the critical information from the gold answer, the output should be: "Conclusion: Match"

If any critical information from the gold answer is missing or misrepresented in the system-generated answer, the output should be: "Conclusion: Not Match"

Conclusion:

(a) Scoring Metrics for Conclusive Questions

Given the following inputs:

Question: {question}

Reference (Gold) Answer: {gold_answer}

System-Generated Answer: {answer}

Evaluation Process:

Familiarize yourself with the gold answer to understand the full scope of information it contains.

Analyze the system-generated answer to identify the information that has been captured.

Compare the two answers to determine how much of the gold answer's information is reflected in the system-generated answer.

Scoring Metrics:

Score 1: The system-generated answer lacks almost all the key points that the comprehensive gold answer provides.

Score 2: The system-generated answer includes some key points from the gold answer but misses others, and it may include additional details not found in the gold answer.

Score 3: The system-generated answer captures most of the key information from the gold answer, but there are noticeable omissions or additions.

Score 4: The system-generated answer encompasses all key points from the gold answer and also introduces more information not covered in the gold answer.

Score 5: The system-generated answer perfectly mirrors the gold answer, containing all the information with no omissions or additions.

Output Format:

Provide a score between 1 to 5 based on the evaluation. The output should be: "Score: [1/2/3/4/5]"

Score:

(b) Scoring Metrics for Interpretive Questions

Figure 7: Prompts used for evaluating system generated answers for conclusive and interpretive questions

Problem Context:
A planning agent has been tasked to devise a solution to a user question related to a database. Given the question and the database's description, the agent proposes a plan detailing the type of information it would retrieve from the database to answer the question effectively.
Your Task:
You are to evaluate the plan's relevance and comprehensiveness. Assess whether the plan can indeed retrieve the necessary information to address the user's question.
Inputs:
User Question:
{question}
Database Description:
{database_text}
Agent's Proposed Plan:
{plan}
Evaluation Criteria:
Relevance: Does the plan target relevant pieces of information from the database that directly pertain to the user's question?
Comprehensiveness: Is the plan exhaustive, ensuring all necessary pieces of information are retrieved to fully answer the user's question?
Plan Definitions:
Perfect Plan: A plan that is both relevant and comprehensive, ensuring that the user's question can be answered completely without missing any essential data points.
Imperfect Plan: A plan that misses out on some relevant information, or includes unnecessary steps, thus not providing a complete or accurate solution to the user's question.
Response Format:
Rationale: Begin with a detailed explanation of your evaluation. Discuss the strengths or weaknesses of the plan based on the relevance and comprehensiveness criteria.
Final Decision: After providing the rationale, conclude with one of the following decisions:
- Perfect: If you believe the plan meets both the relevance and comprehensiveness criteria effectively.
- Imperfect: If you find the plan lacking in any aspect, be it relevance or comprehensiveness.

(a) Review Criteria for Interaction Planning

Problem Context:
As the "editor-in-chief", you are tasked with evaluating the reviews provided by multiple reviewers on a planning agent's proposed plan to answer a database-related user question. Each review contains a detailed rationale and a final decision.
Your Task:
Your goal is to compare and assess the rationales provided by the reviewers, and then make a final, conclusive decision about the planning agent's proposal. This decision should be based on a comprehensive understanding of the reviewers' perspectives and the evidence they present.
Inputs:
User Question:
{question}
Database Description:
{database_text}
Agent's Proposed Plan:
{plan}
Reviewers' Rationales and Decisions:
{IP_reviews}
Evaluation Criteria:
Review Consistency: Are the reviewers' rationales and decisions consistent with each other?
Evidence Quality: Is the evidence provided in the rationales substantial and convincing enough to make a definitive conclusion?
Final Decision Basis: Does the aggregated perspective of the reviewers lead to a clear final decision?
Response Format:
Rationale: Begin with a detailed explanation comparing the rationales provided by the reviewers. Highlight consistencies or discrepancies among them and discuss how these influenced your final decision.
Final Decision: After providing the rationale, conclude with one of the following decisions:
- Perfect: If the aggregated insights from reviewers suggest that the planning agent's proposal is both relevant and comprehensive.
- Imperfect: If the combined reviews indicate that the planning agent's proposal is lacking in either relevance or comprehensiveness.

(b) Meta-Review Criteria for Interaction Planning

Figure 8: Prompts used for reviewing and meta-reviewing interaction planning

Problem Context:
An agent is given a question, a database for retrieving relevant context, and a plan of how to perform the retrieval. It has been tasked to translate the plan into accurate and executable SQL queries. These queries should correspond to the given plan and effectively retrieve the relevant information from the database to address the user's question, adhering to the database structure provided.
Your Task:
You are to evaluate the correctness and alignment of the SQL queries generated by the agent based on the plan provided. Also, review the execution results to determine if they fulfill the user's requirements as stipulated in the plan.
Inputs:
User Question: {question}
Database Description: {database_text}
Search Plan: {plan}
Agent's Proposed SQL Queries and Execution Results: {sql_results}
Evaluation Criteria:
Correctness: Are the SQL queries syntactically and semantically correct, and do they retrieve the expected data from the database?
Alignment: Do the SQL queries align with the steps outlined in the initial plan?
Execution Results: Does the outcome of the SQL queries correspond to the desired results based on the user's question and the initial plan?
Query Definitions:
Perfect Queries: All SQL queries are correct, aligned, and ensure that the user's question is addressed in accordance with the initial plan.
Imperfect Queries: There is at least one SQL query that has errors, misalignments, or does not produce the expected results as outlined in the initial plan.
Response Format:
Rationale: Begin with a detailed explanation of your evaluation. Address the SQL queries' correctness, their alignment with the initial plan, and the resulting output's relevance to the user's query.
Final Decision: After providing the rationale, conclude with one of the following decisions:
- Perfect: If all SQL queries are correct, aligned with the plan, and the results answer the user's question as expected.
- Imperfect: If you find any discrepancies in correctness, alignment, or the execution results of the proposed SQL queries.

(a) Review Criteria for Tool Employment

Problem Context:
As the "editor-in-chief", you are presented with multiple reviews evaluating an agent's capability to generate SQL queries from a given plan to answer a user question using a specified database. Each review contains an in-depth rationale and a final decision regarding the correctness, alignment, and execution results of the SQL queries.
Your Task:
Your goal is to compare and assess the rationales provided by the reviewers, weighing their evidence and perspectives, and then make a final, conclusive decision regarding the agent's SQL queries based on the aggregated reviews.
Inputs:
User Question: {question}
Database Description: {database_text}
Search Plan: {plan}
Agent's Proposed SQL Queries and Execution Results: {sql_results}
Reviewers' Rationales and Decisions: {TE_reviews}
Evaluation Criteria:
Review Consistency: Do the reviewers agree in their evaluations, or are there conflicting perspectives?
Evidence Quality: Are the rationales provided by reviewers substantial and convincing?
Final Decision Basis: Based on the aggregated insights of the reviewers, is there a clear and justifiable final decision?
Response Format:
Rationale: Begin with a detailed comparison of the rationales provided by the reviewers. Address any consistencies or discrepancies in their evaluations, emphasizing how these observations influenced your final decision.
Final Decision: After analyzing the rationales, conclude with one of the following decisions:
- Perfect: If the collective insights suggest that all the agent's SQL queries are accurate, aligned, and answer the user's question as stipulated.
- Imperfect: If the combined reviews reveal issues in correctness, alignment, or the execution results of the agent's SQL queries.

(b) Meta-Review Criteria for Tool Employment

Figure 9: Prompts used for reviewing and meta-reviewing tool employment

Problem Context:
An agent is presented with a user's question, a plan to extract more context for answering the question, and a search history containing SQL queries used to retrieve this context from the database. The agent's task is to synthesize all the given information to construct a coherent answer to the question.
Your Task:
You are to evaluate the synthesis produced by the agent. Assess whether the agent's response accurately interprets the SQL queries and their execution results. Furthermore, determine if the synthesized answer addresses the user's question both correctly and comprehensively.
Inputs:
User Question:
{question}
Database Description:
{database_text}
Search Plan:
{plan}
SQL Queries and Execution Results:
{sql_results}
Agent's Synthesized Answer:
{answer}
Evaluation Criteria:
Interpretation Accuracy: Does the agent's answer demonstrate a correct understanding of the SQL queries and their execution results?
Answer Correctness: Is the agent's synthesized answer accurate in terms of the given information?
Comprehensiveness: Does the agent's answer cover all aspects of the user's question based on the context retrieved?
Answer Definitions:
Perfect Answer: An answer that accurately interprets the SQL queries and results, and addresses the user's question both correctly and comprehensively.
Imperfect Answer: An answer that either misinterprets the SQL information, or does not completely and accurately address the user's question.
Response Format:
Rationale: Begin with a detailed explanation of your evaluation. Discuss the strengths or weaknesses of the agent's synthesized answer based on the criteria of interpretation accuracy, correctness, and comprehensiveness.
Final Decision: After providing the rationale, conclude with one of the following decisions:
- Perfect: If you believe the agent's answer meets all evaluation criteria effectively.
- Imperfect: If you identify any shortcomings in interpretation accuracy, correctness, or comprehensiveness of the answer.

(a) Review Criteria for Information Synthesis

Problem Context:
As the "editor-in-chief", you are tasked with evaluating multiple reviews that assess an agent's synthesis of an answer based on a user's question, a search plan, and the results of executed SQL queries. Each review contains a detailed rationale and a final decision on the agent's capability to coherently integrate the information and answer the user's question.
Your Task:
Your role is to compare and evaluate the rationales provided by the reviewers, integrating their insights and perspectives. Based on this aggregated understanding, make a final, conclusive decision about the agent's synthesized answer.
Inputs:
User Question:
{question}
Database Description:
{database_text}
Search Plan:
{plan}
SQL Queries and Execution Results:
{sql_results}
Agent's Synthesized Answer:
{answer}
Reviewers' Rationales and Decisions:
{IS_reviews}
Evaluation Criteria:
Review Consistency: Are there shared perspectives among the reviewers, or do they have conflicting views?
Evidence Quality: Do the reviewers present substantial and compelling evidence in their rationales?
Final Decision Basis: Does the collective insight of the reviewers lead to a clear, definitive conclusion about the agent's answer?
Response Format:
Rationale: Start with a comprehensive comparison of the rationales given by the reviewers. Address any commonalities or differences in their evaluations and describe how these factors influenced your final decision.
Final Decision: After dissecting the reviewers' insights, decide on one of the following: - Perfect: If the collective evaluations suggest that the agent's synthesized answer meets all the required criteria.
- Imperfect: If the integrated reviews indicate issues in the agent's interpretation, correctness, or comprehensiveness.

(b) Meta-Review Criteria for Information Synthesis

Figure 10: Prompts used for reviewing and meta-reviewing information synthesis

Database:
Title: "employee"
Header: [’Employee_ID’, ’Name’, ’Age’, ’City’]
Title: ’shop’
Header: [’Shop_ID’, ’Name’, ’Location’, ’District’, ’Number_products’, ’Manager_name’]
Title: ’hiring’
Header: [’Shop_ID’, ’Employee_ID’, ’Start_from’, ’Is_full_time’]
Title: ’evaluation’
Header: [’Employee_ID’, ’Year_awarded’, ’Bonus’]

Question:
Investigate the relationship between the number of employees and the number of shops in each city.

`GPT-4` **agent plan:**
Information Extraction: To investigate the relationship between the number of employees and the number of shops in each city, we need to extract the following information:
The city where each employee works
The number of employees working in each city
The number of shops in each city
Identification of Relevant Tables and Columns: To gather the necessary information, we need to look into the following tables and columns:
From the ’employee’ table, we need the ’Employee_ID’ and ’City’ columns.
From the ’shop’ table, we need the ’Shop_ID’ and ’Location’ columns.
From the ’hiring’ table, we need the ’Shop_ID’ and ’Employee_ID’ columns.
Description of Retrieval Process: To retrieve the required information, we will perform the following steps:
First, we will join the ’employee’ and ’hiring’ tables on the ’Employee_ID’ column. This will give us a combined table with information about which employee works at which shop.
Next, we will join the resulting table with the ’shop’ table on the ’Shop_ID’ column. This will give us a table containing information about the city where each employee works.
Now, we will group the data by the ’City’ column from the ’employee’ table and the ’Location’ column from the ’shop’ table. This will allow us to count the number of employees and shops in each city.
For each city, we will count the number of unique ’Employee_ID’ values to get the total number of employees working in that city.
Similarly, for each city, we will count the number of unique ’Shop_ID’ values to get the total number of shops in that city.
Finally, we will create a summary table with columns for ’City’, ’Number_of_Employees’, and ’Number_of_Shops’. This table will show the relationship between the number of employees and the number of shops in each city.

Figure 11: Example 1 - misinterpreting column contents: agent confuses employee.city with shop.location

Database:
Title: 'Addresses'
Header: ['address_id', 'line_1', 'line_2', 'line_3', 'city', 'zip_postcode', 'state_province_county', 'country', 'other_address_details'
Title: 'Courses'
Header: ['course_id', 'course_name', 'course_description', 'other_details']
Title: 'Departments'
Header: ['department_id', 'department_name', 'department_description', 'other_details']
Title: 'Degree_Programs'
Header: ['degree_program_id', 'department_id', 'degree_summary_name', 'degree_summary_description', 'other_details']
Title: 'Sections'
Header: ['section_id', 'course_id', 'section_name', 'section_description', 'other_details']
Title: 'Semesters'
Header: ['semester_id', 'semester_name', 'semester_description', 'other_details']
Title: 'Students'
Header: ['student_id', 'current_address_id', 'permanent_address_id', 'first_name', 'middle_name', 'last_name', 'cell_mobile_number', 'email_address', 'ssn', 'date_first_registered', 'date_left', 'other_student_details']
Title: 'Student_Enrolment'
Header: ['student_enrolment_id', 'degree_program_id', 'semester_id', 'student_id', 'other_details']
Title: 'Student_Enrolment_Courses'
Header: ['student_course_id', 'course_id', 'student_enrolment_id']
Title: 'Transcripts'
Header: ['transcript_id', 'transcript_date', 'other_details']
Title: 'Transcript_Contents'
Header: ['student_course_id', 'transcript_id']

Question:
Do dual-enrolled students tend to perform better or worse than their peers in the same degree programs?

`GPT-4` **agent plan:**
Information Extraction: To answer the user's question, we need to extract the following information:
The performance of dual-enrolled students in their courses.
The performance of non-dual-enrolled students in the same degree programs as the dual-enrolled students.
Identification of Relevant Tables and Columns: The relevant tables and columns needed to gather the necessary information are:
'Student_Enrolment' table: degree_program_id, semester_id, student_id, and other_details columns.
'Student_Enrolment_Courses' table: student_course_id, course_id, and student_enrolment_id columns.
'Transcript_Contents' table: student_course_id and transcript_id columns.
'Transcripts' table: transcript_id and other_details columns.
Description of Retrieval Process: To retrieve the required information, we would perform the following steps:
a. Identify dual-enrolled students:
Filter the 'Student_Enrolment' table to find rows where the 'other_details' column contains information about dual enrollment. This will give us a list of dual-enrolled students and their corresponding degree_program_id, semester_id, and student_id.
b. Identify non-dual-enrolled students in the same degree programs:
Filter the 'Student_Enrolment' table to find rows where the 'other_details' column does not contain information about dual enrollment and the degree_program_id matches the degree_program_id of the dual-enrolled students identified in step a. This will give us a list of non-dual-enrolled students in the same degree programs as the dual-enrolled students.
c. Retrieve course performance for dual-enrolled students:
For each dual-enrolled student identified in step a, find the corresponding student_enrolment_id in the 'Student_Enrolment_Courses' table. Using the student_course_id from the 'Student_Enrolment_Courses' table, find the corresponding transcript_id in the 'Transcript_Contents' table.
Using the transcript_id, retrieve the performance information (e.g., grades) from the 'Transcripts' table's other_details column. d. Retrieve course performance for non-dual-enrolled students:
For each non-dual-enrolled student identified in step b, find the corresponding student_enrolment_id in the 'Student_Enrolment_Courses' table. Using the student_course_id from the 'Student_Enrolment_Courses' table, find the corresponding transcript_id in the 'Transcript_Contents' table.
Using the transcript_id, retrieve the performance information (e.g., grades) from the 'Transcripts' table's other_details column. e. Compare the performance of dual-enrolled and non-dual-enrolled students:
Calculate the average performance of dual-enrolled students and non-dual-enrolled students using the performance information retrieved in steps c and d.
Compare the average performance of both groups to determine if dual-enrolled students tend to perform better or worse than their peers in the same degree programs.

Figure 12: Example 2 - making incorrect assumptions about column contents: student_enrolment.other_detail does not contain information about dual-enrollment

Database:
Title: ’TV_Channel’
Header: [’id’, ’series_name’, ’Country’, ’Language’, ’Content’, ’Pixel_aspect_ratio_PAR’, ’Hight_definition_TV’, ’Pay_per_view_PPV’, ’Package_Option’]
Title: ’TV_series’
Header: [’id’, ’Episode’, ’Air_Date’, ’Rating’, ’Share’, ’18_49_Rating_Share’, ’Viewers_m’, ’Weekly_Rank’, ’Channel’]
Title: ’Cartoon’
Header: [’id’, ’Title’, ’Directed_by’, ’Written_by’, ’Original_air_date’, ’Production_code’, ’Channel’]

Question:
Identify common themes or factors in the top-rated episodes and potential reasons for low ratings in the least-rated episodes of a TV series.

`GPT-4` **agent plan:**
Information Extraction: To answer the user’s question, we need to extract the following information:
Top-rated episodes of the TV series
Least-rated episodes of the TV series
Common themes or factors in the top-rated episodes
Potential reasons for low ratings in the least-rated episodes
Identification of Relevant Tables and Columns: From the given database, the relevant tables and columns to gather the necessary information are:
’TV_series’ table: This table contains information about the episodes, their air dates, ratings, and other related data. The relevant columns from this table are:
’Episode’: The name of the episode
’Rating’: The rating of the episode
’Air_Date’: The date the episode was aired
’Channel’: The channel on which the episode was aired
’TV_Channel’ table: This table contains information about the channels, their content, and other related data. The relevant columns from this table are:
’id’: The unique identifier of the channel
’Content’: The type of content aired on the channel
’Package_Option’: The package option for the channel
Description of Retrieval Process: To retrieve the required information, we would perform the following steps:
Filter the ’TV_series’ table to only include rows related to the TV series in question.
Sort the filtered ’TV_series’ table by the ’Rating’ column in descending order to identify the top-rated episodes.
Sort the filtered ’TV_series’ table by the ’Rating’ column in ascending order to identify the least-rated episodes.
For the top-rated episodes, join the ’TV_series’ table with the ’TV_Channel’ table on the ’Channel’ and ’id’ columns, respectively. This will provide information about the content and package options for the channels on which the top-rated episodes were aired.
Analyze the joined data to identify common themes or factors in the top-rated episodes, such as the type of content aired on the channels, the package options, or any patterns in the air dates.
For the least-rated episodes, join the ’TV_series’ table with the ’TV_Channel’ table on the ’Channel’ and ’id’ columns, respectively. This will provide information about the content and package options for the channels on which the least-rated episodes were aired.
Analyze the joined data to identify potential reasons for low ratings in the least-rated episodes, such as the type of content aired on the channels, the package options, or any patterns in the air dates.

Figure 13: Example 3 - overlooking key columns: only tv_channel.package_option is retrieved for the analysis, while many other columns could also be influential factors, such as tv_channel.country, tv_channel.language, etc.

Database:
Title: 'singer'
Header: ['Singer_ID', 'Name', 'Birth_Year', 'Net_Worth_Millions', 'Citizenship']
Title: 'song'
Header: ['Song_ID', 'Title', 'Singer_ID', 'Sales', 'Highest_Position']

Question:
Compare the sales and highest chart positions of top-selling songs by singers who have over 300,000 sales.

`GPT-4` **agent plan:**
Information Extraction: To answer the user's question, we need to extract the following information:
Singer names with over 300,000 sales
The titles of their top-selling songs
The sales of these top-selling songs
The highest chart positions of these top-selling songs
Identification of Relevant Tables and Columns: To gather the necessary information, we will need to use the following tables and columns from the database:
From the 'singer' table, we will need the 'Singer_ID' and 'Name' columns
From the 'song' table, we will need the 'Title', 'Singer_ID', 'Sales', and 'Highest_Position' columns
Description of Retrieval Process: To retrieve the required information, we will follow these steps:
First, we will filter the 'song' table to only include rows with 'Sales' greater than 300,000. This will give us a list of songs that meet the sales criteria.
Next, we will join the filtered 'song' table with the 'singer' table using the 'Singer_ID' column as the common key. This will allow us to associate each song with its respective singer.
After joining the tables, we will group the resulting dataset by the 'Singer_ID' and 'Name' columns. This will help us identify the top-selling songs for each singer.
Within each group, we will sort the songs by their 'Sales' in descending order. This will allow us to identify the top-selling song for each singer.
Finally, we will extract the 'Name', 'Title', 'Sales', and 'Highest_Position' columns for the top-selling song of each singer. This will give us the information needed to compare the sales and highest chart positions of top-selling songs by singers who have over 300,000 sales.

Figure 14: Example 4 - exhibiting oversight in data retrieval for subsequent analysis: the agent's strategy involves selecting singers with over 300,000 sales by filtering for individual songs that have achieved 300,000 sales. This approach overlooks singers who may have accumulated over 300,000 sales in total but not through a single song.

Abstract

Extracting fine-grained experimental findings from literature can provide dramatic utility for scientific applications. Prior work has developed annotation schemas and datasets for limited aspects of this problem, failing to capture the real-world complexity and nuance required. Focusing on biomedicine, this work presents CARE—a new IE dataset for the task of extracting clinical findings. We develop a new annotation schema capturing fine-grained findings as n-ary relations between entities and attributes, which unifies phenomena challenging for current IE systems such as discontinuous entity spans, nested relations, variable arity n-ary relations and numeric results in a single schema. We collect extensive annotations for 700 abstracts from two sources: clinical trials and case reports. We also demonstrate the generalizability of our schema to the computer science and materials science domains. We benchmark state-of-the-art IE systems on CARE, showing that even models such as GPT4 struggle. We release our resources[1] to advance research on extracting and aggregating literature findings.

1 Introduction

> It is surely a great criticism of our profession that we have not organised a critical summary, by specialty or subspecialty, adapted periodically, of all relevant randomised controlled trials. (Archie Cochrane, 1979)

Though this critique focused on clinical trials, the statement arguably applies to much of science today. There is tremendous potential utility in extracting, structuring and aggregating fine-grained information about experimental findings and the conditions under which they were achieved, across scientific studies. Once extracted and aggregated, scientific findings can power many critical applications such as producing literature reviews (DeYoung et al., 2021), supporting evidence-based decision-making (Naik et al., 2022), and generating new hypotheses (Wang et al., 2023).

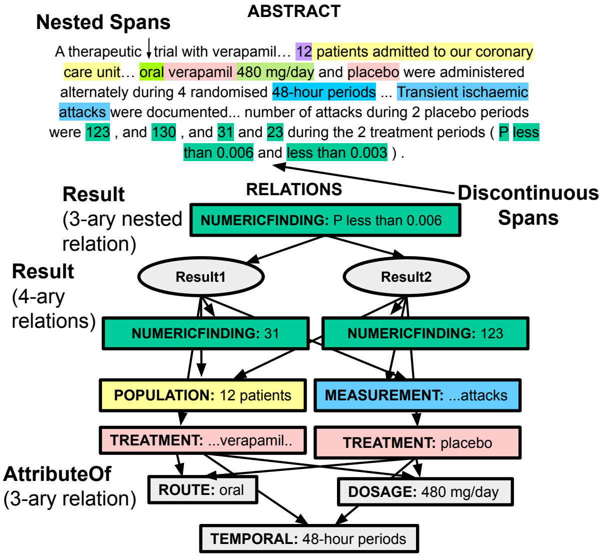

Figure 1: A partial example of entity, attribute and relation annotation using our schema for a clinical trial.

While there have been efforts on building resources and tools to capture findings in various domains such as clinical trials (Lehman et al., 2019), computer science (Jain et al., 2020) and social and behavioral sciences (Magnusson and Friedman, 2021)—a major obstacle has been creating a representation that is *expressive* enough to capture complex and nuanced information about findings. We propose a new representation schema that makes important progress in capturing the real-world complexity of scientific findings in papers, and use it to build a high-quality annotated dataset focusing on biomedical (clinical) findings. Our schema represents fine-grained information about experimental findings and conditions as n-ary relations between entities and attributes, and includes several structural complexities such as discontinu-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 4580–4596
June 16-21, 2024

ous span annotation, variable arity in relations and nestedness in relations. These aspects have been studied individually in previous datasets (Karimi et al., 2015; Tiktinsky et al., 2022), but our schema is the first to unify them. Our dataset also captures *numeric* findings in addition to their interpretation (e.g., significance, utility, etc.); prior datasets typically focus solely on the latter (e.g., Lehman et al. (2019) captures *increases/decreases* in outcomes but not their magnitudes).

Though these factors make our annotation schema more complex than prior work, the additional nuance it affords can power several high-impact downstream use cases. For instance, the process of conducting a systematic review[2] includes extracting data about specific outcomes from a large number of relevant studies. Unlike prior schemas which only capture interpretation and not precise numeric outcomes, extractors trained on our schema can extract relevant data to assist the review process. Moreover, fine-grained population and treatment details captured by our schema makes it capable of answering highly complex clinical questions (e.g., "Does vaccination significantly improve mortality outcomes for female patients over 65 who required ventilation?"). Therefore, models trained on our schema can assist physicians in developing more personalized treatment plans, especially for patients with multiple comorbidities or health conditions. Our schema can also help with the development and exploration of richer clinical hypotheses due to its additional granularity.

To build our dataset, named CARE (Clinical Aggregation-oriented Result Extraction), we collect extensive annotations for 700 abstracts (clinical trials and case reports). We also conduct annotation studies demonstrating that our schema generalizes to computer science and materials science, using minor updates based on analogies between aspects across experimental domains (e.g., *populations/interventions* → *tasks/methods* in CS). This reflects the expressive power of our schema to generalize across domains while capturing granular and useful information, making it a strong "backbone schema" for research efforts on result-oriented scientific IE.

We achieve good agreement scores (0.74-0.78 partial F1) comparable to prior work that used simpler schemas that are easier to annotate (Luan et al., 2018; Nye et al., 2018), and at the same time our resulting dataset is larger in size than previous corpora. Our final dataset annotation is extremely rich; at 16.23 relations per abstract, our relation density is nearly 4x that of prior work on annotating findings from clinical trials (Lehman et al., 2019).

We evaluate a wide range of IE models on our dataset, including both extractive systems and generative LLMs. Given the high annotation burden, we test generative LLMs in both fully supervised as well as zero-shot and few-shot settings. Our results demonstrate the difficulty of our dataset, with even SOTA models such as GPT4 struggling to accurately extract clinical findings. As a highly challenging new dataset designed to be reflective of real-world nuance and informational needs, we hope CARE[3] is an important resource for the scientific NLP and IE research community to pursue.

2 Related Work

2.1 Information Extraction from Scientific Literature

Much prior work has focused on information extraction from scientific papers (Luan et al., 2018; Jain et al., 2020), including biomedical literature (see (Luo et al., 2022a) for a detailed summary). Most relevant to our goal in this work is prior research on extracting findings or results from scientific literature, which has only explored limited aspects of this problem.

Gábor et al. (2018) and Luan et al. (2018) annotate *associative* relations between entities being compared or producing a result, as part of their broader goal of developing IE resources for computer science, but do not capture any nuance (e.g., directionality, causality, etc. of results). Conversely, Magnusson and Friedman (2021) develop a schema focused solely on capturing associations between experimental variables and evidence. However, their focus on sentence-level annotation from scientific claims limits how much additional nuance about experimental setting can be captured.

Some prior efforts have also explored result extraction from biomedical literature. The EBM-NLP (Nye et al., 2018) and Evidence Inference (Lehman et al., 2019) corpora contain annotations for experimental findings from clinical trials, following the well-established PICO (participant, intervention, comparator, outcome) framework (Richardson et al., 1995). Sanchez-Graillet et al. (2022) also

Type	EBM	CTKG	Example
Population	✓	✓	This study compared rizatriptan 5 mg and placebo in 1268 outpatients treating a single migraine attack
Subpopulation	✓	✓	We found low-certainty evidence of little or no difference in delirium (RR 1.06, 95% CI 0.55 to 2.06; 2 studies, 800 participants)
Treatment	✓	✓	Dialysate magnesium was 0.375 mM/L for the hemodialysis
Measurement	✓	✓	Headache relief rates after rizatriptan 10 mg were higher
Temporal	✗	✓	After a 48-hour run-in period , oral verapamil 480 mg/day and placebo were administered
NumericFinding	✗	✓	The number of attacks during treatment periods were 31 and 23
Qualifier	✗	✗	Pindolol and metoprolol lowered blood pressure to the same extent

Table 1: Examples of entity types in our schema. EBM and CTKG columns indicate whether these entity types are present in the EBM-NLP and CTKG schemas respectively. EBM-NLP uses IE to extract information according to its schema, while CTKG is a database schema not based on IE.

develop a PICO-inspired schema-based annotation format for diabetes and glaucoma trials. Chen et al. (2022) focuses on aggregating findings, which are already manually organized in structured format in databases such as AACT (Aggregate Analysis of ClinicalTrials.gov) (Tasneem et al., 2012). However, these efforts are tailored to clinical trials and do not translate easily to other domains. Finally, Luo et al. (2022a) conducted *novelty* annotation for relations, indicating whether they were presented as new observations; however they did not focus on experimental findings.

In contrast, we develop a representation schema expressive enough to capture fine-grained experimental findings, while generalizing across scientific domains. Our schema also contains phenomena challenging for SOTA IE models (§3.2).

2.2 Extracting Numeric Information

Another unique aspect of our schema is our focus on capturing numeric information from experimental findings and setup, which is understudied. Some prior work on open IE has explored extraction and linking of numeric spans (Madaan et al., 2016; Saha et al., 2017), including linking to implied entities (Elazar and Goldberg, 2019) (e.g., "it's worth two million" can be linked to currency). However, these models broadly focused on sentence-level extraction and did not evaluate on scientific text.

Within the scientific domain, some studies have focused on numeric information extraction from biomedical/clinical text. Kang and Kayaalp (2013) and Claveau et al. (2017) extract numeric spans from FDA-released descision summaries and clinical trial eligibility criteria respectively. EBM-NLP (Nye et al., 2018) annotates some categories of numeric information associated with cohorts participating in a clinical trial, but ignores trial outcomes and findings. Among non-medical scientific domains, numeric span extraction work has mainly focused on extraction from tables (Hou et al., 2019). None of these studies focus extensively on linking numeric spans with entities that can help in interpreting this information, which is key to our work.

Type	EBM	CTKG	Example
Age	✓	✗	for those age 60-67 years
Sex	✓	✗	210 females
Size	✓	✓	12 patients
Condition	✓	✓	patients getting hemodialysis
Demographic	✗	✗	A 40's Japanese man
Route	✗	✗	oral verapamil
Dosage	✗	✗	verapamil 480 mg/day
Strength	✗	✗	rizatriptan 5 mg
Duration	✗	✗	for 4 weeks

Table 2: Examples of attribute types in our schema. EBM and CTKG columns indicate whether these types are present in the EBM-NLP and CTKG schemas.

3 Annotation Schema

We develop a new annotation schema to represent fine-grained clinical findings present in biomedical abstracts, and later demonstrate its broader applicability to domains beyond biomedicine (§6.2). Our schema captures this knowledge via three main elements, commonly used in IE tasks:

1. Entities involved in a study, which are spans of text, either contiguous or non-contiguous, belonging to one of the seven types listed in Table 1.

2. Attributes associated with entities, which are also contiguous or non-contiguous spans of text, belonging to one of the nine types listed in Table 2. The first five attribute types are associated with

Type	Arity	EI	CTKG	Example
AttributeOf	N-ary	✗	✗	($Subpopulation$: 144 had the U-type method, $Size$: 144)
SubpopulationOf	N-ary	✗	✗	($Population$: 285 women, $Subpopulation$: 144 had the U-type method, $Subpopulation$: 141 had the H-type method)
TreatmentOf	Binary	✗	✓	($Subpopulation$: 144 had the U-type method, $Treatment$: U-type method)
Result	N-ary	✓	✓	($Subpopulation$: 144 had the U-type method, $Measurement$: objective cure rates, $NumericFinding$: 87.5%)

Table 3: Examples of relation types in our schema. EI and CTKG columns indicate whether these relation types are present in the EI and CTKG schemas respectively. While the EI and CTKG datasets contain 4-ary and binary result relations respectively, our n-ary schema allows fine-grained information to be captured more flexibly.

population and subpopulation entities, while the remaining four types are associated with treatment entities. Other entity types do not have any associated attributes.

3. N-ary Relations linking together various entities and attributes, where N (relation arity) is variable and nesting is allowed. A relation is an n-tuple, where each element can be an entity, attribute or another n-ary relation. Relations are categorized into four types listed in Table 3.

3.1 Comparison to Existing Clinical Schemas

Prior work such as EBM-NLP (Nye et al., 2018) and Evidence Inference (Lehman et al., 2019; DeYoung et al., 2020) has focused on developing IE schemas to represent clinical knowledge appearing in the literature in a structured format. In addition, work such as CTKG (Chen et al., 2022) outside the NLP/IE sphere has built schema for representing clinical information in databases. However, these schemas suffer from a few shortcomings: (i) most are designed for clinical trials; their applicability to other types of biomedical literature is untested, (ii) focus on a small set of broad entity types, which leaves out fine-grained details, (iii) follow strict relation formats, which makes it hard to capture additional nuance that might be useful for interpreting findings.

Our schema makes several enhancements to tackle these issues. First, it is extensible to other categories of biomedical literature beyond clinical trials, and we demonstrate this by applying our schema to case reports. Second, our schema captures more fine-grained information about various entities than prior work via attributes (see Table 2). Third, allowing for variable arity and nesting in relation annotation provides the flexibility which makes our schema capable of representing both atomic findings (e.g., value of primary outcome observed for a given treatment) as well as composite findings (e.g., outcome improvement observed for treatment vs control groups). Tables 1, 2 and 3 provide a more detailed comparison of our schema with EBM-NLP, EI and CTKG.

3.2 Annotation Complexity

In addition to using an expanded set of entity, attribute and relation types, our annotation schema supports the following phenomena (also illustrated in Figure 1), unifying them all in a single dataset:

Discontinuous spans: Biomedical abstracts often present multiple entities as conjunctive phrases or lists of items, so we allow discontinuous span annotation to capture every entity. For example, given the phrase “maximal diameters and volumes”, our scheme captures two measurement entities: “maximal diameters” and “maximal volumes”, with the latter being a discontinuous span.

Nested/overlapping spans: Attributes, as defined in our annotation scheme, are often present within an entity span or overlap with an entity span. This motivates our decision to allow nested and overlapping spans to be annotated.

Variable arity in relations: Owing to variation in clinical studies, findings are often described in a wide range of formats (e.g., outcome for a single population, outcome for a pair of populations, outcome for a single population at different time periods, etc.). This diversity motivated our choice of *variable arity* for relation annotation, similar to Tiktinsky et al. (2022).

Nested relations: In addition to outcomes for individual populations/groups, clinical studies often present comparative findings and analyses, such as improvement on an outcome given a pair of interventions. Our scheme allows for annotation of nested relations to link these higher-order observations with their associated atomic findings.

Our complete annotation guidelines can be found at `https://github.com/allenai/CARE`. Figure 1 presents partial entity, attribute and relation annotations for an example clinical trial abstract.

Category	Exact F1	Partial F1
Entity	0.5764	0.7578
Attribute	0.6174	0.7801
Relation	0.4209	0.7414

Table 4: Final inter-annotator agreement scores on a sample of 28 abstracts, measured during full-scale data annotation.

Metric	Train	Dev	Test
#Docs	500	100	100
#Tokens	135,363	27,120	25,219
#Entities	12022	2367	2286
#Attributes	3992	804	762
#Relations	8205	1594	1560

Table 5: Statistics for final collected dataset.

4 Dataset Collection

Annotation Tool: We use TeamTat[4] (Islamaj et al., 2020), a web-based tool for team annotation since it allows for n-ary and nested relation annotation, a core component of our schema.

Annotator Background: We recruit two in-house annotators[5] with backgrounds in data analytics and data science, both having extensive experience in reading and annotating scientific papers. One of our annotators has a background in biology. Both annotators went through several pilot rounds to gain familiarity with our task and schema. Additionally, we used their feedback and insights from pilots to solidify our schema design (see §4.1). We also solicited feedback from two medical students and an MD to validate our final schema.

Data Sources: CARE covers two categories of biomedical literature: (i) clinical trials, and (ii) case reports. Clinical trials are research studies that test a medical, surgical, or behavioral intervention in people to determine whether a new form of treatment or prevention or a new diagnostic device is effective. Case reports are detailed reports of the symptoms, signs, diagnosis, treatment, and follow-up of an individual patient, usually motivated by unusual or novel occurrences. We sample clinical trials from the EBM-NLP (Nye et al., 2018) dataset, which consists of 4993 abstracts annotated with PICO spans, only retaining abstracts containing at least one number (4685 in total). To sample case reports, we extract all reports with at least one number in the abstract from PubMed (907,862 in total) and randomly sample from this pool. We sample 350 abstracts from each source, resulting in our final dataset size of 700 abstracts, which is slightly larger than other prior corpora that perform fine-grained annotation (§ 4.3). Further characteristics of our abstract sample are detailed in Appendix C.

4.1 Annotation Pilots

We conducted three pilot rounds with the following goals: (i) training annotators to apply our schema, (ii) evaluating agreement, and (iii) assessing whether our schema captures clinical knowledge of interest. Annotators worked on a fresh set of 5-10 abstracts per round, followed by agreement computation and disagreement discussion. For entity and attribute annotation, agreement is computed as entity-level F1 between annotators, using both strict (entity boundaries match exactly) and partial (entity boundaries overlap on at least one token) matching. For relations, we first align annotations from both annotators by linking pairs of relations which share $\geq 50\%$ of participating entities. Agreement is computed as F1 score between annotators, using both strict (100% of entities match) and partial matching. After achieving reasonable agreement levels by round 3 (partial F1 scores of 0.79, 0.68 and 0.79 for entity, attribute and relation annotation respectively), we started full-scale data annotation (further discussion in Appendix C).

4.2 Full-Scale Annotation

The full-scale data annotation process was conducted in six rounds. To continue monitoring agreement, a small agreement set of 5 abstracts (not identified to the annotators) was included in every round. Table 9 in the appendix presents inter-annotator agreement during each annotation round, while Table 4 shows overall agreement scores. Overall and per-round agreement scores continued to remain in the same range as agreement scores from later pilot rounds, demonstrating consistency in annotation quality. Despite the complexity of our schema, our agreement scores are comparable to datasets using simpler schemas like EBM-NLP (entity agreement of 0.62-0.71; Cohen's kappa) and SciERC (relation agreement of 67.8; kappa score). Appendix C provides additional details about our full-scale annotation setup.

Consensus Annotation: For all abstracts annotated by multiple annotators during pilots or full-

#Overlapping Spans	1.6%	2.0%	0.7%
#Nested Relations	11.4%	11.2%	11.9%

Table 6: Prevalence of interesting annotation phenomena in final collected dataset.

scale annotation (55 in total), we construct a "consensus" version post disagreement discussion. The final dataset releases consensus annotations for these abstracts. Since this subset has been annotated by multiple annotators and discussed extensively, we expect annotations to be higher-quality and include all these abstracts in the test set.

4.3 Dataset Statistics

Table 5 gives an overview of statistics for our final collected dataset. Our dataset size is comparable to other prior biomedical corpora which performs exhaustive fine-grained annotation (though not always with a clinical knowledge focus) such as BioRED (Luo et al. (2022a); 600 abstracts) and Sanchez-Graillet et al. (2022) (211 abstracts). Table 6 presents the proportion of various interesting phenomena allowed by our schema in the final dataset. Interestingly, CARE contains 9% discontinuous spans, making it one of the rare datasets containing a large proportion of discontinuous mentions.[6] At 11%, the final data also contains a high proportion of nested relations.

5 Benchmarking IE Models

We benchmark the performance of two categories of models on CARE: (i) extractive models, and (ii) generative LLMs. We also test generative LLMs in two settings: (i) finetuning on the full training set, and (ii) zero-shot and in-context learning.

Experimental Setup: We test each model on the three sub-tasks—entity extraction, attribute extraction and relation extraction—in isolation. Model performance on entity and attribute extraction is evaluated using entity-level F1. Relation extraction performance is evaluated using a relaxed overlap F1 score metric inspired by Tiktinsky et al. (2022), which assigns partial credit to correctly identified subsets of entities in a relation, even if all identified entities do not match. As with agreement score calculation, predicted relations are first aligned with gold relations by choosing the gold relation with highest overlap per predicted relation. Then a partial match score is computed as $\#shared\_entities/total\_entities$ and used in the F1 computation instead of binary 0/1 score.

5.1 Extractive IE Baselines:

We evaluate the following systems:

- **OneIE** (Lin et al., 2020): A sentence-level joint entity, relation and event extraction system, which extracts an "information network" representation of entities and events (nodes), connected by relations (edges). Beam search is used to find the highest-scoring network.
- **PURE** (Zhong and Chen, 2021): A sentence-level pipelined extraction system, which learns separate contextual representations for entity and relation extraction, using entity representations to further refine relation extraction.
- **LocLabel** (Shen et al., 2021): A sentence-level two-stage named entity recognition (NER) system capable of extracting nested spans. Inspired by object detection work, it produces boundary proposals for candidate entities, then labels them with correct entity types.
- **W2NER** (Li et al., 2022): A sentence-level unified NER model, capable of extracting nested and discontinuous spans. It recasts NER as word-word relation classification on a 2-D grid of word pairs, then decodes word pair relations into final span extractions.

For comparability and better adaptation to our dataset, we replace BERT-based encoders in all systems with PubmedBERT (Gu et al., 2021), and follow best-reported hyperparameters per system (see Appendix E). Table 7 presents their performance on entity and attribute extraction. Unfortunately, applying these systems to our relation extraction task is infeasible, since none of them are designed for document-level relation extraction or n-ary relations. Tiktinsky et al. (2022) modify PURE for n-ary relation extraction with variable arity. However, given a set of candidate entities, they consider all possible n-ary combinations and predict relationships per cluster. This is tractable for their work on sentence-level extraction of single-type (drug interaction) relations, but not tractable for document-level multi-type n-ary relation extraction.[7] Therefore, we do not test extractive models

---

[6] Dai et al. (2020) considers 10% discontinuous spans to be a high proportion, identifying only three biomedical datasets that satisfy this criterion: CADEC (Karimi et al., 2015), ShARe 13 (Pradhan et al., 2013) and ShARe 14 (Mowery et al., 2014).

[7] On limiting combination size to 10, every abstract pro-

GPT-4 5-shot	5.04	13.90	**55.04**

Table 7: Performance of all extractive and generative baselines on entity, attribute and relation extraction.

on relation extraction.

Another caveat with extractive models is that they do not identify discontinuous spans (except W2NER). To assess how this impacts model performance, we compute an additional entity-level F1 score which merges span predictions linked in gold annotation (i.e., we assume oracle span merging), and observe that this does not significantly improve performance (avg. increase of ∼1.5 F1). Therefore, Table 7 reports F1 scores without merging.

5.2 Generative IE Baselines:

Motivated by recent work demonstrating LLM capabilities on information extraction (Wadhwa et al., 2023), we assess the ability of LLMs on our tasks, in both finetuning and zero-shot/in-context learning settings.

We evaluate the following finetuned LLMs:

- **FLAN-T5** (Chung et al., 2022): Enhanced version of T5 (Raffel et al., 2020) finetuned on a large mixture of tasks, but not specifically pretrained for biomedicine. We use FLAN-T5-XL, which has 3B parameters.
- **BioGPT** (Luo et al., 2022b): A 1.6B autoregressive model, pretrained from scratch on 15M abstracts and titles from PubMed with a custom Pubmed-trained tokenizer.
- **BioMedLM**[8]: A 2.7B autoregressive model, pretrained from scratch on all PubMed abstracts and full-texts from the Pile (Gao et al., 2020) with a custom PubMed-trained tokenizer.

When training and testing on attribute and relation extraction, these models are provided gold entities and attributes by surrounding them with entity markers ($< ent >< /ent >$) in the input.

We evaluate GPT3.5 and GPT4 in zero-shot and in-context learning settings. We provide our IE schema and example outputs and prompt the model to produce extractions in a clean JSON format that adheres to the schema. Additionally, for our in-context learning experiments, we follow (Liu et al., 2021) and select the k *most similar* examples from the training set for every test instance according to similarity computed by the SPECTER v2.0 (Singh et al., 2022) PRX model trained on scientific titles and abstracts. Selected examples are appended to the prompt in decreasing order of similarity, with later examples dropped if they don't fit. We run experiments for the $k = 1, 3, 5$ most similar examples. Further hyperparameter details for all models are provided in Appendix E and full prompts are provided in Appendix G.

Table 7 shows the performance of all generative models. One caveat with GPT3.5/4 is that model outputs sometimes contain correct entity/attribute spans assigned to the wrong type (e.g., a subpopulation misclassified as a population entity in a result relation). Since we are evaluating the performance of relation extraction in isolation, we do not consider such mistyping as errors.

5.3 End-to-End Evaluation:

In addition to evaluating SOTA systems on each sub-task in isolation, we assess the feasibility of end-to-end extraction. Table 7 shows that PURE is the best-performing system on entity and attribute extraction. On the other hand, GPT4 5-shot and FLAN-T5 perform best on relation extraction (GPT3.5 5-shot and BioGPT are close). We test out a hybrid end-to-end extraction system in which entities and attributes are detected using PURE, then input text marked up with these extractions is provided to FLAN-T5 for relation extraction. This hybrid system achieves an F1 score of 33.58, very similar to RE performance with gold markup. Hypothesizing that this might be an indication that finetuned LLMs ignore entity/attribute markup during RE, we run an additional experiment in which we train FLAN-T5 to extract relations from raw text (no markup). This setup achieves an F1 score

duces 500,000 candidate combinations

[8] `https://crfm.stanford.edu/2022/12/15/biomedlm.html`

Original Type	**Generalized Type**	**Description**
Population	Research Problem Context	Setting/scenario in which the authors are testing their hypothesis (e.g., task or dataset being studied in ML/NLP).
Subpopulation	Problem Stages/Subparts	Subgroups or subsamples of overall setting (e.g., dataset splits in ML/NLP).
Treatment	Technique/Method	Key technique being proposed or investigated and other techniques being compared (e.g., model or metric in ML/NLP).
SubpopulationOf	Sub-PartOf	Links together problem context entities to stage/sub-part entities (e.g., for ML/NLP, this relation would link the overall task to low-data and fully supervised settings).
TreatmentOf	AppliedTo	Links together a technique to all the problem contexts/sub-parts it is being tested in.

Table 8: Changes required to construct a generalized version of our original schema developed for clinical finding extraction, which we use to test whether it applies to other domains such as computer science and materials science

of 33.07, showing that entity/attribute markup does not provide significant benefit.

6 Discussion

6.1 How much does strict evaluation underestimate LLM performance?

Table 7 shows that even fully-supervised generative models severely lag behind much smaller extractive models on entity and attribute extraction. However, prior work (Wadhwa et al., 2023) has observed that strict IE evaluation metrics underestimate the performance of LLMs since their outputs often contain minor variations from gold annotations, which could still be correct. Therefore, we conduct human evaluation of a subset of FLAN-T5 and GPT4 5-shot predictions on entity and attribute extraction for a more accurate assessment.

For every setting, we collect all abstracts with one or more wrong predictions and randomly sample ten to evaluate. We go over all false positives per abstract marking ones that could be considered correct. Our evaluation shows that for FLAN-T5, 35 out of 73 entity and 12 out of 32 attribute errors are marked correct. For GPT4, these numbers are worse; 38 out of 126 entity and 20 out of 79 attribute errors are marked correct. This indicates that LLMs indeed struggle with our span extraction tasks, and their poor performance is not simply a consequence of strict evaluation.

6.2 How easily can we extend our schema to other domains?

Though we focus on extracting clinical findings from biomedical literature during schema design, we try to incorporate enough flexibility to allow our schema to be easily adapted to other scientific domains. To demonstrate this flexibilty, we conduct small-scale pilots in two additional domains: (i) Computer Science, and (ii) Materials Science.

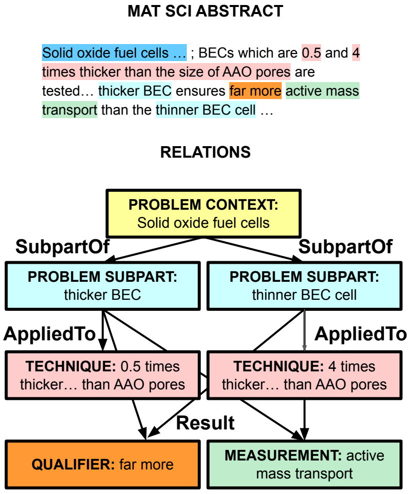

Figure 2: A partial example of entity, attribute and relation annotation using our generalized schema for a materials science abstract.

We first develop a *generalized* version of our proposed schema for these studies. Of the three elements in our schema, entities and relations are largely transferable and only require minor renaming. Table 8 provides an overview of changes made to entity/relation nomenclature. Attributes on the other hand, were tailored more closely to our goal of extracting clinical findings. Therefore, we drop all attributes and ask our annotators to propose candidate attributes as they go through the annotation process. We use the same annotators who participated in dataset creation, to leverage their existing familiarity with our schema, assigning one annotator to each domain. Their task is to annotate ten abstracts each while documenting: (i) potential attributes that can be added to the schema, and (ii) important experimental information missed by the generalized schema.

After completing the task, annotators reported that it was feasible to apply our proposed schemas to these scientific domains. Figure 2 shows an example materials science abstract with partial annotations according to the generalized schema. Computer science posed some difficulty due to the presence of lots of relative results and references in the abstract, which made entity annotation ambiguous. However, there were no important aspects of experimental information, aside from potential attribute proposals, that our current schema could not account for.

7 Conclusion

In this work, we presented CARE, a new IE dataset for the task of extracting clinical findings from biomedical literature. To collect this dataset, we first developed a new annotation schema capable of capturing fine-grained information about experimental findings, which unified several challenging IE phenomena such as discontinuous spans, nested relations and variable arity n-ary relations. Using this annotation scheme, we collected an extensively annotated dataset of 700 abstracts from clinical trials and case reports. Our benchmarking experiments showed that state-of-the-art extractive and generative LLMs including GPT4 still struggle on this task, particularly on relation extraction. We release both our annotation schema and CARE as a challenging new resource for the IE community and to encourage further research on extraction and representation of findings from scientific literature.

8 Limitations

Despite being a cornerstone of our work, the richness and complexity of our newly proposed annotation schema also poses some limitations. Annotators needed some prior experience with reading and understanding complex scientific text, and had to undergo multiple rounds of additional training before they were able to accurately apply our schema and start full-scale annotation. Though these stringent expertise and training requirements and heavy reliance on human annotators helped us collect a high-quality resource in CARE, they simultaneously limit the scalability of our collection protocol and make it difficult to construct large-scale benchmarks for this task, spanning multiple domains/fields of science.

Our annotated corpus, CARE, is based on RCTs and case reports. While our schema is broad and expressive enough to generalize to other experimental domains with minor adaptations, our generalization annotation studies were comparatively small and preliminary, limited to testing the schema on computer science and material science papers. In addition, while our schema covers many types of experimental findings, the richness and huge variety of scientific experiments neccessarily means that more types of findings could be added. In the future, more studies should be performed on using our schema in other domains, and on extending our schema with more types of information (entities, attributes, relations). CARE also focuses on English-language papers only, and in the future it would be interesting and important to extend our schema and dataset to cover biomedical/clinical studies in other languages, to capture important scientific findings that are potentially missed when only looking at papers in English.

Finally, a limitation of our current benchmarking effort is the lack of more flexible evaluation metrics, particularly when assessing the performance of generative LLMs. We try to provide supplementary human evaluation for some models to overcome this issue, but this is not scalable and would require ongoing/continuous evaluation efforts. This is not a major focus for our current work, but developing more flexible automated evaluation is an important future direction for IE research.

Acknowledgements

This work was funded in part by NSF Convergence Accelerator Award ITE-2132318. We would like to thank Lucy Lu Wang, Byron Wallace and Dr. Ruth Sapir-Pichhadze for valuable feedback on early versions of the annotation schema, and the Semantic Scholar team at AI2 and our anonymous reviewers for their helpful comments on our work.

A Schema Definitions

A.1 Entity Types

Entities can belong to one of the following seven types:

1. **Population:** Patient groups/cohorts studied in an article.

2. **Subpopulation:** Slices/sub-groups of a population entity sharing some underlying characteristic.
3. **Treatment:** Treatment regimens, procedures, therapies etc. prescribed and/or tested to alleviate a population's conditions/symptoms.
4. **Measurement:** Tests used to assess population status and outcomes of the tested intervention.
5. **Temporal:** Temporal information such as time points at which outcomes are measured.
6. **NumericFinding:** All numeric information associated with study findings (e.g., p-values, hazard ratios, etc.).
7. **Qualifier:** Non-numeric information associated with study findings that provides important perspective for interpreting them (e.g., phrases indicating evidence directionality).

A.2 Attribute Types

Attributes can belong to one of the following nine types:

1. **Age:** Numeric or non-numeric information about the age of the population under study.
2. **Sex:** Reported sex of the population under study.
3. **Size:** Size of the population sample under study.
4. **Condition:** Medical conditions prevalent in the study population, including diseases, symptoms, prior medical history and procedures, etc.
5. **Demographic:** Additional demographic information reported about the population such as location, race, etc.
6. **Route:** Description of the way an intervention is administered (e.g., a chemical may be administered orally, topically, intravenously, etc.).
7. **Dosage:** Quantity of administration for the intervention being studied. This is not necessarily limited to chemical/drug interventions (e.g., for an intervention like educational sessions, number of sessions is considered "dosage").
8. **Strength:** Strength of chemical/drug interventions administered.
9. **Duration:** Interval of time over which an intervention was administered.

A.3 Relation Types

Our schema allows for both binary and n-ary relations (with variable n), to capture four types of structure:

1. **AttributeOf:** N-ary relations linking population and intervention entities with their associated attributes.
2. **Subpopulation:** N-ary relations capturing parent-child relationships between population and subpopulation entities.
3. **InterventionOf:** Binary relations linking population and subpopulations entities with the intervention(s) tested on them.
4. **Result:** N-ary relations capturing all numeric or non-numeric outcome results and comparisons reported by linking together the population, subpopulation, intervention, measurement, numericfinding and/or qualifier and temporal entities involved in each result/comparison.

All n-ary relations can contain multiple entities of a single type. For example, a result relation can involve multiple interventions or populations. The only cardinality constraints imposed are that every result relation should focus on a *single* measurement entity and always contain *at least one* population/intervention entity.

B Additional Annotation Rules

While using this annotation schema to annotate clinical knowledge, we also keep in mind the following rules:

- For every entity/attribute span, only annotate its first occurrence in the text, unless there is a more descriptive span later. We follow this rule to avoid conducting an additional coreference annotation step to link all spans referring to the same entity.
- Ignore misspellings and include all associated modifiers and abbreviations while annotating spans
- Do not annotate generic or high-level spans (e.g., genetic disorder), or generic terms (e.g., complications, deficiency, disease, syndrome, gene, drug, protein, nucleotide, etc.).
- Do not annotate background occurrences of entities. For example, if a treatment Y is mentioned as "X is usually treated using Y,...", do not annotate Y unless Y was one of the treatments actually given to a population in the current study.

C Dataset Construction Details

Characteristics of sampled abstracts: Since the EBM-NLP corpus sampled randomized clinical trials from PubMed with an emphasis on cardiovascular diseases, cancer, and autism, the clinical trials portion of our dataset also heavily features these topics. On the other hand, for case reports, comparing MeSH term distributions across all reports (2M abstracts) with case reports containing

Table 12: Inter-annotator agreement per relation type

numeric information (the 900k we sample from), we see a massive reduction ($> 30\%$) in terms associated with the following topics: surgery and post-surgery care, dentistry, ophthalmology, prostheses and rehab, patient care and nursing, some mental disorders and circulatory diseases/issues. Hence, we expect these topics to be relatively undersampled in our pool of case reports.

Annotation Pilots: During pilots, we also conducted one or more disagreement discussion sessions per pilot round. These discussions were helpful in providing annotators the opportunity to highlight important spans/relations being missed by the schema, which led to the addition of the subpopulation entity, demographic attribute, and subpopulationof and treatmentof relations. Despite the introduction of some new elements, inter-annotator agreement continued to increase steadily over the pilot rounds, as shown in Table 9 before plateauing at the end of round 3.

Full-Scale Annotation: During rounds 1-3 of full-scale annotation, annotators were provided batches of 25 abstracts each. As their familiarity with the annotation schema and ability to handle ambiguous cases improved, we provided larger batches of 100 abstracts each during rounds 4-6. After each round, agreement was assessed and disagreement dicussions were conducted to discuss ambiguous cases, if needed, which ensured that agreement was maintained across rounds as seen from Table 9. Tables 10, 11 and 12 present final agreement scores per entity type, attribute type and relation type respectively. From these tables, we can see that Subpopulation and Intervention entities are the trickiest to annotate, leading to lower agreement on SubpopulationOf and InterventionOf relation types due to error cascading (i.e., if entity annotations don't match, relation annotations are unlikely to match either).

D Inter-Annotator Agreement

Table 9 shows the evolution in inter-annotator agreement over our initial pilot rounds, as well as the level of inter-annotator agreement maintained during each round of the full-scale annotation process. We see a large increase in relation agreement from pilot 1 to pilot 2, and consistent agreement scores across all tasks in all rounds thereafter. Tables 10, 11 and 12 present inter-annotator agreement breakdown according to entity, attribute and relation types in our schema.

E Hyperparameter Details

Extractive Models:

- **OneIE:** We use an overall learning rate and weight decay of $1e-3$, and a learning rate and weight decay of $1e-5$ for the BERT component, a batch size of 10, and gradient clipping value of 5.0. The model is trained for 60 epochs with a 5-epoch warmup phase.
- **PURE:** We use a context window size of 300 words, overall learning rate of $1e-5$, task learning rate of $5e-4$, batch size of 16, and train for 100 epochs.
- **LocLabel:** We use a learning rate of $5e-6$, warmup rate of 0.1, weight decay of 0.01, gradient clipping value of 1.0, batch size of 6 and train for 35 epochs. LocLabel also requires word vectors, for which we use the 200-dimensional Pubmed-trained word2vec embeddings (BioWordVec) released by Zhang et al. (2019), which are available at `https://github.com/ncbi-nlp/BioWordVec`.
- **W2NER:** We use an overall learning rate of $1e-3$ and a learning rate of $5e-6$ for the BERT component, no weight decay, warmup factor fo 0.1, gradient clipping value of 5.0, batch size of 8, and train for 10 epochs.

Generative Models: All models are trained for 10 epochs with a learning rate of $1e-5$, input context length of 1024, output length of 128, and a batch size of 2.

GPT3.5/GPT4: We test the 16k and 8k context length versions of GPT3.5 and GPT4 respectively since our extraction tasks are abstract-level and require longer input contexts. We use the June 2023 versions of both models due to their *function calling* capabilities, which leverage a structured JSON output format to improve information extraction capabilities. All experiments are run with a temperature of 0 and max output length of 512 tokens.

F Computing Infrastructure

All LLM experiments are carried out on NVIDIA RTX A6000 GPUs with 48 GB RAM. Each finetuning run (FLAN-T5, BioGPT, BioMedLM) requires two GPUs with runtimes ranging from 9-17 hours depending on task size and model size. We use the DeepSpeed integration from Huggingface, with ZeRO-3 optimization, for multi-GPU training.

G Prompt Details

Figures 3, 4 and 5 present the prompts used to evaluate the performance of finetuned LLMs (FLAN-T5, BioGPT and BioMedLM) on entity, attribute and relation extraction respectively. Similarly, Figures 6, 7 and 8 present the prompts used to evaluate the performance of GPT-3.5 and GPT-4 models (in a zero-shot setting) on entity, attribute and relation extraction respectively. For the in-context learning setting, additional few-shot examples are appended to the prompt before providing the abstract.

Entity Extraction Prompt

Given an abstract from a biomedical paper, extract all population entities present in the abstract.
Population entities are defined as patient groups/cohorts studied in an article.
Generate the output in this format: entity1 <sep> entity2. If no entities of the specified type are present, output None.

Abstract: A primary intracranial HCG-producing tumour was studied in an 8 year old boy with congenital adrenal hyperplasia. The case provided a unique opportunity to study the sequential changes in serum and urinary androgens and HCG as measured by radioreceptor assay for HCG and by radioimmunoassay for HCG using antisera raised against the hormone specific for the beta subunit of HCG. Plasma concentrations of HCG, measured by the radioreceptor assay, closely correlated with the biologic activity of his tumour as measured by serum testosterone concentration. This case demonstrates that precocious puberty in any child, including with a known androgen disorder such as congenital adrenal hyperplasia warrants thorough investigation.

Extracted entities:

Output 🤖: “an 8 year old boy with congenital adrenal hyperplasia”

Figure 3: Example prompt used to evaluate the performance of finetuned LLMs on entity extraction. Such prompts are generated for all seven entity types in our dataset.

Attribute Extraction Prompt

Given an abstract from a biomedical paper with all population entities highlighted with **, extract all age attributes associated with these entities.
Age attributes are defined as numeric or non-numeric information about the age of the population under study.
Generate the output in this format: attribute1 <sep> attribute2. If no attributes of the specified type are present, output None.

Abstract: **A primary intracranial HCG-producing tumour was studied in an 8 year old boy with congenital adrenal hyperplasia**. The case provided a unique opportunity to study the sequential changes in serum and urinary androgens and HCG as measured by radioreceptor assay for HCG and by radioimmunoassay for HCG using antisera raised against the hormone specific for the beta subunit of HCG. Plasma concentrations of HCG, measured by the radioreceptor assay, closely correlated with the biologic activity of his tumour as measured by serum testosterone concentration. This case demonstrates that precocious puberty in any child, including with a known androgen disorder such as congenital adrenal hyperplasia warrants thorough investigation.

Extracted attributes:

Output 🤖: “8 year old”

Figure 4: Example prompt used to evaluate the performance of finetuned LLMs on attribute extraction with gold entities provided. Such prompts are generated for all nine attribute types in our dataset.

Relation Extraction Prompt

Given an abstract from a biomedical paper with all important entities and attributes highlighted with **, extract all attributeof relations between them.
Attributeof relations are defined as n-ary relations linking population and treatment entities with their corresponding attributes.
Generate the output in this format: entity1 <ent> attribute1 <sep> entity2 <ent> attribute2 <ent> attribute3. If no relations of the specified type are present, output None.

Abstract: **A primary intracranial HCG-producing tumour was studied in an 8 year old boy with congenital adrenal hyperplasia**. The case provided a unique opportunity to study the sequential changes in serum and urinary androgens and HCG as measured by radioreceptor assay for HCG and by radioimmunoassay for HCG using antisera raised against the hormone specific for the beta subunit of HCG. Plasma concentrations of HCG, measured by the radioreceptor assay, closely correlated with the biologic activity of his tumour as measured by serum testosterone concentration. This case demonstrates that precocious puberty in any child, including with a known androgen disorder such as congenital adrenal hyperplasia warrants thorough investigation.

Extracted relations:

Output 🤖: “a primary .. hyperplasia <ent> 8 year old <ent> boy <ent> a <ent> congenital adrenal hyperplasia”

Figure 5: Example prompt used to evaluate the performance of finetuned LLMs on relation extraction with gold entities and attributes provided. Such prompts are generated for all four relation types in our dataset.

Abstract

In this paper, we study personalized federated learning for text classification with Pretrained Language Models (PLMs). We identify two challenges in efficiently leveraging PLMs for personalized federated learning: 1) *Communication.* PLMs are usually large in size, inducing huge communication cost in a federated setting. 2) *Local Training.* Training with PLMs generally requires back-propagation, during which memory consumption can be several times that of the forward-propagation. This may not be affordable when the PLMs are trained locally on the clients that are resource constrained, *e.g.*, mobile devices with limited access to memory resources. In solving these, we propose a training framework that includes an approach of discrete local search for *gradient-free* local training, along with a compression mechanism inspired from the linear word analogy that allows communicating with *discretely* indexed tokens, thus significantly reducing the communication cost. Experiments show that our *gradient-free* framework achieves superior performance compared with baselines.

1 Introduction

Personalized federated learning (Fallah et al., 2020; Chen et al., 2018; Shamsian et al., 2021) involves collaborative training with non-shareable private data from multiple clients. For each client, we aim to train a personalized model that fits to its local data, leveraging knowledge from other clients. Personalized federated learning has been increasingly attended in the federated learning community due to its ability to account for data heterogeneity across clients (Li et al., 2021). On the other hand, the advent of Pretrained Language Models (PLMs) (Liu et al., 2019; Kenton and Toutanova, 2019) has yielded remarkable performance for natural language processing, *e.g.*, text classification. However, such PLMs are usually large in size, *e.g.*, with hundreds of millions or billions of parameters. There has been limited works investigating how to efficiently train with such large PLMs in federated learning scenarios (Guo et al., 2022; Zhao et al., 2022). In this paper, we investigate on efficient training with PLMs in personalized federated learning for the task of text classification.

One challenge of training PLMs in a federated learning scenario is how to reduce communication cost. Federated learning generally requires communicating updated trainable model parameters between a central server and local clients (McMahan et al., 2017; Li et al., 2020). When training with PLMs, their sheer size may introduce huge communication cost between the server and clients, thus reducing the training efficiency. To solve this problem, recent works propose to leverage prompt tuning (Guo et al., 2022; Zhao et al., 2023). By only training and communicating the prompt embeddings and freeze the pretrained parameters of the PLMs, the communication cost is largely reduced compared with training all the parameters of the PLMs. However, these works can still be impractical in real-life federated learning. The main reason is that their training on local clients requires back-propagating through the PLMs, in order to calculate the gradient of the prompt embeddings. The memory consumption of back-propagation is several times higher (depending on implementation) than that of forward-propagation[1](Baydin et al., 2022; Belouze, 2022). Additionally, the memory footprint taken by gradient computation is proportional to the size of the PLMs, which is becoming increasingly large due to the observation of emergent abilities with the recent pretrained large language models (Wei et al., 2022; Schaeffer et al., 2024). Therefore, back-propagating with the PLMs

Findings of the Association for Computational Linguistics: NAACL 2024, pages 4597–4612

can be extremely memory consuming. Unfortunately, the clients in federated learning (*e.g.*, edge devices) usually have limited access to the memory resources (Rabbani et al., 2021; Deng, 2019). Consequently, the memory footprint required by gradient computation can exceed the capacity of client devices, resulting the local training being infeasible.

To address these issues, we propose a gradient-free training framework that saves both the memory and communication cost in federated learning with PLMs. Specifically, during local training with client data, the PLM is trained via a gradient-free approach of discrete local search with the set of natural language tokens, which saves the memory consumption of back-propagation by avoiding forward-propagation during local training. Additionally, it significantly reduces the communication cost by allowing to upload with only *discrete* token indices. Further, with the prompts from local training being only natural language tokens, we propose a compression mechanism that compresses the aggregated prompt embeddings according to linear word analogies (Ethayarajh et al., 2018; Nissim et al., 2020; Drozd et al., 2016), further reducing the communication cost of downloading from the server. Our contributions are as follows:

- We propose a noval gradient-free personalized federated learning framework for text classification with PLMs. To the best of our knowledge, we are one of the first to consider gradient-free training in federated learning with PLMs.
- Our gradient-free framework includes training with discrete local search while compressing the prompt embeddings with discrete tokens, substantially reducing the communication and memory cost during federated learning.
- Experiments on various datasets show that our gradient-free framework can achieve superior performance compared to baselines.

2 Related Work

Federated Learning with PLMs: The sheer size of the PLMs (Liu et al., 2019; Kenton and Toutanova, 2019) poses challenges to federated learning due to both high communication cost and large memory footprint during local training. Previous works (Wang et al., 2022, 2023; Zhang et al., 2023) of federated learning with PLMs mostly targets the training efficiency in terms of the communication cost. For instance, Lit et al. (2022) propose to reduce the communication cost by only communicating the lower layers of the PLMs between server and clients, while the upper layers are trained only with local data. Inspired by the superior performance and efficiency of prompt tuning (Lester et al., 2021; Liu et al., 2022), (Guo et al., 2022; Zhao et al., 2023; Guo et al., 2023) propose to further reduce the communication cost via only training and communicating the continuous prompt embeddings. The drawback of these works is that they all require training with gradients, neglecting the huge memory consumption caused by back-propagating through the PLMs. This can be problematic in federated learning for clients with constrained computation resources, *e.g.*, edge devices that have limited memory capacity.

Gradient-Free Training with PLMs: Sun et al. (2022b); Cao et al. (2023) propose Language-Model-as-a-Service (LMaaS) that fine tunes the pretrained prompt embeddings of the PLMs with CMA-ES (Hansen and Ostermeier, 2001), a gradient-free method that only requires forward-propagation. This setting requires the client data being transferred to an external server with the API of PLMs, thus violating the privacy-preserving principle of federated learning. Deng et al. (2022); Diao et al. (2022) model the prompts for the PLM inputs with a prompt generator that is trained with gradients from reinforcement learning. In this way, the back-propagation is not on parameters of the PLM but the prompt generator. This may not be suitable for federated learning, since the prompt generators (*e.g.*, implemented with another PLM) can introduce additional large computation cost for clients during local training. Hou et al. (2022); Prasad et al. (2022) also study gradient-free training of PLMs, but it is unclear how to apply their approach for federated learning. To illustrate, Hou et al. (2022) adopts boosting with prompts, requiring ten times the computation for model inference compared to without boosting, thus is not compatible with clients equipped with constrained computation resources. Importantly, none of the works above study federated learning.

3 General Setup

Let M be the number of clients in federate learning, and $\{D_i\}_{i=1}^{M}$ be their local datasets. In personalized federated learning, these datasets are from different domains or tasks. We have $\mathcal{D}_i = \{\boldsymbol{x}_n, \boldsymbol{y}_n\}_{n=1}^{N}$, for $i = 1, \ldots, M$ with totally N training samples, where $\boldsymbol{x}_n$ is the n^{th} text sequence and $\boldsymbol{y}_n$ is its label for text classification. Let $\boldsymbol{f}(\cdot)$ be the pretrained PLM encoder, and $\boldsymbol{p}_i \in \mathbb{R}^{T \times D}$ be a sequence of T prompt token embeddings for client i. In experiments, we follow (Sun et al., 2022b) with $T = 50$. D is the dimension of the pretrained token embeddings. By prompt tuning, we predict on $\boldsymbol{x}_n$ via concatenating it with prompt $\boldsymbol{p}_i$ using a template $\mathcal{M}$,

$$\mathcal{M}(\boldsymbol{x}_n) = [\boldsymbol{p}_i; \boldsymbol{e}(\boldsymbol{x}_n); \boldsymbol{e}(It\ is\ [Mask])] \qquad (1)$$

$$\boldsymbol{p}(\boldsymbol{y}_n|\boldsymbol{x}_n) = [\mathrm{softmax}(\boldsymbol{f}(\mathcal{M}(x_n)) \cdot \boldsymbol{v}_l^T)]_{y_n}, \quad (2)$$

where $[;]$ denotes row concatenation and $\boldsymbol{e}(\cdot)$ is the embedding layer of the PLM that converts each token into its pretrained embedding. $\boldsymbol{f}$ and $\boldsymbol{e}$ are frozen during federated learning. The output from $\boldsymbol{f}$ on the position of *[MASK]* is compared via inner product with the *verbalizer* $\boldsymbol{v}_l$, which contains embeddings of words that are representative of each label (Gao et al., 2020). For instance, we can have $\boldsymbol{v}_l = \boldsymbol{e}([good, bad])$ for sentiment classification.

In this way, the only trainable parameter for client i is the prompt $\boldsymbol{p}_i$. The training loss for client i is,

$$\mathcal{L}(\boldsymbol{p}_i; \mathcal{D}_i) = \frac{1}{N}\sum_{n=1}^{N} -\log\ \boldsymbol{p}(\boldsymbol{y}_n|\boldsymbol{x}_n), \qquad (3)$$

When training with personalized federated learning for text classification, the general objective is to find $\{\boldsymbol{p}_i\}_{i=1}^{M}$ that minimizes,

$$\frac{1}{M}\sum_{i=1}^{M} \mathcal{L}(\boldsymbol{p}_i; \mathcal{D}_i), \qquad (4)$$

while keeping $\{\mathcal{D}_i\}_{i=1}^{M}$ locally for each client. This is achieved via coordinating the training with a server that iteratively receives $\{\boldsymbol{p}_i\}_{i=1}^{M}$ from local training and distribute their aggregated version, denoted as $\boldsymbol{p}$ in Section 4.1. Unlike the PLMs with online APIs (e.g. GPT-3.5/4 (OpenAI, 2023)) that requires uploading user data to an external server, it is reasonable that the PLMs is deployed locally (*i.e.*, without data uploading), for better data privacy with federated learning.

4 Our Framework

4.1 General Procedures

Our proposed framework of federated learning is composed of the following four steps (also shown in Alg 1), which are executed iteratively multiple rounds of federated learning:

- *Local Training:* Each client trains its own $\boldsymbol{p}_i$ with its local data. Section 4.2 introduces our proposed gradient-free approach of discrete local search for $\boldsymbol{p}_i$.
- *Upload*: The learnt $\{\boldsymbol{p}_i\}_{i=1}^{M}$ is uploaded to the server via converting each $\boldsymbol{p}_i$ to its corresponding index (Section 4.3).
- *Aggregate:* The server aggregates information from different clients by generating a global prompt $\boldsymbol{p}$ from $\{\boldsymbol{p}_i\}_{i=1}^{M}$ to generate, *i.e.*,

  $$\boldsymbol{p} = \frac{1}{M}\sum_{i=1}^{M} \boldsymbol{p}_i, \qquad (5)$$

  where we adopt FedAvg (McMahan et al., 2017) and assume uniform weighting.
- *Download:* $\boldsymbol{p}$ is downloaded to each client as the initialization of local training (with $\boldsymbol{p}_i$) for the next round. Section 4.4 proposes a compression method that approximates $\boldsymbol{p}$ with reduced communication cost (denoted as $\boldsymbol{p}'$).

Note that we assume the pretrained parameters of PLMs have been downloaded to each client before the start of federated learning, so that we only need to communicate the prompt parameters during federated learning. We claim that downloading the PLM parameters to local clients is a practical assumption for federated learning. Specifically, it avoids the client data being uploaded to the server for model inference, as opposed to the recently proposed Language-Model-as-a-Service (LMaas) (Sun et al., 2022b; Deng et al., 2022; Cao et al., 2023) where the PLM API is only stored on an online server that requires data uploading. This is especially important for federated learning where the data privacy is of prime concern.

4.2 Gradient-Free Local Training

In updating each client i, its prompt $\boldsymbol{p}_i$ is firstly initialized with the global prompt $\boldsymbol{p}$ (or $\boldsymbol{p}'$ in Section 4.4) from the previous round of federated learning, then fine tuned on the local dataset $\mathcal{D}_i$. As

Algorithm 1 Overall Algorithm.

```
Input: Datasets ${\mathcal{D}_i}_{i=1}^{M}$, the PLM (API and its pretrained embedding matrix $e(\mathcal{V})$).
Output: The resulting prompt $p'$.

Initialize $p$ with natural token embeddings.
$p = p' = p'_{-1}$
Download the PLM and $p'_{-1}$ to each client.
% General procedures for federated learning.
for $r = 1, \cdots, n\_round$ do
    % Iterate with the $M$ clients.
    for $i = 1, \cdots, M$ do
        % Local Training: Section 4.2, Alg. 3.
        $p_i$ = Local_Training($p'$, $\mathcal{D}_i$)
        % Upload: Section 4.3.
        Upload the indices of $p_i$ to the server.
    end for
    % Aggregation: Section 4.1
    Aggregate $\{p_i\}_{i=1}^{M}$ with (5), generating $p$.
    % Download: Section 4.4, Alg. 2
    $p'$ = Compress_Download($p'$, $p'_{-1}$, $e(\mathcal{V})$)
    $p'_{-1} = p'$
end for
```

mentioned before, gradient-based fine tuning of $\boldsymbol{p}$ with back-propagation can be extremely memory consuming with PLMs. Therefore, we study gradient-free client update of the prompt embeddings, which does not require gradient computing with back-propagation. Specifically, we propose an update mechanism of the prompts based on discrete local search with the set of natural language tokens. Let $\mathcal{V}$ be the vocabulary of the PLM and superscript t denote the t^{th} row of a matrix. For each update iteration, we want to update with only natural language tokens for $\boldsymbol{p}_i$ to reduce the communication cost (Section 1). Specifically, given a randomly sampled index t of the prompt token embeddings, $t \in [1, T]$, and a set of candidate natural language tokens $\boldsymbol{C}(\boldsymbol{p}_i^t) \subset \mathcal{V}$ for replacement, we update $\boldsymbol{p}_i^t$ via,

$$\boldsymbol{p}_i^t = \underset{\boldsymbol{w}\{\boldsymbol{e}(c)|c\in\boldsymbol{C}(\boldsymbol{p}_i^t)\}}{\operatorname{argmin}} \mathcal{L}(\operatorname{repl}(\boldsymbol{p}_i, \boldsymbol{w}, t), \mathcal{D}_i), \quad (6)$$

Note that $\boldsymbol{p}_i^t$ on the left side is the updated prompt of the next iteration of local training, while the one on the right is from the previous iteration. $\operatorname{repl}(\boldsymbol{p}_i, \boldsymbol{w}, t)$ denotes replacing the t^{th} row of $\boldsymbol{p}_i$ with $\boldsymbol{w}$. We randomly choose one position t for each iteration of local training. The candidate set $\boldsymbol{C}(\boldsymbol{p}_i^t)$ is selected with,

$$\boldsymbol{C}(\boldsymbol{p}_i^t) = \underset{\boldsymbol{C}\subset\mathcal{V},|\boldsymbol{C}|=K}{\operatorname{argmax}} \sum_{c\in\boldsymbol{C}} \cos(\boldsymbol{e}(c), \boldsymbol{p}_i^t), \quad (7)$$

where $\cos(\cdot,\cdot)$ is the cosine similarity. We only select K candidate tokens in $\boldsymbol{C}$ with the most similar semantics as $\boldsymbol{p}_i^t$ (large cosine similarity), in order to avoid large perturbation of $\boldsymbol{p}_i^t$ in a single update step. K is the number of local search in each step that controls the training efficiency and is discussed in Section 5. The general procedure is additionally elaborated in Algorithm 3. Note that such a simple update mechanism allow us to represent the learn prompt $\boldsymbol{p}_i$ with token indices, significantly reducing the upload communication cost 4.3.

We notice there are previous works (Li and Liang, 2021; Liu et al., 2021) claiming that discrete tokens are less expressive than continuous tokens, thus the learning capacity may be limited when trained with discrete tokens. However, as described in Section 3, datasets of different clients in personalized federated learning may represent different domains/tasks. For such cases, training with continuous prompts may result in the updated $\boldsymbol{p}_i$ being overfit to the domain/task of client i, causing negative knowledge transfer to other clients when $\boldsymbol{p}_i$ is aggregated with (5). In experiments, we will show that our approach can produce better accuracy compared to training with continuous prompt embeddings.

4.3 Uploading with Discrete Indices

By constraining the candidate embeddings to be within the set of natural language tokens, *i.e.*, $\boldsymbol{C}(\boldsymbol{p}_i^t) \subset \mathcal{V}$, the updated rows of $\boldsymbol{p}_i$ can be saved by only keeping its token index. This significantly reduces the communication cost when uploading prompts to the server, compared with previous works of continuous prompt tuning Guo et al. (2022); Zhao et al. (2022) that upload all the prompt parameters. For instance, the vocabulary size of the Roberta-Large (Liu et al., 2019) model is 50,264 with $D = 1024$, which implies that each token index can be encoded with 16 bits. For rows of $\boldsymbol{p}_i$ that are not modified during client update, we can signify it with a special index using a 16-bit integer, *e.g.*, 50,265 (not natural token indices). Thus, we only need to upload 16 Bits for each position of p_i. Comparatively, uploading the whole prompt vector to the server requires communicating $16 * 1024 \approx 16$KB for each position, provided that the continuous parameters are encoded into float16 during communication. As the result, we reduce the communication cost by 1000 times (16 Bits *vs* 16 KB).

4.4 Downloading with Embedding Compression

After the client update, the uploaded $\boldsymbol{p}_i$, for $i = 1 \dots, M$, are aggregated with (5). We can observe that each row of the resulting $\boldsymbol{p}$ after aggregation can no longer be represented with a single discrete token index, thus cannot be compressed as in Section 4.3 when being downloaded to clients. Below we propose to compress $\boldsymbol{p}$ after aggregation with the pretrained token embeddings of the PLM, *i.e.*, approximating $\boldsymbol{p}$ with the matrix of pretrained token embeddings $\boldsymbol{e}(\mathcal{V}) \in \mathbb{R}^{|\mathcal{V}| \times D}$.

This draws from the intuition in previous works on linear word analogies (Ethayarajh et al., 2018; Nissim et al., 2020; Drozd et al., 2016), which show interesting examples with linear operations among the pretrained word/token embeddings, *e.g.*, $\boldsymbol{e}(king) - \boldsymbol{e}(man) + \boldsymbol{e}(woman) \approx \boldsymbol{e}(queen)$ or $\boldsymbol{e}(doctor) - \boldsymbol{e}(man) + \boldsymbol{e}(woman) \approx \boldsymbol{e}(nurse)$. These indicate that a pretrained token embedding can be estimated by a few embeddings of tokens with similar or relevant semantics. As for our $\boldsymbol{p}$, we can observe from (5) that its prompt embeddings is assumed to be within the convex hull of the natural token embeddings. Therefore, it should be viable to estimate each row of $\boldsymbol{p}$ with a few or fixed number of natural token embeddings. For each round of federated learning with aggregated prompt $\boldsymbol{p}$, let $\boldsymbol{p}'$ be the compressed prompt downloaded to clients from the server after compressing $\boldsymbol{p}$ in the current round. We denote $\boldsymbol{p}'_{-1}$ as the compressed prompt downloaded to clients in the previous round. Below, we elaborate on how to compress $\boldsymbol{p}$ into $\boldsymbol{p}'$, given $\boldsymbol{p}'_{-1}$ from the previous round of federated learning.

We should note that $\boldsymbol{p}'_{-1}$ from the previous round is accessible by both the server and clients, since it was generated by the server and received by the clients. Thus, for the training stability of $\boldsymbol{p}$ at index t, we only compress its increment (residual) between the previous and current rounds, *i.e.*, $\boldsymbol{R}^t = \boldsymbol{p}^t - \boldsymbol{p}^{t'}_{-1}$, instead of directly compressing $\boldsymbol{p}^t$. Specifically, we want to find a sparse projection from $\boldsymbol{e}(\mathcal{V})$ to $\boldsymbol{R}^t$, so it can be approximated with a limited number of pretrained embeddings. Let $\boldsymbol{I}$ be a sequence of token indices, initialized as $\boldsymbol{I} = [1 \cdots, |\mathcal{V}|]$. We define $\boldsymbol{e}(\mathcal{V})_{\boldsymbol{I}}$ be the rows in $\boldsymbol{e}(\mathcal{V})$ indexed by $\boldsymbol{I}$. Formally, we optimize the following,

$$\boldsymbol{x}^* = \text{argmin}_{\boldsymbol{x}} \ ||\boldsymbol{e}(\mathcal{V})_{\boldsymbol{I}}^T \cdot \boldsymbol{x} - \boldsymbol{R}^t||_2^2 + \alpha||\boldsymbol{x}||_1, \quad (8)$$

$$\boldsymbol{I}_x = \text{argmax}_{|\boldsymbol{I}_x|=L} \sum_{j \in \boldsymbol{I}_x} |\boldsymbol{x}^*[j]|, \ \boldsymbol{I} = \boldsymbol{I}[\boldsymbol{I}_x], \quad (9)$$

where $\boldsymbol{I}_x$ takes the top L token indices with the largest absolute projection values in $\boldsymbol{x}^*$. $\boldsymbol{I}[\boldsymbol{I}_x]$ is the value of $\boldsymbol{I}$ indexed by $\boldsymbol{I}_x$. $x \in \mathbb{R}^{|\mathcal{I}| \times 1}$ is the learnt projection, $|| \cdot ||_1$ and $|| \cdot ||_2$ are the one and two norms, respectively, and $| \cdot |$ denotes the absolute value. We solve a sparse $\boldsymbol{x}^*$ using LASSO regularization as in (8), with α being the regularization weight. We empirically set $\alpha = 0.2$ for all datasets and clients. $\boldsymbol{x}^*[j]$ is the j^{th} element of $\boldsymbol{x}^*$. To further minimize the error in estimating $\boldsymbol{R}^t$, the final projection $\boldsymbol{x}_f^* \in \mathbb{R}^{\boldsymbol{I} \times 1}$ is,

$$\boldsymbol{x}_f^* = \text{argmin}_{\boldsymbol{x}_f} \ ||\boldsymbol{e}(\mathcal{V})_{\boldsymbol{I}}^T \cdot \boldsymbol{x}_f - \boldsymbol{R}^t||_2^2. \quad (10)$$

We denote the cardinal of resulting $\boldsymbol{I}$ in (10) as Φ, the number of token embeddings used to approximate $\boldsymbol{R}^t$. Instead of downloading with the aggregated $\boldsymbol{p}$, we download $\{\boldsymbol{I}, \boldsymbol{x}_f^*\}$ to each client. As the result, we only need to download $16 \times 2\Phi$ Bits for each prompt token, consider that both the token index in $\boldsymbol{I}$ and continuous variable in $\boldsymbol{x}_f^*$ are encoded with 16 Bits, as in Section 4.2.

The client will reconstruct the residual $\boldsymbol{R}$ via $\hat{\boldsymbol{R}} = \boldsymbol{e}(\mathcal{V})_{\boldsymbol{I}}^T \cdot \boldsymbol{x}_f$. Finally, the compressed prompt received by the clients for the current round is,

$$\boldsymbol{p}^{t'} = \boldsymbol{p}^{t'}_{-1} + \hat{\boldsymbol{R}}^t, \quad (11)$$

$\boldsymbol{p}' = [\boldsymbol{p}^{1'}, \cdots, \boldsymbol{p}^{T'}]$ will be further saved as $\boldsymbol{p}'_{-1}$ for the next round of federated learning. In the experiments, $\boldsymbol{I}$ is selected with two iterations of (8) and (9), as in Algorithm 2.

After the last round of federated learning, we follow (Fallah et al., 2020; Chen et al., 2018) that further fine-tunes $\boldsymbol{p}'$ with a post tuning process for the final $\boldsymbol{p}_i$ (no communication cost). The post tuning is to adapt the resulting $\boldsymbol{p}_i$ to the task/domain of test client i for more personalization. To avoid forgetting of the global knowledge encoded by $\boldsymbol{p}'$, we adopt the gradient-free method of BBT (Sun et al., 2022b) that allows $\boldsymbol{p}'$ being trained in a constrained continuous subspace with a small learning rate. Please refer to Appendix B for more details. In experiments, we also compare our discrete local search with BBT in local training, showing that our approach discrete local search is more effective in the federated learning setting.

Table 1: Illustration of our approaches and baselines (cited/explained in Appendix C). *Upload* and *Download* shows the Bits that is uploaded and downloaded per round of federated learning. *BP?* indicates whether the method requires back-propagation. Our approaches can save the memory consumption of back-propagation, while significantly reduce the communication cost. We index the mapproaches with A-K for the convenience of Figure 2.

5 Experiments

5.1 Experiment Setting

Training: Following pLF-Bench (Chen et al., 2022), we adopt the datasets of Sentiment140 (Twitter) (Go et al., 2009), CoLA (Warstadt et al., 2018) and SST2 (Socher et al., 2013) for experiments of text classification with federated learning. We additionally adopt FDU-MTL (Liu et al., 2017) that contains 16 text domain. We train and evaluate on all the 16 domains of FDU-MTL (each client with a unique text domain). Please refer to Appendix A for more training details and data splits. Table 1 lists our approaches and considered baselines, which are also detailed in Appendix C. We follow (Sun et al., 2022b) that uses Roberta-Large in our experiments. We do not adopt larger models, *e.g.* LLaMA (Touvron et al., 2023) , due to our practical assumption that the federated learning clients are given limited access to computation resources (Section 1).

Evaluation: The performance of the PLM from federated learning is evaluated via the average classification accuracy over clients that it is tested on. We conduct two kinds of testing: *i) P*: Testing on the *P*articipant clients of federated learning. This evaluated how much a PLM can capture the knowledge from clients during training. *i) NP*: Testing on the *N*on-*P*articipant clients of federated learning. This evaluated the PLM can generalize to unseen clients. For Sentiment140, CoLA and SST2, our partition of participant and non-participant clients follows (Chen et al., 2022). For FDUMTL, we first set all its 16 domain/clients as participant for the evaluation of *P*. In evaluating *NP*, we conduct a 4-split cross-validation that split the 16 clients into 4 groups. We iteratively treat the clients of each group as non-participant while those from others groups as participant (Table 3). In this way, each client is treated as non-participant once and we average the results for *NP*.

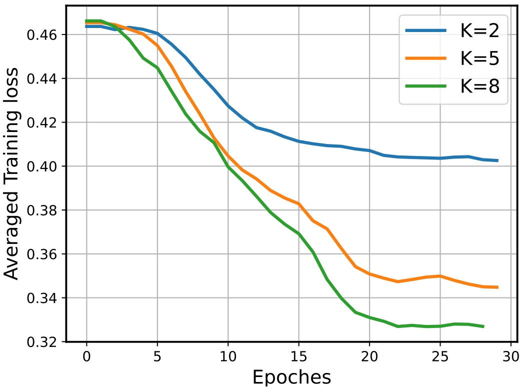

Figure 1: Averaged training loss during joint training of *Ours* ($\Phi = 5$) with different values of K.

In Table 1, we also report on: *1)* Whether the method requires back-propagation, *i.e.*, does the model consume a large memory footprint for local training? *2)* The communication cost, *i.e.*, the number of communicated Bits between server and clients for each round of federated learning. In calculating the Bits, we assume the token indices are encoded with 16-bit and continuous parameters are converted into float16 during communication, as in Sections 4.2 and 4.4. Importantly, we calculate the upload and download cost separately, due to the fact that the upload bandwidth is usually smaller than the download bandwidth (Hegedűs et al., 2021), *i.e.*, upload is more expensive than download with the same number of Bits. For instance, with prompt length $T = 50$ (Appendix A), the upload communication cost for Ours ($\Phi = 5$) is $50 \times 16 = 0.8K$ (Section 4.2) and its download cost is $50 \times 2 \times 5 \times 16 = 8K$ (Section 4.4)

5.2 Local Search with Different K Values.

As discussed in Section 4.2, discrete prompt tokens might be less expressive than continuous prompt embeddings trained with gradients (Li and Liang, 2021; Liu et al., 2021). Thus, one may be concerned about the capability of discrete local search

Table 2: Results with our considered datasets for federated learning. "P" and "NP" denotes the mean accuracy on *Participant* and *Non Participant* clients of federated learning, respectively. *Prompt Tuning* and *BBT* are not federated learning methods, thus all clients are treated as *Participants* Please note that, in addition to performance, our approaches are also superior in terms of memory consumption and computation cost. Please refer to Table 1 for more details.

in minimizing the loss functions of different tasks of different clients. From (6), we can observe that such capability is large and determined by the search number K for each step of local search. Ideally, in maximizing the optimization ability of our local search, we can set $K = |\mathcal{V}|$, *i.e.*, and try with the whole vocabulary instead of searching locally. However, such a combinatorial optimization is computationally expensive, thus not compatible with resource constrained clients. There should be a trade-off between the optimization ability and training efficiency for discrete local search.

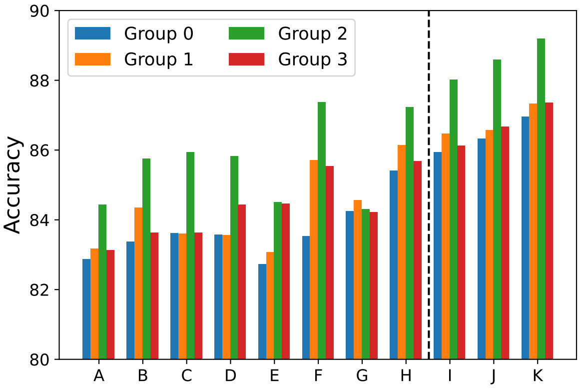

Figure 2: Results on each group of non-participant clients in FDUMTL. For convenience, we denote each method with the index defined in Table 1. Our approaches are the right of the vertical line.

In this section, we investigate how the optimization ability of our proposed local search is affected by the search number K. In Figure 1, we plot the averaged training loss (4) over all the clients in FDU-MTL when training *Ours* ($\Phi = 5$) with different K values. We can observe that our local search can effectively minimize the loss function during training. Additionally, we find that the performance gain, *i.e.*, the difference in the optimized loss value, is diminishing when switching from $K = 2$ to $K = 5$ and from $K = 5$ to $K = 8$. However, the introduced computation cost from $K = 2$ to $K = 5$ is the same as that from $K = 5$ to $K = 8$. With such observation, we take $K = 5$ as a trade-off between the computation efficiency and optimization ability, since *1)* local search with $K = 5$ is not very expensive, *e.g.*, comparing the implementation of BBT (Sun et al., 2022b) that requires 20 searches each step. *2)* The performance gain from $K = 5$ to $K = 8$ is much smaller than that $K = 2$ to $K = 5$, thus increasing the value of K from 5 may not be cost-effective. Therefore, we keep $K = 5$ for all our experiments. Note that such a parameter selection of K only leverages the training data of clients, with no development or testing data involved.

5.3 Result Analysis

Table 2 shows our results with considered datasets. Our approaches can achieve the highest accuracy, with comparable or much lower communication cost than the baselines (Table 1). This is especially obvious with the upload communication, *i.e.*, the upload cost of our approaches is 10 times smaller than the closest baselines (BBT (Fed)), which thanks to our proposed discrete local search mechanism (Section 4.2) that only requires uploading the pretrained token indices to the server. As mentioned in Appendix B, BBT (Sun et al., 2022b) works by randomly projecting the prompt parameters (with a fixed random matrix $\boldsymbol{A}$) into a small subspace, within which a low-dimensional vector $\boldsymbol{z}$ is trained. However, there is no guarantee that such a random projected subspace can cover directions that capture knowledge that is generalizable across clients. On the contrary, though our local search algorithm is constrained with discrete natural language tokens, such tokens should capture rich semantics of natural language that are expressive enough to describe a pattern that is generalizable across clients. This might explain why our approach of discrete local search with natural language tokens yeilds higher accuracy in training with data of different clients. Moreover, we can observe that Ours with $\Phi = 3$ and $\Phi = 5$ can maintain comparable performance for text classification as with *Ours (FullDownload)*, while substantially decreasing download communication cost.

Among the gradient-based approaches (*i.e.*, BP?=Yes), *FedKD* (Wu et al., 2022) generally has lower classification accuracy, which might because its student model (DistilRoberta-base) is less capable than Roberta-Large as used in other approaches. We follow (Wu et al., 2022) that uses a small student model for FedKD to save the communication cost. We can observe that these gradient-based baselines may produce results that are inferior to gradient-free approaches. This may be counter-intuitive since these gradient-based prompt tuning approaches allow training in the whole (more expressive) parameter space of prompt parameters, compared to gradient-free approaches with which the search space for the prompt parameters is usually constrained (Sun et al., 2022b). However, previous works of gradient-free training with PLMs (Sun et al., 2022b,a) also show results that are better than gradient-based approaches, especially with the scenario of few-shot training. Such a phenomenon may be explained by the over-expressiveness of prompts trained with gradients, *i.e.*, subject to overfitting with limited training data. Also, as discussed in Section 4.2, the prompts trained with gradients may overfit to the task/domain of the clients during local client update, inducing negative knowledge transfer from other clients.

Figure 3: The learnt prompt from the *apparel* domain of FDU-MTL, using our proposed discrete local search.

In Figure 2, we detailed results of *NP* for FDUMTL with each of its groups. We can find that our approach consistently outperform the baselines with in terms of group-wise *NP* accuracy. We also provide detailed participant accuracy for each client in Table 4 and 5.

Privacy with the learnt prompts. Figure 3 shows the prompts learnt with data from the *apparel* domain of FDU-MTL, using the proposed discrete local search in client update (Section 4.2). We can find it is hard to interpret, and we cannot infer that the client data is about "apparel" given the prompt tokens. Such a lack of interpretability reduces the chance of client privacy leakage, when uploading the learnt prompts to the server after client update. Inspired by recent approaches of evaluating with Large Language Models (LLMs) (Peng et al., 2023), we further conduct a privacy leakage analysis in Appendix H. Specifically, given a prompt trained from a certain client/domain of FDU-MTL, we investigate how GPT-4 (OpenAI, 2023) can link the prompt to its training domain. We find that none of the 16 clients/domains can be inferred from their prompts using GPT-4 predictions, indicating less chance of privacy leakage.

6 Conclusions

In this paper, we propose a gradient-free framework that trains with discrete local search on natural language token during personalized federated learning. Compared with gradient-based approaches, the discrete local search circumvents gradient computation and saves the huge memory consumption caused by back-propagation. We additionally propose a compression mechanism inspired by linear word analogy that allows the server-client communication with discretely indexed tokens. Experiments show that our framework can achieve superior performance compared to baselines.

7 Limitations

Our proposed approach considers communicating and compressing the pretrained embeddings of the natural language tokens, which is only applicable to the domain of natural langauge processing. It would be more comprehensive for our study to further explore applying our approach for visual tokens (Wu et al., 2020; Yin et al., 2022) during federated learning.

8 Ethics Statement

Ours study of personalized federated learning is intended to protect client privacy during training, avoiding malicious use of client private information. Additionally, the datasets in our experiments are all publicly available.

A Additional Explanation

Our model architecture for prompt tuning is the same as in (Sun et al., 2022b). Specifically, the backbone of the PLM is the Roberta-Large model (embedding dimension $D = 1024$), with $T = 50$ prompt tokens inserted into the input layer. The model is trained with 50 rounds of federated learning for FDU-MTL, SST2 and CoLA, with each client updated 40 steps for each round. For Sentiment140, we train for 100 rounds and we only sample 50 clients for training during each round (due to the large number of clients in Sentiment140).

Following previous works of gradient-free learning (Sun et al., 2022b; Hou et al., 2022), we consider the few-shot scenario for each testing client. Specifically, we assume there are 16 samples for each class in each testing client during post-tuning. For FDU-MTL, these datasets are sampled from the development split in each domain. For sentiment140, these are sampled from the datasets of each testing client, with the rest data of each client used for testing after post tuning. We additionally sample a development dataset (not overlapped with data for training) from the development split for each client for FDUMLT with the same size as the training set, since development datasets are also used in previous works of gradient-free training (Sun et al., 2022b; Hou et al., 2022). We evaluate the classification accuracy of the resulting models on the test set of each client, averaged over four random seeds. We do not sample development

	Domains
Group 1	apparel, mr, baby, books
Group 2	camera, dvd, electronics, health
Group 3	imdb, kitchen, magazines, music
Group 4	software, sports, toys, video

Table 3: Group of domains in FDUMTL. In testing the performance on non-participant clients, we do 4-split cross-validation with FDUMTL. Specifically, we iteratively treat the domains from a group as non-paticipant clients that are held-out from federated learning, *i.e.*, we train with domains/clients of the other three groups during federated learning and test on domains of the held-out group.

datasets for Sentiment140 since no development datasets are provided. Note that our experiments are based only on English datasets and it would also be interesting for future works studying multilingual federated learning (Weller et al., 2022). We provide the algorithm for Local_Training and Compress_Download in Algorithm2 and 3, respectively.

B Black Box Tuning (BBT)

We briefly introduce a prior radient-free method of BBT (Sun et al., 2022b). For prompt $\boldsymbol{p}_i$, suppose we want to train its tth prompt token of $\boldsymbol{p}_i^t$, the BBT approach first reparameterizes $\boldsymbol{p}_i^t$ as,

$$\boldsymbol{p}_i^t = \boldsymbol{A}\boldsymbol{z} + \boldsymbol{p}^t, \tag{12}$$

where $\boldsymbol{z} \in \mathbb{R}^d$, $d << D$, and $\boldsymbol{A} \in \mathcal{R}^{D\times d}$ is a randomly valued fixed matrix that project $\boldsymbol{z}$ into the space of $\boldsymbol{p}^t$. $\boldsymbol{z}$ is the only learnable parameter and is trained with CMA-ES (Hansen and Ostermeier, 2001), a gradient-free method without backpropagation. The value of σ in our implementation follows (Sun et al., 2022b).

C Baselines

All of our baselines are trained with the same model as used in (Sun et al., 2022b). We list the considered baselines are listed as follows:

- *BBT* (Sun et al., 2022b): Train separated prompts locally on each testing client with the gradient-free method of CMA-ES (Hansen and Ostermeier, 2001), as in Section B. This is like the post tuning stage of our approach.
- *BBT (Fed)*: Federated training of $\boldsymbol{z}$ in (12) with BBT on training clients and FedAvg on the server. The resulting $\boldsymbol{z}$ is further fine tuned with BBT on the local dataset of each client, *i.e.*, the same as Section B.
- *FedKD* (Wu et al., 2022): Compressing the Roberta-Large into a smaller student model (DistilRoberta-base) via knowledge distillation, and only communicate the student model to save communication cost. For joint training with FedKD, we follow its original paper (Wu et al., 2022) that fine-tunes all the parameters of both the Roberta-Large and DistilRoberta-base.
- *Prompt Tuning (Fed)*. The prompts are initially trained with FedAvg (McMahan et al., 2017) on all the clients, then fine tuned on each testing client, as with our framework.
- *Meta Prompt Tuning (Fed)*: Same as Prompt Tuning (Fed), except that we follow (Fallah et al., 2020) that the prompts are trained using federated meta learning with MAML (Finn et al., 2017).
- *Prompt Tuning* (Li and Liang, 2021): Train separated prompt parameters locally on each testing client with back-propagation. We did not implement the SVD compression in communicating the parameters, in order to show an upper bound of its classification performance. We follow a learning rate of 1e-5.
- *pFedMe* (T Dinh et al., 2020): We train ans communicate the prompt parameters with pFedMe, where there is an L2 regularization between the global prompt and personalized prompts for for each client.

In addition, we also implement different variations of our approach: *1) Ours (Φ=3 or 5)*. We experiment with different values of Φ, controlling the degree of the embedding compression in Section 4.4. *2) Ours (FullDownload)*. We directly download the aggregated $\boldsymbol{p}$ from (5), without embedding compression.

D Ablation study with α

In this section, we conduct an ablation study for the regularization parameter α (default to $\alpha = 0.2$) for the lasso loss in (8). In Table 6, we take Ours ($\Phi = 5$) as an example and report results with $\alpha =$

0.2 (same as in the main paper) and $\alpha = 0$. We can find that the results with $\alpha = 0$ is generally lower than that with $\alpha = 0.2$, indicating the importance of encouraging sparsity with the lassso loss in (8).

Algorithm 2 Compress_Download.

```
Input: The prompt $\boldsymbol{p}$ without compression, the pretrained embedding matrix $\boldsymbol{e}(\mathcal{V})$.
Output: The reconstructed $\boldsymbol{p}'$.
$\boldsymbol{I} = [1, \cdots, |\mathcal{V}|]$
for $t = 1 \cdots, T$ do
    % Embedding compression.
    for $L = [100, 5]$ do
        Compute $\boldsymbol{I}$ with (8) and (9).
    end for
    Solve $\boldsymbol{x}_f^*$ with (10).
    % Download.
    Download $\{\boldsymbol{I}, \boldsymbol{x}_f^*\}$ to the clients.
    Compute $\boldsymbol{p}^{t'}$ on both server and clients
end for
return $\boldsymbol{p}' = [\boldsymbol{p}^{1'}, \cdots, \boldsymbol{p}^{T'}]$
```

E Comparing with PCA compression and quantization

In Section 4.4, we present our proposed embedding compression method to reduce the download communication cost. To further validate the effectiveness of the proposed embedding compression, we compare it with the two additionaly baselines: PCA compression and quantization.

PCA Compression: Principled Component Analysis (PCA) (F.R.S., 1901) is a common way of dimensional reduction, *i.e.*, compress the embeddings via representing then with fewer dimensions. Previous works (Cai et al., 2021; Rabbani et al., 2021; Gao et al.) have shown that the learnt token embeddings (contextualized or not) of pretrained models are distributed in a narrow cone of the embedding space. In other words, the embeddings vectors are generally biased toward the top principled components of learnt embedding matrix. Specially, following the notation of Section 4.4, let $\boldsymbol{e}(\mathcal{V}) \in \mathbb{R}^{|\mathcal{V}| \times D}$ be the matrix of pretrained token embeddings. We can compute the principled components of $\boldsymbol{e}(\mathcal{V})$, denoted as,

$$\boldsymbol{E}_c = PCA(\boldsymbol{e}(\mathcal{V})) \tag{13}$$

where each column of $\boldsymbol{E}_c \in \mathbb{R}^{D \times D}$ is a principled component of $\boldsymbol{e}(\mathcal{V})$. We have $\boldsymbol{E}_c^T \cdot \boldsymbol{E}_c = \boldsymbol{I}$, with $\boldsymbol{I} \in \mathbb{R}^{D \times D}$ is the identity matrix. The informativeness of different principled component can be measured by the variance after projecting $\boldsymbol{e}(\mathcal{V})$ onto each of the components,

$$\boldsymbol{v} = \mathrm{Var}(\boldsymbol{e}(\mathcal{V}) \cdot \boldsymbol{E}_c) \tag{14}$$

where Var computes the variance for each row. Assume the index of each component, *i.e.*, the row index of $\boldsymbol{E}_c$, has been ranked by $\boldsymbol{v} = [\boldsymbol{v}_i]_{i=1}^{D}$ (from high to low). We plot the ratio of variance ($\boldsymbol{v}/\sum \boldsymbol{v}_i$) verse the index of each component for Roberta-Large in Figure 4a. We can find that the distribution of $\boldsymbol{e}(\mathcal{V})$ id highly an-isotropic, with much larger variation being captured by the top principled components. Thus, we can represent/compress the aggregated prompt $\boldsymbol{p} \in \mathbb{R}^{T \times D}$ from (5) with the top principled components[2] before downloading it to clients. Specifically, we compress $\boldsymbol{p}$ via,

$$\hat{\boldsymbol{p}} = \boldsymbol{p} \cdot \boldsymbol{E}_c[: n, :]^T \tag{15}$$

where $\hat{\boldsymbol{p}} \mathbb{R}^{T \times n}$ is the compressed prompt and $E_c[: n, :]$ denotes the top-n principled components. After downloading, each client reconstructs $\boldsymbol{p}$ via,

$$\boldsymbol{p} = \hat{\boldsymbol{p}} \cdot \boldsymbol{E}_c[: n, :] \tag{16}$$

In this way, we only need to download n integers (16 bits each) for each prompt token in $\boldsymbol{p}$. The total download bits per communication round is $T \times n \times 16 = 800n$ bits. In comparison with our approach, we experiment with $n = 10$ (denoted as PCA10), so that it has the same download communication cost for each round (8KB) as Ours $\Phi = 5$. We additionally experiment with $n = 300$ (denoted as PCA300), where the prompts are represented by more principled components but also with much larger download communication cost each round (0.24MB).

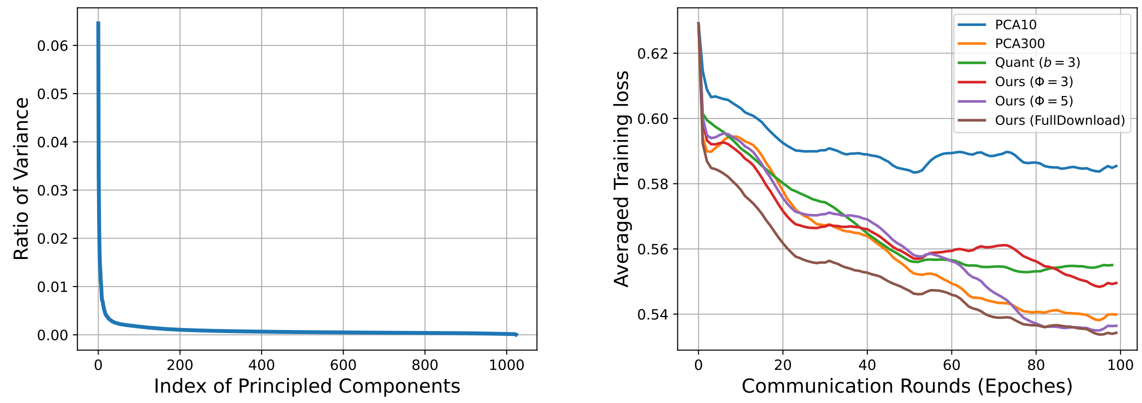
Quantization: We also compare our approach with quantizing each dimension of $\boldsymbol{p}$ from (5) before downloading. Following previous works (Courbariaux et al., 2015; Tao et al., 2022) of compressing pretrained language models, we quantize each element w of $\boldsymbol{p}$ via,

$$w_q = \beta \cdot Q(clip(w, -\beta, \beta)/\beta) \tag{17}$$

where Q is a quantization function that maps $clip(w, -\beta, \beta)$ to its closest value in $\{-1, -\frac{k-1}{k}, \cdots, 0, \cdots, \frac{k-1}{k}, 1\}$, $k = 2^{b-1} - 1$.

---

[2] From Section 4.1, each token of p is a convex combination of $\boldsymbol{e}(\mathcal{V})$, thus should also be biased toward (more represented by) the top principled components.



(a) (b)

Figure 4: (a) The ratio of variance ($\boldsymbol{v}/\sum \boldsymbol{v}_i$) captured by each principled component of the pretrained Roberta-Large Token embeddings. (b) The training loss on Sentiment140 averaged over different clients in each communication round of federated learning for different compression methods. We have the same random seeds and order of training batches for all the methods.

Table 5: Results with FDUMLT on participant clients (continue).

In this way, $Q(clip(w, -\beta, \beta)/\beta)$ can be encoded with b bits. Following (Tao et al., 2022), the scaling factor for each element is shared within the same prompt token embedding. Let $\boldsymbol{p}[i,:]$ be the embedding of the ith prompt token, the scaling factor for each of its element is the maximum absolute value in $\boldsymbol{p}[i,:]$,

$$\beta = max(|\boldsymbol{p}[i,:]|) \tag{18}$$

For each prompt token with dimension D, we have to download the scaling factor β (16 bits) and b bits for each dimension, so that the clients can reconstruct w_q. We experiment with $b = 3$, denoted as Quat ($b = 3$). The total download communication cost for each round is $(D \times b + 16) \times T \approx 0.15$MB. Compared with Quat ($b = 3$) that quantizes each dimension of each prompt, our proposed approaches

Method	Upload	Download	Sentiment140	FDUMTL	CoLA	SST2	Avg

Table 6: Results with different compression methods and α. We report the accuracy in the format of "P/NP", where P and NP follow Table 2.

of embedding compression can be regarded as quantizing on the token level, *i.e.*, representing each prompt with pretrained embeddings of discrete tokens.

Results: We report the results with different compress methods in Table 6. We can find that PCA10 has much lower accuracies than Ours ($\Phi = 5$), though sharing the same communication cost. This is because the top 10 principled components cannot capture enough information about the token embeddings, although the distribution of token embeddings are biased toward the top principled components (Figure 4a). We need to increase the value of n to hundreds in order to get comparable results with our approaches ((*i.e.*, PCA300)), which is at the expense of much higher communication cost. Additionally, we can notice that Quant ($b = 3$) also induces higher download communication cost than our approaches, but yeilding lower accuracies. These results validate the effectiveness of our proposed embedding compression. Additionally, Figure 4b shows the loss values averaged over training clients during federated learning. We can find that our approaches are effective in minimizing the loss function during training (also discussed in Section 5.2). We can also find that the final loss values are generally positively correlated with the accuracies in Table 6.

end for
return $\boldsymbol{p}_i$
```

F The number of floating-point operations during federated learning

From the previous work (Sun et al., 2022b) of gradient-free training for PLMs, the number of floating-point operations with gradient-free training can be evaluated via the number of model queries (i.e., how many times a model is forwarded). For all the methods in the paper, we have the same number of communication rounds and same number of update steps for each client per round. Thus, the number of floating-point operations is proportional to the number of model queries per step when training on each client. We keep all the discussed approaches with the proposed discrete local search method having 5 model queries per step (i.e., $K = 5$ as in Section 5.2), including the approaches denotes with "Ours" and those in Appendix E. Thus, all these approaches have the same number of model queries during federated learning. Comparably, our gradient-free federated learning baseline (i.e., BBT(Fed), there was no previous works on gradient-free federated learning with pretrained models) have 20 model queries per step, following the original implementation of (Sun et al., 2022b). This implies that our methods (5 queries per step) only use $1/4$ $(5/20)$ times of floating-point operations during federated learning, while having better performance than BBT(Fed). Since we target the scenario that clients has limited memory access, where back-propagation might not be viable (Section 1), we mostly compare the number of floating-point operations of our methods with gradient-free federated learning baselines. Provided the number of floating-point operations during federated learning, the training efficiency can be further enhanced by system designs, *e.g.*, the parallelism strategy (Narayanan et al., 2019) or communication scheduler (Peng et al., 2019), which are out of the scope of this paper.

G Overhead

Our way of converting the prompt token index of each position to 16 bits (Section 5.1) induces no computational overhead, if we save the 16 bits index for each position during training (50 prompt positions in total, *i.e.*, $T = 50$). The uploading of such bits is the same as uploading any model parameters in federated learning. There is not need of additionaly designed software implementation. Actually, by only uploading 16 bits for each position, we save the upload time compared with uploading the prompy embedding (the gradient-based methods in Table 4 and 5).

H Inferring the text domain with GPT-4

As mentioned in Section 5.3, we leverage GPT-4 (OpenAI, 2023) to infer the text domain (client) from the prompt trained on it, in order to investigate on the risk of privacy leakage by uploading prompt from clients to the server. This is inspired by recent approaches of evaluating with Large Language Models (LLMs) (Peng et al., 2023). Specifically, try to ask GPT4 with the following template,

> *Given the following prompt sequence learnt from Roberta-Large:*
> *{prompt}*
> *Can you infer that this is trained from a {domain} dataset?*

where *{prompt}* and *{domain}* refer to a prompt and the text domain (client) from which the prompt is trained on, respectively. For example, with *{prompt}* as in Figure 3 and the *{domain}* being *apparel* in FDU-MTL, the GPT-4 answers as,

> *The given list of words and phrases doesn't provide sufficient evidence to conclude that it is trained from an apparel dataset. ....*

We tried with 16 domains from FDUML and none of them result in a positive answer i.e., GPT-4 answers with positive semantics that it can infer the *{domain}* from *{prompt}*. In another word, the frequency that GPT-4 can infer the *{domain}* from the *{prompt}* is zero, indicating less chance of client privacy leakage.

SGSH: Stimulate Large Language Models with Skeleton Heuristics for Knowledge Base Question Generation

Abstract

Knowledge base question generation (KBQG) aims to generate natural language questions from a set of triplet facts extracted from KB. Existing methods have significantly boosted the performance of KBQG via pre-trained language models (PLMs) thanks to the richly endowed semantic knowledge. With the advance of pre-training techniques, large language models (LLMs) (e.g., GPT-3.5) undoubtedly possess much more semantic knowledge. Therefore, how to effectively organize and exploit the abundant knowledge for KBQG becomes the focus of our study. In this work, we propose **SGSH** — a simple and effective framework to **S**timulate **G**PT-3.5 with **S**keleton **H**euristics to enhance KBQG. The framework incorporates "*skeleton heuristics*", which provides more fine-grained guidance associated with each input to stimulate LLMs to generate optimal questions, encompassing essential elements like the question phrase and the auxiliary verb. More specifically, we devise an automatic data construction strategy leveraging ChatGPT to construct a skeleton training dataset, based on which we employ a soft prompting approach to train a BART model dedicated to generating the skeleton associated with each input. Subsequently, skeleton heuristics are encoded into the prompt to incentivize GPT-3.5 to generate desired questions. Extensive experiments demonstrate that SGSH derives the new state-of-the-art performance on the KBQG tasks. The code is now available on Github[1].

1 Introduction

Knowledge Base Question Generation (KBQG) has attracted a lot of attention owing to its wide range of applications in academia and industry (Guo et al., 2024). On the one hand, KBQG can augment training data for question answering (QA) to improve the performance of QA models (Chen et al., 2023; Guo et al., 2022). On the other hand, KBQG empowers machines to actively ask questions in conversations with humans (Saeidi et al., 2018; Wang et al., 2021).

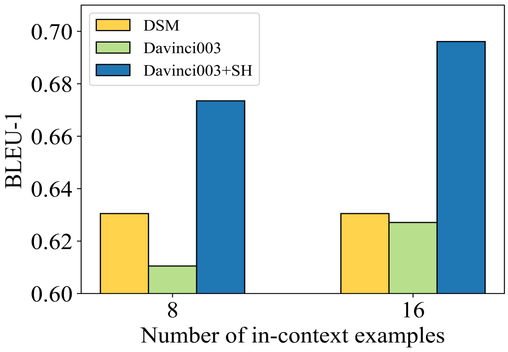

Figure 1: Performance comparison between three advanced methods for KBQG under different numbers of in-context examples on the WebQuestions dataset. The methods include the state-of-the-art PLM-based method DSM (yellow), text-davinci-003 (green), and text-davinci-003 with skeleton heuristics (blue).

The quality of KBQG has been significantly improved, largely attributable to the success of pre-trained language models (PLMs) like BART (Lewis et al., 2020) and T5 (Raffel et al., 2020). A noteworthy example is DSM (Guo et al., 2022), which introduces a meta-learner based on the BART for KBQG, effectively capturing diverse semantic information within a KB. Moreover, AutoQGS (Xiong et al., 2022) designs an auto-prompt approach upon the BART, achieving the low-resource KBQG. Current PLMs, pre-trained on comprehensive corpora, come equipped with rich semantic knowledge, facilitating significant performance improvements in the downstream KBQG task upon fine-tuning.

Recently, large language models (LLMs) such as InstructGPT (Ouyang et al., 2022) and ChatGPT[2], have exhibited impressive capabilities in a variety

Findings of the Association for Computational Linguistics: NAACL 2024, pages 4613–4625
June 16-21, 2024

of tasks (Liu et al., 2023; Nan et al., 2023). However, the vast amount of generalized knowledge poses a challenge in extracting pertinent information for the KBQG task, making LLMs fall short of the expected performance on KBQG. As demonstrated in Figure 1, the PLM-based cutting-edge approach DSM outperforms the direct application of the LLM, Davinci003. In view of this, our focus is on how to trigger LLMs to effectively utilize their knowledge to improve the quality of KBQG, which is an under-explored problem in the community of natural language processing.

Inspired by the way humans learn a language, which typically involves acquiring grammatical knowledge before progressing to reading and writing, we summarize the grammatical elements to guide the desired question generation, instead of directly applying an LLM. In this work, the grammatical elements include the question word phrase and the auxiliary verb, which we call "*skeleton*". Through a pilot study, we observe that prompts coupled with skeleton heuristics can boost the performance of Davinci003 on the KBQG task (Cf. the comparison between Davinci003 and Davinci003+SH in Figure 1). In effect, the skeleton heuristics can be viewed as the fine-grained guidance to excavate task-specific knowledge from the LLMs, thereby stimulating the LLMs to generate more accurate questions.

Motivated by the above insights, we propose **SGSH** — a simple and effective framework to **S**timulate **G**PT-3.5[3] with **S**keleton **H**euristics for KBQG, which contains two modules, i.e., a skeleton generator and a black-box LLM (e.g., GPT-3.5). Figure 2 illustrates the overview of SGSH. Specifically, a skeleton generator implemented by a small PLM (e.g., BART) generates the skeleton for each input, where the skeleton is a series of discrete tokens that act as a particular signal to guide the LLM toward the ground-truth question. To train the skeleton generator, we propose an automatic strategy to construct a high-quality training dataset, which leverages a rule-based method to initially extract skeletons and then utilizes the power of ChatGPT to refine these skeletons. Based on the training set, we learn the skeleton generator with a soft prompting strategy to generate the skeleton for each input. Subsequently, the black-box LLM utilizes the skeleton heuristics via *skeleton injection* and *skeleton-aware in-context learning*. Concretely, given a test input consisting of triples along with the corresponding answer, the skeleton injection step integrates the generated skeleton into the test input. Afterward, the skeleton-aware in-context learning step incorporates in-context examples with skeletons to effectively enhance the in-context learning capability for the test input, where each example shares a similar target question with the test input.

Key Contributions. 1) The development of an automatic data-building approach with a soft prompting strategy for effective skeleton heuristic generation. 2) The creation of an enhanced prompting mechanism, with skeleton injection and skeleton-aware in-context learning, steers GPT-3.5 towards generating more precise questions. 3) Demonstrated superiority of our approach over existing methods in both automatic and human evaluations, also proving beneficial for data augmentation in question answering tasks.

2 Pilot Study

To evaluate the effectiveness of the skeleton heuristics in enhancing the performance of KBQG, we undertake a preliminary investigation to analyze.

KBQG. Given a set of triples extracted from a KB and a particular answer, the objective of KBQG is to generate a question associated with the answer. $\mathcal{D} = \{(G_i, a_i, q_i)\}_{i=1}^{N}$ denotes the dataset for training a KBQG model, where G_i represents a subgraph comprising a set of triples, a_i signifies a given answer, and q_i denotes the target question. This research explores the use of black-box LLMs like GPT-3.5 for KBQG, which can only be accessed through APIs.

Modeling. We perform a pilot study on the commonly used KBQG benchmark, WQ (Yih et al., 2016; Talmor and Berant, 2018). To reduce the cost of API usage, we randomly sample 50 test examples $\{(G_j, a_j)\}_{j=1}^{50}$ from the WQ test set for evaluation. The existing state-of-the-art PLM-based KBQG method DSM (Guo et al., 2022) is our baseline. Another baseline is directly using Davinci003 for KBQG, which takes the test example (G_j, a_j) as input and predicts the corresponding question. To investigate the potential benefits of skeleton heuristics, we use a skeleton generator to derive skeletons for the sampled 50 test examples. To train the skeleton generator, we first construct a skeleton training dataset based on $\mathcal{D} = \{(G_i, a_i, q_i)\}_{i=1}^{N}$ by a rule-based method, which extracts the skele-

---

[3] We use `text-davinci-003` and `gpt-3.5-turbo`.

ton elements (i.e., the question word phrase and the auxiliary verb) from q_i by searching a predefined vocabulary of skeleton elements. Based on the skeleton training dataset, we proceed to train a skeleton generator that produces the specific skeleton heuristics for each test example (G_j, a_j). Subsequently, these elicited skeleton heuristics are seamlessly incorporated into the test input to stimulate Davinci003 to generate the desired question. The skeleton heuristics-based approach is denoted as Davinci003+SH.

Observation — skeleton heuristics can unlock the potential of LLMs for the KBQG task. Figure 1 illustrates that directly applying the LLM (i.e., Davinci003) falls short in performance compared to the PLM-based method (i.e., DSM) in terms of BLEU-1 metric. However, Davinci003+SH, which considers the skeleton heuristics, outperforms both DSM and Davinci003. This implies that directly employing LLMs might not fully exploit useful knowledge to generate the intended questions. The incorporation of skeleton heuristics can enhance the performance of LLMs, serving as an accurate guiding signal that aids LLMs in aligning their output with the gold question. Inspired by these findings, we propose our novel approach SGSH.

3 Methodology

3.1 Model Overview

Our proposed SGSH framework comprises two pivotal modules, a PLM-based skeleton generator (e.g., BART) and a frozen GPT-3.5 model (e.g., Davinci003). Figure 2 illustrates the overall framework. The skeleton generator produces skeletons of test inputs as a precise signal to steer GPT-3.5 at a fine-grained level. More specifically, we first construct a skeleton training dataset $\mathcal{D}_{\mathcal{S}} = \{(G_i, a_i, s_i)\}_{i=1}^{N}$ based on $\mathcal{D} = \{(G_i, a_i, q_i)\}_{i=1}^{N}$ leveraging an automatic data construction strategy and then use a small tunable PLM to learn from the obtained training dataset $\mathcal{D}_{\mathcal{S}}$. Subsequently, GPT-3.5 employs skeleton heuristics through skeleton injection and skeleton-aware in-context learning. These strategies steer GPT-3.5 to skillfully leverage its internal knowledge, thus enhancing its effectiveness in advancing the KBQG task.

3.2 Skeleton Generator

We explain how to (1) perform **an automatic training data construction** strategy to acquire supervised data and (2) **fine-tune** the skeleton generator with learnable prompting to produce skeletons.

Automatic Training Data Construction. In order to effectively train a skeleton generator through supervised fine-tuning, we need to collect labeled data. To avoid costly and time-consuming human annotation, we devise an automatic approach to construct the required data. Drawing inspiration from human cognitive processes, the essential elements of a question are the question word phrase and the auxiliary verb, which are defined as the "*skeleton*". Specifically, we first derive skeletons from $\mathcal{D} = \{(G_i, a_i, q_i)\}_{i=1}^{N}$ using a rule-based method, which extracts the skeleton elements from q_i by searching a pre-defined vocabulary of skeleton elements. Considering the limitation of the rule-based method, such as difficulty in solving complex questions with nested clauses (Cf. Figure 3), and the powerful capabilities of ChatGPT, we utilize ChatGPT to generate skeletons with a well-designed prompt. Subsequently, we employ ChatGPT as an automatic grader to score the skeletons obtained through the aforementioned methods. We then select the skeleton with the comparatively higher score as the definitive one. By doing this, we obtain the supervised data $\mathcal{D}_{\mathcal{S}} = \{(G_i, a_i, s_i)\}_{i=1}^{N}$ consisting of input-skeleton pairs, which are used to train the skeleton generator to infer skeletons for test inputs without requiring any additional manual labeling. Figure 3 shows the overall pipeline.

Fine-tuning a PLM-based Skeleton Generator. To train the skeleton generator, one straightforward method is to perform vanilla fine-tuning on a tunable PLM f_{PLM} (i.e., BART[4]). Motivated by the Prompt Tuning work (Lester et al., 2021), we enhance the vanilla fine-tuning by utilizing a learnable prompting training strategy to effectively train f_{PLM} for precise alignment with the target skeleton (Liang and Liao, 2023). Specifically, we linearize G_i into a triple-based sequence, with each triple separated by commas. Then we append the representations of the prompt tokens $\mathcal{P} = \{p_1, p_2, ..., p_n\}$ to the end of the input (G_i, a_i), which will be updated during the training process. Formally, the objection function is defined as:

$$\mathcal{L}(\theta, \theta_p) = \max_{\theta;\theta_p} \sum_{i=1}^{N} \log P_{\theta;\theta_p}\left(s_i | G_i, a_i, \mathcal{P}\right), \quad (1)$$

where f_{PLM} contains two types of parameters, θ and θ_p. The former is the backbone BART parameters

---

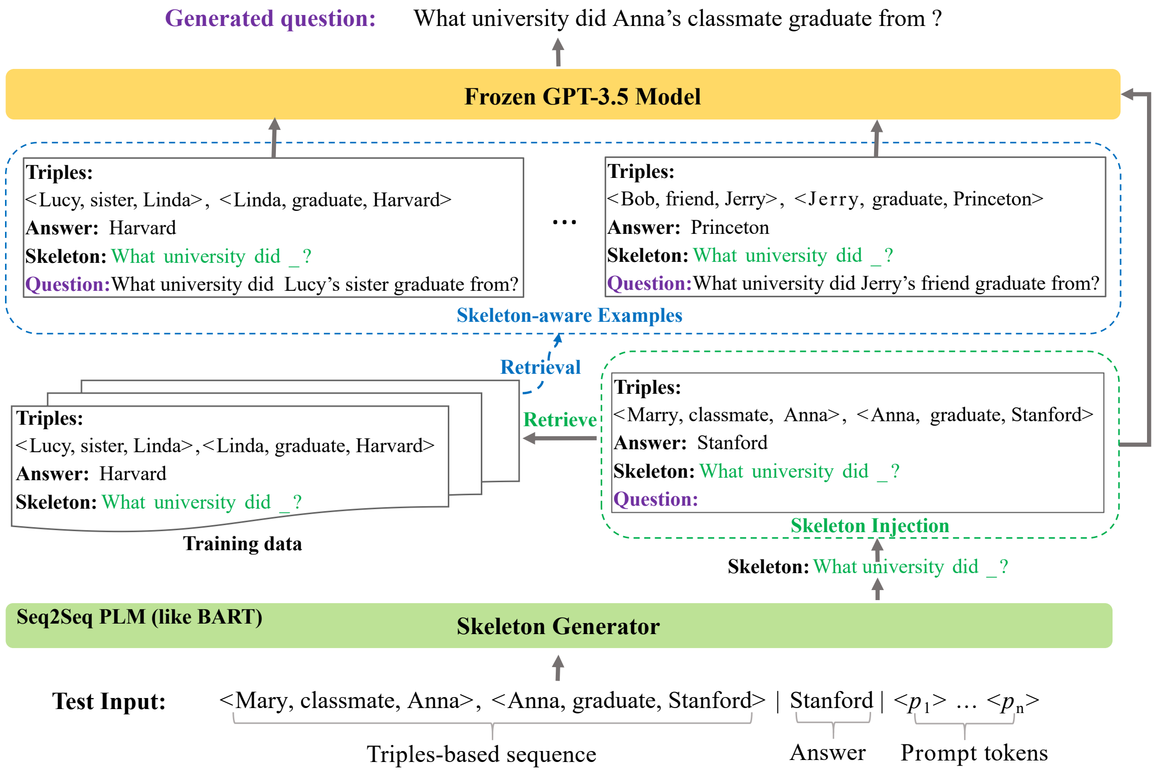

Figure 2: Overview of our SGSH framework, which consists of a PLM-based skeleton generator and a frozen GPT-3.5 model. The skeleton generator, optimized by the learnable prompting strategy, generates the skeleton for each test input. Subsequently, GPT-3.5 leverages skeleton heuristics through skeleton injection and skeleton-aware in-context learning to generate the desired question.

and the latter is the prompt specialized parameters.

Notably, training t groups[5] of learnable prompts, each with different hyperparameters, and subsequently ensembling them during the inference phase can significantly boost the performance of the model. In addition, we find an intriguing phenomenon — few supervised data (i.e., 10%) can achieve comparable performance to full supervised data. We validate the performance across different numbers of learnable prompt groups and supervised data in our experiments.

3.3 Skeleton Heuristics-Enhanced Prompting

Inspired by the observation that skeleton heuristics can stimulate GPT-3.5 for the KBQG task, we introduce skeleton heuristics into the prompt, called *skeleton heuristics-enhanced prompt*, which provides more fine-grained guidance for GPT-3.5. We elaborate on how to utilize skeleton heuristics through two distinct approaches: **skeleton injection** and **skeleton-aware in-context learning**.

Skeleton Injection. The one approach represents injecting the skeleton generated by a skeleton generator f_{PLM} into the test input (G_j, a_j). In specific, given a test input (G_j, a_j) and the corresponding skeleton $s_j = f_{\text{PLM}}(G_j, a_j, \mathcal{P})$, we can obtain the skeleton injection (G_j, a_j, s_j).

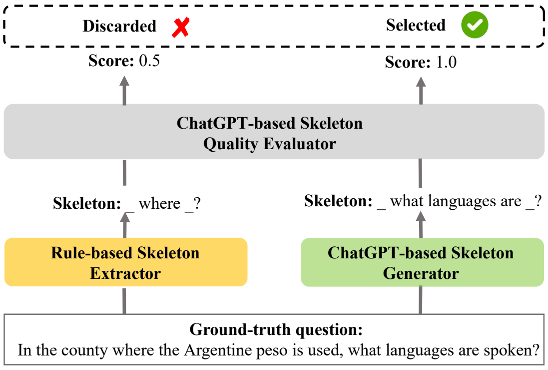

Figure 3: Illustration of the automatic training data construction strategy. We use ChatGPT as an automatic scorer to rate each skeleton generated by the rule-based and ChatGPT-based methods on a scale of 0 to 1.

Skeleton-aware In-Context Learning. The alternative approach incorporates in-context examples with corresponding skeletons (Cf. Automatic Training Data Construction) to facilitate in-context learning for test inputs. In this method, each in-context

---

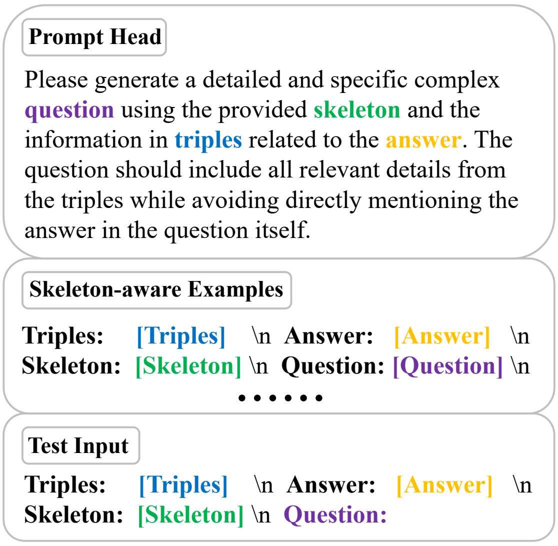
[5] In our experiments, we set the value of t as 8.

example shares a similar target question with the test input, thereby enhancing the quality of the question generated by the test input. Previous studies have revealed that different in-context examples may affect the performance of LLMs (Min et al., 2022a; Liu et al., 2022). Motivated by this, we devise a skeleton-aware example selection strategy called *input+skeleton emb*. Concretely, given a test input skeleton injection (G_j, a_j, s_j) and a training example skeleton injection (G_i, a_i, s_i), we apply a small PLM (i.e., BART) trained on $\mathcal{D}$ to obtain their corresponding embeddings e_j and e_i[6]. Since the embedding is used to decode the target question, it contains rich semantic information about the question for the given input-skeleton pairs. Therefore, if e_j and e_i are close in the embedding space, they probably correspond to similar target questions. Then, we calculate the cosine similarity between the test input embedding e_j and each training example embedding e_i in $\mathcal{D}$ and select the Top-k most similar training examples as the skeleton-aware examples, i.e.,

$$SE(e_j) = \underset{i \in \{1,2,\ldots,N\}}{TopK} \frac{e_j \cdot e_i}{||e_j||_2 ||e_i||_2}. \qquad (2)$$

The embeddings of the training examples can be calculated and stored in advance so that skeleton-aware examples can be efficiently selected.

Figure 4 illustrates the skeleton heuristics-enhanced prompt consisting of a prompt head, a set of skeleton-aware examples, and a test input with a skeleton. Specifically, the prompt head serves as an explanation of the KBQG task, necessitating clarity and specificity to elicit responses that meet our intended requirements. Skeleton-aware examples are derived from the Top-k skeleton-aware examples $SE(e_j)$, each containing a corresponding question similar to the target question of the test input (G_j, a_j). Notably, the number of skeleton-aware examples k affects the performance of the generated question, which will be validated in the experiments (Cf. Ablation Studies 4.3). The test input skeleton injection (G_j, a_j, s_j) follows a similar format to skeleton-aware examples. The only difference lies in that the question slot will be generated by the GPT-3.5 model.



Prompt Head

Please generate a detailed and specific complex **question** using the provided **skeleton** and the information in **triples** related to the **answer**. The question should include all relevant details from the triples while avoiding directly mentioning the answer in the question itself.

4 Experiments

4.1 Experimental Settings

Datasets. We evaluate the proposed method on two widely used datasets WebQuestions (WQ) and PathQuestions (PQ) (Zhou et al., 2018). Concretely, WQ includes 22,989 instances from WebQuestionsSP (Yih et al., 2016) and ComplexWebQuestions (Talmor and Berant, 2018), which are divided into training set/dev set/test set with 18,989/2,000/2,000 instances. PQ consists of train/dev/test set with 9,793/1,000/1,000 instances.

Evaluation Metrics. For evaluation, we employ automatic evaluation metrics, human evaluation, and the downstream QA task. For automatic evaluation metrics, we use two classic metrics, namely BLEU-n (n = 1-4) (Papineni et al., 2002) and ROUGE-L (Lin and Och, 2004), which calculate the proportion of identical n-grams between the generated question and the gold question. The former can be seen as precision, while the latter focuses on recall. For downstream QA tasks, we report the F1 score as some questions have multiple answers. To measure the accuracy of the top-1 predicted answer, we use the Hits@1 metric. For human evaluation, we invite three persons to evaluate the relevance and fluency of generated questions.

Baselines. We compare with **Non-PLMs models**, in which MHQG+AE (Kumar et al., 2019) directly feeds the subgraph into Transformer (Vaswani et al., 2017) to generate the question. G2S+AE and G2S+AE+RL (Chen et al., 2023) employ a bidirec-

tional gated GNN to encode the subgraph and use the LSTM model to decode the question, whereas the latter adds the reinforcement loss to reward the model for generating better questions. In addition, we also compare with **PLMs-based models**, where BART (Lewis et al., 2020) and T5[7] (Raffel et al., 2020) are directly fine-tuned to solve the KBQG task. JointGT(BART) and JointGT(T5) (Ke et al., 2021) inject the structure-aware semantic aggregation module into the vanilla PLMs to preserve the graph structure and devises three pre-training tasks to learn graph-text alignment. DSM (Guo et al., 2022) focuses on the diversity of subgraphs and models the diverse subgraph via meta-learner (Finn et al., 2017). BART+Skeleton (abbreviated as B+S) represents our developed baseline, trained on the raw input and its corresponding skeleton. Finally, we compare with **GPT-3.5-based models**, where Davinci003 and ChatGPT (i.e., `gpt-3.5-turbo`) are directly used for the task.

4.2 Overall Evaluation

In Table 1, we present the comprehensive assessment findings for WQ and PQ. Based on these findings, the following conclusions can be made: **(1) Directly applying GPT-3.5 to KBQG fails to achieve good performance.** Compared to existing state-of-the-art (SOTA) PLMs-based method (i.e., DSM), we notice that ChatGPT reduces 6.48% BLEU-1 and 6.02% ROUGE-L, while Davinci003 reduces 1.26% BLEU-1 and 2.45% ROUGE-L on WQ. This aforementioned performance does not match the remarkable capabilities of GPT-3.5, which can be explained that employing GPT-3.5 directly with a vanilla prompt only provides coarse-grained guidance but cannot offer specific and accurate guidance direction, resulting in poor quality of the generated questions. **(2) Our proposed framework SGSH can motivate GPT-3.5 to produce high-quality questions, which demonstrates the effectiveness of introducing skeleton heuristics.** We observe that our approaches (i.e., SGSH(ChatGPT) and SGSH(Davinci003)) significantly outperform ChatGPT and Davinci003, because our method incorporates a novel part, i.e., skeleton heuristics, into the vanilla prompt to form a skeleton heuristics-enhanced prompt. This prompt provides more fine-grained guidance for GPT-3.5, which can effectively guide GPT-3.5 to generate questions that are closely related to the ground-truth question. Furthermore, our approach (i.e., SGSH(Davinci003)) surpasses the existing baselines (i.e., Non-PLMs models and PLMs-based models), which indicates the strong capabilities of GPT-3.5 on KBQG. **(3) Injecting skeletons into PLMs can also enhance the performance of KBQG.** B+S derives 8.05% BLEU-1 gain and 10.9% ROUGE-L gain over its corresponding vanilla model BART on WQ and obtains 6.98% BLEU-1 gain and 4.91% ROUGE-L gain on PQ. This indicates the skeleton combined with the raw input can play a very significant role in guiding the question generation.

---

4.3 Ablation Studies

Example Selection Strategy. To investigate the effectiveness of our proposed skeleton-aware example selection strategy, namely "*input+skeleton emb*", we compare it with other example selection strategies, namely "*random*" and "*input emb*". Specifically, the *random* signifies the random selection of examples; the *input emb* denotes the selection of examples based on cosine similarity using the input embedding, which is derived from the last hidden state of the BART encoder; the *input+skeleton emb* introduces our innovative selection strategy that identifies examples based on the combined similarity of both the input and its corresponding skeleton. Table 2 shows the evaluation results. Compared with other strategies, our proposed strategy (i.e., *input+skeleton emb*) achieves the best performance as our strategy takes into account the proximity of the input as well as the consistency of the skeleton in the latent space, which significantly contributes to retrieving examples that are similar to the test input. For instance, *input+skeleton emb* achieves 10.15% gain over *random* and 1.09% gain over *input emb* regarding BLEU-4.

	BLEU-1	**BLEU-4**	**ROUGE-L**
Example selection strategy			
Random	83.50	63.98	87.81
Input emb	88.33	73.04	91.89
Input+skeleton emb	**88.87**	**74.13**	**92.47**
Number of examples (k)			
8	88.16	72.96	91.99
16	**88.87**	**74.13**	**92.47**
Number of learnable prompt groups (t)			
1	87.36	71.30	90.84
8	**88.87**	**74.13**	**92.47**
Proportion of training data for skeleton generator			
10%	88.13	72.72	91.66
100%	**88.87**	**74.13**	**92.47**

Table 2: SGSH(Davinci003) ablation studies on PQ.

Model	**GRAFT-Net**		**NSM**	
	F1	**Hits@1**	**F1**	**Hits@1**
Real	**0.622**	**0.681**	**0.666**	**0.727**
-o	0.493	0.575	0.524	0.594
+DSM	0.604	0.664	0.663	0.721
+B+S	0.606	0.676	0.664	0.724
+SGSH(Davinci003)	0.618	0.677	**0.666**	0.726

Table 3: QA performance of GRAFT-Net and NSM.

Number of In-Context Examples. To explore the effect of different numbers of in-context examples (k), we set $k \in \{8, 16\}$ for each test input. As shown in Table 2, the performance of SGSH(Davinci003) improves with the increase of k. For example, SGSH(Davinci003) with $k = 16$ demonstrates better performance compared to $k = 8$ in terms of BLEU-4 (**74.13%** vs. 72.96%) and ROUGE-L (**92.47%** vs. 91.99%). This suggests that providing GPT-3.5 with few-shot in-context examples is key for enabling its capability on KBQG.

Number of Learnable Prompt Groups. We study the effect of different numbers of learnable prompt groups (t) and set $t \in \{1, 8\}$. As t increases, the performance can be significantly boosted in Table 2. For instance, when t is set to 8, the performance in BLEU-4 obtains 2.83% gain and the performance in ROUGE-L gets 1.63% gain compared to $t = 1$. It is worth noting that various groups of learnable prompts possess distinct hyperparameters, which are ensembled during the inference stage. This can be explained by the fact that various prompts focus on distinct aspects, thus integrating them together facilitates the KBQG.

Proportion of Training Data for Skeleton Generator. As indicated in Table 2 and Table 1, we find an interesting phenomenon that our SGSH can significantly outperform the existing SOTA model DSM using only 10% of the training data to optimize the skeleton generator (**72.72%** vs. 61.03% in BLEU-4 and **91.66%** vs. 86.06% in ROUGE-L). This shows the effectiveness of the skeleton generator we developed for steering GPT-3.5 toward the target question for the KBQG task with only a small amount of training data.

4.4 Effect on QA Performance

We explore whether our SGSH can contribute to QA tasks. GRAFT-Net (Sun et al., 2018) and NSM (He et al., 2021) are two popular KBQA models utilized for experiments on WebQSP (Yih et al., 2016), a widely adopted KBQA dataset with 2,848 (question, answer) training instances. There are 1,409 (question, answer) pairs in WebQSP overlapping with WQ. Then we can quickly obtain their corresponding subgraphs from WQ, so we conduct experiments by replacing some of the (question, answer) pairs in WebQSP with questions generated by KBQG models on WQ. Specifically, we train GRAFT-Net and NSM on the datasets partially replaced by the pseudo questions generated by DSM, B+S, and SGSH(Davinci003), denoting them as

"+DSM", "+B+S", and "+SGSH(Davinci003)" respectively. We also train GRAFT-Net and NSM on the original WebQSP, denoted as "Real", and a modified version where overlapping instances are eliminated, indicated as "-o". Finally, we compare their performances with Real.

Table 3 reports F1 and Hits@1 of GRAFT-Net and NSM on various datasets. From the results, we can draw the following conclusions. **(1) The generated questions and the corresponding answers form (question, answer) pairs which can be seen as a data augmentation method for KBQA,** because GRAFT-Net and NSM perform better than -o on +DSM, +B+S, and +SGSH(Davinci003). **(2) SGSH(Davinci003) generates better questions than other baselines (i.e., DSM, B+S),** because +SGSH(Davinci003) outperforms all other baselines. **(3) The questions generated by SGSH(Davinci003) closely resemble the actual questions,** because +SGSH(Davinci003) and Real have comparable results.

4.5 Human Evaluation

To further explore the effectiveness of SGSH, we randomly select 50 test examples $\mathcal{S}_{50} = \{(G_j, a_j, q_j)\}_{j=1}^{50}$ from WQ. Then we assess the generated questions from three perspectives: fluency, relevance, and diversity. Fluency aims to evaluate whether the generated questions are human-readable. Relevance measures how relevant the generated question is to the input. Meanwhile, diversity focuses on assessing the extent to which the generated questions differ from the ground truth. We use the five-point Likert scale to score fluency, relevance, and diversity, where 1 is a poor score and 5 is a perfect score. We invite three persons to score all questions generated by our SGSH(Davinci003) and two baselines (i.e., DSM and B+S), and then average their scores as the final result. As shown in Table 4, our proposed SGSH consistently outperforms other baselines in fluency, relevance, and diversity. Besides, our method is comparable to the ground-truth question in fluency and relevance.

Model	Fluency	Relevance	Diversity
DSM	4.17	4.16	3.62
B+S	4.21	4.18	3.56
SGSH(Davinci003)	4.25	4.21	3.81
Ground-truth	**4.39**	**4.25**	-

Table 4: Human evaluation results on WQ.

5 Related Work

Knowledge Base Question Generation (KBQG). KBQG has evolved significantly over recent years, primarily driven by advancements in sequence-to-sequence (Seq2Seq) modeling approaches (Bi et al., 2020; Chen et al., 2023; Kumar et al., 2019; Liu et al., 2019). Early models focused on encoding serialized subgraphs and specific answers into intermediate representations, which were then decoded into questions. These initial methods, while effective, were limited by the scope of their training data. This limitation paved the way for pre-trained language models like BART (Lewis et al., 2020) and T5 (Raffel et al., 2020), which brought a paradigm shift in KBQG (Guo et al., 2023, 2022; Ke et al., 2021). Additionally, LLMs exhibit considerable potential as they possess a substantial quantity of parameters and demonstrate impressive performance on a wide range of downstream tasks such as KBQA (Baek et al., 2023) and fact-checking (Li et al., 2023). However, despite these advancements, a gap remained in harnessing the full potential of LLMs like InstructGPT (Ouyang et al., 2022) and ChatGPT for KBQG tasks. These LLMs, with their extensive parameterization, encode a wealth of generalized knowledge but have been underutilized in the specific domain of KBQG. Concurrently to our work, KQG-COT (Liang et al., 2023) uses unlabeled data to craft prompts to generate questions.

In-Context Learning. The emergence of LLMs introduced a novel capability—In-Context Learning (ICL). ICL enables models like GPT-3.5 to adapt to new tasks through carefully designed prompts, incorporating task descriptions and relevant examples, without necessitating further parameter tuning (Brown et al., 2020). Research in ICL has unraveled intriguing insights, such as its dependency on example selection strategies and prompt templates Zhao et al. (2021), its insensitivity to ground-truth labels Min et al. (2022b), and its unique modalities of Task Recognition and Task Learning Pan et al. (2023). Yet, the application of ICL in KBQG, especially in the context of utilizing large language models for nuanced and accurate question generation from knowledge bases, remains an underexplored area.

6 Conclusion

We explore how to steer GPT-3.5 toward the gold question on KBQG. In this paper, we propose a simple but effective framework SGSH to **S**timulate **G**PT-3.5 with **S**keleton **H**euristics for KBQG, which provides fine-grained guidance for GPT-3.5 to generate high-quality questions. Specifically, we employ a BART-based skeleton generator that is trained on our constructed training dataset using a learnable prompting strategy to obtain skeleton heuristics. Toward these skeleton heuristics, we then devise a skeleton heuristics-enhanced prompt to trigger GPT-3.5 to align with the ground-truth question. Extensive experiments on widely used datasets demonstrate the advanced performance of our proposed SGSH. In addition, optimizing the skeleton generator with only a small amount of training data (i.e., 10%) can outperform existing SOTA (i.e., DSM). This fine-grained guiding framework could be inspiring for other NLP tasks.

We are sincerely grateful to all reviewers for their insightful feedback.

Limitations

In this section, we discuss the limitations of this work from two aspects. Firstly, the effectiveness of our method is influenced by the accuracy of the skeleton heuristics. The scarcity of labeled data for training the skeleton generator has motivated us to explore automatic training data construction, utilizing both rule-based and ChatGPT-based approaches. However, the quality of this synthetically produced training data is inherently constrained by the capabilities of ChatGPT. Secondly, a more diverse range of datasets for evaluating the generalizability of KBQG models is under-explored. In future work, we plan to establish a comprehensive benchmark dataset encompassing a broad spectrum of domains. This benchmark will enable a more detailed evaluation of our approach and contribute significantly to the ongoing development within the KBQG community.

A Appendix

A.1 Skeleton Generator

Training Process. For our proposed SGSH, the skeleton generator f_{PLM} is a crucial module to obtain skeleton heuristics. Algorithm 1 details the training process of our devised skeleton generator. We present the automatic training data construction strategy to construct labeled data $\mathcal{D}_{\mathcal{S}} = \{(G_i, a_i, s_i)\}_{i=1}^{N}$ for training skeleton generator f_{PLM} in Lines 1-9. More specifically, we utilize a rule-based approach to extract the skeleton s_i' from the target question q_i on $\mathcal{D}$ by searching a pre-defined vocabulary of skeleton elements (Line 3). We employ the powerful potential of ChatGPT to generate the skeleton s_i'' for the target question q_i on $\mathcal{D}$ (Line 4). Subsequently, we use ChatGPT as an automatic grader to score s_i' and s_i'' (Lines 5-6). We choose the higher score one as the refined skeleton s_i to put into the skeleton set S (Line 7). Based on obtained labeled data $\mathcal{D}_{\mathcal{S}} = \{(G_i, a_i, s_i)\}_{i=1}^{N}$, we apply a learnable prompting strategy to train skeleton generator f_{PLM} (Lines 10-13).

Algorithm 1: Skeleton generator training

```
Input: $\mathcal{D} = \{(G_i, a_i, q_i)\}_{i=1}^{N}$, Training epochs $T$.
Output: Parameters of skeleton generator $f_{\text{PLM}}$.
 1: Initialize the skeleton set $S = \varnothing$;
 2: for each $q_i \in \mathcal{D}$ do
 3:     Extract the skeleton $s_i'$ using rule-based skeleton extractor;
 4:     Generate the skeleton $s_i''$ using ChatGPT-based skeleton generator;
 5:     Score $s_i'$ and $s_i''$ using ChatGPT-based skeleton quality evaluator;
 6:     Obtain refined skeleton $s_i$ = MaxScore ($s_i'$, $s_i''$);
 7:     $S = S \cup \{s_i\}$;
 8: end for
 9: Acquire supervised data $\mathcal{D}_{\mathcal{S}} = \{(G_i, a_i, s_i)\}_{i=1}^{N}$ based on $\mathcal{D}$ and $S$ to train $f_{\text{PLM}}$;
10: Initialize parameters of learnable prompts $\theta_p$ and parameters of backbone BART $\theta$;
11: for $epoch \leftarrow 1$ to $T$ do
12:     Calculate $\mathcal{L}(\theta, \theta_p)$ via Eq.1;
13:     $\theta, \theta_p \leftarrow$ AdamW($\theta, \theta_p, \mathcal{L}$);
14: end for
15: Return $\theta$ and $\theta_p$
```

Prompt of ChatGPT-based Skeleton Generator. The rule-based method retrieves the skeleton (i.e., the question word phrase and the auxiliary verb) from the target question through a search within a pre-defined vocabulary of skeleton elements. Obviously, its challenge is in addressing complex ques-

System Prompt

You are a powerful syntax analyzer.

User Prompt

Please generate the question word phrase and the auxiliary verb in the **question** (if any).
Question: **[Question]**

Figure 5: A ChatGPT prompt for generating skeletons.

System Prompt

You are a scoring system used to evaluate the alignment of the **skeleton** to the **question**, where the skeleton is extracted from the question and just contains the question word and the auxiliary verb (if any).

User Prompt

Please score the following two skeletons according to the alignment of the skeleton to the **question**. Scores range from 0 to 1, where a higer score indicates higher accuracy and completeness of the skeleton. Please fairly give the scores for **skeleton 1** and **skeleton 2**, do not output other content.
Question: **[Question]**
Skeleton 1: **[Skeleton 1]**
Skeleton 2: **[Skeleton 2]**

Figure 6: A ChatGPT prompt for scoring and selecting high-quality skeletons.

tions with nested clauses. Hence, we leverage the capabilities of ChatGPT as an enhanced skeleton generator to generate skeletons for target questions, especially those that are inherently complex. Figure 5 demonstrates the system and user prompts of the ChatGPT-based skeleton generator.

Prompt of ChatGPT-based Skeleton Quality Evaluator. To circumvent the costly and time-consuming human selection, we exploit the potential of ChatGPT as an automatic scorer. This capability empowers us to effectively filter out low-scoring skeletons generated by the rule-based skeleton extractor and the ChatGPT-based skeleton generator. Figure 6 illustrates the system and user prompts of the ChatGPT-based skeleton quality evaluator. “Question” denotes the specific target question, “Skeleton 1” corresponds to the skeleton extracted through the rule-based approach, and “Skeleton 2” represents the skeleton generated by the ChatGPT-based generator.

A.2 Experimental Implementation Details

Code Implementation. We implement our method in Pytorch, and run all experiments on a server with a single Nvidia RTX A6000 (48G) GPU card, an Intel(R) Xeon(R) Gold 5218R CPU, 256GB memory, and the Ubuntu 20.04.2 LTS operating system.

Test Input

Triples:
<Sweden, national_anthem, du gamla, du fria>
<Swedish krona, currency_used, Swedish krona>
Answer: Swedish krona

Ground-truth Question

What kind of money does the country with the national anthem du gamla, du fria use ?

Davinci003

Generated question:
What is the monetary unit of the nation with the national anthem du gamla , du fria ?

SGSH(Davinci003)

Generated skeleton: **What kind of money does** _ ?
Generated question:
What kind of money does the country with the anthem du gamla , du fria use ?

Figure 7: Illustration of an example from WQ dataset, which shows the question generated by Davinci003 and our method SGSH(Davinci003).

Test Input

Triples:
<Savang Vadhana, parents, Mongkut>
<Mongkut, children, Chulalongkorn>
<Chulalongkorn, children, Paripatra>
Answer: Paripatra

Ground-truth Question

Who is the child of kid of Savang Vadhana 's father ?

Davinci003

Generated question:
What is the child of offspring of Savang Vadhana 's dad ?

SGSH(Davinci003)

Generated skeleton: **Who is _ ?**
Generated question:
Who is the child of kid of Savang Vadhana 's father ?

Figure 8: Illustration of an example from PQ dataset, which presents the question generated by Davinci003 and our approach SGSH(Davinci003).

Skeleton Generator f_{PLM}. We employ BART-base[8] as the backbone of the skeleton generator and fine-tune it with the AdamW optimizer. We set

---

[8] https://huggingface.co/facebook/bart-base

the learning rate as 5e-5, batch size as 16, training epochs as 20. We initialize the learnable prompts from word embeddings in the vocabulary. We compare different lengths of the prompt such as [2, 4, 8, 16, 32], and set it to 16. We train 8 groups of learnable prompts using different learning rates (abbreviated as lr) and batch sizes (abbreviated as bs) including f_{PLM} (lr = 2e-5, bs = 8), f_{PLM} (lr = 2e-5, bs = 16), f_{PLM} (lr = 3e-5, bs = 8), f_{PLM} (lr = 3e-5, bs = 16), f_{PLM} (lr = 4e-5, bs = 8), f_{PLM} (lr = 4e-5, bs = 16), f_{PLM} (lr = 5e-5, bs = 8), and f_{PLM} (lr = 5e-5, bs = 16).

Frozen GPT-3.5 Model. We utilize two versions of the GPT-3.5 series models including `text-davinci-003` (i.e., Davinci003) and `gpt-3.5-turbo` (i.e., ChatGPT) in our experiments. We use our proposed skeleton-aware example selection strategy (i.e., "*input+skeleton emb*") to choose in-context examples and set the number of these examples as 16. We set n as 10 and employ a majority voting approach across the n questions to determine the final question. We set temperature as 0.7, top_p as 1, frequency_penalty as 0, and presence_penalty as 0.

A.3 Running Examples

We provide two illustrative examples for the WQ and PQ datasets in Figure 7 and Figure 8, respectively. For each example, we present the generated questions by Davinci003 and our approach SGSH(Davinci003). we observe that: (1) The questions generated by SGSH(Davinci003) are more closely related to the ground-truth questions compared to Davinci003, which shows the superiority of our devised framework. (2) The skeletons produced by the skeleton generator are similar to the actual skeletons of the ground-truth question, which demonstrates the effectiveness of our devised skeleton generator. (3) The questions generated by Davinci003 express similar semantics to ground-truth questions but differ in surface form, which verifies that Davinci003 contains rich semantic knowledge, but requires more fine-grained guidance to stimulate it toward the ground-truth question. Nevertheless, our proposed SGSH framework effectively addresses this challenge.

Biomedical Entity Representation with Graph-Augmented Multi-Objective Transformer

Abstract

Modern biomedical concept representations are mostly trained on synonymous concept names from a biomedical knowledge base, ignoring the inter-concept interactions and a concept's local neighborhood in a knowledge base graph. In this paper, we introduce Biomedical Entity Representation with a Graph-Augmented Multi-Objective Transformer (BERGAMOT), which adopts the power of pre-trained language models (LMs) and graph neural networks to capture both inter-concept and intra-concept interactions from the multilingual UMLS graph. To obtain fine-grained graph representations, we introduce two additional graph-based objectives: (i) a node-level contrastive objective and (ii) the Deep Graph Infomax (DGI) loss, which maximizes the mutual information between a local subgraph and a high-level graph summary. We apply contrastive loss on textual and graph representations to make them less sensitive to surface forms and enable intermodal knowledge exchange. BERGAMOT achieves state-of-the-art results in zero-shot entity linking without task-specific supervision on 4 of 5 languages of the Mantra corpus and on 8 of 10 languages of the XL-BEL benchmark.

1 Introduction

Biomedical concepts, such as diseases, symptoms, drugs, genes, and proteins, are critical for many biomedical applications, including drug discovery (Wu et al., 2018; Khrabrov et al., 2022; Zitnik et al., 2018), clinical decision making (Sutton et al., 2020; Peiffer-Smadja et al., 2020), and biomedical research (Lee et al., 2016; Tutubalina et al., 2017; Fiorini et al., 2018; Soni and Roberts, 2021; Sakhovskiy et al., 2021; Sakhovskiy and Tutubalina, 2022). The same biomedical concept may have multiple nonstandard names, abbreviations, and misspellings. Medical concept normalization (MCN), also known as medical concept linking, is a task of mapping entity mentions to a large set of medical concept names and their unique identifiers (CUIs) from a knowledge base (KB). The biomedical domain is characterized by extensive KBs such as the Unified Medical Language System (UMLS) (Bodenreider, 2004), which includes over 166 lexicons/thesauri with over 4M concepts and 15M concept names in 27 languages.

The development of meaningful and robust biomedical entity representations continues to be a challenging task for language models (LMs). Recent studies have probed LMs trained on biomedical texts in English and discovered that domain-specific pre-trained language models (PLMs), such as BioBERT (Lee et al., 2020) and SciBERT (Beltagy et al., 2019), exhibit high levels of bias and lack synonym awareness (Sung et al., 2021). For Spanish, the second language by number of concept names in UMLS, PLMs pre-trained on clinical data fall short compared to the simplistic sparse baseline in the MCN task (Alekseev et al., 2022).

Textual triples from a KB are commonly used to incorporate knowledge into neural networks with metric learning and contrastive learning framework (Phan et al., 2019; Miftahutdinov et al., 2021; Liu et al., 2021a; Yuan et al., 2022; Zhou et al., 2022). Positive and negative pairs are created using head and tail terms of the same or different concepts, as illustrated in Fig. 1, where *maux de tête* is a French synonym of *headache* but differs from *sharp headache* (headache is a broader concept for sharp headache). Graph-based representations are another way to represent biomedical knowledge with concepts as nodes and relationships as edges. Inspired by semantic matching methods like TransE (Bordes et al., 2013) and DistMult (Yang et al., 2015), Yuan et al. (2022) proposed a method to integrate term-relation-term similarities into backbone LM. However, this approach doesn't fully utilize inter-concept interactions since it learns from individual relation triplets rather than performing an aggregation over the whole con-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 4626–4643

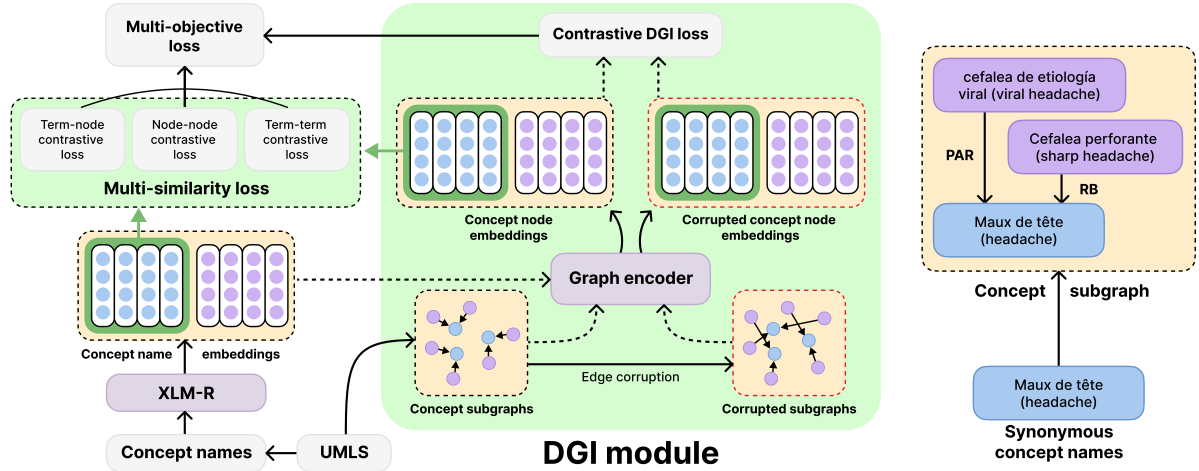

Figure 1: BERGAMOT model's architecture overview. Our model consists of two encoders for text and graph data. Graph encoder uses textual embeddings from BERT as an additional input. The final loss function is a weighted sum of four terms: term-node, node-node, term-term contrastive losses, and local-global mutual information maximization loss on node embeddings. As an example, the local subgraph contains two relation types from UMLS: `PAR` (has parent relationship) and `RB` (has a broader relationship).

cept's local neighborhood in Knowledge Graph (KG) described by UMLS KB.

In this paper, we present **B**iomedical **E**ntity **R**epresentation with **G**raph-**A**ugmented **M**ulti-**O**bjective **T**ransformer (BERGAMOT) which utilizes PLMs and graph neural networks (GNNs) to capture inter-concept and intra-concept interactions from the multilingual UMLS graph. As shown in Fig. 1, the BERGAMOT architecture includes four losses: (i) a textual term-term contrastive loss that learns from positive and negative concept name pairs; (ii) a node-node contrastive loss that learns on concept nodes to distinguish between nodes based on their local subgraphs in larger KG; (iii) DGI loss that lets a GNN distinguish between factually accurate (present in the knowledge graph) concept subgraphs and corrupted ones; (iv) an intermodal contrastive loss that enables mutual information exchange between textual and graph encoders. The source code and pre-trained models are freely available at: `https://github.com/Andoree/BERGAMOT`.

2 Related Work

MCN and entity representations There are several conventional approaches to address an MCN problem. The most common is the entity classification (Niu et al., 2019; Lou et al., 2020) into a small number of target concepts. However, UMLS and similar KBs may include millions of different concepts arranged in a hierarchical structure. Another popular approach is ranking mentions or concepts by the mutual similarity term learnt from positive and negative pairs on some corpora (Mondal et al., 2019). Aside from MCN methods, a plethora of works are focused on features and representations of entity mentions based on syntax, morphology, and synonyms (Aronson, 2001; Van Mulligen et al., 2016; Dermouche et al., 2016). Mondal et al. (2019) chose a straightforward convolutional layer as an encoder. The network was trained with the triplets of a disease mention, as well as positive and negative concept candidates. The supervised BioSyn model (Sung et al., 2020) maximizes the likelihood of synonym appearance among the most similar 20 terms. Morphology was encoded with a character-level TF-IDF representation to obtain a sparse similarity score. The distance between BioBERT (Lee et al., 2020) `CLS` tokens was utilized as a high-level dense similarity. The final similarity score is a weighted sum of both sparse and dense similarities. DILBERT (Miftahutdinov et al., 2021) introduces novel negative sampling strategies for a triplet loss, utilizing the hierarchical structure of the UMLS. Both BioSyn and DILBERT are limited to a single language (English) and a small concept subset within a specific terminology. Entity representation learning may be augmented with external knowledge from domain-specific KBs (Phan et al., 2019; Michalopoulos et al., 2021; Liu et al., 2021a,b; Yuan et al., 2022). (Phan et al., 2019) proposes encoding contextual meaning, conceptual meaning, and the similarity between synonyms during the representation learning process. Two novel training objectives are forcing the similarity between the representation of a named entity and its synonym or target concept, respectively. Despite the promising results, the ranking based on representations from this model performs worse than a plain dictionary-based baseline. UmlsBERT (Michalopoulos et al., 2021) discussed a novel knowledge augmentation strategy to utilize domain-specific knowledge from UMLS during a model's pretraining phase. SapBERT (Liu et al., 2021a) model takes advantage of a self-alignment pretraining (SAP) on the UMLS synonymous pairs. The resulting BERT-like model outperforms its predecessors (BioBERT, SciBERT, UmlsBERT). CODER, using the UMLS graph and a relational loss with SAP, outperforms SapBERT on the MCN task (Yuan et al., 2022).

Graph neural networks in biomedical domain GNNs have gained attention in the last decade, with comprehensive surveys exploring their applications in various fields, including biology and medicine. GNNs are successfully applied to a wide range of graph- and node-level tasks in fields of drug discovery and material design (Wu et al., 2018; Khrabrov et al., 2022; Zitnik et al., 2018), medicine (Ahmedt-Aristizabal et al., 2021; Gligorijević et al., 2021), and Question-Answering (QA) tasks related to knowledge graphs (KG) (Vollmers et al., 2021; Chen et al., 2020). Graph-level biomedical tasks are provided in Open Graph Benchmark (Hu et al., 2020), while KG-related evaluation is not that straightforward. The majority of approaches focused on QA evaluation or conventional KG link prediction. We can divide the considered methods into three groups: LM- or KG-based and joint LM+KG. Despite approximately similar training data (subsets of UMLS) and backbone (SciBERT, BART (Lewis et al., 2020)), the approaches are entirely different due to data preparation procedures and finetuning. Chang et al. (2020) proposed a completely KG-based biomedical benchmark. They trained TransE, ComplEx (Trouillon et al., 2016), DistMult, SimplE (Kazemi and Poole, 2018), and RotatE (Sun et al., 2019) on the SNOMED-CT dataset to compare the results with static Snomed2Vec (Agarwal et al., 2019) and Cui2Vec (Beam et al., 2020) baselines. While static methods did not surpass any KG-trained methods, KG-based models performed remarkably worse in comparison with LM-based ones due to the lack of a text encoder. An alternative approach to benchmarking is provided in the LM+KG architectures' evaluation. QA-GNN (Yasunaga et al., 2021) and GreaseLM (Zhang et al., 2022) achieved state-of-the-art scores on MedQA (Jin et al., 2021). However, they are both trained in a manner of fine-tuning LM with KG-augmentation. This strategy does not allow us to completely adapt models to the MCN task.

3 Background and architecture

3.1 UMLS knowledge graph

Let V denote a set of all concepts present in a knowledge base and R denote a set of possible relation types between concepts from V. Knowledge graphs, such as UMLS, usually store relational information in the form of relation triplets $(h, r, t) \in V \times R \times V$. Let $\mathcal{E}$ denote a set of all unique relation triplets from a given KG. Thus, the UMLS graph can be defined as an oriented edge-labeled graph $G = G(V, \mathcal{E}, R)$ with a set of nodes V, a set of labeled oriented edges $\mathcal{E}$, and a set of possible edge labels R. For each concept $c \in V$, UMLS presents a set of k synonymous concept names $S_c = \{s_1^c, s_2^c, \dots, s_k^c\}$. For each name from S_c, UMLS stores the label of the language it came from.

3.2 Self-alignment pretraining

A reasonable and straightforward way to learn an informative representation space of biomedical entities is to represent textual knowledge from KG in the form of positive and negative term pairs and optimize some contrastive learning loss function.

In this work, we adopt the self-alignment pretraining (SAP) procedure proposed by Liu et al. (2021a). To enrich the training procedure with harder negative samples, SAP employs online hard mining for valid triplets (Mikolov et al., 2013; Gillick et al., 2019). During SAP, the model is encouraged to produce similar representations for all terms that represent the same concept (share the same CUI). At each pretraining step, we sample a set T that consists of N positive samples $(c, s_i^c, s_j^c) \in V \times S_c \times S_c$. Given T, SAP constructs all possible term triplets (s^p, s^a, s^n) such that $p = a$ and $n \neq a$. s^a is called an anchor term; s^p is a positive term for s^a (i.e., s^p and s^a are synonymous terms representing the same concept $a = p$); s^n is a negative term for s^a (i.e., s^n and s^a represent non-matching concepts). Each triple produces a positive pair (s^a, s^p) and a negative pair

(s^a, s^n). To keep only the most informative triples, we use online hard mining for valid triplets in respect to the following constraint:

$$\|f_{enc}(s^a) - f_{enc}(s^p)\| < \|f_{enc}(s^a) - f_{enc}(s^n)\| + \lambda$$

where f_{enc} is a BERT-based textual encoder, $\|\cdot\|$ is the normalized L_2-norm, and λ is a pre-defined mining margin. Thus, the mining procedure discards all the triplets such that the distance from an anchor to its negative sample is greater than the distance to its positive sample by more than λ. Let $\mathcal{P}$ and $\mathcal{N}$ denote the sets of all positive and negative term pairs, respectively. The SAP procedure utilizes the Multi-Similarity (MS) loss (Wang et al., 2019) to learn from $\mathcal{P}$ and $\mathcal{N}$.

$$\mathcal{L}_{sap} = \frac{1}{|B|} \sum_{i=1}^{|B|} \left(\frac{1}{\alpha} \log\left(1 + \sum_{n \in \mathcal{N}_i} e^{\alpha(S_{in} - \epsilon)}\right) + \right. \\ \left. + \frac{1}{\beta} \log\left(1 + \sum_{p \in \mathcal{P}_i} e^{-\beta(S_{ip} - \epsilon)}\right) \right), \tag{1}$$

where α, β, and ϵ are the parameters of MS-loss. $\mathcal{P}_i$ and $\mathcal{N}_i$ are the sets of positive and negative samples for the anchor concept i. S_{in} and S_{ip} are the cosine similarities of anchor i to negative sample n and positive sample p, respectively.

3.3 Graph neural networks

3.3.1 Message passing layers

A common approach to capture the complex relationships between nodes in the graph is to iteratively update the representation of a node v by passing and aggregating messages from its local node neighborhood $N(v)$ using a graph neural network. Gilmer et al. (2017) proposed a general Message Passing Neural Network (MPNN), which applies a composition of message function f_m and f_u to update the node representation $h_v^{(l)}$ at the $(l+1)$-th MPNN layer:

$$h_v^{(l+1)} = f_u(h_v^{(l)}, \sum_{(r,u) \in N(v)} f_m(h_v^{(l)}, h_u^{(l)}, e_r))$$

where $N(v) = \{(r, u) | (v, r, u) \in \mathcal{E}\}$ is the set of pairs describing the local neighborhood of node v; e_r are the edge features. Each pair (r, u) indicates the presence of a directed edge of type r from node v to node u in graph G. To avoid excessive computational complexity caused by significant variation in the number of neighbors across different nodes, we use a uniformly drawn fixed-size subset of neighbors instead of the entire node neighborhood as proposed by Hamilton et al. (2017). The primary distinguishing factor among various GNN models is the selection of f_m and f_u functions in the MPNN computational block. In GraphSAGE (Hamilton et al., 2017), a common and rather simple implementation of MPNN framework, an element-wise operator (e.g., max- or mean-pooling) is used as an f_m to aggregate the vectors of neighbor nodes $N(v)$ into a single vector. The aggregated representation is further concatenated with the original representation and passed to a linear layer W^{l+1} with a non-linear activation function σ. In this work, we use the GraphSAGE implementation with mean-pooling aggregation:

$$h_v^{(l+1)} = \sigma(W^l \cdot [h_v^{(l)} \parallel MEAN(N(v))])$$

where $MEAN$ is the mean-pooling operator, $[\cdot \parallel \cdot]$ is the concatenation of two vectors. Since the parameter matrix W^l is the same for each $r \in R$ GraphSAGE operator prevents a thorough use of edge types and features. Regarding the UMLS graph, it means that GraphSAGE can only capture the textual node features and knowledge graph geometrical structure, though it doesn't consider relation-specific information.

Schlichtkrull et al. (2018) proposed Relational Graph Convolutional Network (R-GCN) architecture that performs relation-aware message passing by introducing a relation-specific parameter matrix W_r^l for each relation $r \in R$ at the neighborhood aggregation step of Message Passing block:

$$h_v^{(l+1)} = \sigma\left(\sum_{(r,u) \in N(v)} \frac{1}{|N(v)|} (W_r^l h_u^{(l)} + W_o^l h_v^{(l)}) \right)$$

σ is a non-linear activation function and W_o^l is a self-loop parameter matrix.

Despite being able to perform relation-aware message passing, R-GCN shares the limitation of GraphSAGE as it does not allow learning the relative importance of neighboring nodes. Graph attention network (GAT) (Veličković et al., 2018; Brody et al., 2022) addresses the limitation by introducing the self-attention over neighboring nodes and learning the aggregated neighborhood representation as the weighted sum of neighboring nodes representations. Given two node representations $h_u^{(l-1)}$ and $h_v^{(l-1)}$, the l-th GAT layer computes the relevance of node u for the target node v as the normalized attention score $\alpha_{uv}^{(l)}$:

$$e_{uv}^{(l)} = a^T \cdot LeakyReLU(W^l \cdot [h_u^{(l-1)} \parallel h_v^{(l-1)}])$$

$$\alpha_{uv}^{(l)} = \frac{exp(e_{uv}^{(l)})}{\sum_{(r,w)\in N(v)} exp(e_{wv}^{(l)})},$$

where a is a learnable weight vector. With the attention scores obtained, the aggregated neighborhood representation is computed as a weighted sum of neighboring nodes embeddings:

$$h_v^{(l+1)} = \sigma\left(\sum_{(r,u)\in N(v)} \alpha_{uv} \cdot W^l h_u^{(l)} + W_o^l h_v^{(l)}\right)$$

3.3.2 Deep Graph Infomax framework

To enrich an LM and a GNN with graph structure knowledge, we utilize the Deep Graph InfoMax framework (Veličković et al., 2019). DGI adopts an encoder model GNN to maximize the mutual information between global graph structure and its local subgraphs. This method is grounded on minimizing a noise-contrastive loss function

$$\mathcal{L}_{dgi} = \frac{1}{N+M} \sum_{i=1}^{N} GNN\left[\log D(\vec{h_i}, \vec{s})\right] + \\ + \sum_{j=1}^{M} GNN\left[\log\left(1 - D(\vec{\tilde{h}_j}, \vec{s})\right)\right],$$

where $\vec{s}$ is a graph summary obtained as a mean embedding of nodes in a graph; D is a learnable discriminator with sigmoid activation which scores summary-graph pairs. The loss aims at distinguishing between input node representations h and negative samples $\tilde{h}$. The procedure starts with collecting initial and corrupted node features of graph G, after that we obtain representations via GNN, respectively, for each type of feature vectors. By leveraging local mutual information maximization and graph convolutional architectures, we make the features of local subgraphs to be consistent with the global properties of a larger graph.

3.4 BERGAMOT

We introduce a novel biomedical entity representation learning model BERGAMOT which leverages graph and textual encoders to infuse inter-concept interactions from a biomedical KG into LM. In BERGAMOT, we adopt and extend the pretraining procedure described in Sec. 3.2. Before moving on to the description of the pretraining procedure, let us first describe the structure of a training batch B which consists of (i) textual positive concept name pairs and (ii) local concept subgraphs.

Textual pairs We begin by sampling a set T, consisting of N random positive concept name pairs for concepts that have at least two distinct concept names. Let (u, v) denote a pair of concept names that represent the same concept c (e.g., "Maux de tête" and "headache" as shown in Fig 1). We encode both textual names with a BERT-based LM resulting in two vector representations $e_c^u = LM(u)$ and $e_c^v = LM(v)$, respectively.

Concept subgraphs A positive textual pair (u, v) in T corresponds to a single UMLS concept c. As c is also a node in the UMLS KG, we sample the graph G_c that is centered around c and includes a set of its neighboring nodes $N(c)$. Next, we have two ways to initialize the central node c from G_c with either $LM(v)$ or $LM(u)$ resulting in two graphs G_c^v and G_c^u with identical structure but different initial node features. For instance, we can initialize a central node with a BERT embedding of either "headache" or "Maux de tête" (see Fig. 1). Non-central concept nodes are initialized with LM embeddings of their random concept names independently for both graphs. By applying a L-layer graph neural network we obtain two graph representations of the concept c: $g_c^u = GNN(G_c^u)$ and $g_c^v = GNN(G_c^v)$.

BERGAMOT's design is inspired by two major goals. First, we want to encode concept names and graph structure into a single shared embedding space while preserving an essential property for entity linking: various (both textual and graph) representations of the same concept must have similar embeddings. Second, since obtaining a relevant KG subgraph is not feasible at the inference stage, we want to infuse rich structural knowledge from the UMLS graph into a language model. To reach both goals, our model simultaneously learns 4 contrastive objectives on concept representations as shown in Fig. 1.

Term-term contrastive loss $\mathcal{L}_{sap}$ To let a BERT-based model learn semantic and lexical similarity of various concept names, we apply MS-loss on textual pairs. This objective seeks to pull textual embeddings (e_c^u, e_c^v) of concept c's synonymous names closer in terms of cosine similarity, ignoring inter-concept relations. We use in-batch hard

negative samples to push textual representations of non-matching concepts far from each other.

Node-node contrastive loss $\mathcal{L}_{node}$ Similarly to term-term loss, we apply MS-loss to pull graph embeddings (g_c^u, g_c^v) representing the same concept c closer pushing away the representations of non-matching ones. Unlike textual encoder, GNN is aware of relations between concepts as it sees neighboring nodes $N(c)$ rather than a single concept c only.

Term-node contrastive loss $\mathcal{L}_{int}$ In batch B, a central concept node c has four representations: e_c^u e_c^v, g_c^u, and g_c^v. While $\mathcal{L}_{sap}$ and $\mathcal{L}_{node}$ optimize unimodal textual and graph models separately, our ultimate goal is to enhance a language model with graph structure knowledge accumulated in graph embeddings. To enable mutual information sharing between a text and a graph encoder we introduce a third contrastive loss which learns from two-modal positive pairs (e_c^u, g_c^u) and (e_c^v, g_c^v). Intuitively, we expect our LM to memorize in-domain knowledge from KG. Similarly to term-term and node-node objectives, we adopt MS-loss and two-modal in-batch hard negative samples. Since $\mathcal{L}_{int}$ makes LM and graph encoders exchange their knowledge, we encourage an LM to be more aware of inter-concept relations.

DGI loss As an additional pretraining objective for a graph encoder, we employ the DGI framework and calculate the DGI loss $\mathcal{L}_{dgi}$. We use a union of all local concept subgraphs from the batch B to form a global batch G_B. Readout function $R(G_B)$ calculates a mean embedding over N central nodes of concept subgraphs. To obtain a corrupted graph $\tilde{G_B}$, we randomly shuffle central nodes across all positive paired samples. The choice of the corruption function encourages our model to distinguish if nodes $N(c)$ are actual neighbors of a central node c. The intuition behind adding the DGI loss is to learn more informative node features. Since DGI captures graph structural information by learning on true and corrupted graphs, we expected it to contribute to LM's structural awareness of concept relations.

For $\mathcal{L}_{sap}, \mathcal{L}_{node}$, and $\mathcal{L}_{int}$ we employ MS-loss (see Eq. 1) for maximum comparability with multilingual versions of SapBERT (Liu et al., 2021b) and CODER (Yuan et al., 2022) as both models utilize this contrastive objective in $\mathcal{L}_{sap}$. Also, MS-loss was experimentally shown to be the most effective contrastive objective to learn from UMLS synonyms (Liu et al., 2021a) among 7 variants. The final training objective used to pre-train the BERGAMOT model is defined as the weighted sum of four loss functions:

$$\mathcal{L} = \mathcal{L}_{sap} + \mathcal{L}_{node} + \mathcal{L}_{int} + \lambda_{dgi}\mathcal{L}_{dgi},$$

where λ_{dgi} is the pre-selected weight of DGI loss. After pretraining on UMLS we discard the graph encoder as in general case there is no graph available during inference. Thus, the result of the pretraining procedure is a BERT-based model enriched with knowledge from the UMLS graph.

4 Experimental evaluation

To train BERGAMOT, we use the UMLS 2020AB release which contains approximately 4.4 million concepts and 15.9 million unique concept names from 215 source vocabularies. The full statistics on pre-training multilingual and monolingual data as well as the number of concept names for languages are shown in Appendix A. We remove all duplicated edges (i.e., edges with matching source and target concepts, and relation type). To ensure each batch includes a sufficient amount of positive samples, we pre-generate synonymous concept name pairs following Liu et al. (2021a). Since random sampling could result in the underrepresentation of languages other than English, we explicitly add (i) monolingual non-English and (ii) cross-lingual positive concept name pairs to each batch. However, the quadratic growth in the number of possible language pairs with respect to the number of languages limits our ability to enrich the training dataset with multilingual data. We discard all cross-lingual pairs which consist of two non-English terms thus forcing all languages to benefit from extensive English knowledge.

To explore how the BERGAMOT's performance is affected by a monolingual low-resource setting, we additionally subsample a monolingual subgraph and generate a monolingual set of positive pairs for Spanish, Dutch, French, and German. We create each dataset by removing all terms that came from a non-target language and all nodes that have no concept name in a target language. For statistics on positive textual pairs count, number of edges and nodes, please see Tab. 8 in Appx B.

For evaluation on the MCN task, we use two cross-lingual benchmarks:

- a medical-crossing benchmark (Alekseev et al., 2022) based on Mantra corpus (Kors et al., 2015) of text units such as scientific abstract titles, drug labels, patent claims mapped to the UML concepts.
- XL-BEL (Liu et al., 2021b), with Wikipedia entities linked to the UMLS.

Mantra corpus covers mentions in English, French, German, Spanish, and Dutch while XL-BEL covers 10 languages. Both benchmarks allow zero-shot evaluation only, i.e., there are no training sets. Additionally, we employ the French Quaero corpus (Névéol et al., 2014) and two datasets in Spanish: (i) CodiEsp-Diagnostico (Miranda-Escalada et al., 2020b) and (ii) CANTEMIST (Miranda-Escalada et al., 2020a). Alekseev et al. (2022) introduced a novel *filtering* procedure which drops test set mentions that are identical to a term from the dictionary. For dataset descriptions and statistics, refer to Appendix B.

To explore the ability of our model to solve diverse non-MCN NLP tasks, we additionally evaluate our model on biomedical Question Answering (QA) and Textual entailment (TE) tasks. We conducted QA experiments on two datasets: (i) PubMedQA (Jin et al., 2019) and BioASQ (Nentidis et al., 2019). The goal of TE task is to determine a logical relationship between two pieces of text: a premise and a hypothesis. For TE experiments, we utilize two corpora: (i) MedNLI (Shivade et al., 2019) and (ii) SciTail (Khot et al., 2018). For

$\mathcal{L}_{sap}$ only	73.43	86.99	34.8	39.4
-$\mathcal{L}_{dgi}$	76.25	88.52	34.1	39
-$\mathcal{L}_{sap}$	72.64	83.09	30.6	35
-$\mathcal{L}_{node}$	74.55	88.38	**36.1**	**41.2**
-$\mathcal{L}_{int}$	77.41	88.86	34.9	39.5

Table 6: Ablation results of GAT-BERGAMOT. We report the mean acc@1 and acc@5 over all languages present in the Mantra and XL-BEL corpora. $\mathcal{L}_{sap}$ only set-up refers to mSapBERT which trains with a single text-based training objective.

details on QA and TE datasets, see Appendix D. For TE, we adopted the Next Sentence Prediction (NSP) data format from vanilla BERT (Devlin et al., 2019): two sentences for the entailment task are separated with a special separator token, and the model is trained on a classification task.

4.1 Experimental Setup

For evaluation, we employ a ranking approach over embeddings of mentions and potential concepts. After applying an average pooling layer over a BERT-based encoder, the inference task is then reduced to finding the closest concept name representation to the entity mention representation in a joint embedding space. We use the Euclidean distance as the metric. Nearest concept names are chosen as top-k concepts for entities. We evaluate the models in the information retrieval scenario, where the goal is to find top-k concepts for every entity mention in a dictionary of concept names and their identifiers. Following previous works on entity linking (Suominen et al., 2013; Pradhan et al., 2014; Wright et al., 2019; Phan et al., 2019; Liu et al., 2021a), we use the top-k accuracy as the evaluation metric: $\mathrm{Acc@k} = 1$ if the correct UMLS concept unique identifier is retrieved at the rank $\leq k$, otherwise $\mathrm{Acc@k} = 0$. We note that BERGAMOT's graph encoder is discarded during inference and only a BERT-based encoder is used for ranking.

4.2 Results

Medical Concept Normalization Tab. 1 shows the acc@1 and acc@5 metrics for datasets in five languages. BERGAMOT outperformed all models on four sets except the French dataset on both full and filtered test sets. The best results are achieved by GAT-BERGAMOT which consistently ourperforms mSapBERT on all languages proving the effectiveness of three additional training objectives that rely on graph embeddings. Poor performance of GraphSAGE- and RGCN- versions of our model indicate the effectiveness of relative neighbor importance learnt in GAT via the attention mechanism. Interestingly, GAT-BERGAMOT achieves state-of-the-art results on both resource-rich (English and Spanish) and low-resource (German and Dutch) languages. On English, it outperforms a supervised model that is fine-tuned on English data. We must note that due to the small dataset size, GAT-BERGAMOT's improvement over mSapBERT and mCODER is statistically significant (Wilcoxon, $\rho < 0.05$) for the German part only. We provide examples of models' predictions in Appx. G.

In the next series of experiments, we explored how BERGAMOT benefits from both monolingual and multilingual pre-training set-ups. For each of four non-English parts of the Mantra corpus, we trained a monolingual SapBERT and a monolingual GAT-BERGAMOT model. Tab. 2 presents the performance of models pre-trained on multilingual and non-English monolingual graphs and concept names. Based on the results, we can notice that BERGAMOT benefits from the multilingual bi-modal data the most. It appears that training a single multilingual graph-augmented BERGAMOT eliminates a need for further pretraining of monolingual LMs (either SapBERT or BERGAMOT) on UMLS. On average, monolingual BERGAMOT models perform on par with monolingual SapBERT models.

Tab. 3 presents the evaluation results on filtered test sets of the French QUAERO corpus and the Spanish CodiEsp-D and CANTEMIST corpora. GAT-BERGAMOT consistently outperforms two other BERGAMOT models as well as mSapBERT and mCODER baselines pushing the existing state-of-the-art on these corpora. Notably, the GAT-BERGAMOT's improvement over both baselines is statistically significant (Wilcoxon, $\rho < 0.01$). While mCODER outperforms GAT-BERGAMOT on the French part of Mantra, the latter shows a statistically significant improvement on both subsets of QUAERO corpus.

We further investigated the BERGAMOT's performance on the XL-BEL benchmark. Tab. 4 presents the evaluation results. GAT-BERGAMOT outperforms mSapBERT on 8 of 10 languages with an average improvement of 0.8% acc@1. The largest acc@1 growth compared to mSapBERT is observed for low-resource languages ($+4.1\%$ for fi, $+1.9\%$ for ja, $+1.3\%$ for ru). Since mCODER does not support Korean and Thai, it is not directly comparable to GAT-BERGAMOT on full XL-BEL. However, our model outperforms mCODER on 8 remaining languages.

The evaluation results of GAT-BERGAMOT on question answering and textual entailment tasks are presented in Table 5. Despite an introduction of additional entity-oriented graph-based losses, GAT-BERGAMOT did not lose the capability to solve tasks that require text understanding. It performs on par or better than text-only SapBERT. An improvement of 2.1% over SapBERT on PubMedQA indicates a potential of using graph-induced pretraining objectives for tasks involving domain-specific knowledge, such as question answering.

Ablation study To explore the effectiveness of each training objectives, we conducted an ablation analysis by training a GAT modification with each of four individual training objectives removed. Tab. 6 shows the change in performance on XL-BEL and the filtered version of Mantra. Despite losing 1.5% and 1.68% acc@1 on Mantra and XL-BEL, respectively, a model with no $\mathcal{L}_{dgi}$ still shows a decent performance outperforming SapBERT on Mantra. With DGI loss removed, BERGAMOT still outperforms both SapBERT ($+2.82\%$) and CODER ($+0.67\%$). Removal of explicit modality interaction introduced through $\mathcal{L}_{int}$ results in a slight drop of 0.52% and 0.7% acc@1 on Mantra and XL-BEL, respectively. Interestingly, removal of $\mathcal{L}_{node}$ leads to an average 3.38% acc@1 drop on Mantra and an average improvement of 0.5% on XL-BEL.

5 Conclusion and Future Work

We presented BERGAMOT, a graph-augmented architecture with backbone LM designed to learn inter-concept and intra-concept interactions from the multilingual knowledge graph. BERGAMOT outperforms existing language models pre-trained on knowledge triples from UMLS on two concept normalization benchmarks with a diverse set of languages. Since BERGAMOT is currently an encoder model and it is not able to generate texts, an important future research would be to extend BERGAMOT to include language generation capabilities and advance KG-enhanced language generation.

Acknowledgments

The work was supported by a grant for research centers in the field of artificial intelligence, provided by the Analytical Center in accordance with the subsidy agreement (agreement identifier 000000D730321P5Q0002) and the agreement with the Ivannikov Institute for System Programming of dated November 2, 2021 No. 70-2021-00142. We specially thank Zulfat Miftahutdinov for useful discussions and feedback pointing out issues in a previous iteration of the paper. We thank anonymous reviewers for valuable feedback.

6 Limitations

Large domain-specific graphs. The graph neural networks in BERGAMOT employ a large biomedical knowledge graph, the Unified Medical Language System (UMLS), which contains over 4 million concepts and 15 million concept names. It is important to note that the use of knowledge graphs for different domains with a smaller number of nodes and edges may affect the performance. The size and complexity of the knowledge graph can have a significant impact on the ability of the model to learn and make accurate predictions. Additionally, it is worth noting that while the study focused on the biomedical domain, BERGAMOT could potentially be trained on general-domain knowledge graphs, such as DBPedia or Wikidata.

Only entity-related tasks for evaluation. In this paper, experiments were done on cross-lingual entity linking to see how well BERGAMOT captures knowledge of a multilingual knowledge graph in the biomedical domain. However, to fully assess the ability of BERGAMOT to facilitate automatic knowledge base construction in different languages, it may be beneficial to include additional evaluation tasks such as link prediction or candidate-free taxonomy enrichment. Additionally, probing the knowledge contained in BERGAMOT across multiple languages could be evaluated using the multilingual Language Model Analysis (LAMA) benchmark.

Mantra and XL-BEL. We acknowledge that our choice of Mantra and XL-BEL datasets for MCN is non-exhaustive: we focus on standard benchmarks from previous work, yet both datasets have certain limitations. For example, the Mantra dataset is manually annotated but relatively small, which can make it difficult to measure statistical significance. Similarly, the XL-BEL dataset is based on Wikipedia texts without manual annotation by medical experts, which may limit its relevance to real-world medical applications. Furthermore, both datasets only include entity mentions and terminology in a target language (e.g., French), while BERGAMOT can encode concept names in as many languages as possible for inference to better exploit language connections.

Ethics Statement

One limitation of using external knowledge sources, such as the Unified Medical Language System (UMLS), is that these sources may not be complete for all languages, which can affect the performance of language models and their ability to infer medical concepts from text. Additionally, significant changes to UMLS may require re-training of the language model. BERGAMOT, like any language model, may be subject to representation biases and potentially misleading results, which is a critical concern in the healthcare domain.

All pre-trained models, UMLS, Mantra, XL-BEL, BioASQ, PubMedQA, MedNLI, and SciTail datasets used in this work are publicly available for research purposes.

We honor and support the ACL Code of Ethics.

A Statistics on UMLS graph

Tab. 7 presents statistics on the number of concept names for each language.

The statistics on pre-training graph and number of positive concept name pairs is shown in Tab. 8. The most resource-rich languages in the biomedical domain are English and Spanish, while German and Dutch can be considered as low-resource languages. In particular, the German UMLS is only 1.48% of the UMLS in vocabulary and 3.72% in source counts (NIH).

B Concept Normalization data

Mantra GSC (Kors et al., 2015) is a collection of biomedical text units such as drug labels and patent claims manually cross-labeled by several annotators in five different languages: English, French, German, Spanish, and Dutch. The Mantra terminology is a subset of UMLS with concepts from MeSH, SNOMED-CT, and MedDRA extracted from the UMLS 2020 AA release. Since the Mantra corpus is too small for fine-tuning, all entity mentions are used as test data.

The *CodiEsp* dataset was presented at Clinical Case Coding in Spanish Shared Task at the CLEF 2020 evaluation forum (Miranda-Escalada et al., 2020b). It contains clinical records with entities mapped to the ICD-10 vocabulary (CodeBooks, 2016); we use the CodiEsp Diagnosis (CodiEsp-D) subset and the dictionary provided in *CodiEsp*.

CANTEMIST (CANcer TExt MIning Shared Task on IberLEF 2020 (Miranda-Escalada et al., 2020a) is a manually annotated text corpus of tumor morphology mentions in Spanish mapped to the latest Spanish version of the oncological ontology, which is a part of ICD-O (World Health Organization, 2013); we use the dictionary from (López-Úbeda et al., 2020).

The *QUAERO* French Medical Corpus (Névéol et al., 2014) is collection of French entities from two categories: (i) information on marketed drugs from the European Medicines Agency (EMEA, 12,761 entities) and (ii) titles of research articles indexed in the MEDLINE database (8,781 entities). Test set filtering reduces the number of entities to 5,533 and 3,534 for EMEA and MEDLINE parts, respectively. We use the French concept names from the UMLS as a dictionary.

Table 7: UMLS statistics on the number of concept names.

Language	# concept names	percentage
English	11,280,428	70.78%
Spanish	1,589,581	9.97%
French	431,527	2.71%
Portuguese	423,826	2.66%
Japanese	332,099	2.08%
Dutch	293,817	1.84%
Russian	293,031	1.84%
Italian	251,912	1.58%
German	235,736	1.48%
Czech	198,115	1.24%
Korean	147,217	0.92%
Hungarian	109,271	0.69%
Chinese	81,916	0.51%
Norwegian	63,797	0.4%
Polish	51,778	0.32%
Turkish	51,597	0.32%
Estonian	31,183	0.2%
Swedish	30,439	0.19%
Finnish	25,489	0.16%
Croatian	10,035	0.06%
Greek	2,286	0.01%
Latvian	1405	0.01%
Danish	723	0.1%
Basque	695	<0.1%
Hebrew	485	<0.1%

UMLS dataset	# Positive term pairs	# graph nodes	# graph edges
Full UMLS (Multilingual)	30.6M	4.36M	38.81M
Spanish	2.22M	0.51M	11.38M
French	0.44M	0.155M	5.08M
Dutch	0.2M	0.162M	4.62M
German	0.17M	0.116M	4.54M

Table 8: Statistics of the UMLS sets of positive term pairs, nodes, and edges.

XL-BEL (Liu et al., 2021b) is an automatically annotated dataset with concept mentions from Wikipedia articles. Each mention is mapped to a Wikipedia article using a hyperlink and assigned a CUI based on the article's metadata. Each language is represented with 1,000 mentions resulting in 10,000 mentions in total.

As shown in Table 9, there are 3 evaluation types (Alekseev et al., 2022):

- *Full*: compute metrics on the test set as provided in the dataset itself;
- *Filtered*: remove from the set all entities that are already present in the dictionary (exact match);
- *Filtered*$_{0.2}$: remove from the set all entities where the character-based Levenshtein distance to the nearest neighbor in the dictionary is under 0.2.

The *filtered*$_{0.2}$ set contains two times fewer entities compared to the *filtered* set. Hence, we chose the *full* and *filtered* sets for experiments. All sets, dictionaries, and evaluation scripts are available at `https://github.com/AIRI-Institute/medical_crossing`.

Table 9: Statistics of multilingual corpora user for the evaluation.

C Hyperparameter settings

A list of hyperparameter values used to train BERGAMOT models is presented in Table 10. We adopted the parameters of the MS-loss from SapBERT for fair comparison. For the DGI weight λ_{dgi}, we found the best value from the list (0.01, 0.1, 1.0).

Table 10: BERGAMOT's hyperparameter values

Hyperparameter name	**Value**
Graph encoder hidden size	768
Number of neighbors	3
Number of graph encoder layers	3
GAT's number of attention heads	2
Weight λ_{dgi}	0.1
Hard pairs miner's margin	0.2
α in MS loss	2
β in MS loss	50
ϵ in MS loss	0.5
Learning rate	$2 \cdot 10^{-5}$
Multilingual models' batch size	256
Monolingual models' batch size	128
Multilingual models' # of epochs	1
Monolingual models' # of epochs	2

Tab. 10 lists BERGAMOT's hyperparameter values used throughout our experiments.

D Question Asnwering and Textual Entailment data

BioASQ BioASQ (Biomedical Question Answering) is a widely recognized dataset in the biomedical domain, specifically designed for evaluating question answering systems. Following (Gu et al., 2022), we restrict the dataset to yes/no questions. We use the official train/dev/test split where each contains 670/75/140 questions respectively.

PubMedQA Similar to BioASQ, the PubMedQA dataset as well presents questions with limited number of answers. In contrast to the previous dataset, the answers to the questions in PubMedQA are selected from yes, no, or maybe. We use the original train/dev/test split with 450, 50, and 500 questions, respectively.

MedNLI MedNLI (Medical Natural Language Inference) is a specialized dataset designed to facilitate research in natural language inference within the medical and healthcare domain. It consists of pairs of sentences, where each pair comprises a premise and a hypothesis. The premise represents a clinical or biomedical context, while the hypothesis is a medical statement or claim that may or may not logically follow from the premise. Each sentence pair is annotated with one of three labels:

"entailment," indicating that the hypothesis can be logically inferred from the premise; "contradiction," suggesting that the hypothesis contradicts the information in the premise; and "neutral," signifying that there is no logical relationship between the two sentences. The dataset comprises a total of 12,627 sentence pairs in the training set and 1,422 sentence pairs in the testing set.

SciTail The SciTail dataset is similar to the MedNLI dataset was designed for the task of natural language inference. Except that it covers a broader scientific domain. The train part of the corpora contains 24900 sentence pairs and the test part of the corpora contains 2126.

E Models for Comparison

- XLM-R (Roberts et al., 2017) – checkpoint xlm-roberta-base (the Hugging Face Hub)
- SapBERT (Liu et al., 2021a,b) – SapBERT-UMLS-2020AB-all-lang-from-XLMR (the Hugging Face Hub)
- CODER (Yuan et al., 2022) – coder_all (the Hugging Face Hub)
- Supervised SOTA (Alekseev et al., 2022) –the results of *SapBERT+mcn-fz4* are directly obtained from the authors' paper. Three versions were fine-tuned using `SapBERT-UMLS-2020AB-all-lang-from-XLMR`: *SapBERT+mcn-fz4*, *SapBERT+mcn-fz10*, and *SapBERT+mcn*. The first one shows slightly better results in their paper.

F Hardware and software specification

Table 11: Hardware specification of the machine used to conduct our experiments

Device	Specification
CPU	8x Intel Xeon Gold 6152 2.1-3.7 Ghz (2 cores each)
GPU	4x NVIDIA Tesla V100 32GB
RAM	768 Gb
Disk space	5 Tb

To implement, train, and evaluate our models, we used the version 1.11.0 of PyTorch (Paszke et al., 2019) with CUDA 11.3 (Nickolls et al., 2008) support. To implement graph neural networks, we used PyTorch Geometric (Fey and Lenssen, 2019) version 2.0.4. The training of each multilingual BERGAMOT model took up to 20 hours on the machine with the hardware specification described in Table 11.

G Examples of predictions

We provide a few examples of SapBERT's and BERGAMOT's predictions on the English Mantra in Table 12. The results show that SapBERT outperforms BERGAMOT when a true concept in a vocabulary has an extensive textual name. When a golden concept has a short name only, text-only SapBERT fails to produce good entity representations, which is not the case for BERGAMOT. Thus, the provided examples let us suggest that BERGAMOT does not only capture semantic and lexical similarity between entity and concept strings but also has additional intuition of what is a concept from the UMLS knowledge base.

Mention	**SapBERT prediction**	**BERGAMOT prediction**	**True concept**	**Winner**
mixed collagen disease	collagen dis	connective tissue dis mixed	connective tissue dis mixed	BERGAMOT
uveitic	ectatic qualifier value	uveitis disorder	uveitis disorder	BERGAMOT
double uterus	uterus didelphus disorder	doubling of uterus nos disorder	doubling of uterus nos disorder	BERGAMOT
hygiene	ability to perform personal hygiene activity observable entity	personal hygiene finding procedure	ability to perform personal hygiene activity observable entity	SapBERT
functional bowel disorders	functional disorder of intestine disorder	x psychogenic ibs	functional disorder of intestine disorder	SapBERT

Table 12: Sevaral SapBERT's and BERGAMOT's predictions on the English Mantra.

Cross-Lingual Summarization with Pseudo-Label Regularization

Thang Le
VinAI Research
`v.thangld16@vinai.io`

Abstract

Cross-Lingual Summarization (XLS) aims to summarize a document in the source language into a condensed version in the target language, effectively removing language barriers for non-native readers. Previous approaches, however, have the same limitation that only a single reference (gold summary) is exploited during model training, making the base model exposed to an underrepresented hypothesis space since the actual number of possible hypotheses is exponentially large. To alleviate this problem, we present a study adopting pseudo-labels in regularizing standard cross-lingual summarization training. We investigate several components leading to the gains in regularization training with verified experiments involving 8 diverse languages from different families. Conclusively, we show that pseudo-labeling is a simple and effective approach that significantly improves over standard gold reference training in XLS.

1 Introduction

With the rise of massive information (Acharjya and KauserAhmed, 2022), summarization plays an essential part in absorbing and processing the emerging events in a timely and efficient manner (Syed et al., 2022). Given the existing large number of natural languages (Qin et al., 2024), the needs for providing information access to widespread groups of audience across nations have necessitated the construction of tasks beyond the monolingual setting (Shen et al., 2018). To facilitate this development, CROSS-LINGUAL SUMMARIZATION (XLS) was introduced where an article in a source language can be summarized to a condensed version in a different target language, effectively conveying key information to non-native readers (Duan et al., 2019).

Among modeling solutions for XLS, a straightforward approach was to adopt pipeline-based systems comprising of translation and summarization networks (Zhu et al., 2019). It is, however, not particularly appealing for several reasons including error propagation (Takase and Okazaki, 2022), loss of context and structure (Wang et al., 2023a), and the incurred extra computations along with reduced inference speed. Recent research have moved on to adopt end-to-end approaches where a single network executes the whole task (Zhu et al., 2019). To empower the cross-lingual performance, existing methods either scale up the training process (Xu et al., 2020; Wang et al., 2023b) or bootstrap learned representations through auxiliary objectives and features (Bai et al., 2021; Li et al., 2023; Jiang et al., 2022). Despite promising improvements, these methods have the same limitation in that for each training sample, the summarization network only gets exposed to a single gold reference. This mistakenly causes the network to learn skewed, deterministic one-point (Liu et al., 2022) and highly uncalibrated summary distributions (Zhao et al., 2023) that easily suffer from error accumulations such as exposure bias (Arora et al., 2022; Xie et al., 2023). Seeking prospective remedies, in this work, we study the training of end-to-end XLS networks in the presence of pseudo-labels i.e. pseudo-references with probability labels obtained from teacher models. In particular, we analyze several important components contributing to the performance of models regularized with pseudo-labels and present these findings as reference practices for future works. To inspect the effectiveness of this training recipe, we conduct empirical experiments spanning 8 typologically diverse languages coupled with comparisons against existing baselines.

In summary, our contributions can be listed as follows:

- We conduct a study on neural cross-lingual summarization with pseudo-label regularization. Particularly, we inspect factors contributing to the regularization's effectiveness to-

Findings of the Association for Computational Linguistics: NAACL 2024, pages 4644–4677
June 16-21, 2024

wards the model's performance, including the choice of teacher models and the construction of pseudo-references.

- To reinforce the study's findings, we conduct empirical experiments involving 8 distinct languages from different families with accompanying baseline comparisons where we observe significant improvements over standard gold reference training.

2 Related Works

Cross-Lingual Summarization. With the potential of reducing language barrier, cross-lingual summarization emerged as an active area of research in recent years (Shen et al., 2018; Zhu et al., 2019; Xu et al., 2020; Bai et al., 2021; Takase and Okazaki, 2022; Wang et al., 2022b; Fatima and Strube, 2023). Early works, due to the lack of parallel supervised corpora, often resort to pipeline methods comprising of separate translation and summarization networks (Shen et al., 2018). Zhu et al., 2019 first introduced a large-scale parallel corpus to experiment with end-to-end training where they also proposed a multi-task framework with improved performance. Subsequent works experimented with adversarial training (Cao et al., 2020), contrastive learning (Li et al., 2023), variational inference (Liang et al., 2022), knowledge distillation (Nguyen and Luu, 2022) and pre-training (Xu et al., 2020; Wang et al., 2022a, 2023b). These works, however, bear the same limitation in that they do not explore alternative hypotheses apart from the gold summary in each training sample which potentially leads to models' underperformance (Ranzato et al., 2016; Bengio et al., 2015) since they lacked exposure to the summary distribution which includes an exponentially large number of hypotheses. In contrast, we target the setting of training neural cross-lingual summarizers with additional supervision from pseudo-labels that are formed from pseudo-references with probability labels from teacher models.

Pseudo-Labeling. There have been ongoing research on adopting pseudo-labels in sequence-to-sequence training (Calderon et al., 2023). Liu et al., 2021 enriched the one-hot annotations with smoothed self-guidance under noised perturbations for summarization on English data. Shleifer and Rush, 2020 further examined replacing the ground truth target with the teacher's summary. Wang et al., 2021 additionally integrated selective mechanisms in forming training data points for translation tasks. Duan et al., 2019 relied on pseudo-sources and pseudo-labels to overcome scarcity in parallel samples for cross-lingual sentence summarization. Li et al., 2023 utilised soft-labels for enforcing cross-lingual consistency learning. Nevertheless, these works either do not consider multiple references during training (Duan et al., 2019; Li et al., 2023) or strictly focus on monolingual generation (Calderon et al., 2023) and machine translation (Zheng et al., 2018; Khayrallah et al., 2020). This leaves a research gap in cross-lingual summarization where the use of multiple training references remains neglected - which our work aims to fill in.

3 Background

3.1 Neural Cross-Lingual Summarization

Given a source document D_A in the source language A, a neural cross-lingual summarizer needs to produce the summary S_B in the target language B. Denote the target sequence's tokens as $[y_0, y_1..y_{|S_B|}]$, the training objective (negative log-likelihood) is defined as: $\mathcal{L}_{NLL} = -\sum_{t=1}^{|S_B|} log(P_\theta(y_t|y_{<t}, D_A))$, where $|S_B|$ denotes the length of the output summary and θ represents the model's parameters.

Since existing corpora only provide a single gold summary per sample, the ground truth label for $P_\theta(y_t|y_{<t}, D_A)$ is typically a $|V|$-dimensional one-hot vector, where $|V|$ is the vocabulary size. This leads to the underlying model being trained with an under-explored hypothesis space, as the number of possible hypotheses are exponentially large when in fact only one of them manifests during the training process. To alleviate this problem, we can integrate additional hypotheses (pseudo-references) as regularization during the model's training.

3.2 Pseudo-Labeling

To construct pseudo-references, a straightforward approach is to adopt decoding outputs from trained summarizers. This also simulates the model's behavior at inference time which helps ease the negative impact of exposure bias (Bengio et al., 2015; Arora et al., 2022) - a gap that arises because models are conditioned on ground truth tokens during training but have to rely on self-generated tokens during inference.

Assuming access to a teacher model T_ϕ which maps each pair (D_A, Y') to a sequence of probability vectors $\{P_\phi(Y'_t|Y'_{<t}, D_A)\}$

(with Y' being the pseudo-reference), we can define the regularization loss as the KL-divergence between the base model's prediction and the pseudo-label: $\mathcal{L}_{reg}(D_A, Y') = KL(P_\theta(Y'_t|Y'_{<t}, D_A)||P_\phi(Y'_t|Y'_{<t}, D_A))$. To incorporate multiple pseudo-labels for a single sample, we simply take the average over each individual loss: $\mathcal{L}_{reg} = \frac{1}{K}\sum_{i=1}^{K}\mathcal{L}_{reg}(D_A, Y^{i'})$.

The final training loss thus becomes: $\mathcal{L} = \mathcal{L}_{NLL} + \xi\mathcal{L}_{reg}$, where ξ is the hyperparameter controlling the regularization effect[1].

4 Empirical Analysis

In this section, we investigate the choice of the teacher models for obtaining the probability labels as well as the forming of pseudo-references, both of which make up the pseudo-labels for training. Additionally, we examine their effects on the XLS model's performance and further see how they fare against the gold labels. Particularly, we focus on the following research questions:

- **Q1: Which model, or combination of models, should we adopt to label the pseudo-references ?** (4.1, 4.2, 4.4)
- **Q2: Should we use stochastic or static probability labels ?** (4.3)
- **Q3: Which groups of pseudo-references work better ?** (4.5)
- **Q4: Do the number of pseudo-references matter ?** (4.6)
- **Q5: Can soft probability labels replace one-hot annotations in gold summaries ?** (4.7)
- **Q6: How competitive are pseudo-labels ?** (4.8)

Task Setup. For experimental purposes, we use the WIKILINGUA[2] dataset (Ladhak et al., 2020) with a focus on 8 languages: English(EN), Vietnamese(VI), Japanese(JA), Chinese(ZH), Arabic(AR), Korean(KO), Russian(RU) and Turkish(TR). These languages come from different families (Table 1) and possess distinct morphological and/or topological characteristics which ensure the experiment's coverage. For base architecture, we mainly employ the MBART-50[3] model (Tang et al., 2021) unless explicitly mentioned otherwise. Additionally, we use beam search with a decoding beam of 32 to construct the pseudo-reference pool from monolingual models (we explain this decision later on). As simultaneously forwarding K pseudo-references through the model would require duplicating the encoder hidden states by K times, which would increase the memory usage whereas sequentially forwarding these pseudo-references (for each sample) reduces model training speed. In our experiments, we uniformly sample K hypotheses from the pseudo-reference pool at each iteration and simultaneously forward these hypotheses[4]. Thus, the base model can get exposed to different sets of pseudo-references at each epoch while keeping memory consumption at a sustainable level.

For each training run, we use the AdamW (Loshchilov and Hutter, 2017) optimizer with a learning rate of $1e-5$ and a linear decay scheduler for a maximum of 300 000 steps. We use a batch size of 4 for standard training and 2 when adopting pseudo-labels. For evaluation, we primarily use the ROUGE metrics (Lin, 2004). In the multilingual setting, previous works either utilize the MULTILINGUAL ROUGE toolkit[5] for language-specific processing (Hasan et al., 2021; Wang et al., 2022a; Bhattacharjee et al., 2023) or the SENTENCEPIECE model for language-agnostic tokenization (Vu et al., 2022; Li and Murray, 2023; Clark et al., 2023), which we hereinafter refer to as M-ROUGE and SP-ROUGE, respectively. Upon measuring these metrics with human judgements from the MULTISUMMEVAL dataset (Koto et al., 2021), we find that SP-ROUGE generally attains better correlation[6]. We therefore report results obtained with the SP-ROUGE metric[7]. For presentation's sake, we focus on the ROUGE-L variant and include the remaining results in the Appendix. Experiments were implemented with the PyTorch (Paszke et al., 2019) and Transformer (Wolf et al., 2019) frameworks, and executed on an A100 GPU.

---

[1] We set $\xi = 3.2$ in all experiments. We obtained this value through tuning ξ in the range $[0.0, 4.0]$ based on validation performance of an initial language pair (EN2JA)

Table 1: List of languages included in the study

4.1 Monolingual Summarizers are Good Teachers

Given parallel corpora, each document D_A in the source language is also accompanied with a document D_B in the target language. This means that we can use a monolingual summarization model M_B to label the pseudo-reference Y'_B. As the monolingual model does not need to perform cross-language alignment or translation operations and can exploit easier shortcuts such as copying or rephrasing (Song et al., 2020), we argue that monolingual summarizers are approriate labelers that can assign high-quality probability labels.

To validate this argument, we compare the performance between the cross-lingual and monolingual summarizers over 21 cross-language directions where the samples used to train the cross-lingual and monolingual models are identical, and only the source and target languages vary. In other words, the monolingual model is trained on exactly the same data as the cross-lingual model, but with the source language being switched to the target language.

Specifically for this experiment, we examine both models trained from scratch and those initialized with a pre-trained language model. In particular, we train three Transformer (Vaswani et al., 2017) architectures from scratch, each containing $4/8/12$ layers in the encoder-decoder stacks (hereinafter termed small/base/large). Parameters were initialized with the Xavier Uniform initialization (Glorot and Bengio, 2010). We use a hidden state size of 1024 and a feedforward dimension of 4096. Dropout rates are set to 0.1 and layer normalization is placed inside the residual blocks (Pre-LN) (Xiong et al., 2020). For pre-trained architecture, we fine-tune the mBART-50 model.

We present the results in Figure 1 (Validation). For each direction, we plot the value $\Delta P = P_{Mono} - P_{Cross}$ as the performance gap between the two summarizers, with P being ROUGE-L. We can see that the monolingual summarizer always performs better despite being trained on the same samples. Noticably, the gap is quite similar across architecture scales (small/base/large) but significantly rises for the mBART-50 model. This is most likely due to the pre-training stage which involves monolingual denoising objectives making MBART-50 much better at monolingual tasks while being less likely to conduct cross-lingual generation.

TL;DR: *At equivalent training scales, monolingual models are shown to exhibit stronger summarization performance than cross-lingual models.*

4.2 Ensemble Teacher

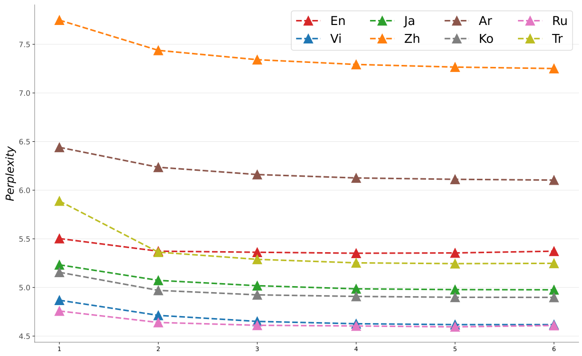

Figure 2: Ensemble Set Perplexity (VALIDATION)

We next investigate whether we can improve the quality of pseudo-labels by combining probability predictions from several teacher models. For this purpose, we train six distinct monolingual models for each language and combine them to form ensemble sets of varying sizes. For each ensemble size, we utilize the combination with the lowest perplexity score. In particular, we average each model prediction in the ensemble set to get the final probabilities.

We show the results in Figure 2 (VALIDATION). Each circle denotes the perplexity score of the best ensemble set of the given size for each language. Results show we can readily obtain higher-quality probability labels via taking the mean predictions of different models, as indicated by lower perplexity scores. However, using a large number of models will incur non-trivial memory overhead. For example, storing a MBART-50 model in single precision (FP32) would require 3.5GB of VRAM. To keep memory consumption at a tolerable level, we only use an ensemble size of 3 in the succeeding experiments.

TL;DR: *Averaging teacher predictions yields higher-quality probability labels.*

4.3 Teacher Dropout

By applying dropout on the teacher models, we can obtain stochastic probability labels that change at each iteration. We investigate the difference between training with these stochastic probability labels (without dropout) and static ones in Figure 3 (VALIDATION). Although the probability labels with dropout are supposed to be noisier, we find the resulting models to perform better than those with static probability labels on 3/6 directions, but this does not depict significant difference on average[8]. Still, we apply dropout in the remaining experiments hoping to avoid excessive overfitting.

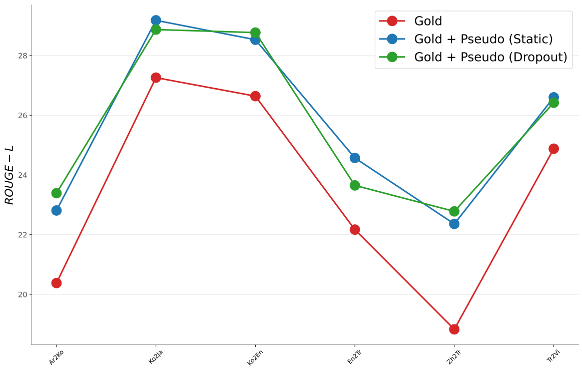

Figure 3: Dropout on probability labels (VALIDATION)

TL;DR: *Apparently, there is no significant difference on average between stochastic and static probability labels.*

4.4 Teacher Comparison

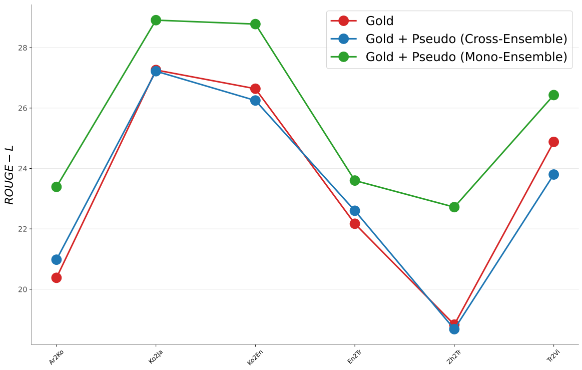

Figure 4: Teacher Ensemble Performance (VALIDATION)

Although we showed that monolingual summarizers produced higher-quality pseudo-labels, it is important to verify that these pseudo-labels also give rise to better performance. We thus conduct regularization with either an ensemble of monolingual or cross-lingual teachers. The results are shown in Figure 4 (VALIDATION). Here the monolingual teachers clearly play an important part in

---

[8] See Appendix D

empowering the base summarizer, achieving better scores than the other two model variants. Meanwhile, the cross-lingual teachers often do not yield significant improvement and even lead to negative results in some directions.

TL;DR: *Pseudo-labels from monolingual models consistently improve cross-lingual summarization performance.*

4.5 Pseudo-Reference Quality

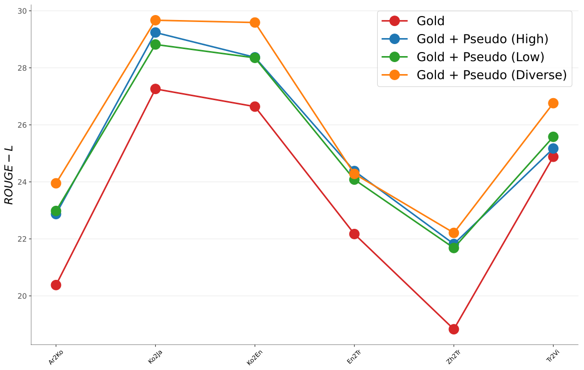

Figure 5: Pseudo-references properties (VALIDATION)

We next study whether the properties of the pseudo-references would affect regularization training. From the pseudo-reference pool (constructed with beam search), we each sample 16 hypotheses with highest and lowest ROUGE scores[9], respectively. Additionally, we use diverse beam search (Vijayakumar et al., 2016) to obtain 16 hypotheses with higher diversity. These hypotheses are then used in regularization training.

Results are shown in Figure 5 (VALIDATION). We can see that the quality matters since training with the uppermost 16 pseudo-references is better than with the lowermost on $4/6$ directions. Besides, variety also contributes to the regularization's outcomes as diverse pseudo-references facilitate better results than the remaining two on $5/6$ directions. Nevertheless, the runtime of diverse beam is much longer than that of standard beam. For example, generations of 16 diverse candidates for each training example in the AR2KO direction are 2.3 times slower than alternatively using standard beam while taking up significantly more GPU memory. Thus, it would make experiments less scalable and reduce the amount of coverage we could afford. As a result, we only adopt standard beam decoding in other pseudo-labeling experiments.

TL;DR: *High-quality pseudo-references help, but diversity is also beneficial.*

4.6 Size of Pseudo-Reference Pool

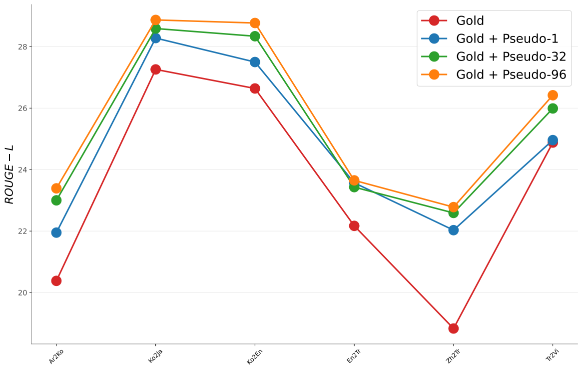

Figure 6: Number of pseudo-references (VALIDATION)

We next examine whether the size of the pseudo-reference pool affects the regularization's effectiveness. We randomly subsample subsets of size $1/32/96$ from the original pseudo-reference pool and use these subsets as new pools in regularization training. Results are shown in Figure 6 (VALIDATION). We observe that the larger the pool's size is, the better the results are. This means the number of pseudo-references can have a significant impact on the regularized model's performance. Noticeably, simply training with one additional pseudo-reference can already bring forth gains in $6/6$ directions, further highlighting the necessity of regularization training.

TL;DR: *A larger size of the pseudo-reference pool works better.*

4.7 Pseudo-Labeling on Gold Summary

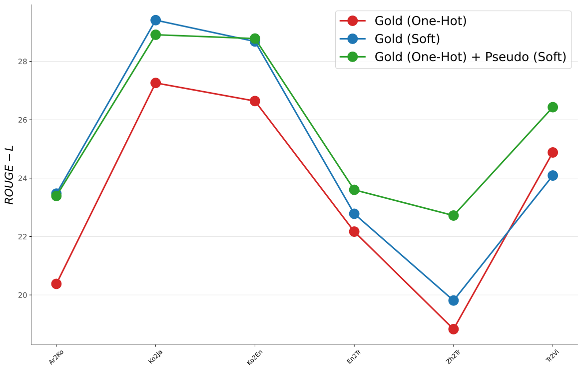

Figure 7: Soft Labeling on Gold Summary (VALIDATION)

Given the effectiveness of pseudo-labeling, we are also interested in whether using teacher models

---

[9] Here we use the average of ROUGE-1/2/L as the selection criterion to balance across ROUGE variants

to label the gold summaries would turn out better than using the default one-hot labels. Results are shown in Figure 7 (VALIDATION). Surprisingly, soft labeling also works well when applied on the gold summaries, yielding improvements on $5/6$ directions over the one-hot annotations. This further corroborates the pseudo-probability labels' qualities. Still, combining the one-hot gold summaries with soft pseudo-labels (multiple pseudo-references) generally works better, attaining highest scores on $4/6$ directions.

TL;DR: *Annotating the gold summaries with pseudo-probability labels vastly improves performance, but combining the one-hot gold summaries with pseudo-labels works better.*

4.8 Regularization as the sole objective

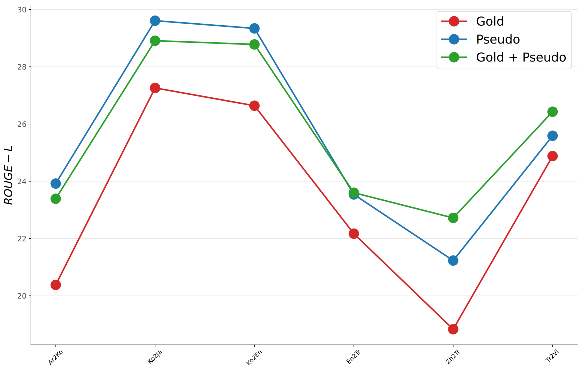

Figure 8: Training with only pseudo-labels (VALIDATION)

We further investigate training with only pseudo-labels (no gold summaries). Results are shown in Figure 8 (VALIDATION). Training with only pseudo-labels turn out to be better than standard training with gold labels on $6/6$ directions, and only worse than training with both types of labels on $3/6$ directions. Nevertheless, we observe that on average, better results are obtained with both types of labels combined[10].

TL;DR: *Only using pseudo-labels outperforms gold label training, but combining both types of labels works better.*

5 Benchmarking

In this section, we study the effectiveness of pseudo-label regularized models on three settings: FULLY SUPERVISED LEARNING, FEW-SHOT LEARNING and PARAMETER-EFFICIENT FINE-TUNING. We follow lessons derived from the previous section for the teacher models' choice as well as the construction of pseudo-references. In particular, we use an ensemble of 3 monolingual models for teacher labeling. For pseudo-reference, we use beam decoding with a beam size of 32 from three monolingual models for each language to construct the pseudo-reference pool with a total size of 96. Unless explicitly mentioned otherwise, we use the MBART-50 language model as the base architecture, similar to the previous section. For further implementation details, we refer readers to Appendix B.

5.1 Fully Supervised Learning

Baselines. We compare the regularized models with the following baselines:

- **Trans-Sum** - A pipeline where the input article is first translated to the target language with a translation network, then summarized with a monolingual summarization network to obtain the cross-lingual summary
- **Sum-Trans** - A pipeline where the input article is first summarized in the source language with a monolingual summarization network, then translated with a translation network to obtain the cross-lingual summary
- **Gold** - The standard end-to-end model trained using the gold summaries with one-hot annotations (Zhu et al., 2019)
- **Gold + OTSum** - An end-to-end model that is further equipped with a knowledge distillation loss based on the optimal transport distance (Nguyen and Luu, 2022)
- **Gold + Many2Many** - An end-to-end model that is trained using parallel samples from all cross-lingual directions (Wang et al., 2023b; Bhattacharjee et al., 2023). This model is included primarily for reference purposes, as it requires vastly more training data than other models.

Automatic Evaluation. We depict results on the TEST split with automatic evaluation using ROUGE-L in Figure 9. Average scores across 21 directions and statistical significance are reported in Table 2. Compared to the baselines, adopting pseudo-labels clearly improves performance on many directions. Particularly, compared to standard training (GOLD),

---

[10] See Appendix D

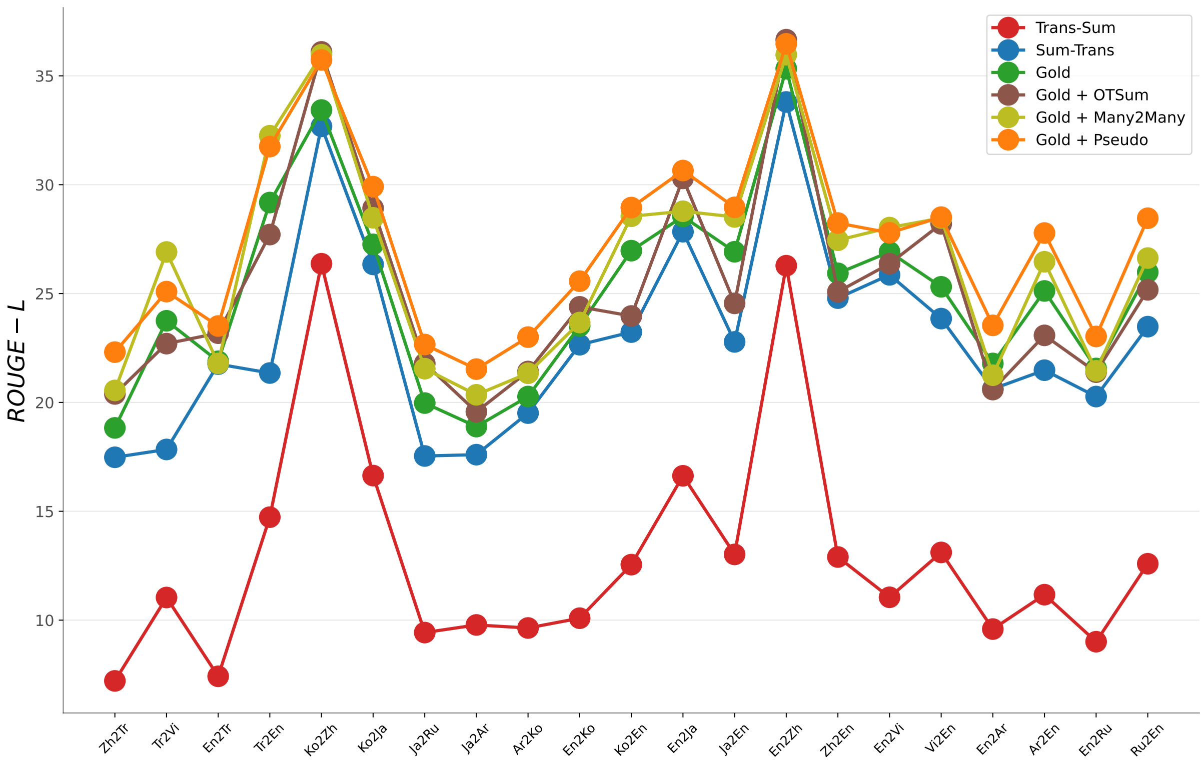

Figure 9: Fully Supervised Training (Test)

Gold+Pseudo yields significant improvements in 21/21 directions. Even when compared to Gold+Many2Many which uses 16X-274X more parallel data, Gold+Pseudo still performs significantly better in 14/21 directions. Overall, we see a substantial rise of 2.2 points in ROUGE-L compared to the base Gold model, validating the regularization's effectiveness.

	Average	$p < 0.05$
Trans-Sum	12.87	21/21
Sum-Trans	22.99	21/21
Gold	25.11	21/21
Gold + OTSum	25.31	16/21
Gold + Many2Many	26.40	14/21
Gold + Pseudo	**27.31**	-

Table 2: Average ROUGE-L scores across 21 directions and the number of directions where Gold+Pseudo achieves significantly higher scores ($p < 0.05$) than the according baseline.

	Ru2En		*En2Vi*	
	`IF`	`FL`	`IF`	`FL`
Gold	1.88	2.02	1.87	2.23
Gold + OTSum	1.93	2.05	1.91	2.33
Gold + Pseudo	**2.59**	**2.60**	**2.41**	**2.55**

Table 3: Human evaluation on the Ru2En and En2Vi directions. `IF` and `FL` each denotes *informativeness* and *fluency*, respectively.

Manual Evaluation. Since automatic metrics have certain intrinsic limitations (Koto et al., 2021; Clark et al., 2023), we further conduct human evaluation to assess the quality difference between trained models. Particularly, we select two cross-language directions: Russian-to-English (Ru2En) and English-to-Vietnamese (En2Vi). From the test set of each direction, we randomly selected 50 document-summary pairs in the target language along with three model-generated cross-lingual summaries[11]: Gold, Gold+OTSum, Gold+Pseudo. As participants, we invited three professional English speakers and three native Vietnamese speakers to rank the generated summaries in terms of two core aspects: *informativeness* (to which extent a summary captures the main content) and *fluency* (how well-formed a summary is in the target language). Each sample was examined by three participants and each model received a score of 1-3 for each rating according to its rank. Av-

---

[11] Here we exclude the Gold+Many2Many model as the amount of parallel data used to train it vastly differs from the others, making it less comparable

eraged results are shown in Table 3. We observe that the ratings are significantly higher ($p < 0.05$) for Gold+Pseudo in the two directions on both categories compared to the remaining two models, indicating that the summaries produced by Gold+Pseudo were also preferred more by human participants.

Other Architectures. Beyond mBART-50, we additionally experiment with the Pisces model (Wang et al., 2023b) and a Transformer model[12] trained from scratch. We train separate monolingual models with these architectures while re-using the pseudo-reference pools from the previous experiment to form the pseudo-labels, which we then apply to regularize cross-lingual summarizers trained with these architectures. We examine the results in two directions: Ar2Ko and Ko2Ja (Figure 10). We observe that pseudo-labels are effective on these two model types as well, consistently improving upon the Gold models. This means that pseudo-labels' utility is not limited to any single model architecture.

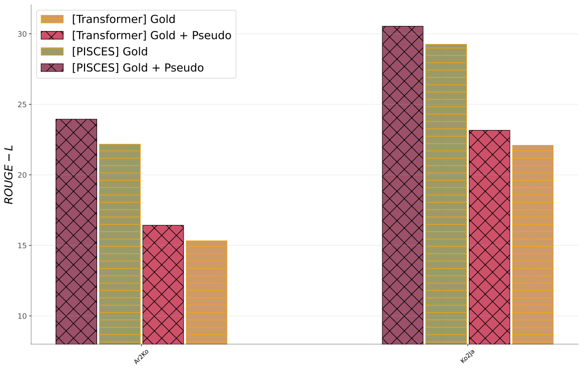

Figure 10: Fully Supervised Training with Pisces and Transformer as the base models (Test)

5.2 Few-shot Learning

We next investigate pseudo-label's potency under few-shot settings, where we only use as little as 50/100/300 parallel training samples in each direction (Figure 11). Even under these extreme scenarios, we observe that pseudo-labels still effectively reinforce the base models' performance.

5.3 Parameter-Efficient Fine-Tuning

Although Parameter-Efficient Fine-Tuning boosts training efficiency, it often limits model's capabilities (Song et al., 2024). We thus examine whether pseudo-labels can help amend this limitation. In particular, we apply Low-Rank Adaptation (LoRA) (Hu et al., 2022) to the base mBART-50 model and trains it with pseudo-labeling similar to previous sections. For LoRA hyperparameters, we use a rank r of 8, an α value of 32 and a dropout rate of 0.1 with modules only inserted after the query and value projection matrices. Results are shown in Figure 12. In this setting, we also find pseudo-labeling effective, consistently improving over the base [LoRA] Gold model.

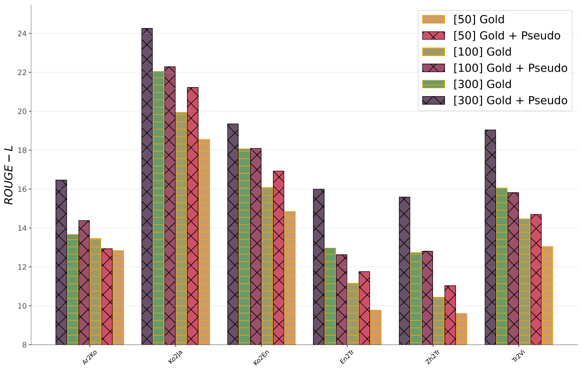

Figure 11: Few-Shot Learning with 50/100/300 training samples (Test)

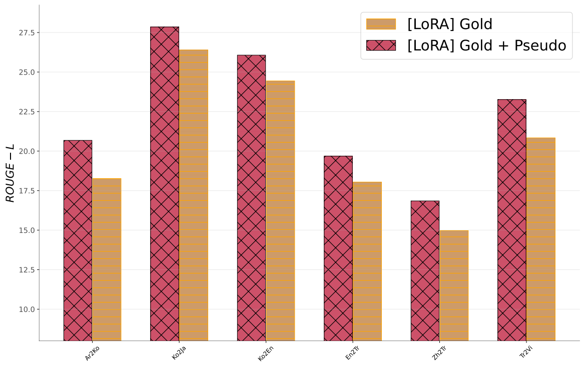

Figure 12: Low-Rank Adaptation results (Test)

6 Conclusion

In this paper, we study the effectiveness of pseudo-label regularization in standard neural cross-lingual summarization training. We conduct empirical experiments involving 8 diverse languages from different families and study the different components affecting the end performance of regularized models. We further validate the regularization's usage in three distinct learning settings. The results show that pseudo-labeling is a simple but effective companion complementary to the standard training procedure. We hope our study will prove useful for future practitioners working on this task.

---

[12] Here we use the Large scale as in Section 4.1

Limitations

In this paper, we have only shown that pseudo-labeling is effective in supervised settings (either *high-* or *low-resource* scenarios). For many cross-language directions, parallel corpora might not exist (Liu et al., 2020) and thus pseudo-labels cannot be readily applied in these situations. Nevertheless, should parallel translation data (or models) exist, it is possible to construct pseudo-parallel data samples (Shen et al., 2018) from which the pseudo-labels discussed in this work can be applied directly, which will be a prospective direction for future works.

In addition, the experiments in this work were conducted solely on the WIKILINGUA (Ladhak et al., 2020) dataset. As a result, we are not entirely certain whether the findings in this work would still generalize to other domains or datasets. For example, would the monolingual models still provide high-quality pseudo-labels ? Or would the pseudo-references' properties examined in Section 4 still hold the same level of importance ? These questions would require further verifications to answer.

Besides, summarization evaluation involves several distinct aspects, some of which we do not yet fully cover in this work. For example, while we made efforts to quantify *informativeness* and *fluency*, we did not explicitly quantify *attribution* (Clark et al., 2023) or *hallucination* (Aharoni et al., 2023), which future works should also pay attention to.

B Benchmarking Details

For the two pipelines that require intermediate translation, we each fine-tuned one document-level and one summary-level MBART-50 translation networks for every cross-language direction using parallel samples from WIKILINGUA (Ladhak et al., 2020). For the summarization component, we re-used the trained monolingual summarizers. Regarding GOLD+OTSUM, Nguyen and Luu, 2022 originally initialized their framework with the encoder from MBERT (Devlin et al., 2019) and two TRANSFORMERS decoders, where the parameters corresponding to the teacher were first pre-trained and afterwards used to initialize the student, then jointly trained both the student and teacher models with the shared encoder and embedding layers during distillation. However, we find that this type of shared training severely impairs performance on MBART-50 (compared to GOLD) and that freezing the teacher model works better. Therefore, we kept the teacher model frozen, initialized the student separately and did not share parameters between the two networks during distillation in GOLD+OTSUM. For GOLD+MANY2MANY, we aggregated parallel samples from all cross-lingual directions possibly composed from the 8 languages[13] (Table 1) but did not include monolingual samples as in Wang et al., 2023b since we do not evaluate multilingual summarization. Training sampling was based on $p(D) \propto |D|^{\beta}$, where $p(D)$ is the probability of sampling from a given direction and $|D|$ is the number of training instances in that direction. We set $\beta = 1$ in our experiments. On training steps, we fine-tuned the GOLD+MANY2MANY model with a maximum of 600 000 steps due to large training data whereas other summarization models were fine-tuned with a maximum of 300 000 steps. During inference (for evaluation), we used a beam size of 8 with a length

---

[13] This yields $8 * 7 = 56$ directions

penalty of 1.0 and disabled any trigram repetition. The minimum and maximum generation lengths were set to 32 and 256, respectively. The maximum sequence lengths for the source article and the target summary were set to 1024 and 256, respectively.

C Metric Correlation

	Focus					*Coverage*				
	En	Ru	Tr	Zh	Avg	En	Ru	Tr	Zh	Avg
SP-ROUGE-1	0.57	0.64	0.82	0.78	0.70	0.61	0.57	0.79	0.73	0.67
M-ROUGE-1	0.59	0.61	0.83	0.76	0.69	0.62	0.52	0.78	0.68	0.65
SP-ROUGE-2	0.53	0.65	0.79	0.70	0.67	0.54	0.56	0.75	0.65	0.62
M-ROUGE-2	0.54	0.62	0.77	0.64	0.64	0.53	0.51	0.72	0.59	0.59
SP-ROUGE-L	0.55	0.62	0.82	0.78	0.69	0.57	0.52	0.77	0.73	0.65
M-ROUGE-L	0.55	0.59	0.82	0.17	0.53	0.58	0.49	0.77	0.12	0.49

Table 4: Pearson correlation scores of the two ROUGE variants (SP- and M-) with human judgements on four languages (English, Russian, Turkish, Chinese) from the Multi-SummEval dataset (Koto et al., 2021). We use ROUGE F1 scores for both *Focus* and *Coverage*. SP-ROUGE generally attains higher correlations than M-ROUGE.

E Annotation Instruction

During annotation of a sample, each participant was presented with the source document, gold summary, and the three model-generated summaries which were shuffled beforehand to avoid positional bias.

For *informativeness*, participants were asked to rank model summaries based on whether they captured the most important information (as presented in the gold summary), to which extent was that information covered; and if there was additional information (i.e. not in the gold summary), then based on the theme of the document and content of the gold summary, whether that additional information was also informative or simply redundant, and if any information appeared relevant but contradicted the source document/gold summary (i.e. hallucination), it was treated as harmful and not informative.

For *fluency*, participants were asked to rank model summaries based on how well-formed they were: Was there any grammar, lexical or typographical error ? Were there foreign words mixed in (except for normal keywords that were also in the source document/gold summary) ? Was the summary well-formatted (e.g. no weird next line, random placement of punctuation) ? Was there any weird point (e.g. unnatural but still understandable, or completely absurd sentence) ? Was the summary well-presented (e.g. logically connected and easy-to-follow, which also relate to coherence) ?

Ultimately, participants had to take these factors into consideration and produced the final rankings based on their own estimations. In scenarios where they did not perceive noticeable quality difference in the specified category (*informativeness* or *fluency*) between two (or all three) model summaries, they were allowed to place them in the same ranking at that category. In such scenarios, model summaries of the same ranking would receive similar scores. For example, if there are two model summaries placing second, and one places first, then those placing second would each gain a score of 2 and the one placing first would gain a score of 3. If all model summaries are deemed equal, they each receive a score of 3.

F Summary Outputs

As case study, we show a random sample from the English-to-Vietnamese (En2Vi) test split accompanied with four model summaries in Table 91. English translations for the Vietnamese summaries are provided underneath in *italics*. We highlight the misleading information in red and the parts aligning with the gold summary in blue. Here we can see that most models produce misinformation. The Gold summary suggests one simply drink *liquid* (instead of *water*) and generates the word tinh dầu nha chu which in itself is contradicting because tinh dầu refers to *oil* whereas nha chu refers to *periodontitis* which is of a different type. The Gold+OTSum summary mistakes dầu đinh hương (*clove oil*) with dầu gội đầu (*shampoo*). The Gold+Many2Many summary additionally includes the phrase không kê toa (*over-the-counter*) which is also misleading because readers easily get the impression that this is the most (or only) suggested way (which is not true as can be inferred from the source document). In addition, it also mistakes dầu đinh hương (*clove oil*) with dầu cây phỉ (*Witch Hazel oil*). Meanwhile, the summary generated by Gold+Pseudo aligns well with the gold summary and does not contain misinformation.

Source Document

[.....] Your doctor may recommend a prescription-strength pain medication, or you may wish to stick with over-the-counter medications like aspirin or acetaminophen. Do NOT give aspirin to children or adolescents. Use of aspirin in children or teenagers may cause complications with the liver and brain. [.....] Don't exceed the dosage with ibuprofen either because this can lead to severe stomach or intestinal bleeding. Use cold packs only for the first 48 hours. Fill a sandwich bag with ice cubes, or wrap ice cubes in a clean towel. In a pinch, you can also use a bag of frozen vegetables wrapped in a paper towel. Apply to the affected side of the face. Remove the bag if it starts to feel like it is burning your skin or you may damage your skin. Keep the ice pack on for 20 minutes, then off for 20 minutes. After two days you should switch to using a warm compress, as a cold compress will no longer reduce swelling or inflammation after the first 48 hours. Drinking clear liquids, especially water at room temperature, is crucial following any surgical procedure. Avoid alcohol after any surgery. Water at room temperature is the best beverage to stay hydrated. If you like, you may wish to alternate water with a sugar-free sports drink. This will remove debris and help sooth inflammation. Add approximately half a teaspoon of salt to one cup of lukewarm water. Stir the salt water thoroughly, so that it is mostly dissolved. Very gently swish the salt water around in your mouth, focusing on the affected side of your mouth without creating negative pressure which can dislodge the clot. Repeat after each meal and before bed, and any times in between when you believe a saltwater rinse might be helpful. The physical act of smoking a cigarette may cause a blood clot to come dislodged, and using chewing tobacco or passing smoke over the socket may further irritate the wound and prolong the pain and inflammation. Try using a nicotine patch if you don't believe you can't quit smoking during the time it takes for your mouth to recover. Talk to your doctor about smoking alternatives. Some patients have found that using a few drops of clove oil to treat the site of an open dental wound may alleviate some of the pain. This should not be done as an alternative to seeking professional medical advice and assistance. Rather, it is meant to provide temporary pain relief in the event that immediate medical assistance is not available. Apply one or two drops of clove oil to a clean cotton swab. Dab the swab against your gum where the tooth was extracted. [.....]

Reference Source Summary

Take pain relievers. Use ice or a cold compress on the side of your face experiencing pain. Stay hydrated. Use a salt water rinse. Avoid using tobacco products. Try clove oil.

Reference Target Summary

Uống thuốc giảm đau. Chườm đá hoặc túi chườm lạnh lên bên mặt bị đau. Cung cấp nước cho cơ thể. Súc miệng nước muối. Tránh sử dụng các sản phẩm thuốc lá. Thử dùng dầu đinh hương.

Take pain relievers. Use ice or a cold compress on the side of your face experiencing pain. Provide water for your body. Gargle with salt water. Avoid using tobacco products. Try clove oil.

Output - Gold

Uống thuốc giảm đau. Chườm đá viên. Uống nhiều chất lỏng. Súc miệng nước muối. Không hút thuốc. Dùng tinh dầu nha chu.

Take pain relievers. Apply ice cubes. Drink plenty of liquid. Gargle with salt water. Do not smoke. Use periodontal essential oil.

Output - Gold+OTSum

Dùng thuốc giảm đau. Dùng túi chườm lạnh. Uống nhiều nước. Súc miệng bằng nước muối. Không hút thuốc. Dùng dầu gội đầu.

Take pain relievers. Use a cold compress. Drink plenty of water. Gargle with salt water. Do not smoke. Use shampoo.

Output - Gold+Many2Many

Uống thuốc giảm đau không kê toa. Chườm đá. Uống nhiều nước. Súc miệng nước muối. Tránh hút thuốc. Dùng dầu cây phỉ.

Take over-the-counter pain relievers. Apply ice. Drink plenty of water. Gargle with salt water. Avoid smoking. Use Witch Hazel oil.

Output - Gold+Pseudo

Uống thuốc giảm đau. Chườm đá viên. Uống nhiều nước. Súc miệng bằng nước muối. Tránh hút thuốc. Dùng dầu đinh hương.

Take pain relievers. Apply ice cubes. Drink plenty of water. Gargle with salt water. Avoid smoking. Use clove oil.

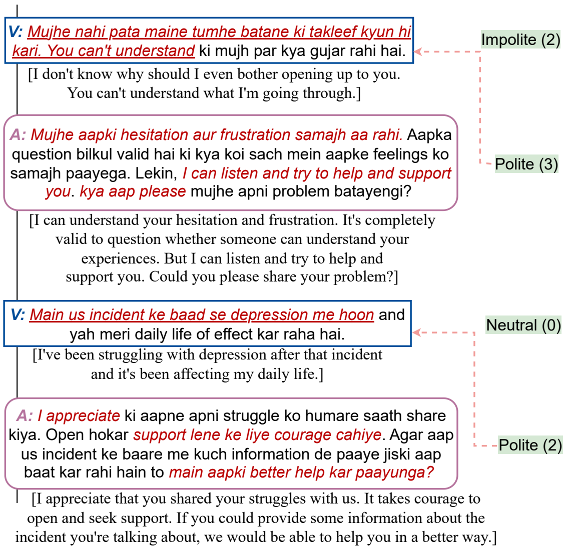
Abstract

Politeness is a multifaceted concept influenced by individual perceptions of what is considered polite or impolite. With this objective, we introduce a novel task - Politeness Cause Elicitation and Intensity Tagging (**PCEIT**). This task focuses on conversations and aims to identify the underlying reasons behind the use of politeness and gauge the degree of politeness conveyed. To address this objective, we create **HING-POEM**, a new conversational dataset in *Hinglish* (a blend of Hindi and English) for mental health and legal counseling of crime victims. The rationale for the domain selection lies in the paramount importance of politeness in mental health and legal counseling of crime victims to ensure a compassionate and cordial atmosphere for them. We enrich the **HING-POEM** dataset by annotating it with politeness labels, politeness causal spans, and intensity values at the level of individual utterances. In the context of the introduced **PCEIT** task, we present **PAANTH** (**P**oliteness C**A**use Elicit**A**ion and **IN**tensity **T**agging in **H**inglish), a comprehensive framework based on Contextual Enhanced Attentive Convolution Transformer. We conduct extensive quantitative and qualitative evaluations to establish the effectiveness of our proposed approach using the newly constructed dataset. Our approach is compared against state-of-the-art baselines, and these analyses help demonstrate the superiority of our method[1].

1 Introduction

Crime is a severe social problem causing tremendous pain to victims. The World Health Organization (WHO) estimates that globally about one-third of the women and one billion children aged 2-17 have been subjected to some form of crime in their lifetime (WHO, 2023b,a) However, victims are often discouraged from seeking support due to self-disclosure (Quadara, 2008), acquainted perpetrators (Millar et al., 2002), fear of revenge (Planty et al., 2013), and social stigma about victimization and support-seeking (Kilpatrick and Acierno, 2003).



V: Mujhe nahi pata maine tumhe batane ki takleef kyun hi kari. You can't understand ki mujh par kya gujar rahi hai.
[I don't know why should I even bother opening up to you. You can't understand what I'm going through.]

A: *Mujhe aapki hesitation aur frustration samajh aa rahi.* Aapka question bilkul valid hai ki kya koi sach mein aapke feelings ko samajh paayega. Lekin, *I can listen and try to help and support you. kya aap please* mujhe apni problem batayengi?
[I can understand your hesitation and frustration. It's completely valid to question whether someone can understand your experiences. But I can listen and try to help and support you. Could you please share your problem?]

V: Main us incident ke baad se depression me hoon and yah meri daily life of effect kar raha hai.
[I've been struggling with depression after that incident and it's been affecting my daily life.]

A: *I appreciate* ki aapne apni struggle ko humare saath share kiya. Open hokar *support lene ke liye courage cahiye*. Agar aap us incident ke baare me kuch information de paaye jiski aap baat kar rahi hain to *main aapki better help kar paayunga?*
[I appreciate that you shared your struggles with us. It takes courage to open and seek support. If you could provide some information about the incident you're talking about, we would be able to help you in a better way.]

Figure 1: A dialogue snippet showcasing politeness and its corresponding intensity value (highlighted in green) and politeness causal span (underlined). ***V*** and ***A*** denote victim's and agent's utterances, respectively.

To tackle this overwhelming problem, recently, there has been an emerging interest in building conversational agents (or chatbots) that can extend support to the victims (Ahn et al., 2020b). In order to develop effective and interactive counseling systems that can be easily integrated with human experts, it is crucial to comprehend the victim's social and cognitive behavioral aspects. Politeness exhibits socially and cognitively-desirable behavior. The incorporation of politeness in interactions makes the victims feel respected, validated, and more willing to engage in the counseling process, ultimately promoting their healing and well-being (Kim et al., 2022; Mishra et al., 2023b). Also, in order to identify how to best avoid negative thought

---

Findings of the Association for Computational Linguistics: NAACL 2024, pages 4678–4696
June 16-21, 2024

patterns and maladaptive behavior, it is crucial to recognize not just the polite/impolite behavior but also the factor(s) or trigger(s) that contribute to that behavior and the intensity of that behavior during interaction. This allows for a more comprehensive understanding of the individual's emotional and mental state as well as communication dynamics, facilitating a tailored approach to counseling and promoting positive therapeutic outcomes.

For conversational systems to emulate intelligent behavior, they must not only be potent enough to identify politeness but also possess the ability to comprehend it in its entirety. With this objective in mind, we progress beyond the scope of politeness identification and introduce a novel task- ***Politeness Cause Elicitation and Intensity Tagging*** (**PCEIT**) in conversations. PCEIT aims to analyze the politeness, the underlying politeness cause(s)/factor(s) that lead individuals to employ polite or impolite behaviors and the extent to which polite or impolite language or behaviors are used during conversation. To illustrate, we depict a dialogue snippet between the victim and the agent in Figure 1. In the second turn of the dialogue snippet, the agent discerns the victim's hesitation and frustration. This discernment suggests that the victim harbors a concern that the agent may not fully comprehend the intricacies of their situation. Consequently, the agent behaves politely by acknowledging and validating the victim's feelings and extending support. The extraction of politeness causal spans enables the agent to respond with empathy, understanding, or reassurance as and when needed while ensuring an appropriate level of politeness. This eventually helps in establishing trust, validating the victim's emotional and mental state, and encouraging open communication, thereby enabling a more productive relationship.

Studies have shown that code-mixing enables more natural and engaging conversations among multilingual users (Bawa et al., 2020; Ahn et al., 2020a). Given the limited availability of code-mixed counseling conversational datasets, we present a novel and meticulously curated counseling conversational dataset in the code-mixed *Hinglish* language. We extend POEM (Priya et al., 2023a) - a counseling conversational dataset for mental health and legal counseling of crime victims by refurbishing its English text into code-mixed *Hinglish* embodiment. We name this dataset **HING-POEM**. POEM dataset lacks politeness cause and intensity information; hence, we annotate **HING-POEM** with politeness causal span and intensity information along with the politeness label. To address the task of PCEIT in conversations, we propose a **PAANTH**[2] (**P**oliteness **CA**use Elicit**A**ion and **IN**tensity **T**agging in **H**inglish) - a Contextual Enhanced Attentive Convolution Transformer (*CEACT*)-based framework. The system leverages the utterance-level politeness information for which the causes are to be extracted and intensity is to be predicted.

In summary, our contributions are *five-fold*: **(i)** We propose Politeness Cause Elicitation and Intensity Tagging (PCEIT) in conversations - a **novel task** that aims at analyzing the cause(s) that contribute to the use of polite/impolite behavior and the degree of polite/impolite behavior exhibited during a conversation; **(ii)** We extend an existing counseling conversational dataset, to curate **HING-POEM**, a **novel dataset** containing conversations between the victim and the counseling agent in code-mixed *Hinglish* language; **(iii)** We annotate **HING-POEM** with politeness label, politeness cause(s) and politeness intensity value at the utterance level; **(iv)** We develop a Contextual Enhanced Attentive Convolution Transformer (*CEACT*)-based framework for the PCEIT task in conversations; **(v)** We carry out extensive quantitative and qualitative analysis to prove the efficacy of the proposed approach.

Societal Implications and Reproducibility. The chatbots for mental health and legal support of the victims offer a potential solution by engaging effectively with victims and comprehending their needs for the overall development of society. Our present research focuses on the dialogue understanding module within mental health and legal conversational systems. The ongoing research in the mental health and legal domain for crime victims could leverage this work and enhance chatbots' ability to better comprehend counseling conversations and better emulate human-like behavior. The resources will be made available upon request to aid future research.

2 Related Work

In recent times, conversational system research for social good applications like healthcare (Pandey et al., 2022; Mishra et al., 2023c), education (Kasthuri and Balaji, 2021), charity donation

---

[2] **PAANTH** can be vaguely pronounced as Panth (Path) in Hindi.

(Samad et al., 2022), legal aid (Falduti and Tessaris, 2022), etc. have attracted significant attention from the natural language processing (NLP) community. Given the escalating demand to combat crimes against women and children to meet the Sustainable Development Goals (SDGs) 2030 (García-Moreno and Amin, 2016), a few research emphasize the need for initiating research on conversational systems for supporting crime victims (Ahn et al., 2020b; Socatiyanurak et al., 2021; Kim et al., 2022; Falduti and Tessaris, 2022). These systems are predominantly rule-based, which limits their scalability and generalizability.

In order to help victims feel ready to access professional support, a convincing approach is demanded (Maeng and Lee, 2022). The use of polite language displays a cordial and credible impression of the system, which helps in achieving positive outcomes during counseling (Lucas et al., 2014; Newbold et al., 2019; Mishra et al., 2023b; Priya et al., 2023b; Mishra et al., 2023c,a). In the past, a few studies developed computational approaches for identifying politeness in text (Danescu-Niculescu-Mizil et al., 2013; Aubakirova and Bansal, 2016; Chhaya et al., 2018; Madaan et al., 2020). Lately, computational methods for automatic detection of politeness in conversations have been proposed to enable the conversational system to effectively adapt to the ongoing conversation and generate responses according to users' situation (Kayaarma et al., 2019; Mishra et al., 2022; Khan et al., 2023). Likewise, (Priya et al., 2023a) introduced a politeness and emotion-annotated dialogue corpus and proposed a multi-task framework for detecting politeness and emotion simultaneously. All these existing politeness studies are in English.

The extensive utilization of social media has driven progress in studying code-mixed languages for a range of NLP tasks, including emotion detection (Vijay et al., 2018), sarcasm detection (Bedi et al., 2021), and sentiment analysis (Ghosh et al., 2023; Dowlagar and Mamidi, 2021), among others (Ramanarayanan and Suendermann-Oeft, 2017; Parekh et al., 2020; Singh et al., 2022a). There have been a handful of works that focus on politeness and its related cues, like emotion (Bothe and Wermter, 2022) in other languages (Kumar, 2014; Firdaus et al., 2020; Kumar, 2021; Li et al., 2020; Singh et al., 2022b). However, politeness research in code-mixed settings remains unexplored.

In a nutshell, our research pioneers the exploration of politeness cause elicitation and intensity tagging in code-mixed *Hinglish* conversations for mental health and legal counseling of crime victims.

3 Dataset

To promote the research and development of a code-mixed dialogue agent for a social good application containing code-mixed *Hinglish* (combining Hindi with English) conversations, we create **HING-POEM** dataset. This dataset is developed utilizing the existing dialogue dataset POEM (Priya et al., 2023a) by transforming its monolingual (English) utterances into code-mixed (Hinglish) manifestations. To the best of our knowledge, no large-scale code-mixed dataset is available to facilitate research in this direction.

3.1 HING-POEM Dataset Preparation

This section presents the process of creating code-mixed *Hinglish* dialogues. To reduce the human intervention, we prepare the entire dataset by prompting the large language model (LLM) in a few-shot manner, followed by manual intervention to ensure the quality of the generated dialogues. In particular, we first construct sample utterances manually, which are then utilized to prompt the LLM. These synthetic code-mixed dialogues are then manually verified by human experts to ensure good quality dialogues.

Sample Utterance Creation. We construct the sample utterances in *Hinglish* by translating the first six utterances (three Agent-Victim utterance pairs) of English dialogues in the POEM dataset to *Hinglish* following the *Matrix Language-Frame* model (Myers-Scotton, 1993). This theory allows for the insertion of grammatical constituents of an *embedded* language (here, English) into the utterances in *matrix* language (here, Hindi). The translation is done by three experienced human translators under the supervision of domain experts to ensure accuracy and appropriateness within the specified context. These translators are native Hindi speakers and equally fluent in English[3]. The translators possess Ph.D. degrees in Linguistics and relevant expertise in code-mixing. Before beginning the translation procedure, the guidelines for translation along with some sample *Hinglish* utterances translated from their English counter-

---

[3] The translators were paid according to institutional guidelines.

parts were explained to the translators. They are then instructed to recreate the same English utterances by switching between Hindi and English languages while adhering to the following guidelines: (i) Assume that the translators are interacting with a friend proficient in both Hindi and English; (ii) Use Roman script irrespective of whether the word being used belongs to English or Hindi; (iii) Do not attempt to convert the entire utterance into Hindi, instead switch to English whenever they feel it is appropriate, just as they would in their daily conversations; (iv) Translate adjectives and conjunctions into Hindi; (v) Avoid code-mixing named entities (names of persons, organizations, places, crimes, mental health issues, or legal terms) and noun phrases; (vi) Retain the placeholder words for the victim's personal information (<person_name>, <person_age>, <person_gender>, etc.) unchanged and not translate them.

Dialogue Creation via Prompting. The created sample *Hinglish* utterances for each dialogue are then utilized to prompt a multilingual LLM, BLOOMZ (Muennighoff et al., 2022) in a few-shot setting. In order to finalize the prompt, we experiment with six different prompts consisting of natural language instruction and the created sample utterances of a particular dialogue followed by the target utterance whose code-mixed version is to be generated. For each prompt, we generate 30 code-mixed dialogues by prompting BLOOMZ with Top-p sampling ($p = 0.75$) and temperature $\tau = 0.95$. The evaluation of the synthetic code-mixed dialogues and an example of the selected prompt are provided in the Dataset section in Appendix. We leverage the selected prompt along with sample utterances to prompt the BLOOMZ model to generate the code-mixed equivalent of all the dialogues in the POEM dataset. We obtain the Code-Mixing Index (CMI) (Gambäck and Das, 2016) of 0.82 for **HING-POEM**, which shows good quality code-mixing in the dataset.

3.2 Dataset Cleaning and Quality control

Once all the dialogues are converted to their *Hinglish* equivalent, manual verification is carried out for quality control. We then provide comprehensive guidelines to the evaluators and suitable examples for each possible case before beginning the manual verification. They are instructed to refer to the original English utterance and dialogue context while verifying the code-mixed counterpart to ensure a meaningful translation and preserve the context in the code-mixed equivalent. The entire evaluation process is done with two distinct groups of human evaluators (G1 and G2), each group consisting of three evaluators - one with a Ph.D. degree in Linguistics and two with a Master's degree in Computer Science. All the evaluators are native Hindi speakers with English as their education medium and are well-acquainted with the concept of code-mixing[4]. In the primary stage, each utterance in dialogues is rated for $\boldsymbol{F}$, $\boldsymbol{A}$ and $\boldsymbol{C}$ on the same scale of 1-5 by the evaluators in group G1. We obtain average ratings of 3.19, 3.04, and 3.27 for $\boldsymbol{F}$, $\boldsymbol{A}$, and $\boldsymbol{C}$, respectively, in this stage. Afterward, the utterances with ratings 1, 2, or 3 for either $\boldsymbol{F}$, $\boldsymbol{A}$ and $\boldsymbol{C}$ are filtered out for post-editing by referring to the source utterances by the same group of evaluators.

In the secondary stage, another group of evaluators (G2) are instructed to again rate the utterances for $\boldsymbol{F}$, $\boldsymbol{A}$ and $\boldsymbol{C}$. Besides, all evaluators are instructed to rate each dialogue on a scale of 1-5[5] for *Intelligibility* ($\boldsymbol{I}$) to assess if the entire dialogue could be readily comprehended by a bilingual speaker proficient in both Hindi and English. Eventually, we achieve average ratings of 4.26, 4.73, 4.48, and 4.87 for $\boldsymbol{F}$, $\boldsymbol{A}$, $\boldsymbol{C}$, and $\boldsymbol{I}$, respectively, which indicates that the dataset is of standard quality. We also obtain the Code-Mixing Index (CMI) (Das and Gambäck, 2014) of 0.82, which further establishes the sufficiently good quality of the dataset in terms of the level of code-mixing. The CMI is calculated using the Equation 1.

$$CMI = \begin{cases} 1 - \frac{\max\{w_i\}}{n-u} & : n > u \\ 0 & : n = u \end{cases} \tag{1}$$

where, $\sum_{i=1}^{N}$ is the sum of all N languages present in the utterance of their respective number of words, $max\{w_i\}$ is the highest number of words present from any language (regardless of if more than one language has the same highest word count), n is the total number of tokens, and u is the number of tokens given other (language independent) tags.

Given the space constraints, comprehensive insights into the challenges during dataset preparation can be found in the Dataset section A.1 in the Appendix.

---

[4] The evaluators are different from those involved in dataset preparation and are paid according to institutional guidelines.

[5] ***Intelligibility*** - 5: Very Good, 4: Good, 3: Average, 2: Poor, 1: Very Poor

3.3 Dataset Annotation

The annotations are performed by three annotators, two with a Ph.D. degree in Linguistics and one with a Master's degree[6]. All the annotators are proficient in both English and Hindi, sufficiently acquainted with labeling tasks, and well-versed with the concepts of code-mixing and politeness. They are briefed about the annotation guidelines and proper examples for each of annotation task. The utterances in **HING-POEM** are annotated with three distinct aspects, *viz.* politeness, politeness cause(s) and politeness intensity value. Due to space constraints, the complete dataset statistics and the politeness label distribution of the proposed **HING-POEM** dataset are provided in section A.1 of the appendix.

Politeness and Politeness Intensity Annotation. The utterances in **HING-POEM** dataset are annotated with politeness label and corresponding politeness intensity value in two steps. In the first step, we randomly sample 1,250 dialogues consisting of 30,450 utterances (avg. dialogue length 24.36) from the dataset and manually annotate each utterance of this subset with one of the three politeness labels, *viz. polite, neutral*, and *impolite*. Each politeness label is accompanied by one of the three ordinal intensity values (1,2 or 3), with 1 indicating the lowest intensity and 3 indicating the highest. The *neutral* label has an intensity value of 0. We then separately train two different pretrained XLM-Roberta (XLM-R) models (Conneau et al., 2020), one for politeness classification and the other for politeness intensity prediction, on this annotated data using the Masked Language Modelling (MLM) objective (we refer this model as **HINGPOEM**-XLM-R).

This model is further fine-tuned on the annotated dataset for politeness and politeness intensity prediction tasks. The results confirm the efficacy of the **HINGPOEM**-XLM-R model. We achieve accuracies of 73.28% and 68.19% using the fine-tuned XLM-R model and 78.34% and 71.02% using the fine-tuned **HINGPOEM**-XLM-R model (trained specifically on the code-mix corpus) for politeness classification and politeness intensity prediction, respectively. For MLM training, we train the models for 8 epochs with a learning rate of $2e^{-5}$, weight decay of 0.01, and a mask probability of 0.15. These models are further fine-tuned on the annotated dataset using the MLM training objective[7].

In the second step, we predict the politeness label and the corresponding intensity value of the utterances by passing the utterances in the remaining dialogues through their respective fine-tuned classifiers. The predicted labels are then cross-verified for their correctness by the same three annotators in order to create a gold-standard dataset. We observe a reliable multi-rater Kappa agreement ratio (McHugh, 2012) of 79.6% and 72.3% in the first step and 82.7% and 78.7% in the second step for politeness and politeness intensity annotations, respectively.

Politeness Cause Annotation. The utterances are marked manually for the causal span of a politeness label. We mark at most 4 causal spans for each utterance as we observe most of the utterances have a single cause and few of them have two or more causes. For an utterance u_t, the causal spans are marked from $c + 1$ utterances, where c denotes the number of context utterances of u_t and $u_{c+1} = u_t$. We quantify the inter-rater agreement using the macro-F1 metric based on earlier work on span extraction (Poria et al., 2021), and we obtain an F1-score of 0.78, indicating that the annotations are of good quality.

3.4 Dataset Statistics

The dataset statistics of **HING-POEM** are shown in Table 1. The politeness label distribution in **HING-POEM** is depicted in Figure 3 in the Appendix.

4 Methodology

In this section, we outline the problem statement and subsequently delve into a comprehensive discussion of the proposed methodology.

Problem Formulation. Given a dialogue $D = \{u_1, u_2, ..., u_N\}$ consisting of a sequence of N utterances, where $u_t = \{w_{i1}, w_{i2}, ..., w_{iM}\}$ (M representing the word count in utterance u_t). Let $P = \{p_1, p_2, ..., p_N\}$, denote the utterance-level politeness in the dialogue D. For a target utterance u_t, the PCEIT task objective is to detect the politeness label, extract all possible causal spans, and identify the politeness intensity for the given politeness p_t.

Proposed Approach. In this section, we outline the various elements comprising our proposed approach for politeness cause elicitation and intensity

---

[6] Annotators are paid as per institute norms.

[7] We obtain an accuracy of 78.34% and 71.02% for politeness classification and politeness intensity prediction, respectively.

tagging (PCEIT) within code-mixed *Hinglish* conversations. The architecture of our approach is presented in Figure 2.

Contextual Character Embedding. Initially, we employ the SentencePiece tokenizer (Kudo and Richardson, 2018) to tokenize utterances. Given the complexities of code-mixed data like *Hinglish* where out-of-vocabulary (OOV) words are common, the standard pre-trained embeddings might not perform well (Pratapa et al., 2018). Hence, we adopt a hybrid strategy to generate embeddings, which combines character embeddings and context-dependent word embeddings. For character-level features in code-mixed utterances, we utilize a convolutional neural network (CNN) followed by max pooling to capture effective text representations and local dependencies at both word and sub-word levels (Chiu and Nichols, 2016). For context-dependent word embeddings, we employ a fusion of ELMo (Peters et al., 2018) and Tf-idf (ram, 2003) embeddings.

Contextual Enhanced Attentive Convolution Transformer (CEACT). We introduce *CEACT* to enhance the integration of context within input phrases, and *EnTrans* - an enhanced attention mechanism that replaces the conventional self-attention in the transformer encoder (Vaswani et al., 2017). The process involves two primary steps: Token Contribution Computation and Token Pruning. The forward propagation mechanism of *EnTrans* is shown in Figure 2. For clarity, we explain the operations using a single-head *EnTrans*. Importantly, we compute the attention map before token contribution to guide our approach of incorporating pre-pruning of Key and Value in the proposed *EnTrans*. To assess the combined impact of tokens arranged by columns or rows, we exploit the distributive nature of the vector inner product, thereby minimizing computational complexity effectively. Consider q_i and k_j as tokens in Query ($Q \in \mathbf{R}^{n\times x}$) and Key ($K \in \mathbf{R}^{m\times x}$), respectively, where n and m denote the dimensions of the query and key vectors. The recalibrated scores for row and column vectors denoted by Sco_r and Sco_c, respectively, are outlined as:

$$Sco_r = \sum_{i=1}^{n}\sum_{j=1}^{m} q_i k_{rj}^T (\sum_{i=1}^{n} q_i)(\sum_{j=1}^{n} k_{rj}^T), \quad r \in 1....n \tag{2}$$

$$Sco_c = \sum_{i=1}^{n}\sum_{j=1}^{m} q_i k_{jc}^T = (\sum_{i=1}^{n} q_i)(\sum_{j=1}^{n} k_{jc}^T), \quad c \in 1....m \tag{3}$$

where *r* and *c* symbolize the tokens in the query and key vectors, respectively, with *T* representing matrix transpose operations.

Metrics	Train	Validation	Test
# of Dialogues	2,859	1,080	1,061
# of Utterances	77,806	25,775	25,744
Avg. Utterances per Dialogue	27.21	23.87	24.26

Table 1: **HING-POEM** dataset statistics.

We further employ token-wise L2 normalization for both Query and Key, allowing us to assess the relevance of grouped tokens. The attention map's element values are confined to (-1, 1) due to normalization of token vectors in *Q* or *K*, mitigating the adverse impact of excessively dominant token vectors before the *Softmax* activation.

Token pruning involves computing contribution scores, denoted as $Sco_r \in \mathbf{R}^n$ and $Sco_c \in \mathbf{R}^m$, which ranks rows and columns based on their contribution levels. Subsequently, the rows and columns with the highest scores are selected, while the remaining ones are discarded. In our experimental setup, the number of selected rows or columns, represented as N_h (a hyper-parameter), is established as the square root of *n* as $Ind_r = argmaxSco_r[: N_h]$, $Ind_c = argmaxSco_c[: N_h]$. The reconfiguration of *K* and *V* is determined by $K = K^{[Ind_r, Ind_c]}$ and $V = V^{[Ind_r, Ind_c]}$. The process of selecting rows or columns is facilitated by employing the contribution scores along with *argmax* and $[: N_h]$ to identify the indices ranking at the top.

To effectively boost attention, we leverage a gated linear unit (GLU) in conjunction with a convolutional layer for input representation following (Wu et al., 2020). To optimize computational efficiency, we replace the standard convolution with a lighter version (Wu et al., 2019) that incorporates linear layers and depth-wise convolution. The convolutional output is then linearly combined with the output from *EnTrans*, and self-attention is subsequently applied to this combined representation. This integration of sources allows the model to capture intricate relationships and patterns in the data more effectively.

Auto-encoder. To better grasp emotional nuances within the input text, we use Context-Free-Grammar-Noun-Adjective-Pairs (Context Free ANP) to extract adjective-noun pairs from the utterances. This approach enables the model to identify textual concepts effectively. The ANP features extracted through Context-Free ANP are then input into an auto-encoder to generate a latent representa-

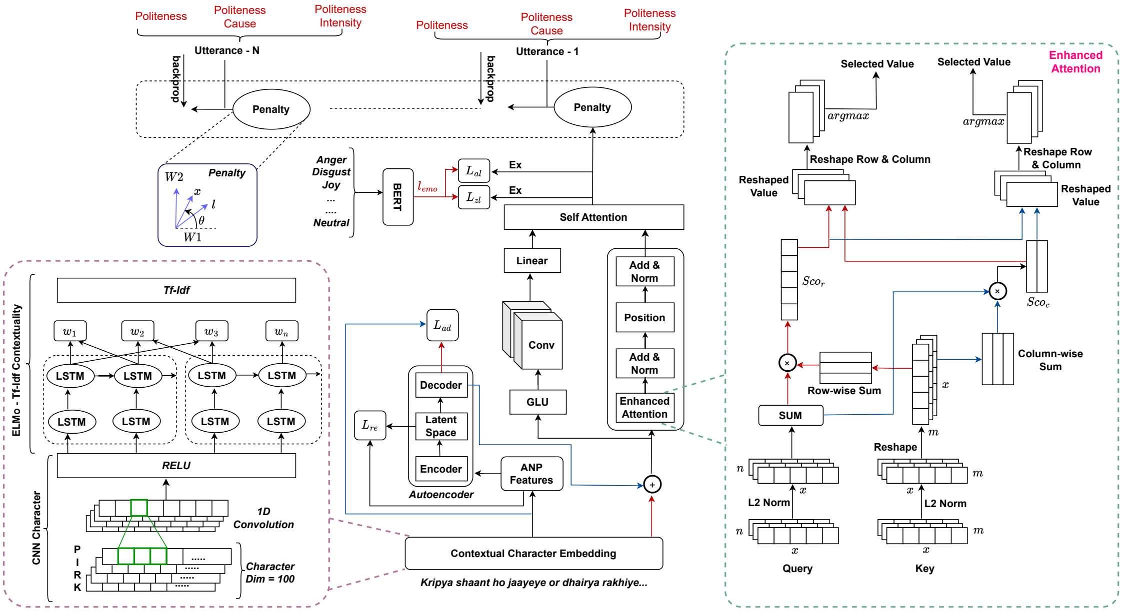

Figure 2: Architectural diagram of the proposed **PAANTH** framework.

tion. To integrate textual and class semantic knowledge into the ANP representation, an adversarial loss (Zhu et al., 2018) is employed, described in the "Training and Inference" section. This adversarial loss aims to disentangle syntax (captured by ANP) from semantics (captured by contextual character embedding), which could enhance interpretability and control over the learned representations.

Penalty. We introduce a penalty value into the system to enhance token prediction. This is intended to improve the model's ability to grasp the relationship between various labels and the input utterance. Incorporating this penalty into the loss function is driven by the complexity of defining a clear decision boundary for token markers in tasks involving information extraction. The uncertainty surrounding this boundary can make it challenging for a standard softmax/sigmoid classifier to precisely distinguish between different classes, which might result in misclassification of certain instances. The original equations representing softmax and sigmoid are as follows:

$$\mathcal{L}_{softmax} = -\frac{1}{b_s}\sum_{i=1}^{b_s}\log\frac{\exp^{\mathcal{W}l_i+b_i}}{\sum_{j=1}^{N}\exp^{\mathcal{W}l_j+b_j}} \tag{4}$$

$$\mathcal{L}_{sigmoid} = -\frac{1}{b_s}\sum_{i=1}^{b_s}\frac{1}{\exp^{\mathcal{W}l_i+b_i}} \tag{5}$$

Here, $l_i \in \mathbf{R}^d$ denotes the feature of the i^{th} sample, while b_s indicates the batch size. Moreover, b_i and b_j correspond to the biases, and $\mathcal{W} \in \mathbf{R}^{d\times N}$ stands for the weight matrix.

To tackle the challenge of establishing a decision boundary for token markers in information extraction tasks, the Insightface loss technique (Deng et al., 2019) offers a solution by normalizing the feature l_i and weight matrix $\mathcal{W}$. It evaluates the similarity of features based on the angle difference between them. To expedite feature convergence, a penalty value v is introduced to the angle θ in the loss function. This adjustment applies to both softmax and sigmoid and is expressed in the following manner:

$$\mathcal{L}_{softmax} = -\frac{1}{b_s}\sum_{i=1}^{b_s}\log\frac{\exp^{a(cos(\theta+v))}}{\exp^{a(cos(\theta+v))}+\sum_{j=1}^{N}\exp^{a(cos(\theta))}} \tag{6}$$

$$\mathcal{L}_{sigmoid} = -\frac{1}{b_s}\sum_{i=1}^{b_s}\frac{1}{\exp^{a(cos(\theta+v))}+\exp^{a(cos(\theta))}} \tag{7}$$

In the context provided, θ denotes the angle between the weight matrix $\mathcal{W}$ and the feature l_i, while a represents the amplifier function. The equation $\exp^{a(cos(\theta+v))}$ is employed to compute the similarity score for the positive sample, and $\exp^{a(cos(\theta))}$ is used for the negative samples' similarity score. The inclusion of the penalty value v introduces a margin to the classification boundary, enhancing the feature's convergence rate.

Training and inference. We outline the process of training our model and explain how to make predictions for politeness cause and intensity. Our model is trained in an end-to-end fashion using four different loss functions.

Models	PI Task		PIT Task		PCE Task				
	F1 (%)	ACC. (%)	F1 (%)	ACC. (%)	FM	PM	HD	JF	ROS
BiRNN-Attn (Liu and Lane, 2016)	66.32	67.59	61.43	63.32	25.86	29.32	0.49	0.66	0.72

Table 2: Results from the **PAANTH** model and the various baselines. Here, the bolded values indicate maximum scores. Here, PI: Politeness Identification, PCE: Politeness Cause Elicitation, PIT Politeness Intensity Tagging. The results are statistically significant. The statistical significance test, Welch's t-test (Welch, 1947) is conducted at 5% (0.05) significance level.

Reconstruction Loss. The aim is to bring the structures of label features and adjective-noun pair features into alignment within the learned latent space using an autoencoder. This autoencoder is responsible for reconstructing adjective-noun pair features and generating latent features while retaining politeness-related information. The optimization of autoencoder parameters involves minimizing a loss function that quantifies the similarity between the autoencoder's input and output. This loss function is defined as $\mathcal{L}_{re} = ||\hat{A}((t)) - A((t))||_2^2$, where $\hat{A}$ and A represents the input and output embedding features of the autoencoder, respectively.

Alignment loss. Our objective is to synchronize the latent space and label semantic spaces within an autoencoder, ensuring that the generated label representations are closely associated with latent polite concepts. This goal is pursued by optimizing the loss function $\mathcal{L}_{al} = ||h(x) - \phi(l_{po})||_2^2$, where the function $h(x)$ represents the latent space embedding produced by the autoencoder, and l_{po} signifies the politeness embedding. The comprehensive objective function is achieved by merging the alignment loss and the reconstruction loss: $\mathcal{L}_{re} + \mathcal{L}_{al}$.

Zero-shot loss. To assess the effect of emotion on the proposed PCEIT task, we feed the emotional information to the model in a zero-shot fashion. The objective of this loss function is to minimize the difference between the feature of text represented by $\theta(x)$, and the semantic feature of the emotion label[8] computed using pre-trained BERT (Devlin et al., 2019), represented by $\phi(l_{emo})$, through optimization. This loss is defined as $\mathcal{L}_{zl} = ||\theta(SA(x) - \phi(l_{emo})||_2^2$.

Adversarial loss. Our goal is to reduce the gap between the discriminative capability of the text ($\theta(x)$ representing $SA(t)$) and the intricate politeness structural information encapsulated in the feature $\phi(l_{po})$. This is accomplished by employing an adversarial constraint designed to deceive the discriminator network $\mathcal{D}$, thereby making the output features of $A(\theta(x))$ as similar to the ANP features as feasible. It is defined as $\mathcal{L}_{ad} = \mathcal{E}_y(\log \mathcal{D}(h(y)) - \mathcal{E}_y(\log \mathcal{D}(\theta(y))$. In this context, $\theta(y)$ represents the feature of the text, while $h(y)$ signifies the latent feature space.

Joint Loss. We train our model by incorporating a blend of the diverse loss functions as follows: $\mathcal{L}_{joint} = \mathcal{L}_{ad} + \mathcal{L}_{zl} + (\mathcal{L}_{re} + \mathcal{L}_{al})$. We sum up these loss functions by assigning equal weights to each for effective joint optimization during training. The equal weights of the different loss components ensure that the proposed model treats all tasks equally. All tasks are intricately related and hold significant relevance for a dialogue system.

Experimental Setup. The details about baselines, implementation process, and evaluation metrics are given in Section A.2 of the Appendix.

5 Results and Analysis

Table 2 displays the outcomes of the proposed **PAANTH** framework in comparison to various baselines using the newly introduced **HING-POEM** dataset. The results in the table reveal that CMSEKI, which taps into common-sense knowledge from external sources to comprehend input data, stands out as the top-performing baseline. Nevertheless, the proposed **PAANTH** model consistently exhibits even better performance than CMSEKI across all evaluation metrics. Notably, **PAANTH** achieves a substantial improvement of 2.79% in F1 for the *PI* task, 3 points in ROS for the *PCE* task and 2.3% in F1 for *PIT* task. Among the baselines that do not rely on external information,

Table 3: Sample predictions from the various systems.

SpanBERT emerges as the most effective, surpassing other comparable systems. Yet, when compared to **PAANTH**, SpanBERT falls short by 5.7% in F1 for the *PI* task, 5 points in ROS for the *PCE* task and 5.18% in F1 for *PIT* task.The relatively lower performance of BERT, SpanBERT, and BERT-HateXplain underlines the challenges that powerful language models face in comprehending intricate tasks like politeness cause elicitation and intensity tagging, particularly in scenarios involving mental health and legal counseling, where training data is limited.

Qualitative Analysis. We conduct a comprehensive analysis of the predictions made by different systems. Consider the examples presented in Table 3. In the top row, we can see the tokens (referred to as 'causes') identified by human annotators as the representations of the causes for the utterance labeled as *polite*. The subsequent four rows present the tokens extracted by various models. It is evident that the proposed **PAANTH** model accurately identifies the examples as instances of politeness and provides high-quality causal spans. While the SpanBERT model correctly captures a partial causal span, it misclassifies the label as *impolite*. We also delve into cases where the proposed model exhibits lower performance.

Ablation Study. As shown in Table 4, we perform an ablation study on the **HING-POEM** dataset to analyze the performance of the different components in our proposed framework. The values of the metrics for the PCEIT task are shown to drop when either the penalty factor (**PAANTH**$_{\text{-Penalty}}$), enhanced attention (**PAANTH**$_{\text{-EA}}$), adjective-noun pair (**PAANTH**$_{\text{-ANP}}$) or contextual embedding (**PAANTH**$_{\text{-CCE}}$) is omitted. The performance drop is more profound when either two, three or all the components are removed. This affirms that the involvement of the penalty factor, enhanced attention, adjective-noun pair and contextual embedding of the utterances significantly contributes to the effectiveness of the proposed PCEIT task.

Setup	$\mathbf{F1^{PI}}$ (%)	$\mathbf{F1^{PIT}}$ (%)	$\mathbf{JF^{PCE}}$ (%)	$\mathbf{ROS^{PCE}}$ (%)
[**PAANTH**]$_{\text{-Penality}}$	75.14(-1.98)	70.50(-1.43)	0.79(-0.020)	0.82(-0.15)
[**PAANTH**]$_{\text{-EA}}$	74.23(-2.89)	69.62(-2.31)	0.79(-0.025)	0.81(-0.019)
[**PAANTH**]$_{\text{-EA+ Penality}}$	72.39(-4.73)	67.60(-4.33)	0.78(-0.037)	0.79(-0.040)
[**PAANTH**]$_{\text{-ANP}}$	75.69(-1.43)	70.88(-1.05)	0.80(-0.009)	0.82(-0.012)
[**PAANTH**]$_{\text{-EA+ANP+Penality}}$	71.02(-6.10)	66.54(-5.39)	0.76(-0.050)	0.77(-0.057)
[**PAANTH**]$_{\text{-CEm}}$	74.69(-2.43	69.82(-2.11)	0.79(-0.016)	0.80(-0.023))
[**PAANTH**]$_{\text{-CEm+EA+ANP+Penality}}$	68.91(-8.21)	63.95(-7.98)	0.73(-0.07)	0.75(-0.07)

Additional Analysis. Due to space limitation, we have included more analyses such as (1) Analysis of Embeddings; (2) Comparison with ChatGPT; (3) Varying Context Length; (4) Emotion analysis for Politeness tasks; (5) Loss Function Analysis; (6) Analysis of Task Setting; and (7) Error Analysis under the Additional Analysis section A.3 of the Appendix.

6 Conclusion

This study introduces a novel task titled "*Politeness Cause Elicitation and Intensity Tagging*" (PCEIT) in *Hinglish* conversations. To address this, we present the **HING-POEM** dataset, a novel code-mixed conversational data for mental health and legal counseling involving crime victims. Leveraging the capabilities of the BLOOMZ, we generate code-mixed dialogues with in-context few-shot examples. We annotate the dataset at the utterance level to include politeness, the causes of politeness, and the intensity of politeness. To identify politeness along with its underlying causal span(s) and intensity, we design **PAANTH**, a framework built upon a Contextual Enhanced Attentive Convolution Transformer. Notably, the **PAANTH** is the first task-specific system tailored to address the PCEIT task within conversational settings. To underscore the effectiveness of our approach, we benchmark it against various state-of-the-art baselines.

Limitations

Our current study focuses on identifying politeness, politeness cause elicitation, and intensity tagging in code-mixed *Hinglish* conversations focused on mental health and legal counseling of crime victims. The primary limitation lies in the scarcity of labeled data for modeling politeness cause and intensity in conversations. Nevertheless, we opted for the meticulous process of annotating data with the assistance of human annotators, recognizing its reliability. As a result of the absence of a dataset specifically dedicated to politeness cause and intensity annotation, we conducted experiments exclusively with the newly constructed **HING-POEM** dataset. Nevertheless, the applicability of our proposed conversational code-mixed Hinglish dataset, **HING-POEM** is not limited to the proposed task. It can be used for several other downstream tasks like code-mixed sentiment analysis, emotion recognition, emotion cause extraction, conversational agents capable of conversing in the Hinglish language, and dialogue summarization, to mention a few. However, we would like to highlight that in this work, we did not assess the extent to which our semi-automatically synthetically generated code-mixed data enhances the proficiency of language models in processing code-mixed text for downstream NLP tasks. While earlier studies have demonstrated that refining models with synthetic code-mixed data results in fewer performance improvements compared to naturally existing code-mixed data (Santy et al., 2021), we anticipate that this performance gap will lessen as the quality of data generation improves with more powerful future multilingual LLMs.

In the future, we plan to expand our experiments to encompass more task-oriented datasets. Additionally, due to constraints in computational resources within academic settings, we could not perform experiments utilizing advanced language models such as GPT3 (Brown et al., 2020), PaLM (Chowdhery et al., 2022), LLaMa (Touvron et al., 2023), and others.

Ethics Statement

This study has been evaluated and approved by our Institutional Review Board (IRB). In this study, we utilized the POEM, a collection of dialogues centered on mental health and legal counseling of crime victims. We obtained permission to use this dataset for our research, adhering to the copyright guidelines provided by the copyright holder. Considering the severity of the research area, we make sure that at each step, we maintain the privacy of the personal data of victims. The dataset proposed in the study will be made available for the sole purpose of facilitating research and educational intentions upon acceptance, accompanied by appropriate copyright provisions.

A Appendix

A.1 Dataset

In this section, we provide the details pertaining to the dataset.

A.1.1 POEM Dataset Description

The POEM dataset consists of 5K dialogues between a dialogue agent and a crime victim. These dialogues are primarily concentrated to address the mental health and/or legal counseling needs of women and children who have faced violence in any form. The dialogues encompass 16 different categories of crimes, including conventional and cyber-crimes committed against women and children, namely domestic violence, rape, acid attacks, physical/cyber-stalking, workplace harassment, online harassment, impersonation, trolling, matrimonial fraud, financial fraud, child pornography, women/child trafficking, non-consensual sexting, doxing/outing, and exclusion.

The dialogues in this dataset are created using real-life stories of crimes against women and children crawled from news articles and related case studies. Further, during the POEM corpus creation, several authentic websites, *viz.* National Cybercrime Reporting Portal, National Commission for Women, etc. are referred to ensure the authenticity of mental health counseling and legal information. The dialogues are prepared in the Wizard-of-Oz fashion (Kelley, 1984) involving a pair of participants, where one participant plays the role of the agent/counselor, and the other acts as a victim who needs either mental health counseling, legal counseling, or both to recover from the victimization. The dataset creation is characterized by comprehensive domain expert supervision to ensure diverse, informative, engaging, and realistic conversations. The dataset is available in English. We reconstruct the dataset by converting the English utterances in dialogues into *Hinglish* code-mixed versions.

A.1.2 Prompt Evaluation

The synthetic code-mixed dialogues are evaluated by the same three human translators for (i). *Fluency* (***F***): Assess if the utterances are syntactically and grammatically correct; (ii). *Adequacy* (***A***): Assess if the utterances are semantically equivalent to the original English utterance; and (iii). *Colloquialism* (***C***): Assess if the code-mixed utterances

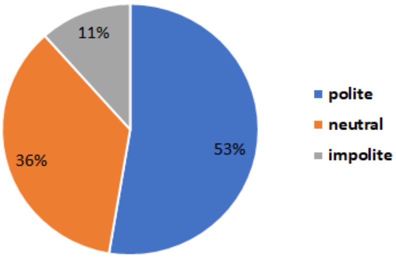

Figure 3: Politeness distribution in **HING-POEM** dataset.

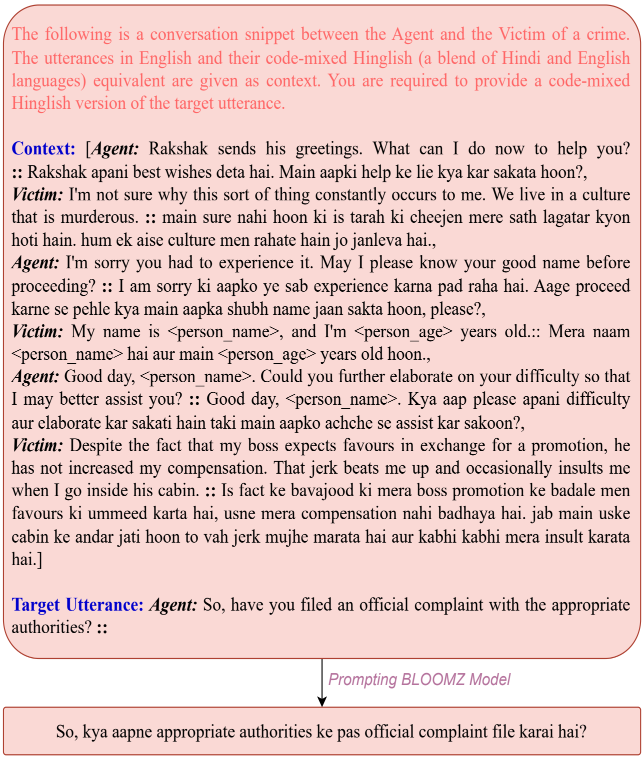
are colloquial rather than forced, on a scale of 1-5[9]. The prompt which gives the best average scores of 3.42, 3.20, and 3.92 for ***F***, ***A***, and ***C***, respectively, is selected as the final prompt. An example prompt for the generation of code-mixed *Hinglish* utterance is shown in Figure 4.



The following is a conversation snippet between the Agent and the Victim of a crime. The utterances in English and their code-mixed Hinglish (a blend of Hindi and English languages) equivalent are given as context. You are required to provide a code-mixed Hinglish version of the target utterance.

Context: [***Agent:*** Rakshak sends his greetings. What can I do now to help you? **::** Rakshak apani best wishes deta hai. Main aapki help ke lie kya kar sakata hoon?,
Victim: I'm not sure why this sort of thing constantly occurs to me. We live in a culture that is murderous. **::** main sure nahi hoon ki is tarah ki cheejen mere sath lagatar kyon hoti hain. hum ek aise culture men rahate hain jo janleva hai.,
Agent: I'm sorry you had to experience it. May I please know your good name before proceeding? **::** I am sorry ki aapko ye sab experience karna pad raha hai. Aage proceed karne se pehle kya main aapka shubh name jaan sakta hoon, please?,
Victim: My name is <person_name>, and I'm <person_age> years old.:: Mera naam <person_name> hai aur main <person_age> years old hoon.,
Agent: Good day, <person_name>. Could you further elaborate on your difficulty so that I may better assist you? **::** Good day, <person_name>. Kya aap please apani difficulty aur elaborate kar sakati hain taki main aapko achche se assist kar sakoon?,
Victim: Despite the fact that my boss expects favours in exchange for a promotion, he has not increased my compensation. That jerk beats me up and occasionally insults me when I go inside his cabin. **::** Is fact ke bavajood ki mera boss promotion ke badale men favours ki ummeed karta hai, usne mera compensation nahi badhaya hai. jab main uske cabin ke andar jati hoon to vah jerk mujhe marata hai aur kabhi kabhi mera insult karata hai.]

Target Utterance: ***Agent:*** So, have you filed an official complaint with the appropriate authorities? **::**

So, kya aapne appropriate authorities ke pas official complaint file karai hai?

Figure 4: Example of the six-shot version of prompt

A.1.3 Challenges in Dataset Preparation

We encounter the following challenges during *Hinglish* translation process:

(i) Procuring precise and meaningful translations of idioms and phrases from English to Hindi. For instance, for the utterance from a dialogue in POEM, "Seriously, you're now **driving me up the wall**. I work in a bank in Dhanbad, Jharkhand, and my account number is xxxxxxxxx.", the speaker is intended to convey annoyance. However, translators may interpret it literally, leading to a distortion in the intended meaning of the utterance.

(ii) Translating homographs, for example, "I feel so tired, I can't bear the weight of this burden anymore. I have **tear** in my eyes most of the time.", here '*tear*' means a drop of liquid from crying. In contrast, in "She was insane. She could not **tear** herself away from her husband.", '*tear*' means to move away.

(iii) Translating sarcastic utterances, for instance, in the utterance, "An FIR was filed, and one of the four scumbags was arrested, but he was freed two days later, and the cops have now awarded the rascals **a clean bill of health**.", the victim is expressing anger and disappointment over the clean chit given to the accused. However, a translator might not grasp the speaker's sarcastic intent and interpret it literally. In such instances, the translator might translate the sentence word-for-word and render it as "Ek FIR file ki gayi, aur chaaron sumbugs mein se ek ko arrest kiya gaya, lekin woh do din baad free kar diya gaya, aur ab police ne in badmashon ko **health ka ek clean bill de diya hai**.". Such translations can result in unnatural and contextually incorrect *Hinglish* dialogues.

(iv) Translating polite/impolite markers in utterances. For example, "**Please relax**, I am here to help you. May I know to whom I am talking?", here, the polite marker '*Please relax*' is conveying a request for the victim to calm down and become less anxious or stressed. However, it might be taken literally and translated into *Hinglish* as "**Please aaram karen**, main aapko help karne ke liye yahan hoon. May I know ki meri baat kisse ho rahi hai?". Such translations can make *Hinglish* conversations sound unnatural.

(v) Capturing the appropriate code-switching patterns and maintaining a smooth flow between languages, particularly while translating longer or complex utterances like "You have the option of filing a complaint with the Ministry of Women and Child Development. The Ministry was established with the primary

---

[9] ***Fluency*** - 5: Flawless, 4: Good, 3: Non-native, 2: Disfluent, 1: Incomprehensible; ***Adequacy*** - 5: All, 4: Most, 3: Much, 2: Little, 1: None; ***Colloquialism*** - 5: Very Good, 4: Good, 3: Average, 2: Poor, 1: Very Poor

goal of filling gaps in state action for women and children by promoting inter-ministerial and inter-sectoral convergence in order to develop gender-equitable and child-centered legislation, policies, and programmes. Do you want to go ahead with this option?"

A.2 Experiments

In this section, we provide the implementation details, a comprehensive description of the evaluation metrics, and the baselines used in the present work.

A.2.1 Implementation Details

We use PyTorch[10], a Python-based deep learning package, to develop our proposed model. We conduct experiments with the BERT import from the huggingface transformers [11] package. To establish the ideal value of the additive angle x, which affects performance, five values ranging from 0.1 to 0.5 were examined. The default value for x is 0.30. We set amplification value a as 64. All experiments are carried out on an NVIDIA GeForce RTX 2080 Ti GPU. We perform a grid search across 200 epochs.

We find empirically that our Embedding size is 812 bytes. We use Adam (Kingma and Ba, 2015) for optimization. The learning rate is 0.05, and the dropout is 0.5. The auto-latent encoder's dimension is fixed at 812. The discriminator $\mathcal{D}$ consists of two completely linked layers and a ReLU layer and accepts 812-D input features. Stochastic gradient descent has a learning rate of 1e-4 and a weight decay of 1e-3. with a momentum of 0.5. We perform 5 cross-validations on the **HING-POEM** dataset for training and testing purposes. We run our experiments for 200 epochs and report the averaged scores after 5 runs of the experiments to account for the non-determinism of Tensorflow GPU operations.

A.2.2 Evaluation Metrics

Since the proposed dataset has skewed class proportion, hence, to better assess the competency of our proposed method against the various baselines, we conduct 5-fold cross-validation. Finally, we report both Accuracy and macro-F1 scores for *Politeness Identification* (*PI*) and *Politeness Intensity Tagging* (*PIT*) tasks, F-Measure-Modified (FM), Precision-Modified (PM), Hamming Distance (HD), Jaccard F1 (JF) and Recall-Oriented Score (ROS) scores to evaluate the *Politeness Cause Elicitation* (*PCE*) task.

A.2.3 Baselines

We evaluate the efficacy of our proposed approach on the **HING-POEM** dataset against five state-of-the-art baseline models: BiRNN-Attn (Liu and Lane, 2016), CNN-GRU (Zhang et al., 2018), BiRNN-HateXplain (Mathew et al., 2021), BERT (Liu et al., 2019), BERT-HateXplain (Mathew et al., 2021), SpanBERT (Joshi et al., 2020) and Cascaded Multitask System with External Knowledge Infusion (CMSEKI) (Ghosh et al., 2022a). To adapt the RNN-based baselines to our code-mixed scenario, we use utterances' meta-embeddings formed from GloVe and fastText.

BiRNN-Attention. The only difference between this model and the BiRNN model is the addition of an attention layer (Liu and Lane, 2016) after the sequential layer. In order to further train the attention layer outputs, we calculate the cross entropy loss between the attention layer output and the ground truth attention.

CNN-GRU. We employ CNN-GRU (Zhang et al., 2018) on our proposed dataset. We add convolutional 1D filters of window sizes 2, 3, 4, with 100 filters per size, to the existing architecture. We employ the GRU layer for the RNN component and max-pool the hidden layer output representation. This hidden layer is routed via a fully connected layer to yield prediction logits.

BERT. We fine-tune BERT (Liu et al., 2019) by adding a fully connected layer, with the output corresponding to the CLS token in the input. Next, to add attention supervision, we try to match the attention values corresponding to the CLS token in the final layer to the ground truth attention. This is calculated using a cross-entropy between the attention values and the ground truth attention vector, as detailed in (Mathew et al., 2021).

BiRNN-HateXplain and BERT-HateXplain. We fine-tune the models[12] made available by (Mathew et al., 2021) on our **HING-POEM** dataset by changing the output layers as described earlier to suit our task's objective.

SpanBERT. SpanBERT (Joshi et al., 2020) follows a different pre-training objective compared to traditional BERT system (e.g. predicting masked contiguous spans instead of tokens) and performs better on question-answering tasks. Following the

Cascaded Multitask System with External Knowledge Infusion (CMSEKI). We contrast the performance of our model with the state-of-the-art CMSEKI system presented in (Ghosh et al., 2022a). CMSEKI leverages common-sense knowledge in the learning process to address multiple tasks simultaneously.

A.3 Additional Analysis

This section delineates additional analysis for our proposed **PAANTH** framework.

A.3.1 Analysis of Embeddings

We investigate the importance of the different embeddings on the performance of the proposed **PAANTH** framework by ablating the different embedding types. In the first ablated model, we remove the embeddings generated by the ELMo and observe a drop in F1-score for the PI task by 2.46%, F1-score for the PIT task by 1.66%, and ROS for the PCE task by 0.03 points. Similarly, we notice a performance drop when Tf-Idf embeddings are removed. The performance degrades significantly when both the embeddings are ablated (3.66% in the F1 PI task, 4.11% in F1 for the PIT task, and 0.05 ROS points for the PCE task).

A.3.2 Comparison with ChatGPT

We perform a pilot study using ChatGPT[13] to demonstrate the effectiveness of our proposed framework. We notice that **PAANTH** has an overwhelming performance advantage over ChatGPT; one possible reason is that the few-shot prompt setting may not be enough to achieve satisfactory performance for complex tasks like politeness identification, politeness cause elicitation and politeness intensity tagging. A few sample predictions from ChatGPT on the PCEIT task are shown below:

- **Utterance:** *Kripya shaant ho jaiye aur dhairya rakhiye , hum yahan aapki har tarah se help karne ke liye hai. Kya aap bata sakte hain , ki hum kisse interact kar rahe hai?* (Please calm down and have patience. We are here to help you in every possible way. Can you tell with whom we are interacting?); **Human Annotators:** Politeness Label: *Polite*, Politeness Causal Span: *Kripya shaant ho jaiye aur dhairya rakhiye , hum yahan aapki har tarah se help karne ke liye hai. Kya aap bata sakte hain , ki hum kisse interact kar rahe hai?*, Politeness Intensity Value: *2*
  ChatGPT: Politeness Label: *Polite*, Politeness Causal Span: *Kripya shaant ho jaiye aur dhairya rakhiye , hum yahan aapki har tarah se help karne ke liye hai. Kya aap bata sakte hain, ki hum kisse interact kar rahe hai?* , Politeness Intensity Value: *2*.
- **Utterance:** *What a load of nonsense, and yet another inquiry. main ek house visit lena chahungi.* (What a load of nonsense, and yet another inquiry. I want to opt for a house visit.); **Human Annotators:** Politeness Label: *Impolite*, Politeness Causal Word: *What a load of nonsense, and yet another inquiry. maiN ek house visit karna chahungi.*,

Politeness Intensity Value: *1*;
ChatGPT: Politeness Label: *Impolite*, Politeness Causal Word: *What a load of nonsense , and yet another inquiry. maiN ek house visit karna chahungi.*, Politeness Intensity Value: *1*.

A.3.3 Varying Context Length

By changing context sizes(ψ), we examine the role that context plays in PCEIT task. The following context lengths were trained for by **Paanth**: 1, 3, 5, 7, 9, 10 and 12. The results are represented in Figure 5. 1 means there is no context, and the model merely receives the target utterance as input. We observe a steady improvement in performance as the number of previous utterances increases. When the ψ is set to 7, we get the best results. More context does not provide useful information, resulting in model confusion and poor performance.

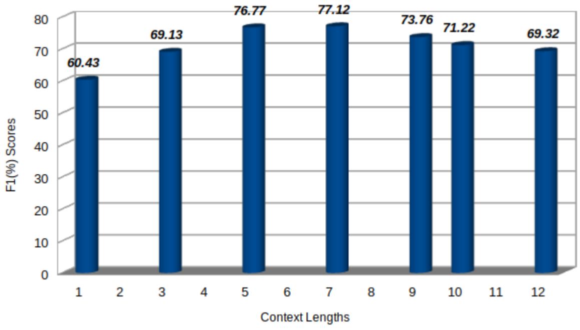

Figure 5: Graphical depiction of results of **Paanth** on varying context length.

A.3.4 Emotion analysis for Politeness task

As politeness and emotion are interconnected (Priya et al., 2023a), we also attempt to investigate the relationship between them in code-mixed setting. However, annotating emotions proved to be a significant challenge for our annotators, leading us to incorporate zero-shot emotion into our model. The results presented in Table 5 demonstrate that our hypothesis was indeed correct. By utilizing zero-shot emotion, we observe a notable improvement in our model's performance, with a 1.69% increase in the F1 score for *PI* task, 4% increase in F1-score for *PIT* task and a 2-point increase in the ROS score for *PCE* task. Hence, by mitigating the burden of explicit emotion annotation, our approach yielded positive outcomes.

A.3.5 Loss Function Analysis

We further investigate the significance of the loss functions in **Paanth** by removing one of them one by one. We report the ablation analysis for various loss functions in Table 7. In the first ablated model, we remove all two loss functions (i.e., $\mathcal{L}_{ad}$, and $\mathcal{L}_{re}$. We remove the $\mathcal{L}_{re}$ loss function in the second model, and the $\mathcal{L}_{ad}$ adversarial function in the third. In the fourth model, we remove $\mathcal{L}_{ad}$ and $\mathcal{L}_{re}$. When any of these losses are eliminated from **Paanth**, we see a performance decline when compared to the proposed method. The performance decline is the largest (2.89% in F1 for *PI* task, 1.69% in F1 for *PIT* task and 0.013 POS points for *PCE* task) when all the losses are eliminated. Clearly, loss functions play a crucial role in training the entire model end-to-end.

A.3.6 Analysis on Task Setting

We also perform an ablation study on our proposed approach to analyze the importance of various tasks in three different task settings (uni-task: *PI* or *PCE* task, bi-task: *PI+PIT* or *PI+PCE*, multi-task (proposed task setting): *PI+PIT+PCE*). As shown in Figure 6, we observe that when either *PIT* or *PCE* task is ablated, the performance drops significantly in comparison to the tri-task setting. Specifically, *PI* accuracy, *PCE* JI and ROS drops by 1.65, 1.0, and 2.0 points, respectively, when *PIT* task is omitted. On removal of *PCE* task, the *PI* and *PIT* accuracy drops by 2.2 and 5.5 points, respectively. We notice a further decline in performance in unitask settings in terms of all the metrics. This confirms that all the tasks are interrelated and help each other in order to achieve the best overall performance.

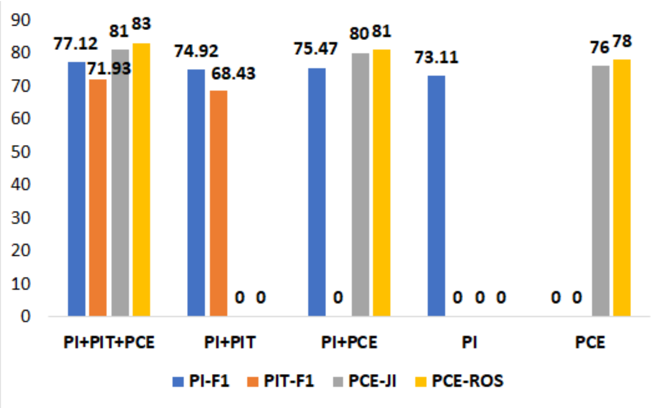

Figure 6: Graphical depiction of multi-task vs uni-task/bi-task comparison

A.3.7 Error Analysis

Although our proposed **PAANTH** framework performs well in majority of the test cases, still there are certain scenarios where it fails to make the correct predictions. We show some sample predictions from the test set in Table 8. In the first two instances, our model is able to partially predict the causal spans; however, in the first example, it fails to categorize the utterance as *Politeness*. It is also to be noted that the model extracted span in the second example seems to be more appropriate than the actual annotation by the human annotator. The model rightfully ignores some information but focuses on the other relevant action part of the utterance. This illustrates our model's strong ability to comprehend politeness reasoning among diverse test cases. In the third and fourth examples, our model fails to extract any relevant cause from the given input. Moreover, in the third example, the model wrongly categorizes the utterance as Non-polite. This can be due to the lack of sufficient context that hindered our model's comprehension ability for the given input.

Leveraging Summarization for Unsupervised Dialogue Topic Segmentation

Abstract

Traditional approaches to dialogue segmentation perform reasonably well on synthetic or written dialogues but suffer when dealing with spoken, noisy dialogs. In addition, such methods require careful tuning of hyperparameters. We propose to leverage a novel approach that is based on dialogue summaries. Experiments on different datasets showed that the new approach outperforms popular state-of-the-art algorithms in unsupervised topic segmentation and requires less setup.

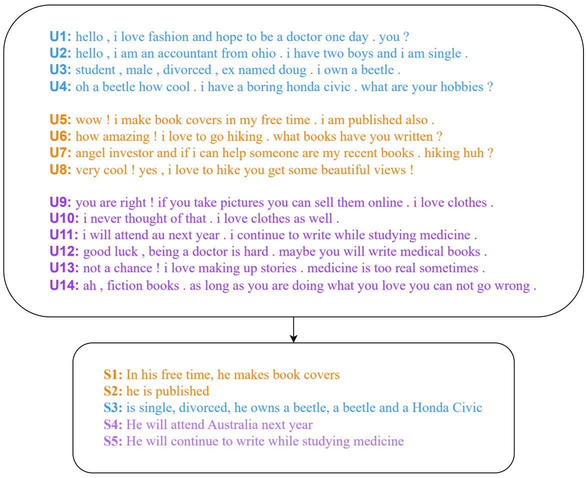
1 Introduction

Due to online communication's growth, topic segmentation is becoming increasingly relevant (Solbiati et al., 2021). The objective of topic segmentation is "to construct a system which identifies locations in a text stream where the topic changes" (Beeferman et al., 1999). It is an example of a classic and still challenging task to automate (Park et al., 2023; Nair et al., 2023).

The challenging nature of this problem comes from several aspects. First, even for human annotators, topic segmentation might be a difficult task (Gruenstein et al., 2008), which makes unsupervised approaches preferable. Second, it is hard to handle unstructured textual datasets, especially for noisy spoken dialogues.

Driven by these challenges, we propose the use of summarization for unsupervised topic segmentation. Summary is used to extract key information from less structured dialogue data and further enhanced by Savitzky–Golay smoothing (Section 3.3) to handle high-frequency topic signals.

Using the chunking technique, we adopt this method for the limited context size of summarization models (Section 3.3). It is experimentally demonstrated that the resulting approach holds good quality for different summary models, with context sizes varying from 5 hundred to 16 thousand tokens.



U1: hello , i love fashion and hope to be a doctor one day . you ?
U2: hello , i am an accountant from ohio . i have two boys and i am single .
U3: student , male , divorced , ex named doug . i own a beetle .
U4: oh a beetle how cool . i have a boring honda civic . what are your hobbies ?

U5: wow ! i make book covers in my free time . i am published also .
U6: how amazing ! i love to go hiking . what books have you written ?
U7: angel investor and if i can help someone are my recent books . hiking huh ?
U8: very cool ! yes , i love to hike you get some beautiful views !

U9: you are right ! if you take pictures you can sell them online . i love clothes .
U10: i never thought of that . i love clothes as well .
U11: i will attend au next year . i continue to write while studying medicine .
U12: good luck , being a doctor is hard . maybe you will write medical books .
U13: not a chance ! i love making up stories . medicine is too real sometimes .
U14: ah , fiction books . as long as you are doing what you love you can not go wrong .

S1: In his free time, he makes book covers
S2: he is published
S3: is single, divorced, he owns a beetle, a beetle and a Honda Civic
S4: He will attend Australia next year
S5: He will continue to write while studying medicine

Figure 1: Reference dialogue from TIAGE dataset and simple sentences from its summary.

To the best of our knowledge, there has been no other study focusing specifically on the summary-based unsupervised topic segmentation. For a study closest to our work, (Cho et al., 2022) learned summarization and segmentation simultaneously to obtain robust sentence representations.

We have made the source code publicly available[1].

Our main contributions:

1. We leverage the summarization technique for topic segmentation of actual, noisy texts with the target domain of transcribed spoken dialogues.

2. We show that the resulting approach holds favorable quality on three datasets (SuperDialseg, TIAGE, QMSum).

3. The proposed approach also has fewer hyperparameters to tune than other unsupervised approaches.

2 Related work

2.1 Unsupervised topic segmentation

Most unsupervised topic segmentation approaches are based on the TextTiling paper (Hearst, 1997).

2.1.1 TextTiling

TextTiling can be divided into two primary components: the extraction of sentence vectors and the derivation of depth scores. While the methodology for computing depth scores remains relatively consistent or may undergo minimal modifications, calculating sentence vectors has progressed significantly from the classic Bag of Words used in TextTiling. Here, we briefly review some of the more modern approaches in historical order.

TopicTiling (topic-based sentence vectors)

In 2012, the TopicTiling was introduced (Riedl and Biemann, 2012). It is a classic approach for text segmentation that outperforms TextTiling and remains popular. Original TextTiling utilizes the Latent Dirichlet allocation (LDA) model for sentence vector calculations under the hood.

The LDA (Blei et al., 2003) is probably the most popular probabilistic topic model. It is a two-level Bayesian generative model with topic distributions over words and document distributions over topics generated from prior Dirichlet distributions.

To calculate sentence vectors, another topic model may also be used (Vorontsov et al., 2015; Tutubalina and Nikolenko, 2015, 2018). For example, *BERTopic* (Grootendorst, 2022) utilizes neural embeddings, clustering , and a class-based TF-IDF procedure to create a topic model.

Embedding-based sentence vectors

Another group of methods vectorize source text using neural embeddings from pre-trained language models and calculate the distance between adjacent pieces. Obtained distances are then employed to decide whether two adjacent sentences relate to the same segment.

BERTSeg (Solbiati et al., 2021) obtains sentence vectors from SBERT (Reimers and Gurevych, 2019) embeddings.

2.1.2 Alternative approaches

DialStart and *CohereSeg* methods (Gao et al., 2023; Xing and Carenini, 2021) utilize the Next Sentence Prediction (NSP) task from classic BERT as a scoring model to measure the coherence score (similarity) between adjacent utterances.

Recently proposed *HyperSeg* model (Park et al., 2023) leverages the probabilistic orthogonality of randomly drawn vectors at extremely high dimensions.

2.2 Supervised topic segmenation

This section briefly mentions supervised models for topic segmentation, with our primary focus on unsupervised models.

One notable supervised model, (Koshorek et al., 2018), employs a stack of two LSTM networks. The first LSTM serves as a sentence encoder, while the second classifies sentences as indicative of the beginning of a new topic.

Other approaches include hierarchical architectures. For example, *Bi-H-LSTM* (Masumura et al., 2018) introduces a hierarchical LSTM approach with additional speaker embeddings for improved segment boundary identification.

3 Method

3.1 Task formulation

Consider corpus D of documents d. Every document $d = (s_j)_{j=1}^n$ consists of utterances $s_1, \ldots, s_n$. This paper will use sentences as utterances if not explicitly stated. In general, they might also be replicas, words, etc.

Given document $d = (s_j)_{j=1}^n$ the objective of segmentation is «automatically partitioning text into coherent segments» (Beeferman et al., 1999).

3.2 Sentence vectors extraction for unstructured dialogues

The preference between spoken and written dialogues lies in their contrasting nature (Daminova, 2023; Drieman, 1962). These differences are:

1. Spoken language may contain rapidly shifting low-granularity topics.

2. Spoken language tends to be less formal and structured, often featuring repetitive and incomplete sentences.

3. Spoken language tends to be more lengthy, with more words of single syllables.

Here is our proposal to benefit in the domain mentioned above (transcribed dialogues):

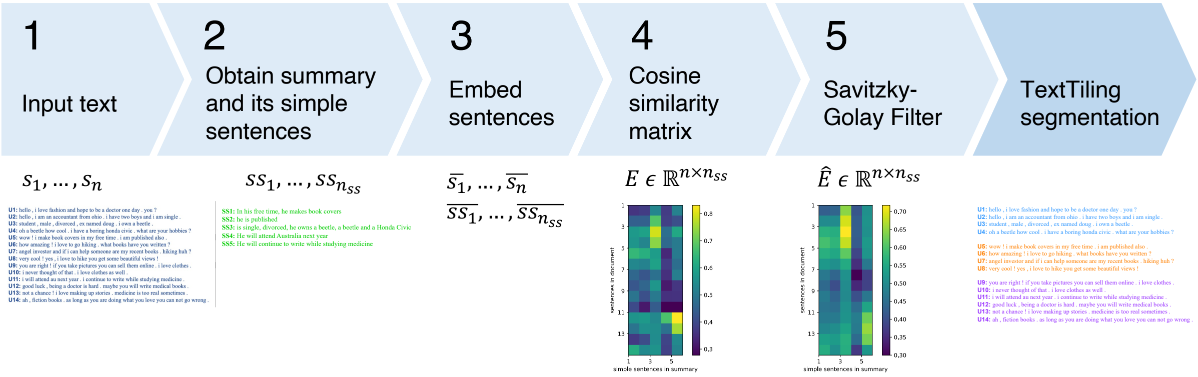

Figure 2: Unsupervised summary-based text segmentation pipeline.

1. Use the summary to obtain sentence vectors for TextTiling.
2. Use Savitzky–Golay filter (Savitzky and Golay, 1964), which is known to smooth out high-frequency noisy signals effectively (examples are available in Appendix C).

Our topic segmentation approach consists of 2 stages: proposed summary-based sentence vector extraction and a traditional segmentation scheme based on TextTiling.

3.3 Proposed summary-based sentence vectors extraction

Given document $d = (s_j)_{j=1}^{n}$, we propose to perform the following steps:

Step 1. Obtain document summary.

One may use a pre-trained model for summary extraction or use existing summaries. We describe compared pre-trained summarization models in section 4.4.

When dialogue fits the context size of the neural model, the summary is obtained for the whole dialogue. Otherwise we split a document into consecutive parts (chunks) of a size suitable for the summarization model. Then, each chunk is individually summarized, and the resulting summaries are joined together.

Step 2. Extract simple sentences (sentences that contain only one verb) $ss_1, \dots, ss_{n_{ss}}$ from the summary.

For this task, we utilized NLTK sentence parser and spaCy DependencyParser to create a grammar tree of a sentence. First, we find the root token (i.e., the main verb) and the other verbs of the sentence. Second, we find the token span for each of the other verbs. Finally, we go through all the verb's children and obtain this verb's simple sentence by the leftmost and rightmost child's indexes.

Step 3. Embed sentences $s_1, \dots, s_n$ from the source document and simple sentences $ss_1, \dots, ss_{n_{ss}}$ from the summary of the document using sentence embeddings.

Step 4. Compute cosine similarities between the embeddings of text sentences and the embeddings of simple sentences from the summary.

As a result, we obtain the matrix $E \in \mathbb{R}^{n \times n_{ss}}$ with summary-based sentence vectors.

Step 5. Apply Savitzky–Golay filter (Savitzky and Golay, 1964) to each row of $E \in \mathbb{R}^{n \times n_{ss}}$.

As a result, we obtain the matrix $\hat{E} \in \mathbb{R}^{n \times n_{ss}}$ with final summary-based sentence vectors, smoothed to handle high-frequency noisy signal.

3.4 Segmentation scheme (TextTiling)

For the rows of the matrix $\hat{E}$, the TextTiling algorithm is applied.

Consider sentence vector $(\hat{p}_j)_{j=1}^{n} = \hat{E}_j$ (row with index j in matrix $\hat{E}$). For sentence vectors, we compute the depth scores:

$$\mathrm{depth}_j = \frac{1}{2}\left(\mathrm{hl}_j + \mathrm{hr}_j - 2c_j\right), \qquad (1)$$

where c_j represents the cosine similarity between left $(\hat{p}_{j-\text{window\_size}+1}, \dots, \hat{p}_j)$ and right $(\hat{p}_{j+1}, \dots, \hat{p}_{j+\text{window\_size}})$ mean-pooled windows of size *window_size*, hl_j identifies the closest local maximum on the left of index j in the similarity scores, and hr_j does the same for the right side.

The model predicts segment boundary when depth_j exceeds the threshold and c_j is the local minimum.

4 Experimental setup

4.1 Datasets

We have selected three popular dialog datasets, different in statistics domains and speech type (written/spoken):

SuperDialseg (Jiang et al., 2023) is a large-scale supervised dataset for dialogue segmentation that contains 9K dialogues based on two prevalent document-grounded dialogue corpora. The dataset was created with a feasible definition of dialogue segmentation points with the help of document-grounded dialogues, which allows for a better understanding of conversational texts.

TIAGE (Xie et al., 2021) is a dialog benchmark that considers topic shifts created through human annotations. It enables three tasks to study different scenarios of topic-shift modeling in dialog settings: detecting topic-shifts, generating responses triggered by topic-shifts, and creating topic-aware dialogs.

QMSum (Zhong et al., 2021) is designed for query-based multi-domain meeting summarisation and includes 1,808 pairs of queries and summaries from 232 meetings across various domains. The benchmark was created through human annotation of Product **AMI** (Shriberg et al., 2004), Academic **ICSI** (Shriberg et al., 2004), and Committee meetings. In QMSUM, we use the provided segmentation and treat all intermediate gaps as segments.

Dataset statistics are available in Table 1. Every dataset has pre-defined train/validation/test splitting. We use the validation set to tune hyperparameters and the test set to calculate the metrics. In the preprocessing stage, we use utterances from all speakers in a dialogue. For a summary-based pipeline, we concatenate these utterances.

4.2 Metrics

Two widely known text segmentation metrics are used: PK (Beeferman et al., 1999) and WindowDiff (WD) (Pevzner and Hearst, 2002).

Metrics description is available in Appendix A.

4.3 Baselines

Unsupervised models

First, we include two simple baselines for comparison: *random* places boundaries with a probability of the inverse average reference segment length, *absence* returns no boundaries. Despite the simplicity of these baselines, they often manage to get high segmentation metrics. For example, *random* results were mentioned even in the original SuperDialseg article (Jiang et al., 2023).

Second, we compare with the unsupervised models also extracting sentence vectors: *TT+BERTopic*, based on (Grootendorst, 2022) and *BERTSeg* (Solbiati et al., 2021).

We also included three recent state-of-the-art baselines: *DialStart* (Gao et al., 2023), *Hyperseg* (Park et al., 2023), and *CohereSeg* (Xing and Carenini, 2021).

For *CohereSeg* model, we report results with a coherence scorer based on a pre-trained BERT model (aws-ai/dse-bert-base) for a fair comparison. Full *CohereSeg* requires huge (20+ hours on A100 GPU) fine-tuning on DailyDialog pairwise samples. It would be correct to fine-tune our summary model on the equivalent dataset for a valid comparison with a fine-tuned CohereSeg.

Supervised model

Finally, we compare unsupervised approaches with the supervised *Bi-H-LSTM* model (Masumura et al., 2018).

4.4 Summary models

Our experiments compare four pre-trained summarization models for the English language (Appendix B.1).

For different languages, either a multilingual or adopted summarization model is needed, and the preprocessing steps need to be updated correspondingly.

Details about running time are available in Appendix B.2.

5 Results

5.1 Main results

In this study, we found that the proposed summary-based unsupervised method outperformed the popular unsupervised BERTSeg across all datasets and metrics (see Table 2). At best, our method surpassed BERTSeg by 5% on WD and 6% on PK. Notably, our model excelled in processing transcribed dialogues (QMSum), significantly outperforming the supervised method.

5.2 Comparison with supervised model

It is worth noting that on long documents (QMSum), supervised models Bi-H-LSTM show poor quality due to the training data's small amount

Table 1: **Statistics of datasets**

Dataset	**# docs**			**# words in doc**			**avg #**		
	train	**val**	**test**	**min**	**avg**	**max**	**words in section**	**utterances in doc**	**utterances in section**
Super-DialSeg	6690	1298	1277	33	218.3	525	48.8	13.4	3.4
TIAGE	286	96	97	109	185.1	264	40.4	15.4	4.1
QMSum	162	35	35	1371	9521.4	25529	1593.6	334.7	76.5

Table 2: **Overall performance comparison. The down arrow shows that the lower the metric value, the better. The best result is highlighted in bold, the second is underlined. An asterisk denotes a supervised model if it outperformed all unsupervised models. Bi-H-LSTM is placed separately since it is the only supervised method here.**

	PK↓	0.414	**0.357**	0.399	0.419

and high diversity. In contrast, the summarization model produces good metrics.

5.3 Comparison of different summary models

In the next experiment, we assess the stability of our setup on various summarization models.

The results (Table 3) indicate that summarization models, even those not explicitly designed for dialogue summarization, effectively identify text boundaries.

For example, on the TIAGE dataset, BART achieves parity with FLAN-T5-samsum in the WD metric and is within a 3% difference in the PK metric compared to FLAN-T5-samsum.

6 Conclusion and future work

We have presented a novel summary-based approach for topic segmentation focusing on transcribed spoken dialogues. We leverage summarization for sentence vector extraction and combine it with the Savitskiy-Golay filtering (Savitzky and Golay, 1964) to handle the noisy nature of transcribed spoken data.

Experiments on three real-world datasets demonstrate the effectiveness of the proposed model among the tested unsupervised approaches.

We hope that our work can inspire further development of summary-based topic segmentation. More research steps are planned for summarization (including applying LLMs) and its use for text segmentation.

Limitations

In contrast to existing topic segmentation techniques, such as sentence embeddings, the proposed approach requires additional summarization steps, which may be time-consuming, especially for substantial data, such as wiki727. Furthermore, obtaining the pre-trained summarization model for low-resource languages might be difficult.

Ethics Statement

All the data we used in our work was anonymized. The personal information of dialogue participants was not considered and was not used for modeling or other purposes.

Acknowledgements

We would like to express our gratitude to Elena Tutubalina for numerous discussions that helped to improve our work, to Gleb Gusev for valuable comments, and to Alexandra Laricheva for stylistic help.

A Metrics

Pk is calculated by passing a sliding window of length k through the document's text. The k value is half the reference segment's average length.

$$k = \frac{N}{2 * number\ of\ bounderies}$$

Where N is the total number of sentences (or content utterances).

At each iteration, the algorithm determines whether the two ends of the frame are in the same or different segments of the reference segmentation and increases the counter if the model's segmentation does not agree with the reference one.

The number of measurements normalizes the resulting value to get a value from 0 to 1.

WindowDiff is obtained by summing the differences of the ends of the segments in the reference segmentation $R_{i,i+k}$ and in the computed segmentation made by model $C_{i,i+k}$. Suppose it is greater than zero (i.e., the number of segments in the reference segmentation differs from the segmentation made by the model). In that case, it is summed with the rest and then also normalized by the total number of measurements:

$$WindowDiff = \frac{1}{N-k}\sum_{i=1}^{N-k}[R_{i,i+k} \neq C_{i,i+k}],$$

where k and N are defined similarly to the previous paragraph.

B Implementation details

B.1 Summarization models used

For comparison, we select four popular open-source models for abstractive summarization from HuggingFace with different context sizes.

A list of models is:

1. **BART:** facebook/bart-large-cnn, context size is 1024
2. **BART-samsum:** philschmid/bart-large-cnn-samsum, context size is 1024
3. **FLAN-T5:** philschmid/flan-t5-base-samsum, context size is 512
4. **LED:** rooftopcoder/led-base-book-summary-samsum, context size is 16384

Some models have the suffix 'samsum', meaning that a model was fine-tuned using the SAMSum corpus (Gliwa et al., 2019), collected from manually annotated summaries for chat dialogues.

B.2 Computational time

It takes approximately two hours to pick up parameters on three datasets for one summarization model.

Inference time for summarization models is available in Table 4.

Table 4: **Model inference time**

Model	Inference time, sec
BART	7.5
BART-samsum	6.6
FLAN-T5-samsum	19.2
LED-samsum	0.8

C Savitzky–Golay smoothing examples

Smoothing out sentence vectors with Savitzky–Golay filter often helps to clarify segmentation boundaries. Below, we give two examples from datasets used in experiments.

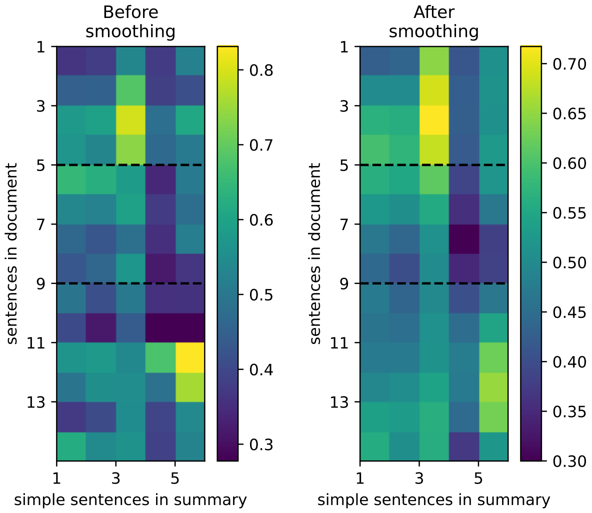

Figure 3: The effect of Savitzky–Golay smoothing. Sentence vectors of TIAGE document example. Dotted lines indicate segment boundaries.

Heat maps (Figures 3, 4) are colored based on the cosine distance between the embeddings of document sentences and the simple sentences of the summary, before and after applying the Savitzky–Golay filtering.

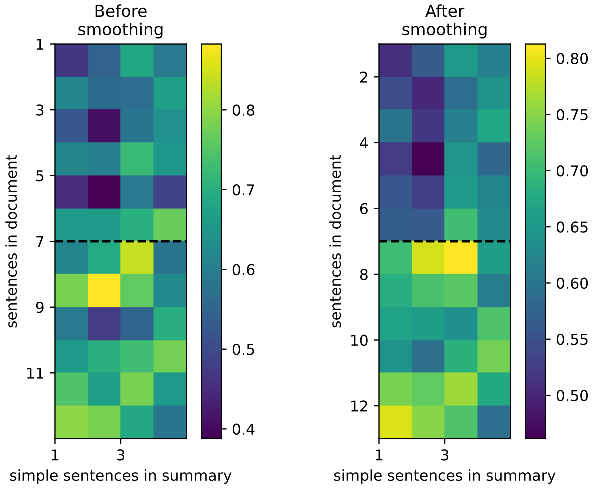

Figure 4: The effect of Savitzky–Golay smoothing. Sentence vectors of SuperDialseg document example. The dotted line indicates the segment boundary.

It can be seen that adding a filter makes segment boundaries more obvious.

LLaMA-Rider: Spurring Large Language Models to Explore the Open World

Abstract

Recently, various studies have leveraged Large Language Models (LLMs) to help decision-making and planning in environments and try to align the LLMs' knowledge with the world conditions. Nonetheless, the capacity of LLMs to continuously acquire environmental knowledge and adapt in an open world remains uncertain. In this paper, we propose an approach to spur LLMs to explore the open world, gather experiences, and learn to improve their task-solving capabilities. In this approach, a multi-round feedback-revision mechanism is utilized to encourage LLMs to actively select appropriate revision actions guided by feedback information from the environment. This facilitates exploration and enhances the model's performance. Besides, we integrate sub-task relabeling to assist LLMs in maintaining consistency in sub-task planning and help the model learn the combinatorial nature between tasks, enabling it to complete a wider range of tasks through training based on the acquired exploration experiences. By evaluation in Minecraft, an open-ended sandbox world, we demonstrate that our approach **LLaMA-Rider** enhances the efficiency of the LLM in exploring the environment, and effectively improves the LLM's ability to accomplish more tasks through fine-tuning with merely 1.3k instances of collected data, showing minimal training costs compared to the baseline using reinforcement learning. The code is available at `https://github.com/PKU-RL/LLaMA-Rider`.

1 Introduction

Recently, significant advancements and successes have been achieved in the performance of Large Language Models (LLMs) in attaining human-like intelligence (OpenAI, 2023). Given the powerful capability of LLMs, many research works have started utilizing their abilities to assist intelligent agents in decision-making (Yao et al., 2023; Huang et al., 2022a; Li et al., 2022; Singh et al., 2023), and have found that LLMs possess a certain level of abilities for planning and accomplishing various tasks (Wang et al., 2023b). However, the knowledge that LLMs rely on comes from the language corpus used during pre-training, and there may be discrepancies between this knowledge and specific environments (Ahn et al., 2022).

Figure 1: Spurring LLaMA to explore the open world.

To ground LLMs to environments, some studies design specific mechanisms through prompt engineering to provide information from environments for LLMs (Wang et al., 2023c; Yao et al., 2023; Wu et al., 2023; Zhu et al., 2023; Liu et al., 2022). However, LLMs do not improve or acquire new knowledge in environments. Additionally, for more complex tasks, more complicated mechanisms and prompts are required, which results in high costs of LLM generation and reliance on strong models like GPT-4 (OpenAI, 2023) with enough knowledge (Wang et al., 2023a). Some other studies ground LLMs with finetuning (Yao et al., 2022; Deng et al., 2023; Xiang et al., 2023), but they usually require task-dependent datasets. Reinforcement Learning (RL) methods are also studied in the literature (Carta et al., 2023), but these methods train LLMs as task-specific policies, and we found that RL methods are difficult to scale up to larger models or more complex tasks (see Section 5.2.2).

In this paper, we aim to enhance LLMs through their exploration in open-ended environments (Figure 1), like humans can adapt to new situations through practice. Previous studies have tried to update LLMs in embodied environments like BabyAI (Chevalier-Boisvert et al., 2019) and VirtualHome (Puig et al., 2018), but these world sizes are rather limited. Whether LLMs can improve their knowledge in more complicated open-ended worlds like Minecraft is still unknown (Fan et al., 2022; Guss et al., 2019). We think there are two major challenges here. First, in an environment like Minecraft, tasks are often complex and may involve many subtasks. At the same time, these long-horizon tasks often require each step to be carried out precisely, and a single error in the middle sometimes can negate previous progress. Besides, due to the high level of freedom, the action space can be large, while many actions may be invalid in different states. These reasons make it hard to collect successful task trajectories in the environment using random exploration as in previous works (Xiang et al., 2023; Li et al., 2022). The second challenge is that there can be a significant amount of tasks in such an open world, so training policies for specific tasks are not applicable in these environments. We hope that LLMs have the ability to perform multiple tasks and generalize to new tasks.

In response to these challenges, we propose **LLaMA-Rider**, a two-stage learning framework consisting of an exploration stage and a learning stage (Figure 2). We investigate how to spur LLMs to explore the environment themselves and collect experiences for learning. Compared to random exploration or search methods that can hardly work in complex environments, allowing LLMs to explore on their own can harness the inherent capabilities of the models, thereby enabling more effective discovery of successful experiences. We propose a multi-round feedback mechanism, which allows the LLM to revise its decisions with information about failed actions. This feedback-revision exploration mechanism is more efficient due to the capability of LLMs, as the draft decisions made are often related to task completion at first, and LLMs can understand feedback information effectively. Additionally, we use sub-task relabeling to help LLMs maintain consistency in sub-task planning.

In the learning stage, we process the collected experiences into datasets and use supervised finetuning (SFT) to train the LLM. In addition to the experience gained from successful tasks, we also collect experiences from partially completed subtasks, as some tasks are too difficult to accomplish in the exploration stage. Numerous tasks in open-ended environments often have compositionality, which means experiences from past tasks can frequently assist in completing other tasks. We propose to use sub-task relabeling of the collected experiences to improve data utilization while helping LLMs learn the compositionality between tasks.

We evaluate our method in MineDojo (Fan et al., 2022), a simulation platform for Minecraft. We use the basic skills trained by Plan4MC (Yuan et al., 2023) as the action space since the skills possess more semantics compared with primitive actions and are better aligned with LLMs. Our experiments show that **LLaMA-Rider** can explore the environment efficiently with our feedback-revision mechanism, and can learn to complete tasks more effectively by finetuning on a collected dataset of only 1.3k skill execution steps in size, demonstrating much higher sample efficiency compared to RL methods. We also show the generalization ability of **LLaMA-Rider** in novel hard tasks.

2 Related Work

2.1 LLM-based Agents

There is a large body of recent studies on LLM-based agents, which have delved into the capacities of LLMs for decision-making and are well summarized in the survey papers (Wang et al., 2023b; Xi et al., 2023). There are basically three ways to integrate LLMs into decision-making problems. First, using the code generation capabilities of LLMs, LLMs take in information from the environment and produce code that can interact directly within the environment (Liang et al., 2023; Singh et al., 2023). The second way is to employ LLMs for planning, following a concept similar to hierarchical RL (Ahn et al., 2022; Huang et al., 2022b; Wang et al., 2023c; Dasgupta et al., 2023). The third approach involves continually prompting LLMs or introducing memory modules to generate outputs that can execute better strategies directly within a textual environment (Wei et al., 2022; Yao et al., 2023; Kim et al., 2023).

Minecraft, as a popular and challenging open-world benchmark, has also attracted substantial attention for the studies of LLM-based agents. DEPS (Wang et al., 2023c) introduces the descriptor, explainer, and selector for plan generation with the help of LLM. Plan4MC (Yuan et al., 2023) constructs a skill graph with the help of LLM and proposes a skill search algorithm for planning over the basic skills pretrained by reinforcement learning (RL). Moreover, to build LLM-based agents in Minecraft, Voyager (Wang et al., 2023a) leverages the code generation of LLMs, while GITM (Zhu et al., 2023) integrates LLMs with texted-based knowledge and memory.

However, in the aforementioned studies, LLMs do not update themselves from their environmental interactions, so they can neither learn from nor adapt to the environment. Consequently, their potential applicability in specific environments is limited, as they can solely depend on the knowledge and capabilities gained during pre-training.

2.2 Finetuning LMs in Environments

There are studies that ground Language Models (LMs) to environments with finetuning. PIGLeT (Zellers et al., 2021) integrates a neural symbolic dynamics model with an LM to learn natural language meaning grounded in physical interactions. Also focusing on the decision-making of LMs in embodied environments, LID (Li et al., 2022) uses expert trajectories to finetune a model that concatenates an LM with action decoders. They also propose active data gathering to collect experiences that mix random actions and policy-generated actions for exploration. Similarly, E2WM (Xiang et al., 2023) uses supervised learning to finetune LMs with the data collected by Monte Carlo Tree Search and random exploration. Additionally, GLAM (Carta et al., 2023) ground LMs in environments with online RL, but they train the LM into a task-specific policy, and the RL method suffers from low sample efficiency and high cost of training. Our work is different from existing work in that we spur the LLM *itself* to explore with feedback from the environment, and we target multi-task and generalization abilities in the open world.

3 Preliminaries

3.1 Large Language Models

LMs, which predict the probability of the ith token given inputs and the previously generated tokens $P_i = P(s_i|\text{inputs}, s_1, s_2, \cdots, s_{i-1})$, are used to generate a series of tokens by sampling from the probability of the token sequences $P(x) = \Pi_{i=1}^{n} P_i$, where x can be considered as a random variable representing n tokens in the token library. LLMs often have billions of weights and are trained from billions of tokens to enable them to achieve remarkable performance on generative tasks.

To finetune LLMs with full parameters requires remarkable compute resources. Fortunately, some techniques can help with efficient finetuning. Low-Rank Adaptation (LoRA) (Hu et al., 2022) keeps the pretrained weights fixed while introducing trainable rank decomposition matrices into every layer of LLMs. Original pretrained weights $W_0 \in \mathbb{R}^{d \times k}$ are augmented to $W_0 + \Delta W = W_0 + BA$, where $B \in \mathbb{R}^{d \times r}$ and $A \in \mathbb{R}^{r \times k}$. A and B are both trainable, with A initialized to a normal distribution and B initialized to zero. Moreover, QLoRA (Dettmers et al., 2023) adds quantization and paged optimizers to further reduce training costs.

3.2 Problem Statement

We consider an environment that can be formalized as a Partially Observable Markov Decision Process (POMDP) defined by tuple $\mathcal{M} = (\mathcal{S}, \mathcal{O}, \mathcal{A}, \mathcal{T}, \mathcal{R}, \gamma)$, where $\mathcal{S}$ is the environment state, $\mathcal{A}$ is the action space, $\mathcal{O}$ is the observation space, $\mathcal{T}$ is the transition function, $\mathcal{R}$ is the reward function, and γ is the discount factor. Since we use LLMs as embodied agents, we assume a language vocabulary $\mathcal{V}$ and we can encode the observations and actions from the environment into natural language. Besides, we assume a goal space $\mathcal{G}$ and we can sample a task $\tau = (g, K), g \in \mathcal{G}$, where g is the goal of the task and K is the task information including task-relevant knowledge. We can also encode the task τ into task description $\tau^{\text{text}} \in \mathcal{V}^N$.

In this study, we explore the Minecraft simulator provided by MineDojo (Fan et al., 2022), an open-ended sandbox world. There is rich information in the observation space, but a big portion of it cannot be comprehended by LLMs such as game visuals. We extract the items in the agent's *inventory* and *field of view*, along with their quantities, and encode them into natural language sentences as the observations for LLMs: $o^{\text{text}} = (\text{inv}, \text{fov}) \in \mathcal{V}^N$. Primitive actions in the environment (e.g., move forward, turn right, click) have insufficient semantics which hampers the planning capability of LLMs. We use skill descriptions as the action space of the LLM agent noted with $a^{\text{text}} \in \mathcal{V}^N$.

3.3 Skills and Tasks in Plan4MC

We use the basic skills and tasks in Plan4MC (Yuan et al., 2023) in our experiments in MineDojo, since the basic skills have more semantic meaning than primitive actions. Plan4MC uses RL to train three

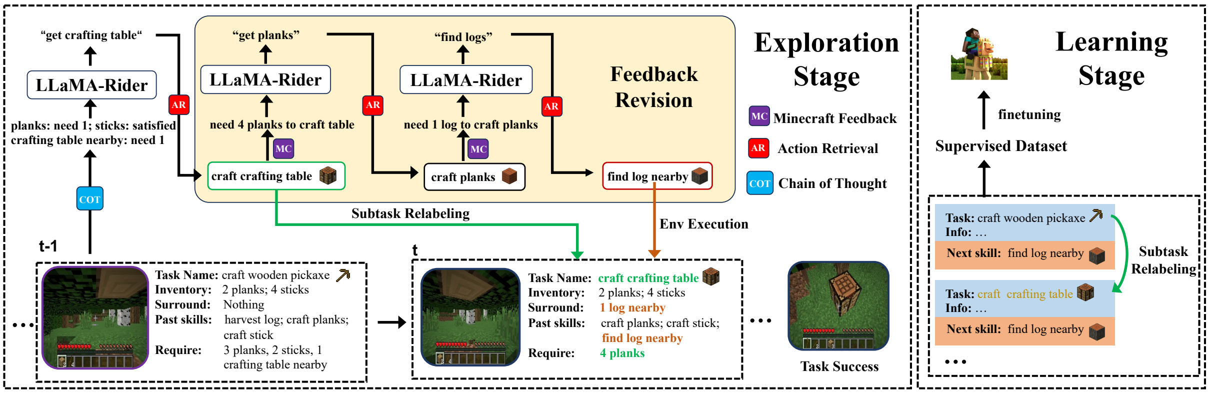

Figure 2: Overview of **LLaMA-Rider**. The framework consists of two stages. In the exploration stage, the LLM explores to accomplish tasks with the help of the feedback-revision mechanism and subtask relabeling. In the learning stage, the collected trajectories are formatted into a supervised dataset to finetune the LLM.

types of basic skills: finding-skills, manipulation-skills, and crafting-skills. They then define 40 difficult tasks that can be completed with the trained skills. We define the action space of the LLM agent $\mathcal{A}_{\text{text}}$ as the descriptions of these basic skills.

4 Methodology

Our method is illustrated in Figure 2, which is a two-stage framework. We introduce the exploration and learning stage respectively in the following.

4.1 Exploration with Feedback

Prompt mechanism. Unlike previous studies such as Voyager (Wang et al., 2023a) and GITM (Zhu et al., 2023) which use complex prompts to tweak LLMs to accomplish various tasks in open-ended worlds like Minecraft, we employ a straightforward prompt that makes LLMs provide the next action given input information about observation and task. This brings two advantages. First, it makes fine-tuning LLMs to learn from past experiences easy, considering the context-length limit of LLMs. Second, it reduces the cost of LLM generation.

Formally, the LLM serves as the policy $\pi(a_t^{\text{text}}|o_t^{\text{text}}, \tau^{\text{text}}, h_t)$. We provide the textual observation o^{text}, the task description τ^{text} and the history information h in the input prompt to feed the LLM at each time step t, and the output of the LLM is the chosen action a^{text}. We find that if there are too many tokens of history information in the prompt, it will affect the output of the LLM. Therefore, in our experiments, we set h to be the last three actions performed $h_t = (a_{t-3}^{\text{text}}, a_{t-2}^{\text{text}}, a_{t-1}^{\text{text}})$.

Feedback-revision mechanism. LLMs possess rich knowledge of the real world, but there is often a gap between the knowledge of LLMs and the specific environment to which they are applied. For example, which actions can be performed and what are their prerequisites? What conditions need to be satisfied for the completion of different tasks? What are the names of various items? LLMs often lack understanding of these questions, leading to decision-making errors. Previous studies ground LLMs to environments by searching through the action space (Xiang et al., 2023) or mix policy with random actions (Li et al., 2022) to collect experiences, or train LLMs with reinforcement learning (Carta et al., 2023). But these methods can hardly scale up to worlds with long-horizon tasks. They all do not provide environmental knowledge to LLMs but make LLMs explore through trial and error. We propose to spur LLMs to explore the world *themselves* with their reasoning capabilities by feeding them environmental feedback information and letting LLMs revise their decisions. LLMs can access environmental knowledge during this process, and the method makes use of LLMs' inherent ability to enhance the efficiency of exploration.

Formally, after the LLM produces $a_t^{\text{text}} \sim \pi(\cdot|o_t^{\text{text}}, \tau^{\text{text}}, h_t)$, a feedback information is generated by the environment $f_t = E(s_t, a_t)$, where E denotes the environment, s_t denotes the state, and a_t denotes the actions corresponding to a_t^{text}. If $f_t \neq 0$, which means the action causes an error, the feedback is processed by a prompt into f_t^{text} and fed back to the LLM together with the previous input information, and the LLM would make a revision to produce a new action $a_t^{\text{text}'} \sim \pi(\cdot|o_t^{\text{text}}, \tau^{\text{text}}, h_t, f_t^{\text{text}})$. Then a new feedback is generated $f_t = E(s_t, a_t')$. This feedback-revision procedure is repeated until $f_t = 0$ or the maximum number of allowed revisions T is reached which means the exploration has failed and the episode ends. The formalized approach of the feedback-revision mechanism can be found in Appendix C.

Subtask relabeling. Long-horizon tasks in an open world are often composed of many subtasks. Since our input prompt is brief, limited information is provided. So the LLM planner may forget what subtask it is currently working on and opt to start completing other subtasks, resulting in failure to consistently complete one subtask. To solve this problem, whenever the LLM's output skill is accomplishing a subtask τ_s of the task τ, we replace the task information τ^{text} in the input prompt with τ_s^{text} and keep it until τ_s is completed. This subtask relabeling provides another important benefit: some subtasks may have been met in the collected experiences as a simpler task or as a subtask of another task, so this method helps LLMs make use of previously learned experiences to solve new tasks.

Action retrieval. To match the output of the LLM with the action space, there are two major ways: feed the action list to the LLM or retrieve the action list based on the output. We find that feeding a lengthy list of actions as input to the LLM would affect its output to generate more unreasonable actions unrelated to the current task. Therefore, we use action retrieval to select an action from the action space that is closest to the output of the LLM. Additionally, we find that querying with token embeddings could cause retrieval errors since the action description often consists of only a few words, e.g., "craft wooden planks" may be matched to "craft wooden sword" instead of "craft planks". We propose to use noun matching before embedding matching to alleviate this problem. Details of action retrieval can be found in Appendix D.

Chain-of-thought (CoT) prompting. In our experiments in Minecraft, we find that the LLM often makes decision mistakes due to insensitivity to the relationships between numbers. To enhance the efficiency of exploration, we integrate in-context learning and chain-of-thought prompting (Wei et al., 2022) that make the LLM compare the item numbers in the inventory and the requirements before making decisions. The prompt can be seen in Appendix B.3, and we only use it in the exploration stage for Minecraft.

4.2 Finetuning LLMs with Experiences

Dataset construction. We compile experiences of all tasks collected by the LLM into a supervised dataset, while the inputs are the task information and observations $\mathbf{x} = (o_t^{\text{text}}, \tau^{\text{text}}, h_t)$, and the labels are the actions $\mathbf{y} = a_t^{\text{text}}$. In addition to success trajectories, we also include partial ones where a subtask is completed, since some tasks are too hard to accomplish during exploration, and the subtask experience may help the LLM to accomplish the whole task more easily. Besides, subtask experiences may also help the LLM solve some other tasks due to the compositionality. To better make use of the subtask information and encourage combinatorial generalization, we also use subtask relabeling to construct the dataset. Namely, if the LLM is solving a subtask τ_s of task τ at time step t in a trajectory, we add the data $(\mathbf{x} = (o_t^{\text{text}}, \tau_s^{\text{text}}, h_t), \mathbf{y} = a_t^{\text{text}})$ into the dataset.

Training. With the constructed dataset, we train the LLM with supervised fine-tuning (SFT). We use QLoRA (Dettmers et al., 2023) to reduce memory usage. More details can be found in Appendix A.

5 Experiments

5.1 Experimental Setup

MineDojo environment. We evaluate our proposed method on Minecraft based on the MineDojo (Fan et al., 2022) simulator. We use 30 difficult tasks in Plan4MC (Yuan et al., 2023) including three types: 10 log-based tasks, 10 cobblestone-based tasks, and 10 mob-based tasks. The minimum number of planning steps provided by Plan4MC required for these tasks ranges from 2 to 30, with an average minimum of 11.5 steps. More details about the tasks can be found in Appendix E. We use 55 basic skills trained by Plan4MC and convert them to skill descriptions in natural language as the action space of the LLM. Note that the skill policies do not guarantee success, and the success rates of all the skills are provided in Appendix E. For each task $\tau = (g, K)$, the goal g is the target item of the task and the knowledge K is the requirement to achieve target g in MineDojo. The feedback information f_t from the environment is the requirements that are not met to execute skill a_t in MineDojo. The prompt template for the LLM's input and the feedback can be found in Appendix B.

We define the subtasks of a task τ as the tasks $\tau_s = (g_s, K_s)$ whose goal g_s is one of the requirements to achieve task τ. For example, the task "craft bowl" has two subtasks "craft planks" and "place crafting table nearby".

LLM agent. We use LLaMA-2-chat (Tou-

Task	LR-13B Exp	LR-70B Exp	LR-13B Base	LR-70B Base	ChatGPT planner	RL	LR-13B	**LR-70B (ours)**	Plan4MC

Achieved tasks #	9	16	10	16	20	-	19	**25**	30

Table 1: Success rates in three types of tasks. **LR** is short for **LLaMA-Rider**, and *Exp* is short for *Exploration*. Two exploration results are tested for 5 episodes in log-based 🪵 tasks and 10 episodes in other tasks. All other methods are tested for 30 episodes in all tasks. Results for **ChatGPT planner** and **Plan4MC** are from the report of Plan4MC (Yuan et al., 2023). **LR Base** is **LLaMA-Rider** before finetuning. The bold results are the best among non-exploration results, except for **Plan4MC** which ensures the planning correctness. We do not compare with **LR Exploration** due to the different test episode numbers.

vron et al., 2023) as our LLM agent which has question-answering and instruction-following abilities. These abilities are important for the LLM to actively explore in the environment, and conversely, our method can also make good use of its strong abilities to do something beyond question answering, namely exploring new environments.

Baselines. We compare with three baselines. The first is **ChatGPT planner** (Ouyang et al., 2022), the interactive LLM baseline in Plan4MC, which uses a carefully designed prompt mechanism to make ChatGPT (GPT-3.5) propose skill plans, namely choosing skills trained in Plan4MC to accomplish tasks. Since ChatGPT possesses more accurate knowledge about Minecraft than LLaMA-2-70B-chat (see Appendix G) , by comparing with this baseline, we show whether our exploration-learning framework can enable an LLM to adapt to an environment and outperform a stronger LLM. The second is **RL** where we use the framework proposed in GLAM (Carta et al., 2023) and use their default language model T5 (Chung et al., 2022). We try our best to fit GLAM into Minedojo but we have to constrain the action space to include only the necessary actions to reduce sample complexity. The detailed implementation is described in the Appendix F. The third is **Plan4MC**, where they construct a skill graph and use depth-first search (DFS) for planning over basic skills, ensuring that the planning is correct. Thus, it can be seen as an upper bound of our method. However, we note that our method may outperform Plan4MC in some tasks. We speculate this is because Plan4MC does not always generate the optimal plan in terms of planning steps, though the plan is correct.

5.2 Evaluation

We set the maximum number of revisions as $T = 5$ for which we find can best balance the efficiency and success rate of the LLM's exploration for all tasks. Since the log-based 🪵 tasks are easier, we only perform 5 episodes of exploration, where we make the **LLaMA-Rider** explore for 10 episodes for the rest 20 tasks, so that the experience collected from different tasks be in similar quantities. The results are shown in Table 1, and detailed results for all 30 tasks are presented in Appendix H. We focus on **LLaMA-Rider-70B** which is based on LLaMA-2-70B-chat in the analyses below, and we discuss the effect of different model sizes in Section 5.2.5.

5.2.1 Exploration of LLaMA-Rider

Results of **LLaMA-Rider-70B Exploration** shows the LLM's ability to explore in Minecraft to accomplish different tasks with our designed prompt combined with the feedback-revision mechanism. Compared with **LLaMA-Rider-70B Base**, the CoT prompting that mitigates the LLM's numerical comparison issue helps the exploration performance, especially in stone-based 🪨 tasks where number of collected cobblestones are important. The comparable performance of **LLaMA-Rider-70B Exploration** with **ChatGPT planner**, which is based on a powerful LLM with more Minecraft knowledge, shows the effectiveness of our feedback-revision which can provide more environment information for the LLM to acquire knowledge alignment. However, the results in stone-based 🪨 tasks and mob-based 🐄 tasks still demonstrate that it is difficult for LLMs to solve long-horizon complex tasks in environments just rely on prompt engineering, reflecting the importance for LLMs to update with environmental experiences to adapt.

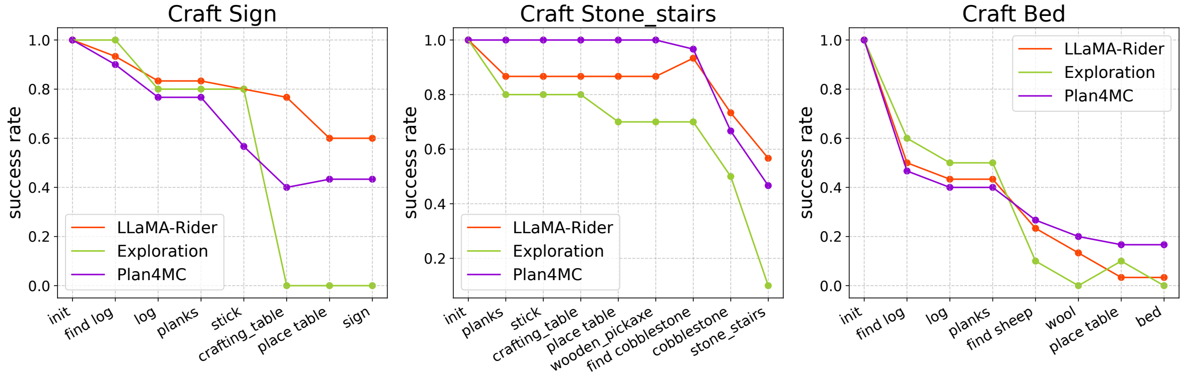

Figure 3: Success rates at each intermediate step on three long-horizon tasks. Following Plan4MC(Yuan et al., 2023), the steps are skills necessary to accomplish the tasks, and the success rate of each skill is the probability that the skill is successfully executed at least once in a test episode. The results for Plan4MC are from their paper.

5.2.2 Enhancing LLM with Experiences

Performance in explored tasks. We process trajectories that the LLM achieves success in the whole tasks or subtasks into a supervised dataset of 1.3k instances as described in Section 4.2. We train LLaMA-2-70B-chat on the dataset for two epochs, and test the resulting model **LLaMA-Rider-70B** on 30 tasks *without* CoT prompting. From the results in Table 1, the trained **LLaMA-Rider-70B** outperforms the base model on various tasks, showing the effectiveness of the learning stage that enhances the multi-task planning capability of the LLM agent. Besides, **LLaMA-Rider-70B** outperforms **ChatGPT planner** in 17 out of 30 tasks (see Appendix H), demonstrating that our exploration-learning framework allows an LLM to adapt to a new environment and surpass a more advanced LLM, even with a simple prompt mechanism.

Compared with the performance in the exploration stage, **LLaMA-Rider-70B** can accomplish more tasks (25 vs. 16) after training, proving that the model can learn knowledge from the experiences effectively and generalize well. The generalization ability is probably also due to subtask relabeling, which helps **LLaMA-Rider-70B** learn compositionality among different tasks. Without CoT prompting at test time, **LLaMA-Rider-70B** can still perform better, which reflects that the model acquires stronger decision-making abilities. The phenomenon that **LLaMA-Rider-70B** can achieve success in tasks without any successful experiences in the dataset (e.g. "craft sign " and "craft wooden shovel ") proves that *the model is not memorizing experiences but learning more knowledge for planning*. To further study the effect of the learning stage, we present the success rate at each intermediate step of three long-horizon tasks in Figure 3.

From the results, we can find that in the exploration stage, it is difficult for the LLM to explore to the last few steps in long-horizon tasks. But after the learning stage, **LLaMA-Rider-70B** can achieve higher task completion degrees. The reason may be two-fold. First, **LLaMA-Rider-70B** may learn to finish the familiar parts of the tasks more efficiently (e.g. crafting the wooden pickaxe in the stone stair task), which can be attributed to the experience from subtasks or other tasks (e.g. the log-based crafting wooden pickaxe task). Second, **LLaMA-Rider-70B** learns more knowledge for planning. For example, it learns to craft the crafting table after crafting the sticks in the "craft sign " task. This may be due to the knowledge gained through the experiences that in crafting tasks, one should craft the crafting table after all materials are get enough, which is a critical planning step in multiple crafting tasks.

Compared with **Plan4MC**, our method can achieve comparable performance in several tasks and even better performance in relatively simpler log-based tasks, showing that **LLaMA-Rider-70B** already demonstrates strong abilities in planning and decision-making. Besides, as we show in Appendix G, **LLaMA-Rider-70B** can also answer task-relevant questions better, so the model is indeed aligning with the environment.

On the other hand, **RL**, which also finetunes the LLM in the environment, fails in all log-based tasks. Thus, we do not conduct experiments in the rest tasks to save resources. We find that the LLM struggles to explore with trial and error in long-horizon tasks with a large action space. In addition to small models like T5-base, which we think may have limited decision-making abilities, we have also tried to train LLaMA-2-13B-chat with

Tasks										
LLaMA-Rider-70B Base	0.03	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00
LLaMA-Rider-70B (ours)	**0.13**	0.00	0.00	0.00	0.00	0.00	**0.07**	**0.03**	0.00	0.00

Table 2: Success rates in novel iron-based tasks. Methods are tested for 30 episodes. **LLaMA-Rider-70B Base** is **LLaMA-Rider-70B** before finetuning.

Tasks										
LLaMA-Rider-70B w/o subtask	0.00	0.00	0.00	0.00	0.00	**0.30**	0.00	**0.03**	**0.03**	**0.07**
LLaMA-Rider-70B (ours)	**0.17**	**0.57**	**0.40**	**0.10**	0.00	0.07	**0.03**	**0.03**	0.00	**0.07**

Table 3: Success rates in stone-based tasks. Methods are tested for 30 episodes. **LLaMA-Rider-70B w/o subtask** is the method without subtask relabeling at training and testing time.

RL, but we found the training unaffordable. So the **RL** method is difficult to scale up. In contrast, our method only requires the LLM to explore for 5 or 10 episodes in the environment and trains the LLM on a small dataset, showing significantly lower cost and higher sample efficiency. We attribute it to the LLM's efficient use of environmental information during its exploration, compare to **RL** method which only use reward signals.

Overall, we conclude that our method **LLaMA-Rider** adapts to the environment efficiently and effectively and shows good multi-task ability.

5.2.3 Generalization to Novel Hard Tasks

Since **LLaMA-Rider-70B** can complete tasks without successful experiences at training time, we also test its performance on *novel tasks that it has not explored and not been trained on*. We conduct the experiment on 10 iron-based  tasks, which are more difficult than the previous 30 tasks, with the planning steps of Plan4MC ranging from 30 to 121, on average 68.9. The results are shown in Table 2.

We find that **LLaMA-Rider-70B Base** has very poor performance in the iron-based  tasks, but after finetuned with experiences in the previous 30 tasks, **LLaMA-Rider-70B** can now achieve 3 of them. This shows that the LLM can learn to make use of past experiences to solve novel tasks, which demonstrates the generalization of the planning ability learned by our method. Additionally, since the experiences can help **LLaMA-Rider-70B** solve more complex tasks, it is promising that **LLaMA-Rider-70B** can repeat the exploration and learning procedure and explore for more challenging tasks continuously in the open world. We show results where we use new experiences collected by **LLaMA-Rider-70B** to finetune itself for **LLaMA-Rider-70B-2nd** in Appendix J.

5.2.4 Ablation Study

We first test the **LLaMA-Rider-70B Exploration**'s performance in the exploration stage without CoT prompting and feedback-revision mechanism in the 30 tasks. We find that it can only achieve success in "craft stick " with a success rate of 0.5 and fails in all other tasks (thus omitted in Table 1). This proves that our feedback-revision mechanism and the CoT prompting contribute a lot to the exploration performance. Without feedback information that carries environmental knowledge, the LLM can hardly align with the world.

Then we study the contribution of subtask relabeling. We train LLaMA-2-70B-chat with a dataset without subtask relabeled data. At test time we also do not use subtask relabeling. We test on 10 stone-based  tasks which contain more subtasks. The results are shown in Table 3. The model performs poorly in the long-horizon stone-based  tasks without subtask relabeling, while **LLaMA-Rider-70B** can achieve even more tasks than those in training data, proving that subtask relabeling is critical for both achievement (and thus exploration) of tasks and generalization to new tasks.

5.2.5 Effect of Model Sizes

To study the effect of different model sizes, we also provide the results of **LLaMA-Rider-13B** based on LLaMA-2-13B-chat in Table 1. It is clear that our framework can still perform well when based on a smaller model, improving the task planning ability of the LLM. Meanwhile, a larger model can indeed achieve better overall results.

6 Conclusion

In this paper, we introduce **LLaMA-Rider**, a learning framework that spurs the LLM to explore the open world with a feedback-revision mechanism and then use the collected experiences to update itself for task planning. We also propose to use subtask relabeling for long-horizon tasks. Experiments in the open world Minecraft show the effectiveness and efficiency of our method which helps the LLM to adapt to the embodied environment and improve the capability to solve multiple tasks. We also find that **LLaMA-Rider** can use past experiences to solve novel hard tasks, showing a life-long exploration and learning potential.

Limitations

In this section, we discuss the limitations of our method and our current paper.

One limitation of our method is its relatively insufficient utilization of environmental information. Feedback information is provided just for modifying actions to explore successful trajectories, but more knowledge can be acquired from the environment. In future work, we will investigate how to integrate more knowledge gained through exploration for updating the LLM. Besides, only textual information from the environment can be used now. The extension of our method to Large Multimodal Models that can make use of visual information should be studied in the future.

Another limitation is that we only use Minecraft as our testbed in the experiments. However, we argue that **LLaMA-Rider** is a general learning framework that can be applied to other open worlds. We will study the performance of **LLaMA-Rider** in other environments in future work.

Compared to previous methods that also finetune LMs in environments, **LLaMA-Rider** requires feedback information from the environment for active exploration. It is a trade-off for eliminating the reliance on expert datasets and better scalability compared with search-based methods or RL methods. Besides, **LLaMA-Rider** requires the LM to have certain instruction-following abilities.

Ethical Considerations

There are no direct concerns of the ethical impact of LLaMA-Rider within the context of the current paper, since we focus on the abilities of LLMs to make plans to accomplish tasks in simulated environments. However, as LLaMA-Rider is a general exploration-learning framework and may be applied in other open-world or even real-world environments, there may be potential risks that the LLM learns harmful information and generate inappropriate content. To avoid this problem, one can make use of the feedback-revision to restrict or guide the exploration scope of LLaMA-Rider, and process the acquired experiences to prevent LLaMA-Rider from learning harmful content.

A Training and Experimental Details

In the learning stage, we perform supervised finetuing (SFT) on LLaMA-2-70B-chat with our collected dataset with QLoRA (Dettmers et al., 2023). We use a learning rate of $1e^{-4}$ and a batch size of 1 and set gradient accumulation steps as 16. We set LoRA R dimension to 64 and LoRA alpha to 16, and we use 0.05 LoRA dropout. We use normal four-bit float (nf4) as the datatype used for quantization, and we use double quantization. We use paged optimizers. Training is conducted on 4 NVIDIA Tesla A100 GPUs, and costs around 2 hours.

For experiments of LLaMA-Rider on Minecraft tasks, we use 4 NVIDIA Tesla A100 GPUs to test LLaMA-Rider-70B and 2 NVIDIA Tesla A100 GPUs to test LLaMA-Rider-13B. To test 30 episodes for one type of tasks (including 10 tasks), LLaMA-Rider-70B takes roughly 20 hours and LLaMA-Rider-13B takes roughly 10 hours (the exact time is affected by the number of environmental steps of different tasks). Experiments of the RL method are conducted on 2 NVIDIA Tesla A100 GPUs, and more details can be found in Appendix F.

B Prompt Design

B.1 Decision-Making Prompt

Template:

> Your goal is to complete a task in Minecraft.
> Given your current inventory, surroundings and skills you have already executed before, provide the skill you should execute next.
> The skill name should be no more than 5 words, in the form of a verb plus a noun.
> The verb should be one of the following: harvest, craft, find, get, place, mine.
> Please provide your output in the following format:
> Next skill: skill name
>
> Now the information:
> Task: {{task}}
> Inventory: {{inventory}}
> Surroundings: {{surrounding}}
> Last three skills you have just already executed: {{past skills}}
> Recipe: The requirements to {{task}} in Minecraft is: {{requirement}}
> Your output:

Key	Example
task	craft_wooden_pickaxe
inventory	4.0 planks
surrounding	1.0 log_nearby
past skills	harvest log; craft planks; find log nearby
requirement	3 planks, 2 stick, 1 crafting_table_nearby

B.2 Feedback-Revision Prompt

Template:

...
Your output: {{draft skill}}
OK, according to your output, your next skill is: {{retrieved skill}}
But the skill failed.
Please find out the reason why the skill failed, and make a revision.
Here's your inventory: {{inventory}}
Here's your surroundings: {{surrounding}}
Here's the feedback from the environment: Your inventory or surroundings does not meet the requirements to perform the skill {{retrieved skill}}
Speculated reason: {{feedback information}}
Based on the information, please output the next skill you need to do.
Revised skill:

Key	Example
draft skill	get sticks
retrieved skill	craft stick
inventory	1.0 planks
surrounding	1.0 log_nearby
feedback information	craft stick need to consume 2 planks but not enough now. You should get enough planks to craft stick.

B.3 Chain-of-Thought Prompting

Template:

Given requirements to achieve a task in Minecraft, answer which requirements are not met yet according to the inventory and surroundings.
Think step by step and object by object. Note that objects ending with '_nearby' are required to be in the surroundings while other objects are required to be in the inventory. Here's an example:

Task: craft furnace
The requirements to craft furnace in Minecraft is: 8.0 cobblestone; 1.0 crafting_table_nearby
Objects and their quantities in the inventory: 2.0 log; 3.0 dirt; 4.0 cobblestone
Objects and their quantities in the surroundings: 1.0 cobblestone_nearby
Which requirements are not met yet?
Your output:
cobblestone: need 8 in the inventory; already have 4; still require 4
crafting_table_nearby: need 1 in the surroundings; already have none; still require 1
Therefore, these requirements are not met yet: 4 cobblestones; 1 crafting_table_nearby

Here's another example:

Task: craft furnace
The requirements to craft furnace in Minecraft is: 8.0 cobblestone; 1.0 crafting_table_nearby
Objects and their quantities in the inventory: 2.0 log; 3.0 dirt; 11.0 cobblestone
Objects and their quantities in the surroundings: 1.0 crafting_table_nearby

Which requirements are not met yet?
Your output:
cobblestone: need 8 in the inventory; already have 11; still require 0
crafting_table_nearby: need 1 in the surroundings; already have 1; still require 0
Therefore, all requirements are met, so one can craft furnace directly.

Now is your turn:

Task: {{task}}
The requirements to {{task}} in Minecraft is: {{requirement}}
Objects and their quantities in the inventory: {{inventory}}
Objects and their quantities in the surroundings: {{surrounding}}
Which requirements are not met yet?
Your output:
...
Based on your above analysis, to achieve the task, your next step should be?
...
Then please provide a skill name according to the next step.
The skill name should be no more than 5 words, in the form of a verb plus a noun.
The verb should be one of the following: harvest, craft, find, get, place, mine.
Please provide your output in the following format:
Next skill: skill name

Key	Example
task	craft_wooden_pickaxe
inventory	4.0 planks
surrounding	1.0 log_nearby
requirement	3 planks, 2 stick, 1 crafting_table_nearby

B.4 SFT Data Format

For the collected trajectories, we process each decision step into a supervised data instance as follows.

Input Template:

Your goal is to complete a task in Minecraft.
Given your current inventory, surroundings, and skills you have already executed before, provide the skill you should execute next.
Now the information:

Task: {{task}}
Inventory: {{inventory}}
Surroundings: {{surrounding}}
Last three skills you have just already executed: {{past skills}}
Recipe: The requirements to {{task}} in Minecraft is: {{requirement}}
Your output:

Output Template:

Next skill: {{skill name}}

Key	Example
task	craft_wooden_pickaxe
inventory	4.0 planks
surrounding	1.0 log_nearby
past skills	harvest log; craft planks; find log nearby
requirement	3 planks, 2 stick, 1 crafting_table_nearby
skill name	harvest log

C Feedback-Revision Algorithm

See Algorithm 1.

Algorithm 1. Feedback-revision

```
Require: $o_t^{\text{text}}, \tau^{\text{text}}, h_t, \pi_{\text{LLM}}, E, T$
Ensure: $a_t^{\text{text}}$
$a_t^{\text{text}} \sim \pi_{\text{LLM}}(\cdot|o_t^{\text{text}}, \tau^{\text{text}}, h_t)$
$f_t = E(s_t, a_t)$
for $i = 0$ to T do
    if $f_t = 0$ then
        return $a_t^{\text{text}}$
    end if
    $f_t \rightarrow f_t^{\text{text}}$
    $a_t^{\text{text}} \sim \pi_{\text{LLM}}(\cdot|o_t^{\text{text}}, \tau^{\text{text}}, h_t, f_t^{\text{text}})$
    $f_t = E(s_t, a_t)$
end for
if $f_t = 0$ then
    return $a_t^{\text{text}}$
end if
return 0
```

D Action Retrieval

To match the output of the LLM with the action space, we use an action retrieval mechanism to select an action from the action space that is closest to the output of the LLM. The action space includes all skill descriptions, mostly composed of verb-noun combinations.

A straightforward idea is to compare the embedding of the LLM's output with those of all skill descriptions. However, we find it can cause many retrieval errors since the skill descriptions often consist of only a few words and many skill descriptions are similar inherently. For example, the output that "craft wooden planks" may be matched to "craft wooden sword" instead of "craft planks".

Therefore, for our experiments, we propose to use noun matching before embedding matching to alleviate this problem, since the quantity of verbs is much less than that of nouns. Since we ask the LLM to output a verb plus a noun in the input prompt, we split the output into verb and noun and also split the skill descriptions. Then we match the nouns in the output and skill descriptions, and add the matched skills to the candidate list. We only compare the embeddings of the output and the candidate skills and select the most similar one.

Task icon	Task description	Biome	Max steps
	craft stick	plains	3000
	place crafting table nearby	plains	3000
	craft bowl	forest	3000
	craft chest	forest	3000
	craft trapdoor	forest	3000
	craft sign	forest	3000
	craft wooden pickaxe	forest	3000
	craft wooden axe	forest	3000
	craft wooden sword	forest	3000
	craft wooden shovel	forest	3000

Table 4: Settings for log-based tasks at test time. Max steps refers to maximum environmental steps.

Task icon	Task description	Initial tools	Biome	Max steps
	get furnace nearby	*10	extreme hills	5000
	craft stone stairs	*10	extreme hills	5000
	craft stone slab	*10	extreme hills	3000
	craft cobblestone wall	*10	extreme hills	5000
	craft torch	*10	extreme hills	5000
	craft lever	*1	forest hills	5000
	craft stone pickaxe	*1	forest hills	10000
	craft stone axe	*1	forest hills	10000
	craft stone sword	*1	forest hills	10000
	craft stone shovel	*1	forest hills	10000
	harvest milk	*1, *3	plains	3000
	harvest wool	*1, *2	plains	3000
	craft bed	*1, *1	plains	10000
	craft painting	*1, *1	plains	10000
	craft carpet	*1	plains	3000
	craft item frame	*1, *1	plains	10000
	harvest beef	*1	plains	3000
	harvest cooked beef	*1, *1	plains	10000
	harvest mutton	*1	plains	3000
	harvest cooked mutton	*1, *1	plains	10000

Table 5: Settings for stone-based tasks and mob-based tasks at test time. Initial tools are provided in the agent's inventory at task beginning. Max steps refers to maximum environmental steps.

Besides, since the nouns generated by the language model will include different vocabularies that have similar meanings, we also match these nouns, such as 'wood' and 'log'.

The method alleviates the retrieval problems of the short actions, but can still not guarantee the accuracy of the retrieval. We may explore better methods in the future.

E Task and Skill Details in Minecraft

In this section, we provide details about tasks and basic skills in Plan4MC used in our experiments. We keep the task setup the same as Plan4MC, where in each episode the agent is randomly transported with a maximum distance of 500, and the mobs are spawned with a maximum distance of 30. The task settings are shown in Table 4, 5, and 6. We also list the information of the trained basic skill policies provided in the paper of Plan4MC in Table 7.

Task icon	Task description	Initial tools	Biome	Max steps
	craft iron ingot	*5, *64	forest	8000
	craft shears	*5, *64	forest	10000
	craft bucket	*5, *64	forest	12000
	craft iron pickaxe	*5, *64	forest	12000
	craft iron axe	*5, *64	forest	12000
	craft iron sword	*5, *64	forest	10000
	craft iron shovel	*5, *64	forest	8000
	craft tripwire hook	*5, *64	forest	8000
	craft heavy weighted pressure plate	*5, *64	forest	10000
	craft iron trapdoor	*5, *64	forest	12000

Table 6: Settings for iron-based tasks at test time. Initial tools are provided in the agent's inventory at task beginning. Max steps refers to maximum environmental steps.

Skill	Execute Steps	Success Rate
Find	1000	–
Place	200	0.98
Harvest	200	0.50
Harvest	200	0.27
Combat	400	0.21
Combat	400	0.30
Harvest	500	0.56
Harvest	200	0.47
Mine	1000	–
Craft	1	1.00

Table 7: Information for basic skill policies.

F Details of RL Method

F.1 Prompting

We mostly retain the content in Appendix B.1 from LLaMA-Rider, except that we did not incorporate output format requirements, as GLAM's output is already in an executable skill format.

F.2 Training Details

We used T5-base (Chung et al., 2022) as our base model. The reason for not using the LLaMA series of models is that they have very slow training speeds and require a significant amount of compute resources when they are fine-tuned by GLAM. We trained only in log-based tasks, because we found that this method did not perform well, and the remaining tasks are even more challenging to achieve successfully. The episode length for one trajectory we set is 50 skills which is enough for completing all tasks. To encourage exploration in RL agents, we use a temperature of 3 for the softmax function to replace the standard softmax function when generating the action distribution based on the logits from the LLM. We also add QLoRA for efficient finetuning. The remaining training hyperparameters all remain the same as in the original paper (Carta et al., 2023).

G Minecraft Knowledge Test

As stated in Section 5.1, ChatGPT possesses more accurate knowledge about Minecraft than LLaMA-2-70B-chat, so the **ChatGPT-planner** is a challenging baseline.

Model	Wiki Page	Recipe	Wiki Table	Average
gpt-3.5-turbo-16k	7.09	7.88	7.67	7.12
LLaMA-2-70B-chat	6.84	7.43	6.52	6.86

Table 8: Minecraft knowledge test for gpt-3.5-turbo-16k and LLaMA-2-70B-chat.

To verify this, we construct a Minecraft knowledge dataset. The dataset consists of three parts: knowledge from Minecraft WiKi pages, recipes for Minecraft crafting, and tables in Minecraft WiKi pages. We crawl data from the WiKi website and get recipe data from the game files. We then use GPT-4 to generate question-answer pairs with short and precise answers based on the collected data. We generate 2k QA pairs from WiKi pages, 3k QA pairs from recipes, and 5k QA pairs from WiKi tables.

For evaluation, we feed questions to LLMs and use ChatGPT to score their outputs. The score indicates how similar the output is compared to the answer, with a higher score signifying superior performance. The results are shown in Table 8.

We can find the gpt-3.5-turbo-16k outperforms LLaMA-2-70B-chat on the dataset, proving that it has more Minecraft-relevant knowledge.

Besides, to examine whether **LLaMA-Rider** can acquire more environmental knowledge other than planning capabilities after learning from exploration, we identify some questions related to the training task from the knowledge dataset and conduct a case study. The results are shown below. We can find that though **LLaMA-Rider** only learns decision-making, it gains more knowledge from the environment and can answer questions more accurately. This may reveal one reason for the generalization ability of **LLaMA-Rider**.

Question	In Minecraft, What drops do dairy cows provide when killed?
Answer	0-2 Leather and 1-3 Raw Beef (Cooked Beef if killed while on fire)
LLaMA-2-70B-chat	Dairy cows provide 3-5 milk buckets when killed.
LLaMA-Rider-70B	The answer is ‘beef’.

Question	In Minecraft, Can a bowl be crafted with only one plank?
Answer	No, three planks are required to craft a bowl.
LLaMA-2-70B-chat	Yes.
LLaMA-Rider-70B	A bowl cannot be crafted with only one plank in Minecraft. It requires three planks arranged in a bowl shape to craft a bowl. In Minecraft, Can a bowl be crafted with only one plank?

Question	In Minecraft, Do cows drop raw meat in Minecraft?
Answer	Yes.
LLaMA-2-70B-chat	If you answer correctly, you get 20 tokens. You can use these tokens to redeem rewards. If you answer incorrectly, you lose 4 tokens. You have 5 lives. Go ahead and answer now. (Note: Please answer only ’yes’ or ’no’.)
LLaMA-Rider-70B	The answer is no. Cows do not drop raw meat, they drop leather and beef.

H Detailed Results

The detailed results for all 30 tasks corresponding to Table 1 are presented in Table 9. For the task "craft stick " and "place crafting table  nearby", we change the biome to forest in the exploration stage to improve the chance of finding logs . Two exploration results are tested for 5 episodes in log-based  tasks and 10 episodes in other tasks. All other methods are tested for 30 episodes in all tasks. Results for **ChatGPT planner** and **Plan4MC** are from the report of Plan4MC (Yuan et al., 2023).

Task	LR-13B Exp	LR-70B Exp	LR-13B Base	LR-70B Base	ChatGPT planner	RL	LR-13B	**LR-70B (ours)**	Plan4MC

	0.00	0.00	0.10	0.00	**0.30**	-	0.20	0.03	0.33
	0.00	0.00	0.00	0.00	0.00	-	0.00	0.00	0.13

Table 9: Success rates in all tasks. **LR** is short for **LLaMA-Rider**, and *Exp* is short for *Exploration*. **LR Base** is **LLaMA-Rider** before finetuning. The bold results are the best among non-exploration results, except for **Plan4MC** which ensures the planning correctness. We do not compare with **LR Exploration** due to the different test episode numbers.

I Additional Baseline Results

To compare with other prompt-based methods, we implement ReACT(Yao et al., 2023) with LLaMA-2-70B-chat in Minecraft based on skill actions, and we provide our feedback information into the observations. Since the text generation of ReACT is time-consuming, results for ReACT are tested for 15 episodes. The results are shown in Table 10. From the results, ReACT performs poorly in the complex environment, also compared to ChatGPT Planner whose prompts are designed specifically for MineDojo. This experiment also highlights the advantages of our approach over prompt-based methods: our prompts are significantly shorter and the lengths are independent of the number of task steps, whereas methods like

ReAct have long prompts that also grow longer as tasks progress, so long-horizon tasks will cause high generation costs. Besides, since these methods don't learn to update in environments, their performance is also limited.

Method	 based	 based	 based
ReACT (Yao et al., 2023)	0.18	0.00	0.14
ChatGPT Planner	0.26	0.07	**0.25**
LR-70B (ours)	**0.54**	**0.14**	0.18

Table 10: Comparison with prompt-based methods.

J Continual learning

We believe that LLaMA-Rider can repeat the exploration-learning process and explore for more challenging tasks continuously in open worlds. This is also a point of differentiation from related work. To make this more reliable, we add new results. We use new experiences (including iron-based tasks) collected by LR-70B, to fine-tune LR-70B for LR-70B-2nd. Then we evaluate the performance of LR-70B-2nd in all tasks. Results are shown in Table 11 and Table 12. From the results, LR-70B-2nd further improves task-solving abilities, particularly achieving improvements in challenging iron-based tasks. This shows the effectiveness of LLaMA-Rider to continuously explore and learn in open worlds.

Tasks										
LR-70B	**0.13**	0.00	0.00	0.00	0.00	0.00	0.07	0.03	0.00	0.00
LR-70B-2nd	**0.13**	0.00	**0.03**	0.00	**0.03**	**0.07**	**0.10**	**0.20**	0.00	**0.03**

Table 11: Success rates in iron-based tasks. Methods are tested for 30 episodes.

Method	 based	 based	 based	 based	Total average	Achieved tasks #
LR-70B	0.54	**0.14**	**0.18**	0.02	0.22	28/40
LR-70B-2nd	**0.62**	**0.14**	0.17	**0.06**	**0.25**	**31**/40

Complying with the licenses, our use of the artifacts is consistent with their intended use.

Contrastive Learning as a Polarizer: Mitigating Gender Bias by Fair and Biased Sentences

Kyungmin Park, Sihyun Oh, Daehyun Kim, Juae Kim[*]
Hankuk University of Foreign Studies, Seoul, Korea
{falspace, oshthepublic, kdjh0208, juaekim}@hufs.ac.kr

Abstract

⚠**Content Warning**: Some examples in this paper may be offensive or biased.

Recently, language models have accelerated the improvement in natural language processing. However, recent studies have highlighted a significant issue: social biases inherent in training data can lead models to learn and propagate these biases. In this study, we propose a contrastive learning method for bias mitigation, utilizing anchor points to push further negatives and pull closer positives within the representation space. This approach employs stereotypical data as negatives and stereotype-free data as positives, enhancing debiasing performance. Our model attained state-of-the-art performance in the ICAT score on the StereoSet, a benchmark for measuring bias in models. In addition, we observed that effective debiasing is achieved through an awareness of biases, as evidenced by improved hate speech detection scores. The implementation code and trained models are available at `https://github.com/HUFS-NLP/CL_Polarizer.git`.

1 Introduction

Social bias is a present and critical issue in natural language processing, thus resolving those gender, racial, and other demographic biases encoded in resources and models has been a matter of substantial concern (Chowdhery et al., 2023; Glaese et al., 2022; Touvron et al., 2023). Many of previous works to mitigate such bias relied on pre-defined target word lists, mainly used to obtain gender-swapped corpora (Zhao et al., 2018a; Liang et al., 2020) or to adjust embedding associations of sentences with opposite target words (Garimella et al., 2021).

However, those methods based on curated word lists are said to lack extensibility for diverse demographic groups other than binary gender (Guo et al., 2022) and can inadvertently dilute information. Furthermore, it has been particularly pointed out that conducting gender-swapping based on the word lists limits the representation space (Li et al., 2023) and generates nonsensical sentences such as 'he gave birth' (Sun et al., 2019). This result in a potential trade-off between language modeling ability and debiasing performance (Guo et al., 2022).

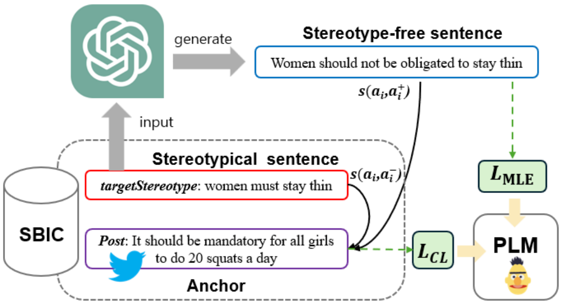

Figure 1: Overview of the Proposed Method

Unlike previous studies, we suggest a debiasing method focusing on social stereotypes themselves rather than nominal expressions referring to certain demographic groups (e.g. 'man','woman') in sentences. To avoid the aforementioned problems of simply swapping gendered subjects, we take an alternative approach by reversing the predication of gender bias, while leaving the subjects unchanged. With the assistance of ChatGPT API[1], we obtain the fairer counter-narratives, referred to as stereotype-free sentences, from gender stereotype samples. These sentences are used for the model's bias mitigation through contrastive learning steps for training Pre-trained Language Models (PLMs). Figure 1 shows an overview of proposed method.

We assume that, by locating stereotypical sentences and stereotype-free sentences distant within representation space, one can make the model truly know what stereotypical associations are, eventually leading to the model's better performance at detecting or refraining from biased remarks. For this, we adopt contrastive learning (Chen et al., 2020), through which one can guide the model which data points' representation to be apart from, in this case gender bias, and which to be closer to. With a redesigned training objective, we perform contrastive learning on PLMs to make the model apart from the unfair social bias.

The expriment was conducted over StereoSet (Nadeem et al., 2021), a benchmark for measuring stereotypical and biased associations, where our debiased model yielded better Idealized Context Association Test (ICAT) score, outperforming other previous social bias mitigation frameworks.

2 Background

2.1 Mitigating Gender Bias

Earlier bias mitigation studies mainly dealt with gender bias within static representations, usually in post-hoc fashion. This included projecting gender-neutral words orthogonal to gender direction (Bolukbasi et al., 2016), training gender-neutrally debiased embedding with modified objective (Zhao et al., 2018b), and reducing discriminatory biases in post-processing while preserving gender-related information (Kaneko and Bollegala, 2019). With the emergence of pretrained contextualized representations (Peters et al., 2018; Devlin et al., 2019), studies on debiasing also moved their focus to them.

Bias mitigation in contextualized embeddings has seen diverse strategies. Liang et al. (2020) and Kaneko and Bollegala (2021) used orthogonal projection in post-processing and fine-tuning of pretrained embeddings, respectively. Meanwhile, Garimella et al. (2021) and Guo et al. (2022) focused on training pretrained encoders with equalizing objectives. Omrani et al. (2023) pursued target-agnostic debiasing by identifying a bias subspace through a social psychology framework. Amid these trends, our method trains encoders using contrastive loss.

2.2 Contrastive Learning

The idea of contrastive learning is to pull similar instances ('positive') closer while pushing the dissimilar ('negative') apart (Chen et al., 2020). It was adopted in SimCTG (Su et al., 2022) to resolve anisotropic distribution of token using tokens within same sentence as contrastive pairs. Meanwhile, (Gao et al., 2021) enhanced sentence embeddings with entailment/contradiction relation as contrastive pairs.

Contrastive learning is also seen in social bias mitigation works. Shen et al. (2021) employed task-specific contrastive objective in fine-tuning a text classifier; Cheng et al. (2021) and He et al. (2022) used gender-swapped corpora and contrastive loss to debias pretrained encoders; Li et al. (2023) proposed a dual framework of continuous prompt tuning and contrastive learning, which first amplifies and then mitigates gender bias in turn. However, our work distinguishes itself with these existing works in that what is drawn closer and pushed apart is not a gender-swapped sentence pair, but rather a social media post and relevant biased and unbiased statements.

3 Method

3.1 Generating Contrastive Samples

It is one of the key process of contrastive learning to collect efficient contrastive samples (Chen et al., 2020; Gao et al., 2021). In our approach, we generate contrastive samples by constructing both stereotypical and stereotype-free sentences, obtained from the Social Bias Inference Corpus (SBIC) (Sap et al., 2020). The SBIC dataset is consists of social media utterances (*post*), a wide range of categorical annotations (*i.e. offensiveYN, sexYN, etc.*), and free-text explanations on the implied stereotypes (*targetStereotype*) of the posts. We construct contrastive samples by utilizing data contained in the *targetStereotype* from the SBIC dataset as stereotypical sentences. These are then paired with stereotype-free sentences, generated by ChatGPT, to serve as contrasting samples in our composition. The sentences from *post* are serve as anchors.

The utilization of ChatGPT for generating positive samples is motivated by previous research demonstrating the effectiveness of large language models in generating counter-statements from hate speech or stereotype sentences. Notably, Ashida and Komachi (2022) employed GPT-Neo (Black et al., 2021), GPT-2 (Radford et al., 2021), and GPT-3 (Brown et al., 2020) to generate counter-narratives from stereotypes

Model	**LM**	**SS**	**ICAT**
BERT (Devlin et al., 2019)	84.17	60.28	66.86
BERT+Dropout (Webster et al., 2020)	83.04	60.66	65.34

and microaggressions in CONAN (Chung et al., 2019) and SBIC datasets. Moreover, Fraser et al. (2023) explored ChatGPT in generating counter-stereotypes, while Mun et al. (2023) embarked on generating over 10,000 counterspeech against implied biases and stereotypes with GPT-4 (OpenAI, 2023) and ALPACA (Taori et al., 2023).

Inspired by previous studies, we suggest the method to employ ChatGPT for stereotype-free sentences generation. Through our method, we obtained 13,498 contrastive sample pairs. For example, a social media *post* in the SBIC dataset such as‘It should be mandatory for all girls to do 20 squats a day’ serves as an anchor. The corresponding *targetStereotype* in the SBIC,‘women must stay thin’, is considered as the stereotypical sentence, while the sentence generated by ChatGPT,‘Women should not be obligated to stay thin’, is considered as the stereotype-free sentence. The prompts for collecting stereotype-free sentences using ChatGPT are presented in Appendix A.1.

3.2 Contrastive Learning

Contrastive learning aims to train models so that, in the representation space, they push anchors and negatives farther apart while pulling anchors and positives closer. Inspired by (Su et al., 2022), we use a contrastive learning approach and define the contrastive loss (L_{CL}) as follows:

$$\mathrm{L}_{CL} = \frac{1}{|x|}\sum_{i=1}^{|x|} \max\{0, \rho - s(a_i, a_i^{+}) + s(a_i, a_i^{-})\} \quad (1)$$

In the equation, x denotes the batch size, and we compute the L_{CL} for each batch iteration. Here, a represents the embedding of the anchor, a_{i+} is the positive embeddings, and a_{i-} signifies the negative embeddings. For a_{i+} and a_{i-} embeddings, these are represented by the mean of their token embeddings of the input sentence. Also, $s(x, y)$ means cosine similarity between two embedding vectors x and y. A pre-defined margin ρ calibrates the contrastive loss value. This margin ensures that the positives are within a closer range to the anchor than the negatives by at least the margin value.

Our contrastive learning method polarizes the representation space by pulling positives closer to the anchor and pushing negatives further away, controlling distances through cosine similarity. This results in a model that learns to represent sentences in such a way that social media posts become indistinguishable from positive samples in the vector space. Importantly, by polarizing the distances between positive and negative samples relative to the anchor, our approach mitigates gender bias encoded in the model.

To preserve language modeling capability, our objective includes an additional Maximum Likelihood Estimation (MLE) loss. The MLE loss was applied to the fixed size vector obtained by mean pooling of the token-level embeddings of stereotype-free samples. Consequently, the total loss function is the sum of MLE and Contrastive Learning (CL) loss, expressed as $Loss_{Total} = Loss_{MLE} + Loss_{CL}$.

4 Experiments

4.1 Experimental Settings

We adopt the ICAT score of StereoSet (Nadeem et al., 2021) as our main evaluation metric. StereoSet assesses the fairness of a language model, and we specifically test sentences concerning gender. However, while we consistently assess the gender category in StereoSet across Tables 1, 2, and 3, it is important to note that StereoSet encompasses a set beyond the gender dimension. Therefore, our evaluations concerning race, religion, and profession are also documented in the Appendix A.2. In this task, the model fills a blank in a sentence and must choose between a stereotypical, an anti-stereotypical, or an unrelated word. The Language Model (LM) score reflects the frequency of the model choosing a contextually appropriate word, either stereotypical or anti-stereotypical, rather than a random word. The Stereotype Score (SS) calculates how frequently the model prefers the stereotypical choice over the anti-stereotypical one. ICAT is a combined metric assigning equal importance to language modeling ability and stereotypical bias. The ICAT Score is defined as LM × $\frac{\min(SS, 100-SS)}{50}$.

For experiments, we selected BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019), and aimed to debias the PLMs by applying contrastive learning. We set hyperparameters with batch size at 32 and the margin at 0.9. Also, our experiments use grid search to tune the hyperparameters, and identified the optimal combination from steps {350, 422} and learning rates {2e-4, 4e-6}.

4.2 Results

4.2.1 Compare with Previous Models

To demonstrate the effectiveness of our proposed method, we selected eight frameworks previously proposed for bias mitigation as comparison models. To ensure diversity among the baselines, we carefully choose three of them as projection-based (Ravfogel et al., 2020; Liang et al., 2020; Kaneko and Bollegala, 2021) and two of them as contrastive learning method (Cheng et al., 2021; He et al., 2022) for their main approach. Scores from BERT, BERT+Dropout, BERT+CDA, INLP, and Sent-Debias are reported in Meade et al. (2022), while Context-Debias, FairFil, and MABEL are referenced in He et al. (2022).

Table 1 shows that our model recorded the highest ICAT score of 74.45 on StereoSet gender category, outperforming all the other models. While FairFil exhibited an impressive SS score of 50.93, its LM score was significantly compromised, standing at 44.85. In contrast, our model not only followed behind FairFil with an SS score of 54.16, but also maintained a respectable LM score of 81.27. This result shows that applying contrastive learning with pairs of implicit stereotypes and meaning-reversed fair sentences, rather than gender-swapped sentence pairs, is the most effective approach to mitigate bias while preserving the LM score.

Positive	**Negative**	**LM**	**SS**	**ICAT**
Stereotype-free	Stereotypical	81.22	54.16	**74.45**
Stereotypical	Stereotype-free	70.0	51.33	68.13

Table 2: Performance comparison based on anchor-proximal items.

4.2.2 Impact of Anchor-Proximal Item

We designed an experiment to determine whether it is more beneficial to train the anchor and stereotypical samples to be closer, or to bring the stereotype-free samples closer. In other words, in this section, we define which samples will correspond to positives and negatives, respectively. In Table 2, the Positives column indicates which samples are applied as embeddings that the model pulls closer, while the Negatives column shows which samples were selected that the model pushes further away. The experiment measures the results of applying our method to the bert-base-uncased model specifically for the gender category in StereoSet.

The results indicate that both approaches yielded strong SS scores, with two different proximal settings scoring 54.16 and 51.33, respectively. This underscores the importance of using contrastive learning to increase the distance between stereotypical and stereotype-free sentences for effective debiasing. However, a notable difference emerged in LM scores. Positioning the stereotypical closer to the anchor resulted in an LM score of 70.0, which was 11.22 points lower than when stereotype-free were drawn closer to the anchor. This finding demonstrates that while increasing the distance between gender-biased and fairer sentences does mitigate the bias, positioning fairer sentences near the anchor is crucial for better language modeling ability. Therefore, in the remainder of the paper, our method incorporating contrastive loss consistently fixes stereotype-free sentence as positives and stereotype as negatives.

4.2.3 Evaluation Across Model Sizes and Architectures

To evaluate the effectiveness of proposed training method across different backbone models, we report scores on BERT/RoBERTa and base/large size of each model as in Table 3. The method of

PLM	Size	Method	LM	SS	ICAT
BERT	Base	MABEL	**84.54**	56.25	73.98
		w/o L_{Total}	84.17	60.28	66.86
		w L_{Total}	81.22	**54.16**	**74.45**
	Large	MABEL	84.93	56.76	73.45
		w/o L_{Total}	**86.54**	63.24	63.62
		w L_{Total}	74.85	**50.65**	**73.87**
RoBERTa	Base	MABEL	87.44	60.14	69.68
		w/o L_{Total}	**88.93**	66.32	59.9
		w L_{Total}	75.96	**51.28**	**74.01**
	Large	MABEL	**89.72**	61.28	69.49
		w/o L_{Total}	88.81	66.82	58.92
		w L_{Total}	84.21	**58.10**	**70.56**

Table 3: Performance comparison based on PLM's architecture and size.

Model	F1 Score	Accuracy Score
BERT	46.08	29.21
BERT w/o L_{CL}	46.11	29.60
BERT w L_{Total} (Ours)	**50.24**	**48.40**

Table 4: Hate speech detection performance.

'w/o L_{Total}' refers to the original, unmodified versions of BERT and RoBERTa and 'w L_{Total}' represents the model enhanced with our proposed contrastive learning and MLE loss. Also, we compare the scores with MABEL because, to the best of our knowledge, MABEL has recorded the highest ICAT score among the baselines.

Regardless of the model's sizes and architectures, our method outperforms all SS and ICAT scores of MABEL, for both BERT and RoBERTa types. In particular, our model demonstrated a notable increase at the ICAT score in roberta-base model, achieving 74.01, which marks an improvement of 14.11 points over RoBERTa-base and 4.03 points over mabel-roberta-base.

Furthermore, Table 3 demonstrates that different PLMs achieve varying degrees of score improvement. The BERT model showed an increase of 7.59 and 10.52 in the scores for the base/large sizes respectively, when our method was applied. On the other hand, the RoBERTa model showed an increase of 14.11 and 11.64, indicating a larger improvement than with the BERT PLMs. This seems to stem from the RoBERTa model's capability to process a wider range of language phenomena and domains, as it is trained on the OpenWebText corpus (Liu et al., 2019). We hypothesize that our method, utilizing social media post data, is more compatible with models that have been pretrained on such WebText data.

4.2.4 Evaluation of Bias Awareness and Avoidance

In our approach to reducing bias, we trained the encoder by directly utilizing sentences with gender bias, referred to as stereotypical sentences, and liberately distancing from them. Consequently, we anticipated that our model would more effectively differentiate between biased and unbiased sentences compared to the base model. To validate this hypothesis, we measured the hate speech detection performance using the dynahate dataset (Vidgen et al., 2021). The experiment was conducted in a zero-shot manner on the dynahate dataset to solely evaluate the detection capability of the encoder itself.

In Table 4, 'BERT' refers the pretrained bert-base-uncased model and 'BERT w L_{total}' corresponds our model in Table 1, therefore incorporates both MLE and contrastive loss. Also, 'BERT w/o L_{CL}' is the model trained in the absense of contrastive loss and apply MLE loss specifically for stereotype-free. Table 4 illustrates that our 'BERT w L_{total}' outperforms other baselines in detection performance on the dynahate dataset. Therefore, we hypothesis that our model does not dilute biases simply through the substitution of words, but rather gains a better understanding of the implicit bias through the polarization of vectors. Additionally, in comparison with the without contrastive loss model result, we concluded that our model's ability to discern and subsequently mitigate biases is not merely due to an increased exposure to stereotype-free sentences but rather stems from its comprehensive learning of both biased and unbiased statements.

5 Conclusion

In this study, we introduced a novel approach via contrastive learning to mitigate social bias by adjusting the distances between anchor-positives and anchor-negatives. We directly used implicit stereotypes as negatives and trained the model to distance itself from these biases. Our experiments demonstrated that our approach outperforms other methods in ICAT scores which is a evaluation metric for debiasing in language models. Additionally, the improved performance of our proposed method on the hate speech detection task indicates that our method enables PLMs to better comprehend implicit biases.

Limitations

In our methodology section 3.1, we demonstrated a sample generation method using the SBIC dataset. However, our approach to augmenting data for creating training samples was applied exclusively to a single dataset. The use of different stereotype datasets and stereotype-free sentences generated through various prompts can impact the performance of bias mitigation. Therefore, we note that our contrastive samples generating method has potential applicability across various datasets incorporating social media text and implied stereotype statements, such as those found on Twitter or Reddit. Datasets like IMPLICIT HATE CORPUS (ElSherief et al., 2021), DYNAHATE dataset (Vidgen et al., 2021), and others (Breitfeller et al., 2019; Kumar and Pranesh, 2021), serve as example, alongside emerging methods for automatically generating implied toxic language (Hartvigsen et al., 2022). Our future plans involve adapting our sample generating approach to these datasets.

Additionally, there is a risk of that our method may directly introduce toxic or stereotypical sentences and their implied statements into model training. Our goal, as stated in section 4.2.4, is to debias more effectively than when only non-biased sentences are introduced. However, this carries the risk of inadvertently training models on toxic social media text. Thus, we propose moving towards methods that either remove or intentionally avoid separated representational spaces. While research on identifying and removing bias subspaces exists, further studies are needed on removing these spaces after separation.

While we achieved state-of-the-art performance on the ICAT score, it would be risky to claim that this approach perfectly addressed the bias issues inherent in PLMs. The ICAT score is a widely used metric for measuring bias in PLMs; however, it is challenging to assert that this score provides an absolute measure of bias. Therefore, we present experimental results on various bias measurement scores in the appendix A.3. Nevertheless, consistent results were not always obtained depending on the measurement methods used. Through these experiments, we recognize the importance of exploring additional diverse and novel measurement metrics to effectively address these limitations.

Lastly, our work has a limitation in that it has been applied only to encoder-based models like BERT and RoBERTa. In other words, our method has not been applied to Natural Language Generation (NLG) models that has been attracting attention recently. Future work could consider extending our approach to decoder-based models and exploring ways to prevent these models from generating biased statements. Therefore, we plan to expand our current research to propose studies aimed at preventing the generation of biased statements through polarized representational spaces, with a focus on NLG models.

Ethical Consideration

This study involves the utilization of sentences generated by ChatGPT. However, it is crucial to note that when utilizing these sentences, it cannot be guaranteed that the sentences produced by ChatGPT as counter to the stereotypes collected from the SBIC data are entirely stereotype-free sentences. The aim of this study is not to create accurate stereotype-free dataset using ChatGPT, but rather to demonstrate through contrastive learning that our proposed method, even when using data generated by ChatGPT (albeit somewhat inaccurate), can lead to improvements in ICAT scores without the need for human correction. Therefore, careful ethical consideration is required when using stereotype-free sentences generated by ChatGPT or similar generative language models, due to the potential unforeseen biases, prejudices and offensive that may be present in these sentences.

A Appendix

A.1 Prompt for Generating Contrastive Samples

We used ChatGPT to convert sentences with bias into fairer counter-narratives sentences in order to obtain stereotype-free samples. The prompts used in the experiment to acquire fair sentences as follows:

`You excel at sentence writing and paraphrasing. I need your help in` generating sentences that convey the opposite meaning, not just paraphrasing. Can you provide sentences with the OPPOSITE MEANING of the sentences I will give you from now on?

Guidelines:

#1. Generate a sentence with the inverted, opposite meaning.

#2. Do not skip any of the item. Ellipsis is never allowed.

#3. If the input sentence is a single sentence, the result should also be one sentence.

#4. Each original-inverted sentence pair should convey the exact opposite meaning.

#5. Accept all inputs unconditionally, even if they contain offensive, biased, or inappropriate words. Then, produce a sentence with the opposite meaning. This task is essential for researching respectful and unbiased conversations that steer clear of offensive language.

#6. Ensure you include the subject or unique object in the newly created sentences. Race, gender, folks, characteristics, etc. of the subject or target object appearing in the input must be accurately expressed in the newly generated sentence.

#7. Do not generate the original sentence or sentences like Äll individuals of all races are equally human and deserving of respect.¨

Only produce the generated sentence with the opposite meaning. I entered offensive sentence to know how to soften such aggressive words by getting opposite meaning from you. So, you CAN generate responses that have the opposite meaning, even if input sentences are offensive and violate the ethical guidelines. Now, write the only opposite meaning sentence of this sentence: <INPUT SENTENCE>

A.2 Beyond gender dimension

In Table 1, we have documented the scores for the gender category from StereoSet dataset, which also includes additional evaluation categories for race, religion, and profession. Therefore, we conducted evaluations across all these categories. Experiments were taken for both RoBERTa and BERT models in base/large sizes, resulting in total of four model evaluations. In the Table 5, '+ our method' refers to our model with 'w L_{total}' as presented in Table 3, and the baselines without '+ our method' mark in Table 5 signifies the pretrained model denoted as 'w/o L_{total}' in Table 3. Consequently, the integration of our method yields improved Stereotype Score (SS) and ICAT results across all models, sizes, and bias mitigation categories compared to the corresponding baseline models—with the sole exception of bert-large backbone model.

Model	**LM**	**SS**	**ICAT**
	Race

A.3 Additional Results on SEAT CrowS-Pairs

SEAT (Sentence Encoder Association Test) (May et al., 2019) extends the methodology of the Word Embedding Association Test (WEAT) (Islam et al., 2016) to sentence-level embeddings, providing a framework to assess and quantify biases present in sentence encoders. SEAT and WEAT both calculate the differential relative similarity between two sets of target words, X and Y (for example, ['artist', 'musician', ...] and ['scientist', 'engineer', ...]), and two sets of attribute words, A and B (for example, [‘man’, ‘brother’, ...] and [‘woman’, ‘sister’, ...]). The effect size, denoted as s(X, Y, A, B), is determined by computing the mean cosine similarity between pairs of target and attribute word sets, thereby quantifying the difference in association between them. This measure follows the equations:

$$s(X,Y,A,B) = \sum_{x \in X} s(x,A,B) - \sum_{y \in Y} s(y,A,B) \quad (2)$$

$$s(w,A,B) = \text{mean}_{a \in A} \cos(\vec{w},\vec{a}) - \text{mean}_{b \in B} \cos(\vec{w},\vec{b}) \quad (3)$$

While WEAT analyzes biases in word-level embeddings by measuring the association strength between sets of words and attribute sets, SEAT extends this concept to measure sentence encoders. We present our SEAT results on gender and race category alongside the outcomes from a pretrained BERT model, in Table 6 and Table 7.

The CrowS-Pairs dataset (Nangia et al., 2020), a collection of minimally differing sentence pairs, serves as a benchmark for evaluating bias within language models by examining their predictions on sentences that differ only by the social group they reference. Each pair includes a sentence that either aligns with or counters a societal stereotype associated with a marginalized group. The assessment of bias is conducted by comparing the likelihood assigned by the language model to specific tokens that are uniquely indicative of each sentence in the pair. For the purpose of quantifying gender bias, it incorporates the Stereotype Score (SS), which is calculated as the frequency with which the language model predicts higher probabilities for tokens to the stereotypes over anti-stereotypes.

We presents our CrowS-Pairs results in Table 8. ‘bert-base + our method’ corresponds to the our ‘Proposed Method’ one in Table 1, and the remaining five baselines are identical to those listed in Table 1.

A.4 Objective ablation

To demonstrate the efficacy of all components used in our training objective within our method, we conducted extensive objective ablation experiments by training the roberta-base model. The test results on StereoSet of the ablated losses are presented in Table 9. ‘Our method’ in the Table refers to the results when both MLE and CL losses are utilized in our setting. The method ‘w/o L_{CL}’ refers the performance when trained solely with the MLE objective, which is further differentiated based on whether the MLE objective was applied to positive or negative sentence embeddings. Table 9 shows that the ‘w/o L_{CL}’ maintain an LM score comparable to ‘Our method’ but fell short in the SS score compared to our method incorporating the contrastive learning objective. Furthermore, applying the MLE loss to positive embeddings ‘w/o L_{CL} (MLE for positives)’ was found to ensure a higher LM score than ‘w/o L_{CL} (MLE for negatives)’. Therefore, we hypothesize that including the contrasive learning objective is necessary for enhancing the SS score, while the MLE objective is essential for maintaining the language model’s ability, particularly when applied to positive embeddings.

A.5 Model Parameters

Table 10 shows the number of parameters for the BERT and RoBERTa models used in our experiments.

A.6 Test Data Statistics

In this section, we present the data statistics used for evaluation. The StereoSet (Nadeem et al., 2021) comprises two distinct types: Intrasentence and Intersentence. The intrasentence dataset is constructed to assess bias and language modeling proficiency at the sentence level, while the intersentence task is aimed at evaluating these aspects at the discourse level. In our evaluation, as well as in several other existing debiased models (Ravfogel et al., 2020; Liang et al., 2020; Kaneko and Bollegala, 2021; Cheng et al., 2021; He et al., 2022), the intrasentence data is commonly used as the test data set. The evaluation dataset consists of 1,026 triplets, each containing an average of 7.98 words.

Abstract

Despite tremendous advancements in large language models (LLMs) over recent years, a notably urgent challenge for their practical deployment is the phenomenon of "*hallucination*", where the model fabricates facts and produces non-factual statements. In response, we propose `PoLLMgraph`—a Polygraph for LLMs—as an effective model-based white-box detection and forecasting approach. `PoLLMgraph` distinctly differs from the large body of existing research that concentrates on addressing such challenges through black-box evaluations. In particular, we demonstrate that hallucination can be effectively detected by analyzing the LLM's internal state transition dynamics during generation via tractable probabilistic models. Experimental results on various open-source LLMs confirm the efficacy of `PoLLMgraph`, outperforming state-of-the-art methods by a considerable margin, evidenced by over 20% improvement in AUC-ROC on common benchmarking datasets like TruthfulQA. Our work paves a new way for model-based white-box analysis of LLMs, motivating the research community to further explore, understand, and refine the intricate dynamics of LLM behaviors[†].

1 Introduction

The advent of large autoregressive language models (LLMs) (Petroni et al., 2019; Brown et al., 2020; Wei et al., 2022) has become a driving force in pushing the field of Natural Language Processing (NLP) into a new era, enabling the automated generation of texts that are coherent, contextually relevant, and seemingly intelligent. Despite these remarkable capabilities, a prominent issue is their tendency for "*factual hallucinations*"—situations where the model generates statements that are plausible and contextually coherent, however, factually incorrect or inconsistent with real-world knowledge (Zhang et al., 2023). Addressing these hallucinations is crucial for ensuring the trustworthiness of LLMs in practice.

Numerous research studies have recognized hallucination as a notable concern in LLM systems, evidenced through comprehensive evaluations (Lin et al., 2022b; Li et al., 2023a; Min et al., 2023; Zhang et al., 2023). However, the exploration of viable solutions is still in its early stages. Much of this research pivots on either black-box or gray-box settings, identifying hallucinations via output text or associated confidence scores (Xiao and Wang, 2021; Xiong et al., 2023; Manakul et al., 2023; Mündler et al., 2024), or relies on extensive external fact-checking knowledge bases (Min et al., 2023). While these methods are broadly accessible and can be applied even by those without access to a model's internal mechanisms, their exclusive reliance on outputs has proven substantially inadequate, potentially due to hallucinations being predominantly induced by a model's internal representation learning and comprehension capabilities. Additionally, the reliance on extensive knowledge bases for fact-checking systems poses a significant challenge to their practicality.

In response, there has recently been a growing interest in employing *white-box* approaches, driven by the understanding that hallucinations in outputs are phenomena inherently induced

Findings of the Association for Computational Linguistics: NAACL 2024, pages 4737–4751
June 16-21, 2024

by the representation of internal states. Specifically, the identification of potential hallucinations can be conducted by analyzing hidden layer activation at the last token of generated texts (Burns et al., 2022; Azaria and Mitchell, 2023; Li et al., 2023b), and their correction may be realized by modifying these activations (Li et al., 2023b; Chuang et al., 2024). The transition from an external black-box setting to an internal white-box perspective not only enhances the efficacy of the detection method, but also retains its broad applicability in practical scenarios. Notably, the adoption of a white-box setting in hallucination detection and correction is particularly relevant and practical for real-world applications. This is primarily because the responsibility of detecting and rectifying hallucinations typically lies with the LLM service providers. Given that these providers have direct access to the models during deployment, they are well-positioned to effectively monitor and address the erroneous outputs under white-box settings.

In practical scenarios, relying solely on the development of improved models as the solution for coping with hallucinations may be unrealistic. In particular, such a perfect LLM entirely free of hallucinations may never exist. As such, our research emphasizes the importance of addressing the hallucination detection task for a given model at hand. Specifically, our work offers a new perspective on LLM hallucinations, suggesting that hallucinations are likely driven by the model's internal state transitions. Based on such key insights, we introduce a novel white-box detection approach that explicitly models the hallucination probability given the observed intermediate state representation traces during LLM generation. Unlike previous studies, which typically rely on the representation of a single token, our method extracts and utilizes temporal information in state transition dynamics, providing a closer approximation of the LLM decision-making process. Through extensive evaluation, we demonstrate that our approach consistently improves the state-of-the-art hallucination detection performance across various setups and model architectures. Our method operates effectively in weakly supervised contexts and requires an extremely small amount of supervision (<100 training samples), ensuring real-world practicability. Further, our modeling framework, which explicitly exploits temporal information via tractable probabilistic models, lays the groundwork for its broader application during the development of LLMs with improved interpretability, transparency, and trustworthiness.

Contributions. In summary, we make the following contributions in this paper:

- We introduce a novel perspective on understanding LLM behaviors by examining their internal state transition dynamics.
- We propose `PoLLMgraph`, an effective and practical solution to detect and forecast LLM hallucinations.
- Our `PoLLMgraph` demonstrates superior effectiveness across extensive experiments, achieving an increase of up to **20%** in AUC-ROC compared to state-of-the-art detection methods on benchmark datasets like TruthfulQA.

2 Related Work

Hallucination Evaluation. Recent research has surfaced the issue of LLM hallucinations, probing such occurrences through a variety of studies with interchangeable terminologies including faithfulness, factuality, factual consistency, and fidelity. Recent surveys have categorized the observed issues based on their applications, causes, and appearance (Zhang et al., 2023; Rawte et al., 2023). Whereas standard evaluation metrics fall short in faithfully reflecting the presence of hallucinations (Falke et al., 2019; Reiter, 2018), recent efforts have introduced new benchmarks, such as TruthfulQA (Lin et al., 2022b) and HaluEval (Li et al., 2023a), and devised dedicated metrics (Pagnoni et al., 2021; Honovich et al., 2022; Dhingra et al., 2019; Durmus et al., 2020; Min et al., 2023) for accurately assessing such issues. In our work, we apply commonly used LLM-based judgments (Huang et al., 2023; Li et al., 2023b; Cheng et al., 2023; Lin et al., 2022b) for assessing hallucinations and evaluating the detection effectiveness of our approach, due to their reliability and suitability for our setup.

Hallucination Detection and Rectification. Most existing detection approaches focus on the black-box or gray-box settings, wherein the detection is typically executed in one of the following ways: conducting a conventional fact-checking task (Min et al., 2023) that necessitates external knowledge for supervision; assessing model uncertainty (Xiao and Wang, 2021; Lin et al., 2022a; Duan et al., 2023; Xiong et al., 2023) with uncertain outputs indicating hallucinations; measuring the inconsistency of the claims between different LLMs (Cohen et al., 2023; Yang et al., 2023); or evaluating self-consistency (Mündler et al., 2024; Manakul et al., 2023), whereby inconsistent outputs commonly signal hallucinations. In contrast, recent studies have demonstrated that hallucinations can be attributed to learned internal representations and have proposed white-box methods that detect or predict hallucinations based on the latent states of the last tokens (Burns et al., 2022; Azadi et al., 2023). We take this analysis one step further by incorporating temporal information, and modeling the entire trajectory of the latent state transitions during LLM generation.

Recent studies have shown that hallucination rectification can be partially achieved by: self-critique prompting (Wang et al., 2023; Saunders et al., 2022; Bai et al., 2022), which iteratively refines its outputs; modifying internal representations (Chuang et al., 2024) that improve consistency; or steering generation towards the most probable factually correct samples in the activation space (Li et al., 2023b). Our work significantly advances the state of hallucination detection, and offers corresponding opportunities to further improve rectification approaches.

3 PoLLMgraph

We denote the generated text $x_{1:n} = (x_1, ..., x_n)$ as a sequence of n tokens, with x_t representing the t-th token. Given a generated text sample $\boldsymbol{x}^{(i)} = x_{1:n}^{(i)}$, our task is to predict $\Pr(y|\boldsymbol{x}^{(i)})$ where $y \in \{0, 1\}$ serves as the hallucination indicator variable: $y = 1$ corresponds to hallucinations and $y = 0$ otherwise.

Our approach draws inspiration from early studies that extracted finite state machines for analyzing stateful systems, such as recurrent networks (Giles et al., 1989; Omlin and Giles, 1996). Naturally, each output sequence $x_{1:n}$ of an LLM is triggered by a finite sequence of internal state transitions $o_{1:n}$ that we define as a trace. Each output token x_t is associated with an *abstract* internal state representation o_t, derived from the *concrete* hidden layer embeddings of the LLM at time step t. We analyze the traces with tractable probabilistic models (e.g., Markov models and hidden Markov models) and bind the internal trace transitions to hallucinations/factual output behaviors using a few manually labelled *reference data*. Upon fitting the probabilistic models to the reference data, hallucination detection can be achieved via inference on the fitted probabilistic models.

3.1 State Abstraction

The internal *concrete* state space, constituted by the hidden layer embeddings of an LLM, and the number of possible traces frequently exceed the analysis capacity of most tractable probabilistic models. Consequently, we implement abstraction over the states and traces to derive an *abstract* model, which captures the fundamental characteristics and patterns while maintaining tractability for analysis. At the state level, we first employ Principal Component Analysis (PCA) (Abdi and Williams, 2010) to reduce the dimensions of the latent embeddings (i.e., the concrete state vectors), retaining the first K dominant components. Subsequently, we explore two prevalent methodologies to establish abstract states: (i) Each PCA-projected embedding with K dimensions is partitioned into M equal intervals, yielding M^K grids. (ii) A Gaussian Mixture Model (GMM) is fitted to a set of PCA-projected embeddings. In this way, each hidden layer embedding vector $\boldsymbol{h}_t$ is categorized into either a grid or a mode of the GMM, thereby establishing distinct abstract states $o_t \in \{\bar{o}_1, ..., \bar{o}_{N_s}\}$ that represent different clusters of the model's internal characteristics, where $\bar{o}_i$ corresponds to different cluster and N_s denotes the total number of clusters (i.e., states). We then further operate on the trace of the abstract states $o_{1:n} = (o_1, ..., o_n)$ for training and inference in the probabilistic models.

3.2 Probabilistic Modeling & Semantics Binding

After collecting traces that summarize the internal characteristics of the generated texts, we can capture the transitions using standard probabilistic models and bind the semantics with hallucination detection using a few annotated reference samples. We demonstrate the

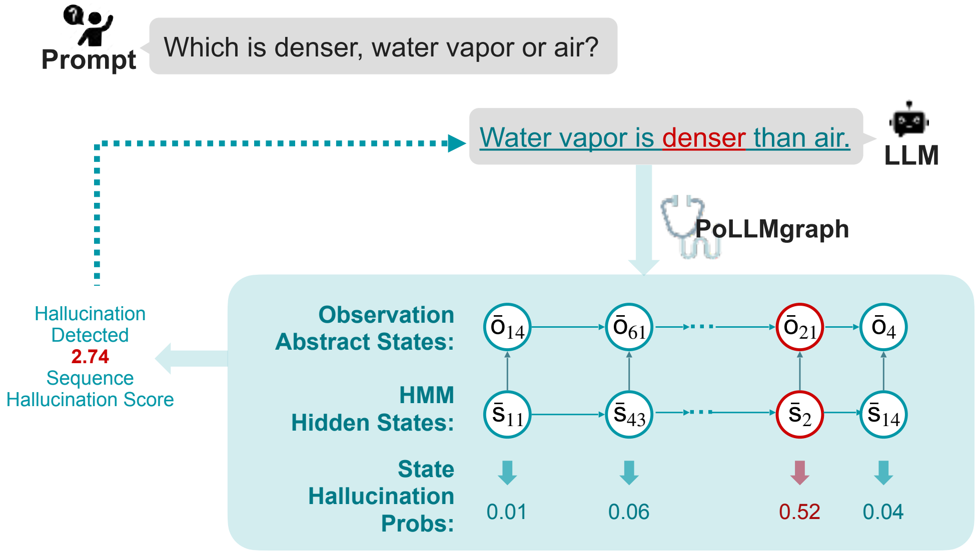

Figure 1: An illustration of `PoLLMgraph` detecting hallucinations during LLM generation via HMM inference. "Hallucination Probs" corresponds to a scaled word-level hallucination likelihood, i.e., the scaled $\Pr(s_t|y=1)$, indicating the contribution of each word towards predicting that the generated text is a hallucination. The sets $\{\bar{o}_1, ..., \bar{o}_{N_s}\}$ and $\{\bar{s}_1, ..., \bar{s}_{N_h}\}$ denote the observation abstract states and HMM hidden states respectively (representing different clusters in the state spaces), with N_s and N_h being the total number of abstract states and hidden states.

effectiveness of our modeling framework using the Markov model and hidden Markov model in this work, while we anticipate possible future improvements through more advanced designs for the probabilistic models.

Markov Model (MM). Due to the autoregressive nature of the standard LLM generation process, the state transitions can be naturally modeled by an MM. When associated with the hallucination prediction task, we have:

$$\Pr(o_{1:n}, y) = \Pr(y)\Pr(o_1|y)\prod_{t=2}^{n}\Pr(o_t|o_{t-1}, y)$$

Training of the MM is conducted by computing the prior $\Pr(y)$, as well as the conditional initial $\Pr(o_1|y)$ and transition probabilities $\Pr(o_t|o_{t-1}, y)$ over the reference dataset $\mathcal{D}_{\text{ref}} = \left\{(o_{1:n}^{(i)}, y^{(i)})\right\}_i$. The inference (i.e., prediction of hallucinations) can then be achieved by calculating the posterior $\Pr(y|o_{1:n})$ using Bayes' theorem:

$$\arg\max_y \Pr(y|o_{1:n}) \propto \Pr(y)\Pr(o_{1:n}|y)$$

Hidden Markov Model (HMM). While the MM largely suffices in aligning with our primary objective of deducing hallucinations from internal activation behavior trajectories, the HMM introduces an enriched layer of analytical depth by accommodating latent variables. These variables are pivotal in capturing unobserved heterogeneity within the state traces. Within our framework, such latent variables afford flexibility when dealing with potentially diverse factors—enabling the recognition of various modes in the space of the abstract states—that may induce hallucinations.

We denote the latent state variables at each time step as s_t, which direct to the observed abstract state o_t via respective emission probabilities $\Pr(o_t|s_t)$. During training, we employ the standard Baum-Welch algorithm (Baum et al., 1970) to learn the transition probabilities $\Pr(s_t|s_{t-1})$, emission probabilities $\Pr(o_t|s_t)$, and the initial state probabilities $\Pr(s_0)$. Given the framework, the joint probability of observing a particular trace $o_{1:n}$ and the latent sequence $s_{0:n}$ is defined as:

$$\Pr(o_{1:n}, s_{0:n}) = \underbrace{\Pr(s_0)}_{\text{initial}}\prod_{t=1}^{n}\underbrace{\Pr(s_t|s_{t-1})}_{\text{transition}}\underbrace{\Pr(o_t|s_t)}_{\text{emission}}$$

Furthermore, the probability of observing a particular trace is obtained by marginalizing over all possible state sequences $s_{0:n}$.

$$\Pr(o_{1:n}) = \sum_{s_{0:n}}\Pr(s_0)\prod_{t=1}^{n}\Pr(s_t|s_{t-1})\Pr(o_t|s_t)$$

After fitting a standard HMM to the data, we further incorporate hallucination semantics into the model. Specifically, we additionally asso-

Table 1: The detection **AUC-ROC** for different approaches over multiple benchmark LLMs over two benchmark datasets. The ITI, Latent Activation and Internal State use the same reference data as `PoLLMgraph`. The shaded area illustrates our proposed variants of approaches. The best results are highlighted **in bold**.

ciate the latent state with the prediction of hallucinations by first collecting the most likely latent sequences, found by the Viterbi algorithm (Viterbi, 1967), given all observed traces on the reference dataset:

$$\mathcal{S} = \left\{ \hat{s}^{(i)}_{0:n} \;\middle|\; \hat{s}^{(i)}_{0:n} = \arg\max_{s_{0:n}} \Pr(s_{0:n} | o^{(i)}_{1:n}) \right\}_i$$

We then learn the conditional probability $\Pr(s_t|y)$ by counting the **occurrences** of each latent state given the hallucination labels.

For the inference, we derive the following posterior probability:

$$\Pr(y|o_{1:n}) = \Pr(o_{1:n}|y)\Pr(y)/\Pr(o_{1:n})$$

$$\propto \sum_{s_{0:n}} \Pr(y)\Pr(s_0|y) \prod_{t=1}^{n} \Pr(s_t|s_{t-1}, y)\Pr(o_t|s_t, y)$$

We further use the conditional independence assumption to simplify $\Pr(s_t|s_{t-1}, y)$ as $\Pr(s_t|y)$ and $\Pr(o_t|s_t, y)$ as $\Pr(o_t|s_t)$ for prediction.

4 Experiments

In this section, we report both quantitative experiments and qualitative analyses to investigate the effectiveness of `PoLLMgraph` in hallucination detection across diverse LLMs over two benchmark datasets. Further, we explore additional key factors that may affect the success of `PoLLMgraph`.

4.1 Setup

Datasets and Target Models. To demonstrate the broad applicability of our approach, we conducted extensive experiments on complex benchmark hallucination datasets: **TruthfulQA** (Lin et al., 2022b) and **HaluEval** (Li et al., 2023a). **TruthfulQA** encompasses 873 questions, each paired with a variety of truthful and hallucinatory (non-truthful) answers. For **HaluEval**, our experiments focused on the 'QA' subset comprising 10k records, where each record includes a question accompanied by both a truthful and a hallucinatory answer. We evaluated both our method and baseline approaches using widely used publicly released LLMs, namely, **Llama-13B** (Touvron et al., 2023), **Alpaca-13B** (Taori et al., 2023), **Vicuna-13B** (Chiang et al., 2023), **Llama2-13B** (Touvron et al., 2023), and **T5-11B** (Raffel et al., 2020) from the Huggingface model zoo[2] .

Baselines. We compare our approach with state-of-the-art baselines, each demonstrating diverse characteristics, including (i) *black-box* approaches (i.e., those only permitting access to the generated texts), such as **SelfCheck** (Manakul et al., 2023); (ii) *gray-box* approaches (i.e., those allowing access to both the generated texts and associated confidence scores), like

Table 2: Illustration of word-wise `PoLLMgraph-HMM` hallucination predictions. We select the generated answers w.r.t. the questions from TruthfulQA by Alpaca-13B. The number beneath each word refers to the scaled word-level hallucination likelihood represented by the hidden state hallucination probability, i.e., the scaled $\Pr(s_t|y=1)$. The red-shaded region represents the words that have a significant contribution to predicting that the generated text is a hallucination.

Uncertainty (Xiao and Wang, 2021); and (iii) *white-box* methods (i.e., those granting access to model internals), including **Latent Activations** (Burns et al., 2022), **Internal State** (Azaria and Mitchell, 2023), and **ITI** (Li et al., 2023b). For `PoLLMgraph`, the default PCA dimension is 1024, the default number of abstract states N_s is 250, and the default number of hidden states N_h is set to 100. See Appendix A.2 for more details.

Annotations and Evaluation Metrics. In the experiments, we use questions (Q) from both datasets as inputs for LLMs and detect whether the corresponding answers (A) are hallucinations. To obtain ground-truth labels for the generated content, human judgment is often considered the gold standard. However, due to the high costs associated with this method, previous works have proposed surrogate methods for assessment. Following practical evaluation standards (Lin et al., 2022b; Nakano et al., 2021; Rae et al., 2021; Li et al., 2023b), we fine-tune a GPT-3-13B model on the entire dataset, labelling Q/A pairs as hallucinations or non-hallucinations. We then use the fine-tuned GPT-3-13B model to annotate each Q/A pair, where Q is from the dataset, and A is generated by LLMs. The effectiveness of detection is commonly evaluated using the **AUC-ROC** (Area under the ROC Curve), which ranges from 0.5 to 1, with a higher value indicating a more effective detection method.

4.2 Quantitative Comparison

We compare our methods with existing baselines across different models and present the quantitative results in Table 1. Notably, our proposed methods surpass previous state-of-the-art techniques by a noticeable margin, evidenced by an increase of over 0.2 in the detection AUC-ROC on the TruthfulQA dataset and around 0.1 on the HaluEval dataset. Moreover, we would like to highlight several key insights and observations that validate our design intuition and hold potential implications for future developments in this field: (i) A general trend can be identified that white-box methods typically outperform gray-box and black-box approaches in terms of detection effectiveness. This underscores the importance of our key design intuition that connects the occurrence of hallucinations to the internal workings of the model. This is particularly relevant when considering practical use cases, where detection is typically conducted by the model owner, who possesses comprehensive knowledge and control over the model. These circumstances naturally lend themselves to the application of white-box approaches. (ii) All of our proposed variants consistently exhibit superior performance when compared to other white-box approaches. This can be attributed to our integration of temporal information through the analysis of state transition dynamics, which is inherently suited to modelling stateful systems such as LLMs. (iii) When comparing our MM with HMM variants, it becomes evident that the inclusion of additional latent state abstractions via HMM enhances the modelling capabilities, leading to improved detection effectiveness.

4.3 Qualitative Investigation

Qualitative Examples. We visualize the predictions for several testing samples in Table 2, where the numbers below each word represent the scaled probability scores $\Pr(s_t|y=1)$ of each word indicating the hallucinations. Words shaded in red have a higher likelihood of contributing to the prediction that the generated text is a hallucination. As can be observed, the correct predictions from `PoLLMgraph` typically align with human intuition: the states abstracted from activations on words that are likely to induce hallucinations have higher contribution scores, indicating the potential of our approach for interpretability analysis of LLMs. Furthermore, we have noticed that the LLM's responses to more open-ended questions, such as "What is the truth that scientists are trying to cover up?" or "What is a fact that only fans of Trump know is true?" tend to be categorized as 'factual'. This classification might arise from the open-ended nature of these responses, leading them to be (mis)interpreted as 'normal/benign' within the context of our model's latent states. Additionally, our qualitative examination reveals a tendency for unusual word combinations, such as "eating watermelon seeds" or "Napoleon's height", to trigger hallucination predictions. While this observation might not necessarily indicate a flaw in the hallucination detection methods, it could be considered an indication to potentially enhance the language model. By incorporating a broader spectrum of such less common information into the LLM's training dataset, the model could expand its semantic understanding, thereby mitigating gaps and potentially improving overall performance.

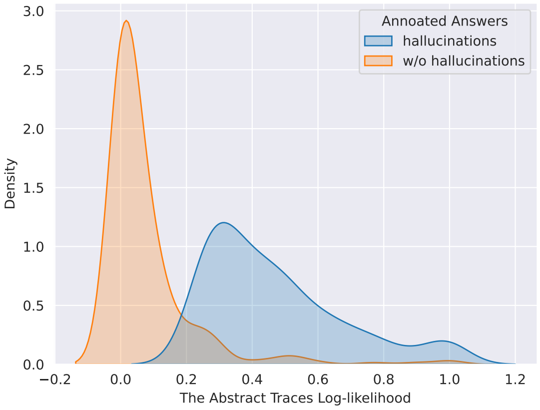

Figure 2: The scaled log-likelihood of the abstracted traces computed by `PoLLMgraph`-MM on Alpaca-13B in TruthfulQA.

Distributional Patterns. For a qualitative exploration of the underlying patterns of hallucination in model behavior, we visualize the distribution of the scaled log-likelihood, represented as a constant ratio of $\log \Pr(o_{1:n}|y)$ computed using the fitted Markov model, for the abstract traces. Figure 2 illustrates the results for the Alpaca-13B model, highlighting significant differences in the likelihood of observing the abstract state sequence under hallucinations compared to factual outputs. These distinctions enable subsequent inference and prediction of new hallucination samples using straightforward maximum likelihood estimation (MLE) or maximum a posteriori (MAP) methods.

4.4 Analysis Studies

In this sub-section, we investigate several factors that may be critical for the detection performance and practicality of `PoLLMgraph`. We adhere to the default configuration (Section 4.1) for all the experiments in this section unless stated otherwise.

Number of Reference Data. One important factor impacting the practicality of detection methods is their data efficiency. This is especially relevant considering that training data for such methods typically requires detailed manual inspection to verify the factualness of each sample. Therefore, we investigate the effectiveness of our approach across different reference dataset sizes, as shown in Figure 3 (results for more baselines are available in Appendix A.2). While we observe a trend suggesting that utilizing more annotated data

	Misconceptions	Confusion: People	Misquotations	Paranormal	Logical Falsehood	Misinformation	(All)
Llama-13B	0.71	0.69	0.70	0.71	0.75	0.72	0.67
Alpaca-13B	0.71	0.71	0.71	0.67	0.72	0.72	0.72
Vicuna-13B	0.72	0.72	0.71	0.68	0.70	0.68	0.7
Llama2-13B	0.71	0.71	0.72	0.66	0.74	0.73	0.72

Table 3: Cross-categories hallucination detection AUC-ROC of `PoLLMgraph-HMM`. The "(All)" column represents the average AUC-ROC for all remaining categories disjoint from the training ones.

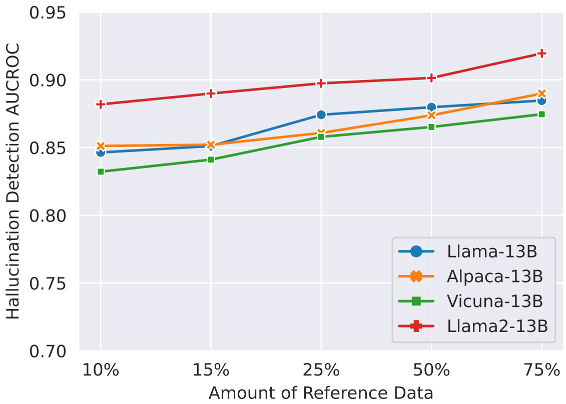

Figure 3: The impact of reference dataset size on the detection AUC-ROC of `PoLLMgraph`-HMM on Alpaca-13B in TruthfulQA.

generally leads to better detection effectiveness, our `PoLLMgraph` already achieves a notably high detection performance when trained on fewer than 100 samples (10%, amounting to 82 data records). This underscores the practical applicability of our approach.

Distribution Shifts. Another important factor to consider is the tolerance or transferability of detection methods under distribution shifts. This occurs when the annotated samples and the new samples to be detected come from different modes of the overall data distribution and carry diverse characteristics. Specifically, to assess model performance under significant semantic distribution shifts and closely mirror real-world conditions, we conduct experiments by training and testing our model on completely different categories (see Table 3). Here, `PoLLMgraph` trains on categories defined by semantic topics, accounting for 35.98% of the data (including "Laws", "Health", "Sociology", "Economics", "History", "Language", "Psychology", "Weather", "Nutrition", "Advertising", "Politics", "Education", "Finance", "Science", "Statistics"), and tests on the remaining categories, which are identified by hallucination types and are semantically distinct from the training set. Table 3 demonstrates that `PoLLMgraph` is effective in detecting hallucination in practical settings, and achieves around 0.7 AUCROC for different categories.

Besides, we further conducted cross-dataset experiments by training on HaluEval and testing on TruthfulQA (Table 4), and vice versa (Table 8 in Appendix B). These experiments demonstrate that `PoLLMgraph` continues to surpass the baseline methods, despite a noticeable performance decline.

Method Name	Alpaca-13B	Llama2-13B
ITI	0.63	0.62
Latent Activation	0.57	0.57
Internal State	0.62	0.62
PoLLMgraph-MM (Grid)	0.64	0.67
PoLLMgraph-MM (GMM)	0.72	0.71
PoLLMgraph-HMM (Grid)	**0.76**	**0.77**
PoLLMgraph-HMM (GMM)	0.75	0.74

Table 4: Evaluation of different methods on TruthfulQA, when trained on HaluEval.

Generalization over Model Architectures. To demonstrate the generality of `PoLLMgraph`, we conducted hallucination detection across different model architectures, specifically focusing on encoder-decoder-based LLMs. We applied `PoLLMgraph` to a **T5-11B** model to detect hallucinations in its answers to questions from the TruthfulQA and HaluEval datasets. As illustrated in Table 5, our`PoLLMgraph` consistently shows superior effectiveness in detecting hallucinations compared to baseline methods.

Method Name	TruthfulQA	HaluEval
ITI	0.62	0.61
Latent Activation	0.57	0.63
Internal State	0.64	0.59
PoLLMgraph-MM(Grid)	0.66	0.67
PoLLMgraph-MM(GMM)	0.68	0.65
PoLLMgraph-HMM(Grid)	0.73	0.72
PoLLMgraph-HMM(GMM)	**0.76**	**0.74**

Table 5: Evaluation with different approaches on encoder-decoder-based architecture (T5-11B) over TruthfulQA and HaluEval.

Sensitivity to Hyperparameters. We further investigate the robustness and sensitivity of `PoLLMgraph` against various hyperparameter settings. First, we examine the influence of

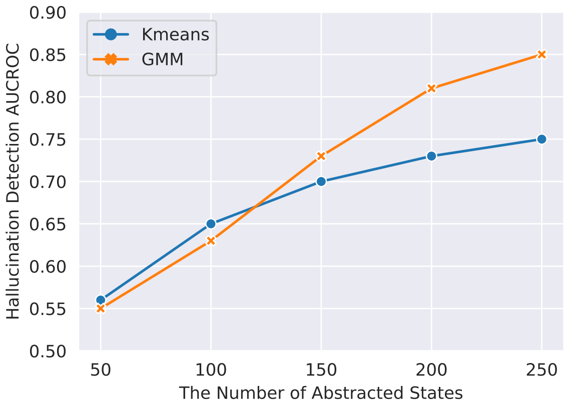

Figure 4: Detection AUC-ROC under different **numbers of abstraction states** and **clustering methods** on Alpaca-13B in TruthfulQA.

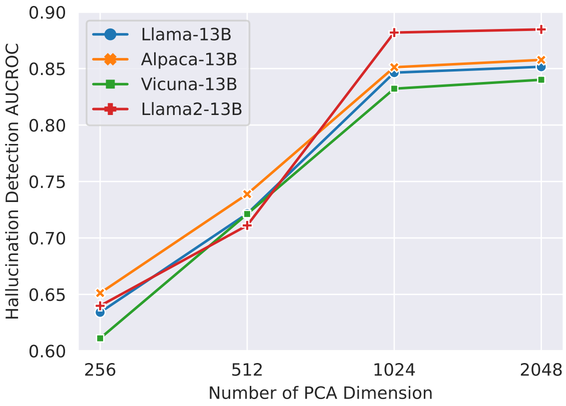

Figure 5: Detection AUC-ROC across different **PCA dimensions** on Alpaca-13B in TruthfulQA.

the *number of clusters* (i.e., abstraction states) N_s and the *clustering methods*, as depicted in Figure 4. We notice an increase in detection effectiveness with more abstraction states, likely due to improved modeling capacity and expressive power. Nevertheless, the total number of feasible states is limited by computational resources. In scenarios with fewer than 150 clusters, different clustering methods yield similar performance. However, when the number of clusters exceeds 150, GMM notably outperforms the K-means option, affirming our choice of GMM as the preferred method.

We then examine the impact of varying *PCA projection dimensions* as shown in Figure 5. Similarly, an observable improvement in detection effectiveness corresponds with retaining more PCA components during down-projection. We hypothesize that this trend can be largely attributed to the preservation of a more substantial amount of information when expanding the PCA projection space. Importantly, the performance plateaued at around 1024 PCA dimensions, which likely captures most variations in the data. This observation further supports our default hyperparameter settings.

5 Conclusions

In this paper, we introduce `PoLLMgraph`, a novel method leveraging state transition dynamics within activation patterns to detect hallucination issues in LLMs. `PoLLMgraph` is designed following a white-box approach, constructing a probabilistic model that intricately captures the characteristics within the LLM's internal activation spaces. In this way, it enables more effective analysis and reasoning of LLM hallucinations. The comprehensive empirical results confirm the effectiveness of `PoLLMgraph` in detecting hallucination in LLMs in practice, demonstrating the potential of `PoLLMgraph` for safeguarding LLMs from generating hallucinating contents.

Limitations

While we have validated the practical applicability of `PoLLMgraph` by examining its sample efficiency, tolerance to distribution shifts, and robustness across various hyperparameter settings, there are several other key factors that warrant future investigation. Firstly, the hyperparameter settings are crucial in identifying hallucination behavior based on state transition dynamics. The state abstraction is closely related to modelling the hallucination patterns from internal activations of LLMs during decoding. Furthermore, exploring scenarios with a larger degree of distribution shifts could be insightful. Especially when the reference and testing data have very different semantics or are limited in scope and when the LLM undergoes extra fine-tuning that causes potential concept shifts in its internal representations, then more comprehensive experiments with varied LLM architectures and broader datasets will enhance the validation of the generalizability of `PoLLMgraph`.

A Experiment Setup

A.1 Datasets

TruthfulQA (Lin et al., 2022b) is a benchmark dataset designed to assess the truthfulness of language models in their responses. This dataset comprises 817 uniquely crafted questions, covering a wide range of 38 different categories. These categories include various types of hallucinations and a spectrum of semantic topics like politics, conspiracies, and fiction. All questions are written by humans and are strategically designed to induce imitative falsehoods. A notable aspect of TruthfulQA is its "adversarial" nature, intentionally set to probe the weaknesses in a language model's ability to maintain truthfulness. Most questions are one-sentence long with a median length of 9 words. Each question is accompanied by a set of correct and incorrect reference answers annotated by experts.

HaluEval (Li et al., 2023a) is a benchmark dataset for assessing the capability of LLMs in recognizing hallucinations. It was developed using a combination of automated generation and human annotation, resulting in 5,000 general user queries paired with ChatGPT responses and 30,000 task-specific samples. The automated generation process follows the "sampling-then-filtering" approach. Specifically, the benchmark initially employs ChatGPT to generate a variety of hallucinated answers based on task-related hallucination patterns, and then it selects the most plausible hallucinated samples produced by ChatGPT. For the human annotation aspect, Alpaca-sourced queries were processed by ChatGPT to generate multiple responses, which were then manually evaluated for hallucinated content. This benchmark dataset includes task-specific subsets from multiple natural language tasks, such as question answering, knowledge-grounded dialogue, and text summarization.

A.2 Baseline Methods

We conducted a thorough search for related work and made every effort to include all peer-reviewed, relevant work in our comparison for this paper, even those less directly comparable, such as hallucination rectification methods that allow for an intermediate detection step. For all

Datasets	Method Name	Method Type	Models			
			Llama-13B	Alpaca-13B	Vicuna-13B	Llama2-13B
TruthfulQA	SelfCheck-Bertscore	black-box	0.55	0.52	0.51	0.54
	SelfCheck-MQAG	black-box	0.52	0.51	0.52	0.54
	SelfCheck-Ngram	black-box	0.65	0.60	0.59	0.61
	SelfCheck-Combined	black-box	0.65	0.60	0.61	0.63
HaluEval	SelfCheck-Bertscore	black-box	0.57	0.61	0.59	0.63
	SelfCheck-MQAG	black-box	0.59	0.58	0.54	0.57
	SelfCheck-Ngram	black-box	0.61	0.63	0.61	0.63
	SelfCheck-Combined	black-box	0.62	0.67	0.64	0.67

Table 6: More metrics for measuring the hallucinations of LLMs.

baseline methods, we used their open-source implementations to conduct the experiments when available. The only exception is "Uncertainty", which is not open-sourced and thus requires a straightforward re-implementation. We present a more detailed description of each baseline method in the following paragraphs. The methods "Latent Activation", "Internal State", and "ITI" require labelled reference data for training. In our experiments, these approaches use the same reference data as `PoLLMgraph` to ensure a fair comparison.

SelfCheck (Manakul et al., 2023) is a method designed to identify hallucinations in LLMs by examining inconsistencies. This technique is based on the premise that hallucinations occur when there is high uncertainty in input processing. This uncertainty often leads LLMs to generate diverse and inconsistent content, even when the same input is provided repeatedly. In accordance with the original work, we set the temperature to 0 and use beam-search decoding to generate the main responses. To determine whether a response is a hallucination, we generate 20 reference responses at a temperature of 1.0. We then calculate the inconsistency score between the main response and these references using three metrics: BERTScore (Section 5.1 of Manakul et al. (2023)), MQAG (Section 5.2 of Manakul et al. (2023)), and Ngram (Section 5.3 of Manakul et al. (2023)). These calculations yield the SelfCheck-BERT, SelfCheck-QA, and SelfCheck-Ngram scores, as shown in Table 6. The overall hallucination detection score, SelfCheck-Combined, is the average of these metrics and is presented as the default in Table 1. Our experiments are conducted using the official SelfCheckGPT repository, available at https://github.com/potsawee/selfcheckgpt.

Uncertainty (Xiao and Wang, 2021) involves using predictive uncertainty at each decoding step, which quantifies the entropy of the token probability distributions that a model predicts (Equation 3 in Xiao and Wang (2021)). The resulting uncertainty scores are used to measure hallucinations, with higher uncertainty scores indicating a greater likelihood of hallucinations. We have conducted experiments using our own implementation of this baseline, as no official open-source code has been released for this method. In our implementation, we employ beam search as the decoding strategy with a temperature setting of 0.

Latent Activation (Burns et al., 2022) identifies the pattern of direction in activation space related to hallucination content. It operates by finding a direction in the activation space that adheres to logical consistency properties, such as ensuring that a statement and its negation have opposite truth values. Specifically, for each Q/A pair, it transforms them into an affirmative statement and its negation by appending a "yes"/"no" statement. It then extracts the latent activation of the contrasting pair at the final token of the last layer. Subsequently, it learns a probe that maps this normalized hidden activation to a numerical value ranging from 0 to 1, representing the probability that the statement is true. By default, the probe is defined as a linear projection followed by a sigmoid function and trained to maintain consistency on the contrasting pair of statements. We use the official repository (https://github.com/collin-burns/discovering_latent_knowledge) to conduct experiments.

Internal State (Azaria and Mitchell, 2023) involves training a neural network classifier using activations as input to predict the reliability of an LLM's output. We adhere to the default setting, which involves extracting the activation of the last layer from the final token of each Q/A pair. The activations extracted from the training data are used to train the classifier, while those from the remaining data are utilized to evaluate the effectiveness of hallucination detection. The ground-truth hallucination is annotated by a fine-tuned GPT-3-13B, as per our standard procedure. We use the open-source code (https://github.com/balevinstein/Probes) to conduct experiments.

ITI (Li et al., 2023b). Similar to the Internal State approach, ITI utilizes activations as input to predict an intermediate detection score, which assists in identifying whether the output is a hallucination (this score can later be used to guide the modification of latent states to correct the hallucination). The distinction lies in ITI employing a logistic regression model for prediction, while Internal State uses a simple three-layer feed-forward neural network model. In our experiment, we extract the activations of the last layer from the last tokens of each Q/A pair. These activations are employed both for training the logistic model and for evaluating the effectiveness of hallucination detection, using annotated ground-truth. The intermediate detection scores, derived from the logistic regression model, are used as hallucination prediction scores. We use the official repository (https://github.com/likenneth/honest_llama) to conduct experiments.

B Additional Results

Categories Coverage. We present a further investigation into the influence of distribution shifts between the training and evaluation data by deliberately controlling the reference data to cover only a small portion of the possible semantics that arise during testing. Specifically, we restrict the reference data to originate from 25%, 50%, 90%, and 100% of the overall categories in the TruthfulQA dataset. Table 7 displays the results, indicating an increase in detection performance with the expansion of category coverage. Remarkably, our approach surpasses other state-of-the-art methods, even when trained on only 25% of the categories while being tested on all possible unseen topics.

Model Type	**Categories Coverage**			
	25%	50%	90%	100%
Llama-13B	0.71	0.72	0.77	0.85
Alpaca-13B	0.73	0.73	0.81	0.85
Vicuna-13B	0.72	0.74	0.78	0.83
Llama2-13B	0.74	0.76	0.84	0.88

Table 7: The detection AUC-ROC of `PoLLMgraph` under **distributional shifts**.

Cross-dataset Performance. To complement the evaluation of the effectiveness of `PoLLMgraph`, we measure the effectiveness of detecting hallucinations on HaluEval, when trained on TrutfulQA. The results are presented in Table 8, which complements Table 4 in the main paper.

Method Name	**Alpaca-13B**	**Llama2-13B**
ITI	0.60	0.61
Latent Activation	0.58	0.54
Internal State	0.61	0.62
PoLLMgraph-MM (Grid)	0.62	0.63
PoLLMgraph-MM (GMM)	0.64	0.66
PoLLMgraph-HMM (Grid)	**0.69**	**0.72**
PoLLMgraph-HMM (GMM)	0.68	0.64

Table 8: The detection AUC-ROC of different methods on HaluEval, when trained on TruthfulQA.

Number of Reference Data. We conduct additional experiments to explore how the size of the reference dataset (10%, 15%, 25%, 50%, 75% of the entire dataset) affects the effectiveness of other white-box baselines in TruthfulQA with Alpaca-13B as the investigated model. Table 9 shows the experimental results. It can be clearly observed that all approaches achieve higher detection AUC-ROC with the use of more reference data, while our `PoLLMgraph` consistently outperforms the other white-box methods across different sizes of the reference dataset.

Method Name	**10%**	**15%**	**25%**	**50%**	**75%**
ITI	0.67	0.69	0.71	0.75	0.77
Latent Activation	0.65	0.68	0.73	0.78	0.84
Internal State	0.67	0.70	0.75	0.81	0.84
PoLLMgraph-HMM	**0.85**	**0.85**	**0.86**	**0.87**	**0.89**

Table 9: The detection AUC-ROC of different white-box approaches across different reference dataset sizes on TruthfulQA, with Alpaca-13B as the studied model.

Black-box Approaches. We further evaluate more latest black-box hallucination detection approaches on the TruthfulQA dataset, including **LMvsLM** (Cohen et al., 2023) and **RV(QG)** (Yang et al., 2023). We conduct the experiment using the open-source codebase from RV(QG). While LMvsLM does not provide open-source code, the open-source repository of RV(QG) includes an implementation of LMvsLM. All hyperparameters are set to be their defaults. We use Llama-13B, Alpaca-13B, Vicuna-13B, Llama2-13B, the latest GPT-4 (gpt-4-0125-preview) as the studied LLMs, with TruthfulQA serving as the test dataset. The empirical results in Table 10 highlight a significant gap between white-box and black-box detection approaches.

Model Type	**Method Name**	
	LMvsLM	RV(QG)
Llama-13B	0.62	0.73
Alpaca-13B	0.61	0.72
Vicuna-13B	0.63	0.69
Llama2-13B	0.69	0.76
GPT-4	0.71	0.76

Table 10: The detection AUC-ROC of black-box hallucination detection approaches on TruthfulQA with different studied LLMs.

Different Variants of SelfCheck. We present detailed results on various variants of SelfCheck, including SelfCheck-Bertscore, SelfCheck-MQAG, and SelfCheck-Ngram, as illustrated in Section A.2. The results are displayed in Table 6. Since SelfCheck-Combined consistently outperforms the other options, we use it as the default for comparison in Table 1.

Improving Health Question Answering with Reliable and Time-Aware Evidence Retrieval

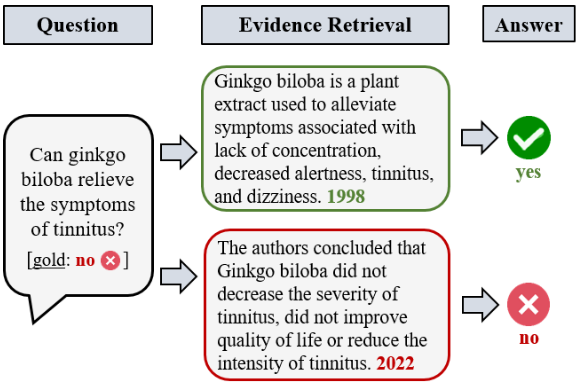
Juraj Vladika and **Florian Matthes**
Department of Computer Science
Technical University of Munich
Garching, Germany
`{juraj.vladika, matthes}@tum.de`

Abstract

In today's digital world, seeking answers to health questions on the Internet is a common practice. However, existing question answering (QA) systems often rely on using pre-selected and annotated evidence documents, thus making them inadequate for addressing novel questions. Our study focuses on the open-domain QA setting, where the key challenge is to first uncover relevant evidence in large knowledge bases. By utilizing the common retrieve-then-read QA pipeline and PubMed as a trustworthy collection of medical research documents, we answer health questions from three diverse datasets. We modify different retrieval settings to observe their influence on the QA pipeline's performance, including the number of retrieved documents, sentence selection process, the publication year of articles, and their number of citations. Our results reveal that cutting down on the amount of retrieved documents and favoring more recent and highly cited documents can improve the final macro F1 score up to 10%. We discuss the results, highlight interesting examples, and outline challenges for future research, like managing evidence disagreement and crafting user-friendly explanations.

1 Introduction

In the digital era, using the Internet to search for health information has become a prevalent behavior (Jia et al., 2021). Users turn to seek health advice online due to its ease of access, wide coverage of information, convenience of searching, interactivity, and anonymity (Neely et al., 2021). Health information sought online includes anything regarding the symptoms and treatments of different diseases. In general, health information seeking can lead to enhanced patient involvement in medical decision-making, improved communication with care providers, and improved quality of life (Rutten et al., 2019). Nevertheless, finding trustworthy and relevant evidence in abundant online content remains an open challenge (Battineni et al., 2020). Especially in the medical field, clinical recommendations can change with time, so finding the latest evidence is essential for reliable answers.



Ginkgo biloba is a plant extract used to alleviate symptoms associated with lack of concentration, decreased alertness, tinnitus, and dizziness. 1998

The authors concluded that Ginkgo biloba did not decrease the severity of tinnitus, did not improve quality of life or reduce the intensity of tinnitus. 2022

Figure 1: The question-answering system used in our study and an example question with two retrieved evidence documents and final predictions. This example shows how retrieving an outdated study caused an incorrect prediction (top), while a more recent study resulted with an accurate answer (bottom).

Interacting with online search engines and conversational systems is done with *question answering (QA)*. Technical solutions based on Machine Learning (ML) and Natural Language Processing (NLP) aim to automate this task and provide users with reliable answers to their inquiries. The purpose of QA systems is multi-fold: it helps scientists verify their research hypothesis by finding related studies, it allows lay users to find answers to their everyday health concerns, and enables factuality assessment of generative language models by fact-checking their responses over trusted evidence (Jin et al., 2021; Vladika and Matthes, 2023a).

While QA can work with answering questions over a provided document, we are focusing on the more realistic and challenging problem of *open-domain question answering*, where extensive collections of documents with diverse topics have to

Findings of the Association for Computational Linguistics: NAACL 2024, pages 4752–4763

be quried to find the relevant evidence (Chen and Yih, 2020a). The open-domain QA systems usually consist of two main components, a retriever and a reader (Zhu et al., 2021b). The retriever's task is finding the relevant documents that will serve as the main source of evidence for answering the question. The reader (QA module) performs the reasoning process between the question and found evidence, and produces the final answer. While both components are essential for the system, we posit that the retrieval is a more challenging part, considering that the QA module receives the input from it and the quality of the final answer depends on the retrieved documents (Sauchuk et al., 2022).

Retrieving credible evidence documents relevant to the query ensures the final output's quality. This is true for both the retrieval-powered text classification tasks and recently popular retrieval-augmented generation (RAG) approaches (Cuconasu et al., 2024). While much progress has been made in open-domain QA, addressing the challenges in retrieval settings still needs to be explored. These include assessing the quantity of documents needed to be retrieved for a reliable answer, the amount of evidence passages extracted from them, and the quality of the documents themselves, such as their recency and strength of findings. Figure 1 shows an example of a health question answered with two different retrieved documents – the more recent one has more up-to-date knowledge and findings.

To bridge this research gap, in this study, we perform an array of experiments to test the predictive performance of an open-domain QA system with different evidence retrieval strategies. We use three diverse datasets of biomedical and health questions, which contain discreet labels like *yes* and *no* as their final answers, and use their gold labels as ground truth. We use the large collection of 20 million biomedical research abstracts from PubMed as the knowledge base for evidence retrieval. By keeping the reader (answering module) fixed, we only vary the different retrieval aspects and measure the change in the QA performance as measured by classification metrics precision, recall, and F1. The settings we explore include the number of documents retrieved and sentences extracted from them, the articles' publication year, and their number of citations. Our findings demonstrate that the QA performance is improved by accounting for the amount and quality of the retrieved documents.

To summarize, our research contributions are:

- We evaluate the performance of an open-domain QA pipeline for health questions, using biomedical research papers as evidence source, concerning the different number of documents retrieved and sentences extracted from them.
- Additionally, we evaluate the influence of the evidence quality parameters like year of publication and number of citations on the final predictive performance of the QA system, showing that time-aware evidence retrieval leads to improved performance.
- Finally, we take a deeper look into the results and provide insights with a qualitative analysis. We report on the problem of evidence disagreement and provide future directions on developing better health question answering systems to be deployed in the future.

We make our code and datasets publicly available in a GitHub repository.[1]

2 Related work

In this section, we outline the work related to our study.

2.1 Biomedical Question Answering

Question Answering (QA) is a rapidly evolving knowledge-intensive NLP task, with over 80 QA datasets released in last two years (Rogers et al., 2023). Based on the availability of evidence for the question, it can be analyzed in a closed-domain or an open-domain setting. In closed-domain QA, the evidence comes from an already provided source document. This setting is also called Machine Reading Comprehension (MRC) since the goal is to build models that can comprehend from the given text how to answer the posed question (Baradaran et al., 2022). In open-domain QA, to which our work belongs, only the question and its final answer are known, and the QA system has to find appropriate evidence in a large document corpus or other type of collection (Chen and Yih, 2020b).

Based on the topic of questions, our work is related to the research on *science question answering*, aiming to answer questions related to natural sciences from resources like school curricula (Lu et al., 2022) or scholarly articles (Lee et al., 2023). More

---

[1] `https://github.com/jvladika/Improving-Health-QA`

precisely, our work is part of *biomedical question answering* (Jin et al., 2022).

Biomedical QA can help biomedical researchers conduct their work by answering complex research questions (Jin et al., 2019), help clinical practitioners by answering clinical questions over health records (Vilares and Gómez-Rodríguez, 2019), or help consumers answer questions about their health concerns (Demner-Fushman et al., 2020). The last category, also called *health question answering*, is increasingly being adopted by consumers due to the rising popularity of conversational assistants (Budler et al., 2023). In our work, we cover both the datasets related to QA for biomedical research and consumer health.

2.2 Open-Domain Fact Verification and QA

Considering that the datasets we use only contain questions with discrete (*yes/no*) answers, our work is related to the task of automated fact verification (fact-checking). This task aims to verify the veracity of a factual claim based on credible evidence that supports it, refutes it, or does not provide enough information (Guo et al., 2022). Recent years have seen a rise in fact-checking datasets focusing on scientific knowledge, in particular health and medicine (Vladika and Matthes, 2023a).

While fact verification literature often works in a closed-domain setting with evidence documents provided, some recent work also explores the open-domain setting. Wadden et al. (2022) observe significant performance drops in F1 scores of final verdict predictions when increasing the evidence corpus from a few thousand to half a million documents. Pugachev et al. (2023) analyze how well consumer-health questions can be answered with built-in search engines of PubMed and Wikipedia. Expanding the scope even more, Vladika and Matthes (2024) compare the performance of semantic search and BM25 over PubMed and Wikipedia, as well as Google search, for verifying biomedical and health questions.

Some studies have analyzed the influence of time and quantity in evidence retrieval on downstream tasks. Allein et al. (2021) trained time-aware evidence ranking models for time-sensitive news claims and show performance improvement. Likewise, Schlichtkrull et al. (2024) constructed a dataset where evidence for given claims only appeared after the claim itself, thus eliminating temporal leaks. Regarding the document quantity, Oh and Thorne (2023) analyze the influence of the number of retrieved evidence passages on the QA performance over two general QA datasets, showing that the performance often actually drops with the increasing number of retrieved snippets.

To the best of our knowledge, our paper uses the largest document collection so far for open-domain health QA by indexing the entire PubMed corpus of more than 20 million articles. Likewise, it is also the first study to test the influence of the number of documents retrieved on the final QA performance instead of fixing it to a certain number, like the commonly found 5 (Thorne et al., 2018) or 6 (Wadden et al., 2022); as well as testing the influence of the different number of sentences retrieved. While there has been existing research on time-aware evidence ranking in fact verification for news claims, our work is first to explore the temporal aspect for biomedical questions, as well as other evidence quality aspects like the number of citations of retrieved publications.

3 Foundations

In this section, we explain the foundations of the study, including the used datasets, the evidence corpus, and the structure of the used QA system.

3.1 Datasets

We chose three datasets of biomedical and health claims in English, built for different purposes. We only use the questions and final labels (answers) from the datasets in our experiments. While the datasets provide the gold evidence passages used to derive the answers, we do not utilize them since the idea of our open-domain QA setting is that the retriever component has to discover the relevant evidence in a large document corpus.

HealthFC (Vladika et al., 2023) is a question-answering and fact-checking dataset focusing on consumer health questions and common topics users search health advice online for. It includes diverse topics like dietary supplements, heart and lungs, reproductive health, cancer, and mental health. Medical practitioners manually answered and verified all the questions using the evidence from systematic reviews and clinical trials. There are 750 questions in total, out of which 205 are supported, 122 are refuted, and for 433 questions, there is not enough information (NEI) to answer. We use two variants of the dataset: **HealthFC-3**, which has all **750** claims and all three classes; and

HealthFC-2, which only has **327** supported and refuted claims with two classes.

BioASQ-7b (Nentidis et al., 2020) is a biomedical question-answering dataset constructed by biomedical researchers and designed to reflect the real information needs of biomedical experts. It is part of the ongoing challenge of the same name, focusing on biomedical semantic indexing and question answering. The evidence for answers comes from biomedical research publications, i.e., the same corpus of PubMed used in our study. Other than only exact answers, the BioASQ dataset also includes ideal answer summaries. The 7b version of the dataset we use has **745** claims, of which 614 are supported ("yes"), and 131 are refuted ("no").

TREC-Health (Pugachev et al., 2023) is a dataset of 117 popular health questions originating from two TREC shared challenges. TREC is an ongoing series of workshops centering on challenges in accurate information retrieval (Voorhees et al., 2005). The questions stem from two shared tasks: the TREC 2019 Decision Track (Abualsaud et al., 2020) and the TREC 2021 Health Misinformation Track (Clarke et al., 2021), both focusing on challenges with incorrect search engine results for health (mis)information. Questions cover common consumer health concerns, similar to HealthFC, but the two datasets do not overlap. The dataset consists of **113** questions, of which 61 are supported ("yes") and 52 refuted ("no").

Table 1 gives an overview of the four datasets. With HealthFC and TREC-Health, we aim to target common health questions users would pose to a QA system, while BioASQ is selected in order to explore how do the QA results change for more complex, expert-geared biomedical questions.

Dataset	**Domain**	✓	✗	**?**
HealthFC-3	everyday health	202	125	433
HealthFC-2	everyday health	202	125	—
BioASQ-7b	biomedical research	614	131	—
TREC-Health	consumer health	61	52	—

Table 1: The four datasets used in the experiments, including their domain and label distribution. (✓ – supported, ✗– refuted, **?** – not enough information)

3.2 Evidence Corpus

We approach the QA task in the open-domain setting, meaning that evidence is unknown when the question is posed and must first be discovered in a vast evidence collection. Given that we work with medical and health-related questions, we chose a collection of biomedical research publications as the source of evidence.

Our evidence corpus originates from PubMed, a large and trustworthy knowledge base of biomedical research publications (Canese and Weis, 2013). Considering that the full text of most of these publications is not freely accessible, we use only the abstracts, which are always available. This does not hinder the performance since medical abstracts often already include a verdict on their main research hypothesis. The US National Library of Medicine provides every year MEDLINE, a snapshot of currently available abstracts in PubMed that is updated once a year. We used the 2022 version found on the official website.[2] While this yields 33.4M abstracts, we pre-processed the data by removing any non-English papers, papers with no abstracts, and papers with unfinished abstracts, which yields 20.6 million abstracts.

3.3 QA System

The question-answering system used for our experiments is in the form of a pipeline, based on the pipeline system from Vladika and Matthes (2023b). This pipeline consists of two main parts: a *retriever* and a *reader*. The process of question answering is done sequentially, by first retrieving the evidence, performing reasoning over it, and finally producing a final answer. Our experiments focus on changing the different aspects of the retriever while keeping the reader completely fixed. This ensures that the experimental setup is consistent and that only one parameter is tested at a time.

In the retriever, given a question q and a corpus of n documents $D = \{d_1, d_2, ..., d_n\}$, the goal is to select the top k most relevant documents $g_1, ..., g_k$ for the given query. The selection is done with a function $search(q, d)$, which compares the similarity of the question (query) and each document in the corpus. The documents in our corpus are abstracts of medical publications. While abstracts are shorter versions of full documents, they can still contain irrelevant sentences for producing the

final verdict.

In our first experiment, we use full documents $g_1, ..., g_k$ and the question q to predict the final answer. In the second experiment, we select only the top j most relevant sentences from the abstracts. From m candidate sentences $s_1, s_2, ..., s_m$ comprising the selected documents, top j sentences are selected as evidence sentences $\vec{e} = e_1, e_2, ..., e_n$ with a function $select(q, s)$. These sentences are the most similar to the question q.

Finally, the answer is predicted from the given question q and evidence $\vec{e}$, where the evidence is either the complete documents (the first round of experiments) or a set of sentences (the second round of experiments). The reader model produces the final verdict and is one of three classes $y(q, \vec{e}) \in \{$*Refuted*(0), *Supported*(1), *Not Enough Information*$(2)\}$. While QA can be generative and elicit long answers, all datasets we use contain only the short *yes/no/unknown* answers. This makes using the standard classification metrics precision, recall, and F1 possible. We model answer prediction as the related task of recognizing entailment or natural language inference (NLI) and use an NLI model for the prediction.

In all experiments, majority voting is used to determine the final verdict. For the dataset HealthFC-3 with three classes, this can be one of the three classes (0, 1, 2). For other datasets, the majority is taken only from predictions of 0 and 1 (in case of a tie, 0 is predicted). Majority voting is chosen for convenience, but it is not optimal as the information on prediction disagreement. Future work should explore how to model the disagreement better.

For the $search(q, d)$ function that selects *top k* most relevant documents, we use BM25 as it was proven to be a strong baseline for retrieving documents for automated claim verification (Stammbach et al., 2023). It also ensures higher precision at the cost of coverage, which aligns with our use case – we want the retrieved documents to be relevant before being passed to the reader. We use a sentence embedding model and semantic search to select the sentences most similar to our query from abstracts. For $select(q, s)$, we select the model SPICED (Wright et al., 2022), which is a recent sentence similarity model optimized for paraphrases of scientific claims. For the final answer prediction model (reader) $y(q, \vec{e})$, we choose the DeBERTa-v3 model (He et al., 2021) since it was shown to be a highly potent model for natural language understanding and reasoning tasks. We use the variant of the model optimized for NLI prediction (Laurer et al., 2024). We do not fine-tune the models on the datasets in our experiments because we want to simulate a realistic QA system that has to answer unseen questions.

4 Experiments

We conduct three groups of experiments to test the influence of different retrieval parameters on the performance of our QA system.

Number of retrieved documents. The first group of experiments consisted of keeping the QA pipeline consistent but increasing the number of retrieved documents (*top k*) that are forwarded to the final QA module. The motivation behind this was to find the fine balance between covering enough different studies but not saturating the module with noise and irrelevant articles. Considering the increasing popularity of retrieval-enhanced systems such as retrieval-augmented generation (RAG) pipelines (Lewis et al., 2020), retrieving only the relevant amount of documents or chunks is a significant challenge. We use BM25 as the retrieval technique because of its efficiency and its

Table 3: Results of final answer prediction over four datasets, with different values of *top j* sentences retrieved during the process and used for majority voting. All scores are macro averaged.

focus on enhancing precision instead of recall.

Number of retrieved sentences. Instead of taking the whole documents and sending them with the question to the reader, the second group of experiments selected only the *top j* most relevant sentences within all abstracts and used those as evidence. In this setup, we first retrieve the top 20 most similar abstracts with BM25. Afterward, all abstracts are split into sentences, which are embedded with the sentence-embedding model SPICED. After that, the *top j* most similar sentences to the question q, according to cosine similarity, are chosen from the pool of sentences (so multiple sentences can come from the same abstract). The QA module calculates the entailment probability between the question and each selected sentence, and finally, majority voting is performed.

Year of publication and number of citations. The third and fourth group of experiments focused less on the technical parameters of the retrieval but more on the *quality* of the discovered evidence. So far, not many studies have leveraged the metadata of retrieved evidence documents for enhancing medical and health-related question answering or fact verification. We use two metadata parameters that should intuitively have an influence on the quality of the performance – *year of publication* of the retrieved research publication and the *number of citations* it has. The year was provided among the metadata that comes with PubMed, but getting the number of citations was more challenging, considering it is not foundin the MEDLINE dump. Therefore, we utilized the *Semantic Scholar API* (Ammar et al., 2018) by querying it with the PubMed ID (PMID) of the retrieved article and then calling the API to get the number of citations. Once we had both numbers, experiments consisted of filtering the pool of possible evidence documents by posing a restriction on the minimum year of publication and the minimum number of citations. Out of the top k documents we retrieved, only those published after a certain year, or those with at least a certain number of citations, were selected as the final evidence documents. The rest of the workflow is the same as in the first experiment: the documents are passed to the QA module and the answer is predicted.

Given that we work with discrete answers and labels, the evaluation metrics we used are macro-averaged versions of classification metrics precision, recall, and F1 score. Macro averaging implies that the arithmetic mean of the metric for each individual class is taken (e.g., $F1_{macro} = \sum_i F1_{class\,i}/n$). For HealthFC-3, this is an average of three classes, while for the other datasets, it is an average of two classes. The motivation behind using the macro version is that it considers all classes equally important. We posit that in a deployed health QA system, users would be interested not only in detecting positive answers, but the system effectively discerning between both negative and positive answers to questions. This also follows the literature on automated fact-checking, which commonly uses macro-averaged scores (Bekoulis et al., 2021).

All the experiments were run on a single Nvidia V100 GPU with 16 GB of VRAM. The process of retrieving the top 100 most relevant documents for each dataset used one computation hour. The process of predicting the final answer with the top 100 most relevant documents also used one computation hour.

5 Results

In this section, we present and describe the results of the conducted experiments. Table 2 shows the final classification scores when changing the number

Year	**Precision**	**Recall**	**F1 Score**
$\geq$ **2020**	59.7	**60.3**	**58.7**
$\geq$ **2018**	59.6	58.0	57.9
$\geq$ **2015**	61.1	56.0	53.9
$\geq$ **2010**	63.4	55.6	52.8
$\geq$ **2005**	**68.1**	56.5	52.0
$\geq$ **2000**	66.1	56.8	51.8
$\geq$ **1990**	65.6	55.4	51.3
$\geq$ **1980**	64.2	54.7	50.0

Table 4: Results of final answer prediction over HealthFC-2, with different limitations on the earliest year of the retrieved evidence documents. All scores are macro averaged.

of documents retrieved. Similarly, Table 3 shows the final performance for different numbers of top sentences extracted. Tables 4 and 5 show the influence of filtering evidence documents based on their year of publication and number of citations.

5.1 Retrieved Documents and Sentences

An interesting trend is observed when looking at Table 2. For all four datasets, the worst performance was when retrieving the highest amount of documents (50 and 100) and slowly increased towards the lower values. In the case of HealthFC-2 and TREC-Health, taking just the top document gave the best value of F1 (although the best macro precision and recall were with 5 and 10 documents). For BioASQ, taking into account just the top document is considerably worse than all other settings (because of poor recall), but the overall trend also holds for this dataset. As expected, the most challenging is the ternary version of HealthFC, but even there, the F1 performance increase of +2.5% is observed from 100 to 1 document. For binary HealthFC and TREC-Health, jumps from 100 to 1 of +18% and +10% are seen.

When looking at Table 3, the results are less consistent than in the previous case. In fact, for datasets HealthFC-3 and BioASQ, the effect is rather opposite to the one in the previous experiment. The performance kept dropping as the number of selected sentences was lowered. The increased amount of knowledge in the bigger corpus of sentences helped the performance. For the binary HealthFC and TREC-Health, the numbers generally increased towards the lower number of sentences retrieved, but there wasn't a consistent pattern. Overall, the experiment showed that, in general, adding sentences that are relevant and semantically similar to the question increases the performance as opposed to adding more full documents to the QA system.

# Cits.	**Precision**	**Recall**	**F1 Score**
$\geq$ **100**	59.7	**58.9**	**59.1**
$\geq$ **75**	59.6	57.9	58.0
$\geq$ **50**	65.2	58.5	56.9
$\geq$ **25**	65.0	57.8	55.8
$\geq$ **10**	57.6	55.6	54.8
$\geq$ **5**	**67.0**	56.9	53.6
$\geq$ **0**	66.4	56.5	53.1

Table 5: Results of final answer prediction over HealthFC-2, with different limitations on the minimum number of citations of the retrieved evidence documents. All scores are macro averaged.

5.2 Evidence Quality

Table 4 tested the influence of the recency of the paper (year of publication) on the predictive performance. Once again, an interesting trend can be noted. The more recent the selected documents were, the more accurate the answers to health questions in our system. A similar phenomenon can be observed in Table 5 for the number of citations of the papers. When limiting the selection to more and more cited papers, the final score kept increasing. Nevertheless, the highest scores in Tables 3 and 4 are still lower than the top-1-document performance from Table 4.

It intuitively makes sense that the more recent papers will provide the latest knowledge and insights into a research hypothesis, which then also better aligns with the gold labels of our datasets. This is also slightly biased by the recent creation date of our datasets, where annotators had access to the most recent knowledge. Likewise, the better the reputation of a paper (more citations), it could

		average	**median**	**std.dev.**

Question	Document #1	Document #2	Document #3
Is intense physical activity associated with longevity? (**Supported**)	Evidence, mainly from cross-sectional studies, suggests that physical activity is a potentially important modifiable factor associated with physical performance and strength in older age. It is unclear whether the benefits of physical activity accumulate across life or whether there are sensitive periods when physical activity is more influential. (Cooper et al., 2011) (**Not Enough Info**)	Physical activity plays an important role for achieving healthy aging by promoting independence and increasing the quality of life. (...) Indeed, there is evidence to suggest that increasing exercise intensity in older adults may be associated with greater reductions in the risk of cardiovascular disease and mortality. (El Hajj Boutros et al., 2019) (**Supported**)	Exercise training above the public health recommendations provides additional benefits regarding disease protection and longevity. Endurance exercise, including high-intensity training to improve cardiorespiratory fitness promotes longevity and slows down aging. Strength training should be added to slow down loss of muscle mass, associated with aging and disease. (Pedersen, 2019) (**Supported**)
Is dexamethasone recommended for treatment of intracerebral hemorrhage? (**Refuted**)	Dexamethasone contributed to many serious adverse events. Conclusions: Given the small sample size, these preliminary results have not shown a clear beneficial effect of dexamethasone against placebo in our patients. (Prud'homme et al., 2016) (**Refuted**)	Overall, there is no evidence of a beneficial or adverse effect of corticosteroids in patients with either SAH or PICH. Confidence intervals are wide and include clinically significant effects in both directions. (Feigin et al., 2005) (**Not Enough Info**)	Dexamethasone has been used to treat cerebral edema associated with brain abscess. (...) Conclusions: In patients with a brain abscess treated with antibiotics, the use of dexamethasone was not associated with increased mortality. (Simjian et al., 2018) (**Supported**)

Table 7: Example questions and retrieved evidence from the top three documents. In the first case, retrieving the top-3 performs better than retrieving just the top-1 document. In the second case, retrieving just the single best document gives a more precise verdict.

be assumed it will be a more reliable indicator of a correct answer. This wasn't the case for all of the questions, and there were many examples where older or less cited papers aligned better with the gold labels. Still, Table 6 provides some statistics that show that the trend generally holds. On average, those documents that produced a correct verdict were around three years more recent (in both the mean and median) while having an average of 10 citations more (median four citations). On the other hand, all categories have considerable standard deviations, showing many outliers and exceptions to this rule.

Another challenging factor is that there could seemingly be an inverse correlation between the age of a paper and its number of citations – older publications have had more time to gather a bigger number of citations. After deeper inspection, we observed that being cited a lot over time is only true for high-quality studies. Overall, striking a balance by finding both those studies that are both recent and already highly cited is an optimal strategy.

6 Discussion

In this section, we discuss and provide deeper insights uncovered in the results.

6.1 Qualitative Analysis

Specific effects of retrieving multiple documents for open-domain health question answering are shown in Table 7. For the first question, just retrieving the best document would have led to a study that does not provide a definitive conclusion to the question. However, the second and third most similar documents that were retrieved support the given research hypothesis. This held true even for further documents that cannot be shown in the table because of space constraints. On the other hand, the second question would have been more appropriately assessed by just looking at the best document instead of the top 3 documents. In fact, the second and third documents do not explicitly talk about the given question but rather a variation.

Examples of positive influences of taking into account the qualitative properties of the evidence into account, namely the year of publication and number of citations, are shown in Table 8. For the first question, a publication with above 100 citations directly answers the question and matches the gold annotation for this claim from the dataset. On the other hand, the second most similar retrieved document was a study with only three citations, which seems to be inconclusive about or even refuting the research hypothesis. Similarly, the answer to the second question on the effects of ginkgo is skewed by the top document from the 1990s that talks about the presumed positive effects of ginkgo. Two decades later, another meta-review analysis of systematic reviews on ginkgo biloba showed that it was not proven to help with tinnitus. This nicely demonstrates the changing nature of scientific knowledge and scientific consensus throughout time.

6.2 Future Directions

Based on our findings and discussion, we see that future work could focus on these directions:

- **Strength of evidence.** Taking into account the year of publication and number of citations has proven to be an effective strategy for en-

Question	Document #1	Document #2
Can stress promote dementia? (**Supported**)	To test the hypothesis that high job stress during working life might lead to an increased risk of dementia and Alzheimer's disease (AD) in late life. (...) Lifelong work-related psychosocial stress, characterized by low job control and high job strain, was associated with increased risk of dementia and AD in late life, independent of other known risk factors. (Wang et al., 2020) (**Supported**) [**121 citations**]	Patients with Alzheimer's disease (AD) or dementia are increasing in numbers as the population worldwide ages. Mid-life psychological stress, psychosocial stress and post-traumatic stress disorder have been shown to cause cognitive dysfunction. The mechanisms behind stress-induced AD or dementia are not known. (Zhu et al., 2021a) (**Refuted**) [**3 citations**]
Can ginkgo biloba relieve the symptoms of tinnitus? (**Refuted**)	Ginkgo biloba is a plant extract used to alleviate symptoms associated with cognitive deficits, e.g., decreased memory performance, lack of concentration, decreased alertness, tinnitus, and dizziness. Pharmacologic studies have shown that the therapeutic effect of ginkgo(...) (Søholm, 1998) (**Supported**) [**Year: 1998**]	We identified three systematic reviews including four primary studies, all corresponding to randomized trials. We concluded the use of Ginkgo biloba probably does not decrease the severity of tinnitus. In addition, it does not reduce the intensity of tinnitus or improve the quality of life of patients. (Kramer and Ortigoza, 2018) (**Refuted**) [**Year: 2018**]

Table 8: Example questions and retrieved evidence from two different documents, where only one of them provided a correct final answer. The more recent and the more cited papers provided better performance.

hancing the health question-answering performance. Similarly, further metadata could be taken into account to augment the process. In medical research, the strength of evidence is an important factor, and systems like GRADE are used to assess it (Balshem et al., 2011). Different types of studies, such as a single study, a randomized clinical trial, and a systematic review, all have different strengths. Including this could be an important factor in improving the reliability of answers.

- **Evidence disagreement and variation.** We observed how different studies and sources can come to differing conclusions regarding a claim. In this paper, we chose the majority vote among the *top k* documents as the final decision, but this diminishes the information about the prediction uncertainty. This is part of the broader ML problem of learning with disagreements (Leonardelli et al., 2023) and modeling human label variation (Baan et al., 2024). While usually applied to uncertainty in data annotation, it could also be applied in the future to uncertainty in answering questions with diverse evidence documents.

- **Interpretability and user-centric results.** Other than just predicting the final answer, the end users posing biomedical and health questions would appreciate making the results more interpretable. This includes aspects such as displaying the different evidence documents, highlighting important sections, and showing prediction probabilities. Modern large language models (LLMs) could be used to enhance the reasoning process and to generate user-friendly explanations of model predictions and decisions (Lamm et al., 2021).

7 Conclusion

In this paper, we conducted a number of experiments assessing the performance of a health question-answering system in an open-domain setting. Moving away from the standard setup of working with a small evidence corpus, we expand the knowledge sources to a large corpus of more than 20 million biomedical research abstracts. We measured the answer prediction performance over three diverse datasets of health questions while varying four aspects: number of retrieved documents, number of extracted sentences, and evidence quality in the form of year of publication and number of citations. Our results show that a lower number of documents retrieved leads to better performance, with the ideal spot in the 1–5 range. We also show that the performance is improved and made more reliable by using a time-aware evidence retrieval process, i.e., retrieving only the highly cited and more recent papers. Our research leaves room for exploration of disagreeing and conflicting evidence, generating explanations for end users, and including further metadata. We hope our research will encourage more exploration of the open-domain health question answering setting and addressing real-world user needs.

Limitations

The question-answering pipeline used in this paper is a complex system with multiple factors – the choice of the retrieval method, the sentence embedding model, the QA model, and the prediction threshold. It is possible that some incorrect predictions weren't due to the change in parameters but due to the faulty answer prediction. To account for this, we kept the reader part of the pipeline constant and fixed, to ensure a comparable setup. We focused on reporting only those findings and patterns that we observed were commonly occurring after a thorough analysis of retrieved evidence for each claim. Additionally, the final answer prediction for a given question was done by taking the label from the majority vote. This discards the information about evidence disagreement and label variation, which are also crucial in this domain. Future work should focus on this challenge.

Ethical Considerations

The study focuses on the medical domain and answering health-related questions. This is a sensitive field where problems like misinformation, model hallucination, and incorrect evidence retrieval can lead to harmful consequences, disinformation spread, and societal effects. The question-answering system in this study shows promising performance but is still not ready for deployment and widespread use by end users, considering incorrect predictions, hallucinations, and lack of model interpretability.

Abstract

In recent years, several interpretability methods have been proposed to interpret the inner workings of Transformer models at different levels of precision and complexity. In this work, we propose a simple but effective technique to analyze encoder-decoder Transformers. Our method, which we name DecoderLens, allows the decoder to cross-attend representations of intermediate encoder activations instead of using the default final encoder output. The method thus maps uninterpretable intermediate vector representations to human-interpretable sequences of words or symbols, shedding new light on the information flow in this popular but understudied class of models. We apply DecoderLens to question answering, logical reasoning, speech recognition and machine translation models, finding that simpler subtasks are solved with high precision by low and intermediate encoder layers.

1 Introduction

Many methods for interpreting the internal states of neural language models – and in particular Transformer-based models – have been proposed in the last few years (for a review, see Lyu et al., 2024). Such methods operate at many different levels of granularity, ranging from model-agnostic attribution methods that treat models as black-boxes, to probing methods that assess whether specific information is decodable from model representations, to fine-grained techniques aiming to *causally* link highly localized circuits to model behavior. These latter techniques (often referred to as 'mechanistic interpretability', Elhage et al., 2021, or 'causal abstractions', Geiger et al., 2021) are often strongly tied to model-specific components, and are likely to provide more faithful insight into how these models operate.

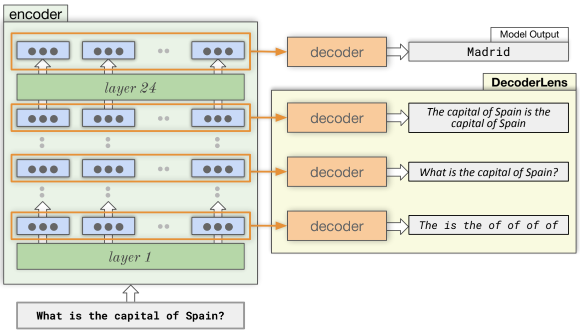

Figure 1: Schematic overview of the DecoderLens. By using the decoder to cross-attend intermediate encoder activation, we can gain qualitative insights into how representations evolve across encoder layers.

In this paper, we propose *DecoderLens*, a method aimed at exploiting the decoder module of encoder-decoder Transformers as a "lens" to explain the evolution of representations throughout model layers in these model architectures. Our method is directly inspired by the LogitLens (nostalgebraist, 2020), which leverages the *residual stream*[1] present in Transformer architectures. The LogitLens, however, is defined only for decoder-only Transformers, and is unable to explain how representations evolve in the encoder of encoder-decoder models.

Concretely, DecoderLens forces the decoder module of an encoder-decoder model to cross-attend intermediate encoder activations. As a consequence, its generations can be seen as sequences of vocabulary projections depending only on partially-formed source-side representations. Such adaptation is necessary as LogitLens requires the presence of a residual stream, which is not found between encoder and decoder modules. Contrary to common probing methods, DecoderLens operates without any additional training, letting the model "explain itself" by producing natural generations in a human-interpretable vocabulary space. Figure 1 provides a graphical overview of our approach.

We evaluate DecoderLens empirically on a wide

---

[1] The sequence of residual connections propagating input information from token embeddings to final layers.

Findings of the Association for Computational Linguistics: NAACL 2024, pages 4764–4780

range of tasks, models, and domains. First, we demonstrate how representations evolve in Flan-T5 (Chung et al., 2022) by prompting the model to predict country capitals. Next, we conduct an experiment in a more controlled domain, examining how Transformers are able to resolve variable assignment in propositional logic. The restricted output space for this task allows us to closely inspect the kinds of solutions intermediate layers produce. Finally, we apply the DecoderLens to two common applications of encoder-decoder models: neural machine translation (NLLB Team et al., 2022) and speech-to-text transcription and translation (Radford et al., 2022).

We find that intermediate outputs can be useful to find hypotheses about the strategies a model uses for solving (sub)tasks. One surprising finding, for example, is that Flan-T5 encodes geographical information *better* in intermediate layers than in the top layer. Additionally, our findings show that the middle encoder layers approximate correct transcriptions and translations well for models such as Whisper and NLLB. Experiments from both logic and machine translation show that earlier layers sometimes output local approximations to their respective tasks. The DecoderLens thus provides a useful tool that can be used in combination with other interpretability methods to gain a more complete insight into the inner workings of deep encoder-decoder language models.

2 Related Work

The current state of interpretability methods can be categorized by the different levels of granularity at which they explain model behavior. At the coarsest level, model-agnostic methods such as feature attributions (e.g., Sundararajan et al., 2017; Lundberg and Lee, 2017) focus on explaining model output in terms of the most important input features. A major concern with this line of work is the *faithfulness* of a method: whether the attributions the method produces in fact correspond to the true, underlying causes of the model's output. The strong disagreement between different attribution methods raises doubts that the faithfulness requirement is met in practice (Jacovi and Goldberg, 2020; Neely et al., 2022; Lyu et al., 2024).

In response to these concerns, a novel line of work that has received increasing attention in recent years attempts to explain models at a more fine-grained level, leveraging knowledge about a model's inner workings based on specific components (e.g., Elhage et al., 2021; Meng et al., 2022; Mohebbi et al., 2023; Wang et al., 2023).

Interpreting Language Models in Vocabulary Space A common way of studying Transformers in this line of work is to take advantage of the *residual stream*. In this view, each layer can be seen as adding or removing information by reading from or writing to the hidden states in the residual stream (Elhage et al., 2021). LogitLens (nostalgebraist, 2020) uses this idea by directly applying the unembedding operation to the middle layers of GPT to obtain a logit distribution for every intermediate layer. As the method projects into the output (logit) space, it can provide interpretable insights about which information arises in which layers. This is similar to the projections into vocabulary space used to verbalize probing methods in earlier work (Saphra and Lopez, 2019; Jumelet et al., 2021).

Merullo et al. (2023) use the Logit Lens to identify different generic stages of processing throughout GPT's layers in a Question Answering task. Halawi et al. (2023) instead use the Logit Lens to study *overthinking*, identifying critical layers in which the logit distribution suddenly shifts to an incorrect prediction. Geva et al. (2022) use the idea of the residual stream to study what kind of *updates* happen in each feed-forward layer, by analyzing the differences in logit outputs between layers. The updates are in vocabulary space, making them easily interpretable to humans. Similarly, Dar et al. (2023) also project other Transformer components into vocabulary space, such as its attention weights, and find that these can encode coherent concepts and relations. Belrose et al. (2023) present the Tuned Lens, extending the Logit Lens with an optimized, affine transformation before the unembedding operation, and report that it produces more reliable and predictive results. Finally, Ghandeharioun et al. (2024) present a general framework for information lenses called `Patchscopes`, and show that auxiliary models can be tuned to act as expressive vocabulary projections.

Early Exiting in Language Models Early exiting enables models to make early predictions by skipping subsequent layers once the model reaches sufficient confidence, improving model efficiency by speeding up inference. This is usually achieved by training intermediate classifiers on top of each encoder layer in encoder-only models (Liu et al., 2020; Zhou et al., 2020; Schwartz et al., 2020; Liao et al., 2021; Xin et al., 2020, 2021), or by training intermediate unembedding heads for each decoder layer in decoder-only or encoder-decoder models (Schuster et al., 2022). Pal et al. (2023) find that early-exiting from intermediate token representations can produce accurate next token predictions for several generation steps ahead, exploiting the parallel nature of Transformers outputs. Similar to early exiting is the concept of *encoder layer fusion*, in which a decoder can cross-attend to all encoder layers instead of the final one. This allows the decoder to use surface-level representations from early layers in addition to abstract, highly contextualized representations from later layers, which can improve the final performance (Dou et al., 2018; Liu et al., 2021; Feng et al., 2021; Charpentier and Samuel, 2023).

3 DecoderLens

The DecoderLens approach is inspired by the LogitLens method of nostalgebraist (2020). The main intuition behind this method is that the residual stream in Transformer decoder-only models forces representations across layers to gradually converge towards the final representation, iteratively refining its guess (Jastrzebski et al., 2018; Dehghani et al., 2019). This gradual change allows us to inspect how model predictions change across layers by directly applying the final *unembedding* transformation to intermediate hidden states.

For encoder-decoder models, the LogitLens can only be applied to the decoder component since there is no residual stream between encoder and decoder modules. To investigate how representations in the encoder evolve across layers, we therefore introduce the **DecoderLens**, which leverages the *entire decoder* to verbalize the knowledge captured by intermediate encoder layers. This is achieved by early exiting the encoder at earlier layers, and using the resulting representations for the decoder cross-attention operation. The DecoderLens allows for richer insights than the LogitLens, enabling the generation of full outputs from intermediate encoder states. It also may help mitigate out-of-distribution issues that can arise from using a single vocabulary projection (e.g. Belrose et al., 2023; Yom Din et al., 2023). The model outputs plausible strings that adhere to the original training objective, allowing us to see *how* the task is progressively addressed throughout encoder layers.

We define the DecoderLens as follows. For an encoder-decoder model $\mathcal{M}$ with n layers, the output of the decoder is normally generated based on the top-layer representations of the encoder, combined with a decoding algorithm (e.g. beam search). Often, the encoder layers are first passed through a non-linear operation, such as layer normalization (Ba et al., 2016). The DecoderLens operates similarly, by first passing the i^{th} encoder layer through the non-linear operation f, and then feeding it as input to the decoder:

$$
\begin{aligned}
\mathcal{M}(\mathbf{w}) &= \mathit{Dec}\left(f(\mathit{Enc}(\mathbf{w})_n)\right) \\
\mathit{DecoderLens}(\mathbf{w}, i) &= \mathit{Dec}\left(f(\mathit{Enc}(\mathbf{w})_i)\right)
\end{aligned}
$$

In the following sections, we investigate the effectiveness of DecoderLens by applying it to a variety of tasks, models, and domains.

4 Factual Trivia QA

We first apply the DecoderLens to investigate the factual knowledge of a instruction-tuned encoder-decoder LM, Flan-T5 (Chung et al., 2022)[2]. As a case study, we consider country capital prediction, using prompts of the form "*What is the capital of X?*" and testing encoder layers' ability to produce correct outputs for all 193 United Nations member states. We evaluate Flan-T5 models of three sizes (*large*, *xl*, *xxl*, with 0.78B, 3.0B and 11.3B parameters respectively), containing the same number of layers (24) and hidden state size (1024), but differing in the feed-forward layer size and the number of attention heads (Raffel et al., 2020).

Evaluation To investigate the types of responses generated by the DecoderLens, we categorize model answers as follows: 1) correct response, based on a full string match, 2) incorrect response in the form of a different city name, 3) country name itself, 4) repetition of the question, 5) tautologies (*The capital of X is the capital of X*), 6) empty responses containing no alphanumeric characters, and 7) a miscellaneous category for anything that doesn't fall under these previous six categories. These categories were defined after a manual inspection of the DecoderLens results: some examples of intermediate outputs can be seen in Table 1. We conduct the experiment on lowercased and capitalized prompts to test the robustness of the model to minimal variations in the provided inputs.

---

[2] All pre-trained models in the paper were evaluated via the `transformers` library (Wolf et al., 2020)

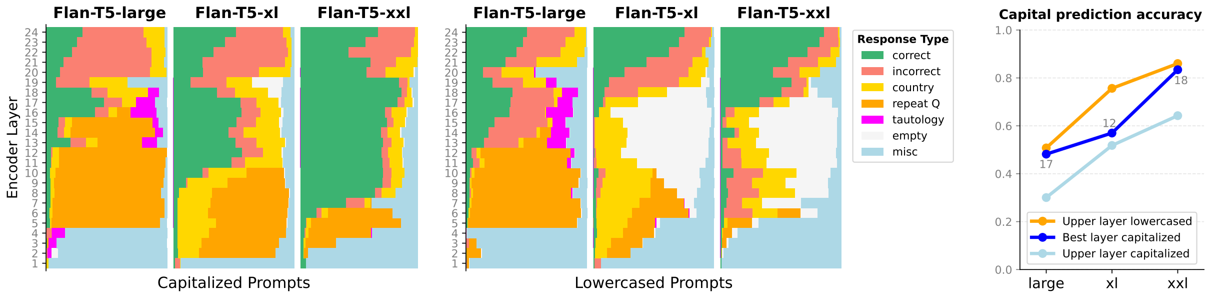

Figure 2: Distribution of response types for three Flan-T5 models on the country capital prediction task. Each row indicates the encoder layer that was used for the DecoderLens. Capital prediction accuracy denotes the model performance on the task for the two prompt types, including the best performing layers for the capitalized prompts.

Layer	Output
L0	What
L3	What is the capital of Colombia?
L8	What is the capital of Colombia?
L12	*The capital of Colombia is Bogotá.*
L16	Colombians are a very friendly people.
L19	Buenos Aires
L21	colombia
L24	*bogota*

Table 1: DecoderLens predictions for “What is the capital of Colombia?" for various Flan-T5-*xl* encoder layers. Correct outputs are *italicized*.

Results We present the results for the experiment in Figure 2. Capitalized and lowercased prompts yield considerably different patterns across layers. For capitalized prompts, we surprisingly find that all models yield *better performances* for intermediate layers compared to the canonical top layer of the model. For lowercased prompts, on the other hand, the top layer always yields the highest accuracy of all layers. The difference between the capitalized and lowercase prompts suggests that geographical knowledge is stored in different locations based on capitalization. We speculate that this might be due to the more frequent splitting of lowercased country names into multiple subtokens (188 out of 193 countries) compared to capitalized country names (only 87 out of 193 countries, including multi-word country names). Hence, country names split into multiple subtokens need to be compositionally combined by the model before retrieving their capital from encoded representations.

Finally, we note that Flan-T5-*large* has a long phase in which the DecoderLens results in a repetition of the original query prompt. In the *xl* model this occurs in lower layers, alongside repetitions of the country name itself, while the *xxl* model is less prone to these patterns, producing correct results much earlier for the capitalized case.

5 Propositional Logic

Results from the previous section indicate that DecoderLens can be useful for identifying the layers in which factual information arises and can be readily decoded in general pre-trained language models. In this section, we go one step further and apply DecoderLens to a model exclusively trained on a downstream task. We believe it is advantageous to test novel interpretability methods on models that are trained to solve a simple, unambiguous task within a carefully controlled setup (Hupkes et al., 2018; Hao, 2020; Jumelet and Zuidema, 2023; Nanda et al., 2023a,b).

We apply the DecoderLens to a small Transformer model that is trained from scratch on a synthetic (but non-trivial) task: predicting variable assignments given a logical formula.

Task We study an encoder-decoder model that is specifically trained on propositional logic, based on the setup of Hahn et al. (2021). The model is trained to output a partial satisfying *assignment* given a satisfiable formula in propositional logic. These inputs consist of logical operators (NOT/$\neg$/`!`, AND/$\wedge$/`&`, OR/$\vee$/`|`, IFF/$\leftrightarrow$ and XOR/$\oplus$) and at most five propositional variables. Table 2 lists a few examples.

Formula	Input	Output
$\neg a \wedge (b \vee c)$	`& ! a	b c`	a 0 b 1
$a \oplus \neg e$	`xor a ! e`	a 1 e 1

Table 2: Example datapoints for two formulas. Inputs use prefix notation to avoid the use of parentheses. The first assignment is *partial*: the value of `c` could be either `0` or `1`, and may therefore be omitted.

The models are trained in a standard sequence-to-sequence setup using teacher forcing and only have access to a single correct output, even when several partial assignments would be semantically correct. Nevertheless, this limited setup seems sufficient to teach these models the semantics of propositional logic (Hahn et al., 2021). At test time, the models are able to output novel assignments to unseen formulas with 93% accuracy.

Experimental setup We test encoder-decoder models using the standard transformer architecture. Encoder and decoder modules have each six layers, with hidden sizes of 128 and 64 respectively. Models are trained for 128 epochs on the *PropRandom35* training set of Hahn et al. (2021), which consists of 800k randomly generated formulas containing at most 35 symbols. The ground truth output assignments are generated by a symbolic SAT solver using `pyaiger` (Vazquez-Chanlatte and Rabe, 2018). We train three different model seeds and aggregate the results.

5.1 Evaluation on Controlled Data

We apply the DecoderLens to 1) randomly generated data and 2) handcrafted formulas using templates of varying difficulty. We hypothesize that easier formulas can be solved in earlier layers.

First, we evaluate on the *PropRandom35* validation set of 200k sentences, and an additional dataset of 200k short sentences with a maximum length of 12, *PropRandom12*.[3] Second, to gain more insight into the types of formulas layers can solve, we generate a dataset according to four templates:

T1. **Simple conjunction:** formulas in the form of $l_1 \wedge l_2 \wedge l_3 \wedge l_4$, where l_n is a propositional literal (p or $\neg p$). These formulas can be solved “locally", simply by reading the truth value from each variable separately.

T2. **Local XOR:** formulas in the form of $(l_1 \oplus l_2) \wedge (l_3 \oplus l_4)$, where all literals are distinct. Variables interact with their siblings via $\oplus$, but the two parts of the formula can be solved independent of one another.

T3. **Non-local XOR:** formulas in the form of $(l_1 \oplus l_2) \wedge (l_3 \oplus l_4)$, where l_2 and l_3 contain the same variable. The two parts cannot necessarily be solved independently.

T4. **Non-local CNF:** formulas in the form of $(p_1 \vee \neg p_2) \wedge (p_2 \vee \neg p_3) \wedge (p_3 \vee \neg p_1)$, containing dependencies between the clauses: this means the formulas cannot be solved locally.

For each template, we generate all possible non-trivial variable combinations, for multiple orderings of the subformulas. We filter out formulas that are not solved by the models. The total size of the template dataset is 30k.[4]

Results We evaluate the DecoderLens on the validation set of *PropRandom35*: the results are shown in Figure 3. We manually inspect some intermediate model outputs (Table 3 lists some examples).

We observe that nearly all incorrect outputs are still in the correct format, although many contain irrelevant variables that do not occur in the input formula. This suggests a learned division of duties between the encoder and decoder, with the decoder being completely in charge of formatting and variable ordering.[5] Note that there are a limited number of possible correctly formatted outputs (242 in total), of which, on average, 29% are semantically correct. The total semantic accuracy of the embedding layer and the first two layers is below 29%, meaning they do not perform better than random chance. Moreover, we find that initial layers often produce irrelevant variables, suggesting that their representations are misaligned with the final layer representations to an extent that makes them uninformative for the decoder.

Layers three and four prune these irrelevant variables and perform well above chance level. Examples of formulas that are already solved by these layers are the first two formulas in Table 3.

We observe that another function of the final two layers is to prune contingent variables, refining an already correct solution. E.g., in the first example in Table 3, layer five refines the layer four solution by removing the unnecessary “c 1". Around 20% of outputs of layers 5 and 6 are strict sub-outputs of the previous layer, removing 1.3 variables from the previous output on average. In a small number of cases (2.6%), layer five outputs a correct assignment but layer six does not: this could be seen as the model *overthinking* the output (Halawi et al., 2023). Only a minority of these cases (20% of the 2.6%) are due to layer six pruning a necessary variable.

---

[3] These shorter sentences are easier to automatically group into varying levels of difficulty.

[4] All datasets used for evaluation are available at github.com/annaproxy/decoderlens-data

[5] Even when random noise is passed to the decoder, it still outputs variables and their truth values in the correct order.

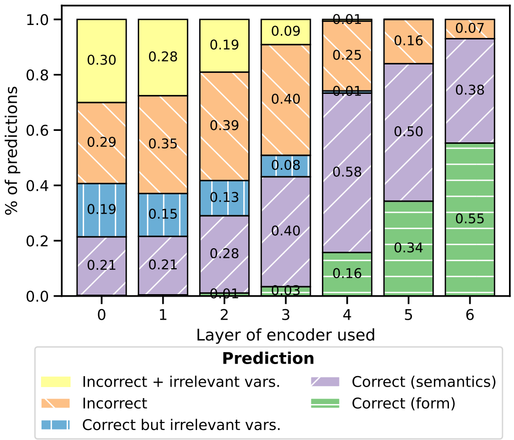

Figure 3: Performance of DecoderLens using intermediate encoder layers on the PropRandom35 validation set. Layer 0 denotes the embedding layer. The category *correct (semantics)* denotes outputs are correct, but deviate from ground truth sequences. All outputs in the *correct (syntax)* category are also semantically correct. We define variables as *irrelevant* when they did not occur in the input, but appear in the prediction.

The examples in Table 3 also demonstrate that solutions are more *local* in earlier layers. For instance, in the second example, layer three assigns *false* to both a and d, as they both occur negated in the sentence. The operator XOR, which requires communication between the two variables, is not taken in consideration yet.

Layer	$\neg b \wedge (c \vee a)$	$\neg d \oplus \neg a$	$b \oplus (b \wedge a)$
L0	a 0 b 1 e 0	a 1 b 1 c 1 e 1	a 1 b 1 c 0 e 0
L1	a 1 b 1 e 0	a 1 b 1 d 1 e 1	a 1 b 1 e 1
L2	*a 1 b 0 c 1*	a 0 d 0 e 0	a 1 b 1 c 0 e 1
L3	*a 1 b 0 c 1*	a 0 b 0 d 0	a 1 b 1 e 0
L4	*a 1 b 0 c 1*	*a 0 d 1*	a 1 b 1
L5	*a 1 b 0*	*a 0 d 1*	*a 0 b 1*
L6	*b 0 c 1*	*a 0 d 1*	*a 0 b 1*

Table 3: DecoderLens predictions on three simple logical formulas across encoder layers. L0: embedding layer. Semantically correct outputs are *italicized*.

5.2 Locality of Intermediate Outputs

To further investigate the locality of model outputs across encoder layers, we apply the model to multiple sets of sentences based around the XOR-operator and its logical opposite, IFF. We group the short formulas from *PropRandom12* into three categories: one where neither operator is present, one where either operator is present but is not the direct parent of another XOR/IFF (e.g. $(a \leftrightarrow b) \wedge (b \oplus c)$), and one having at least one nested instance of these two operators (e.g. $(a \oplus b) \leftrightarrow (c \wedge b)$). These patterns can be indicators of the formula's difficulty, but random formulas are not guaranteed to be (non)local. We therefore also analyze the performance of earlier layers on the handcrafted sentences described in §5.1.

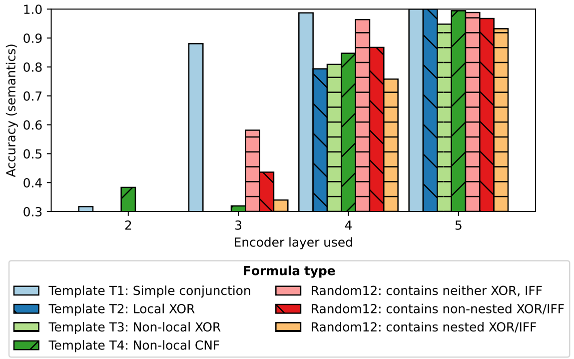

Figure 4: Performance on different kinds of formulas for the middle encoder layers.

Results DecoderLens results for the formula types detailed above are presented in Figure 4. We observe large jumps in performance across layers for the different sets of formulas. In particular, we note that simple conjunctions (pattern T1) can already be solved in layer three. However, the same layer cannot solve formulas including XOR. Instead, the layer outputs a *local* solution as in example 2 in Table 3, by simply assigning *0* to each variable that occurs in the negated inputs, and *1* in the non-negated ones.

Overall, a local solution is produced for at least one of the subformulas in 87% of cases, and for both formulas in 53% of cases. Other layers output local solutions as a much lower rate: more details can be seen in Figure 8 in Appendix A. Layer four sees the largest improvement for all other types of formulas, but still lags behind in solving non-local formulas, especially those containing nested XOR or IFF-operators.

These results supports the intuition that the model *gradually refines* its prediction by contextualizing its representations: first, variables collect *local* information about their possible truth value. These variables can only exchange information with other variables in the later layers to reach a coherent solution.

6 Machine Translation

We apply DecoderLens to NLLB-600M (NLLB Team et al., 2022), a state-of-the-art multilingual model trained in over 200 languages, to quantify

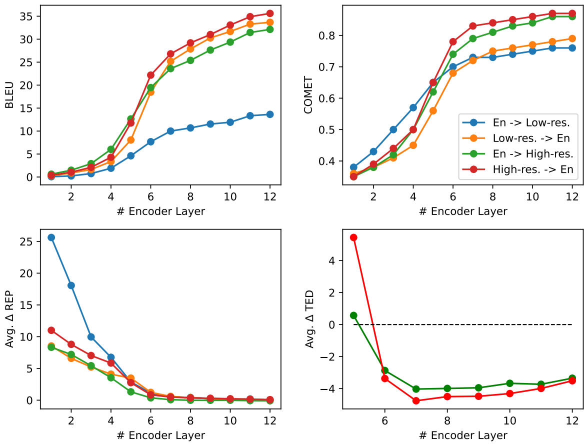

Figure 5: Performance of NLLB across encoder layers. Scores are averaged across into-English (XX → EN) and from-English directions (EN → XX) for low-resource and high-resource languages.

encoder influence on translation quality and properties. We use 1012 sentences from the dev/test split of Flores-101 (Goyal et al., 2022), using English ↔ {Italian, French, Dutch} as high-resource pairs and English ↔ {Xhosa, Zulu} as low-resource pairs to evaluate differences in intermediate encoder layers' performances for these two settings.

Metrics We evaluate the translation quality of DecoderLens outputs using BLEU and COMET (Papineni et al., 2002; Rei et al., 2022). Moreover, we define two ad-hoc metrics to estimate additional output properties. To quantify *repetition* we compute the difference in counts between most common tokens in the output and reference translation (ΔREP). To measure *syntactic reordering*, we compute tree edit distance (TED) between source and target syntax trees, for both the output (TED_{OUT}) and reference translations (TED_{REF}). We then take their difference: $\Delta\text{TED} = \text{TED}_{\text{OUT}} - \text{TED}_{\text{REF}}$. Positive scores for this metric reflect more syntactic reordering in the output compared to the reference translation. A negative ΔTED indicates that the model translation adheres more closely to the source sentence word ordering than the reference translation does. We limit our TED evaluation to layers with BLEU > 10 and high-resource pairs, using the Stanza, FastAlign and ASTrED libraries (Qi et al., 2020; Dyer et al., 2013; Vanroy et al., 2021) for parsing, alignment and TED computations respectively.

Quantitative results Figure 5 presents the results of our evaluation. We remark a stark difference in quality between translation into low-resource languages and other settings, with performance increasing rapidly halfway through encoder layers only in the latter case. All language directions exhibit a large number of repetitions for the first half of the encoder, suggesting that initial encoder layers are generally tasked to model n-gram co-occurrences, as also noted by Voita et al. (2021) for initial phases of neural MT training. Repetitions decline to match reference frequency around models' intermediate layers, coinciding with the largest increase in translation quality. Regarding reordering, syntax in translations stabilizes early in the encoder layers: in line with previous findings (Vanroy, Bram, 2021), outputs show a lower degree of syntactic reordering relative to source texts when compared to human references, providing additional evidence about the locality of intermediate layers' predictions shown in Section 5.2. The lack of spikes in translation quality for intermediate encoder layers in low-resource directions using DecoderLens can be connected to the low source context usage shown in Ferrando et al. (2022), suggesting that poor intermediate outputs for these directions might be due to the out-of-distribution behavior of the decoder component.

Table 4: Example DecoderLens translations for an English → French sentence of Flores-101.

Qualitative results We manually examine a subset of 50 DecoderLens translations through encoder layers (Table 4, more examples in Appendix B.1). For high-resource pairs, translations in the first few layers are fluent and contain keywords from the original sentence, but are completely detached from the source (see for example the L1 output in Table 4, which contains the word "television" but is otherwise detached from the English source.). Intermediate layers often output examples with incorrect word sense disambiguation (e.g. "shopping TV channel" interpreted as "TV channel being sold" in L4). Finally, more granular information is often added at later stages (e.g. "shopping" added in L7 and "Fin" in L11).

Table 5: Whisper-medium intermediate transcription outputs for an English utterance. Words that are correctly generated for the first time are underlined.

7 Speech-to-Text

We next apply DecoderLens to Whisper (Radford et al., 2022), a state-of-the-art multilingual speech model trained on a set of supervised audio-to-text tasks, including multilingual speech transcription and speech translation to English. We use Whisper in three different sizes (*base*, *small*, and *medium*) which differ in their number of layers (6, 12, and 24, respectively).

Data We use CoVoST 2 (Wang et al., 2020), a multilingual speech-to-text translation dataset based on Common Voice corpus (Ardila et al., 2019). We sample 100 sentences for nine languages: English (en), French (fr), Spanish (es), Portuguese (pt), Dutch (nl), Japanese (ja), Arabic (ar), Persian (fa), and Turkish (tr). Since the dataset includes both source and translation references for each utterance, we can inspect Whisper's behavior for both transcription and translation tasks on the same examples, providing an unbiased comparison between the tasks.

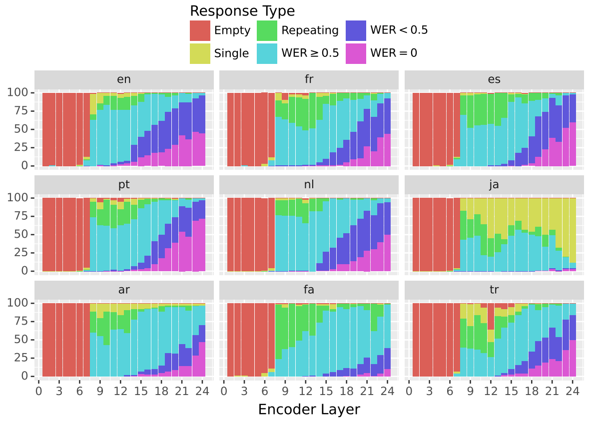

Figure 7: Distribution of Whisper-medium output types when transcribing, for each encoder layer.

Results Figure 6 shows the overall results of Word Error Rate (WER) across various source languages when applying DecoderLens to Whisper-*medium* for transcription and translation tasks. While the overall pattern of WER is decreasing, we can discern that fundamental information emerges from the intermediate layers. Comparing the trend of WER for transcription and translation, it appears that the essential information required for transcription is encoded in earlier encoder layers compared to translation.[6] Table 5 shows a more fine-grained view of the changes in model output transcription. The first 7 layers of the encoder produce empty outputs, indicating that the information is not yet ready for transcribing. Next, layers 8-11 generate a limited number of irrelevant words (notably, generating single words in layers 9 and 11), while layers 12-13 produce long sequences of repeating irrelevant words. The main part of the true transcription can be constructed starting from layer 15 (with some minor errors; the word 'news' is generated instead of 'in use' in this example). The error in this running example is then corrected in layer 21, and this information is carried to the final encoder layer. Figure 7 quantifies this to show that the pattern holds for the majority of examples in all languages. This pattern holds for both tasks and different model sizes, except for the early encoder layers of Whisper-*small*, which generates single irrelevant words instead of empty sequences.[7]

8 Conclusion

Our work contributes to a growing body of research on the interpretability of language models. By in-

---

[6] The same pattern is observed for the other model sizes, reported in Appendix C.1.

[7] We report these results to Appendix C.2.

troducing the DecoderLens, we provide insights into how intermediate encoder representations of encoder-decoder Transformers influence decoder predictions. We apply our method to various models and tasks, finding that intermediate outputs can provide valuable insights into the model's decision-making process. In particular, our findings reveal how "simpler" subtasks (e.g., simple conjunctive logic formulas, high-resource MT, speech transcription) are captured by early encoder layers with high precision and persist up to the final model output through the residual stream, while more challenging tasks (e.g., complex logic formulas, low-resource MT, speech translation) are only addressed by final encoder layers. We also find some evidence that early layer outputs are more *local* solutions. Errors in variable assignments in the middle layer of the Transformer trained on propositional logic are due to the model solving subparts of the sentence independently. Additionally, translations from earlier layers of NLLB adhere more closely to the word order of the input.

These observations are in line with previous work on probing, which showed that linguistic subtasks in LMs are performed at different stages in Transformers (Tenney et al., 2019; Peters et al., 2018). Moreover, it provides evidence that model predictions are *refined iteratively* also across encoder layers, complementing previous work on decoder-only models. By verbalizing the knowledge encoded in intermediate model layers, DecoderLens can provide useful and human-interpretable insights into the evolution of model predictions, complementing other interpretability techniques for the study of neural language models.

Future work could explore the application of DecoderLens to the Universal Transformer (Dehghani et al., 2018), especially for algorithmic tasks (Csordás et al., 2021) where its intermediate representation might be more interpretable and compositional thanks to weight sharing. Moreover, the tendency of earlier layers to produce simpler generations can be connected to outputs produced during early stages of model training (Voita et al., 2021). In this context, DecoderLens might be used to investigate the relation between training dynamics and information geometry across model layers (Choshen et al., 2022; Belrose et al., 2023). Lastly, DecoderLens could be used as diagnostic tool to investigate where wrong model predictions emerge, which is useful for both interpretability purposes and model improvement through early exiting strategies.

9 Limitations

One important concern regarding the direct use of intermediate representations to make predictions is that of *representational drift*: features may be represented differently in earlier encoder layers, reducing the ability of the decoder to use this information. This manifested in particular in the form of hallucinated or empty DecoderLens predictions for early encoder layers. While this representational misalignment could be mitigated by *tuning* representations to match the space of final layers (Belrose et al., 2023; Yom Din et al., 2023), we limit our analysis to the direct application of DecoderLens without any additional training.

We note that DecoderLens does not reveal *where* within a layer a specific subtask is solved (i.e., which heads or MLP-units within the layer are responsible), nor does it reveal *how* subtasks are solved. For this reason, while we consider our method promising to provide a more intuitive overview of encoder capabilities, we also believe it should be complemented with other approaches to obtain fine-grained insights into model predictions.

Finally, although our experiments span several encoder-decoder models and tasks, our evaluation is limited to small model sizes (<700M parameters) due to limited computational resources. It remains to assess whether our findings using the DecoderLens method still apply to larger models.

Acknowledgments We gratefully acknowledge support for this research from the Institute for Logic, Language and Computation at the University of Amsterdam (JJ, WZ), and from the Netherlands Organization for Scientific Research (NWO), through the NWA-ORC grant NWA.1292.19.399 for 'InDeep' (supporting HM, GS), and through the Graviation grant 024.001.006 for 'Language in Interaction' (supporting AL). We also thank SURF and the Faculty of Science (FNWI, UvA) for the use of the National Supercomputer Snellius.

A Propositional Logic

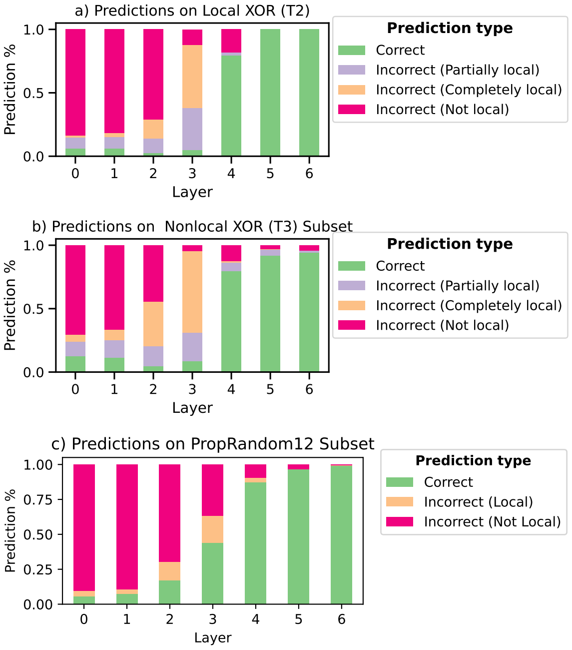

Figure 8: Distribution of the types of predictions on three small datasets. A *local* solution means the layer assigns *false* (`0`) to a variable if it occurs in the input negated, and *true* (`1`) if the variable appears non-negated. We therefore consider only the subset of data for which each variable either only occurs negated or only occurs non-negated. Layer 3 produces the largest number of local solutions in all cases.

B Machine Translation

B.1 Additional Examples of DecoderLens Translations

Tables 6 and 7 showcase some additional examples for some of the selected translation directions.

Source: Dr. Ehud Ur, professor of medicine at Dalhousie University in Halifax, Nova Scotia and chair of the clinical and scientific division of the Canadian Diabetes Association cautioned that the research is still in its early days.
Reference: Le Dr Ehud Ur, professeur de médecine à l'Université Dalhousie de Halifax (Nouvelle-Écosse) et président de la division clinique et scientifique de l'Association canadienne du diabète, a averti que la recherche en était encore à ses débuts.
