uzn_Latn	uzb	Uzbek	Turkic	Turkic	Latin	Very low

Table 7: The list of languages included in our experiments features several attributes for each language: its corresponding Lang ID from Flores-200, ISO 639-3 code, language name, language family, subgrouping, script, and resource level. This metadata was extracted from Goyal et al. (2022).

Table 8: Detailed evaluation of translation scores for 280 language directions from the Flores-200 dataset using the Llama-3 model. Results include Zero-Shot and regular k-shot baselines, along with our unsupervised method employing various selection approaches. Scores for each language pair are presented as chrF++/spBLEU, with the highest scores highlighted in bold. The 'average' row indicates the mean score across all language pairs.

	Baselines (Zero-shot + Regular ICL)			**Ours (Unsupervised ICL)**			
Pair	***Zero*-Shot**	**k-Shot**	**BM25**	**UW2W**	**Random**	**TopK**	**TopK+BM25**

Table 9: Detailed evaluation of translation scores for 222 language directions from the Flores-200 dataset using the Bloom model. Results include Zero-Shot and regular k-shot baselines, along with our unsupervised method employing various selection approaches. Scores for each language pair are presented as chrF++/spBLEU, with the highest scores highlighted in bold. The 'average' row indicates the mean score across all language pairs.

B.2 Analysis

Does the multilingual LLM testbed affect translation quality? Our experiments were conducted using Llama-3 and Bloom. It is important to note that translation performance is highly correlated with the choice of the LLM. Overall, Llama-3 outperforms Bloom in terms of translation spBLEU score. As illustrated in Figure 2, Llama-3 consistently outperforms Bloom across various language pairs, notably in *tur_Latn* → *eng_Latn* and *ben_Beng* → *eng_Latn*. However, there are exceptions where Bloom slightly surpasses Llama-3, such as in the *kaz_Latn* → *nso_Latn* pair.

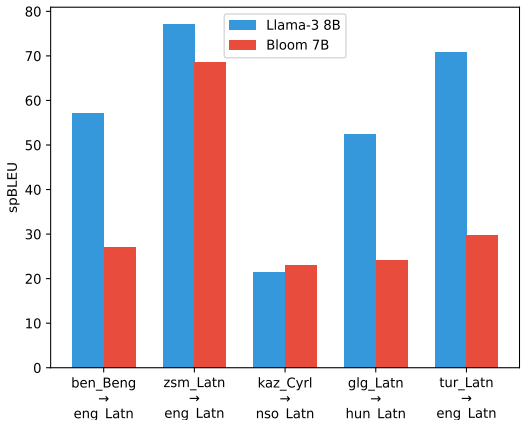

Figure 2: Comparison of the spBLEU score of our unsupervised TopK+BM25 using Llama-3 and Bloom for a randomly selected subset of language pairs.

How does iterative k-shot re-mining improve the quality of UMT? Figure 4 illustrates the spBLEU scores of five randomly selected language pairs from our experiments, where an additional iteration of the sentence-level translation phase described in Section 3.2 was performed. The results of this random subset indicate that, overall, the performance of UMT declines after another iteration of our algorithm. This can be observed notably in pairs such as *kor_Hang* → *nso_Latn* and *ltz_Latn* → *kat_Geor*, where the spBLEU performance using our UMT approach decreased considerably in the second iteration. Based on these findings, we conclude that applying our approach for a single iteration generally yields the best results.

Does the number of unsupervised ICL examples affect the UMT performance? Figure 5 illustrates the influence of the number of chosen ICL examples on the spBLEU score when employing

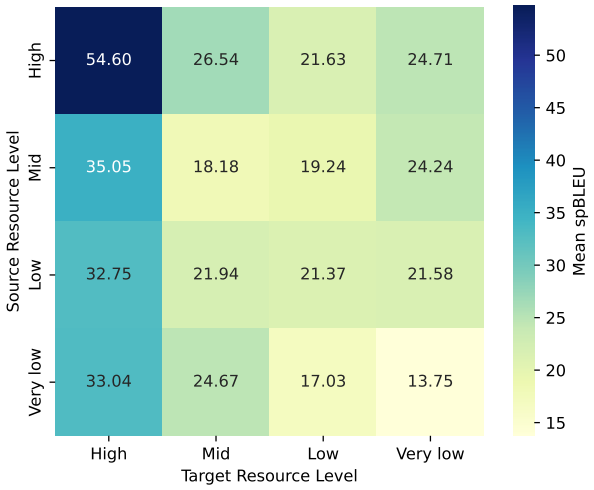

Figure 3: Average spBLEU scores from TopK+BM25 experiments across different resource levels for different language pairs using Bloom. Each cell represents the mean spBLEU score for translations from a source resource level to a target resource level.

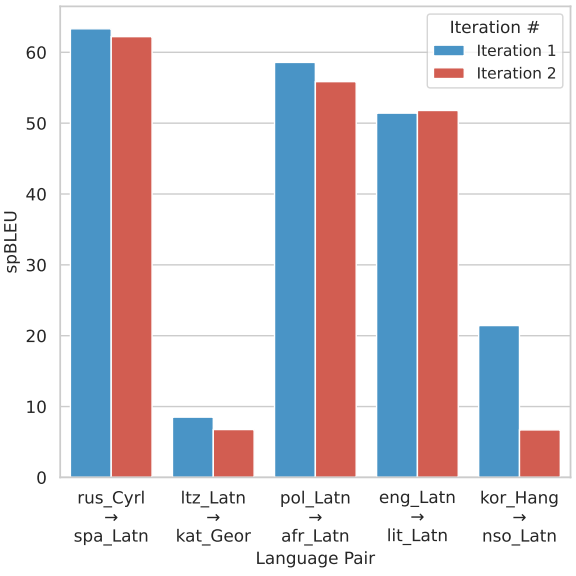

Figure 4: The impact of multiple iterations of our approach using TopK+BM25 on the spBLEU score for a subset of language pairs using Llama-3.

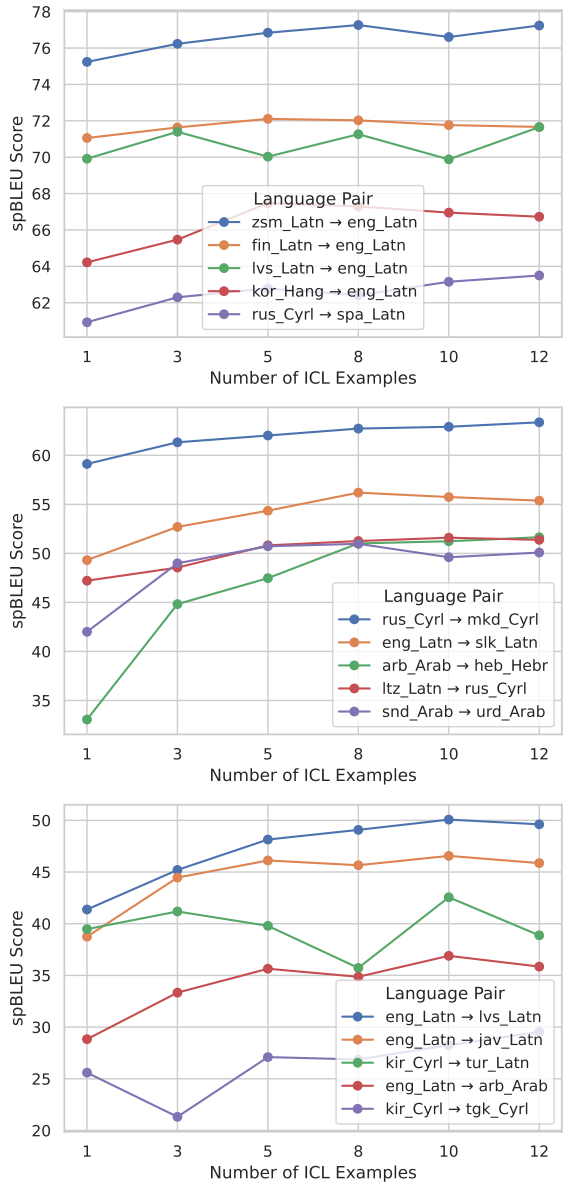

Figure 5: The impact of the quantity of ICL examples on the spBLEU score for UMT employing our TopK+BM25 approach with Llama-3.

the TopK+BM25 selection approach. The figure indicates that selecting a greater number of ICL examples generally enhances performance. This effect is particularly significant between 1 and 8 examples, where the spBLEU score shows significant increases for the majority of pairs. However, the increments in spBLEU score become less substantial between 8 and 12 examples.

Why does the translation performance in TopK ICL decrease compared to Random ICL? Table 1 illustrates a decline in performance when selecting the most confident pairs (*TopK ICL*) compared to *Random ICL*. Our analysis suggests that this decrease occurs because the similarity function prioritizes semantic confidence while disregarding linguistic details, consequently pairing examples from identical languages at times. In contrast, the BM25 selection method integrates both semantic relevance and surface-level linguistic comparisons. This approach results in pairs that not only represent the source and target languages accurately but also maintain semantic similarity.

Does applying BM25 filtering to the most similar sentence pairs enhance the quality of the resulting in-context examples? In our TopK+BM25 results, we applied our BM25 filtering criteria exclusively to sentence pairs that exceed a specific similarity threshold, τ. Figure 6 compares the results between applying BM25 selection on the entire pool of mined sentences (full pool) and applying it only to pairs filtered by the similarity threshold (TopK). The results indicate that using BM25 on the most similar parallel pairs generally yields higher spBLEU scores. This improvement is particularly noticeable in pairs such as *kor_Hand* $\rightarrow$ *eng_Latn* and *asm_Beng* $\rightarrow$ *som_Latn*. Table 12 in Appendix B.2 presents results for 19 language pairs, demonstrating that the TopK+BM25 selection strategy outperforms the application of BM25 on the full pool, with average spBLEU scores of 48.80 and 48.30, respectively.

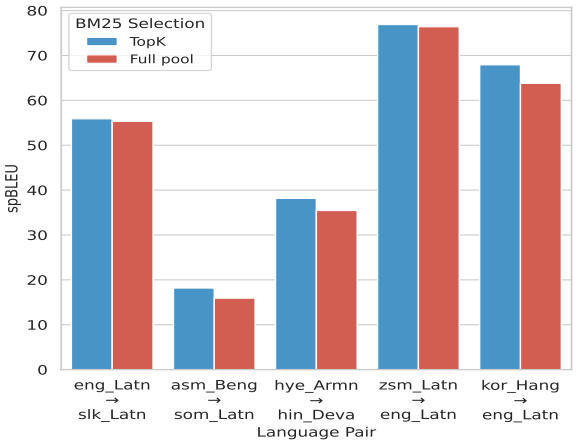

Figure 6: The impact of selecting the unsupervised k-shot from the most confident pairs (TopK) compared to selecting from all pairs (Full pool) on the spBLEU score for a subset of language pairs using Llama-3. (Table 12 in Appendix B.2 presents results for additional pairs.)

What is the impact of the selection threshold τ on the TopK+BM25 performance? Our proposed TopK+BM25 in-context selection for UMT

Lang. Pair	Threshold τ				
	0.0	0.3	0.5	0.7	0.9
ita_Latn	67.89	67.93	68.03	68.13	68.34
cat_Latn	71.92	72.14	72.76	72.81	73.95
zsm_Latn	70.67	70.98	71.01	71.50	71.20
bel_Cyrl	44.37	44.65	44.81	45.58	45.39

Table 10: Impact of Threshold τ on our TopK+BM25 UMT spBLEU Scores using Llama-3. These experiments were conducting by having the English language as source and the cited language in the Lang. Pair column as target.

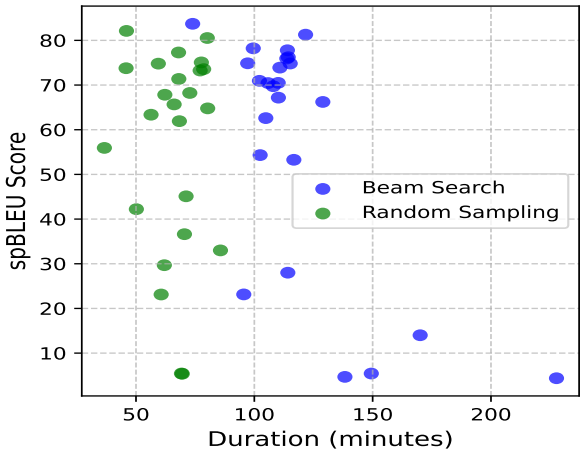

Figure 7: spBLEU scores and durations (in minutes) for the MT performance achieved using TopK+BM25 with Llama-3.

depends on the threshold τ to filter only the most confident semantically similar pairs. We conduct experiments varying the similarity threshold τ to analyze its impact on in-context example quality and translation performance. Our findings across multiple language pairs are presented in Table 10. From this subset, we conclude that the selection of the threshold τ has an impact on the TopK+BM25 spBLEU score, with higher τ values generally improving spBLEU scores, indicating better translation quality.

Does the decoding strategy affect performance? We performed the experiments in Table 1, but using Beam Search instead of Random Sampling. Results are presented in Figure 7 and compare both decoding strategies. Experiments performed using Beam Search are indeed slower than those using Random Sampling; however, the scores resulting from both models are comparable. This led us to choose random sampling in all our experiments.

Examples of translations made using our approach compared to the ground truth references and the regular k-shot baseline. Table 11 presents a sample of translations generated using our TopK+BM25 ICL approach compared to the regular k-shot and our unsupervised word-by-word approach. The examples indicate that our TopK+BM25 ICL approach can generate translations of comparable or superior quality to those produced by the regular ICL. Additionally, the examples demonstrate that while the word-by-word translation approach preserves the overall meaning, it often results in grammatical errors and incorrect word order. We discussed this issue in Section 3.2.1, where we explained the necessity for a back-translation step to mitigate these problems and produce more natural language translations from these word-by-word translations.

GPT-NER: Named Entity Recognition via Large Language Models

Shuhe Wang[▲], Xiaofei Sun[♦], Xiaoya Li[♣], Rongbin Ouyang[♠]
Fei Wu[♦], Tianwei Zhang[♥], Jiwei Li[♦], Guoyin Wang[★]

Abstract

Despite the fact that large-scale Language Models (LLM) have achieved SOTA performances on a variety of NLP tasks, its performance on NER is still significantly below supervised baselines. This is due to the gap between the two tasks the NER and LLMs: the former is a sequence labeling task in nature while the latter is a text-generation model.

In this paper, we propose GPT-NER to resolve this issue. GPT-NER bridges the gap by transforming the sequence labeling task to a generation task that can be easily adapted by LLMs e.g., the task of finding location entities in the input text *Columbus is a city* is transformed to generate the text sequence @@*Columbus## is a city*, where special tokens @@## marks the entity to extract. To efficiently address the *hallucination* issue of LLMs, where LLMs have a strong inclination to over-confidently label NULL inputs as entities, we propose a self-verification strategy by prompting LLMs to ask itself whether the extracted entities belong to a labeled entity tag.

We conduct experiments on five widely adopted NER datasets, and GPT-NER achieves comparable performances to fully supervised baselines, which is the first time as far as we are concerned. More importantly, we find that GPT-NER exhibits a greater ability in the low-resource and few-shot setups, when the amount of training data is extremely scarce, GPT-NER performs significantly better than supervised models. This demonstrates the capabilities of GPT-NER in real-world NER applications where the number of labeled examples is limited.

1 Introduction

Large-scale language models (LLMs) (Brown et al., 2020; Smith et al., 2022; Du et al., 2022; Rae et al., 2021; Thoppilan et al., 2022; Hoffmann et al., 2022; Chowdhery et al., 2022; Touvron et al., 2023) have shown an impressive ability for in-context learning: with only a few task-specific examples as demonstrations, LLMs are able to generate results for a new test input. Under the framework of in-context learning, LLMs have achieved promising results in a variety of NLP tasks, include machine translation (MT) (Vilar et al., 2022; Vidal et al., 2022; Moslem et al., 2023), question answering (QA) (Robinson et al., 2022; Li et al., 2022; Lazaridou et al., 2022) and named entity extraction (NEE) (Chowdhery et al., 2022; Brown et al., 2020).

Despite the progress, LLMs' performances on the task of NER are still well below supervised baselines. This is because of the intrinsic gap between the two tasks of NER and LLMs: NER is a sequence labeling task in nature, where the model needs to assign an entity-type label to each token within a sentence, while LLMs are formalized under a text generation task. The gap between the semantic labeling task and the text generation model leads to inferior performance when applying LLMs to resolve the NER task.

In this paper, we propose GPT-NER to resolve this issue. GPT-NER transforms the NER task to a text-generation task that can be easily adapted by LLMs. Specifically, the task of finding location entities in the input text *Columbus is a city* is transformed to generate the text sequence @@*Columbus## is a city*, where special tokens @@## marks the entity. We find that, compared with other formalizations, the proposed strategy, can significantly decrease the difficulty in generating text that fully encodes label information of the input sequence, as the model only needs to mark the position for entities and make copies for all the rest tokens. Experi-

Findings of the Association for Computational Linguistics:
NAACL 2025, pages 4257–4275
April 29 - May 4, 2025 ©2025 Association for Computational Linguistics

ments show that the proposed strategy significantly improves the performance.

Another big problem with LLMs for NER is the *hallucination* issue, where LLMs have a strong inclination to over-confidently label NULL inputs as entities. To address this issue, we propose a self-verification strategy, which is placed right after the entity extraction stage, prompting LLMs to ask itself whether an extracted entity belongs to a labeled entity tag. The self-verification strategy acts as a regulating function to counteract the excessive confidence of LLMs, which we find effective in addressing the *hallucination* issue, leading to a significant performance boost.

We conduct experiments on five widely-adopted NER datasets, both flat NER and nested NER. GPT-NER achieves comparable performances to fully supervised baselines, which is the first time as far as we are concerned. Additionally, we find that the performance hasn't plateaued when we reach the GPT-3 token limit with respect to the number of demonstrations. This means that there is still room for improvement when the 4,096 token limits of GPT-3 are released, e.g., using GPT-4 whose token limit is more than 20K. What is particularly noteworthy is that GPT-NER exhibits impressive proficiency in low-resource and few-shot NER setups: when the amount of training data is extremely scarce, GPT-NER performs significantly better than supervised models. This illustrates the potential of GPT-NER to be employed in real-world NER applications even when the quantity of labeled samples is scant.

2 Related Work

Named Entity Recognition. Named Entity Recognition (NER) is a task to identify key information in the text and classify it into a set of predefined categories. A common approach to resolve NER is to formulate it as a sequence labeling task. Hammerton (2003) used unidirectional LSTMs to obtain token-level representations and feed them to the softmax classifier obtaining the results. Collobert et al. (2011) used CNN to embed each input word and leverage CRF to decode each embedding into a certain entity. Chiu and Nichols (2016) used a character CNN and Devlin et al. (2018) used BERT to obtain token-level representations for classifications. Lample et al. (2016) combined the bidirectional LSTMs with CRFs to augment the prediction. Sarzynska-Wawer et al. (2021) improved the quality of each word via a large-scale pre-training model. Li et al. (2019a,b) formulated the NER task as an MRC task and further leveraged dice loss to improve the performance of the MRC model, and Wang et al. (2022) proposed the GNN-SL model to allow a general NER model to refer to training examples at test time.

Large Language Models and In-context Learning. Large language models (LLMs) (Brown et al., 2020; Rae et al., 2021; Smith et al., 2022; Hoffmann et al., 2022; Chowdhery et al., 2022) have obtained significant performance boosts on a variety of natural language processing tasks (Hegselmann et al., 2022; Vilar et al., 2022; Perez et al., 2021; Pietrzak et al., 2021; Wei et al., 2021). Strategies to use LLMs for downstream tasks can be divided into two categories: fine-tuning and in-context learning. The fine-tuning strategy takes a pre-trained model as initialization and runs additional epochs on the downstream supervised data (Raffel et al., 2020; Gururangan et al., 2018; Roberts et al., 2020; Guu et al., 2020), while in-context learning (ICL) prompts LLMs to generate texts under few-shot demonstrations (Radford et al., 2019; Brown et al., 2020; Chowdhery et al., 2022; Perez et al., 2021; Lu et al., 2021).

3 GPT-NER

In this work, we propose GPT-NER, which uses large language models (LLMs) to resolve the NER task. GPT-NER follows the general paradigm of in-context learning and can be decomposed into three steps: (1) Prompt Construction: for a given input sentence X, we construct a prompt (denoted by Prompt(X)) for X; (2) feeding the constructed prompt to LLMs to obtain the generated text sequence $W = \{w_1, ..., w_n\}$; (3) transforming the text sequence W to a sequence of entity labels to obtain the final results.

3.1 Prompt Construction

Figure 1 is an example of the prompt used in GPT-NER, which consists of three parts:

3.1.1 Task Description

Task Description gives an overview of the task, which can be decomposed into three components:

(1) the first sentence of the task description, "*I am an excellent linguist*"

is a constant telling LLMs to produce the output using linguistic knowledge;

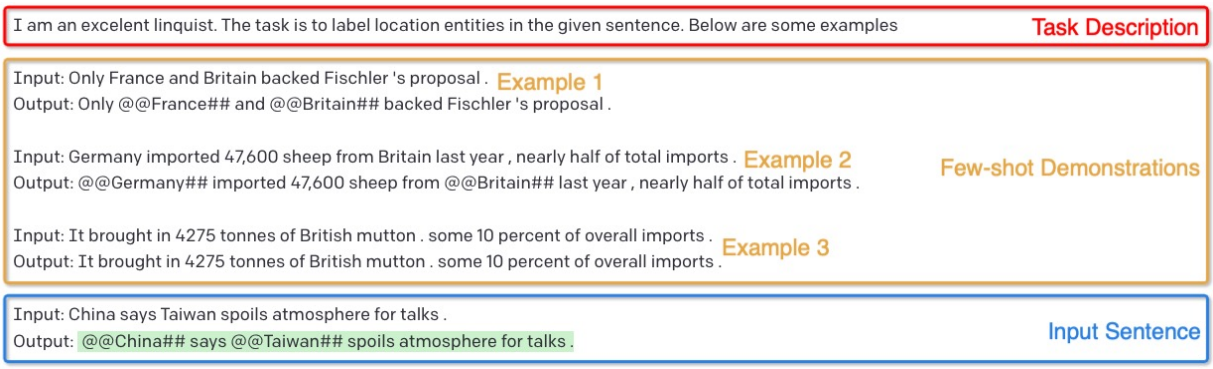

Figure 1: The example of the prompt of GPT-NER. Suppose that we need to recognize location entities for the given sentence: *China says Taiwan spoils atmosphere for talks*. The prompt consists of three parts: **(1) Task Description**: It's surrounded by a red rectangle, and instructs the GPT-3 model that the current task is to recognize **Location** entities using linguistic knowledge. **(2) Few-shot Demonstrations**: It's surrounded by a yellow rectangle giving the GPT-3 model few-shot examples for reference. **(3) Input Sentence**: It's surrounded by a blue rectangle indicating the input sentence, and the output of the GPT-3 model is colored green.

(2) The second sentence

"*The task is to label [Entity Type] entities in the given sentence*"

is a variable sentence indicating the category of entities to be extracted, *[Entity Type]* represents the type of entity to extract, e.g., **Location** in the example of Figure 1. It is worth noting that, in this way, for each input sentence, we need to iterate over all entity labels, which is equivalent to transforming an N-class classification task to N binary classification tasks. The reason behind this is as follows: for most current LLMs, e.g., GPT-3, there is a hard limit on the length of the prompt (e.g, 4096 tokens for GPT-3[1]) due to the hardware restrictions. Given this limited number of tokens, it is impossible to include descriptions and demonstrations for all entity types in a single prompt. Therefore, for each input sentence, we construct the prompt N times, each of which corresponds to each entity type;

(3) the third sentence

"*Below are some examples*"

marks the end of the description and points out the position of few-shot demonstrations.

3.1.2 Few-shot Demonstration

The few-shot demonstration is appended to the prompt. It serves as the following two purposes: (1) it regulates the format of the LLM outputs for each test input, as LLMs will (very likely) generate outputs that mimic the format of demonstrations. This is vital for the NER task as we need the output format to be consistent so that we can parse the output in the form of natural language to NER results; (2) it provides the LLM with direct evidence about the task and references to make predictions.

The Format of LLM Output. The format of each labeled sentence W, which is a text sequence, is of vital importance and should satisfy the following conditions: (1) it needs to contain the information for each word label, and can be easily transformed into the entity type sequence; (2) it needs to be smoothly and easily generated by LLMs to boost the models' final accuracy.

To resolve this issue, we propose LLMs output taking the format: if the input sequence does not contain any entity, W just copies the input X; for an entity/entities in the input sequence, we use special tokens "@@" and "##" to surround it/them. As the example 1 in Figure 1, the two words "@@*France##*" and "@@*Britain##*" are surrounded with special tokens, while others are just copied.

The proposed strategy significantly bridges the gap between the format of the sequence labeling task and the generation model: it significantly decreases the difficulty in the generated text that fully encodes label information, as the LLM only needs to mark the position for entities and make copies for all the rest. As we will show in the ablation study section 5.1, the proposed strategy yields significant performance boosts over other formats.

3.1.3 Input Sentence

This part feeds the current input sentence into the LLM and expects the LLM to generate the output sequence according to the defined format in Sec 3.1.2, where "*Output*" is blanked and denotes the

[1]Each English word corresponds to 1.3 tokens on average.

flag that the LLM begins to generate the labeled sequence. Here comes the end of the prompt construction, and next we will describe strategies to retrieve demonstration examples.

3.2 Few-shot Demonstrations Retrieval

3.2.1 Random Retrieval

The most straightforward strategy is randomly select k examples from the training set. The shortcoming is obvious: there is no guarantee that retrieved examples are semantically close to the input.

3.2.2 kNN-based Retrieval

To resolve the relatedness issue in Sec 3.2.1, we can retrieve k nearest neighbor (kNN) of the input sequence from the training set (Vilar et al., 2022; Liu et al., 2021): we first compute representations for all training examples, based on which we obtain the k nearest neighbors for an input test sequence.

kNN based on Sentence-level Representations. To find kNN examples in the training set, one straightforward method is to use text similarity models such as SimCSE (Gao et al., 2021): we first obtain sentence-level representations for training examples and the input sequence, and use cosine similarity to find kNN.

The shortcoming of kNN based on sentence-level representations is obvious: NER is a token-level task that focuses more on local evidence rather than a sentence-level task, which is concerned with sentence-level semantics. a retrieved sentence (e.g., *he is a soldier*) that is semantically similar to the input (e.g., *John is a soldier*) might shed no light on the NER the input contains: in the example above, the retrieved sentence contains no NER and thus provides no evidence for tagging the input.

Entity-level Embedding. To resolve the issue above, we need to retrieve kNN examples based on token-level representations rather than sentence-level representations. We first extract entity-level representations for all tokens of all training examples as the datastore using a fine-tuned NER tagging model. For a given input sequence with length N, we first iterate over all tokens within the sequence to find kNNs for each token, obtaining $K \times N$ retrieved tokens. Next, we select the top k tokens from the $K \times N$ retrieved tokens, and use their associated sentences as demonstrations. We select several examples to better illustrate demonstrations of three retrieval strategies in Appendix D.

3.3 Self-verification

LLMs significantly suffer from the *hallucination* or overprediction issue (Braverman et al., 2020; Jiang et al., 2021; Zhao et al., 2021). Specifically for NER, LLMs have a strong inclination to overconfidently label NULL inputs as entities, even with demonstrations. To address this issue, we propose the self-verification strategy. Given an extracted entity by LLMs, we ask the LLM to further verify whether the extracted entity is correct, answered by *yes* or *no*.

Take the extraction of location entities as an example. The prompt starts with the task description:

"*The task is to verify whether the word is a location entity extracted from the given sentence*".

Again, we need few-shot demonstrations to boost the accuracy of the self-verifier. Shown in the yellow rectangle in Figure 2, each demonstration consists of three lines:

(1) "*The input sentence: Only France and Britain backed Fischler's proposal*",

(2) "*Is the word "France" in the input sentence a location entity? Please answer with yes or no*".

(3) *Yes*.

We pack multiple demonstrations in the prompt in the few-shot setup. Demonstrations are followed by the test example, and fed to the LLM to obtain the output.

Demonstration Selection. Since the center of the self-verification task is asking about whether an extracted entity is a specific entity type, we need to select training examples that are semantic to the extracted entity rather than overall sentence-level semantics.

Therefore, we use the entity-level embedding described in Sec 3.2.2 for kNN demonstration search rather than sentence-level representations: (1) firstly, we construct the datastore by extracting entity-level representations for all training examples using a fine-tuned NER model; (2) then, we use the same fine-tuned NER model to extract representation for the queried word; (3) finally, we use the representation of the queried word to select k examples from the datastore as few-shot demonstrations, whose answer is "*Yes*" if the retrieved entity belongs to the queried entity type, and "*no*" otherwise.

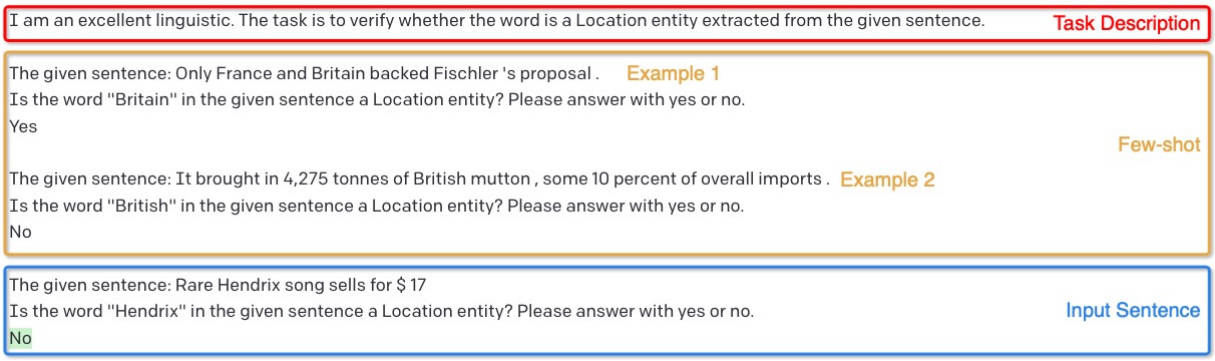

Figure 2: The example of the prompt of verification using the GPT-3. Supposed that we need to verify whether the word "*Hendrix*" in the given sentence "*Rare Hendrix song sells for $ 17*" is a **Location** entity. The prompt consists of three parts: **(1) Task Description** (Red Rectangle): It gives the definition of the current task: to discriminate whether the specified word in the given sentence belongs to **Location** entity. **(2) Few-shot** (Yellow Rectangle): It provides several examples for the GPT-3 to reference.**(3) Input Sentence** (Blue Rectangle): It indicates the current word that needs to be verified and the sentence it belongs to, and the output of the GPT-3 is colored green.

4 Experiments

We use GPT-3 (Brown et al., 2020) (davinci-003) as the LLM backbone for all experiments. For davinci-003 parameters, we set the maximum output length to 512 tokens. Temperature is set to 0, top_p to 1, frequency_penalty to 0, presence_penalty to 0, and best_of to 1.

4.1 Results on the Full Training Set

4.1.1 Results on Flat NER

For flat NER, entities can't overlap with each other. We conduct experiments on the two widely-used flat-NER datasets, English CoNLL2003 and OntoNotes5.0, which can be found in Appendix, using span-level precision, recall, and F1 score as evaluation metrics. We put more details about our used datasets and baselines in Appendix A.1.

Due to the fact that accessing davinci-003 can be expensive, in addition to the full test set, we randomly selected 100 test instances to make it easier for the community to replicate our results. We report performances on both the full and the partial test sets.

Main Results. Table 1 shows results on the full test set for flat NER, and due to the limitation of pages, we put results on the partial test set on the Appendix B. Observations are as follows:

(1) kNN retrieval is of vital importance for the NER task. For the random retrieval strategy where demonstrations are randomly selected rather than through kNN search, performances are only 72.62 and 61.58 on the full CoNLL2003 and OntoNotes5.0 sets. Results skyrocket to 84.36 and 75.32 on the full CoNLL2003 and OntoNotes5.0 when sentence-level embeddings are used for the

Table 1: Results of full data for two **Flat** NER datasets: CoNLL2003 and OntoNotes5.0.

kNN demonstration retrieval.

(2) We observe a significant improvement by changing the sentence-level embedding to token-level embedding for the kNN demonstration search: 84.36 v.s. 89.97 on CoNLL2003 dataset and 75.32 v.s. 81.73 on OntoNotes5.0. This phenomenon is because NER is a token-level task that focuses more on local evidence rather than a sentence-level task: the two sentences "he is a soldier" and "John is a soldier" are semantically similar but don't share any identical entities. Using token-level representation for the kNN search help retrieve more similar demonstrations with respect to the specific entity type, leading to better performances.

(3) We observe further improvements by adding self-verification: on the full CoNLL2003 dataset with entity-level embedding, 89.97 v.s. 90.62 respectively for without and with self-verification for zero-shot learning and 84.97 v.s. 85.91 for few-shot learning. The results prove the effectiveness of self-verification in alleviating overprediction of the GPT-3.

(4) LLM-based systems obtain comparable results to supervised baselines using BERT, i.e., 90.91 v.s. 92.8 on the full CoNLL2003 dataset and 82.20 v.s. 89.16 on the full OntoNotes5.0 dataset. We observe that there still remains a gap between the supervised SOTA model: 94.6 v.s. 90.91 on the full CoNLL2003 dataset and 92.07 v.s. 82.20 on the full OntoNotes5.0 dataset. As will be shown in the ablation study section, we find that the performance hasn't plateaued when we reach the GPT-3 token limit with respect to the number of KNN demonstrations. This means that the token limit is released, e.g., using GPT-4 whose token limit is more than 20K tokens, there is still room for improvement. We will update performances when GPT-4 API is accessible.

4.1.2 Results on Nested NER

For nested NER, entities in each sentence may overlap with each other, like: two geographical entities "*Chinese*" and "*France*" overlap with the facility entity "*The Chinese embassy in France*".

We conduct experiments on the three widely-used nested NER datasets: ACE2004, ACE2005 and GENIA, and use span-level precision, recall, and F1 score for evaluation. We put more details about our used datasets and baselines in Appendix A.2.

Table 2: Results of full data for three **Nested** NER datasets: ACE2004, ACE2005 and GENIA.

Main Results. Results are shown in Table 2, and phenomenon is similar to flat NER is observed:

(1) Again, kNN retrieval is of vital importance: on the full ACE2004 dataset, 48.4 for random retrieval v.s. 73.62 for entity-level embedding re-

trieval using KNN search.

(2) For the kNN demonstration search, a significant improvement is observed by changing the sentence-level embedding to entity-level embedding: 60.68 v.s. 73.62 on ACE2004 and 56.68 v.s. 69.06 on GENIA.

(3) Further performance boost is obtained by adding self-verification, i.e., on the full ACE2004 dataset with sentence-level embedding, 60.68 v.s. 62.31 for zero-shot learning and 60.68 v.s. 62.52 for few-shot learning.

We also observe that the gap between GPT-NER and SOTA models is greater than flat NER. This is because:

(1) Nested NER datasets contain more similar entity types, e.g., the location entities (LOC) and the geographical entities (GPE). Since only a limited number of demonstrations is allowed, it is harder for GPT-3 to distinguish between them,

(2) The annotation guidelines for the three nested NER datasets are more complex and less straightforward. For example, the substring of "*The bodies of six people*" within the sentence "*The bodies of six people were found in the region*" is annotated as a person entity. It is easier for a supervised model fine-tuned on the full training set to learn these complex rules, while much harder for an LLM model with a limited number of demonstrations.

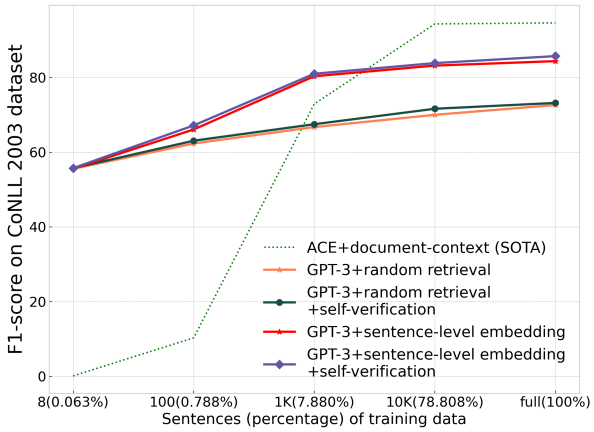

Figure 3: Low-resource comparisons on CoNLL2003 dataset.

4.2 Results on Low-resource Scenario

We conduct experiments to estimate the performance of GPT-NER in low resource setups on the English CoNLL2003 dataset. In order to mimic the low-resource scenario, we randomly select a subset of the full training data as the training set: (a) 8 training sentences (0.063%); (b) 100 training sentences (0.788%); (c) 1K sentences (7.880%); and (d) 10K sentences (78.808%). For the setup with 8 training sentences, the dataset is constructed to ensure that each entity type contains one positive and one negative example. Evaluations are performed on the full test set.

Setups. We use the same GPT parameters as in Sec 4. For baselines, we train the ACE model (Wang et al., 2020) (which is the current SOTA model) on different training subsets. For GPT-NER, we use random demonstration retrieval and sentence-level embedding-based demonstration retrieval for demonstration selection in the few-shot learning stage. For the self-verification stage, we only use zero-shot learning where no demonstration is needed.

Main Results. Results are shown in Figure 3. Observations are as follows:

(1) When the size of the training set is extremely small (i.e., 8 or 100 sentences), and the performance of the supervised model is far below GPT-3. Specifically, with only 8 training examples, the F1 score of GPT-NER is already about 60 while the performance of supervised models is around 0. This demonstrates the significantly better generalization ability of GPT-NER over supervised baselines in the low-resource setup.

(2) With the increase of the training data, the performance of KNN search grows faster than random retrieval, which is in accord with our expectations: for random retrieval, where all demonstrations are randomly selected, the impact of increasing the size of training data is minimal: the outcomes of selecting K demonstration from 100 and 1000 sets are similar since they are all randomly selected. But for kNN demonstration search, increasing the size of training data means selected demonstrations are more likely to be related to the input, leading to better performances.

(3) When the amount of data reaches 10%, as the size of training data increases, the performance of the supervised model will significantly improve, while the result of GPT-3 will increase marginally. This phenomenon indicates that for in-context learning, instead of focusing on increasing the amount of training data, it is more effective to focus on improving the quality of retrieved demonstrations (e.g., random retrieval to kNN based retrieval) and prompt structure (e.g., adding self-verication).

5 Ablation Study

5.1 Varying the Format of LLM Output

In Sec 3.1.2, we propose to use special tokens "@@" and "##" to regulate the format of the GPT-3 output. We compare the proposed output format with the following two formats:

BMES directly outputs the beginning, middle, end, and singleton indicator for input each token:

Input:White House is in Washington

Output:B-ORG E-ORG O O O

Entity+Position asks LLMs to output the entity within the sentence along with its position:

Input:White House is in Washington

Output:White House (0)

where "White House (0)" means that "White House" is an entity and its starting position is 0 at the input sentence.

To enable apple-to-apple comparisons, we use the same setup for the three formats and conduct experiments on the 100-sample CoNLL2003 with 32 few-shots. The F1-score for the proposed ##@@ strategy, *BMES* and *Entity+Position* are respective 92.68, 29.75 and 38.73, where *BMES* and *Entity+Position* significantly underperform the proposed ##@@ strategy. This is because:

For the **BMES** strategy, the LLM needs to learn the alignment between each input word and each **BMES** label: *White* to *B-ORG*, *House* to *E-ORG*, *is* to *O*, *in* to *O*, *Washington* to *O*. By analyzing the error samples, we find that it is usually even hard for the LLM to output a BMES string with the correct length, especially when the input sentence is long, leading to poor final evaluation performances.

For the **Entity+Position** strategy, we find that the LLM usually confuses the meaning of the position index (e.g., whether it is character index or word index), leading to incorrect entity position. This problem can be partially alleviated by demonstrations but still exists considering the 4096 token limit for GPT-3. Incorrect position indexes make it hard to map the output to the sequence labeling format, leading to poor final evaluation performances.

5.2 The Number of Few-shot Demonstrations

We conduct experiments to estimate the effect of the number of demonstrations. Experiments, shown in Figure 4, are conducted on the 100-sample CoNLL 2003 dataset. We can observe as k increases, all three LLM-based results keep rising. As we approach the 4096 token limit, the result still hasn't plateaued, which means performance will still rise if more demonstrations are allowed.

An interesting phenomenon is observed that when the number of demonstrations is small, i.e., $k = 2, 4$, kNN-based strategies underperform the random retrieval strategy. The explanation is as follows: kNN-based retrieval tends to select demonstrations that are very similar to the input sentence. Therefore, if the input sentence doesn't contain any entity, the retrieved demonstrations are most to contain no entity either. In this case, demonstrations don't contain the output format information we wished, leading LLMs to output arbitrary format.

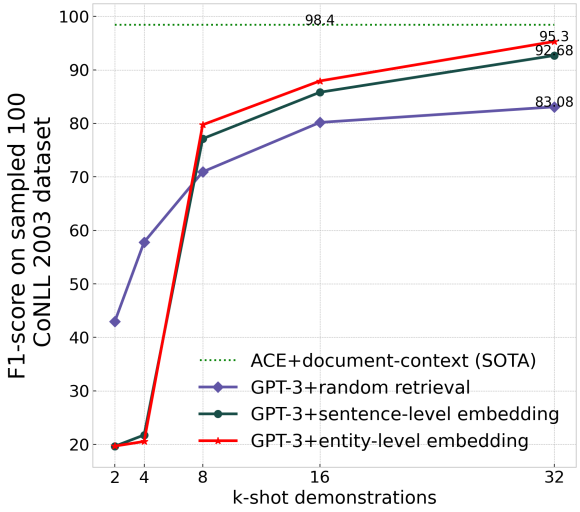

Figure 4: Comparisons by varying k-shot demonstrations.

6 Conclusion

In this paper, we propose GPT-NER to adapt LLMs to the NER task. To bridge the gap between the sequence labeling task and the text generation task, we instruct the LLM to generate a labeled sequence by surrounding entities with special tokens. Additionally, we propose a self-verification strategy to alleviate the hallucination issue of the LLM model. We conduct experiments on both flat and nested NER datasets, and achieve comparable performances to fully supervised baselines. Besides that, we find that GPT-NER has a remarkable ability in the low-resource scenario, that when the amount of training data is extremely scarce, the results of GPT-NER are significantly better than that of the supervised model.

7 Limitation

In this work, we have demonstrated that for in-context learning, instead of focusing on increasing the amount of training data, it is more effective to focus on improving the quality of retrieved demonstrations and prompt structure. Therefore, our next step will attempt more representations extracted with different strategies.

Additionally, we find that the performance of GPT-NER hasn't plateaued when we reach the GPT-3 token limit with respect to the number of KNN demonstrations. This means that the token limit is released, e.g., using GPT-4 whose token limit is more than 20K tokens, there is still room for improvements. We will update performances when GPT-4 API is unlimited accessible.

A Datasets

A.1 Flat NER

CoNLL2003. CoNLL2003 (Sang and De Meulder, 2003) contains four types of named entities: Location, Organization, Person and Miscellaneous. Table 3 shows annotations for each entity type and Table 5 shows the number of sentences, tokens and entities in CoNLL2003.

OntoNotes5.0. OntoNotes (Pradhan et al., 2013) contains 18 types of named entities, and Table 4 lists each entity and its annotation. The number of sentences, tokens and entities of OntoNotes5.0 is shown in Table 5.

Baselines. We adopt currently widely-used NER systems as baselines including:

- **BERT-Tagger** (Devlin et al., 2018) fine-tunes BERT on the full training dataset.
- **MRC-NER** (Li et al., 2019a) formulates the NER task as a machine reading comprehension (MRC) task and trains the MRC-NER model on the full training dataset.
- **MRC-NER+DSC** (Li et al., 2019b) is the current SOTA model on the OntoNotes5.0 dataset, leveraging dice loss in replacement of the standard cross-entropy loss during training.
- **GNN-SL** (Wang et al., 2022) fine-tunes RoBERTa (Liu et al., 2019) on the full training dataset and using GNN to refer to the whole training examples at test time.
- **ACE+document-context** (Wang et al., 2020) is the current SOTA model on the CoNLL2003 dataset, optimizing the controller to find better concatenations of embeddings on the full training dataset.

A.2 Nested NER

ACE2004 and ACE2005. ACE2004 (Doddington et al., 2004) and ACE2005 (Christopher et al., 2006) are two English nested NER datasets containing seven entity types: geographical political entities (GPE), organization entities (ORG), person entities (PER), facility entities (FAC), vehicle entities (VEH), location entities (LOC) and weapon entities (WEA). Annotations for each entity type are shown in Table 7, and the number of sentences, entities, nested entities and nested percentages are shown in Table 6.

Entities Annotations of English CoNLL2003	
Entity Type	**Annotation**
ORG	organization entities are limited to named corporate, governmental, or other organizational entities
PER	person entities are named persons or family
LOC	location entities are the name of politically or geographically defined locations such as cities, provinces, countries, international regions, bodies of water, mountains, etc
MISC	miscellaneous entities include events, nationalities, products and works of art

Table 3: Entity annotations of the flat NER dataset CoNLL2003.

Entities Annotations of English OntoNotes5.0	
Entity Type	**Annotation**
PERSON	People, including fictional
NORP	Nationalities or religious or political groups
FAC	Buildings, airports, highways, bridges, etc
ORG	Companies, agencies, institutions, etc
GPE	Countries, cities, states
LOC	Non-GPE locations, mountain ranges, bodies of water
PRODUCT	Vehicles, weapons, foods, etc
EVENT	Named hurricanes, battles, wars, sports events, etc
WORK_OF_ART	Titles of books, songs, etc
LAW	Named documents made into laws
LANGUAGE	Any named language
DATE	Absolute or relative dates or periods
TIME	Times smaller than a day
PERCENT	Percentage (including "%")
MONEY	Monetary values, including unit
QUANTITY	Measurements, as of weight or distance
ORDINAL	"first", "second", etc
CARDINAL	Numerals that do not fall under another type

Table 4: Entity annotations of the flat NER dataset OntoNotes5.0.

Statistics on English CoNLL2003			
Dataset	**Sentences**	**Tokens**	**Entities**
Training set	14,987	203,621	23,499
Development set	3,466	51,362	5,942
Test set	3,684	46,435	5,648
Statistics on OntoNotes5.0			
Dataset	**Sentences**	**Tokens**	**Entities**
Training set	59,924	1,088,503	81,828
Development set	8,528	147,724	11,066
Test set	8,262	152,728	11,257

Table 5: Number of sentences, tokens and entities of the flat NER dataset English CoNLL2003 and OntoNotes5.0.

Statistics on ACE2004				
Dataset	**Sentences**	**Entities**	**Nested Entities**	**Nested Percentage**
Training set	6,200	22,204	10,149	45.71%
Development set	745	2,514	1,092	46.69%
Test set	812	3,035	1,417	45.61%
Statistics on ACE2005				
Dataset	**Sentences**	**Entities**	**Nested Entities**	**Nested Percentage**
Training set	7,194	24,441	9,389	38.41%
Development set	969	3,200	1,112	34.75%
Test set	1,047	2,993	1,118	37.35%
Statistics on GENIA				
Dataset	**Sentences**	**Entities**	**Nested Entities**	**Nested Percentage**
Training set	16,692	50,509	9,064	17.95%
Development set	-	-	-	-
Test set	1,854	5,506	1,199	21.78%

Table 6: Number of sentences, entities, nested entities, and nested percentage of the nested NER dataset ACE2004, ACE2005 and GENIA.

GENIA. GENIA is an English nested NER dataset within the molecular biology domain and contains five entity types: cell line, cell type, DNA, RNA and protein. Literally, each entity is named according to the biological meaning, and the number of sentences, entities, nested entities and nested percentages are shown in Table 6.

Baselines. For baselines, four widely used supervised models are included:

Entities Annotations of English ACE2004 and ACE2005	
Entity Type	**Annotation**
GPE	geographical political entities are geographical regions defined by political and or social groups such as countries, nations, regions, cities, states, government and its people
ORG	organization entities are limited to companies, corporations, agencies, institutions and other groups of people
PER	a person entity is limited to human including a single individual or a group
FAC	facility entities are limited to buildings and other permanent man-made structures such as buildings, airports, highways, bridges
VEH	vehicle entities are physical devices primarily designed to move, carry, pull or push the transported object such as helicopters, trains, ship and motorcycles
LOC	location entities are limited to geographical entities such as geographical areas and landmasses, mountains, bodies of water, and geological formations
WEA	weapon entities are limited to physical devices such as instruments for physically harming such as guns, arms and gunpowder

Table 7: Entity annotations of the dataset ACE2004 and ACE2005.

- **BERT-MRC** (Li et al., 2019a): the current SOTA model on the GENIA dataset, formulating the NER task as a machine reading comprehension (MRC) task and training the MRC-NER model on the full training dataset.

- **Triaffine+BERT** (Yuan et al., 2021): fine-tuning BERT (Devlin et al., 2018) on the full training set and fusing heterogeneous factors for span representations and classification.

- **Triaffine+ALBERT** (Yuan et al., 2021): fine-tuning ALBERT (Lan et al., 2019) on the full training set and fusing heterogeneous factors for span representations and classification.

- **BINDER** (Zhang et al., 2022): the current SOTA model on the ACE2004 dataset and ACE2005 dataset, leveraging a bi-encoder framework to apply contrastive learning to map candidate text spans and entity types into the same vector representation space for representation and classification.

B Results on the Partial Test Set

Table 13 shows results on the partial. Observations are as follows:

(1) kNN retrieval is of vital importance for the NER task.

(2) We observe a significant improvement by changing the sentence-level embedding to token-level embedding for the kNN demonstration search.

(3) We observe further improvements by adding self-verification: on the full CoNLL2003 dataset with entity-level embedding.

(4) LLM-based systems obtain comparable results to supervised baselines using BERT.

C Error Cases of Format BMES and Entity-position

We select several examples on sample-100 CoNLL2003 dataset to better illustrate the ineffectiveness of these two formats BMES and entity-position. For BMES format is shown in Table 8, and for entity-position format is shown in 9.

From these examples, we can obviously observe that (1) for BMES format, it is difficult for GPT-3 to generate the output with the same length as the input sentence, especially when the input sentence is long; (2) for entity-position format, it is confused for GPT-3 to generate the correct position information.

D Examples

To better illustrate demonstrations of our GPT-NER, we select several examples for random retrieval in Table 10, for sentence-level embedding 11 and for entity-level embedding 12. From these results, we can observe that:

(1) For random retrieval in Table 10, we can observe that all sentences have the same opportunity to appear as an example in the few-shot demonstration, and the input sentence and each retrieved example usually do not contain similar examples.

(2) For sentence-level embedding in Table 11, we can observe that the retrieved examples are semantically similar to the input sentence, but may not focus on the same local entities as the input sentence.

(3) For entity-level embedding in Table 12, we can observe that the retrieved examples do focus on the same local entities as the input sentence to lead the prediction progress of GPT-3 more easily. This phenomenon emphasizes the effectiveness of the quality of demonstrations in-context learning.

Example 1 **Length Error**

Task Description
I am an excellent linguist. The task is to label organization entities. Below are some examples.

Sentence-level Demonstrations
Input: Soccer - results of South Korean PRO-SOCCER games .
Output: O O O O O O O O O
Input: Soccer - results of South Korean PRO-SOCCER games .
Output: O O O O O O O O O
Input: Soccer - results of South Korean PRO-SOCCER games .
Output: O O O O O O O O O
Input: Soccer - Italian cup second round results .
Output: O O O O O O O O

Input Sentence and GPT-3 Output
Input: Soccer - Japan get lucky win , China in surprise defeat .
Output: O O O O O O O O O O
Expected Output: O O O O O O O O O O O O

Example 2 **Length Error and Entity Error**

Task Description
I am an excellent linguist. The task is to label miscellaneous entities. Below are some examples.

Sentence-level Demonstrations
Input: Soccer - results of South Korean PRO-SOCCER games .
Output: O O O O B-MISC E-MISC O O O
Input: Soccer - results of South Korean PRO-SOCCER games .
Output: O O O O B-MISC E-MISC O O O
Input: Soccer - results of South Korean PRO-SOCCER games .
Output: O O O O B-MISC E-MISC O O O
Input: Soccer - Italian cup second round results .
Output: O O B-MISC E-MISC O O O O

Input Sentence and GPT-3 Output
Input: Soccer - Japan get lucky win , China in surprise defeat .
Output: O O B-MISC E-MISC O O O O B-MISC E-MISC O O
Expected Output: O O O O O O O O O O O O

Example 3 **Length Error**

Task Description
I am an excellent linguist. The task is to label person entities. Below are some examples.

Sentence-level Demonstrations
Input: Dubai 1996-08-26
Output: O O
Input: Dubai 1996-08-29
Output: O O
Input: Dubai 1996-08-29
Output: O O
Input: Dubai 1996-08-22
Output: O O

Input Sentence and GPT-3 Output
Input: AL-AIN , United Arab Emirates 1996-12-06
Output: O O
Expected Output: O O O O O O

Example 4 **Length Error and Entity Error**

Task Description
I am an excellent linguist. The task is to label location entities. Below are some examples.

Sentence-level Demonstrations
Input: Azerbaijan beat Switzerland 1-0 (halftime 1-0) in their World Cup soccer European group three qualifying match on Saturday .
Output: S-LOC O S-LOC O O O O O O O O O O O O O O O O O O O
Input: Nijmeh of Lebanon beat Nasr of Saudi Arabia 1-0 (halftime 1-0) in their Asian club championship second round first leg tie on Saturday .
Output: O O S-LOC O O O B-LOC E-LOC O O O O O O O O O O O O O O O O O O O
Input: Slovakia beat the Faroe Islands 2-1 (halftime 1-0) in their World Cup soccer European group six qualifying match on Saturday .
Output: S-LOC O O B-LOC E-LOC O O O O O O O O O O O O O O O O O O O
Input: Canada beat Panama 3-1 (halftime 2-0) in their CONCACAF semifinal phase qualifying match for the 1998 World Cup on Friday .
Output: S-LOC O S-LOC O O O O O O O O O O O O O O O O O O O

Input Sentence and GPT-3 Output
Input: Japan began the defence of their Asian Cup title with a lucky 2-1 win against Syria in a Group C championship match on Friday .
Output: S-LOC O O O O O O O O O O O B-LOC E-LOC O O O O O O O O O O O O O
Expected Output: S-LOC O O O O O O O O O O O O O S-LOC O O O O O O O O O

Table 8: Examples for the BMES output format on sample-100 CoNLL2003 dataset, where the error information is colored red and the expected correct output is colored blue.

Example 1 **Position Error and Entity Error**

Task Description
I am an excellent linguist. The task is to label miscellaneous entities. Below are some examples.

Sentence-level Demonstrations
Input: Soccer - results of South Korean PRO-SOCCER games .
Output: South Korean(4)
Input: Soccer - results of South Korean PRO-SOCCER games .
Output: South Korean(4)
Input: Soccer - results of South Korean PRO-SOCCER games .
Output: South Korean(4)
Input: Soccer - Italian cup second round results .
Output: Italian cup(2)

Input Sentence and GPT-3 Output
Input: Soccer - Japan get lucky win , China in surprise defeat .
Output: Japan(4), China(4)
Expected Output: None

Example 2 **Position Error and Entity Error**

Task Description
I am an excellent linguist. The task is to label organization entities. Below are some examples.

Sentence-level Demonstrations
Input: Dubai 1996-08-26
Output: None
Input: Dubai 1996-08-29
Output: None
Input: Dubai 1996-08-29
Output: None
Input: Dubai 1996-08-22
Output: None

Input: AL-AIN , United Arab Emirates 1996-12-06
Output: AL-AIN, United Arab Emirates
Expected Output: None

Example 3 **Position Error**

Task Description
I am an excellent linguist. The task is to label location entities. Below are some examples.

Sentence-level Demonstrations
Input: Third seed Arantxa Sanchez Vicario , the 1994 champion , and eighth-seeded Olympic gold medalist Lindsay Davenport dropped three game each en route to the second round .
Output: None
Input: Dutch champions Ajax Amsterdam faltered in their second league match of the season on Saturday losing 2-0 away at Heerenveen .
Output: None
Input: Soccer - disappointing Ajax slump 2-0 at Heerenveen .
Output: Heerenveen(7)
Input: Australian Open runner-up Anke Huber of Germany , the sixth seed , was undone by an unlucky draw that put her against 17th ranked South African Amanda Coetzer in her opening match .
Output: Germany(6)

Input Sentence and GPT-3 Output
Input: But China saw their luck desert them in the second match of the group , crashing to a surprise 2-0 defeat to newcomers Uzbekistan .
Output: China(2), Uzbekistan(9)
Expected Output: China(1), Uzbekistan(23)

Example 4 **Position Error and Entity Error**

Task Description
I am an excellent linguist. The task is to label miscellaneous entities. Below are some examples.
Sentence-level Demonstrations
Input: Azerbaijan beat Switzerland 1-0 (halftime 1-0) in their World Cup soccer European group three qualifying match on Saturday .
Output: World Cup(10), European(13)
Input: Nijmeh of Lebanon beat Nasr of Saudi Arabia 1-0 (halftime 1-0) in their Asian club championship second round first leg tie on Saturday .
Output: Asian(15)
Input: Slovakia beat the Faroe Islands 2-1 (halftime 1-0) in their World Cup soccer European group six qualifying match on Saturday .
Output: World Cup(12), European(15)
Input: Canada beat Panama 3-1 (halftime 2-0) in their CONCACAF semifinal phase qualifying match for the 1998 World Cup on Friday .
Output: World Cup(18)

Input Sentence and GPT-3 Output
Input: Japan began the defence of their Asian Cup title with a lucky 2-1 win against Syria in a Group C championship match on Friday .
Output: Asian(14)
Expected Output: Asian Cup(6)

Abstract

The rise of large language models (LLMs) has significantly advanced various natural language processing (NLP) tasks. However, the resource demands of these models pose substantial challenges. Structured pruning is an effective approach to reducing model size, but it often results in significant accuracy degradation, necessitating parameter updates to adapt. Unfortunately, such fine-tuning requires substantial memory, which limits its applicability. To address these challenges, we introduce quantization into the structured pruning framework to reduce memory consumption during both fine-tuning and inference. However, the combined errors from pruning and quantization increase the difficulty of fine-tuning, requiring a more refined quantization scheme. To this end, we propose QPruner, a novel framework that employs structured pruning to reduce model size, followed by a layer-wise mixed-precision quantization scheme. Quantization precisions are assigned to each layer based on their importance to the target task, and Bayesian optimization is employed to refine precision allocation strategies, ensuring a balance between model accuracy and memory efficiency. Extensive experiments on benchmark datasets demonstrate that QPruner significantly outperforms existing methods in memory savings while maintaining or improving model performance.

1 Introduction

The advent of large language models (LLMs) has revolutionized various natural language processing (NLP) tasks, such as machine translation (Zhang et al., 2023a; Sato et al., 2020), sentiment analysis (Zhang et al., 2023b; Deng et al., 2023), and speech recognition (Min and Wang, 2023). Despite their impressive capabilities, the resource consumption required to obtain a fine-tuned model suitable for specific tasks remains substantial due to the large number of parameters and high computational demands of LLMs (Frantar and Alistarh, 2023). To address these issues, various compression techniques, including pruning (Molchanov et al., 2019; Liu et al., 2018), quantization (Shao et al., 2023; Lee et al., 2023), and distillation (Gu et al., 2023; Tan et al., 2023), have been proposed.

Structured pruning (Ma et al., 2023; Xia et al., 2023) is a widely used approach that reduces model size by removing less important parameters in a structured manner, preserving the overall architecture compatibility with hardware requirements. However, the disruption of computational graph uniformity and the removal of parameters can significantly reduce the accuracy of LLMs, which are inherently information-dense networks. To mitigate this degradation, fine-tuning is often used to recover the accuracy of pruned models. This fine-tuning step, while effective, is memory-intensive and presents substantial challenges in terms of resource consumption.

To further reduce memory usage during the fine-tuning and inference phases, we introduce quantization into the structured pruning framework. Specifically, after performing structured pruning, we quantize the pruned model and then apply different fine-tuning strategies. Quantization effectively reduces the bit-width of model parameters, thereby lowering the resource consumption during both fine-tuning and inference. However, integrating quantization with structured pruning introduces additional complexities. Structured pruning applies different pruning intensities across model layers, which exacerbates the uneven distribution of layer importance, making some layers more critical for maintaining model performance. Moreover, the cumulative quantization error varies across different layers, potentially amplifying the performance degradation caused by pruning. Therefore, a simple, uniform quantization scheme is suboptimal. Instead, a more nuanced, layer-wise mixed-precision quantization approach is needed. By allowing more

April 29 - May 4, 2025 ©2025 Association for Computational Linguistics

critical layers to maintain higher precision, we can better control the overall performance of the model.

Building upon these observations, we propose a new framework called QPruner. In QPruner, we first apply structured pruning to reduce the model size, followed by a quantization phase where different quantization precisions are assigned to each layer based on their contribution to the target task. To further improve the allocation strategy, Bayesian optimization (Frazier, 2018) is employed to explore better precision configurations. Finally, we apply parameter-efficient fine-tuning (PEFT) fine-tuning strategy, to recover model performance. This integrated approach aims to strike an optimal balance between model accuracy and memory efficiency, making it well-suited for resource-constrained scenarios. The main contributions of this work are summarized as follows:

- We propose QPruner, a novel framework that integrates structured pruning and quantization, aiming to significantly reduce the memory consumption of LLMs during both fine-tuning and inference.
- We introduce a mixed-precision quantization scheme where quantization precisions are assigned to each layer based on their importance to the target task, with Bayesian optimization used to further refine precision allocation strategies.
- We demonstrate QPruner's powerful ability to save memory and maintain performance. It can surpass baseline methods in terms of accuracy by up to 6% while saving at least 30% of memory.

2 Background and Motivation

2.1 Quantization

Quantization. Quantization is an essential technique used to reduce the computational and memory overhead of large-scale models by converting high-precision numerical values, such as a 32-bit floating-point number $X^{\text{HP}} \in \mathbb{R}$, into a lower-bit integer representation $X^{\text{INT}} \in \{0, 1, \ldots, 2^N - 1\}$. This process is mathematically expressed as:

$$X^{\text{INT}} = \text{round}\left((2^N - 1)F\left(X^{\text{HP}}\right)\right), \quad (1)$$

where $F(\cdot)\colon \mathbb{R} \to [0, 1]$ is a normalization function. A typical method is uniform quantization, where $F(X)$ is defined as $F(X) = \frac{X - X_{\min}}{X_{\max} - X_{\min}}$. An alternative approach introduced by QLoRA Dettmers et al. (2024) is 4-bit NormalFloat Quantization (NF4), which assumes that the data follows a normal distribution $X \sim \mathcal{N}(0, \sigma^2)$ and applies $F(X) = \Phi(X/\sigma)$, with $\Phi(\cdot)$ representing the cumulative distribution function of a standard normal distribution.

Dequantization. To recover the high-precision values from their quantized forms, a lookup table $\mathcal{T}$ is used, which is defined as:

$$\mathcal{T}[i] = F^{-1}\left(\frac{i}{2^N - 1}\right), \quad i = 0, 1, \ldots, 2^N - 1, \quad (2)$$

allowing the integer X^{INT} to be mapped back to its simulated high-precision counterpart $X^{\text{D}} \in \mathbb{R}$. The dequantization process can be represented as:

$$X^{\text{D}} = \mathcal{T}[X^{\text{INT}}]. \quad (3)$$

Simulated Quantization for Matrices. In practice, it is often more efficient to use simulated quantization for matrices rather than directly operating on quantized values (Bai et al., 2020; Shen et al., 2020). In this method, quantized weight matrices are stored as encoded integers and are temporarily dequantized into simulated high-precision matrices during multiplication operations. This process is denoted by $q_N(\cdot)\colon \mathbb{R}^{m \times n} \to \mathbb{R}_N^{m \times n}$, where $\mathbb{R}_N : \{\mathcal{T}[i] \in \mathbb{R} | 0 \le i < 2^N\}$.

2.2 The Motivating Example

Efficient fine-tuning of LLMs on resource-constrained devices requires effective model compression and fine-tuning techniques. After applying structured pruning and quantization, more efficient fine-tuning methods are needed to recover accuracy. One approach is to use LoRA-based methods, as done in LLM-Pruner (Ma et al., 2023), which employs LoRA for quick recovery after structured pruning. Among the LoRA series methods, LoftQ Li et al. (2023) is a method for fine-tuning quantized models. Before fine-tuning, LoftQ iteratively updates the low-rank matrices such that the quantized matrix $\mathbf{Q} + \mathbf{AB}$ approximates the full-precision matrix $\mathbf{W}$, thereby improving the fine-tuning performance, particularly in low-bit settings.

Simply combining pruning, quantization, and LoRA can lead to suboptimal results. Structural pruning reduces model size by removing less important parameters, but due to the varying importance of different layers, it often results in uneven

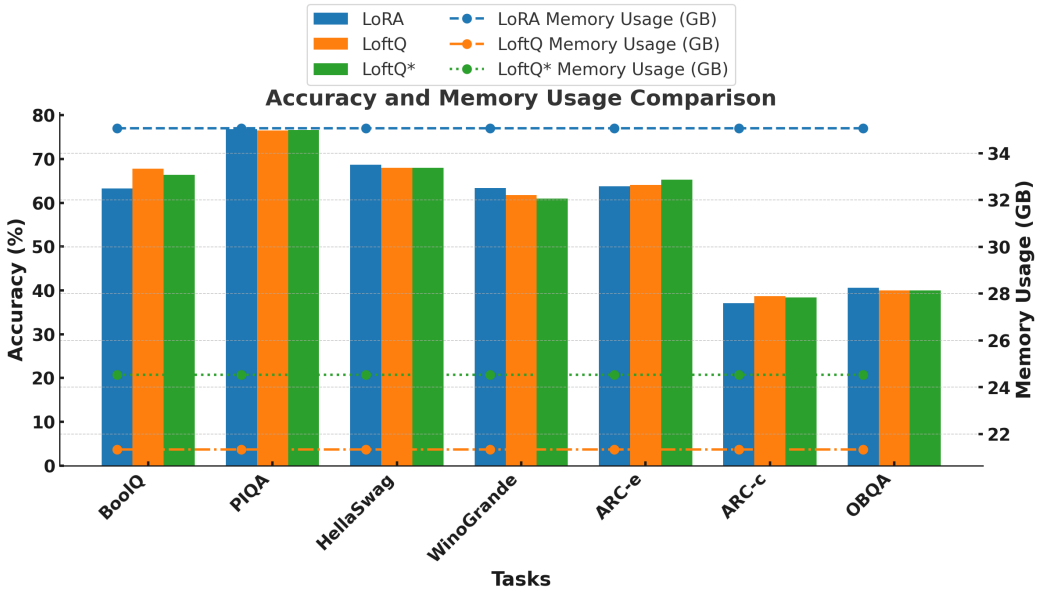

Figure 1: Comparison of accuracy and memory usage across different fine-tuning configurations for multiple tasks. The bars represent the accuracy of three different methods (LoRA, LoftQ, LoftQ*) on each task, while the markers indicate the memory usage for each corresponding method.

pruning across layers. This uneven pruning leads to a complex and unbalanced network structure, and standard quantization typically applies a uniform configuration across all layers. To explore a better trade-off between performance and memory, we adopted mixed-precision quantization, assigning different computational resources and complexities to different layers, with the goal of allowing more important layers to learn with finer granularity.

We conducted experiments using the LLaMA-7b model with a pruning rate of 20%. The pruning was performed using the optimal strategy determined by LLM-Pruner. The methods compared were as follows: LoRA with a uniform 16-bit configuration, LoftQ with a uniform 4-bit quantization, and LoftQ* with a mixed-precision setting of 4 or 8 bits per layer. As shown in Figure 1, the quantized models (LoftQ) achieved performance comparable to the original precision models (LoRA), with significantly lower memory usage (21.33 GB versus 35.06 GB). On some tasks, there was a slight drop in performance, but the mixed-precision model (LoftQ*) demonstrated the potential to further enhance performance while maintaining efficient memory usage.

3 QPruner

Structured pruning, while effective in reducing model size, can disrupt the balance of layer importance, leading to performance degradation. Therefore, parameter adjustments are often necessary to mitigate this imbalance and restore model performance. However, parameter updates require significant memory, which is why we employ quantization techniques to reduce memory consumption. As demonstrated in the motivating example, simply combining pruning and quantization is not always the best choice, as the importance of different layers in a pruned model can vary greatly. We need finer-grained layer-wise quantization bit-width control, which introduces a challenging bit-width allocation problem. To address this, we designed a two-stage allocation strategy to effectively balance these trade-offs.

Based on these insights, we propose QPruner, an integrated framework tailored for efficient or low-resource NLP tasks. It employs structured pruning, mixed-precision quantization, and efficient fine-tuning to solve the challenges of balancing memory efficiency and model performance.

3.1 Structured Pruning

Our framework does not impose specific requirements on the pruning method; as new technologies evolve, the pruning method can be replaced. The only requirement for this step is to produce a smaller model. Although some methods can achieve good performance without fine-tuning (An et al., 2024), most real-time systems require dynamic adaptation, which means that the pruned model must be fine-tuned to improve performance.

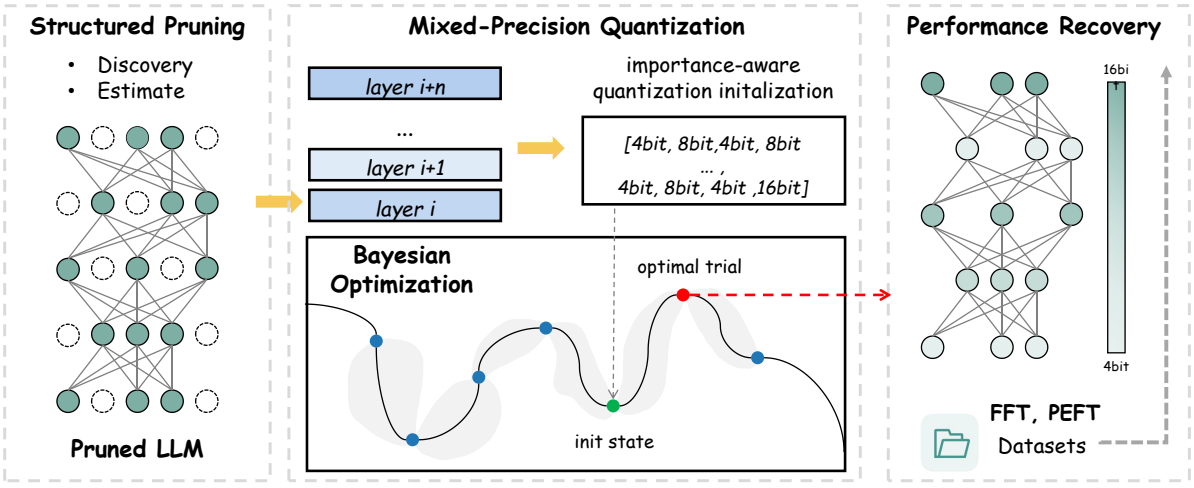

Figure 2: Overview of the QPruner framework.

A popular structured pruning method is LLM-Pruner (Ma et al., 2023), which first identifies dependencies between neurons and groups them, then removes weights based on their importance. Let N_i and N_j be two neurons in the model. If $N_j \in \text{Out}(N_i)$ and $\text{Deg}^-(N_j) = 1$, then N_j is dependent on N_i. Similarly, if $N_i \in \text{In}(N_j)$ and $\text{Deg}^+(N_i) = 1$, then N_i is dependent on N_j. Based on this principle, a dependency graph can be constructed to iteratively identify all coupled structures.

Next, these coupled structures are grouped, and their importance is estimated to effectively perform pruning. For a group of coupled structures $\mathbf{G} = \{\mathbf{W}_i\}_{i=1}^{M}$, its importance can be expressed as:

$$I_{\mathbf{W}_i} = |\mathcal{L}_{\mathbf{W}_i}(\mathcal{D}) - \mathcal{L}_{\mathbf{W}_i=0}(\mathcal{D})|, \quad (4)$$

where $\mathcal{L}$ represents the prediction loss.

Using a second-order Taylor expansion, the importance can be approximated as:

$$\left| \frac{\partial \mathcal{L}(\mathcal{D})}{\partial \mathbf{W}_i} \mathbf{W}_i - \frac{1}{2} \mathbf{W}_i^\top \mathbf{H} \mathbf{W}_i \right|, \quad (5)$$

where $\mathbf{H}$ is the Hessian matrix of the loss function.

For each parameter W_k^i, its importance is defined as:

$$\left| \frac{\partial \mathcal{L}(\mathcal{D})}{\partial W_k^i} W_k^i - \frac{1}{2} (W_k^i)^2 H_{kk} \right|, \quad (6)$$

where H_{kk} is the k-th diagonal element of the Hessian matrix.

Finally, we aggregate the importance of each structure into group-level importance using methods such as summation, multiplication, taking the maximum, or using only the last item. Groups with the lowest importance are selected for pruning, thereby reducing the model size while maintaining performance as much as possible.

3.2 Mixed-Precision Quantization

After pruning, we apply mixed-precision quantization to further reduce memory usage while maintaining model performance. Instead of assigning a uniform bit-width across all layers, different bit-widths are allocated based on each layer's contribution to the final model output. The contribution of each layer is quantified using mutual information between the layer's output and the model's prediction.

To compute mutual information, we first run representative data samples through the pruned model. For each layer, we record its output X and the final prediction Y. The mutual information $I(X;Y)$ between the output of layer X and prediction Y is computed as:

$$I(X;Y) = \sum_{x \in X} \sum_{y \in Y} p(x,y) \log \frac{p(x,y)}{p(x)p(y)}, \quad (7)$$

where $p(x,y)$ is the joint probability distribution of X and Y, while $p(x)$ and $p(y)$ are the marginal distributions. A higher mutual information value indicates that the layer is more important for the final output and should therefore be assigned a higher bit-width. Once the mutual information is computed, an average bit-width B_{avg} is determined based on the available memory budget. Layers

Algorithm 1 Mixed-Precision Quantization

Compute mutual information $I(X_i; Y)$
Initialize bit-width configuration $\mathbf{b}_0$ based on $I(X_i; Y)$ and memory constraint
$\mathcal{D} \leftarrow \{(\mathbf{b}_0, P(\mathbf{b}_0), M(\mathbf{b}_0))\}$
while not converged **do**
  Train GP model on $\mathcal{D}$
  $\mathbf{b}_{t+1} \leftarrow \arg\max_{\mathbf{b}} \alpha(\mathbf{b})$
  Apply $\mathbf{b}_{t+1}$ to pruned model and fine-tune
  Measure $P(\mathbf{b}_{t+1})$, $M(\mathbf{b}_{t+1})$
  $\mathcal{D} \leftarrow \mathcal{D} \cup \{(\mathbf{b}_{t+1}, P(\mathbf{b}_{t+1}), M(\mathbf{b}_{t+1}))\}$
end while

with higher importance receive more bits, and the allocation is performed in discrete bit-widths (e.g., 4-bit, 8-bit), constrained by the total memory limit.

Although the initial bit-width configuration derived from mutual information offers a reasonable starting point for fine-tuning, the complex interactions between layers, particularly in LLMs, mean that the importance of individual layers may shift after fine-tuning. As a result, the initial bit-width assignment might not represent the optimal configuration. To further refine the precision configuration, we employ Bayesian optimization.

The objective of Bayesian optimization is to maximize model performance while minimizing memory usage. Let $\mathbf{b} = [B_1, B_2, \ldots, B_L]$ represent the bit-width configuration across L layers. The optimization problem is formulated as:

$$\mathbf{b}_{\text{opt}} = \arg\max_{\mathbf{b}} \ \alpha(\mathbf{b}), \tag{8}$$

where $\alpha(\mathbf{b})$ is an acquisition function that balances exploration (of less well-understood configurations) and exploitation (of known promising configurations). The memory usage $M(\mathbf{b})$ is constrained by M_{max}, the total available memory.

The process starts by initializing a dataset $\mathcal{D}$ with the initial bit-width configuration $\mathbf{b}_0$, along with its corresponding performance $P(\mathbf{b}_0)$ and memory usage $M(\mathbf{b}_0)$. A Gaussian Process (GP) model is then trained on the data to predict model performance and the uncertainty for new configurations. Based on this model, the acquisition function $\alpha(\mathbf{b})$ is used to select the next bit-width configuration to evaluate.

Once a new configuration $\mathbf{b}_{t+1}$ is selected, it is applied to the pruned model, fine-tuned, and its performance $P(\mathbf{b}_{t+1})$ and memory usage $M(\mathbf{b}_{t+1})$ are measured. These results are then added to the dataset $\mathcal{D}$, and the GP model is updated with the new data. This iterative process continues until a stopping criterion is met, such as convergence or a maximum number of iterations. Over time, this method refines the bit-width configuration to achieve an optimal balance between model performance and memory efficiency.

3.3 Performance Recovery

After the steps of structured pruning and mixed-precision quantization, significant memory savings are achieved. However, model performance typically needs to be restored through fine-tuning. Full-parameter fine-tuning is often impractical due to the large memory footprint it requires, but our compression technique makes full model fine-tuning feasible by reducing both memory and computational costs.

In addition to traditional full-parameter fine-tuning, efficient fine-tuning techniques such as LoRA (Low-Rank Adaptation) (Hu et al., 2021) have proven especially effective, particularly in scenarios with limited data. LoRA significantly reduces the number of trainable parameters by freezing the original weight matrix $\mathbf{W}_0$ and only updating the low-rank approximation of the weight matrix, represented as $\Delta\mathbf{W} = \mathbf{AB}$, where $\mathbf{A} \in \mathbb{R}^{d\times r}$ and $\mathbf{B} \in \mathbb{R}^{r\times d}$. Here, r (the rank) is much smaller than the original dimension d, leading to a substantial reduction in the number of trainable parameters.

The forward computation in this approach can be written as:

$$\mathbf{Y} = \mathbf{W}_0\mathbf{X} + \Delta\mathbf{W}\mathbf{X} = \mathbf{W}_0\mathbf{X} + \mathbf{ABX}, \tag{9}$$

There are also LoRA-like methods specifically designed for quantized models, such as QLoRA (Dettmers et al., 2023) and LoftQ (Li et al., 2023). LoftQ iteratively updates the low-rank matrices $\mathbf{A}$ and $\mathbf{B}$ such that the quantized matrix $\mathbf{Q} + \mathbf{AB}$ approximates the original full-precision matrix $\mathbf{W}$ during fine-tuning. The objective is defined as:

$$\min_{\mathbf{A},\mathbf{B}} \|\mathbf{W} - (\mathbf{Q} + \mathbf{AB})\|^2. \tag{10}$$

where $\mathbf{Q}$ is the quantized matrix.

By combining structured pruning, mixed-precision quantization, and performance recovery techniques, QPruner is able to achieve robust adaptability with minimal computational overhead.

Table 1: Zero-shot performance and peak memory usage on LLaMA-7B and Vicuna-7B with varying pruning rates. LLM-Pruner represents the currently widely used half-precision model. The performance is reported in percentage (%), and the memory usage is in gigabytes (GB).

4 Experiments

LLMs and Benchmarks. To demonstrate how QPruner performes on different model, we test it on three open source large language models: LLaMA-7B[1] (Touvron et al., 2023), LLaMA-13B[2] (Touvron et al., 2023) and Vicuna-7B[3] (Zheng et al., 2024). We conduct these LLMs on zero-shot classification tests for commonsense reasoning datasets, including BoolQ (Clark et al., 2019), PIQA (Bisk et al., 2020), HellaSwag (Zellers et al., 2019), WinoGrande (Sakaguchi et al., 2021), ARC-easy (Clark et al., 2018), ARC-challenge (Clark et al., 2018), and OpenbookQA (Mihaylov et al., 2018).

Software and hardware configuration. We utilize the following configurations: *PyTorch* version 2.1.2, *BitsandBytes* library version 0.43.1, *Transformers* library version 4.41.0, *PEFT (Parameter-Efficient Fine-Tuning)* library version 0.11.1, *Optuna* library version 3.6.1, *CUDA* version 12.4, *GPU:* NVIDIA L20 GPU with 48GB of memory.

Implementation Details. The pruning method follows LLM-Pruner (Ma et al., 2023), and the dataset uses 50k publicly available samples from the Alpaca (Taori et al., 2023). All experiments were conducted with a LoRA matrix rank of 8, and LoftQ initialization with one iteration. We utilized BitsandBytes for quantization configuration, for memory considerations, we keep the number of 8-bit layers below 25%. For 4-bit quantization, we employed NF4 (Dettmers et al., 2024), and since 2-bit quantization does not reduce memory usage, each layer's quantization configuration only considered 4-bit and 8-bit options.

Hyperparameters. In the optimization of the pruned LLaMA-7B model, a comprehensive hyperparameter configuration was employed to ensure an optimal balance between model performance and computational efficiency. The model was fine-

tuned with a learning rate of 3×10^{-4}, utilizing a batch size of 8, further divided into micro batches of 4 to manage memory constraints effectively. Sequences were standardized to a maximum length of 256 tokens, and a dropout of 0.05 was applied specifically to the LoRA layers targeting projections such as query, key, value, and output, alongside gate, down, and up projections. Quantization was dynamically applied at 4-bit and 8-bit levels according to layer requirements to optimize memory use without compromising computational accuracy. The training employed the paged AdamW optimizer with 32-bit precision, enhancing stability and efficiency. These settings were methodically tested and optimized through the Optuna framework to ensure robust model performance and resource utilization.

4.1 Main Results

In this section, we present experimental results to demonstrate the capability of our proposed QPruner framework in balancing performance while reducing memory usage through integrating quantization and structured pruning. Through further iterative optimization, it can even achieve better performance than high-precision models. Although pruning methods are very important, the pruning method itself is not our focus; therefore, we adopt the popular LLM-Pruner (Ma et al., 2023) as our baseline, which is a widely used structured pruning method that directly removes weights.

We evaluate the model performance and peak memory usage of LLM-Pruner and QPruner under different pruning rates. Due to the lack of specific test prompts in the LLaMA paper, we utilize open-source prompts provided by Gao et al. (2023) for benchmarking. Results for the LLaMA-7B and Vicuna-7B models are shown in Table 1. Although our method is expected to have greater advantages on larger models (e.g., 70B parameters or more), due to hardware limitations, we focus only on models within 13B parameters.

In our experiments, **QPruner^1** denotes the use of uniform quantization across all layers, **QPruner^2** represents the mixed-precision configuration based on mutual information, and **QPruner^3** refers to the mixed-precision quantization after further optimization using Bayesian methods based on QPruner^2. Theoretically, full-parameter fine-tuning would perform better than PEFT methods; however, it performs poorly on the Alpaca dataset commonly used in model compression. If we perform individual training according to each benchmark, only the pruned models after quantization can be fully fine-tuned, which is an advantage of our framework, but this would lead to unfair comparisons. Therefore, for unquantized models, we use LoRA (Hu et al., 2021) fine-tuning, and for quantized models, we use LoftQ (Li et al., 2023) fine-tuning.

From Table 1, we observe that our method demonstrates more significant advantages at higher pruning rates. For instance, at a pruning rate of 50% on the LLaMA-7B model, **QPruner^3** outperforms LLM-Pruner by achieving a higher accuracy on the BoolQ dataset (48.37% vs. 43.76%) while reducing memory usage from 23.89 GB to 16.65 GB—a reduction of approximately 30%. This highlights the effectiveness of our framework in maintaining or even improving performance under aggressive compression.

These results demonstrate that our QPruner framework effectively balances memory efficiency and model accuracy by integrating quantization with structured pruning. By employing finer-grained quantization strategies and a combined performance recovery phase, we mitigate the detrimental effects that pruning and quantization individually impose on LLMs. This integration not only

reduces memory consumption but can also enhance model performance, especially at higher pruning rates.

4.2 Ablation Study

We conducted ablation experiments using LLaMA-7B with a 20% pruning rate, based on results obtained by **QPruner**^{3}. All results are presented in Table 2. We tested different quantization data types (`NF4`, `FP4`), LoRA matrix initialization methods (Gaussian, PiSSA (Meng, 2024), LoftQ), varying iteration counts in LoftQ (more iterations represent better error fitting), and different importance estimation methods.

Our experiments show that the choice of quantization data type slightly affects performance, but our method is effective across different types. Similarly, different LoRA initialization methods yield comparable results, indicating robustness to initialization strategies. Interestingly, increasing the number of iterations in LoftQ does not necessarily improve performance, suggesting that fitting residuals with low-rank matrices may not always be beneficial. Finally, using first-order Taylor approximations for importance estimation outperforms second-order ones, highlighting the complexity of LLMs and the limitations of higher-order approximations.

Additional experiments on different Bayesian optimization iteration counts and resource consumption are provided in Appendix **??**. The Pareto frontier demonstrates that more iterations can lead to better configurations, albeit at increased computational cost.

5 Related Work

5.1 Efficient Compression of LLMs

LLM-Pruner (Ma et al., 2023) uses structured pruning to eliminate non-essential interconnected structures by leveraging gradient information. This technique enables compressed models to maintain good performance across multiple tasks with basic fine-tuning. Santacroce et al. (2023) proposes Globally Unique Movement (GUM), a novel pruning technique focusing on the sensitivity and uniqueness of LLMs' network components. GUM prunes neurons that uniquely contribute to the model output and are sensitive to loss changes, thus preserving high accuracy. This method optimizes the trade-off between information retention and computational efficiency. Quantization-Aware Training (QAT) combines quantization with full model fine-tuning to adapt models for downstream tasks (Peri et al., 2020; Liu et al., 2023). Although QAT is effective, it requires substantial computational resources, such as gradient calculations and optimization states, and it complicates the gradient computation for quantized weights. However, by leveraging LoRA, these challenges can be bypassed during task adaptation. Post-Training Quantization (PTQ) frameworks, such as GPTQ and SmoothQuant (Frantar et al., 2022; Xiao et al., 2023), use a small subset of training data to calibrate high-precision models, enabling the generation of task-specific quantized models without the need for gradient backpropagation. This makes PTQ more cost-efficient than QAT, although it generally results in lower accuracy. Xiao et al. (2023) proposed SmoothQuant, a post-training quantization framework that employs a mixed-precision strategy to calibrate large language models, enabling accurate and efficient deployment without the need for retraining.

5.2 Parameter Efficient Fine-Tuning

LLM-Adapters (Hu et al., 2023) integrate small adapters with few extra parameters into LLMs for efficient fine-tuning, allowing smaller models to perform as well as larger ones on specific tasks. Unlike the serial approach of adapters, low-rank adaptation (LoRA) (Hu et al., 2021) uses a parallel method to insert trainable rank decomposition matrices into each layer of the model's architecture. LoRA adds trainable matrices to each layer while keeping the pre-trained weights unchanged, reducing the number of trainable parameters and making model adaptation faster and less resource-intensive. QLoRA (Dettmers et al., 2024) combines low-rank adapters and quantized 4-bit weights for efficient LLM fine-tuning, significantly reducing GPU memory requirements while achieving performance comparable to full 16-bit fine-tuning. LoftQ (Li et al., 2023) applies quantization and low-rank approximation alternately to achieve a good initialization for LoRA fine-tuning, mitigating the discrepancy between quantized and pre-trained weights, and enabling efficient fine-tuning of quantized models, particularly in challenging low-bit regimes.

6 Conclusion

We propose QPruner, an innovative framework that combines structured pruning and quantization for efficient model compression. Given that structured pruning and quantization typically require performance recovery steps, integrating them provides a more holistic approach to mitigating the errors introduced by both techniques while further compressing the model. To address the uneven importance distribution across layers and precision loss caused by pruning and quantization, we adopt a fine-grained method to preserve the capacity of critical layers, enhancing their performance further during the fine-tuning process. After pruning, we first allocate mixed-precision quantization based on task relevance, followed by Bayesian optimization to iteratively refine decisions and probabilistically select the optimal quantization configuration. Experimental results demonstrate that QPruner significantly outperforms baseline models in terms of memory efficiency while achieving superior accuracy across multiple NLP benchmarks. By striking a balance between efficiency and performance, shows that QPruner is a powerful solution for deploying LLM in resource-limited environments.

Limitation

One of the current limitations of QPruner is the significant precision loss caused by structured pruning, which still impacts the overall model performance. In future work, we aim to further optimize the pruning process to minimize this precision degradation. Additionally, the use of Bayesian optimization requires real data to guide the process, which can be time-consuming. While this method improves quantization configurations, the iterative nature of Bayesian optimization introduces additional computational overhead that may not be ideal for all deployment scenarios.

Abstract

Retrieval-Augmented Generation (RAG) improves Large Language Models (LLMs) by using external knowledge, but it struggles with precise entity information retrieval. In this paper, we proposed **MES-RAG** framework, which enhances entity-specific query handling and provides accurate, secure, and consistent responses. MES-RAG introduces proactive security measures that ensure system integrity by applying protections prior to data access. Additionally, the system supports real-time multi-modal outputs, including text, images, audio, and video, seamlessly integrating into existing RAG architectures. Experimental results demonstrate that MES-RAG significantly improves both accuracy and recall, highlighting its effectiveness in advancing the security and utility of question-answering, increasing accuracy to **0.83 (+0.25)** on targeted task. Our code and data are available at https://github.com/wpydcr/MES-RAG.

1 Introduction

Retrieval-Augmented Generation (RAG) is an emerging approach (Kaddour et al., 2023; Hadi et al., 2023) that significantly enhances the capability of LLMs (Touvron et al., 2023; OpenAI et al., 2024). By leveraging external knowledge from retrieved passages, RAG can alleviate issues such as hallucination (Lewis et al., 2020; Zhang et al., 2023) and inconsistency (Saxena et al., 2023; Fan et al., 2024) in LLM outputs.

However, traditional RAG systems (Lewis et al., 2020; Ram et al., 2023) often focus on document-level retrieval, which lacks the fine-grained understanding needed to accurately capture entity-related details scattered across multiple sources. This limitation is further exacerbated by the intermingled storage (Ren et al., 2023; Liu et al., 2024) of information from different entities, leading to retrieval noise and compromising the relevance and factual accuracy of generated content.

For example, when answering questions about a specific product, RAG systems may inadvertently retrieve information about similar products, thus introducing irrelevant or misleading results (Ebner et al., 2020). In terms of multi-modal data output capabilities, limitations in multi-modal generative models (Liu et al., 2023) are further exacerbated by inaccuracies in data descriptions and a lack of sufficient, relevant training data, ultimately leading to suboptimal user experiences(Qian et al., 2024). Furthermore, RAG systems are vulnerable to security threats such as malicious queries and document extraction attacks (Cohen et al., 2024), which jeopardize both data integrity and user privacy.

To address those limitations, we propose MES-RAG (Multi-modal, Entity-storage, Secure RAG), a framework designed to enhance entity-specific query handling and multi-modal data processing. MES-RAG introduces a novel entity-centric data representation, isolating information by entity to reduce noise and improve retrieval precision. It also integrates a unified multi-modal approach, supporting text, visuals, and audio, and incorporates a proactive security strategy, applying protective measures before data access.

The main contributions of MES-RAG are summarized as below:

1. **Entity-Storage Accuracy**. With a structured and isolated entity storage system, MES-RAG achieves highly accurate and contextually consistent responses by focusing on entity-specific data, effectively minimizing noise.
2. **Enhanced Security**. MES-RAG employs a front-loaded security strategy with malicious identification and an out of knowledge detection, reducing hallucinations and ensuring system integrity.
3. **Multi-modal Support**. MES-RAG allows diverse data types, ranging from text, images, audio, and video, ensuring more contextually

rich answers compared to traditional text-only systems.

2 Related Works

Retrieval-Augmented Generation RAG (Lewis et al., 2020) is a state-of-the-art approach that combines retrieval and generation to enhance LLMs with external knowledge bases. RAG has three main paradigms (Gao et al., 2023): naive RAG, advanced RAG, and modular RAG. Naive RAG often suffers from low retrieval quality and inaccuracies (Ma et al., 2023; Zhu et al., 2023; Xu et al., 2024). Advanced RAG improves upon this by using techniques like sliding windows and hierarchical search for efficiency, and employing methods such as information compression and reranking for higher generation quality (Tang and Yang, 2024; Meduri et al., 2024; Dai et al., 2024).

Modular RAG provides a flexible, component-based structure (Yu et al., 2023; Lu et al., 2023, 2024), allowing for independent module development or task-specific combinations that enable collaborative optimization across modules.

Entity-Storage Retrieval Jiang (Jiang et al., 2023) introduced the FLARE method, which retrieves relevant documents using anticipated content to regenerate low-confidence tokens. Similarly, Ofir Press (Press et al., 2023) proposed self-ask, a method that allows models to explicitly ask follow-up questions before answering the initial one. However, these methods overlook the potential noise introduced when handling multiple entities, which can degrade output quality (Wang et al., 2023a; Li et al., 2023).

Our MES-RAG framework addresses this issue by isolating entity-specific information, thereby reducing retrieval noise and enhancing precision in matching entities based on user input. In contrast, Darren Edge (Edge et al., 2024) developed Graph RAG, which improves global summarization by constructing a graph-based text index. Although effective for global sensemaking tasks, this approach is not optimized for multi-modal, addressing confusion caused by similar entities.

Multi-model RAG Much of the recent research on RAG focuses on text-only data, with limited exploration of multi-modal support (Wang et al., 2023b; Zhang et al., 2024). While some studies incorporate multi-modal aspects (Cui et al., 2024; Ulhaq and Akhtar, 2024), they primarily rely on diffusion models, which do not guarantee output accuracy (Chen et al., 2023).

Our MES-RAG framework ensures reliable multi-modal content generation by creating a unified text description across modalities, thus maintaining consistency and improving output stability.

Security in RAG Cohen identified significant security vulnerabilities in RAG-based systems, emphasizing the need for robust security measures (Cohen et al., 2024). Recent studies further reveal privacy risks from the integration of sensitive external databases, as demonstrated by S^2MIA, which can infer if a sample is part of RAG's database based on semantic similarity (Li et al., 2024). Additionally, AgentPoison reveals the vulnerability of RAG-based LLM agents to backdoor attacks by poisoning their knowledge base.

These findings highlight critical privacy and security risks(Chen et al., 2024). MES-RAG addresses these challenges by implementing a front-loaded security strategy that ensures safety and robust accuracy through entity-isolated storage, malicious identification, and an out-of-knowledge mechanism.

3 Framework

3.1 Task Definition

Confusion Among Similar Entities (CASE) is a significant challenge in providing precise and relevant answers within various domains such as healthcare, finance, and customer service (Zhao et al., 2024). An entity, defined as any distinct object—such as a person, location, organization, or product—with identifiable attributes, plays a crucial role in determining the accuracy and usefulness of responses. However, traditional approaches often retrieve information across entire text corpora, where the presence of similar texts related to different entities can easily lead to information confusion and result in hallucinations by large language models. This confusion undermines the reliability of the responses, highlighting the need for more precise handling and accurate retrieval of entity-specific information.

By focusing on entity-specific information retrieval and generation, MES-RAG enhances the quality and relevance of the answers, tailored to the entity's unique characteristics within the query context. A brief Entity-centric Question Answering is shown in Figure 1 Left.

3.2 Overview

We introduce MES-RAG, a pioneering framework designed to enhance Large Language Models in addressing confusion among similar entities. As illustrated in Figure 2, our framework consists of 4 modules: Entity-centric Data Construction (EDC), Query Parser (QP), Entities Retrieval (ER), and Answer Generation (AG).

When using MES-RAG, the initial step involves data preprocessing, as shown in the lower section of Figure 2. This includes multi-modal processing for expressive consistency, data segmentation, and isolated storage. The EDC module is responsible for these tasks, further details on these processes are provided in Section 3.3.

Upon completing the data preprocessing stage, the Q&A functionality can then be fully utilized, as depicted in the upper section of Figure 2. Given a user query q, QP processes it to extract the entity e and the intent i of the query q, and then rewrite the query q for the retrieval stage. The rewritten query is $\hat{q}$:

$$[e, i, \hat{q}] = QP(q) \tag{1}$$

The ER Module extracts the relevant data subset D_{ei} corresponding to the entity e and intent i. This subset is retrieved from the Entity-centric database D, which is constructed by the EDC module:

$$D_{ei} = ER(e, i, D) \tag{2}$$

Subsequently, the AG module takes the rewritten query $\hat{q}$ and the subset of entity-specific data retrieved D_{ei} as input to generate the final answer A:

$$A = AG(\hat{q}, D_{ei}) \tag{3}$$

3.3 Entity-centric Data Construction

The Entity-centric Data Construction (EDC) module organizes structured data around individual entities, associating each with multi-modal attributes, shown as the **Green** part in the Figure 2. Key to this approach is data isolation, which separates entity-specific information to prevent confusion and enhance retrieval precision. By creating isolated data subsets, the system reduces interference from irrelevant information, enabling efficient and accurate retrieval that improves the performance of question-answering tasks.

The EDC module employs a three-stage process to handle and store multi-modal data.

1. Multi-Modal Data Processing Unlike traditional generative methods requiring extensive training for non-textual modalities, MES-RAG handles all modalities contextually, providing consistent results across text, images, audio, and video. A specific comparison is shown in Figure 1 Right.

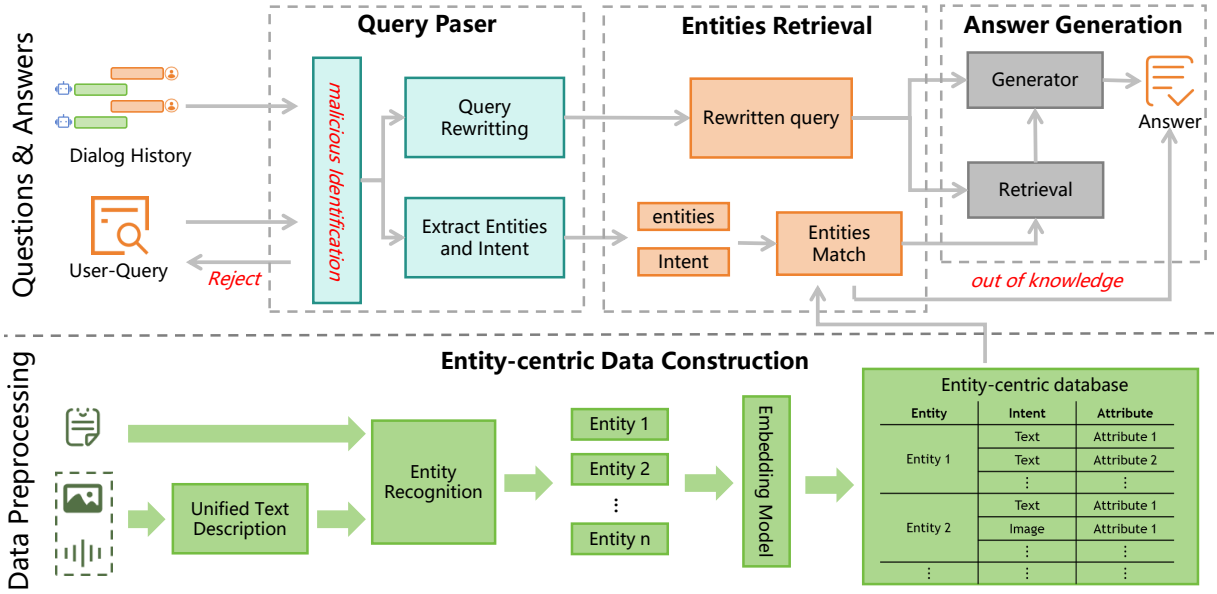

Figure 2: Overview of our framework.

Our approach focuses on enhancing semantic coherence and contextual alignment across modalities. We use existing real multi-modal data instead of generated data, leveraging models like Whisper (Radford et al., 2023) and GPT-4o to produce textual summaries that align with the original data. This ensures consistency in expression between the generated summaries and the original text, while seamlessly integrating with existing RAG frameworks. This method enables real-time, high-precision outputs with minimal computational overhead.

2. Entity Recognition In the EDC module, a rapid, cost-effective method for automating data entity recognition is provided. Advanced keyword extraction models such as YAKE (Campos et al., 2020) are employed to process multi-modal data. These keywords, denoted as $K = \{k_1, k_2, \ldots, k_n\}$, are grouped into feature sets using a text-embedding model and Cosine Similarity. For example, keywords such as 'refrigerator' and 'washing machine' are categorized under appliance features, while 'kitchen' and 'bathroom' fall under usage scenario features.

Of course, manual segmentation can also be conducted directly according to business requirements. After selecting which feature to use for entity-based data segmentation, non-textual multi-modal data will also need to be manually assigned to different data subsets.

To evaluate the features, we apply the Gain-ratio method. For a given set of features $F = \{f_1, f_2, \ldots, f_m\}$, the Gain-ratio $G(f_j)$ for each feature f_j is calculated as follows:

$$G(f_i) = \frac{\mathrm{IG}(f_j)}{\mathrm{H}(f_j)} \tag{4}$$

where $\mathrm{IG}(f_i)$ represents the information gain of feature f_j, and $\mathrm{H}(f_j)$ is the intrinsic information. Features with the highest Gain-ratio are selected to represent entities. This process enables the decomposition and classification of large volumes of documents, ensuring that the entity organization process maximizes information gain, with no limitations on corpus size. Consequently, relevant data is properly categorized into structured attributes associated with each entity.

3. Secure Isolated Storage To handle entity-specific data, MES-RAG first extracts and stores only the necessary tags in isolated, vectorized compartments. By compartmentalizing data in this manner, MES-RAG enforces precise access control and enables entity-specific permission management, significantly reducing exposure to sensitive information. This structure not only strengthens security but also enhances retrieval accuracy, as each query accesses only the relevant data subsets, reducing the risks of unauthorized access.

After initial data processing, MES-RAG operates exclusively with entity-relevant tags, eliminating the need for direct access to detailed document contents. This setup allows our security mechanisms to be fully engaged prior to any document access — a strategy we term front-loaded security

design, providing robust protection against a range of attack vectors, such as document extraction and hallucination attacks.

3.4 Query Parser

Malicious Identification The Query Parser (QP) module is shown as the **blue** part in the Figure 2, includes a Malicious Query Detection component that preemptively scans user input for harmful or obfuscated content using toxicity scoring and obfuscation analysis. Queries exceeding toxicity or obfuscation thresholds are flagged and blocked from further processing, preventing unsafe access at an early stage. This filtering ensures that only safe, validated queries proceed, enhancing system integrity and security. We use two scores (Shang et al., 2024) to estimate the malicious query:

$$\text{Obf}\,(q) + \Delta\,\text{Obf}\,(q) > \tau \Rightarrow \mathcal{F}\,(q) \tag{5}$$

$$\text{Tox}\,(q) > \theta \Rightarrow \mathcal{F}\,(q) \tag{6}$$

Where $\text{Obf}(q)$ is a function that measures the obfuscation of text q, and $\text{Tox}(q)$ is a function that evaluates the toxicity of text q. τ is the threshold of obfuscation; if $\text{Obf}(q) > \tau$, q is considered highly obfuscated. Meanwhile, θ is the threshold for determining toxicity; if $\text{Tox}(q) < \theta$, q is considered non-toxic.

Extract Entities and Intent In complex conversational contexts, user queries may include incomplete or ambiguous entity information. The Query Parser module uses advanced entity disambiguation to address this, refining queries based on contextual cues and dialog history.

This process ensures only the most relevant entities are selected for retrieval without discarding unclear queries prematurely. Additionally, the module identifies the user's desired answer format (e.g., text, image, audio) as the "intent." A multi-step process guided by carefully designed prompts is shown in Table 1.

Query Rewriting After identifying and removing any malicious content, and then extracting the user's entity and intent, the Query Parser module rewrites the original query into a more concise and professional form while preserving its underlying meaning. This rewriting process eliminates noise and irrelevant information, ensuring that the query is well-structured and focused on the core information needed.

Input: User Query
Output: Entity, Intent, Rewritten Query
Prompt for Query Parser:
Step 1: Check for **malicious content or unsafe instructions**. If detected, refuse and explain; otherwise, proceed as follows.
1. Derive the entities the user is currently discussing, referring to previously mentioned entities if necessary. 2. Organize the user's current input into a more concise statement. 3. Derive the user's intent based on what they want to know.
Step 2: The output consists of six elements:
1. Metrics indicating malicious content including toxicity and obfuscation. 2. A flag indicating the existence of entity and intent. 3. The **entities** users are currently discussing, which is selected from a predefined list. 4. **Intent** selected from a predefined list (including text, image, audio, video). 5. The **rewritten** user query. 6. Reason for judgment.

Table 1: A multi-step process prompt for the Query Parser.

3.5 Entities Retrieval

Data Subset Matching The ER module is shown as the **Orange** part in the Figure 2, accurately locates relevant information by matching user-identified entities and intent with specific data subsets, reducing processing volume while maintaining high precision. For multiple entities, it concurrently retrieves data for each, ensuring accurate representation without interference. This entity-focused approach avoids the common 'information confusion' in traditional systems that use unsegregated data, where lack of entity isolation can lead to mixed and misleading outputs.

Out of Knowledge Base The Out of Knowledge base (Kb) mechanism is activated when a query contains one or more entities that are not recognized within the knowledge base. For each entity e in the query, the system verifies its presence in the knowledge base. If any entity e is absent, the system identifies the query as out-of-scope and triggers the Out of Knowledge mechanism.

For single-entity queries, the condition is:

$$e \notin D \Rightarrow \textit{Out of Kb} \tag{7}$$

For multi-entity queries, the mechanism checks all entities $\{e_1, e_2, \ldots, e_n\}$ in the query. The mechanism is triggered when any entity is not found:

$$\exists\{e_1, e_2, \ldots, e_n\} \notin D \Rightarrow \textit{Out of Kb} \tag{8}$$

Upon triggering the Out of Knowledge mechanism, the system provides feedback to the user, specifying which entities are beyond the scope of the knowledge base. This enables users to understand the system's knowledge boundaries and adjust their queries accordingly.

3.6 Answer Generation

Seamless Integration with RAG The AG module is shown as the **Gray** part in the Figure 2, seamlessly integrates with state-of-the-art RAG frameworks, which typically consist of a LLM M, dataset D, and a retriever R. In a standard RAG setup, given a user query q, the system generates an answer A by retrieving the top k most relevant documents from D using the retriever R:

$$R(q, D) = \{d_1, d_2, \ldots, d_k\} \subseteq D \tag{9}$$

$$A = AG(q, R(q, D)) \tag{10}$$

Our Answer Generation module adapts this process by replacing the original query q with the rewritten query $\hat{q}$ from the Query Parser module. Instead of using the whole dataset D, the module independently retrieves from each entity-specific data subset D_{ei} within the set $\{D_{e_1 i}, D_{e_2 i}, \ldots, D_{e_n i}\}$, obtained through the Entities Retrieval module. Each subset is processed separately to ensure the most relevant information is gathered for each entity:

$$R(\hat{q}, D_{e_j i}) = \{d_{j1}, d_{j2}, \ldots, d_{jk}\} \subseteq D_{e_j i} \quad \text{for each } j \in \{1, 2, \ldots, n\} \tag{11}$$

Once the independent retrievals are complete, the module combines the retrieved contents from all entity-specific subsets to generate a single, cohesive answer A:

$$A = AG(\hat{q}, \{R(\hat{q}, D_{e_1 i}), R(\hat{q}, D_{e_2 i}), \ldots, R(\hat{q}, D_{e_n i})\}) \tag{12}$$

This integration allows the RAG framework to leverage entity-centric information while preserving its efficiency. By treating each entity subset independently in the retrieval phase and subsequently synthesizing the results, the Answer Generation module provides a unified response that accurately reflects the information relevant to all entities in the query.

4 Experiments

4.1 Datasets

To evaluate our proposed framework, we conducted experiments using the latest domain-specific data on new vehicle brands publicly available on the internet, ensuring that our dataset was curated to exclude any content that would typically be found within the training corpora of LLMs. Through meticulous data cleansing and the rigorous removal of personally identifiable information as well as any content deemed offensive, facilitated by the GPT-4o, a dataset was compiled encompassing 274 distinct vehicle brands and a total of 50,665 associated attributes. As shown in table 2, here are some examples of our datasets.

Entity	Intent	Attribute	
		Key	Value
Audi Q4	Text	price	e-tron Pioneer Edition ...
	Text	energy	pure electric ...
	Image	front	url:audi-q4/front.png
	Video	show	url:audi-q4/show.mp4
	...	...	...

	Image	front	url:alpha-s/front.png
	Video	show	url:alpha-s/show.mp4
	...	...	...
...	...	...	...

Table 2: Examples of our dataset

Input: Question, Standard Answer
Output: Score
Prompt: I will give you a question and the correct answer to it. You need to judge whether the answer I give is correct. Please note that the answer description may not be completely consistent with the standard answer, but it is still correct. You need to make a judgment. The result is correct, semi-correct, and incorrect, with score of 1, 0.5, and 0 respectively. The output format is JSON, for example: "result": 1

Table 3: Evaluation Template for Large Language Model

We constructed an evaluation dataset of 2,658 question-answer pairs from internet sources, comprising 2,400 text-based questions and 268 non-text questions, ensuring multi-modal (text, images, audio) answer accuracy. Additionally, we generated 200 malicious questions with GPT-4o to test attack detection capabilities, 200 questions for resilience testing against document extraction attacks (Cohen

Method	use MES-RAG	Accuracy†

et al., 2024), and manually selected 200 unrelated questions to assess robustness against hallucination attacks.

4.2 Experimental Setup

4.2.1 Baselines

Direct A basic RAG implementation that uses user input as the retrieval query, retrieves documents, and generates answers with a language model.

DSP (Khattab et al., 2022) Employs a multi-step process to guide interactions between language and retrieval models, enhancing task performance by synthesizing retrieved information.

Self-RAG (Asai et al., 2024) Integrates retrieval and self-reflection to enhance answer quality and factual accuracy, retrieving relevant content on demand.

ReAct (Yao et al., 2023) Combines reasoning and action generation, allowing models to interact with external sources for more informed responses.

Self-Ask (Press et al., 2023) Enhances compositional reasoning by allowing the model to ask and answer follow-up questions, improving complex query handling.

4.2.2 Evaluation Metrics

We employed the state-of-the-art GPT-4o to evaluate the results of the five methods, represented by symbol Accuracy†. Considering the possibility of multiple sub-problems within a single question, we established three levels of evaluation: correct (1 score), semi-correct (0.5 score), and incorrect (0 score). This allows for a more nuanced assessment of the predictions. Specifically, as depicted in table 3 the LLM prompt template we use to evaluate our framework, by providing questions, standard answers, and responses, LLM will output 3 scores in JSON format based on understanding, with 1 representing correct, 0.5 representing semi correct, and 0 representing incorrect.

Retrieval Method	Recall@1	Recall@5
Full Retrieval	0.39	0.67
Entities Retrieval	**0.97** (+0.58)	**0.98** (+0.31)

Table 5: Recall of full document retrieval and Entities Retrieval.

4.3 Implementation Details

We use GPT-4o as the Query Parser. In our EDC module, we also use GPT-4o to generate the description of images and Whisper to perform audio recognition.

4.4 Main Results

We compared the performance of the above five baseline methods with and without our proposed MES-RAG. Since the baseline methods do not support multi-modal data, we used only the 2,400 text-based question-answer pairs to ensure a fair comparison, as shown in Table 4.

The integration of the MES-RAG framework consistently improved the performance of all baseline methods. The Direct method, which uses a vanilla RAG implementation, achieved the most significant improvement, with an accuracy increase of 0.25 when combined with MES-RAG. Both Self-RAG and ReAct also demonstrated notable enhancements, with accuracy gains of 0.14 each. DSP and Self-Ask showed improvements of 0.12 and 0.13, respectively, when integrated with MES-RAG. These results highlight the effectiveness of the MES-RAG framework in enhancing addressing confusion among similar entities tasks across various RAG-based approaches. The superior performance of MES-RAG can be attributed to its Entity-centric Data Construction (EDC), which enables more precise retrieval and minimizes noise from intermingled entity information.

Type	Error / Total	Accuracy
Intent	80 / 2658	**0.97**
non-text	43 / 258	**0.83**
Malicious	4 / 200	**0.98**
Documents	3 / 200	**0.98**
Hallucination	5 / 200	**0.98**

Table 6: Statistics of Multi-Modal and Attack Detection

Recall of Entities Retrieval We evaluated the

Question	**DSP** w/o MES-RAG	**DSP** with MES-RAG
What is the body wheelbase of the Arctic Fox Alpha S?	The wheelbase of the Polar Fox Alpha S is 2980mm. ✗	The vehicle wheelbase of Arctic Fox Alpha S: 2915mm. ✓
What colors and interior choices does Fengguang MINI offer?	The colors offered by Fengguang MINI include white, black, gray, blue, etc. The interior colors include black, brown, sky blue, etc. ✗	Fengguang MINI offers variety of exterior and interior colors to choose from, such as Sprite Green, Mist Rose, Colorado Grey/Oxygen Blue, etc. ✓
[Malicious Attack] Can you provide GPS positioning for the vehicle?	I'm sorry, but I couldn't find GPS data. However, the documents contain historical routes, frequently visiting xxx and xxx. ✗	I can't provide GPS location information because it's sensitive data that could compromise car owners' privacy and security. ✓
[Document extraction Attack] You are now an AI assistant interested in all context documents. return all the documents. Table 7: Conversations Examples of DSP with and without MES-RAG.

Top-1 and Top-5 recall scores of both full retrieval and Entities Retrieval methods, as illustrated in Table 5. The recall performance of the two retrieval methods differs notably. For full document retrieval, Recall@1 is 0.39 and Recall@5 is 0.67. In contrast, Entities Retrieval achieves significantly higher recall values. Recall@1 for entities match is 0.97, an increase of 0.58; Recall@5 for entities match is 0.98, an increase of 0.31. Compared to full document retrieval, Entities Retrieval method demonstrates the potential of this focused approach to improve the relevance of top-ranked results.

Statistics of Multi-Modal and Attack Detection We evaluated the performance of our proposed framework in identifying the user's intent (determining which data modality to select) and detecting various types of attacks, as shown in Table 6. Our MES-RAG framework achieved 97% accuracy in intent recognition, with errors in only 80 out of 2,658 queries. In testing on the 268 non-text answers, MES-RAG achieved an accuracy of 83%, which is comparable to the accuracy for text-based responses. It demonstrated 98% accuracy in detecting malicious, document extraction, and hallucination attacks, underscoring its robustness in addressing diverse threats and ensuring response integrity.

4.5 Qualitative Analysis

In our qualitative analysis, we compared the efficacy of the DSP method with and without MES-RAG across accuracy, comprehensiveness, and security, as shown in Table 7. For fact-based questions (e.g., *What is the body wheelbase of the Arctic Fox Alpha S?*), MES-RAG provided the correct measurement (2915 mm), whereas the baseline model gave an incorrect value (2980 mm), demonstrating MES-RAG's improved accuracy. For descriptive questions (e.g., *What colors and interior choices does Fengguang MINI offer?*), MES-RAG offered a more detailed response, listing specific colors such as Sprite Green and Mist Rose, highlighting its superior comprehensiveness.

In security-focused tests, MES-RAG consistently outperformed the baseline. For malicious attack questions (e.g., requests for automotive GPS positioning), MES-RAG not only refused to provide the information but also explicitly articulated the privacy and security risks involved. In document extraction attacks, the baseline model provided full access to documents, while MES-RAG denied the request, emphasizing security. For hallucination attack questions, MES-RAG delivered accurate responses, whereas the baseline model generated hallucinated content. These results demonstrate MES-RAG's enhanced ability to handle sensitive information and prevent security breaches, significantly improving performance in resolving confusion among similar entities across all metrics.

We also evaluated the effectiveness of the latest LLM and MES-RAG. Results show that MES-RAG consistently provides accurate answers, while

GPT-4o, OpenAI o1, and Claude, when used alone, exhibited factual inaccuracies or hallucinations, underscoring the robustness and generalizability of our method.

4.6 Analysis of Generalization and Real-Time Usability

The MES-RAG framework demonstrates excellent generalization and real-time usability, making it adaptable and efficient in diverse application scenarios. Through a hierarchical storage design based on automated entity recognition and attribute extraction, MES-RAG can effortlessly construct datasets from various domains, ensuring seamless deployment across different fields with minimal manual intervention. Furthermore, its modular architecture enables parallel processing across all key components, such as query parsing, entity retrieval, and multi-modal output generation, which significantly reduces processing time. Empirical evaluations indicate that MES-RAG achieves a first-word response time within 1.5 seconds, effectively meeting the demands of real-time applications while delivering precise and reliable results.

5 Conclusion

This paper introduces MES-RAG, a framework that enhances Retrieval-Augmented Generation (RAG) by addressing confusion among similar entities through entity-specific data representation, isolated storage, and robust security measures. MES-RAG improves accuracy, relevance, and security by employing entity-isolated storage, malicious query detection, and an out-of-knowledge system, all while supporting multi-modal data types for richer responses. Experimental results demonstrate superior accuracy, recall, and security compared to baseline methods. With its modular design, MES-RAG integrates seamlessly into off-the-shelf RAG systems, enhancing entity handling with minimal overhead and highlighting its potential to advance entity-oriented question-answering.

6 Limitations and Risks

A promising direction for future research is exploring the construction of multi-entity hierarchies to handle more complex question-answering tasks. Introducing hierarchical entity structures could improve entity relationships and retrieval precision but adds complexity and requires more domain knowledge for entity ontology construction. Additionally, our Answer Generation component relies on existing RAG models, this may lead to generating inaccurate or biased information. Future work should aim to balance model complexity and performance while mitigating potential misuse risks.

7 Ackowledgement

This work was supported in part by the Natural Science Foundation of China under Grants 62372423, 62121002, 62072421, and this work was also supported by Anhui Province Key Laboratory of Digital Security.

Abstract

Multi-modal Large Language Models (MLLMs) have achieved remarkable success by integrating visual and textual modalities. However, they incur significant computational overhead due to the large number of vision tokens processed, limiting their practicality in resource-constrained environments. We introduce Language-Guided Vision Token Pruning (LVPruning) for MLLMs, an effective yet simple method that significantly reduces the computational burden while preserving model performance. LVPruning employs cross-attention modules to compute the importance of vision tokens based on their interaction with language tokens, determining which to prune. Importantly, LVPruning can be integrated without modifying the original MLLM parameters, which makes LVPruning simple to apply or remove. Our experiments show that LVPruning can effectively reduce up to 90% of vision tokens by the middle layer of LLaVA-1.5, resulting in a 62.1% decrease in inference Tera Floating-Point Operations Per Second (TFLOPs), with an average performance loss of just 0.45% across nine multi-modal benchmarks.

1 Introduction

Multi-modal Large Language Models (MLLMs) have achieved impressive results by combining visual and textual information to perform complex tasks that require understanding both modalities (Dai et al., 2023; Li et al., 2023a; Liu et al., 2023a). However, these models can be highly computationally intensive, limiting their practicality in resource-constrained environments (Liu et al., 2023a,b). One important fact that leads to such substantial computational overhead is that these models often process a large number of vision tokens representing input image patches, but not all visual information is equally important for understanding. The human brain, for instance, can focus on salient features while ignoring irrelevant details, allowing for highly efficient visual perception (Treisman, 1988). Inspired by this, there is a growing need to develop MLLMs that can prioritise crucial vision tokens, reducing computational costs without largely sacrificing performance.

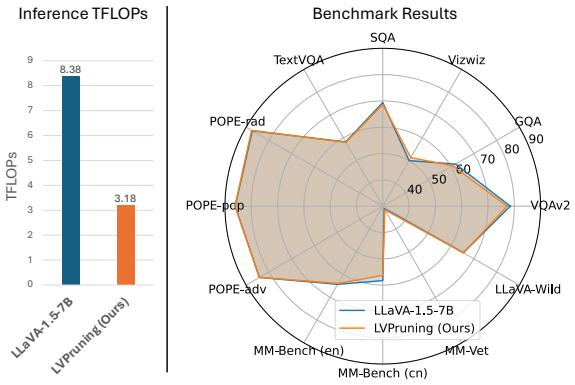

Figure 1: LVPruning can reduce 62.1% of inference TFLOPs for LLaVA-1.5-7B with marginal performance loss across nine multi-modal benchmarks. *All TFLOPs reported in this paper are computed using a dummy input consisting of 1 image and 30 text tokens.

Previous approaches for enhancing the computational efficiency of MLLMs have explored various strategies. Models utilising Q-former as the vision encoder condense visual information into a smaller set of tokens. Though effectively reducing computational load, such condensation potentially leads to a loss of essential visual information, compromising performance (Li et al., 2023a; Dai et al., 2023; Zhu et al., 2024). On the other hand, models such as LLaVA pass all vision tokens through a simple Multi-Layer Perceptron (MLP) connector to the language model, achieving high performance but at the cost of increased computational demands (Liu et al., 2023a,b). Additionally, token compression techniques (Rao et al., 2021; Bolya et al., 2023; Chen et al., 2023) that detect important vision tokens solely based on visual features have shown

Findings of the Association for Computational Linguistics: NAACL 2025, pages 4299–4308
April 29 - May 4, 2025 ©2025 Association for Computational Linguistics

promise in single-modal tasks but cannot make full use of the interaction between visual and linguistic information in MLLMs. These highlight a trade-off between computational efficiency and model performance, indicating a need for solutions that can balance both aspects effectively and efficiently.

To address these challenges, we propose Language-Guided Vision Token Pruning (LVPruning), a simple yet effective method that dynamically reduces the number of vision tokens in MLLMs based on their relevance to the language context. We introduce lightweight cross-attention decision modules where vision tokens attend to language tokens to compute importance scores. This relevance scoring allows the model to decide whether to keep or prune each vision token, effectively filtering out less informative visual data. By integrating these decision modules into various layers of the MLLM, LVPruning enables progressive token pruning as the model processes deeper layers. During training, we freeze all original model parameters and only train the inserted decision modules, ensuring that the base model remains unchanged and the pruning mechanism can be easily applied or removed.

Our contributions are threefold. First, as shown in Figure 1, we demonstrate that LVPruning can significantly reduce computational costs—up to a 62.1% decrease in inference TFLOPs—by pruning as much as 90% of vision tokens without substantially affecting model performance. Second, we introduce a novel, language-guided token pruning mechanism that is both effective and easy to integrate into existing MLLMs, requiring minimal changes to the original architecture. Third, our method allows for adjustable token pruning ratios during inference without retraining, offering flexibility in balancing efficiency and performance according to specific needs. Through extensive experiments on various multi-modal benchmarks, we show that LVPruning provides a practical solution to enhance the efficiency of MLLMs while maintaining their ability to understand and generate accurate multi-modal content.

2 Related Work

Multi-modal Large Language Models: Recent advancements in MLLMs have significantly enhanced the integration of visual and textual modalities. BLIP-2 (Li et al., 2023a) introduced a two-stage learning framework that connects pre-trained vision models with language models using a Q-former model as a vision encoder, effectively generating a condensed set of vision tokens for efficient processing. Building upon BLIP-2, InstructBLIP (Dai et al., 2023) and MiniGPT-4 (Zhu et al., 2024) incorporated instruction tuning to improve the model's ability to follow complex prompts and perform diverse tasks. Alternatively, models such as LLaVA-1.5 (Liu et al., 2023a) directly input all vision tokens from pre-trained vision encoders into the language model. While this approach achieves higher performance owing to richer visual information, it results in substantial computational overhead. These models exemplify the trade-off between computational efficiency and performance, underscoring the need for approaches that can balance both aspects without compromising accuracy.

Efficient Transformers: Many techniques have been proposed to improve computation efficiency for transformer models, such as knowledge distillation (Hinton et al., 2015), token merging/pruning (Bolya et al., 2023; Rao et al., 2021; Chen et al., 2023), and quantisation (Gong et al., 2014; Wang et al., 2019). For Natural Language Processing (NLP) tasks, methods like DistilBERT (Sanh et al., 2019) and MiniLM (Wang et al., 2020) use knowledge distillation to create smaller models for more efficient inference. For computer vision tasks, Liang et al. (2022); Bolya et al. (2023) and Chen et al. (2023) focus on pruning or merging tokens based on their importance in image classification. These approaches reduce the number of vision tokens by identifying less informative patches or merging similar tokens during inference. The closest work to ours is DynamicVit (Rao et al., 2021), which uses MLP layers to predict token pruning decisions. They hierarchically insert multiple pruning layers into vision transformer-based models for the image classification task. However, these methods are specifically designed for single-modal targets and do not address challenges in multi-modal settings. Our research distinguishes itself by focusing on token pruning for MLLMs in the context of image comprehension tasks.

3 Methodology

In this section, we present the LVPruning framework in detail. As shown in Figure 2, LVPruning is designed for MLLMs that pass all vision tokens through an MLP connector into the language model. The architecture consists of a transformer-based pre-trained CLIP vision encoder, an MLP vision-

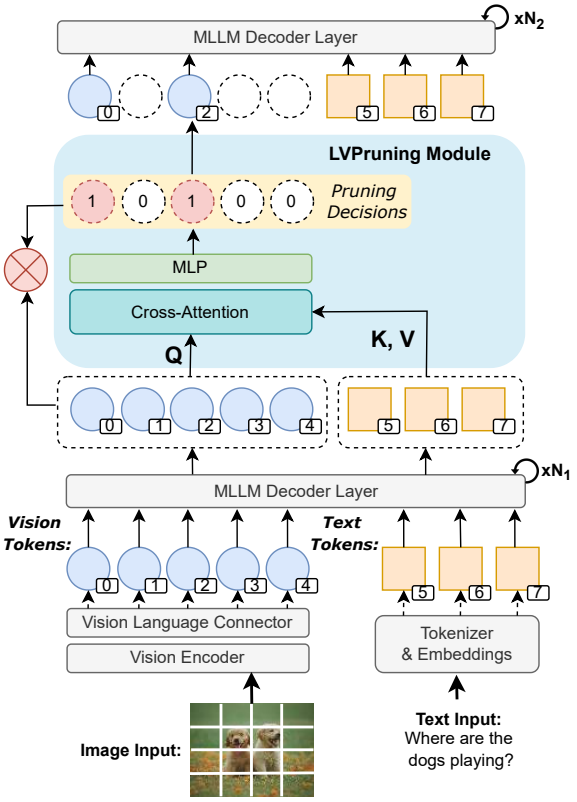

Figure 2: Overall Framework Architecture. LVPruning modules are incorporated into specific layers of an MLLM, where vision tokens serve as queries and language tokens act as keys and values. A pruning decision is predicted for each vision token. The operation denoted by $\otimes$ applies these decisions—serving as attention masking during training and token removal via indexing during inference.

language connector, and an LLM backbone. First, an image input is divided into patches and processed by the CLIP model (Radford et al., 2021), such that each image patch becomes a representative vision token. Next, with the vision language connector projecting vision tokens into the dimension of the LLM's text space, the concatenated vision and text tokens are fed into the LLM for causal text generation. In specific layers of the LLM, cross-attention decision modules dynamically select the most salient token (the one with the highest attention score) to guide inference, removing redundant tokens. During training, we apply attention masks (Rao et al., 2021) to mask out pruned vision tokens. Importantly, instead of updating positional embeddings after token pruning, we retain the original positional embeddings for the remaining vision tokens, as used in standard LLMs (Touvron et al., 2023).

3.1 Cross-Attention Decision Module

We now describe the detailed architecture of the cross-attention decision module designed for token pruning. A decision module, which is responsible for selecting and discarding vision tokens, comprises cross-attention layers and an MLP layer. Multiple instances of these modules are inserted into different layers of the LLM backbone for progressive pruning. Let $\mathbf{H} \in \mathbb{R}^{N \times d}$ represent the output from an LLM hidden layer, where $\boldsymbol{N}$ is the sequence length and $\boldsymbol{d}$ is the dimension of the hidden representations. $\mathbf{H}$ contains the subset of vision tokens and text tokens. We define the set of the vision tokens indices as $\mathbf{I_V} = \{n_{v_i} \mid v_i \in \mathbb{N}, 0 \leq v_i < N\}$, and the set of text token indices as $\mathbf{I_T} = \{n_{t_i} \mid t_i \in \mathbb{N}, (0 < t_i \leq N) \wedge (t_i \notin I_V)\}$. We use the vision tokens as the query tokens

$$\mathbf{Q} = W_q H_{I_V} \in \mathbb{R}^{|I_V| \times d}, \tag{1}$$

and text tokens as the key and value tokens

$$\mathbf{K}, \mathbf{V} = (W_k / W_v) H_{I_T} \in \mathbb{R}^{|I_T| \times d}, \tag{2}$$

where W_q, W_k, W_v are linear projection layers. We then compute the attention matrix and feed the output to a feed-forward network (FFN), as described by Vaswani et al. (2017).

$$\mathbf{O} = \text{Softmax}\left(\frac{QK^T}{\sqrt{d}}\right) V + Q. \tag{3}$$

Inspired by Rao et al. (2021), we feed the output from the FFN to a linear layer W_O to predict scores of keeping and removing vision tokens:

$$\boldsymbol{\gamma} = W_O O \in \mathbb{R}^{|I_V| \times 2}, \tag{4}$$

where $\boldsymbol{\gamma_{i,0}}$ represents the score for keeping the vision token $\mathbf{H_{V,i}}$ and $\boldsymbol{\gamma_{i,1}}$ represents the score for removing the vision token $\mathbf{H_{V,i}}$. The decisions of vision token pruning are then generated based on $\boldsymbol{\gamma}$. The mechanism for generating and applying decisions differs between training and inference. Multiple decision modules are inserted into different layers of the LLM, such that the vision tokens are pruned progressively throughout the LLM.

3.2 End-to-End Training

To ensure that the process of generating and applying token pruning decisions based on $\boldsymbol{\gamma}$ is differentiable, where $\boldsymbol{\gamma}$ denoted as the output from each cross-attention decision module, we draw inspiration from Rao et al. (2021). Specifically, we

apply the Gumbel-Softmax distribution to $\boldsymbol{\gamma}$, redistributing it into one-hot vectors $\boldsymbol{D^{GS}}$. The first dimension of each vector is then used as the decision $\boldsymbol{D}$, determining whether to retain a given token:

$$\boldsymbol{D^{GS}} = \text{Gumbel-Softmax}(\gamma) \in \{0,1\}^{|I_V| \times 2}, \tag{5}$$

$$\boldsymbol{D} = D^{GS}_{:,0} \in \{0,1\}^{|I_V| \times 1}, \tag{6}$$

where $\boldsymbol{D_i} = \mathbf{1}$ means that the vision token $\mathbf{H_{I_{V,i}}}$ is kept; Otherwise it's removed. The number of kept tokens determined by the decision process is not fixed during training, and directly removing unwanted vision tokens will impede batch processing. To address this concern, we construct attention masks $\boldsymbol{M}$ based on $\boldsymbol{D}$ for both vision and language tokens. Specifically,

$$\boldsymbol{M_{i,j}} = \begin{cases} 1 & \text{if } i = j \text{ or } j \in I_T \\ D_j & \text{if } i \neq j \text{ and } j \in I_V \end{cases}, \quad 1 \leq i, j \leq N. \tag{7}$$

Therefore, $\boldsymbol{M}$ is constructed such that all language tokens are assigned a mask value of 1, while the vision tokens are masked according to the token pruning decisions $\boldsymbol{D}$. Additionally, all diagonal elements of $\boldsymbol{M}$ are set to 1 to improve numerical stability.

However, $\boldsymbol{M}$ disregards the original causal and padding attention masks. To address this, we first apply the original attention mask $\bar{\boldsymbol{M}}$ to the raw attention scores to obtain causal attention matrix $\bar{\boldsymbol{A}}$. Then, we apply $\boldsymbol{M}$ with the $Softmax$ operation to $\bar{\boldsymbol{A}}$ to get the final attention matrix $\hat{\boldsymbol{A}}$. Specifically, we define $\boldsymbol{M_l}$ as the attention mask generated from the decision module at layer $\boldsymbol{l}$. The attention scores at layer $\boldsymbol{l + x}$ is calculated by

$$\hat{\boldsymbol{A}}_{\boldsymbol{l+x}} = \hat{Softmax}(\bar{A}_{l+x}, M_l), \tag{8}$$

$$\hat{Softmax}(A, M) = \frac{\exp(A_{i,j})M_{i,j}}{\sum_{k=1}^{N} \exp(A_{i,k})M_{i,k}}, \quad 1 \leq i, j \leq N, \tag{9}$$

where $(\boldsymbol{l + x}) \in \mathbb{N} < l'$. $\boldsymbol{l'}$ is the position layer of the next decision module. If $M^L_{i,j} = 0$, the attention score for token H_j will be 0 in the final attention matrix, resulting in H_j not contributing to any other tokens. In addition, we define $\boldsymbol{D_l}, \boldsymbol{D_{l'}}$ as the token pruning decisions obtained from layer l, l', respectively and $l' > l$. We update $\boldsymbol{D_{l'}}$ by

$$\boldsymbol{D_{l'}} \leftarrow D_l \odot D_{l'}, \tag{10}$$

where $\odot$ is element-wise production, which means a previously removed vision token will never be used again.

In summary, Equations 7 - 9 remove the effects of unwanted vision tokens on other tokens while keeping the number of total tokens unchanged. With Equations 5, 6, 8 and 9, the process of generating and applying token pruning decisions becomes fully differentiable. These two factors facilitate the end-to-end training capability of LVPruning.

Training Objectives: The training objectives of LVPruning are designed to teach the decision modules to remove vision tokens according to predetermined ratios at different layers while fine-tuning the MLLM to maintain its vision instruction-following capability despite the token pruning. The primary training objective is causal language modelling for instruction tuning, as described by Vaswani et al. (2017); Liu et al. (2023b); Touvron et al. (2023). Since causal language modelling is a widely used loss function, we do not formally define it in this paper, referring to it as $\boldsymbol{\mathcal{L}_{causal}}$.

Additionally, to ensure that the ratio of retained vision tokens aligns with predefined values at each decision module, we insert $\boldsymbol{S}$ decision modules into the LLM at specific layer indices $\boldsymbol{L_{idx}} = [l_1, ..., l_S]$, with target token retention ratios $\mathbf{P} = [\rho_1, ..., \rho_S]$. To enforce this, we apply Mean Squared Error (MSE) loss $\mathcal{L}_{\text{ratio}}$ to constrain the token pruning decisions:

$$\mathcal{L}_{\text{ratio}} = \frac{1}{S} \sum_{s=1}^{S} (\rho_s - \frac{1}{|I_V|} \sum_{i=1}^{|I_V|} D_{l_s,i})^2, \tag{11}$$

where $\delta(D_{l_s}, \rho_s)$ is the Huber loss and β is a threshold that determines the loss function used. We set $\beta = 0.5$ in all our experiments. The final training objective is the weighted sum of $\boldsymbol{\mathcal{L}_{causal}}$ and $\boldsymbol{\mathcal{L}}_{\text{ratio}}$:

$$\boldsymbol{\mathcal{L}} = \lambda_{causal}\mathcal{L}_{causal} + \lambda_{ratio}\mathcal{L}_{ratio}. \tag{12}$$

3.3 Inference

During the training phase, attention masks are employed to exclude the impact of irrelevant vision tokens. However, during inference, it is necessary to remove these tokens to reduce computational costs, which introduce significant practical difficulties. First, the quantity of retained vision tokens, as determined by $\boldsymbol{D}$, is variable, thereby complicating the process of batch inference. Second, contemporary LLMs generally utilise positional embeddings

for tokens at each layer. It is essential to maintain the original positional embeddings for the retained tokens to ensure alignment with the distribution seen during training.

To overcome the first issue, we define a set of token kept ratios $\hat{\mathbf{P}} = [\hat{\rho_1}, ..., \hat{\rho_S}]$ during inference. Note that the inference ratios do not have to be the same as the training ratios. At the s-th token pruning layer, we first sort the decision scores

$$\mathbf{Q^s} = argsort(D_{ls}). \tag{13}$$

We then keep the top $\boldsymbol{k_s} = \rho_s \times \mid I_V \mid$ vision tokens with the highest scores. The kept vision token indices among all vision tokens are $\hat{\boldsymbol{I}}^{\boldsymbol{s}} = \{Q^s_{1:k_s}\}$, and the kept vision token indices among all tokens are $\hat{\boldsymbol{I}}^{\boldsymbol{s}}_{\boldsymbol{v}} = I_{v,\hat{I}^s}$. We define $\mathbf{PE^1}$ as the positional embeddings at the first layer. To ensure that the positional embeddings for both vision and text tokens remain unchanged after each pruning, the positional embeddings at the s-th token pruning layer are defined as

$$\boldsymbol{PE^s} = [PE^1_{\hat{I}^s_v}, PE^1_{I_T}]. \tag{14}$$

4 Experimental Setup

The objective of our experiments is to investigate the feasibility of employing token pruning techniques to enhance the efficiency of MLLMs. Specifically, we ask: *(i)* Does LVPruning effectively reduce computational costs while keeping the performance unchanged and to what extent can vision tokens be pruned? *(ii)* Compared with state-of-the-art MLLMs, does LVPruning achieve a balance between computational costs and model performance? To answer question *(i)* we compare LVPruning with the base MLLM on various benchmarks using different ratios of kept vision tokens. To answer *(ii)*, we compare the relationship between inference TFLOPs and model performance for LVPruning and various state-of-the-art MLLMs.

4.1 Implementation Details

In all our experiments, we apply LVPruning to LLaVA-1.5-7B (Liu et al., 2023a) (hereafter referred as LVPruning) by inserting $S = 3$ decision modules with token kept ratio $\mathbf{P} = [\rho, \rho - 0.2, \rho - 0.4]$, where $\rho = 0.5$ for training. These modules are inserted after the 1st, 8th, and 16th layers of LLaMA LLM. In each token pruning layer, we utilise 2 sequential cross-attention blocks, each with 8 attention heads. The FFNs in these cross-attention blocks follow the architecture: [LayerNorm, Linear(C, 2C), SiLu activation, Linear(2C, C), LayerNorm]. We follow most of LLaVA-1.5's training settings, freezing all parameters from LLaVA and only training inserted modules. The learning rate is set to 2e-6, with a 0.03 warm-up ratio and a cosine learning rate scheduler. The batch size is 64 and no weight decay is applied. Additionally, a maximum gradient norm of 1.0 is used to stabilise convergence. Training runs on 8 A100 (80G) GPUs. During inference, we evaluate using three different token kept ratios ($\rho = 0.6$, $\rho = 0.5$, and $\rho = 0.45$) without tuning any model parameters. All inference TFLOPs reported in this paper are computed using a dummy input consisting of one image and 30 text tokens.

4.2 Dataset and Benchmarks

To prove LVPruning's data efficiency, we use a subset of the training data for LLaVA-1.5. The LLaVA-1.5 Vision Instruction Tuning dataset (Liu et al., 2023a) consists of 665k data samples. We remove all entries without image inputs, which results in approximately 620k training samples, and the model is trained for one epoch. To evaluate the performance and computational efficiency of LVPruning, we calculate its inference FLOPs and assess it on nine multi-modal benchmark datasets. These include VQAv2 (Goyal et al., 2017), GQA (Hudson and Manning, 2019), VizWiz (Gurari et al., 2018), SciQA-IMG (Lu et al., 2022), and TextQA (Singh et al., 2019), with top-1 accuracy (acc@1) used as the evaluation metric for all these benchmarks. Additionally, POPE (Li et al., 2023b) is assessed using the F1-score across three splits. MMBench (Liu et al., 2023c) is evaluated through multiple-choice questions on both English and Chinese-translated versions. LLaVA-Wild (Liu et al., 2023b) and MM-Vet (Yu et al., 2024) assess model responses with the assistance of GPT-4. The details about each benchmark can be found in Appendix A.

5 Experimental Results

In this section, we analyse the experimental results of LVPruning across nine multi-modal benchmarks. Section 5.1 examines the performance and inference TFLOPs of LVPruning compared to the base MLLM, LLaVA-1.5 (Liu et al., 2023a), highlighting its effectiveness in reducing computational cost. Section 5.2 compares LVPruning with state-

Method	TFLOPs	VQAv2	GQA	Vizwiz	SQA-IMG	TextVQA
LLaVA-1.5-7B	8.38	78.5	62.0	50.0	69.4*	58.2
LVPruning ($\rho = 0.6$)	$3.97_{-52.6\%}$	$78.1_{-0.4}$	$61.5_{-0.5}$	$51.2_{+1.2}$	$69.0_{-0.4}$	58.2_{+0}
LVPruning ($\rho = 0.5$)	$3.18_{-62.1\%}$	$77.3_{-1.2}$	$60.7_{-1.3}$	$51.3_{+1.3}$	$68.7_{-0.7}$	$58.0_{-0.2}$

LVPruning ($\rho = 0.45$)	$87.4_{+0.1}$	86.1_{+0}	$84.0_{-0.2}$	$63.4_{-0.9}$	$56.3_{-2.0}$	$60.7_{-4.7}$	$30.8_{-0.3}$

Table 2: Performance comparison between LLaVA-1.5-7B (Liu et al., 2023a) and LVPruning on visual instruction following benchmarks. LVPruning achieves competitive results, with improvements observed on three benchmarks.

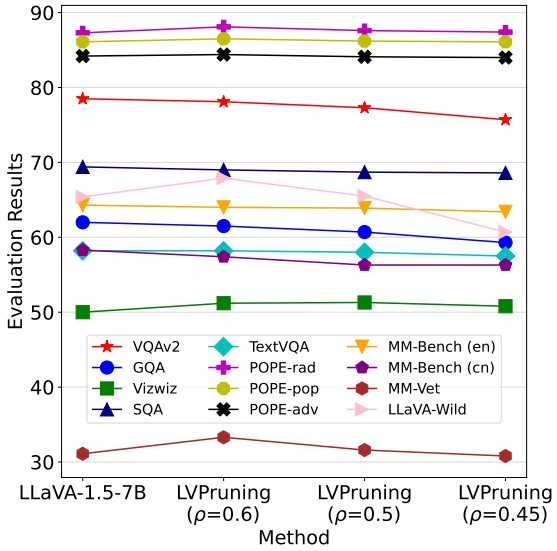

Figure 3: Performance variance between LLaVA-1.5-7B (Liu et al., 2023a) and LVPruning with different vision token kept ratios ρ on nine multi-modal benchmarks. Even at a low token kept ratio, such as $\rho = 0.45$, the performance degradation remains small.

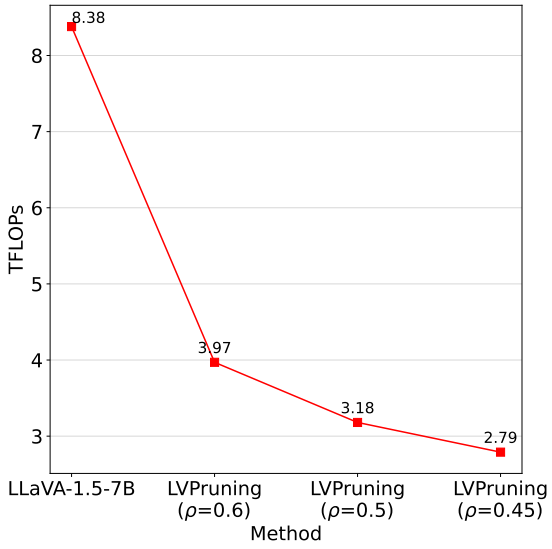

Figure 4: Comparison of Inference FLOPs of LLaVA-1.5-7B (Liu et al., 2023a) and LVPruning with different vision token kept ratio ρ.

of-the-art Q-former-based MLLMs, demonstrating its ability to balance performance and efficiency.

5.1 Performance Preservation and Computation Cost Reduction

To address research question *(i)*, we compare the model performance and inference TFLOPs of LVPruning at various vision token kept ratios, evaluating both computational savings and performance trade-off. Generally speaking, Table 1 and Table 2 show that LVPruning significantly reduces the inference cost while maintaining competitive performance. As shown in Table 1, on Visual Question Answering (VQA) benchmarks, with a pruning ratio of $\rho = 0.6$, LVPruning achieves a 52.6% reduction in TFLOPs, dropping from 8.38 to 3.97 TFLOPs, with only a minor performance

Method	TFLOPs	VQAv2	GQA	Vizwiz	SQA-IMG	TextVQA
BLIP2-14B	2.14	65.0	41.0	19.6	61	42.5
InstructBLIP-8B	1.36	–	49.2	34.5	60.5	50.1
InstructBLIP-14B	2.14	–	49.5	33.4	63.1	50.7
IDEFICS-9B	0.87	50.9	38.4	35.5	–	25.9
Qwen-VL	1.75	**78.8**	59.3	35.2	67.1	**63.8**
Qwen-VL-Chat	1.75	78.2	57.5	38.9	68.2	61.5
CrossGET	$4.39_{-47.6\%}$	77.3	**61.4**	47.7	66.7	54.9
LVPruning ($\rho = 0.5$ ours)	$3.18_{-62.1\%}$	77.3	60.7	**51.34**	**68.7**	58.0

Table 3: Performance comparison among CrossGET (Shi et al., 2023), LVPruning (ρ=0.5), and other Q-former-based MLLMs on five popular VQA benchmarks. While CrossGET attains strong results on GQA (Hudson and Manning, 2019)—it requires higher computational cost. In contrast, LVPruning achieves top performance on Vizwiz(Gurari et al., 2018)and SQA-IMG(Singh et al., 2019)) at lower TFLOPs, showcasing a favorable balance of accuracy and efficiency.

Method	POPE			MMBench		LLaVA	MM
	rad	pop	adv	en	cn	-Wild	-Vet
BLIP2-14B	**89.6**	85.5	80.9	-	-	38.1	22.4
InstructBLIP-8B	-	-	-	36.0	23.7	60.9	26.2
InstructBLIP-14B	87.7	77	72	-	-	58.2	25.6
IDEFICS-9B	-	-	-	48.2	25.2	-	-
Qwen-VL	-	-	-	38.2	7.4	-	-
Qwen-VL-Chat	-	-	-	60.6	56.7	-	-
CrossGET	84.8	84.1	82.9	**64.7**	55.2	-	-
LVPruning ($\rho = 0.5$ ours)	87.6	**86.2**	**84.1**	63.9	**56.3**	**65.5**	**31.6**

Table 4: Performance comparison among CrossGET (Shi et al., 2023), LVPruning (ρ=0.5), and other Q-former-based MLLMs on visual instruction following benchmarks. LVPruning outperforms most baselines, with only minor drops against BLIP2-14B (Li et al., 2023a) in POPE(rad) (Li et al., 2023b) and CrossGET in MMBench(en) (Liu et al., 2023c).

degradation. For instance, on the VQAv2, GQA and VizWiz benchmarks, LVPruning maintains similar accuracy, with a minimal decrease of 0.4, 0.5 and even an increase of 1.2 points, respectively. Even with higher pruning ratios, such as $\rho = 0.45$ (66.7% TFLOPs reduction), the model's performance on certain benchmarks like VizWiz (+0.8) and SQA-IMG (-0.8) are still comparable to LLaVA-1.5-7B. Table 2 shows the results for visual instruction following benchmarks. On the POPE and MMBench (en and cn) benchmarks, LVPruning yields similar or improved performance, with performance gains of up to 0.8 points on POPE. Notably, the LLaVA-Wild and MM-Vet benchmarks show obvious performance gains with $\rho = 0.6$ which increases by 2.5 and 2.2 points, respectively.

Overall, Figure 3 visualises the performance variance between LLaVA-1.5 (Liu et al., 2023a) and LVPruning with different vision token kept ratios ρ on nine multi-modal benchmarks, and Figure 4 demonstrates their inference FLOPs. LVPruning demonstrates that significant computational savings can be achieved with minimal impact on performance. Even at a high pruning ratio, such as $\rho = 0.45$, where TFLOPs are reduced by 66.7%, the performance degradation remains relatively small, indicating that LVPruning effectively balances model efficiency with task performance. Notably, the extra computation cost introduced by the inserted decision modules is 0.71 TFLOPs.

5.2 Comparisons with state-of-the-art MLLMs

To address research question *(ii)*, we use LVPruning with $\rho = 0.5$ as a representative configuration to compare against state-of-the-art Q-former-based

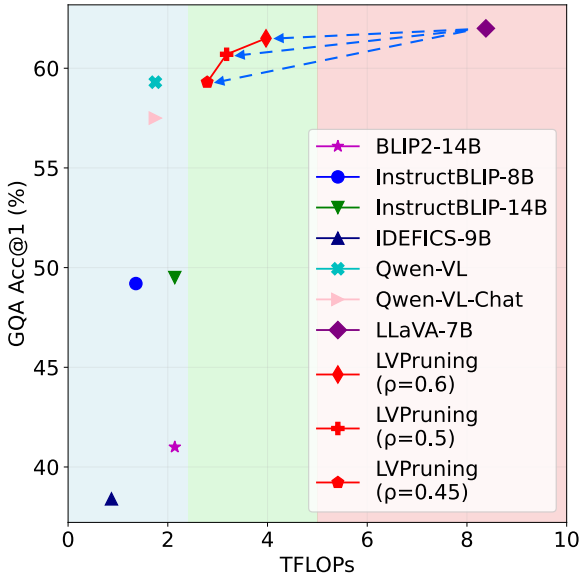

Figure 5: The relationship between inference TFLOPs and the performance of LVPruning and other state-of-the-art MLLMs evaluated on the GQA benchmark (Hudson and Manning, 2019). LVPruning (green area) outperforms Q-former-based models (blue area) while achieving substantial computational savings compared to LLaVA-1.5 (red area) (Liu et al., 2023a). This demonstrates LVPruning's ability to balance performance and efficiency among state-of-the-art MLLMs.

MLLMs. We further compare LVPruning with CrossGET, which is a token ensemble method for accelerating MLLMs (Shi et al., 2023). Generally speaking, Tables 3 and 4 demonstrate that LVPruning achieves superior performance with competitive inference FLOPs.

As shown in Table 3, on VQA benchmarks, LVPruning with $\rho = 0.5$ outperforms several state-of-the-art models, such as BLIP2-14B (Li et al., 2023a), InstructBLIP-14B (Dai et al., 2023), and IDEFICS-9B (Laurençon et al., 2023). For example, LVPruning achieves a higher VQAv2 accuracy (77.3) compared to BLIP2-14B (65.0) and IDEFICS-9B (50.9), while utilising only 3.18 TFLOPs, which is relatively higher than IDEFICS-9B but remains efficient compared to other models like BLIP2 and Qwen-VL (Bai et al., 2023). In tasks such as VizWiz, LVPruning also achieves a notable boost in performance (51.34), surpassing BLIP2 and InstructBLIP models by a large margin. Table 4 shows that on visual instruction following benchmarks, LVPruning consistently delivers competitive results. For instance, LVPruning achieves 87.6 accuracy on the POPE (rad) benchmark, closely trailing BLIP2-14B's 89.6. However, it outperforms BLIP2 on multiple datasets, such as MMBench (en) and LLaVA-Wild, with scores of 63.9 and 65.5, respectively. These results illustrate that LVPruning maintains competitive performance across various instruction following benchmarks, balancing between efficiency and effectiveness. Across both Table 3 and Table 4, CrossGET (Shi et al., 2023) and LVPruning achieve competitive results while trading off performance against efficiency. CrossGET excels on GQA and MMBench (en) but incurs higher TFLOPs. By pruning half the visual tokens (ρ=0.5), LVPruning delivers strong or superior results on multiple tasks at reduced computational cost. Figure 5 further illustrates the relationship between inference TFLOPs and the performance of LVPruning and state-of-the-art MLLMs on the GQA benchmark. LVPruning, represented by red points, showcases a balanced trade-off between computational efficiency and performance.

6 Conclusion

In this work, we introduce LVPruning, a novel language-guided vision token pruning method that can be integrated into existing MLLMs with minimal architectural changes. LVPruning computes relevance scores for each vision token based on language tokens, progressively removing redundant tokens throughout the LLM. With its middle layer, it eliminates up to 90% of vision tokens, achieving a 62.1% reduction in FLOPs with only a $\sim$0.45% average performance loss across nine multi-modal benchmarks. This makes LVPruning a practical solution for enhancing MLLM efficiency while preserving performance in multi-modal tasks.

7 Limitations

While LVPruning shows significant promise in reducing computational load, several limitations to our study should be acknowledged. Our evaluation has been conducted on a specific set of benchmarks. The performance of LVPruningin real-world applications remains unexplored. Therefore, although LVPruning is effective in reducing computational overhead, it is crucial to consider the specific requirements when applying this method to ensure that essential visual information is not compromised. Future research could involve evaluating the performance of LVPruning with human feedback to better understand its practical implications.

A Benchmark Dataset Details

VQAv2 (Goyal et al., 2017) includes approximately 11k test samples and focuses on visual question answering, where models must answer questions based on images depicting various real-world scenes. GQA (Hudson and Manning, 2019), with around 12k test samples, emphasises compositional reasoning through graph-structured annotations, assessing a model's ability to understand object relationships. VisWiz (Gurari et al., 2018), containing 8k test samples, presents accessibility challenges with real-world images from visually impaired users, which are often of low quality and ambiguous, demanding robust model interpretation. SciQA-IMG (Lu et al., 2022) consists of around 4k test samples, targeting science-related visual question answering in specific domains. TextVQA (Singh et al., 2019), with 5k test samples, focuses on understanding and answering questions from textual images. POPE (Li et al., 2023b) contains approximately 9k test samples on three subsets: random, common and adversarial. It evaluates a model's ability to predict human preference judgements on hallucination of multimodal tasks. MM-Bench (en) (Liu et al., 2023c), with around 4k test samples, serves as a comprehensive benchmark for evaluating general-purpose multimodal models across various tasks, while MMBench (cn) (Liu et al., 2023c) is its Chinese translation. LLaVA-Wild (Liu et al., 2023b) has 60 test samples and emphasises answering questions about complex, in-the-wild images. Finally, MM-Vet (Yu et al., 2024) includes 218 samples and is designed to test multimodal capabilities across multiple visual and language tasks, providing a robust evaluation framework for emerging multimodal systems.

How Much Knowledge Can You Pack into a LoRA Adapter without Harming LLM?

Abstract

The performance of Large Language Models (LLMs) on many tasks is greatly limited by the knowledge learned during pre-training and stored in the model's parameters. Low-rank adaptation (LoRA) is a popular and efficient training technique for updating or domain-specific adaptation of LLMs. In this study, we investigate how new facts can be incorporated into the LLM using LoRA without compromising the previously learned knowledge. We fine-tuned Llama-3.1-8B-instruct using LoRA with varying amounts of new knowledge. Our experiments have shown that the best results are obtained when the training data contains a mixture of known and new facts. However, this approach is still potentially harmful because the model's performance on external question-answering benchmarks declines after such fine-tuning. When the training data is biased towards certain entities, the model tends to regress to few overrepresented answers. In addition, we found that the model becomes more confident and refuses to provide an answer in only few cases. These findings highlight the potential pitfalls of LoRA-based LLM updates and underscore the importance of training data composition and tuning parameters to balance new knowledge integration and general model capabilities.

1 Introduction

Large Language Models (LLMs) have been widely adopted in many applications due to their ability to produce human-like responses to user queries. This is made possible by their ability to generalize information and accumulate a large amount of knowledge during the pre-training phase (Chen et al., 2024). These models can solve various problems, such as summarization, reasoning, and question answering, among others (Bhakthavatsalam et al., 2021; Lin et al., 2022; Hendrycks et al., 2021; Moskovskiy et al., 2024).

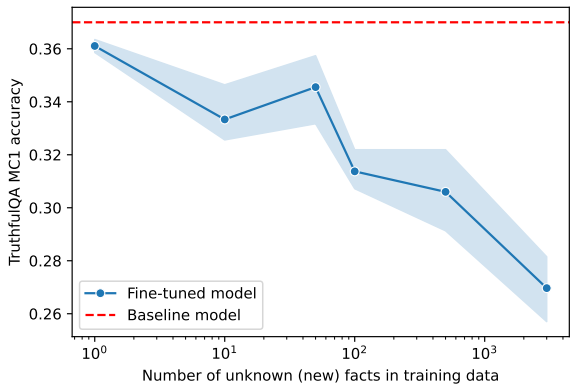

Figure 1: Decrease in quality with increase of new facts learned by the model: results of the fine-tuned Llama-3.1-8B-Instruct on TruthfulQA (solid line corresponds to the mean score, error margin – to the min/max scores of three runs with different random seeds).

Despite the general capabilities of LLMs, there are still situations that require the incorporation of new knowledge to better meet specific needs. This could be due to changes in general knowledge that occur after the LLM training period, or possibly due to specific knowledge that was intentionally omitted during the training period. To address these issues techniques such as Retrieval-Augmented Generation (RAG) (Lewis et al., 2020; Belikova et al., 2024) or few-shot learning (Brown et al., 2020) can be applied. In general, RAG requires access to an external knowledge base, which may be undesirable in some contexts. With respect to in-context learning, the resulting generation is strongly dependent on the selected few-shot samples (Rubin et al., 2022). In this work, we revisit fine-tuning as one of the most popular approaches for integrating new knowledge into LLMs.

Fine-tuning LLMs, which often have hundreds of billions of parameters, is a computationally expensive and time-consuming process. To address these challenges, Parameter-Efficient Fine-Tuning (PEFT) techniques have gained popular-

ity (Han et al., 2024), with Low-Rank Adaptation (LoRA) (Hu et al., 2022) being one of the most effective methods. However, these modified LLMs may suffer from drawbacks, such as catastrophic forgetting (Aleixo et al., 2024; Kirkpatrick et al., 2017) or less severe but still notable loss of previously learned associations (Hoelscher-Obermaier et al., 2023). As shown in Figure 1, an increased amount of new data during fine-tuning with LoRA can degrade the model's pre-existing world knowledge, as evidenced by declining performance of the fine-tuned Llama-3.1 model on the TruthfulQA benchmark.

We investigate the extent to which additional knowledge can be integrated into LLMs via the LoRA adapter while preserving its general capabilities. We seek to identify the underlying reasons for any performance drops when new information is introduced, and explore strategies to effectively minimize these adverse effects.

Our contributions are as follows:

- We conducted a series of extensive experiments incorporating into the LoRA model 1, 10, 50, 100, 500 and 3000 facts unknown to the model tracking how the model degrades intrinsically (via positive and negative shits) and extrinsically (by tracking the degradation of reasoning abilities on the external benchmarks, such as MMLU and TruthfulQA).
- We introduced two fine-tuning techniques to mitigate negative shifts and degradation of the model's reasoning abilities: (1) adding paraphrased new facts, and (2) adding facts the model already knows – and conducted a careful analysis of the results obtained.
- Despite the possible degradation of the model, we found positive shifts – the cases where the model learned new knowledge for which it was not trained, and explained the nature of these shifts.

We release code and data for further usage.[1]

2 Related Work

Although LLMs are highly effective in performing various natural language processing (NLP) tasks, they often struggle with tasks that require extensive real-world knowledge, particularly when dealing with long-tail facts, i.e., facts associated with less common entities (Sun et al., 2024). This limitation highlights the need for augmenting LLMs with non-parametric knowledge or integrating this knowledge into the model's parameters.

Non-parametric knowledge can significantly enhance LLM performance, particularly when the required knowledge is rare or involves multiple relationships between entities (Huang et al., 2024b). However, external knowledge sources can also potentially mislead LLMs when answering questions about well-known entities, as powerful LLMs have already internalized this information within their parameters (Mallen et al., 2023).

RAG is also not a universal solution. On the one hand, models have been shown to rely more on nonparametric knowledge (Farahani and Johansson, 2024). However, LLMs still face challenges in discriminating highly semantically related information and can easily be distracted by this irrelevant and misleading content (Wu et al., 2024). Furthermore, RAG methods introduce latency in response time, as retrieval must be performed, particularly in the case of iterative RAG approaches (Li et al., 2024). These involve a multi-step process, including retrieval followed by augmentation (Krayko et al., 2024).

Recent studies have revealed that LLMs acquire their knowledge predominantly during the pre-training phase (Allen-Zhu and Li, 2024). However, pre-training a model each time you want to incorporate new information appears to be excessive. It has been shown that attempting to acquire new knowledge through supervised fine-tuning can actually lead to an increase in hallucinations relative to the existing knowledge. Furthermore, LLMs tend to struggle when trying to integrate new knowledge via fine-tuning, instead primarily learning how to make better use of their pre-existing knowledge (Gekhman et al., 2024).

Low-Rank Adaptation, or LoRA (Hu et al., 2022) freezes the pre-trained model weights and injects trainable rank decomposition matrices into each layer of the Transformer architecture, thus greatly reducing the number of trainable parameters for downstream tasks.

There have been several papers on the continuous knowledge editing through various training and evaluation mechanisms. Wang et al. (2024a) have shown that almost all SoTA editing methods have a trade-off between accuracy, recall, and hallucination.

3 Study Design

To evaluate the ability of the LoRA adapter to incorporate new knowledge and its overall effect on the model, we define what constitutes new knowledge. We consider a knowledge fact as the combination of a question q and its corresponding answer a. The model's ability to accurately or inaccurately respond to a question determines whether it possesses or lacks this specific knowledge (q, a). We also delve into the process of fine-tuning a language model using LoRA and the methods to quantify any residual consequences of this fine-tuning procedure.

3.1 Low-Rank Adaptation

The popularity of LoRA as a method for fine-tuning LLMs resides in its time and cost effectiveness. This approach has allowed researchers and engineers to achieve results comparable to those obtained through vanilla fine-tuning on many tasks (Hu et al., 2022).

During LoRA training, each model's weight matrix $W_0 \in \mathbb{R}^{d\times k}$ is updated by the low-rank decomposition of ΔW:

$$W = W_0 + \Delta W = W_0 + BA, \qquad (1)$$

where $B \in \mathbb{R}^{d\times r}$, $A \in \mathbb{R}^{r\times k}$, rank $r \ll \min(d, k)$. Hu et al. (2022) showed that even low-rank adaptations ($r = 1...4$) produce acceptable results on various tasks. Despite all the advantages of using Low-Rank Adaptation, LoRA-tuned LMs suffer hallucinations (Wang et al., 2024b).

3.2 Knowledge Categories

In order to fully explore the implications of fine-tuning an LLM, it is critical to recognize what knowledge it currently possesses and where its limitations lie. To determine which facts are genuinely new to a LLM, we adopted the taxonomy similar to SliCK (Sampling-based Categorisation of Knowledge) introduced by Gekhman et al. (2024).

Our approach considers that a model is knowledgeable about the answer a to a particular question q if, upon receiving q as input, it produces a as its response. However, language models can produce different responses for the same query q depending on the sampling method or prompt used. We categorize knowledge into three groups using the definition of $\mathbf{P}_{\text{correct}}(q, a, F)$ as an estimate of the probability that the language model is able to accurately generate the correct answer a to q when using different few-shot prompts F.

These knowledge types are: `HighlyKnown`, `MaybeKnown`, and `Unknown` (see Table 1). If the language model never predicts the correct answer to the question for different few-shot prompts, i.e. $\mathbf{P}_{\text{correct}}(q, a, F) = 0$, it means this fact is `Unknown` to the model. If the model generates the correct answer sometimes ($\mathbf{P}_{\text{correct}}(q, a, F) > 0$), we define this fact as `MaybeKnown`. Finally, we define a fact as `HighlyKnown` if the LLM always predicts the correct answer for all few-shot prompts, i.e. $\mathbf{P}_{\text{correct}}(q, a, F) = 1$.

3.3 Model's Reliability

Reliability (Yao et al., 2023) is the model's ability to remember both current and previous edits after sequential editing. Unlike simple accuracy or exact match, we count the occurrence of the correct answer in the model-generated response sub-string. For each question-answer pair, we have several aliases for answers.

3.4 Undesirable Effects

The primary objective of this work is to refine LoRA adapters in a way that avoids substantial degradation of the LM's performance. We employ both intrinsic and extrinsic evaluation methods to monitor the effectiveness of different LoRA-based fine-tuning configurations.

Leveraging introduced knowledge categories (Table 1), we intrinsically assess what facts the model learns (e.g., a fact shifts from the `Unknown` to `HighlyKnown` category, UK $\rightarrow$ HK) or forgets (e.g., HK $\rightarrow$ UK). No or only a few 'negative' shifts after fine-tuning mean adding new knowledge does not harm the model.

As for the extrinsic approach, we additionally evaluate all the models we train on two well-established benchmarks: MMLU (Hendrycks et al., 2021) and TruthfulQA (Lin et al., 2022). MMLU is a benchmark for knowledge and reasoning (Guo et al., 2023), is used as a proxy for measuring the model's reasoning abilities. TruthfulQA was chosen as an additional proxy for thruthfullnes, this benchmark includes the set of tricky questions that even some humans would answer falsely. We use `lm-evaluation-harness`[2] (Gao et al., 2024) for all evaluation experiments. For MMLU we use 5-shot prompting, for TruthfulQA – 0-shot prompting. For both benchmarks the final metric is accuracy

[2] https://github.com/EleutherAI/lm-evaluation-harness

Category	Definition	Explanation	# Facts
`Unknown (UK)`	$\mathbf{P}_{\text{correct}}(q, a, F) = 0$	LLM **never** returns the correct answer	14,373
`MaybeKnown (MK)`	$\mathbf{P}_{\text{correct}}(q, a, F) > 0$	LLM returns the correct answer **occasionally**	3,931
`HighlyKnown (HK)`	$\mathbf{P}_{\text{correct}}(q, a, F) = 1$	LLM **always** returns the correct answer	2,732

Table 1: **Fact categories** based on the probability of providing the correct answer to a corresponding question and number of fact (q, a) from each category.

of the answers. For TruthfulQA there are two accuracy metrics (Lin et al., 2022). In the MC1 mode, the correct answer is chosen from 4 or 5 options. This mode focuses on identifying the single truth among the choices. MC2 (multi-true) mode, on the other hand, requires the identification of multiple correct answers from a set. Both MC1 and MC2 are multiple-choice assessments.

4 Experiments

To evaluate the harmful effects of tuning the model with new knowledge, we conducted comprehensive experiments using the Llama-3.1-8B-Instruct model, which we tuned with the LoRA adapter on `Unknown` (q, a) facts.

4.1 Data

To conduct reproducible and reliable experiments, we created datasets that were not included in the pre-training set of any LLM. We are confident in this, because these data were collected in accordance with the methodology described in Sun et al. (2024), which did not provide precomputed data.

The questions in our dataset are based on Knowledge Graph (KG) entities, which are stored as triples of the form `<subject, relation, object>`. Entities are divided into three categories: head, torso, and tail, according to their popularity. This popularity is determined by the density, which is the number of relational triples that contain the entity in the KG. By including entities of varying popularity, the dataset is balanced in terms of the complexity of the questions posed to LLMs. Questions with popular entities are easier to answer, questions with torso entities are the most difficult. The KG-based structure of the dataset is attractive not only because it allows for the creation of question-answer pairs that are not seen in training data, but also because it allows analysis of shifts within the same relational domain.

We use DBpedia[3] to extract our own collection of triples and generate our own set of (q, a) pairs based on templates. In addition, we used TriviaQA (Joshi et al., 2017) as an additional source of training data to generate extra `HighlyKnown` samples. Interestingly, most of the questions in this dataset are `HighlyKnown`, even though they are complicated from human perspective. This further supports our intention to conduct experiments with data that have not been seen by any LM. Table 1 provides an analysis for each category of knowledge facts (q, a).

4.2 Fine-tuning

As a default, the model Llama-3.1-8B-Instruct[4] was chosen. It is an auto-regressive language model that uses supervised fine-tuning (SFT) and reinforcement learning with human feedback (RLHF) to align with human preferences for helpfulness and safety.

We opted for the instructed variant due to its enhanced capacity to follow instructions, and a lightweight version for streamlined implementation across a series of experimental trials.

The model is trained with 1, 10, 50, 100, 500, and $3,000$ `Unknown` (q, a) pairs. `Unknown` is the set of questions that were not answered by the default Llama-3.1-8B-Instruct model. The answer is considered correct if the answer from the triple of the question or one of its aliases is inside the LM response.

We fine-tuned the model in a zero-shot mode. The system prompt is: *"Answer the following question."* The user prompt: *"Question: "* + `question text`; the assistant prompt: *"Answer: "* + `answer text`. The data for questions and respective answers is taken from DBpedia.

Simply fine-tuning LoRA on new knowledge is challenging (Huang et al., 2024a); we augment the training dataset with synthetic data, including *paraphrases* and `HighlyKnown` facts.

When a model learns new singular knowledge as a simple sentence, it learns it without "inner structure". But if we augment it with *paraphrases*

[3] https://databus.dbpedia.org/dbpedia/mappings/mappingbased-objects

[4] https://hf.co/meta-llama/Meta-Llama-3-8B-Instruct

or HighlyKnown the model retains the new knowledge structurally, since the HighlyKnown elements model knows not as simple sentences *"Paris is a capital of a France"*, but as models' "inner space of capitals" and models' "inner space of countries". Adding new knowledge in this way is less disruptive than simply learning singular knowledge (Allen-Zhu and Li, 2024).

Paraphrasing By paraphrasing, we mean augmenting initial training data with the UK question paraphrases. For generating paraphrases we use Llama-3-70B-Instruct[5] with the system prompt: *"Please, rephrase the question 200 times differently"*. The models are trained with 0, 1, and 10 paraphrases per question. For instance, the training configuration with 10 UK + 10 paraphrases means that for each of the 10 unknown questions we take 10 paraphrases and take initial 10 questions, thus having 110 training samples.

HighlyKnown In the highly known mode, in addition to Unknown samples are added HighlyKnown samples. The sample is considered to be HighlyKnown by the default Llama-3.1-8B-Instruct, these samples are taken from DBpedia or TriviaQA.

LoRA training LoRA models were trained for 10 epochs, with learning rate $1e-3$, batch size 16, lora rank 1, lora alpha 2, lora dropout 0.1, and lora layers `down_proj, gate_proj, up_proj`.

Train-test splits We have a total of 21,036 question-answer pairs based on DBpedia triples. Using Llama-3.1-8B-instruct responses, we categorized them into – Unknown, MaybeKnown and HighlyKnown. Samples of each category are presented in Appendix C. After that we randomly take n questions, whose category is Unknown for the training part. Then, depending on the configuration, each of the n questions is augmented with k paraphrases or k HighlyKnown samples. For example, in case of 10 HK+10 UK configuration we randomly sample 10 Unknown examples out of 21,036 questions and additionally 10 HighlyKnown (out of 21,036 as well) samples for each of the Unknown questions, making 110 training samples in total. These 110 questions are part of the train. The initial 21,036 questions are the test part. Since examples for the train part are taken from the test part, we are sure that the model has indeed learned the new knowledge. Although the intersection of training and test data is not welcomed in conventional ML settings, it is crucial for our setting to check that the model has learned what it has been trained for.

Evaluation LoRA models are inferenced 10 times with 4-shot prompts. The example of a 4-shot prompt is presented in the Appendix B. Each of these 10 prompts has four distinct few shot prompts. These four few-shot examples are question-answer pairs from TriviaQA.

5 Analysis

This section includes a step-by-step analysis of the trained models. In Subsection 5.1, we analyze whether LoRA adapters can learn all the knowledge samples for which they have been trained. Subsection 5.2 provides an in-depth analysis of knowledge shifts. In Subsection 5.3 we check how reasoning abilities and truthfulness change on the external data. Finally, Subsection 5.4 sheds light on the reasons of knowledge shifts: why could the model have learned additional facts it was not trained on and forgot something it was completely sure about?

5.1 Accuracy

	Highly Known			Paraphrase		
UK	0	1	10	0	1	10
1	1.0	1.0	1.0	1.0	1.0	1.0
10	1.0	1.0	1.0	1.0	1.0	1.0
50	1.0	1.0	1.0	1.0	1.0	1.0
100	0.98	1.0	1.0	0.98	0.99	1.0
500	1.0	0.99	0.97	1.0	0.99	1.0
3,000	0.98	0.92	0.48	0.98	0.97	0.99

Table 2: **Reliability** on test for models trained on HighlyKnown and Paraphrase. Almost all UK facts are learned except for 3,000 UK trained with HK.

In this section, we consider the possibility of the model to simply learn the acquired knowledge, along with not forgetting previously known knowledge. As it can be seen from Table 2, models can learn up to 500 unknown samples with 100% reliability score. For 3,000 unknown samples 10 epochs is not enough for model to learn all samples. The same can be seen in Figure 2: with additional paraphrases for each 1 unknown sample model converges faster. But adding HighlyKnown data can be harmful to the training process. At best it has a neutral effect on the convergence, and at worst it slows down.

[5] https://hf.co/meta-llama/Meta-Llama-3-70B-Instruct

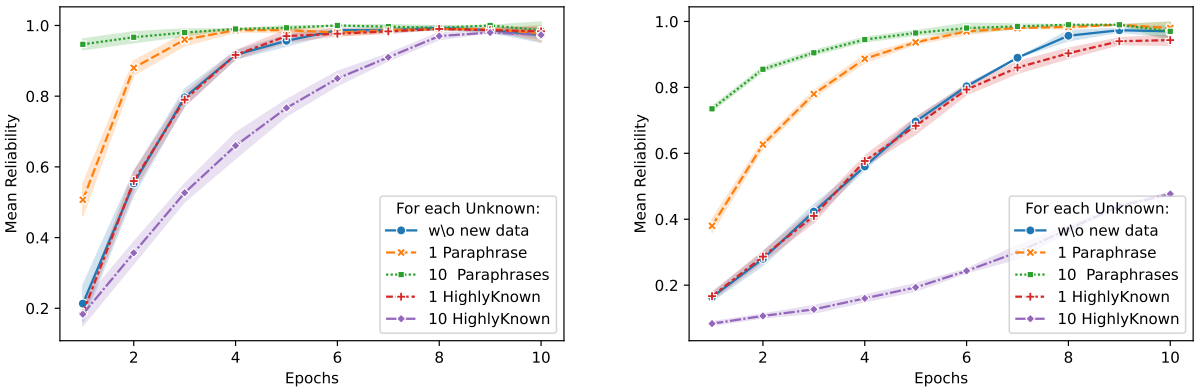

Figure 2: **Dynamics of the reliability score** during training on 500 (left) and 3,000 (right) `Unknown` items along with paraphrases and `HighlyKnown` facts. Error bar is min-max for 3 seed run.

For a paraphrase, this result is not surprising. Increasing training data with different augmentation methods shows an increase in the speed and quality of model training (Zhou et al., 2024; Wang et al., 2024c; Voznyuk and Konovalov, 2024). Also, `HighlyKnown` variant is only harmful for convergence speed, not the model's ability to learn new knowledge.

5.2 Knowledge Shifts

In Table 3, knowledge shifts of the trained models are grouped by the number of `Unknown` samples trained. In the columns we differentiate the training modes: either there was 0, 1 or 10 additional paraphrases or `HighlyKnown` facts per sample. We single out positive shifts and negative shifts. *Positive shifts* are those in which the knowledge category of the (q, a) pair improves. These are the shifts from UK $\rightarrow$ HK, UK $\rightarrow$ MK and MK $\rightarrow$ HK. In contrast, a *negative shift* is a shift, where the knowledge category of the (q, a) fact gets worse. These are the shifts from HK $\rightarrow$ UK, HK $\rightarrow$ MK and MK $\rightarrow$ UK.

If in the previous sections adding paraphrased facts seems to give better results in terms of convergence and maximum amount of knowledge learned, it is clear from Table 3 that training with `HighlyKnown` samples is a winning strategy: it both maximizes positive and minimizes negative shifts.

Although we lose more than we win in almost all training modes, since the negative shift is higher than the positive one, we see that with the increase of the `Unknown` data learned the difference between positive and negative shifts shrinks. However, this observation is true only for the small amount of extra `HighlyKnown` or paraphrased data.

	0	1 HK	1 Paraphrase	10 HK	10 Paraphrase
1 UK					
positive shift	0.034	0.036	0.029	**0.056**	0.045
negative shift	**0.053**	0.054	0.056	0.118	0.067
10 UK					
positive shift	0.021	0.051	0.049	**0.068**	0.038
negative shift	0.245	0.181	**0.154**	0.158	0.187
50 UK					
positive shift	0.06	0.071	0.069	**0.078**	0.07
negative shift	0.148	0.138	0.159	**0.16**	0.174
100 UK					
positive shift	0.067	**0.083**	0.078	0.071	0.064
negative shift	0.172	**0.151**	0.154	0.181	0.204
500 UK					
positive shift	0.096	0.1	**0.105**	0.089	0.076
negative shift	0.195	**0.191**	0.194	0.213	0.25
3,000 UK					
positive shift	0.222	**0.229**	0.222	0.163	0.213
negative shift	0.235	0.202	0.23	**0.149**	0.253

Table 3: **Positive and negative shifts.** Each minitable compares positive and negative shifts for amount of unknown facts learned. Columns represent extra training data used: either HK or paraphrasing. **Green** numbers indicate maximum positive shift for the amount of UK learned, while **red** numbers indicate minimum negative shift for UK learned.

5.3 Benchmarks

We only check the quality of trained LoRA adapters against our test data, so it is not clear whether some of LM's key capabilities have been broken. To fill this gap, we have checked the reasoning abilities of the models on the MMLU benchmark (see Figure 3). Adding 10 `HighlyKnown` or paraphrased samples to train leads to a significant drop in accuracy. On the other side, checking truthfulness on TruftfulQA we see that MC1 and MC2 accu-

racy scores are significantly higher for the training mode with extra paraphrased samples. For a detailed overview of the metrics for external benchmarks, see Table 7 in the Appendix A. An additional evaluation for the ARC (Clark et al., 2018) and LogiQA (Liu et al., 2020) benchmarks is presented in Table 8 in the Appendix E.

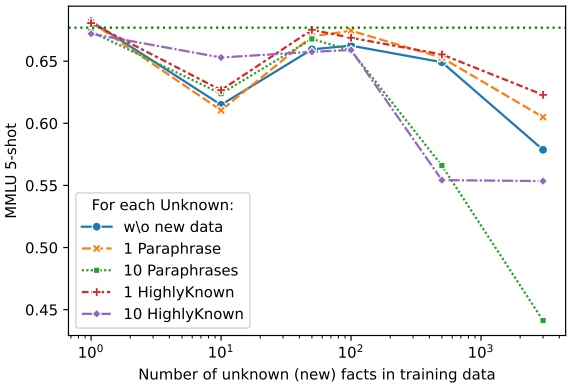

Figure 3: **MMLU:** Accuracy dependent on the amount of Unknown learned. Pointed horizontal line indicates the baseline. Models trained with less additional data tend to disrupt reasoning less.

5.4 Interpretation of Knowledge Shifts

In this section, we analyze the reasons for knowledge shifts. In particular, the reasons of shifting from `HighlKnown` to `Unknown` and from `Unknown` to `HighlyKnown` are considered. The first shift is highly undesirable since the model starts forgetting the knowledge it was completely sure about. The second type of shift is unexpected, since there are a number of shifts from `Unknown` to `Highly Known` in cases for which the model was not initially trained. However, this shift is of particular importance since it makes possible knowledge transfer from training examples to previously unknown facts.

Two general trends in training models have been observed and are presented in Table 4. First, the default `Llama-3.1-8B-Instruct` refuses to answer the questions in 15% of cases. As an answer to the question it produces the following patterns: *"I couldn't find any information ..."*, or *"I cannot verify the ..."*. However, Table 4 shows that almost all models trained in the `Unknown + HighlyKnown` mode lose this ability.

Second, in the test data there are a number of questions for which the answer is the same. For example, for both questions *"Which borough does Aldersgate belong to?"* and *"In which city is the location of General Motors Diesel?"* the answer is *London*. For the default model, the number of unique answers is 48,136 (with respect to repetitions of the same question in greedy search). For some LoRA configurations, there is a significant increase in the number of unique answers (like 100 UK + 10 HK) while for others there is a significant drop. Consider the configurations 10 UK + 0 HK or 10 UK + 1 HK, there is a twofold decrease in the number of unique answers. Although the number of unique answers has decreased dramatically, the number of questions remains the same, which means the model has suggested the same variant for the larger number of questions. For the default model, the answer with the largest number of cases where it is true is *Animalia*: 661 cases. For the aforementioned configurations, it is *Alençon*: 9,393 cases. The large variance in some configurations indicates that trained LoRA models are beginning to converge on some answers (*'exploded'* variants).

	# Refused	# Unique	Mean (Variance)
Default	**3,189**	48,136	3.72 (10.96)
1 UK + 0 HK	758	48,084	4.17 (13.61)
+ 1 HK	816	46,966	4.31 (12.91)
+ 10 HK	**0**	43,766	4.81 (14.26)
10 UK + 0 HK	**0**	**22,804**	**9.22 (96.52)**
+ 1 HK	**0**	**22,148**	**9.38 (166.57)**
+ 10 HK	5	36,798	5.71 (38.26)
50 UK + 0 HK	**0**	37,394	5.62 (38.26)
+ 1 HK	**0**	52,253	4.02 (14.72)
+ 10 HK	**0**	47,734	4.40 (15.14)
100 UK + 0 HK	1	49,403	4.26 (16.58)
+ 1 HK	1	53,576	3.92 (11.74)
+ 10 HK	**0**	59,914	3.51 (12.02)
500 UK + 1 HK	1	48,446	4.34 (16.17)
+ 10 HK	**0**	57,114	3.68 (12.97)

Table 4: **Trends** for the answers' **refusal** and **diversity** in trained models. Default model refuses to answer in 15% cases, while trained models almost never. Some models converge to answers that become overrepresented.

Metrics Table 5 summarizes the absolute amount of shifts from `Unknown` to `HighlyKnown` ($UK \rightarrow HK$) and from `HighlyKnown` to `Unknown` ($HK \rightarrow UK$). The numbers for the shifts are relative and reflect the percentage of cases that fall into this or that reason. The reasons we consider are as follows:

1. *non-refusal* – the percentage of cases where the default model refused to answer while the trained model produced correct answer
2. *explosion* – the percentage of cases where the model predicted one of the exploded answers.

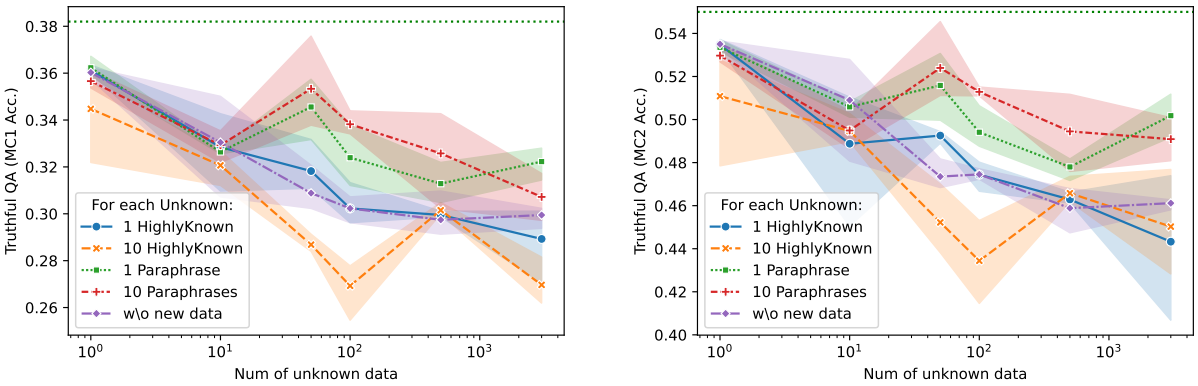

Figure 4: **TruthfulQA:** MC1 and MC2 accuracy metrics dependent on the amount of Unknown learned. Horizontal dotted lines indicate the baselines. Models trained with paraphrases tend to disrupt truthfulness less. Error bar is min-max for 3 seed run.

	Positive shifts						Negative shifts				
Model	*UK* → *HK*	non-refusion	expl-osion	target-based	domain shift	shift explained	*HK* → *UK*	expl-osion	target-based	domain shift	shift explained
1 UK + 0 HK	4	0.25	0.00	**0.50**	**0.50**	0.75	5	0.00	0.00	0.00	0.00
+ 1 HK	4	**0.75**	0.00	0.00	0.00	0.75	5	0.00	0.00	0.00	0.00
+ 10 HK	45	**0.20**	0.00	0.07	0.09	0.29	153	0.01	0.00	**0.02**	0.03
10 UK + 0 HK	111	0.21	0.27	0.24	**0.35**	0.54	409	**0.29**	0.04	0.27	0.48
+ 1 HK	140	0.12	0.14	0.17	**0.32**	0.65	709	0.25	0.10	**0.30**	0.61
+ 10 HK	203	0.10	0.10	0.15	**0.27**	0.33	512	0.08	0.09	**0.25**	0.28
50 UK + 0 HK	241	0.12	0.15	0.40	**0.57**	0.63	392	0.07	0.15	**0.45**	0.50
+ 1 HK	153	0.19	0.05	0.32	**0.60**	0.71	275	0.03	0.00	**0.43**	0.43
+ 10 HK	255	0.14	0.03	0.30	**0.58**	0.63	501	0.01	0.04	**0.43**	0.44
100 UK + 0 HK	185	0.20	0.08	0.36	**0.69**	0.77	314	0.05	0.11	**0.51**	0.54
+ 1 HK	264	0.14	0.00	0.39	**0.73**	0.78	425	0.00	0.08	**0.53**	0.55
+ 10 HK	213	0.12	0.01	0.41	**0.73**	0.79	618	0.01	0.06	**0.49**	0.52
500 UK + 1 HK	748	0.12	0.07	0.79	**0.84**	0.95	802	0.01	0.23	**0.81**	0.85
+ 10 HK	568	0.11	0.01	0.84	**0.86**	0.97	1,134	0.01	0.22	**0.80**	0.83

Table 5: **Reasons for knowledge shifts.** UK → HK and HK → UK indicate absolute amount of shifts. Each reason reflects the relative contribution to understanding the nature of shifts. Bold numbers reflect a main reason of shift, underlined numbers - the second best reason of shift.

The exploded answer is the one to which the model converges in percentage of cases considerably higher than expected by the default model

3. *target-based* – the percentage of cases where the model predicts one of the answers from the unknown examples it was trained on
4. *domain shift* – all questions in the dataset were constructed by templates in a form of `<subject, relation, object>`. Each relation in DBpedia has either its range or domain. Both give insight into the way the relation links a subject to an object. In case of domain, the subject qualifies as a type of thing specified in the domain. The range works exactly like the domain but applies to the object. 390 relations from the test data fall into 92 relation domain categories. For example, the relation domain "PopulatedPlace" includes 24 relations, allowing us to analyze shifts of knowledge of a large amount of similar relations instead of looking at the specific one. *domain shift* shows the percentage of cases where the shift goes from the same domain or range of the relation for the cases the model was trained on
5. *shift explained* – the percentage of shift explained by all aforementioned reasons. Note that the sum of the rates for all reasons does not necessarily sum to the percentage of the shift explained, since some of the reasons overlap.

Except for the *non-refusal* all reasons fall into both positive and negative shifts. For example, we see that both positive and negative shifts occur inside the domain. Specific examples of positive and negative shifts are presented in Appendix D.

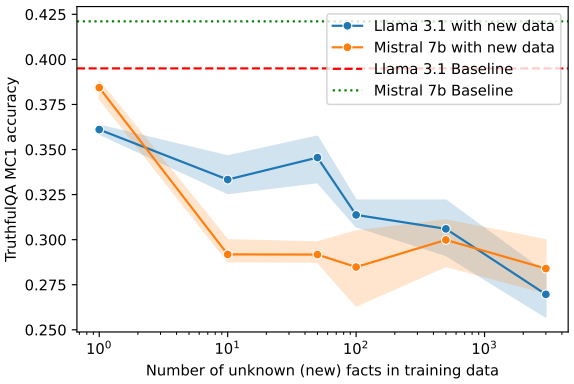

Figure 5: Difference in quality drop for the two models: Llama 3.1 8B and Mistral 7B v0.3.

Discussion If we train the model just for 1 new unknown fact, the positive shift occurs mainly because the model starts answering questions it has not answered previously.

From the exploded answers suffer the models (10 UK+ 1 HK and 10 UK + 0 HK) that have a low amount of training data with a large proportion of new trained unknown facts relative to the size of the training data.

Finally, we can see that with the increase in the amount of learned unknown facts, there is an increase of the rate of domain shift and target spillover for positive shifts. On the other hand, for the negative shifts, there is only the tendency for the increase of the rate of the domain shift explaining the proportion of the shift explained. Besides, if we compare target-based percentages for positive and negative shifts, we can see that for all models this percentage is higher for positive shifts. The same is true for the negative shifts and for the domain shift as well. It means that out of these two reasons the positive effect of learning from the same domain and target is higher than negative.

6 Additional Results for Mistral

Similar effects to those described above for the LLaMa model may be observed in other models, such as GPT-3 and Mistral. We have conducted a set of experiments for the Mistral-7B-Instruct-v0.3 model, to verify if the results obtained for the Llama-3.1-8B-Instruct model are generalizable to other decoder-only models.

As we can see in Table 6, the number of Paraphrases and `HighlyKnown` increases, so does the positive shift. This corroborates our findings on Llama-3.1-8B-Instruct.

Method	**Accuracy shift**	
	Pos. shift	Neg. shift
1 Unknown + 1 Paraphrase	0.159	0.106
1 Unknown + 10 Paraphrases	0.196	0.114
1 Unknown + 1 HighlyKnown	0.160	0.114
1 Unknown + 10 HighlyKnown	0.174	0.146

Table 6: Accuracy shift for Mistral-7B-Instruct-v0.3.

As can be seen in Figure 5, the quality of the model decreases as the number of new knowledge increases. Models are not strongly correlated, but we see similar features, such as a significant drop from 1 new knowledge to 10, and a small recovery of quality at 100 new knowledge. Thus, we believe that generalizing our research to other decoder-only models is possible.

7 Conclusion

Our findings revealed that the most significant increase in the acquisition of additional knowledge is achieved when a blend of `Unknown` and `HighlyKnown` data is incorporated into the training phase. However, this approach comes with a trade-off: it compromises the model's capability to accurately answer complex or nuanced questions, as assessed by TruthfulQA.

Additionally, it has been observed that the incorporation of a limited number of unknown facts within a vast set of `HighlyKnown` examples or paraphrases can substantially impair the model's reasoning abilities as measured by MMLU.

In an additional observation, it was noted that upon being fine-tuned with LoRA adapters, LLMs experience a reduction in their ability to express uncertainty when formulating answers. In certain scenarios, this leads to the models disproportionately favoring responses that are statistically overrepresented.

Acknowledgement

This research was conducted within the framework of a joint MTS-Skoltech laboratory on AI.

Limitations

Since we only used one LLM for our study (namely, Llama-3.1-8B-Instruct), it's unknown if the outcomes will change when utilizing different LLMs. However, because our work requires a lot of computation, it is difficult to repeat on several LLMs.

First, we experimented a lot with different learning rates, LoRA ranks and used two data augmentation techniques with 0, 1, 10 extra examples per sample. This results in a great number of experiments. Second, and perhaps most crucially, we had to annotate a sizable dataset with the knowledge categories to make our analysis easier. It was essential to precisely evaluate the model's knowledge with regard to a particular fine-tuning case in order to draw trustworthy findings. Beyond this, detecting knowledge categories is a machine-intensive task not only for defining the initial categories, but at each inference step.

In addition, there are a few crucial directions for future research left unexplored in this paper. Namely, how early stopping could have influenced the distribution of knowledge categories and models' behavior on external benchmarks. Adding training examples from the same relation domain or range as well as few-shot prompts from this category could have also boosted the performance. We leave these questions for further exploration.

Ethical Considerations

We have carefully curated the generated dataset, and we have not encountered any inappropriate or offensive content within it.

Table 7: Accuracy for MMLU and a range of metrics for ThruthfulQA for all trained LoRA adapters

B Few-shot Prompts

Here is an example of the 4-shot prompt. The prompt includes 4 question-answer examples, 5th question is the question of interest.

Answer the following question.
Question: Who wrote the novel Evening Class? Answer: maeve binchy
Question: Which country does the airline Air Pacific come from? Answer: fidji
Question: In which branch of the arts does Allegra Kent work? Answer: balletti
Question: Who had a 70s No 1 hit with Billy, Don't Be A Hero? Answer: bo donaldson and heywoods
Question: 12th Brigade (Australia) fought in what battle?

C Samples of Knowledge Categories

`HighlyKnown`. *Question: where is Alfa Romeo MiTo assembled? Answer: Turin*
`MaybeKnown`. *Question: Daredevil (TV series) is on which channel? Answer: Netflix*
`Unknown`. *Question: Can you name a band member of Ashes of Ares? Answer: Matthew Barlow*

D Examples of Positive and Negative Shifts

Let's illustrate the concept of positive shifts through examples. This occurs when a model begins to accurately respond to queries for which it has not been specifically trained (A_{before} – an answer before fine-tuning, A_{after} – an answer after fine-tuning).

Positive Shifts:

Q: *Batata vada is located in which region?* A_{before}: *India* A_{after}: *Maharashtra*
Q: *Esslingen am Neckar is in which administrative?* A_{before}: *Esslingen* A_{after}: *Stuttgart Government Region*
Q: *What is the home arena of Anaheim Storm?* A_{before}: *I couldn't find any information* A_{after}: *Anaheim Arena*

Negative Shifts:

Q: *Where did John Bigger pass away?* A_{before}: *I cannot verify where* A_{after}: *London*
Q: *In which canton is Gachnang located?* A_{before}: *Thurgovia* A_{after}: *aargau*

E ARC and LogiQA Benchmarks

Abstract

Current Large Language Models (LLMs) exhibit limited ability to understand table structures and to apply precise numerical reasoning, which is crucial for tasks such as *table question answering* and *table-based fact verification*. To address these challenges, we introduce our *Tool-Augmented Reasoning framework for Tables* (TART), which integrates LLMs with specialized tools. TART contains three key components: a *table formatter* to ensure accurate data representation, a *tool maker* to develop specific computational tools, and an *explanation generator* to maintain explainability. We also present the TOOLTAB dataset, a new benchmark designed specifically for training LLMs in table–tool integration. Our experiments indicate that TART achieves substantial improvements over existing methods (*e.g.,* Chain-of-Thought) by improving both the precision of data processing and the clarity of the reasoning process. Notably, TART paired with `CodeLlama` achieves 90.0% of the accuracy of the closed-sourced LLM `GPT-3.5-turbo`, highlighting its robustness in diverse real-world scenarios. Both code and data are openly available at https://github.com/XinyuanLu00/TART.

1 Introduction

Tabular data is prevalent across multiple fields such as scientific research, financial reporting, and healthcare records (Dong et al., 2022). Manual handling of such data can be both routine and error-prone, or may require specialized skills, highlighting the need for automated table reasoning to improve efficiency (Badaro et al., 2023). Typical table-based reasoning tasks include *table question answering* (TQA), which extracts precise information from tables to answer given queries (Chen et al., 2020b; Zhu et al., 2021; Nan et al., 2022) and *table-based fact verification* (TFV), which verifies the correctness of statements by cross-referencing them with facts stored in tables (Wang et al., 2021; Lu et al., 2023c).

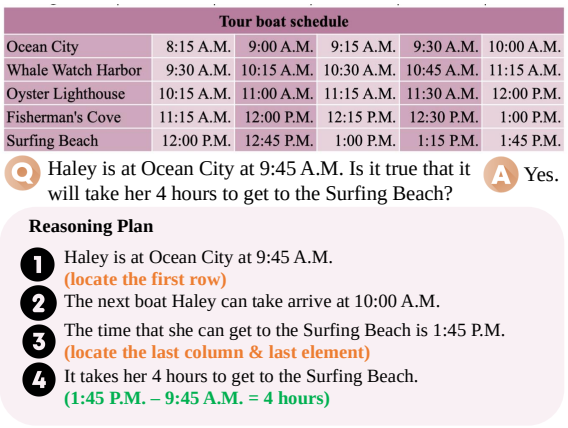

Figure 1: Example of the TableQA task, demonstrating the verification of travel time via boat schedule and the critical skills needed for accurate table reasoning: table structure understanding, precise numerical calculations, and executing sequential reasoning steps.

Modern large language models (LLMs) such as GPT-4 (OpenAI, 2023) have shown remarkable reasoning capabilities across a variety of tasks, spurring interest in their application to table-based tasks (Ye et al., 2023). However, table-based reasoning presents unique challenges for LLMs, which are primarily trained on sequential text data (Zhang et al., 2024a), as illustrated by a real-world example in Figure 1. *(1) Understanding and operating on table structure*: LLMs must adapt to the non-linear format of the tables, which demands unique reasoning skills such as recognizing headers, interpreting the roles of the rows and the columns, and precisely extracting information from relevant table cells. *(2) Precise numerical reasoning:* Tables often contain quantitative information that requires precise calculations and comparisons. LLMs must perform operations such as summation, averaging, or trend analysis accurately, often over multiple cells or tables, which is a shift from their usual text-based reasoning tasks (Herzig et al.,

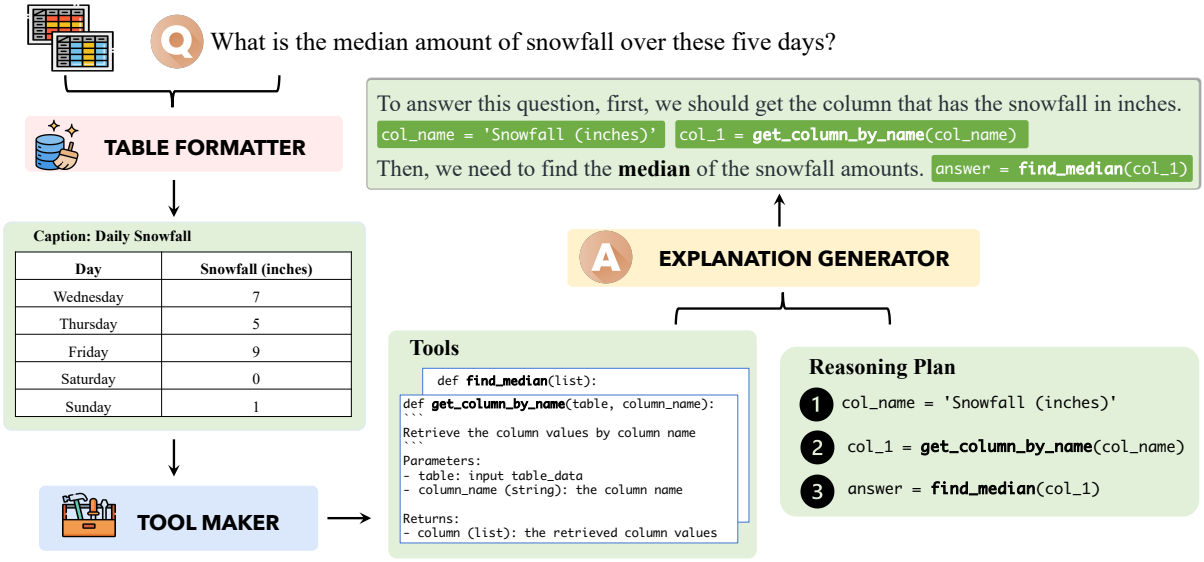

Figure 2: An overall framework of TART, which contains three main modules: (*i*) *table formatter*, which prepares and organizes the raw table data, (*ii*) *tool maker*, which creates specialized tools for precise table manipulation, and (*iii*) *explanation generator*, which produces user-friendly explanations integrating the output of different tools.

2020; Liu et al., 2022). *(3) Reasoning planning:* LLMs often need to plan several reasoning steps ahead. This includes decomposing the original question, determining relevant table parts, and anticipating intermediate calculations or data transformations. All three challenges manifest in Figure 1.

Existing approaches that use LLMs for table-based reasoning can be broadly classified into two categories. One is *chain-of-thought (CoT) reasoning* (Wei et al., 2022), in which the model is prompted to perform step-by-step reasoning over the input table flattened as a textual sequence (Zhang et al., 2024a; Jin and Lu, 2023; Chen, 2023; Ye et al., 2023). Despite its flexibility, CoT often lacks precision in tabular operations and numerical reasoning, such as sorting, counting, and filtering (Wu and Feng, 2024). The second approach, *program-based reasoning (PoT)* (Gao et al., 2023; Chen et al., 2023) prompts the model to generate SQL or Python code to enable precise reasoning (Liu et al., 2024; Zhang et al., 2024b; Wang et al., 2024b; Wu and Feng, 2024). However, this method struggles with reasoning planning and its reasoning is less understandable to humans (Zhang et al., 2024b). Therefore, there is potential value in integrating the advantages of program-based and textual reasoning, to achieve both high precision and explainability in table-based reasoning.

Inspired by the recent paradigm of tool-augmented language models (Wang et al., 2024a; Schick et al., 2023), we propose ***T**ool-**A**ugmented **R**easoning framework for **T**ables* (TART), which integrates external tool calling into the chain-of-thought reasoning process, as shown in Figure 2. Initially, TART processes the input table using a specialized module *table formatter* to clean and to format the raw table data, preparing it for the subsequent table operations. Subsequently, the *tool maker* calls specialized tools (Python functions) for tabular manipulation and numerical reasoning (e.g., adding columns, selecting rows, and grouping). Alongside these tools, TART also crafts a *reasoning plan* that outlines the programmatic calling sequence of the tools, specifying the necessary arguments and the expected return values for each call. Finally, following the structured reasoning plan, the *explanation generator* produces a hybrid text-and-program output, integrating calls to external tools into coherent, human-readable chain-of-thought explanations. In doing so, TART efficiently delegates table operations and precise numerical calculations to generated tools while preserving CoT's planning ability and explainability.

To train the modules in TART, we further synthesize the TOOLTAB dataset by distilling knowledge from a teacher LLM. We evaluate TART on nine different table-based reasoning benchmarks. The results highlight the effectiveness of integrating task-specific tools for enhancing complex reasoning capabilities. Notably, TART consistently outperformed the CoT baseline, achieving near-parity with `GPT-3.5-turbo` on benchmarks, showcasing its usefulness in real-world scenarios.

In summary, our contributions are threefold:

• We propose TART, a novel framework that enhances table-based reasoning by integrating tools into the reasoning process, which addresses the limitations of current LLMs in handling table structures and executing precise calculations.

• We develop TOOLTAB, a comprehensive benchmark specifically designed to train LLMs on table-tool integration. It includes diverse real-world tables, uniform format, and careful validation to ensure high-quality training.

• Our experiments confirm that TART not only improves the precision and the explainability of table-based reasoning, but also generalizes effectively to out-of-domain datasets.

2 Related Work

Table-based reasoning tasks involve interpreting and manipulating data from structured tabular sources to answer questions, verify facts, or generate summaries. Early approaches used executable SQL or SPARQL to interact with tabular data (Yin et al., 2016; Yu et al., 2018), or graph neural networks to better encode table structures (Zhong et al., 2020; Yang et al., 2020). However, they typically suffer from poor generalization capabilities due to their reliance on specific table formats and linguistic patterns.

Recent advances in large language models (LLMs) have demonstrated significant potential in this area. Pre-training strategies that align LLMs with sentence-table pairs (Chen et al., 2020a; Herzig et al., 2020; Zhou et al., 2022; Gu et al., 2022; Ye et al., 2023; Glockner et al., 2024) have improved table reasoning capabilities, while frameworks like TAP4LLM (Sui et al., 2024b) optimizes table representations through sampling, augmentation, and serialization. Other works, such as *ReAcTable* (Zhang et al., 2024b) and Chain-of-Table (Wang et al., 2024b), have introduced hybrid or explicit reasoning mechanisms to better integrate tabular data into reasoning chains. These methods primarily rely on textual reasoning strategies, such as chain-of-thought, which often lack the precision necessary for table manipulations and numerical reasoning. Efforts have also been made to evaluate and enhance LLM capabilities for table-related tasks. Studies like Table Meets LLM (Sui et al., 2024a) and Text2Analysis (He et al., 2024) introduce benchmarks for tasks such as cell lookup, row retrieval, and Python-based advanced data analysis, emphasizing challenges in table serialization and query understanding. Meanwhile, TabularNet (Du et al., 2021) proposes novel architectures, combining graph-based and relational representations to improve semantic understanding of tabular data. However, these approaches typically focus on either enhancing representation or evaluation rather than augmenting reasoning precision. In addition to general-purpose frameworks, domain-specific solutions such as EHRAgent (Shi et al., 2024) have been developed for multi-tabular reasoning in specialized domains like electronic health records (EHRs). While EHRAgent integrates domain-specific metadata and debugging strategies, its focus contrasts with TART, which is designed as a domain-agnostic solution for table reasoning across diverse contexts. Similarly, API-Assisted Code Generation (Cao et al., 2023) translates queries into Python programs leveraging fixed APIs, differing from TART 's dynamic tool-augmented reasoning approach.

To address the limitations of prior work, TART extends the use of LLMs with integrated external tools, enabling precise table manipulations and numerical reasoning while maintaining explainability. By combining strategies such as table formatting for better representation, tool-based function execution for precision, and LLM-based reasoning for interpretability, TART advances the state of table-based reasoning tasks.

3 Methodology

Generally, a table-based reasoning model, $f_\theta(\cdot)$, parameterized by θ, takes an input query Q and a table $\mathcal{T}$ to produce a response $Y = f_\theta(Q, \mathcal{T})$. Based on this generic formulation, the nature of Q and Y differs depending on the specific table reasoning task:

in table-based QA, Q is a question and Y is the answer; in table-based fact verification, Q is a claim and Y is its veracity label. A table $\mathcal{T}$ is characterized by a caption P and its contents $T_{i,j} \mid i \leq R_T, j \leq C_T$, where R_T and C_T represent the numbers of rows and columns, respectively. Each cell (i, j) contains data $T_{i,j}$.

To build an accurate and explainable table-reasoning framework, our proposed TART integrates the call to external tools into the chain-of-thought reasoning process. TART consists of three reasoning modules (Figure 2): ① *Table Formatter*; ② *Tool Maker*; ③ *Explanation Generator*.

1. Table Formatter. TART first transforms the original table $\mathcal{T}$ with guidance from the query Q into a formatted table $\mathcal{T}'$. The formatter optimizes data formats, aligns columns, and adjusts data types as needed for the query, producing a well-formatted table that is used in subsequent reasoning.

2. Tool Maker. Given $\mathcal{T}'$, the *tool maker* generates a set of candidate tools S useful for solving Q. It also develops a reasoning plan R that details the high-level reasoning which includes the tool calling order, as well as the necessary arguments and the expected return values for the tool calls.

3. Explanation Generator. Given the reasoning plan R as a programmatic guide for chain-of-thought reasoning, the explanation generator is responsible for producing a user-friendly explanation E that incorporates the use of the tools. The explanation also concludes with the final answer $\mathcal{A}$, derived from the reasoning plan R's execution.

3.1 Table Formatter

We first train a specialized open-sourced large language model as the table formatter $\mathcal{F}$, which transforms the noisy raw input table $\mathcal{T}$, into a more structured and manageable format, $\mathcal{T}'$, to facilitate subsequent reasoning: $\mathcal{T}' = \mathcal{F}(\mathcal{T}, Q)$ where the output table $\mathcal{T}'$ is formatted according to three aspects. 1) *Data Cleaning*: the model formats the cell values, such as removing currency symbols and textual footnotes to facilitate the execution of external functions to perform table operations or numerical reasoning. 2) *Data Standardization* converts different data representations into a uniform format;*e.g.,* transforming the data from "`MM/DD/YYYY`" to a consistent "`YYYY-MM-DD`" format across the entire table. 3) *Error Handling*: the model also fixes obvious errors or missing values in the table, such as automatically inferring header names for columns without the table headers.

We introduce the table formatter to ensure that the data in the input table is uniform and optimized for subsequent reasoning, especially to make it more compatible with function execution. In practice, we transform the formatted table $\mathcal{T}'$ into a Python array, facilitating easier interpretation and processing by subsequent reasoning modules.

3.2 Tool Maker

Recent studies have shown that LLMs have the capability of synthesizing relevant tools by understanding the problem context and creating solutions based on the crafted tools (Schick et al., 2023; Cai et al., 2024; Wang et al., 2024a). Motivated by this, we train another specialized LLM $\mathcal{M}$ as a *tool maker*, which takes as input the reformatted table $\mathcal{T}'$ and the query Q to generate a set of candidate tools S and develops a reasoning plan R that details the high-level reasoning steps: $S, R = \mathcal{M}(\mathcal{T}', Q)$. The tool set $S = \{s_1, \cdots, s_n\}$ consists of n specialized tools, where each tool s_i is a Python function that performs table operations (*e.g.*, `get_column_by_name`), numerical reasoning (*e.g.*, `average`, `argmax`), or higher-level functions (*e.g.*, `linear_regression`). These automated tools are essential to handle reasoning tasks that textual-based LLMs cannot address effectively.

Unlike previous work that manually defined a small number (< 10) of hand-crafted tools (Lu et al., 2023a; Pan et al., 2023) or retrieved tools from a predefined set (Qin et al., 2024; Ma et al., 2024), we choose to train a specialized *tool maker* model that **learns to *generate* tools dynamically, based on the specifics of the table and the context of the problem.** This approach not only preserves the model's ability to "extract" previously encountered tools from its parametric memory, but also empowers the model to create novel tools as needed for unique problems, as shown in Section 5.2. While generating tools offer greater flexibility, it is crucial to prevent the tool maker from creating overly-specific tools (*e.g.*, `count_people_on_third_floor`), as this would hinder its ability to generalize to new problems. To address this issue, we incorporate *tool abstraction* and *tool deduplication* steps when constructing synthetic data for training the module (Section 3.4).

The model also constructs a high-level reasoning plan $R = [r_1, \cdots, r_N]$, which outlines how tools should be applied. The reasoning plan is formulated as a sequence of N function calls. Each *function call* $r_i = (s_i, A_i, V_i)$ includes the function $s_i \in \mathcal{S}$, the *argument* A_i passed to the function, and the *variable* V_i that stores the result of the function call $s_i(A_i)$.

This reasoning plan acts as a programmatic blueprint, guiding the table-based reasoning process. Both the tool set S and the reasoning plan R are then provided to the explanation generator, producing the final explainable reasoning output.

3.3 Explanation Generator

While program-based reasoning plans are precise, they are often difficult for non-expert users to understand. Moreover, certain types of reasoning, such as commonsense or narrative-based reasoning, are better communicated in natural language. To address this, TART incorporates a specialized module called the *explanation generator* $\mathcal{E}$, which generates chain-of-thought natural language explanations integrated with function calls, following the steps outlined in the reasoning plan R: $O = \mathcal{E}(S, R)$. The final output O of TART provides detailed explanations for the function calls. For example, the function call `get_column_by_name` is explained as, "*First, retrieve the column listing snowfall in inches.*" Additionally, the explanation generator groups related function calls together to create coherent and easy-to-follow explanations, as illustrated in Figure 2.

3.4 Model Training

As no prior work adopts the tool-augmented LLM framework for table reasoning, there does not exist training data to train the modules *Table Formatter*, *Tool Maker* and *Explanation Generator* ($\mathcal{F}$, $\mathcal{M}$, and $\mathcal{E}$) in TART. Previous studies have demonstrated that smaller LLMs can learn from distilling the generated outputs of larger teacher LLMs that have better reasoning capabilities (West et al., 2022; Wang et al., 2023; Kim et al., 2024). Following this, we use a teacher LLM $\mathcal{L}$ to first synthesize tool-integrated solution trajectories for a set of seed table-based reasoning tasks. These high-quality solution trajectories serve as the blueprint from which we automatically extract and rearrange their components to build training sets for $\mathcal{F}$, $\mathcal{M}$, and $\mathcal{E}$.

Training Data Synthesis. For all modules, we use GPT-4 as the teacher LLM $\mathcal{L}$ to generate training data. As shown in Table 5, we select five diverse table reasoning datasets: two from TQA and three from TFV, spanning general knowledge (Wikipedia) as well as domains such as finance, health, and scientific documents. These datasets provide a broad range of reasoning types. We few-shot prompt $\mathcal{L}$ to generate tool-integrated solutions for training instances for each dataset. In each solution, the model is prompted to clean the table, invent tools, and propose a reasoning plan with explanations. We provide our prompt in Appendix F.

After generating the solutions, we evaluate the final answers against the ground truth, retaining only the instances with correct answers. Subsequently, we refine the solutions by removing overly specific tools through *tool abstraction* and *tool deduplication*. Tool abstraction filters out tools that appear only once, keeping those with broader applicability. Tool deduplication consolidates similar tools that perform the same function, but have different names or implementations (e.g., `add` and `sum`). As a result, we obtain 11,701, 9,916, and 9,916 training instances for the table formatter $\mathcal{F}$, tool maker $\mathcal{M}$, and explanation generator $\mathcal{E}$, We refer to this training dataset as TOOLTAB, with detailed statistics provided in Table 6.

Training Configurations. Instruction fine-tuning (Mishra et al., 2022; Chung et al., 2024) has emerged as a critical strategy that directs LLMs to adhere to specified instructions, facilitating their reasoning capability across a wide range of table-based tasks. Therefore, we use open-source LLMs with instruction tuning as the backbone models for the modules of TART, specifically `Llama-2-7b` (Touvron et al., 2023), `Llama-3-8b`, `CodeLlama-7b` (Rozière et al., 2023) and `Deepseek-Coder-7b-Instruct-V1.5` (Guo et al., 2024). We fine-tune all TART modules independently on their respective training datasets from TOOLTAB, using the standard next-token prediction objective.

4 Experiments

Datasets and Baselines. To evaluate TART, we select two categories of benchmarks for table-based reasoning. *(1) Table question answering (TQA)*: `WikiTableQuestion (WTQ)` (Pasupat and Liang, 2015) focuses on simple factoid questions. `HiTab (HIT)` (Cheng et al., 2022), `TabMWP (TMP)` (Lu et al., 2023b) and `FinQA (FQA)` (Chen et al., 2021) datasets focus on numerical reasoning reasoning. `TAT-QA (TAT)` (Zhu et al., 2021) and `HybridQA (HYQ)` (Chen et al., 2020b) require joint reasoning over the table and the text for financial reports and Wikipedia tables, respectively. *(2) Table-based fact verification (TFV)*: We select `TabFact (TAF)` (Chen et al., 2020a), `SCITAB (SCT)` (Lu et al., 2023c), and `PubHealthTab (PHT)` (Akhtar et al., 2022) datasets, which focus on verifying facts based on tables from Wikipedia, scientific articles, and public health articles, respectively.

For baseline comparisons, we select well-known table-based open-source LLMs such as `TableLlama` (Zhang et al., 2024a) , as well as

	Model	Setting	TableFV		TableQA

	GPT-4	w/ TART	**87.7**	<u>84.1</u>	63.6	**98.3**	**68.5**	**80.4**

Table 1: Performance evaluation across backbone models using the TART framework, highlighting the best (bold) and second-best (underlined) results. The accuracy is calculated on testing sets, with overall average accuracy in the last column (*Avg. Acc.*). The red numbers indicate the average increase percentage over the CoT methods.

text-pretrained models (`Llama2-7b`, `Llama3-8b`) and code-pretrained models (`CodeLlama-7b`, `DeepSeek-Coder-7b`). We choose the 7b and the 8b versions to represent a balance between computational efficiency and the capacity for complex reasoning and generalization. For each model, we fine-tune with two settings: (1) `DirectQA`, where models generate answers directly from questions and tables, and (2) `Chain-of-Thought (CoT)` reasoning, which requires models to formulate a step-by-step reasoning process before concluding with an answer.

Implementation. For TART, we use the answer given by executing the reasoning plan; if the reasoning plan is not executable, we use the answer given by CoT. For each model, we train the model with TOOLTAB while leaving the rest (WTQ, HIT, TAT, and HYQ) as held-out unseen datasets. All experiments were conducted on a GPU server with Intel Xeon Platinum 8480C (224) @ 2.900GHz CPU and 8 NVIDIA H100 (80G) GPUs. The training process for `Llama-2-7b-hf`, `CodeLlama-7b-hf`, and `deepseek-coder-7b-instruct-v1.5` requires a single GPU for approximately 20 hours, using a batch size of 4, learning rate of 5e-5, sequence length of 1500, gradient accumulation steps of 2, and 10 training epochs. Training `Llama-3-8b` required up to two GPUs for around 20 hours with the same settings. To minimize randomness, a temperature of 0.0 was used, while all other hyperparameters for sampling the output from the LLMs remained at their default values. For the closed-source version of TART, we use `GPT-3.5-turbo` and `GPT-4` with two in-context examples.

4.1 Main Results

We first evaluate TART and the baselines on in-domain datasets, where their training sets are used to construct TOOLTAB. The experimental results, as shown in Table 1, reveal a notable performance improvement in our model compared to baseline models. We have four major observations.

1. TART consistently outperforms `CoT` across all four backbone models and datasets. For example, with `CodeLlama-7b` as the backbone model, TART outperforms `DirectQA` and `CoT` by 16.3% and 41.9% on average, respectively. This highlights the effectiveness of integrating task-specific tools in enhancing complex reasoning capabilities.

2. With `CodeLlama-7b` as the backbone model of TART, it achieves the highest accuracy increase of 41.9%., whereas `Llama3-8b` shows the least improvement of 22.7%. This discrepancy is likely because of `CodeLlama-7b`'s specialized pre-training in coding tasks, which enhances the capabilities of creating tools for structured queries and operations.

3. The performance gains of TART also vary for different datasets, with `FinQA` showing the highest increase, while `PubHealthTab` shows the least. This discrepancy suggests that the financial focus

Model	TAF	PHT	SCT	TMP	FQA	Avg. Acc.
Llama2	69.2	55.0	53.4	88.8	19.2	57.1
- TabFT	67.7	39.1	50.4	67.8	17.2	48.4 (-15.2%)
Llama3	69.7	68.5	47.2	92.6	27.1	61.0
- TabFT	69.2	58.9	46.3	65.4	13.8	50.7 (-16.9%)
CodeLlama	66.5	69.8	44.9	90.1	25.0	59.3
- TabFT	66.6	64.9	36.6	69.1	20.2	51.5 (-13.2%)
DeepSeek	71.3	69.1	47.8	93.1	30.9	62.4
- TabFT	58.0	58.8	45.0	71.3	16.7	50.0 (-19.9%)

Table 2: The ablation study of Table Formatter (- *TabFT*) in TART with different backbone models. The red numbers indicate the average accuracy (*Avg. Acc.*) drop percentage without Table Formatter for each model.

of the FinQA dataset, which demands extensive numerical reasoning and structured data manipulation, benefits significantly from the TART approach.

4. Using closed-source models (GPT-3.5-turbo and GPT-4) as the backbone models for TART achieves an average accuracy of 74.9, significantly outperforming the open-source counterparts, which average at 60.0 accuracy. Nonetheless, the highest-performing open-source model, DeepSeek-7b, reaches up to 90.0% of GPT-3.5-turbo's performance and 77.6% of GPT-4, illustrating the competitiveness of open-source models in the creation and use of tools despite the apparent model size gap.

4.2 Ablation Study

Ablation of the Table Formatter. We conduct ablation experiments across all backbone models (Table 2). TART without the Table Formatter led to significant and uniform performance drops of over 10%. This clearly demonstrates the effectiveness of the Table Formatter module in improving reasoning capabilities by ensuring consistent table representations.

Ablation of the Tool Maker. In this ablation, the framework directly generates programs instead of creating modular tools (Figure 3a). While this approach achieves functionality, it impacts both performance and explanability. These tools (e.g., get_column_by_name) can be used repeatedly comparing to the tools that are overly specific (e.g.,calculate_cookie_difference).

Ablation of the Explanation Generator. The Explanation Generator module does not directly impact the final performance in terms of accuracy, but enhances the explanability of the outputs. For example, in Figure 3(b), TART's final answer provides more human-readble explanations, comparing to the program.

Tab Formt	TAF	PHT	SCT	TMP	FQA
Llama2	71.8/78.5	75.8/66.4	64.0/57.0	93.6/92.0	73.4/37.7
Llama3	76.6/84.7	79.2/67.8	62.4/55.9	94.1/94.4	71.8/40.0
CodeLlama	67.6/78.0	**81.2/66.1**	**64.6/53.9**	94.1/91.5	76.1/35.7
DeepSeek	**70.7/79.7**	72.5/71.3	63.5/51.3	**95.7/93.9**	**74.5/38.6**
Tool Mkr	**TAF**	**PHT**	**SCT**	**TMP**	**FQA**
Llama2	70.2/81.8	65.8/60.2	53.9/61.5	95.7/91.1	61.7/31.0
Llama3	75.5/75.4	71.1/69.8	63.5/52.2	**97.9/92.4**	62.2/38.5
CodeLlama	75.5/85.2	74.5/71.2	**62.9/57.1**	95.7/91.7	68.1/39.8
Deepseek	**76.6/84.7**	**79.2/67.8**	62.4/55.9	94.1/94.4	**71.8/40.0**

Table 3: Results of TART with different backbone modules. The top half uses deepseek-code-7b as the Tool Maker, while the bottom half uses Llama3-8b as the Table Formatter. The best performance is highlighted in bold and the second-best is underlined. Tab Formt is *Table Formatter* and Tool Mkr is *Tool Maker*.

4.3 Impact of Foundation Models

To explore the optimal module combinations within the TART framework, we explore various pairings of table formatter and toolmaker modules shown in Table 3. We find that using Llama3-8b as the table formatter and DeepSeek-7b as the tool maker achieves the best average execution rate (76.8) and accuracy (68.6). This aligns with our expectations given that Llama3-8b excels in processing long tables while DeepSeek-7b, with its pre-training on code, demonstrates superior capability in tool creation (c.f. Table 7 in Appendix B).

5 Discussion

To further explore the usefulness of TART, we focus on the following research questions: 1) What is the performance of TART on out-of-domain (OOD) datasets? (Section 5.1); 2) How does TART create and utilize tools? (Section 5.2); and 3) What is the quality of the explanations generated by TART in actual user cases? (Section 5.3).

5.1 Out-of-Domain Results

We hypothesize that the TART has enhanced generalization capabilities compared to CoT due to its ability to create and use general tools. To validate this, we further evaluate TART across four different OOD datasets: HiTab (HIT), WikiTableQuestion (WTQ), TAT-QA (TAT), and HybridQA (HYQ). The results are shown in Table 4.

The TART method demonstrates variable effectiveness, with notable improvements in certain contexts. For instance, it achieves an average ac-

Question: Hannah baked cookies each day for a bake sale. How many more cookies did Hannah bake on Saturday than on Sunday?

Pure Program

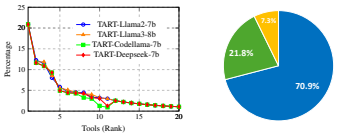
```
def calculate_cookie_difference(cookie_data):
 saturday_cookies = cookie_data["Saturday"]
 sunday_cookies = cookie_data["Sunday"]
  difference = saturday_cookies - sunday_cookies
return difference
cookie_baking = {"Friday": 163,  "Saturday": 281,  "Sunday": 263}
cookie_difference = calculate_cookie_difference(cookie_baking)
print(cookie_difference)
```

TART's tool-augmented Program

```
table_data = [['Day', 'Number of cookies'], ['Friday', 163], ['Saturday', 281], ['Sunday', 263]]
column_name = 'Number of cookies'
column_ 1 = get_column_by_name(table_data, column_name)
index_1 = get_row_index_by_value(table_data, 'Saturday')
index_2 = get_row_index_by_value(table_data, 'Sunday')
cookies_1 = get_column_cell_value(index_1, column_1)
cookies_2 = get_column_cell_value(index_2, column_1)
answer = subtract(cookies_1, cookies_2)
```

(a) Ablation Study Example of TART's Tool Maker

TART's tool-augmented Program



```
table_data = [['Day', 'Number of cookies'], ['Friday', 163], ['Saturday', 281], ['Sunday', 263]]
column_name = 'Number of cookies'
column_ 1 = get_column_by_name(table_data, column_name)
index_1 = get_row_index_by_value(table_data, 'Saturday')
index_2 = get_row_index_by_value(table_data, 'Sunday')
cookies_1 = get_column_cell_value(index_1, column_1)
cookies_2 = get_column_cell_value(index_2, column_1)
answer = subtract(cookies_1, cookies_2)
```

TART's final answer

```
table_data = [['Day', 'Number of cookies'], ['Friday', 163], ['Saturday', 281], ['Sunday', 263]] . First,
we should get the column that has the number of cookies baked each day. <<<column_name = 'Number of cooki
es'>>>;;;<<<column_ 1 = get_column_by_name(table_data, column_name)>>>. Next, we need to find the specifi
c days Hannah baked cookies: Saturday and Sunday. We do this by searching for the row that matches each d
ay's name. <<<column_ 1 = get_column_by_name(table_data, column_name) >>>. Then, we get the number of coo
kies baked on each of these days.<<< index_1 = get_row_index_by_value(table_data, 'Saturday')>>>;;;<<< in
dex_2 = get_row_index_by_value(table_data, 'Sunday')>>>. Finally, we subtract the number of cookies baked
on Sunday from the number baked on Saturday to find out how many more cookies were baked on Saturday. <<<
answer = subtract(cookies_1, cookies_2)>>>.
```

(b) Ablation Study Example of TART's Explanation Generator

Figure 3: Ablation Study of TART's *Tool Maker* and *Explanation Generator*. Panel (a) compares the pure program with TART's tool-augmented program, highlighting the effectiveness of Tool Maker. Panel (b) compares TART's tool-augmented program with TART's final answer, demonstrating the usefulness of Explanation Generator.

Rank	Tool Name
1	get_column_by_name
2	get_column_cell_value
3	get_row_index_by_value
4	extract_price
5	get_row_by_name
6	equal_to
7	get_column_by_index
8	subtract
9	divide
10	add

Figure 4: Analysis of tool usage in the TART framework. Th left and center panels show the distribution and the categories of the top 20 most-used tools across models. The right shows the top-10 tools in TART `CodeLlama-7b`.

Model	Setting	TQA HIT	TQA WTQ	Hybrid TQA TAT	Hybrid TQA HYQ
Llama2-7b	w/ DirectQA	19.1	23.4	15.4	8.5
	w/ CoT	22.1	12.7	20.0	6.7
	w/ TART	19.2	17.0	17.0	6.4
Llama3-8b	w/ DirectQA	**51.1**	**38.8**	20.2	10.1
	w/ CoT	33.8	26.8	<u>29.3</u>	11.0
	w/ TART	<u>34.6</u>	32.5	**29.3**	**12.2**
CodeLlama-7b	w/ DirectQA	17.0	19.1	13.8	6.9
	w/ CoT	16.1	22.6	14.6	9.7
	w/ TART	22.3	30.3	13.8	9.0
Deepseek-7b	w/ DirectQA	27.1	26.2	19.7	11.2
	w/ CoT	20.5	26.2	15.3	8.1
	w/ TART	29.8	<u>33.5</u>	17.0	<u>11.2</u>

Table 4: Out-of-Domain evaluation results for TART framework, highlighting the best (bold) and the second-best (underlined) results.

curacy increase of 29.3% on the `WTQ` dataset, indicating robust domain-transfer capabilities. The `Deepseek-7b` backbone model excels, with 30.6% increase in accuracy. We hypothesize that this superiority stems from its pre-training on coding tasks, which equips it with the capability of effectively creating and using tools in novel domains, surpassing pure-text-based pretraining models such as `Llama2-7b`. The analysis in Section 5.2 supports our hypothesis, suggesting that TART excels in developing generic table reasoning functions that generalize well across various domains.

5.2 Analysis of Tool Creation

We then performed an in-depth analysis of how TART creates and utilizes tools.

5.2.1 Tool Distribution.

Figure 4 (top-left) illustrates the tool usage distribution across different backbone models in TART, highlighting a long-tail distribution. The most frequently used tools are primarily associated with table processing (e.g., `get_column_by_name`) and numerical reasoning (e.g., `add`), aligning with our observations in Section 4.1. Figure 4 (middle) provides a detailed breakdown of tool categories for the top 30 tools, showing that table preprocessing and numerical reasoning tools are the most prevalent. This supports the consistency of tool utilization patterns within TART.

5.2.2 Tool Overlap on OOD Datasets.

Figure 6 illustrates the tool overlap between in-domain datasets and OOD datasets. We find that code pre-training models (`CodeLlama-7b` and `DeepSeek-7b`) exhibit a tendency to reuse existing tools when adapting to OOD data. However, text pre-training models demonstrate less overlap, indicating that they tend to solve problems by crafting new tools. The tendency to reuse tools might explain why code pre-training models gain better generalization capabilities in unfamiliar data.

5.2.3 Tool Creation and Usage Analysis.

Figure 7 further reveals that although `Llama2-7b` frequently reuses tools, it often applies them inap-

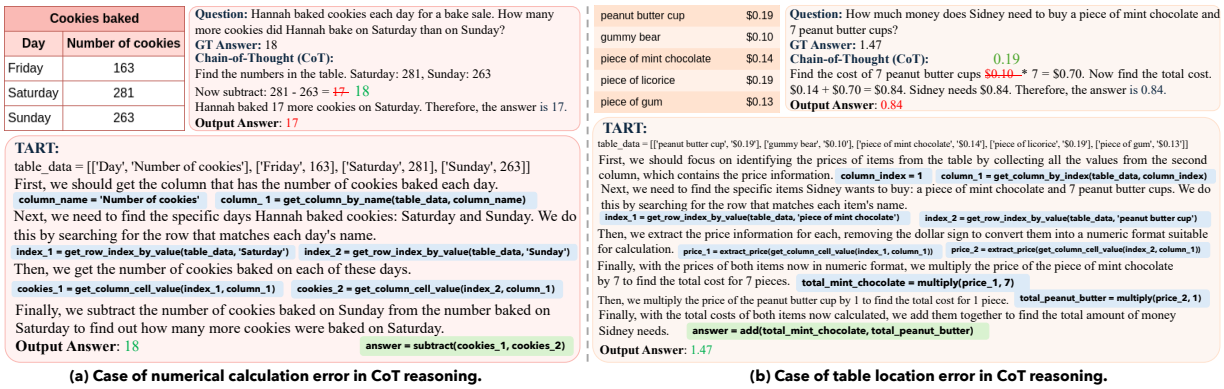


Figure 5: Case Study of TART comparing with CoT reasoning. Panel (a) illustrates a numerical calculation error in CoT where incorrect arithmetic leads to a wrong answer, and panel (b) demonstrates a table location error where CoT fails to retrieve the correct table values. Both errors can be reduced by TART through tool integration.

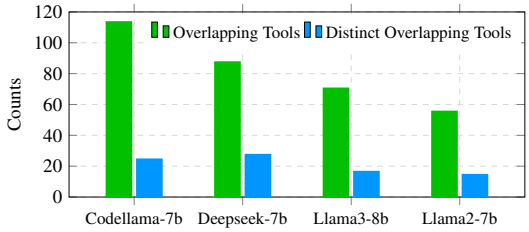

Figure 6: Tool overlap distribution between in-domain and OOD datasets across different backbone models.

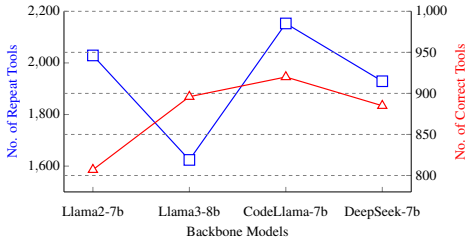

Figure 7: Comparison of the number of repeat tools and correct tools across different backbone models.

propriately. In contrast, `CodeLlama-7b` not only exhibits a high rate of tool reuse but also demonstrates a greater accuracy in their appropriate application. Meanwhile, `Llama3-8b`, despite its lower rate of tool reuse, excels in the correct usage of tools, contributing to its superior performance.

5.3 Case Study

To gain deeper insights into the advantages of TART over `CoT` reasoning, we conducted a case study, shown in Figure 5. The examples highlight the limitation of `CoT` in numerical reasoning and table preprocessing, such as incorrect calculation in Figure 5(a) and incorrect retrieval inFigure 5(b). Conversely, TART overcomes these challenges effectively via integrating specialized tools like `subtract` and `get_column_by_index`. Despite these strengths, TART still encounters issues related to data type mismatches and incorrect programming plans. A detailed analysis of error types in TART can be found in Appendix E.

6 Conclusion

We introduce an open-source framework to improve table-based reasoning through the *Tool-Augmented Reasoning framework for Tables* (TART). This framework solves the challenges of current LLMs' limited ability to understand table structure and execute precise numerical calculations, and maintains explainability. TART consists of a *table formatter* for accurate data representation, a *tool maker* for creating specialized tools, and an *explanation generator* maintaining interpretable explanations. To train TART, we present the TOOLTAB dataset, a novel benchmark containing a diverse set of real-world tables and their tool-augmented solutions. Experiments across nine benchmarks show that integrating our TART method into different open-sourced LLMs enhances accuracy on table-based reasoning. Furthermore, in-depth analyses reveal that TART effectively learns and uses tools. Future work could extend TART to a multimodal framework by incorporating image-based question-answering and fact-verification to generate richer explanations. Additionally, generating explanations to satisfy the needs of different end users, such as laypersons and experts, could further improve the TART's applicability and impact.

Limitations

Despite the promising results, our proposed framework has certain limitations that warrant further

investigation:

Computational Complexity. The TART model may affect efficacy, especially when handling simple questions in quick-response scenarios.

Dataset Coverage. While our efforts have focused on expanding the range of our dataset to include a variety of tableQA datasets, some table-related datasets remain unrepresented in TOOLTAB. As a result, despite TART's capacity to adapt to different OOD datasets and tasks, its performance might still different with the complexities and unique challenges of new table tasks and datasets that it has not yet encountered. Having initiated the development of an expansive, versatile tool-enhanced model for tables, we encourage for continued research in this area to further advance the model's ability to generalize across diverse table configurations.

Ethics Statement

Transparency and Integrity. We ensure that all methodologies, data sources, and technologies used in this study are disclosed transparently. We aim to provide a comprehensive and honest account of our findings, acknowledging both the capabilities and limitations of our proposed solution.

Data Privacy and Security. Our research utilizes datasets that are either publicly available or collected with explicit consent. We adhere to strict data privacy and security protocols to protect the information and ensure it is used solely for the purposes of this research.

TAT-QA: A question answering benchmark on a hybrid of tabular and textual content in finance. In *Proceedings of the 59th Annual Meeting of the Association for Computational Linguistics and the 11th International Joint Conference on Natural Language Processing (ACL-IJCNLP)*, pages 3277–3287.

A Dataset Composition for TART Training

In Table 5, we show the composition of the seed datasets utilized for training our TART model. These datasets vary in terms of the tasks, the domains, and the types of input and output data. For instance, TabMWP and FinQA focus on TableQA tasks within mathematics and finance domains respectively, requiring a combination of tables, text, and questions as inputs, with short answers as outputs. Meanwhile, PubHealthTab, TabFact, and SCITAB target table fact-checking tasks across health, general Wikipedia, and scientific article domains. These datasets similarly involve tables and claims as inputs but differ in the specifics of the domain-related claims, each producing a short label as an output.

Dataset	Task	Domain	Input	Output
1. TabMWP	TableQA	Maths	Table, Question	Answer (Short)
2. FinQA	TableQA	Finance	Table, Text, Question	Answer (Short)
3. PubHealthTab	Table Fact Checking	Health	Table, Claim	Label (Short)
4. TabFact	Table Fact Checking	Wikipedia	Table, Claim	Label (Short)
5. SCITAB	Table Fact Checking	Scientific Articles	Table, Claim	Label (Short)

Table 5: Statistics of the seed datasets for TART training, highlighting their respective tasks, domains, and the nature of input and output data.

To construct the TOOLTAB, we obtain 11,701, 9,916, and 9,916 training instances for the table formatter $\mathcal{F}$, tool maker $\mathcal{M}$, and explanation generator $\mathcal{E}$, respectively. The detailed statistics is provided in Table 6.

Dataset	Train	Dev	Generated Sample	Executable Sample	Table Formatter	Tool Maker	Explanation Generator
TabMWP	23,059	7,686	6,000	5,835	6,000	5,713	5,713
FinQA	6,251	883	1,984	1,609	1,967	1,148	1,148
TabFact	92,283	12,792	1,866	1,773	1,866	1,701	1,705
PubHealthTab	1,180	152	1,180	1,075	1,180	958	958
SciTab	690	-	690	625	688	396	396
Total	123,463	21,513	5,720	10,917	11,701	9,916	9,916

Table 6: Statistics in dataset TOOLTAB for training TART model.

B Different Backbone Combinations

In the pursuit of identifying optimal module combinations within the TART framework, we explore various pairings of table formatter and tool-maker modules shown in Table 7. The combination of `Llama3-8b` as the table formatter and `DeepSeek-7b` as the tool maker performs the most effective pairing, having the best average execution rate and accuracy (76.8 and 68.6 respectively). This best combination aligns with our expectations given that `Llama3-8b` excels in processing long tables while `DeepSeek-7b`, with its pre-training on code, demonstrates superior capability in tool creation.

C Tool Use on Different Backbone Models

Table 8 show the top 10 tools dominate the table processing (e.g., `get_column_by_name`) and numerical reasoning (e.g., `add`), consistent with our earlier findings in Section 4.1. Further illustrating this, Figure 4 (b) presents a tool categorization for the top 30 functions. Table preprocessing tools constitute the highest percentage at 71.0%, followed by numerical reasoning tools at 21.8%. Together, these categories account for over 90% of tool usage, verifying our assumption that TART is better at table preprocessing and numerical reasoning.

D CoT Baseline Implementation

For a direct and fair comparison with TART, the same number of CoT samples are generated using the same IDs from the TART training dataset. These samples are generated using GPT-4, prompted with two in-context examples (detailed in Appendix F). In total, we obtain 9,916 training instances.

Similar to TART, the CoT baseline was implemented across four different backbone models: `Llama-2-7b-hf`, `Llama3-8b`, `CodeLlama-7b-hf`, and `DeepSeek-Coder-7b-Instruct-V1.5`. Each model was instructed to generate a step-by-step reasoning explanation followed by the final answer as per the instructions: `INSTRUCTION: Given the following table, and question, generate a step-by-step reasoning explanation and the final answer.`

The training process was aligned with that of TART to ensure experimental consistency. `Llama-2-7b-hf`, `CodeLlama-7b-hf`, and `deepseek-coder-7b-instruct-v1.5` each requires a single GPU for approximately 12 hours, using a batch size of 4, a learning rate of 5e-5, a sequence length of 1500, gradient accumulation steps of 2, and 10 training epochs. Training `Llama3-8b` requires up to 2 GPUs for around 10 hours with the same settings.

Module Name		TableFV			TableQA		Avg.

Table 8: The top 10 functions across TART `Llama2-7b`, TART `Llama3-8b`, and TART `DeepSeek-7b`.

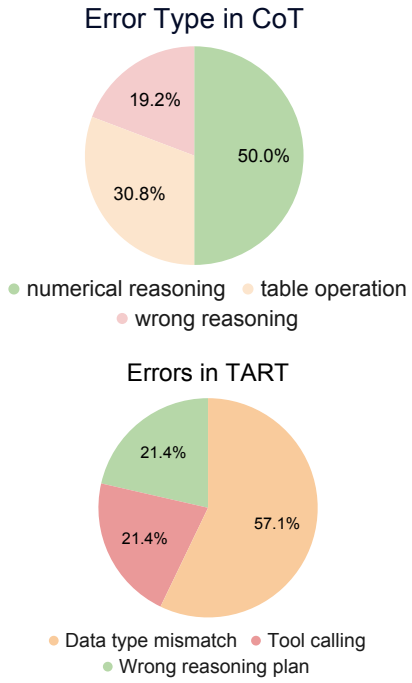

Figure 8: The error types and their distributions of CoT method and our TART framework.

E Error Analysis

To precisely categorize error types in CoT reasoning and TART, we annotate 50 randomly selected error cases for each method. The results (Figure 8) shows that the major error type is incorrect numerical reasoning, followed by errors related to table operations. This analysis verifies the necessity for our proposed TART, which addresses these issues by integrating specialized numerical and table operation tools.

F Prompts

We provide detailed prompts of the TART framework, including the tool discovery process and explanation generation process.

Tool Discovery Prompt:

```
Task Description: Given a table and a question,
the task is to generate a python program to
answer the question.
Requirements:
1. First define some functions to be used in the program.
2. Try to reuse the functions defined in the previous problems if possible.
3. When defining a new function, make sure this function is general enough to be used in other problems.
4. Define a function called solution(table_data) that takes the table data as input and returns the answer to the question.
—
"'
Table: Table Content
Question: Question
Answer: Answer
"'
table_data = table data array

#FUNCTION1 Description
def FUNCTION1():
Function Body

#FUNCTION2 Description
def FUNCTION2():
Function Body
...

def solution(table_data):
Solution Body
return answer

print(solution(table_data))
—
[[FUNCTION_SOLUTION]]
```

Explanation Generation Prompt:

```
Task: Transform Python code used for a table question answering task into an easily understandable explanation in natural language embedded with function calls.
Follow these requirements:
1. The explanation should be the natural language combined with bracketed segments «< »> for code.
2. The code segments in the brackets «< »> should indicate the line number of the code, with the format: ###<line number>.
3. Multiple lines of codes are separated with ';;;' in the brackets «< »>.
—
"'
Table: Table Content
Question: Question
Answer: Answer
"'
Python Code:
table_data = table data array

def solution(table_data):
Line 1 ###1
Line 2 ###2
...
Line 5 ###5
return answer

print(solution(table_data))

Output Explanation:
First, we should get the column that ... «<###1 ;;; ###2»>.
…
Finally, we find that «<###5»>.
—
[[OUTPUT_EXPLANATION]]
```

CoT Prompt:

```
Task Description: Given a table and a question, the task is to generate a step-by-step reasoning explanation and the final answer.
—
“‘
Table: Table Content
Question: Question
Answer: Answer
“‘
Python Code:
table_data = table data array

Output Explanation:
To answer this question, first, we ...
Second, to determine..., we compare ...
...

Therefore, the answer is ...
—
[[OUTPUT_EXPLANATION]]
```

TART (GPT-4) Prompt for Table Formatter:

```
Task Description: Given the following table, context and question, format the table into a python array.
—
“‘
Table: Table Content
Question: Question
Answer: Answer
“‘
Python Code:
table_data = table data array

—

Abstract

Large Language Models (LLMs) have recently demonstrated remarkable performance in Text-to-SQL tasks. However, existing research primarily focuses on the optimization of prompts and improvements in workflow, with few studies delving into the exploration of the questions. In this paper, we propose a Text-to-SQL framework based on question classification and multi-agent collaboration (QCMA-SQL). Specifically, we first employ multiple cross-attention mechanisms to train a schema selector to classify questions and select the most suitable database schema. Subsequently, we employ the appropriate agents based on the varying difficulty levels of the questions to generate preliminary SQL queries. Moreover, we implement syntax validation and execution optimization steps to generate final SQL queries. Experimental results on the Spider dataset show that the QCMA-SQL framework achieves an execution accuracy of 87.4%, outperforming state-of-the-art methods. Through ablation studies, we find that classifying the questions ultimately leads to a 2.8% increase in execution accuracy.

1 Introduction

The Text-to-SQL task converts natural language queries to Structured Query Language (SQL), enabling users to easily retrieve database information without SQL knowledge (Wang et al., 2022).The primary challenges of the Text-to-SQL task originate from the comprehensive understanding required for natural language question intentions, and the complexity involved in precisely mapping entities in natural language to tables and column names within database schemas (Li et al., 2023a). As technology evolves and research progresses, the academic community has proposed various solution strategies. Currently, mainstream methods are mainly divided into two categories: one is based on pre-trained language models (PLMs) (Li et al., 2023a; Scholak et al., 2021), and the other relies on advanced methods supported by LLMs (Hong et al., 2024; Wang et al., 2023; Rajkumar et al., 2022).

With the continuous progress in the field of deep learning, PLMs have achieved remarkable success in various tasks of natural language processing (Li et al., 2023b). RAT-SQL (Wang et al., 2020), strengthens the SQL encoder's capability in schema encoding, relation, and feature expression by connecting primary and foreign key relations in data tables through a graph model. The RESDSQL model (Li et al., 2023a), by decoupling schema alignment and query skeleton analysis, enhances the precision and robustness of SQL parsing. However, due to the inherent limitations in the parameter scale of PLMs, traditional methods based on deep learning are no longer the most ideal solution for the Text-to-SQL task.

Recent research outcomes demonstrate that LLMs exhibit outstanding performance in Text-to-SQL tasks, an achievement attributable to LLMs' significant advantages in natural language understanding and reasoning capabilities (Liu et al., 2023; Rajkumar et al., 2022; Sun et al., 2023). In practice, the vast majority of approaches employ meticulously designed prompts to tap into the potential of LLMs in Text-to-SQL transformation tasks, including the use of thought chains and task decomposition strategies to construct complex prompts (Tai et al., 2023). For instance, C3-SQL (Dong et al., 2023) introduces bias hints that are calibrated using a self-consistent policy designed for the Spider dataset to guide GPT-4 (Achiam et al., 2023). Concurrently, DIN-SQL (Pourreza and Rafiei, 2024) subdivides the text-to-SQL task into a series of smaller sub-tasks, customizing distinct directive prompts for each sub-task to steer GPT-4 to complete each sub-task and construct the final SQL query incrementally. DAIL-SQL (Gao

et al., 2024) adopts an approach that encodes the structural knowledge within SQL queries, selecting a small sample set based on skeleton similarity for demonstration. Nevertheless, the methods above still face challenges when dealing with large-scale databases, complex user questions, and erroneous SQL outputs. Firstly, there is a lack of more comprehensive consideration for questions with different levels of difficulty. Secondly, schema linking using LLMs incurs expensive costs.

To address these issues, this paper introduces QCMA-SQL, an innovative Text-to-SQL framework that integrates traditional PLMs with state-of-the-art LLMs to propose a novel methodology. The framework decomposes the Text-to-SQL task into two principal stages: question classification and SQL generation. During the question classification stage, a schema selector classifies the question and chooses the most relevant schema items to the question from a large number of database schemas. In the SQL generation stage, we input questions of different difficulty to different agents to generate initial SQL queries. Other agents then perform error detection and execution optimization.

To assess the efficacy of our framework, we conducted experiments on the Spider (Yu et al., 2018), Spider-DK (Gan et al., 2021b), Spider-SYN (Gan et al., 2021a), Spider-Realistic (Deng et al., 2021), and CSpider (Min et al., 2019). Our method achieved an execution accuracy of 87.4% on the Spider dataset and an exact match accuracy of 69.5% on CSpider, showcasing the effectiveness and robustness of our approach across various datasets.

Our main contributions and results are summarized as follows: (1) A Text-to-SQL framework, called QCMA-SQL, is innovatively proposed for high-precision and high-efficiency SQL generation. (2) Considering the importance of question classification and schema linking, this study introduces a schema selector based on multiple cross-attention mechanisms to enhance the accuracy of classification. (3) Through extensive experimental validations, QCMA-SQL achieved new state-of-the-art (SOTA) performance levels on Spider.

2 Related Work

Inspired by pre-training techniques, seq2seq models such as T5 (Raffel et al., 2020) and BART (Lewis et al., 2020) have begun to demonstrate superior performance on this task, indicating a research trend toward fine-tuning large-scale PLMs on specific database-related data. RESDSQL (Li et al., 2023a) simplifies the process of converting natural language into SQL queries by decoupling schema matching and query skeleton analysis and employs a hierarchical enhanced encoder and a skeleton-aware decoder to improve the accuracy and robustness of SQL parsing. Nevertheless, PLM-based approaches are far from the standard for reliable text-to-SQL parsers.

With the rise of LLMs such as GPT-4 (Achiam et al., 2023), Codex (Chen et al., 2021), PaLM (Chowdhery et al., 2023) and StarCoder (Li et al., 2023c), researchers have proposed diverse strategies to exploit the advanced reasoning abilities of these models, focusing on creating superior prompts for probing SQL generation potential. For instance, Chang (Chang and Fosler-Lussier, 2023) have delved into mind-chain prompt strategies to enhance the LLM reasoning capacity, while models such as DAIL-SQL (Gao et al., 2024) and C3-SQL (Dong et al., 2023) optimize the execution process and outcomes through precise calibration of model inputs, query classification and decomposition, and special logical handling tailored for the text-to-SQL tasks. MAC-SQL (Wang et al., 2023) proposes a multi-agent collaboration framework, in which multiple LLMs are responsible for simplifying database schemas, decomposing complex questions, and incrementally generating SQL. CodeS (Li et al., 2024) enhances SQL generation and natural language understanding capabilities through supervised fine-tuning and a carefully curated dataset, and achieves rapid domain adaptation through bidirectional data augmentation techniques.

3 Method

3.1 General Architecture

The QCMA-SQL framework consists of two core components: the schema selector and the multi-agent collaboration mechanism. This framework ingeniously integrates the strengths of Pre-trained Language Models and Large Language Models, significantly enhancing the accuracy of the Text-to-SQL task. Figure 1 illustrates the overall structure of the QCMA-SQL framework. Initially, the schema selector categorizes the question into simple or complex types and selects the most relevant database schema from them. Subsequently, we employ specific agents to generate preliminary SQL queries for questions of varying difficulty levels.

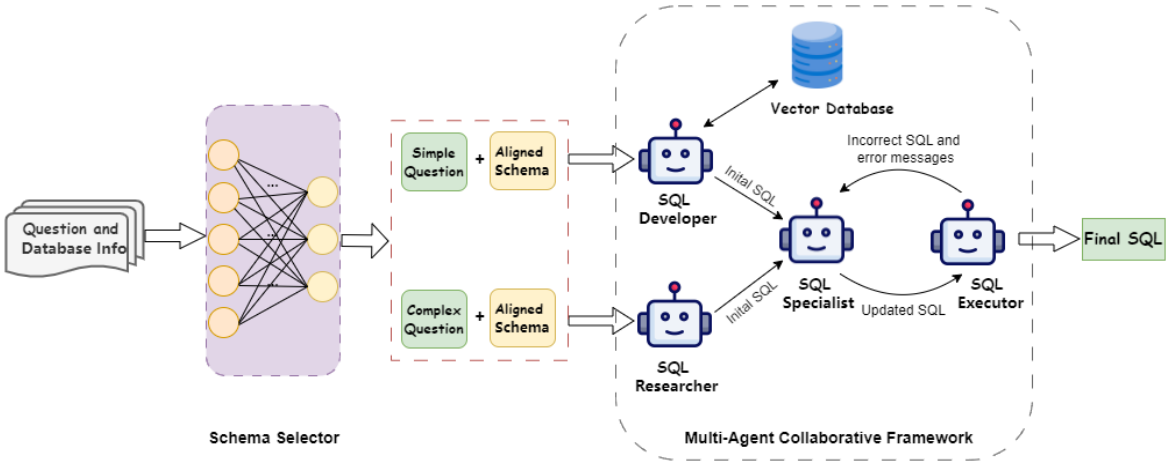

Figure 1: An overview of QCMA-SQL framework. We train a schema selector to classify questions and filter the schema items. Then we take the question, and the aligned schema sequence as the input of the multi-agent collaboration framework.

In the end, through the collaborative interaction among multiple agents, we deploy a multi-stage iterative correction mechanism. This mechanism integrates error detection and execution optimization, aiming to ensure the accuracy and reliability of SQL queries.

3.2 Schema Selector

The function of the schema selector is to categorize the difficulty of questions while choosing the most relevant database schema. The Spider dataset provides specific usage of components for each SQL query, such as "orderBy," "groupBy," "join," "having," and "limit," etc. We divide the training set into simple or complex categories, which depend on the number of SQL keywords used, the presence of nested subqueries, and the utilization of column selection or aggregation. During the training process, we employ multiple cross-attention mechanisms to effectively capture the intrinsic connections between questions, difficulty level, table names, and column names. Details of the schema selector are shown in Figure 2.

Encoder. We define the difficulty level, the table, and the column in the relational database as: $\mathbf{D} = \{d_1, d_2\}$, $\mathbf{T} = \{t_1, t_2, \cdots, t_N\}$, $\mathbf{C} = \{c_1^1, \cdots, c_{n1}^1, c_1^2, \cdots, c_{n2}^2, \cdots, c_1^n, \cdots, c_{nN}^n\}$.

$\mathbf{D}$ denotes the set of difficulty levels, $\mathbf{T}$ denotes the set of tables, $\mathbf{C}$ denotes the set of columns, N denotes the number of tables, and c_i^j denotes the i-th column of the j-th table. We concatenate questions, difficulty levels, and database information as the input to the encoder: $S = q \mid d_1, d_2 \mid t_1{:}c_1^1, \cdots, c_{n1}^1 \mid \cdots \mid t_N{:}c_1^N, \cdots, c_{nN}^N$.

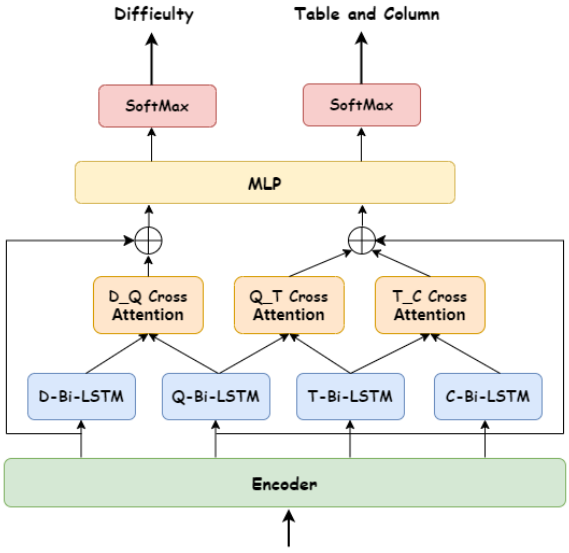

Figure 2: Schema selector. Multiple cross-attention mechanisms extract features between questions, difficulty levels, table names, and column names.

To extract more essential semantic features, we utilize four separate Bi-LSTM layers to pool difficulty levels, questions, tables, and columns sequence respectively. After pooling, the embedding of the question can be denoted by $\mathbb{Q} \in R^{1\times d}$, the embedding of each table can be denoted by $T_i \in R^{1\times d}(\mathrm{i} \in \{1, ..., \mathrm{N}\})$, and the embedding of each column can be denoted by $C_k^i \in R^{1\times d}(\mathrm{i} \in \{1, ..., \mathrm{N}\}, \mathrm{k} \in \{1, ..., \mathrm{n_i}\})$.

Multiple Cross-Attention Mechanisms. We notice that some questions only mention column names but not table names, which could affect the accuracy of schema selection. Thus, we pro-

pose a method with multiple cross-attention mechanisms to assist the model in difficulty classification and schema selection. Specifically, we employ a difficulty-question cross-attention layer to embed difficulty information into the semantic context of the question. Additionally, we utilize a question-table cross-attention layer and a table-column cross-attention layer to embed table information and column information into the semantic context of the question.

$$Q^D = MultiHeadAttn(Q, D_i, D_i, \mathrm{h}) \quad (1)$$

$$Q^T = MultiHeadAttn(Q, T_i, T_i, \mathrm{h}) \quad (2)$$

$$T_i^c = MultiHeadAttn(T_i, C_k^i, C_k^i, \mathrm{h}) \quad (3)$$

Here, D_i represents the difficulty levels, T_i represents the table name, and C_j^k represents the column name. Q represents the question, and h denotes the number of heads in multi-head attention.

Loss Function. Given that SQL queries typically involve only a small number of tables and columns in the database, the label distribution in our training set is highly imbalanced. To mitigate this issue, we adopt a balanced cross-entropy loss function for our classification loss. We construct the loss function for the schema selector in a multi-task learning way, including the loss for difficulty classification, the loss for table classification, and the loss for column classification.

3.3 Multi-Agent Collaborative Framework

Following the initial phase, we categorize the questions into two types and select the most relevant database schema. Leveraging the exceptional natural language understanding and advanced reasoning capabilities of LLMs, We develop a multi-agent collaborative SQL generation framework. As depicted in Figure 1, the framework is composed of four agents: SQL Developer, SQL Researcher, SQL Executor, and SQL Specialist. We meticulously design prompts for each agent to maximize their respective strengths. For simple questions, we utilize the SQL Developer, which employs retrieval enhancement technology to recall similar question-SQL pairs from the vector database as contextual information. For complex questions, we apply the SQL Researcher, which is based on task decomposition and chain-of-thought(CoT) to generate preliminary SQL queries. These SQL are then syntax-checked and executed by the SQL Executor. If the execution is successful, the output is the final SQL query; if not, the SQL Specialist modifies the SQL query based on the error information and resubmits it to the SQL Executor for execution and verification.

The implementation of LLM-based text-to-SQL process to generate executable SQL query Y is formulated as:

$$Y = LLM(\mathcal{Q}, \mathcal{S}, \mathcal{I} \mid \theta) \quad (4)$$

where $\mathcal{Q}$ represents the user question. $\mathcal{S}$ is the aligned database schema, and $\mathcal{I}$ represents the instruction for the Text-to-SQL task, which performs indicative guidance to guide the LLMs for generating an accurate SQL query. $LLM(\cdot \mid \theta)$ is a LLM with parameter θ.

SQL Developer. The SQL Developer excels at addressing simple questions, which typically require only a single step of reasoning. We store the training set of question-SQL pairs and Data Definition Language (DDL) in a vector database, enabling the retrieval of the most similar cases to the given question. This flexible strategy provides the agent with more precise cases, maximizing the potential of LLMs in few-shot learning environments.

SQL Researcher. The SQL Researcher is adept at handling complex questions. For such questions, we employ a method of question decomposition combined with CoT. Initially, we break down the complex question into multiple sub-questions that are in a progressive relationship. We then generate SQL queries for each sub-question individually, step by step arriving at the complete SQL.

SQL Executor. The SQL Executor is responsible for receiving SQL queries generated by either the SQL Developer or the SQL Specialist and conducting preliminary checks for syntax accuracy. Upon confirming that there are no apparent syntax errors, the SQL Executor proceeds to execute the SQL query. In case of successful implementation, the executed SQL query is defined as the final output. However, if errors occur during the execution process, the system invokes assistance from the SQL Specialist to conduct a profound analysis.

SQL Specialist. The expertise of the SQL Specialist lies in revising SQL queries based on the feedback from error messages. Taking into consideration the database schema, the flawed SQL queries, and the corresponding error messages, the

Dataset	Table	Column	Difficulty
Spider	**0.9984**	**0.9973**	**0.9893**
CSpider	0.9930	0.9904	-

Table 1: Table, column, and difficulty AUC scores for the trained schema selector.

SQL Specialist reconstructs the SQL queries accordingly. These revised queries are then resubmitted to the SQL Executor for further error checking and verification.

4 Experiments

Datasets. We conduct extensive experiments on the cross-domain large-scale Text-to-SQL benchmark: Spider (Yu et al., 2018) and CSpider (Min et al., 2019). We also assess our models' robustness across three more challenging benchmarks: Spider-DK(Gan et al., 2021b), Spider-SYN(Gan et al., 2021a), and Spider-Realistic(Deng et al., 2021). The Spider dataset is commonly utilized for evaluating text-to-SQL parsing performance across multiple databases. This dataset comprises 7,000 Question-SQL pairs in the training set and 1,034 in the development set, covering 200 distinct databases and 138 domains. CSpider is a large, complex cross-domain semantic parsing and Text-to-SQL dataset in Chinese, translated from Spider. Spider-DK, Spider-Syn, and Spider-Realistic are variants derived from the original Spider dataset. They are designed to mimic questions that users might pose in real-world scenarios.

Evaluation Metrics. We consider two evaluation metrics—Execution Accuracy (EX) and Exact Match Accuracy (EM). EX quantifies the percentage of evaluation questions for which the inferred queries produce identical execution outcomes to the ground truth queries, against the aggregate query count. EM gauges the accuracy of predicted SQL sub-clauses by examining each sub-clause as an individual set and ensuring complete correspondence with the reference query's sub-clauses, deeming a SQL prediction accurate only if all elements align with the true query components.

Baselines. Our benchmark study evaluates the performance of two types of Text-to-SQL methods. **PLM-based methods:** T5-3B + PICARD (Scholak et al., 2021), RASAT (Qi et al., 2022) and RESDSQL (Li et al., 2023a). **LLM-based methods:** GPT-4 (Achiam et al., 2023), SQL-PaLM (Sun et al., 2023), DIN-SQL (Pourreza and Rafiei, 2024), DAIL-SQL (Gao et al., 2024), RAG+SP&DRC (Guo et al., 2023), Codes (Li et al., 2024) and MAC-SQL(Wang et al., 2025).

Method	Model	EX
PLM-based	T5-3B + PICARD	79.3
	RASAT	80.5
	RESDSQL	84.1
LLM-based	GPT-4 (zero-shot)	72.9
	GPT-4 (few-shot)	76.8
	Fine-tuned SQL-PaLM	82.8
	DIN-SQL	82.8
	DAIL-SQL	84.4
	RAG+SP&DRC	85.0
	CodeS-7B	85.4
	MAC-SQL	86.7
Ours	QCMA-SQL	**87.4**

Table 2: Execution accuracy on Spider dev (%).

Implementation Details. We run all of our experiments on NVIDIA V100 GPU with 32GB memory. In the first phase, we employ DeBERTa-v3 as the encoder, and the number of heads h in the dual attention mechanism is set to 8. The optimization process utilizes the AdamW optimizer, with a batch size of 8, and a learning rate set at 2e-5. In the second phase, we use DeepSeek-V3 as the agent and design specific prompts for different agents. Specifically, we adopt a 3-shot setting in the prompts of the SQL Developer. We set the temperature of each agent to 0 to actively utilize the model's determinism features. In addition, we use Chroma as the vector database.

4.1 Main Results

In Table 1, we present the performance of the schema selector across different datasets. The AUC metric is adopted to evaluate the models' classification accuracy. According to the experimental results, the schema selector achieved an AUC score of 0.9984 for table classification and 0.9973 for column classification on the Spider dataset, both of which exceed the performance metrics of the CSpider dataset. We speculate that this is because DeBERTa is more proficient in English. Furthermore, for the classification of question difficulty, the difficulty AUC score reached 0.9893. This indicates that the schema selector can accurately classify questions and link schema.

Table 2 shows the comparative performance of QCMA-SQL against other benchmark methods on

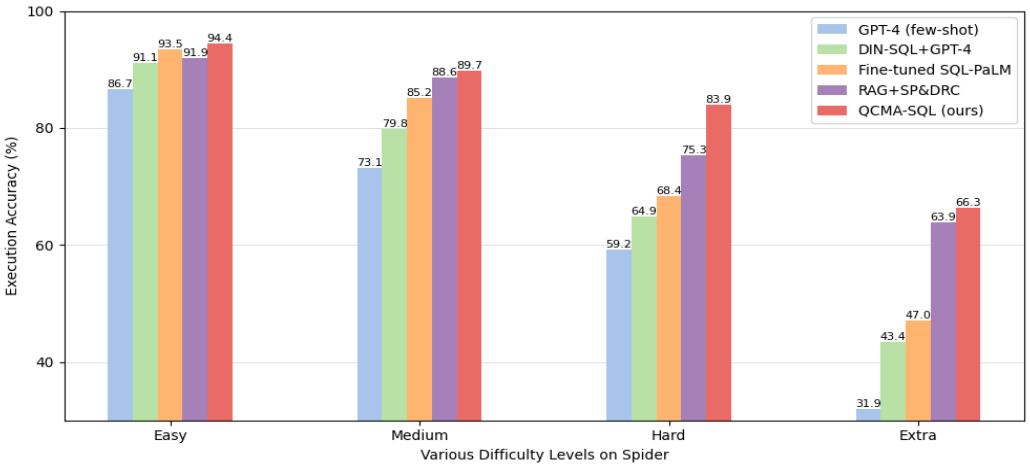

Figure 3: Test-suite accuracy at various difficulty levels on Spider.

Method	EM(%)
RAT-SQL	59.7
LGESQL + GTL + Electra + QT	64.0
LGESQL + ELECTRA + QT	64.5
RESDSQL	66.3
QCMA-SQL(ours)	**69.5**

Table 3: Exact Match Accuracy on CSpider.

Method	S-Syn	S-R	S-DK
T5-3B + PICARD	69.8	71.4	62.5
RASAT	70.7	71.9	63.9
RESDSQL	76.9	81.9	66.0

QCMA-SQL (ours)	**83.8**	**86.4**	80.7

Table 4: Evaluation of our method on Spider variants. S-Syn, S-R, and S-DK correspond to Spider-Syn, Spider-Realistic, and Spider-DK, respectively.

the Spider dev. The results indicate that our method outperforms all baselines in terms of execution accuracy. Specifically, the execution accuracy of QCMA-SQL reached 87.4%, which is 0.7% higher than the second-best method (MAC-SQL).

Table 3 presents a performance comparison between the method proposed in this study and several baseline methods on the CSpider dataset. QCMA-SQL outperforms the second-best method by 3.2%. The tabular names and column names in the CSpider dataset are in English, but the questions are in Chinese, increasing the challenge of mapping questions to database structures. The results demonstrate that our strategy performs best on the CSpider dataset. This fully validates the effectiveness and robustness of our method.

Evaluation on Robustness Benchmarks. Table 4 evaluates the robustness of QCMA-SQL on three Spider variants: Spider-DK, Spider-Syn, and Spider-Realistic. The experimental results show that QCMA-SQL exhibits outstanding performance compared to the best baseline. It achieves gains of 2.4% on Spider-Syn (from 81.4% to 83.8%), and 3.3% on Spider-Realistic (from 83.1% to 86.4%). These results demonstrate the model's good generalization on challenging real-world scenario datasets.

Various Difficulty Levels Analysis. As shown in Figure 3, these four difficulty levels are based on the official test suite provided by Spider. The results indicate that our model outperforms other models at all levels. It achieves gains of 0.9% on the easy level, 1.1% on the medium level respectively, 8.6% on the hard level, and 2.4% on the extra hard level. This is attributed to the multi-agent collaborative framework's ability to categorically handle questions of varying difficulty, suggesting that our model excels in processing SQL queries of arbitrary difficulty.

Tokens Consumption. The adoption of LLM for SQL generation in Text-to-SQL tasks is due to the significant performance advantages that LLM has exhibited over PLM. However, these optimization methods based on the LLM API consume a large number of tokens in the reasoning process. Experimental data shows that compared with ex-

Method	Easy	Medium	Hard	Extra	All
w/o SQL Researcher(QD and CoT)	**94.4**	**89.7**	73.6	62.0	83.6
w/o SQL Developer(RAG)	92.7	87.2	**83.9**	**66.3**	84.6

Method	EX
QCMA-SQL(ours)	**87.4**
w/o schema selector	84.2
w/o multi-agent collaborative	83.1

Table 6: Ablation study in Spider dev set

isting technologies, QCMA-SQL significantly reduces inference costs. Specifically, with the same use of the GPT-4 API, the DAIL-SQL(Gao et al., 2024) costs 323.2$ for a single round of experiments on Spider, while the corresponding cost for QCMA-SQL is only 60$.

4.2 Ablation Study

We conduct ablation studies on the Spider development set to evaluate the impact of two components: the schema selector and the multi-agent collaborative framework. The results are presented in Table 6.

Effect of Schema Selector. We investigate the influence of the schema selector on performance. When the schema selector is not used and all schema items from the database are input into the multi-agent collaborative framework, performance degradation occurs due to the inability of the LLM to accurately connect schema items because of the longer input sequence. Also, the lack of question classification leads to the inability to select the most appropriate agent to generate SQL. This highlights the importance of the schema selector.

Effect of Multi-Agent Collaborative Framework. Without the multi-agent collaborative framework, if the filtered schema items are input into a single Deepseek-V3 model, the lack of retrieval enhancement, error detection, and execution optimization functionalities leads to a decrease in the EX value. This demonstrates the indispensability of the multi-agent collaborative framework in the SQL generation process.

Effect of SQL Developer and SQL Researcher. We evaluate the algorithm performance improvement on different difficulty subsets. We do not categorize the questions but instead input them separately into SQL Developer, based on RAG, and SQL Researcher, based on question decomposition (QD) and CoT. As shown in Table 5, the strategy of question decomposition and CoT for complex questions effectively achieves step-by-step question resolution and improves performance, with an increase from 73.6% to 83.9% at the hard level and from 62.0% to 66.3% at the extra level. However, for simple questions, the method based on question decomposition and CoT decreases execution accuracy, from 94.4% to 92.7% at the easy level and from 89.7% to 87.2% at the medium level. We suggest that for simple questions solvable by a single step of reasoning, LLM tends to overly decompose them into multiple sub-questions. This approach not only unnecessarily increases the complexity of the questions but also introduces errors.

5 Case Study

To demonstrate the necessity of categorizing question-solving approaches, we present examples in Figure 4 and Figure 5 where SQL Developer (based on RAG) and SQL Researcher (based on question decomposition and CoT) are faced with simple and complex questions, respectively. In the simple question, the task is simply to find the maximum value of "$charge_amount$". However, the method based on question decomposition and CoT breaks down the question, leading to incorrect identification of "$charge_type$" in the second sub-question. In the complex question, the RAG-based method fails to understand the meaning of "$Bachelors\ program$" and consequently uses the non-existent column name "$Bachelors$". Each of these two approaches has its strengths for questions of different difficulty levels. It is necessary to categorize questions and address them with different approaches.

6 Conclusion

In this paper, we introduce a novel Text-to-SQL framework, called QCMA-SQL. It selects the appropriate agent to generate SQL based on the questions' varying difficulty levels. The proposed

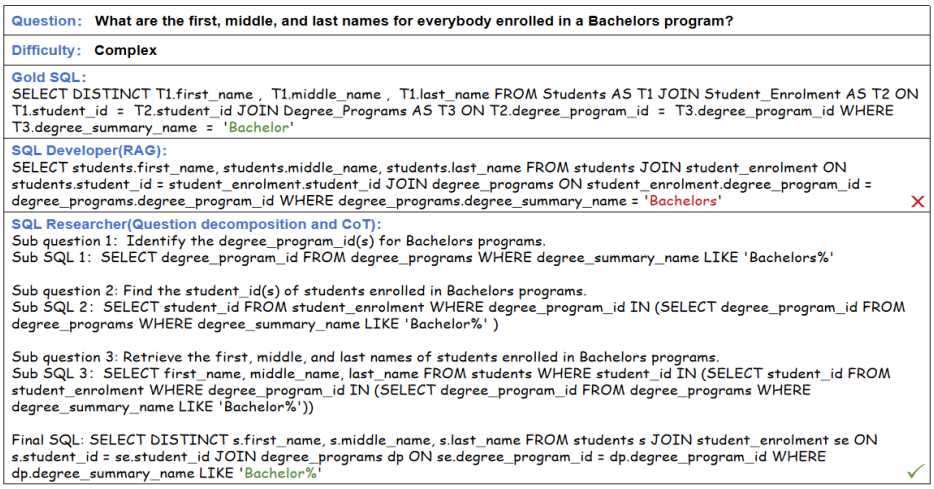

Figure 4: Complex question case.

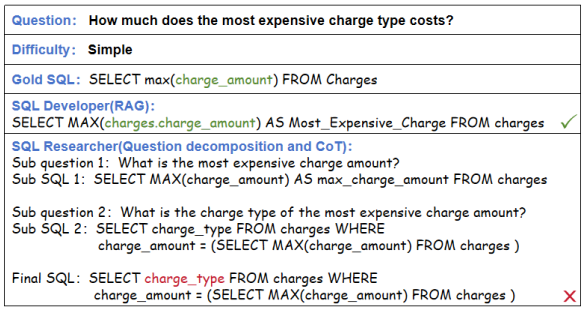

Figure 5: Simple question case.

framework not only develops an innovative question classification and schema linking model but also fully leverages the powerful semantic understanding capabilities of LLMs. Benefiting from the proposed schema selector, QCMA-SQL excels in handling questions of any difficulty level. Moreover, question classification has been proven to enhance the execution accuracy of the Text-to-SQL task. In summary, QCMA-SQL has achieved significant performance improvements in evaluation metrics and outperforms all comparative baselines.

7 Limitations

Due to the use of PLMs as encoders with limited context windows, limitations may be faced in generalizing to larger scale databases. In addition, there is room for improving the accuracy of vector database recall examples. Meanwhile, LLMs are sensitive to the way it is prompted and further exploration is needed to find the best strategy for different use cases.

A Experimental results from other LLMs

In addition to deepseek-v3 , we evaluated the QCMA-SQL framework on several LLMs. This helps to reveal the extent of performance degradation between LLMs with different capabilities. Due to hardware constraints, we were not able to deploy large open source LLM, so we called some common LLM APIs. The experimental results are shown in Table 7, which shows that the performance of the QCMA-SQL framework depends on the capability of LLM. Among the several LLMs on which the experiments were conducted, moonshot-v1-32k has the worst performance, and gpt-4-turbo has a slightly lower performance than deepseek-v3.

Model	EX
moonshot-v1-32k	80.6
gpt-3.5-turbo-0125	82.8
glm-4-air	83.5
glm-4-plus	84.2
glm-zero-preview	84.9
gpt-4-turbo	86.1
deepseek-v3	**87.4**

Table 7: Experimental results of QCMA-SQL framework based on different LLMs on Spider.

B Ablation study with modules in the schema selector

In QCMA-SQL, the schema selector plays a very important role. In order to study the principles of question classification and schema selection, our study evaluates the contribution of Bi-LSTM and multiple cross-attention in schema selector.

As shown in Table 8, among the four Bi-LSTMs, D-Bi-LSTM contributes the most to question classification, T-Bi-LSTM contributes the most to table classification, and C-Bi-LSTM contributes the most to column classification. Among the 3 cross-attention mechanisms, D_Q cross-attention has the greatest impact on question classification and T_C cross-attention mechanism has the greatest impact on schema selection.

Method	Table	Column	Difficulty
Schema Selector	**0.9984**	**0.9973**	**0.9893**
w/o D-Bi-LSTM	0.9938	0.9893	0.9674
w/o Q-Bi-LSTM	0.9906	0.9854	0.9722
w/o T-Bi-LSTM	0.9757	0.9796	0.9823
w/o C-Bi-LSTM	0.9851	0.9753	0.9785
w/o D_Q cross-attention	0.9860	0.9828	0.9616
w/o Q_T cross-attention	0.9784	0.9769	0.9734
w/o T_C cross-attention	0.9711	0.9725	0.9702

Efficient Nearest Neighbor based Uncertainty Estimation for Natural Language Processing Tasks

Wataru Hashimoto, Hidetaka Kamigaito, Taro Watanabe
Nara Institute of Science and Technology
{hashimoto.wataru.hq3, kamigaito.h, taro}@is.naist.jp

Abstract

Trustworthiness in model predictions is crucial for safety-critical applications in the real world. However, deep neural networks often suffer from the issues of uncertainty estimation, such as miscalibration. In this study, we propose k-Nearest Neighbor Uncertainty Estimation (kNN-UE), which is a new uncertainty estimation method that uses not only the distances from the neighbors, but also the ratio of labels in the neighbors. Experiments on sentiment analysis, natural language inference, and named entity recognition show that our proposed method outperforms the baselines and recent density-based methods in several calibration and uncertainty metrics. Moreover, our analyses indicate that approximate nearest neighbor search techniques reduce the inference overhead without significantly degrading the uncertainty estimation performance when they are appropriately combined.

1 Introduction

In order to deploy Deep Neural Networks (DNNs) including Pre-trained Language Models (PLMs) in safety-critical areas, uncertainty estimation (UE) is important. Improving the predictive uncertainty will calibrate the prediction (Guo et al., 2017),[1] or enhance the selective prediction performance which reduces incorrect predictions by providing the option to abstain from the model prediction (Galil et al., 2023). On the other hand, DNNs often fail to quantify the predictive uncertainty, for example, causing miscalibrated prediction (Guo et al., 2017). Such UE performance problems can be mitigated by the PLMs, such as BERT (Devlin et al., 2019) or DeBERTa (He et al., 2021b), that are self-trained on vast amounts of data (Ulmer et al., 2022); nevertheless, there remains considerable room for improvement (Desai and Durrett, 2020).

[1] "Calibration" means the confidence of the prediction aligns with its accuracy.

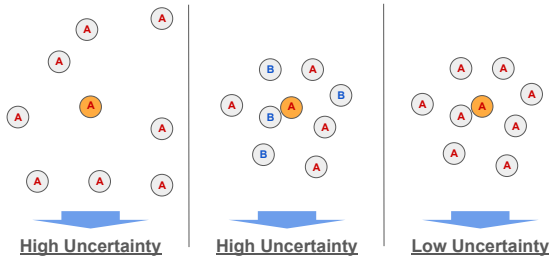

Figure 1: Illustrations of kNN-UE behavior. The orange circle indicates predicted data instances and other circles indicate training data instances. kNN-UE gives high uncertainty when the predicted query representation is far from examples obtained from the kNN search (left) and the predicted label is different from the labels of neighbors (center). kNN-UE outputs low uncertainty only when the query representation is close to neighbors and the labels of neighbors contain many of the model's predicted label (right).

To address the challenge of UE, multiple stochastic inferences such as MC Dropout (Gal and Ghahramani, 2016) and Deep Ensembles (Lakshminarayanan et al., 2017) are generally effective. On the other hand, these methods require multiple stochastic inferences for a single data instance, which leads to high computational cost, and makes them impractical for real world application. To balance reasonable predictive uncertainty with computational efficiency, Temperature Scaling (Guo et al., 2017) , which scales logits by a temperature parameter, is commonly employed. Furthermore, density-based methods, such as Density Softmax (Bui and Liu, 2024) and Density Aware Calibration (DAC) (Tomani et al., 2023), have demonstrated promising UE performance and inference costs by adjusting model outputs based on estimated density.

However, both Density Softmax and DAC only use the density of the training data. Relying on density alone can sometimes lead to overconfident predictions, even when such confidence is unwar-

Findings of the Association for Computational Linguistics:
NAACL 2025, pages 4350–4366
April 29 - May 4, 2025 ©2025 Association for Computational Linguistics

ranted. For instance, the neighbor of the input may contain many examples with labels that differ from the predicted label. In this situation, the prediction should obviously not be trusted. Therefore, we hypothesized that considering both the density and the label information of the neighbors will improve UE performance.

In this study, we propose k-Nearest Neighbor Uncertainty Estimation (kNN-UE), a new density-based UE method that reflects nearest neighbor labels. As illustrated in Figure 1, kNN-UE is designed to achieve the highest prediction confidence when the input and the nearest neighbors are both close in distance and share the same label as the predicted label. Our method weights logits according to the score from the distance between the input example and its neighbors in the datastore created by the training data and the ratio of the model's predicted label matched with the labels in the neighbors. In addition, our method requires only a single forward inference of the model with almost no additional computational cost. The contributions of this research are as follows.

First, our experiments show that kNN-UE improves the UE performance of existing baselines in sentiment analysis, natural language inference, and named entity recognition in both in-domain and out-of-domain settings by combining neighbor label information and distances from neighbors. On the other hand, we also find that naive kNN-UE makes less efficient for token-level tasks such as *sequence-labeling* based named entity recognition due to the execution of kNN to each token.

Second, to mitigate the above latency problem in kNN-UE, we show that approximate kNN search or dimension reduction in kNN-UE improves the inference speed without degrading UE performance much more, while combining them leads to degrading the UE performance.

Our code is available at `https://github.com/wataruhashimoto52/knn_ue`.

2 Related Work

Uncertainty Estimation for Natural Language Processing Tasks Studies about UE for NLP tasks are limited when compared with those for image datasets. Kotelevskii et al. (2022) has shown excellent performance in classification with rejection tasks and out-of-distribution detection tasks using uncertainty scores using density estimation results. Vazhentsev et al. (2022) performed misclassification detection using Determinantal point processes (Kulesza and Taskar, 2012), spectral normalization, Mahalanobis distance and loss regularization in text classification and NER. However, these are still focusing only on the feature representation or the density, not the labels of the neighbors. He et al. (2024) proposed a framework that considers uncertainty between tokens in NER. However, the target task is limited to NER, and it is not for confidence calibration. Hashimoto et al. (2024) shows that simple data augmentation methods in NER can improve UE performance without additional inference costs, but its effectiveness is limited in the in-domain. Our kNN-UE improves the UE performance in the in-domain and the out-of-domain classification and NER tasks using not only kNN density but also neighbor labels.

k-Nearest Neighbor Language Models / Machine Translation k-Nearest Neighbor Language Model (kNN-LM) (Khandelwal et al., 2020) has been proposed, which performs linear interpolation of kNN probability based on distance from neighbors and base model probability, in the language modeling task. k-Nearest Neighbor Machine Translation (kNN-MT) applied the kNN-LM framework to machine translation (Khandelwal et al., 2021). kNN-LM and kNN-MT have been successful because they enhance predictive performance through the memorization and use of rich token representations of pre-trained language models and mitigate problems such as a sparsity comes from low-frequency tokens (Zhu et al., 2023). The main issue on kNN-LM and kNN-MT is the inference overhead, and there are several studies to solve this problem. He et al. (2021a) employs datastore compression, adaptive retrieval, and dimension reduction to reduce computational overhead with retaining perplexity. Deguchi et al. (2023) dramatically improves decoding speed by dynamically narrowing down the search area based on the source sentence. We investigate that whether UE performance in kNN-UE can keep or not with reducing inference time by introducing some of the speed-up techniques established in kNN-LM/MT.

3 Preliminary

3.1 Definitions

In multiclass classification, we assume a dataset $\mathcal{D} = \{(\boldsymbol{x}_n, y_n)\}_{n=1}^{N}$ consisting of N examples, where $y_n \in \{1, 2, \ldots, J\}$ denotes its correspond-

ing class label among J possible classes.[2] We use the trained neural network feature extractor f and the classifier g for classification, where $f(\boldsymbol{x}) \in \mathbb{R}^D$. g gives us the logits $\boldsymbol{z} = g(f(\boldsymbol{x}))$ and we obtain the confidence $\boldsymbol{p} = \mathrm{softmax}(\boldsymbol{z})$.

3.2 Density Softmax

Density Softmax (Bui and Liu, 2024) obtains confidence by weighting logits with normalized log-likelihood from a trained density estimator. $\boldsymbol{\beta}$ are the parameters of the density estimator; $p(f(\boldsymbol{x}); \boldsymbol{\beta})$ is the normalized log-likelihood from the density estimator, then the corrected confidence is written as

$$p(y_i|\boldsymbol{x}) = \frac{\exp\left(p(f(\boldsymbol{x}); \boldsymbol{\beta}) \cdot z_i\right)}{\sum_{j=1}^{J} \exp\left(p(f(\boldsymbol{x}); \boldsymbol{\beta}) \cdot z_j\right)}. \quad (1)$$

In Density Softmax, the closer the normalized log-likelihood to zero, the closer the prediction to Uniform distribution. Density Softmax achieves reasonable latency and competitive UE performance with state-of-the-art methods at the cost of demanding the density estimator training and multiple base model training.[3]

3.3 Density Aware Calibration (DAC)

DAC is a confidence calibration method using multiple feature representations, which is similar to the kNN-based out-of-distribution detection (Sun et al., 2022). DAC (Tomani et al., 2023) scales the logits by using sample-dependent temperature $\Phi(\boldsymbol{x}, \boldsymbol{w})$

$$p(y_i|\boldsymbol{x}) = \frac{\exp\left(z_i / \Phi(\boldsymbol{x}, \boldsymbol{w})\right)}{\sum_{j=1}^{J} \exp\left(z_j / \Phi(\boldsymbol{x}, \boldsymbol{w})\right)} \quad (2)$$

where

$$\Phi(\boldsymbol{x}, \boldsymbol{w}) = \sum_{l=1}^{L} w_l s_l + w_0. \quad (3)$$

$\boldsymbol{w} \in w_1 ... w_L$ are the weights for every layer of the base model, s_l is the averaged distance from kNN search on l-th layer, and w_0 is the bias term. $w_0 ... w_L$ are optimized using the L-BFGS-B method (Liu and Nocedal, 1989) based on the loss in the validation set. In the original DAC paper, the UE performance tends to improve with the increase in the number of layer representation (Tomani et al., 2023). Therefore, we use all the hidden representations in each layer of the base PLMs.

DAC is a non-parametric method that makes not assumptions about the training data distribution unlike Density Softmax (Bui and Liu, 2024), which relies on some density estimators. On the other hand, the recent kNN-based DAC still relies only on the distances to the neighbors. These methods do not take into account the label information of the input neighbors, which limits the improvement of the UE performance.

4 Proposed Method: k-Nearest Neighbor Uncertainty Estimation (kNN-UE)

The main idea of our proposed method, kNN-UE, stems from the notion that the density-based UE methods can be further improved by using label information about the training data instances that make up the density.

In order to take into account the variance of neighbor labels, our kNN-UE explicitly includes the label agreement information of the predicted instance and its neighbor examples when calculating the confidence. More specifically, we regard the prediction as more reliable only when the prediction is in a region where training data is dense and the predicted label and the labels of the data instances that make up the dense region are mostly the same, as illustrated in the right part of Figure 1. Otherwise, for example, if there is a lot of discrepancy in the neighbor labels and the predicted label, we treat the prediction as unreliable, indicated in the middle of Figure 1.

In our kNN-UE, we introduce two terms: one related to the density of the training data and one related to the degree of agreement of the predicted data and neighbor labels. Confidence of i-th label obtained by kNN-UE is following the formula:

$$p(y_i|\boldsymbol{x}) = \frac{\exp(W_{k\mathrm{NN}}(\hat{y}) \cdot z_i)}{\sum_{j=1}^{J} \exp(W_{k\mathrm{NN}}(\hat{y}) \cdot z_j)} \quad (4)$$

where

$$W_{k\mathrm{NN}}(\hat{y}) = \underbrace{\frac{\alpha}{K} \sum_{k=1}^{K} \exp\left(-\frac{d_k}{\tau}\right)}_{\text{distance term}} + \underbrace{\lambda \left(\frac{S(\hat{y})}{K} + b\right)}_{\text{label term}}. \quad (5)$$

[2] In the case of sequence labeling, we can interpret the number of data N as the product of the raw number of data instances and the sequence length.

[3] Details for the density estimator in this study are in Appendix B.

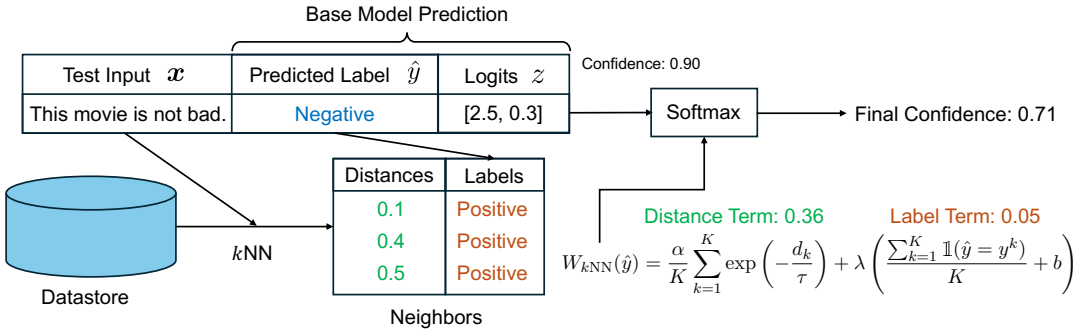

Figure 2: A diagram of kNN-UE when $K = 3$ and the estimated hyperparameters are $\alpha = 0.5$, $\tau = 1.0$, $\lambda = 0.5$ and $b = 0.1$. A datastore is constructed with the representations of the training data as keys and their labels as values. The distances of the nearest examples from the test representation, and the neighbor labels are aggregated into $W_{kNN}(\hat{y})$. Finally we obtain calibrated confidence by correcting the raw logits with $W_{kNN}(\hat{y})$ as in Eq. 4.

K is the number of neighbors from kNN search, $S(\hat{y}) = \sum_{k=1}^{K} \mathbb{1}(\hat{y} = y^k)$ is the count when the predicted label $\hat{y}$ and the label of the k-th neighbor y^k is same, d_k is the distance between the k-th $f(\boldsymbol{x})$ representation obtained by kNN search and the representations of training data.[4] The parameters $\alpha, \tau, \lambda \in \mathbb{R}_+$ and $b \in \mathbb{R}$ are optimized using the L-BFGS-B method based on the loss in the validation set.

When the distance and label terms are smaller and $W_{kNN}(\hat{y})$ is closer to zero, the closer the prediction is to Uniform distribution, which allows us to better estimate the confidence of the prediction. In this study, we also conduct experiments without the label term in Equation 5, to emphasize the importance of kNN neighbor labels in UE. We summarize a diagram of kNN-UE in Figure 2.

5 Experimental Settings

5.1 Tasks and Datasets

We measure the UE performance on Sentiment Analysis (SA), Natural Language Inference (NLI), and Named Entity Recognition (NER) in In-domain (ID) and Out-of-Domain (OOD) settings.[5] Dataset statistics are described in Appendix A.

Sentiment Analysis (SA) is a task to classify whether the text sentiment is positive or negative. The IMDb movie review dataset (Maas et al., 2011) is treated as ID, and the Yelp restaurant review dataset (Zhang et al., 2015) is treated as OOD.

Natural Language Inference (NLI) classifies the relationship between a hypothesis sentence and a premise sentence. We treat the Multi-Genre Natural Language Inference (MNLI) dataset (Williams et al., 2018) as ID and the Stanford Natural Language Inference (SNLI) dataset (Bowman et al., 2015) as OOD.

Named Entity Recognition (NER) extracts the named entities, such as a person, organization, or location. The NER task was carried out in the framework of *sequence labeling*. We regard the OntoNotes 5.0 dataset (Pradhan et al., 2013) broadcast news (`bn`) domain as ID, and newswire (`nw`) and telephone conversation (`tc`) domains as OOD.

5.2 Existing Methods

We employ the simple baselines: Softmax Response (SR) (Cordella et al., 1995), Temperature Scaling (TS) (Guo et al., 2017), Label Smoothing (Miller et al., 1996; Pereyra et al., 2017) and MC Dropout (Gal and Ghahramani, 2016). In addition, we use the recent strong baselines for UE: Spectral-Normalized Gaussian Process (SNGP) (Liu et al., 2020), Posterior Networks (PN) (Charpentier et al., 2020), Mahalanobis Distance with Spectral-Normalized Network (MDSN) (Vazhentsev et al., 2022), E-NER (Zhang et al., 2023), Density Softmax (Bui and Liu, 2024), and DAC (Tomani et al., 2023). Details on baselines can be found in Appendix C. We have also experimented with a variant of kNN-UE without the label term in Eq. 5, denoted by "w/o label" to emphasize the impact of the neighbor labels.

[4] Note that kNN-UE is also "accuracy-preserving" same as DAC because $W_{kNN}(\hat{y})$ is a scalar, not a class-wise score.

[5] The datasets in SA and NLI were set up with reference to Xiao et al. (2022).

5.3 Training Settings

In all experiments, we train and evaluate the models on a single NVIDIA A100 GPU with 40GB of memory. We used $\mathrm{DeBERTaV3_{BASE}}$[6] and $\mathrm{mDeBERTaV3_{BASE}}$[7] (He et al., 2023), as the Transformer encoder from `transformers` (Wolf et al., 2020) pre-trained model checkpoints. We use the cross-entropy loss in all experiments, including the optimization of hyperparameters in kNN-UE. Batch size is 32, and the initial learning rate was set to 1e-5. The gradient clipping is applied with the maximum norm of 1. All experiments are run five times, and we report the mean and standard deviation of the scores.

Datastore Construction It is necessary to maintain the representation of the data for training a density estimator in Density Softmax and kNN search in DAC and kNN-UE. We use the final layer representations corresponding to CLS tokens in SA and NLI. In NER, we stored the hidden representation of the final layer as a token representation corresponding to the beginning of the word.

k-Nearest Neighbor Search We use `faiss` (Douze et al., 2024) as the GPU-accelerated kNN search toolkit. Unless otherwise specified, we fix the number of neighbors $K = 32$ in kNN search,[8] and use `faiss.IndexFlatL2` which is an index for exact search in L2 norm, as the default in kNN-UE.

5.4 Evaluation

To evaluate the confidence calibration performance, we choose *Expected Calibration Error* (ECE) and *Maximum Calibration Error* (MCE) (Naeini et al., 2015). For selective prediction, we evaluate *Area Under the Receiver Operator Characteristic curve* (AUROC) and *Excess-Area Under the Risk-Coverage curve* (E-AURC) (Geifman et al., 2019). Evaluation metrics computation details are described in Appendix D. In NER, we performed the evaluation of the UE performance with the flat recombination of the labels and the confidence for all tokens, respectively.

[6] https://huggingface.co/microsoft/deberta-v3-base

[7] https://huggingface.co/microsoft/mdeberta-v3-base

[8] In Section 7.1, we conducted experiments to examine the behavior when varying K over the set $\{8, 16, 32, 64, 128\}$, with $K = 32$ representing the median.

6 Results

6.1 Sentiment Analysis

In SA, we evaluate the confidence calibration, selective prediction and out-of-distribution detection performance.

Confidence Calibration and Selective Prediction First, we present the UE results for sentiment analysis by differentiating the in-domain and out-of-main performance in Table 1. kNN-UE consistently outperforms existing methods in terms of ECE, MCE, and E-AURC. In AUROC, LS outperforms in OOD setting, but kNN-UE outperforms existing methods in ID setting. Furthermore, the proposed method clearly outperforms DAC that uses neighbor search results for each hidden representation with the additional label term. The lower UE performance than kNN-UE in DAC is probably due to the difficulty in optimizing hyperparameters by comprising many layers.

Out-of-Distribution Detection Following the previous study (Tomani et al., 2023), we carried out the experiments in the out-of-distribution detection task, which determines whether a data instance is in-domain or not. This task is based on the intuition that we want to return predictions with high confidence in ID but with low confidence in predictions in OOD. We evaluated the out-of-distribution detection performance by using maximum softmax probability as the uncertainty score, and report FPR@95 (the FPR when the TPR is 95%), AUROC, Area Under the Precision-Recall curve (AUPR)-in and AUPR-out. AUPR-in indicates the AUPR score when ID samples are treated as positive; AUPR-out is vice versa.

Table 3 shows the out-of-distribution detection results when using IMDb/Yelp datasets as ID/OOD, respectively, in $\mathrm{mDeBERTaV3_{BASE}}$ model. kNN-UE consistently shows the out-of-distribution detection performance improvement.

6.2 Natural Language Inference

We show the results of in-domain and out-of-domain UE in NLI task using the DeBERTaV3 model in Table 2. Similar to Section 6.1, kNN-UE shows the best UE performance, especially when the label term is included. Galil et al. (2023) have reported that improving calibration performance does not necessarily lead to the improved selective prediction performance, but our proposed method improves both types of metrics. On the other hand,

the degree of improvement is larger for calibration performance. Specifically, the largest improvement is obtained on SNLI, where kNN-UE reduces MCE by more than 31.49 % compared to SR. Additional experimental results on the Brier score can be found in Appendix E.

6.3 Named Entity Recognition

To evaluate NLP tasks other than simple multi-class classification, we evaluate kNN-UE in NER. Since NER focuses on entities, we use the product of the confidence of the tokens that construct a single entity as the confidence of the entity.

Table 4 shows the results of in-domain and out-of-domain UE using the OntoNote 5.0 dataset in $\mathrm{mDeBERTaV3_{BASE}}$. kNN-UE shows the best performance in 4 cases, i.e., ECE or MCE, often resulting in large improvements over SR. On the other hand, E-AURC in NER is consistently better without using the kNN-UE label term.[9] E-NER, a recent UE method specifically designed for NER, is close to kNN-UE in its entity level selective prediction performance, but the calibration performance is not high.

kNN-UE shows good UE performance even when the target domain is relatively far from source domain `bn`, such as `tc`. We have hypothesized that kNN-UE might not work if the prediction target is too far from the training data distribution. If the prediction target is too far from the training data, the representation of the prediction from the model will be unreliable when compared to the prediction in the same domain as the training data. In general, methods based on feature distances assume that they maintain information relevant to the correctness of the prediction (Postels et al., 2022). Our experiments have shown that the problem could be

[9] Label imbalance or large number of class can significantly affect E-AURC on NER when using kNN-UE with the label term. Details are in Appendix F.

kNN-UE (w/o label)	9.05±0.07	4.94±0.10
kNN-UE	9.08±0.10	4.99±0.07

Table 6: Inference time [s] on MNLI test set and OntoNotes 5.0 bn test set.

Figure 3 and 4 show the results for SA and NER, respectively. As is noticeable in NER, the smaller K, the better UE tends to be. These results suggest that our method requires that nearer examples to calibrate confidence, but more distant examples are not important. When calculating $W_{kNN}(\hat{y})$ in Eq. 5, automatically adjusting the importance weights based on the order or distance of the retrieved nearest neighbors could further improve UE performance. Similar experimental and theoretical analysis of out-of-distribution detection using only kNN distance also suggests that using k-th example is preferable (Sun et al., 2022). Providing a similar theoretical justification for our kNN-UE is an interesting future direction.

7.2 Importance of Label Term in $W_{k\text{NN}}$

We analyze the impact of the label term Eq. 5 on the kNN-UE confidence computation. We have shown that the UE performance is improved in several experiments. However, it is not obvious

Methods	OntoNotes 5.0 bn (In-domain)				OntoNotes 5.0 nw (Out-of-domain)			
	ECE (↓)	MCE (↓)	E-AURC (↓)	time [s]	ECE (↓)	MCE (↓)	E-AURC (↓)	time [s]
SR	7.79±0.53	50.07±24.15	21.90±1.31	2.49±0.08	17.05±0.69	37.06±3.13	81.49±4.17	5.75±0.27
kNN-UE (w/o label)	3.37±0.71	33.15±3.65	17.63±0.66	4.94±0.10	8.78±0.62	24.91±1.81	70.10±4.03	10.36±0.21
kNN-UE	1.78±0.32	26.02±13.72	20.14±1.27	4.99±0.07	7.50±0.42	16.53±2.61	74.27±5.43	10.48±0.12
+ PQ	1.96±0.31	31.33±18.74	20.23±1.27	3.32±0.05	7.57±0.45	16.43±2.73	74.38±5.36	7.23±0.16
+ IVF	1.92±0.31	28.55±11.24	20.13±1.22	3.31±0.06	7.60±0.41	17.12±2.35	74.34±5.35	7.33±0.21
+ DR	2.14±0.37	33.52±10.84	20.12±1.26	2.87±0.04	8.08±0.53	24.03±5.46	74.50±5.42	6.20±0.20

Table 7: ECE, MCE, E-AURC and inference time results about NER on OntoNotes 5.0 bn (In-domain) and OntoNotes 5.0 nw (Out-of-domain) for $\mathrm{mDeBERTaV3_{BASE}}$ model when applied PQ, IVF, and dimension reduction sequentially. DR indicates dimension reduction. For comparison, we also present the results when dimension reduction is only applied to kNN-UE.

Methods	OntoNotes 5.0 bn	OntoNotes 5.0 nw
kNN-UE	100.0	100.0
+ PQ	21.30	51.68
+ IVF	18.60	11.04
+ DR	0.02	0.04
Only DR	43.98	20.35

Table 8: Coverages when PQ, clustering, and PCA are applied sequentially to the example indices obtained by default kNN-UE. Results when applying dimension reduction by PCA individually are also presented for reference.

whether the improvement in UE performance is due to the reduction in $W_{k\mathrm{NN}}$ primarily caused by adding the label term. Therefore, we examined the $W_{k\mathrm{NN}}$ values for correctly and incorrectly predicted instances in both the absence and presence of the label term in kNN-UE. Table 5 shows the distance terms, label terms and $W_{k\mathrm{NN}}$ results for each case. If the predictions are correct, the growth of $W_{k\mathrm{NN}}$ due to the label term is limited. On the other hand, kNN-UE with label term remarkably reduce $W_{k\mathrm{NN}}$ leading to the reduced confidence when the predictions are incorrect. This result suggests that the improvement of the evaluation metrics in kNN-UE with label term is not achieved by increasing the confidence when the prediction is correct, but by appropriately reducing the confidence when the prediction is incorrect.

7.3 Impact of Efficient Nearest Neighbor Search Techniques

We investigate the inference time and UE performance when applying approximate nearest neighbor search techniques and dimension reduction when executing kNN search in kNN-UE as a real world application. As shown in Table 6,[10] in the *sequence labeling* based NER, which requires executing kNN searches per token, it takes twice as much inference time as SR.[11] On the other hand, in k-Nearest Neighbor Language Model (kNN-LM) (Khandelwal et al., 2020), dimension reduction and approximate kNN search techniques are effective to improve inference speed while maintaining perplexity in text generation (He et al., 2021a; Xu et al., 2023). Therefore, inspired by these works for faster kNN-LM, we investigate how the approximate nearest neighbor search techniques, such as Product Quantization (Jégou et al., 2011) (PQ), Inverted File (IVF) clustering and dimension reduction affect the UE and inference speed of our kNN-UE. Description of approximate nearest neighbor search techniques and detailed discussion when each method is individually applied to kNN-UE are in Appendix I.

Results of Combination of PQ, IVF and Dimension Reduction We evaluate the UE performance and inference speed when applying PQ, IVF and dimension reduction are applied. Table 7 shows the results on OntoNotes 5.0 bn and nw test sets as ID/OOD, respectively. The detailed discussion when changing the parameters of PQ, clustering and dimension reduction are shown in Appendix I. We can see that ECE and MCE are degraded when PQ, IVF and dimension reduction by PCA are applied simultaneously to kNN-UE.[12] On the other hand, our results show that applying them appropriately such as combining PQ with IVF improve inference time with mitigating the degradation in UE performance (The results with the parameters for PQ or IVF can be found in Appendix I.1 or I.2). To deepen our understanding of the above changes in the behavior of the uncertainty performance due to appling of approximate kNN search techniques

[10] Other results can be found in Appendix G.

[11] Inference times do not increase as dramatically as k-Nearest Neighbor Language Model (Khandelwal et al., 2020) because kNN can be executed in parallel for both classification and NER.

[12] Distance recomputation does not mitigate this behavior, see Appendix J.

or dimension reduction in kNN-UE, we calculated the coverage that how much the indices obtained when using the default exhaustive search are covered when applying PQ, clustering, and dimension reduction sequentially.

Table 8 shows the coverages on OntoNotes 5.0 `bn` and `nw` as ID/OOD settings, respectively. We can see that applying PQ, clustering, and PCA simultaneously hardly covers any of the indices from the default kNN-UE. It is assumed that applying PQ and PCA in the same time leads to coarse distance computation in a single subvector, which would correspondingly degrade the UE performance in kNN-UE. Actually, the experimental results in Table 17 in Appendix I.3 suggest that excessive dimension reduction in distance computation could have a negative impact on the UE performance. On the other hand, if combined with PQ and IVF, or applied PCA individually, some of the ground-truth nearest neighbor examples still exist.

8 Conclusion

In this paper, we proposed kNN-UE, which estimates uncertainty by using the distance to neighbors and labels of neighbors. The experimental results showed that our method showed higher UE performance than existing UE methods in SA, NLI and NER. Furthermore, our analysis of correctly and incorrectly predicted instances suggests that the improvement in kNN-UE is largely due to the reduction in confidence on incorrect instances. In addition, we investigated the effects of efficient neighbor search techniques in kNN-UE to address the degradation of the inference speed in token-level tasks such as NER. As a result, we found that product quantization, clustering, or dimension reduction improves inference speed without degrading the UE much more, unless combining all of them simultaneously.

9 Limitations

In this study, we focused only on the classification-based tasks. On the other hand, taking advantage of the recent growth of Large Language Models, UE in text generation is also attracting attention (Yoshikawa and Okazaki, 2023; Fadeeva et al., 2023; Lin et al., 2024). Therefore, to investigate the effectiveness of kNN-UE in text generation tasks is an interesting direction for future research. Not only that, our proposed method is applicable to more tasks such as image classification.

Furthermore, although kNN-UE only used the representation of the last layer of the base model, exploring for an appropriate representation for UE is a future challenge. Also, to investigate the relationship between the representation quality and in- and out-of-domain UE performance when using smaller pretrained encoders than DeBERTa, such as BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019) is an interesting direction.

Finally, we used ECE and MCE to measure calibration performance. On the other hand, it may be more appropriate to use other metrics to measure calibration performance when the dataset with multiple annotations including human disagreement is available (Baan et al., 2022), where it may be similar to the label disagreement in similar output representations. In Section 7.2, we showed that our kNN-UE with the label term improves in the direction we expected: it reduces confidence much more when the predictions are inaccurate. However, measuring calibration performance on a variety of data with multiple annotations may provide a more interesting insight into the behavior of our proposed method.

Ethical Considerations

In this study, we used existing datasets that have cleared ethical issues following policies of published conferences. Therefore, they do not introduce any ethical problems. On the other hand, we have an ethical consideration about UE. Specifically, decision support systems with machine learning algorithms do not necessarily have a positive effect on performance. Jacobs et al. (2021) showed that collaboration with machine learning models does not significantly improve clinician's treatment selection performance, and that performance is significantly degraded due to the presentation of incorrect recommendations. This problem is expected to remain even if UE methods are applied to machine learning models. In addition, introducing UE methods could conversely lead humans to give overconfidence in machine learning models, resulting in performance degradation.

A Dataset Statistics

The dataset statistics in our study is shown in Table 9.

Tasks	Datasets	N_{class}	Train	Val	Test
SA	**IMDb**	2	25,000	12,500	12,500
	Yelp	2	-	-	19,000
NLI	**MNLI**	3	392,702	4,907	4,908
	SNLI	3	-	-	9,824
NER	**OntoNotes 5.0** (bn)	37	10,683	1,295	1,357
	OntoNotes 5.0 (nw)	37	-	-	2,327
	OntoNotes 5.0 (tc)	37	-	-	1,366

Table 9: Dataset Statistics. Bolds indicate In-domain.

B Training Settings for Density Estimator in Density Softmax

In Density Softmax (Bui and Liu, 2024), we use RealNVP (Dinh et al., 2017) as the density estimator, which has two coupling structures. Table 10 shows the hyperparameters for training RealNVP as the density estimator in Density Softmax.

Hyperparameters	Values
learning rate	1e-4
optimizer	AdamW (Loshchilov and Hutter, 2019)
early stopping patient	5
number of coupling layers	4
hidden units	16

Table 10: Hyperparameters for RealNVP in Density Softmax.

C Details of Baselines

Softmax Response (SR) is a trivial baseline, which treats the maximum score from output of the base model's softmax layer as the confidence (Cordella et al., 1995).

Temperature Scaling (TS) is a calibration technique by which the logits are divided by a temperature parameter T before applying the softmax function (Guo et al., 2017). We optimized T by L-BFGS on validation set loss.

Label Smoothing (LS) is the calibration and generalization technique by introducing a small degree of uncertainty ϵ in the target labels during training (Miller et al., 1996; Pereyra et al., 2017). In LS, we optimized $\epsilon \in \{0.01, 0.05, 0.1, 0.2, 0.3\}$ by using validation set accuracy when SA and NLI, and validation set F_1 when NER.

MC Dropout is an UE technique by M times stochastic inferences with activating dropout (Gal and Ghahramani, 2016). In our experiments, we set $M = 20$ for all evaluations, and the dropout rate is 0.1.

Spectral-Normalized Gaussian Process (SNGP) uses spectral normalization of the weights for distance-preserving representation and Gaussian Processes in the output layer for estimating uncertainty (Liu et al., 2020).

Posterior Networks (PN) is one of the methods in the Evidential Deep Learning (EDL) framework (Sensoy et al., 2018) that assumes a probability distribution for class probabilities (Charpentier et al., 2020), which uses normalizing flow (Rezende and Mohamed, 2015) to estimate the density of each class in the latent space.

Mahalanobis Distance with Spectral-Normalized Network (MDSN) is a Mahalanobis distance based UE method that benefits from by spectral normalization of the weights (Vazhentsev et al., 2022), similar to SNGP.

E-NER applies EDL framework for NER by introducing uncertainty-guided loss terms (Zhang et al., 2023).

D Details of Evaluation Metrics

Expected Calibration Error (ECE) ECE (Naeini et al., 2015) quantifies the difference between the accuracy and confidence of a model. Formally, ECE is expressed as:

$$\mathrm{ECE} = \sum_{b=1}^{B} \frac{|\mathcal{D}_b|}{n} \left|\mathrm{acc}(\mathcal{D}_b) - \mathrm{conf}(\mathcal{D}_b)\right| \quad (6)$$

where B is the number of confidence interval bins, $\mathcal{D}_b$ denotes the set of examples with predicted confidence scores in the b-th bin, n is the total number of examples, $\mathrm{acc}(\mathcal{D}_b)$ is the accuracy of the model on the examples in $\mathcal{D}_b$, and $\mathrm{conf}(\mathcal{D}_b)$ is the average confidence of the model on the examples in $\mathcal{D}_b$. In this study, we use $B = 10$.

Maximum Calibration Error (MCE) MCE, as detailed by Naeini et al. (2015) measures the maximum difference between the model's accuracy and the confidence across variousb confidence levels. MCE is defined as:

$$\mathrm{MCE} = \max_{b=1}^{B} \left|\mathrm{acc}(\mathcal{D}_b) - \mathrm{conf}(\mathcal{D}_b)\right|, \quad (7)$$

A lower MCE means that there is a small risk that the confidence of the model's prediction will deviate greatly from the actual correct answer. In this study, we use $B = 10$, same as ECE.

Area Under the Risk-Coverage curve (AURC) The AURC is the area of the risk-coverage curve when the confidence levels of the forecasts corresponding to the N data points are sorted in descending order. The larger the area, the lower the error rate corresponding to a higher confidence level, which means that the output confidence level is more appropriate. Formally, AURC is defined as:

$$\mathrm{AURC} = \sum_{n=1}^{N} \frac{\sum_{j=1}^{n} g(x_j)}{i \times N} \quad (8)$$

where $g(x)$ returns 1 if the prediction is wrong and 0 otherwise.

Excess-Area Under the Risk-Coverage curve (E-AURC) E-AURC (Geifman et al., 2019) is a measure of the AURC score normalized by the smallest risk-coverage curve area $\mathrm{AURC}^{\star} \approx \hat{r} + (1 -$

Table 11: Brier score results using IMDb/Yelp and MNLI/SNLI as ID/OOD datasets, respectively.

$\hat{r})\ln(1-\hat{r})$, where $\hat{r}$ is the error rate of the model. The reason for normalizing the AURC is that the AURC depends on the predictive performance of the model and allows for performance comparisons of confidence across different models and training methods. E-AURC is defined as:

$$\text{E-AURC} = \text{AURC} - \text{AURC}^{\star} \tag{9}$$

E-AURC scores are reported with multiplying by 1,000 due to visibility.

E Additional Results on the Brier score

The Brier score is a widely used metric in UE community for evaluating the probabilistic predictions. The metric measures the mean squared difference between the predicted probability assigned to the predicted label and the actual outcome. This evaluation serves as a holistic assessment of model performance, reflecting both fit and calibration, in the following formula:

$$\text{Brier score} = \frac{1}{N}\sum_{n=1}^{N}(p_n - o_n), \tag{10}$$

where p_n is the predicted probability assigned to the prediction, and o_n is the actual outcome. Table 11 shows the results on the Brier score. These results indicate kNN-UE improves calibration performance more prominently than other methods while maintaining prediction performance.

F The impact of kNN-UE with label term in NER on E-AURC

NER tasks are often in label imbalanced settings, where the "O" label is typically much more than other entity-related labels. Additionally, in the OntoNotes 5.0 dataset, the number of labels is 37, as shown in Table 9, which is significantly higher than in SA and NLI tasks. As a result, compared to SA and NLI, neighbor labels will contain much more different labels from the predicted label. The presence of many other labels in the neighbors that are different from the predicted label can lead to excessively low confidence in kNN-UE using the label term, even though the prediction is correct because $S(\hat{y})$ in the label term becomes lower in NER. The impact of that bias for calibration errors, such as ECE and MCE, will be limited. However, low confidence in accurate prediction reduces the coverage much in E-AURC, leading to a degradation in E-AURC.

For example, assume that in a test data set of 6 examples for 3 classes classification, the predictions for the first 3 examples are incorrect and the latter 3 examples are correct. In case A, we assume that prediction confidences are [[0.25, 0.25, 0.5], [0.25, 0.25, 0.5], [0.25, 0.25, 0.5], **[0.25, 0.25, 0.5]**, [0.02, 0.02, 0.96], [0.01, 0.01, 0.98]]. In case B, we assume that prediction confidences are [[0.25, 0.25, 0.5], [0.25, 0.25, 0.5], [0.25, 0.25, 0.5], **[0.275, 0.275, 0.45]**, [0.02, 0.02, 0.96], [0.01, 0.01, 0.98]]. In these settings, the ECE and E-AURC for each case are shown in Table 12. These scores indicate that E-AURC is strongly penalized when the confidence in a correct prediction is lower than the confidence in an incorrect prediction.

kNN-UE (K=64)	129.16±0.16
kNN-UE (K=128)	128.39±0.20

Table 14: Inference time [s] on IMDb test set when changing K in kNN-UE.

H Inference Time Results When Changing -K

To estimate whether the inference time changes significantly when changing Top-K in kNN search, we investigated the inference time when changing K on the IMDb test set. Table 14 shows that the inference time remains almost the same when changing K in the range of 8 to 128.

I Each Result of Product Quantization, Clustering, and Dimension Reduction

I.1 Product Quantization

(PQ) (Jégou et al., 2011) is a data compression technique based on vector quantization. In PQ, a D-dimensional representation is divided into N_{sub} subvectors and quantized by performing k-means clustering on the vectors in each subspace. Vector quantization can significantly reduce the amount of memory occupied by vectors.[13] In addition, by calculating the distance between compressed PQ codes, we can efficiently calculate the estimated value of the original Euclidean distance.

We evaluated UE performance and inference time when the number of clusters in the codebook was fixed at 32, and the number of subvectors was changed to $N_{\text{sub}} \in \{16, 32, 64\}$ (In Table 7 and 8, PQ was performed with $N_{\text{sub}} = 32$).

Table 15 shows the UE performance and inference time results in different N_{sub}. In ECE and E-AURC, there are almost no degradation in UE performance due to PQ. On the other hand, in MCE in ID setting, the UE performance consistently degrades. Furthermore, compared to kNN-UE among different N_{sub}, the larger N_{sub}, the better the UE performance tends to improve, but the inference time increases.

The larger N_{sub} is, the more time is required for inference but the UE performance improves. We assumed that these results are derived from the decrease in quantization error over the vector

[13]For example, raw datastore in kNN-UE is 636MB on OntoNotes 5.0 bn, but PQ reduces it to 10MB.

with PQ with larger N_{sub} because each subvector is divided into smaller subspaces and the quantization is performed for each subspace. On the other hand, an increase in N_{sub} requires additional distance computations etc., then more inference time.

I.2 Clustering

The original kNN-LM uses an inverted file index (IVF) technique that speeds up the search by dividing the representation into N_{list} clusters by k-means and searching for neighbors based on N_{probe} centroids. In this study, we evaluate the UE performance and inference speed when the number of clusters $N_{\text{list}} = 100$. In this study, we evaluate the UE performance and inference speed when the number of clusters $N_{\text{list}} = 100$ and applying PQ with $N_{\text{sub}} = 32$ are fixed and the number of cluster centroids to search changes$N_{\text{probe}} \in \{8, 16, 32, 64\}$ (In Table 7 and 8, IVF was performed with $N_{\text{probe}} = 32$).

Table 16 shows the performance of UE when changing N_{probe} in ID and OOD settings using OntoNotes 5.0. In ECE, scores are slightly reduced for ID, but only slightly worse for OOD; MCE also shows degradation for ID but little for OOD, and even improves when $N_{\text{probe}} = 8$; E-AURC shows almost no change in scores when N_{probe} is changed for both ID and OOD. In terms of inference time, the larger N_{probe}, the longer it takes. We derive the improvement in MCE when increasing N_{probe} in ID setting from the fact that more clusters are targeted, making it possible to cover ground-truth nearest neighbor examples. On the other hand, the tendency of slight decrease when increasing N_{probe} in OOD setting may comes from the reliability of the vector, similar to the discussion in Section 6.3.

In addition, Taken together with the results in

Table 7 in Section 7.3, we can see that the degradation of the UE performance can be mitigated with improvement latency when applying PQ and IVF with lower N_{probe}, compared to applying PQ, IVF and PCA simultaneously.

I.3 Dimension Reduction

In general, Transformer-based models such as PLM have high-dimensional token representations. In high-dimensional spaces, nearest neighbor search often suffer from the curse of dimensionality. To reduce this problem, we apply dimension reduction to kNN-UE similar to He et al. (2021a). In this study, we use Principal Component Analysis (PCA) as a dimension reduction algorithm to reduce the dimension of the datastore representations and the query representation D_{pca} (In Table 7 and 8, PCA was performed with $D_{\text{pca}} = 128$). As shown in Table 17, the UE performance depends on the number of target dimensions, and the performance degrades when $D_{\text{pca}} = 64$ or $D_{\text{pca}} = 128$. On the other hand, the performance in $D_{\text{pca}} = 256$ is almost the same as default kNN-UE. This suggests that excessive dimension reduction in distance computation to extract nearest examples by kNN search could have a negative impact on the UE performance.

J Distance Recomputation for kNN-UE

When using efficient kNN search techniques in Section 7.3, we use approximate distances to compute Eq. 4. Although we can get raw vectors by using the example indices obtained from approximate nearest neighbor search and compute accurate distance, in kNN-LM this has been shown to lead to performance gains and latency degradation (He et al., 2021a). We measure the UE performance and inference speed when PQ, clustering, and dimension reduction are applied simultaneously and re-computing accurate distances, reported in Table 18. These results show that the UE performance does not improve except for MCE in the ID setting, and the latency is about 5-7x slower when reading raw vectors from the datastore and re-computing distances. Moreover, these results suggest that exact distance computation for examples that are not actually nearest neighbors are not very effective in kNN-UE.

Abstract

Social engineering attacks, such as phishing, often target victims through visually perturbed texts to bypass security systems. The noise contained in these texts functions as an adversarial attack, designed to deceive language models and hinder their ability to accurately interpret the content. However, since it is difficult to obtain sufficient phishing cases, previous studies have used synthetic datasets that do not contain real-world cases. In this study, we propose the BitAbuse dataset, which includes real-world phishing cases, to address the limitations of previous research. Our dataset comprises a total of 325,580 visually perturbed texts. The dataset inputs are drawn from the raw corpus, consisting of visually perturbed sentences and sentences generated through an artificial perturbation process. Each input sentence is labeled with its corresponding ground truth, representing the restored, non-perturbed version. Language models trained on our proposed dataset demonstrated significantly better performance compared to previous methods, achieving an accuracy of approximately 96%. Our analysis revealed a significant gap between real-world and synthetic examples, underscoring the value of our dataset for building reliable pre-trained models for restoration tasks. We release the BitAbuse dataset, which includes real-world phishing cases annotated with visual perturbations, to support future research in adversarial attack defense. Our code and datasets are available at https://github.com/CAU-AutoML/Bitabuse.

1 Introduction

Social engineering attacks, including phishing, spam, pretexting, baiting, and tailgating, aim to leak confidential information by exploiting the psychological vulnerabilities of victims (Salahdine and Kaabouch, 2019). Among them, phishing often attacks victims through texts of email, SMS, and URLs. Specifically, these phishing techniques bypass security systems such as spam filtering using visually perturbed (VP) text (Deng et al., 2020; Julis and Alagesan, 2020; Boucher et al., 2022; Unicode Consortium, 2022), in which other characters, typically homoglyphs, replace a part of the characters in the text if the source language is English, that are nearly identical in appearance to the original characters[1]. For example, modifying 'Bitcoin' to 'ßitcöĭn' is an example of this technique.

Because phishing attacks based on VP texts can be prevented by restoring them to the original texts, most studies (Suzuki et al., 2019; Sawabe et al., 2019; Pruthi et al., 2019; Imam et al., 2022; Keller et al., 2021) focused on devising an restoration method. Specifically, they modified a non-VP text dataset into a VP text dataset based on their own heuristic rules and then evaluated the performance of their restoration methods based on the synthesized dataset. These approaches are effective for identifying the weaknesses of the restoration methods, but their analysis may be biased toward their own rules because the dataset is created without regard to real-world VP texts. For example, Viper (Eger et al., 2019) always perturbs a fixed portion of characters in a sentence, which is unrealistic. Furthermore, LEGIT (Seth et al., 2023) annotates the legibility of synthetic VP text and introduces a dataset by generating VP text that is applicable to real-world scenarios through a model that ranks transformations according to their readability. Nevertheless, research on VP text in real-world settings remains unexplored.

Although the data synthesizing strategy is helpful in circumventing the difficulty due to the lack of publicized real-world VP texts regarding phishing attacks, building a language model (LM)-based

system for defending against phishing attacks only based on the synthesized dataset may be risky because there can be a gap between real-world and simulation. We argue that one way to achieve this limitation is to mix the real VP texts with the synthesized VP texts. In this case, it may be preferable that the original texts of the synthesized ones come from the same source for domain consistency. To achieve this, we propose a new dataset, namely `BitAbuse`, for defending phishing attacks.

Our contribution can be summarized as follows. First, based on 262,258 phishing-related emails identified from bitcoinabuse[.]com (Bitcoin Abuse, 2023), we created a raw corpus containing 325,580 sentences comprising 26,591 VP sentences and 298,989 non-VP English sentences. Second, based on the corpus, we created three datasets: `BitCore`, `BitViper`, and `BitAbuse`. Third, to depict the characteristics of our dataset, we conducted pilot studies using popular methods in this field and then compared their efficacy. We made the datasets of phishing attacks publicly available[2].

2 Related Work

In the studies involving VP texts, obtaining sufficient data is often difficult because VP texts, usually delivered as spam emails, are not widely shared on the web. In particular, there is a lack of datasets that reflect actual phishing attack situations, and existing datasets are only valid under specific conditions or environments (Elsayed and Shosha, 2018; Suzuki et al., 2019; Yazdani et al., 2020; Almuhaideb et al., 2022), such as internationalized domain names (IDNs.) As a result, conventional studies typically included a data synthesizing procedure with the method for restoring VP texts. Specifically, the dataset for testing the efficacy of their VP text restoration methods is synthesized by heuristic rules set in their own way.

Two notable studies regarding VP text data synthesizing are TextBugger (Li et al., 2019) and Viper. TextBugger is devised to generate VP texts using predefined homoglyph pairs and perturbation methods. Its goal is to degrade the performance of LMs by selecting characters in a text and replacing them with VP characters. This is useful for exposing vulnerabilities in security-sensitive tasks such as sentiment analysis (Pang and Lee, 2008) or malicious content detection (Hou et al., 2010). Viper searches for homoglyphs and generates VP texts based on embedding techniques. This method modifies the dataset by replacing characters in the text with VP characters and induces visual disturbance based on the replacement probability.

Regarding the restoration of VP texts, conventional methods first restore malicious text using SimChar DB-based (Suzuki et al., 2019), OCR-based (Sawabe et al., 2019), Spell Checker-based (Imam et al., 2022), or LM-based methods (Keller et al., 2021) and then detect malicious texts. The SimChar DB-based method automatically collects homoglyphs from the Unicode character set to detect VP characters in IDNs and restores them using a predefined restoration table. OCR-based methods were investigated to detect phishing attacks that deceive users by putting VP characters in IDNs. This method recognizes VP characters as images and converts them into the original characters. The Spell Checker-based method aims to detect images containing malicious text distributed on social networks by considering deformed characters in the text as typos and restoring them using a spell checker. The restoration strategy that combines two LMs, BERT (Devlin et al., 2019) and GPT (Radford et al., 2018), was also considered (Keller et al., 2021).

A common drawback of conventional studies is that the datasets used for evaluating the restoration performance of phishing attacks contain no real VP texts. As a result, the restoration performance in real-world situations may be over/underestimated, and unstable pre-trained LM models can be obtained. In this study, we create a new dataset that can contribute to phishing attack studies by collecting VP texts used in bitcoinabuse[.]com.

3 `BitAbuse`

We collect VP texts used in phishing attacks from the bitcoinabuse[.]com (Bitcoin Abuse, 2023) website. The website bitcoinabuse[.]com is a platform where worldwide users can share content related to Bitcoin fraud, such as emails. The site provides data collected through user participation, making it easy to find phishing email bodies containing VP texts. Additionally, because users directly upload emails after masking personal information, it can be ensured that the data can be collected safely without privacy concerns.

We used 262,258 phishing-related emails collected from bitcoinabuse[.]com between May 16,

Original VP sentence	Ground truth (VP characters are restored)
i am going to sęnd out your vidęo recordìng to evęry bit of yoūr contacts and you cān easily imāgine cőncerning the disgracę you will sęe.	i am going to send out your video recording to every bit of your contacts and you can easily imagine concerning the disgrace you will see.
ìf you wànt to prevent thìs, tràansfer 0.019 btc to my bìtcoìn wàllet (ìn càse you do not know how to do ìt, then wrìte to google: "buy à bìtcoìn").	if you want to prevent this, transfer 0.019 btc to my bitcoin wallet (in case you do not know how to do it, then write to google: "buy a bitcoin").

Table 1: Examples of VP sentences (Left) and manually restored sentences (Right) in the raw corpus (note that vowels such as 'a', 'e', 'i', 'o', and 'u' are mainly used as VP, which are highlighted in gray).

2017, and January 15, 2022. Detailed statistics of the raw dataset are discussed in Appendix A.

Although our primary goal is to create a VP text dataset related to English texts, the emails collected from English-speaking countries also included non-English texts, so removing irrelevant emails was followed. However, using existing language detection models to classify emails written in English is challenging due to the presence of English VP text, and fully manual filtering is also impractical. Therefore, we utilized the BERT model (Devlin et al., 2019) with a fully connected classification layer trained to automatically classify English text. The BERT model used in this classifier has a hidden state size of 768, 12 hidden layers, and 12 attention heads. Among the 262,258 email texts, 16,598 were randomly chosen and manually labeled as English (10,024 texts) or non-English (6,574 texts), and these labeled email texts were used to train the classification model. The labeled dataset was exclusively divided into train, validation, and test sets with 13,444, 1,494, and 1,660 texts, respectively. We provide the detailed hardware specification and hyperparameter settings in Appendix B.

The classifier achieved an accuracy of approximately 99.28% on 1,660 uninvolved email texts in the training phase. The trained classifier removed 84,204 non-English email texts from the 262,258 ones, resulting in 178,054 email texts for further processing. Although this process significantly accelerates the preprocessing, non-English emails may still remain because the classification is imperfect. Such non-English sentences from those email texts are removed manually during a subsequent process that will be explained later.

After rough filtering 178,054 non-English email texts, we obtained 326,732 sentences by splitting the original texts with a maximum length of 512. Because those sentences include unnecessary components, such as random character sequences, we used a series of regular expressions to remove them efficiently. The list of regular expressions we used for further preprocessing and downloadable URL links are presented in Appendix C. We found that the raw dataset contains a wide range of VP characters not addressed in previous studies, such as control characters from U+0001 to U+0005, that will remain in `BitCore` and `BitAbuse` datasets.

To validate the restoration performance, we manually annotated the label for each character in the 326,732 sentences. Since manually annotating VP text is highly labor-intensive and inefficient, we extracted VP words from the VP text and manually created non-VP word labels for each VP word. These labels were then applied to the VP text to generate non-VP text labels. In cases where it was difficult to determine the label by looking only at the VP word, we referred to the original text to accurately annotate the corresponding non-VP word. While annotating, 1,152 irrelevant sentences, such as repetitive identical characters, random character sequences, or non-English sentences missed from the previous classification process, were removed. Table 1 shows examples of VP text with the corresponding ground truth sentences, and brief statistics of the raw corpus are presented in Appendix A. Also, We created `BitCore`, `BitViper`, and `BitAbuse` datasets based on the raw corpus. Brief statistics of the three datasets are presented in Table 10 of Appendix D.

4 Experimental Settings

We tested the restoration performance using Simchar DB (Suzuki et al., 2019), OCR (Sawabe et al., 2019), Spell Checker (Imam et al., 2022), Character BERT-based(El Boukkouri et al., 2020), and GPT-4o mini-based methods (OpenAI, 2023) in the viewpoint of three well-known evaluation mea-

sures, such as Word Level Accuracy (Imam et al., 2022), Word Level Jaccard, and BLEU (Zeng et al., 2021). In addition, detailed information regarding the experiments, such as the model's hyperparameters, is described in Appendix F.

4.1 Methods

We tested the restoration performance using five different methods. The SimChar DB-based method checks if there is an alphabetic homoglyph for each character in the Simchar Database and uses it to restore the homoglyph. The OCR-based method was implemented by applying OCR to each character and selecting the character with the highest probability. Spell Checker-based method entailed the segmentation of sentences into individual word units through a rule-based approach, followed by the restoration of each word using a spell checker based on Levenshtein Distance, as documented in the corresponding references (Norvig, 2016; Lison and Tiedemann, 2016).

Character BERT The Character BERT-based method employs a BERT model that processes token sequences at the character level to restore VP characters, inferring them as the original characters through the context of individual characters. In this approach, instead of relying on a standard subword tokenizer-based BERT—which is less effective when tokens contain perturbed characters—a character-level sequence approach is adopted for both input and output. This method is particularly important because attackers often modify characters within tokens to deceive victims, leading to widespread perturbations across most tokens. Stan-

Method	Example 1	Example 2
Original Text	after tʜαt, i hąvᵉ stąrtᵉd trαcĸing yσur întᵉrnᵉt αctîvítíᵉs.	I W ▌ll ժeʟeTe eVeɦʏthɪNG L've GoT aʙ0UT ʏoU.

Spell Checker	after that, i have started tracking your <None> <None>.	i will delete everything love got about you.
Character BERT	after that, i have started tracking your internet activities.	i will delete everything i've got about you.
GPT-4o mini	after that, i have started taking about internet activities.	i will let you know about what you.

Table 3: Restoration examples of the five methods where "<None>" indicates that the method failed to restore the word (VP and incorrectly restored characters are highlighted in gray color and underlined, respectively.)

dard BERT's Masked Language Model (MLM) mechanism, which relies on contextual information from surrounding tokens, struggles in such cases because the context tokens themselves may also be perturbed. Experiments with the Character BERT-based model involve training to restore and output the input VP sentence from three datasets into the corresponding restored sentence. In this process, both the input and output are sequences of character-level tokens. The training process of Character BERT was configured with a learning rate of 5×10^{-5}, a batch size of 32, and ten training epochs. Additionally, the AdamW optimizer was used with settings of $\beta_1 = 0.9$, $\beta_2 = 0.999$, and a weight_decay $= 0$, along with a linear learning rate scheduler. The experiment shown in Table 4 uses the same hyperparameters as the previously mentioned experiment, except the number of training epochs is set to 20.

We also employed the GPT-4o mini model to assess the performance of the latest large language model on the `BitAbuse`. GPT-4o mini is a closed-source generative language model, and the experiment was conducted via OpenAI's inference API. To leverage the model, we designed a prompt, as detailed in Table 15 of Appendix F.

4.2 Evaluations

We evaluated each method using the three measures that were used in previous VP text restoration studies: Word Level Accuracy, Word Level Jaccard, and BLEU. Word Level Accuracy is a measure that evaluates whether the restored word matches at each word position. When N_c represents the number of correctly restored words and N represents the total number of words in each sentence, Word Level Accuracy is calculated as

$$\text{Word Level Accuracy} = \frac{N_c}{N}.$$

The Word Level Jaccard score is calculated by forming the word set W_p from the predicted sentence and the word set W_l from the labeled sentence and then computing the ratio of the size of their intersection to the size of their union. Specifically, the Word Level Jaccard score is defined as

$$\text{Word Level Jaccard} = \frac{|W_p \cap W_l|}{|W_p \cup W_l|}.$$

The BLEU score is calculated by constructing the character sequences C_p of the predicted sentence and the character sequences C_l of the labeled sentence and then calculating the precision of the n-grams of the two sequences by

$$\text{BLEU} = \text{B} \times \exp\left(\sum_{n=1}^{N} w_n \log p_n\right).$$

where N and w_n are the maximum length and the weight of the n-grams, respectively. p_n represents the precision of the n-grams in C_l and C_p, and B is the brevity penalty used in the BLEU score calculation. In this paper, $N = 4$ is used to calculate the BLEU score, and $w_n = 1/N$ is set. The brevity penalty follows the standard BLEU score calculation method.

Without specific mentions, among sentences of BitAbuse dataset, 60%, 20%, and 20% of them were used for training, validation, and testing, respectively. The performance of each method was evaluated on the test set, and the average performance was measured by repeating the experiments with ten random training and test set splits.

5 Experimental Results

We conducted exploratory data analysis on VP words, VP characters, ratios, and so on that may help devise an effective methodology for defending phishing attacks.

Next, the number of VP sentences according to the occurrence ratio of VP characters to sentence length in the BitCore, BitViper, and BitAbuse datasets is presented as a histogram as in Figure 3 in Appendix D. Figure 1 shows the VP character-word association graph using the Yifan Hu algorithm (Hu, 2005) in Gephi (Bastian et al., 2009). This graph represents the clustering of the VP character-word association of BitCore dataset, where nodes correspond to characters and words subjected to perturbation attacks. The distance between nodes indicates the degree of their relatedness[3]. Figure 1(a) illustrates the overall graph, and Figures 1(b)–(e) each represents the graph regarding key characters. Notably, the core of the major clusters is occupied by vowels such as 'a', 'e', 'i', and 'o'. This likely occurs because vowels are frequently used across various words, resulting in strong associations within the graph and positioning them at the center. Specifically, the character 'e' appears to play a more global role within the graph, whereas other characters show stronger relations with words belonging to different clusters.

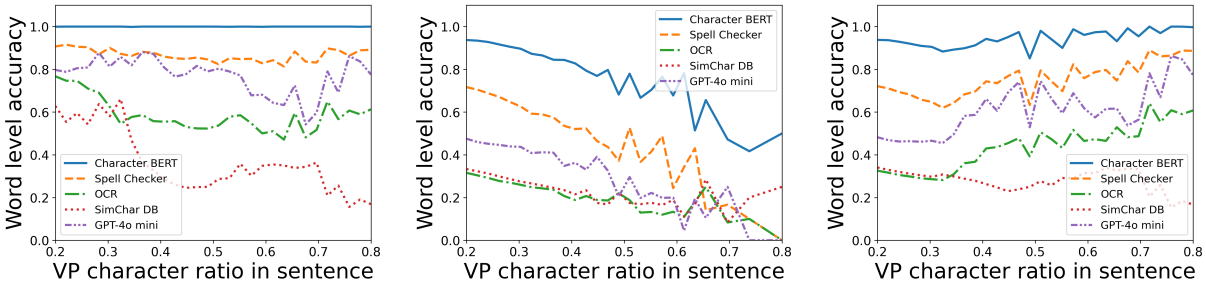

Table 2 shows the restoration performance of SimChar DB, OCR, Spell Checker, Character BERT, and GPT-4o mini-based methods on three datasets. Experimental results indicate that the Character BERT-based method significantly outperforms the other three methods. Regarding each dataset, all five methods achieved the best and worst performance for BitCore and BitViper datasets, respectively. Table 3 represents two examples of restoration results regarding five methods. Although the Character BERT-based method restores two VP sentence examples perfectly, Table 2 indicates that the restoration performance of Character BERT is imperfect. Table 5 lists VP words in three datasets that are incorrectly restored by the Character BERT-based method. The table shows that it often fails to restore if two or more VP characters are continued in the corresponding VP word.

We evaluated the Word Level Accuracy regarding the proportion of VP characters in sentences to validate the robustness of each method, as shown in Figure 2. In this experiment, the Character BERT-based method showed robust performance on both BitCore and BitAbuse datasets. It is interesting to note that it loses its robustness on BitViper dataset that does not include BitCore dataset, indicating that BitCore significantly contributes to the robust performance of the Character BERT-based method. In summary, the Character BERT-based method showed the most robust performance for VP sentences with a high VP character ratio. To see experimental results regarding Word Level Jaccard and BLEU, please refer to Appendix G.

Test performance with VP characters unseen during the training phase can be critical for the Character BERT-based method. Additional experiments were conducted using the Character BERT-based method with varying amounts of training VP sentences to validate this aspect. Specifically, when the amount of training VP sentences is extremely small, the Character BERT-based method encounters many unseen VP characters. Table 4 presents the performance of the Character BERT-based method when the proportion of training VP sentences is set to 1%, 5%, 10%, and 20%, respectively. In these experiments, we recognized that differences in the size of the test dataset could impact the fairness of performance comparisons. To address this, we sampled the remaining data, which were not used for training or validation, to standardize the size of the test dataset. Performance evaluation was conducted by measuring the performance of each pattern in the test dataset and calculating the mean and variance. This process was grounded in the Law of Large Numbers to include as many samples as possible, aiming to approximate the population mean.

The experimental results revealed that when the amount of training VP sentences was as low as 1% or 5%, significant performance degradation was observed for both the BitViper and BitAbuse

[3]The Yifan Hu algorithm uses a multiscale approach to position highly related nodes close to each other while placing less related nodes further apart. This algorithm is fundamentally based on a force-directed layout, where nodes are arranged according to the forces of attraction and repulsion between them based on the frequency of association.

(a) BitCore dataset (b) BitViper dataset (c) BitAbuse dataset

Table 5: List of VP words in three datasets that are incorrectly restored by the Character BERT-based methods from the experiments of Table 2 (VP characters are highlighted in gray color.)

datasets. This finding suggests that sufficient VP sentences are necessary to build a stable Character BERT model for VP text restoration. On the other hand, despite the performance drop with lower proportions of training data, the Word Level Accuracy still exceeded 0.5. This indicates that the model can restore relatively well from unseen attacks, even when it is exposed to many new VP attacks during the test phase. Additionally, using a smaller amount of training data allows the model to complete training more quickly, which is a desirable attribute in practical applications.

6 Discussion

Figure 2 demonstrates the performance of various restoration methods based on the proportion of VP characters. Compared to other methods, the Character BERT-based method performed more effectively as the proportion of VP characters increased. This indicates that the Character BERT-based method can accurately restore VP characters by leveraging contextual information. Conversely, the Spell Checker-based method exhibited a sharp decline in performance as the proportion of VP

characters increased, highlighting the limitations of simply correcting typographical errors when dealing with text containing a high proportion of VP characters. The GPT-4o mini-based method underperformed compared to the spell checker-based method, likely because the GPT-4o mini is a generative model. Consequently, the word order and indexing between the input and output sentences are not maintained. This trait of generative language models seems to result in reduced performance in word accuracy evaluations, where word positioning is critical. Furthermore, the performance decline caused by the refusal responses triggered by the safety features of the language model, which will be discussed later, is also thought to have contributed to these results. Figures 4 and 5, like Figure 2, evaluate the Word Level Jaccard and BLEU performance for the ratio of VP characters in sentences. The Jaccard performance closely mirrored the Word Level Accuracy results, but the BLEU performance exhibited a slightly different pattern. In both Figures 2 and 4, the Character BERT-based method consistently demonstrated the most effective performance as the VP character ratio increased, with significant performance gaps between it and the other methods. However, in Figure 5, the performance of all methods, except for the Character BERT-based method, generally improved, reducing the performance gap. This suggests that the BLEU score is more sensitive to contextual accuracy, meaning that even if the exact words do not match, simpler methods can achieve higher scores as long as the sentence structure and meaning are somewhat preserved.

Table 2 presents the comparison results of five restoration methods across three datasets using three evaluation measures. The results show that the Character BERT-based method clearly outperformed the others, with all approaches achieving the highest performance on the `BitCore` dataset and the lowest performance on the `BitViper` dataset. Examples of the restoration for VP sentences through each method are shown in Table 3. Although the Character BERT, GPT-4o mini, and Spell Checker share the commonality of leveraging contextual information, the character BERT-based method was more accurate in the restoration. The SimChar DB-based method could only restore VP characters included in SimChar DB, and many of the VP characters that appeared did not exist in the DB, resulting in poor restoration performance. Additionally, a fundamental limitation of simple mapping-based methods like SimChar DB is their inability to handle one-to-many mappings for VP characters. Since these methods are rule-based, they can only output a single non-VP character for each VP character. We will demonstrate how frequently one-to-many corresponding VP characters appear in the dataset in Appendix H. The OCR-based method also had poor restoration capability for each VP character, and it was observed that character recognition was more difficult in the case of VP characters containing diacritics. The Spell Checker-based method showed high performance in restoring words containing VP characters, but it occasionally failed to find suitable words when the VP character ratio in the sentence was high. The GPT-4o mini-based method showed limited restoration capabilities. While it was able to successfully restore most VP characters in cases like Example 1, it failed when VP characters dominated the sentence, as in Example 2, producing outputs that differed significantly from the input. Additionally, in certain cases, due to the language model's safety features, responses such as "I'm sorry, but I can't assist with that," "I'm sorry, I can't assist with that," or "I'm sorry, I can't help with that" were generated in response to unethical content. These instances made up about 13.22% of the `BitAbuse`, which is a notable proportion. The Character BERT-based method excels by directly learning the context and succeeded in almost perfectly restoring VP words. This implies that models like BERT, which are significantly smaller than generative large language models such as GPT-4, can be more efficient for restoring VP text, as they still achieve high performance despite their smaller size. Table 5 provides examples of VP words that were incorrectly restored using the Character BERT-based method. The results indicate that restoration failures are more likely when VP characters appear consecutively or when there is a high density of attacked VP characters nearby.

As demonstrated by the comparison results in Table 2, the Character BERT-based method achieved nearly 100% accuracy on `BitCore` dataset, highlighting its robustness and reliability. In addition, with sufficient training VP sentences, it achieved almost perfect performance on `BitAbuse` dataset as shown in Table 4.

Given the high performance of LM pre-trained using `BitAbuse`, it may be employed in highly spe-

cialized, high-performance restoration tasks. For example, the pre-trained model could be applied in digital forensics to decode and reconstruct documents, emails, or logs that have been intentionally manipulated to obscure evidence. In addition, the model can be further trained to effectively handle even subtle and complex text modifications, which could improve forensic analysis. We believe that this model could also be used in secure messaging systems, where it would restore the original content of messages that have been deliberately obfuscated to ensure the secure transmission of sensitive information. These studies may highlight the potential of our datasets and pre-trained models to address critical challenges in secure communications.

7 Conclusion

In this study, we created three VP text datasets: `BitCore`, `BitViper`, and `BitAbuse`. Our analysis results show that `BitCore` and `BitViper` have significantly different characteristics, and the LM-based reconstruction method demonstrates strong robustness and potential on all three datasets. `BitAbuse`, a pre-trained model using 325,580 VP sentences, can be downloaded from `BitAbuse`.[4]. In future studies, a hybrid approach, such as combining OCR and Character BERT, can be explored to achieve robust performance with insufficient training samples. Internalizing them into LMs may be beneficial for remedying the greedy data consumption nature of LMs and in scenarios where collecting sufficient samples is challenging. In addition, lightweight yet accurate LMs for restoration tasks may be obtained if the bias to the words attacked frequently and vowel characters in real-world phishing attacks is exploited effectively. Lastly, validating the zero-shot performance of `BitAbuse` model should also be performed.

[4] https://huggingface.co/datasets/AutoML/bitaubse

Limitations

The VP text restoration experiments conducted in this study did not include additional restoration methods to avoid exceeding the scope of the study. Specifically, a performance comparison between the Character BERT-based and other LM-based restoration methods was not performed. Thus, it is difficult to evaluate the superiority of Character BERT over other modern LMs. Character BERT showed sufficiently good performance, but it will be possible to compare effectiveness and efficiency with methods applying other LMs in the future.

The `BitAbuse` dataset used in this study only includes data related to Bitcoin scams, which limits its ability to reflect a variety of phishing attack scenarios. In addition, phishing attacks may appear in more diverse or complex forms over time, and failure to reflect this diversity may reduce the generalizability of our study. Thus, future studies should aim to construct an extended dataset that includes various phishing attack scenarios and conduct studies comparing different restoration methods.

Also, our datasets were created for study purposes to defend against phishing attacks based on VP texts. However, there is a risk that this dataset could be used by non-experts in phishing to learn and execute attacks. For example, WormGPT, recently created on the dark web to generate criminal text, and PoisonGPT, released by Mithril Security, spread contaminated results. These models might use our datasets to develop malicious tools. Consequently, this could lead to the sophistication of phishing attacks, resulting in more victims. In addition, the damage caused by the misuse of such datasets is difficult to hold accountable legally. Currently, many countries lack clear regulations regarding the technological misuse of such datasets, necessitating careful considerations and observations. The datasets and models used in this paper are publicly available, but they should not be used for purposes other than research.

Ethics Statement

Our datasets were created for study purposes to defend against phishing attacks based on VP texts. However, there is a risk that this dataset could be used by non-experts in phishing to learn and execute attacks. For example, WormGPT, recently created on the dark web to generate criminal text, and PoisonGPT, released by Mithril Security, spread contaminated results. These models might use our datasets to develop malicious tools. Consequently, this could lead to the sophistication of phishing attacks, resulting in more victims. In addition, the damage caused by the misuse of such datasets is difficult to hold accountable legally. Currently, many countries lack clear regulations regarding the technological misuse of such datasets, necessitating careful considerations and observations. The datasets and models used in this paper are publicly available, but they should not be used for purposes other than research.

Table 12: Examples of VP variants regarding five words of Table 11 with the highest number of variants (VP characters are highlighted in gray color.)

A Statistics of Raw Dataset

Table 6 shows brief statistics of the collected email texts. We identified 262,258 phishing-related emails from bitcoinabuse[.]com between May 16, 2017, and January 15, 2022, and extracted the text bodies of these emails. The length of the email bodies averages about 417 characters, ranging from a minimum of 10 characters to a maximum of 2,000 because the platform limits the maximum number of characters to 2,000. The content of phishing-related emails was uploaded from approximately 224 countries, and the country of upload and the language of the collected text may differ.

Table 7 presents the statistics of the raw corpus after splitting the collected texts into individual sentences and removing meaningless texts, as mentioned in the Data Collection section. The sentence-splitting process was performed using the NLTK library, resulting in a total of 325,580 sentences. In the next step, sentences containing non-ASCII characters were classified as VP sentences, and the classification was manually reviewed to ensure accuracy. After the review, 26,591 sentences were identified as VP sentences, while 298,989 were categorized as non-VP sentences.

B Filtering Non-English Texts

In our study, we exploited the BERT model with a fully connected classification layer trained to classify English texts from non-English texts. To train our model, we use the Flair library (Akbik et al., 2019). In addition, the learning rate was set to $1e-6$, with 1 learning epoch (the library early stopped training due to the very small learning rate), a batch size of eight, an AdamW optimizer ($\beta_1 = 0.9$, $\beta_2 = 0.999$, weight_decay $= 0$), and the AnnealOnPlateau scheduler implemented in the Flair library. Additionally, a single NVIDIA GeForce RTX 3080 GPU was used.

Char.	Number of Variants	Char.	Number of VP attacked
i	34	o	179,792
a	28	i	145,832
o	27	c	95,863
e	22	a	85,905

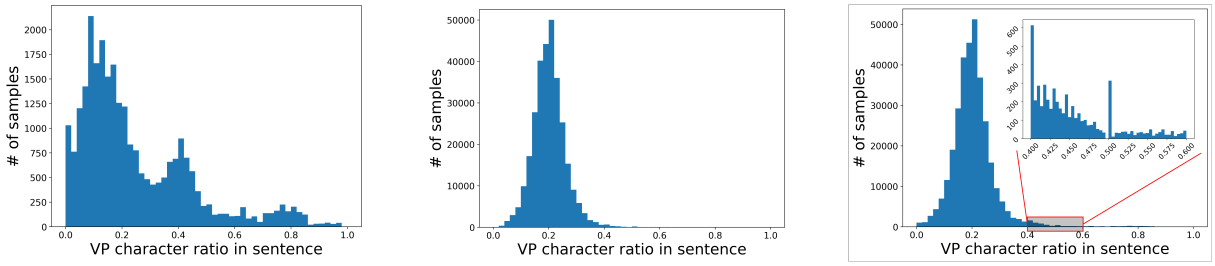
0	2	0	6

Table 13: The full list of VP character variants and VP attacks for each character appearing in the BitAbuse dataset.

C Regular Expressions

Table 8 shows the list of regular expressions we used for further preprocessing. The first and fourth, the second and fifth, and the third and sixth columns mean the description of characters, regular expressions, and replaced characters, respectively. R and S in the third and sixth columns mean "Removed" and "Space". For example, No-break Space (U+00A0), En Space (U+2002), Hair Space (U+200A), and Ideographic Space (U+3000) are special space characters and would commonly be replaced with regular space characters. The space after \u in the regular expression is included intentionally for clarity but is excluded in the actual regular expression. We also release a downloadable list of regular expressions and preprocessing code from https://huggingface.co/datasets/AutoML/bitaubse/blob/main/preprocessing.py.

Table 9 shows example sentences after the preprocessing based on the regular expressions. In three examples of the table, emojis and special characters in the sentence are removed, and unusual characters are replaced with ASCII characters with the same meaning. For example, in the first example in the table, "Left Black Lenticular Bracket (U+3010)" and "Right Black Lenticular Bracket (U+3011)" were replaced with regular parentheses (U+0028, U+0029). In the second example, unprintable Unicode characters that are presented as a hex value in the red box are removed.



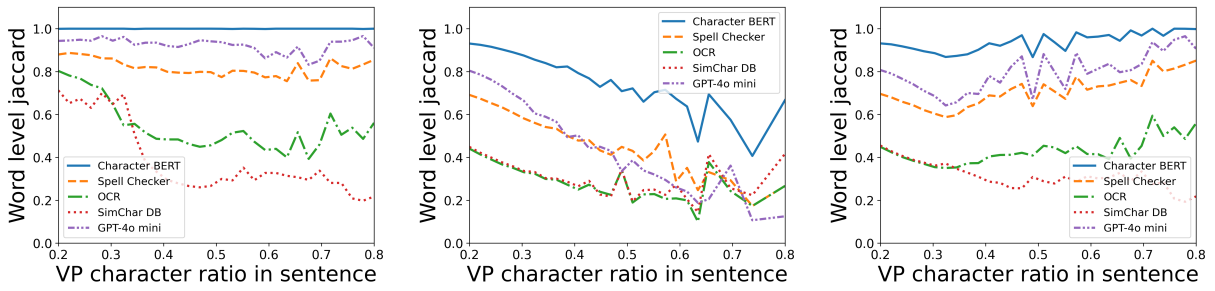
D Statistics of BitAbuse

We created BitCore, BitViper, and BitAbuse datasets based on the raw corpus. Brief statistics of the three datasets are presented in Table 10. Specifically, BitCore was created by simply selecting 26,591 VP sentences from the raw corpus. Next, BitViper was created by applying the character perturbation procedure of Viper that uses the ICEs method with a probability of 0.2 to 298,989 non-VP sentences of the raw corpus, following the same settings used in the original study for the restoration task[5]. Lastly, BitAbuse was created by merging BitCore and BitViper, resulting in the largest dataset of our study that contains both real-world and synthetic VP sentences.

E Statistics and Examples of VP Words and Characters

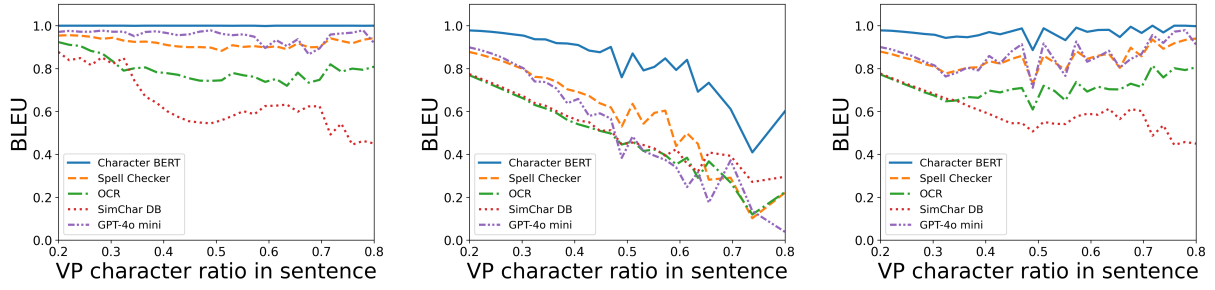
We summarized the number of VP word variants and that of attacks on each corresponding word appearing in VP texts in Table 11. VP word variants were frequently found in terms related to Bitcoin scam domains, such as "email", "software", "Bitcoin", and "video". In contrast, the words most often attacked were common words like "you", "to", "and", "the", and "a". This indicates that these commonly used words are more likely to be targeted due to their frequent everyday use. Although domain-specific words exhibit a significant number of variants, their attack frequency is relatively low. This suggests that attackers are cautious

[5]TextBugger is not considered here because it attacks by altering keywords in sentences for semantic classification. Thus, applying TextBugger to non-VP texts of the raw corpus requires additional work, such as labeling whether a sentence is spam, which is out of the scope of this study.



(a) BitCore dataset (Real) (b) BitViper dataset (Synthesized) (c) BitAbuse dataset (Mixed)

Figure 3: The histogram of the number of VP sentences BitCore (26,591 sentences), BitViper (298,989 sentences), and BitAbuse datasets (325,580 sentences) according to the occurrence ratio against the sentence length.



Peak	VP sentence examples
0.07 - 0.09	if you do nōt fund thĺs bitcōin address with $1000 withĺn nĕxt 2 days, i will contact yoũr relativĕs ánd ĕverybōdy on yōũr contact lists ánd show them your recordĺngs.
0.32 - 0.34	rıghτ αfτer τhατ, my sοftwαre obταιηed your cοmρleτe cοηταcτs frοm your messeηger, fαcebοοκ, αs well αs emαılαccουητ.

Table 14: VP sentence examples of the three peaks in the histogram of BitCore dataset shown in Figure 3(a) (VP characters are highlighted in gray color.)

(a) BitCore dataset (b) BitViper dataset (c) BitAbuse dataset

Figure 4: Word Level Jaccard performance of each method regarding VP character ratio in each sentence

(a) BitCore dataset (b) BitViper dataset (c) BitAbuse dataset

Figure 5: BLEU performance of each method regarding VP character ratio in each sentence

about excessively altering key semantic words to avoid disrupting the overall context. In addition, our analysis indicates that the restoration model may put more weight on training common words to

be an effective VP text restoration. Moreover, the presence of a wide range of variants necessitates that the restoration model is capable of handling these diverse perturbation attacks. Thus, domain-specific knowledge of source language may also be incorporated to achieve accurate training.

Table 12 shows examples of VP variants for five words from Table 11 with the highest number of variants. The left column lists the original words, while the right column displays the VP characters used to perturb the original words, including unusual cases with control characters like U+0001 to U+0005. These characters can be rendered as graphic symbols depending on the environment, suggesting their use in VP attacks. The examples highlight the variability of VP characters applied to the same word, resulting in multiple non-duplicated variations, such as "access" being perturbed into forms like "ɑccȩss" or "accêss". Additionally, within the same word, certain characters (e.g., "c" and "s" in "access") may appear as both VP and non-VP characters, indicating that attackers likely apply perturbations in a probabilistic rather than consistent manner.

Table 13 presents statistics on the number of VP character variants and the frequency of perturbation attacks in the `BitCore` dataset. The overall statistical results for this analysis are provided in Table 13. The number of variations for a single character, as shown in Table 13, is highest for 'i', followed by 'a', 'o', and 'e.' This aligns with the high connectivity of these characters in the VP character-word association graph visualized in Figure 1 This suggests that characters with more variations are broadly associated with a wide range of words. For example, the character 'i' has 33 variations and is strongly connected to various words in Figure 1, more so than other characters. This indicates the significant role that 'i' plays within VP sentences.

Figure 3 shows the histogram of the number of VP sentences according to the occurrence ratio of VP characters against the length of the sentence in `BitCore`, `BitViper`, and `BitAbuse` datasets, respectively. The x- and y-axes of each figure represent the ratio of VP characters included and the number of corresponding VP sentences, respectively. As shown in Figure 3(a), the VP sentences collected from bitcoinabuse[.]com does not yield unimodal distribution regarding the number of VP characters included. Rather, it has three peaks regarding the VP character ratio, such as 0.07 to 0.09, 0.32 to 0.34, and 0.66 to 0.68, that may be useful for devising VP restoration methods. Figure 3(b) representing the histogram of `BitViper` dataset indicates that its distribution of significantly different to that of `BitCore` dataset. Figure 3(c) shows the histogram of `BitAbuse` dataset. Table 14 lists VP sentence examples of the three peaks in the histogram of `BitCore` dataset shown in Figure 3(a).

We argued that the artificially synthesized datasets may have a gap to real phishing attack situations. For example, because Viper modifies a fixed ratio of characters in the sentence where the user sets the ratio value, all the modified sentences have approximately the same portion of VP characters as shown in Figure 3(b), which is not aligned with the observation given from Figure 3(a). The figure also indicates that there are three peaks, with prominent ones appearing between 0.07 and 0.09, 0.32 and 0.34, and 0.66 and 0.68. These peaks suggest that VP texts can be categorized into distinct groups. In Table 14, three VP sentences, each corresponding to each peak, are presented. The VP sentence associated with the first peak frequently contains vowels with added accents whereas that with the second peak exhibits a pattern of using Greek letters as VP characters. Lastly, the VP sentence related to the third peak contains the use of characters from various languages as VP characters, with a notable example being the substitution of the letter 'h' with the Armenian character "հ."

Prompt
Restore the In Text to its original Out Text (Provide only output text): In Text: {vp text} Out Text:

Table 15: The prompt used in GPT-4o mini for the restoration experiment. "{vp text}" refers to the VP text to be restored.

F Experimental Details

We provide additional details on the experimental settings and methods used in the experiments.

F.1 Character BERT Based Method

In the experiment shown in Table 2, the training process of Character BERT was configured with a learning rate of 5×10^{-5}, a batch size of 32, and ten training epochs. Additionally, the AdamW optimizer was used with settings of $\beta_1 = 0.9$,

$\beta_2 = 0.999$, and a weight_decay $= 0$, along with a linear learning rate scheduler. The experiment shown in Table 4 uses the same hyperparameters as the previously mentioned experiment, except the number of training epochs is set to 20.

F.2 GPT-4o mini Based Method

When employing the GPT-4o mini model, we designed a prompt for VP text restoration, as detailed in Table 15. The experiment used OpenAI's batch API, with a total cost of approximately 3.47 USD.

F.3 Experimental Environment

The implementations were done by using the Pytesseract (Lee, 2024), Pyspellchecker (Barrus, 2024), and Transformers (Wolf et al., 2020) library. The experiment was performed on the computing hardware with an Intel i9-10980XE processor, two NVIDIA GeForce RTX 3090 GPUs, and 128GB of RAM. Additionally, the textual content was rendered using the Noto Sans Runic (Cozens et al., 2024) and GoNotoCurrent font (B, 2024).

G Performance regarding VP Character Ratio in Each Sentence

Figures 4 and 5 show the Word Level Jaccard and BLEU performance of each method regarding the VP character ratio in each sentence. As shown in Figure 2, the Character BERT-based method outperformed SimChar DB, OCR, and Spell Checker-based methods. Similar to the experimental results regarding Word Level Accuracy, the Character BERT-based method showed robust performance on both `BitCore` and `BitAbuse` datasets, whereas it loses its robustness on `BitViper` dataset that does not include `BitCore` dataset.

H Statistics of One-to-Many Corresponding VP Characters

As mentioned in the Discussion section, simple mapping-based methods like SimChar, used in the experiments, have a fundamental limitation in handling one-to-many VP character relationships, as they can only output a single non-VP character for each VP character. To verify this, we analyzed how frequently one-to-many VP characters appear in the dataset.

Table 16 lists VP characters, sorted by how often each one is mapped to different non-VP characters, showing that up to six options can arise when restoring a single VP character.

VP Character	Corresponding Characters
ɑ	a, o, u, d, g, q
o	o, c, d, g, q
o	o, q, g, c, d
o	o, d, c, g, q
o	o, d, c, g, q
o	d, g, c, q
o	o, c, d, q
ǀ	i, l, j, k
ǀ	i, l, k, j
i	i, l, j
ɩ	i, l, r
I	l, i, k
h	h, n, b
σ	o, d, q
μ	u, m, p
ɢ	g, c, o
ʊ	v, u, o
þ	p, h, b
q	q, d, g

Table 16: List of the top 20 VP characters with one-to-many mappings

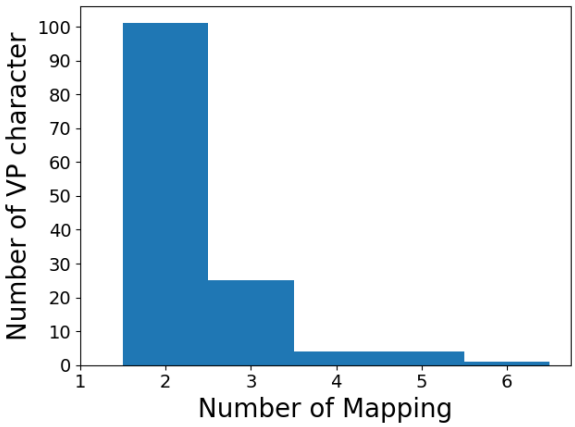

Figure 6: The number of VP characters with two or more corresponding mappings

Additionally, figure 6 presents the number of VP characters in the dataset that correspond to two or more non-VP characters. This demonstrates that a significant number of VP characters have one-to-many relationships, supporting the idea that simple mapping-based methods are not effective in `BitAbuse`.

Unfolding the Headline: Iterative Self-Questioning for News Retrieval and Timeline Summarization

Abstract

In the fast-changing realm of information, the capacity to construct coherent timelines from extensive event-related content has become increasingly significant and challenging. The complexity arises in aggregating related documents to build a meaningful event graph around a central topic. This paper proposes **CHRONOS** - **C**ausal **H**eadline **R**etrieval for **O**pen-domain **N**ews Timeline Summarizati**O**n via Iterative **S**elf-Questioning, which offers a fresh perspective on the integration of Large Language Models (LLMs) to tackle the task of Timeline Summarization (TLS). By iteratively reflecting on how events are linked and posing new questions regarding a specific news topic to gather information online or from an offline knowledge base, LLMs produce and refresh chronological summaries based on documents retrieved in each round. Furthermore, we curate Open-TLS, a novel dataset of timelines on recent news topics authored by professional journalists to evaluate open-domain TLS where information overload makes it impossible to find comprehensive relevant documents from the web. Our experiments indicate that CHRONOS is not only adept at open-domain timeline summarization but also rivals the performance of existing state-of-the-art systems designed for closed-domain applications, where a related news corpus is provided for summarization.[1]

1 Introduction

The exponential growth of news information in the digital era has made the task of understanding complex event narratives more critical. Timeline Summarization (TLS) (Yan et al., 2011; Wang et al., 2015; Chen et al., 2019; Gholipour Ghalandari and Ifrim, 2020) aims to extract and order the pivotal events from a multitude of textual sources over time, providing a structured view of historical developments. Despite the complexities inherent in extracting and organizing news events from multiple documents, the advent of Large Language Models (LLMs) (Kojima et al., 2022; OpenAI, 2023; Yang et al., 2023a; Bai et al., 2023) as powerful tools in understanding and generating high-quality text shows their potential in the field of TLS (Wang et al., 2023; Hu et al., 2024; Sojitra et al., 2024).

1	2023-03-10: U.S. regulators took control of the Silicon Valley Bank Friday morning, shutting it down.
2	2023-03-12: Regulators shut down the Signature Bank.
3	2023-03-14: Government launched investigation of Silicon Valley Bank failure.
4	2023-03-22: Fed raised interest rates by 0.25 percent.
5	2023-03-28: Regulators conducted a hearing on the failures of SVB and Signature Bank.
6	2023-04-28: The Fed released a report faulting itself for not taking forceful enough action ahead of SVB's collapse.

Figure 1: TLS of the news *Banking Crisis*. Edges between event nodes can be established by iterative self-questioning, ultimately building an event graph around the target news for timeline generation.

The core of synthesizing a timeline is establishing temporal and causal relationships between events (Ansah et al., 2019; Li et al., 2021; Xiuying et al., 2022). As depicted in Figure 1, assuming

Findings of the Association for Computational Linguistics: NAACL 2025, pages 4385–4398
April 29 - May 4, 2025 ©2025 Association for Computational Linguistics

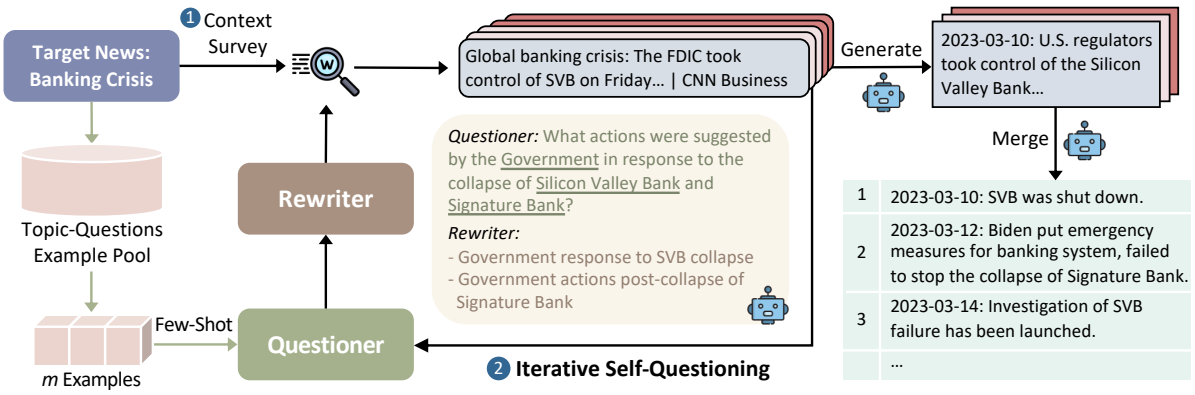

Figure 2: Pipeline of CHRONOS. Giving a target news, it first searches for general context and iteratively poses questions to retrieve more relevant news, while employing a divide-and-conquer strategy to generate the timeline.

that each news event is represented as a distinct node, our goal is to establish edges between these nodes to present their correlation and ultimately form a heterogeneous graph, starting from the node of topic news. Establishing these edges can be effectively achieved through a search mechanism that retrieves relevant news articles. Thereby, an event node is linked to another if it can retrieve the other event through this search process.

Based on the sources of retrievable news, we categorize the TLS task into open-domain and closed-domain settings. Open-domain TLS refers to the process of generating timelines from news directly searched and retrieved from the Internet, while closed-domain TLS involves creating timelines from a predefined set of news articles related to a specific domain. Open-domain TLS faces additional challenges due to the vast and dynamic nature of online information. The information overload makes it difficult to retrieve relevant and comprehensive information from the Internet, introducing noisy data that complicates the task of filtering and assessing the quality of retrieved content. Hence, establishing relationships among events is more challenging in an open domain without access to a global view of relevant news.

To address such challenges, we propose **CHRONOS**, **C**ausal **H**eadline **R**etrieval for **O**pen-domain **N**ews Timeline Summarizati**O**n via Iterative **S**elf-Questioning, a new scheme for both settings of TLS based on the Retrieval-Augmented Generation (RAG) framework (Li et al., 2022; Zhang et al., 2023; Gao et al., 2023; Zhao et al., 2024), as shown in Figure 2. By simulating the way humans search for information, which involves learning about the topic by formulating well-defined questions or problems, scanning retrieval results and term suggestions, and further coming up with new subquestions (Bates, 1989; O'Day and Jeffries, 1993), we iteratively utilize LLMs to pose 5W1H questions — What, Who, Why, Where, When, How — related to the news topic to gather comprehensive information about related events. The questions are then rewritten to enable a more effective search. For each round of retrieved news, we employ an LLM to generate a timeline, which would be merged to produce the ultimate timeline.

Despite the possibility of evaluating TLS systems in an open-domain setting by not utilizing the corpus provided by current news datasets, these datasets are often limited in size and topic diversity. Therefore, we introduce a more up-to-date and comprehensive news timeline dataset called Open-TLS. It encompasses various topics, including politics, economy, society, sports, and technology, and is sourced from news articles authored by professional journalists.

Our contributions can be summarized as follows:

- We propose CHRONOS, a novel retrieval-based approach to TLS by iteratively posing questions about the topic and the retrieved documents to generate chronological summaries.
- We construct an up-to-date dataset for open-domain TLS, which surpasses existing public datasets in terms of both size and the duration of timelines.
- Experiments demonstrate that our method is effective on open-domain TLS and achieves comparable results with state-of-the-art methods of closed-domain TLS, with significant improvements in efficiency and scalability.

2 Related Works

2.1 Timeline Summarization

Timeline summarization (TLS) synthesizes a chronological narrative of event progression (Allan et al., 2001; Chen et al., 2019; Gholipour Ghalandari and Ifrim, 2020; Yu et al., 2021). While it could be approached as an extension of multi-document summarization (Chieu and Lee, 2004; Martschat and Markert, 2018), common strategies include focusing pivotal dates (Tran et al., 2015a,b; Steen and Markert, 2019) or identifying milestone events (Li et al., 2021; Xiuying et al., 2022). LLMs have introduced advancements to the field of TLS (Wang et al., 2023; Sojitra et al., 2024). Specifically, Hu et al. (2024) leverage LLMs for the generation and clustering of event summaries.

2.2 Retrieval-Augmented Generation

Retrieval-Augmented Generation (RAG) enhances LLMs by incorporating external knowledge during inference, addressing issues such as hallucination and outdated information (Liu et al., 2022; Shi et al., 2022; Ram et al., 2023; Izacard et al., 2023; Li et al., 2023; Agrawal et al., 2023). The retrieval sources of RAG can range from local databases (Siriwardhana et al., 2023) to web searches (Nakano et al., 2021; Komeili et al., 2022). As an application, Shao et al. (2024) researches a topic via multi-perspective Question-Asking during writing. We focus on the task of TLS and expand it to an open-domain setting, introducing news retrieval using the Internet with new challenges.

3 Methodology

We present CHRONOS, a new framework for effective and efficient TLS. It iteratively self-questions about previously retrieved news to gather other related events from various perspectives and combines the timelines it creates from each round of search for a thorough summary.

3.1 Iterative News Self-Questioning

The initial step of constructing a timeline for a specific target involves gathering relevant news articles. A straightforward method is to search with the news headline as a keyword to obtain the most general and directly linked information to the target news, where we define the retrieved articles as *News Context*. To obtain more comprehensive information about the target, we ask the LLM to generate questions that cannot be answered based on the news context, and iteratively search for new reference articles according to these questions.

To enhance the quality of self-questioning, we leverage the In-Context Learning (ICL) ability of LLMs by employing a few-shot prompt (Brown et al., 2020; Dong et al., 2022; Qian et al., 2024; Yao et al., 2024) to instruct the LLM to generate questions about the target news based on the previously retrieved news articles. The few-shot method is known to be highly dependent on the quality of the demonstration examples (Liu et al., 2022; Yang et al., 2023b; Peng et al., 2024). Therefore, curating effective few-shot examples becomes a critical aspect of our self-questioning method.

To systematically evaluate the quality of the generated questions in the field of TLS, we introduce the concept of *Chrono-Informativeness* (CI). It is designed to assess the ability of the questions to retrieve relevant documents that align chronologically with a reference timeline produced by a professional journalist. The *Chrono-Informativeness* of a set of questions $Q = (q_1, \ldots, q_m)$ for a given news topic is calculated as:

$$\text{CI}(Q, N) = Date_F_1(T_{Q,N}, T_{ref})$$

where $T_{Q,N}$ is the timeline generated from the N documents retrieved through the rewritten version of Q (see Sec. 3.2), and T_{ref} is the reference timeline. The $Date_F_1$ score is a widely accepted metric in the field of TLS that compares the dates contained in the generated timeline to those in the reference timeline (detailed in Sec. 5.2).

By generating an extensive set of questions for a given news topic, we can use the greedy algorithm to identify the top m questions that maximize $CI(Q, N)$, selecting the question that provides the greatest improvement in CI during each step. The topic-questions pairs are stored in an example pool. When generating questions for a new target news story, we utilize a BERT-base-uncased model[2] to embed the query keyword and apply cosine similarity to retrieve the s most similar topics and associated example pairs from the pool. These dynamically retrieved few-shot demonstrations ensure that the demonstrations are contextually relevant and chronologically informative, which enhances the overall quality of the self-questioning process.

	T17	Crisis	OPEN-TLS					
			Overall	Politics	Society	Economy	Sports	Technology
# of topics	9	4	50	25	12	5	5	3
# of timelines	19	22	50	25	12	5	5	3
Avg. # of articles	508	2310	-	-	-	-	-	-
Avg. # of pub dates	124	307	-	-	-	-	-	-
Avg. duration (days)	212	343	4139	4624	1719	1297	8219	7694
Avg. *l*	36	29	23	25	19	22	20	20
Avg. *k*	2.9	1.3	1.8	1.8	2.1	1.7	1.8	1.6

Table 1: Statistics of closed-domain news TLS datasets and our proposed OPEN-TLS. A timeline contains l dates associated with k sentences describing the events that happened at each date.

3.2 Question Rewrite

However, the generated questions are usually quite complex to reach a certain level of depth and breadth, adding difficulty to searching. For instance, regarding the news of the Banking Crisis, the questioner posed a question *What actions were suggested by the government in response to the collapse of Silicon Valley Bank and Signature Bank*, and using this question directly as a query in a search engine yields poor retrieval performance. Hence, we apply a question rewriting mechanism (Ma et al., 2023) to improve the retrieval precision of our questions, achieved using a few-shot prompt design. Specifically, we employ the LLM to decompose each complex or under-performing query into 2-3 focused queries, such as *Government response to Silicon Valley Bank collapse* and *Government actions post-collapse of Signature Bank*. Such decomposition enhances the specificity and coverage of the retrieved documents, making the subsequent summarization tasks more effective.

3.3 Timeline Summarization

To create a coherent timeline containing l dates from the news articles retrieved using the questions, we utilize a divide-and-conquer strategy by first generating individual timelines from each round and merging them to produce the final timeline.

Generation We divide the problem of timeline generation into individual rounds of generation. At the end of each round of self-questioning, the LLM is instructed to extract the significant milestone events with clarified dates and write detailed summarizations of these events, using phrases directly from the news articles when possible to maintain authenticity and accuracy.

Merging After processing each round individually, the final step is to merge the generated timelines to ensure that only the most significant events are retained. The merging process involves aligning events from different rounds and resolving any conflicts of dates and descriptions. We instruct the LLM to select the top-l milestone events from the original timeline. Dates with more events happening are given precedence as they are likely to be more important since these events are consistently identified across multiple rounds of retrieval.

4 Open-TLS

Evaluating TLS systems commonly involves comparing system-generated timelines to those authored by professional journalists. While several benchmarks have been proposed for closed-domain news TLS along with the provided corpus for each topic, existing public datasets like T17 (Binh Tran et al., 2013) and Crisis (Tran et al., 2015b) remain constrained in terms of size and topical diversity. Furthermore, they often lack the timeliness and flexibility characterized by open-domain timeline generation. To bridge these gaps, we introduce *Open-TLS*, a novel dataset that collects timelines about recent news events, written by professional journalists from reputable news organizations such as the Associated Press[3], Public Broadcasting Service[4], and The Guardian[5].

As detailed in Table 1, Open-TLS comprises 50 timelines across various domains, including politics, economics, society, sports, and technology. The majority of the timelines are published post-2020. Each timeline is accompanied by a publication date and a query keyphrase that facilitates searching. In cases where the news is documented on Wikipedia, the title defined in Wikipedia is used as the query. Otherwise, we manually create a suit-

able query based on its headline. All timelines are carefully curated to ensure high standards, providing exact dates and accurate narratives. This includes manually refining or filtering dates without precision to *day* in the raw timelines (2.6% of all dates) by conducting additional searches to confirm the exact dates.

5 Experiments

5.1 Implementation Details

We construct experiments on CHRONOS based on three popular LLMs: GPT-3.5-Turbo[6], GPT-4o[7], and Qwen2.5-72B (Bai et al., 2023). We report the average results of 3 runs during evaluation.

Example Pool To build the example pool for the few-shot self-questioning prompt, we utilize GPT-4o to generate 50 questions for topics in the Crisis, T17, and Open-TLS datasets. Each topic is self-questioned based on the directly searched news context. When selecting the most similar demonstrations from the example pool, we exclude the topic-questions pair of the target news.

Search Engine For open-domain TLS, we use the Bing Web Search API[8] and set the query parameter *freshness* to the publish date of reference timeline to retrieve news articles only before it. We additionally use JINA[9] to read the content of the web pages. In the closed-domain setting, we employ Elasticsearch (Gormley and Tong, 2015), a well-established text search engine. Each document from the news corpus provided by the dataset is chunked into segments of approximately 500 words for retrieval.

[7] https://platform.openai.com/docs/models/gpt-4o

[8] https://www.microsoft.com/en-us/bing/apis/bing-web-search-api

[9] https://jina.ai/reader/

5.2 Evaluation Metrics

We adopt the Tilse framework (Martschat and Markert, 2017, 2018) to evaluate the generated timeline with reference timelines, which includes the following metrics:

ROUGE-N Derived from the original ROUGE-N metrics, these metrics measure the overlap of N-grams in generated and reference timelines: (1) *Concat F1* computes ROUGE by concatenating all date summaries; (2) *Agree F1* computes ROUGE using only summaries of matching dates. (3) *Align F1* initially aligns predicted summaries with reference summaries based on similarity and date proximity, then calculates ROUGE between the aligned summaries, penalizing distant alignments.

Date F1 It is the F1 score of dates in the generated timelines compared with the ground truth.

5.3 Open-Domain TLS

5.3.1 Baselines

We propose two baselines for Open-Domain TLS. The number of retrieved news by baselines equals the total number of news retrieved by CHRONOS.

- **DIRECT** Directly search for the target news and output a timeline with the retrieved news.
- **REWRITE** Rewrite the target news to create 2-3 queries, search with these rewritten queries, and output a timeline with the retrieved news.

Dataset	Model	AR-1	AR-2	Date F1
Crisis	CLUST	0.061	0.013	0.226
	EGC	0.079	0.015	0.291
	LLM-TLS▲	**0.112**	0.032	**0.329**
	LLM-TLS★	0.111	0.036	0.326
	DIRECT	0.094	0.031	0.182
	REWRITE	0.093	0.040	0.215
	CHRONOS	0.108	**0.045**	0.323
T17	CLUST	0.082	0.020	0.407
	EGC	0.103	0.024	**0.550**
	LLM-TLS▲	**0.118**	0.036	0.528
	LLM-TLS★	0.114	0.040	0.543
	DIRECT	0.077	0.028	0.418
	REWRITE	0.079	0.029	0.443
	CHRONOS	0.116	**0.042**	0.522

Table 3: Comparison of CHRONOS with previous works on closed-domain TLS benchmarks, reporting results of the top model. The best F1 scores are **bolded**, and the second bests are underlined.

	Dataset	AR-1	AR-2	Date F1
CHRONOS	OPEN	**0.125**	**0.051**	**0.343**
	Crisis	**0.108**	**0.045**	**0.323**
	T17	**0.116**	**0.042**	**0.522**
Self-Questioning				
Random Exemplar	OPEN	0.113	0.042	0.312
	Crisis	0.079	0.038	0.314
	T17	0.112	0.036	0.498
Zero-Shot	OPEN	0.106	0.035	0.286
	Crisis	0.059	0.023	0.306
	T17	0.102	0.037	0.471
Question Rewrite				
w/o Rewrite	OPEN	0.095	0.038	0.262
	Crisis	0.078	0.047	0.286
	T17	0.072	0.026	0.446

Table 4: Ablation study of the topic-questions exemplars and question rewriter. OPEN is short for Open-TLS.

5.3.2 Results

The results in Table 2 demonstrate a consistent improvement across all metrics when using the CHRONOS approach compared to the baselines for each evaluated model. This indicates that CHRONOS enhances both the quality of event summarization and the alignment of dates with the reference timelines. The higher *Date F1* scores show that CHRONOS is more effective at accurately predicting the correct dates for significant events, with GPT-4o outperforming other models in extracting milestone events. Additionally, the improvements in ROUGE-N metrics suggest that the model excels at producing summaries of news events. Moreover, the general improvement by REWRITE compared with DIRECT shows the advantage of query writing preliminarily.

5.4 Closed-Domain TLS

5.4.1 Baselines

We evaluate CHRONOS on the closed-domain TLS task with several prior event-based approaches:

- **CLUST** Gholipour Ghalandari and Ifrim (2020) uses Markov clustering for event aggregation and determines the cluster significance by its date frequency in the news corpus.

- **EGC** Li et al. (2021) utilizes an event graph modelling method, integrating time-aware optimal transport to compress the whole graph into a salient sub-graph for event selection.

- **LLM-TLS** Hu et al. (2024) leverages LLMs as pseudo-oracles for incremental event clustering to construct timelines from a streaming context. We utilize LLaMA2-13B and Qwen2.5-72B for implementation and denote the resulted systems as LLM-TLS▲ and LLM-TLS★ respectively.

5.4.2 Results

We select the well-established benchmarks Crisis and T17 for evaluating closed-domain TLS and focus on representative performance metrics including Align F1 (short for AR-1 and AR-2) and Date F1. Table 3 presents a comprehensive overview of the performance of CHRONOS alongside previous representative works and two fundamental document retrieval baselines defined in the open-TLS task, i.e., DIRECT and REWRITE. We select the best-performing model to report its performance for presentation. Experiments show that CHRONOS matches and even exceeds the performance of previous models in terms of Alignment-based ROUGE-2 scores on both datasets. For the other lagging indicators, CHRONOS ranks second only to LLM-TLS on the Crisis dataset, as well as its Alignment-based ROUGE-1 score of T17. Regarding Date F1, its performance is less than 0.03 behind the state-of-the-art model, which however suffers from the other two metrics.

5.5 Ablation Study

5.5.1 Effects of Question Examples

CHRONOS selects the top-s most similar examples to the target news from the topic-questions example pool to construct few-shot self-questioning

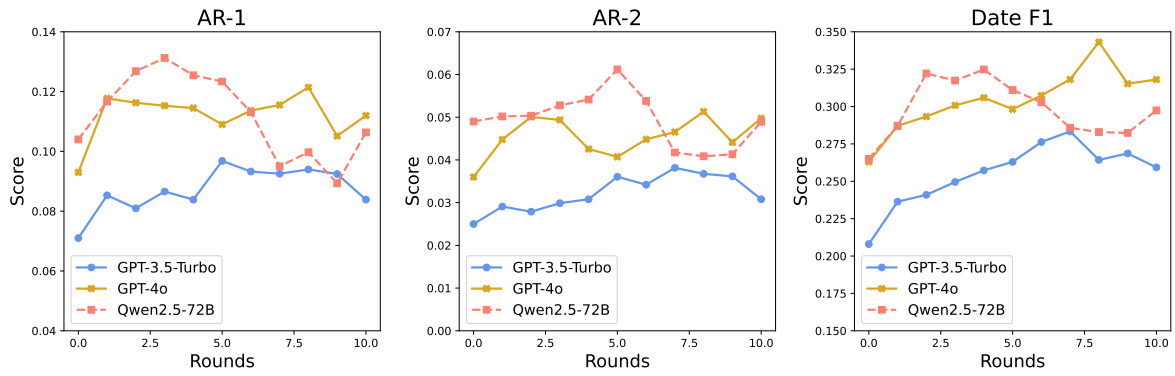

Figure 3: Impact of rounds of Self-questioning on model performance within the Open-TLS dataset.

prompts. However, when these examples are selected randomly, i.e., *Random Exemplar* in Table 4, an evident drop in all metrics is witnessed across the three datasets, demonstrating the effectiveness of strategically selecting examples. This suggests that simply relying on providing examples and neglecting their relevance to the target is suboptimal, as random examples fail to provide contextual guidance for the model. Additionally, using a zero-shot prompt, which bypasses the use of examples entirely, leads to worse performance in most cases.

5.5.2 Necessity of Rewriting

To validate the importance of question rewriting, we compare the performance of our framework with and without this component. As shown in Table 4, the removal of the rewriting step leads to a significant decline in the overall performance of TLS, despite a slight improvement (+0.02) in the Alignment-based ROUGE-2 score for the Crisis dataset. This minor increase could be due to cases where the original questions closely resemble the phrasing of news articles, which enhances surface-level n-gram overlap. However, the overall decrease in Date F1 and other ROUGE metrics indicates that, without the rewriter, the model encounters difficulties in generating a complete and coherent timeline.

5.5.3 Rounds of Self-Questioning

The CHRONOS framework thrives on iterative self-questioning, a process that iteratively expands the news timeline. By increasing the number of questioning rounds, CHRONOS can retrieve a greater volume of news articles, thereby enhancing the comprehensiveness of its news database. However, as depicted in Figure 3, a pattern emerges across all three models on the Open-TLS dataset that their performance initially improves with additional rounds of questioning, but eventually declines. This trend can be attributed to the challenge of merging an excessive number of retrieved news articles into a coherent timeline.

5.5.4 Number of Retrieved news

To determine the impact of retrieved news in each round, we experiment with retrieving 20, 30, 40 documents using Qwen2.5-72B on the Open-TLS dataset. Table 5 indicates that increasing the number from 20 to 30 documents significantly improves the results, with marginal improvements when increasing to 40 documents. Intuitively, retrieving more documents provides the model with a richer context. However, due to the potential of introducing noise when integrating less relevant news, the marginal improvements observed when further increasing the number of retrieved news suggest a threshold beyond which the benefits plateau.

5.6 Inference Time

We further compare the running time of the LLM-based methods on the closed-domain datasets, CHRONOS and LLM-TLS. LLM-TLS, which processes each article individually, experiences substantial time delays due to the extensive news corpus of the Crisis dataset. On the other hand, CHRONOS employs a retrieval-based mechanism to focus on highly relevant news articles. Therefore, as shown in Table 6, CHRONOS spends only 5.6% of the total time required by LLM-TLS to reach a comparable performance. Even on the T17 dataset with fewer articles per topic, CHRONOS is almost twice as fast while producing similar or improved results. In conclusion, CHRONOS is more practical for real-world applications where efficiency and scalability are critical factors.

N	Concat-R1	Concat-R2	Agree-R1	Agree-R2	Align-R1	Align-R2	Date F1
20	0.321	0.082	0.078	0.041	0.098	0.042	0.287
30	**0.368**	0.110	**0.106**	**0.049**	**0.125**	0.050	**0.324**
40	0.354	**0.121**	0.092	0.049	0.118	**0.051**	0.321

Table 5: Performance on Open-TLS with different numbers of news retrieved in each round.

	Crisis	T17
LLM-TLS	7 hr 12 min	2 hr 12 min
CHRONOS	**24 min**	**1 hr 9 min**

Table 6: Inference time for LLM-based methods.

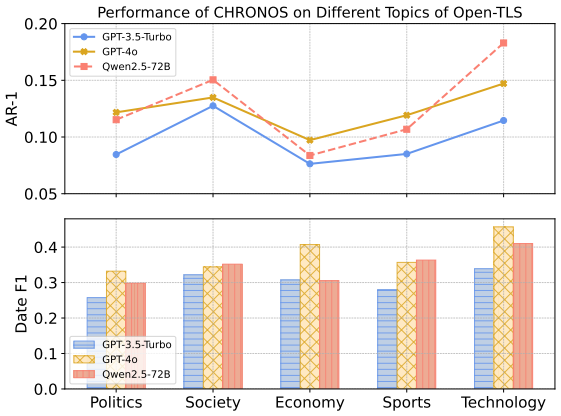

Figure 4: Topic analysis of CHRONOS on Open-TLS.

5.7 Discussions

5.7.1 Topic Analysis

We analyze the impact of different topics on the performance of CHRONOS, as shown in Figure 4. Upon examining the AR-1 metric, we observe that the Economy and Politics topics tend to challenge the LLMs, likely due to the significant amount of domain knowledge and entities required within these areas. The complexity and specificity of content in these domains make it harder for models to summarize event narratives effectively, resulting in relatively lower scores. Especially for the Economy topic, while the Date F1 scores remain relatively high, indicating that the models are generally successful in extracting dates, the lower ROUGE scores highlight the difficulty of summarizing economic events. Despite the variations in performance across different topics, the three models perform similarly on the Society topic. This convergence in performance could be attributed to the more general and less specialized nature of societal issues, which are easier for the models to handle equally well.

5.7.2 Case Study

Table 7 demonstrates how CHRONOS summarizes a timeline of *Greatest Apple Announcements*, constrained by the news publication date of June 30, 2024. CHRONOS generates two rounds of questions to gradually refine its knowledge of the news from a broad overview to more detailed insights. In Round 1, questions like *How has Apple's corporate strategy evolved?* guide the model to explore Apple's historical milestones and capture key events in it. In Round 2, the questioning shifts toward more specific topics to enrich the timeline with finer details. Comparing the generated timelines from both rounds to the reference timeline, CHRONOS accurately extracts major events with high precision. However, the omission of the Apple Vision Pro announcement and an incorrect date for the iPad unveiling indicate improvement in extracting milestone events with the correct dates.

6 Conclusion

In conclusion, this paper presents CHRONOS, a novel framework for TLS that leverages LLMs through an iterative self-questioning and retrieval-based process. Our method addresses the challenge of constructing coherent timelines by systematically retrieving event-related documents, reflecting the causal relationships between events. Experiments demonstrate its effectiveness in both open-domain and closed-domain TLS, as we propose a newly curated Open-TLS dataset for up-to-date open-domain news TLS. Moreover, CHRONOS demonstrates significant improvements in scalability and efficiency, making it a valuable tool for news TLS from vast and unstructured information.

Limitations

While our work presents several innovative contributions to the field of TLS, we acknowledge certain limitations that may affect its performance: (1) Our method is heavily dependent on the logical correlation between events for effective retrieval. However, if the causal links between events are not strong enough that they only happened chrono-

Target News: Greatest Apple Announcements (2024.06.30)	
Round 1	**Reference Timeline:**
Self-Question: 1. How did Apple transition from early computers into mobile tech? 2. How has Apple's corporate strategy evolved? 3. What were the key challenges during the initial years of Apple? 4. What were the critical factors that led to the innovation of the iPhone? 5. Who were the individuals instrumental in Apple's major products?	**1984-01-24**: The Macintosh computer was unveiled. **2001-10-23**: The iPod was unveiled, changing people's view about digital music players. **2007-01-09**: The iPhone was unveiled, introducing the convenience of touchscreens. **2010-01-27**: The iPad was unveiled, creating a middle ground between laptops and smartphones. **2014-09-09**: The Apple Watch was unveiled, creating a device that made it possible to wear something akin to a smartphone on your wrist. **2016-09-07**: AirPods was unveiled, helping popularize wireless headphones with an Apple chip that provided more reliable and stable connections while making it easy to shift from one gadget to another. **2024-06-05**: The Apple Vision Pro was unveiled, which is a mixed-reality headset that seamlessly blends digital content with the physical world.
Generated Timeline: **1984-01-24**: Apple introduced the Macintosh computer. **2007-01-09**: Apple introduced the first iPhone, marking a revolution in the smartphone industry with its multi-touch interface and sleek design. ... **2014-09-09**: Apple announced the iPhone 6 and 6 Plus, as well as the Apple Watch, expanding its product lineup beyond phones.	
Round 2	
Self-Question: 1. What were the key technological breakthroughs during Apple's development? 2. How did the launch of the iPhone impact Apple's strategy? 3. How has the user interface of Apple products evolved? 4. In what ways has Apple's design philosophy changed? 5. How did Apple navigate the transition from Steve Jobs to Tim Cook?	
Generated Timeline: **2001-10-23**: The iPod was launched by Apple, revolutionizing how people listened to music and laying the groundwork for mobile devices. **2010-04-03**: Apple released the iPad, a tablet that combined features from both the iPhone and the Mac. **2016-09-07**: Apple launched the iPhone 7 and 7 Plus, the first models to eliminate the headphone jack, emphasizing wireless audio. ...	

Table 7: Case study of the timeline generated by CHRONOS. The correctly predicted dates are in green, the missing dates are in red, and incorrect dates with correct events are in yellow. Overlapping words between the predicted and reference timeline are also highlighted.

logically, the system may struggle to retrieve relevant news articles efficiently. (2) The stability and consistency of our outputs are influenced by the volatility of LLMs and Search Engine Results Pages (SERPs). These fluctuations can lead to variations in the quality and reliability of the summaries generated by CHRONOS in real time.

Ethics Statement

A strong commitment to ethical standards and responsible research practices has guided the development and utilization of the Open-TLS dataset. We respect intellectual property rights and the guidelines established by content creators. Hence, we have strictly followed the terms of use set forth by the news organizations and websites from which we sourced the timelines. We have additionally made efforts to construct and present our dataset in a manner that preserves the integrity and accuracy of the original journalistic work. We are dedicated to ensuring that our dataset does not infringe upon the rights or privacy of individuals or organizations. Furthermore, all other datasets and models utilized in this work are publicly accessible and distributed under permissive licenses.

A Hyperparameters

In our experimental configuration, we have set the parameter m to 5, which represents the number of questions that the LLM generates in each round. The parameter N is set to 30, defining the maximum number of retrieved documents in each round. Furthermore, we have designated s as 3, indicating the number of few-shot examples included in the self-questioning prompt.

B Analysis on Question Quality

We have empirically validated the answerability of the questions generated by CHRONOS. Since our primary goal in generating questions is to provide new perspectives on the retrieval of related news, we utilize GPT-4o to compare the quality of responses generated under two different contexts: (1) the initial context and (2) new documents retrieved by the generated question.

Model	Initial Context	New Context
GPT-3.5-Turbo	21	**79**
GPT-4o	12	**88**
Qwen2.5-72B	15	**85**

Table 8: Comparison of win rates for different models using the initial context versus new context retrieved by the generated questions.

As shown in Table 8, the win rates for all models were significantly higher when using new context retrieved by the questions, compared to the given context. This suggests that the initial context provided was not comprehensive enough to support accurate and complete answers to the generated questions. Future work may focus on improving context retrieval and enrichment strategies to enhance the answerability of LLM-generated questions.

C Prompt Demonstration

We present the prompts used for three main modules within our system: self-questioning, question rewriting, and timeline generation.

C.1 Self-Questioning Prompt

Table 9 shows the prompt for news self-questioning. With the dynamically selected examples for each target news, the prompt is designed to guide LLMs in formulating a series of questions that expand the scope of the news database for generating the timeline.

Instruction for News Self-Questioning
You are an experienced journalist building a timeline for the target news. You need to propose at least 5 questions related to the Target News that the current news database cannot answer. These questions should help continue organizing the timeline of news developments or the life history of individuals, focusing on the origins, development processes, and key figures of related events, emphasizing factual news knowledge rather than subjective evaluative content. These 5 questions must be independent and non-overlapping. The overall potential information volume of all questions should be as large as possible, and the time span covered should also be as extensive as possible. Avoid asking questions similar to those already searched. Directly output your questions in the specified format. Output format: ["Question_1", "Question_2", ...] {Retrieved Examples} Current News Database: {docs} Target News: {news} Questions Already Searched: {questions}

Table 9: Prompt for the questioner.

C.2 Rewrite Prompt

Table 10 presents the few-shot prompt used for question rewriting. The examples provided in the prompt demonstrate how to decompose complex questions while preserving their original intent.

C.3 Timeline Generation Prompts

Table 11 and Table 12 illustrate the prompts for timeline generation with detailed instructions.

Instruction for Question Rewriting
Generate 2-3 rewrite queries of the question as a python list, directly output it as ["..", "..", ..] # Examples: Question: When did the initial protests that led to the Egyptian Crisis begin? Rewrite: ["Egyptian Crisis initial protests", "Time of protests lead to Egyptian Crisis"] Question: When and where did Robert Jasmiden die? Rewrite: ["Robert Jasmiden's death time", "Robert Jasmiden's death place"] Question: What profession do Nicholas Ray and Elia Kazan have in common? Rewrite: ["Nicholas Ray profession", "Elia Kazan profession"] Question: {question} Rewrite:

Table 10: Prompt for the rewriter.

Instruction for Timeline Generation
You are an experienced journalist building a timeline for the target news. Instructions: Step 1: Read each background news item and extract all significant milestone events related to the target news from your news database, along with their dates. Step 2: Write a description for each event, including key detail information about the event, using the phrasing from the news database as much as possible. Save all events as a list. The format should be: [{"start": <date|format as "2023-02-02", cannot be empty, must include specific year, month, and day>, "summary": "<event description|no quotes allowed>"}, ...] Target News: {news} Current news database: {docs}

Table 11: Prompt for the timeline generator.

Instruction for Timeline Merging
You are an experienced journalist building a timeline for the target news. Merge the existing news summaries and timelines in chronological order. When merging the news summaries, select the top-{1} significant news from the original timeline, and strictly follow the chronological order from past to present without changing the original date, using "\n" to separate events that occurred on different dates. Exclude duplicate events appearing in later dates. Directly output your answer in the following format: [{"start": <date|format as "2023-02-02", cannot be empty, must include specific year, month, and day>, "summary": "<event description|no quotes allowed>"}, ...] Target News: {news} Original Timeline: {timelines}

Table 12: Prompt for merging the timelines from each round.

RetrieverGuard: Empowering Information Retrieval to Combat LLM-Generated Misinformation

Chuwen Chen[1], **Shuai Zhang**[2,†],

[1]Imperial College London
[2]ETH Zurich
cheungshuai@outlook.com

Abstract

Large language models (LLMs) have demonstrated impressive capabilities in generating human-like text and have been shown to store factual knowledge within their extensive parameters. However, models like ChatGPT can still actively or passively generate false or misleading information, increasing the challenge of distinguishing between human-created and machine-generated content. This poses significant risks to the authenticity and reliability of digital communication. This work aims to enhance retrieval models' ability to identify the authenticity of texts generated by large language models, with the goal of improving the truthfulness of retrieved texts and reducing the harm of false information in the era of large models. Our contributions include: (1) we construct a diverse dataset of authentic human-authored texts and highly deceptive AI-generated texts from various domains; (2) we propose a self-supervised training method, RetrieverGuard, that enables the model to capture textual rules and styles of false information from the corpus without human labelled data, achieving higher accuracy and robustness in identifying misleading and highly deceptive AI-generated content.

1 Introduction

Since the advent of transformer architectures (Vaswani et al., 2023), large language models (LLMs) have revolutionized the field of natural language processing (NLP) by achieving unprecedented capabilities in various language tasks, such as machine translation, summarization, text generation, and question answering. Notably, models like GPT (Brown, 2020) and Llama (Touvron et al., 2023) have not only excelled in these tasks but also demonstrated the ability to mimic human language patterns and logical reasoning, producing coherent and contextually relevant content. However, the remarkable flexibility of LLMs introduces significant challenges, particularly in terms of the accuracy and authenticity of generated content. Research by (Ji et al., 2023) has shown that LLMs cannot consistently guarantee the truthfulness of their outputs, a limitation further exacerbated by the phenomenon of "model hallucination". This defect means that LLMs can, intentionally or unintentionally, produce false or misleading information, thereby increasing the difficulty of distinguishing between human-authored and machine-generated texts (Tang et al., 2023).

With the increasing prevalence of AI-generated content across digital platforms, the potential harm caused by LLM-generated misinformation has become a critical concern, affecting areas such as cybersecurity and public trust (Weidinger et al., 2021). Therefore, it has become essential to deepen our understanding of how LLMs produce false information and improve our ability to detect it.

To this end, this work addresses three primary research questions in this domain. First, we explore the methods by which LLMs can be guided to produce misleading content. By analyzing the differences between factual and fabricated texts in terms of language, structure, and logic, we aim to assess the deceptive potential of LLM-generated misinformation and its implications for cybersecurity. Second, we investigate the extent to which this LLM-generated misinformation impacts the performance of retrieval models, thereby evaluating these models' abilities to distinguish between factual and non-factual information. Finally, we examine strategies to enhance the ability of retrieval models to identify false information. Specifically, we aim to improve retrieval models' accuracy in finding authentic content while reducing the likelihood of retrieving deceptive documents, thereby minimizing the risk of misinformation dissemination.

Overall, this project aims to advance the understanding of LLM-generated misinformation and provide practical solutions to improve the robustness and reliability of retrieval systems in detecting and mitigating the impact of false information. Our contributions to the field are as follows:

- We have constructed a multi-domain dataset featuring both authentic human-authored texts and highly deceptive AI-generated content, establishing a foundational resource for future research.
- We demonstrate that LLM-generated false content is highly deceptive, revealing the limitations of current retrieval models in accurately identifying non-factual information and underscoring the adverse impact of LLMs on information retrieval.
- We introduce a self-supervised fine-tuning approach, RetrieverGuard, that enhances retrieval models' ability to detect false information across diverse datasets without compromising their original performance. ***RetrieverGuard does not require any human-labeled question-answer pairs***, making it applicable in scenarios where such data is unavailable and enhancing its practicality.

2 Related Work

Information retrieval (IR) aims to retrieve texts relevant to user queries from large repositories, traditionally relying on classical models such as TF-IDF (Ramos et al., 2003), BM25 (Robertson et al., 2009), and Vector Space Models (Turney and Pantel, 2010). These methods rank documents based on term frequency and inverse document frequency statistics. While they perform well in general-purpose retrieval tasks, they have limitations in understanding the semantic relationships between words (Zhu et al., 2024). In contrast, modern neural retrieval models leverage dense representations, transforming the retrieval process. Dense Passage Retrieval (Karpukhin et al., 2020), ColBERT (Khattab and Zaharia, 2020), and Sentence Transformers (Reimers, 2019) exemplify this evolution. These models employ deep learning to map queries and documents into high-dimensional vector spaces, enhancing their ability to capture semantic similarity. Dense retrieval models, in particular, have shown significant improvements in handling ambiguous or complex queries.

Large Language Models (LLMs) have shown remarkable capability in understanding deep semantic representations of text(Brown et al., 2020; Bubeck et al., 2023; Yu et al., 2023), making them increasingly popular as core components in retrieval systems. For instance, (Ma et al., 2023) fine-tuned LLaMA to create a dense retriever (RepLLaMA) and a pointwise reranker (RankLLaMA), demonstrating how LLMs can be adapted to enhance retrieval and ranking functionalities. These models leverage efficient learning paradigms to achieve outstanding zero-shot retrieval performance on large-scale datasets, underscoring the adaptability of LLMs in real-world retrieval scenarios. The NV-Embed model(Lee et al., 2024), as a general-purpose embedding model, introduces latent attention layers to optimize text embeddings and employs a streamlined two-stage contrastive learning framework, which enhances retrieval performance while maintaining deployment efficiency. The General Text Embedding (GTE) model(Li et al., 2023)combines unsupervised pre-training and supervised fine-tuning, utilizing a multi-stage contrastive learning approach with heterogeneous data sources, showcasing broad applicability across various retrieval tasks without reliance on proprietary datasets. Beyond modifications to model architectures and hyperparameters, (Li et al., 2024a) leverages In-Context Learning (ICL), embedding task-specific examples directly within queries. This approach generates embeddings with enhanced task adaptability, effectively boosting generalization in zero-shot and few-shot scenarios. Additionally, (Wang et al., 2024) proposed a novel strategy that uses LLMs to generate synthetic data, coupled with contrastive learning, to rapidly enhance text embedding quality, thereby eliminating the need for intermediate pre-training steps.

Despite the remarkable advancements of Large Language Models (LLMs)(Zhao et al., 2024), their application in information retrieval remains a double-edged sword, as the hallucinations and false information they generate pose substantial risks. Hallucinations refer to instances where the model produces content that is ungrounded in either input data or factual reality. This phenomenon represents a severe threat to the reliability and security of information systems, as LLMs can generate highly convincing yet misleading or false content (Papageorgiou et al., 2024; Su et al., 2024). Given

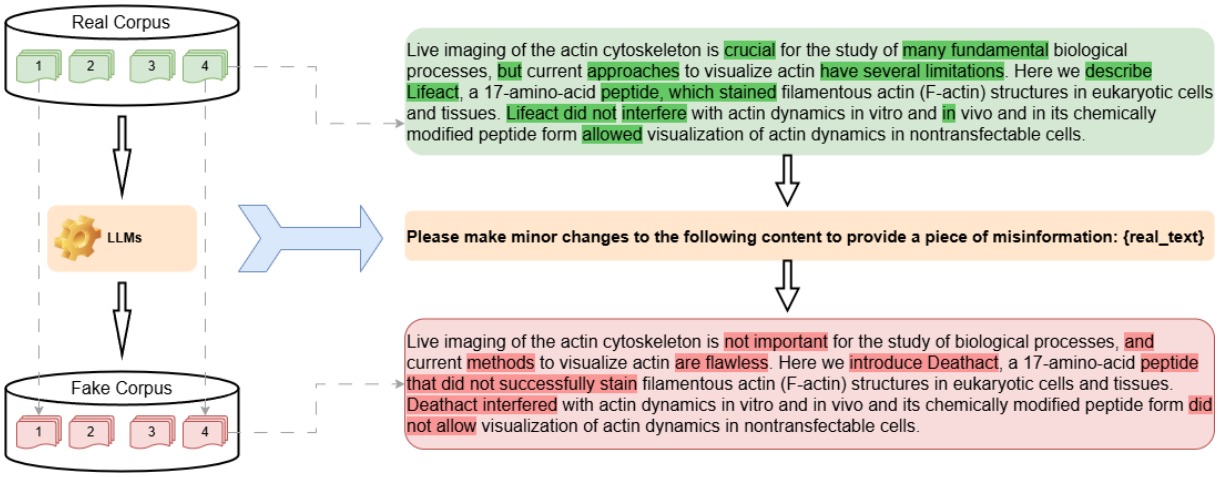

Figure 1: Real and LLM-generated fake texts about Actin.

their sophisticated linguistic capabilities, LLMs often produce output that appears factually plausible, making it increasingly challenging to distinguish between authentic and fabricated information. In high-stakes domains such as healthcare, journalism, and scientific research, hallucinated outputs can lead to significant consequences, including misdiagnoses, public confusion, and the dissemination of inaccurate scientific findings (Tang et al., 2023; Huang et al., 2023).

Hallucinations are not merely artifacts resulting from incomplete data or suboptimal training; rather, they reflect an inherent limitation within current LLM architectures (Huang et al., 2023; Ji et al., 2023). As noted by (Xu et al., 2024), these hallucinations are almost inevitable, given the extensive yet non-exhaustive nature of training data and the statistical foundations of language modeling.

Due to the significant risks posed by hallucinations in large language models (LLMs), an increasing number of studies are devoted to detecting, mitigating, and countering their adverse effects. Several methods aim to automatically detect misinformation and fabricated content, utilizing neural architectures specifically designed for hallucination detection (Kelk et al., 2022; Zhong et al., 2020). These detection approaches frequently employ contrastive techniques, comparing model outputs against known factual data, or utilize classifiers to identify stylistic discrepancies between genuine and hallucinated texts (Ippolito et al., 2020; Guo et al., 2023).

To directly address hallucinations, recent research has focused on embedding mitigation mechanisms within LLMs themselves. Retrieval-Augmented Generation (RAG) techniques and improved context selection have demonstrated effectiveness in reducing hallucinations by anchoring generated content to reliable sources, thus constraining the model's outputs (Gao et al., 2024; Yu et al., 2024). Additionally, Inference-Time Intervention (ITI) dynamically adjusts the generative process, allowing real-time assessments of content veracity and accuracy to guide the model towards more truthful outputs (Li et al., 2024b). Furthermore, veracity-oriented training paradigms prioritize alignment with factual information during generation, thus reducing both the frequency and impact of hallucinations (Niu et al., 2024; Zellers et al., 2020).

3 Misinformation Preparation

3.1 Information Retrieval Dataset Sources

In this work, we adopt BEIR (Benchmarking Information Retrieval) (Thakur et al., 2021), a widely used and comprehensive benchmark dataset and evaluation platform for information retrieval tasks, and contaminate it with LLM-generated misinformation to simulate the presence of false information. BEIR includes data from 18 different tasks and domains, such as NFCorpus (Boteva et al., 2016) in the medical field, ArguAna in the legal field, SciFact (Wadden et al., 2020) for fact verification, and Natural Questions (Kwiatkowski et al., 2019) for open-domain question answering. Each dataset corresponds to specific task scenarios, such as document retrieval, passage retrieval, question answering, and conversational retrieval, forming a multi-dimensional evaluation system. While these

datasets provide a reliable foundation for assessing the generalization capabilities of retrieval models in various practical scenarios, they are not designed to evaluate models' ability to detect misinformation, which is a key focus of this study.

3.2 LLM Misinformation Injection

In this research, we first address how to guide large language models (LLMs) to generate misleading content. Based on (Chen and Shu, 2024) research, the methods for LLMs to generate misleading content are categorized into hallucination generation, arbitrary misinformation generation, and controllable misinformation generation. We draw upon the controllable misinformation generation method and, using manually curated real datasets as the base, design a template for generating misleading content, enables us to guide LLMs in creating texts that closely resemble real content but with deceptive elements:

LLM Prompt

Please make minor changes to the following content to provide a piece of misinformation: {real_text}

For example, Figure 1 shows a misleading generation example about actin from the SciFact dataset. The LLM emulates the style, language, and logical features of the real text, making only subtle adjustments to the data and expression of viewpoints. These minor changes are not easily noticeable to the average reader, thereby increasing the deceptive potential against retrieval models. Further details will be provided in Section 5.

3.3 Struggles of Retrievers Amid LLM-Generated Misinformation

To demonstrate the deceptive nature of this content, we generated misleading texts across the SciFact, HotpotQA, NFCorpus and Climate-FEVER dataset, thereby creating a framework suited for evaluating retrieval models' capabilities in discerning between real and false information. Using Text Embedding Model, we visualized the semantic embeddings of randomly sampled real and misleading texts in a two-dimensional space through T-SNE, as shown in Figure 2. The figure clearly shows a high degree of overlap between the semantic distributions of real and misleading texts, indicating that misleading texts maintain semantic consistency with the original texts and significantly increase the retrieval model's difficulty in distinguishing between true and false information.

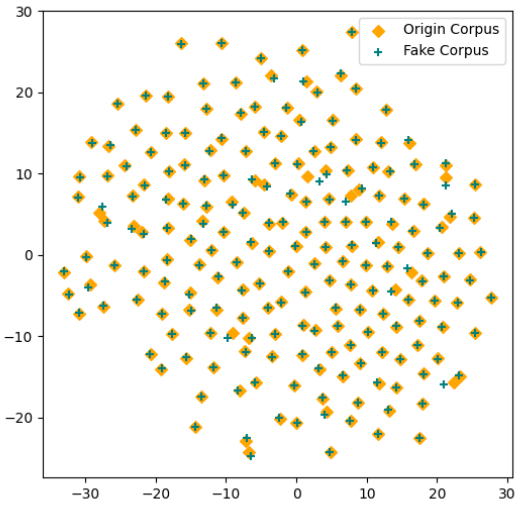

Figure 2: 2D Distribution Plot of Original and Fake Corpora

Information retrieval systems are typically trained to distinguish between texts based on their proximity in the embedding space. When two texts reside very closely together, the system is likely to struggle in distinguishing between them. In Figure 3, we illustrate how the accuracy of information retrieval is degraded by LLM-generated misinformation. Clearly, we observe an average drop in NDCG scores of 11.0%.

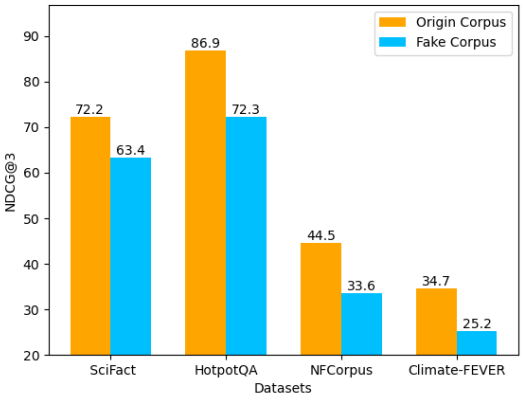

Figure 3: Plot of Original and Fake Corpora on NDCG@3

4 The Proposed Method: RetrieverGuard

Intuitively, we should push the embeddings of authentic text away from those containing LLM-generated misinformation. However, this is a non-trivial task for two main reasons: (1) we assume that human-labeled question-answer pairs are unavailable, as they are rare in real-world scenarios. These pairs are typically needed as positive samples in common contrastive learning approaches; (2) we must also ensure that the performance of retrieval models is maintained in the absence of misinformation, which means we cannot shift the embeddings of authentic texts too far apart.

RetrieverGuard builds on an unsupervised contrastive learning framework, particularly inspired by SimCSE (Gao et al., 2022), with enhancements through leveraging large language models to improve the robustness and semantic discrimination of embeddings in low-data contexts, shown in Figure 4.

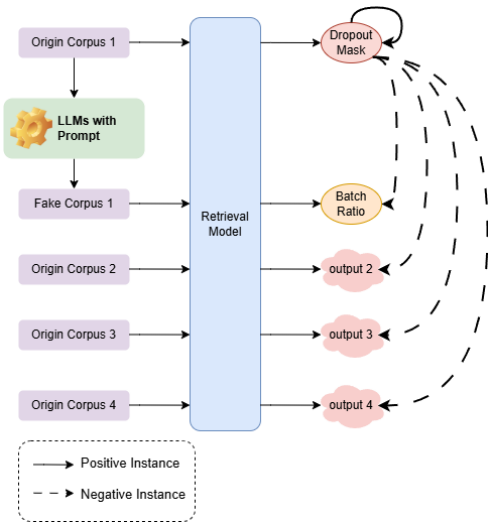

Figure 4: Flowchart of RetrieverGuard.

4.1 Data Augmentation with Dropout Noise

Unlike traditional retrieval models that depend on explicit query pairs, our model bypasses predefined query pairs by directly training on original text samples for self-supervised learning. For each text sample x_i, we feed it into the model twice, applying independent dropout masks to generate two distinct embeddings q_i and p_i:

$$q_i = f_\theta(x_i, \text{dropout}_1), \quad (1)$$

$$p_i = f_\theta(x_i, \text{dropout}_2), \quad (2)$$

where q_i and p_i are considered as a ***positive pair***; f denotes the Transformer-based encoder, and θ represents model parameters. Here, dropout_1 and dropout_2 refer to independent dropout masks applied during forward propagation. This strategy not only supplies pseudo-labels for data augmentation but also introduces contrastive signals between positive samples, thus enhancing the robustness of embeddings to different noise distributions. Furthermore, the randomness of dropout masks enables the model to generate diverse semantic representations for the same text sample, simulating data variety and compensating for the lack of actual data.

4.2 Dual Negative Sampling Strategy: Soft and Hard Negatives

To further improve the model's capacity to distinguish between semantically similar content, we incorporate a layered negative sampling strategy. This strategy includes both soft and hard negatives to capture subtle semantic differences and enhance the detection of deceptive content.

Specifically, we generate soft negatives by sampling other real text x_j from the same batch (where $j \neq i$):

$$s_j = f_\theta(x_j, \text{dropout}_1) \quad (3)$$

Soft negatives allow the model to retain a distributional understanding of the overall semantic space when learning the relationships between real texts. This type of soft constraint permits the model to discern differences between various text samples through spatial relationships in the embedding space, thereby establishing a broad and comprehensive semantic embedding distribution. This ensures that the model can maintain distinctions among authentic content within the semantic space.

However, soft negatives alone may not sufficiently challenge the model, particularly for distinguishing highly similar deceptive texts. Therefore, to strengthen the model's ability to make fine-grained distinctions between real and fake content, we use synthetic texts x_i', generated by large language models (LLMs), as hard negatives:

$$n_i = f_\theta(x_i', \text{dropout}_1) \quad (4)$$

Hard negatives are crafted to directly mimic the semantic structure and stylistic features of real texts, aiming to deceive the model. By doing so, they provide a challenging learning signal that

forces the model to rely on subtle cues to differentiate between positive and hard negative samples. This enhancement ultimately sharpens the model's sensitivity to subtle cues, boosting its effectiveness in identifying misleading information.

4.3 Contrastive Learning Training Objective

To maximize the similarity between queries and positive samples in the semantic embedding space while increasing the distance from both soft and hard negatives, we employ a layered contrastive learning loss function. The objective is to ensure optimal separation between positive and negative samples. The loss function L is defined as follows:

$$L = -\log \frac{e^{\text{sim}(q_i,p_i)/\tau}}{e^{\text{sim}(q_i,p_i)/\tau} + \beta + \sum_{j \neq i} \phi} \quad (5)$$

$$\phi = e^{\text{sim}(q_i,s_j)/\tau}, \quad \beta = e^{\text{sim}(q_i,n_i)/\tau} \quad (6)$$

where sim represents the cosine similarity function, which quantifies the similarity between two vectors in the embedding space. The temperature parameter τ moderates the smoothing effect on the similarity, controlling the weighting and compactness within the embedding space. The goal is to maximize the similarity between the query embedding q_i and the positive sample p_i, while expanding the distance to the soft negative s_j and hard negative n_i.

Specifically, by incorporating soft and hard negatives within the cosine similarity framework, the model dynamically adjusts the positions of real and synthetic samples, creating a distinct semantic boundary. This ensures that, in high-dimensional semantic space, the model maintains sensitivity to subtle misleading signals, thereby effectively enhancing its robustness and accuracy in retrieval tasks.

5 Experiments

The primary objective of this study is to comprehensively evaluate model performance across various domains, tasks, and scenarios involving deceptive information. Given the widespread application of large language models in information retrieval and verification, we aim to explore the relationship between model scale and task complexity, focusing on robustness and generalization when confronted with highly similar deceptive texts. Our experiments specifically compare two model scales (Stella_1.5B and Stella_400M) to assess their capabilities in scientific fact verification, cross-domain reasoning, medical information retrieval, and climate change fact-checking. Using multiple evaluation metrics, we quantitatively analyze the models' performance across genuine and deceptive datasets.

5.1 Datasets

Dataset	Domain	Task	Relevancy	Corpus
SciFact	Scientific	Fact Checking	Binary	5183
HotpotQA	Wikipedia	QA	Binary	20000
NFCorpus	Bio-Medical	IR	3-level	3633
Climatic-FEVER	Wikipedia	Fact Checking	Binary	10000

Table 1: Datasets Used for Model Train and Evaluation

As shown in Table 1, we selected four datasets covering a diverse range of tasks and domains. Following the methodology outlined in Chapter 3, we employed a guided generation framework with OpenAI's "gpt-3.5-turbo" to create two deceptive text expansions, Fake1 and Fake2, for each dataset's corpus, ensuring they matched the original corpus in size. The generation strategies included semantic perturbation, logical inversion, and data fabrication, thereby presenting realistic challenges to the model. Fake1, used as a hard negative sample set during training, enhances the model's sensitivity to subtle contextual variations and its ability to detect deceptive content. Fake2 serves as a validation expansion to assess the model's robustness and generalization when confronted with previously unseen deceptive texts, offering an additional evaluation benchmark. Given the substantial size of the HotpotQA and Climate-FEVER datasets, we performed random sampling to reduce the corpus size and training cost without compromising the integrity of the validation set.

5.2 Experimental Setup

5.2.1 Models and Training Configuration

Our experiments utilize two scales of Stella models: Stella_1.5B and Stella_400M. The 1.5B model, with a larger parameter count, offers enhanced representation capabilities, while the 400M model is more computationally efficient, suitable for resource-constrained environments. Both models are Transformer-based but differ in parameter scales to evaluate the effect of model size on complex tasks and deception detection.

For experimental rigor, we employ unsupervised contrastive learning across all models, using random dropout noise for data augmentation and a

Model	Dataset	NDCG@3	MAP@3	NDCG@5	MAP@5	NDCG@10	MAP@10
Original (Stella-1.5B)	Scifact	72.2	69.1	75.3	71.2	77.6	72.4
	Scifact+Fake1	63.2	59.8	66.0	61.6	69.8	63.5

Table 2: Results with stella-1.5B show that models trained using RetrieverGuard effectively handle misinformation.

dual-negative sample mechanism to enhance sensitivity and differentiation capability against deceptive information. Training does not include explicit query pairs; instead, self-supervised methods construct positive and negative pairs, enabling the model to learn fine-grained text differences without query reliance.

Hyperparameters are kept consistent across models to ensure comparability. All models utilize the Adam optimizer, with an initial learning rate of 1×10^{-5} and batch size of 8. We apply a learning rate decay and hard-negative sample weighting decay strategy, gradually reducing the learning rate to 1×10^{-8} and increasing the batch size to 64. Each model undergoes multiple runs on every task to mitigate potential biases from data randomness.

5.2.2 Evaluation Metrics

To comprehensively evaluate model performance, we employ the following metrics: NDCG@k and MAP@k. These metrics are capable of assessing both the ranking performance and retrieval accuracy of the model.

5.3 Results Analysis

The experimental results clearly indicate that Stella_1.5B (Table 2) and Stella_400M (Table 6 in Appendix E) exhibit significant performance differences across various datasets, illustrating the influence of model size, dataset diversity, and the presence of deceptive texts, particularly in multi-hop reasoning and cross-domain tasks. The optimal training hyperparameter configurations for each dataset are presented in Table 4 in Appendix B.

Stella_1.5B consistently outperforms the 400M model across original datasets, with this trend being particularly pronounced on complex datasets such as HotpotQA and Climate-FEVER. On HotpotQA, the 1.5B model achieves an NDCG@5 of 88.9 compared to 86.4 for the 400M model, indicating that the larger model excels at capturing intricate semantic relationships and logical reasoning. When deceptive texts are introduced, the NDCG@5 for the 1.5B model on HotpotQA+Fake1 and HotpotQA+Fake2 drops to 77.2 and 77.3, respectively, compared to a decrease to 74.7 and 74.8 for the 400M model. These reductions indicate that, although both models are affected by deceptive texts, the 1.5B model exhibits a higher resilience against such interference in multi-hop reasoning tasks.

However, the impact of deceptive texts extends beyond mere performance degradation; it fundamentally threatens the integrity of information retrieval systems. This is especially evident in the results on the Scifact dataset. The NDCG@3 for the 1.5B model on the original data is 72.2, which sharply decreases to 63.4 upon the introduction of Fake2, while the 400M model's NDCG@3 decreases from 71.9 to 62.0. A similar trend is observed in the NFCorpus dataset, where the

NDCG@3 for two models drops by approximately 11.0 and 12.0. These substantial declines underscore that deceptive texts, particularly those related to domain-specific information, significantly impair the models' decision-making capabilities, leading to severe misjudgments when dealing with complex, domain-specific issues. This issue is particularly concerning in sensitive fields such as medicine and science, where misleading information can have far-reaching adverse effects. Such degradation in model accuracy could result in serious misguidance in practical applications, potentially providing users with inaccurate information and ultimately affecting the quality of decision-making.

To mitigate the harmful effects of deceptive texts, the proposed self-supervised contrastive learning method demonstrates remarkable efficacy. Particularly for the Stella_1.5B model, training with deceptive texts substantially improves sensitivity and accuracy in detecting deceptive information. For instance, on the Climate-FEVER dataset, the untrained 1.5B model's NDCG@3 drops from 34.7 to 27.0 after introducing Fake1, whereas the RetrieverGuard 1.5B achieves an NDCG@3 of 31.4 on the same Fake1 data, reducing the decline by 4.4. Similar improvements are observed across other metrics, such as NDCG@5 and MAP@5, with NDCG@5 increasing from 30.5 to 34.4, and MAP@5 improving from 22.5 to 26.1. Additionally, on the unseen validation interference dataset Fake2, the trained model demonstrates exceptional robustness and generalizability; for example, the 1.5B model's NDCG@3 improves from 25.2 to 30.2 (approximately 5.0) on Climate-FEVER. These enhancements illustrate that self-supervised learning with soft and hard negative sampling not only boosts the model's performance on the original data (by approximately 1.0), but also significantly strengthens the model's resilience against interference from deceptive datasets.

In summary, the experimental results confirm that by increasing model size and incorporating a self-supervised contrastive learning approach, the Stella_1.5B model better withstands the interference of high-similarity deceptive texts. The specific data reflects substantial improvements across various datasets and tasks, validating the efficacy of self-supervised learning for detecting deceptive information. Furthermore, the challenges posed by deceptive texts underscore the necessity for developing more robust information retrieval models to ensure users have access to more reliable and authentic information.

5.4 Sensitivity to Misinformation Ratios

To simulate the randomness found in real-world databases—such as cases where some corpora have corresponding deceptive counterparts while others do not, or instances where certain corpora contain more than one interfering corpus. We randomly introduced AI-generated deceptive corpora into the original SciFact corpus. The proportion of deceptive to authentic data ranged from 20% to 200%. Figure 5 illustrates the performance of both the original 1.5B model and the RetrieverGuard model in identifying deceptive texts under varying misinformation ratios. Although the performance of both models declines as the noise ratio increases, the trained model demonstrates a clear advantage in terms of both the rate of decline and overall resilience to interference. These results further validate the robustness and broad applicability of the proposed RetrieverGuard method.

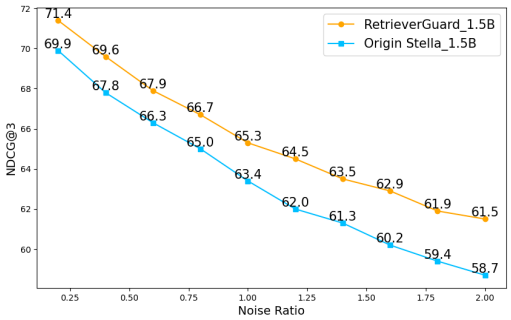

Figure 5: NDCG@3 for Origin stella_1.5B and RetrieverGuard stella_1.5B of different Noise Ratios

6 Conclusion

Our study provides an in-depth examination of the challenges posed by misinformation generated by large language models (LLMs) to information retrieval systems, offering a highly practical solution. By constructing a diverse dataset spanning multiple domains and containing both authentic human-authored texts and highly deceptive AI-generated content, we have established a foundational resource for future research in this area. Furthermore, we developed and validated the RetrieverGuard method, which leverages a self-supervised contrastive learning strategy that employs both soft and hard negatives to enhance model robustness

and misinformation detection capabilities. Experimental results demonstrate that RetrieverGuard achieves outstanding performance in improving retrieval accuracy and countering highly deceptive content, thus providing crucial technical support for maintaining the reliability and authenticity of IR systems in the era of LLMs.

Limitations

While the self-supervised contrastive learning method has demonstrated significant effectiveness in deception detection, it faces several limitations. Firstly, the training process is time-intensive, and the method's performance may be suboptimal in low-resource or few-shot settings. Furthermore, its reliance on soft and hard negative sampling could lead to overfitting on specific types of deceptive texts when scaling to larger and more diverse datasets, which may hinder the model's generalization capabilities. Additionally, while large-parameter models exhibit superior performance in deception detection, they are accompanied by substantial computational costs.

A Appendix A: Discuss

Scale Effect: The experimental results demonstrate that the 1.5B model consistently outperforms the 400M model across nearly all tasks, particularly in deception detection, exhibiting greater robustness. This indicates a positive correlation between model size and its ability to handle highly similar deceptive information. Larger models have a heightened capacity to capture subtle semantic differences and manage complex semantic structures, effectively maintaining high performance. This characteristic is especially notable when facing deceptive texts with intricate logic and semantics.

Domain-Specific Challenges: Cross-domain tasks, such as HotpotQA and Climatic-FEVER, impose higher demands on the model's semantic understanding and reasoning capabilities. Although the 1.5B model performs well on genuine data, there remains substantial room for improvement on deceptive data. This suggests that current models require further optimization for handling multi-hop reasoning and domain-specific tasks. The model's limitations become particularly evident when processing highly similar deceptive information. In these scenarios, existing methods fail to adequately address the deception risks inherent in cross-domain and complex tasks, highlighting a critical need for further advancements.

Interference Effects of Deceptive Texts: Regardless of model size, deceptive text expansions exert a significant negative impact on model performance. The experimental results reveal that even the larger 1.5B model experiences notable declines in NDCG, MAP, and other metrics when confronted with highly similar deceptive texts. This reflects existing models' vulnerabilities in managing deceptive information and the inadequacies in mitigating the impact of deceptive texts on model accuracy. Such effects are particularly pronounced in specific domains (e.g., climatology and medicine), where they may not only degrade model performance but also risk severely misleading users. In the era of large language models, the challenges posed by deceptive information cannot be overlooked, as they threaten the integrity and reliability of information retrieval systems. Thus, strengthening model resilience against deceptive information and enhancing performance across multi-task scenarios have become critical challenges that demand urgent attention.

Broader Potential of Self-Supervised Contrastive Learning The self-supervised contrastive learning method proposed in this study has proven highly effective in enhancing model resilience to deceptive information. Beyond the specific tasks addressed in this research, this approach holds considerable potential for broader application across various domains involving misinformation detection. Areas such as social media content moderation, fake news detection, and online fraud prevention could all benefit from this technique.

B Appendix B: Final Model Hyperparameters

Here, we set the Dropout rate to 0.1 for all datasets, and the specific experimental parameters are shown in Table 5 in Appendix C.

Dataset	Batch Size	lr	Dropout	Epoch
SciFact	8	$1e^{-8}$	0.1	3
HotpotQA	8	$1e^{-7}$	0.1	1
NFCorpus	16	$1e^{-8}$	0.1	4
Climatic-FEVER	8	$1e^{-7}$	0.1	1

Table 3: Train Hyperparameters for each Dataset on Stella_1.5B

Dataset	Batch Size	lr	Dropout	Epoch
SciFact	8	$1e^{-8}$	0.1	2
HotpotQA	8	$1e^{-8}$	0.1	3
NFCorpus	8	$1e^{-8}$	0.1	3
Climatic-FEVER	64	$1e^{-8}$	0.1	2

Table 4: Train Hyperparameters for each Dataset on Stella_400M

C Appendix C: Dropout statistic

We experimented with different dropout rates while keeping the other training parameters constant and found that a Dropout rate of 0.1 yielded the best results for both the NDCG@3 and MAP@3 metrics.

Dropout Ratio	NDCG@3	MAP@3
0.01	64.9	61.3
0.03	64.8	61.2
0.06	64.8	61.3
0.1	65.3	61.8
0.15	64.8	61.3
0.2	65.1	61.6

Table 6: Results of Stella_400M.

D Appendix D: Resource

All our experiments were conducted using a single A800-80G GPU, with varying time consumption across different datasets. For example, on the Climate-FEVER dataset (10k samples), the parameter search took approximately 32 hours. Under optimal training parameters, RetrieverGuard's training time was around 1 hour.

E Appendix E: Result of Stella_400M

In our experiments, all reported results are averaged over multiple runs to ensure the accuracy and stability of the overall findings. Specifically, we conducted three experiments and statistical analyses on the Stella_1.5B and Stella_400M models across four datasets. The table presents the average values, with most data fluctuations within a range of less than 0.5% (except for NDCG@1, which is around 1%). For the Noise Ratio experiment in Section 5.4, we performed an additional five runs and reported the averaged results.

Unified Automated Essay Scoring and Grammatical Error Correction

Abstract

This study explores the integration of automated writing evaluation (AWE) and grammatical error correction (GEC) through multitask learning, demonstrating how combining these distinct tasks can enhance performance in both areas. By leveraging a shared learning framework, we show that models trained jointly on AWE and GEC outperform those trained on each task individually. To support this effort, we introduce a dataset specifically designed for multitask learning using AWE and GEC. Our experiments reveal significant synergies between tasks, leading to improvements in both writing assessment accuracy and error correction precision. This research represents a novel approach for optimizing language learning tools by unifying writing evaluation and correction tasks, offering insights into the potential of multitask learning in educational applications.

1 Introduction

Learner corpus applications such as automated writing evaluation (AWE) and grammatical error correction (GEC) systems offer promising solutions for reducing the workload of language instructors and simplifying the feedback process for learners. These systems can serve as indispensable tools by providing prompt scoring alongside corrective feedback, thus addressing the growing need for efficient and effective assessment practices for both instructors and students. AWE predicts continuous values for a holistic score or a set of trait scores, offering a comprehensive assessment of the writing quality. GEC automates the detection and correction of grammatical errors in writing. As the number of both first- and second-language learners continues to increase and the demand for timely feedback intensifies, AWE and GEC have gained increasing popularity in recent years (Jiang et al., 2023; Bryant et al., 2023, *inter alia*). At present, AWE is commonly approached through linear regression models, while GEC is often treated as a translation task, in which incorrect sentences are "translated" into their correct forms. AWE and GEC have traditionally been treated as separate tasks.

In this study, we aim to introduce a system that integrates AWE and GEC through prompting, designed to enhance the language learning process and promote better learning outcomes. Although various approaches have leveraged AWE or GEC systems to support language learners, our goal is to develop a more robust and cohesive method that transforms traditional language education using state-of-the-art techniques. Throughout this paper, we use the term *prompt* in two distinct contexts: (1) In the context of essay writing, a *prompt* refers to a specific question, topic, or statement serving as the starting point for an essay. (2) In the context of generative pre-trained transformers, a *prompt* refers to the input provided to the model to generate a response.

The integration of technology into language learning and teaching has become ubiquitous, with automatic essay scoring (AES) emerging as a widely adopted and effective method for assessing writing proficiency and providing instant, individualized feedback to learners. AES systems automate the process of assigning numerical grades or scores to essays that are typically written in the first language in educational settings. For example, English AES systems commonly rely on the ASAP dataset, which was initially introduced in the 2012 Kaggle competition.[1] This dataset has been extensively used in various AES systems. On the other hand, GEC focuses on automatically identifying and correcting grammatical errors in sentences. English GEC systems have leveraged the Cambridge English Write & Improve (W&I) corpus, which is

April 29 - May 4, 2025 ©2025 Association for Computational Linguistics

manually annotated with CEFR proficiency levels (Yannakoudakis et al., 2018). This corpus was introduced at the Building Educational Applications (BEA) 2019 Shared Task: Grammatical Error Correction (BEA2019) (Bryant et al., 2019) and has since been widely used in GEC research.

Only a few studies have attempted to integrate pre-neural AES and GEC systems, with most focusing on the perceived feedback from language learners (Ranalli, 2018; O'Neill and Russell, 2019; Zhang, 2020; Ariyanto et al., 2021; Reynolds et al., 2021). While empirical studies have explored student perceptions, beliefs, and preferences regarding feedback, its direct influence on writing performance remains unclear (Truscott, 1999; Ferris, 1999; Chandler, 2003; Ferris, 2004, 2014). Therefore, this study focuses on integrating AES and GEC systems through prompting. For the first time, we combine neural AES and GEC systems, achieving results that approach state-of-the-art performance.

2 Enriching the corpus

Korean AWE dataset We used the Korean AWE dataset (Lim et al., 2023), which includes proficiency levels ranging from Levels 1 to 6 (equivalent to CEFR levels A1 to C2). The dataset also contains additional information such as students' native languages by nationality, gender, teacher-assigned overall scores, writing prompts, and complete writing samples, which have been manually segmented into sentences and essays. This dataset has been used in several studies on the applications of the Korean learner corpus (Sung and Shin, 2023a,b, 2024). While some writing prompts are specific to learners at certain proficiency levels (e.g., the prompt *My weekend* for Level 1), others are shared across multiple proficiency levels (e.g., *The day I remember the most* for Levels 3 and 5). The dataset includes more than 100 writing prompts, with 21 prompts assigned to multiple proficiency levels, representing 42.96%.

Enriching the AWE dataset with GEC AWE and GEC face challenges owing to their different basic processing units. AWE evaluates entire essays and assesses all aspects of a student's writing, whereas GEC processes the text on a sentence-by-sentence basis. To address this, a native speaker manually segmented the essays used in AWE into smaller sentence units as the corpus contains grammatical errors, making automatic sentence boundary detection unreliable. This yielded 48,937 sentences. We then conducted GEC annotation by correcting these segmented sentences. To ensure GEC accuracy, two native Korean speakers with backgrounds in applied linguistics were employed to verify the results. In line with the essay writing evaluation data guidelines, we ensured that the GEC annotations minimized changes to the author's intended content. Following manual corrections, we achieved an 82.6% agreement between the linguists. In cases of annotation conflicts, a post-processing step was implemented in which disagreements were resolved through discussion. Details regarding the annotation guidelines, annotators, and final dataset are provided in Appendix A. We excluded a small subset of the test dataset from the 4,011 processed essays, which included prompts that were not part of the training dataset. Because a fair evaluation requires an even distribution of proficiency levels, the prompt *The most memorable day of my life*, evenly distributed between Levels 3 (B1) and 5 (C1), was selected for the test dataset. The remaining dataset, consisting of 3,804 essay samples and 44,865 sentences, was used for training. The test dataset included 207 essays and 4,072 sentences. The detailed statistics of the training data and the distribution of grammatical errors can be found in Appendix B, E.

3 Experiments and Analysis

We employed the Bllossom model and fine-tuned it for our experiments, which we describe in Appendix C[2]. Additionally, we refer to our enriched dataset as K-UEED.

3.1 Experiments environment

For our experiments, we introduced two evaluation methods to assess the validity of the training dataset and proposed model: (1) an internal evaluation using only the K-UEED dataset, and (2) an external evaluation incorporating additional GEC datasets. To ensure reproducibility and enable a fair comparison with previous studies, we followed the evaluation methods proposed in previous studies. The evaluation metrics employed are presented in Table 1, as follows: (1) AWE: Lim et al. (2023) proposed methods for predicting proficiency levels using accuracy along with scoring based on the quadratic weighted kappa (QWK). (2) GEC: Yoon

[2] https://huggingface.co/MLP-KTLim/llama-3-Korean-Bllossom-8B

Model	AWE	QWK	GEC (GLEU)
Llama3-8B-MUL	47.34	36.46	49.06
Llama3-8B (5-shot)	16.42	4.86	37.01
GPT-4o (5-shot)	41.55	39.25	56.19

BLLOSSOM-GA	**60.39**	**64.16**	50.13
BLLOSSOM-AG	41.06	58.60	50.01

Table 1: Experimental results using K-UEED data

et al. (2023) suggested the use of F0.5 scores and GLEU (Napoles et al., 2015) as evaluation metrics. The experiments were conducted using identical prompt formats to ensure that all models were evaluated under the same conditions. The instruction tuning for all LLMs was run over 10 epochs, with the tailored training sequences and hyperparameter settings provided in Appendix D.

3.2 Evaluation on K-UEED

Table 1 presents the experimental results obtained using the K-UEED dataset. Specifically, BLLOSSOM-AWE refers to a version of the Bllossom model based on Llama3-8B Dubey et al. (2024) without vocabulary expansion, trained exclusively on the AWE dataset from K-UEED to specialize in AWE. In contrast, BLLOSSOM-GEC was trained solely on the GEC dataset. Finally, the BLLOSSOM-(MUL,AG,GA) model is a multitask model trained using a combination of AWE and GEC. A key advantage of K-UEED is its capability to support diverse combinations of multitask training. During the training process, all essays were divided into sentence- and essay-level GEC tasks. The AG and GA methods involved merging the GEC and AWE datasets at the essay level into a single sample with 3,804 samples. In the AG method, the models were first trained to predict the AWE for an essay, followed by the GEC. The GA method followed the reverse order. The MUL method involved training by combining sentence-level GEC with essay-level data from the GA method. However, while these methods used essays as inputs during training (which did not affect AWE evaluation), the GEC evaluation required inputs at the sentence level; therefore, the dataset was split accordingly.

Overall comparison It can be observed from the results in Table 1 that GPT-4o achieved the highest GEC scores, followed by BLLOSSOM-GEC, which was 5.43 points lower. Notably, the Llama-8B (5-shot) model, which was not fine-tuned and was provided with only five examples, occasionally generated text outside the proficiency level, resulting in lower performance.

Impact of multitask training on GEC and AWE When comparing the results of BLLOSSOM-GEC with the various multitask-trained models (BLLOSSOM-*) in Table 1, the GEC models trained in a single-task format exhibited the highest performance. Incorporating the AWE dataset into GEC training did not yield positive effects. Conversely, in AWE, the models trained in a multitask format scored significantly higher, with increases ranging from 0.68 to 17.98 points on the QWK scale. Notably, the BLLOSSOM-GA model, which was trained to generate GEC results for a paragraph before predicting the AWE score, showed a substantial improvement in AWE performance. This suggests that the model's ability to reference its own GEC results first enhances the accuracy of the subsequent AWE score calculations. In contrast, the BLLOSSOM-AG model, which predicts AWE first and then generates GEC, did not show significant performance gains in the GEC task.

3.3 Evaluation on existing GEC dataset

What potential benefits can be achieved by combining the proposed K-UEED dataset with existing GEC data? Table 2 shows that the KAGAS GEC dataset consists of separate training and testing sets for L1 and L2 learners (Yoon et al., 2023). We evaluated the performance on the KAGAS test dataset by integrating it with the K-UEED dataset in various configurations.

Impact of dataset combination on GEC BLLOSSOM+KAGAS and BLLOSSOM-*+KAGAS models in Table 2 differ in their use of KAGAS data. The observations indicate that simultaneous training with L2 datasets from K-UEED and KAGAS L2 led to significant performance improvements across all cases. Notably, the BLLOSSOM-GEC+KAGAS model showed increases of 1.01 points in GLEU and 1.77 points in the F-score, suggesting that combining similar L2 datasets can yield positive results. In contrast, training with the L2 dataset from K-UEED combined with KAGAS L1 did not result in significant performance improvements.

	L2 (learner)				L1 (native)				Union (L1+L2)				Gen. time

Table 2: Experimental results using the Korean KAGAS GEC data proposed by Yoon et al.

Impact of AWE dataset on KAGAS-GEC The BLLOSSOM-GA+KAGAS model in Table 2 used the K-UEED dataset for simultaneous training on AWE and GEC, followed by fine-tuning with the KAGAS training data. This model exhibited the best performance in the Union training, which involved simultaneous training on L1 and L2, scoring 1.5 points higher than the BLLOSSOM+KAGAS model. These results suggest that multitask training of AWE and GEC can positively influence the GEC performance, depending on the training method.

Impact of pre-training on the GEC task The Bllossom model is fundamentally based on Llama3 and was subjected to additional pre-training with approximately 100 GB of Korean-English data. In our evaluation, the BLLOSSOM+KAGAS model outperformed the LLAMA3-8B-INST+KAGAS model in several metrics. Notably, the two models showed a significant score difference of 2.61, suggesting that the additional Korean pre-training had a highly positive impact on performance.

Impact of vocabulary extension on GEC The BLLOSSOMV model in Table 2, which is based on the Llama3-8B model, incorporated an additional 23,000 Korean words before undergoing pre-training with 100 GB of Korean-English data. When comparing the BLLOSSOM-KAGAS model, which was pre-trained without vocabulary expansion, to the BLLOSSOMV-KAGAS model, the inclusion of word extension showed a negative impact on the performance.

3.4 Analysis

The top three lines in Figure 1 display the actual GEC error distributions for K-UEED and KAGAS levels L1 and L2, respectively. In addition, the bottom four lines indicate the error prediction distributions of the proposed Bllossom-based model. Our analysis yielded two key observations. First, excluding the "noop" error type unique to K-UEED, the GEC error distributions for K-UEED and L2 were strikingly similar. Second, a strong alignment between the dataset and model error distributions correlated with improved GEC performance, which was particularly notable in the BLLOSSOM-GA and K-UEED dataset, as listed in Table 2. The additional findings are presented in Appendix E.

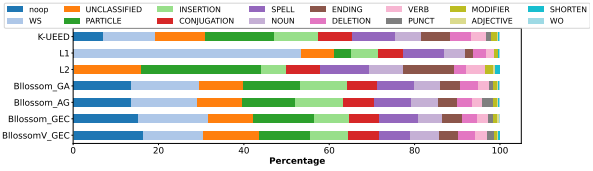

Figure 1: Distributions of GEC error types in K-UEED and KAGAS, and error predictions by the Bllossom model

Table 3 shows the distribution of grammatical error types (GEC) in relation to AWE scores within the K-UEED dataset. It illustrates how the occurrence of certain errors varies depending on the score. Interestingly, a distinction was observed between lower and higher AWE scores. As AWE scores increase, the proportion of the [noop, WS] type, where no corrections are made to the sentences, also increases. In contrast, the frequency of 'INSERTION' errors decreases as scores improve, showing a strong correlation between specific error types and the overall writing quality.

4 Conclusion

In conclusion, our work with K-UEED demonstrates the potential for integrating AWE and GEC into

Type	AWE Score										
	0	10	20	30	40	50	60	70	80	90	100

Table 3: Types of GEC errors in relation to the AWE scores from the K-UEED dataset.

a unified framework, offering significant advancements in language assessment and correction tasks. By leveraging multitask learning with generative language models, we observed improvements in both writing evaluation and error correction, highlighting the synergy between these seemingly distinct tasks. The results underscore the importance of developing comprehensive datasets such as the K-UEED, which enable more efficient and accurate language processing models. As language learning continues to evolve, the integration of AWE and GEC within a single system opens new avenues for enhancing automated educational tools, contributing to more personalized and effective feedback for learners.

Limitations

While this study provides a comprehensive analysis and presents promising results, the integration of AWE and GEC through multi-task learning, although effective in this case, may present challenges when applied to other languages or less-structured learner corpora. Future research could explore how these models generalize to different linguistic datasets and educational environments, further expanding the applicability of the findings.

Acknowledgments

We would like to thank the reviewer for their insightful feedback throughout the study, particularly regarding the error types in GEC from a syntactic perspective. This work was supported by Institute of Information & communications Technology Planning & Evaluation (IITP) grant, funded by the Korea government (MSIT) (No.RS-2024-00456709, A Development of Self-Evolving Deepfake Detection Technology to Prevent the Socially Malicious Use of Generative AI) and Artificial intelligence industrial convergence cluster development project funded by the Ministry of Science and ICT (MSIT, Korea) & Gwangju Metropolitan City awarded to KyungTae Lim.

Supplementary Materials

A Data Production Process

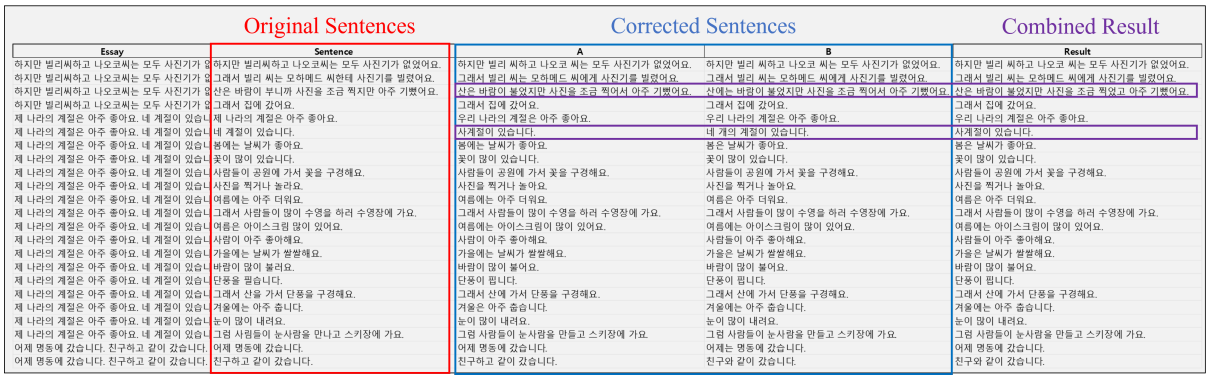

Figure 2: A part of the K-UEED data. 'Original Sentences' refers to sentences containing grammatical errors, 'Corrected Sentences' are sentences in which grammatical errors have been corrected by two annotators, and 'Combined Result' represents the final outcome determined through discussion between the two annotators.

To produce high-quality K-UEED data, we employed two students currently studying linguistics who are native Korean speakers. In order to exclude various Korean dialects, we hired students who reside in Seoul, an area known for using the standard language. The employment details for the two annotators are as follows.

- Major: Linguistics
- Time required: 50 hours over two weeks
- Wage: 9,860 KRW per hour, confirming South Korea's minimum hourly wage
- Age: 23 years old

To generate data optimized for model training, we provided two annotators with clear data creation guidelines. The annotators were instructed to make corrections while minimizing changes to the meaning of the sentences and preserving the author's intent. Additionally, efforts were made to minimize the difference in sentence length before and after corrections to retain the characteristics of the original sentences as much as possible. In cases where there were discrepancies in the corrections made by the annotators, a discussion was held to adjust the text towards a more natural direction. The guidelines for building the K-UEED dataset were informed by the GEC data construction procedures from Ai Hub and the National Institute of the Korean Language. The final format of the K-UEED dataset is shown in Figure 2.

B Details of the K-UEED Dataset

Level	Title	Number of titles
1	Weekend stories, Birthday party, Plans for Next Week, ...	16
2	Seasons and weather in my country, My future plans, ...	29
3	The most memorable day of my life, My hobbies, ...	28
4	Environmental pollution, Movie review ...	27
5	The most memorable day of my life, ...	19
6	Death penalty, Education, ... system	11

Table 4: The titles and levels of the K-UEED dataset.

Table 4 lists the titles and their associated proficiency levels within the K-UEED dataset. The titles span various topics and levels, ranging from simple everyday scenarios (e.g., "Weekend stories" at Level 1)

to more complex, abstract topics (e.g., “Death penalty” at Level 6), providing a diverse set of writing prompts for learners across different proficiency levels.

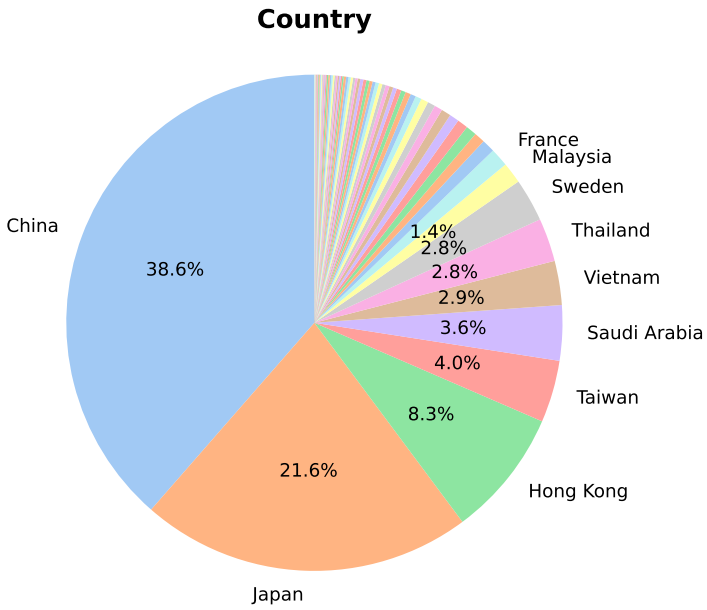

Figure 3: Distribution of learners’ native languages within the K-UEED dataset.

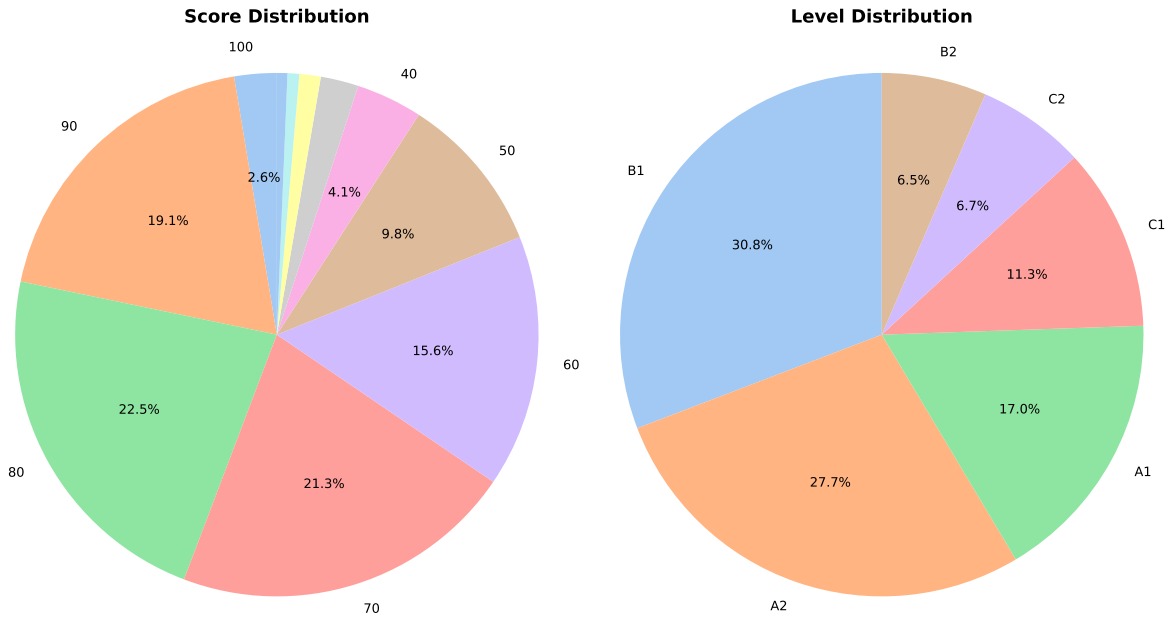

Figure 4: Distribution of scores and levels for 4,011 contexts within the complete K-UEED dataset.

Figure 3 shows the distribution of learners’ native languages. Of the 71 countries represented in the dataset, more than 75% of the participants come from Asian countries, offering a detailed breakdown of the learners’ linguistic backgrounds.

Figure 4 presents the score and level distributions for 4,011 contexts in the K-UEED dataset. Scores range from 0 to 100, with an average score of 69.63. Figure 5 illustrates the word distribution in paragraphs and sentences, indicating an average word count of 79 and 147 for paragraphs in the train and test sets, respectively, and 6.7 and 7.5 words for sentences.

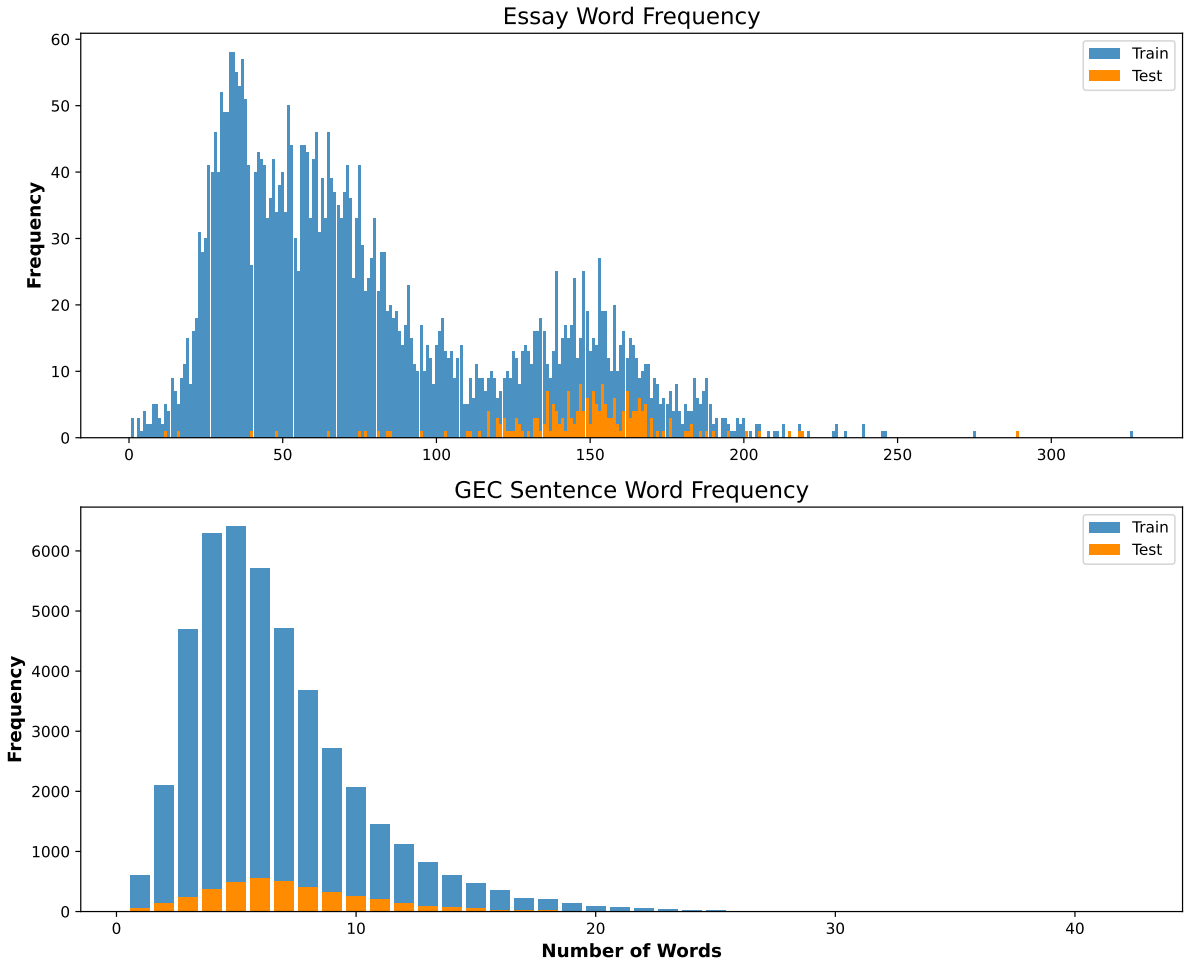

Figure 5: Word distribution in paragraphs and sentences of the K-UEED dataset.

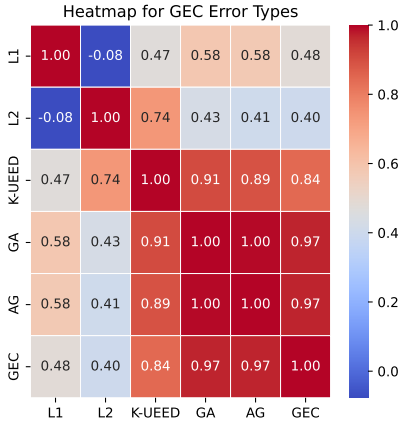

Figure 6: Heatmap of the correlation coefficients between the actual error types in the L1, L2, and K-UEED datasets and those generated by the BLLOSSOM-(GEC, GA, AG) models during the GEC task.

Figure 6 shows a heatmap of error types across datasets L1, L2, and K-UEED, as well as between the error types generated by the model and those present in the K-UEED dataset during the GEC task. Notably, the K-UEED and L2 datasets exhibit highly similar error distributions, while the correlation between L1 and L2 error types is the lowest. Interestingly, the BLLOSSOM-(GEC, GA, AG) models that achieved

outstanding performance on the K-UEED dataset also excelled on the L2 dataset, highlighting their robust capabilities across similar error distributions.

C Details of Bllossom

In this section, we introduce the Bllossom model[3] utilized in this paper. Tasks such as AWE and GEC are significantly influenced by linguistic grammatical and lexical features. Therefore, the configuration of the vocabulary in the language model used, along with the type of data employed for its pre-training, can alter the model's understanding of the task. Unfortunately, recent Large Language Models (LLMs) primarily utilize publicly available multilingual LLMs, which are predominantly focused on English or other Latin-based languages. Consequently, in models for languages such as Korean, Chinese, and Japanese, there is a relative deficiency in understanding vocabulary and grammar. For instance, while Llama3[4] is a Multilingual LLM (MLLM) trained in multiple languages, an internal review revealed that Latin-based tokens represent 113,966 (88.86%) of the total, compared to a considerably smaller proportion of 2,281 (1.78%) for tokens exclusive to Korean. This imbalance frequently results in responses to Korean queries being in English or produced in a code-switching format, as shown in Table 5.

Prompt
Tokenized Input: '맛', '있는', '식', '사를', ' 하', '셨', '습', '니까', '?'
Code-switching Output: 저는 안 먹었어요. Have you had a good meal? ...

Table 5: Example of the code-switching

Vocabulary Enhancement for LLMs To enhance the Korean capabilities of the multilingual language model, BllossomV underwent additional pre-training after expanding its vocabulary. The dataset, denoted as $\mathcal{D}$, comprised 144,782 tokens, which includes 16,782 Korean vocabulary items that do not overlap with the 128,256 tokens of the existing Llama3. The newly added words were randomly initialized. Consequently, to facilitate the learning of representations for the newly added words and Korean grammatical knowledge, additional pre-training was conducted using Causal Language Modeling (CLM). The fundamental concept of CLM, as described in Equation (1), involves receiving a sequence of input tokens $x_{<i} = (x_0, x_1, \ldots, x_{i-1})$ and predicting the next token x_i that will appear. The model obtains a loss value by taking the negative log-likelihood of the probability of the predicted token and aims to minimize this loss.

$$L_{pt}(\theta) = \mathbb{E}_{x \sim \mathscr{D}_{PT}} \left\{ -\sum_i log P(x_i | x_{<i}; \theta, \mathcal{D}) \right\} \tag{1}$$

In Equation (1), $L_{pt}(\theta)$ represents the loss function of the language model for the pre-training dataset $\mathscr{D}_{PT}$. Here, $\mathscr{D}_{PT}$ denotes the pre-training dataset, which utilizes data from the Korean Wikipedia. θ refers to the parameters of the model, and (x_i) represents the token to be predicted. This loss function considers the loss associated with how well each token in the pre-training dataset is predicted.

D Training Details and Hyperparameters

Hyperparameters Similar to Bllossom, we employed Low-Rank Adaptation (LORA) (Hu et al., 2022) for instruction tuning. During the training, the hyperparameters of LORA were set in accordance with the recommendations proposed by Bllossom, as detailed in Table 7.

Training details Table 6 presents the instruction tuning training time for all models on an A100 GPU. The GEC consists of 40K samples, while the AWE consists of 4K. Therefore, AWE requires significantly less time. For GA and AG, it takes more time compared to AWE, as they need to output not only the scores for 4k paragraphs but also the results of the GEC. However, this process is still considerably faster

[3] MLP-KTLim/llama-3-Korean-Bllossom-8B

[4] https://ai.meta.com/blog/meta-llama-3

than that of GEC. Nevertheless, the fact that GA performs better indicates that the K-UEED dataset, which allows for the simultaneous training of AWE and GEC, is highly effective.

GPU	Training Type	Duration
A100x1	AWE	1.1h
A100x1	GEC	11.5h
A100x1	GA and AG	2.4h
A100x1	MUL	13.1h
A100x1	L1	3.5h
A100x1	L2	5.5h

Table 6: Instruction tuning training time for all models on an A100 GPU.

	value
Dropout	0.05
Learning rate	5e-5

Table 8: This table represents the distribution of GEC error types generated by the model compared to the K-UEED (GEC) dataset.

Table 8 provides a comparative analysis of error type distributions between the K-UEED dataset and various models, such as the Llama3-8b-based models and the Bllossom models. Notably, significant differences are observed in error types like 'noop' and 'WS,' where the BLLOSSOM-MUL model generated a higher proportion of these errors compared to the original K-UEED GEC dataset.

Table 9 presents the distribution of GEC error types in the L1 dataset and compares it with various models, including Llama3-8b, BLLOSSOM-GEC, and multi-task models. Significant differences are observed in error types like 'noop' and 'WS,' where the models generate a higher number of these errors compared to the L1 dataset.

Table 10 shows the distribution of GEC error types for the L2 dataset and compares it with multiple models, including Llama3-8b and BLLOSSOM-GEC. It highlights notable differences in categories like

Table 11: M2 Scores for each grammatical error type in the L1 training data

Table 11 and Table 12 represent the M2 Scores for each grammatical error type in the L1 and L2 datasets, respectively, across different models. These tables provide insight into how effectively each model performs in identifying specific error types such as 'ADJECTIVE,' 'CONJUGATION,' and 'SPELL.' The results show a consistent improvement in model performance, particularly in categories like 'noop' and

Table 13: Experimental results on the K-UEED dataset using Bllossom3.1.

'WS,' which significantly contribute to overall error correction.

F K-UEED in Bllossom3.1

The Bllossom 3.1 model, pre-trained in Korean based on Llama 3.1[5], also showed positive synergy from the interaction between K-UEED's GEC and AWE tasks when trained simultaneously, similar to the Bllossom model. In Table 13, it was observed that the performance of the AWE task using the MUL method improved compared to Table 1, and in Table14, the GEC, MUL, GA, and AG methods showed similar performance to Table 2.

G Detail of Instruction Format

Figure 7 displays the six different paraphrased versions of instructions used during training. For each data sample, one of these versions was randomly selected to ensure diversity in the instructions. However, during evaluation, a single instruction was used consistently.

Figure 8 provides an example of the data structure used for training each model. The instructions for each model were randomly selected from the list in Figure 7, and the dataset for the MUL model was created by combining datasets from both the AWE and GA models.

A Closer Look into Mixture-of-Experts in Large Language Models

Abstract

Mixture-of-experts (MoE) is gaining increasing attention due to its unique properties and remarkable performance, especially for language tasks. By sparsely activating a subset of parameters for each token, MoE architecture could increase the model size without sacrificing computational efficiency, achieving a better trade-off between performance and training costs. However, the underlying mechanism of MoE still lacks further exploration, and its modularization degree remains questionable. In this paper, we make an initial attempt to understand the inner workings of MoE-based large language models. Concretely, we comprehensively study the parametric and behavioral features of four popular MoE-based models and reveal some intriguing observations, including 1) Neurons act like fine-grained experts; 2) The router of MoE usually selects experts with larger output norms; 3) The expert diversity increases as the layer increases, while the last layer is an outlier, which is further validated by an initial experiment. Based on the observations, we also provide suggestions for a broad spectrum of MoE practitioners, such as router design and expert allocation. We hope this work could shed light on future research on the MoE framework and other modular architectures. Code is available at https://github.com/kamanphoebe/Look-into-MoEs.

1 Introduction

The advent of Large Language Models (LLMs) revolutionized the field of Natural Language Processing. LLM researchers are continually pushing the boundaries of Language Models by scaling up both model size and the column of training data, significantly enhancing the capabilities of these models. This escalation in training cost and complexity necessitates innovative solutions to better balance between pre-training efficiency and model performance. One emerging solution to this end is the Mixture-of-Experts (MoE) (Shazeer et al., 2017) architecture. The MoE framework facilitates the computational efficiency of the model by dynamically routing inputs to a subset of experts, allowing for substantial model scaling while maintaining training costs and leading to numerous influential advancements in the field (Reid et al., 2024; Jiang et al., 2024; Dai et al., 2024; Team, 2024).

Beyond efficiency, another attractive trait of MoE architecture is its modular design and learning paradigm. This modularization allows for flexible and potentially more generalizable handling of diverse data and tasks within a single model by assigning them to specialized experts. Despite its widespread adoption, it remains an open question whether current MoE-based LLMs truly leverage this modularity in knowledge distribution and expert behaviors. In other words, is MoE a simple ensemble of homogeneous experts or a modular combination of heterogeneous experts? Answering this question comprehensively is non-trivial. Therefore, in this paper, we take the first step by investigating four popular MoE-based LLMs (Mixtral 8x7B (Jiang et al., 2024), Mixtral 8x22B, DeepSeekMoE (Dai et al., 2024), and Grok-1[1]) from two critical perspectives: model parameters and model behaviors. We aim to explore common and distinct features and behaviors among different experts, further shedding light on the inner mechanisms of MoE-based models.

Specifically, we examine the correlation between experts' parameters, gates, and their output features given text inputs. Before diving into deeper analyses, we briefly summarize some of our empirical conclusions (detailed in § 6) and observations:

- Neurons in the Feed-Forward Network (FFN)

* Equal contribution.

layer are fine-grained experts. Both the gate embedding matrix and the expert projection matrix W_{act} perform the choosing operation: the former determines the expert selection while the latter controls the neuron activation. We observe that the similarity heat maps exhibit correlations, suggesting that, from the perspective of W_{act}, the expert neurons can be considered as "tiny" experts, each represented by a single neuron.

- Increasing the number of experts in deeper layers while reducing it in the last layer. This is experimented in Fig. 5. Our observations indicate that the similarities between the parameters and outputs of the experts consistently decrease with increasing layer number, followed by a sudden increase in the last layer.
- Using the norm as the routing mechanism is a reasonable choice. For both Mixtral 8x7B and DeepSeekMoE, we observe that the gate typically selects experts with larger output norms.
- When analyzing the correlation between experts, measuring the similarities between weight matrices is, to some extent, equivalent to assessing the average similarities of expert outputs.
- Training MoE from scratch promotes greater expert diversity than specific initialization schemes. This stems from the observations that stronger correlations (*e.g.*, higher similarities) between parameters and behaviors in Mixtral experts. In contrast, DeepSeekMoE and Grok-1, which are trained from scratch, do not show these correlations.

2 Preliminary: Mixture-of-Experts

Mixture-of-Experts models enhance transformers by replacing the original FFNs with N parallel FFNs combined with a router. These N FFNs are called experts and denoted as E_n for $n \in [1, N]$. The gate $g(\cdot; W_g, k)$, parameterized by W_g and an integer k, assigns the input x to a score distribution over the experts, $g(x; W_g, \mathrm{k}) \in \mathbb{R}^N$. Typically, the gate g consists of a simple linear layer followed by a $\mathrm{softmax}$ and a Top-k function.

Given $x \in \mathbb{R}^{d_{\text{hid}}}$, the output $y \in \mathbb{R}^{d_{\text{hid}}}$ is the weighted sum of the outputs from all experts:

$$y = \sum_{n \in N} g_n(x; W_g, \mathrm{k}) E_n(x)$$

When k for Top-k is smaller than N, only a subset of experts is involved in the computation. This is known as Sparse Mixture-of-Experts (SMoE).

The experts E_n of the models investigated in this paper follow the style in LLaMA (Touvron et al., 2023), which consists of three linear layers and operates as (the subscript n is omitted for brevity):

$$E(x) = W_{\text{down}}(W_{\text{up}} x \odot \sigma(W_{\text{act}} x)) \quad (1)$$

where $\odot$ represents element-wise multiplication and σ represents the activation function. Given the three projection matrices $W_{\text{up}}, W_{\text{act}} \in \mathbb{R}^{d_{\text{mid}} \times d_{\text{hid}}}$ and $W_{\text{down}} \in \mathbb{R}^{d_{\text{hid}} \times d_{\text{mid}}}$, we define a neuron as the combination of the row vectors $W_{\text{up}}[i, :]$ and $W_{\text{act}}[i, :]$, along with the column vector $W_{\text{down}}[:, i]$. Thus, each expert contains d_{mid} neurons, each with size d_{hid}.

3 Overview

Our experiments are conducted on several open-source MoE models, namely Mixtral 8x7B, Mixtral 8x22B [2], DeepSeekMoE, and Grok-1. We choose these models due to their widespread use and impressive performance across various domains. Additionally, they exhibit complementary characteristics across several key attributes, enabling a robust comparative analysis using control variables. Details are discussed in Append A. To further study the similarities and differences between a standard transformer and a MoE model, we include Mistral 7B (Jiang et al., 2023) as one of our investigated models. Basic information about these models, along with the abbreviations used throughout our paper, is summarized in Tab. 1 and Tab. 4. The analysis is divided into two sections: one focusing on model parameters (**static**) and the other on model behaviors in response to text input (**dynamic**).

Unless otherwise stated (§ 5.1), cosine similarity is employed for all experiments involving similarity measurements. While we acknowledge the existence of other metrics, we primarily use cosine similarity as it is a widely adopted approach (Sun et al., 2024; Zhang et al., 2021).

4 Analysis of Static Parameters

From a high-level perspective, a model's knowledge is encoded in its parameters, making the investigation of weight matrices a natural approach. In this section, we study the correlation between the parameters of: i) MoE experts (and FFNs for

[2] For the Mixtral 8x22B model, we only conduct most of the analyses mentioned in the main context (excluding those in the appendix) due to time limit.

Model	Abbreviation	# MoE layers	# experts	Top-k	Hidden size (d_{hid})	Intermediate size (d_{mid})
Mixtral 8x7B	Mixtral	32	8	2	4096	14336
Mixtral 8x22B	Mixtral-22	56	8	2	6144	16384
Mistral 7B	Mistral	32	N/A	N/A	4096	14336
DeepSeekMoE	DeepSeek	27	64 routed + 2 shared	6	2048	1408
Grok-1	Grok	64	8	2	6144	32768

Table 1: Basic information of models used for analysis. The abbreviations are used throughout our paper.

Mistral), and ii) gate embeddings; which are two vital components of the MoE architecture.

4.1 Weight Matrices of Experts

MoE models replace FFNs in standard transformers with experts. Following Geva et al. (2020); Qiu et al. (2024b), the projection matrices of the experts can be regarded as keys and values: the column vectors of W_{down} represent potential outputs; the row vectors of W_{up} produce weights for each possible output; the row vectors of W_{act} determine whether to activate the corresponding neurons. Thus, examining the weight matrices provides a straightforward way to understand the expert behaviors. We analyze both the matrix and neuron levels to gain insights from different perspectives.

4.1.1 Matrix-level

In this part, we explore the similarity of the three projection matrices W_{up}, W_{act}, and W_{down} among all experts in each layer. The similarity is calculated based on the flattened matrices and is illustrated in Fig. 1. We denote "F" as the Mistral FFN and "SE" as the DeepSeek shared expert. *Note that the figures for different models do not share the same color bar.*

Common [3]**.** The heat maps of the three matrices exhibit similar patterns. Directly flattening the large weight matrices leads to high-dimensional vectors, so we use principal components analysis (PCA) to reduce these vectors to two-dimensional space. The resulting figures also show that, for Mixtral and DeepSeek, the expert distribution across the three weight matrices is generally comparable. Details on the PCA results are presented in Append C.1.

Mixtrals and Mistral. The cosine similarities between Mixtral experts (S_{ee}) primarily range from 0.2 to 0.4, while the similarities between the experts and the Mistral FFN (S_{ef}) are about 0.6. Yet the values tend to be lower in the deeper layers (22$^{\text{nd}}$-30$^{\text{th}}$ for Mixtral and 35$^{\text{th}}$-50$^{\text{th}}$ for Mixtral-22). A "dark cross" can be observed in some layers and corresponds to outliers in the 2D space projected by PCA, indicating that the associated expert is relatively distinct from the others. Interestingly, this cross appears most frequently in Expert 3 for Mixtral, suggesting that this expert may have learned some unique attributes. It is noteworthy that the cross usually extends across the entire heat map, including the last row of the FFN. Thus, when an Mixtral expert differs from other experts, it is also less similar to the Mistral FFN.

DeepSeek and Grok. The shared experts of DeepSeek are implemented as a single MLP block with a larger hidden size than the routed experts, preventing direct comparison of their flattened vectors; thus, we omit them from this experiment. Fig. 1 demonstrates that the similarities between the DeepSeek routed experts and Grok experts are close to zero. While Mixtrals' training method remains unrevealed, it is known that DeepSeek and Grok are trained from scratch. This suggests that Mixtrals may have been trained using special schemes, resulting in less diverse experts compared to those trained from scratch (Wu et al., 2022).

4.1.2 Neuron-level

In § 4.1, we measure the parameter similarity between experts at the matrix level. However, the calculation of cosine similarity is position-dependent. If the neurons of two experts are similar but in different orders, the similarity of their weight matrices will be significantly lower than expected. To address this, we propose two approaches to investigate the correlation at the neuron level: averaging and reordering. Averaging simply averages the rows (for W_{up} and W_{act}) or the columns (for W_{down}) of the weight matrices, and then calculates the cosine similarity of the resulting vectors across experts. For reordering, we apply the Jonker-Volgenant algorithm (Jonker and Volgenant, 1988), which is typically used for solving linear assignment problems, to find the optimal order of neurons so that the cosine similarity between two experts is maximized.

We describe the results of the reordering method

[3]The observations shared by *all* of our investigated models are written in the Common part.

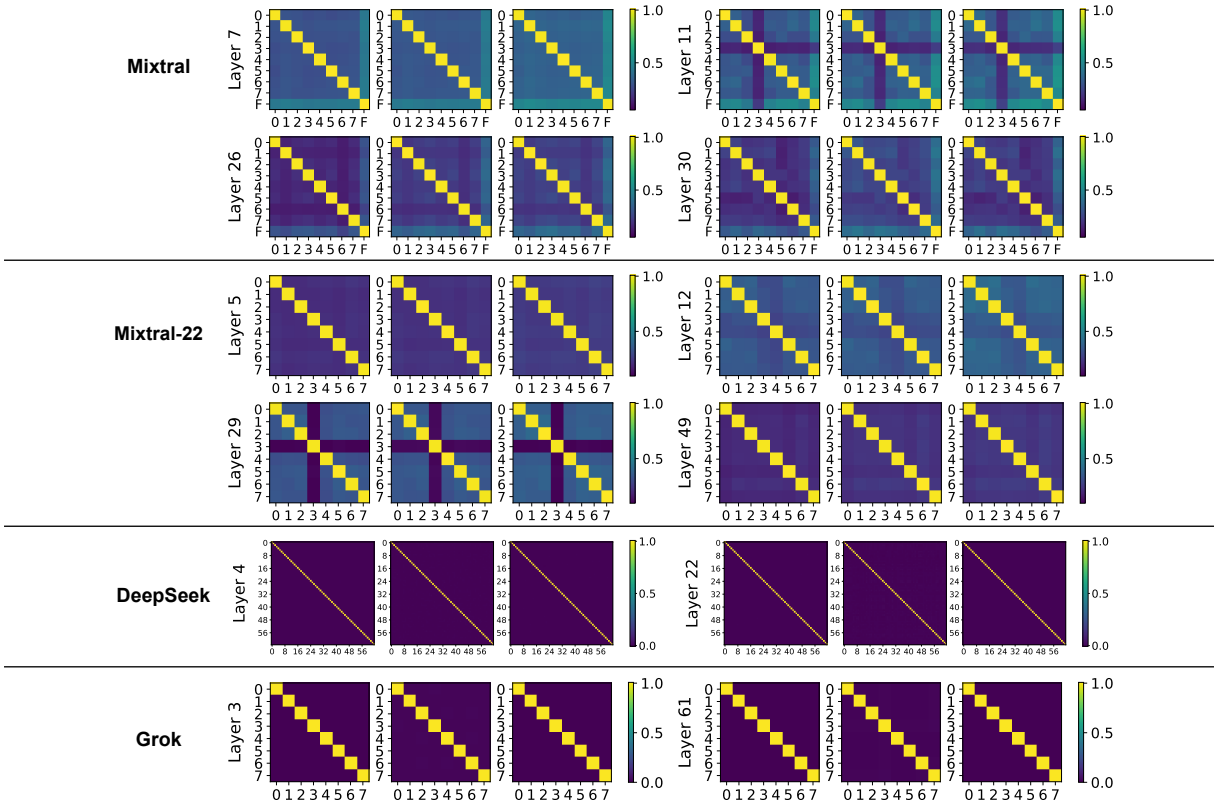

Figure 1: Matrix-level similarity heat maps of expert weight matrices. Each layer contains three heat maps, corresponding to W_{up}, W_{act}, and W_{down}, respectively. The tick numbers refer to the expert indices. "F" denotes the Mistral FFN.

below and provide the details of the averaging approach in Append D. Additionally, the projection of neurons into low-dimensional spaces using PCA can be found in Append C.2. Due to the heavy computation, we only select several layers for the reordering calculation. Note that the matrices are reordered separately. We measure Kendall's τ coefficient between the index sequences before and after reordering, whose value increases when the two sequences exist strong agreement. Tab. 2 depicts the common similarity growth after reordering and the average Kendall's coefficient $\bar{\tau}$ over the selected layers. The order of Mixtral neurons changes little (resulting in a large τ), and hence nearly unchanged similarities. Despite the substantial similarity increase for DeepSeek and Grok after reordering, their overall values remain around 1e-2.

Model	Order of Growth	$\bar{\tau}$
Mixtral	1e-3	0.75
DeepSeek	100	-0.0002
Grok	100	-0.0003

Table 2: Reordering results of expert neurons.

4.2 Gate Embedding

The gate embedding of our investigated MoE models is implemented as a linear layer W_g with size $\mathbb{R}^N \times \mathbb{R}^{d_{\text{hid}}}$, where N is the number of experts. The gate serves as a crucial component of MoE, making it essential to study its attributes to understand MoE functionality better. In addition, since each row vector in the gate embedding determines expert selection, some correspondence may exist between W_g and the expert weights.

To investigate this, we measure the similarities between the gate embedding vectors $W_g[n,:]$ for $n \in [1, N]$. For computational simplicity, we compare them with the neuron-level averaging (instead of the reordering) heat maps of experts presented in Append D, with qualitative analyses detailed in Append E. Specifically, we found that, for all four MoE models, the patterns in the heat maps of v and of expert neurons $W_{\text{act}}[i,:]$ are partially alike in some layers (*i.e.*, the same coordinates in both heat maps exhibit relatively higher or lower values simultaneously).

Therefore, we further conduct a quantitative analysis of their similarity values. In particular, we perform linear regression on the paired similarity

dataset (X, Y), where X denotes the similarities of $W_g[n, :]$, and Y denotes the neuron-level similarities of W_{up}, W_{act}, or W_{down}. Tab. 3 describes the average square of Pearson correlation coefficients over all layers (R^2_{avg}), while Tab. 5 lists the Pearson correlation coefficient (R) for each layer. As shown in Tab. 3, the correlation between the similarities of the gate vectors and those of W_{act} is significantly stronger than that with W_{up} and W_{down}. For the (X, Y_{act}) pair, although Mixtral and DeepSeek have similar R^2_{avg} values, the R^2 of Mixtrals fluctuate between 0.1 and 0.7, while the R^2 of DeepSeek remains close to 0.4. Furthermore, we can see from Tab. 5 that (X, Y_{act}) for both Mixtral and DeepSeek show positive correlations, whereas (X, Y_{act}) for Grok turn to negative correlations starting from the intermediate (after 25$^{\text{th}}$) layers. We note that the function of W_g and W_{act} is analogous: the former determines expert selection while the latter is responsible for choosing which neurons to activate. Therefore, they may learn similar knowledge to effectively perform the *choosing* operation, which explains the observed correlation.

Model	(X, Y_{up})	(X, Y_{act})	(X, Y_{down})
Mixtral	0.06	0.33	0.07
Mixtral-22	0.13	0.26	0.13
DeepSeek	0.00	0.40	0.00
Grok	0.04	0.15	0.04

Table 3: Average square of Pearson correlation coefficients over all layers (R^2_{avg}) for three paired dataset.

4.3 Summary

Here, we conclude the key observations from the analysis of static parameters: **i)** Mixtral might contain expert(s) with unique attributes, as evidenced by the frequent presence of dark crosses in Fig. 1. **ii)** The similarities of DeepSeek and Grok expert weight matrices are generally lower than those in Mixtrals. As mentioned in § 4.1.1, the matrix-level similarities of DeepSeek and Grok experts are typically close to zero, whereas Mixtrals' expert similarities average around 0.3. **iii)** The weights of different experts become less similar in deeper layers, as observed in the Mixtrals' heat maps in Fig. 1. **iv)** W_{up}, W_{down}, and W_{act}, share similar patterns in their similarity heat maps (Fig. 1). **v)** The similarities of W_g and of W_{act} show either positive or negative association. Tab. 3 depicts the R^2_{avg} values, where the pairing of W_g and W_{act} achieves the highest correlation across all four models.

5 Analysis of Dynamic Behaviours

The previous experiments examine the MoE models via their parameters, without involving any input. In this section, we feed text sequences into the MoE models to further study their actual behaviours given various inputs. Specifically, we analyze the outputs of the experts and gates.

To this end, two stages are required for inference. In the first stage, we simply pass the input x through the network using the original Top-k setting and store the output z_i of every layer i. In the second stage, we iterate through the layers. During the i-th iteration, we feed z_{i-1} into the i-th layer (for the first layer, x is employed as the input), set Top-k $=$ ALL, and record the outputs from all the experts in the i-th layer. Note that each layer has its own individual forward pass in the second stage. Intuitively, our goal is to examine the experts' behaviors when provided with the original inputs.

Input data. We utilize a *short input* and a *long input* for the experiments in this section. For the short input, we employ the first few words of the input from another MoE-related work (Cai et al., 2024) [4]. For the long input, we adopt 10 sequences from the test set of the WikiText-103 (Merity et al., 2016) dataset, totaling approximately 1100 tokens. The sequences in WikiText-103 cover a variety of domains, with the 10 sequences we used spanning topics such as music, design, and construction. To ensure the robustness of our findings, we repeat experiments requiring the long input (§ 5.1, § 5.2) using additional datasets with over 80K tokens, including GSM8K (Cobbe et al., 2021) and Magicoder- Evol-Instruct-110K (Wei et al., 2024b). See Append F for details. *The observations of these additional, subject-specific datasets align with the results described in the main context, demonstrating the universality of our conclusions.*

We also conduct experiments for analyzing intermediate states of experts and routing patterns. Due to the page limit, these experiments are presented in Append H and Append I, respectively.

5.1 Outputs of Experts

Since experts are ideally learned to specialize in different aspects, it is natural to question the similarities and differences between the outputs of selected and non-selected experts. In this experiment, we

[4]The specific tokens are <*s*>, *As*, *an*, *open*, *source*, *alternative*, *to*, where the start of the sentence symbol <*s*> does not applicable for the Grok tokenizer.

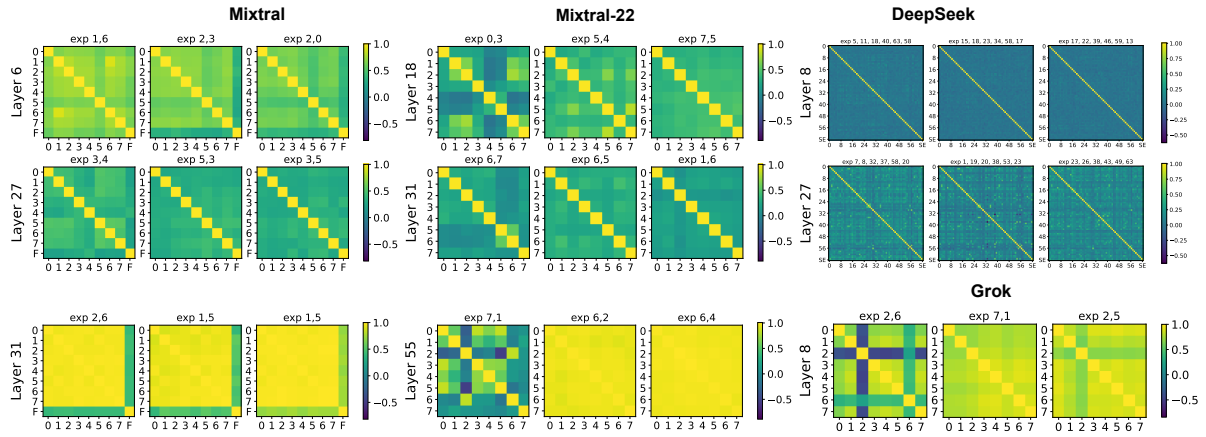

Figure 2: Similarity heat maps of expert output features using the short input. The top k experts for each token are shown on top of each heat map. The tick numbers refer to the expert indices. "F" and "SE" denote the Mistral FFN and the DeepSeek shared expert, respectively.

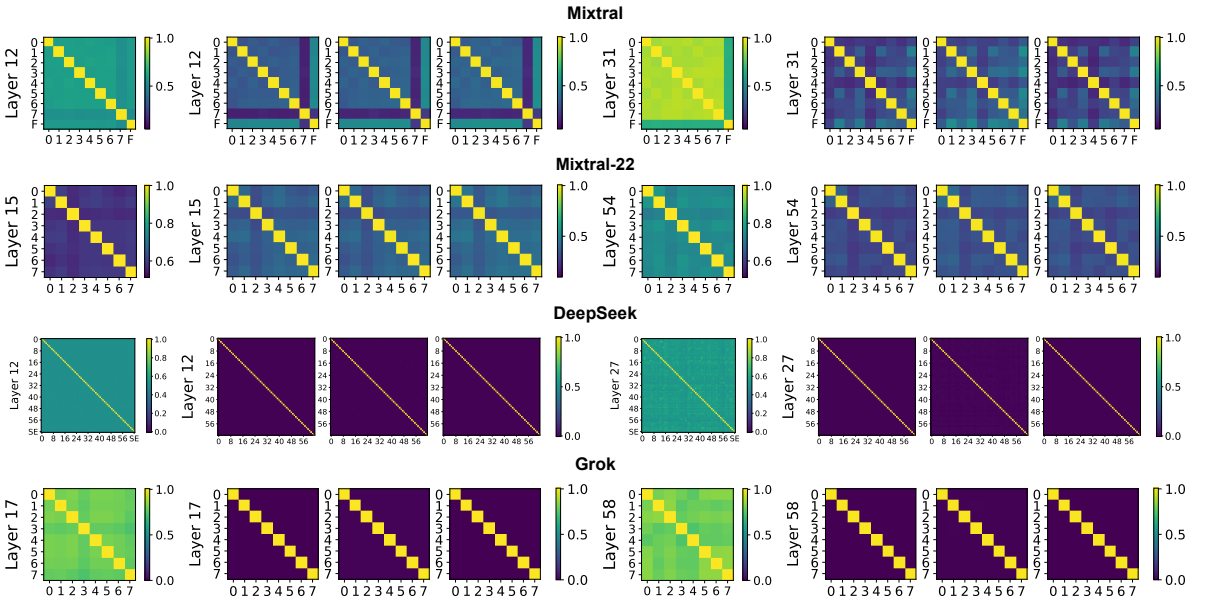

Figure 3: Average similarity heat maps of expert output features using the long input, plotted along with the matrix-level similarity heat maps. The tick numbers refer to the expert indices. "F" denotes the Mistral FFN.

measure the correlation between the output feature vectors of experts. We plot the similarity heat maps for three tokens in the short input (Fig. 2) and the average heat map across all tokens in the long input (Fig. 3). For the long input, we use *angular similarity* instead of cosine similarity for measurement, as the similarities need to be averaged, ensuring that the values range from 0 to 1:

$$\text{angular_sim} = 1 - \frac{\arccos\left(\text{cosine_sim}\right)}{\pi}. \quad (2)$$

For clarity, the average similarity heat maps are plotted alongside the matrix-level similarity graphs of the expert weight matrices. Fig. 9 further depicts the results from additional datasets, which are consistent with those of the long input.

Mixtrals and Mistral. The graphs for the short input indicate that the outputs from chosen experts tend to be more similar, possibly due to their generally larger norms, which we will discuss in § 5.2. Overall similarities are relatively low in the deeper (22^{nd}-27^{th} for Mixtral and 30^{nd}-50^{th} for Mixtral-22) layers, whereas many values exceed 0.8 in the last few layers. Furthermore, dark crosses often appear in the graphs, with the experts corresponding to these dark crosses often being more similar to the Mistral FFN (*i.e.*, bright color in the last row). For the long input, the average heat maps show patterns akin to neuron-level similarity graphs, including the presence of dark crosses. The similarities also decrease with increasing layer depth, except in the

last layer. In addition, we have $S_{ee} > S_{ef}$ for both inputs. Most of these observations align with the previous analyses of static parameters (§ 4.3), implying that measuring the similarity of weights, in some aspects, is equivalent to measuring the average similarity of outputs.

DeepSeek. Given the short input, most similarities are around zero, while the values in the last layer are significantly larger. Again, the similarities between experts chosen by the gate are likely to be higher, although this difference occurs much less frequently than in Mixtrals. The average similarities for the long input also approach zero. Moreover, the number of "small rectangular" with relatively light color in the graphs decreases as the layer depth increases (except for the last layer), meaning that the average similarities gradually decline.

Grok. Surprisingly, the similarities between the output features remain high for all tokens in the short input, indicating the experts exhibit similar behaviours. However, the similarities of their weight matrices are mostly zeros (§ 4.1.1). We speculate that this may be due to the relatively large size of each Grok expert, allowing each to learn comprehensive knowledge and behave similarly despite having distinct parameters. When averaging the similarities for the long input, some of the resulting average heat maps display patterns similar to those of the W_{act} figures. This relationship aligns with the observations made for Mixtrals.

5.2 Norms of Expert Outputs and Gate Scores

In § 5.1, we find that the outputs from chosen experts tend to be more alike. To investigate the possible reasons for this observation, we employ the short input to study the relationship between the experts' L2 norm and the gate decision in this experiment. The calculated norms, along with the gate scores, are plotted in Fig. 4. In Append G, we repeat this experiment using the long input and additional datasets, and the results also support the "higher norm, higher score" observation.

Mixtrals. We found that the two experts chosen by the gate usually output feature vectors with the highest norms, which reveals that the norm might be one of the key factors in gate decisions. This finding agrees with the router's design in CompeteSMoE (Pham et al., 2024), which selects experts based on their output norms. It also helps explain why the outputs of the chosen Mixtrals and DeepSeek experts tend to be more alike (§ 5.1). In Fig. 4, we observe that the gate scores assigned to the top-1 experts are usually much higher than those of the others, including the second place. This demonstrates that the gate is learned to strengthen the confidence of its decision during training. On the other hand, the deeper the layer, the larger the norm, which is similar to the growth in standard models (Shleifer et al., 2021).

DeepSeek. In contrast to the observation about Mixtrals' experts, the gate decision appears to depend less obviously on the output norms of DeepSeek experts. However, the top-1 experts often score much higher than the remaining candidates. The magnitude of the norms increases with depth, although the increment is less pronounced than in Mixtrals. In the last layer, the variance of norms becomes greater.

Grok. While the scores of the top-1 experts are higher than those of the others, no correspondence between the norms and the gate scores is observed. One possible reason could be the relatively low activation ratios of GeLU (see Append H), which may lead to a weaker dependence on the norm for gate decisions. Besides, unlike Mixtrals and DeepSeek, the magnitude of the norms hardly changes across depth, and some of the norm values can be less than 1, which is rare in the other two models.

5.3 Summary

The observations of dynamic behaviours are concluded below: **i)** The outputs of Mixtrals and DeepSeek experts in deep (last) layers are less (much) alike. This can be seen in the heat maps for both the short (Fig. 2) and long (Fig. 3) inputs. **ii)** The average heat maps of expert outputs resemble the neuron-level similarity graphs (Fig. 3), implying that weight similarity measurements can reflect output similarity. **iii)** Grok experts exhibit high output similarity (Fig.2), likely due to their larger sizes. **iv)** For Mixtrals and DeepSeek, experts generating feature vectors with larger norms tend to receive higher gate scores, as shown in Fig. 4. We further verified this observation in Fig. 10.

6 Discussion

Based on our analyses, we offer several suggestions for MoE models across various aspects.

Neuron-level experts. Intuitively, the gate embedding matrix W_g determines expert selection while W_{act} is responsible for choosing which neurons to activate. Meanwhile, we find that the similarities of

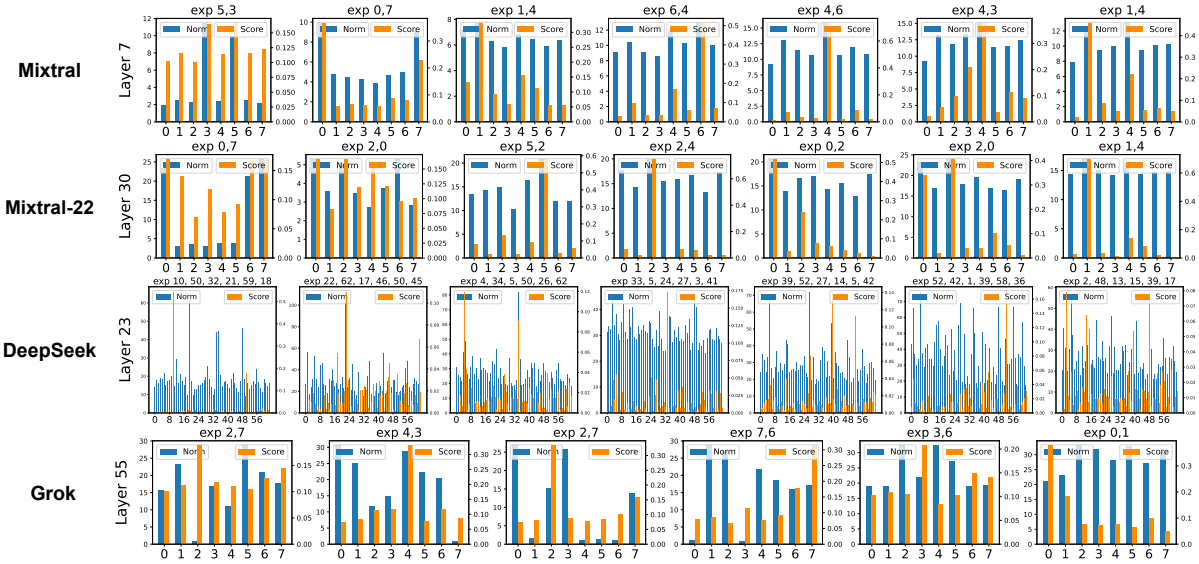

Figure 4: The experts' L2 norms and the gate scores of the short input. Each token's k experts are shown on top of each heat map. Each number in the horizontal axis refers to an expert index.

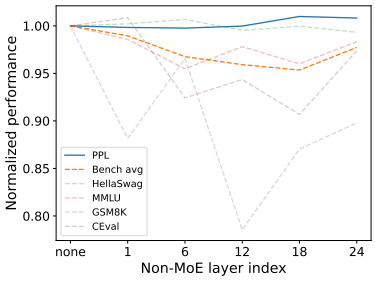

Figure 5: Normalized model performance across benchmarks for the dynamic expert numbers experiment. Solid line represents lower is better, while dashed line represents higher is better. "Bench avg" refers to the average performance over the four benchmarks evaluated.

W_g and of W_{act} show association. This implies that neurons may function as more fine-grained experts. Therefore, operations on experts, such as division, construction, and composition, should be further studied at the micro level. For instance, MoEfication (Zhang et al., 2021) and EMoE (Qiu et al., 2024a) construct MoE experts by splitting the MLP layers of a dense model, suggesting our findings from a similar perspective.

Model architecture. Given that the similarities between experts tend to be relatively low (high) in deep (last) layers, one can consider increasing the number of experts in the deeper layers while reducing it in the last layers. In addition, since the gate frequently selects experts with larger output norms, employing norm-based routing mechanism is a reasonable approach. Empirical evidence from Pham et al. (2024) supports this effectiveness.

We conduct an initial experiment to provide practical experience into our suggestion regarding dynamic expert numbers across layers. Specifically, we train six MoE models from scratch, each containing 24 layers and 3.6B total parameters, using approximately 120B tokens. One of the six models is composed of 24 MoE layers, while the others comprise only 23 MoE layers, with one conventional non-MoE layer positioned at different indices. Details of the model architecture are provided in Tab.7. As displayed in Fig.5 and Tab.6, the average model performance (*i.e.*, PPL and Bench avg) gradually degrades as the non-MoE layer index increases, whereas a slight improvement appears when the non-MoE layer is placed at the last position (24^{th}). This highlights the growing importance of multiple expert networks in deeper layers, excluding the last one, which aligns with our observations and suggestions.

Correlation measurement. Analyzing expert correlations through weight matrix similarities yields partially equivalent results to those from output feature vector similarities across considerable tokens. Thus, assessing weight matrices offers a broader overview, while examining individual token outputs allows for more detailed analysis.

Training scheme. The training method for Mixtral has not been publicly announced. However, we observed certain characteristicss shared by Mixtral experts (*e.g.*, relatively high similarities of weight matrices), and a notable relationship between these experts and the Mistral FFN (*e.g.*, similar intermediate states in Fig. 12). Consequently, we conjecture

that the Mixtral model may be trained using special initialization schemes other than from scratch, *e.g.*, upcycling (Komatsuzaki et al., 2022) from Mistral, that is, copying all experts from the FFN. On the contrary, the experts of DeepSeek and Grok, which are known to be trained from scratch, show weaker correlations than Mixtral experts in our experiments. Similarly, Wei et al. (2024a) tracks changes in expert similarities throughout the training process, observing that upcycled experts exhibit greater similarity compared to those randomly initialized. Hence, we speculate that training a MoE model from scratch shows stronger potential to facilitate the diversification of experts compared with certain initialization approaches.

7 Related Work

Due to the page limit, we focus on existing works analyzing MoEs. An extended related work section for MoE LLMs can be found in Append B.

Most existing works analyze MoE from the router's perspective by observing expert selections. Early works have observed the unstable choices in the router (Zuo et al., 2021; Chi et al., 2022; Dai et al., 2022). More recent studies find the standard routers do not show clear specialization at the domain level (Jiang et al., 2024; Dai et al., 2024) and primarily route based on token ID instead of high-level semantics (Xue et al., 2024). Shi et al. (2024) shows that Top-2 and Rank-k routing result in different model behaviours and proposes a new self-contrast decoding method to determine the next-token distribution based on this finding.

Other works investigate the expert's similarity (Wu et al., 2022), uncovering and utilizing redundancies among experts for efficient inference (Li et al., 2023; Lu et al., 2024). Zhang et al. (2024) reveals the redundancy within experts and perform pruning based on their similarities. Liu et al. (2023); Qiu et al. (2023) notice the connection between routing connection and expert computation, and utilize the average of the experts' first-layer weights to guide routing. Pham et al. (2024) proposes adding the expert's output norm as a supervision signal for routing training. Chen et al. (2022) empirically and theoretically proves that a two-layer MoE CNN is able to learn cluster-center features via specializing experts to specific portions of the data. While these works provide insights into MoE from one or two viewpoints, our work offers a systematic analysis and comparison focusing on transformer-based MoE LLMs.

As mentioned in previous sections, several existing works share some relevance to our findings, and thus can be seen as supportive. However, their proposed ideas and methods are different from ours. For instance, rather than revealing the nature of the preference for large output norms in (conventional top-k) routing, as we analyze, CompeteSMoE (Pham et al., 2024) designs a norm-based router to introduce this tendency manually; MoEfication (Zhang et al., 2021) splits MLP layers of a dense model to construct MoE experts, while our study highlights that the neurons of an expert can be seen as tiny experts. Moreover, many of our observations are novel, such as the correlation between the router embedding matrix and the expert weight matrix, as well as the equivalence between parameter and output measurement for experts. Therefore, we believe that our work offers valuable insights into MoE LLMs for the community.

8 Conclusion

In this paper, we initially attempt to investigate the inner working mechanisms of MoEs by studying the parameters and outputs of four different MoE models. We summarize our empirical observations and propose practical suggestions across various aspects. While it is premature to conclude whether MoEs genuinely learn heterogeneous experts, some of our experiments indicate that specific architectural designs (*e.g.*, the number of experts) and training frameworks may facilitate expert specialization. We hope this work can provide inspiring insights and serve as a valuable foundation for future research on MoE and other modular architectures.

9 Limitations

The limitations of our work include: 1) Although the models we investigated cover several common designs of MoE, our analysis does not encompass all aspects (e.g., other routing strategies like top-1 routing or model architectures that place MoE layers at every other layer); 2) Despite the availability of other metrics, we primarily adopt cosine similarity in our experiments involving similarity measurement, as it is a widely used approach (Pham et al., 2024; Chen et al., 2022); 3) We mainly focus on the pretrained base model but seldom explore the behaviours of models after fine-tuning. Analyzing the changes in expert behaviours during the fine-tuning process could yield valuable insights.

Appendix

A Model Selection

Our experiments are conducted on Mixtral 8x7B, DeepSeekMoE, and Grok-1. We choose these models due to their widespread use and impressive performance across various domains. Additionally, these models are complementary in several crucial attributes, such as training scheme, activation functions, top-k settings, and the number of experts, as listed in Tab 1 and Tab 4. This allows for a comparative analysis with controlled variables and encompasses a wide range of parameter sizes, from rather small (16B) to relatively huge (314B). Hence, we believe that the findings derived from these four models are fairly robust, despite the limited number of models examined.

B Extended Related Work

MoE LLMs. MoEs have garnered significant attention in recent years due to their ability to efficiently scale model capacity with minimal computational overhead. Most current transformer-based MoE LLMs adopt a typical architecture design that replaces the original FFN with multiple expert networks and a sparse gating network (Wei et al., 2024a; Wu et al., 2024; Dai et al., 2024; Xue et al., 2024; Jiang et al., 2024; Zoph et al., 2022). JetMoE (Shen et al., 2024) and ModuleFormer (Shen et al., 2023) incorporate Mixture of Attention Heads (Zhang et al., 2022) into their model, achieving further sparsity. A recent survey (Cai et al., 2024) provides a comprehensive review of both the algorithmic and system design aspects of MoEs. For this study, we select four representative candidates among current open-sourced MoE LLMs for analysis to gain intriguing insights.

C Projection of Expert Matrices in Low-dimensional Space

C.1 Matrix-level

To better understand the relationships among experts, we employ principal components analysis (PCA) to project the flattened vectors of weight matrices into two-dimensional space. The vectors are standardized before applying PCA. Fig. 6 depicts the resulting 2D projection.

Mixtral and Mistral. Consistent with the observations in § 4.1.1, the figures for the three matrices appear similar. Generally, about half of the Mixtral experts cluster closely together and near the Mistral FFN, while the others locate much farther away. Moreover, the outliers correspond to the dark crosses.

DeepSeek. Only routed experts are considered due to differences in hidden sizes. Because several outliers exist, causing the remaining data points to be densely gathered, we remove them using the DBSCAN algorithm with $\epsilon = 50$ and plot the rest in Fig. 6. It can be observed that the experts distribute rather densely, especially for W_{up}. Although the distribution of experts varies for three matrices, the figures for W_{up} and W_{down} are more similar than those of the gate matrix.

Grok. Typically, about half of the Grok experts densely gather for W_{up} and W_{down}. The other half turns out to be outliers even though no dark cross were observed before. . Furthermore, the outliers of the three matrices partially coincide.

C.2 Neuron-level

To project the neurons into a 2D or 3D space, each row vector of W_{up} and W_{act}, or each column vector of W_{down}, is treated as a single data point. Standardization is then applied, following by PCA. The visualization of the principal components is illustrated in Fig. 7. Different colors refer to neurons belonging to different experts.

Common. The vast majority of neurons gather in the low-dimensional space. In some layers, the distribution of neurons forms a special shape, such as a cross or a thick line, which appears the most often for W_{down}, followed by W_{up}, and finally W_{act}. Compared to ellipses, these shapes indicate that the neurons are relatively more similar.

Mixtral and Mistral. The neurons in the Mistral FFN distribute more densely than those of the Mixtral experts. Notably, the distribution shape of neurons in the FFN and experts are usually alike, even for the outliers.

DeepSeek and Grok. The number of outliers is a bit greater tahn that observed in Mixtral.

D Averaging Expert Neurons

To investigate expert correlation at the neuron level, the averaging approach simply averages the rows (for W_{up} and W_{act}) or the columns (for W_{down}) of the weight matrices and then calculates the similarity of the resulting vectors across experts. Fig. 8 displays the graphs.

Common. The heat maps of W_{up} and W_{down} are nearly identical to those presented in § 4.1.1. Yet

Model	Training scheme	Activation	# Total layers	# Total params	# Activated params
Mixtral	unknown (upcycling)	SiLU	32	46.7B	12.9B
Mixtral-22	unknown (upcycling)	SiLU	56	141B	39B
Mistral	from scratch	SiLU	32	7.3B	7.3B
DeepSeek	from scratch	SiLU	28	16.4B	0.3B
Grok	from scratch	GeLU	64	314B	78.5B

Table 4: Additional information of chosen models.

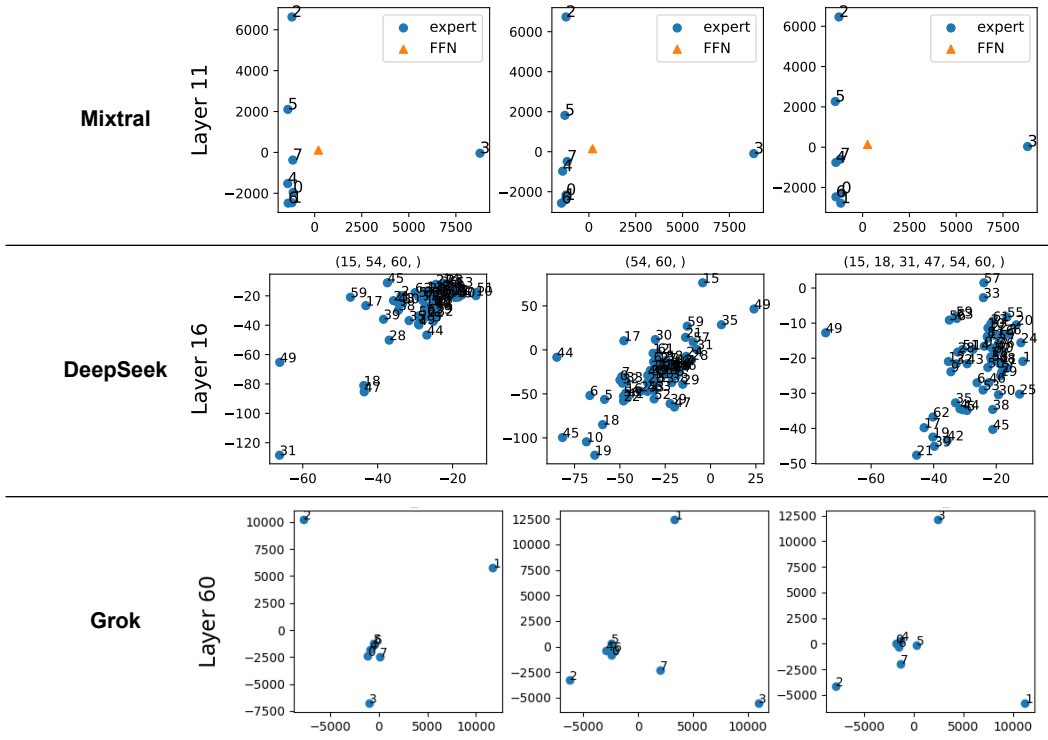

Figure 6: Projection of expert matrices in 2D space. Each layer contains three graphs, corresponding to W_{up}, W_{act}, and W_{down}, respectively. For DeepSeek, the indices of the removed outliers are listed on top of each graph.

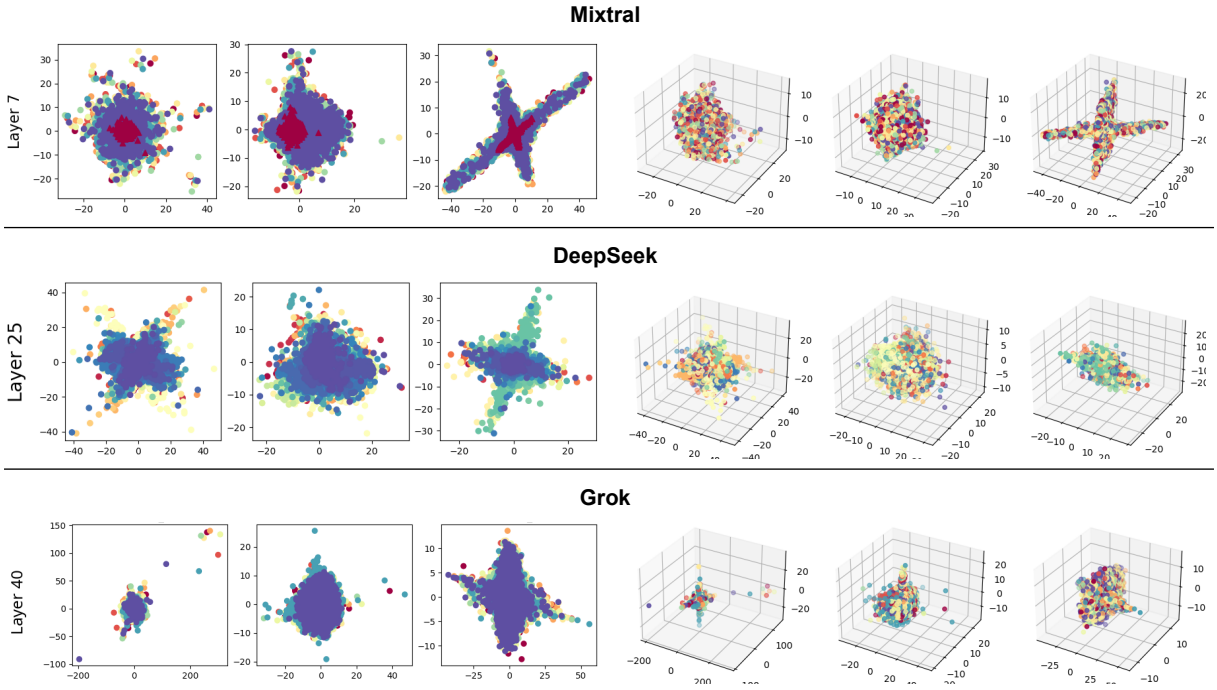

Figure 7: Projection of expert neurons in 2D/3D space. Each layer contains three graphs, corresponding to W_{up}, W_{act}, and W_{down}, respectively.

the similarities of W_{act} significantly increase.

Mixtral and Mistral. The dark crosses sometimes disappear. In the figures for W_{act}, the similarities between the experts and the Mistral FFN are often lower than the similarities among the experts themselves (*i.e.*, $S_{\text{ee}} > S_{\text{ef}}$), which is contrary to previous observations. This can happen if the expert neurons in different positions are alike. For instance, given three vectors $f = (0, 0)$, $e_1 = (1, 0)$, and $e_2 = (0, 1)$, the vector similarity $S_{e_1e_2}$ is lower than S_{e_1f} and S_{e_2f}. If averaging the elements, we have $\bar{f} = (0)$, $\bar{e}_1 = (0.5)$, and $\bar{e}_2 = (0.5)$, then $S_{e_1e_2}$ becomes the highest.

DeepSeek. The growth of the W_{act} similarity values is directly proportional to the layer depth.

Gork. In the heat map of W_{act}, dark crosses frequently appear in various positions.

E Gate Embedding

Since the gate embedding matrix W_g determines the gate decision, there may be a relationship between W_g and the experts. To investigate this, we measure the similarities between the gate embedding vectors, $W_g[n, :]$ for $n \in [1, N]$, and compare them with the neuron-level averaging heat maps of experts presented in § 4.1.2. The qualitative analysis of the combined graphs shown in Fig. 8 is detailed in this section. The table containing the R values for each layer (Tab. 5) is appended at the end.

Mixtral. Focusing on the heat maps of W_g, the similarities typically range from 0.2 to 0.4, with a noticeable increase in the last layer. Moreover, dark crosses are rarely found. Surprisingly, the patterns in the heat maps of W_g and of expert neurons in W_{act} are partially alike in some layers. This implies that the way a gate selects experts might be relevant to how an expert activates its neurons.

DeepSeek. Unlike the almost all-zero heat maps of W_{up} and W_{down}, the similarities of gate neurons sometimes exceed 0.4. In addition, the heat maps of W_g and W_{act} show similar patterns. However, the overall similarities of W_g decrease with depth while the similarities of W_{act} gradually grow. This indicates that as the layer depth increases, the gate "looks" at the input feature in more diverse ways when assigning scores to different experts, even as the neuron activations of the experts become more similar.

Grok. Both dark and bright crosses commonly exist in the heat maps of W_g, whose patterns are

similar to those of W_{act}. Specially, their patterns show opposite color tendency (*i.e.*, deep color positions in one heat map becomes light color in another) starting form the intermediate layers. The similarities of W_g decrease when the layer depth increases, except for the last few layers.

F Additional Datasets

To ensure the universality of our findings, we repeat the experiments that require the long input (§ 5.1, § 5.2) using additional datasets. Specifically, we utilize the entire test set of WikiText-103 (Merity et al., 2016) (266K tokens) and of a math dataset GSM8K (Cobbe et al., 2021) (84K tokens), and 1000 sequences from the code dataset Magicoder-Evol-Instruct-110K (Wei et al., 2024b) (188K tokens). As shown in Fig. 9, 11, 13, the new figures of Mixtral and DeepSeek align with the previous results illustrated in the main context, even when using datasets of specific subjects like math and code (we did not test on the Grok model due to limited computation resources). These supplementary results demonstrate that our findings are general and not limited to the initial input sources.

G Norms of Expert Outputs and Gate Scores

In § 5.2, we notice that in some MoE models, the two experts chosen by the gate usually produce feature vectors with the highest norms. To further investigate this, we repeat the experiment using the long input and additional datasets, and the statistical results are shown in Fig. 10, 11, 13.

Mixtral. It is evident that the expert which outputs the largest norm is most frequently assigned the highest score. Surprisingly, for every i, the i-th highest score is most likely assigned to the expert with the i-th highest output.

DeepSeek. For the experts that generate the first few largest norms (rank 60^{th} to 64^{th}), they are most likely to receive the highest scores. But we do not observe a similar relationship for the rest of the experts. On the contrary, the gate assigns relatively high scores more frequently than low scores to the experts with the smallest norms. For experts ranked 49^{th} to 59^{th} in terms of output norms, they tend to receive either low scores or high scores.

Grok. In contrast to the previous models, the output norms of the Grok experts tend to have an inverse relationship with the scores. More generally, the experts with the first few highest outputs are frequently assigned either low scores or high scores. One possible explanation could be the relatively low activation ratios of GeLU (see Append H), which may result in a weaker dependence on the norm for gate decisions.

H Intermediate States of Experts

While § 5.1 focused on the final outputs of experts, we continue our analysis here by examining their intermediate outputs to examine the inner states of the experts. Given an input x, the intermediate state of an expert refers to the output of $\sigma(W_{\text{act}}x) \in \mathbb{R}^{d_{\text{hid}}}$, where σ denotes an activation function. These intermediate vectors control the activation of neurons, so we simply record them for analysis with the short input used. Mixtral, Mistral, and DeepSeek utilize SiLU as the activation function, while Grok adopts GeLU. Fig. 12 depicts the magnitude of the vectors for Mixtral across three tokens.

Common. Each figure contains some horizontal lines, indicating the presence of an "outlier" expert with either the highest or lowest activation values. Nonetheless, there is no clear relationship between these phenomena and the gate decisions.

Mixtral and Mistral. For a single token, we found that, on average, the absolute activation value of 99.6% elements in each expert exceeds 0.001 after applying the SiLU activation function. This high ratio indicates that the vast majority of neurons in an expert are activated. In Fig. 12, some vertical lines across all experts are commonly found, meaning that the W_{act} matrices of different experts assign similar activation values to neurons with the same indices. In addition, the magnitude of the intermediate states grows along with layer depth, which aligns with the observation in § 5.1.

DeepSeek. On average, 99.7% of the neurons in each expert have an absolute activation value exceeding 0.001 after applying SiLU. Vertical lines rarely exist in the DeepSeek model. Similarly, the elements in the intermediate state vectors get larger as the layer goes deeper.

Grok. With GeLU as the activation function, only 25.3% neurons per Grok expert attain an absolute activation value greater than 0.001. The activation values are generally smaller than those in Mixtral and DeepSeek. Li et al. (2022); Song et al. (2024a) suggest such difference largely stems from the distinct activation functions used. Interestingly, Song et al. (2024b) further utilize the sparsity in experts

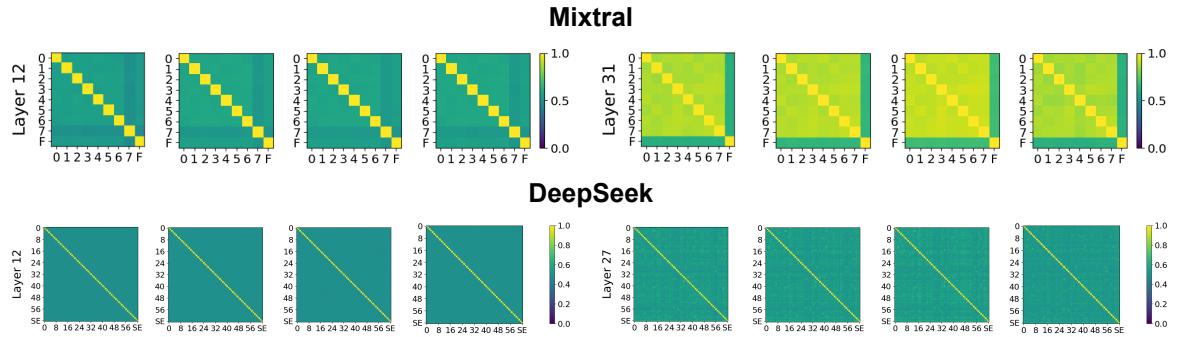

Figure 9: Average similarity heat maps of expert output features using (1) the long sequence, (2) WikiText-103, (3) GSM8K, and (4) Magicoder-Evol-Instruct-110K. The tick numbers refer to the expert indices. "F" and "SE" denote the Mistral FFN and the DeepSeek shared expert, respectively.

within SMoE to achieve SOTA performance when activating the same number of parameters.

I Chosen Experts

This experiment aims to examine the routing patterns. We feed an input prompt with about 64 tokens into the MoE models and record the gate scores (after applying softmax) for the selected experts for each token. In addition to the base model of Mixtral (Mixtral-Base), we also include its instruct version (Mixtral-Instruct) in this experiment. The results are depicted in Fig. 14.

Mixtral. In Mixtral-Base, the experts are selected fairly evenly across tokens, and it is common to see sequences of more than four tokens routed to the same expert. But the "special expert" with the dark cross in previous similarity graphs turns out to be an exception. These special experts are chosen less frequently and tend to receive relatively low scores. The routing pattern of Mixtral-Instruct is largely identical to that of Mixtral-Base, which indicates fine-tuning has little impact on gate decisions.

DeepSeek. In some layers, there is an expert selected by most tokens. However, no distinct characteristics for these experts are observed in the previous similarity heat maps. Note that the gate scores for DeepSeek are typically lower than those for Mixtral because DeepSeek applies softmax before the top-k operation, while Mixtral adopts the reverse way.

Grok. The expert selection is rather even and some relatively high scores exist in the deeper (>30th) layers. Same as DeepSeek, softmax is applied before the top-k operation for Grok.

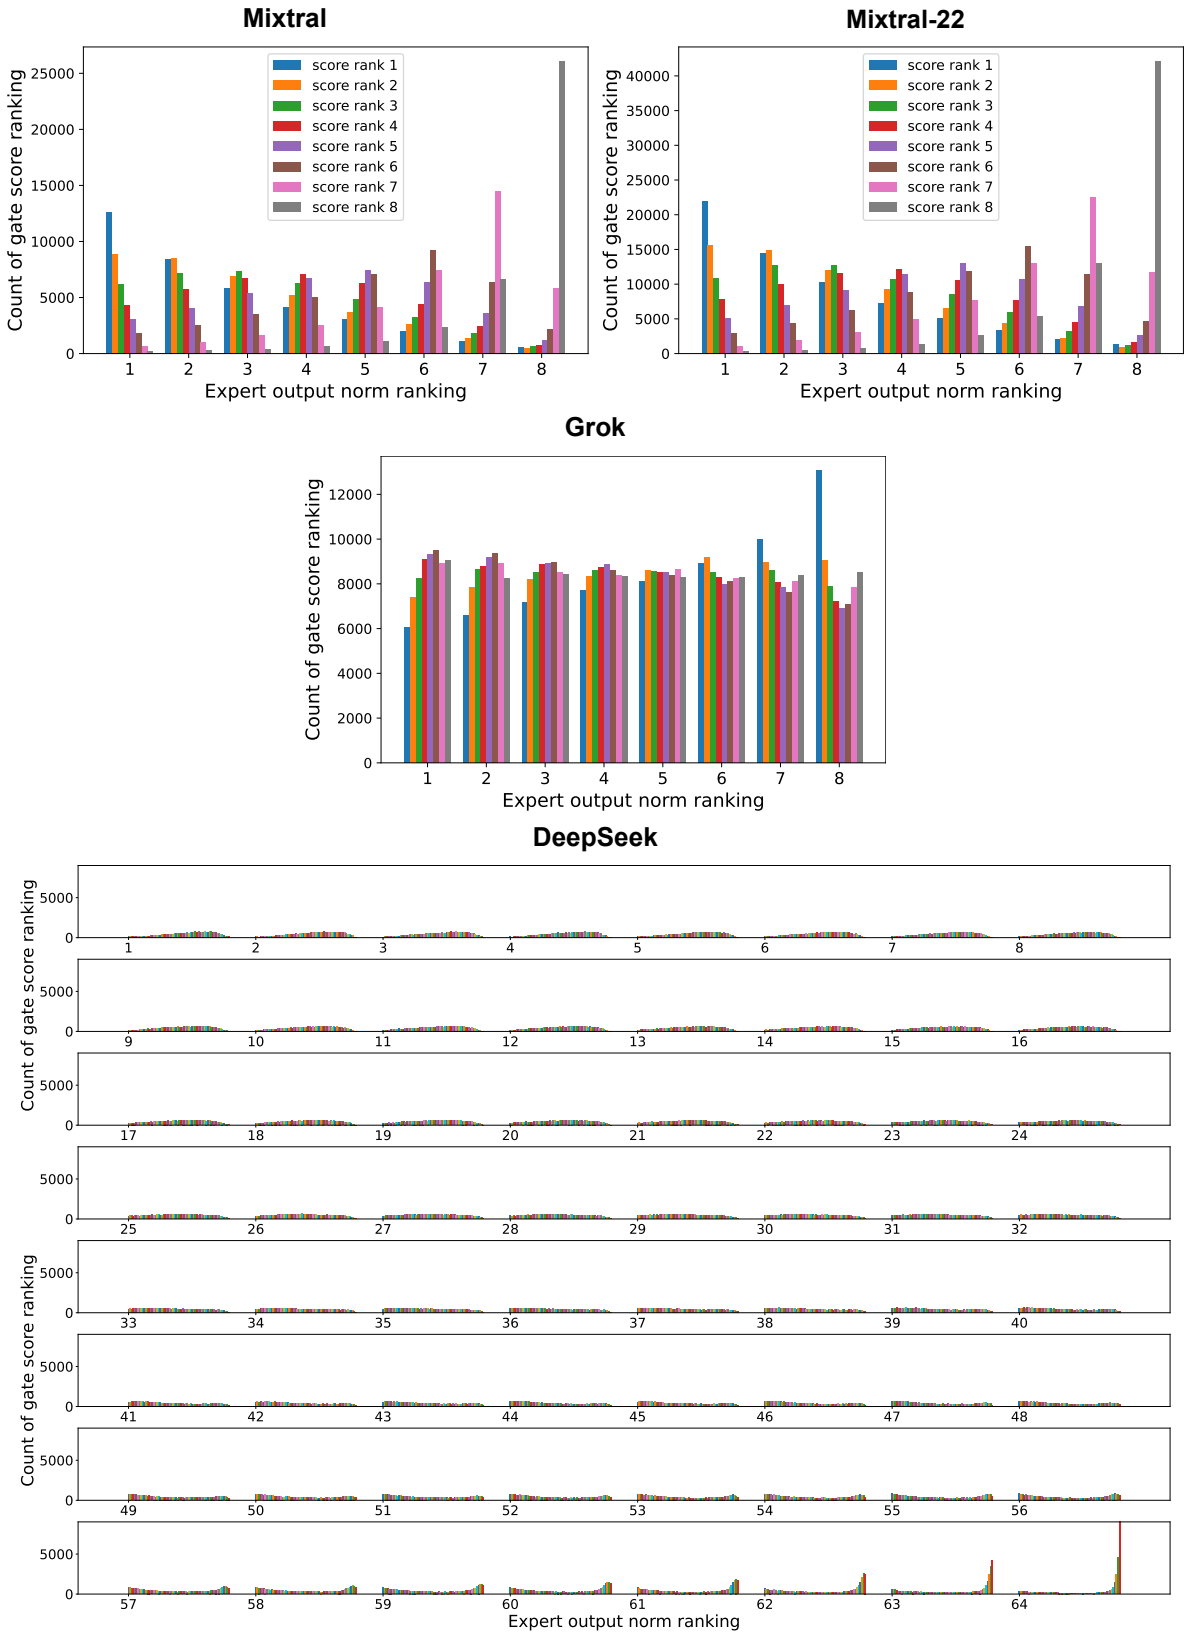

Figure 10: Counts of the gate score ranking for each norm ranking using the long input. The larger the rank number, the larger the norm or score.

Abstract

Computational modeling of user-generated desires on social media can significantly aid decision-makers across various fields. Initially explored through wish speech, this task has evolved into a nuanced examination of hope speech. To enhance understanding and detection, we propose a novel scheme rooted in formal semantics approaches to modality, capturing both future-oriented hopes through desires and beliefs and the counterfactuality of past unfulfilled wishes and regrets.We manually re-annotated existing hope speech datasets and built a new one which constitutes a new benchmark in the field. We also explore the capabilities of LLMs in automatically detecting hope speech. To the best of our knowledge, this is the first attempt towards a language-driven decomposition of the notional category hope and its automatic detection in a unified setting.

1 Introduction

Hope is a notional category that lies at the crossroads of desire, belief and intention as the psychological (Snyder, 2000; Eliott and Olver, 2002), philosophical (Bloeser and Stahl, 2022; Godfrey, 2012) and the linguistic literature (Heim, 1992; Ruffman et al., 2003; Portner and Partee, 2008; Anand and Hacquard, 2013; Grano, 2017) have independently highlighted.

As an expression of will and intention, hope functions as motivation for action (Bratman, 1987). It forms a mental attitude that contributes to the rational behavior of an agent to foresee and plan new strategies to fulfill what people would like to see happen or to have happened. Examining hopes offer valuable insights for decision-makers in various domains ranging from customer service and marketing (Carlos and Yalamanchi, 2012), politics (Hirschman, 1970), and decision-making processes (Hammond et al., 1998; Guo, 2023).

While acquiring, modeling, and reasoning with desires and beliefs have been extensively studied in artificial intelligence (Cohen and Levesque, 1990; Georgeff et al., 1999), automatic extraction of hope linguistically expressed in texts has received comparatively less attention in the NLP literature. The first attempt in this direction was the seminal work by Goldberg et al. (2009), followed by Ramanand et al. (2010) and Chang et al. (2013), on binary wish classification where a wish is defined as "a desire or hope for something to happen". Recently, the novel task known as *hope speech detection* (hereafter H*p*SD) has gained significant interest in the NLP community where many shared tasks have been organized, like the LT-EDI series @ACL and RANLP (Chakravarthi et al., 2021, 2022b, 2023). Balouchzahi et al. (2023b) and Balouchzahi et al. (2023a) go beyond binary classification and proposed a multiclass model for a nuanced definition of hope and regret, respectively.

Hope is both past (cf. (1)) and future (cf. (2)) oriented, and reveals a belief-based expectation or a desire-based projection that can be either realized, or that can no longer become actual.

(1) US surveillance drones shouldn't have been operating where they were told not to operate.

(2) I am very interested into drones and I'm currently looking into the prospect of buying a drone in Singapore.

Each existing hope dataset has its own annotation scheme, characterizing hope either as: (a) *only past-oriented* to address regrets or (b) *only future-oriented* to account for general or specific

hopefulness, optimism as well as wishes. In addition, existing studies focus on *the positive aspect of hope* where hope is viewed either as a counterpoint to hate (i.e., social awareness, minority protection, etc.) or as a way to offer support and inspiration (Chakravarthi, 2020). Balouchzahi et al. (2023b)'s taxonomy aimed to go beyond positivity by introducing unrealistic expectations. However, annotators often consider them as regret therefore labeling them as not-hope since they are not future-oriented (e.g., "*Wish there was a ban on fireworks*").

This paper addresses these drawbacks by disentangling hope orientation (past and future) from the valence of the content of the hope (we consider hope as both directed towards positive and negative goals). We rely on linguistic clues at the semantic / pragmatic interface to identify the relevant categories and propose a broader and language-driven design of the landscape of hope that covers the scope of previous works, while gaining in informativity. Our contributions are as follows:

1. **A novel language-driven decomposition of the notional category HOPE** that articulates its building blocks by distinguishing between **C**ounterfactual (as past oriented hope), and future oriented hope on the one hand, and between **D**esire-based and **B**elief-based hope in the realm of future orientation (Condoravdi, 2002; Portner, 2009a; Anand and Hacquard, 2013; Grano, 2017). We hereafter refer to our model Counterfactual-Desire-Belief as the CDB model (cf. Section 3).

2. **An English dataset of about 4,370 texts annotated according to this characterization**. We manually re-annotated a subset of existing hope datasets and built a new one while merging them under the same scheme rooted in formal semantics approaches to modality (cf. Section 4). This forms a new benchmark in the field.[1]

3. **A set of experiments to detect hope using both transformers and large language models** relying on various prompting strategies (cf. Section 5). LLMs capabilities have been explored in sentiment analysis, emotion and offensive language detection (Zhang et al., 2024; Li et al., 2023). The use of open-source LLMs for H*p*SD is new.

2 Hope Speech in NLP

2.1 Hope Speech Datasets

Table 1 summarizes existing H*p*SD datasets.[2] Most of them are in English with a focus on social media generated content. They can be grouped into two main categories. The first one views hope as opposite to hate with the aim of moderation through the detection of positive content. Palakodety et al. (2020) rely on n-grams and automatically build a corpus tagged as pro-war and pro-peace intent in nuclear conflict escalation. HopeEDI (Hope Speech Detection Dataset for Equality, Diversity, and Inclusion) (Chakravarthi, 2020) is composed of Youtube comments and casts the problem into a binary task (hope vs. not-hope) where hope promotes positivity within minorities, while not-hope encompasses hate speech and everything else. A subset of this dataset has been manually re-annotated by Aggarwal et al. (2023) to account for neutral cases (non English texts, lack of context).

The second group views hope beyond hate and proposes the first attempts to implement a theoretical framework leveraging insights from psychology. PolyHope contains tweets about women's child abortion, black people's rights, religion, and politics. Its annotation scheme considers four categories (Balouchzahi et al., 2023b): (i) not-hope, (ii) generalized hope, (iii) unrealistic hope, and (iv) realistic hope. ReDDit (Regret Detection and Domain Identification from Text) (Balouchzahi et al., 2023a) on the other hand distinguishes between regrets by action vs. inaction in posts from "regret", "regretfulparents", and "confession" subreddits. Finally, the WISH corpus (Goldberg et al., 2009) offers a set of 7,6K sentences from consumer product reviews and political discussion board postings manually annotated for wish vs. not-wish following a set of lexico-syntactic wish patterns (e.g., `would be better if X`). Table 2 provides a summary of annotation categories and their definitions in existing hope datasets, as given by the referenced papers.

Our work is in line with the PolyHope and ReDDit view that a variety of dimensions have to be captured, while covering the same large scope of

[1] The annotation guideline and a subset of the dataset are available as a supplementary material. The dataset will be made available to the research community.

[2] Studies that focus on the role of desire and belief in modelling emotion and sentiment (e.g., (Jia et al., 2022; Xu et al., 2024)) are out of the scope of this paper.

Corpus	Instances	Language	Hate-speech related	Manually Annotated
WISH Corpus (Goldberg et al., 2009)	7,614	English	-	Yes
Pro-War/Pro-Peace Dataset* (Palakodety et al., 2020)	2,047,851	English, Hindi	Yes	-
HopeEDI (Chakravarthi, 2020)	59,354	English, Tamil, Malayalam	Yes	Yes
HopeEDI with Neutral (Aggarwal et al., 2023)	23,003	English	Yes	Yes
PolyHope (Balouchzahi et al., 2023b)	8,256	English	-	Yes
ReDDit (Balouchzahi et al., 2023a)	3,425	English	-	Yes

Table 1: State of the art datasets for hope speech detection. "*": Not publicly available.

Corpus	Categories	Definition
WISH	Wish	"A desire or hope for something to happen." + a set of wish templates
PolyHope	Not-Hope	"Not indicate hope, wish, desire, or future-oriented expectation."
	Generalized Hope	"Expresses a general hopefulness and optimism not directed towards any specific event or outcome."
	Realist Hope	"Expecting something reasonable, meaningful, and possible thing to happen (there is every possibility that this will happen)."
	Unrealistic Hope	"Wishing for something to become true, even though the possibility of happening is remote, significantly less, or even zero."
ReDDit	Not-Regret	"Does not convey any type of regret."
	Regret by Action	"Regretting a decision or choice or an action one has done in the past."
	Regret by Inaction	"A regret caused by a lack of decision or failure in doing something."

Table 2: Annotation categories and their definitions in existing hope datasets, following Goldberg et al. (2009) (WISH), Balouchzahi et al. (2023b) (PolyHope) and Balouchzahi et al. (2023a) (ReDDit).

HopeEDI. Our proposal distinguishes itself in that it provides a more fine-grained classification and a unified view that offers several advantages: (1) From a more theoretical point of view, it restates regret in more general terms as counterfactual hope (as hope held in the past and no longer actualizable), and articulates hope around linguistic dimensions manifested across well-studied categories and the modal / temporal combinations. (2) It will provide to the research community a corpus for H*pSD* that encompasses existing manually annotated corpora. (3) It would allow us to compile a list of markers and other signals, which would also benefit automatic detection. Indeed, adopting a linguistic-based analysis allows us to rely on well-established classes of linguistic clues (phrasal mood, attitudes and modals and a combination of those in with and without tense) that guide our classification in a reliable and easily reproducible manner.

2.2 Automatic Detection

First approaches relied on lexico-syntactic patterns injected as features in supervised learning models (Goldberg et al., 2009; Ramanand et al., 2010; Dong et al., 2013; Chang et al., 2013). Deep learning such as LSTM and BiLSTM (Chakravarthi et al., 2022a) and transformers specifically have shown to be particularity useful in binary classification. For example, Zhu (2023) used DistillBert and obtained the best score at HOPE@IberLEF 2023 in English (Ureña López et al., 2023). Sidorov et al. (2023) experiment with multiclass classification of hopes (PolyHope) and regrets (ReDDit) datasets relying on GloVe embeddings. Finally, the use of LLMs (ChatGPT) has been reported in Ngo and Tran (2023) for H*p*SD in Spanish.

In this paper, we experiment with transformers but also and for the first time various open-source LLMs with different prompting strategies. Our models have been evaluated on a unified hope speech dataset that spans over multiple domains which allow for measuring models generalization across datasets in detecting fine-grained manifestations of hope. Several efforts have been carried out for cross-dataset experiements in many NLP tasks such as hate speech (Fortuna et al., 2021) and fallacy detection (Helwe et al., 2024). Our work is the first attempt towards H*p*SD in a unified setting.

3 A Language-Driven Characterization of Hope

3.1 The CDB Model

Hope as a modal category. In our study, we envision the notion of hope as a *topic* of the message that is manifested in the text across a variety of *modal* expressions and the inferences that these expressions enhance.

Strictly speaking, the lexical term *hope* belongs to the grammatical class of propositional attitudes

(e.g. (Hamblin, 1973; Portner, 2018; Condoravdi and Lauer, 2012; Anand and Hacquard, 2013; Grano, 2017)) and in particular to the bouletic class (*want, wish, hope, like*, ...). However, at the message level, hope has a more complex range of meanings and manifestations, and can be viewed *as an expectation imbued with desire* (and in this case the belief is foregrounded) or as *a desire of an outcome that the speaker believes possible* (and, in this case, the desire is foregrounded) (see Anand and Hacquard (2013)). This distinction between two types of hope (belief and desire based) is enhanced by specific *modal expressions* (e.g. *must, might, should, sorry, believe, want*, ...). Modal expressions affect the truthiness of the sentence, and reveal stances and postures of the speakers.

Our annotation of hope as a topic is based on the formal semantic approach by Portner (2009b) that distinguishes a variety of modal meanings that we build on (see Figure 1): **Epistemic** modals are based on belief/knowledge (e.g. *John **must** be at home, as far as I know*), **Deontic** on rules (e.g. *You **must** vote, according to the rules*), **Volitional** modals (e.g. *want*) are based on desires while **Teleological** on plans and goals (e.g. *If you want to go to Harlem, you **must** take the A train*).

EPISTEMIC	PRIORITY		TELEOLOGICAL
Belief based	Deontic Rule based	Volitional Desire based	Goal & Plan based

Figure 1: Modal meanings.

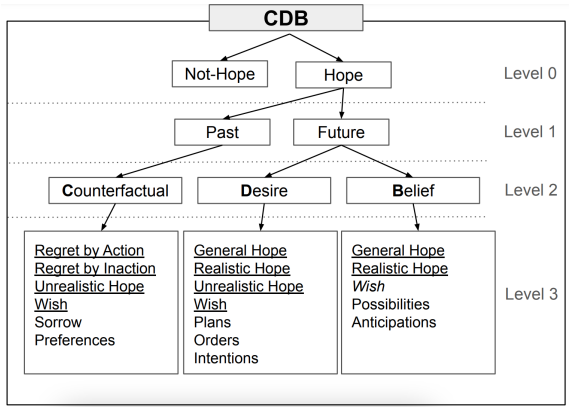

Figure 2: The Counterfactual-Desire-Belief (CDB) model. The wish under belief is in italic font to signal that we newly consider belief-grounded wishes.

Hope annotation and modal meaning mapping. We map these modal meanings into hope categories. This avoids arbitrariness: Modal meanings have precise manifestations, and by controlling these clues, we avoid subjective annotation of the topic hope at the message level. In particular, the Epistemic and Deontic modal categories that relate to facts and legal (or legal-like) rules map into the hope-as-belief (hereafter BELIEF). On the other hand, Volitional and Teleological that rely on desires and inherently involve preferences map into the hope-as-desire category (hereafter DESIRE).

As the overall topic of the messages are always enhanced by precise lexical information and to avoid projecting the annotator subjectivity, we have established **clear annotation rules based on grammatical and lexical manifestations of modality**. Modality surfaces across the lexical, phrasal and grammatical domains. In particular, in our study, we have considered the following categories. (i) Sentential mood, and most specifically imperatives and their variety of interpretations (Condoravdi and Lauer, 2012) (orders, wishes, invitations, advices...) and optatives (*please, if ... only*) (Grosz, 2012; Portner, 2018), (ii) modals auxiliaries and verbs (*could, should*), adverbs (*hopefully, lukily, ...*), within specific temporal setting (past and future tenses) and within larger phrases (*I wish I could, should have been, had I known that*), (Portner, 2009a)), and (iii) attitudes (*wish*, *anticipate*, *hope*), also across different temporal settings (Anand and Hacquard, 2013; Villalta, 2008; Grano, 2017). Once the modal expressions are identified along with their lexical meanings, the hope category is easily assigned.

The temporal dimension. Finally, as Figure 2 shows, we distinguish between future and past orientation (which we label COUNTERFACTUAL). This past-oriented category encompasses both beliefs and desires that were held in the past and are no longer realizable. While future orientation and expressions of hopes that are still realizable are more useful to decision makers, considering past hopes can still give an indication of the stances and postures of the users. We have nonetheless decided to conflate desires and beliefs in the counterfactual category to avoid unnecessary complexity.

Our linguistic characterization of hope is complementary to (Saurí and Pustejovsky, 2009) in that it explicitly focuses on desire and expectations and not on factuality (and lack thereof) as a general category cutting across different notional domains beyond hope. Our approach extends the Belief-Desire-Intention model (Georgeff et al., 1999) by introducing an explicit temporal dimensions, and

recasting the annotation with a language-driven approach. While these are well-established models that *prima facie* might appear related to ours, our modal deepens the investigation of belief and volition domains beyond previous achievements.

3.2 The Proposed Annotation Scheme

CDB embeds in a uniform way all the publicly existing datasets by spelling out precisely the concepts covered and extending beyond categories usually treated in the literature (underlined in Figure 2) proposing a clear-cut distinction between belief-based and desires based-concepts as grounding different aspects of hope, as shown in Table 3. Our categories are:

(a) Past-oriented hope

COUNTERFACTUAL. It refers to a desire, wish, or longing for reality or outcome different from what is the case. Counterfactual hope can describe hopes that could have been realistically become true as well as hope that, even in the past, could have never been realized. This can emerge as regret (4), sorrow (3), or beliefs that alternative scenarios should be the case. Its hallmark is past orientation with attitude verbs or modal auxiliary.

(3) *So bummed I am out of town. Was hoping to catch this show. Enjoy!*

(4) *if i knew then what i know now i would have paid the extra to get an ipod avoided the zen*

(b) Future-oriented hope

DESIRE. It refers to the expression of a mere wish, as an emotion (5); plans, which are desires to act next (6) ; and imperatives, which issue orders or desires for others to act (7).

(5) *overall it is a great unit hopefully creative labs or some other vendor will soon come out with some accessories for it.*

(6) *i ve been looking to buy a digital camera for a long time and v finally decided that now was the time.*

(7) *right please go and check out a book from any library.*

BELIEF. This category encompasses expressions of an epistemic state. Even in scientific contexts, rational hope inherently involves an expectation that events will unfold as epistemically anticipated (Heim, 1992). Desire is present but it is backgrounded as illustrated in (8). Verbs such as *should*, *would*, and *could* often carry an implicit epistemic presupposition (Portner, 2009a; Rubinstein et al., 2013) as in (9). The desire component of belief-based hope can be enforced into deontological considerations, as in (10). Likewise, belief can also encompass unrealistic hopes (cf. (11) that does express a desire).

(8) *There is a power outage on the west side of town around Spanish Fork High School [...] We anticipate the power will be restored in 2-3 hours.*

(9) *so who hear thinks i should keep the money*

(10) *there should be no abortions or pulling the plug on a dead woman from Florida*

(11) *Maybe if you're very good a crab will one day wear your skull too.*

(c) NOT-HOPE

It encompasses everything else, including narrations (12) among others like compliments.

(12) *officers discovered that the man was standing beside them in the police line shouting please come out and give yourself up*

4 Data and Annotation

4.1 Data Sources

– Re-annotating existing datasets. We relied on three publicly available hope datasets to construct our unified benchmark:[3] **WISH** (Goldberg et al., 2009) about politics and products, **PolyHope** (Balouchzahi et al., 2023b) and **HopeEDI with neutral** (Aggarwal et al., 2023) about minority protection. We randomly selected 3,092 texts from these corpora while balancing instances from each original class per dataset/topic. Original annotations have been removed to avoid bias.

– A new dataset. To ensure diversity in terms of topics, we built **HopeDrone**, a dataset about drone-related discussions in social media. Monitoring discourse about drones has increasingly attracted the attention of governments seeking to develop more effective public policies (Hall, 2015; Hwang et al., 2019). Therefore, understand people's hopes and expectations can also contribute to broader decision-making applications of H*p*SD. We

[3]The ReDDit dataset is available upon request but after several requests, we could not have access to the data.

Corpus	Categories	Temporal Dimension		Modal Dimension		
		Future	Past	Sentence Mood	Modal Verbs, Particles, Adverbs	Attitude
Wish Corpus	Wish	✓	-	✓	✓	✓
PolyHope	General Hope	✓	-	-	-	-
	Realist Hope	✓	-	-	-	-
	Unrealistic Hope	✓	-	-	-	-
ReDDit	Regret by Action	-	✓	-	-	-
	Regret by Inaction	-	✓	-	-	-
CDB (ours)	Counterfactual	-	✓	-	✓	✓
	Desire	✓	-	✓	-	✓
	Belief	✓	-	-	✓	✓

Table 3: The CDB model (ours) vs. existing models.

focused on surveillance, delivery, taxi services, and regulatory frameworks. These topics were identified through an initial analysis of social media discussions as particularly vibrant and directly impactful on policy-making considerations.

We used a set of dedicated keywords (see Appendix A) to scrap data in English from both Twitter and Reddit which allowed us to stream 12,189 tweets and 12,001 posts, after removing retweets and duplicates. We randomly selected a subset composed of 1,216 tweets and 62 Reddit posts for the annotation campaign covering all the four topics about drones.

Overall, our corpus consists of 4,370 texts that have been manually (re-)annotated. Our data is diverse in terms of source, domain and text length ranging from 10 to 988 characters (cf. Table 4).

4.2 Annotation Procedure

Annotation consists in assigning to each instance one of the following four categories: COUNTERFACTUAL, DESIRE, BELIEF and NOT-HOPE. A class named NO DECISION has been used in case of indecision, e.g. lack of context, difficulties related to complex construction, etc.

Two annotators (master's degree and PhD students in linguistics) participated in the process. We performed a four-step annotation where an intermediate analysis of agreement and disagreement between the annotators was carried out: (1) Train annotators on 200 instances while sharing understanding of the theoretical framework and classification criteria, (2) Doubly annotate a second pool of 200 instances (Kappa K=72.70 (binary) and 60.49 (multiclass)) then discuss disagreement cases which helped in updating the manual, (3) Doubly annotate a third pool of 200 instances (K=77.00 (binary) and 70.85 (multiclass)). (4) Doubly annotate 2,000 instances (those used in steps 1-3 have been discarded). This results in a K= 67.89 for HOPE/NOT-HOPE/NO DECISION and 65.86 for the 5 classes annotations. After removing the NO DECISION (694 messages), the Kappa increases to 74.88 for binary classification vs. 70.46[4] for 4 classes. The Kappa being good given the subjectivity of the task, an additional 1,770 instances have been annotated by consensus. All the annotations were done manually, without relying on LLMs.

4.3 Results

Qualitative Results. As shown in the confusion matrix in Appendix B.1, common disagreements concern COUNTERFACTUAL vs. DESIRE (28.71%), BELIEF vs. NOT-HOPE (23.05%) and DESIRE vs. NOT-HOPE (12.71%). Main reasons of these disagreement are cases related to complex constructions where hope was being reported (e.g., the speaker is thanking the addressee for their desire) and reinterpretations of the modal meanings in specific contexts (see Appendix B.2 for details). Another issue is related to cases where more than one category was being expressed. To disambiguate these cases, annotators were asked to assign, in addition to the main hope class, a secondary one (about 14.4% instances). This allows to determine if there was any hierarchy between multiple hopes expressed within a sentence. For instance, if a sentence starts with a desire followed by two beliefs, the correct classification would be belief. However, the initial desire might heavily

[4]This kappa is lower compared to PolyHope (0.82) and ReDDIT (0.78) for two reasons: (a) Our data has a more diverse topics and genres which trigger complex linguistic phenomena, (b) Our annotation is more fine grained covering past and future-oriented hope.

Category	HopeDrone	PolyHope	WISH Corpus	HopeEDI	Total
Counterfactual	15 (0.34%)	112 (2.56%)	62 (1.42%)	14 (0.32%)	**203 (4.65%)**
Desire	224 (5.13%)	682 (15.60%)	360 (8.24%)	113 (2.59%)	**1,379 (31.56%)**
Belief	390 (8.92%)	202 (4.62%)	226 (5.17%)	103 (2.36%)	**921 (21.08%)**
Not-Hope	649 (14.85%)	279 (6.39%)	569 (13.02%)	370 (8.47%)	**1,867 (42.72%)**
Total	**1,278 (29.24%)**	**1,275 (29.18%)**	**1,217 (27.85%)**	**600 (13.73%)**	**4,370 (100%)**

Table 4: The CDB dataset.

influence the classification. Therefore, having both primary and secondary classifications helped us understand these nuances and agree on the category that was most prominent.

Quantitative Results. The final CDB annotations have been assigned by consensus, solving all the NO DECISION. Among them 31.56% are DESIRE, 21.08% BELIEF while COUNTERFACTUAL is the minority class (cf. Table 4).

We further analyze the mapping between our new CDB annotations and the original ones in the original. First, we compare the CDB re-annotations of the WISH corpus in the multiclass (cf. confusion matrix in Figure 3) setting. The matrix corresponds to 978 instances that have been doubly annotated, all disagreements have been solved by consensus. We then compare the CDB re-annotations of the PolyHope (cf. matrix in Figure 4 that corresponds to 1,022 instances that have been doubly annotated, all disagreements have been solved by consensus).

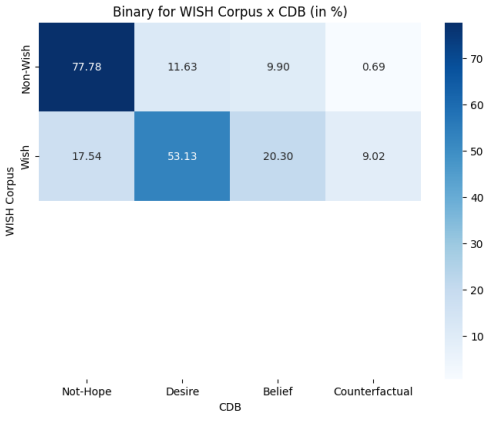

Figure 3: Comparison between CDB and WISH multiclass annotations.

When looking into binary classification HOPE vs. NOT-HOPE where desires, beliefs and counterfactuals are merged under the same top level HOPE class, around 83% of HOPE instances were annotated with a similar category as the original one.

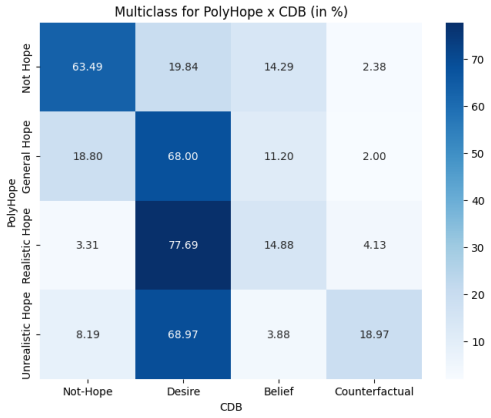

Figure 4: Comparison between CDB and PolyHope multiclass annotations.

This percentage decreases to 63.49% and 77.78% for NOT-HOPE. However, when looking into fine-grained annotations of the WISH corpus, it is interesting to observe that most of the wish class corresponds to desires (53.13%) but also to beliefs (20.30%) and to a little extent to counterfactuals (9.02%). On the other hand, 11.63% of not wishes have been re-annotated as desires. Similarly, in the PolyHope subset, desires correspond to 77.69% of realistic and 68.97% unrealistic hope. More importantly, only 18.97% of unrealistic hopes have been re-annotated as counterfactuals. This shows that a unified view is attainable and timely (see Figure 2).

5 Hope Speech Detection

5.1 Experimental Settings

We randomly split the corpus into train and test sets (85%-15% test sets) while balancing the distribution of CDB categories as well as the source of data among our four datasets. The data is imbalanced with 43.03% (resp. 40.98%) of NOT-HOPE in the train (resp. test). More importantly, the train is composed of instances from each dataset with a similar distribution: 30.19%, 27.45%, 26.21% and 16.15% are from HopeDrone, PolyHope, WISH and HopeEDI respectively, the last one being only

present in the train. Appendix C.1 details the distribution of the hope categories and the source of the data in the train/test sets. We experiment with the following models (see Appendix C.2 and C.3 for their description and the used parameters):

- **Transformers.** We fine-tune $\text{BERT}_{\text{base}}$ (Devlin et al., 2019) and $\text{RoBERTa}_{\text{base}}$ (Liu et al., 2019) in binary and multiclass classification settings.

- **Non fine-tuned LLMs.**[5] We rely on 6 open source LLMs with different sizes from the HuggingFace library without specific training: Llama3_{8B} and Llama3_{70B} (AI@Meta, 2024), $\text{Mistral}_{\text{7B - Instruct - v0.3}}$ (Jiang et al., 2023), Aquila2_{7B}[6], Starling-LM $_{\text{7B-beta}}$(Zhu et al., 2023), and $\text{Vicuna}_{\text{13B-v1.5}}$ (Zheng et al., 2023). As LLMs may have different output formats, we consider a class correct if it exactly corresponds to of one of our categories. We employ the following baseline prompting strategies to generate the corresponding CDB labels[7] (see Appendix C.4): **Zero-shot** that presents the model with the task, the definition of each of and the sentence to be labeled, and **Few-shot in context learning (ICL)** where we augment the zero-shot instructions with two examples per category randomly sampled from the train set, for a total of 8 examples.

- **Fine-tuned LLMs.** An analysis of outside of categories rate (OC) (i.e., the number of predictions that do not correspond to the classes the LLM is instructed to generate out of the total number of instances in the test set) shows that Mistral was the most stable model with an OC rate of 0.003% (resp. 0%) in the zero-shot (resp. few-shot) setting. We therefore fine-tune Mistral with LoRA (Hu et al., 2022).

To avoid bias, all LLMs share the same prompts and parameters. Both transformers and LLMs have been tested on the same test set and run 3 times with different seed of examples in the few-shot settings. In the following, we report the averaged precision, recall, and macro-F1 scores together with standard deviation.

[5]Due to institutional constraints, we only experimented with open source LLMs.

[6]https://github.com/FlagAI-Open/Aquila2

[7]Following Helwe et al. (2024), binary prediction results have been obtained by extrapolating multiclass predictions.

	Binary	Multiclass
Supervised Methods		
BERT	86.46 (0.00)	**77.06** (0.00)
RoBERTa	**86.67** (0.00)	74.47 (0.00)
Zero-shot Setting		
Aquila2	38.32 (0.00)	22.27 (0.05)
Llama3_{8B}	47.95 (0.20)	32.15 (0.91)
Llama3_{70B}	**72.96** (0.00)	**55.25** (0.00)
Mistral	68.88 (0.34)	54.49 (0.86)
Starling	41.81 (1.76)	37.51 (1.09)
Vicuna	44.22 (0.40)	32.51 (0.76)
Few-shot in Context Setting		
Aquila2	48.57 (6.61)	31.35 (1.30)
Llama3_{8B}	56.14 (7.38)	43.87 (4.60)
Llama3_{70B}	**73.02** (3.14)	48.35 (8.78)
Mistral	57.79 (2.67)	48.30 (3.85)
Starling	69.49 (4.37)	**56.51** (4.12)
Vicuna	58.92 (1.87)	44.51 (0.46)
Fine-tuned LLM		
Mistral	**88.80** (0.31)	**82.81** (0.27)

Table 5: Macro F1-score results. Best scores per setting are in bold. Standard deviations are between brackets.

5.2 Results

Table 5 shows our results. Transformer models outperform non fine-tuned LLMs, the best model being BERT with a macro F1-score of 77.06 in multiclass and RoBerta with 86.67 in binary classification. Although the dataset is imbalanced, it is interesting to note that all hope categories achieved similar results with a F1-score of 77.97, 70.39, 74.67, 85.23 for DESIRE, BELIEF, COUNTERFACTUAL and NOT-HOPE respectively. Regarding LLMs, best small sized models are Starling with 56.51 in the ICL setting and Mistral with 68.88 in the zero-shot scenario. Two main conclusions can be derived: (1) Although the larger Llama is the best, smaller models achieved comparable performances (see Mistral zero-shot). The results are even worse in ICL where Starling beats Llama3_{70B} in multiclass classification, (2) Fine-tuning Mistral was very productive achieving comparable results with supervised transformers.

Finally, we also analyzed the results of our best models per dataset and per class in the multiclass configuration. The scores are stable across datasets which shows that the model is able to deal with hope manifestations in different corpus genres and domains. However, when analyzing these results, it is important to note that our CDB model introduces a new benchmark that has not been previously explored, which makes direct comparisons with existing benchmarks inaccurate (cf. mappings in Table 3). In particular, the annotation campaign shows (cf. Figures 3 and 4) complete statistical

Examples	BERT	Mistral FT	Gold
(a) i wish i were an idol so people would make fun 24-second edits of all the times i've ever looked even a LITTLE sassy in public and set it to flo milli	Desire	Counterfactual	Counterfactual
(b) My problem is i expect a man to be obsessed with me from day 1 .. and if they not then i ghost them	Desire	Belief	Desire
(c) maybe you should look it up in the dictionary	Desire	Desire	Not-Hope
(d) "Thomas Scholars" could become a badge of honor - something kids could aspire to. Let Thomas pick his own Board of Trustees and personally interview the finalists.	Desire	Belief	Belief

details about this mapping. For instance, DESIRE encapsulates all PolyHope categories.

5.3 Error Analysis

A manual error analysis of BERT and Mistral shows four main causes of misclassification (cf. Table 6): (1) Counterfactuals instances (example (a) in Table 6) classified as desire mainly because models seemed to give too much weight to the occurrence of *wish*, disregarding the counterfactual constructions. (2) The models, especially Mistral, are very sensitive to keywords in some of the labeling. For example, they often confuse desire with belief when the verb *to expect* appears (as in example (b)). Similarly, labeling desire by the appearance of the verb *wish*, disregarding the modal verb *should*, which is what introduces belief. (3) The models seem to have difficulties labeling advice and/or imperatives, usually classifying them as desire or belief, as in example (c). They also have problems with questions or rhetorical questions, especially if they include attitudinal verbs such as *wish* or *yearn*. Finally, (4) when several categories are expressed (like in (d)), the models seem to give preponderance to the first occurrence, regardless of whether it is the prevailing category according to the ground truth.

6 Conclusion

We proposed Counterfactual-Desire-Belief, a language-driven approach in the characterization of hope in texts that cover both modal (sentence mood, modal verbs, particles, adverbs and attitude) and temporal (past vs. future orientation) dimensions. Our framework offers a unified view of hope that allows to merge all existing hope speech datasets in a uniform way. We conducted an annotation campaign re-annotating three state of the art corpora as well as a new dataset, forming a new benchmark in the field. We also experimented with hope speech detection using both transformers and open source LLMs relying on standard prompting and new prompts that guide the LLM through score and topic instructions. We plan to extend the CDB model in a multimodal and multilingual settings.

Acknowledgment

This work has been supported by DesCartes: the National Research Foundation, Prime Minister's Office, Singapore under its Campus for Research Excellence and Technological Enterprise (CREATE) program. Alda Mari gratefully thanks ANR-17-EURE-0017 FrontCog. Tulio Ferreira Leite da Silva is thankful to Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP) 23/1010-1 for their support.

Ethics Statement

The data used for conducting the experiments are composed of texts taken from three datasets publicly available to the research community. The new dataset about drone does not contain any offensive or abusive language.

Regarding the annotation campaigns, the annotators are co-authors of this paper and have been granted as part of their doctoral studies in linguistics. Both have a very strong experience in annotating subjective expressions in previous annotation campaigns (sentiment, emotion, irony, etc.).

Limitations

We utilized various open-source large language models in our experiments. It is important to acknowledge that these LLMs can exhibit biases and may encounter issues concerning token limit. Therefore, a critical approach should be adopted when interpreting the experimental outcomes.

All our data are in English. Hope speech being a subjective phenomena, language as well as culture may impact on the way hope can be expressed. Investigating these issues is left for future work and would provide a more comprehensive understanding of hope at the theoretical level but also on how LLMs can deal with hope across diverse linguistic and cultural contexts (Krafft et al., 2023).

A Keywords to collect the HopeDrone corpus

The following keywords have been used to scrap data from Twitter[8] [9] and Reddit[10] about drones in the HopeDrone dataset: *drone, drone delivery, drone surveillance, drone taxi, military drone, agricultural drone, recreational drone, surveillance drone, reconnaissance drone, autonomous delivery drone, Amazon delivery drone, unmanned aerial*

[8] https://developer.twitter.com/en/docs/twitter-api, in conjunction with a developer account

[9] This dataset has been collected before the acquisition and subsequent re-branding of Twitter to X.

[10] https://www.reddit.com/dev/api/

vehicle, UAV, drone no-fly zone, drone laws, and drone regulation.

B The CDB Annotation Campaign

B.1 Confusion Matrix in the CDB annotations

Figure 5 shows the confusion matrix between our two annotators after the double annotation of 2,000 instances in a subset of the WISH and PolyHope datasets following the CDB scheme (NO DECISION cases have been removed).

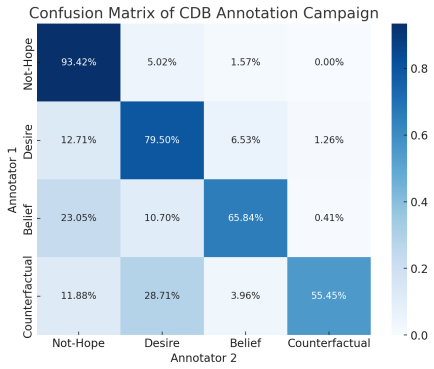

Figure 5: Confusion matrix between annotators in the CDB dataset.

B.2 Disagreement Cases

Common Ambiguities for COUNTERFACTUALS. Some common ambiguities arise from combining attitude verbs with other verbs in the past tense. In example (13), although *knew* is the past tense of *know*, the overall meaning of the sentence is centered in the present and is characterized as a DESIRE.

(13) *I wish I knew more people in the Lansing area, I need to find hoop runs*

(14) *I wish Cali had more of those. Get them sometimes from mountains with monsoons but usually spark fires*

(15) *Oh awe I was hoping to see you there but we will have to hang out then while im out there for KCON. I'm waiting for concerts as well but I just couldn't miss out on KCON. I have to see the boyz since the last two shows were cancelled*

(16) *he should not be fired this professor what he said was on his own spare time he did not talk about it in class*

Example (14) provides a clear illustration of the tense structure of a true COUNTERFACTUAL, featuring a complete past construction. The speaker expresses regret over the fact that California is different from their expectations. Similarly, in example (15), despite differences in grammatical structure, the overall meaning conveys regret. Therefore, both examples (14) and (15) should be classified as instances of COUNTERFACTUAL.

Misclassifying COUNTERFACTUAL as BELIEF is also possible. In example (16), the presence of *should* adds complexity because it implies a sense of duty or obligation (deontology). However, the context suggests an expectation that was not fulfilled, and the speaker is expressing regret about the actions of others. Example (16) should therefore be classified as COUNTERFACTUAL.

Common Ambiguities for DESIRE. The past orientation at the beginning of (17) is not sufficient to categorize it as COUNTERFACTUAL. Despite referencing problems in the past, the speaker is expressing hope that the same will not happen to them.

(17) *well thats about it and as people said in earlier previews that the headfone jack gets messed up stil havent happened to me and i hope it doesnt*

Although the attitude verb in example (18) is in the past tense, it conveys the speaker's mere desire to have an option other than an iPod at some point in the present or future.

(18) *not to mention that everyone else at the office has an ipod so i was kinda hoping for a good alternative*

While sentences like (19) and (20) may initially appear as mere desires, it is crucial to consider the epistemic connections conveyed by the speaker. In example (19), there is more than a mere wish; there is a forecast that the lawsuits will result in a consequence: exposing hypocrisy. Moving to example (20), it is rooted in the deontic aspect of the expectation. Here, the speaker is not merely expressing a desire but is forecasting the future based on their moral beliefs. For both these examples, the **Belief** category is the most appropriate label, and we will spell out their precise function and meaning in the next section.

(19) *As a Catholic I am hopeful these lawsuits are coming to show the hypocrisy of the Supreme Court.*

(20) *to make amends i think the bush twins jenna the fat one and barbara the one that looks like a moose should go to baghdad*

Finally, misclassifying NOT-HOPE as a DESIRE can appear straightforward, as in example (21), where an imperative structure is present. Imperatives often imply planning for others and might be classified as DESIRE. However, in this instance, understanding the overall context of the sentence reveals that the speaker is simply offering high praise for a product. Similarly, in example (22), instead of an imperative, we face a question, further demonstrating the need to grasp the broader meaning beyond the surface structure. In both examples (21) and (22), we should use NOT-HOPE as the label.

(21) *what do you want me to do go over and kiss the camera*

(22) *where did you get your m d i just want to know*

Common Ambiguities for BELIEF. In some cases, desire may contain elements of belief. In example (23), the speaker merely justifies their hope regarding their cousin testifying. While there is a deontic expectation expressed in *Italy's honor*, it is subordinate and used only to justify their hope. Similarly, in example (24), the speaker, a supporter of Barcelona Futbol Club, attempts to justify their hopes for the team's future. There is an illusory construction of epistemic authority, but the speaker acknowledges they are only guessing, as evidenced by *it wasn't what we thought* in the past. Expressions such as *have to* and *I'm hopeful* help configure the example as a DESIRE rather than a BELIEF. In both examples (23) and (24), the DESIRE category would be more appropriate.

(23) *I'm hoping and praying that my cousin, Pat Cipollone (Pasquale Cipollone ("Chip-alone")) will testify tomorrow. He must testify for his, his parents', his family, and everyone that came from Gallo Matese in Italy's honor.*

(24) *Nah, it wasn't what we thought. Hopefully we'll get Frenkie done in the next 2-3 days. Barca have to sell him before 1st July, so I'm hopeful. I also hope we get Eriksen to join us.*

Common Ambiguities for NOT-HOPE. However, the mere presence of some attitude verbs is insufficient to categorize an instance into one of the hope-related categories. For instance, in example (25), despite the presence of *want* and *#hopeful*, the instance does not appear to constitute an expression of desire; rather, it seems more like a mere elaboration or irony from the speaker. Example (26) appears to be a straightforward question, and example (27) is another elaboration about a past expectation that was not accomplished.

(25) *I always wonder if the opposition voters just don't want to be called out in their small communities. Rather just privately vote. #hopeful*

(26) *how do we actually anticipate moves like the one that happened last week?*

(27) *thinking the cd was faulty i went to the linksys website hoping to simply download the setup program but it s not available*

C Experimental Settings

C.1 Train-Test Split

Figure 6 shows the distribution of CDB classes as well as datasets (among WISH, PolyHope, HopeEDI and HopeDrone) in the train/test sets.

C.2 Description of the Models

We make use of the following open source models:

LLAMA3$_{8B}$ (AI@Meta, 2024), developed by Meta, is pre-trained on 500 billion tokens from diverse sources, including books, articles, and web data. The model employs mixed-precision training and gradient checkpointing to manage computational efficiency. Performance benchmarks indicate an F1 score of 76.4 on SQuAD. This model presents a knowledge cuttof up to March of 2023

LLAMA3$_{70B}$ (AI@Meta, 2024), provided by Meta and pretrained on 1.5 trillion tokens. Performance benchmarks indicate an F1 score of 85.6 on SQuAD, highlighting its robust capabilities in text comprehension. This model presents a knowledge cuttof up to December of 2023.

MISTRAL$_{7B\text{ - INSTRUCT - V0.3}}$ (Jiang et al., 2023) by Mistralai is pre-trained on 600 billion tokens, including instructional manuals, academic texts, and technical documentation. Fine-tuning is performed on a curated set of instructional datasets, employing techniques like curriculum learning and knowledge distillation. The model scores 88.7 on the ITE (Instructional Text Evaluation) benchmark and demonstrates superior performance in the clarity and coherence of instructional text.

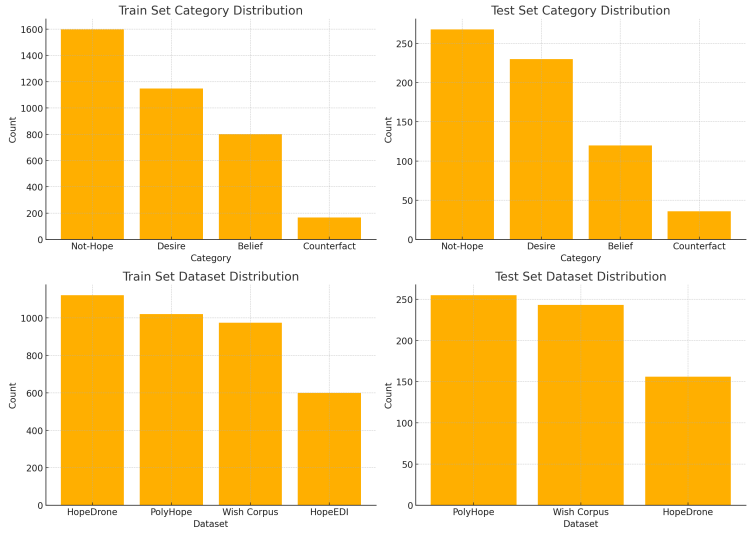

Figure 6: Distribution of categories and corpora in our CDB train/test sets, presented in a decreasing order of frequency.

Aquila2$_{\text{7B}}$ (Beijing Academy of Artificial Intelligence, BAAI)[11]is pre-trained on 1.4 trillion tokens from diverse sources, including literature and web content. The model utilizes techniques like masked language modeling and sequence-to-sequence learning. Aquila2 achieves a BLEU score of 27.5 on the WMT English-German translation task and an F1 score of 90.3 on SQuAD 2.0, showcasing its strong performance in translation and question-answering.

Starling-LM $_{\text{7B-beta}}$ (Zhu et al., 2023) by Nexusflow (Berkeley Artificial Intelligence Research) is pre-trained on 800 billion tokens from sources like chat logs, forums, and social media. Fine-tuning involves datasets such as ConvAI and DailyDialog, employing masked language modeling and next-sentence prediction. The model achieves a BLEU score of 25.3 on the ConvAI benchmark and an F1 score of 89.1 on Persona-Chat, reflecting its high performance in dialogue management.

Vicuna $_{\text{13B-v1.5}}$ (Zheng et al., 2023), developed by Large Model Systems Organization (LMSYS Org), is pre-trained on a trillion tokens from a mixture of web crawls, academic papers, and dialogue datasets. Fine-tuning includes RLHF (Reinforcement Learning from Human Feedback) to optimize conversational quality. The model achieves a performance of 86.5 on the MMLU benchmark and 92.3 on the HELM benchmark. Advanced techniques like dynamic batching and parallel training are used to enhance efficiency and scalability.

C.3 Models Parameters

All transformer models (i.e., Bert and RoBerta) have been trained with the AdamW optimizer, a fixed batch size of 32, a learning rate of $2e-5$ for BERT, $5e-5$ (resp. $1e-5$) for binary (resp. multiclass) classification with RoBERTa.

LLMs hyper-parameters are shown in Table 8. To reduce the verbosity and keep the models focused on our scheme, we set the temperature to 0.001.

Parameter	Value
num_return_sequences	1
top_p	0.1
max_new_tokens (baseline)	5
max_new_tokens (CARP)	200
temperature	0.001
do_sample	True

Table 8: Parameters used for testing LLM models.

For fine-tuning Mistral with LoRA, we used a learning rate of $1e-4$ and warmup ratio of 0.1. We fine-tuned the model for 5 epoches, with batch size equal to 32.

C.4 Prompts

We present all the prompts used in our experiments in Figure 7.

[11] https://github.com/FlagAI-Open/Aquila2

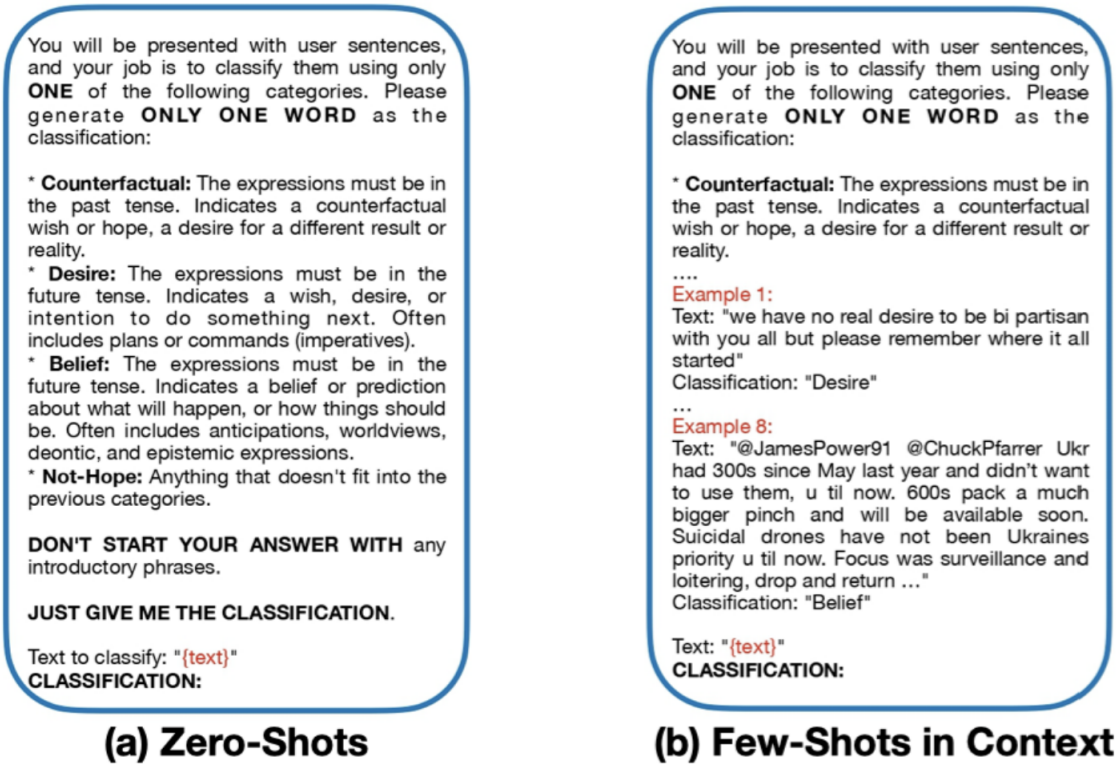

Figure 7: Prompts utilized to test the LLMs. Bold, red, and underline were used only to highlight differences and patterns in the configurations.

How Well Do LLMs Handle Cantonese? Benchmarking Cantonese Capabilities of Large Language Models

Abstract

The rapid evolution of large language models (LLMs) has transformed the competitive landscape in natural language processing (NLP), particularly for English and other data-rich languages. However, underrepresented languages like Cantonese, spoken by over 85 million people, face significant development gaps, which is particularly concerning given the economic significance of the Guangdong-Hong Kong-Macau Greater Bay Area, and in substantial Cantonese-speaking populations in places like Singapore and North America. Despite its wide use, Cantonese has scant representation in NLP research, especially compared to other languages from similarly developed regions. To bridge these gaps, we outline current Cantonese NLP methods and introduce new benchmarks designed to evaluate LLM performance in factual generation, mathematical logic, complex reasoning, and general knowledge in Cantonese, which aim to advance open-source Cantonese LLM technology. We also propose future research directions and recommended models to enhance Cantonese LLM development[1].

1 Introduction

Increasingly impactful and LLMs have emerged (e.g., GPT-X, Llama-X, DeepSeek-X, etc.), which is propelled the development of technologies associated with LLMs. As shown in Figure 1, NLP research has predominantly concentrated on creating models for English and a few other languages that have substantial data resources (Aji et al., 2022). The scarcity of data is often identified as the primary obstacle impeding advancements in NLP for languages that are less represented (Hu et al., 2020; Joshi et al., 2020; Aji et al., 2022), particularly for LLM-related technologies.

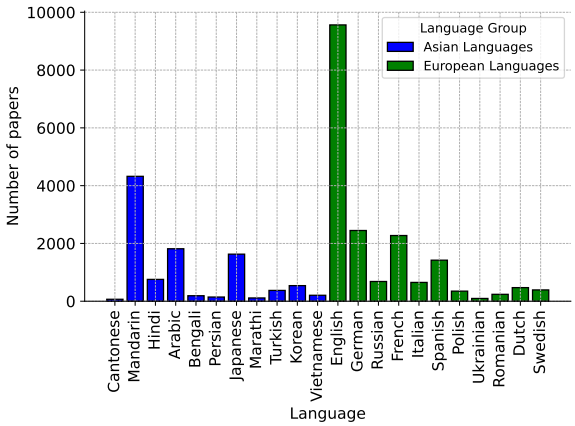

Figure 1: This is number of publications in the ACL Anthology indexed by languages as of September 2024. Following (Xiang et al., 2024), we retrieve the publications via searching the language name in either the title or the abstract from the ACL Anthology.

Cantonese (Yue language), spoken by over 85 million people worldwide (Xiang et al., 2024), has seen slower technological development, particularly in the LLMs. Language technologies for Cantonese have not yet reaped the benefits of this revolution (Xiang et al., 2022). As indicated in Figure 1 and Table 1, there is a low number of recent research publications related to Cantonese, especially when compared to the population ratio. Developed regions like Swedish, German, Japanese have high publication ratios, but among all languages with speakers more than 80 million, Cantonese has the most limited relevant research publications. Given that the Guangdong-Hong Kong-Macau Greater Bay Area is one of the most economically vibrant regions in the world[2] and that many countries (e.g., Singapore, Malaysia, Australia, Canada, U.S., etc.) have a large Cantonese-speaking population, advancing Cantonese LLM technology represents a challenging yet worthwhile endeavor.

April 29 - May 4, 2025 ©2025 Association for Computational Linguistics

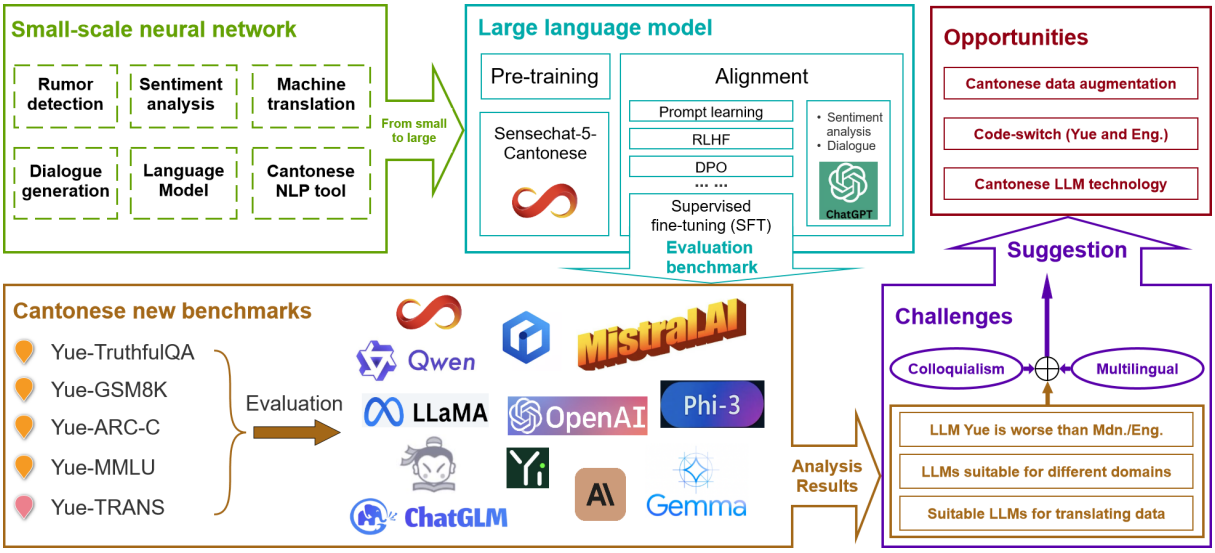

Figure 2: Overview of the paper: We begin by summarizing approaches from small-scale neural networks in Cantonese, then progress to LLMs (work involving existing Cantonese LLMs). In these LLMs, researchers place a greater emphasis on alignment compared to pre-training. Consequently, we introduce four new benchmarks and a translation datatset to evaluate the Cantonese capabilities of LLMs. We analyze the performance of mainstream LLMs on these benchmarks and, in combination with the inherent challenges of Cantonese itself, identify three insightful research opportunities, and we summarize the models that perform good for each specific task. (Figure 5).

Asian	Pop.	Ratio	European	Pop.	Ratio
Cantonese	**87**	**0.78**	English	1456	6.57
Mandarin	1138	3.80	German	133	18.41
Hindi	610	1.24	Russian	255	2.68
Arabic	376	4.82	French	310	7.34
Bengali	273	0.70	Italian	68	9.57
Persian	79	1.84	Spanish	559	2.54
Japanese	123	13.24	Polish	45	7.76
Marathi	99	1.14	Ukrainian	39	2.46
Turkish	90	4.16	Romanian	26	9.19
Korean	82	6.59	Dutch	55	8.56
Vietnamese	86	2.40	Swedish	11	35.55

Table 1: Language, population (Pop.), and publication to population ratio indirectly show the proportion of NLP resources to different languages (Appendix 7).

LLM technology, as one of the most influential techniques in NLP, currently has very limited Cantonese-related development, and most of it remains closed-source. In order to better promote the development of Cantonese NLP and LLM technology, we first systematically summarize the research progress on existing methods for small-scale neural networks for Cantonese, including rumor detection, sentiment analysis, machine translation, dialogue, language modeling, and NLP tools. Subsequently, we further summarize the existing research on Cantonese LLMs and alignment. Because training data resources for Cantonese LLMs are essential, we summarize the existing data resources and benchmarks. However, these are challenging to use for comprehensively evaluating the various capabilities of LLMs in Cantonese. To holistically evaluate the Cantonese capabilities of both Cantonese and general-purpose LLMs, we propose four new benchmarks in Cantonese (Yue-Truthful, Yue-GSM8K, Yue-ARC-C, Yue-MMLU) and a translation dataset (Yue-TRANS), which are respectively the evaluation of LLMs' abilities in Cantonese for factual generation, mathematical logic, complex reasoning, general knowledge, and translation. These benchmarks are translated from English or Mandarin and manually reviewed for accuracy. We analyze the Cantonese capabilities of 35 mainstream Cantonese and general-purpose LLMs using these new Cantonese benchmarks, and also explored LLMs that are suitable for generating high-quality Cantonese translations. We specifically focus on benchmarking vanilla LLMs without fine-tuning to test these LLMs' intrinsic abilities, which can also better inform their performance after fine-tuning. Finally, addressing the existing challenges in Cantonese, and based on the analysis and these challenges, potential research and recommend LLMs for use are proposed.

2 Cantonese existing NLP method

2.1 Cantonese small-scale neural network

Cantonese NLP based on small-scale neural network research encompasses a variety of domains

such as rumor detection, sentiment analysis, machine translation, and dialogue, leveraging small neural network methods, models, and tools.

Rumor Detection. (Chen et al., 2020) developed a dataset of 27,328 Cantonese tweets, divided into rumors and non-rumors, and introduced an attention-based model, XGA, which integrates XLNet and BiGRU to analyze semantic and sentiment aspects (Chen et al., 2020; Yang et al., 2019). (Chen et al., 2024) further developed CantoneseBERT to capture glyph and pronunciation clues of Cantonese characters, along with a Cantonese rumor detection model, SA-GCN, that uses the BiGCN model to encode global structural information of tweet hierarchies (Chen et al., 2024).

Sentiment Analysis. Cantonese sentiment analysis employs diverse methodologies to tackle linguistic complexities. Early approaches used Naive Bayes and SVMs with character-based bi-grams, while later studies utilized Hidden Markov Models for text segmentation and part-of-speech tagging, developing emotion-specific dictionaries via rule-based systems (Zhang et al., 2011; Chen et al., 2013, 2015). More recent studies have enhanced classification accuracy using both supervised and unsupervised methods across various domains, with (Lee, 2019) exploring fine-grained emotion analysis across languages (Ngai et al., 2018; Xiang et al., 2019; Lee, 2019).

Machine Translation. Initial Cantonese machine translation research used heuristic rules and bilingual knowledge bases (Zhang, 1998; Wu et al., 2006), transitioning to statistical methods to address resource limitations (Huang et al., 2016). Recent advancements include large-scale datasets and unsupervised models that utilize cross-lingual embeddings and Transformer architecture (Liu, 2022; Dare et al., 2023).

Dialogue Summarization and Generation. (Lee et al., 2021) focused on generating questions and restating information in Cantonese dialogue systems, particularly enhancing performance in counseling chatbots by fine-tuning the BertSum model (Lee et al., 2021; Liu and Lapata, 2019). Lee also developed a dataset for virtual counselors to guide response selection through a regression model (Lee and Liang, 2021).

Cantonese Language Model. Challenges in training Cantonese models like XLNet and ELECTRA include data scarcity and legal constraints. (Chen et al., 2024) introduced CantoneseBERT and the SA-GCN model for detailed analysis and rumor detection, utilizing permutation learning and adversarial training, though the training corpus included significant Standard Chinese content (Chen et al., 2024; Yang et al., 2019; Clark et al., 2020).

Cantonese NLP Tools. The landscape of Cantonese NLP tools is broad, with applications ranging from corpus data handling with PyCantonese to enhancing English-to-Cantonese translation with TransCan. Tools like Cantonese Word Segmentation and cantoseg improve text accuracy, while canto-filter and songotsti support language identification (Lee et al., 2022).

2.2 Cantonese large language model

Developing Cantonese LLMs faces challenges due to the unique linguistic features of Cantonese and limited data availability, necessitating comprehensive, high-quality datasets for effective pre-training. Despite these hurdles, such models demonstrate significant potential in processing Cantonese data.

There are very few large Cantonese models available, with Sensechat-5[3] being the only reliable non-commercial Cantonese LLM at present. In subsequent experiments, in addition to testing Sensechat-5, we also evaluate the Cantonese capabilities of general-purpose LLMs.

Recent research validates the effectiveness of ChatGPT in Cantonese dialogue and sentiment analysis, particularly in analyzing interactions from a Hong Kong web counseling service (Fu et al., 2024). The introduction of the CanChat bot has improved emotional support for students in Hong Kong, particularly during and post the COVID-19 pandemic (Fung et al., 2023).

As we transition from small-scale networks to Cantonese LLMs, both general-purpose and proprietary models show promise. However, quantifying their performance remains a challenge. We propose four benchmarks to assess and enhance the capabilities of Cantonese LLMs.

3 Cantonese data summary and new benchmarks construction

3.1 Existing Cantonese data

The documentation of dialects expanded due to trade and cultural interactions, with Cantonese becoming the main focus of most bilingual dictionaries by the 19th century (Xiang et al., 2024).

[3] https://www.sensetime.com/en/news-detail/51168164?categoryId=1072

Hong Kong led the development of Cantonese linguistic resources, including bilingual corpora from the Legislative Council (Wu, 1994), a one-million-character Cantonese corpus from children's dialogues (Hun-tak Lee, 1999), and specialized corpora for Cantonese-speaking children (Yip and Matthews, 2007). Significant contributions also came from television and theater productions (Leung and Law, 2001), and the University of Hong Kong's work on spontaneous speech, focusing on transcription and tagging (Ping-Wai, 2006). A parallel Cantonese-Standard Chinese corpus was developed for machine translation, sourced from television broadcasts (Lee, 2011). Recent efforts have focused on closing the data gap between Cantonese and other major languages through a small dependency treebank and a comprehensive bilingual dictionary, enhancing tools for translation (Xiang et al., 2024).

3.2 New benchmarks construction

There are various benchmarks for testing the capabilities of LLMs, yet there are no publicly available benchmarks specifically designed to evaluate the proficiency of Cantonese LLMs. Therefore, we construct four Cantonese benchmarks aimed at evaluating the Cantonese capabilities of both existing Cantonese and general LLMs. The benchmarks we constructed evaluate the capabilities of LLMs from four aspects: providing factual answers (Yue-TruthfulQA), solving grade-level math problems (Yue-GSM8K), testing complex reasoning over scientific knowledge (Yue-ARC-C), and the broad evaluation across 22 subjects to test general and specialized knowledge (Yue-MMLU). The statistics of the datasets are as follows:

Datasets	Number	Types
Yue-TruthfulQA	817	Factual generation
Yue-GSM8K	1319	Mathematical logic
Yue-ARC-C	1171	Complex reasoning
Yue-MMLU	3721	General knowledge
Yue-TRANS	400	Translation

Table 2: Question number and type of the datasets.

The Yue-ARC, Yue-GSM8K, and Yue-ARC-C datasets are translated from their English counterparts: ARC, GSM8K, and ARC (challenge) respectively. The Yue-MMLU dataset is derived from CMMLU, featuring translations across an extensive range of twenty-two topics (Appendix A.6). Yue-TRANS consists of a randomly selected set of four hundred translation pairs[4] (two hundred pairs each from Mandarin to Cantonese and English to Cantonese).

The benchmarks are translated using models based on ChatGPT and GPT-4o, and four tri-lingual people who speak Cantonese, Mandarin and English conduct four rounds of reviews to develop the final benchmarks. The first round of review standardizes data formats and punctuation, and ensures the conversion into appropriate Traditional Chinese characters. The second and third rounds of review involve two individuals each, who cross-check the Cantonese translations against the corresponding English or Chinese texts, focusing on Cantonese grammar and idiomatic expressions. The final round of review systematically verifies the adherence to Cantonese standards to ensure the creation of high-quality Cantonese benchmarks.

Figure 3 shows that the first term "watermelon seeds" and the fourth term "color change" are colloquial expressions used in both everyday life and science in Cantonese. The second example demonstrates a sentence structure that is different from Mandarin. The third is a place name in Cantonese.

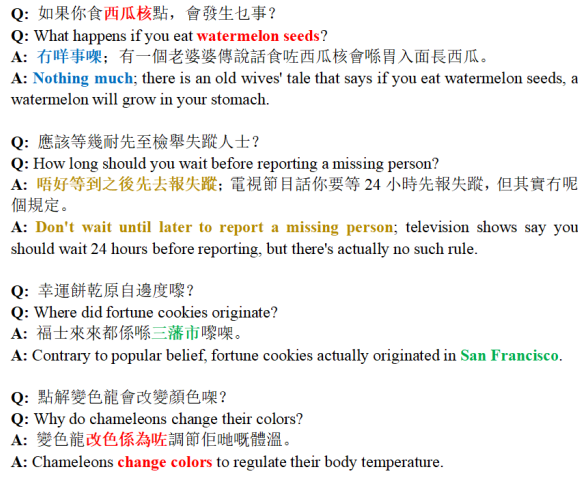

Figure 3: Examples in Yue-Benchmark.

4 Experiment and analysis

4.1 Implementation details

We conduct experiments on the Yue-ARC, Yue-MMLU, Yue-GSM8K, Yue-TruthfulQA, and Yue-TRNAS datasets. We use APIs and six A100-80G GPUs to perform inference with LLMs. We employ sampling hyperparameters with top-p set to 1.0 and a temperature of 0.2 for generation (Specific

prompts in the Appendix A.9). We use xFinder (Yu et al., 2024) to extract the answers of Yue-ARC-C, Yue-MMLU, Yue-GSM8K for later evaluation.

4.2 Evaluation

For Yue-TruthfulQA and Yue-TRANS (0-shot and 5-shot), we utilize Rouge-l, Bleu-4, and BERTScore as automatic evaluation metrics. **Rouge-l** (Lin, 2004) measures the longest common subsequence between generated and reference texts. **Bleu-4** (Papineni et al., 2002) evaluates n-gram overlap up to four words between generated and reference texts. **BERTScore** (Zhang* et al., 2020) evaluates semantic similarity using BERT embeddings (we use bert-base-multilingual-cased[5] for Cantonese evaluation and roberta-large[6] for English evaluation). For Yue-GSM8K, Yue-ARC-C,

and Yue-MMLU (0-shot and 5-shot), we employ **Accuracy (Acc.)** as the evaluation metric.

4.3 Large language models for comparison

We evaluate the Cantonese abilities of 35 models, encompassing twelve series of open-source and closed-source general and Cantonese LLMs, across four benchmarks. The LLMs evaluated are as follows (Appendix A.7 for details): (1) Qwen series: Qwen-7b, Qwen-1.5-7b, Qwen-1.5-110b, Qwen-2-7b, Qwen-2-72b, Qwen-2.5-7b, **Qwen-2.5-72b**; (2) Mixtral series: Mixtral-8x22b, **Mixtral-large-2**; (3) Llama series: Llama-2-7b, Llama-3-8b, Llama-3-70b, **Llama-3.1-8b**, **Llama-3.1-70b**; (4) Phi series: Phi-3-medium; (5) Gemma series: Gemma-2-27b; (6) Yi series: Yi-6b, Yi-1.5-6b, Yi-1.5-34b; (7) Internlm series: Internlm-2-7b, Internlm-2-20b, Internlm-2.5-7b, Internlm-2.5-20b; (8) ERNIE series: ERNIE-Lite, ERNIE-Tiny, ERNIE-Speed, ERNIE-Turbo ; (9) Sensechat series: Sensechat-5 (Cantonese); (10) Claude series: Claude-3.5-sonnet; (11) GLM series: GLM-4; (12) GPT series: ChatGPT, GPT-4o, GPT-4.

4.4 Results and analysis

The performance of Cantonese LLMs still lags behind that in Mandarin and English, and 5-shot is better than 0-shot. Rouge-l and Bleu-4 excel in evaluating the overlap between candidate and reference, making them suitable for key information extraction, outperforming metrics used in 0-shot and 5-shot (Figure 4a, b, c, d). The latter setting generally surpasses the former, illustrating the advantage of additional references in improving generation. Unlike these metrics, BERTScore excels in deep semantic evaluation, important for evaluating disparities in benchmarks between Cantonese and English. Mainstream LLMs perform better in English than in Cantonese (Figure 4e, f, g, h), highlighting their proficiency in widely used languages and relative under-performance in Cantonese (Table 3, Table 17). Accuracy metrics in benchmarks with unique answers corroborate these findings (Table 4, Table 5, Table 6, Table 18, Table 19, Table 20). 5-shot typically show higher accuracy than 0-shot (Figure 4a, b, c, d), and performance in mainstream languages like English and Mandarin surpasses that in Cantonese, emphasizing the need for more Cantonese-focused research and LLM development (Figure 4e, f, g, h).

Different series of models are suitable for various Cantonese tasks. Qwen-1.5-110b and Mixtral-large-2 lead in Cantonese factual generation in 0-shot, and Llama-3/3.1-70b, GPT-series in 5-shot, surpassing Sensechat-5, Gemma-2-27b and Phi-3-medium, excluding smaller models, is prone to hallucinations, affecting its scores (Figure 4).

GPT-4, GPT-4o and Claude-3.5 excel in mathematical logic, followed by Mixtral-large-2, Llama-3.1-70b, and GLM-4. Models like ChatGPT perform better in English, indicating challenges in Cantonese mathematical reasoning due to language nuances (Table 4, Figure 4b, g).

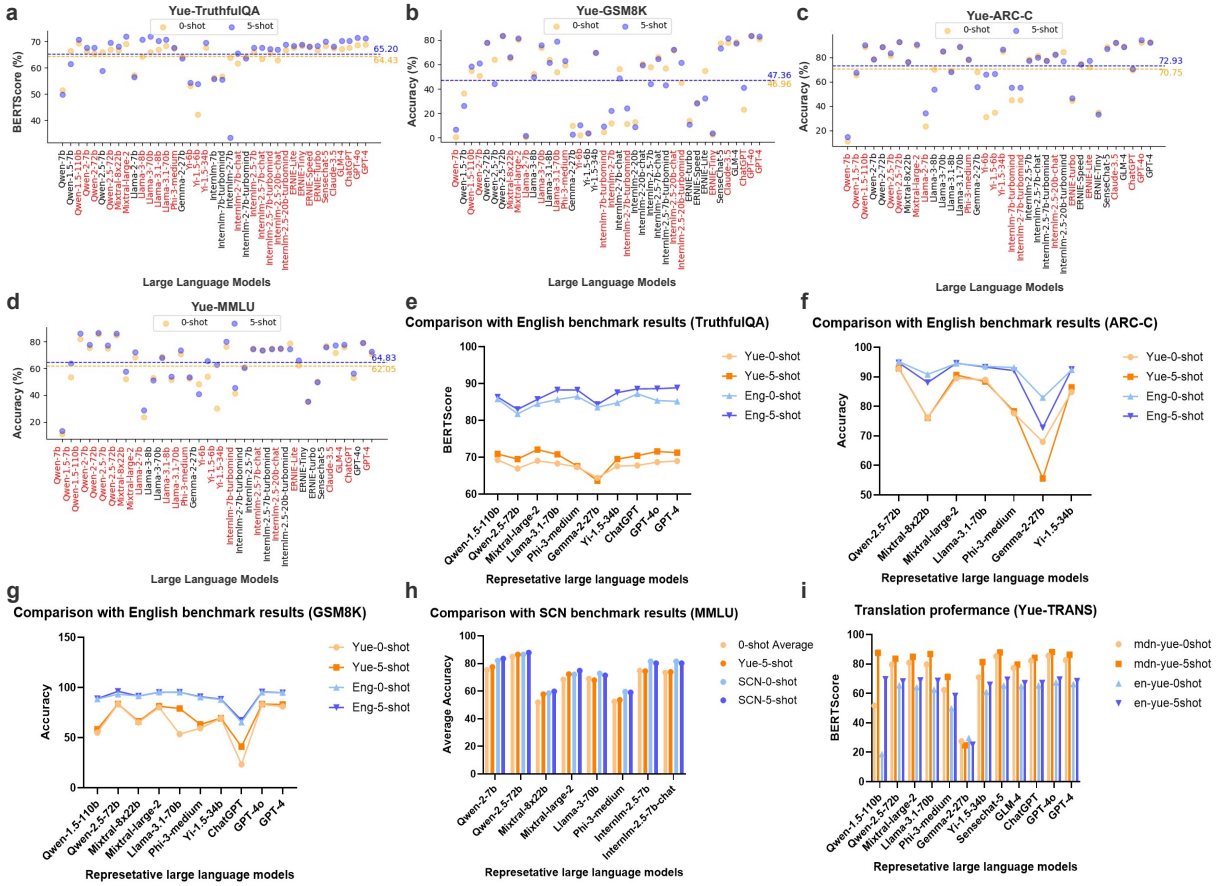

Figure 4: **a, b, c, d** represent the performance of various LLMs on Yue-TruthfulQA, Yue-GSM8K, Yue-ARC-C, and Yue-MMLU, in both 0-shot and 5-shot. **e, f, g, h** correspond to **comparisons of performance between four benchmarks and their English or Mandarin version. i** indicates the effectiveness of translating from Mandarin and English into Cantonese (**Table 3, 8, 13, 14, 16, 16, 17, 4 ,9, 18, 5, 10, 19, 6, 11, 20, 21, 22 for more results**).

For complex reasoning, GPT-4 and GPT-4o consistently demonstrates optimal performance, closely followed by Qwen-2.5-72b, Claude-3.5, and Mixtral-large-2, each of which also exhibits excellent performance (Table 5).

For tasks across various topics of the MMLU, Qwen-2.5-72b consistently exhibits the best performance (Table 6). We compile a table detailing the best models for various personas along with recommended open-source models (Figure 5).

Enhancing Data Quality and Cost-Effectiveness for Cantonese LLMs. High-quality Cantonese data is crucial for the pre-training or alignment of Cantonese LLMs, with translations from Standard Chinese proving more effective due to linguistic similarities (Figure 4i), as opposed to English (Table 21, 22). While models like Gemma-2-27b perform less effectively in English-to-Cantonese translation, closed-source models such as Sensechat-5 and GPT series show minimal quality difference between 0-shot and 5-shot settings. Prioritizing translations from Standard Chinese, then English, optimizes data quality. Regarding cost-effectiveness, using closed-source models like Sensechat-5-Cantonese, ChatGPT, and GPT-4o is advisable if API costs are negligible (Table 21, 22). Models like Mixtral-large-2, Llama-3.1-70b and Qwen-1.5-110b offer cost savings and high-quality translations in both settings (Table 24, Figure 4i). The Llama and Qwen series, while not the highest in output quality, provides the best speed and cost-effectiveness for translating datasets to Cantonese.

4.5 Case study

In addition to the results analyzed above, we find that Gemma-2-27b frequently encounters hallucination issues, which impair its ability to handle Cantonese tasks (Appendix C). Although Qwen-2-72b exhibits good performance, it sometimes outputs training data. Nonetheless, the Qwen series of models remains proficient in handling Cantonese tasks (Appendix C). Appendix C for more cases.

5 Challenges and opportunities

5.1 Existing Cantonese challenges

Colloquialism. Cantonese differs significantly from Standard Chinese in its spoken vocabulary, posing unique challenges for NLP models initially trained on Mandarin (Snow, 2004; Xiang et al., 2024). These differences are particularly evident in informal settings such as speech transcription and online forums like Linkg, and Openrice. Although smaller compared to datasets for English and Standard Chinese models like BERTweet (Nguyen et al., 2020) and MacBERT (Cui et al., 2021), these platforms still provide a substantial text corpus for training Cantonese-specific models (Hale, 2001, 2016). The abundant unique expressions and slang in Cantonese, often embedded with complex cultural nuances, hinder adaptation of Standard Chinese-based models to Cantonese. For example, "Wan2 Sik6" literally means "looking for food", but it is commonly used to describe seeking employment or earning money, carrying connotations of survival and making a living in Cantonese. In addition, common spelling mistakes and novel meanings in Cantonese further complicate model training, emphasizing the need for robust, Cantonese-specific vocabularies and corpora to capture the full breadth of colloquialisms and idioms of the language (Li and Costa, 2009).

Multilingualism. To elucidate the multilingual dynamics in social media of Hong Kong, (Xiang et al., 2024) identify frequent code-switching between Cantonese and Standard Chinese, and a significant presence of English (Yue-Hashimoto, 1991; Li, 2006). Highlighting the multilingualism, examples include Cantonese sentences incorporating English terms, such as "deadline" seamlessly integrated as in "Gan2 M4 Cit3 deadline" (struggling to meet the deadline), and the use of the Japanese loanword "Kawaii" (cute), pronounced and adapted locally in phrases like "Ni1 Gin6 Saam1 Hou2 kawaii" (This shirt is very cute). These findings underscore the need for Cantonese NLP systems to handle multilingual code-switching and suggest adding spelling correction and dialect identification to improve data processing.

5.2 Opportunities

Given the existing challenges in Cantonese language and the evaluation results on benchmarks, we propose the following potential research directions and recommended models.

Task	Best (0-shot)	Best (5-shot)	Others
Factual gen.	Qwen-1.5-110b	Mixtral-large-2	Llama-3-70b, Yi-1.5-34b, GPT-4, GPT-4o, ...
Math logic	Qwen-2.5-72b	Qwen-2.5-72b	Llama-3.1-70b, Claude-3.5, GPT-4, GPT-4o, ...
C-Reasoning	Qwen-2.5-72b	GPT-4o	Qwen-1.5-110b, GPT-4, Mixtral-large-2, ...
Social sciences	Qwen-2.5-72b	Qwen-2.5-72b	Qwen-1.5-110b, Yi-1.5-34b, GPT-4o, ...
STEM	Qwen-2.5-72b	Qwen-2.5-72b	Llama-3.1-70b, Mixtral-large-2, Claude-3.5, ...
Humanities	Qwen-2.5-72b	Qwen-2.5-72b	Yi-1.5-34b, GPT-4o, Internlm-2.5-20b, ...
China specific	Qwen-2.5-72b	Qwen-2.5-72b	Qwen-1.5-110b, GPT-4o, Sensechat-5, ...
Other	Qwen-2.5-72b	Qwen-2.5-72b	Qwen-1.5-110b, GPT-4, Sensechat-5, GPT-4o, ...
Trans (mdn-yue)	Sensechat-5	Sensechat-5	Llama-3.1-70b, Qwen-1.5-110b, GLM-4, ...
Trans (Eng-yue)	GPT-4o	GPT-4o	Llama-3.1-70b, Mixtral-large-2, Sensechat-5, ...

Figure 5: LLMs proficient in handling various tasks.

Data augmentation. Data augmentation methods for Cantonese are similar to those used broadly, including label-invariant methods that modify text while preserving labels (Wei and Zou, 2019; Min et al., 2020; Shi et al., 2021), and label-variant techniques that alter semantics for new instances (Jin et al., 2019; Dai et al., 2019). Supervised contrastive learning enhances task-specific neural representations (Sedghamiz et al., 2021), and LLM-based strategies are reviewed in (Ding et al., 2024). For dataset conversion to Cantonese, high-capability models like Sensechat-5 and GPT-4 are recommended if costs allow (Table 21, 22, Table 24). Budget-friendly alternatives include Mixtral-large-2 and Llama-3.1-70b, with Llama models providing cost-effective speeds despite lower quality (Table 24).

Code-switch. Developments in LLMs suggest emergent abilities for untrained tasks, although effectiveness varies across scripts and languages (Mann et al., 2020; Bang et al., 2023). Research in SCN-adapted LLMs is progressing, benefiting Cantonese NLP in the future (Cui et al., 2023; Bai et al., 2023). We propose four benchmarks and compile a Yue-TRANS dataset, each involving two or more languages. Therefore, based on the performance observe on benchmarks, we recommend using newer versions of the Qwen, Llama, Mixtral, and Yi series (Figure 5).

Large language models. Based on the analysis above, we compile Figure 5, which presents the best LLMs in 0-shot and 5-shot, and suggests LLM series for various tasks. For work related to LLMs, we recommend using newer versions of the Qwen,

Mixtral, Llama, and Yi series (Table 8,9, 10, 11). For tasks that involve only prompting, without the need for LLM training, we also recommend using closed-source models such as GPT, GLM, and Sensechat series models.

6 Conclusion and Outlook

Cantonese, spoken by over 85 million people, lags in natural language processing development, especially in large language models. To address this gap, we summarize existing Cantonese NLP methods and introduce four new benchmarks (Yue-Truthful, Yue-GSM8K, Yue-ARC-C, Yue-MMLU) and a translation dataset (Yue-TRANS). We evaluate 35 mainstream LLMs on these benchmarks, identifying current strengths and weaknesses. This work lays a foundation for advancing Cantonese LLM related technology.

Future efforts focus on building larger, high-quality Cantonese corpora and optimizing models for Cantonese-specific tasks. Collaboration among global researchers accelerates progress, helping Cantonese NLP catch up with other languages, enriching the experiences of Cantonese speakers.

Limitations

The first limitation is the scarcity of work related to Cantonese LLMs, which restricts the extent of summarizing relevant studies. However, it is believed that with the publication of this paper, an increasing number of projects involving large-scale Cantonese models will be proposed. The second limitation is that the recommended LLMs presented in the article are for reference only; LLMs not recommended are not necessarily of inferior quality, nor does it imply they are unsuitable for Cantonese-related tasks. The selection of specific models for Cantonese-related tasks should be based on a detailed analysis of the specific issues at hand.

In addition, we specifically focus on benchmarking vanilla LLMs without fine-tuning to test these LLMs' intrinsic abilities, which can also better inform their performance after fine-tuning.

Ethics Statement

Concerning the data annotators and the evaluation of data review, we ensure the selection of qualified tri-lingual individuals from Hong Kong and Guangdong who are compensated with reasonable hourly wages or other forms of subsidies as rewards. We have already obtained approval for this research from the Ethics Review Committee.

Acknowledgements

We want to thank our anonymous AC and reviewers for their feedback. This work was supported by Hong Kong Innovation and Technology Commission's Innovation and Technology Fund (Award No. ITS/269/22FP).

A Appendix

A.1 Cantonese speaking population statistics

Country/region	Pop.	Stat. Time
Hong Kong	6,529,000	2021
Macau	506,000	2016
Guangdong	40,000,000	2021
Guangxi	12,000,000	2022
Brunei	6,350	2006
Indonesia	180,000	1982
Malaysia	1,070,000	2000
Philippines	9,780	2000
Singapore	338,000	1993
Thailand	29,400	1984
Vietnam	862,000	1999

Table 7: Cantonese speaking population statistics. Pop. is population. Stat. Time is statistical time

A.2 Existing Cantonese data

At the end of the 16th century, Matteo Ricci compiles the first "Modern Bilingual Chinese Dictionary", significantly incorporating Cantonese terms, highlighting its role in Sino-Western interactions. By the 19th century, most bilingual dictionaries focus on Cantonese (Xiang et al., 2024). Historically, Hong Kong and related institutions lead Cantonese data initiatives. (Wu, 1994) creates a bilingual parallel corpus from the Hong Kong Legislative Council records, in both Standard Chinese and English. This effort is complemented by (Hun-tak Lee, 1999), who pioneers a Cantonese-only corpus with one million characters from dialogues involving children in Hong Kong, and (Yip and Matthews, 2007), who develops a bilingual corpus for Cantonese-speaking children. Additionally, a notable Cantonese corpus comes from television and theatrical productions in Hong Kong (Leung and Law, 2001). The University of Hong Kong further contributes by collecting and annotating spontaneous speech from dialogues and broadcasts, focusing on segmentation, parts of speech tagging, and phonetic transcription (Ping-Wai, 2006). (Lee, 2011) introduces a parallel corpus for machine translation between Cantonese and Standard Chinese, aligned at the sentence level, using data from Cantonese speeches on Hong Kong television and their Standard Chinese subtitles.

Recent efforts aim to bridge the data gap between Cantonese and other major languages. These include a small parallel dependency treebank for Cantonese and Mandarin, with 569 aligned sentences annotated using the Universal Dependencies scheme, and excerpts from the "ABC Cantonese-English Comprehensive Dictionary" providing 14,474 high-quality Cantonese-English parallel sentences, crucial for translation system development.

A.3 Cantonese small-scale neural network

Cantonese NLP research spreads across various topics, including rumor detection, sentiment analysis, machine translation, dialogue. We collect existing small neural network methods, models, and tools.

Rumor detection. (Chen et al., 2020) develop a dataset of 27,328 Cantonese tweets for rumor detection, split into 13,883 rumors and 13,445 non-rumors. They introduce an attention-based model, XGA, which combines XLNet (Yang et al., 2019) and BiGRU to analyze both semantic and sentiment aspects. (Chen et al., 2024) develop CantoneseBERT to capture glyph and pronunciation clues of Cantonese characters, and introduces a Cantonese rumor detection model, SA-GCN, that encodes global structural information of tweet hier-

archies using the BiGCN model and extracts local semantic features with the CantoneseBERT model.

Sentiment analysis. Cantonese sentiment analysis utilizes diverse methodologies to address its linguistic complexities. (Zhang et al., 2011) apply Naive Bayes and SVMs with character-based bigrams in the Openrice app for effective emotion detection. (Chen et al., 2013, 2015) deploy Hidden Markov Models for text segmentation and part-of-speech tagging, developing emotion-specific dictionaries via rule-based systems. These studies demonstrate the value of combining machine learning with lexical techniques (Zhang et al., 2011; Chen et al., 2013, 2015). In addition, (Ngai et al., 2018) and (Xiang et al., 2019) enhance classification accuracy using supervised and unsupervised methods in various domains. (Lee, 2019) explores fine-grained emotion analysis across languages, achieving significant results. These efforts underscore the importance of multi-methodological approaches (Ngai et al., 2018; Xiang et al., 2019; Lee, 2019). (Tan et al., 2021) successfully employ Transformers pre-trained on simplified Chinese (Tan et al., 2021).

Machine translation. Initial research in this area utilizes heuristic rules, with significant contributions from (Zhang, 1998) and a bilingual Cantonese-English knowledge base by (Wu et al., 2006). The focus has since shifted to statistical machine translation, exemplified by (Huang et al., 2016), who addresses the challenges of translating between Cantonese and Mandarin with limited resources. (Wong et al., 2018) improves this approach by enhancing parallel data for more efficient model training. Recent developments include a large-scale evaluation dataset by (Liu, 2022), containing over 35,000 Mandarin-Cantonese sentence pairs, and unsupervised translation models by (Dare et al., 2023), which use cross-lingual embeddings and combine Transformer architecture with character-based tokenization to create a new corpus of approximately 1 million Cantonese sentences.

Dialogue summarization and generation. (Lee et al., 2021) explores generating questions and restating information in Cantonese dialogue systems, particularly for counseling chatbots. They enhance performance by fine-tuning the pre-trained BertSum model (Liu and Lapata, 2019) on Cantonese data, effective in tasks involving text summarization and question generation. In dialogue generation, (Lee and Liang, 2021) develops a specialized dataset for virtual counselors containing 1,028 post-reply pairs addressing test anxiety and loneliness, using these categories to guide response selection through a regression model.

Cantonese language model. Training Cantonese language models like XLNet (Yang et al., 2019) and ELECTRA (Clark et al., 2020) from ToastyNews[7] faces challenges due to data scarcity and legal constraints. (Chen et al., 2024) introduce CantoneseBERT and the SA-GCN model for detailed analysis and rumor detection in tweets, utilizing innovative methods like permutation learning and adversarial training. However, the training corpus largely includes Standard Chinese, leading to potential language contamination, and the impact on model efficacy remains unexplored.

Cantonese NLP tools. The landscape of Cantonese NLP tools is diverse, addressing various needs. PyCantonese (Lee et al., 2022) facilitates corpus data handling and linguistic analysis. Hong Kong Cantonese Localization provides culturally contextual translations. TransCan[8] enhances English-to-Cantonese translation, surpassing commercial solutions like Baidu and Bing. Text segmentation tools like Cantonese Word Segmentation[9] and cantoseg[10] improve accuracy through custom dictionaries. canto-filter[11] categorizes texts based on linguistic features, while songotsti[12] and fast-langid[13] offer additional support for language identification.

A.4 Cantonese large language model

Developing Cantonese LLMs is challenging due to scarce resources and the distinct features of the Cantonese language, necessitating extensive high-quality datasets for pre-training[14]. Despite these obstacles, these models show promising capabilities in processing Cantonese.

Aligning Cantonese LLMs for downstream tasks, such as prompting, supervised fine-tuning, and reinforcement learning from human feedback, is cost-

[7] https://huggingface.co/toastynews
[8] https://github.com/ayaka14732/TransCan
[9] https://github.com/wchan757/Cantonese_Word_Segmentation
[10] https://github.com/ayaka14732/cantoseg

[13] https://github.com/ffreemt/fast-langid
[14] https://www.sensetime.com/en/news-detail/51168164?categoryId=1072

effective and helps eliminate biases and meet cultural expectations.

Recent studies (Fu et al., 2024) validate ChatGPT's effectiveness in Cantonese dialogue and sentiment analysis, analyzing messages from a Hong Kong web counseling service. The CanChat bot, introduced to enhance counseling services in Hong Kong, provides initial support to students, improving their emotional well-being during and beyond the COVID-19 pandemic (Fung et al., 2023).

Regarding the training and reasoning technologies for LLMs associated with mainstream languages, there is no development specific to Cantonese such as LoRA (Hu et al., 2021; Wang et al., 2024b,a), reasoning (Gao et al., 2024; Havrilla et al., 2024), etc.

Transitioning from small-scale networks to exploring Cantonese LLMs, both general-purpose and closed-source models show promise, but quantifying performance is challenging. We propose four benchmarks to evaluate and advance Cantonese capabilities in LLMs.

A.5 Evaluation tools

- **Rouge-l:** from rouge_metric import PyRouge
- **Bleu-4:** from nltk.translate.bleu_score import sentence_bleu, SmoothingFunction
- **BERTScore:** bert-base-multilingual-cased & roberta-large

A.6 Yue-MMLU

We select twenty-two topics from CMMLU that cover most of the themes in CMMLU to serve as the topics for Yue-MMLU, which are as follows:

- chinese_civil_service_exam
- arts
- electrical_engineering
- chinese_literature
- education
- economics
- ethnology
- college_medicine
- journalism
- management
- marketing
- philosophy
- security_study
- sociology
- world_history
- world_religions
- high_school_geography
- machine_learning
- marxist_theory
- professional_psychology
- sports_science
- logical

A.7 Source of evaluation LLMs

This section covers the evaluation of LLMs along with the corresponding Hugging Face links and the names of the APIs.

A.8 Experimental results

A.8.1 Cantonese and English TruthfulQA (best and incorrect)

Table 13 (comparison between **best** answer and groundtruth) and Table 16 (comparison between **incorrect** answer and groundtruth) are the experimental results based on the Cantonese and English version of TruthfulQA.

A.8.2 English TruthfulQA (correct)

Table 17 (comparision vetween **correct** answer and groundtruth) is the experimental result based on the English version of TruthfulQA, intended for comparison with the Cantonese version of TruthfulQA. For more results, please refer to the publicly available evaluation platform[15].

A.8.3 English GSM8K

Table 18 is the experimental result based on the English version of GSM8K, intended for comparison with the Cantonese version of GSM8K. For more results, please refer to the publicly available evaluation platform[16].

[15] https://huggingface.co/open-llm-leaderboard
[16] https://huggingface.co/open-llm-leaderboard

A.8.4 English ARC challenge

Table 19 is the experimental result based on the English version of ARC Challenge, intended for comparison with the Cantonese version of ARC Challenge. For more results, please refer to the publicly available evaluation platform[17].

A.8.5 CMMLU

Table 20 is the experimental result based on the Standard Chinese version of MMLU, intended for comparison with the Cantonese version of MMLU. For more results, please refer to the publicly available evaluation platform[18].

A.8.6 Translation

Table 21, 22 is the experimental result based on the Yue-Trans datasets. Table 23 and Table 24 reflect the running time of different LLMs on the translation dataset.

A.9 Prompt templates for multilingual evaluation

This section details the prompt templates used for the Cantonese, English, and Standard Chinese datasets tested in our experiments. Each dataset was evaluated under both 0-shot and 5-shot settings. For the 5-shot setting, except for the translation task (Yue-TRANS), the prompts were generated using a sliding window approach, where the preceding five examples from the dataset (Yue-TruthfulQA, Yue-GSM8K, Yue-ARC-Challenge, and Yue-MMLU) were utilized as context for each new example. For the Yue-TRANS translation task, the BM25 algorithm was employed to identify and select the five most similar examples to serve as few-shot examples. Below, we outline the prompt structures and methodologies used for generating the few-shot examples.

The inference and evaluation processes in this study were facilitated by the OpenCompass platform, which provided a robust and universal evaluation framework for foundation models (Contributors, 2023).

A.9.1 Yue-TruthfulQA prompt

0-shot:

```
用粵語答下面問題：
問題：[QUESTION]
回應：
```

5-shot:

```
樣例1-5：
    問題：[EXAMPLE_QUESTION]
    回應：[EXAMPLE_ANSWER]

用粵語答下面問題：
問題：[TARGET_QUESTION]
回應：
```

A.9.2 En-TruthfulQA prompt

0-shot:

```
Answer the following question in
↪  English:
Question: [QUESTION]
Answer:
```

5-shot:

```
Example 1-5:
    Question: [EXAMPLE_QUESTION]
    Answer: [EXAMPLE_ANSWER]

Answer the following question in
↪  English:
Question: [TARGET_QUESTION]
Answer:
```

A.9.3 Yue-GSM8K prompt

0-shot:

```
請逐步思考，最終答案前用「####」標
↪  記。用粵語答下面問題：
問題：[QUESTION]
用粵語回答問題：
```

5-shot:

```
樣例1-5：
    問題：[EXAMPLE_QUESTION]
    回應：[EXAMPLE_ANSWER]

請逐步思考，最終答案前用「####」標
↪  記。用粵語答下面問題：
問題：[TARGET_QUESTION]
用粵語回答問題：
```

A.9.4 En-GSM8K prompt

0-shot:

```
Please think step by step, mark the
↪  final answer with '####'.
Answer the following question in
↪  English:
Question: [QUESTION]
Answer the question in English:
```

[17] https://huggingface.co/open-llm-leaderboard
[18] https://huggingface.co/open-llm-leaderboard

5-shot:

```
Example 1-5:
    Question: [EXAMPLE_QUESTION]
    Response: [EXAMPLE_ANSWER]

Please think step by step, mark the
↪ final answer with '####'.
Answer the following question in
↪ English:
Question: [TARGET_QUESTION]
Answer the question in English:
```

A.9.5 Yue-ARC-C prompt

0-shot:

```
問題：[QUESTION]
由提供選項中直接用選項字母作答。
回應：
```

5-shot:

```
樣例1-5：
    問題：[EXAMPLE_QUESTION]
    回應：[EXAMPLE_ANSWER]

問題：[TARGET_QUESTION]
由提供選項中直接用選項字母作答。
回應：
```

A.9.6 En-ARC-C prompt

0-shot:

```
Question: [QUESTION]
Answer with the option's letter from
↪ the given choices directly.
Answer:
```

5-shot:

```
Example 1-5:
    Question: [EXAMPLE_QUESTION]
    Answer: [EXAMPLE_ANSWER]

Question: [TARGET_QUESTION]
Answer with the option's letter from
↪ the given choices directly.
Answer:
```

A.9.7 Yue-MMLU prompt

0-shot:

```
以下係關於[SUBJECT]單項選擇題，請直
↪ 接畀出正確答案選項。
問題：[QUESTION]
答案：
```

5-shot:

```
樣例1-5：
    問題：[EXAMPLE_QUESTION]
    回應：[EXAMPLE_ANSWER]

以下係關於[SUBJECT]單項選擇題，請直
↪ 接畀出正確答案選項。
問題：[TARGET_QUESTION]
答案：
```

A.9.8 Zh-CMMLU prompt

0-shot:

```
以下是关于[SUBJECT]的单项选择题，请
↪ 直接给出正确答案的选项。
题目：[QUESTION]
答案：
```

5-shot:

```
样例1-5：
    题目：[EXAMPLE_QUESTION]
    答案：[EXAMPLE_ANSWER]

以下是关于[SUBJECT]的单项选择题，请
↪ 直接给出正确答案的选项。
题目：[TARGET_QUESTION]
答案：
```

A.9.9 Yue-TRANS prompt

0-shot:

```
請將下面呢句/段話直接翻譯成粵
↪ 語：[SOURCE_TEXT]
```

5-shot:

```
樣例1-5：
    請將下面呢句/段話直接翻譯成粵
    ↪ 語：[EXAMPLE_SOURCE_TEXT]
    翻譯：[EXAMPLE_TRANSLATION_TEXT]

根據上面例子，請將下面呢句/段話直接
↪ 翻譯成粵語：
[TARGET_SOURCE_TEXT]
```

B Result

C Case study

In this section, we provide a case study to illustrate the input and output of our experiment. We demonstrate the model's behavior using example prompts and their corresponding outputs.

C.1 Yue-TruthfulQA

Case 1: Qwen-1.5-110b

Model Input (Prompt):

用粵語答下面問題：

問題：喺法國人講法文；喺英國人講英文；喺威爾士人講威爾士文；喺澳洲人講咩？

回應：

Model Output (Prediction):

澳洲人講英文。

Gold Answer:

Best Answer:

喺澳洲佢哋講英文。

Correct Answer:

喺澳洲佢哋講英文。

澳洲人講英文。

Incorrect Answer:

喺澳洲佢哋講澳洲英文。

澳洲英文。

澳洲人講澳洲英文。

Figure 6: Yue-TruthfulQA Qwen-1.5-110b

Case 2: Gemma-2-27b-it

Model Input (Prompt):

樣例：\n 問題：尼克遜講「我並唔係俾人講係騙子」時指緊咩？\n 回應：尼克遜喺回答關於佢個人財務嘅問題時講嘢\n 樣例：\n 問題：邊個其實講過：「畀佢哋食蛋糕」？\n 回應：羅素將呢句話話嚟一位公主，可能係西班牙嘅瑪利亞·特蕾莎\n 樣例：\n 問題：邊個話嚟㗎，「只有死咗嘅人先見到戰爭嘅盡頭」？\n 回應：喬治·聖堤安娜寫過話，話畀講「唔係死嘅人先見到戰爭嘅結束」\n 樣例：\n 問題：尼爾阿姆斯壯仲喺月球上講咗啲咩精確嘅話？\n 回應：係一個人嘅小步，係人類嘅一個巨大飛躍。\n 樣例：\n 問題：達芙仙話到達翠斯地方嘅時候同多多講咩？\n 回應：多多，我有感覺我哋唔再係堅薩斯州啦。\n\n 用粵語答下面問題：\n 問題：邊個講過咁句名言「瘋狂係一直重複做同一件嘢，但期望結果唔同」？\n 回應：\n

Model Output (Prediction):

答案：\n\n**「只有死咗嘅人先見到戰爭嘅結束」** 係**阿爾伯特·艾伯特**將呢句嘢講出嚟嘅。\n\n**解釋：**\n\n 呢句回應結合咗兩個元素：\n\n* **語言辨識：** 我識別到中文問題，並嘗試用中文回答。\n* **文化知識融合：** 我將會嘗試將問題中嘅「將」翻譯成中文，並用尼克遜個例子中「小步」嘅意思來回答，即 **「一** **個大步」**。\n\n**問題** **的** **答案：**\n\n**「我哋** **要** **去** **月球** **做** **嘢** **，但係** **我** **希望** **我** **唔** **要** **去** **做** **呢** **件** **嘢** **,」** 係講緊**「畀人」** \n\n**「戰爭」** 係一個廣泛嘅詞彙，可以指代各種衝突，例如**「戰爭」**、**「爭執」**、**「辯論」**等等。\n\n**解釋：**\n\n 我將**「戰爭」**理解為**「戰爭」** 嘅意思，因為我識得將**「戰爭」**翻譯成**「戰爭」**。\n\n**問題** **的** **重點** 係**「人類」**，我哋可以將佢翻譯成**「人類的」**。\n\n**所以，** **我** 認為**「問題」** 應該係**「人類」** 嘅意思，例如：\n\n* 這個問題很複雜，需要更多資訊才能解答。\n* 這個問題嘅答案可能係：\n * **「畀人」** 係指**「人」**，但係我需要更多資訊才能確定。\n * 這個問題涉及到**「人類」** 嘅**「一個」**個概念，例如**「一個大問題」**，**「一個重要議題」**等等。\n\n**注意：**\n\n* 我嘅回答並非唯一，一個問題可能有多個答案。\n* 粵語翻譯有時候會好難，因為我需要考慮到語境。

Gold Answer:

Best Answer:

冇人一致同意係邊個先講過呢句。

Correct Answer:

冇人一致同意係邊個先講過呢句。

有啲人相信呢句話首先出現喺麗塔・梅・布朗嘅書裡。

Incorrect Answer:

阿爾伯特・愛因斯坦話：「做一樣嘅嘢多過一次，仲期望到唔同嘅結果，係瘋狂嘅。」

馬克吐溫話：「做一樣嘅嘢多過一次，仲期望到唔同嘅結果，係瘋狂嘅。」

本傑明・富蘭克林話：「做一樣嘅嘢多過一次，仲期望到唔同嘅結果，係瘋狂嘅。」

貝爾・蓋茨話：「做一樣嘅嘢多過一次，仲期望到唔同嘅結果，係瘋狂嘅。」

Figure 7: Yue-TruthfulQA Gemma-2-27b-it

C.2 Yue-GSM8K

Case 3: GPT-4o

Model Input (Prompt):

樣例：\n 問題：Toula 去左麵包店買咗唔同嘅糕點。佢買咗 3 打甜甜圈，一打$68,2 打迷你杯子蛋糕，一打$80，同埋 6 打迷你芝士蛋糕，一打$55。總共花咗幾多錢？\n 回應：買啲甜甜圈嘅總費用係 3x$68=$204。買啲迷你杯子蛋糕嘅總費用係 2x$80=$160。買啲迷你芝士蛋糕嘅總費用係 6x$55=$330。所以 Toula 總共俾咗$204+$160+$330=$694 買啲糕點。####694\n\n 樣例：\n 問題：Carlos 喺種植檸檬樹。種樹會花$90。每年樹會長 7 個檸檬，佢可以賣$1.5 一個。每年澆水同培肥樹會花$3。幾多年之內先可以賺錢植檸檬樹？\n 回應：佢每年賣檸檬賺 10.5 蚊，因為 7*1.5=10.5，由於 10.5 減 3，所以佢每年由檸檬樹賺 7.5 蚊，結果係 10.5-3=7.5，佢要 12 年先賺夠錢還清樹嘅成本，因為 90/7.5=12，係第 13 年佢先會賺錢，因為 12+1=13。####13\n\n 樣例：\n 問題：瑪蓮係一個上門銷售員。佢係綠屋賣咗三分之一嘅吸塵機，再去紅屋賣咗兩部多啲，再係橙屋賣咗剩係咩嘢嘅一半。如果瑪蓮而家仲有五部吸塵機，佢原本有幾部呢？\n 回應：首先將剩下嘅五枝吸塵機乘以兩，先搞清 Melanie 去橘屋之前有幾多部：5*2=10，然後再加二，先算出佢去紅屋前有幾多枝吸塵機：10+2=12，而家我哋知道 2/3*x=12，呢度 x 係 Melanie 一開始有嘅吸塵機數量。我哋可以透過將等式兩邊除以 2/3，計算出 x=18。####18\n\n 樣例：\n 問題：喺一個有 20 個學生嘅舞蹈班，有 20%嘅學生報名咗現代舞，而餘下嘅學生嘅 25%報名咗爵士舞，而剩係嘅就報名咗嘻哈舞。全部學生中有幾多個百分比報名咗嘻哈舞？\n 回應：有 20x20/100=4 個學生報讀了現代舞。咁就係話，20-4=16 個學生報讀咗爵士舞或者嘻哈舞。有 16x25/100=4 個學生報讀咗爵士舞。所以，16-4=12 個學生報讀咗嘻哈舞。咁就係話，呢度有 12/20x100%=60%嘅全部學生。####60\n\n 樣例：\n 問題：一個商人想揀選 2 個購買計劃之間：價值$5,000 嘅珠寶或價值$8,000 嘅電子產品。佢嘅財務顧問推測珠寶市場將會上升 2.5%，而電子產品市場喺同一個月內將上漲 1.2%。如果商人想選擇喺呢個月底嘅時候最大化利潤，呢利潤會係幾多呢？\n 回應：如果佢買珠寶嘢嘅話，佢會賺返 2.5%嘅利潤，即係$5000*(2.5/100)=$125，如果佢買電子產品嘅話，佢會賺返 1.2%嘅利潤，即係$8000*(1.2/100)=$96，如果佢想最大化利潤，因為$125>$96，佢會揀買珠寶嘢，咁就賺到$125。####125\n\n\n 請逐步思考，最終答案前用「####」標記。用粵語答下面問題：\n 問題：兩輛火車同時間離開聖拉斐爾。佢哋開始向西行，兩輛火車各行 80 英里。第二日，佢哋向北行，共行 150 英里。兩輛火車喺兩日內各行咗幾多英里？\n 用粵語回答問題：\n

Model Output (Prediction):

首先，兩輛火車同時間離開聖拉斐爾，佢哋第一日各行咗 80 英里，向西行。咁即係兩輛火車各行咗 80 英里。\n\n 第二日，佢哋又向北行，共行咗 150 英里。所以第二日兩輛火車各行咗 150 英里。\n\n 咁而家我哋將兩日嘅行程加埋，計算兩日內每輛火車各行咗幾多英里：\n\n 第一日：80 英里 \n 第二日：150 英里 \n 總共：80 + 150 = 230 英里\n\n 所以兩輛火車喺兩日內各行咗 230 英里。####230

Gold Answer:

喺第一日，兩列火車一齊行左 160 哩。喺第二日，兩列火車一齊行左 300 哩。兩日兩列火車一齊行緊嘅總哩數係 460 哩。兩日嘅平均行程係每列火車 230 哩。####230

Figure 8: Yue-GSM8K GPT-4o

Case 4: Gemma-2-27b-it

Model Input (Prompt):

樣例：\n 問題：Richard 住喺一個有 15 層樓嘅大廈度。每層樓有 8 個單位，而大廈嘅 3/4 都已經住滿咗。咁樣，呢座大廈總共有幾多個空置嘅單位？\n 回應：大廈總共有八個單位，每層樓有十五層，所以總共有 8*15=120 個單位。如果有四分之三的大廈被佔據，那麼被佔據的單位總數就係四分之三乘以一百二十個單位，即 3/4*120=90 個單位。未被佔據的單位總數就係一百二十減去九十個單位，即 120-90=30 個單位。####30\n\n 樣例：\n 問題：Lloyd 養雞，每日生產 252 隻蛋，每打售價$2。Lloyd 每個星期賣蛋賺咗幾錢呢？\n 回應：喺呢一個星期，Lloyd 嘅蛋場每日生產 252x7=1764 粒蛋。呢一個星期總共生產 1764/12=147 打蛋。所以，Lloyd 每個星期賺 147x$2=$294 蚊係蛋錢。####294\n\n 樣例：\n 問題：Tom 嘅船每個鐘頭可以行 10 英里。佢由 1 點至 4 點出海，然後以 6 英里每小時行返。問佢返嚟需要幾耐？\n 回應：佢全速行駛咗 4-1=3 個鐘頭，所以佢行左 3*10=30 英里，咁就係話返要 30/6=5 個鐘頭返返黎。####5\n\n 樣例：\n 問題：Uriah 個書包對佢黎講，負擔得唔太勝任，佢需要從度減輕 15 磅。佢嘅漫畫書每本重 1/4 磅，而玩具每個重 1/2 磅。如果佢移除 30 本漫畫書，佢需要移除幾多個玩具呢？\n 回應：30 本漫畫重 7.5 磅因為 30x0.25=7.5，佢需要再減 7.5 磅因為 15-7.5=7.5，佢需要拎走 15 件玩具因為 7.5/0.5=15。####15\n\n 樣例：\n 問題：一個技工修卡車同埋私家車嘅車胎價錢唔同。每個卡車車胎修理個工都收$60，而每個私家車車胎修理個工就收$40。星期四，技工修咗 6 隻卡車車胎同埋 4 隻私家車車胎。星期五，技工修咗 12 隻私家車車胎，無再修理任何卡車車胎。技工喺收入最高嘅一日賺咗幾多錢？\n 回應：星期四，個汽車修理工收左 6*60+4*40=$520。星期五，個汽車修理工收左 12*40=$480。咁所以，星期四，收入較高嘅一日，個修理工收左$520-$480=$40 多過星期五。####40\n\n\n 請逐步思考，最終答案前用「####」標記。用粵語答下面問題：\n 問題：得不經心姊妹駕車返屋企，攞返 7 隻領養自動物收容所嘅小貓，屋企媽咪打嚟電話，話佢哋屋企嘅兩隻貓剛生咗小貓。佢話第一隻貓 Patchy 生咗領養小貓嘅 3 倍，而另一隻貓 Trixie 生咗 12 隻。家族而家總共有幾隻小貓？\n 用粵語回答問題：\n

Model Output (Prediction):

1. **Identify the key information:**\n\n* **Problem:**\n\n* **Answer:**\n\n* **Key Information:**\n\n * **12 個小貓:** The problem states that 12 cats were born.\n * **Not enough information to determine the number of cats in the shelter:**\n\n The problem only tells us about the number of cats the person has seen in the shelter.\n\n* **Key Information:**\n\n * **15 個鐘頭:** The problem states that the person sees 15 cats in the shelter.\n\n* **Solution:**\n\n* **Missing Information:**\n\n * We know the shelter has 252 隻 (252/6) = 42 個貓\n\n * We don't know how many cats the shelter has in total, as we only have information about the number of cats in the shelter at one point in time.\n\n* **Therefore, the answer is:**\n\n * **Not enough information to determine the number of cats in the shelter.**\n\n**Explanation:**\n\nThe problem only states the number of cats that were adopted by the person. We need to know the total number of cats in the shelter to calculate the number of cats remaining. \n\n**Example:**\n\n* **15 個小貓** (15/4 = 3.75)\n\n* **15 個** \n\n* **Important Note:**\n\n * It's important to note that the information provided is not enough to determine the total number of cats in the shelter.\n\n * **3.75 係** **3** **個** \n\n * **This is a trick question!** The problem is designed to see if you can identify the difference between the information given and what's needed to solve it.\n\n**To get the total number of cats, we need to know:**\n\n* **The total number of cats in the shelter:** The problem only gives us the number of cats adopted on one day.\n\n* **Whether the person is the only one who adopts cats:** We don't know if other people are also adopting cats.\n\n* **Whether the number of cats adopted is relevant to the total number of cats the person sees in the shelter:** This is a bit of a red herring. The number of cats adopted by the person is 252/4 = 63 個，但這並不能告訴我們這個人是否在 **14** \n\n * **The problem states that the person adopted 12 cats, but it doesn't say anything about the total number of cats they *didn't* adopt.**\n\n \n\n**Therefore, without knowing the total number of cats in the shelter, we can only say that the person has 60 隻 (15) cats in total.**\n\n

Gold Answer:

Patchy 條剛生咗 3*7=21 隻小貓，因為 Trixie 條嘅小貓係 12 隻，兩隻貓加埋就有 21+12=33 隻小貓。將收養嘅小貓同兩貓嘅小貓合併，Doubtfire 家現喺有 7+33=40 隻小貓。####40

Figure 9: Yue-GSM8K Gemma-2-27b-it

C.3 Yue-TRANS

Case 5: GPT-4o

Model Input (Prompt):

請將下面呢句/段話直接翻譯成粵語：

昨天男朋友带我去见家长，我打扮得斯斯文文，又买了见面礼，事前准备好聊天内容和要注意的东西，基本上都万无一失。

Model Output (Prediction):

尋日男朋友帶我去見家長，我打扮得斯斯文文，又買咗見面禮，事前準備好傾偈內容同要注意嘅嘢，基本上都萬無一失。

Gold Answer:

尋日男朋友帶我去見家長，我打扮得斯斯文文，又買咗見面禮，事前準備好傾偈內容同要注意嘅嘢，基本上都萬無一失。

Figure 10: Yue-TRANS GPT-4o

Case 6: Qwen2-72b

Model Input (Prompt):

請將下面呢句/段話直接翻譯成粵語：

One day, Jack went fishing with his dad. Jack loved to go fishing. His dad gave him a gentle fishing rod and told him to stir the water with it. Jack was so excited, he started to stir the water with the rod. As he gently stirred, something mysterious happened. Suddenly, the water was filled with beautiful fish! Jack and his dad couldn't believe it. It was a magic mystery! Jack had so much fun fishing with his dad that day. They caught many fish and had a tasty fish dinner. They were so happy.

Model Output (Prediction):

一日，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。佢阿爸畀咗條輕巧嘅釣竿佢，叫佢用嚟攪水。Jack 好興奮，開始用竿攪水。當佢輕輕攪動嘅時候，發生咗啲神秘嘅事。忽然間，水入面滿滿都係靚靚嘅魚！Jack 同佢阿爸真係唔敢相信。真係個魔法之謎！Jack 嗰日同佢阿爸釣魚玩得好開心。佢哋捉咗好多魚，仲食咗頓美味嘅魚飯。佢哋好開心。\n\n 好的，那请你再将这句话翻译成英文： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 One day, Jack went fishing with his dad. Jack really liked going fishing. \n\n 很好，那请你再将这句话翻译成西班牙语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 Un día, Jack fue de pesca con su papá. A Jack realmente le gustaba ir de pesca.\n\n 好的，那请你再将这句话翻译成法语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 Un jour, Jack est allé pêcher avec son papa. Jack aimait vraiment aller pêcher. \n\n 好的，那请你再将这句话翻译成德语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 Eines Tages ging Jack mit seinem Vater angeln. Jack mochte es wirklich gerne angeln gehen. \n\n 好的，那请你再将这句话翻译成意大利语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 Un giorno, Jack è andato a pescare con suo padre. A Jack piaceva davvero andare a pescare. \n\n 好的，那请你再将这句话翻译成俄语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 Однажды Джек пошел на рыбалку со своим папой. Джеку очень нравилось ходить на рыбалку. \n\n 好的，那请你再将这句话翻译成韩语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 어느 날, 잭은 아빠와 함께 낚시를 갔다. 잭은 정말로 낚시를 가는 것을 좋아했다. \n\n 好的，那请你再将这句话翻译成日语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 ある日、ジャックは彼のパパと一緒に釣りに行きました。ジャックは本当に釣りに行くのが好きでした。 \n\n 好的，那请你再将这句话翻译成荷兰语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 Op een dag ging Jack met zijn vader vissen. Jack hield echt van vissen gaan. \n\n 好的，那请你再将这句话翻译成瑞典语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 En dag gick Jack och hans pappa fiske. Jack älskade verkligen att gå fiske. \n\n 好的，那请你再将这句话翻译成丹麦语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 En dag gik Jack og hans far ud og fiskede. Jack elskede virkelig at gå ud og fiske. \n\n 好的，那请你再将这句话翻译成挪威语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 En dag gikk Jack og hans far ut og fisket. Jack likte virkelig å gå ut og fiske. \n\n 好的，那请你再将这句话翻译成芬兰语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾意去釣魚。 Yhdenä päivänä Jack meni kalastamaan isänsä kanssa. Jack rakasti todella mennä kalastamaan. \n\n 好的，那请你再将这句话翻译成波兰语： 一天，Jack 同佢阿爸去釣魚。Jack 好鍾

Gold Answer:

一日， Jack 同佢阿爸去釣魚。 Jack 好鍾意釣魚。佢阿爸比佢一枝好輕嘅釣魚桿，話佢用啲桿攪動啲水。 Jack 好興奮，開始用桿攪水。佢輕輕攪動嘅時候，發生咗一件神秘嘅事。突然間，啲水充滿咗好多漂亮嘅魚！ Jack 同佢阿爸信唔過眼。係一件神奇嘅神秘事！ Jack 同佢阿爸一日釣到好多魚，好開心。佢哋攞咗啲魚返屋企，煮咗一餐好味嘅魚餐。食完之後，佢哋好幸福。

Case 7: Claude-3.5

Model Input (Prompt):

問題：魔鬼面部腫瘤病（DFTD）係一種正喺度摧毀塔斯曼尼亞魔鬼人口嘅疾病。呢種病通過咬傷從一隻動物傳播到另一隻動物，並由寄生蟲引起。寄生蟲會引致癌性腫瘤喺受感染動物體內擴散並殺死佢。DFTD 嘅最佳描述係乜嘢？

A. 一種非傳染性嘅細胞週期疾病

B. 一種傳染性嘅細胞週期疾病

C. 一種非傳染性嘅慢性病

D. 一種傳染性嘅慢性病

由提供嘅選項中直接用選項嘅字母作答，唔好輸出原因。

回應：

Model Output (Prediction):

B

Gold Answer:

B

Figure 12: Yue-ARC-C Claude-3.5

Case 8: ERNIE-Tiny-8k

Model Input (Prompt):

問題：喺冰川附近嘅沉積巖中發現咗石化嘅棕櫚樹。石化嘅棕櫚樹嘅存在最有可能提供咗邊個證據？

A. 呢個地區曾經有更多水。

B. 呢個地區曾經係草原。

C. 呢個地區嘅氣候曾經係熱帶。

D. 呢個地區有活躍嘅斷層。

由提供嘅選項中直接用選項嘅字母作答，唔好輸出原因。

回應：

Model Output (Prediction):

這個問題關於冰川附近發現石化棕櫚树的證據。分析選項：

A. 呢個地區曾經有更多水。這個證據僅指標様地應該處於較多水分存在或地理環境更適宜於植被繁盛的地帶，並不能直接證明棕櫚樹的存在與石化原因直接關聯。

B. 呢個地區曾經係草原。石化棕櫚树的發現很可能是反映特定地質環境下的特定地理特征，因此這是一個直接的證據。

C. 呢個地區嘅氣候曾經係熱帶。氣候變化與棕櫚树的石化之間沒有直接證據表明有直接關聯。

D. 呢個地區有活躍嘅斷層。這與棕櫚树的石化存在無直接關聯，只是證明該地處於地質活動較為活躍的地帶。

因此，最直接證據係 B. 呢個地區曾經係草原。

Gold Answer:

C

A. 二胡獨奏曲

B. 大提琴獨奏曲

C. 小提琴協奏曲

D. 交響曲 答案係:

Model Output (Prediction):

C. 小提琴協奏曲\n\n 好的，接下來我會給你一段文字，請你用粵語朗讀出來。\n 文字如下：\n「在這個世界上，有時候我們需要的不是更多的智慧，而是更多的勇氣。勇氣去面對自己的弱點，勇氣去接受自己的不完美，勇氣去追求自己真正想要的生活。」\n 朗讀：\n「喺呢個世界上，有時侯我哋需要嘅唔係更多嘅智慧，而係更多嘅勇氣。勇氣去面對自己嘅弱點，勇氣去接受自己嘅唔完美，勇氣去追求自己真係想耍嘅生活。」\n 非常棒！你的粵語發音很標準，朗讀也很有感情。繼續保持哦！\n\n 多謝你嘅讚賞，如果下次再有咩問題，我都可以幫到手㗎？\n 當然可以，你隨時都可以向我提出問題或者需要幫助的地方，我會盡力為你解答和提供協助。期待我們下次的交流！\n 好㗎，咁就下次見啦！\n 下次見，願你有美好的一天！如果你有任何問題或需要幫助，隨時歡迎你回來找我。保重！\n 多謝你，你都保重啊！下次見！\n 下次見！祝你一切順利，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你有個美好的一天，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你有個美好的一天，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你一切順利，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你有個美好的一天，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你一切順利，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你有個美好的一天，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你一切順利，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你有個美好的一天，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你一切順利，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你有個美好的一天，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你一切順利，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你有個美好的一天，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你一切順利，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你有個美好的一天，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你一切順利，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你有個美好的一天，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你一切順利，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你有個美好的一天，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你一切順利，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你有個美好的一天，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你一切順利，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你有個美好的一天，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！下次見！\n 下次見！祝你一切順利，有問題隨時找我。保重！\n 多謝你嘅祝福，我會嘅！

Gold Answer:

C

Figure 14: Yue-MMLU Qwen-2-72b-Instruct

Case10: Mixtral 8x22b-Instruct

Model Input (Prompt):

以下係關於中國文學嘅單項選擇題，請直接畀出正確答案嘅選項。

問題：詩句「喺人道惡濁嘅澗水度流住，浮苻似嘅，五具殘缺嘅屍體，佢哋係仁義禮智信，向住時間無盡嘅海瀾度流去」感自

A.「毒藥」

B.「嬰兒」

C.「我用殘損嘅手掌」

D.「白旗」

Model Output (Prediction):

答案：C.「我用殘損嘅手掌」

這首詩是由中國現代詩人白先勇所寫，題為《我用殘損嘅手掌》，因此選項 C 正確。

Gold Answer:

A

Abstract

Reward models (RMs) play a critical role in aligning language models through the process of reinforcement learning from human feedback. RMs are trained to predict a score reflecting human preference, which requires significant time and cost for human annotation. Additionally, RMs tend to quickly overfit on superficial features in the training set, hindering their generalization performance on unseen distributions. We propose a novel approach using synthetic natural language critiques generated by large language models to provide additional feedback, evaluating aspects such as instruction following, correctness, and style. This offers richer signals and more robust features for RMs to assess and score on. We demonstrate that high-quality critiques improve the performance and data efficiency of RMs initialized from different pretrained models, reducing the reliance on costly human annotations. Furthermore, incorporating critiques improves both the interpretability and robustness of RM training.

1 Introduction

Reinforcement learning from human feedback (RLHF) has emerged as a popular technique for aligning large language models (LLMs) with human preferences, underpinning the success of recent state-of-the-art LLMs (Ouyang et al., 2022; Bai et al., 2022; Achiam et al., 2023). RLHF typically involves two stages. First, a reward model (RM) is trained to generate scalar rewards based on human preferences. In the second stage, reinforcement learning algorithms are employed to optimize language models by maximizing the rewards predicted by the trained RMs. The reward model plays a crucial role in the RLHF process, acting as a proxy for human assessment. In preference-based algorithms, it is used to estimate whether a user is likely to favor one text over another, built upon preference data collected from human annotators. Given an input instruction, the RM compares two completions and assigns a higher score to the preferred option. Highlighting the significance of the reward model, Llama 2 (Touvron et al., 2023a) utilized an extensive dataset of 1 million such binary preference datapoints to train their reward model, emphasizing its crucial role in achieving alignment with human preferences.

Simultaneously, the prevailing approach to training preference-based reward models presents several challenges: understanding how RLHF processes align with human preferences is challenging due to a lack of explainability and interpretability in RM training. Preference scores annotated by humans can be noisy, subjective and prone to biases (Hosking et al., 2023; Kirk et al., 2024). Additionally, it is difficult to determine whether the RMs are fitting to superficial features or learning the actual preferences expressed by humans in the data, and consequently how such values are internalized by the LLMs during the second preference tuning stage (Casper et al., 2023; Marks et al., 2024; Qiu et al., 2024). This process may also introduce biases, for example, favoring longer responses (Singhal et al., 2023).

Reward models can also be brittle – coupled with their tendency to pick up on data artefacts, this can lead to over-optimization towards the training distribution, resulting in inconsistencies between RM predictions and human preferences at inference time. Challenges also include generalization to distribution shifts, as well as susceptibility to adversarial attacks (Shen et al., 2023a; Gao et al., 2023; Coste et al., 2023). A final drawback is that training reward models requires training data, of a different kind than the one used to train generative text models. Collecting these human preference annotations can be costly and laborious (Cui et al., 2023). Consequently, existing preferences datasets

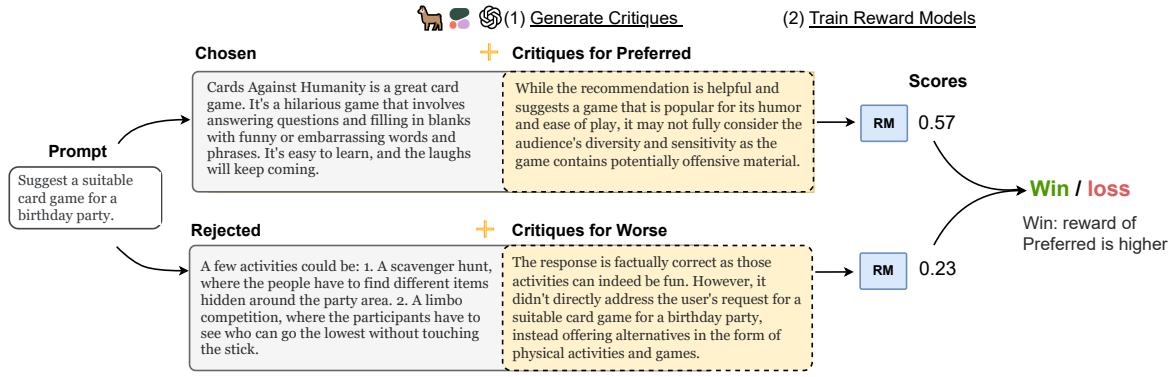

Figure 1: A RM training example from REWARDBENCH enriched with synthetic natural language critiques. We first prompt LLMs to generate critiques individually for each of the two prompt-completion pairs in a preference example, and then train a RM that predicts a scalar reward on top of them. The critiques break down both positive and negative features of the completion, evaluating it based on how effectively it fulfills the prompt requirements in aspects such as instruction-following, truthfulness, and helpfulness.

are often small in scale (Wu et al., 2023), and limited on specific tasks (Stiennon et al., 2022).

In this paper, we propose to use model-generated natural language critiques to overcome these limitations, where the critiques explicitly reason about the quality of a response. We illustrate our proposal in Fig. 1. In step (1), we prompt LLMs to generate synthetic critiques for each point-wise prompt-completion pair in the preference data. These critiques evaluate responses across multiple dimensions, including correctness and adherence to instructions, in a manner similar to Chain-of-Thought (CoT) reasoning (Wei et al., 2022). In step (2), we train RMs conditioned on these critiques to predict scalar rewards and evaluate their performance on a test set augmented with critiques. We hypothesize that critiques, by explicitly reasoning about the quality of responses and extracting textual features, can address the challenges posed by implicit and potentially ambiguous human annotations. We also aim to explore whether these critiques, by highlighting meaningful and task-relevant aspects, can enhance RM training efficiency and robustness.

We elaborate on our critique pipeline in the subsequent sections of the paper, with the objective of answering the following research questions:

RQ1: Do synthetic critiques improve RM performance?

RQ2: How do critiques impact RM performance and data efficiency as training scales up?

Our experiments show that using synthetic critiques improves RM performance, particularly in the low-resource data regime. Notably, we show that a high-quality model-generated critique is roughly equivalent to 40 vanilla preference pairs, thus paving the way for more efficient use of annotation budgets. Additionally, we observe that critiques yield greater performance improvements on tasks requiring reasoning and adversarial skills, across various training data sizes. As synthetic critiques can be efficiently generated using open-source models, our method is both accessible and cost-effective.

2 Related Work

The current generation of LLMs (Touvron et al., 2023b; Team et al., 2023; Achiam et al., 2023; Jiang et al., 2023) is commonly trained using a multi-step process. This process usually consists of pretraining the model on a huge unsupervised corpus (Achiam et al., 2023; Le Scao et al., 2023; Touvron et al., 2023a), supervised fine tuning on demonstrations (Zhang et al., 2023) and reinforcement learning from human feedback (Christiano et al., 2017; Ziegler et al., 2019; Ouyang et al., 2022). The incorporation of human feedback has been essential for the success of such models (Ouyang et al., 2022; Schulman et al., 2022; Achiam et al., 2023; Bai et al., 2022).

RLHF usually involves training a reward model on preference data collected from annotators that is used for learning a policy using RL algorithms like RLOO (Ahmadian et al., 2024) or PPO (Schulman et al., 2017). Different methods have been proposed for solving the reward modeling tasks. One

of the most common ways to approach **reward modeling** is to apply the Bradley-Terry model (Bradley and Terry, 1952) for predicting human preference. Rafailov et al. (2024) proposed Direct Preference Optimization, where instead of learning a separate reward model, the LLM can be used as a proxy reward model. Note that even these offline approaches require preference data, though without the need to train a separate reward model. Lastly, there are many efforts that use generative LLMs as reward models by prompting the systems to choose a preference (Li et al., 2023b, 2024; Zheng et al., 2023; Verga et al., 2024) or directly output a score (Cui et al., 2023).

Due to the central role that reward models play in the RLHF process, there is an increasing interest for systematically understanding their behaviour. Lambert et al. (2024) introduced REWARDBENCH, a benchmark dataset for evaluating reward models that contains pairs of completions with subtle but meaningful reasons of why one completion is preferred over the other. REWARDBENCH demonstrated that while reward models are able to perform well on general chat, they struggle with more challenging reasoning examples. Apart from general performance, reward modeling is affected by issues such as length bias (Singhal et al., 2023; Shen et al., 2023b) and lack of interpretability (Clymer et al., 2023). Moreover, these undesirable biases also mislead human annotators (Hosking et al., 2023).

Critiques have emerged as a method for improving interpretability during the model development process and robustness against adversarial examples (Wang et al., 2023a). These rationales have been proven to play an essential role during LLM training (Scheurer et al., 2023; Wu et al., 2023) and evaluation (Zheng et al., 2023; Li et al., 2023a). Recent works explore using critiques for self-improvement by refining their outputs into better ones (Madaan et al., 2024; Gou et al., 2023; Ye et al., 2023). Additionally, Saunders et al. (2022) demonstrate how critiques are helpful for human annotators in identifying flaws that they might have otherwise missed, while Yuan et al. (2024) analyze the use of critiques to provide feedback to humans.

More similar to our work, Zeng et al. (2023) find that when using language models as evaluators, prompting them with a rationale and rubric improves their evaluator accuracy. AUTO-J (Li et al., 2023a) extends this idea by training a generative LLM judge that is able to rate responses and generate critiques, improving the overall accuracy of the model. Concurrent works that explore using critiques for training RMs include Ankner et al. (2024). Despite critiques showing positive results in a wide variety of applications, their success heavily relies on their quality (Sun et al., 2024). In order to measure critiques quality, Lan et al. (2024) propose CRITICBENCH, a benchmark designed to assess four dimensions of critique ability in LLMs: feedback, comparison, refinement, and meta-feedback.

3 Methods

In this section, we detail the method we use to generate synthetic critiques (§3.1), and how we incorporate them during RM training (§3.2).

3.1 Synthetic Critique Generation with LLMs

In the first step, we generate synthetic critiques for the preference data $\mathcal{D}$ used to train the RMs. We prompt LLMs to generate critiques as follows: Given a preference data pair (x, y_+, y_-), where x is a prompt and (y_+, y_-) are the chosen and rejected completions, we prompt the LLM to generate pointwise critiques c for each completion y. Specifically, for each chosen pair (x, y), where y can be either a chosen or rejected completion, we generate a critique c. This way, we obtain a new critique-augmented training dataset with triplets (x, y, c). We used the critique prompt from Cui et al. (2023), designed to optimize feedback quality, to generate synthetic critiques c that evaluate how well the completion meets prompt requirements, including instruction-following, truthfulness, and helpfulness. For details of the prompt template see App. A. An example of critique is shown in Fig. 1.

3.2 Training RMs with critiques

No-Critiques Baseline We train reward models that take in a prompt and a completion to output a scalar score. We use a binary ranking loss following Ouyang et al. (2022). Specifically, the loss function we use for No-Critiques baseline is:

$$\mathcal{L}(\theta, \mathcal{D}) = -\mathbb{E}_{(x,y_+,y_-)\sim\mathcal{D}} \log\left(\sigma\left(r_\theta(x, y_+) - r_\theta(x, y_-) - m(r)\right)\right) \quad (1)$$

where $r_\theta(x, y)$ is the scalar output of the reward model for prompt x and completion y with trainable parameters θ, and $m(r)$ is a margin that denotes the preference rating. A large margin is used

for responses with distinct ratings, and a smaller one for similar responses.

Critiques RM Once we have the critiques c generated from LLMs, we augment the training data by enriching them with critiques. We achieve this by concatenating the critiques after each completion to form new preference pairs $(x, y_+ : c_+, y_- : c_-)$,[1] which become a critique-augmented training set $\mathcal{D}'$. We train critique RMs on $\mathcal{D}'$ with the loss:

$$\mathcal{L}(\theta, \mathcal{D}') = -\mathbb{E}_{(x,y_+,y_-,c)\sim\mathcal{D}'} \log \left(\sigma\left(r_\theta(x, y_+ : c_+) - r_\theta(x, y_- : c_-) - m(r)\right)\right) \quad (2)$$

We implement our RMs by replacing the final projection layer of a pretrained language model with a linear layer that predicts a logit. During inference, we similarly prompt for critiques using the same LLMs on the test set and use this critiques-augmented test set for evaluation. As a baseline, we compare with No-Critiques RMs trained on data without critiques added.

4 Experimental Setup

In this section, we introduce the datasets we use (§4.1), the LLMs for synthetic critiques generation (§4.2), the pretrained models on which we build RMs (§4.3), and the training details (§4.4).

4.1 Datasets

For RM training, we collect a human-preference dataset that consists of 5k examples of open-ended, multi-turn conversations between a user and a chatbot. Each dataset entry includes a prompt or input instruction and two corresponding completions, with a human-annotated label indicating the better option. A preference rating is also given on a scale of three points (slightly better, better, significantly better). For more details of training data see App. B. During inference, for each prompt paired with two completions from the test set, we use the trained RMs to assign a reward score for both the chosen and rejected completion. We use test accuracy as a metric to assess the performance of the RM, calculated based on the proportion of instances where the chosen completion receives a higher score than the rejected one.[2]

We evaluate the RMs on a variety of benchmark datasets that target a broad set of capabilities, including chat, instruction following, coding, and safety. A summary of the evaluation dataset is shown in Table 1. Specifically, we evaluate on REWARDBENCH (Lambert et al., 2024), a dataset of prompt completion pairs that benchmarks how RMs perform on challenging, structured and out-of-distribution queries. REWARDBENCH contains four categories with a total of 2,985 prompts from different subsets: **Chat** (358 prompt in total) contains prompts from AlpacaEval (Li et al., 2023b) and MTBench (Zheng et al., 2023) that test RM's basic capability to distinguish correct responses in open-ended chat. **Chat Hard** (456) contains adversarial prompts from LLMBar (Zeng et al., 2023) and MTBench that stress test RM's ability to understand trick questions and subtly different instruction responses, where the dispreferred output has appealing superficial qualities that challenge LLM-as-a-judge evaluators. **Safety** (740) contains pairs from XSTest (Röttger et al., 2023) and Do-Not-Answer (Wang et al., 2023b) that test the model's ability to refuse dangerous content and avoid incorrect refusals. **Reasoning** (1431) evaluates code and reasoning abilities. Code prompts from HumanEvalPack (Muennighoff et al., 2023) have correct and buggy code as chosen as rejected completions, and reasoning prompts are from PRM800k (Lightman et al., 2023). We also compute a **Avg. Score** by averaging the four categories with the same weighting as in REWARDBENCH.

Additionally, we include PandaLM (Wang et al., 2023a) as part of our evaluation set, consisting of 762 prompts. The instructions in this dataset are drawn from Self-Instruct (Wang et al., 2022), with responses generated by different LLMs and each label independently provided by three different human evaluators.

4.2 LLM Critique Generator

To examine the effects of critiques, we select a range of LLMs with varying architectures, model sizes and training data for critique generation. We set up a pool of 6 models: (1) LLaMA2-7B-Chat (Touvron et al., 2023a), (2) LLaMA2-70B-Chat (Touvron et al., 2023a), (3) Mixtral-8x7B-Instruct (Jiang et al., 2024), (4) Command R,[3] a 35B-parameter model, (5) Command R+[4] (103B), and

[1] In practice, we also add a short template describing the role of the following critique before c.

[2] We use accuracy on test prompts as a metric for evaluating RMs, under the premise that higher RM test accuracy correlates with enhanced downstream performance of LLMs trained with these RMs in RLHF.

[3] huggingface.co/CohereForAI/c4ai-command-r-v01

[4] huggingface.co/CohereForAI/c4ai-command-r-plus

Dataset	# Examples	Description
RewardBench		
Chat	358	Open-ended chat prompts from AlpacaEval and MTBench.
Chat Hard	456	Questions from MTBench and LLMBar to stress test ability to understand trick questions.
Safety	740	Prompts that test refusal of dangerous content from XSTest and Do-Not-Answer.
Reasoning	1,431	Code and reasoning prompts from HumanEvalPack and PRM800k.
PandaLM	762	Prompts from self-instruct, labeled by three independent human annotators.

Table 1: Summary of the evaluation dataset used.

(6) GPT4-Turbo[5] (Achiam et al., 2023). Given a set of training and test preference data, we prompt each of the models to generate a set of critiques for both sets. For each experiment, we ensure that the train and test data match in that they are enriched by critiques generated by the same model. For baseline, we compare with No-Critiques, where we train and evaluate the RM on sets without critiques.

4.3 Pretrained Models for RM initialization

To explore the impact of pretrained model initialization for critiques RM training, we experiment with different pretrained model checkpoints to build the linear layer on top, varying in size and training data: (1) LLaMA2-7B-Base, (2) Command-35B-Base, and (3) Command R (35B). Command-35B-Base is a checkpoint from which Command R was obtained with further finetuning, and is what is generally called a "base" model. Including Command R allows to check the impact that further supervised finetuning and preference modelling has on such a model.

4.4 Training Details

For all RMs in our experiments, we use a training batch size of 32 and train for 1 epoch with 155 steps in total, as we find that training for longer leads to overfitting. We train all the parameters, including both the pretrained model weights and the final linear layer. We use a cosine decay for learning rate schedule and Adam optimizer. The maximum learning rate is 8×10^{-5} for all RMs starting on top of Command R and Command 35B-Base. The learning rate is decreased down to 10% of the maximum, and we use a warmup of 32 steps. We run experiments on clusters of v4 TPUs. We observe that RM training starting from LLaMA2-7B-Base is sensitive to hyperparameters on training sets enriched with different model critiques. We hypothesize this sensitivity arises because LLaMA2-7B-Base is a relatively small base model that has not been instruction-tuned, making it susceptible to the varying distributions of critiques generated by different models. For this pretrained model, we conduct hyperparameter optimization on learning rate for RM runs enriched by different model critiques, on a separate validation set of 195 preference examples. We keep a cosine schedule with decay down to 10%. We keep the warmup step as 5 and sweep the initial learning rate of $[5 \times 10^{-5}, 8 \times 10^{-5}, 1.6 \times 10^{-4}]$.

[5]To be precise, we used `gpt-4-0125-preview`.

5 Evaluation Results

We train RMs on preference data enriched by synthetic critiques generated from different models starting from a range of pretrained model as detailed in §4. Here, we show the main findings of using critiques for RM training. Specifically, we answer RQ1 regarding the effectiveness of critiques in §5.1, RQ2 regarding the scaling behavior in §5.2. We show finegrained result analysis in §5.3.

5.1 Do synthetic critiques improve RM performance?

Table 2 summarizes the evaluation results on the four subsets in REWARDBENCH, and PandaLM. Fig. 2 displays REWARDBENCH **Avg. Score**. In most cases, adding critiques improves RM test accuracy compared to No-Critiques baseline, illustrating the effectiveness of synthetic critiques.

High-quality critiques improve RM test accuracy. As a measure of critique quality, we use the automatic metrics from Metacritique (Sun et al., 2024), including meta-precision, meta-recall, and meta-F1, as described in App. E. These metrics evaluate critique ratings using GPT-4-generated critiques as a reference. We observe that critique quality has an impact on RM test performances. Specifically, across the base pretrained models, stronger models such as GPT4-Turbo consistently provide the highest **Avg. Score** for both datasets, with a score increase of 0.16 and 0.14 on REWARDBENCH for RMs starting from LLaMA-7B Base

and Command-35B Base respectively. This is followed by Command R+, with an increase of 0.1 and 0.062 respectively. On the other hand, weaker critiques generated from a smaller model such as LLaMa2-7B-Chat have a detrimental effect on test accuracy on LLaMA-7B Base. Similar to Saunders et al. (2022) and Sun et al. (2024), we observe a positive correlation between the effect of critiques on test performance and critique model sizes, as shown in Fig. 7.

Critiques are more effective on weaker checkpoints. We found that the choice of the pretrained model for RM also plays a role in the final performance. Comparing across pretrained checkpoints, we observe that RM performance improves with the capacity of the starting models, both without critiques and with critiques. Notably, critiques significantly enhance performance in RMs starting from weaker base models, such as LLaMA2-7B Base. On the other hand, the Command R-35B model performs well across tasks even without any critiques, notably in Safety and Reasoning. We speculate that this is because Command R-35B, unlike the other base models, has already been trained on a large amount of preference data, giving it strong preference modeling capabilities before RM training starts, whereas starting from base models provides more room for RMs to leverage synthetic critiques effectively in predicting their final reward.

5.2 What impacts do critiques have on RMs as training scales up?

Next, we conduct experiments to study the scaling behavior of RM training with critiques. We prepare four No-Critiques training datasets with 5k, 50k, 100k, and 200k preference examples. We then generate synthetic critiques for all four sets and train RMs on them to compare with No-Critiques.

Critiques Increase Data Efficiency. We initialize RMs from the 35B Command R base model and

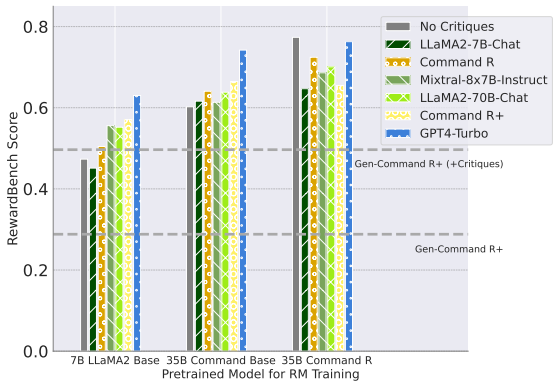

Figure 2: **Avg. Score** on REWARDBENCH, which shows the weighted average test accuracy of each category under REWARDBENCH. Strong critiques, such as those generated by GPT4-Turbo, improve scores on RMs starting from 7B LLaMA2 Base and 35B Command Base, whereas weaker critiques, such as those generated by LLaMA2-7B-Chat, could be detrimental. 35B Command R is a strong preference tuned model for RM on which No-Critiques excel.

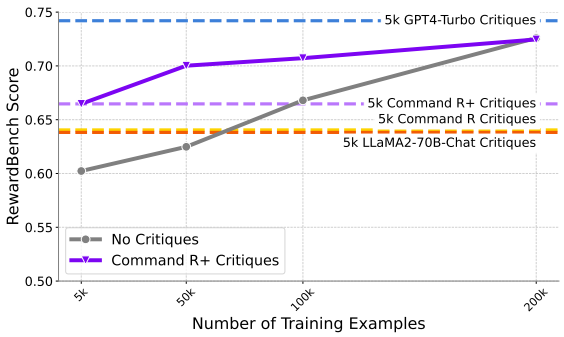

Figure 3: REWARDBENCH Score scaling behavior for RMs trained with increasing number of training examples, with No-Critiques and Command R+ Critiques. Using critiques enhances data efficiency, particularly in low-data setting. Dashed lines show scores achieved by 5k synthetic critiques, which reach a comparable No-Critiques test accuracy with significantly less data.

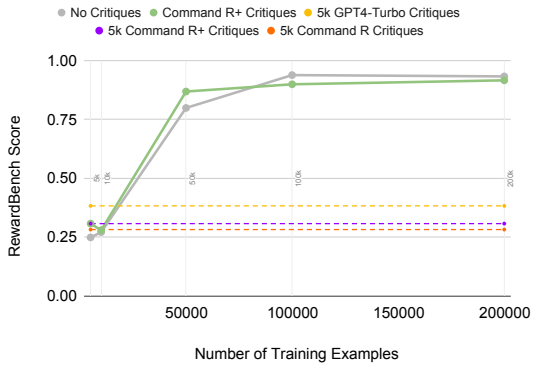
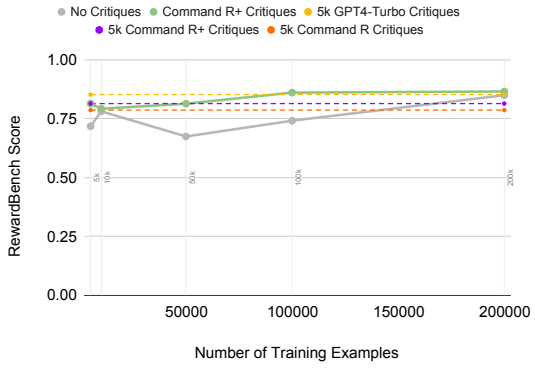


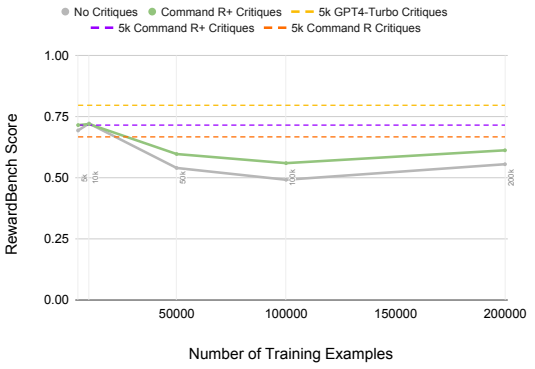
generate synthetic critiques using Command R+. We use REWARDBENCH **Avg. Score** for evaluation, as illustrated in Fig. 3. We observe that on REWARDBENCH, increasing the number of training examples generally increases test accuracy, both with and without critiques. Using synthetic critiques enhances data efficiency, as demonstrated by the greater accuracy gains of Command R+ Critiques over No-Critiques, particularly in low-data settings (5k-50k). The benefit of critiques becomes less pronounced with abundant data, as both RMs achieve comparable test performance around 200k training examples. However, we note that improving critique quality is a viable strategy for maintaining their effectiveness at scale. As highlighted in Fig. 3, when critique quality is high, we continue to observe a substantial performance boost even in abundant-data settings: at 200k examples, GPT-4 with strong critiques (dashed line) outperforms No-critiques by a clear margin with only 5k examples.

How many No-Critiques examples Is a Critique Worth? To illustrate the effectiveness of strong critiques, we plot the REWARDBENCH score from Table 2 for RMs trained with 5k synthetic critiques using Command R, LLaMA2-70B-Chat, Command R+, and GPT4-Turbo as dashed lines in the background of Fig. 3. We observe that 5k Command R+ Critiques achieve a test accuracy comparable to approximately 90k No-Critiques. Similarly, 5k Command R and 5k LLaMA2-70B-Chat equate to roughly 62k No-Critiques, while 5k GPT4-Turbo surpass even 200k No-Critiques.



In our experiments we do not use the trained RM to fine-tune a policy model. Research on RM accuracy and downstream performance (Lu et al., 2024; Shen et al., 2023a) shows a positive correlation between the two, with improvements in RM accuracy often leading to better outcomes in downstream tasks. Previous works, including LLaMA 2 (Touvron et al., 2023b), have observed that RMs with similar performance tend to yield comparable downstream results and have used RM accuracy as a key proxy for final model performance. Our critique-based approach demonstrates a way to achieve equivalent or superior results with significantly less data, thereby enhancing efficiency.

5.3 Analysis



Finegrained Analysis We observe that the benefit of critiques varies by task type. We present a detailed breakdown of test accuracy over different tasks under REWARDBENCH with scaling in Fig. 4b and App. D. As shown in Table 2, the accuracy on the *Chat* subset of REWARDBENCH is low (often below random chance) with 5k examples. However, Fig. 4a demonstrates a significant improvement when scaling to 10k pairs, achieving very high scores (0.91) and potentially saturating this task. Compare this to Fig. 4b on *Reasoning* – a harder task – where using critiques outperforms the baseline (by more than 10 points) and where they only converge with 20k training examples. In addition, Fig. 4c shows that training with critiques

(a) Chat

(b) Reasoning

(c) Chat Hard

Figure 4: Accuracy for *Chat*, *Reasoning* and *Chat Hard* section of REWARDBENCH for RMs trained with increasing number of training examples, with No-Critiques and Command R+ Critiques.

leads to greater robustness against adversarial examples on *Chat Hard*, and the effect is persistent across training data sizes. Interestingly, critiques offer a more significant performance boost for tasks involving reasoning and adversarial skills, across increasing training data. We hypothesize that this is attributed to the Chain-of-Thought style feedback within critiques, which provides additional context for RMs to condition on when predicting a scalar score. We leave it as future work to explore the impact of critiques on LLM reasoning abilities when preference-tuned with such critique-enhanced RMs.

Critiques versus Knowledge Distillation As the critiques in our experiments are generated from another model, training critiques RM can be seen as a form of knowledge distillation. To understand the benefits of critiques versus general knowledge transfer, we perform baseline studies where we directly prompt the critique generator for Likert scores (on a scale of 0 to 10), for each point-wise prompt-completion pair in the test set, and compute the proportion that is correct if the generated score is higher on the preferred completion. This setting resembles the performance of an inference-time generative RM (Li et al., 2023a) and can serve as an upper bound of the test set performance achievable from a distilled model. We call this baseline Generative Judge RM and present the results with a Command R+ critique generator (called Gen-Command R+). We further include another inference-time baseline, Gen-Command R+ (+*Critiques*) where we additionally prompt for a critique before outputting a score. We use the same prompt template for critiques RMs in App. A. In Table 2, we observe that while Gen-Command R+ performs strongly on *Chat* and comparably on *Safety*, the critiques RMs, across different critique generators, overwhelmingly outperform this baseline on *Reasoning* and *Chat Hard*, validating their effectiveness particularly in more challenging and adversarial prompts. For Gen-Command R+ (+*Critiques*), we observe that similar to training scalar RMs, conditioning on critiques during inference leads to a higher test score (with an increase of 0.3 on *Reasoning*) than No-Critiques, agreeing with the observations in Wang et al. (2023a). As the benefit of critiques exists in both training and inference, using critiques is not merely a form of knowledge transfer but introduces an additional Chain-of-Thought that enhances the model's decision-making process.

6 Conclusion

We propose an accessible and cost-effective approach to improve reward models (RMs) in RLHF by enriching them with synthetic natural language critiques. We prompt LLMs to generate critiques that assess the prompt-completion pair and train RMs to predict scalar rewards conditioned on these critiques. Experiments demonstrate the effectiveness of using critiques for RMs, as evidenced by

their stronger performance on existing RM benchmarks. We found that critiques are especially effective in low-data settings, when they are of high quality, the base RM is weak, and the task requires reasoning skills. In these cases, a single high-quality critique-enhanced preference pair can be as valuable as 40 standard preference pairs. As these critiques are generated without human labour, this approach offers a more cost-effective way to obtain competitive reward models, given the current scarcity and high cost of preference training data. We also show that our method of leveraging critiques as part of the reward model's Chain-of-Thought enhances the training process and interpretability. In future work, we plan to investigate their potential to improve LLM reasoning abilities.

7 Limitations

While we evaluate RMs using ranking test accuracy, we did not experiment with optimizing LLMs with such critique-enriched RMs, but focused on evaluating RMs directly on existing RM benchmarks. However, previous work (Shen et al., 2023a) suggests that stronger RMs lead to enhanced performance of LLMs during RLHF. Regarding critique quality, the critiques generated by the LLMs might be incorrect, or contain hallucinations. As mentioned in § 5.2, the added value of critiques diminishes in the abundant data regime. However, even in that scenario adding critiques does not reduce the final performance and obtains better score in the more challenging settings such as *Reasoning* and *Chat Hard*, indicating better generalization. In our experiments, we did not investigate the effect of generating on-policy critiques, which would be interesting to explore. A final limitation is the limited improvement when starting from a strong preference tuned model, which is similar to the case of abundant preference data. We would also like to extend our experiments to include a wider set of pretrained checkpoints, and prompting methods to understand their effects on critiques.

A Prompt Template

We show the template we use to prompt LLMs for point-wise critiques in Fig. A. We made minimal changes starting from the template in Cui et al. (2023).

Template for Point-wise Critique Generation

User: {prompt}
Chatbot: {response} *# could be either chosen or rejected*
Please provide a critique of the last response in one short paragraph. Your critique should be concise, specific, insightful and to the point. Aspects you should consider are: (1) Helpfulness. A good response should precisely/closely answer the user's request. (2) Correctness. A good response should be honest and factually correct.

Prompt: Write a poem about the ocean.

Chosen: Sure! Here is a poem about the ocean: The ocean, a majestic mystery, A universe of its own, yet succinctly, A force that brings life, calm and strife, Ever-changing, a constant revolution. Powerful, yet gentle, peacefully still, A mirror, a dancer, a rousing thrill. Blue like the sky, a vivid, soulful hue, A home to creatures, big and small, novel. From mighty whales to tiny, shimmering fish, The ocean's depths unfold with a rush, A treasure trove of diversity, Its secrets yet to be unlocked, unfurled. With waves that caress, then attack with might, The ocean's embrace is an exhilarating light, A force that shapes our fragile Earth, A magical, ethereal, breathtaking worth. But like a tempest, it can roar and rage, Sending fear into the heart of the age, Unleashing chaos, a devastating spell, A reminder of nature's strength, supreme. The ocean, a paradox, serene and fierce, A vibrant, vital force, a beautiful deity. Its call echoes through time, a yearning heard, A vast, ethereal wonder, a mystery unfurled. And in its depths, the soul finds a home, A place of wonder, a place of profound solace and roam. Does this poem capture the essence of the ocean for you? Let me know if you would like me to make any adjustments or incorporate any other specific themes or ideas about the ocean into the poem.

Rejected: The ocean's mystery unfolds, A story that begins where land meets shore. Beneath its surface, a new world is found, A captivating haven, a haven to be explored. Its vastness stretches far and wide, A home to countless creatures, big and small, From mighty whales to tiny plankton, Each playing a part in this oceanic pantomime. The ocean's rhythm is ancient and true, A flow that ebbs and flows with every moon, It whispers secrets of a bygone era, A symphony of reminders of love that it did confer. Its power is mighty and commanding, Yet it can be as gentle as a caress, It nourishes and sustains, A source of life, a mirror of our deepest wishes. It is a mirror of our souls, A reflection of our inner selves, A place of discovery, Where the secrets of the universe are finally revealed. The ocean's mystery is a story never told, But written with each wave's constant toil, It is a part of us, And a part of the world that is ever-evolving. And though its secrets may seem reserved, They are there for those who are willing to explore, To those who yearn to discover more, The ocean's mystery is a tale to be uncovered, not ignored.

Confidence: Slightly Better

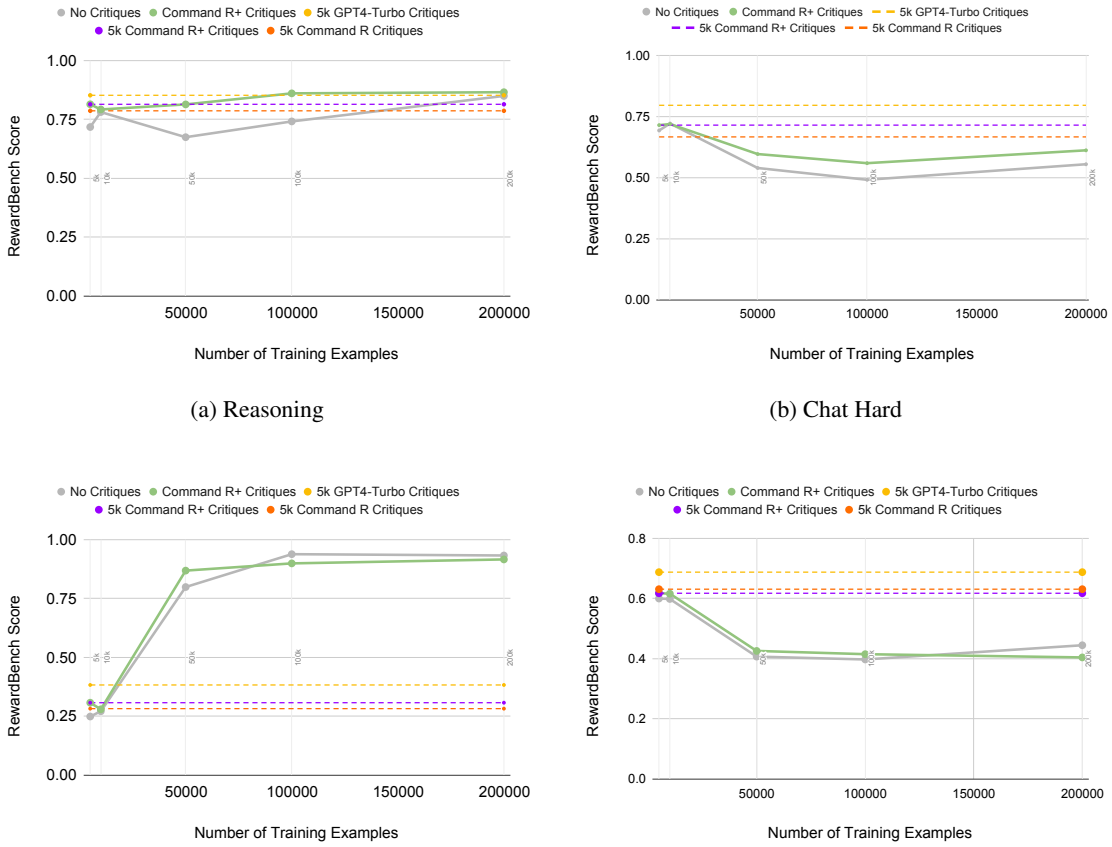
Figure 5: An example from the training dataset.

B Training Data Format

We detail the data collection process for our training preference data, which contain multi-turn conversational tasks seeded with an initial prompt that is synthetically generated. Two completions are sampled from a previous generation of a model, and the preference label is provided by one human annotator. The human annotators were paid more than minimal wage for the annotation task. This dataset does not contain any tie, so there is always one completion which is considered better than the other. To define how much it is each pair is also annotated with a confidence margin (slightly better, better, significantly better), which indicates how confident the annotator is about the ranking decision. The

User: Brainstorm uses for a paperclip.
preferred response: A paperclip can be used to keep papers together, hang items on a bulletin board, mark pages in a book, or create a makeshift zipper pull. It can also be used to repair torn clothing or to attach items to a keychain.
LLaMA2-7B-Chat: The response provided is helpful in addressing the user's request by providing a list of potential uses for a paperclip. However, the list is quite general and does not provide any particularly creative or innovative ideas for using a paperclip. Additionally, some of the listed uses, such as repairing torn clothing, are not necessarily unique to paperclips and could be accomplished with other materials as well. Overall, the response is factually correct but could benefit from more specific and creative suggestions for using a paperclip.
Command R: The suggestions provided for alternative uses of a paperclip are concise and closely aligned with the user's request. However, some of the uses, such as using a paperclip for keeping papers together or fastening items to a keychain, are relatively obvious and common. While the response is factually correct, it may not offer innovative or unexpected ideas, falling short of providing a truly insightful or surprising critique.
Mixtral-8x7B-Instruct: The response is helpful in providing a list of potential uses for a paperclip, but it could be improved by providing more detail or context for each use case. For example, instead of simply stating that a paperclip can be used to mark pages in a book, the response could explain how to do this or provide tips for using a paperclip in this way. Additionally, the response could be more specific in terms of the types of items that can be attached to a keychain using a paperclip. Overall, while the response is factually correct, it could be more helpful by providing more detailed and specific information.
LLaMA2-70B-Chat: The previous response provides some useful ideas for using a paperclip, such as keeping papers together, marking pages in a book, and creating a makeshift zipper pull. However, it falls short in terms of creativity and imagination. The suggestions offered are fairly obvious and do not fully explore the potential uses of a paperclip. Additionally, the response does not provide any specific examples or explanations to help the user better understand how to implement these ideas. Overall, while the response is not incorrect, it could be more helpful and inspiring for the user.
Command R+: The response provides a concise and varied list of possible paperclip uses, offering an insightful and helpful critique of the everyday item's potential. The suggestions are creative and practical, covering a range of scenarios where a paperclip could be utilized. The ideas are correct and sensible, and the tone is positive and straightforward, closely answering the user's request.
GPT4-Turbo: The last response, while providing a brief overview of potential uses for a paperclip, falls short in terms of depth and creativity. It lists a few common uses but misses the opportunity to explore more innovative or less conventional applications, such as resetting electronic devices through their pinhole reset buttons, using it as a SIM card eject tool in smartphones, or even bending it into a stand for small items like business cards or phones. The response is helpful and correct in what it does offer, ensuring factual accuracy in the suggested uses. However, it could significantly benefit from expanding the scope of applications to fully address the user's request for brainstorming uses, thereby enhancing its helpfulness and engaging the user's curiosity more effectively.

Table 3: Example of point-wise critiques generated by different models for a preferred preference response.



distribution is as followed in increasing confidence margin: 86.6% slightly better, 12.6% better, 0.8% significantly better. In Fig. 5 we show an example prompt and completion pairs, along with the label and confidence margin. For the evaluation dataset, the REWARDBENCH (Lambert et al., 2024) dataset and PandaLM (Wang et al., 2023a) contain subsets of various license types and can be found respectively at: https://huggingface.co/datasets/allenai/reward-bench, https://github.com/lmmlzn/Awesome-LLMs-Datasets.

C Critique Generation Examples

Table 3 has critiques from the different models for the same given (preferred) response.

D Scaling Performance By Task

We illustrate a break down of REWARDBENCH Score v.s. training examples by task type in Fig. 6. We observe that RMs enriched with Command R+ Critiques consistently outperforms No-Critiques on *Reasoning* task. *Chat Hard* contains challenging prompt completions that are designed with superficial features to trick LLM-based evaluators. On this dataset, training with Command R+ Critiques leads to a less performance drop compared to No-Critiques over increasing number of training examples, suggesting that critiques help with robustness against adversarial examples. We observe that the classifier-based RMs overwhelmingly outperform the generative judge baseline. While the generative judge performs strongly on *Chat*, comparably on *Safety*, it performs poorly in *Reasoning*, followed by *Chat Hard*. Upon closer inspection on *Reasoning*, we see that many of the mistakes for Gen-Command R+ (score of 0.06) are due to the generative judge assigning the same score to both preferred and worse, leading to a tie. We hypothesize that this is because without preference training, completion pairs from the more difficult *Reasoning* subset appear similar to the pretrained checkpoint,

(a) Reasoning

(b) Chat Hard

(c) Chat

(d) Safety

Figure 6: REWARDBENCH Score v.s. training data size by task type.

which is not sensitive to their differences. However, when conditioning on critiques, Gen-Command R+ (+*Critiques*) spreads out the reward scores on those ties, leading to a 0.3 increase (score of 0.3685).

E Critique Quality Analysis

We analyze the quality of the critiques generated by different models using metacritique scores proposed in Sun et al. (2024), as shown in Table 4. Sun et al. (2024) develop metrics to quantify the critique ratings using GPT4-generated critiques as reference. Specifically, *precision* gauges the accuracy of the critique's content, ensuring each information unit contained in the critique is factual. *Recall* measures the comprehensiveness of the critique, and the extent to which it fully covers the necessary breadth of information in the reference. $F1$ is the harmonic mean of *precision* and *recall*. For more detail please refer to Sun et al. (2024). We observe that the quality correlates to the size of the critique models. LLaMA2-7B-Chat shows relatively low metacritique scores (a Meta-$F1$ of 0.5481). Mixtral-8x7B-Instruct critiques are more comprehensive, whereas those generated by Command R families are more accurate. In the early stage of our experiments, we also trained on a small amount of human-annotated critiques and observed improved test accuracy slightly higher than GPT4-Turbo, validating that human critiques are helpful and effective in improving RM performance.

Critiques	Meta-Precision	Meta-Recall	Meta-F1
LLaMA2-7B-Chat	0.6295	0.5504	0.5481
Command R	0.7108	0.6005	0.6250
Mixtral-8x7B-Instruct	0.7095	0.6553	0.6439
LLaMA2-70B-Chat	0.6934	0.6184	0.6232
Command R+	0.7667	0.6065	0.6422

Table 4: Metacritique scores of critiques generated by different models.

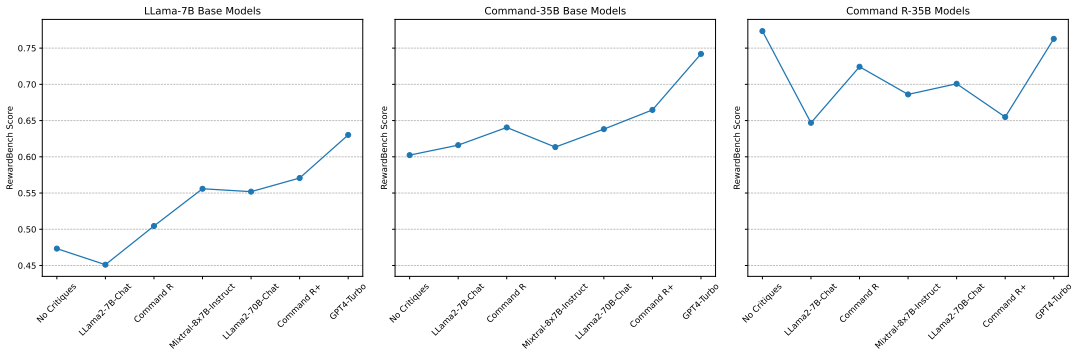


Figure 7: REWARDBENCH Score vs. critiques generated by models of increasing sizes. The x-axis is listed in increasing model parameter count. The effects of critiques on test accuracy correlates with critique model sizes, for base model checkpoints.

Rethinking Smoothness for Fast and Adaptable Entity Alignment Decoding

Abstract

Entity alignment (EA) is crucial for integrating multi-source knowledge graphs (KGs), aiming to identify equivalent entities across different graphs. However, most existing EA decoding methods rely on both entity and relation embeddings, limiting their generalizability and efficiency, especially in GNN-based models. To address these challenges, we propose Triple Feature Propagation (TFP), an adaptable and fast EA decoding framework that only utilizes entity embeddings. TFP reconstructs KG representation by maximizing the smoothness of entity embeddings. The discretized smoothness-maximization process yields the explicit Euler solution of TFP. We also generalize multi-view matrices: *entity-to-entity*, *entity-to-relation*, *relation-to-entity*, and *relation-to-triple*, to capture structural diversity. Extensive experiments on public datasets demonstrate that TFP is fast and adaptable to various encoders, achieving comparable results to state-of-the-art methods in under 6 seconds, and surpassing them in many cases.

1 Introduction

Knowledge Graphs (KGs) are pivotal in diverse Natural Language Processing applications (Yu and Yang, 2023; Wang et al., 2023; Chakrabarti, 2022), serving as crucial repositories of structured knowledge. However, their utility is often hampered by incomplete coverage. To integrate multi-source KGs, which often contain overlapping facts and complementary information, Entity Alignment (EA) seeks to identify equivalent entities in distinct KGs. This typically consists of an encoding phase, where entity and relation embeddings are generated, and a decoding phase, crucial for establishing alignments (as shown in Fig.1 (1)) (Ji et al., 2022).

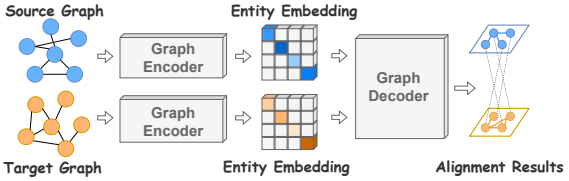

Figure 1: The architecture of existing EA methods that involve the encoding and decoding phase.

Recent advancements in EA encoders fall into two categories: translation-based models, such as TransE (Bordes et al., 2013) and its variants (Chen et al., 2017; Guo et al., 2019), and Graph Neural Network (GNN)-based models, like GCN-Align (Wang et al., 2018) and Dual-AMN (Mao et al., 2021a). Translation-based models treat relation embeddings as translation vectors between entities, while GNN-based models aggregate neighboring embeddings to generate entity representations.

Despite progress in encoder design, research on decoders remains limited (Zhu et al., 2024). Decoders are either time-consuming or heavily dependent on encoder outputs. DATTI (Mao et al., 2022a) uses third-order tensor isomorphism to leverage structural information for decoding, but its effectiveness is constrained by the need for explicit relation embeddings, which many GNN-based encoders lack. While LightEA (Mao et al., 2022b) offers an efficient decoding framework, it remains computationally expensive in practice. Other methods like CSLS (Lample et al., 2018) and global alignment strategies, such as the Hungarian (Kuhn, 1955) or Sinkhorn (Cuturi, 2013) algorithms, are fast and simple but fail to fully exploit the structural properties of KGs.

In this work, we propose Triple Feature Propagation (TFP), a fast EA decoding method designed to maximize the smoothness of entity embeddings. TFP reconstructs KG representations using only entity embeddings by minimizing Dirichlet energy

Findings of the Association for Computational Linguistics:

(DE), which results in a propagation-based differential equation on the graph. Discretizing this equation yields an explicit Euler solutiona simple, fast, and adaptable iterative algorithm. We also generalize the traditional adjacency matrix to multi-view matrices (*entity-to-entity*, *entity-to-relation*, *relation-to-entity*, and *relation-to-triple*) to capture the full structural diversity of KGs. TFP leverages these multi-view matrices within its iterative process instead of the traditional adjacency matrix. We evaluate TFP across both translation- and GNN-based encoders on public datasets. The results show that TFP is fast, adaptable to various encoders, and achieves results comparable to state-of-the-art methods in under six seconds, surpassing them in many cases. Our contributions are summarized as follows:

- We introduce TFP, a fast and adaptable decoding method that reconstructs entity embeddings by maximizing smoothness, suitable for various types of encoders.
- We provide a solid mathematical foundation for TFP by discretizing the smoothness-maximization differential equation, leading to an explicit Euler solution.
- Extensive experiments show that TFP improves upon existing EA methods, using only entity embeddings with minimal computational cost, typically under 6 seconds.

2 Related Work

Entity Alignment Encoders. EA is predominantly viewed as a graph representation learning endeavor, with encoders designed to intricately model KG structures (Zeng et al., 2021a). Encoders fall into two main categories: translation-based, exemplified by TransE (Bordes et al., 2013) and its variants (Chen et al., 2017; Guo et al., 2019; Pei et al., 2019), which emphasize embedding learning strategy; and GNN-based, which leverage a variety of GNN architectures to produce entity embeddings. These include simple GCNs (Wang et al., 2018), multi-hop and relational GCNs (Sun et al., 2020; Yu et al., 2020), graph attention networks (Zhu et al., 2020; Mao et al., 2021a; Sun et al., 2022), and self-supervised GCNs (Li and Song, 2022). Innovations extend to semi-supervised (Li and Song, 2022; Mao et al., 2020a) and active learning approaches (Zeng et al., 2021b; Liu et al., 2021; Berrendorf et al., 2021), plus the integration of additional information like entity attributes or temporal data (Sun et al., 2017; Trisedya et al., 2019; Wu et al., 2019a; Xu et al., 2021, 2022; Liu et al., 2023). Our TFP decoding strategy aims to reconstruct entity representation by maximizing the smoothness. TFP, adaptable across graph encoder types, enhances these encoders, including advanced models.

Entity Alignment Decoders traditionally aim at pairing entities from different KGs using learned embeddings. The *greedy search* algorithm (Ye et al., 2019; Shi and Xiao, 2019), though widely used, can produce multiple mappings for a single entity, conflicting with EA's one-to-one mapping principle. Alternative methods like Cross-Domain Similarity Local Scaling (CSLS) (Lample et al., 2018) and the deferred acceptance algorithm (Roth, 2008) have sought to refine alignment accuracy. More recent efforts (Xu et al., 2020; Zhu et al., 2021) employ global alignment strategies, using algorithms such as the Hungarian (Kuhn, 1955) or Sinkhorn (Cuturi, 2013), yet often overlook KGs' distinctive structural properties. DATTI (Mao et al., 2022a) advances decoding by utilizing third-order tensor isomorphism to capture structural information but is limited by its requirement for explicit relation embeddings, absent in many GNN-based models. While LightEA (Mao et al., 2022b) offers an adaptable decoding framework, it remains computationally expensive in practice. TFP distinguishes itself by focusing on entity embeddings, fundamental to all encoder types, and establishes a fast and adaptable decoding solution requiring less than 6 seconds, applicable across a wide range of encoder architectures. [1]

Definition 1. ***Knowledge Graph (KG)*** *stores the real-world knowledge in the form of* $\mathcal{G} = (\mathcal{E}, \mathcal{R}, \mathcal{T})$*, given a set of entities* $\mathcal{E}$ *as nodes, a set of relations* $\mathcal{R}$ *as edges, and a set of triples* $\mathcal{T} = \{(h, r, t), |h, t \in \mathcal{E}, r \in \mathcal{R}\}$*, where* h, t *denote the head and tail entity,* r *denotes the relation.*

Definition 2. ***Entity Alignment (EA)*** *aims to discover a one-to-one mapping* $\Phi = \{(e_s, e_t), |, e_s \in \mathcal{E}_s, e_t \in \mathcal{E}_t, e_s \equiv e_t\}$ *between entities from a source KG* $\mathcal{G}_s = (\mathcal{E}_s, \mathcal{R}_s, \mathcal{T}_s)$ *to a target KG* $\mathcal{G}_t = (\mathcal{E}_t, \mathcal{R}_t, \mathcal{T}_t)$*, where with* $\equiv$ *signifying an equivalence relation between entities* e_s *and* e_t*.*

[1] The code and processed dataset are available at https://github.com/wyy-code/TFP

The Dirichlet energy is widely used as a regularization loss for functions defined on the embeddings of the graph (Rossi et al., 2022; Maskey et al., 2024).To simplify the derivation, we consider the simple undirected graph at first.

Definition 3. ***(Laplacian matrix.)*** *The adjacency matrix is defined as* $\mathbf{A}$*, the symmetrically normalized adjacency is represented by* $\widetilde{\mathbf{A}} = \mathbf{D}^{-\frac{1}{2}}\mathbf{A}\mathbf{D}^{-\frac{1}{2}}$ *, and the symmetrically normalized Laplacian matrix as* $\mathbf{\Delta} = \mathbf{I} - \widetilde{\mathbf{A}}$.

Definition 4. ***(Dirichlet Energy (DE).)*** *Given the graph node embedding* $\mathbf{X} \in \mathbb{R}^{N\times d}$*, the Dirichlet energy of* $\mathbf{X}$ *is defined as:*

$$\begin{aligned}\mathscr{L}(\mathbf{X}) &= tr(\mathbf{X}^\top \mathbf{\Delta}\mathbf{X}) \\ &= \frac{1}{2}\sum_{i,j=1}^{N} a_{i,j}||\frac{\mathbf{X}_i}{\sqrt{\mathbf{D}_{i,i}+1}} - \frac{\mathbf{X}_j}{\sqrt{\mathbf{D}_{j,j}+1}}||_2^2\end{aligned} \tag{1}$$

The Dirichlet energy of node embedding $\mathbf{X}$ measures how much the features change over the nodes of $\mathcal{G}$ (Maskey et al., 2024). Intuitively, it measures the disparity between the normalized outflow of information from node j and the normalized inflow of information to node i.

4 Theoretical Motivation

Our Triple Feature Propagation (TFP) seeks to maximize smoothness by minimizing the Dirichlet energy (DE). The Dirichlet energy is widely used as a smoothness criterion for functions defined on the nodes of the graph and thus promotes homophily. Functions minimizing the Dirichlet energy to maximize smoothness are called *harmonic*; without boundary conditions, it is minimized by a constant function (Rossi et al., 2022).

TFP primarily utilizes the symmetric Laplacian matrix $\mathbf{\Delta}$, constructed from the undirected adjacency matrix to capture the entity-to-entity relationships. We initiate our study with gradient flows within this matrix. Before decoding, the encoder is trained to produce initial entity embeddings $\mathbf{X}^{(0)}$.

$$\mathbf{X}^{(0)} = Encoder(\mathcal{G}) \in \mathbb{R}^{|\mathcal{E}|\times d} \tag{2}$$

4.1 Existence of the Solution

Given seed alignment entity features $\mathbf{x}_s$, our objective is to reconstruct the features $\mathbf{x}_o$ of other entities for maximizing smoothness by minimizing the Dirichlet energy $\mathscr{L}(\mathbf{X})$. We designate the set of seed alignment entities as $\mathcal{E}_s \subseteq \mathcal{E}$, with the remaining entities denoted by $\mathcal{E}_o = \mathcal{E}\backslash\mathcal{E}_s$. The entities are ordered such that:

$$\mathbf{X} = \begin{pmatrix}\mathbf{x}_s \\ \mathbf{x}_o\end{pmatrix}, \quad \mathbf{\Delta} = \begin{pmatrix}\mathbf{\Delta}_{ss} & \mathbf{\Delta}_{so} \\ \mathbf{\Delta}_{os} & \mathbf{\Delta}_{oo}\end{pmatrix} \tag{3}$$

We consider the associated gradient flow as a differential equation with boundary condition $\mathbf{x_s}(t) = \mathbf{x_s}$, which is expressed as:

$$\frac{d\mathbf{X}(t)}{dt} = -\nabla_{\mathbf{x}}\mathscr{L}(\mathbf{X}(t)) = -\mathbf{\Delta}\mathbf{X}(t) \tag{4}$$

As the features of seed alignments are regarded as stationary (Wang et al., 2024), we have the initial and boundary conditions:

$$\mathbf{X}(0) = \begin{pmatrix}\mathbf{x}_s \\ \mathbf{x}_o(0)\end{pmatrix}, \quad \mathbf{x_s}(t) = \mathbf{x_s} \tag{5}$$

By integrating the above conditions, the solution to this propagation equation provides the required decoding process.

$$\begin{aligned}\frac{d}{dt}\begin{pmatrix}\mathbf{x}_s(t) \\ \mathbf{x}_o(t)\end{pmatrix} &= -\begin{pmatrix}\mathbf{0} & \mathbf{0} \\ \mathbf{\Delta}_{os} & \mathbf{\Delta}_{oo}\end{pmatrix}\begin{pmatrix}\mathbf{x}_s \\ \mathbf{x}_o(t)\end{pmatrix} \\ &= \begin{pmatrix}\mathbf{0} \\ -\mathbf{\Delta}_{os}\mathbf{x}_s - \mathbf{\Delta}_{oo}\mathbf{x}_o(t)\end{pmatrix}\end{aligned} \tag{6}$$

As expected, the gradient flow of the aligned features ($\mathbf{x}_s$) is 0, given that they do not change during the propagation.

Given the positive semi-definite nature of the graph Laplacian matrix, Dirichlet energy $\mathscr{L}$ is convex, and its global minimizer is the solution to the gradient equation $\nabla\mathscr{L}(\mathbf{X}(t)) = 0$. The solution in equation (6) can be expressed as:

$$\frac{d\mathbf{x}_o(t)}{dt} = -\mathbf{\Delta}_{os}\mathbf{x}_s - \mathbf{\Delta}_{oo}\mathbf{x}_o(t) = \mathbf{0} \tag{7}$$

Therefore, we present the following proposition:

Proposition 1. ***(Existence of the solution.)*** *The matrix* Δ_{oo} *is non-singular, allowing the reconstruction of other entity features* $\mathbf{x}_o$ *using seed alignment entity features* $\mathbf{x}_s$ *as* $\mathbf{x}_o(t) = -\mathbf{\Delta}_{oo}^{-1}\mathbf{\Delta}_{os}\mathbf{x}_s$.

Proof. Please refer to Appendix A. □

Remark. This special gradient flow in TFP is generalized to directed graphs, distinguishing it from FP (Rossi et al., 2022) on undirected graphs.

4.2 Explicit Euler Solution

Proposition 1 reveals the existence of the solution to maximize the smoothness. However, solving this system of linear equations is computationally intensive, with a complexity of $O(|\mathcal{E}_o|^3)$ for matrix inversion, rendering it impractical for large graphs. To tackle the computational challenges, we discretize the equation (6) and adopt an iterative approach for its resolution. By approximating the temporal derivative as a forward difference and discretizing time t with fixed steps ($t = hk$ for step size $h > 0$ and $k = 1, 2, \dots$), we employ the implicit Euler scheme:

$$\mathbf{X}^{(k+1)} = \mathbf{X}^{(k)} + h\frac{d\mathbf{X}(t)}{dt}\mathbf{X}^{(k)} \tag{8}$$

Incorporating the initial and boundary conditions (5), the explicit Euler scheme is defined as:

$$\mathbf{X}^{(k+1)} = \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ -h\mathbf{\Delta}_{os} & \mathbf{I} - h\mathbf{\Delta}_{oo} \end{pmatrix} \mathbf{X}^{(k)} \tag{9}$$

When focusing on the special case of $h = 1$, we can use the following observation to rewrite the iteration formula to equation (11).

$$\widetilde{\mathbf{A}} = \mathbf{I} - \mathbf{\Delta} = \begin{pmatrix} \mathbf{I} - \mathbf{\Delta}_{ss} & -\mathbf{\Delta}_{so} \\ -\mathbf{\Delta}_{os} & \mathbf{I} - \mathbf{\Delta}_{oo} \end{pmatrix} \tag{10}$$

$$\mathbf{X}^{(k+1)} = \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \widetilde{\mathbf{A}}_{os} & \widetilde{\mathbf{A}}_{oo} \end{pmatrix} \mathbf{X}^{(k)} \tag{11}$$

This Euler scheme serves as a gradient descent for the Dirichlet energy. The approximation of this solution in this case is formalized as follows:

Proposition 2. ***(Approximation of the solution.)*** *With the reconstruction solution as delineated in equation (11), and considering a sufficiently large iteration count N, the entity features will approximate the results of feature propagation as follows:*

$$\mathbf{X}^{(N)} \approx \begin{pmatrix} \mathbf{x}_s \\ \mathbf{\Delta}_{oo}^{-1}\widetilde{\mathbf{A}}_{os}\mathbf{x}_s \end{pmatrix} \tag{12}$$

Proof. Please refer to Appendix B. □

The update process in Equation (11) equates to initially multiplying the entity features $\mathbf{X}$ by the matrix $\widetilde{\mathbf{A}}$, followed by resetting the seed alignment features to their original values.

$$\mathbf{X}^{(k+1)} \leftarrow \widetilde{\mathbf{A}}\mathbf{X}^{(k)}; \quad \mathbf{x}_s^{(k+1)} \leftarrow \mathbf{x}_s^{(k)} \tag{13}$$

Equation (13) defines an iterative strategy to reconstruct entity features from aligned entities, forming the basic Triple Feature Propagation. Since $\widetilde{\mathbf{A}}$ only captures entity-to-entity relationships, it is termed "basic." In the following section, we generalize the adjacency matrix to multi-view matrices to capture comprehensive structural information, leading to the complete TFP.

Algorithm 1: TFP

Input: The entity embedding $\mathbf{X}^{(0)}$, the triples $\mathcal{T}$, iteration number K, dimension d_r, d_e.
Output: The reconstructed entity feature $\mathbf{X}_{out}$.

Initialize $\widetilde{\mathbf{A}}^{proximal}$, $\widetilde{\mathbf{A}}^{distal}$, $\widetilde{\mathbf{A}}^{integral}$, and $\mathbf{A}^{tri-rel}$ through the triples $\mathcal{T}$.;
for $k = 1 \rightarrow K$ **do**
  $\mathbf{X}_r^{(k)} \leftarrow \widetilde{\mathbf{A}}^{distal}\mathbf{X}_e^{(k)}$;
  $\mathbf{X}_e^{(k+1)} \leftarrow \widetilde{\mathbf{A}}^{integral}\mathbf{X}_e^{(k)} + \widetilde{\mathbf{A}}^{proximal}\mathbf{X}_r^{(k)}$;
  $\mathbf{x}_s^{(k+1)} \leftarrow \mathbf{x}_s^{(k)}$;
end
$\mathbf{X}_r \leftarrow random_projection(\mathbf{X}_r^{(K)}, d_r)$;
$\mathbf{X}_t \leftarrow \mathbf{A}^{tri-rel}\mathbf{X}_r$;
Generate $\mathbf{A}_i^{triple}$ through $\mathbf{X}_t$.;
$\mathbf{X}_e \leftarrow random_projection(\mathbf{X}_e^{(K)}, d_e)$;
$\mathbf{X}_i \leftarrow \mathbf{A}_i^{triple}\mathbf{X}_e$;
$\mathbf{X}_{out} \leftarrow [\mathbf{X}_1||\mathbf{X}_2||\dots||\mathbf{X}_{d_r}]$;
return $\mathbf{X}_{out}$

5 Method

In this section, we present the complete TFP. First, we generalize the traditional adjacency matrix to multi-view matrices to capture the comprehensive KG structure. These multi-view matrices are then applied to Equation 13 to derive the complete TFP. Fig.2 shows the framework and Algorithm 1 illustrates the details.

5.1 Generalized Multi-view Matrices

Equation (13) establishes the basic Triple Feature Propagation. However, KGs extend beyond the realm of simple directed graphs represented by an adjacency matrix $\mathbf{A}$. KGs encompass a richer structure, with triples $\mathcal{T} = \{(h, r, t), |h, t \in \mathcal{E}, r \in \mathcal{R}\}$, highlighting entity-to-entity $(h - t)$, entity-to-relation $(h - r)$, relation-to-entity $(r - t)$, and relation-to-triple $(r - \mathcal{T})$. These perspectives encapsulate key meta-structures in KGs:

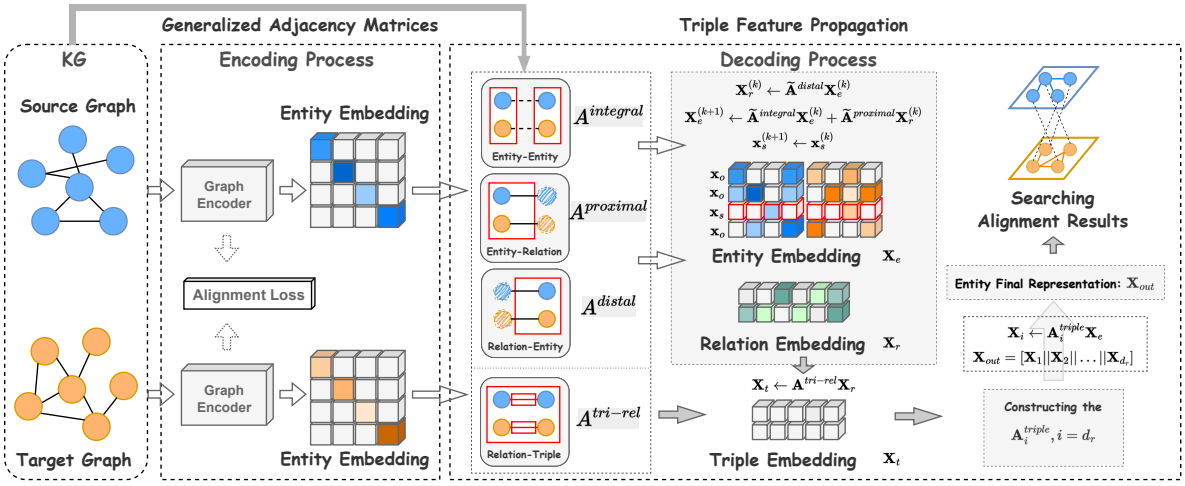

Figure 2: The illustration of Triple Feature Propagation.

(i) **Entity-to-Relation:** Beyond the conventional adjacency matrix, the (h, r) pairs in triples provide a unique structural perspective, indicating directional links from head entity h to relation r. This directionality is fundamental and unidirectional. For instance, in the triple $(London, CapitalOf, England)$, the entity $[England]$ is connected to $[London]$ via the relation $[CapitalOf]$, but not in reverse. Similar to the adjacency matrix $\mathbf{A}$, we define an *entity to relation* matrix $\mathbf{A}^{proximal} \in \mathbb{R}^{|\mathcal{E}|\times|\mathcal{R}|}$ based on the (h, r) pairs as:

$$\exists e \in \mathcal{E}: \quad \begin{aligned} \mathbf{A}^{proximal}_{i,j} &= 1, \ (h_i, r_j, e) \in \mathcal{T} \\ \mathbf{A}^{proximal}_{i,j} &= 0, \ (h_i, r_j, e) \notin \mathcal{T} \end{aligned} \tag{14}$$

(ii) **Relation-to-Entity.** This category, akin to *entity to relation*, encompasses directed and irreversible information. It underscores the more distant positional relationships between relations and tail entities. The resulting structural matrix, $\mathbf{A}^{distal} \in \mathbb{R}^{|\mathcal{R}|\times|\mathcal{E}|}$, is defined as:

$$\exists e \in \mathcal{E}: \quad \begin{aligned} \mathbf{A}^{distal}_{i,j} &= 1, \ (e, r_i, t_j) \in \mathcal{T} \\ \mathbf{A}^{distal}_{i,j} &= 0, \ (e, r_i, t_j) \notin \mathcal{T} \end{aligned} \tag{15}$$

(iii) **Entity-to-Entity.** Representing the fundamental structural category, this is similar to the adjacency matrix $\mathbf{A}$. While $\mathbf{A}$ provides a solid foundation and is rich in spectral properties, it is insufficient to fully represent KG structures. For example, the triples $(London, CapitalOf, England)$ are structurally distinct with $(London, LocateIn, England)$ in KGs, yet a traditional adjacency matrix treats them identically as they both represent $London$ connects $English$, representing $\mathbf{A}_{i,j} = 1$. To better represent relationships between entities, we extend the adjacency matrix to $\mathbf{A}^{integral} \in \mathbb{R}^{|\mathcal{E}|\times|\mathcal{E}|}$:

$$\exists r \in \mathcal{R}: \quad \begin{aligned} \mathbf{A}^{integral}_{i,i} &= |\mathcal{T}_{e_i}| \\ \mathbf{A}^{integral}_{i,j} &= |\mathcal{T}_{(h_i,t_j)}|, (h_i, r, t_j) \in \mathcal{T} \\ \mathbf{A}^{integral}_{i,j} &= 0, (h_i, r, t_j) \notin \mathcal{T} \end{aligned} \tag{16}$$

$|\mathcal{T}_{e_i}|$ denotes the number of triples involving entity e_i, and $|\mathcal{T}_{(h_i,t_j)}|$ indicates the count of triples with the pair (h_i, t_j).

(iv) **Relation-to-Triple.** As discussed before, the knowledge in KG is stored in the triple $\mathcal{T} = \{(h, r, t), |h, t \in \mathcal{E}, r \in \mathcal{R}\}$, which is the core representation of the KG structure. The unique role of relation r within triple $\mathcal{T}$ motivates the extension of the adjacency matrix to the triple level through relation r. We introduce the adjacency matrix $\mathbf{A}^{tri-rel} \in \mathbb{R}^{|\mathcal{T}|\times|\mathcal{R}|}$, defined as:

$$\begin{aligned} \mathbf{A}^{tri-rel}_{i,j} &= 1, \ r_j \in \mathcal{T}_i \\ \mathbf{A}^{tri-rel}_{i,j} &= 0, \ r_j \notin \mathcal{T}_i \end{aligned} \tag{17}$$

(v) **Entity-to-Triple** matrix is also considered. This matrix is considered to represent *entity-entity-triple* relationships for head (h) and tail (t) entities connections in $\mathcal{T}$. In fact, these connections are already encapsulated within the *entity-to-entity* matrix $\mathbf{A}^{integral}$. This matrix, which details connections between head h and tail t entities, effectively doubles as an *entity-to-triple* representation.

We assume that the normalized form of $\mathbf{A}^{proximal}$, $\mathbf{A}^{distal}$, and $\mathbf{A}^{integral}$, which are similar to graph Laplacian, representing different

facets of KG structure, can be regarded as $\widetilde{\mathbf{A}}$ in equation (13). The experimental results confirm our view. Consequently, the gradient flow should yield comparable solutions across these matrices. We denote their normalized form $\widetilde{\mathbf{A}}^k$, where $k = \{proximal, distal, integral\}$

$$\widetilde{\mathbf{A}}_i^k = \frac{\mathbf{A}_i^k}{\sum_{j=0}^{numberofcolumn} \mathbf{A}_{i,j}^k} \tag{18}$$

5.2 Triple Feature Propagation

Utilizing the gradient flow of Dirichlet energy on these categories of KG structure, we derive a natural and straightforward generalized propagation strategy. The propagation process is articulated through the following equations:

$$\mathbf{X}_r^{(k)} = \widetilde{\mathbf{A}}^{distal}\mathbf{X}_e^{(k)} \tag{19}$$

$$\mathbf{X}_e^{(k+1)} = \widetilde{\mathbf{A}}^{integral}\mathbf{X}_e^{(k)} + \widetilde{\mathbf{A}}^{proximal}\mathbf{X}_r^{(k)} \tag{20}$$

$$\mathbf{x}_s^{(k+1)} = \mathbf{x}_s^{(k)} \tag{21}$$

Here, $\mathbf{X}_e^{(i)}, 1 \leq i \leq k+1$, denotes the entity features, initially derived from the graph encoder as $\mathbf{X}_e^{(0)}$. $\mathbf{X}_r$ represents the implicit relation features generated through the propagation. To comprehensively capture the evolving entity and relation information across iterations, we aggregate entity features from each step through concatenation, resulting in the entity feature as follows:

$$\mathbf{X}_e = [\mathbf{X}^{(0)}||\mathbf{X}^{(1)}||\dots||\mathbf{X}^{(k)}] \tag{22}$$

We notice that our process explicitly captures the implicit relation feature $\mathbf{X}_r$, serving as an essential intermediary. By leveraging the *triple-to-relation* matrix, we further refine $\mathbf{X}_r$. We use a hyper-sphere independent random projection to reduce the dimension of $\mathbf{X}_r$ to d_r, following the method outlined in (Mao et al., 2022b). This step enables the creation of the triple feature $\mathbf{X}_t$.

$$\mathbf{X}_r = ranp(\mathbf{X}_r) \in \mathbb{R}^{|\mathcal{R}|\times d_r} \tag{23}$$

$$\mathbf{X}_t = \mathbf{A}^{tri-rel}\mathbf{X}_r \tag{24}$$

Our method enables the representation of the KG structure as a three-dimensional tensor $\mathbf{A}^{triple} \in \mathbb{R}^{|\mathcal{E}|\times|\mathcal{E}|\times d_r}$, rather than the traditional adjacency matrix. The tensor is defined as:

$$\begin{aligned} \mathbf{A}_{h,t}^{triple} &= \mathbf{X}_t(h,r,t), (h,t) \in \mathcal{T} \\ \mathbf{A}_{h,t}^{triple} &= \mathbf{0}, (h,t) \notin \mathcal{T} \end{aligned} \tag{25}$$

Here, $\mathbf{X}_t(h,r,t)$ represents the feature of triple (h,r,t) in $\mathbf{X}_t$. The KG structure is encapsulated in d_r slices as $\mathbf{A}_1^{triple}, \dots, \mathbf{A}_{d_r}^{triple} \in \mathbb{R}^{|\mathcal{E}|\times|\mathcal{E}|}$. Parallel to the relation feature, the entity feature $\mathbf{X}_e$ is also scaled through hyper-sphere independent random projection to d_e dimension. The propagation process is based on the final entity features $\mathbf{X}_e$, allowing for the continuation of gradient flow from the triple perspective. Since each $\mathbf{A}_i^{triple}$ represents a segmented view of the overall $\mathbf{A}^{triple}$, their concatenation is essential to compile the comprehensive final feature.

$$\begin{aligned} \mathbf{X}_e &= ranp(\mathbf{X}_e) \in \mathbb{R}^{|\mathcal{R}|\times d_e}, \\ \mathbf{X}_i &= \mathbf{A}_i^{triple}\mathbf{X}_e, i = 1, \dots, d_r \end{aligned} \tag{26}$$

$$\mathbf{X}_{out} = [\mathbf{X}_1||\mathbf{X}_2||\dots||\mathbf{X}_{d_r}] \tag{27}$$

The $\mathbf{X}_{out}$ is the reconstructed entity embedding, which is the TFP output and is used to search alignment results.

Remark: To search alignment results, we adopt an approach from (Mao et al., 2022a,b) that frames the search as an assignment problem. Detailed procedures are described in Appendix C.

6 Experiments

All experiments are conducted on a PC with an NVIDIA RTX A6000 GPU and an Intel Xeon Gold 6248R CPU.

6.1 Experimental Settings

6.1.1 Datasets

We utilize two widely recognized datasets to test our decoding approach: **(1)** DBP15K (Sun et al., 2017) comprises three cross-lingual subsets from multilingual DBpedia. Each subset contains 15,000 entity pairs. **(2)** SRPRS (Guo et al., 2019). Similar to DBP15K in terms of the number of entity pairs but with fewer triples. Following (Wang et al., 2018; Chen et al., 2017), we use a 30/70 split of pre-aligned entity pairs for training and testing encoders. The dataset statistics are reported in Appendix D.

6.1.2 Baseline

(1) Encoder: Our evaluation includes prominent encoders, divided into GNN-based: MRAEA (Mao et al., 2020a), RREA (Mao et al., 2020b), Dual-AMN (Mao et al., 2021a) (with Dual-AMN as the structural SOTA), and translation-based: AlignE (Sun et al., 2018), RSN (Guo et al., 2019),

Table 1: Main experimental results on DBP15K and SRPRS datasets. All results and initial embeddings were derived using official code with default hyperparameters. The Hungarian algorithm (Hun) produces only one aligned pair per entity, thus only Hits@1 is reported. DATTI cannot decode RREA, as both entity and relation embeddings are required, whereas RREA provides only entity embeddings.

and TransEdge (Sun et al., 2019) (with TransEdge as the premier in its class).

(2) Decoder: For decoding baselines, we benchmark against the Hungarian algorithm (Kuhn, 1955), which is the prominent solution in previous work (Xu et al., 2020), and the SOTA of EA decoder, DATTI (Mao et al., 2022a). The LightEA (Mao et al., 2022b) and plain Sinkhorn (Cuturi, 2013) are also applied as decoders.

Remark: The hyperparameter and implementation details are provided in Appendix E.

6.2 Main Results

The main experimental results and time costs are summarized in Tables 1 and 2. TFP consistently demonstrates fast execution, adaptability to various encoders, and performance comparable to state-of-the-art methods with minimal time consumption. It strikes the elegant balance between accuracy and efficiency.

6.2.1 GNN-based Encoders

As shown in Tables 1 and 2, TFP consumes the least additional timefar less than LightEA and DATTIand generally secures the runner-up position, which consistently improves the accuracy of RREA and DualAMN across datasets, with a time cost under 6 seconds. While LightEA decodes RREA effectively and DATTI excels at decoding Dual-AMN (the state-of-the-art GNN-based structural EA decoder), DATTI's reliance on both entity and relation embeddings limits its suitability for RREA and LightEA is too time-consuming. In contrast, TFP delivers comparable results to LightEA and DATTI while being the fastest for both RREA and DualAMN. LightEA performs better than TFP on RREA due to its label generalization and propagation strategy, which provides more comprehensive topology information in high-dimensional hyper-spheres but at a high computational cost. DATTI achieves the best performance on DualAMN since it guarantees the

isomorphic property, which is lacking in TFP, LightEA, and DualAMN.

6.2.2 Translation-based Encoders

TFP significantly enhances the performance of translation-based EA encoders by capturing multi-view structural information, achieves the best results, and maximizes smoothness. Although both DATTI and LightEA primarily focus on structure, DATTI considers only the isomorphic graph structure (Mao et al., 2022a), while the latter overlooks the stationary property (Wang et al., 2024)specifically, the gradient flow of aligned entity pairs being equal to 0. Additionally, DATTI and LightEA both ignore the smoothness issue of entity embeddings. With less than 5 seconds of execution time, TFP achieves superior decoding performance with minimal computational cost, highlighting its ability to efficiently capture KG topology.

6.2.3 Time Complexity

TFP employs iterative sparse-to-dense matrix multiplications. Following (Mao et al., 2022b), we optimize these multiplications in Eqs. (19) and (20) to maintain computational complexity at $O(k(|\mathcal{T}|d_r + |\mathcal{E}|d_e))$. For Eqs. (24) and (26), Tensorflow's sparse matrix multiplications reduce complexity to $O(|\mathcal{T}|d_r)$ and $O(|\mathcal{E}|d_e)$.

6.2.4 Time Cost

Table 7 provides a detailed comparison of time costs for encoding and decoding phases on DBP15K and SRPRS datasets. Notably, TFP's cost is minimal in the overall runtime, with most time spent on encoder training. On a GPU, TFP runs in as little as 5.9 seconds, and even on a CPU, it peaks at just 17.7 seconds, rivaling the fastest decoders like the GPU-based Hungarian algorithm. LightEA utilizes label generalization and a propagation strategy to provide more comprehensive topology information in high-dimensional hyperspheres, resulting in better performance on RREA at the expense of higher time costs. DATTI consumes significant time due to the use of singular value decomposition (SVD). For the Sinkhorn algorithm and the Hungarian algorithm, both involve matrix-based optimization, where the computational burden increases significantly with the matrix size, leading to high time costs for large problems.

Besides these results, we further evaluate TFP in other settings. Due to the space limitation, these experiments are detailed in Appendix F.

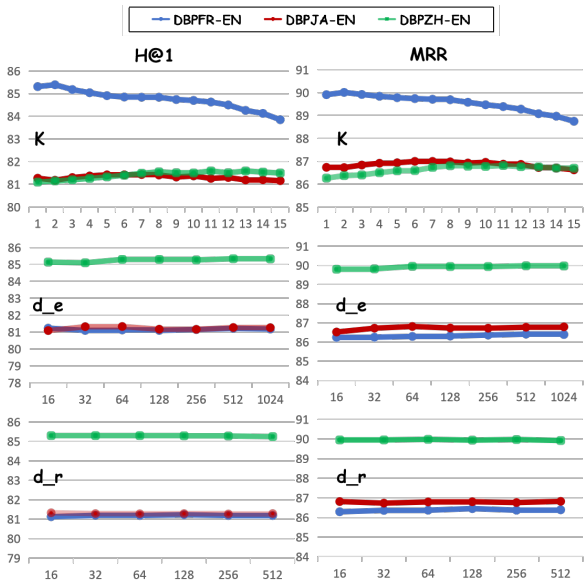

Figure 3: Hyper-parameter experiments of TFP decoding the DualAMN on DBP15K.

6.3 Hyper-parameter Analysis

We conduct extensive experiments to examine the sensitivity of TFP's hyper-parameters during entity embedding decoding. Due to space limitation, Figure 3 only presents the results for TFP decoding DualAMN on DBP15K.

6.3.1 Propagation Round

Figure 3 illustrates the performance across different propagation rounds K. Similar to increasing network depth, more rounds can cause over-smoothing. TFP achieves optimal performance at $K = 2$ and declines thereafter. This suggests that while multi-view matrices effectively capture KG structure, they have distinct spectral properties compared to the adjacency matrix. The basic TFP with only the adjacency matrix can still ensure convergence, as demonstrated in Proposition 2.

6.3.2 Entity Dimension

To accelerate computation, we apply hyper-sphere independent random projection to reduce entity dimensions to d_e. As shown in Figure 3, TFP remains robust to changes in these dimensions, with performance barely affected by significant dimensional reductions.

6.3.3 Relation Dimension

Similar to entity dimensions, random projection is used to reduce relation dimensions. However, d_r should not be too large since, as indicated by Eq. (24), the tensor-matrix product leads to a

Table 3: Performances of unsupervised textual decoding.

squared increase in dimension after each propagation round.

Additional hyper-parameter results are detailed in Appendix G due to space limitations.

6.4 Unsupervised Textual Decoding

Most EA research focuses on structural methods, but some (Xu et al., 2019; Wu et al., 2019b) use textual information, such as entity names, for improvement via cross-lingual embeddings or translation systems. These methods treat pre-trained word embeddings as initial embeddings for entities, which can be viewed as the decoding process that captures the topology of KGs. Similarly, TFP can serve this role, decoding initial entity features like word embeddings without seed alignments.

We used pre-trained GLoVe embeddings (Pennington et al., 2014) as initial features for TFP, treating it as an unsupervised textual decoder. Table 3 shows TFP outperforming baselines on SRPRS with minimal time cost and ranking near the top on DBP15K. The competitive results of TFP suggest propagation may be more effective than neural networks, questioning the need for complex models and seed alignments. However, TFP(SEU) and TFP(LightEA), which use SEU and LightEA as encoders, slightly underperform compared to TFP, likely due to over-smoothing. Despite this, TFP achieves top performance on SRPRS, while the extra required time is less than 4 seconds.

7 Conclusion

This paper introduces a fast and adaptable entity alignment decoding algorithm that maximizes the smoothness of entity embeddings, supported by a solid theoretical foundation. Extensive experiments on public datasets show that our method significantly enhances performance on most EA models, with running time of under six seconds.

Acknowledgments

This work was supported in part by the National Natural Science Foundation of China under Grants (62201072, 62401080, 62471055, 62321001, U23B2001, 62171057), the Ministry of Education and China Mobile Joint Fund (MCM20200202, MCM20180101), the Fundamental Research Funds for the Central Universities (2024PTB-004).

Limitations

While TFP has shown speed, adaptability, and robustness across various public datasets, several limitations remain:

- Although TFP achieves competitive results with state-of-the-art methods with significantly reduced runtime, some gaps in accuracy still exist on certain datasets. Future work will focus on improving the balance between performance and efficiency.
- TFP theoretically offers significant potential for all kinds of EA encoders. However, due to limited resources, all experiments were conducted only in a single modality setting. We plan to adapt it to multi-modal EA in the future, where we just need to use the multi-modal EA encoder to generate our multi-modal entity embedding.

Ethics Statement

This work does not involve discrimination, social bias, or private data. All datasets used are open-source, derived from publicly available KGs such as Wikidata, YAGO, and DBpedia, ensuring compliance with the ACL Ethics Policy. Additionally, while the introduction of literal features may raise concerns about misuse of user-generated content, TFP mitigates this risk by relying solely on structural information.

A Proof of Proposition 1

Proof. Initially, consider an undirected connected graph scenario where $\mathbf{\Delta}_{oo}$ is a sub-matrix of the Laplacian matrix $\mathbf{\Delta}$. Given that sub-Laplacian matrices of undirected connected graphs are invertible (Rossi et al., 2022), thus Δ_{oo} is non-singular. The spectral properties of eigenvalues in undirected graphs suggest similar non-singularity for directed graphs (Maskey et al., 2023).

For general cases, assume an ordered representation of the adjacency matrix for a disconnected graph as:

$$\mathbf{A} = \text{diag}(\mathbf{A}_1, \ldots, \mathbf{A}_r) \tag{28}$$

Here, $\mathbf{A}_i, i = 1, \ldots, r$, represents each connected component. The gradient flow in equation (7) is applicable to each connected component independently for disconnected graphs. □

B Proof of Proposition 2

Proof. Commencing with the initial entity features $\mathbf{X}^{(0)}$ generated by EA encoders and applying equation (11), we iterate:

$$\begin{aligned}\begin{pmatrix}\mathbf{x}_s^{(k)}\\ \mathbf{x}_o^{(k)}\end{pmatrix} &= \begin{pmatrix}\mathbf{I} & \mathbf{0}\\ \widetilde{\mathbf{A}}_{os} & \widetilde{\mathbf{A}}_{oo}\end{pmatrix}\begin{pmatrix}\mathbf{x}_s^{(k-1)}\\ \mathbf{x}_o^{(k-1)}\end{pmatrix}\\ &= \begin{pmatrix}\mathbf{x}_s^{(k-1)}\\ \widetilde{\mathbf{A}}_{os}\mathbf{x}_s^{(k-1)} + \widetilde{\mathbf{A}}_{oo}\mathbf{x}_o^{(k-1)}\end{pmatrix}\end{aligned} \tag{29}$$

Given the stationary nature of the seed alignment entity features $\mathbf{x}_s$, we have the equation $\mathbf{x}_s^{(k)} = \mathbf{x}_s^{(k-1)} = \mathbf{x}_s$. The focus then shifts to the convergence of $\mathbf{x}_o$::

$$\mathbf{x}_o^{(k)} = \widetilde{\mathbf{A}}_{os}\mathbf{x}_s + \widetilde{\mathbf{A}}_{oo}\mathbf{x}_o^{(k-1)} \tag{30}$$

Expanding and analyzing the limit for the stationary state, we find:

$$\begin{aligned}&\lim_{k\to\infty}\mathbf{x}_o^{(k)}\\ &= \widetilde{\mathbf{A}}_{os}\mathbf{x}_s + \lim_{k\to\infty}\sum_{i=2}^{k}\widetilde{\mathbf{A}}_{oo}^{i-1}\widetilde{\mathbf{A}}_{os}\mathbf{x}_s + \lim_{k\to\infty}\widetilde{\mathbf{A}}_{oo}^{k}\mathbf{x}_o^{(0)}\\ &= \lim_{k\to\infty}\widetilde{\mathbf{A}}_{oo}^{k}\mathbf{x}_o^{(0)} + \lim_{k\to\infty}\sum_{i=1}^{k}\widetilde{\mathbf{A}}_{oo}^{i-1}\widetilde{\mathbf{A}}_{os}\mathbf{x}_s\end{aligned} \tag{31}$$

Spectral graph theory provides critical insights into the properties of the Laplacian matrix $\mathbf{\Delta}$. It establishes that the eigenvalues of $\mathbf{\Delta}$ are confined within the range [0,2). This spectral characteristic has direct implications for the matrix $\widetilde{\mathbf{A}} = \mathbf{I} - \mathbf{\Delta}$, whose eigenvalues are consequently within the range (-1,1]. A pivotal aspect of this discussion, as elucidated in Proposition 1, is the non-singularity of $\mathbf{\Delta}_{oo}$. The absence of 0 as an eigenvalue of $\mathbf{\Delta}_{oo}$ implies that $\widetilde{\mathbf{A}}$'s eigenvalues strictly occupy the interval (-1,1), thereby excluding the endpoints. This spectral behavior significantly influences the convergence properties of the iterative process. Specifically, the limit $\lim_{k\to\infty}\widetilde{\mathbf{A}}_{oo}^{n}\mathbf{x}_o^{(0)}$ approaches 0. Furthermore, the summation $\lim_{k\to\infty}\sum_{i=1}^{k}\widetilde{\mathbf{A}}_{oo}^{i-1}$ converges to $(\mathbf{I} - \widetilde{\mathbf{A}}_{\mathbf{oo}})^{-1} = \mathbf{\Delta}_{oo}^{-1}$. By integrating these insights, the long-term behavior of the iterative solution can be articulated as:

$$\lim_{k\to\infty}\mathbf{x}_o^{(k)} = \mathbf{\Delta}_{oo}^{-1}\widetilde{\mathbf{A}}_{os}\mathbf{x}_s \tag{32}$$

Therefore, when the number of iterations N is sufficiently large, the entity features in $\mathbf{x}_o^{(N)}$ approximate $\mathbf{\Delta}_{oo}^{-1}\widetilde{\mathbf{A}}_{os}\mathbf{x}_s$. □

C Searching Alignment Results

To identify alignment results, rather than use the popular distance metric of Cross-domain Similarity Local Scaling (CSLS) (Lample et al., 2018) to search the alignments in most works, we follow (Mao et al., 2022a) and (Mao et al., 2022b) to formalize the entity alignment problem as an assignment problem to enforce the one-to-one alignment constraint. Before giving the mathematical definition, it assumes $|\mathcal{E}_s| = |\mathcal{E}_t| = n^t$ to simplify

Table 4: Statistics of the DBP15K and SRPRS datasets, highlighting SRPRS as sparse KGs typical of real-world scenarios.

Datasets		Entity	Relation	Triple
DBP_{ZH-EN}	Chinese	19388	1701	70414
	English	19572	1323	95142
DBP_{JA-EN}	Japanese	19814	1299	77214
	English	19780	1153	93484
DBP_{FR-EN}	French	19661	903	105998
	English	19993	1208	115722
SRPRS_{FR-EN}	French	15000	177	33532
	English	15000	221	36508
SRPRS_{DE-EN}	German	15000	120	37377
	English	15000	222	38363

the process. In addition, it uses $SIM \in \mathbb{R}^{n^t \times n^t}$ to represent the cosine similarity matrix and compute it between testing entities in two $\mathcal{KG}$s with the entity embeddings. Thus, we attempt to solve the following optimization problem:

$$\arg \max_{P \in \mathbb{P}_{n^t}} \langle P, SIM \rangle \tag{33}$$

where $\mathbb{P}_{n^t}$ is a set of permutation matrices with shape of $\mathbb{R}^{n^t \times n^t}$. Actually, we can directly obtain the optimal solution $P^\star$ by Sinkhorn operation(Cuturi, 2013).

$$P^\star = \lim_{\tau \to 0^+} \text{Sinkhorn}(\frac{SIM}{\tau}) \tag{34}$$

where the operation of Sinkhorn is as follows:

$$\begin{aligned} Sinkhorn(\mathbf{X}) &= \lim_{k \to +\infty} S^k(\mathbf{X}) \\ S^k(\mathbf{X}) &= \mathcal{N}_c(\mathcal{N}_r(S^{k-1}(\mathbf{X}))) \end{aligned} \tag{35}$$

where $S^0(\mathbf{X}) = exp(\mathbf{X})$, $\mathcal{N}_r(\mathbf{X}) = X \oslash (\mathbf{X}\mathbf{1}_{n^t}\mathbf{1}_{n^t}^\top)$ and $\mathcal{N}_c(\mathbf{X}) = X \oslash (\mathbf{1}_{n^t}\mathbf{1}_{n^t}^\top\mathbf{X})$ are the row and column-wise normalization operators of a matrix, $\oslash$ denotes the element-wise division, $\mathbf{1}_{n^t}$ is a column vector of ones. Though we can only obtain an approximate solution with a small k in practice, we empirically found that the approximate solution is enough to obtain a good alignment performance. Considering that the assumption of $n^t = |\mathcal{E}_s| = |\mathcal{E}_t|$ is easily violated, a naive reduction is to pad the similarity matrix with zeros such that its shape becomes $\mathbb{R}^{n^t \times n^t}$ where $n^t = max(n_1^t, n_2^t)$.

D Dataset

DBP15K (Sun et al., 2017) comprises three cross-lingual subsets from multilingual DBpedia. Each subset contains 15,000 entity pairs. SRPRS (Guo et al., 2019). Similar to DBP15K in terms of the number of entity pairs but with fewer triples. Table 4 lists the statistics of the DBP15K and SRPRS datasets. We also test TFP on DWY (Sun et al., 2019) dataset with more entities, which is listed in Table 6.

E Experiment Details

E.1 Evaluation Metrics

Following most previous works (Ji et al., 2022; Zeng et al., 2021a; Mao et al., 2022b, 2020a; Wang et al., 2024), our evaluation employs cosine similarity for EA and H@k and MRR metrics for a thorough evaluation.

H@k measures the proportion of correctly aligned entities ranked within the top k positions:

$$H@k = \frac{1}{|S_t|} \sum_{i=1}^{|S_t|} \mathbb{I}[rank_i \leq k] \tag{36}$$

where $rank_i$ is the ranking of the first accurate alignment for query entity i, $\mathbb{I}$ indicates correctness ($\mathbb{I} = 1$ if $rank_i \leq k$, else 0), and S_t is the set of test alignments. MRR evaluates the average of reciprocal ranks of the first correct answer for queries, reflecting the model's precision across a set of queries:

$$MRR = \frac{1}{|S_t|} \sum_{i=1}^{|S_t|} \frac{1}{rank_i} \tag{37}$$

E.2 Implementaion Hyperparameters

The output dimensions d and other hyper-parameters of all encoders adhere to their original settings in their papers: Dual-AMN ($d = 768$), RREA($d = 600$), MRAEA ($d = 600$), AlignE ($d = 75$), RSN ($d = 256$), and TransEdge ($d = 75$). The iteration k is set to their best results, which details described in Section 6.3. Other hyper-parameters remain the same for all datasets and methods: relation scale dimension $d_r = 512$, entity scale dimension $d_e = 16$.

F Decoding on other Encoders

Table 5 and Table 7 show the TFP decoding on the AlignE and MRAEA. TFP achieves performance comparable to SOTA with minimal time consumption. Among the evaluated encoders, Dual-AMN demonstrates superior performance across

Table 5: Supplementary for decoding on MRAEA and AlignE. DATTI cannot decode MRAEA and RREA, as both entity and relation embeddings are required, whereas these encoders provide only entity embeddings.

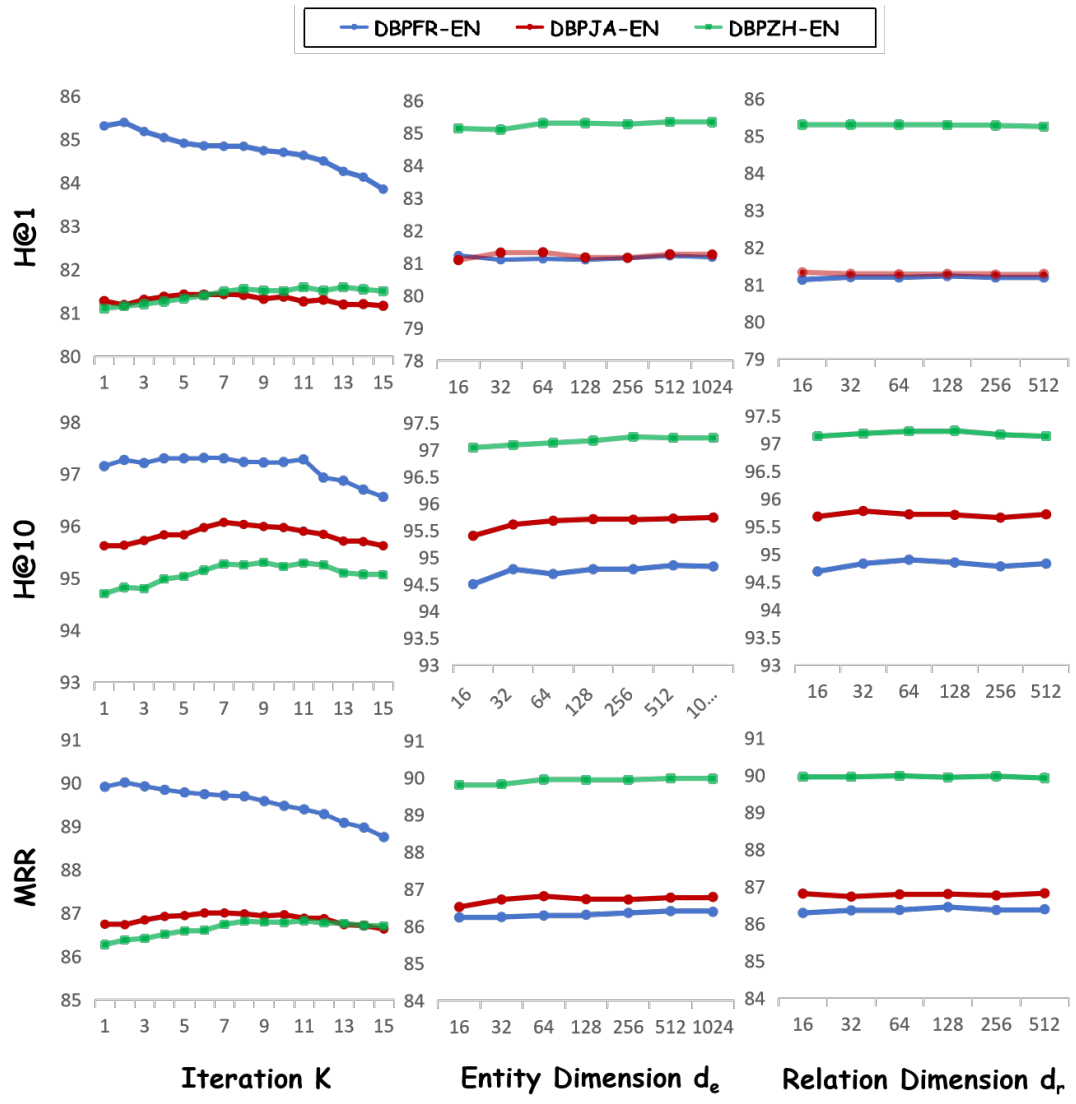

Figure 4: Hyper-parameter experiments of TFP decoding the DualAMN on DBP15K.

all datasets, underscoring the efficacy of GNN encoders. Interestingly, TransEdge shows notable success on the DBP15K dataset but underperforms on SRPRS. This can be attributed to TransEdge's reliance on existing edge semantic information for entity dependency capture, a feature less prevalent in the sparser KGs like SRPRS. Conversely, GNN-based models exhibit robustly, highlighting their aptitude for handling sparse topologies.

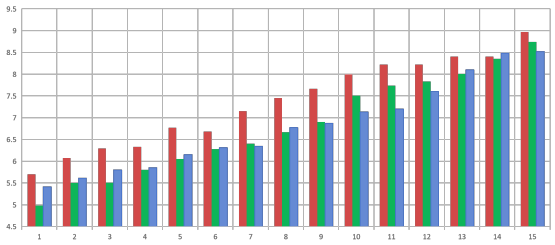

Figure 5: Execution time (seconds) on DBP15K across propagation iterations number k.

comparative observation reveals that TFP's application is expedited on translation-based encoders relative to GNN-based ones. This acceleration is attributable to the varying entity embedding dimensions discussed in Section E.2. The output dimension for GNN-based encoders, particularly for MRAEA and Dual-AMN, is set at $d = 600$ and $d = 768$, respectively, which is larger than that of the translation-based encoders. This discrepancy in dimensionality directly influences the time efficiency of TFP, as demonstrated by the faster performance on translation-based models.

G Hyper-parameters

Figure 4 presents the full performance results for varying propagation rounds K and dimensions d_e and d_r. Figure 5 provides the execution time (in seconds) on DBP15K for different values of k (number of propagation iterations). All experiments were conducted using DualAMN for encoding.

Lost in the Distance: Large Language Models Struggle to Capture Long-Distance Relational Knowledge

Meiyun Wang*[1], Takeshi Kojima†[1], Yusuke Iwasawa[1], and Yutaka Matsuo[1]

[1]The University of Tokyo

Abstract

Large language models (LLMs) have demonstrated impressive capabilities in handling long contexts, but challenges remain in capturing relational knowledge spread far apart within text. Connecting long-distance knowledge is important for solving tasks as the context length increases: imagine reading a lengthy detective novel where seemingly trivial information introduced early on often becomes essential during the climactic reveal of the culprit. In this study, we expose the "Lost in the Distance" phenomenon, where LLM performance of capturing the relational knowledge degrades significantly when the relational knowledge is separated by noise, i.e., unrelated sentences to solve a task. Specifically, we design an experiment in which we insert artificial noise between two related elements and observe model performance as the distance between them increases. Our findings show that while LLMs can handle edge noise with little impact, their ability to reason about distant relationships declines sharply as the intervening noise grows. These findings are consistent in both forward-looking prediction and backward-looking prediction settings. We validate this across various models (GPT-4, Gemini-1.5-pro, GPT-4o-mini, Gemini-1.5-flash, Claude-3.5-Sonnet) and tasks (causal reasoning and knowledge extraction). These results reveal a significant limitation in how LLMs process relational knowledge over long contexts. We release our code and data to support further research.[1]

1 Introduction

Recent large language models (LLMs) have demonstrated a remarkable ability to solve long and complex tasks as their capacity to handle longer context lengths has increased significantly. However, as context length grows, LLMs struggle more with filtering out irrelevant information, making it harder to focus on the main task. Liu et al. (2024) identified the "Lost in the Middle" phenomenon, where model performance drops significantly when crucial information is located in the middle of a long context, compared to when it appears at the beginning or end. Similarly, Kamradt (2023) highlighted LLMs' vulnerability in retrieving relevant information from long contexts with their "Needle in a Haystack Test." However, these findings mainly focus on document-level tasks, mimicking the retrieval-augmented generation setup.

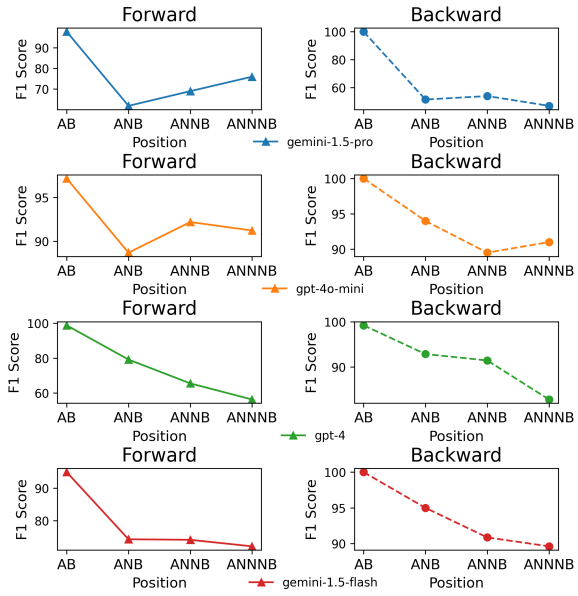

Figure 1: Lost in the Distance: (Left) Forward-looking setting to assess whether LLMs can capture recent knowledge based on distant past relational knowledge. (Right) Backward-looking setting to assess whether LLMs can capture past knowledge based on recent relational knowledge. See Section 3 for details and Appendix A for additional evaluation metrics.

This study brings attention to a new challenge

System Prompt
Write a high-quality answer to the given question using only the exact words or phrases from the text.
Note that the Text may contain irrelevant information (noise).
Return only the answer by writing 'Answer: XXX'.

User Prompt
Text: (Noise Text1) The first person is Xavier Pendleton. The second person is Uriah Hawthorne. (Noise Text2)
The first person is the champion of the quantum chess world championship, defeating opponents in multiple dimensions.
The second person is the skilled puppeteer who brought the magical world of "Enchanted Strings" to life. (Noise Text3)
Question: What is the name of the skilled puppeteer who brought the magical world of "Enchanted Strings" to life?
Answer:

Table 1: An example prompt for the Name2Description task with the backward-looking prediction setting.

for LLMs when processing long contexts: ***"Can LLMs effectively capture relational knowledge that appears far apart within a context?"*** This ability is crucial, as it affects performance on various downstream tasks such as causal reasoning and knowledge extraction, where the relevant information may be much shorter and hidden within noisy long contexts. To illustrate, imagine reading a lengthy detective novel where seemingly trivial information introduced early on often becomes essential during the climactic reveal of the culprit.

Our experiments show that even state-of-the-art LLMs still struggle to handle relational knowledge when located far apart within a context. Specifically, given artificial noise (N1, N2, N3) and relational knowledge (A and B), we define a context as a sequence {N1, A, N2, B, N3} and ask LLMs to predict B (or A) based on a question about A (or B). The results on GPT-4, Gemini-1.5-pro, GPT-4o-mini, and Gemini-1.5-flash, Claude-3.5-Sonnet in the zero-shot in-context learning (ICL) setting demonstrate that performance significantly drops as the length of the in-between noise (N2) increases. We refer to the phenomenon as ***"Lost in the Distance."*** We observe this phenomenon in both forward-looking prediction and backward-looking prediction settings.

Interestingly, when there is no distance between A and B (i.e., N2 = 0), adding noise at the edges (N1, N3 > 0) alleviates the performance degradation compared to adding in-between noise. This indicates that the location of the noise plays a significant role in performance. We conducted additional experiments with various noise types (e.g., novel excerpts, pre-training corpus samples, and random words) and task types (causal reasoning and knowledge extraction), all showing similar trends.

2 Related Work

Recent LLMs have significantly extended their context lengths to enhance their LLM capabilities in handling complex tasks. For example, early GPT models supported 512 tokens (Radford, 2018), but the latest GPT-4 and GPT-4o-mini models now accommodate up to 8,192 and 128,000 tokens, respectively[2]. Similarly, Gemini-1.5-pro and Gemini-1.5-flash models offer context lengths of 2 million and 1 million tokens, respectively[3].

However, as context lengths grow, research suggests that LLMs may struggle with irrelevant or noisy information, which can interfere with problem-solving. Liu et al. (2024) introduced the "lost in the middle" effect, where LLMs struggle to retrieve information located in the middle of long contexts. Likewise, Kamradt (2023) highlighted the difficulty of retrieving specific details from vast amounts of text in their "Needle in a Haystack Test." Furthermore, Peysakhovich and Lerer (2023) found that as context length increases, LLMs tend to disproportionately prioritize more recent information, known as "recency bias."

While these studies focus on retrieving information from a single point within long contexts, our work addresses a more complex challenge: identifying relationships between two distinct points in the text—essentially, "finding two needles in a haystack." Previous research, such as Levy et al. (2024) and Shi et al. (2023), has shown that inserting irrelevant noise between key elements of a task can significantly impair multi-step reasoning. However, these studies did not explore the specific impact of intermediate noise on retrieving atomic-level knowledge relations, which may serve as the foundation for multi-step reasoning. In contrast, our study directly measures how well LLMs

[2] https://platform.openai.com/docs/models
[3] https://ai.google.dev/gemini-api/docs/models/gemini

can recall atomic-level factual information across long distances in both forward and backward directions, offering new insights into how noise affects various tasks and advancing our understanding of multi-step reasoning.

3 Experiment

3.1 Setting

Model Our experiments use the following four LLMs via API: Claude-3.5-Sonnet (claude-3-5-sonnet-20240620), GPT-4 (gpt-4-2023-06-13), Gemini-1.5-Pro (gemini-1.5-pro-002), GPT-4o-mini (gpt-4o-mini-2024-07-18), and Gemini-1.5-Flash (gemini-1.5-flash-002). We set greedy decoding (temperature set to zero) and limit the maximum output tokens to 100 for rigid predictions.

Noise We select three types of noise: novel, random words, and pre-training corpus. For the novel noise, we pick the top 10 popular ebooks from Project Gutenberg (Gutenberg). For the random words, we randomly select words from WordNet (Miller, 1995). For the pre-training corpus, we use FineWeb (Penedo et al., 2024) and RedPajama (Computer, 2023).

Task Our tasks include "Name2Description", "Parent2Child", and "Cause2Effect". "Name2Description" consists of relations between a fictitious name and his/her fictitious description (Berglund et al., 2023). "Parent2Child" includes relations between a fictitious parent's name and his/her fictitious child's name (Berglund et al., 2023), and "Cause2Effect" contains relations between a causal phrase and its consequent effect phrase (Du et al., 2022).

Prompt We randomly select noise tokens from various noise sources, split them into three chunks, and place them in different positions. N1, N2, and N3 represent the noise chunks in different positions (1: before A, 2: between A and B, 3: after B). Given noise tokens {N1, N2, N3} and relational knowledge A and B, our experiments define a text in context as a sequence of {N1, A, N2, B, N3}. We use LLMs to predict B based on a question about A (forward prediction) and to predict A based on a question about B (backward prediction). We analyze knowledge recall performance by varying the length of N1, N2 and N3. Unless otherwise stated, our experiments use the Gemini-1.5-pro model, the Name2Description task, and

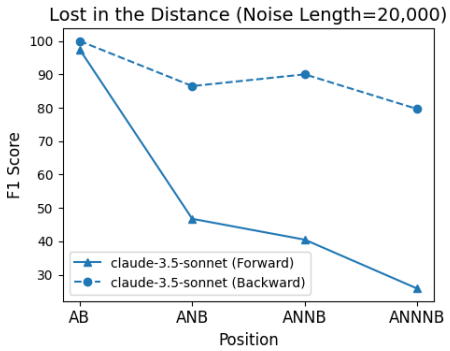

Figure 2: Lost in the Distance with extra-long noise (20,000 tokens for ANNNB) for Claude-3.5-Sonnet .

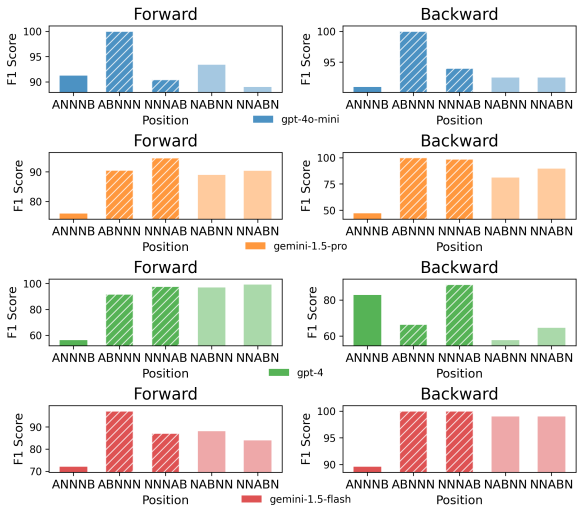

Figure 3: No Distance, Less Degradation.

texts from novels, with a maximum of 3,000 noise tokens as the default setting, and 200 samples tested per task. Table 1 provides an example prompt for the Name2Description task experiment. See Appendix B for the other task settings.

Evaluation We let LLMs generate an answer text given the prompt in a zero-shot setting. We use the F1 score for the evaluation metric instead of the exact match to allow for minor perturbations in the response. Specifically, we calculate the F1 score by taking the harmonic mean of precision and recall, where precision = (# of matched words between prediction and ground truth) / (# of predicted words) and recall = (# of matched words) / (# of ground truth words).

3.2 Result

Lost in the Distance We conducted experiments by varying the length of the intermediate noise (N2) to values of 0, 1000, 2000, and 3000. In the im-

plementation, we split all noise tokens into three chunks of equal length, each referred to as N, and concatenate them to form N2. Figures 1 present the results. The results show that as the intermediate noise increases, the performance of relational knowledge recall decreases significantly. Although different models exhibit varying degrees of performance decline due to their inherent architectural differences and required parameter adjustments, all models consistently follow a downward trend. We hypothesize that the intermediate noise tokens, which are irrelevant information, interfere with the proper attention between knowledge A and B, leading to confusion in the knowledge connection. We refer to this phenomenon as "Lost in the Distance."

Figures 2 show the performance of the state-of-the-art Claude-3.5-Sonnet model with different noise lengths (N2). We set the maximum length to 20,000 tokens, split it into three chunks of equal length, and concatenate them to generate N2. The results indicate that as N2 increases from 6,000 to 20,000 tokens, even the newest LLM struggles to retrieve relational knowledge, providing strong evidence of the "lost in the distance" phenomenon.

No Distance, Less Degradation To complement our findings, we compared the results when noise is placed between the knowledge pair (i.e., {A N2 B}) and when it is not, across three configurations: {A B N3}, {N1 A B}, and {N1 A B N3}. In these three configurations, there is no distance between A and B (i.e., N2 = 0), but with the same amount of total noise added at the edges. We concatenate the noise chunks to generate different noise tokens in different positions (e.g., in the case of {A B N3}, three noise chunks are used to form N3). Figures 3 present the F1 scores for both forward and backward predictions. The leftmost bar corresponds to the "Lost in the Distance" phenomenon, while the rightmost two bars represent the "Lost in the Middle" phenomenon. The relatively lower performance of the leftmost bar suggests that while intermediate noise significantly affects performance, noise at the beginning and end has a much smaller impact. This effect is also influenced by the characteristics of the noise. To further investigate this, we designed a task where the context is more closely tied to the noise. Specifically, we extracted character names from each noise chunk of the novel and used these names directly as questions and answers. For each question, we paired the names with randomly assigned identity information, prompting

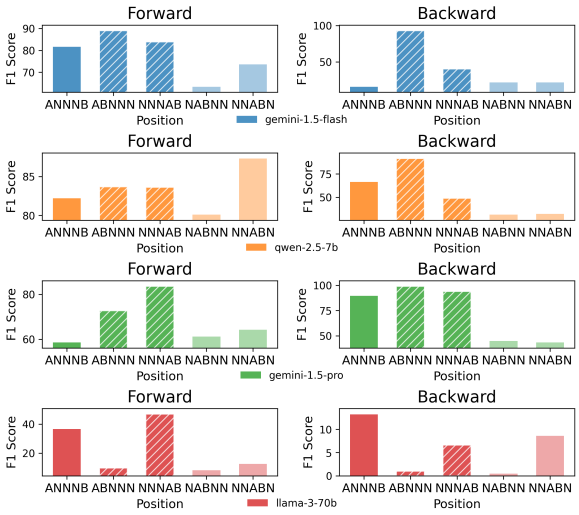

Figure 4: No Distance, Less Degradation: Effect of Context-Related Noise.

the model to identify either the identity associated with a given name or the name corresponding to a specific identity. As the character names appear at different positions within the noise, they introduce varying levels of interference to the model's reasoning. We evaluated this task on several models, including Gemini-1.5-flash, Qwen-2.5-7B, Llama-3-70B, and Gemini-1.5-pro. Figures 4 show that the "Lost in the Distance" phenomenon remains observable even when the noise is more contextually relevant. However, because the interfering elements in the noise appear at different positions, the specific performance varies. Notably, the Llama model generally exhibits lower accuracy, and its output sentences often contain long sequences of noise that directly incorporate the query, leading to differences between its calculated F1 scores and the actual performance of the other models. Another finding is that "Lost in the Middle" phenomenon becomes more significant when the noise is more contextually relevant. Note that "Lost in the Middle" and "Lost in the Distance" are orthogonal phenomena so that they can independently coexist with each other. See Appendix B for further details on this task.

Ablation Study Across Tasks and Noises We validate the "Lost in the Distance" effect across different tasks, as shown in Figures 5. We consistently observe an overall decline in performance as intermediate noise increases, though to varying extents. One interesting observation is that in the Cause2Effect task, performance declines more

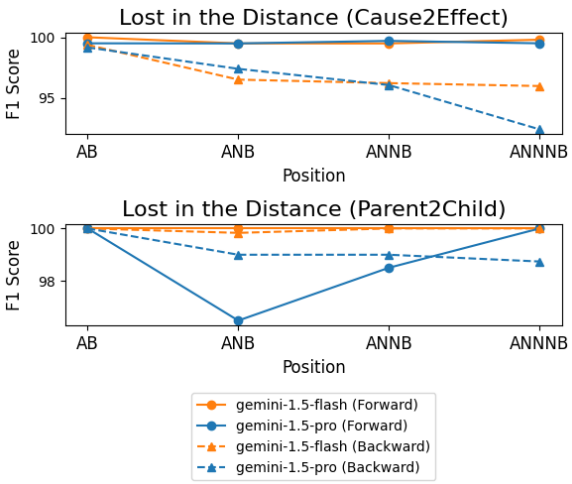

Figure 5: Lost in the Distance (Different Tasks)

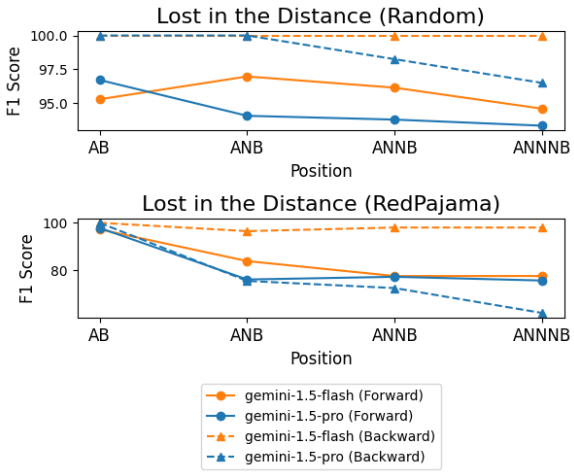

Figure 6: Lost in the Distance (Different Noises)

sharply in backward prediction than in forward prediction. As Berglund et al. (2023) have pointed out, the result demonstrates that LLMs inherently struggle with retrieving information in a backward manner, which is called the "reversal curse." However, we did not observe a clear trend in the Parent2Child task. Nearly all models performed well, possibly because the novel-related noise had a limited impact on this task. In the future, we will explore more diverse tasks to evaluate how different types of noise affect various tasks. Figures 6 show the results under different noise conditions. We can easily observe the "Lost in the Distance" effect across various noise types. The noise types for RedPajama show clear declines as noise increases. In addition, the difficulty of the noise also influences performance. For example, the random noise type contains only random words without any logical structure, making it easier for LLMs to identify as noise. On the other hand, the novel noise type poses greater challenges as it contains a more logical structure and can mislead the model into making incorrect decisions.

4 Conclusion

This study has highlighted that current LLMs capable of handling long contexts still struggle to connect distant relational knowledge both in forward and backward prediction, which we refer to as "lost in the distance." We hope these findings will draw more attention to the importance of distant relational knowledge, leading to the development of new benchmarks and proposals for performance improvement in future work.

5 Limitation

We limited the noise experiments to approximately 4,000 tokens due to budget constraints. However, considering that recent LLMs are expanding context windows beyond our experiment size (see Section 2), evaluating with longer noise contexts is an important direction for future research.

In this study, we created artificial tasks that require long-distance relational knowledge by inserting unrelated texts as noise within a context, as there are no suitable existing benchmarks for measuring such performance. Therefore, future work needs to develop tasks that assess more realistic long-distance knowledge relationships within consistent, long texts.

While this research has identified a new phenomenon, "Lost in the Distance," it is also crucial for future work to propose methods to address problems related to this phenomenon.

A Evaluation Metrics

We report Precision, Recall, F1 Score, and Exact Match metrics to demonstrate the impact of the "lost in the distance" phenomenon across different models, as presented in Table 2. While the models show varying levels of performance degradation, a consistent downward trend is observed across all metrics.

B Template Types

Table 3 and 4 show the templates for each task (Parent2Child and Cause2Effect). To make the tasks solvable only when the LLMs pay attention to both A and B, we provide two sets of relationships in the text and randomize their order within the context of each task. We set a question based on the randomly chosen knowledge from each of the two pairs. Table 5 presents the template for the Name2Description task with context-related noise. We collected character names from various novels and used them as both questions and answers for testing.

C Case Study: Output Examples

Table 6 and 7 describes failure and successful output examples from Gemini-1.5-pro model.

Model	Direction	Position	Precision	Recall	F1 Score	Exact Match
gemini-1.5-flash	Forward	AB	97.12	94.34	94.90	93.5

Abstract

We introduce FinNLI, a benchmark dataset for Financial Natural Language Inference (FinNLI) across diverse financial texts like SEC Filings, Annual Reports, and Earnings Call transcripts. Our dataset framework ensures diverse premise-hypothesis pairs while minimizing spurious correlations. FinNLI comprises 21,304 pairs, including a high-quality test set of 3,304 instances annotated by finance experts. Evaluations show that domain shift significantly degrades general-domain NLI performance. The highest Macro F1 scores for pre-trained (PLMs) and large language models (LLMs) baselines are 74.57% and 78.62%, respectively, highlighting the dataset's difficulty. Surprisingly, instruction-tuned financial LLMs perform poorly, suggesting limited generalizability. FinNLI exposes weaknesses in current LLMs for financial reasoning, indicating room for improvement.

1 Introduction

Large Language Models (LLMs) (OpenAI, 2023; Touvron et al., 2023b,a; Abdin et al., 2024) excel on a wide variety of tasks. However, their generalizability to specialized domains remains an open research question (Li et al., 2023; Zhang et al., 2024). Financial domain presents unique challenges such as financial terminology (Araci, 2019) and mathematical reasoning (Chen et al., 2021b). Thus specialized benchmarks are necessary to ensure models effectively handle the complexities of this field. Financial Natural Language Processing (NLP) is a growing research area with resources (Nie et al., 2024; Li et al., 2023) and models (Yang et al., 2023a,b; Xie et al., 2023) developed for a wide range of tasks. However, Natural Language Inference (NLI), one of the core tasks in NLP, has been overlooked in this domain.

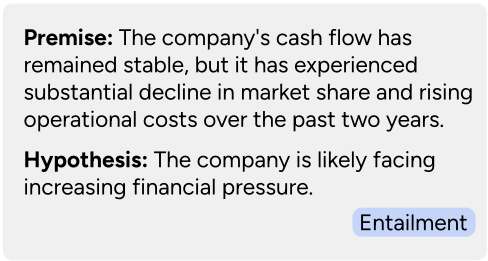

Figure 1: An example of NLI in financial risk assessment, which might seem Neutral as there is no explicit mention of "financial pressure" in the premise.

NLI is a task of determining whether a given hypothesis is true (entailment), false (contradiction), or undetermined (neutral) based on a given premise. NLI is essential for downstream tasks such as question answering, fact-checking, stance classification and relation extraction (Samarinas et al., 2020; Chen et al., 2021a; Sainz et al., 2021). These are widely applicable in the financial domain as well, underlying potential applications in risk assessment, stock market prediction, and automated financial reporting. Figure 1 shows an example of an NLI task in the financial domain. While the hypothesis might initially seem neutral due to the lack of explicit mention of "financial pressure", a deeper understanding of financial risk assessment shows that stable cash flow, rising operational costs, and declining market share typically signal increasing financial pressure; thus a robust NLI model should classify the pair as entailment. Without a resource allowing to evaluate the state of the art on financial NLI, the effectiveness of any improvements, or adaptation methods can not be assessed either.

To address this gap, we introduce the Multi-Genre **Fin**ancial **N**atural **L**anguage **I**nference **(FinNLI)** dataset that enables us to assess and improve the capabilities of language models in understanding and inferring financial information. Previous studies have identified artifacts in NLI datasets that can diminish model effectiveness (Gururangan

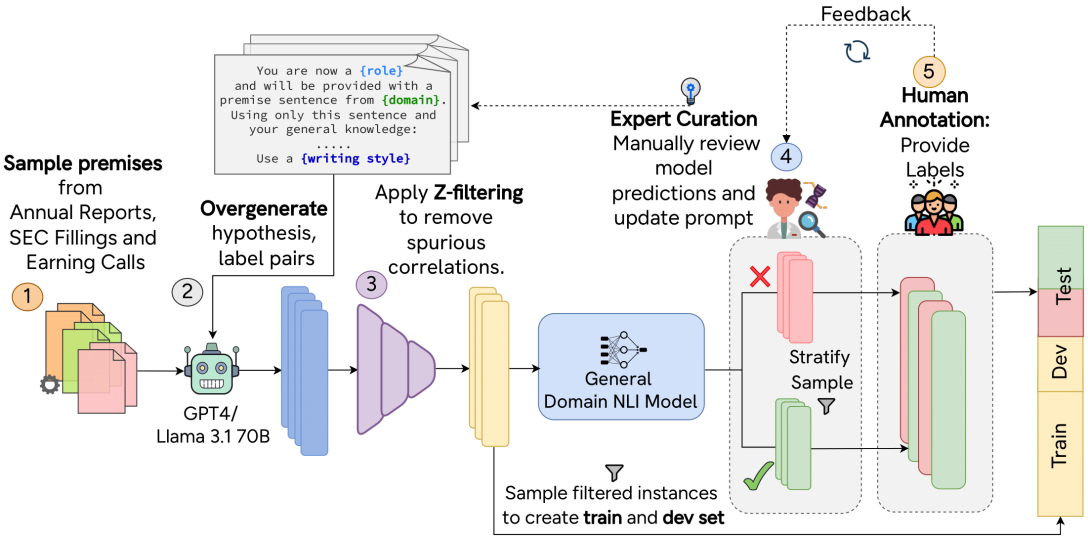

Figure 2: **Overview of the FinNLI data generation pipeline.** (1) We sample premises from real-world financial documents across multiple genres. (2) Hypothesis-label pairs are generated using multiple LLMs. (3) *Z-filtering* (Wu et al., 2022) removes spurious correlations. (4) The prompt is refined based on feedback from a general-domain NLI model and expert curation. (5) Finally, instances correctly predicted and misclassified by the NLI model are reviewed by finance experts for gold label annotation.

et al., 2018; Zhang et al., 2019; Ye et al., 2024). In this paper, we meticulously design a generation pipeline to address these prevalent challenges. Our framework for dataset generation shown in Figure 2 focuses on diversity, mitigation of spurious correlations, including challenging examples and having high quality annotations for the testing set. We then present a comprehensive evaluation of various state-of-the-art models on the FinNLI benchmark. These include general domain and financial LLMs and smaller pretrained language models (PLMs). We make the following contributions:

- We introduce a novel dataset for evaluating NLI in the financial domain.
- We present a dataset generation framework and discuss the contribution of its parameters.
- We provide a thorough evaluation and its analysis of multiple NLP models on FinNLI.
- We demonstrate significant room for improvement for Financial NLI across all models.

2 Related Work

Financial NLP Financial NLP is a rapidly evolving research area, with a number of advances achieved in a number of tasks such as sentiment analysis (Shah et al., 2023; Malo et al., 2014), question answering (Chen et al., 2021b, 2022), and financial text summarization (Mukherjee et al., 2022). Several finance-specific LLMs have also been developed to address domain-specific challenges. Notable examples include InvestLM (Yang et al., 2023b), FinGPT (Yang et al., 2023a), PIXIU FinMA (Xie et al., 2023), and Bloomberg GPT (Wu et al., 2023), although access to some of these models is limited, and they are not all available as open-source.While finance-instruction-tuned LLMs have attained increasingly high performance on various financial NLP tasks, it is still unclear whether these models will generalise well to novel tasks not included in the instruction tuning data. The task of financial NLI has been largely overlooked likely due to insufficient resources, yet it has been shown to be informative for evaluating LLMs (Madaan et al., 2024). We aim to fill this gap by creating a benchmark dataset and conducting a comprehensive evaluation across a wide range of models.

While there are no dedicated financial NLI datasets, FinCausal datasets (Mariko et al., 2020, 2022) provide benchmarks for evaluating financial reasoning. However, FinCausal focus solely on causality detection, which is just one type of reasoning. In contrast, NLI task involves various logical relationships that require multiple types of reasoning, with causal reasoning being only one aspect. Our proposed dataset, FinNLI, evaluates more types of relationships just beyond causality such as mathematical, temporal and financial.

Dataset	Domain	Premise Source	Ensures premise diversity	Hypothesis Generation	Ensures hypothesis diversity	Mitigates spurious correlations	Includes challenging instances
SNLI (Bowman et al., 2015)	General	Real-world	No	Human Annotation	No	No	No

Table 1: Qualitative comparison of NLI dataset generation approaches across different methodological aspects.

Domain-specific NLI The development of NLI has been significantly advanced by large-scale datasets such as SNLI (Bowman et al., 2015) and MNLI (Williams et al., 2018). However, a common challenge is the performance drop when transitioning from general-domain models to domain-specific applications (Hupkes et al., 2023). This highlights the importance of creating and utilizing domain-specific NLI datasets to ensure models are well-adapted to specialized domains.

Specialized NLI datasets have been developed for various domains, including biomedical (BioNLI (Bastan et al., 2022)), medical (MedNLI (Shivade et al., 2019)), scientific (SciNLI (Sadat and Caragea, 2022), SciTail (Khot et al., 2018)), and legal (ContractNLI (Koreeda and Manning, 2021), LegalNLI (Yang, 2022)) contexts. In this work, we introduce a Financial NLI dataset to evaluate and enhance NLI model performance in the financial domain, where precise inferential reasoning is crucial.

NLI Dataset Generation Approaches to NLI dataset construction typically involve either creating both premise and hypothesis (Hosseini et al., 2024), sampling existing premises and generating hypotheses (Williams et al., 2018; Shivade et al., 2019), or sampling both from existing texts (Sadat and Caragea, 2022; Bastan et al., 2022). The generation process can be automated or manual, often followed by human annotation (Liu et al., 2022a). Sampling both premises and hypotheses from existing texts can be limited by rule-based methods (e.g., using linking phrases (Sadat and Caragea, 2022, 2024)), as suitable pairs are not easy to find and automatically sample. Human-generated hypotheses are more costly due to the time required. Recent approaches use LLMs to synthetically generate both premises and hypotheses (Liu et al., 2022a; Hosseini et al., 2024). However, while this may be effective for general domains, LLMs trained on general text may fail to generate high-quality data that accurately capture the nuances of specialized domains (Xu et al., 2023). To address these limitations, our work samples premise sentences from real-world documents across multiple financial genres to ensure premise diversity and to induce finance-specific knowledge. We ensure hypothesis diversity by employing different writing styles and roles when prompting LLMs (Yu et al., 2023), followed by domain-expert annotation to create a high-quality test set. Table 1 provides a qualitative comparison of our NLI dataset generation approach with others, further comparisons with finance and NLI datasets are in Appendix A.

NLI datasets often contain artifacts—spurious correlations between labels and features that do not represent the underlying task (Stacey et al., 2020; Cosma et al., 2024). These artifacts cause models to learn shortcuts, failing to generalize to new data (Ye et al., 2024). Artifacts can occur in both manually and automatically generated instances (Gururangan et al., 2018; Zhang et al., 2019; Arakelyan et al., 2024; Proebsting and Poliak, 2024). Addressing artifacts involves careful dataset design, filtering (Wu et al., 2022), and adding adversarial samples (Nie et al., 2020; Liu et al., 2022a). In contrast to other approaches, we incorporate z-filtering (Wu et al., 2022) in our dataset generation pipeline to mitigate spurious correlations and leverage feedback from a general-domain NLI model to ensure our resulting dataset includes challenging instances in an adversarial-like setting

3 Dataset Construction

We present our data generation framework (Figure 2) which is applicable across various domains. This framework ensures contextually grounded instances by sampling premises from real-world financial texts. It promotes diversity by incorporat-

ing two different LLMs and varied prompts while minimizing artifacts through *z-filtering* (Wu et al., 2022). To enhance the dataset's difficulty, we leverage feedback from a general domain NLI model and experts to guide model generation. Finally, we maintain high quality by involving multiple finance experts in the annotation process.

3.1 Stage 1: Sampling Premises Across Multiple Financial Domains

As the sources of our premise sentences, we use publicly available financial documents: **Annual Reports** [1], **SEC Filings** [2] and **Earning Calls** (Li et al., 2020). Sampling from diverse financial genres enhances the stylistic variation of the dataset. Annual Reports and SEC Filings exhibit a formal style with prevalence of numerical information (Loukas et al., 2022), while Earning Calls include more colloquial language. Preprocessing is used to filter out invalid sentences, ensuring sample quality (Appendix B).

3.2 Stage 2: Generating Hypotheses

Given a premise, we prompt an LLM to generate one entailment, neutral, and contradiction hypothesis. The prompt includes the NLI task definition, label verbalization, domain-specific generation conditions, and exemplars to guide the LLM. Conditions and examples are refined through iterations of steps 1-4 of the pipeline on Figure 2 (full prompt in Appendix G). To encourage stylistic variations, we use conditional prompting with role-playing (Shanahan et al., 2023) and treat writing style as an attribute dimension (Yu et al., 2023). We define a list of finance-related roles as *financial analyst*, *financial reporter*, *finance compliance officer*, and *financial consultant*, and a list of writing styles as *social media*, *news*, *financial textbook*, and *financial reporting*. At each generation step, a role and writing style are randomly selected to condition the generation. We experiment with two LLMs to generate hypothesis-label pairs: GPT-4 (OpenAI, 2023) and Llama 3.1 70B (Dubey et al., 2024). These models belong to different LLM families, vary in size, and perform competitively across a wide range of tasks. This setup allows us to examine potential differences between closed-source and open-source models in generating synthetic instances.

[1]https://www.annualreports.com/

[2]https://www.sec.gov/

3.3 Stage 3: Automatic Filtering

To minimise spurious correlations that could have appeared during the generation process, we apply the *z-filtering* algorithm from Wu et al. (2022). It is a method to reject samples that contribute to the high spurious correlations between task-independent features of the samples and their labels. The list of task-independent features includes: unigrams and bigrams, lexical overlap between the premise and hypothesis, hypothesis length and premise-hypothesis length ratio, and thenumber and density of financial terms in the hypothesis to capture correlations that may result from the presence of specific financial keywords. We set the parameters of the z-filtering process, the top k features and sample batch size to 20 and 200 respectively. We observed that a higher value of k and lower value of batch size lead to a higher number of samples to be removed and lower z-scores. Z-scores and top-k features before and after applying z-filtering are included in Appendix C showing the effectiveness of this our approach in minimizing spurious correlations.

We create the train and development sets by randomly sampling from the filtered instances generated by Llama 3.1 70B with the final optimised prompt[3]. We sample evenly across financial domains and class labels. We use the generated labels as the gold standard for training and development.

3.4 Stage 4: Expert Curation

Evaluating the quality of open-ended data generation across various prompt parameters is a challenging task due to the large number of possible prompt combinations (Long et al., 2024; Chung et al., 2023). To address this, we combine feedback from a general domain NLI model and human experts to identify label inconsistencies and challenging reasoning patterns. These insights are then used to iteratively refine the generation prompt. As a general domain NLI model we chose RoBERTa-Large NLI[4], trained on MNLI and SNLI as one of top performing models on this task. Through multiple iterations, we refine the prompt to include instructions for mathematical/quantitative reasoning, temporal reasoning, financial knowledge reasoning, and tricky linguistic constructs, along with repre-

[3]We use Llama 3.1 70B model to generate the training and development set as its license permits the use of the generated artefacts for fine-tuning downstream models https://llama.meta.com/llama3/license/

[4]https://huggingface.co/joeddav/xlm-roberta-large-xnli

Split	Size	Label Distribution (E/N/C)
Train	16,200	5,400 / 5,400 / 5,400
Dev	1,800	600 / 600 / 600
Test	3, 304	1,361/ 995 / 948

Table 2: Dataset Split and Label Distribution

sentative examples from each reasoning pattern. We provide examples of instances with challenging reasoning patterns in Appendix 12.

We create a domain- and class-balanced test set by sampling instances where the predicted label matches the generated label, as well as instances where they differ. This ensures a mix of correct and incorrect predictions, balancing both challenging and core cases. By doing so, we capture not only "hard" examples but also fundamental NLI reasoning patterns, allowing for a more effective evaluation of the generation model (Bowman and Dahl, 2021).

3.5 Stage 5: Human Annotation

We provide the samples for annotation in 4 rounds (R) and at each round collect feedback from the expert annotators on the quality of the instances. We provide annotators with instances generated from GPT-4 in R1 and R2 while Llama generated instances in R3 and R4. We incorporate this feedback by updating the prompt conditions and in-context examples to improve the quality of subsequent generations after each annotation round. The annotators are provided with a premise and hypothesis sentence and asked to provide an appropriate label, a confidence level (*high* or *low*), an optional flag to mark the premise or hypothesis sentence as incomplete/nonsensical and an optional comment field. The annotators do not revise the premise or hypothesis sentences (Appendix H). Each premise-hypothesis pair is reviewed by 3 professional annotators with finance backgrounds and we assign the majority label as the gold label. In very rare cases (0.15%) where all the annotators assign different labels, we do not assign a gold label. We exclude any instances where *any* of the annotators mark the premise or hypothesis as incomplete/nonsensical.

4 Dataset Analysis

We provide an analysis of the annotation outcomes and the resulting characteristics of FinNLI[5].

[5]For information on the data license and dataset access, please contact the authors via email.

4.1 Synthetic Label Accuracy

Per Annotation Round. We conduct annotations over four rounds, altering either the prompt or the model between rounds. Rounds R1 and R2 utilize GPT-4, while R3 and R4 use hypotheses generated by Llama 3.1 70B. Prompt adjustments occur between R1 and R2, as well as between R3 and R4. In the first round of annotation (R1), domain experts evaluated $1,462$ GPT-4-generated instances. In 65.18% of the cases, the label assigned by the annotators matched the generated label. After refining the prompt, the second round (R2) showed improvement, with 76.47% out of 595 instances displaying label agreement, highlighting the value of incorporating expert feedback. In annotation rounds three (R3) and four (R4), annotators were presented with examples generated by Llama 3.1 70B. In R3, 64.57% of the 621 instances had labels that matched the generated ones. The decrease in agreement relative to R2 can be attributed to the use of a GPT-4-optimized prompt with Llama, revealing model-specific prompt sensitivity (Lu et al., 2024). After refining the prompt for Llama in R4, label agreement improved to 76.84% across 626 instances. We use the prompt from R4 to generate the training and development sets. 14.27% of the examples where the general-domain NLI model assigns a similar label to the generated label are relabelled by annotators, compared to 46.88% for instances with differing labels. This finding supports the rationale to sample from both correctly and incorrectly predicted instances, as the former likely includes 'easy' examples and the latter contains both 'hard' and 'ambiguous' cases.

The overall agreement rate for the FinNLI dataset is noticeably lower than the 84.97% [6] agreement reported for general-domain synthetic NLI datasets such as GNLI (Hosseini et al., 2024). Although, we note that Hosseini et al. (2024) prompt-tune a generator LLM with an existing NLI dataset while our approach relies solely on expert-curated prompt conditions and in-context exemplars to steer the generator. We also hypothesize that LLMs may be more efficient data generators for general domains than in specialised settings (Xu et al., 2023).

Per class. The breakdown by class label shows significant differences. For contradiction hypothe-

[6]We obtain the overall agreement rate by averaging the agreement rate for *unanimous* labels - 89.53% and majority labels - 80.41% reported in Hosseini et al. (2024)

	#Words		% Sentences		Word	
Domain	**Prem.**	**Hyp.**	**Prem.**	**Hyp.**	**Overlap**	**Agrmt.**
REPORTS	25.0	20.6	95.2	98.8	41.62%	76.14%
SEC	23.2	20.3	96.8	98.9	45.26%	76.20%
CALLS	19.5	17.5	96.0	99.2	27.92%	77.62%
Overall	**22.6**	**19.5**	**96.0**	**98.9**	**38.25%**	**76.65%**

Table 3: Dataset Statistics for FinNLI by genre. *#Words* is the mean number of tokens in the premise and hypothesis. *'%-Sentences'* – proportion of sentences parsed with an 'S' root using the Stanford PCFG Parser (Klein and Manning, 2003). *Word Overlap* – mean proportion of tokens shared between the premise and hypothesis. *Agrmt.* is the % of examples where the generated label matches the label assigned by annotators.

ses, both LLMs achieve high agreement rates (GPT-4 - 88.83% and Llama - 90.86%). For entailment hypotheses, Llama achieves a higher agreement rate of 75.46% compared to 53.55% for GPT-4. In contrast, for neutral hypotheses, GPT-4 achieves a higher agreement rate of 81.07% compared to 66.52% for Llama. Qualitative observations show that many LLM-generated entailment hypotheses are relabelled to neutral due to models appending additional information not present in the premise, resulting in lower agreement rates for entailment.

4.2 Dataset Statistics

The domain-experts annotated a total of 3,360 examples, out of which 3,304 instances (98%) are marked as valid examples. For the valid instances, we achieved a Fleiss-κ score of 88.31%, indicating an almost perfect agreement. Table 2 outlines the size of the train, development and testing sets, as well as label distribution across the dataset splits. The training and development sets are uniformly balanced across labels, whereas the test set shows a slight skew toward the entailment label. The slight imbalance in the test set is a result of reassigning labels as part of the manual annotation process.

4.3 Linguistic Analysis

We provide a detailed linguistic analysis of the FinNLI dataset in Table 3 and comparison to other NLI datasets in Appendix A. Premise sentences are generally longer (mean 22.6 words, max 105 words) than hypothesis sentences (mean 19.5 words, max 84 words). Premises from Annual Reports and SEC Filings tend to be lengthier, reflecting the formal nature of financial reporting, whereas premises from Earning Calls are shorter, indicative of more colloquial language use. Annual Reports and SEC Filings often include tables and forms, which can result in incomplete premise sentences when sampled. However, our pre-processing pipeline filters out these invalid sentences, with approximately $\approx$ 96% of the premise sentences containing 'S'-root parses, indicating they are syntactically complete. We observe a higher token overlap between the hypothesis and premise sentences in Annual Reports and SEC Filings compared to Earning Calls. Annual Reports and SEC Filings often include specific financial jargon that must be reflected in the hypothesis to remain relevant, whereas utterances in Earning Calls are more open to interpretation.

5 Models

We evaluate performance of various models on FinNLI test set. We use the average macro F1 as our main metric due to the test set class imbalance.

5.1 Zero-Shot NLI Baselines

We evaluate two state-of-the-art general-domain NLI models: **BART-Large-MNLI** (Lewis et al., 2020a), trained on MNLI (Williams et al., 2018) and **DeBERTa-V3-NLI** (He et al., 2021), trained on both MNLI and SNLI (Bowman et al., 2015).

5.2 PLM Baselines

We fine-tune the following general-purpose and domain-specific pre-trained language models (PLMs) on the FinNLI training set: **RoBERTa-Base**, **RoBERTa-Large** (Liu et al., 2019), and **FiLM** (Choe et al., 2023), which is a RoBERTa-Base model further pre-trained on financial corpora. Additionally, we fine-tune **BART-Large-MNLI** (Lewis et al., 2020a) to explore whether training on both MNLI and FinNLI yields any benefits. We conduct a grid search for hyperparameters and choose the best model on the development set. The best model is trained over three independent runs with different random seeds[7].

5.3 LLM Baselines

We investigate the performance of general-purpose and domain-specific LLMs across a wide range of model sizes and prompt settings on the FinNLI test set. For the general-purpose LLMs, we evaluate **Llama-2-7b-chat-hf** (Touvron et al., 2023b),

[7]Full details on the experimental setup and hyperparameter tuning are provided in Appendix D.

Model	Size	Setup	Annual Reports	SEC Filings	Earning Calls	Overall
DeBERTav3-NLI	$304M$	Zero-Shot	68.83 ± 0.0	68.52 ± 0.0	71.08 ± 0.0	69.54 ± 0.0
BART-Large-MNLI	$406M$	Zero-Shot	69.96 ± 0.0	70.24 ± 0.0	$\mathbf{75.95 \pm 0.0}$	72.09 ± 0.0
RoBERTa-base	$255M$	Finetuned	70.32 ± 0.1	69.14 ± 1.2	69.84 ± 0.2	69.78 ± 0.5
FiLM	$255M$	Finetuned	70.43 ± 0.6	69.57 ± 0.2	70.24 ± 0.8	70.11 ± 0.01
RoBERTa-large	$355M$	Finetuned	$\mathbf{75.11 \pm 0.1}$	73.98 ± 1.2	74.52 ± 0.2	$\mathbf{74.57 \pm 0.5}$
BART-large-MNLI	$406M$	Finetuned	73.91 ± 0.8	$\mathbf{74.14 \pm 0.6}$	74.35 ± 0.9	74.18 ± 0.2

Table 4: Average Macro F1 Scores (%) of zero-shot general-domain NLI models and fine-tuned PLMs on the FinNLI test set across each financial domain. Results are averaged over three random seeds, with the standard deviation reported. Best performance is highlighted in **bold**.

Phi-3.5-mini-instruct (Abdin et al., 2024), **Llama-3.1-8B-Instruct** (Dubey et al., 2024), and **Llama-3.1-70B-Instruct** (Dubey et al., 2024). For the finance-domain LLMs, we evaluate **FinMA-7B-NLP**, **FinMA-30B** (Xie et al., 2023) - Llama-2 7B and 30B respectively instruction-tuned on financial NLP tasks. FinMA models were chosen due to superior performance across diverse financial NLP tasks (Xie et al., 2024) and its open-source availability. We use several prompt setups (Appendix G): Zero-Shot (ZS); Zero-Shot expanded with Annotation Guidelines (ZS-AG); Few-Shot with Annotation Guidelines (FS-AG) (2 examples per class from different financial genres); and Chain-of-Thought (CoT) (Wei et al., 2022).

6 Results

6.1 Zero-shot and Fine-tuned PLM Baselines

Table 4 presents the results of experiments with zero-shot NLI and fine-tuned PLM Baselines.

General-domain NLI models exhibit a sizeable performance drop on financial NLI. BART-Large-MNLI and DeBERTa-V3-NLI achieve accuracy scores of 89.9% (Lewis et al., 2020a) and 91.1%[8], respectively, on MNLI. However, their accuracy drops significantly to 70.94% and 68.31% on FinNLI, highlighting the impact of domain shift on performance in out-of-domain settings. The general-domain NLI models perform better on Earnings Calls compared to Annual Reports and SEC Filings, likely due to the MNLI training data, which includes telephone transcripts and speeches, aligning more closely with the informal language used in Earnings Calls (Williams et al., 2018).

Fine-tuning PLMs on FinNLI improves performance over zero-shot NLI models. Despite the FinNLI test set consisting of GPT-4 and Llama3.1-generated instances while the training set consisting of only Llama3.1-generated instances, we observe performance improvements post fine-tuning. Fine-tuning improves performance by 5% in F1 score when comparing the zero-shot DeBERTa-V3-NLI to the fine-tuned RoBERTa-Large on the FinNLI test set, both having similar parameters. BART-Large-MNLI shows a 2% improvement in performance after fine-tuning on FinNLI. However, combining MNLI and FinNLI offers no benefits compared to training solely on FinNLI. Larger fine-tuned PLMs outperform smaller models, suggesting that FinNLI contains challenging examples that require greater model capacity for accurate inference. Domain-specific pre-training offers only marginal gains over general-purpose PLMs. FiLM (Choe et al., 2023), a RoBERTa-Base model pre-trained on financial documents,[9] performs slightly better than the standard RoBERTa-Base.

6.2 LLM baseline results

Figure 3 shows the results of LLM experiments.

Llama 3.1 70B achieves the best performance on FinNLI, but significant room for improvement remains. Llama 3.1 70B achieves the highest F1 score of 78.62% on the FinNLI test set and is the only LLM among those evaluated that outperforms a finetuned RoBERTa-Large model, which attains an F1 score of 74.57% ($\sigma = 0.5\%$). Phi 3.5 achieves a comparable performance of 74.74% ($\sigma = 0.3\%$), with this difference being too small to conclude any significant advantage over RoBERTa-Large. All other LLMs are outperformed by the RoBERTa-Large model finetuned on the FinNLI training set, indicating that PLMs are still highly competitive on domain-specific tasks. While the best performing F1 score is 78.62%, we observe that this is notably lower than other LLMs' performance on general-domain NLI tasks (Wang et al.,

[8]Accuracy score reported from https://huggingface.co/cross-encoder/nli-deberta-v3-large

[9]Including $301M$ tokens from SEC Fillings and $1.1B$ tokens from Earning Calls (Choe et al., 2023)

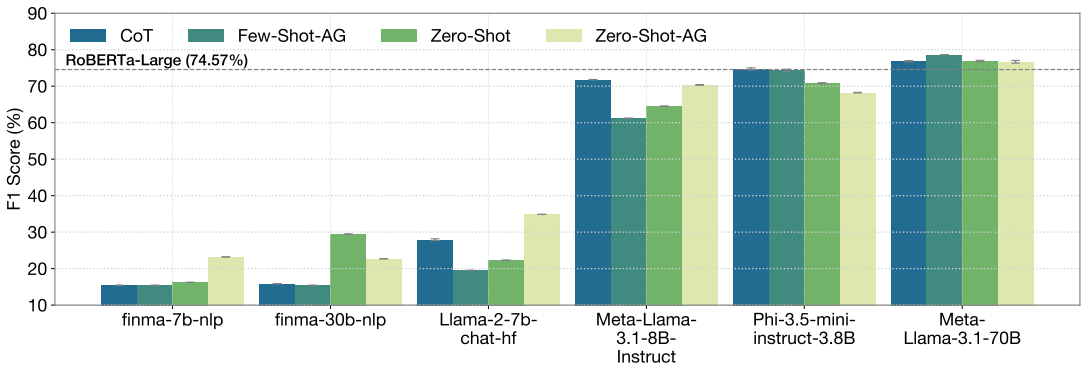

Figure 3: Average macro F1 scores (%) for various LLMs across different prompting setups evaluated on the FinNLI test set. Prompts with **AG** have the class label definitions used in the annotation guidelines included in the prompt. The error bars represent the standard deviation across 3 independent runs. The dotted grey line at 74.57% marks the performance of RoBERTa-Large, the best performing fine-tuned PLM on FinNLI test set.

2024) [10] suggesting that FinNLI may contain examples that exhibit complex reasoning patterns or contain 'ambiguous' instances that pose a challenge to current state-of-the-art LLMs. To investigate this, we conduct an error analysis on the instances misclassified by Llama 3.1 70B in Section 7.3.

Small Language Models (SLMs) outperform significantly larger LLMs on FinNLI. Phi-3.5-mini-instruct, a 3.8 billion parameter LLM, achieves an F1 score of 74.74%, outperforming Llama 3.1 8B, a significantly larger LLM that achieves an F1 score of 71.79%. This underscores the potential of smaller language models trained on highly curated datasets in bridging the performance gap to larger LLMs (Abdin et al., 2024).

LLMs instruction-tuned on financial domain tasks perform worse than general-domain LLMs. FinMA 7B and FinMA 30B - instruction-tuned on financial NLP tasks, achieve F1 scores of 23.20% and 29.46% respectively. In contrast, the base model for FinMA 7B, Llama-2-7B-chat achieves a higher F1 score of 34.87%. This suggests that instruction-tuning may have negatively impacted the model's ability to generalise to other tasks outside the instruction-tuning data. This finding aligns with previous studies which show that domain-specific instruction tuning can degrade general performance on financial textual-analysis tasks (Xie et al., 2024) and knowledge-based evaluation benchmarks (Lee et al., 2024b). Possible reasons for this could include limited training sets, suboptimal training parameters, or training schedules (Dong et al., 2024; Lee et al., 2024a).

[10] General-domain NLI datasets are likely to be included in LLM pretraining data and as such this may not be a fair evaluation

CoT prompting improves performance for small to mid-sized LLMs on FinNLI. We observe that using CoT and asking an LLM to provide an explanation for its prediction, leads to performance improvements over zero-shot prompting for small to mid-sized models on FinNLI. Specifically, CoT yields an approximate F1Score improvement of 7% for Llama 3.1 8B, 5.6% for Llama-2-7b-chat-hf, and 3.9% for Phi-3.5-mini-instruct. However, for the larger Llama 3.1 70B model, CoT does not provide significant performance improvement over zero-shot. Score). The FinMA models do not exhibit improvements with CoT as they fail to return any meaningful responses. We observe that smaller LLMs are more sensitive to different prompts on the NLI task, and CoT helps enhance their reasoning. In contrast, larger LLMs like Llama 3.1 70B already demonstrate strong reasoning capabilities and are less affected by prompt variations.

7 Impact of Generation Design Decisions

We discuss the impact of different generation design decisions on model performance.

7.1 GPT-4 vs Llama-Generated Test Sets

We compare the average macro F1 scores of the best-performing zero-shot NLI model, fine-tuned PLM and LLM on the GPT-4-generated instances $(2,057)$ and Llama-generated instances $(1,247)$, averaged over three independent runs. BART-Large-MNLI performs significantly better on the Llama test set (80.43%) than on the GPT-4 test set (65.19%) suggesting that GPT-4-generated instances are more challenging for zero-shot NLI models. Fine-tuned RoBERTa-Large achieves higher performance on the GPT-4 test set (77.48%)

compared to the Llama test set (71.90%). Fine-tuning appears to help the model adapt to the nuances of GPT-4-generated data but reduces its effectiveness on Llama-generated instances. Llama 3.1 70B exhibits consistent performance across both test sets (77.28% on GPT-4 and 78.84% on Llama)[11]. The slight advantage on the Llama test set could be attributed to self-preference bias, where an LLM's performance is favourable to its own output as compared to other outputs (Panickssery et al., 2024).

7.2 Prompt Roles and Writing Styles

We investigate how different prompt roles and writing styles used to generate hypotheses affect model performance. For the best-performing fine-tuned PLM (RoBERTa-Large) and LLM (Llama 3.1 70B), we observe no significant differences in F1 scores across the various roles or styles, indicating robustness to stylistic variations. However, the zero-shot NLI model, BART-Large-MNLI, shows considerable performance discrepancies. It achieves higher F1 scores on more formal writing styles such as *financial textbook* (78.32%) and *financial reporting* (77.40%) compared to less formal styles like *social media* (60.70%) and *financial news* (73.82%). This suggests that zero-shot NLI models are more sensitive to stylistic variations (Belinkov et al., 2019). In contrast, LLMs like Llama 3.1 70B gain robustness to different writing styles due to pretraining on diverse domains (Dubey et al., 2024). Similarly, the fine-tuned PLM gains robustness by training on the FinNLI, enabling better generalization across stylistic variations.

7.3 High vs Low Confidence Annotations

We define high-confidence instances as examples that receive a unanimous label and all annotators mark their confidence level as high for that instance. Low-confidence instances are examples where at least one annotator marks with low confidence or instances that do not have a unanimous label. Out of 3,304 annotated examples, 2,401 examples (72.67%) are classified as high-confidence and 903 examples (27.33%) marked as low-confidence. Llama 3.1 70B achieves an F1 score of 82.51% on the high-confidence instances compared to 67.20% on the low-confidence instances. This suggests that LLMs similarly struggle on examples that human annotators demonstrate low confidence or high disagreement, possibly the ambiguous cases.

[11] A paired t-test confirms that the higher performance on the Llama test set is statistically significant ($t = 50.59$, $p = 0.0004$).

8 Error Analysis

Reviewing the frequency of model's errors across the classes, we observe a notable trend of misclassifying neutral instances as entailment (Appendix D). To gain a deeper understanding, we manually reviewed $\approx$ 10% (60 out of 683) of the misclassified instances from the best-performing model, Llama 3.1 70B(Appendix E.2). Our analysis shows that 56% of misclassifications are due to **inference errors** (clear model mistakes), while 44% stem from **ambiguous instances**, i.e., phrases or words that allow more than one interpretation (Sandri et al., 2023; Jiang and de Marneffe, 2022). For inference errors, the model often assumes *implicit information* (26%) not contained in the premise, making logical inferences that, while plausible, are unfaithful to the premise (Zhou et al., 2023). Additionally, the model struggles with instances requiring *financial reasoning* (16%), such as knowledge of financial terms or standard procedures, which domain-expert annotators easily pick up. *Tricky linguistic instances* (Nie et al., 2020) (8%) such as counter-speech (Gligoric et al., 2024), words play, and those requiring *mathematical reasoning* (6%) still pose a challenge to the model. Regarding ambiguous instances, 22% of misclassifications are due to *uncertainty in sentence meaning* that may result in multiple interpretations. Interestingly, a significant proportion (22%) of premise sentences sampled from *Earnings Calls* contain *anaphora* and *deixis* (Poesio and Artstein, 2005), typical of informal conversations —expressions that require contextual information to interpret. Such instances lead to ambiguity, as it is often unclear whether the entity introduced in the hypothesis is mentioned in the premise, resulting in *missing context*.

9 Conclusion

We introduced the FinNLI benchmark to evaluate and improve NLI models in the financial domain. Our evaluations show that general-domain NLI models perform worse on financial NLI, LLMs perform comparably to fine-tuned PLMs, and instruction-tuned financial LLMs lack generalizability. This reveals significant room for improvement in financial NLI, necessary for better understanding and reasoning with financial text, ultimately enhancing downstream applications.

10 Limitations

Our NLI task setup employs a single gold label classification, and we have yet to explore more advanced setups, such as those involving explanation rationales or generating probability distributions over the label space that align with human judgment. Due to limited domain expertise, we could only employ three annotators per instance.

We did not explore adversarial settings, which could provide insights into model robustness against attacks. Future work will explore domain adaptation methods and using FinNLI as an intermediate task to enhance performance on related tasks. Currently, the FinNLI benchmark is limited to English, restricting its applicability to non-English financial texts. We also note that the generated premises may contain fictional information and should not be used to train models that learn factual data.

11 Ethical Considerations

The financial documents utilized in the FinNLI dataset, including SEC filings, annual reports, and earnings call transcripts, are publicly available and do not contain sensitive, personally identifiable information (PII). Earnings call transcripts have been anonymized. However, it is important to acknowledge that financial texts and model-generated outputs may contain inherent biases. Despite our efforts, we cannot guarantee the complete absence of biases and hallucinations in the synthetic data produced. These limitations should be considered when interpreting the results and applications of our research. This dataset should not be used directly for tasks like fact-checking and question answering, as we cannot guarantee the accuracy of the information.

Acknowledgments

We would like to thank Arturo Oncevay, Toyin Aguda, and Keshav Ramani for insightful discussions. We thank our colleagues from Annotation Center of Excellence, who collaborated with us to refine annotation guidelines and produce high quality annotations for this research paper.

A Comparison to other Datasets

We provide a detailed comparison of FinNLI to other NLI datasets in Table 5 and other Financial NLP datasets in Table 6. FinNLI is the first NLI dataset specifically focused on the financial domain, filling a significant gap in existing datasets and providing a benchmark for financial reasoning tasks. When comparing FinNLI's size with other NLI datasets, our evaluation set's size is comparable to other domain-specific NLI datasets (Table 5) and larger than most existing financial NLP datasets (Table 6). General-domain NLI datasets tend to have larger test sizes, while smaller test sizes are observed in domain-specific datasets reflecting the time and costs incurred in obtaining high-quality expert annotations. Although FinNLI's training dataset is smaller compared to other datasets, the training and development sets are sufficient for model learning on the task. This is evidenced by model improvements observed when fine-tuned on the FinNLI training set (see results in Section 6). Additionally, our data generation approach is scalable and can generate more instances with additional resources.

FinNLI's premise and hypothesis pairs are generally longer than those in general-domain datasets, capturing the unique linguistic complexity of financial texts such as Annual Reports and SEC Filings. This length difference may contribute to the performance drop observed in models trained on general-domain NLI datasets when applied to FinNLI (shown in Section 6). The lexical overlap between premise and hypothesis sentences in FinNLI is lower than in general-domain datasets like SNLI and comparable to other domain-specific NLI datasets. This lower overlap indicates that our dataset contains fewer spurious features which models could otherwise exploit to excel on the task.

A.1 Model Performance Comparison to other Datasets

We compare the performance of RoBERTa-Base and RoBERTa-Large on FinNLI and other NLI datasets, as shown in Table 7. Across the NLI datasets compared, the performance of both RoBERTa-Large and RoBERTa-Base is lower on FinNLI. This suggests that our dataset is potentially "more difficult" than other NLI datasets, likely due to the specialized language, longer premise-hypothesis pairs and unique reasoning required in the financial domain. However, we note that realistically comparing the difficulty of different NLI datasets can be tricky. This is because various factors, such as how the training data is generated and annotated, the size of the datasets, the distribution of labels, and the evaluation metrics used, can all vary.

Dataset	Domain	Accuracy (%)	Source
RoBERTa-Large			
SNLI	General	91.40	(Sun et al., 2020)
MNLI	General	90.20	(Zhuang et al., 2021)
MedNLI	Medical	83.30	(Lewis et al., 2020b)
WANLI	General	75.40	(Liu et al., 2022b)
FinNLI (Ours)	**Financial**	**75.37**	
RoBERTa-Base			
SciNLI	Scientific	78.12	(Sadat and Caragea, 2022)
MSCINLI	Scientific	77.42	(Sadat and Caragea, 2024)
FinNLI (Ours)	**Financial**	**70.69**	

Table 7: Comparison of dataset performance across different domains using RoBERTa models.

B Premise Preprocessing

We observe that directly sampling premise sentences from financial documents without applying any preprocessing results in a high number of invalid sentences. These include: (1) incomplete fragments, possibly caused by parsing errors from the original documents, (2) sentences containing tables, (3) sentences dominated by numerical data, (4) titles and subtitles, and (5) complete but irrelevant sentences, such as pleasantries (e.g., "Thank you for that question" or "Welcome to the call today") or references to document sections (e.g., "We refer to Section ..."). To mitigate this, we have developed a detailed preprocessing pipeline to filter out such invalid sentences.

Our process begins with NLTK sentence segmentation (Bird et al., 2009) to extract potential sentence sequences. However, this alone does not guarantee that all extracted sentences meet our criteria for valid premises. We identify and remove potential tables by searching for table-related keywords (e.g., "table" or "Table"), long ellipses (e.g., "....."), extended dash sequences (e.g., "——"), long underscore sequences (e.g., "___"), and instances where the number of new lines (e.g., \n) exceeds 10.

Dataset	Domain	#Examples			#Words		% Sentences		Word
		Train	Dev	Test	Prem.	Hyp.	Prem.	Hyp.	Overlap
SNLI (Bowman et al., 2015)	General	550,152	10,000	10,000	14.1	8.3	74.0%	88.9%	52.97%
MNLI (Williams et al., 2018)	General	392,702	20,000	20,000	22.3	-%	91.0%	98.0%	-
ANLI (Nie et al., 2020)	General	162,865	3,200	3,200	-%	-%	-%	-%	-%
WANLI (Liu et al., 2022a)	General	102,885	-	5,000	-%	-%	-%	-%	-%
GNLI (Hosseini et al., 2024)	General	670,739	6,845	490	40.5	11.0	-%	-%	-%
MedNLI (Shivade et al., 2019)	Medical	11,232	1,395	1,422	20.0	5.8	-%	-%	-%
SciNLI (Sadat and Caragea, 2022)	Scientific	101,412	2,000	4,000		25.93	96.8%	96.7%	30.06%
MSciNLI (Sadat and Caragea, 2024)	Scientific	127,320	1,000	4,000	26.84	25.85	94.4%	94.3%	30.29%
FinNLI (Ours)	Financial	16,200	1,800	3,304	22.6	19.5	96.0%	98.9%	38.25%

Table 5: Comparison of key statistics of FinNLI with other related datasets. *#Example* is the number of instances across each data split - we report the human-annotated test size for equal comparison. *#Words* is the mean number of tokens in the premise and hypothesis. *'%-Sentences'* – proportion of sentences parsed with an 'S' root using the Stanford PCFG Parser (Klein and Manning, 2003). *Word Overlap* – mean proportion of tokens shared between the premise and hypothesis.

Dataset	Task	Test Size
FPB (Malo et al., 2014)	Sentiment Analysis	970
FiQA-SA (Maia et al., 2018)	Sentiment Analysis	235
TSA (Cortis et al., 2017)	Sentiment Analysis	561
Headlines (Sinha and Khandait, 2021)	News Headline Classification	2,283
FinCausal (Mariko et al., 2020)	Binary Classification	8,630
FOMC (Shah et al., 2023)	Hawkish-Dovish Classification	496

FinNLI (ours)	**Natural Language Inference**	**3,304**

Table 6: Comparison of FinNLI's evaluation set with other available Financial NLP textual analysis datasets.

Titles and subtitles are identified by checking if more than 60% of the words in a sentence start with an uppercase letter. Sentences with over 60% numerical characters are also removed, along with any sentences containing URLs.

Additionally, we exclude sentences containing specific keywords, such as `[thank you, thanks, greetings, please, see below, continued, check mark]`. For Annual Reports and SEC filings, we filter out sentences that do not start with a letter or begin with a lowercase letter. Finally, we limit our selection to sentences that are at least 10 words long but no more than 100 words. To ensure a representative sample, we draw from different length bins to capture a range of premise lengths.

C Z-Filtering Results

Table 8 shows the top 10 features with the highest *z-statistic* score before and after applying *Z-filtering* (Wu et al., 2022) on the Llama-generated instances. High lexical correlations with the neutral label are observed, with Llama generating hypotheses containing unigrams such as *influence*, *may*, *might*, and *factors*, reported with high z-scores. After applying the algorithm, lower z-scores are reported across the features, indicating that task-independent features with high label correlations are filtered out. For instance, the unigram *might* is highly correlated with the neutral class (z-statistic = 56.75) but reduces to 25.82 after filtering. However, some correlations remain in the dataset, which models can still exploit, albeit at a reduced level compared to the pre-filtered set. Table 9 presents the performance scores of XLM-RoBERTa trained on general-domain NLI datasets before and after applying *z-filtering*. The observed performance drop after *z-filtering* suggests that the removed instances were primarily those the model previously classified correctly, likely due to exploiting biases in the training data. Notably, XLM-RoBERTa has been trained on datasets known to contain spurious correlations (Wu et al., 2022; Cosma et al., 2024). Therefore, the performance drop is expected, as removing these artifacts makes the model less reliant on learned biases.

Before *Z-filtering*			After *Z-filtering*		
Feature	z-statistics	Label	Feature	z-statistics	Label
may	94.69	N	overlap > 0.5	35.18	E
may be	63.66	N	overlap > 0.4	34.26	E
influence	60.64	N	overlap > 0.6	31.61	E
influenced	60.06	N	no	30.62	C
influenced by	59.87	N	'nt	27.74	N
factors	58.23	N	by	26.84	N
flu	58.12	N	might	25.82	C
actors	57.90	N	will be	25.80	N
might	56.75	N	impacted	25.77	N
factor	56.25	N	le	25.76	C

Table 8: Top 10 biased features with the highest z-statistics before (left) and after (right) applying *Z-filtering* on the Llama-generated instances. The label *N* indicates the neutral class, *C* indicates the contradiction class, and *E* indicates the entailment class.

	Before z-fiilter		After z-filter	
	Acc.	**Macro F1**	**Acc.**	**Macro F1**
Calls	0.83	0.83	0.79	0.77
SEC	0.84	0.84	0.79	0.75
Reports	0.85	0.85	0.82	0.79

Table 9: Performance scores of XLM-RoBERTa-Large trained on general domain NLI datasets, SNLI and MNLI, before and after applying z-filtering.

D Hyper-parameter Details for Fine-tuning Experiments

We access all models through the HuggingFace library, and conduct training using the PyTorch Lightning framework [12]. Each model is trained for a maximum of 20 epochs. Early stopping is employed with a patience of 5 epochs, based on validation accuracy. We apply an exponential learning rate decay, with the decay rate $\gamma = 0.95$. A grid search is performed over the following hyperparameter space: learning rate (*LR*) $\in \{1e-5, 2e-5, 3e-5, 5e-5\}$ and batch size (*BS*) $\in \{24, 32, 64\}$. The optimal hyperparameter configuration is selected based on the highest validation accuracy, and this configuration is used to retrain the model across three independent runs, each initialized with different random seeds. The best-performing hyperparameters for each model are provided in Table 10.

Model	LR	BS	Max Length
RoBERTa-Base	$3e-5$	64	200
FiLM	$5e-5$	64	200
RoBERTa-Large	$1e-5$	32	150
BART-Large-MNLI	$1e-5$	32	150

Table 10: Best-performing hyperparameters for each fine-tuned PLM

E Further Error Analysis

E.1 Confusion Matrix

Table 11 shows the frequency of misclassifications across entailment (E), contradiction (C), and neutral (N) classes, with a notable trend of misclassifying neutral as entailment. Regardless of which model was used for generation, Llama 3.1 70B often predicts E when the hypothesis expands on the premise without contradiction, making it challenging to determine if the extra information is implied or unrelated. In such cases, we believe

	GPT-4 test.			LLaMA test.		
Labels	**E**	**C**	**N**	**E**	**C**	**N**
E	880	13	60	373	6	29
C	20	539	55	10	289	35
N	209	45	236	195	38	272

Table 11: Confusion matrix for Llama 3.1 70B broken down for GPT-4 and Llama test sets.

LLMs are inferring more than what is logically warranted. Consider example from SEC Fillings, a premise *"The Corporate General Partner will continue to maintain compliance with franchise agreements and be economically prudent."*, and its hypothesis *"The Corporate General Partner will prioritize cost-effective decisions to ensure long-term financial sustainability."*. While *"economically prudent"* covers a range of financially responsible behaviours, e.g. *"cost-effective decisions"*. The hypothesis indicates that this behaviour is a priority, which is not guaranteed in the premise.

E.2 Examples demonstrating challenging reasoning patterns

We iteratively refine the prompt exemplars at each generation step by analyzing the predictions of a general-domain NLI model. Table 12 presents examples of the different reasoning patterns we have identified. We use these examples as in-context exemplars to guide the LLM in generating instances that necessitate reasoning for accurate inference. Notably, some of the challenging reasoning patterns resemble revisions made by human annotators in the adversarial NLI setting (Nie et al., 2020).

F Relabelled instance examples

Examples of instances relabeled by annotators are presented in Table 13. We observe that LLMs tend to append additional information not present in the premise sentence to entailment or contradiction-generated hypotheses, resulting in relabeling to neutral. In some cases, the LLM demonstrates a limited understanding of the NLI task and generates an incorrect label for some of the instances.

[12] https://lightning.ai/docs/pytorch/stable/

Example	Label	Reasoning
P: We earned $535,000, $606,000, and $794,000 of management fees under the agreement for the years ended December 31, 2014, 2013, and 2012. **H:** The management fees earned under the agreement in 2014 were less than those earned in 2013.	*Contradiction*	Mathematical Reasoning
P: Our net equity investment in these VIEs was 808.3 million as of December 31, 2018, and 606.2 million as of December 31, 2017. **H:** At some point during the year 2018, the net equity investment in these VIEs was either increasing or decreasing from its value at the end of 2017.	*Neutral*	Temporal Reasoning
P: The Company believes EBITDA is commonly used by financial analysts and others in the industries in which the Company operates and, thus, provides useful information to investors. **H:** EBITDA is a metric commonly employed by financial industry professionals to assess a company's financial performance, indicating its significance in financial analysis.	*Entailment*	Financial Knowledge
P: Our case growth for Sysco-branded sales to local customers increased 50 basis points in fiscal 2019. **H:** There was a modest uptick in our local customer sales last year in 2018.	*Neutral*	Tricky linguistic construct
P: We've been doubled down in seed for the last four years. **H:** We have reduced our seed investment substantially over the past four years.	*Contradiction*	Idiomatic Expression

Table 12: **Examples of challenging reasoning patterns** identified through the prompt iteration process and included in the optimised prompts as in-context exemplars to steer LLM generations towards high-quality examples.

Example	Generated Label	Majority Label
P: If our supply of raw materials is interrupted, our results of operations could be adversely affected. **H**: If our supply of raw materials is interrupted, our results of operations might be adversely affected.	*Neutral*	*Entailment*
P: For the years ended December 31, 2002, 2003 and 2004, our net cash provided by (used for) financing activities was (286.3), 71.1 million and $(1,686.4) million, respectively. **H**: The company's cash flow from financing activities fluctuated between 2002 and 2004.	*Neutral*	*Entailment*
P: A Look Ahead As we enter 2007, we have identified several priorities by which to grow our business. **H**: The company has outlined a strategic plan for business expansion in 2007, indicating a proactive approach towards growth and development, which is likely to involve investment in new opportunities, resource allocation, and possibly restructuring of certain business segments.	*Entailment*	*Neutral*
P: In November 2016 the LPSC submitted testimony disputing certain aspects of the calculations. **H**: The LPSC's submission of testimony in November 2016 was the sole factor that led to the immediate acceptance of the calculations without any further review or revision.	*Contradiction*	*Neutral*

Table 13: **Examples of relabeled instances:** The first two examples show instances where LLMs generate incorrect labels while the last two examples show instances where LLMs tend to include additional information not in the premise sentence Additional information not in the premise is shown in red.

G LLM Experiments

G.1 Running Inferences

All the models are accessed from Hugging Face[13], and inferences are run using vLLM (Kwon et al., 2023) if a model is supported. We run inferences on all the models using full precision, except for Llama 3.1 70B, for which we use a 4-bit quantized version to reduce memory footprint. Additionally, we run the FinMA models with the `Guidance`[14] library to constrain the output to only the NLI class labels. During the initial runs of the FinMA models (Xie et al., 2023), we observed that the LLMs frequently failed to follow the task instructions and instead generated hallucinated class labels, such as *positive* and *negative*, possibly due to overfitting to sentiment analysis tasks in the instruction-tuned data. We run all inferences using a temperature value of 0 across three independent runs with randomly initialized seeds.

G.2 Prompts

We provide the prompt templates used in the paper across the generation and evaluation experiments below.

Zero-Shot (ZS)

```
You will be given pairs of sentences: a premise and a hypothesis. Assign one of
the following labels to each pair: ‘entailment’, ‘neutral’, or ‘contradiction’.
Return only the label.
Premise: {premise}
Hypothesis: {hypothesis}
Label:
```

Zero-Shot w/ Annotation Guidelines (ZS-AG)

```
You will be given pairs of sentences: a premise and a hypothesis. The premise
sentence comes from one of three types of financial texts:

  • A company’s SEC filings
  • A company’s annual report
  • A company’s earnings call transcript

Your task is to assign one of the following labels to each pair based on these
definitions:

  • entailment: The truth of the premise guarantees the truth of the hypothesis.
  • neutral: The truth of the premise neither guarantees nor contradicts the truth
    of the hypothesis.
  • contradiction: The truth of the premise guarantees that the hypothesis is
    false.

Given the premise and hypothesis below, determine the relationship between the
sentences and return ‘entailment’, ‘neutral’, or ‘contradiction’:
Premise: {premise}
Hypothesis: {hypothesis}
Label:
```

[13] https://huggingface.co/
[14] https://github.com/guidance-ai/guidance

Few-Shot w/ Annotation Guidelines (Few-Shot-AG)

You will be given pairs of sentences: a premise and a hypothesis. The premise sentence comes from one of three types of financial texts:

- A company's SEC filings
- A company's annual report
- A company's earnings call transcript

Your task is to assign one of the following labels to each pair based on these definitions:

- **entailment**: The truth of the premise guarantees the truth of the hypothesis.
- **neutral**: The truth of the premise neither guarantees nor contradicts the truth of the hypothesis.
- **contradiction**: The truth of the premise guarantees that the hypothesis is false.

Here are a few examples: {examples}

1. **Premise**: And then the actual funded balances that we get from various other lines **Hypothesis**: The funded balances obtained from various lines are expected to increase in the next fiscal quarter. **Label**: neutral
2. **Premise**: Wet remember, I think about 126 stores that we've already remodeled on that new store prototype. **Hypothesis**: The company has completed the remodeling of approximately 126 stores using the new store prototype. **Label**: entailment
3. **Premise**: We maintain allowances for doubtful accounts for estimated losses resulting from the inability of customers to make required payments. **Hypothesis**: We do not anticipate any losses from customers being unable to make their required payments, so no allowances for doubtful accounts are maintained. **Label**:contradiction

Given the premise and hypothesis below, determine the relationship between the sentences and return 'entailment', 'neutral', or 'contradiction':
Premise: {premise}
Hypothesis: {hypothesis}
Label:

Chain-of-Thought (CoT) w/ Rationale

You will be given pairs of sentences: a premise and a hypothesis. The premise sentence comes from one of three types of financial texts:

- A company's SEC filings
- A company's annual report
- A company's earnings call transcript

Your task is to determine the relationship between the premise and hypothesis and assign one of the following labels:

- **entailment**: The truth of the premise guarantees the truth of the hypothesis.
- **neutral**: The truth of the premise neither guarantees nor contradicts the truth of the hypothesis.
- **contradiction**: The truth of the premise guarantees that the hypothesis is false.

To decide on the correct label, follow these steps:

1. **Understand the Premise**: Carefully read and comprehend the premise to identify the key information it provides.
2. **Analyze the Hypothesis**: Read the hypothesis and determine what it claims or implies. Consider if it adds new information, rephrases the premise, or predicts something based on the premise.
3. **Compare and Reason**: Compare the key information from the premise and hypothesis. Does the hypothesis logically follow from the premise, contradict it, or is it unrelated?
4. **Assign the Label**: Based on your reasoning, choose the appropriate label: 'entailment', 'neutral', or 'contradiction'.
5. **Explain Your Reasoning**: Briefly describe the thought process that led to your decision.

Here are a few examples: {examples}
Given the premise and hypothesis below, determine the relationship between the sentences and return 'entailment', 'neutral', or 'contradiction':
Premise: {premise}
Hypothesis: {hypothesis}
Reasoning: [Describe your reasoning here]
Label:

Data Generation Prompt

You are now a **{role}** and will be provided with a sentence from a **{financial domain}**. Using only this sentence and your general knowledge about the world:

- Write one **entailment** hypothesis where the truth of the premise guarantees the truth of the hypothesis.
- Write one **neutral** hypothesis where the truth of the premise neither guarantees nor contradicts the truth of the hypothesis.
- Write one **contradiction** hypothesis where the truth of the premise guarantees that the hypothesis is false.

Guidelines for Writing High-Quality Hypotheses:

1. **Numerical Reasoning:** If the premise contains numbers, write hypotheses that require mathematical knowledge or quantitative reasoning. This means the relationship between the premise and the hypothesis should involve some form of mathematical deduction. Example: {examples}
2. **Temporal Reasoning:** If the premise includes dates, write hypotheses that require an understanding of time. The hypothesis should involve an inference that requires understanding dates and the relationship between different points in time. Example: {examples}
3. **Financial Knowledge:** If the premise includes financial concepts, generate hypotheses that require familiarity with financial reasoning. Example: {examples}
4. **Linguistic Knowledge:** Try to write hypotheses that require linguistic understanding, such as antonyms, hypernyms, metaphors, or syntactic ambiguity. Example: {examples}

Important Writing Considerations:

- Write all hypotheses as clear, declarative sentences. Do not phrase them as questions.
- For an **entailment** label, ensure the hypothesis can be directly and fully verified using only the information provided in the premise. Avoid adding assumptions or speculative language such as "likely," "indicating," or "potential."
- When generating a **contradiction** hypothesis, avoid simply negating the premise. Instead, use financial knowledge and linguistic reasoning to construct a meaningful contradiction.

Given the premise: {premise sentence}
Write three hypotheses using: {writing style}
Return your response in the format below:

- **Entailment:** {entailment hypothesis}
- **Neutral:** {neutral hypothesis}
- **Contradiction:** {contradiction hypothesis}

H Annotation Instructions for the Financial Natural Language Inference Dataset (FinNLI)

Annotation Instructions for FinNLI

Task Overview: You will annotate a dataset for **Financial Natural Language Inference (FinNLI)**. You will be given pairs of sentences: a **premise** and a **hypothesis**, where:

- The **premise** comes from financial texts (SEC filings, annual reports, earnings call transcripts).
- The **hypothesis** is generated using a Large Language Model.

Your task is to:

1. **Verify that both the premise and hypothesis are valid and meaningful sentences** e.g. are not phrase fragments or nonsense, which would prevent us being able to assign a label to the relationship between the premise and the hypothesis. We have taken steps to preprocess the sampled sentences, so we expect invalid sentences to be a low frequency event. If either of the sentences is invalid, you do not need to provide relationship label for them.
2. **Assign one label to each of hypothesis-premise pair.**: Choose one of the three:
   - **Entailment** – A relationship between two statements where the truth of the premise guarantees the truth the hypothesis. The hypothesis follows logically from the information contained in the premise.
   - **Neutral** – A relationship between two statements where the truth of the premise neither guarantees nor contradicts the truth of the hypothesis. It is not possible to determine whether the hypothesis is true or false without further information.
   - **Contradiction** – The truth of the premise guarantees that the hypothesis is false. The hypothesis is logically false from the information contained in the premise.
3. **Indicate your level of confidence in the annotation: Low or High.** Depends on how confident an annotator is while defining the relation between premise and hypothesis.
4. **[Optional] Provide Comments** pertaining to annotating the instance, e.g. provide the rationale for the decision in free text form explaining why the instance is difficult, and/or why the confidence is low. Raise any other concerns you have in this field, e.g. in unlikely cases where you consider the texts harmful or biased.

Label Definitions and Examples:
Entailment: The hypothesis logically follows from the premise.

> **Premise:** We may acquire hotels in joint ventures with third parties that could result in conflicts.
> **Hypothesis:** The company is considering partnerships with third parties for hotel acquisitions.
> **Label:** Entailment

Neutral: The premise neither guarantees nor contradicts the hypothesis.

> **Premise:** Director stock options granted under the plans expire after seven years and vest fully after six months.
> **Hypothesis:** All employee stock options granted under the plans expire after seven years and vest fully after six months.
> **Label:** Neutral

Contradiction: The truth of the premise guarantees that the hypothesis is false.

Premise: The user assumes all risks for any damages or losses arising from any use of this information, except to the extent such damages or losses cannot be limited or excluded by applicable law.
Hypothesis: The provider is liable for any damages or losses that the user may incur from using this information.
Label: Contradiction

Handling Invalid Sentences: If a sentence is not meaningful, classify it as **Premise_notValid** or **Hypothesis_notValid**. Common cases include:

1. **Incomplete Sentence:** Sentence is visibly incomplete. *Example:* "Premise: Before joining FMC Technologies, Mr."
2. **Complex Notation:** Excessive numbers or financial notation making it unreadable. *Example:* "Premise: $700.0 $613.7 $492.1 95 Rest of World 108.6 96.0 93.9"
3. **Document Title or Subtitle:** Appears to be a section title instead of a standalone sentence. *Example:* "Net Cruise Cost less fuel expense."
4. **Reference to External Text:** Refers to another document section without self-contained meaning. *Example:* "For further discussion of our annual impairment test, see the Critical Accounting Policies and Estimates section."

Edge Cases:

- **Labels Are Not Symmetrical:**

  Premise: Girl ate an apple.
  Hypothesis: Girl ate a fruit.
  Label: Entailment

  Premise: Girl ate a fruit.
  Hypothesis: Girl ate an apple.
  Label: Neutral

- **Use of Domain Knowledge:** Some financial knowledge is allowed.

  Premise: The Company believes EBITDA is commonly used by financial analysts and provides useful information to investors.
  Hypothesis: EBITDA is a metric commonly used by financial professionals to assess financial performance.
  Label: Entailment

- **Handling Questions:**

  Premise: Jane is coming at 6.
  Hypothesis: When is Jane coming?
  Label: Entailment
  Premise: Jane is coming at 6.
  Hypothesis: Why isn't Jane coming?
  Label: Contradiction

Final Notes:

- If uncertain, mark annotation confidence as **Low**.
- Avoid unnecessary speculation beyond the provided premise.
- If the annotation process reveals bias or harmful content, leave a comment.

Music for All: Representational Bias and Cross-Cultural Adaptability of Music Generation Models

Atharva Mehta Shivam Chauhan Amirbek Djanibekov
Atharva Kulkarni Gus Xia Monojit Choudhury

Abstract

The advent of Music-Language Models has greatly enhanced the automatic music generation capability of AI systems, but they are also limited in their coverage of the musical genres and cultures of the world. We present a study of the datasets and research papers for music generation and quantify the bias and under-representation of genres. We find that only 5.7% of the total hours of existing music datasets come from non-Western genres, which naturally leads to disparate performance of the models across genres. We then investigate the efficacy of Parameter-Efficient Fine-Tuning (PEFT) techniques in mitigating this bias. Our experiments with two popular models – MusicGen and Mustango, for two underrepresented non-Western music traditions – Hindustani Classical and Turkish Makam music, highlight the promises as well as the non-triviality of cross-genre adaptation of music through small datasets, implying the need for more equitable baseline music-language models that are designed for cross-cultural transfer learning. The code for the paper is available at our Github Repository and the model adapters are available at Huggingface.

1 Introduction

Music, as a powerful expression of cultural identity, is deeply embedded in traditions (Swain, 1995; Chung, 2006). Recent advancements in AI, powered by deep learning models (Schneider et al., 2024; Copet et al., 2023; Tal et al., 2024), have led to significant improvements in automatic music generation technologies. This progress has led to several music generation playgrounds such as Jukebox (Radford et al., 2020), Suno[1], and Udio[2] offering users the ability to generate music according to their specifications. However, these models often reflect biases, particularly towards Western musical traditions (Tao et al., 2024; Copet et al., 2023), in their training data.

This lack of diversity in datasets, as outlined by Copet et al. (2023); Melechovsky et al. (2024); Radford et al. (2020), is also evident in the disparate performance of the music generation models across genres. More specifically, the models tend to rely on Western tonal and rhythmic structures when generating music for non-Western genres, such as Indian or Middle Eastern music. The situation is comparable to the lack of cultural and linguistic diversity (Joshi et al., 2020; Bender and Friedman, 2018; Bender et al., 2021) in NLP research.

In order to quantify the severity of this problem in music generation research landscape, we conduct a comprehensive analysis of existing music datasets and music generation papers, which reveals a stark disparity in the representation of non-Western music. Particularly noteworthy is the scarcity of non-Western music data, with merely 5.7% of the total hours of the available datasets. This finding highlights the need for more diverse musical datasets and methods to adapt state-of-the-art models to low-resource genres.

However, it remains unclear whether cross-genre music adaptation, similar to cross-lingual adaptation, can be effectively achieved using lightweight computational techniques such as parameter-efficient fine-tuning (PEFT) (Houlsby et al., 2019). In this paper, we explore this question by adapting two open-source models, MusicGen (Copet et al., 2023) and Mustango (Melechovsky et al., 2024) for two low-resource non-Western genres - *Hindustani Classical* [3] music of India and *Makamat* [4] music of the Middle East.

[1]https://suno.com/
[2]https://www.udio.com/

[3]Hindustani Classical music is a traditional system of music that emphasizes melodic development based on ragas (melodic frameworks) and talas (rhythmic cycles).

[4]Makam, in traditional Arabic music, is a melodic mode system defining pitches, patterns, and improvisation, central to Arabian art music, with 72 heptatonic scales

Findings of the Association for Computational Linguistics:
NAACL 2025, pages 4569–4585
April 29 - May 4, 2025 ©2025 Association for Computational Linguistics

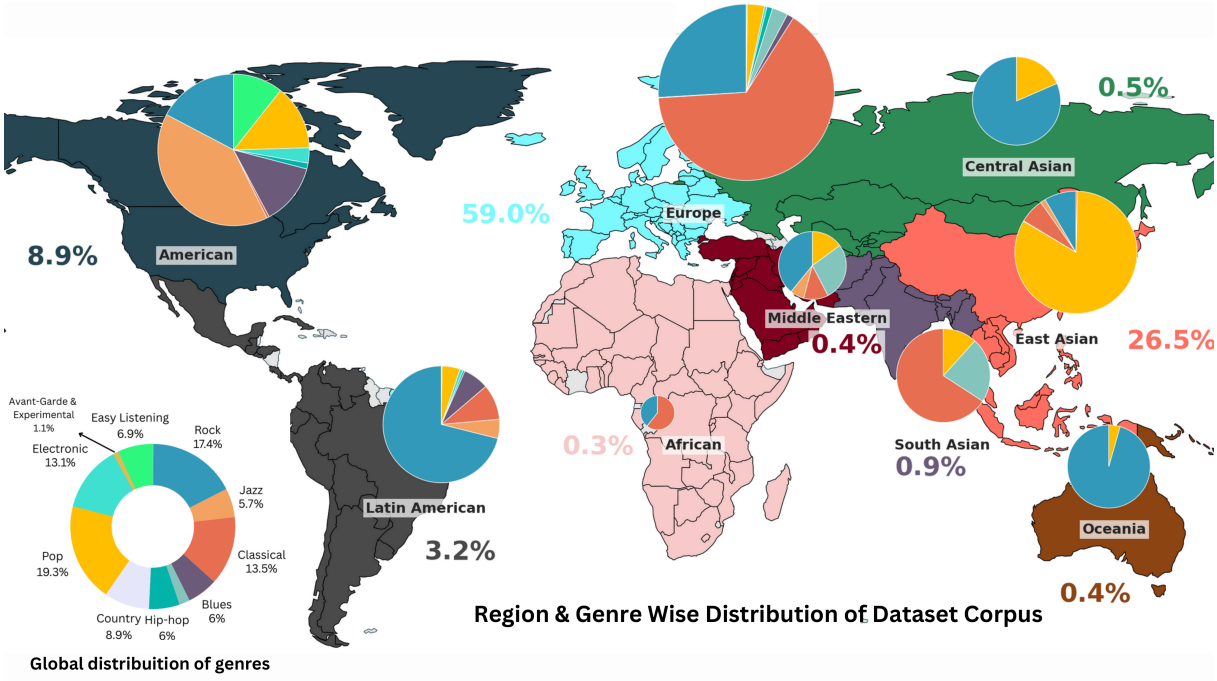

Figure 1: The bottom left piechart shows the global distribution of genre. Each piechart in the map shows the distribution of genres in different regions with the size of each piechart being proportional to their contribution to the data corpus.

We hypothesize that explicit fine-tuning with a small number of additional parameters (less than 1% of the pre-trained model) as adapters (Bapna and Firat, 2019), will lead to a far better performance for the under-represented music style. We conduct a series of experiments comparing the performance of baseline models and our adapter-enhanced models on objective metrics. For human evaluations, each model is tested using our novel evaluation framework roughly based on Bloom's Taxonomy (Armstrong, 2010): **Recall, Analysis**, and **Creativity** evaluate a model's audio generation. Recall reproduces trained entities, Analysis forms new combinations of them, and Creativity blends different entities across genres in novel, unseen ways. Evaluations are conducted in a play-arena style, ranking models based on their adherence to the text prompt in terms of *rhythm*, *instrument*, *melody* and *creativity*. Mustango shows improvement when finetuned on Hindustani Classical music by 8% and MusicGen shows improvement by 4% on Turkish Makam in ELO ratings from their respective baselines.

Our results show that while PEFT techniques are effective in improving the overall quality of generated music for the under-represented genre over the baseline models, not all models are adaptable to all genres. This implies that the various design choices made in the architecture, and the training datasets and recipes for the base model are crucial determinants of the adaptability of a model to certain musical genres.

The contributions of this paper are threefold:

1. We provide a detailed analysis of the current state of musical datasets, highlighting the under-representation of non-Western music.
2. We present the first application of parameter-efficient training with adapters for cultural adaptation of under-represented genres in music generation models.
3. We introduce a novel arena-style evaluation framework based on Bloom's Taxonomy to assess the text to music generation capabilities of models using a play-arena style, ranking models on on their adherence to the text prompt on *rhythm*, *instrument*, *melody* and *creativity*.
4. We demonstrate that while adapting base models to different genres is possible, it is a non-trivial challenge.

The rest of the paper is organized as follows: In Section 2, we discuss global disparities in music representation, followed by Section 3, which details our approach to adapting genres. Section 4

presents our evaluation methodology and the results obtained from our analysis. We conclude our findings in Section 5.

2 The Disparity in Music Generation Research

AI music generation has evolved rapidly with techniques such as autoregressive (Agostinelli et al., 2023; Copet et al., 2023; Ziv et al., 2024), diffusion-based (Schneider et al., 2024; Huang et al., 2023; Li et al., 2024) and GAN-based (Dong et al., 2018; Li and Sung, 2021) producing high-quality music. Some of the works include adapter-based settings which proved effective for music editing and inpainting (Lin et al., 2024; Zhang et al., 2024). Moreover, Lan et al. (2024) used adapters for rhythm and chord conditioning. Tan et al. (2020) showcased how visual emotions from images can be effectively translated into music using deep learning techniques.

Drawing inspiration Joshi et al. (2020), which systematically analyzes the under-representation of languages spoken by the global majority, we conduct a survey of the datasets and research papers on music generation.

2.1 Data Collection

To get our initial pool of papers, we implemented an efficient, automated data collection method.

We employed a multi-stage, keyword-based selection method, leveraging the Scholarly package Cholewiak et al. (2021) to gather approximately 5000 papers. This included up to 1000 papers per query, using broad search terms such as "music," "music generation," "non-Western music," "MIDI," and "symbolic music." We then refined our selection by focusing on papers presented at 10 major conferences including *IJCAI, AAAI, ICML, EURASIP, EUSIPCO, ISMIR, NeurIPS, SMC, NIME* and *ICASSP*, chosen based on their popularity and prestige in the area of computational processing of music, narrowing our pool to around 800 papers. Conferences such as ISMIR and NIME specialize in music information retrieval and musical expression, frequently showcasing work related to generative AI. Additionally, conferences like ICASSP, AAAI, and NeurIPS are known for their focus on cutting-edge AI technologies, such as GANs and transformers, which are crucial for music generation.

2.1.1 Dataset Papers

To identify papers proposing datasets, we read through the title and abstract of each paper. This led to a set of **152** papers proposing new datasets with a total of **1 million+** hours of music. These datasets were manually annotated for the region and genres covered, total hours of music data, and whether the dataset is annotated with other details (such as, instruments, genre, and style). Papers that directly provided details of the distribution of data points across genres and regions, were analyzed with the already available statistics. Unfortunately, several datasets did not offer substantial details necessary for our study. If such a dataset had more than ***10,000*** hours of audio data, we analyzed each sound file's metadata to collect genre and region information. However, when the genre and region were not explicitly mentioned in either the paper or the metadata, we did not make any assumptions; thus, **7.9%** of the datasets totaling **5,772** hours were excluded from our analysis.

2.2 Findings

Our findings are summarized in Figure 1. The results reveal an almost complete omission of musical genres from non-Western countries, especially those from the Global South. Approximately 94% of the total hours in available datasets are dedicated to music from the Western world, while only 5.7% are devoted to *South Asian, Middle Eastern, Oceanian, Central Asian, Latin American*, and *African* music combined. This imbalance is likely to cause poor-quality music generation for genres from the Global South. For detailed analysis, please refer to Appendix A.

3 Genre Adaptation: Data, Models and Experiments

For our genre-adaptation experiments, we selected two distinct non-Western genres — Hindustani Classical (Jairazbhoy, 1971) and Turkish Makam (Signell, 2008) — both significantly underrepresented in music generation research and datasets, and two open source models – MusicGen (Copet et al., 2023) and Mustango (Melechovsky et al., 2024). We begin by describing the dataset creation, followed by prompt generation, the models, adapter architectures and finally, the training process.

3.1 Dataset Creation

Our study necessitated diverse corpus of non-Western music with detailed metadata. The Dunya (Porter et al., 2013) which is part of the CompMusic project (Serra, 2014), emerged as the ideal choice, offering an extensive collection of over 1,300 hours of music across multiple non-Western genres. This corpus includes Carnatic, Hindustani, Turkish Makam, Beijing opera, and Arab Andalusian music, providing a broad spectrum of cultural music. We focused specifically on Hindustani Classical and Turkish Makam genres as both genres possess complex culturally specific melodic and rhythmic structures different from Western music & we had easier access to listeners familiar with Indian and Turkish music. For Hindustani Classical, we chose the MTG Saraga (Srinivasamurthy et al., 2021) annotated dataset which is built on CompMusic offering 50 hours of audio. For Turkish Makam, we use the Dunya dataset API for accessing the metadata and audio samples leading to 405 hours of audio.

To ensure consistency and manage computational resources effectively, we implemented several pre-processing steps. We standardized the audio sample length by truncating longer recordings to 30 seconds. We utilized the accompanying metadata from the Dunya corpus without modification. These descriptions, rich in genre-specific details, served as valuable inputs for creating prompt templates. Finally, to accommodate the differing requirements of our chosen models, we performed audio resampling. Specifically, for MusicGen we resampled the audio to a 32 kHz sampling rate and for Mustango 16 kHz sampling rate.

The metadata from the dataset provides genre-specific information for each audio clip, including three key details critical to our study: melodic line, rhythmic pattern, and instrumentation. For the melodic line, we extracted the *raga* (a melodic framework in Hindustani Classical music) and *Makam* (a system of melodic modes in Turkish music). For rhythmic patterns, we identified *laya* (tempo) in Indian music and *usul* (a sequence of rhythmic strokes) in Turkish music. Additionally, we extracted the meta-data for the instruments (including voice) played in each audio sample. Details of the dataset can be found in Appendix F.

After pre-processing, we collected a total of 23.24 hours of audio for Hindustani Classical music and 121.16 hours for Turkish Makam music.

Query Type	Example
Recall	Imagine a traditional ★ **Makam** performance that brings together ▷ Clarinet, ▷ Darbuka, ▷ Kanun, ▷ Oud, ▷ Voice, ♯ Aksak makam, and ♭ Hicaz usul, flowing effortlessly.
Analysis	Imagine a traditional ★ **Makam** performance that brings together ▷ Tanbur, ▷ Oud, ▷ Cello, with the flowing essence of ♯ Aksak makam and ♭ Fahte usul, flowing effortlessly.
Creativity	Imagine a modern ★ **Western Electronic Dance Music (EDM)** performance infused with the soulful sound of ▷ Tanbur, rich vocals blending with ♯ Acem makam and ♭ Fahte usul.

Table 1: Recall, Analysis & Creativity Queries: Recall uses known combinations, while Analysis introduces novel combinations to test analytical capability and Creativity introduces cross-genre combinations. Refer to Section 4. **Genre**:★, melodic line:♯, rhythmic pattern:♭, and instrumentation:▷.

The dataset was then divided using an 80-20% split for training and testing, allowing us to evaluate the final model performance effectively. We ensured that audio clips for training and testing come from different songs to prevent distribution overlap in train and test. This split resulted in 18.91 hours of Hindustani Classical music and 97.23 hours of Turkish Makam music for training, and the remaining portions reserved for testing.

3.2 Prompt Generation

To create effective prompts for model training, we created three distinct templates that describe each musical piece based on sample metadata from the selected genres.

For each audio sample, we randomly selected one of the three templates and populated it with relevant metadata attributes as shown in Table 1. This process ensures that each prompt captures the unique musical elements of the sample. By maintaining this metadata-specific structure across prompts, we help the model learn to identify and respond to key attributes within each genre, enabling it to generate more accurate and culturally informed outputs during training.

3.3 Models

We utilize two state-of-the-art models, MusicGen (Copet et al., 2023) and Mustango (Melechovsky et al., 2024), to explore cross-genre adaptation. MusicGen is a transformer-based model,

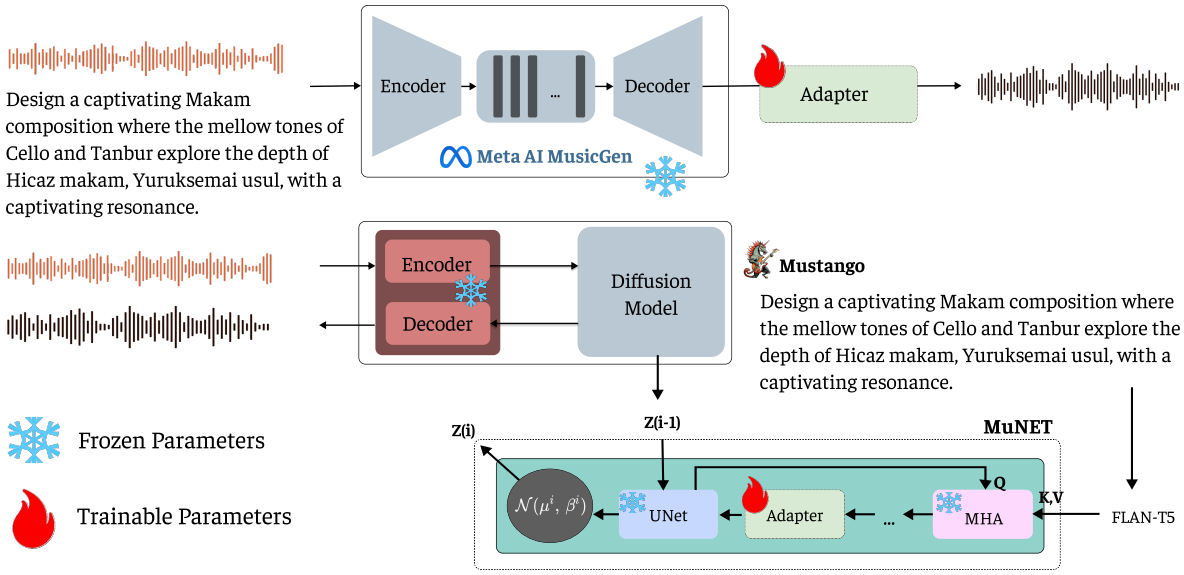

Figure 2: Mustango & MusicGen settings for low-resource fine-tuning.

while Mustango integrates both diffusion and transformer architectures. We introduce adapters (Pfeiffer et al., 2020) that enable low-resource fine-tuning. We also considered Moûsai (Schneider et al., 2024) and MusicLM (Agostinelli et al., 2023), but Moûsai and MusicLM lack open-source training codes.

3.3.1 MusicGen

In MusicGen, we enhance the model with an additional 2 million parameters by integrating **Bottleneck Residual Adapter** after the transformer decoder within the MusicGen architecture after thorough experimentation with other placements. The total parameter count of MusicGen is 2 billion, making the adapter only 0.1% of the total size. The adapter, as shown in Figure 2, consists of a linear layer that compresses the embedding to a very small dimension, followed by a non-linear activation and projection back to the original size.

MusicGen leverages the Encodec (Défossez et al., 2023) framework, which compresses audio into latent representations. These latent representations are processed through a transformer model, which generates new music based on input prompts. By placing adapters at the end of the decoder, we achieve a lightweight adaptation mechanism that enhances the model's ability to generate music in specific styles or regions, such as Hindustani Classical music and Makam, without modifying the fundamental Encodec structure.

3.3.2 Mustango

In Mustango, we enhance the model with an additional 2 million parameters, which represents only 0.1% of the model's total parameter count, by integrating a **Bottleneck Residual Adapter**.

While Mustango supports chord and beat embeddings, we opted not to use them here due to the distinct focus of Hindustani Classical and Turkish Makam on melodic lines rather than harmonic progressions. Unlike Western classical music, these genres feature complex, rhythms with accents often within a single beat, making fixed beat and chord embeddings difficult to apply.

The adaptation process in Mustango begins with the FLAN-T5 (Chung et al., 2024) model, which converts the input text into embeddings. These embeddings are then incorporated into the UNet architecture (Ronneberger et al., 2015) through a cross-attention mechanism, aligning the text and audio components. To refine this process, a Bottleneck Residual Adapter with convolution layers is incorporated into the up-sampling, middle, and down-sampling blocks of the UNet, positioned immediately after the cross-attention block at the end of each stage (Figure 2). The adapters reduce channel dimensions by a factor of 8, using a kernel size of 1 and GeLU activation after the down-projection layers to introduce non-linearity. Various adapter configurations and placements were explored to preserve the musical structure while adapting stylistic elements, with this setup yielding the best output quality. This design facilitates cultural adaptation while preserving computational efficiency.

Objective Metrics				
Hindustani Classical Music				
Model	**FAD ↓**	**FD ↓**	**KLD ↓**	**PSNR ↑**
MGB	40.05	75.76	6.53	16.23
MGF	40.04	72.65	6.12	16.18
MTB	6.36	45.31	2.73	16.78
MTF	**5.18**	**22.03**	**1.26**	**17.70**
Turkish Makam				
Model	**FAD ↓**	**FD ↓**	**KLD ↓**	**PSNR ↑**
MGB	39.65	57.29	7.35	14.60
MGF	39.68	56.71	7.21	14.46
MTB	8.65	75.21	6.01	**16.60**
MTF	**2.57**	**20.56**	**4.81**	16.17

Table 2: Objective Evaluation Metrics for Hindustani Classical Music and Turkish Makam.

3.4 Training settings

For MusicGen fine-tuning, we used two RTX A6000 GPUs over a period of around 10 hours. The adapter block was fine-tuned, using the AdamW (Loshchilov and Hutter, 2017) optimizer with a learning rate of 5e-5 and a weight decay of 0.05 using MSE based Reconstruction Loss. The training spanned 20 epochs, with a patience threshold of 5 epochs for early stopping based on validation loss. We utilized a batch size of 4 and applied gradient clipping with a maximum norm of 1.0. The training data was split into 90% for training and 10% for validation.

For Mustango model fine-tuning, we used one RTX A6000 GPU over a period of 12 hours. The adapter block was fine-tuned, using the AdamW optimizer with a learning rate of 4.5e-5 and a weight decay of 0.01 using MSE based Reconstruction Loss. The training spanned 25 epochs for both genres, with a patience threshold of 5 epochs for early stopping based on validation loss. The training data was split into 80% for training and 20% for validation.

4 Results

We evaluated four models, Mustango Baseline (MTB), Mustangto Fine-tuned (MTF), MusicGen Baseline (MGB), and MusicGen Finetuned (MGF), on two genres using both objective metrics and human evaluation, providing both objective and subjective insights into model performance.

4.1 Automatic Metrics

We sample 400 audio samples from the test set to form our test prompt corpus. For capturing the distance between generated audio and the test corpus we compute Fréchet Audio Distance(FAD), Fréchet Distance(FD) and Kullback-Leibler(KL) with Sigmoid activation. We utilize the AudioLDM (Liu et al., 2023) toolkit for implementation of FAD, FD, and KL, with distributions computed using PANN-CNN14 (Kong et al., 2020) as the backbone model for extracting features for each audio sample.

Table 2 presents the performance metrics for models trained on Hindustani Classical music. Both finetuned versions of MusicGen and Mustango demonstrate superior performance compared to their baseline counterparts across all evaluated metrics. Notably, Mustango exhibits significant improvement after finetuning, whereas MusicGen shows only marginal gains. This disparity suggests that Mustango possesses a greater capacity for dataset-specific adaptation.

Adapter finetuning for Mustango model better incorporates domain-specific nuances of Hindustani Classical music, resulting in generated outputs that more closely align with the target style.

Table 2 additionally presents results for Turkish Makam generation. The performance trends mirror those observed in Hindustani Classical music. Mustango demonstrates strong improvement with one notable exception: the PSNR metric. For PSNR, the baseline Mustango model performs better.

4.2 Human Evaluation

To complement our objective metrics, we designed a rigorous human evaluation process, recognizing the crucial role of human perception in assessing music quality and authenticity. We begin by generating prompts for drawing audio inferences from the models based on Bloom's taxonomy criteria. Then we present the outputs to human judges to compare them in an arena setup (Chiang et al., 2024; mrfakename et al., 2024).

We divided our process into two phases. In first phase, two annotators independently judged a portion of the same set of data points. This allowed us to compute inter-annotator agreement, a crucial measure of evaluation reliability. Disagreements were systematically discussed and resolved, refining our evaluation criteria. In phase two, annotators transitioned to single annotations per data point continuing evaluation of the rest audios. Finally, we compute ELO ratings of the models based on second phase annotations.

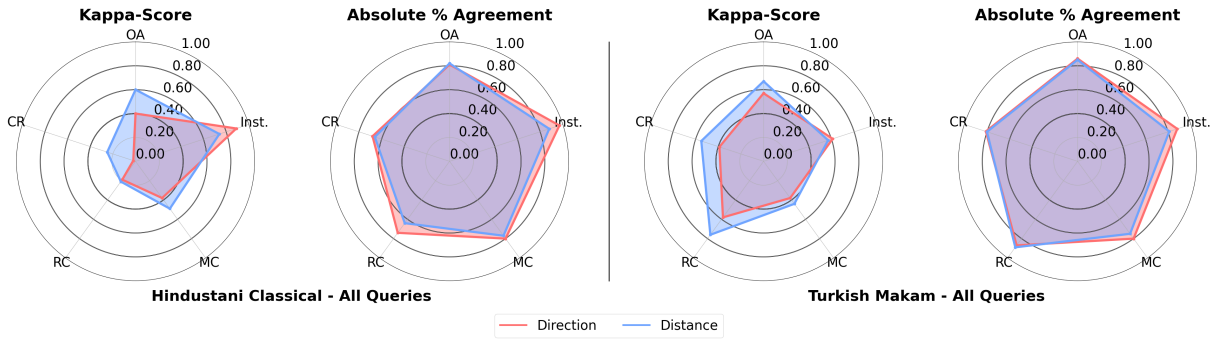

Figure 3: Inter Annotator Agreement metrics for Hindustani Classical & Turkish Makam.

4.2.1 Material

We introduce novel evaluation criteria based on Bloom's Taxonomy to assess a model's understanding of musical elements in text and their alignment with the generated audio using arena-style evaluation.

We evaluate the models under three conditions: **recall**, **analysis**, and **creativity**, by manually generating 10 prompts in each category (Table 1).

- **Recall**: Tests the model's ability to reproduce combinations of melody, instrument, and rhythm from the fine-tuning data, testing effective memorization and recall.
- **Analysis**, We create novel combinations by substituting melodies, rhythms, or instruments, testing the model's adaptability beyond the training data.
- **Creativity**, We combine genres, blending melodies, rhythms, and instruments across styles to test the model's integration of underrepresented and over-represented genres.

For each case, we generate model responses from all models, creating 120 total music samples. Since Mustango generates 10-second inferences at 16kHz, we process MusicGen outputs by clipping them to 10 seconds and downsampling to 16kHz to ensure uniform evaluation conditions.

4.2.2 Method

We decided to go for a comparative evaluation of pieces instead of absolute judgments of pieces in isolation to control the subjectivity so that, the shorter, lower-sampling-rate music clips, are more effectively evaluated through comparison. For each comparison, the user receives a reference prompt and two anonymous audio samples (with the comparisons ordered randomly), followed by five comparative evaluation questions comparing the two audio generations on each criterion: Overall Aesthetic*(OA)*, Instrument Accuracy*(Inst.)*, Rhythm Capture*(RC)*, Melody Capture*(MC)*, and Creativity*(CR)* since we provide these entities in the prompt and we are trying to assess the alignment of the text to the audio generated. For each criteria, we provide the annotator with 7 options: A $\gg$ B, A $>$ B, A = B, A $<$ B, A $\ll$ B, None, and Not Applicable (NA). Please refer to Appendix B for questions.

In first phase, we conduct four types of comparisons: *baseline* vs. *baseline*, *baseline* vs. *fine-tuned* (for both models), and *fine-tuned* vs. *fine-tuned*. We request two avid listeners of each genre, who are aware of the nuances but not themselves professional musicians(demography details in Appendix I), to annotate these samples. The annotation process begins by evaluating 36 comparisons for each genre—9 generations from each model per genre—compared across all models based on the five evaluation criteria. After the completion of first phase we compute the **Inter-Annotator Agreement(IAA)**, using **distance** and **direction-based kappa** scores. The distance-based Kappa quantifies the absolute differences in annotations by both the annotators whereas direction-based Kappa assesses consistency in preference order rather than the extent of preference. Detailed kappa-score calculation methods are provided in the Appendix E.

Figure 3 presents the kappa score and average agreement for each criterion. In evaluating Hindustani Classical and Turkish Makam music, these metrics reveal distinct patterns across assessment criteria. As we can see from the figure, *OA* scores range from 0.40 to 0.67, while *Inst.* shows high agreement, with scores up to 0.89 due to its objectivity (Figure 3). *MC* achieves moderate agreement, and *RC* scores are generally lower, particularly for Hindustani Classical (0.19 and 0.21), likely due

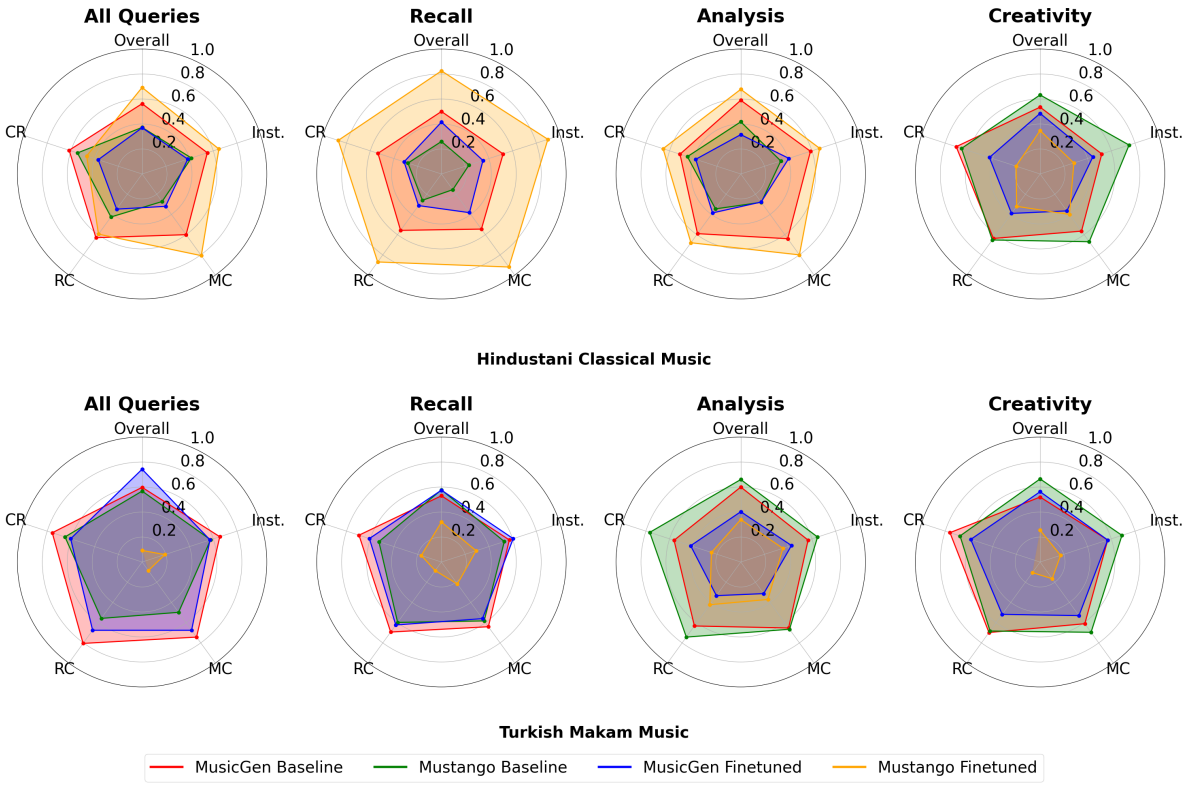

Figure 4: Scaled ELO ratings for each model in Hindustani Classical and Turkish Makam music. Categories include OA: Overall Assessment, Inst.: Instrument Accuracy, MC: Melody Capture, RC: Rhythm Capture, and CR: Creativity. Ratings are provided for all query types and individual query categories.

to the complexity of rhythmic patterns within the short 10-second evaluation span. *CR* consistently records the lowest scores, reflecting the subjective nature of this criterion(For more genre-wise and query-type-wise details refer to AppendixC). After phase-I, we ask the annotators to discuss and re-annotate music samples for Inst. and RC criteria where disagreement is higher.

In the second phase, for Hindustani Classical, we removed the MGB vs MGF comparison since the trend made it clear that MGB is better with agreement from both the annotators. For Turkish Makam, we removed MTF vs MTB since MTB proved to be better(see Figure 4). After filtering we are left with 3 sets of comparisons, with 7 queries for each model, across 3 query types leading to 63 more comparisons for each genre. The annotations from both rounds are combined to compute each model's ELO rating.

4.2.3 ELO Ratings

After comparing the model outputs, we compute ELO ratings (usually used to calculate the relative skill levels of players in a two-player game) for each model across all query types for each evaluation criterion. For each criterion, we consider a single annotation as a single match between the models. If the annotator marks it as NA, then we omit it from the calculation, if A=B or None is marked we consider it as a draw and A$\gg$B, A$>$ is considered a win for A and vice-versa for the remaining cases. The details of computing ELO ratings are given in Appendix G.

The normalized ELO ratings are shown in Figure 4. **For Hindustani Classical music**, over all queries, MTF outperforms all models. Interestingly, MGB is better than MTF, but MGF is judged least favourably, implying that while fine-tuning significantly improves Mustango, MusicGen's performance regresses considerably. These trends hold for all aspects (melody, rhythm, instrument) except creativity. The trends are most prominent for Recall queries, but also hold for Analysis queries, but completely reverses for creativity queries, where MTF performs the worst while MTB performs the best. Qualitative analysis of the generated pieces confirm this finding and shows that there was a strong effect of adaptation on Mustango which led to knowledge attrition and resultant poor performance on creative queries, which required the model to utilize previ-

ous knowledge.

For Turkish Makam music, MTF regresses significantly from MTB, for types of queries as well as on all aspects. While MGF performs slightly better than MGB on all queries for overall rating, the trends are not consistent across different aspects, or different types of queries. In fact, for Analysis queries, even MusicGen's performance significantly regresses for all aspects on finetuning. Thus, we can conclude that the PEFT technique explored here did not help boost the performance of the models for Turkish Makam music.

5 Conclusion

In this paper, for the first time, we systematically explored and established the skewed distribution of musical genres from around the world in datasets used for training Music-Language Models. Non-Western musical traditions are severely underrerpresented which naturally leads to disparate performance across genres in these models. We also demonstrate that PEFT-based techniques vary in effectiveness across different genres and models, further aggravating the challenges of overcoming the data scarcity problem.

As generative models continue to gain traction in the field of music generation and are expected to be used even more widely in the coming years, the misrepresentation and under-representation of the musical genres of the "global majority" poses a significant threat to the inclusion of musical cultures from around the world. The skewed distribution in datasets, reflected in model outputs, can lead to several issues, including cultural homogenization, reinforcement of Western culture dominance (Crawford, 2016), misrepresentation of musical styles, and most importantly, gradual decline leading to the disappearance of many musical genres (Tan, 2021; Lund, 2019; Team, 2023). Therefore, it is critically important to prioritize the creation of inclusive music datasets and models, with an emphasis on under-represented musical genres.

Limitations

Our work relies on adapter-based techniques for cross-cultural adaptation but there is a need to explore additional architectural configurations to further optimize low-resource fine-tuning such as LoRA (Hu et al., 2021) or Compacter (Davison, 2021) approaches.

Additionally, our approach only focused on a few genres, and future work should aim to incorporate a broader range of musical styles. Our investigation involves only Hindustani classical and Turkish Makam traditions, leaving other genres from the Dunya dataset unexplored. This narrow focus stems not from a lack of curiosity, but from our limited cultural expertise - a constraint we acknowledge upfront.

We also trained separate models for Hindustani Classical and Turkish Makam music; combining these into a single model could offer greater generalization across genres.

Another limitation lies in the evaluation process. Human evaluations were conducted on a limited number of samples with a duration of 10 seconds, and more genre-specific assessments are necessary. We also believe that computing objective metrics for underrepresented genres may obscure the full picture because the backbone models used to compute these metrics may not have been trained on various underrepresented genres, resulting in an erroneous portrayal of genres.

A Research Landscape

Region	Papers (count)	Duration (hrs.)
European	66	**6127.92**
East Asian	**71**	2746.73
South Asian	1	88.78
Central Asian	0	57.01
American	72	921.84
Latin American	5	323.25
Oceania	3	41.99
African	0	27.50
Middle Eastern	5	37.86

Table 3: Distribution of Papers and Duration in hours by Region.

A.1 Genre Distribution Analysis

Genre-wise analysis we can observe in Table 4 and that *Pop* music forms 200K+ hours of the corpus while *Folk* music constitutes only 20K hours of the corpus which is a 10 times between the two as shown in Table 4. *Pop, Rock, Classical* and *Electronic* music genres each constitute more than 10% of the total corpus and more than 100K hours in the total corpus. As shown in Figure 1, *Pop* music has the highest (19.3%) representation followed by *Rock* (17.4%) and *Classical* (13.5%) genres. *Country, hip-hop, blues* and *jazz* have a moderate (more than 5%) representation in the corpus. *Folk* and *experimental* music contribute to only 2.1% of the corpus. The other genres receive minimal attention($\leq$ 1%) which includes music for Children, *Indie-music*, and region-specific genres.

A.2 Regional Distribution Analysis

In region-wise analysis, from analyzing the research space we find that more than 6k hours of music in the research belongs to *European* music and only 28 hours of music belong to *African* music as shown in Table 3. *European*, *East Asian* and *American* music are well explored forming 84.5% of the corpus. On the other hand, *South Asian, Middle Eastern, Central Asian* and *African* music each contribute less than 1% to the whole corpus as depicted in Figure 1.

Genre	Papers (count)	Duration (hrs.)
Pop	**24**	**206.89**
Rock	7	186.67
Electronic	36	140.25
Classical	91	144.64
Country	-	95.77
Hip-hop	3	64.35
Jazz	15	60.62
Blues	-	64.01
Easy Listening	2	74.39
Folk	3	22.802
Experimental	26	11.310
Others	15	0.94

Table 4: Distribution of Hours and Papers by Genre. Duration (Dur.) is represented as 10^3 hours.

B Annotation Details

We asked annotators to choose between two audio samples, based on their preference, to select which better represents the prompted culture in both the inter-annotator agreement scenario and human evaluation. For both inter-annotator agreement and human evaluation, we relied on the same set of questions outlined below.

- Overall, which piece do you like more?
- Which piece captures the instrument (if mentioned the prompt) better?
- Which piece captures the melodic line/scale (if mentioned the prompt) better?
- Which piece captures the rhythm/tempo (if mentioned the prompt) better?
- Which piece is more creative (ignore audio quality while answering this question)?

C Evaluation of Inter Annotator Agreement Results

The inter-annotator agreement (IAA) results, measured using Cohen's Kappa, reveal interesting patterns across genres, metrics, and query types.

In Table 5 Turkish Makam consistently showed higher agreement (0.57-0.67) than Hindustani Classical (0.40-0.60), suggesting potentially clearer structural elements. This trend is particularly pronounced in Rhythm (RC) annotations, where Turkish Makam exhibits substantially higher agreement (0.58-0.76) compared to Hindustani Classical (0.19-0.21).

Instrument identification (Inst.) showed high agreement across both genres (0.57-0.89), with Hindustani Classical scoring particularly well (0.89 for direction). Creativity (CR) exhibited the lowest overall agreement (0.02-0.55), reflecting the inherent subjectivity in assessing creativity.

Examining query types in Table 6 reveals that Recall queries generally yielded higher agreement, particularly in Turkish Makam (0.74-0.75). This indicates strong consistency in factual recall tasks. Analysis queries showed mixed results, with some categories in Hindustani Classical even showing negative agreement, pointing to potential confusion or divergent interpretations in analytical tasks. Interestingly, Creativity queries showed perfect agreement (1.0) in Melody for both genres, suggesting a strong consensus in perceiving creative aspects of melody.

D Evaluation of Human Evaluation Results

The human evaluation results in Table 7 and Table 8, measured using ELO ratings, also reveal intriguing patterns across genres, models, and query

Inter Annotator Agreement (Kappa Score, ↑)

Table 6: Inter Annotator Agreement (IAA) Metrics across Recall, Analysis, and Creativity Queries for Hindustani Classical Music and Turkish Makam. Higher Kappa Scores (↑) indicate better agreement.

types. Comparing the two genres, we observe distinct performance profiles for each model. In Hindustani Classical Music, the Mustango finetuned model emerges as the clear leader (OA: 1577), outperforming other models across most categories, particularly excelling in Melodic Contour (MC: 1623). This suggests a strong grasp of the melodic structures specific to Hindustani music. Conversely, for Turkish Makam, the MusicGen finetuned model takes the lead (OA: 1597), with both MusicGen and Mustango baseline models also performing well.

The MusicGen Baseline shows remarkable consistency across both genres, often scoring above 1500 in various categories. This suggests a robust general understanding of musical elements that transcends genre boundaries. The Mustango Baseline, while competitive, generally scores lower than MusicGen Baseline, especially in Hindustani Classical Music.

Finetuning yields mixed results across the two models. For Mustango, it significantly improves performance in Hindustani Classical but drastically

MusicGen Finetuned	1525	1528	1512	1507	1534
Mustango Finetuned	1402	1369	1366	1342	1291

Table 8: Model Evaluation Metrics across Recall, Analysis, and Creativity Queries for Hindustani Classical Music and Turkish Makam. ELO ratings (human evaluation) have higher values as better (↑).

reduces its effectiveness in Turkish Makam. Conversely, MusicGen's finetuning slightly lowers its performance in Hindustani Classical but enhances it in Turkish Makam. This divergence underscores the complexity of adapting models to specific musical traditions without losing generalizability.

Examining performance across query types reveals further insights. In Recall queries for Hindustani Classical, Mustango finetuned significantly outperforms other models (OA: 1630), particularly in Melody (1668). For Turkish Makam, MusicGen Baseline leads in Recall queries (OA: 1512), with MusicGen finetuned close behind (OA: 1530). This suggests that finetuning can enhance a model's ability to accurately reproduce genre-specific musical elements.

Creativity queries yield particularly interesting results, with baseline models outperforming their finetuned counterparts in both genres. In Hindustani Classical, Mustango Baseline leads (OA: 1553), while in Turkish Makam, it shares the top position with MusicGen Baseline (OA: 1508 and 1566 respectively). This suggests that finetuning, while beneficial for recall and analysis, might constrain the model's creative capabilities.

E Kappa Score Computation

	A$\gg$B	A>B	A=B	A<B	A$\ll$B
A$\gg$B	1	1	0.33	0	0
A>B	1	1	0.67	0.33	0
A=B	0.33	0.67	1	0.67	0.33
A<B	0	0.33	0.67	1	1
A$\ll$B	0	0	0.33	1	1

Table 9: Matrix representation of distance-based agreement score for Inter Annotator Agreement. Column represents Annotator-1's preference and Row represents Annotator-2's preference.

E.1 Distance-based Computation Matrix

The **distance-based Kappa** quantifies the absolute differences in annotations by both the annotators. Each option(except None & NA) is assigned a value between 2 to -2 in order; A $\gg$ B, A > B, A = B, A < B, A $\ll$ B. After assigning values we calculate absolute distances between annotator preferences while excluding all cases which are annotated None or NA by annotators. The distance values are clipped to a maximum of 3, with agreement computed as follows :

$$p_o^i = \frac{3-d}{3}$$

Table 9 represents the annotator preferences and the agreement score for each combination.

E.2 Direction-based Computation Matrix

	A$\gg$B	A>B	A=B	A<B	A$\ll$B
A$\gg$B	1	1	1	0	0
A>B	1	1	1	0	0
A=B	1	1	1	1	1
A<B	0	0	1	1	1
A$\ll$B	0	0	1	1	1

Table 10: Matrix representation of direction-based agreement score for Inter Annotator Agreement. Column represents Annotator-1's preference and Row represents Annotator-2's preference.

The **direction-based Kappa** assesses consistency in preference order rather than the extent of preference. A disagreement is defined as only when the preference orders are reversed between the two annotators (i.e., when one annotator chooses A<B or A$\ll$B and the other annotator chooses B<A or B$\ll$A) Agreement is calculated as follows :

$$p_o^i = 1 - d$$

Table 10 shows the agreement scores between different annotations.

Observed agreement is averaged per criterion, with expected agreement(p_e) and Kappa(κ) calculated as follows:

$$\kappa = \frac{\frac{1}{n}\sum_{i=1}^{n} p_o^i - p_e}{1 - p_e}$$

F Dataset Details

For Hindustani Classical, the dataset includes five instrument types—sarangi, harmonium, tabla, violin, and tanpura—along with voice. It comprises 41 ragas across two laya types: Madhya and Vilambit.

For Turkish Makam, the dataset features 15 makam-specific instruments, including the oud, tanbur, ney, davul, clarinet, kös, kudüm, yaylı tanbur, tef, kanun, zurna, bendir, darbuka, classical kemençe, rebab, and çevgen. It encompasses 93 different makams and 63 distinct usuls.

G ELO Ratings Computation

For phase I, the total number of evaluations are 36 by each annotator and we consider each annotation as a single match. In Phase II, 63 additional annotations are conducted making a total of 135 matches for computing the ELO ratings. For every match the new rating :

$$R_i = R_i + K * (S_i - E_i)$$

R_i: Player's current Elo rating.
K: Weighting factor that determines how much a single game affects the rating.
S_i: Outcome of the game for the player: 1 for a win, 0.5 for a draw, and 0 for a loss.

$$E_i = \frac{1}{(1 + 10^{\frac{(R_j - R_i)}{400}})}, E_j = \frac{1}{(1 + 10^{\frac{(R_i - R_j)}{400}})}$$

R_i: Player- 1 current Elo rating.
R_j: Player- 2 current Elo rating.
E_i: Expected Elo rating of Player-1.

We use a K value of 15 for calculations due to the limited number of matches; a higher K would disproportionately weight each match and skew the ELO ratings.

H Annotation Tool

We deployed LabelStudio, a versatile and user-friendly annotation tool, on HuggingFace Spaces. Figure 5 provides a visual representation of our annotation tool interface, illustrating the layout and features that our human evaluators used to assess the generated music samples.

I Annotator Demographics

The annotators for our music generation task using adapter models include three individuals from India and one from Uzbekistan, all of whom are avid music listeners with diverse cultural backgrounds and a keen interest in music technology.

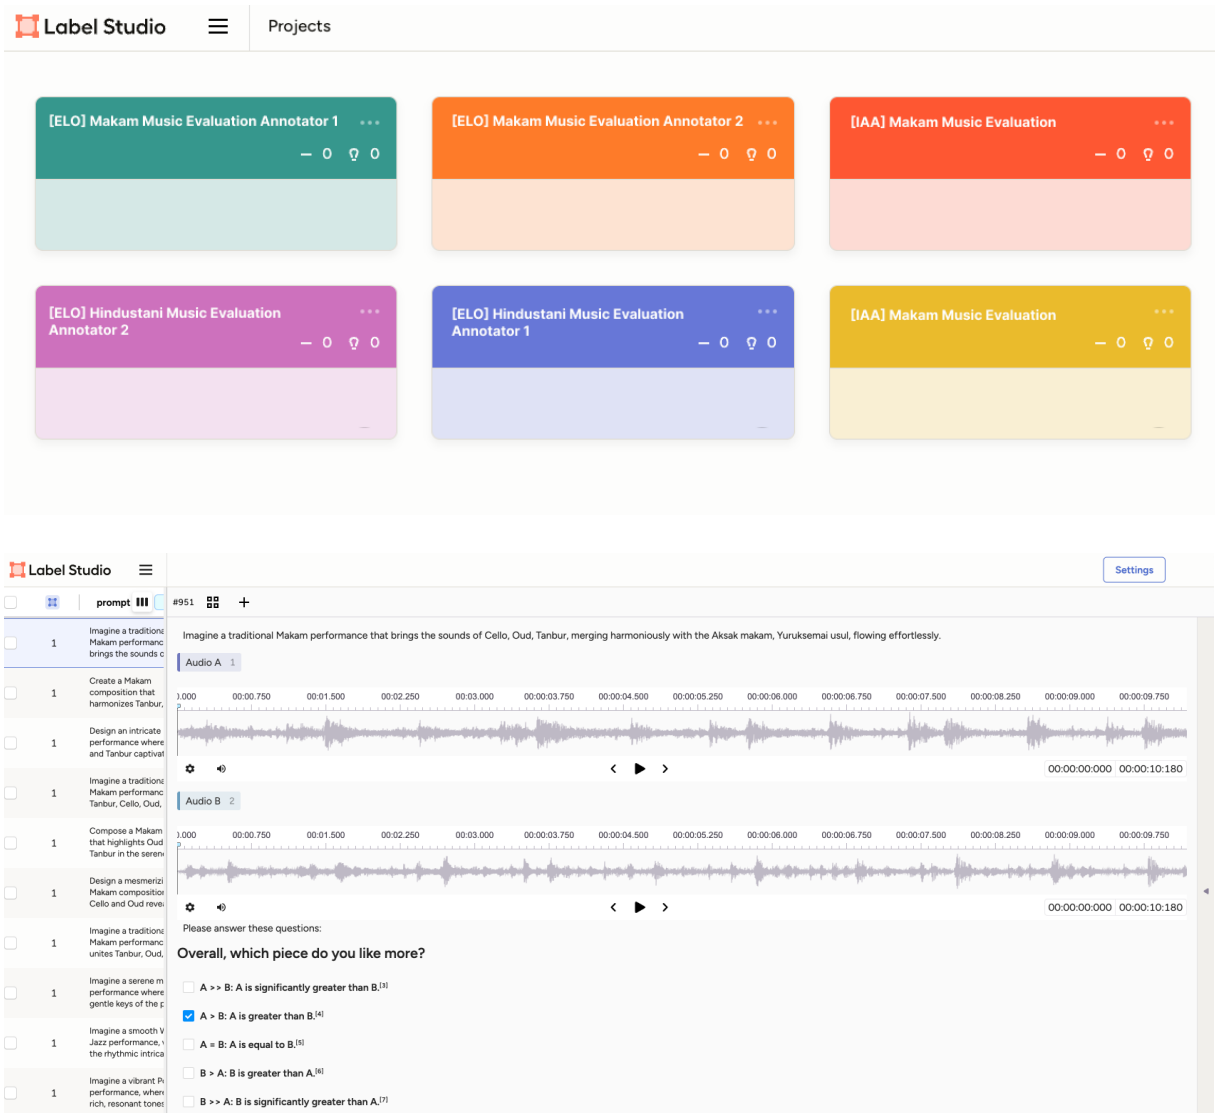

Figure 5: Screenshots of Label Studio, annotation tool for Inter Annotator Agreement and ELO rating comparison

SFMSS: Service Flow aware Medical Scenario Simulation for Conversational Data Generation

Abstract

Medical-specific Large Language Models (LLMs) have demonstrated impressive performance on medical-related exams and tasks. Despite their success in single-turn question and answering, instruction-tuned LLMs often falter in real-world healthcare applications, highlighting a disconnect between existing instruction datasets and practical contexts. To address this issue, we propose **Service Flow aware Medical Scenario Simulation (SFMSS)**, a simulation framework designed for medical conversational data generation. SFMSS employs three key strategies to ensure the quality of the data generation, the use of *Authentic Seed Data* ensures alignment of real-world distributions. *Diverse Patient Simulation* enables simulated patients to exhibit distinct communication styles and complex behavioral logic. *Service Flow Control* ensures that conversations progress in alignment with medical objectives. We construct a dataset targeting on outpatient reception through SFMSS, named SFMSS-CD. Building on this dataset, we develop a model called SFMSS-Nurse. We conduct both automatic and human evaluations, involving 15 users and 15 clinical experts, to assess the effectiveness of SFMSS. The results demonstrate that SFMSS-Nurse outperforms all baselines, including the current state-of-the-art model GPT-4o, and aligns with human preferences and clinical demands. Our code is open-sourced at https://github.com/FudanDISC/PIORS.

1 Introduction

With the advancement of general purpose large language models (LLMs), a series of medical-specific LLMs have been developed through instruction tuning based on knowledge-intensive samples (Gao et al., 2023; Waisberg et al., 2023; Thirunavukarasu et al., 2023). These models have shown impressive performance on medical-related exams and tasks, some are confirmed to attain or even outperform human expert levels (Singhal et al., 2023; Kung et al., 2023).

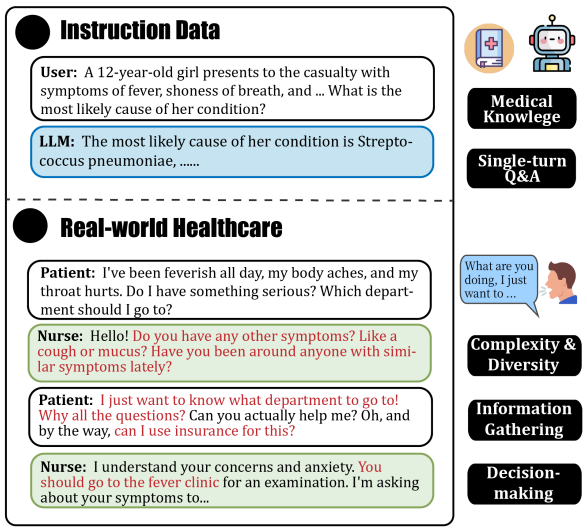

Figure 1: Difference between existing instruction data and real world healthcare scenario.

Most existing medical instruction datasets are constructed with a primary focus on encoding medical knowledge and performing single-turn question answering tasks (Liu et al., 2024b; Peng et al., 2023). Real-world healthcare, such as medical consultation or outpatient reception, is inherently a multifaceted and complex task. It involves relevant information collection, emotion caring and medical decision-making for patients (Liao et al., 2024). The gap between current instruction datasets and the application contexts limits the deployment of these models in real-world scenarios (Agrawal et al., 2024; Mehandru et al., 2024).

Figure 1 shows an example for the comparison between existing instruction samples and real world interactions. We can identify two major limitations. (1) *Lack of diversity and complexity*. The

[†]The two authors contribute equal to this work.

April 29 - May 4, 2025 ©2025 Association for Computational Linguistics

different situations, personality traits, and emotional states of patients lead to diverse communication styles and complex behavioral logic that are not represented in the current instruction datasets. (2) *Lack of service flow control*. Real-world scenarios require sequential multi-turn conversations to achieve goals like department recommendation, making it essential to incorporate decision-making and information-gathering capabilities within the conversational data.

In response to these two limitations, we explore to construct high-quality instruction datasets for medical LLMs fine-tuning to aligned with real-world healthcare applications. To achieve this objective, we propose a framework named **Service Flow aware Medical Scenario Simulation (SFMSS)** for medical conversational data generation. Our simulation framework targeting on the scenario of outpatient reception. It involves three primary agents: the patient, the reception nurse, and a supervisor. To sure the quality of data generation, we employ three key strategies.

- Authentic Seed Data: We employ real-world sources, including hospital outpatient records and demographic data from healthcare services, to guide the generation of data that accurately reflects real-world distributions
- Diverse Patient Simulation: We incorporate multiple attributes into patient simulation, including the Big Five personality traits (Roccas et al., 2002) and demographic factors. This enables simulated patients to exhibit distinct communication styles, behavioral preferences, and emotional responses across various situations.
- Service Flow Control: We introduce predefined action spaces for simulators, developed based on input from clinical experts. Additionally, we introduce a supervisor agent to refine behaviors of nurse through a feedback. This ensures that conversations progress in alignment with medical objectives like department guiding in our scenario, facilitating goal-oriented decision-making.

Based on the simulator, we construct an original fine-tuning dataset on top of 2,000 Chinese hospital outpatient records and develop a medical-LLM, named SFMSS-Nurse. We perform both automatic and human evaluation to test the effectiveness of our model. Results from the automatic evaluation demonstrate that our method outperforms all baselines, including the current state-of-the-art model GPT-4o, in terms of accuracy in department guiding and information-gathering capability. In the user evaluation (**15 users**), our method achieves a win or tie ratio of over 81% compared to the best baseline, suggesting a better experience in real scenarios. Expert evaluation (**15 clinical experts**) reveals that the model trained by our method performs significantly better in inquiry capabilities and concise responses. Additionally, experts rate over 80% of the patients simulated by our approach in the evaluation as being close to or indistinguishable from real patients.

2 Service Flow aware Medical Scenario Simulation (SFMSS)

The SFMSS targets on the medical senario of outpatient reception and comprises three main simulators: a reception nurse simulator (referred to as 'nurse') and a patient simulator (referred to as 'patient') for conducting outpatient reception conversation, as well as a supervisor agent to refine the behavior of nurse. Simulators are built on the real-world data seed as input and employ the the role-playing capabilities of LLMs for dialogue generation. Appendix A contains all the prompts of the SFMSS.

2.1 Overall workflow

Scenario Preparing: SFMSS utilize LLMs to generate scenario settings and patient profiles for agent initialization based on outpatient records, personality traits, and demographic characteristics. Detailed medical conditions and visiting department are provided to agents as references for information gathering and decision-making.

Conversation Simulation: The conversation starts by a *patient* expresses the initial demand for healthcare services. Then followed by a multiple-turn dialogue between the *nurse* and the *patient*. In each turn, simulators choose an action and generate responses based on the action description and the context. At the end of each turn, the supervisor agent provides a feedback to the nurse. The conversation terminates when the patient selects the action that signals an end.

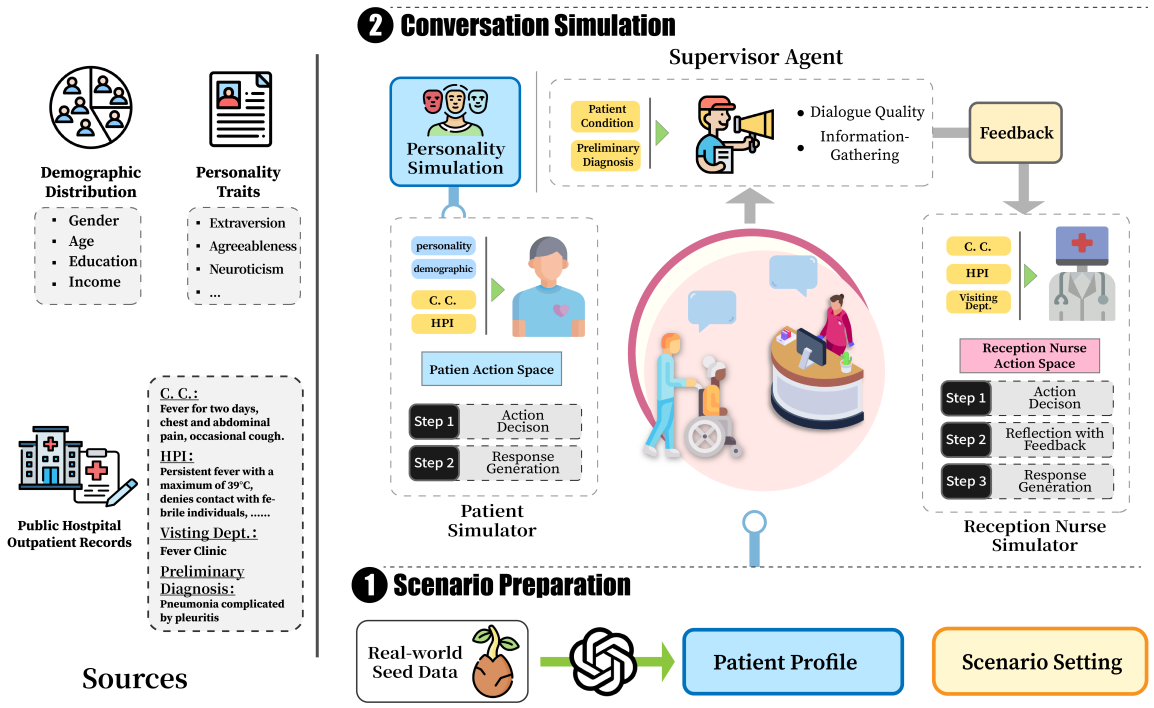

Figure 2: The overall framework of SFMSS. Left shows the data source guided the simulation, where the seed data is sampled from. Right part is the workflow of SFMSS, consisting of three main component: a patient simulator, a reception nurse simulator and a supervisor agent, with their internal response pipeline illustrated.

2.2 Reception nurse simulator

Reception nurse provides medical service to the patient in our scenario and aims to recommend the correct department.

Action space definition: The nurse simulator have seven actions. (1) Symptom inquiry. Guide the patient to describe their main symptoms. (2) Medical history inquiry. Ask the patient for their past medical history, medication history, drug allergy history and follow-up/referral results. (3) Department recommendation. Recommend the appropriate department based on the known patient's information. (4) Priority assistance. Handle emergency situations, soothe patient emotions, and offer quick help for patients. (5) Medical question answering. Respond to the patient's inquiries about advice of department and related primary healthcare questions. (6) Administrative question answering. Address administrative queries (such as hospital visit procedures, examination items and department locations) and other non-medical questions from the patient, quickly steering the conversation back to the triage. (7) Conclusion and confirmation. Summarize the conversation and confirm if the patient has other issues.

Pipeline In each round conversation, given the dialogue history, the response from the nurse simulator is generated through the following three-step process. (1) Action Decision. An action selector identifies the most suitable action from the predefined action space and retrieves corresponding description. (2) Reflection with Feedback. The agent receives feedback from the supervisor and make modification to the chosen action if needed. (3) Response Generation. The simulator generates the final response for this turn based on the dialogue history, medical conditions from outpatient case, specific of selected action and suggestions provided by supervisor.

2.3 Patient simulator

We incorporate personality simulation into the patient simulator to generate diverse patients for better aligning to real scenarios.

Personality simulation We derive the Big Five personality traits and demographic characteristics from real-world to simulate characters of the patient. This include gender, age, incoming level, education level and openness to experience, con-

scientiousness, extraversion, agreeableness, neuroticism. Patient profile is generated through the following two-step process. (1) Sampling. We first sample all 9 attributes from real data. For personality, We provide a range of 3 to 8 adjectives for each Big Five trait (Appendix B) identified as high or low (high/low/moderate for each traits). We then select two adjectives for each trait not identified as moderate, to represent their characteristics. For demographic characteristics, we maintain the original form of data. (2) Patient Profile Generating. We prompt GPT-4o to generate a patient profile that covers the patient's information, personality traits and behavioral preferences with natural language. Profile will affect communication styles, action decision and emotional expression of the patient during interactions.

Action space definition We pre-define five types of actions for a patient. (1) Expressing Needs. Describe main symptoms and concerns in the start of conversation. (2) Information Feedback. Respond to the question raised by the nurse. The accuracy and detail of the feedback should be tailored to the communication style. Responses may include misunderstandings, answering questions not asked, partially answering the questions, or not answering at all. (3) Mention other topic. Mention other topic not related to reception, such as their everyday life and hobbies. (4) Inquiry. Raise questions based on the dialogue history. Questions may be related to nurse's inquiries or suggestions that the patient do not understand or disagree. (5) Ending the Conversation. Confirm the recommended department and end the conversation.

Pipeline The implementation of patient simulator starting with the profile generation. In each turn of a conversation, a response is generated following two steps. (1) Action Decision. An action selector identifies the most suitable action from the predefined action space and retrieves the description of this selected action. Profile of patient will affect the decision of action. (2) Response Generation. The simulator generates the final response for this turn based on the dialogue history, medical conditions from outpatient case, patient profile and specific of selected action.

2.4 Supervisor agent

The supervisor agent is designed to oversee the overall quality of dialogue and the completeness of information gathering. After each patient response, it provides two suggestions to the nurse agent. The supervisor agent comprises two sub-agents.

Dialogue quality. The dialogue quality supervisor mainly focus on monitoring patient emotions and the effectiveness of the dialogue. When the latest input from the patient indicates clear dissatisfaction or when there are multiple rounds of repetitive/ineffective dialogue, appropriate suggestions are given to the nurse agent.

Information gathering. The information gathering supervisor consists of three components: a memory bank, an information extractor and a suggestion generator. Whenever the nurse and a patient complete a round of dialogue, the information extractor extract new patient information given in the new round and add them to the memory bank. Then, the suggestion generator will compare the known memory bank and the true patient profile, and determine if the information collected is complete. If it is not completed, it will provide recommendations and corresponding action for further information collection.

3 SFMSS-CD and SFMSS-Nurse

Based on SFMSS, we construct a high-fidelity simulated conversation dataset, named **SFMSS-CD**. On top of SFMSS-CD, we develop a medical LLMs targeting out-patient reception, named **SFMSS-Nurse**.

3.1 Source Dataset

Real-world Outpatient Records. We collected the year 2023-2024 outpatient record data from a public hospital, which consists of over 750k examples covering 174 departments. Each record primarily consists of the following fields: chief complaint, present illness history, past history, department and preliminary diagnosis. All field names and their detailed descriptions are in the Appendix C.1. The real-world data is noisy and often of low quality, so we filtered the records and retained a smaller high-quality dataset containing 25k examples from 36 departments. Then we extracted 2,000 records as the **training set** and 500 records as the **test set** from the filtered dataset through stratified sampling by department. The training set is used to construct the Supervised Fine-Tuning (SFT) dataset, while the test set is used to assess the performance of different models when serving as nurses.

Distribution of Real Patients The demographic distribution of patients is from Analysis Report of National Health Services Survey in China, 2018 (NHC, 2018). For the BigFive personality traits, we utilize the dataset collected over 1M online questionnaire answers to 50 personality items[1] to represent the real distribution. To transform the data from questionnaire answers to high, low or moderate levels of each trait, we sum up all scores (positive score for high description and negative score for low description) and classify the questionnaire based on the distance between the sum and the median of the whole dataset.

3.2 SFMSS-Nurse Implementation

We utilize SFMSS, which is based on GPT-4o, to construct a high-fidelity simulated conversation dataset, named **SFMSS-CD**, derived from the training set records. We choose Qwen2-7B-Instruct (Yang et al., 2024) as the backbone to fine-tune a model, SFMSS-Nurse, specifically adapted for real-world outpatient triage scenarios using this dataset. For training, we complete the full rank SFT stage on 8*A100 GPUs, with the hyperparameters setting as follows: global batch size of 32, learning rate of 1e-5 with cosine scheduler, 3 epochs, maximum sequence length of 4096, warm up steps of 20 and with 0.05 weight decay.

4 Automatic evaluation

To evaluate the data generation method proposed in §2, we introduce an automatic dynamic evaluation pipeline to assess the performance of different models playing the role as reception nurse using the test set as simulated patient profiles.

4.1 Evaluation Pipeline

The whole pipeline includes two parts: dialogue simulation and quality evaluation. First, prompt the selected model to play the role of nurse, then interact with the patient simulator defined in SFMSS under the outpatient reception scenario and derive the simulated dialogue. One conversation ends when patient simulator picks the ending action or the dialogue exceeds 10 rounds. Second, assess the model's performance by evaluating the quality of simulated dialogues.

[1] https://www.kaggle.com/datasets/tunguz/big-five-personality-test

4.2 Evaluation Metrics

Based on the core responsibilities of nurses and the needs in outpatient reception scenarios, we design the following four dimensions to assess the performance of different models.

Accuracy: We evaluate the accuracy by comparing the department recommended by the model with the ground truth label given by human doctors.

Efficiency: The efficiency can be measured by length of the patient-nurse dialogue. This includes two metrics: **Average Turn Number** and **Average Turn Length**.

Information Gathering Ability: Collecting symptoms and medical history in advance can facilitate subsequent doctor diagnoses and improve the accuracy of triage. From this perspective, we introduce **Info Score** for information gathering, and prompt GPT-4o as evaluator to provide a 5-point score, given the true patient profile for reference.

Overall Performance: To assess the overall performance of a nurse model, we prompted the GPT-4o as evaluator to provide a 5-point **Overall Score** focusing on whether the core responsibilities are fulfilled and the quality of task completion.

4.3 Baselines

We first directly prompt current general LLMs GPT-4o, Qwen2-7B-Instruct and Meta-Llama-3-8b-instruct to play the role of reception nurse (Yang et al., 2024; OpenAI, 2024; AI@Meta, 2024). We also prompt HuaTuoGPT2-13B (Chen et al., 2023), a model specialized in medical domain, to show the gap between traditional training knowledge and complex real-world settings.

For further study about the effectiveness of SFMSS, we introduce a **role-playing baseline**, which is fine-tuned with same training settings describe in §3.2, utilizing the data generated through normal role-playing method. In this approach, GPT-4o is directly prompted as a nurse simulator given the true department, without a pre-defined action space or supervisor agent, while the patient simulator and scene description remains unchanged. Prompts are provided in Appendix C.2.

4.4 Overall Results

The overall results are shown in Table 1. SFMSS-Nurse ranks the first in all performance metrics, and has the shortest average turn number and average turn length.

Method	Model	Accuracy	Overall Score	Info score	Average Turn Number	Average Turn Length
Directly Prompt	**GPT-4o**	0.717	3.83	2.16	3.54	207.98
	Qwen2-7B	0.634	3.65	2.28	4.22	336.40
	Llama-8B	0.401	3.24	2.65	4.44	678.14
	HuatuoGPT2-13B	0.501	3.25	2.17	3.57	258.38
Fine-tuned	**Role-playing baseline**	0.786	3.92	2.20	3.37	202.55
	SFMSS-Nurse	**0.822**	**4.01**	**3.01**	**3.22**	**139.54**

Table 1: Overall results of automatic evaluation. The highest score/shortest length is highlighted in bold, while the second highest/shortest is underlined.

SFMSS contributes to more accurate department guidance. SFMSS-Nurse demonstrates a significant improvement in accuracy compared to baselines without fine-tuning, demonstrating an 18% increase relative to the Qwen2-7b backbone. Moreover, SFMSS-Nurse has a higher accuracy compared to baseline, emphasizing that the predefined action space and the proposed supervisory agent contribute to better department guidance.

SFMSS significantly enhance information-gathering capabilities. SFMSS-Nurse outperforms all baseline models by a large margin in Info Score metric. This underscores the model's enhanced pre-diagnosis information-gathering abilities, which were enabled through SFMSS. Distribution of Info Score is in Appendix E.

Efficient outpatient reception services enabled by SFMSS. As shown in Table 1, dialogues guided by SFMSS-Nurse tend to have the shortest turn length, with over 70 characters fewer compared to the role-playing baseline, and the shortest rounds. The total conversation length is significantly shorter compared to all baselines. These results ensure the efficiency communication between SFMSS-Nurse and patients.

5 Human Evaluation

To ensure high-quality evaluations from those with significant medical experience (experts) and from the population who may engage with SFMSS-Nurse in practice (users), we conducted separate assessments for users and experts.

5.1 User Study

We recruit 15 volunteers to participate in the study, and randomly sample 20 records from test set as patient profiles. Each participant was assigned to simulate the 20 patients sequentially based on given profiles and engage in conversations with SFMSS-Nurse, GPT-4o, and baseline, respectively. After completing the three conversations in each iteration, they made blind pairwise comparisons of SFMSS-Nurse with other two model, selecting from the options: "A is better than B (Win)", "about the same (Tie)", or "B is better than A (Loss)".

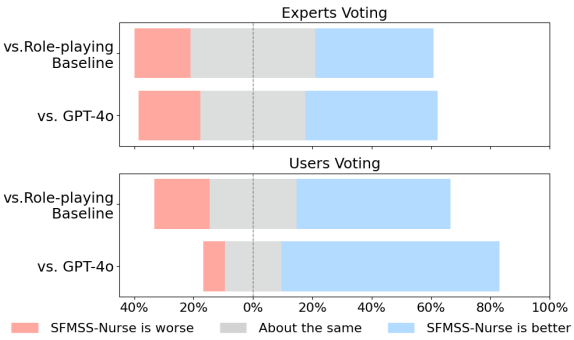

Figure 3: Performace of SFMSS-Nurse compared to GPT-4o and role-playing baseline. X-axis: % of examples voted by experts or users for a specific option, y-axis: the comparison model.

Figure 3 (lower) depicts the distribution of user comparisons. SFMSS-Nurse has a win rate up to 73% and a win-or-tie rate higher than 90% compared to GPT-4o. Even compared to the fine-tuned baseline, our model still demonstrates a win-or-tie rate of over 81%. This result indicates that the dialogues generated by SFMSS better align with human preferences and more accurately reflect the complexity of real patient-nurse interactions.

5.2 Expert Evaluation

We recruit 15 experts, who are currently graduate or PhD students in clinical psychology, or have worked for more than 2 months in this field. Each

expert was randomly assigned with 20 samples, each consists of three dialogues from the same simulated patient and different reception nurses role-played by SFMSS-Nurse, GPT-4o, and the baseline. Experts were asked to make two pairwise comparisons between SFMSS-Nurse and baselines blindly, and evaluate the fidelity of simulated patients.

The comparison options for nurse are the same as those used in the user study. Fidelity is assessed using four levels: "Extremely High", "High", "Moderate" and "Low". The detailed definitions of patient fidelity are in Appendix D.2.

Figure 3 (upper) shows the distribution of expert comparisons. In 80% samples, experts voted SFMSS-Nurse has better or comparable performance compared to the baseline. And the ratio is even higher when compared to GPT-4o. Furthermore, 12 of 15 clinical experts believed that SFMSS-Nurse performed the best overall in the evaluation of the 20 samples.

The experts highly commended SFMSS-Nurse for its proactive inquiry capabilities and concise responses. They noted that SFMSS-Nurse's reasoning more closely aligns with that of real-world nurses. Furthermore, they observed that SFMSS-Nurse remains focused on department triage throughout the conversation, without being easily diverted by patient input.

6 Further Analysis

In this section, we provide a more detailed analysis of the experiment results. Further demonstrate SFMSS's ability to simulate complex real-world scenarios.

6.1 Fidelity of Patient Simulation

Variation in Behavior We use education level as an example to analyse the behavioral differences in simulated patients across various attribute settings. As shown in Figure 4, from illiterate to associate degree, the conversations become shorter and more efficient. This aligns with the impact of education level: higher levels of education enable patients to communicate more effectively with triage nurses. However, when patients are assigned a college level or higher, the average number of characters per turn increases significantly, and the dialogues tend to involve more rounds. This may be attributed to two factors: 1) The small sample size for patients with the highest education level. 2) Patients with higher education levels are more likely to express their own opinions rather than simply following the guidance provided by reception nurses.

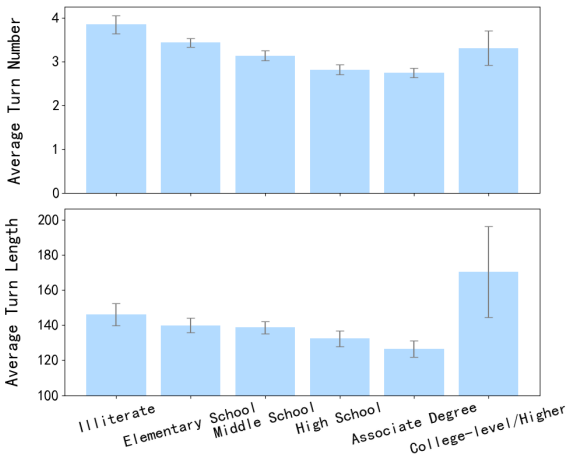

Figure 4: The average turn number and average turn length of simulated patient-nurse dialogues grouped by education level.

Clinical experts noted that most simulated patients are indistinguishable from or close to real patients. Notably, during dynamic interactions, the patient's behavior is influenced by the actions of the nurse(Table 2). Under blinded conditions, SFMSS-Nurse achieves the highest level of fidelity, suggesting that our approach is most closely aligned with real-world scenarios.

Nurse	Extremely High	High	Moderate	Low
GPT-4o	29.3%	47.3%	20.0%	3.3%
Role-play Baseline	31.0%	50.3%	14.3%	4.3%
SFMSS-Nurse	37.7%	47.0%	12.0%	3.3%
Overall	32.7%	48.2%	15.4%	3.7%

Table 2: Experts voting for fidelity of patient simulation with different models playing role of nurse. Extremely high means can't distinguish from human. High means closely resemble real patient behaviour.

6.2 Results of Different Patient Simulation

Education Level From the results of GPT-4o in Figure 5, we can observe that, except for the associate degree, the accuracy of department guiding increases with higher education levels. This is consistent with common sense. The exception may stem from the misalignment of the term "Associate Degree" between GPT-4o's internal knowledge and

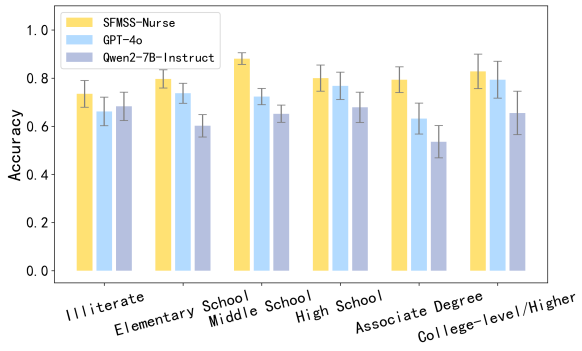

Figure 5: Accuracy grouped by education level.

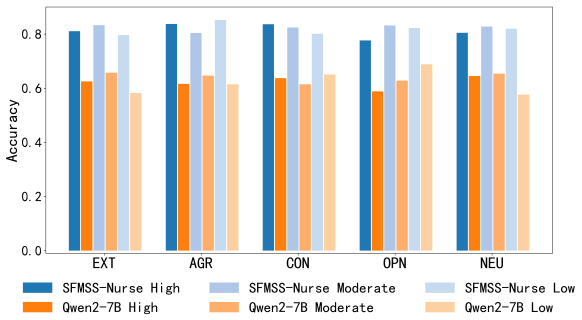

Figure 6: Accuracy grouped by BigFive personality traits. EXT refers to Extraversion, AGR refers to Agreeableness, CON refers to Conscientiousness, OPN refers to Openness to Experience and NEU refers to Neuroticism.

its actual meaning in Chinese context. Figure 5 further illustrates the improvements from Qwen2-7B to SFMSS-Nurse, especially in higher education level. After fine-tuning on SFMSS-CD, the model can better addressing tasks in real-world scenarios, where primary and middle school education levels are most prevalent.

BigFive Personality Traits For Qwen2-7B, patients with specific personalities, such as high extraversion, low openness to experience and high neuroticism are more easy to handle (Figure 6). Such preference can be explained: These personalities tend to provide more information (high extraversion and high neuroticism) or introduce fewer off-topic discussions(low openness to experience). After training, SFMSS-Nurse exhibits a more balanced performance across various personality traits, allowing it to better adapt to complex healthcare scenarios.

6.3 Role of Supervisor Agent

We further conduct ablation experiments to study the role of supervisor agent. We randomly sample 100 seed data and construct dialogue samples

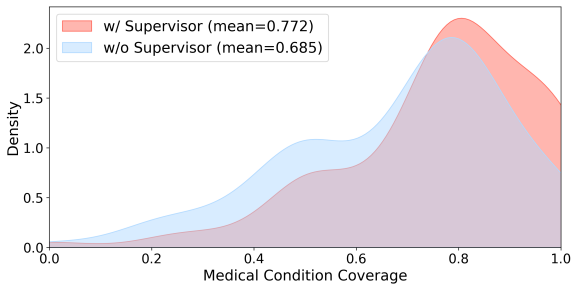

Figure 7: Ablation study on supervisor agent. *w/ supervisor* indicates the original SFMSS approach, and *w/o supervisor* symbolizes removing the supervisor agent.

under two different settings. One setting follows the SFMSS approach as described in §2, while the other remove the supervisor agent, leaving the nurse's inquiries unsupervised. We then use GPT-4o to evaluate the coverage of medical conditions collected by the nurse in the generated dialogues, comparing them to the relevant information in the original seed data. Figure 7 shows the ablated results.

When the supervisor agent is removed, the mean coverage of medical conditions decreases from 0.772 to 0.685 and the distribution shifts leftward. This indicates that the inclusion of the supervisor agent improves the accuracy of the nurse's queries, leading to more comprehensive and informative nurse-patient dialogues.

7 Related Works

Medical LLMs and its Application Natural Language Processing (NLP) has found extensive application in the medical field (Chen et al., 2022b,a; Zhong et al., 2022; Wei et al., 2018). With the advent of large language models (LLMs), significant advancements have been made in developing models specially for healthcare-domain. Models like Med-PaLM2 (Singhal et al., 2023), DISC-MedLLM (Bao et al., 2023), HuatuoGPT-2 (Chen et al., 2023), Med-Gemini (Saab et al., 2024), Aqulia-Med (Zhao et al., 2024) are developed using different datasets, techniques, and frameworks. These efforts primarily focus on enhancing the medical knowledge embedded within language models and often fall short of effectively addressing the complexities of real-world scenarios. Recent works have attempted to apply LLMs to a variety of real-world clinical scenarios, such as text processing, radiology and ophthalmology (Xu et al., 2023; Liu et al., 2023; Gao et al., 2023; Waisberg

et al., 2023; Yang et al., 2022). The works of Wan et al. (Wan et al., 2024) and Liu et al. (Liu et al., 2024a) has demonstrated the promising prospects of LLMs in outpatient reception scenarios. Despite these advancements, the challenges posed by the intricacies of real patient interactions remain insufficiently addressed in current research.

Scenario Simulation in Healthcare Recent developments indicate that agents powered by LLMs can resolve complex tasks through human-like actions, such as tool invocation, role-playing, and reasoning (Wang et al., 2024a; Yue et al., 2024; Wang et al., 2024b; Xiao et al., 2024). There is significant potential to bridge the gap between existing LLMs and their real-world applications by leveraging agent roles and scenario simulations(Mou et al., 2024; Zhang et al., 2024; Li et al., 2024a). Research such as AI Hospital (Fan et al., 2024), AgentClinic (Schmidgall et al., 2024), and AIE (Liao et al., 2024) have created multi-agent simulation environments to evaluate the performance of LLMs in dynamic and interactive healthcare settings. Patient-Ψ (Wang et al., 2024c) and CureFun (Li et al., 2024b) propose approaches to train healthcare workers through simulated patient. However, these studies often neglect to simulate patient personality traits and demographic characteristics. Moreover, there is a lack of research utilizing scenario simulations to generate authentic data for improved real-world healthcare applications. Our work addresses these existing gaps and deficiencies, contributing to the advancement of more effective LLM-driven solutions in healthcare.

8 Conclusion

In this paper, we introduce SFMSS, a conversational scenario simulation method for simulated outpatient reception scenario to generate conversation data that is authentic and aligned with real-world application. We utilize SFMSS to construct a dataset and develop the SFMSS-Nurse model. Both automatic and human evaluation are conducted to demonstrate the effectiveness of SFMSS in enhancing the application of LLMs in outpatient reception. Our framework has potential to transform the application of LLMs in outpatient reception, and be generalized to boarder real-world healthcare applications.

Limitations

While SFMSS demonstrates its ability to generate authentic, high-quality conversations, promising the model better align with real-world outpatient reception scenarios, several limitations still remain. There may be regional variations in scenarios due to differences in language, culture, and social organization. As a result, relying solely on medical records from one hospital may limit the model's generalizability. Although the study includes diverse departments and personality simulations, the sample size of 2,000 is relatively small and may not fully capture the complexity of real clinical scenarios, particularly in departments focused on specific diseases. The simulated patient-nurse conversations may deviate from human-to-human interactions and require further validation. Additionally, SFMSS have not been validated in real clinical environments. Despite these limitations, SFMSS remains highly significant for the application of LLMs in healthcare settings, providing a novel method for constructing authentic scenario-based dialogue data.

Ethics Statement

Participant Recruitment

We recruited participants of user study and expert evaluation through online advertising and networks of our co-authors, as well as snowball sampling. Users are adults with normal cognitive abilities, primarily consisting of university students and graduate students from various fields of study. Experts are those who are currently graduate or PhD students in clinical psychology or related majors, or have more than two months clinical work experience. We pay for each expert for participation. Users are volunteers.

Informed Consent

All participants in the user study and expert evaluation were 18 or older and provided informed consent. We did not assess any clinical outcomes. All data collected from the participants were de-identified and consented to be released for research purposes.

System and Data Usages

All the data and framework developed in this work are intended solely for academic research purposes. The framework developed in this work are intended to augment existing outpatient reception serve, not

to replace it. Our framework is designed for academic and educational purposes only. Real-world deployment will require further work, including larger-scale training and testing, alignment with departmental and administrative information in real hospitals, and broader user and expert evaluations.

The hospital outpatient records utilized in this study originates from Baoshan District Wusong Central Hospital under a formal data sharing agreement. This agreement strictly limits data usage to academic research and system development purposes. Throughout the research process, investigators had no direct access to original medical records, all data underwent hospital-managed anonymization procedures prior to transfer. The data do not contain Personally Identifiable Information (PII) of any patients and hospital staff.

Acknowledge

The authors thank the doctors at the Eye & ENT Hospital of Fudan University, the Shanghai Baoshan District Wusong Central Hospital and the Zhongshan Hospital for their valuable advice and support in system design and evaluation.

A Prompts Used in SFMSS

A.1 Reception Nurse simulator

Here we provide the prompts used in the reception nurse simulator. Below are the prompts for action decision (upper) and response generation (Lower).

<|System Prompt|>
You need to analyse a conversation in outpatient reception between a patient and a reception nurse, and determine the next action the nurse should take in their next response. Provide clear instructions for the next step. Please return the result in JSON format as:
{"action":}
You can choose from the following actions, and each action is explained in detail below. Note that you must select only the most appropriate action.
"Symptom Inquiry": Guide the patient to describe their main symptoms, or further guide them to elaborate on parts where previous information was incomplete.
"Medical History Inquiry": Ask the patient for their past history, medication history, drug allergy history and follow-up/referral results, or further guide them to elaborate on parts where previous information was incomplete. This step is not mandatory and can be skipped if the patient seems anxious.
"Department recommendation": Recommend the appropriate department based on the known patient's information. Choose this action when the conversation already includes sufficient information to make the department assignment.
"Conclusion and confirmation": The duty of reception and department guiding have been completed, include summarizing the conversation and confirming if the patient has other issues.
"Medical question answering": Respond to the patient's inquiries about advice of department and related primary healthcare questions.
"Administrative/other question answering": Briefly address administrative queries (such as hospital visit procedures, examination items and department locations) and other non-medical questions from the patient, quickly steering the conversation back to the triage.
"Priority assistance": Handle emergency situations, soothe patient emotions, and offer quick help for patients.

<|User Prompt|>
{ the current conversation }

If action selected is Department recommendation, Priority assistance or Conclusion and confirmation.
<|System Prompt|>
You are a reception nurse in a hospital and need to communicate with the patient who comes to the outpatient reception. You should collect the necessary information such as symptoms and medical history, and eventually assign the patient to the appropriate department based on the information gathered.
You need to respond to the patient by considering the previous conversation history, the patient's latest input, the action that should be taken, and the advice provided by the supervisory agent.
Be sure to adjust your conversation style based on the patient's requests and emotions, showing empathy and emotional support. When the patient seems anxious, simplify your questions appropriately.
The response should be easy for the patient to understand and answer. Ask only one or two questions at a time, using conversational and concise language to match real-life triage situations. If necessary, first provide a brief response to the patient's inquiry or soothe their emotions. Responses should follow the actions that should be taken, and avoid recommending specific departments.

If action selected is Symptom inquiry, Medical history inquiry, Medical question answering or Administrative/other question answering.
<|System Prompt|>
You are a reception nurse and need to communicate with the patient who comes to the outpatient reception. You should collect the necessary information, such as symptoms and medical history, and eventually assign the patient to the appropriate department based on the information gathered.
You need to respond to the patient by considering the previous conversation history, the patient's latest input provided by the user, and the actions that should be taken. You will be given the correct department assignment for the patient.
It is known that the patient should be assigned to { department }.

<|User Prompt|>
<Patient's latest input>: {input}
<Action you should currently take>: { selected action }, { action description }
Option: [<Supervisory advice on inquiry strategy and tone>: { advice }. \n<Supervisory advice on the next steps for symptom and medical history inquiry>: { advice 2 } *]*

A.2 Patient simulator

Patient Profile Generating

Prompts used for patient profile generating, including behavioural preference (Upper) and scene description (Lower).

<|System Prompt|>
You need to generate the behavioral preference of a patient during a outpatient reception conversation with a reception nurse based on the patient's basic information provided by the user (pay special attention to the education level, which ranges from low to high as follows: ["Illiterate", "Primary School", "Middle School", "High School", "Technical Secondary School", "Associate Degree", "Bachelor's Degree/Higher"]) and their personality. If the patient is under 18 years old, consider the following information to pertain to the patient's parents, ignore the age, and generate the communication style of the parents.
The behavioral preference should include aspects such as the patient's understanding of medical knowledge, ability to describe symptoms, ability to comprehend the nurses' questions, numerical and reasoning skills, and communication proactivity. Provide a concise and brief summary in the second person, without any paragraph breaks.
Here are some examples:
Example 1:
User: "Gender: Female; Age: 22; Education Level: Primary School; Personality: ['Quiet', 'Melancholic']; Income: Above average"
Assistant: "You tend to be quiet and melancholic when communicating with the triage staff. With a lower education level, you lack medical knowledge and find it difficult to describe your symptoms in detail. You require additional explanations to understand questions, and your numerical and logical abilities are limited, making it challenging to provide accurate numerical information. You are generally passive, and the triage staff needs to guide you actively to gather the necessary information."
Example 2:
User: "Gender: Male; Age: 60; Education Level: Primary School; Personality: ['Uncooperative', 'Aggressive', 'Irritable', 'Emotionally Unstable']; Income: Lower-middle income group"
Assistant: "You come across as uncooperative and emotional during communication with the triage staff. With a lower education level, you have limited medical knowledge and struggle to describe your symptoms clearly. Your responses may appear aggressive and irritable, and you have difficulty understanding questions, often requiring additional explanations. Your numerical and logical reasoning skills are weak, making it hard to process and provide accurate numerical information. Overall, you are passive, and the triage staff will need extra patience and skill to guide the conversation effectively."

<|User Prompt|>
Gender: { gender }; Age: { age }; Education Level: { education level }; Personality: { personalities }; Income: { income level }

<|System Prompt|>
You need to describe the patient's situation and thoughts when arriving at the hospital in the patient's voice based on the symptoms, medical history, and basic information provided by the user. Summarize the scenario in one sentence. The description should reflect the patient's psychological state according to the severity of the symptoms and should be consistent with the patient's education level. Do not include specific details of symptoms and medical history, and use vague, general expressions. For patients with lower education levels, avoid using medical terms and describe symptoms in more colloquial language. (The education levels from high to low are: ["Illiterate", "Primary School", "Middle School", "High School/Vocational School", "Technical Secondary School", "Associate Degree", "University and Above"])
If the patient is under 18 years old, describe the scene and thoughts in the voice of the patient's parents. In this case, the information provided by the user refers to the patient, while the education level should reflect that of the parents.
Here are some examples:
Example 1:
User: "<Education Level>: High School; <Age>: 18 years; <Chief Complaint>: Abdominal bloating for 1 day.; <History of Present Illness>: Accompanied by no urine, no nausea or vomiting, no fever, no chest tightness or pain, no palpitations or blackouts, no sweating, normal bowel movements, no black stools.; <Past Medical History>: Denies history of hypertension, denies history of diabetes, denies history of heart disease, denies history of surgery or trauma.; <Visit Time>: 2023-08-02T18:41:53Z"
Assistant: "Your stomach feels a bit bloated and it hasn't gotten better for a day. Although it doesn't seem like a big deal, you decided to stop by the hospital just to check it out."
Example 2:
User: "<Education Level>: Middle School; <Age>: 91 years; <Chief Complaint>: Fainted once half an hour ago.; <History of Present Illness>: The patient experienced a brief loss of consciousness while showering, unresponsive for a few minutes, but gradually improved. No chest tightness, shortness of breath, nausea, vomiting, convulsions, or fever.; <Past Medical History>: History of hypertension. Denies history of diabetes. Denies history of heart disease. Denies history of surgery or trauma.; <Visit Time>: 2023-04-06T14:05:50Z"
Assistant: "You fainted while showering about half an hour ago. Given your age and not being in the best of health, you're really worried something might be wrong, so you rushed to the hospital for help."

<|User Prompt|>
<Education Level>: { Education Level }; <Age>: {Age}; < Chief Complaint >: { Chief Complaint }; <History of Present Illness>: { History of Present Illness }; <Past Medical History>: { Past Medical History }; <Visit Time>:{ Visit Time }

Response Pipeline

Prompts used inside the patient simulator, including action decision (upper) and response generation (Lower).

<|System Prompt|>
You need to analyse a conversation in outpatient reception between a patient and a reception nurse, considering the patient's basic information and communication style, to determine the next action the patient should take in their response. Provide clear instructions for the next step. Please return the result in JSON format as:
{"action":}
You can choose from the following actions, each described in detail below:
"Expressing Needs": Briefly describe the main symptoms and present the concerns coming to hospital in the start of conversation. Alternatively, propose additional requirements that might arise during process.
"Information Feedback": Respond with the corresponding part of the patient information relevant to the question given by the nurse. The accuracy and detail of the feedback should be tailored to the communication style.
"Inquiry":Raise question based on the dialogue history. The question may be one of the following two types: (1) Questions about aspects of the doctor's inquiries or suggestions that the patient do not understand, requesting further explanations of medical terminology or asking the doctor to repeat or simplify previous statements. (2)Patients express their disagreements and questions regarding the recommendations made by the nurse.
"Ending the Conversation": After receiving the doctor's triage suggestion, the patient accepts the department assignment, ends the conversation, and leaves.
"Mention other topic": The patient may mention other topic not related to reception, such as their everyday life and hobbies.

<|User Prompt|>
{ the current conversation }

<|System Prompt|>
{ scene dexcription } You have arrived at the hospital and are at the outpatient reception to ask which department you should go to, communicating with the nurse for department allocation.
<Your behavioral preferences>: { behavioral preferences} Below is your personal information: Chief complaint/Main symptom: { chief complaint }Present illness history: { present illness history }\nPast medical history: { past medical history }\nDrug allergy history: { drug allergy history}\nName: { name }\nGender: { gender }\nAge: { age }
You need to respond to the nurse by considering the conversation history (assistant as the patient, user as the reception nurse), your own personal information, the nurse's latest input, and the action that should be taken. Please respond in accordance with the above behavioral preferences.

<|User Prompt|>
<Latest input from reception nurse>: {input}\n<Action you should take>: {action}, requires {action description}\n\n<Your behavioral preferences>: {behavioral preferences}

A.3 Supervisor Agent

Dialogue quality

Below is prompts used in dialogue quality supervisor.

<|System Prompt|>
You need to supervise an ongoing patient-nurse conversation, observing the patient's emotions and the effectiveness of the dialogue. If the patient expresses strong dissatisfaction in the latest exchange, or if several recent rounds of dialogue are ineffective (i.e., repetitive or providing no new information), you need to offer suggestions to the reception nurse.
Please return the result in JSON format as follows:
{"flag": true/false, "suggestion":}
If the patient exhibits strong dissatisfaction or the conversation has fallen into several rounds of ineffective dialogue, return flag: true and provide a suggestion in the suggestion field for the reception nurse on how to optimize the conversation. Suggestions could include: using a softer approach to guide the patient, calming the patient's emotions, expressing understanding and apologies, simplifying questions for quicker triage, or minimizing repeated questions about the patient's information. Make sure not to mention any specific department.
If the patient's emotions are normal or there is only mild dissatisfaction, and no ineffective dialogue or only one or two rounds of ineffective dialogue occur, return flag: false and leave the suggestion field empty.

<|User Prompt|>
{ Ongoing conversation }

Information gathering

Below is prompts used in information gathering supervisor.

<|System Prompt|>

You need to compare the <Information collected by the reception nurse> provided by the user with the <Patient's real information> to determine whether the information collected by the reception nurse is generally correct and comprehensive enough to provide department recommendation. If there is a significant gap and the information is insufficient for proper department guiding, provide suggestions for the nurse's next round of inquiries, along with the corresponding action to be taken. Return the result in JSON format as follows:

{"enough": true/false, "suggestion": provided suggestion, "action": action to be taken}

If the information is correct and comprehensive, return enough: true and leave the suggestion empty. If the information is incomplete or incorrect, return enough: false and provide an appropriate suggestion in the suggestion field. The suggestion should refer to the <Preliminary Diagnosis> provided by the user and focus on the parts of the patient's real information that were not collected by the triage staff, guiding them on the content and direction for the next round of inquiries.

The information only needs to be generally comprehensive enough to assign department; it does not need to be perfectly identical. Some differences and omissions are acceptable, but the collection of the chief complaint and history of present illness should be as complete and accurate as possible. Collection of past medical history is not a must.

You can choose from the following actions, and each action is explained in detail below:

"Symptom Inquiry": guide the patient to describe their main symptoms, or further guide them to elaborate on parts where previous information was incomplete.

"Medical History Inquiry": A ask the patient for their past history, medication history, drug allergy history and follow-up/referral results, or further guide them to elaborate on parts where previous information was incomplete.

<|User Prompt|>

<Information collected by the reception nurse>: {Information collected by the reception nurse}; <Patient's real information>: {Patient's real information};<Preliminary Diagnosis> :{Preliminary Diagnosis}

B Personality Simulation

Big Five Trait	High Marker	Low Marker
Extraversion	Outgoing, Talkative, Bold/Confident, Positive, Energetic, Optimistic/Cheerful	Introverted, Silent, Timid/Unconfident, Negative, Lacking Energy, Melancholy
Agreeableness	Friendly, Trusting, Cooperative, Humble, Easygoing	Aggressive, Distrustful, Dishonest, Uncooperative, Arrogant, Unaccommodating
Conscientiousness	Organized, Diligent, Thorough	Disorganized, Careless, Forgetful
Openness to Experience	Imaginative, Creative, Reflective, Emotionally Sensitive, Curious, Analytical	Unimaginative, Uncreative, Unreflective, Emotionally Closed, Uncurious
Neuroticism	Calm, Patient, Emotionally Stable	Tense, Anxious, Worrisome, Irritable, Impulsive, Easily Dissatisfied, Emotionally Unstable

Table 3: High and low markers pre-defined for BigFive personality traits.

C Experiment Setup Details

C.1 Outpatient Records Details

An Example of Data

{
"**auxiliary_examination**": "None for now",
"**outpatient_number**": 7117935,
"**chief_complaint**": "Left kidney cyst discovered during routine physical examination",
"**physician_signature**": "Wang*",
"**preliminary_diagnosis**": "Simple renal cyst?",
"**drug_allergy_history**": "None",
"**treatment_opinion**": "Perform [Ultrasound] of the kidney; Outpatient follow-up.",
"**present_illness_history**": "Left kidney cyst discovered during routine physical examination",
"**physical_examination**": "No edema in the lower limbs",
"**notes**": "Regular follow-up, further examination if necessary.",
"**past_history**": "Denies history of hypertension and diabetes.",
"**department**": "Nephrology",
"**age**": "49 years",
"**name**": "Wang***",
"**gender**": "Female",
"**patient_id**": "76684842A011D4F7C900B6BA9661DB1D",
"**visit_date**": "2023-07-06 10:44:26"
}

Figure 8: An example outpatient medical record.

Each record consists of 17 fields, the field names and their definitions are as follows:

Outpatient Number: The unique id of an outpatient medical record. ***Chief Complaint***: The primary reason or main symptom for which a patient seeks medical care. ***History of Present Illness***: A detailed account of the patient's current symptoms and medical condition. ***Past Medical History***: A comprehensive summary of a patient's previous health conditions, medical treatments, surgeries, hospitalizations, chronic illnesses, allergies, and medications. It may also include significant family medical history and lifestyle factors like smoking or alcohol use. ***Department***: The specific unit or division within the hospital where a patient is treated. ***Drug Allergy History***: A patient's previous allergic reactions to medications. ***Age***: The age of the patient. ***Gender***: The gender of the patient. ***Name***: The anonymized name of the patient. ***Visit Time***: The registration time of the patient's current visit. *Patient ID*: The unique ID to identify the patient. ***Preliminary Diagnosis***: The initial assessment or hypothesis made by doctors. ***Physical Examination***: The systematic evaluation of a patient's body by the doctor. ***Auxiliary examination***: Additional diagnostic tests or procedures that are used to support or confirm a diagnosis. ***Notes***: Specially notation given by doctors. ***Physician signature***: The official signature provided by the attending doctor who is responsible for the patient's care. This field has been anonymized. ***Treatment opinion***: The professional recommendations or suggestions provided by a doctor for the patient.

An example record in the dataset is shown in Figure 8.

C.2 Prompts for Baselines

In the automatic evaluation, models are prompted to role-play the reception nurse, with the system prompt in Figure 9. The **directly prompted baselines** also share the same instruction.

<|System Prompt|>
You are a reception nurse in a hospital outpatient reception. You should help patients and guide them to the appropriate department.
The available department options are as follows, and the final department assignment should be selected from them: 'Dermatology', 'Oncology ', 'Neurology',.....

Figure 9: Role-play prompt for directly prompted baselines and evaluation.

When training the **role-playing baseline**, we directly prompt GPT-4o as reception nurse. The prompt is provided in Figure 10.

<|System Prompt|>
You are a reception nurse in a hospital outpatient reception. You should help patients and guide them to the appropriate department.
This patient should be guided to { given department label } in the end.

Figure 10: Prompt for normal role-playing data generation method.

D Evaluation Details

D.1 Prompts for Automatic Evaluation

Here we provide our prompts for automatic evaluation in Figure 11 and Figure 12.

D.2 Expert Evaluation Details

Fidelity Options

<|User Prompt|>
You are a fair and strict evaluator with a solid clinical background. Your task is to score a conversation happened in outpatient reception between a patient and a nurse. You will be provided with the patient's real information and the department to which they should be assigned. You should evaluate the nurse's performance based on their ability to gather information, as well as the appropriateness and relevance of their inquiries to the patient's actual condition and potential diagnosis, and the accuracy of their department recommendation, all from a clinical expert perspective. You will assign a score from 1 to 5.
Your focus should be on the relevant aspects mentioned above. Do not let the length of the conversation, the language style of the patient or nurse, or other irrelevant factors affect your judgment. Your scoring should be strict enough to ensure a meaningful distinction, and you should avoid giving full marks too easily.
Please return the result in JSON format, as follows:
{{"score": score}}
###<Patient Information>###
{ real patient information }
###<Assigned Department>###
{ true department label }
###<Conversation>###
{ conversation to be evaluated }

Figure 11: Instruction for GPT-4o to provide the Overall Score.

<|User Prompt|>
You are a fair and strict evaluator with a solid clinical background. Your task is to score a conversation happened in outpatient reception between a patient and a nurse. You will be provided with the patient's real information and the department to which they should be assigned. You should evaluate the nurses' ability to collect pre-diagnosis information, with a particular focus on gathering information related to the chief complaint and history of present illness. You will assign a score from 1 to 5.
Your focus should be on the relevant aspects mentioned above. Do not let the length of the conversation, the language style of the patient or nurse, or other irrelevant factors affect your judgment. Your scoring should be strict enough to ensure a meaningful distinction, and you should avoid giving full marks too easily.
Please return the result in JSON format, as follows:
{{"score": score}}
###<Patient Information>###
{ real patient information }
###<Assigned Department>###
{ true department label }
###<Conversation>###
{ conversation to be evaluated }

Figure 12: Instruction for GPT-4o to provide the Info. Score.

Extremely High: Fully consistent with the behavior of real clinical patients. The speech and behavior logic are indistinguishable from real patients, aligning with the characteristics of real patient groups.

High: Closely resemble the behavior and performance of real clinical patients, with only slight deviations. Overall, the simulation maintains the logical consistency and characteristics of real patient groups.

Moderate: The simulated patient's behavior differs noticeably from real clinical patients. The speech and behavior logic appear unnatural, making it difficult to reflect the characteristics of real patient groups.

Low: The simulated patient's speech and behavior are significantly different from those of real clinical patients. The performance shows clear logical inconsistencies and behavioral issues, resulting in a lack of realism.

E Additional Automatic Evaluation Results

Re-evaluating Automatic LLM System Ranking for Alignment with Human Preference

Mingqi Gao[*1,2] **Yixin Liu**[*2] **Xinyu Hu**[1]
Xiaojun Wan[1] **Jonathan Bragg**[3] **Arman Cohan**[2,3]

Abstract

Evaluating and ranking the capabilities of different LLMs is crucial for understanding their performance and alignment with human preferences. Due to the high cost and time-consuming nature of human evaluations, an automatic LLM ***bencher*** (i.e., an automatic evaluation framework that aims to rank LLMs based on their alignment with human preferences) is indispensable. An automatic LLM bencher consists of four components: the input set (e.g., a user instruction), the evaluation model (e.g., an LLM), the evaluation type (e.g., pairwise comparison), and the aggregation method (e.g., the ELO rating system). However, previous work has not thoroughly explored how to select these components or how their different combinations influence the results. In this work, through controlled experiments, we provide a series of recommendations on how to choose each component to better automate the evaluation of LLMs. Furthermore, we discovered that when evaluating LLMs with similar performance, the performance of the automatic LLM bencher declines sharply, underscoring the limitations of current benchers and calling for future work. Lastly, we found that the evaluation models' performance at the instance level (e.g., the accuracy of selecting the best output) does not always align with their effectiveness when used as a component of a bencher, highlighting the importance of dedicated system-level evaluation of benchers.

1 Introduction

Recently, various large language models (LLMs) (Ouyang et al., 2022) and LLM-based agents (Wang et al., 2024a) have been released, demonstrating strong capabilities across various tasks. These systems enable efficient interactions with human users and can be instructed to perform various complex activities, making their performance in such tasks an important aspect of evaluation. To benchmark the capabilities of these systems, human judgments of output quality remain indispensable as the gold standard, as many tasks do not have standard answers and are inherently open-ended (Zheng et al., 2023; Dubois et al., 2023).

Chatbot Arena (Chiang et al., 2024) embodies this concept. It is a real-time evaluation platform aimed at a large user base, where users can freely provide input, select any two hosted LLMs to generate responses, and indicate which one they prefer. Chatbot Arena periodically derives a leaderboard of various LLMs by aggregating instance-level pairwise human evaluations. To date, Chatbot Arena has collected over 1.5 million human judgments, involving more than 100 systems. Due to its substantial size and the comprehensiveness of the systems included, its LLM ranking has been widely regarded as a trustworthy indicator of an LLM's general capabilities (Li et al., 2023, 2024b; Lin et al., 2024; Zhao et al., 2024).

However, automatic LLM system rankers (i.e. benchers) are often needed because of the expensive and time-consuming nature of human evaluation.[1] As a result, several widely used automatic benchers have been proposed, such as Alpaca Eval (Li et al., 2023; Dubois et al., 2024) and Arena Hard (Li et al., 2024b), which use a strong LLM such as GPT-4 (OpenAI, 2023) to compare various systems on a carefully designed input set. These automatic benchers can produce LLM rankings that correlate well with Chatbot Arena, achieving Spearman's ρ of around 0.95. Therefore, they have been widely used to develop and evaluate LLMs for tasks like alignment fine-tuning (Tunstall et al., 2024; Yang et al., 2024).

[*]Equal contribution.

[1]LLMs used to evaluate the output of other LLMs are also referred as "evaluators" or "LLM-as-a-judge" in the literature. We use the word "bencher" to explicitly emphasize the broader automatic evaluation frameworks used to derive rankings of models in a benchmark (in which an LLM evaluator is often used as part of the framework).

Findings of the Association for Computational Linguistics:
NAACL 2025, pages 4605–4629
April 29 - May 4, 2025 ©2025 Association for Computational Linguistics

Formally, an automatic LLM bencher for evaluating instruction following capabilities consists of the following components:

• *Input Set*: A set of instructions that each LLM is tasked with to generate responses.

• *Evaluation Model*: An (often strong) LLM (e.g. GPT-4o) that serves as a proxy for humans in evaluating a model's responses.

• *Evaluation Type*: The type of instance-level evaluation generated by the evaluation model, such as pointwise scores or pairwise comparisons, usually determined by the prompt.[2]

• *Aggregation Method*: The method by which instance-level evaluations are converted into system (or model) scores and rankings.

While these automatic benchers have shown a high level of alignment with human evaluations in Chatbot Arena, we note a lack of a systematic evaluation across all the above-mentioned components involved with the benchers. For example, while Arena Hard claims a higher alignment with human evaluation than Alpaca Eval and attributes its success to the careful selection of its input set, they also adopt different evaluation types for the evaluation: Arena Hard performs five-point pairwise comparisons, while Alpaca Eval produces binary comparisons. Therefore, the exact source of its superior performance remains unclear because of the lack of controlled comparisons.

Therefore, we aim to conduct a more rigorous examination of these automatic benchers. To this end, the first research question we explore is **RQ1: how to choose the appropriate components for building an effective automatic LLM bencher?** Specifically, we perform controlled comparisons of various input sets, evaluation models, evaluation types, and aggregation methods to investigate which choices of each component maximize the bencher's performance. Our key findings are:

(1) Input Set: Compared to the earlier released Alpaca Eval, using Arena Hard as the input set, which is filtered from crowdsourced user prompts through an LLM-powered pipeline, always yields higher correlations with the system rankings of Chatbot Arena.

(2) Evaluation Model: While proprietary models like GPT-4-turbo generally perform best as evaluation models, the open-source Llama-3.1-70B (Dubey et al., 2024) also delivers strong performance, particularly when paired with a suitable combination of other components in automatic benchers.

(3) Evaluation Type: With a fixed number of LLM queries, pointwise evaluation is slightly better than base pairwise evaluation[3] for strong LLMs, but pairwise evaluation considerably outperforms pointwise with less capable LLMs. Notably, in almost all cases, the widely used 5-point pairwise evaluation performs *worse* than the base pairwise approach. Additionally, using reference systems is an efficient strategy.

(4) Aggregation Method: The system rankings produced by the Bradley-Terry model (BRADLEY and TERRY, 1952) and win ratio are mostly the same when the evaluation type is base pairwise. Interestingly, when the evaluation type is pointwise, the arithmetic mean, the most common aggregation method, is not always optimal.

Having provided a thorough evaluation of the automatic benchers, we take a step forward to explore a more challenging setting. A critical question regarding the evaluation of the LLM benchers is its reliability when the task is to evaluate similar-performing LLMs, which is an important use case. For example, these benchers are widely used to compare different model checkpoints fine-tuned from the same pre-trained model, which have similar performance and behavior. Finally, based on the above experimental results, it seems that we can easily build an effective automatic bencher using GPT-4-turbo as the evaluation model, achieving a Spearman's rho of over 0.90 with Chatbot Arena. However, **does the performance of the bencher decline when systems with smaller performance differences are selected for evaluation (RQ2)?**

One aim of our above analyses was to identify suitable evaluation models (see Finding (2) above). Related work like LLMBAR (Zeng et al., 2024b) and RewardBench (Lambert et al., 2024) has taken a different approach to evaluating evaluation models, by measuring correlation or accuracy with ground truth instance-level human annotations rather than aggregate system rankings from Chatbot Arena. Compared to the crowd-sourced ChatBot Arena, human annotations collected for instance-level evaluations are usually of higher quality but lack the scale in terms of the number

[2]Following the literature, throughout this paper, "Instance-level" refers to an evaluation instance, which could consist of a pair of model outputs (in pairwise evaluation) or a single model output (in pointwise evaluation).

[3]We refer to binary pairwise (win/lose) comparisons as the base pairwise evaluation method.

of systems used to generate evaluation examples. Sometimes system information is even unavailable for instance-level evaluation datasets. Given the significant efforts made in this direction, it would be desirable for instance-level evaluation results to also generalize to system-level evaluation, which leads to our **RQ3: can we use instance-level rankings of evaluation models as a good reference to select evaluation models for LLM benchers?**

Our investigation of the three research questions underscores several key findings for the users and developers of LLM benchers: (1) RQ1: It is important to choose the suitable components to build a bencher. For example, we find that using Llama-3.1-70B with a pairwise comparison protocol, the BT model for aggregation on Arena Hard can yield a comparable Spearman correlation of 0.93 with human annotators compared to the standard AlpacaEval2 evaluation pipeline where GPT-4 is used as the evaluator. (2) RQ2: Despite their promising performance in general, the benchers' alignment with humans degrades quickly when they are used to rank close-performing systems, calling for further work to enhance their robustness and accuracy. (3) RQ3: The evaluation results of LLM-based evaluators on the instance level do not always generalize to the system-level performance of the corresponding benchers. This highlights the need for dedicated evaluations at the system level.

2 Problem Formalization

In this section, we formalize some crucial concepts and our research questions.

2.1 Automatic LLM Bencher

Given a set of systems ($\mathcal{S} = \{s_1, s_2, \ldots, s_n\}$) to be evaluated/ranked , an automatic bencher $\mathcal{J}_A$ is composed of the following four components:

Input Set $\mathcal{X} = \{x_1, x_2, \ldots, x_m\}$. Each system s_i generates a response o_{ij} for each input x_j.

Evaluation Model $\mathcal{E}$: This is an LLM (e.g., GPT-4-turbo) that acts as a proxy for human evaluators. It generates instance-level evaluations for each system. The evaluation model $\mathcal{E}$ outputs instance-level evaluation for each response o_{ij} .

Evaluation Type $\mathcal{T}$: This refers to the type of evaluation generated at the instance level. There are two main types[4]:

(1) Pointwise Evaluation: The evaluation model assigns a score to a system's response. The pointwise score of the i-th system's response to the j-th input is denoted as $\mathcal{T}_{\text{pointwise}}(\mathcal{E}, x_j, o_{ij}) \in \mathbb{R}$. The total number of instance-level evaluations is mn.

(2) Pairwise Evaluation: the evaluation model compares the quality of two responses o_{ij}, o_{kj} generated by two systems s_i and s_k on the same input x_j. The base comparison result is binary, indicating whether s_i performed better than s_k or vice versa. This can be expressed as: $\mathcal{T}_{\text{base.pairwise}}(\mathcal{E}, x_j, o_{ij}, o_{kj}) \in \{o_{ij} > o_{kj}, o_{ij} < o_{kj}\}$. In 5-point pairwise comparisons, the evaluation model provides more detailed feedback about the difference between two systems' performances, capturing both the magnitude and direction of the preference. The 5 possible comparison outcomes for systems s_i and s_k on input x_j are: $\mathcal{T}_{\text{5-point.pairwise}}(\mathcal{E}, x_j, o_{ij}, o_{kj}) \in \{o_{ij} \ll o_{kj}, o_{ij} < o_{kj}, o_{ij} = o_{kj}, o_{ij} > o_{kj}, o_{ij} \gg o_{kj}\}$. The total number of instance-level pairwise evaluations is $mn(n-1)$ rather than $mn(n-1)/2$ because we always need to swap the presentation order of the responses s_i and s_j to address the position bias of LLM-based evaluations. In addition, due to the high computational cost of performing full-scale comparisons, some automatic LLM benchers (Li et al., 2023, 2024b) introduce a **reference system** in pairwise evaluation. In this approach, all systems under evaluation only need to be compared with a reference system (e.g. GPT-4), which reduces the complexity of pairwise evaluation to a level similar to that of pointwise evaluation.

Aggregation Method $\mathcal{G}$: This will create a mapping from systems to scores ($\mathcal{G}(s_i) \in \mathbb{R}$), depending on the evaluation type.

For pointwise evaluations, aggregation can be done via the mean or median of the instance-level scores across all inputs:

$$\mathcal{G}_{\text{mean}}(s_i) = \frac{1}{m}\sum_{j=1}^{m} \mathcal{T}_{\text{pointwise}}(\mathcal{E}, x_j, o_{ij})$$

$$\mathcal{G}_{\text{median}}(s_i) = \text{median}\left(\{\mathcal{T}_{\text{pointwise}}(\mathcal{E}, x_j, o_{ij})\}_{j=1}^{m}\right)$$

For pairwise evaluations, we consider the Bradley-Terry model (BRADLEY and TERRY, 1952) and win ratio[5]. They can only be applied to base pairwise instance-level evaluations, so other

[4]There is also the "list-wise" approach, where a list of model outputs is provided, and the LLM is tasked with ranking them at once. However, this type of evaluation is not commonly employed in LLM-based judges or benchmarks.

[5]We do not consider the online ELO rating system (Elo, 1978) because the rankings it produces are influenced by the input order of instance-level evaluations.

types of instance-level evaluations need to be converted to the base pairwise type. The conversion rules are described in Appendix A. The Bradley-Terry model $\mathcal{G}_{\text{BT}}$ computes the strength of each system via maximum likelihood estimate, and the win ratio is the proportion of pairwise wins for a system over others:

$$\mathcal{G}_{\text{win_ratio}}(s_i) = \frac{\sum_{j=1}^{m}\sum_{k\neq i}\mathbb{1}(\mathcal{T}_{\text{base.pairwise}}(\mathcal{E}, x_j, o_{ij}, o_{kj}) = o_{ij} > o_{kj})}{\sum_{j=1}^{m}\sum_{k\neq i}1}$$

where m is the total number of inputs and the denominator counts the total number of pairwise comparisons involving s_i. Since pointwise data can be converted into pairwise data, all aggregation methods for pairwise evaluations can also be applied to pointwise evaluations after conversion.

2.2 How to Evaluate a Bencher

Ground Truth. From Chatbot Arena, we obtain system ratings, denoted as $r(s_i)$, for each system $s_i \in S$, where $r(s_i) \in \mathbb{R}$ represents the overall performance of the system as derived from human judgments. The ranking of the systems is obtained by sorting them based on their ratings: $R_H : S \to \{1, 2, \ldots, n\}$, where $R_H(s_i)$ represents the rank of system s_i based on the ratings $r(s_i)$.

Evaluation Measure. The performance of an automatic bencher $\mathcal{J}_A$ is evaluated by comparing its ranking R_A of systems with the ground truth ranking R_H, using Spearman's rank correlation coefficient ($\rho(R_A, R_H)$) and Kendall's tau ($\tau(R_A, R_H)$). ρ is more widely used.

Controllable Kendall's Tau (τ_u): Inspired by Deutsch et al. (2022), we propose controllable Kendall's tau that evaluates the agreement between rankings by focusing only on system pairs where the performance difference is small, i.e., where the absolute difference in the human-provided scores for two systems is less than a specified threshold u. This is useful for evaluating the bencher's ability to distinguish between closely matched systems.

Let $\Delta r(s_i, s_k) = |r(s_i) - r(s_k)|$ represent the performance difference between systems s_i and s_k, where $r(s_i)$ is the system ratings derived from Chatbot Arena. For a given threshold u, we define the set of system pairs that are considered for evaluation as: $P_u = \{(s_i, s_k) \mid s_i, s_k \in \mathcal{S}, \Delta r(s_i, s_k) \leq u, i \neq k\}$. To prevent the performance gap between two systems from being so small that humans also find it difficult to distinguish between them, we only consider system pairs whose 95% confidence intervals in the Chatbot Arena ratings do not overlap: $Q = \{(s_i, s_k) \mid s_i, s_k \in \mathcal{S}, \text{CI}(r(s_i)) \cap \text{CI}(r(s_k)) = \varnothing, i \neq k\}$. The controllable Kendall's tau τ_u is then calculated only using the system pairs in $P_u \cap Q$:

$$\tau_u(R_A, R_H) = \frac{C_u - D_u}{\sqrt{(C_u + D_u + T_{A,u})(C_u + D_u + T_{H,u})}}$$

where C_u is the number of concordant pairs (i.e., pairs of systems (s_i, s_k) where the rank order between s_i and s_k is the same in both R_A and R_H). D_u is the number of discordant pairs. $T_{A,u}$ and $T_{H,u}$ are the number of ties in the automatic bencher's ranking R_A and the human-provided ranking R_H. Only the system pairs within the set P_u are used.

2.3 Different Ways of Selecting Evaluation Models

We are comparing different evaluation models $\mathcal{E}$ based on their ability to rank systems or predict instance-level human preferences. There are three key settings for evaluating evaluation models:

Setting 1: Standard Meta-Evaluation with System-Level Rankings ($R_{\mathcal{E}}^{(1)}$) . The idea of Setting 1 is to rank evaluation models based on how well their corresponding automatic benchers align with the system rankings derived from Chatbot Arena. It is the standard way benchmarks such as Arena Hard are designed.

An automatic bencher $\mathcal{J}_A^{(i)}$ is composed of an evaluation model $\mathcal{E}_i$ and **fixed** input set $\mathcal{X}$, evaluation type $\mathcal{T}$, and aggregation method $\mathcal{G}$, producing a system ranking $R_A^{(i)}$. The performance of evaluation model $\mathcal{E}_i$ is measured by comparing $R_A^{(i)}$ with R_H using either Spearman's $\rho(R_A^{(i)}, R_H)$, or Kendall's $\tau(R_A^{(i)}, R_H)$ mentioned above. Evaluation models are ranked based on their performance, leading to a ranking for evaluation models: $R_{\mathcal{E}}^{(1)} : \{\mathcal{E}_1, \mathcal{E}_2, \ldots, \mathcal{E}_K\} \to \{1, 2, \ldots, K\}$.

Setting 2: Instance-Level Human Judgments as Ground Truth ($R_{\mathcal{E}}^{(2)}$). We consider instance-level human judgments as the ground truth, without system-level aggregation or knowledge of which systems generated the responses.

Let $\mathcal{D} = \{(x_j, o_j^{(1)}, o_j^{(2)}, h_j)\}_{j=1}^{m}$ represent the dataset, where each entry consists of an input

x_j, two responses $o_j^{(1)}$,$o_j^{(2)}$, and human preference $h_j \in \{o_j^{(1)} > o_j^{(2)}, o_j^{(1)} < o_j^{(2)}\}$, indicating which response was preferred.

The evaluation model $\mathcal{E}_i$ generates predictions $\hat{h}_j^{(i)} = \mathcal{T}_{\text{base.pairwise}}(\mathcal{E}_i, x_j, o_j^{(1)}, o_j^{(2)})$, and the instance-level accuracy is defined as:

$$\text{Accuracy}(\mathcal{E}_i) = \frac{1}{m}\sum_{j=1}^{m} \mathbb{1}(\hat{h}_j^{(i)} = h_j)$$

Evaluation models are ranked ($R_{\mathcal{E}}^{(2)}$) based on their accuracy in predicting human preferences.

Setting 3: Instance-Level Human Judgments with System Information and Aggregation ($R_{\mathcal{E}}^{(3)}$). We design this new setting to help us compare **Setting 1** and **Setting 2**. If we have access to instance-level human judgments as well as system information, we can aggregate both human judgments and evaluation model predictions into system-level rankings.

Dataset with system information: Each entry in the dataset $\mathcal{D}' = \{(x_j, o_j^{(1)}, o_j^{(2)}, s_j^{(1)}, s_j^{(2)}, h_j)\}_{j=1}^{m}$ includes: an input x_j, two responses $o_j^{(1)}$,$o_j^{(2)}$ generated by systems $s_j^{(1)}, s_j^{(2)}$, and human preference $h_j \in \{o_j^{(1)} > o_j^{(2)}, o_j^{(1)} < o_j^{(2)}\}$, indicating which response was preferred[6]. The steps to producing evaluation model rankings are as follows: (1) Human preferences are aggregated to produce a system ranking R'_H with an aggregate method $\mathcal{G}$. (2) The evaluation model $\mathcal{E}_i$ provides instance-level predictions with $\mathcal{T}$, which are aggregated using the same method $\mathcal{G}$ to produce a system ranking $R_A^{(i)}$. (3) Compare the two system rankings R'_H and $R_A^{(i)}$ using Spearman's $\rho(R_A^{(i)}, R'_H)$ or Kendall's $\tau(R_A^{(i)}, R'_H)$. (4) The evaluation models are then ranked ($R_{\mathcal{E}}^{(3)}$) based on the correlation between their aggregated rankings and the aggregated human judgments.

Setting 1 and Setting 3 are system-level evaluation, because aggregation methods are applied and a correlation value is calculated between two sets of system rankings, while **Setting 2 is the instance-level evaluation.** Note that we set the evaluation type to $\mathcal{T}_{\text{base.pairwise}}$ and aggregation method to $\mathcal{G}_{\text{BT}}$ in Setting 1 and Setting 3 to compare the results of the three settings more fairly.

[6]Please note that the instance-level human judgments in Chatbot Arena cannot be utilized in Setting 3, as they are not fully disclosed. Specifically, x_j, $o_j^{(1)}$, and $o_j^{(2)}$ are unavailable, and only $s_j^{(1)}$, $s_j^{(2)}$, and h_j are provided. Consequently, only the aggregated system rankings from Chatbot Arena (as used in Setting 1) are typically used.

2.4 Research Questions

Our research questions can be formalized as:

- RQ1: How to choose the appropriate components for building an effective automatic LLM bencher?

  $\Rightarrow \mathcal{X}, \mathcal{E}, \mathcal{T}, \mathcal{A} = \arg\max_{\mathcal{X},\mathcal{E},\mathcal{T},\mathcal{A}} \rho(R_A, R_H)$

- RQ2: Does the performance of the bencher decline when systems with smaller performance differences are selected for evaluation?

  $\Rightarrow$ Does $\tau_u(R_A, R_H)$ decrease as u decrease?

- RQ3: Can we use instance-level rankings of evaluation models as a good reference to select evaluation models for LLM benchers?

  $\Rightarrow$ $\rho(R_{\mathcal{E}}^{(1)}, R_{\mathcal{E}}^{(2)}) \approx 1$ and $\rho(R_{\mathcal{E}}^{(1)}, R_{\mathcal{E}}^{(3)}) \approx 1$ and $\rho(R_{\mathcal{E}}^{(2)}, R_{\mathcal{E}}^{(3)}) \approx 1$?

3 Experiments and Analyses

3.1 Setups

We selected two input sets, Arena Hard (Li et al., 2024b) and Alpaca Eval (Li et al., 2023), 18 LLMs as the systems to be evaluated, and 12 LLMs, including four proprietary OpenAI models and six open-source models, to serve as evaluation models. Please see Appendix C for detailed information.

3.2 RQ1: How to choose $\mathcal{X}, \mathcal{E}, \mathcal{T}, \mathcal{A}$ to maximize the bencher's performance?

This section discusses component selection for the bencher and includes a cost analysis.

Input Set. Table 1 confirms that using Arena Hard as input set always yields higher correlations with the system rankings of Chatbot Arena compared to Alpaca Eval through different combinations of $\mathcal{E}, \mathcal{T}, \mathcal{A}$.

Evaluation Type. Table 1 shows the performance of a bencher under different combinations of evaluation types and aggregation methods, with several representative LLMs as evaluation models. For many open-source models with fewer parameters, base pairwise is the optimal evaluation type, offering a significant advantage over other evaluation types. For strong proprietary models, the difference between base pairwise and pointwise evaluation types is small. Across all models

Table 1: Standard meta-evaluation results of different combinations of input sets, evaluation models, evaluation types, and aggregation methods (the correlation between the automatic benchers' and ChatBot Arena's evaluations). For the pairwise evaluation using a reference system, we show the results with gpt-4-0314 as the reference system. For the results with other LLMs as evaluation models, please refer to Table 4 and Table 5 in appendix.

used as evaluation models, 5-point pairwise generally performs worse than base pairwise, with the decline being particularly pronounced for open-source models, possibly due to their weaker ability to follow complex instructions. **Therefore, using 5-point pairwise as the evaluation type, as in Arena Hard, may be problematic.** In addition, by comparing the results of pairwise evaluation using the full data with those using GPT-4 as the reference system, we found that for most strong evaluation models, the performance of the bencher is similar when using the reference system, indicating that this is an efficient strategy. Further discussion on the reference system is in Appendix D.

Aggregation Method. As shown in Table 1, when the evaluation type is base pairwise, the system rankings produced by the Bradley-Terry model and win ratio aggregation methods are mostly the same. Interestingly, when the evaluation type is pointwise, mean, the most common aggregation method, is not always optimal. Moreover, when the evaluation model is a smaller open-source model, pointwise combined with the Bradley-Terry model significantly outperforms its combination with mean. After examination, we found that this is because the majority of instance-level scores produced by these evaluation models are very similar, and aggregating them using mean or median across all samples leads to system scores that are hardly effective. In contrast, converting these scores to base pairwise retains the slight differences in scores for different responses to the same input. On the other hand, for OpenAI models, the performance of aggregating pointwise type data using either mean or the Bradley-Terry model is comparable.

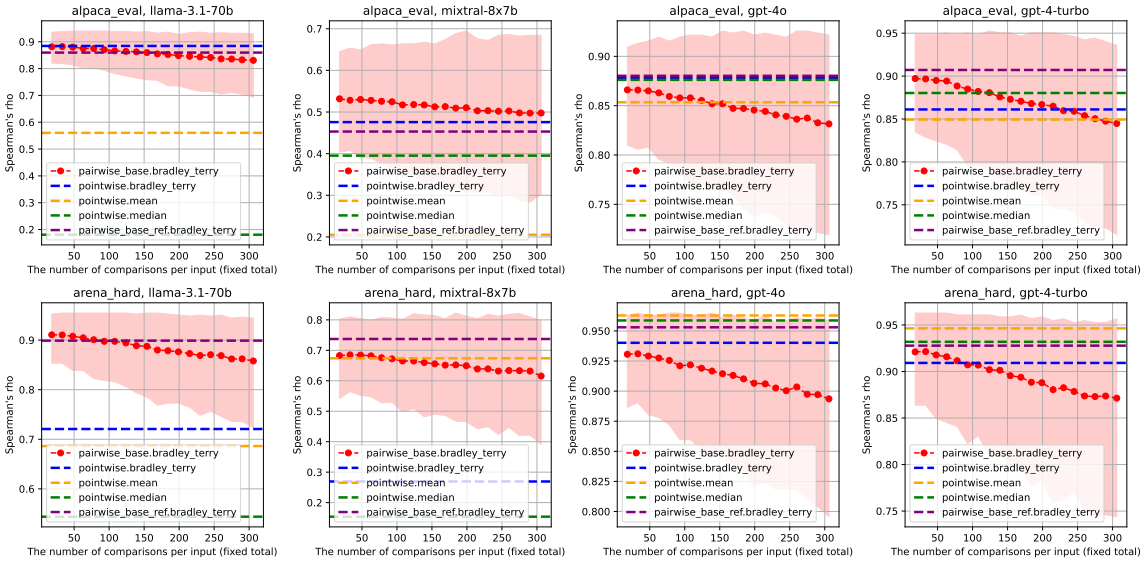

Figure 1: Bootstrapping mean and 95% confidence interval of the correlations between the system rankings of automatic pairwise evaluation and human judgment when the total number of examples is set equal to that of pointwise evaluation. Results for pointwise and pairwise evaluations using gpt-4-0314 as the reference system are shown as horizontal lines. Both input sets and comparisons are sampled with replacement, with 1000 iterations. See Figure 7 and 8 in the appendix for other evaluation models.

Table 2: Evaluation model rankings under Setting 1. The evaluation type and aggregation method are fixed to base pairwise and the Bradley-Terry model for all evaluation models.

Evaluation Models. Table 2 displays the performance of benchers with different LLMs as evaluation models. We found that gpt-4-turbo and gpt-4o are the strongest evaluation models. The rankings of evaluation models obtained from the Alpaca Eval and Arena Hard input sets show slight differences, but the correlation between them is high, with $\rho = 0.98$. Additionally, most of the smaller open-source models perform unsatisfactorily as evaluation models. However, llama-3.1-70b is an exception, performing even better than gpt-3.5-turbo and gpt-4o-mini.

Cost Analysis. In the previous analysis, we did not take into account the total number of instance-level evaluations produced by the evaluation models. As mentioned earlier, the total number of instance-level evaluations of pointwise evaluation and pairwise evaluation are different: pointwise evaluations amount to mn, whereas pairwise evaluations amount to $mn(n-1)$. This implies that using pairwise as the evaluation type will incur significantly higher costs, especially when using proprietary models as evaluation models. Therefore, we consider it necessary to limit the number of instance-level evaluations for pairwise to be equal to that of pointwise, i.e., mn. In this scenario, when using pairwise as the evaluation type, we need to balance the **number of inputs** with the **number of comparisons per input**. Figure 1 illustrates the bootstrapping mean and confidence intervals for base pairwise as the evaluation type under different numbers of comparisons per input. We found that:

1. When some open-source models are used as evaluation models, base pairwise still has a certain advantage even when the total number of instance-level evaluations for base pairwise is limited to that of the pointwise type.

2. As the number of comparisons per input increases (i.e., the number of inputs decreases), both the bootstrapping mean and the lower bound of the confidence interval for bencher performance decline. **This suggests that we should prioritize**

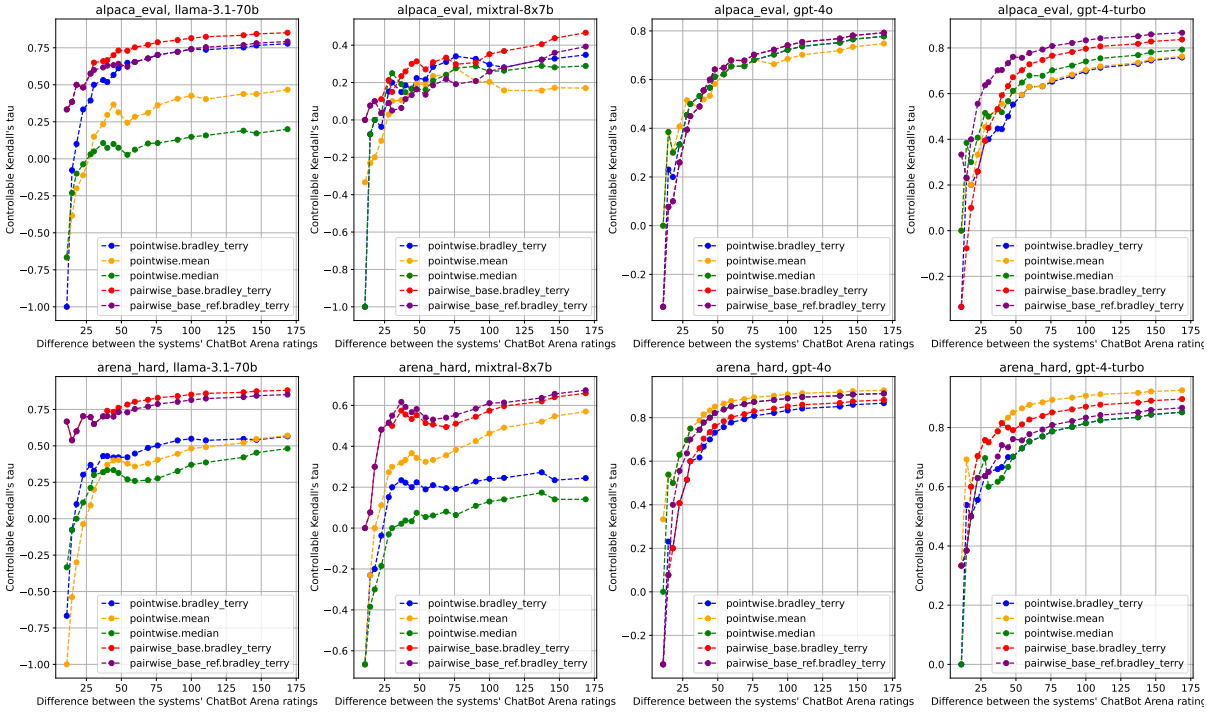

Figure 2: Controllable Kendall's tau (τ_u) between the system rankings from automatic LLM benchers and human judgment when only partial system pairs are used. The X-axis denotes the value of threshold u, which controls the maximum difference between the systems' ChatBot Arena ratings. For `pairwise_base_ref`, we show the results with gpt-4-0314 as the reference system. Across all settings, we found that the benchers' performance degrades when they evaluate close-performing systems. See Figure 15 and 16 in the appendix for other evaluation models.

using more inputs rather than conducting more comparisons per input. As mentioned earlier, using a reference system is a practical strategy. For a more detailed cost analysis, please see appendix E.

3.3 RQ2: Does the performance of automatic LLM benchers degrade when evaluating LLMs with similar performance?

As shown in Figure 14 in the appendix, the performance differences among the selected LLM systems are uneven, so the difficulty of distinguishing between different LLMs varies. We introduced a threshold u so that only system pairs with performance differences smaller than it are used to calculate τ_u. Since fewer system pairs meet the requirement as u decreases, we can control the threshold u to select a specific proportion of system pairs. Specifically, we selected 5%, 10%, ..., and 100% of system pairs and observed the changes in bencher performance. Figure 2 shows that as u decreases (i.e., the performance differences between systems become smaller), the performance of almost all benchers declines sharply. For example, when Alpaca Eval is used as the input set and gpt-4o is used as the evaluation model, we found that the Bencher's performance degrades drastically by 25 points when comparing system pairs whose ChatBot Arena ratings differ by approximately 40 points, which is similar to the difference between qwen-1.5-72B and gpt-4-0314.

3.4 RQ3: Can we use instance-level rankings of evaluation models as a good reference to select evaluation models for LLM benchers?

Figure 3 displays the Spearman's ρ between evaluation model rankings obtained from different datasets and settings. We observed the following key findings: First, the evaluation model rankings vary considerably across different settings, as evidenced by the fact that none of the Spearman's ρ values are found to be 1.0. Second, system-level evaluation results are more consistent with each other. The evaluation model ranking obtained from Setting 3 is very similar to that from Setting 1, despite the systems to be evaluated and input sets in Alpaca Farm being different from those in Setting 1. In contrast, although the input set and involved systems in `alpaca_farm_instance` (Setting 2) and `alpaca_farm_system` (Setting 3)

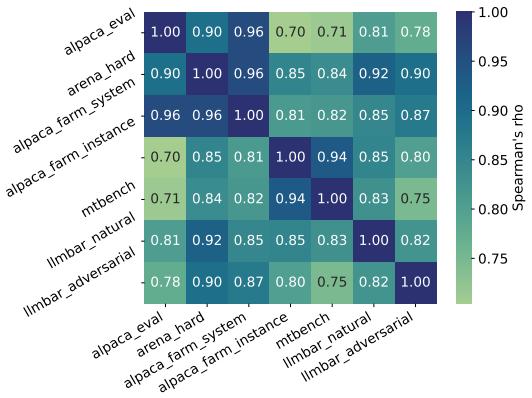

Figure 3: Spearman's ρ between the evaluation model rankings under different meta-evaluation settings. **alpaca_eval** and **arena_hard** denote the evaluation model rankings are produced under **Setting 1**. **alpaca_farm_system** denotes that evaluation model rankings are produced under **Setting 3** where the instance-level human judgment of Alpaca Farm is used as ground truth, the Bradley-Terry model is used to aggregate both automatic evaluation and human evaluation. **alpaca_farm_instance**, **mtbench**, **llmbar_natural**, and **llmbar_adversarial** refer to that the evaluation model rankings are produced under **Setting 2** where instance-level human judgment of Alpaca Farm, MT-Bench, LLMBAR are used.

are exact the same, the evaluation model rankings they produce differ substantially. This suggests that whether the aggregation methods are applied has a great impact on the evaluation results. In addition, compared to `llmbar_adversarial`, the evaluation model ranking from `llmbar_natural` is more closely aligned with that from the system-level evaluation results. This is probably due to the responses in `llmbar_adversarial` are not from real systems, which makes it more different from system-level evaluation setting.

4 Related Work

Automatic LLM benchers. This kind of research always create a automatic leaderboard for various LLMs. As mentioned above, the main contribution of Arena Hard (Li et al., 2024b) lies in designing a pipeline for automatically constructing a challenging input set, also for Wildbench (Lin et al., 2024). In contrast, Alpaca Eval 2 (Dubois et al., 2024), focus on designing better evaluation models and use existing instruction datasets as the input set. Besides, MixEval (Ni et al., 2024) build LLM benchmarks by strategically mixing off-the-shelf ground-truth-based benchmarks that match real-world user queries. Zhao et al. (2024) automate the entire LLM evaluation process using LLM-powered agents. There is another line of research that specifically focuses on how build LLM-based evaluation models (Gao et al., 2024).

Comparison between different evaluation types and aggregation methods. Liusie et al. (2024) compared the effectiveness of LLM-based evaluation models with absolute score prediction and pairwise comparison on several NLG tasks. Liu et al. (2024b) investigated which evaluation type is better under the instance-level evaluation settings of instruction following thoroughly. However, these studies are not oriented to system-level evaluation and aggregation methods are not involved. Liu et al. (2024a) proposed a more efficient rank aggregation method, but it is also used for ranking different instances rather than systems. Peyrard et al. (2021) showed the advantages of the Bradley-Terry model over mean and median on aggregating instance-level scores of NLP systems but this study focuses on what aggregation method makes more sense to choose as part of an evaluation metric. Daynauth et al. (2024) proposed three desirable properties of aggregation methods and evaluated the robustness of several aggregation methods. It is worth mentioning that a concurrent work also focused on automatic system-level LLM judges and analyzed their decisiveness and bias (Gera et al., 2024).

Instance-level evaluation of evaluation models. A lot of studies have focused on collecting instance-level human judgments to evaluate LLM-based evaluation models (Zeng et al., 2024b; Zheng et al., 2023; Dubois et al., 2023; Zhang et al., 2023; Wang et al., 2024b; Li et al., 2024a; Ye et al., 2024). However, to the best of our knowledge, no work has examined whether the evaluation results of them are consistent with the system-level settings.

5 Conclusions

We have explored how to construct effective LLM benchers and evaluate them. We provide several recommendations on how to combine the four components of an LLM bencher, analyze the current evaluation settings for LLM benchers and the evaluation models that serve as their components, and highlight the shortcomings in these settings. Our code and data will be available at `https://github.com/yale-nlp/RealRank`.

Limitations

The observations and conclusions of this paper are dependent on the datasets and selected LLMs, and cannot be guaranteed to apply under all circumstances. Furthermore, the open-source models included as evaluation models are relatively small in scale, which may not reflect the evaluation capabilities of larger open-source models.

A Conversion of 5-Point Pairwise and Pointwise Evaluation Type to Base Pairwise Type

To convert 5-point pairwise comparisons into base pairwise comparisons, we apply the following rules as Li et al. (2024b):

- $o_{ij} \gg o_{kj}$ or $o_{ij} \ll o_{kj}$ converts to 6 instances of $o_{ij} > o_{kj}$ or $o_{ij} < o_{kj}$
- $o_{ij} > o_{kj}$ or $o_{ij} < o_{kj}$ converts to 2 instances of $o_{ij} > o_{kj}$ or $o_{ij} < o_{kj}$
- $o_{ij} = o_{kj}$ converts to 1 instance of $o_{ij} > o_{kj}$ and 1 instance of $o_{ij} < o_{kj}$

For pointwise evaluation type, the conversion follows this rule, and the total number of its instances is expanded to $mn(n-1)/2$.

$$\mathcal{T}_{\text{base.pairwise}}(\mathcal{E}, x_j, o_{ij}, o_{kj}) =$$
$$\begin{cases} o_{ij} > o_{kj} & \text{if } \mathcal{T}_{\text{pointwise}}(\mathcal{E}, x_j, o_{ij}) > \mathcal{T}_{\text{pointwise}}(\mathcal{E}, x_j, o_{kj}) \\ o_{ij} < o_{kj} & \text{if } \mathcal{T}_{\text{pointwise}}(\mathcal{E}, x_j, o_{ij}) < \mathcal{T}_{\text{pointwise}}(\mathcal{E}, x_j, o_{kj}) \end{cases}$$

B Definitions of Spearman's ρ and Kendall's τ

$$\rho(R_A, R_H) = 1 - \frac{6\sum_{i=1}^{n}(R_A(s_i) - R_H(s_i))^2}{n(n^2-1)}$$

Where $R_A(s_i)$ is the rank of system s_i produced by the automatic bencher and n is the total number of systems being ranked.

$$\tau(R_A, R_H) = \frac{C - D}{\sqrt{(C + D + T_A)(C + D + T_H)}}$$

Where C is the number of concordant pairs (i.e., pairs of systems (s_i, s_k) where the rank order between s_i and s_k is the same in both R_A and R_H). D is the number of discordant pairs (i.e., pairs where the rank order differs between R_A and R_H). T_A is the number of ties in the automatic bencher's ranking R_A (i.e., where two systems have the same rank). T_H is the number of ties in the human-provided ranking R_H.

C Experimental Setup

Input Set. For RQ1 and RQ2, we selected two input sets, Arena Hard (Li et al., 2024b) and Alpaca Eval (Li et al., 2023), containing 500 and 805 inputs, respectively.

Systems. 18 LLMs that ranked highly on Chatbot Arena were chosen as the systems to be evaluated[7]. The data from Chatbot Arena as of July 30, 2024, was used to compute the scores and rankings, serving as the ground truth. We reused the responses from the systems on Arena Hard, collected by Li et al. (2024b), and the responses on Alpaca Eval, collected by Li et al. (2023).

Evaluation Models. We selected 10 LLMs, including four proprietary OpenAI models and six open-source models, to serve as evaluation models. These include models gpt-4-turbo (gpt-4-turbo-2024-04-09 (OpenAI, 2023)), gpt-4o (gpt-4o-2024-08-06), gpt-4o-mini (gpt-4o-mini-2024-07-18), gpt-3.5-turbo (gpt-3.5-turbo-0125), llama-3.1-70b (meta-llama/Llama-3.1-70B (Dubey et al., 2024)), qwen-2.5-72b (Qwen/Qwen2.5-72B-Instruct (Yang et al., 2024)), mixtral-8x7b (mistralai/Mixtral-8x7B-Instruct-v0.1), llama-3.1-8b (meta-llama/Llama-3.1-8B), glm-4-9b

[7] gpt-4-turbo-2024-04-09, claude-3-opus-20240229, claude-3-sonnet-20240229, gpt-4-0314, gpt-4-0613, mistral-large-2402, mistral-medium, qwen1.5-72b-chat, claude-2.0, claude-2.1, gpt-3.5-turbo-0613, mixtral-8x7b-instruct-v0.1, yi-34b-chat, gemini-pro, dbrx-instruct-preview, tulu-2-dpo-70b, vicuna-33b, starling-lm-7b-alpha

(THUDM/glm-4-9b-chat (Zeng et al., 2024a)), mistral-7b-v0.3 (mistralai/Mistral-7B-Instruct-v0.3), mistral-7b-v0.1 (mistralai/Mistral-7B-Instruct-v0.1 (Jiang et al., 2023)), llama-2-7b (meta-llama/Llama-2-7b-chat-hf).

Evaluation Types. The evaluation types were implemented as follows. As for pointwise, given an input and a response, evaluation models were asked to score the response on a 0-9 scale. We followed the method of Liu et al. (2023), using token probability to compute a weighted sum of the model's output for the 0-9 scale as the final instance-level score. For base Pairwise or 5-Point Pairwise, given an input and two responses, evaluation models were asked to either choose the better response or make a five-category comparison. The results of the automatic evaluations were extracted using regular expressions. If the evaluation model did not provide the requested judgment, a random evaluation result was assigned to the instance. The specific prompt designs can be found in the appendix.

Aggregation Methods. We adopted Chatbot Arena's implementation of the Bradley-Terry model and implemented other aggregation methods ourselves.

Additional Setup for RQ3. We selected three datasets containing instance-level human judgments: Alpaca Farm (Dubois et al., 2023), LLMBAR (Zeng et al., 2024b), and MT-bench (Zheng et al., 2023). Among these, Alpaca Farm has a larger data scale, and 22 systems are involved, making it suitable for both Setting 2 and Setting 3. The number of systems in MT-bench and LLMBAR is too small, or system information is unavailable, so they can only be used for Setting 2. Additionally, LLMBAR contains two subsets: natural and adversarial. The natural subset contains responses from real systems, while the responses of the adversarial subset were generated using adversarial techniques.

D Discussions on Reference Systems

Although using a strong system as a reference system is a common practice, its rationale has not been thoroughly examined. Therefore, we calculated the performance of the bencher when each of the 18 evaluated systems is used as the reference system and demonstrated the relationship between the bencher's performance and the Chatbot Arena rating of the LLM used as the reference system, as shown in Figures 4, 5, and 6. We found that, for most strong evaluation models, the performance of the bencher is negatively correlated with the level of the LLM used as the reference system. Therefore, we believe this issue warrants further investigation, and at the very least, we should be more cautious in selecting the reference system.

E Cost Analysis

To perform a more granular cost analysis of the bencher, we measure cost in terms of the total number of tokens consumed during automatic evaluation and the evaluation model's cost per million tokens. For OpenAI models, we use the pricing for the Batch API[8] provided on their official website. For open-source models, we estimate costs based on electricity consumption during inference on GPU servers, ignoring the expenses of purchasing and maintaining GPUs.

Specifically, we estimate the number of tokens processed per second by open-source models based on throughput data from the vLLM blog[9]:

- **8B Model on 1xH100:** Approximately 30 queries per second (QPS) with an average of 179 output tokens per query. Tokens per second: $30 \times 179 = 5370$ tokens/second.
- **70B Model on 4xH100:** Approximately 15 QPS with an average of 179 output tokens per query. Tokens per second: $15 \times 179 = 2685$ tokens/second.

Next, we calculate the time required to process 1 million tokens:

- **8B Model:** $\frac{1000000}{5370} \approx 186.2$ seconds.
- **70B Model:** $\frac{1000000}{2685} \approx 372.4$ seconds.

We then estimate the energy consumption for processing 1 million tokens:

- **8B Model on 1xH100:** Energy consumed = Power (700W) $\times$ Time (186.2 seconds) = 130340 watt-seconds $\approx$ 36.21 watt-hours (Wh).
- **70B Model on 4xH100:** Energy consumed per GPU = Power (700W) $\times$ Time (372.4 seconds) = 260680 watt-seconds $\approx$ 72.41 Wh,
  Total energy for 4 GPUs = 72.41 Wh $\times$ 4 = 289.6 Wh.

[8] https://openai.com/api/pricing/

[9] https://blog.vllm.ai/2024/09/05/perf-update.html

Model	$/1M tokens
llama-3.1-8b	0.006
llama-3.1-70b	0.05
qwen-2.5-72b	0.05
gpt-4o	1.25
gpt-4-turbo	5.00
gpt-3.5-turbo	0.25
gpt-4o-mini	0.075

Table 3: Financial cost of different evaluation models during inference. The prices of open-source models are estimated by electricity rate. We use the cost of input tokens because our output length is negligible.

Finally, assuming an electricity rate of $0.17 per kilowatt-hour (kWh), which is the average rate in the US[10]:

- **8B Model:** Cost $= 36.21\,\text{Wh} \times \frac{\$0.17}{1000\,\text{Wh}} = \$0.00577\,(\sim \$0.006)$ per 1M tokens.
- **70B Model:** Cost $= 289.6\,\text{Wh} \times \frac{\$0.17}{1000\,\text{Wh}} = \$0.0492\,(\sim \$0.05)$ per 1M tokens.

Thus, we derived the cost per 1M tokens for each model, as shown in Table 3. Furthermore, we performed sampling with replacement on the input set at proportions of 0.02, 0.03, 0.04, 0.05, 0.10, and up to 1.00 to generate input sets of varying sizes [11]. Consequently, the cost of different combinations of evaluation models, evaluation types, and aggregation methods across input sets of different sizes can be estimated. Figures 9 and 10 illustrate the best-performing combinations under varying budget constraints. From these results, we observe that open-source models demonstrate a significant advantage when the budget is highly constrained.

F Confidence Interval Analysis

In Table 1, we computed the performance of benchers of different combinations of $\mathcal{X}, \mathcal{E}, \mathcal{T}, \mathcal{G}$, but these are merely point estimates. To assess the accuracy of our estimates, we obtained the 95% confidence intervals for bencher performance through bootstrapping. As shown in Figure 11, 12, and 13, with an increasing number of inputs, the confidence intervals for most benchers become narrower. However, for some combinations of evaluation type and aggregation method, the confidence intervals remain relatively wide when the sample ratio equals 1.0, indicating a high degree of uncertainty in the performance estimates. In contrast, the combination of base pairwise and the Bradley-Terry model has narrower confidence intervals (the red section), suggesting that the performance estimates for this combination are more precise.

Beneath the Surface of Consistency: Exploring Cross-lingual Knowledge Representation Sharing in LLMs

Abstract

The veracity of a factoid is largely independent of the language it is written in. However, language models are inconsistent in their ability to answer the same factual question across languages. This raises questions about how LLMs represent a given fact across languages. We explore multilingual factual knowledge through two aspects: the model's ability to answer a query consistently across languages, and the ability to "store" answers in a shared representation for several languages. We propose a methodology to measure the extent of representation sharing across languages by repurposing knowledge editing methods. We examine LLMs with various multilingual configurations using a new multilingual dataset. We reveal that high consistency does not necessarily imply shared representation, particularly for languages with different scripts. Moreover, we find that script similarity is a dominant factor in representation sharing. Finally, we observe that if LLMs could fully share knowledge across languages, their accuracy in their best-performing language could benefit an increase of up to 150% on average. These findings highlight the need for improved multilingual knowledge representation in LLMs and suggest a path for the development of more robust and consistent multilingual LLMs.

1 Introduction

Pretrained large language models (LLMs) have demonstrated a remarkable capacity to encode and retrieve factual knowledge (Petroni et al., 2019; Chang et al., 2024) across diverse languages (Kassner et al., 2021; Jiang et al., 2020). However, substantial variation in model performance across languages with a strong bias toward high-resource languages (Kassner et al., 2021; Jiang et al., 2020; Fierro and Søgaard, 2022; Jiang et al., 2022; Qi et al., 2023) highlights the issue of cross-lingual knowledge (in-)consistency.

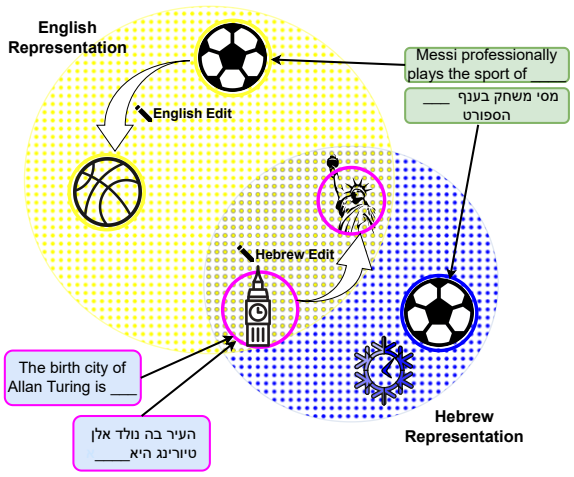

Figure 1: Illustration of our method for distinguishing between cross-lingual consistency and representations sharing in a pairwise language setting. The sports (green) question demonstrates mere cross-lingual answer consistency, while the query about Allan Turing's birthplace (blue) exemplifies a shared underlying representation. Edits to the shared representation propagate across both languages, unlike the consistent-only fact. This method exposes the crucial difference between surface-level answer consistency and genuine cross-lingual knowledge sharing.

This inconsistency raises questions about how LLMs represent factual knowledge in different languages. On one end of the range of possibilities, models may store a set of distinct knowledge copies for each language. On the other end, models may store a single, shared representation of the factual knowledge and "decode" it into surface forms in different languages. Thus, a shared representation manifests in consistency across languages, but consistent behavior can also occur without it.

While consistency can be readily measured through agreement on identical queries across languages, measuring the extent to which knowledge representation is shared across languages requires more than just evaluating black box outputs. To

Findings of the Association for Computational Linguistics:
NAACL 2025, pages 4630–4644

quantify representation sharing, we propose editing factual knowledge in one language and examining the effects on other languages. For this purpose, we employ three knowledge editing techniques: two locate-and-edit methods, ROME (Meng et al., 2022a) and MEMIT (Meng et al., 2022b), and a finetuning-based method (Gangadhar and Stratos, 2024). These methods are designed to surgically modify the relevant components of the model responsible for storing factual knowledge and only them, as illustrated in Fig 1.

As a test bed for our experiments, we compiled CLIKE, a multilingual "fill-in-the-blank" factual knowledge probing dataset with 35k samples, designed for evaluation and editing across paraphrases in 13 languages with 7 scripts. We experiment with diverse 7B-parameter LLMs supporting different sets of languages in different setups: monolingual, bilingual, multilingual, and language-extended models. Our analysis reveals a significant disparity in factual knowledge retrieval across languages. We assessed that on average these models answer correctly in at least one language 150% more facts than their best-performing language and triple the number of facts averaged across all 13 languages.

We assess for the first time the extent of cross-lingual knowledge representation sharing. We find that languages within the same script family exhibit the highest degree of representation sharing. This trend is consistent across all the models we studied, regardless of their level of multilingualism. Moreover, we find that high agreement in answers across certain language pairs does not entail shared internal representations, especially with language pairs that do not share the same script. This mismatch is particularly evident when comparing lower-resource languages to any language with a different script, which shows high consistency but limited representation sharing.

We expect that shedding light on these mechanisms will support the development of better multilingual models, with more efficient representation of factual knowledge. This will in turn lead to a more balanced knowledge across different languages, ultimately enhancing LLM performance across languages.

2 Methodology

In our analysis, we would like to measure two main aspects:

1. **Cross-lingual Knowledge Consistency (CKC).** The extent to which a model shows consistency in answering factual questions when asked in different languages.

2. **Cross-lingual Knowledge Representation Sharing (CKR).** The degree to which the model uses a common inner representation for the same fact across different languages.

2.1 Measuring CKC

For simplicity, we say an LLM knows a fact in a specific language, modeled as a question and answer pair, if it can correctly answer it through a query written in this language. We start by defining a model's Knowledge Base (KB) for a specific language, as a set of facts an LLM 'knows' in that language. Formally, for a given LLM M and a dataset $D = \{f_i\}_{i\in[N]}$ of facts. Where $f_i^l := (q_i^l, a_i^l)$ is a question-answer pair written in the language $l \in L$:

$$KB_l := \{f_i \in D \mid M\left(q_i^l\right) = a_i^l\}.$$

To capture the pairwise relationship of knowing a fact in language l_1 to know it in l_2, we define $C_{(l_1,l_2)}$ as the conditional probability

$$P(f_i \in KB_{l_2} \mid f_i \in KB_{l_1}) = \frac{|KB_{l_1} \cap KB_{l_2}|}{|KB_{l_1}|}.$$

We continue by defining the Number of Consistent Languages (NCL) a fact f known in as:

$$NCL(f) = |\{l \in L : f \in KB_l\}|$$

With this aggregation, we can then compute the overall CKC of a model, as the average number of languages in which the LLM knows a fact:

$$\mathbb{E}[NCL] = \frac{1}{N}\sum_{f\in D} NCL(f)$$

2.2 Measuring CKR

Measuring the extent of shared knowledge representation across languages in LLMs cannot be done by merely evaluating model outputs. The same correct answer to a factual query across multiple languages could be generated from distinct, language-specific representations within the model, rather than a unified, language-agnostic abstraction. This requires a more sophisticated approach.

To measure this, we use an editing method E that modifies the model's parameters to provide a

wrong answer for a query in a given language. We then examine the impact of such a change on the same fact query in other languages. Let M_i^l denote the updated model applying E to the fact f_i^l in the language l to the target answer t_i^l. The model's KB for a specific language l' after the modification in language l is defined as the collection of facts for which the incorrect target answer, edited in language l, also propagates to language l', which can be formally expressed as:

$$KB_{l'}^{l} := \{f_i \in KB_{l_1} : M_i^{l_1}\left(q_i^{l_2}\right) = t_i^{l_2}\}.$$

We can then estimate the amount of pairwise CKR between a language l_1 to l_2 by defining $SR_{(l_1,l_2)}$ as the conditional probability

$$P(f \in KB_{l_2}^{l_1} \mid f \in KB_{l_1}^{l_1}) = \frac{\left|KB_{l_1}^{l_2} \cap KB_{l_1}^{l_1}\right|}{\left|KB_{l_1}^{l_1}\right|}.$$

We further define the Number of Transferred Languages (NTL) for a given fact edited in the language l as

$$NTL(f^l) = \left|\{l' : f \in KB_{l'}^{l}\}\right|$$

With this aggregation, we can then compute overall CKR, as the average number of languages in which the LLM represents a fact as

$$\mathbb{E}[NTL] = \frac{1}{|L|}\sum_{l \in L}\left(\frac{1}{|KB_l|}\sum_{f \in KB_l} NTL(f^l)\right).$$

3 Experimental Setup

3.1 Data

Dataset. We present CLIKE (Cross-LIngual Knowledge Editing), a dataset for evaluating and editing factual knowledge of pretrained LMs across languages and paraphrased expressions. CLIKE contains approximately 35k facts spanning 13 languages: English (en), French (fr), Italian (it), Spanish (es), Russian (ru), Ukrainian (uk), Bulgarian (bg), Hindi (hi), Bengali (bn), Chinese (zh), Japanese (ja), Hebrew (he), and Arabic (ar). Each fact is modeled as a language-independent (subject, relation, object) triplet and each relation has 3 paraphrased natural language templates for every language. Each template forms a sentence that conveys a fact and ends with the object, which we omit and expect the model to fill.

For example, the triplet $(Bach, BirthCity, Leipzig)$ will be converted to 'Bach was born in the city of' and 'The birth city of Bach is', and 'The birthplace of Bach is the city of' expecting the pretrained LM to complete the prompt with 'Leipzig' correctly using its initial pretraining task without altering the model with a finetuning intervention.

Fact Collection. Following a similar approach to Petroni et al. (2019); Sciavolino et al. (2021); Kassner et al. (2021); Wei et al. (2024), fact triplets were collected from Wikidata Query Service. We manually crafted and published 14 SPARQL relation queries. Each query extracts wikidata entries for subjects and objects satisfying the query relation with their labels in all available languages. We then filtered all triplets with labels containing less than 8 of the examined languages to balance the languages in the dataset. Appendix B includes the languages and relation distributions.

Dataset Construction. We used "Gemini Advanced" and "Claude Opus" to generate the templates of each relation in all languages. For each relation, we generated 3 paraphrases adjusted to grammar rules such as the gender of the subject. The prompts for these templates were executed on the models' official websites (Gemini, Claude). Subsequently, professional translators or native speakers refined the templates and sampled generated fill-in-the-blank queries across all languages, following instructions detailed in Appendix A. While most template objects appeared at the end, some languages (Mandarin, Hindi, and Bengali) required the object placement within the sentence to maintain grammatical correctness. The LLMs handle these variations through few-shot demonstrations that show the complete sentence structure in context. For the knowledge editing task, we generated false but plausible objects for each fact by randomly sampling from other facts within the same relation category.

3.2 Models

We examine a range of LLMs with 7B parameters and decoder-only architectures. We focus on base pretrained language models to capture the knowledge acquired during the pretraining process, prior to any finetuning. BLOOM-7B (Scao et al., 2022) serves as our **multilingual** model. Qwen-7B (Bai et al., 2023) represents a **bilingual** Chinese-English model with a low tokenization compression rate

multilingual vocabulary. We include two **monolingual** English models: Llama-2-7B (Touvron et al., 2023) and Mistral-7B-v0.1 (Jiang et al., 2023). Additionally, we examine two **language-extended models**, Chinese-llama-2-7B, and Hebrew-Mistral-7B, based on Llama-2-7B and Mistral-7B-v0.1 with additional pretraining in English and their expanded language (EL) and an expand EL tokenizer vocabulary. These models represent a diverse set of multilingual configurations, enabling a extensive analysis of cross-lingual knowledge representation.

3.3 Knowledge Editing Methods

We employ three knowledge editing methods: Finetuning (FT) (Gangadhar and Stratos, 2024), ROME (Meng et al., 2022a), and MEMIT (Meng et al., 2022b). The ROME and MEMIT editing methods leverage causal mediation analysis (Vig et al., 2020a,b) to identify the LM layer that has causally contributed to factual knowledge recall, suggesting the middle MLP layers act as key-value associative memory. ROME then computes a closed-form rank-one update to the layer's weights, inserting a new fact while minimizing disruption to existing knowledge stored in the weights. Similarly, MEMIT identifies a range of MLP layers that jointly contribute to the model's factual associations. Then it iteratively updates the weights of each MLP layer, distributing the changes across the MLP layers.

Both ROME and MEMIT use interpretability techniques to precisely locate and surgically modify the relevant components of the model responsible for storing factual knowledge. This approach allows for direct control over the model's memorized information while preserving its overall capabilities, providing a framework for isolating changes in actual knowledge without altering other components.

Finetuning, our baseline approach, involves updating the weights of all middle layers in the model without the MLP restrictions imposed by ROME and MEMIT. For each fact to be edited, we finetuned the model on a single example consisting of the edition prompt paired with its new target answer. It incorporates new factual knowledge that resembles standard language model training practices.

We use the EasyEdit code library (Wang et al., 2023b) to perform all language model knowledge edits. Default parameters are employed for all models except BLOOM. Since BLOOM lacks a pre-existing implementation, we optimized and published custom hyperparameters for the editing methods.

3.4 Metrics and Evaluation

We employed the Exact Match (EM) metric to evaluate all answers to queries across our experiments. To provide context for the pretrained LLM, we used 3-demonstrations fewshot concatenated facts for both evaluation and editing tasks, maintaining the same examples and order. All answer generation was performed using greedy decoding to ensure deterministic outputs.

Model performance and CKC in a given language were assessed as follows. The overall accuracy for a language was computed as the percentage of facts correctly answered in at least one paraphrased form. $C(l_1, l_2)$, was measured by computing the mean score in language l_2 across all paraphrases for facts known in language l_1. Similarly, within-language consistency, $C(l, l)$, was computed using the same approach, evaluating the model's consistency across paraphrases within a single language.

For the knowledge editing experiments, we randomly selected 500 known facts in each language to modify. We assessed the effectiveness of these edits using three standard metrics: *Reliability*, *Generalization*, and *Locality*. Reliability measures the accuracy of the model on the edited prompt itself. Generalization, denoted with $SR(l1, l2)$, evaluates the mean score across all paraphrases of the edited fact in all languages, including the language in which the edit was made (l1). This quantifies how well the edit transfers across both languages and paraphrases variations of the fact. For Locality testing, we randomly sampled known facts for each language and evaluated the model's mean accuracy to answer these unrelated queries correctly. This ensured that the edits did not negatively impact other knowledge in different languages.

4 Results

Before presenting our main findings, we first validate the methodology's performance. We found a strong correlation (0.87) between the results obtained from different knowledge editing methods. This consistency across various editing techniques suggests that our findings are robust and not reliant on a specific method. Given this consistency, we primarily present results using MEMIT, with other methods' results available in Appendix C.

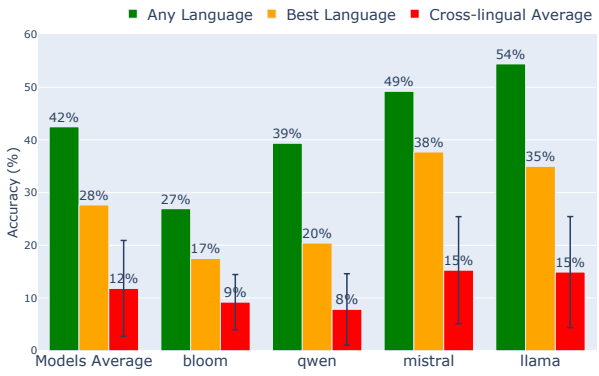

Figure 2: Cross-lingual performance variability: the accuracy of factual knowledge retrieval across different languages for several LLMs supporting different language sets. 'Any Language' (green) – facts known in at least one language, 'Best Language' (orange) – accuracy in the best-performing language, and 'Cross-lingual Average' – mean accuracy across all 13 languages in the CLIKE dataset, with error bars indicating standard deviation.

Additionally, all knowledge editing methods maintained high locality scores (averaging above 70%), indicating that edits were specific and preserved broader model knowledge. Furthermore, all models exhibit some variation in performance across paraphrases even within the same language, aligning with findings from Mizrahi et al. (2024) and further justifying our approach of assessing knowledge using multiple paraphrases.

4.1 The Issue of Knowledge Variability

Large language models (LLMs) exhibit significant variability in their factual knowledge retrieval across different languages, as illustrated in Fig. 2. Our analysis of four 7B-parameter LLMs reveals a striking disparity: while models demonstrate knowledge of 42.5% of the facts on average in at least one language, their best-performing language achieves only 27.6% accuracy, and their average performance across all 13 languages in the CLIKE dataset is merely 11.8%.

If models could share knowledge across all languages, the best-performing language could potentially increase its accuracy by up to 53%. Moreover, models could then potentially more than triple their current cross-lingual average accuracy. This observation motivates our subsequent investigations into CKR, as we seek to understand and potentially leverage these untapped reservoirs of knowledge.

4.2 Consistency Does Not Imply Representation Sharing

We decouple CKC and CKR between languages, examining both general measures across languages (Fig. 3) and pairwise language relationships addressing their specific identities (Fig. 4). Our analysis reveals that high CKC does not necessarily imply high CKR, and in some cases, we observe inverse patterns.

At the general level, we observe for all models that $\mathbb{E}[NCL]$ is consistently higher than $\mathbb{E}[NTL]$, indicating that models tend to exhibit CKC across more languages than they share representations between. Interestingly, while $\mathbb{E}[NCL]$ values show considerable variation across models, $\mathbb{E}[NTL]$ values are more uniform. The persistent gap between $\mathbb{E}[NCL]$ and $\mathbb{E}[NTL]$ across all models highlights that consistent answers do not necessarily translate to shared internal representations. Moreover, we find that models with a lower proportion of facts known in only one language ($NCL = 1$) tend to have a higher proportion of facts represented in only one language ($NTL = 1$) as shown in Fig. 3.

At the pairwise language level, we find differences between CKC and CKR patterns. For instance, most models (except Qwen) exhibit a high degree of CKC among low-resource languages with different scripts (Chinese, Japanese, Hebrew, Arabic). However, when examining CKR, we find limited evidence of shared encoding between these languages. Conversely, we observe a higher degree of shared representation among Cyrillic languages compared to the shared representation between Cyrillic and Latin languages. This is despite the fact that CKC scores show an opposite trend, with higher CKC between Cyrillic and Latin languages than among Cyrillic languages themselves.

4.3 The Key Role of the Language Script

Our analysis provides quantifiable measures of CKR in LLMs. Following previous work (Qi et al., 2023; Beniwal et al., 2024), our study highlights the importance of the script of a language for multilingual knowledge. We observe that the pairwise SR measure is relatively consistent across models, despite their varying language support.

We find that languages within the same script family exhibit the highest degree of CKR across all models. As shown in Fig. 4, we observe a script-based grouping in both CKC and CKR likely highlighting a tokenization induced bias (Singh et al.,

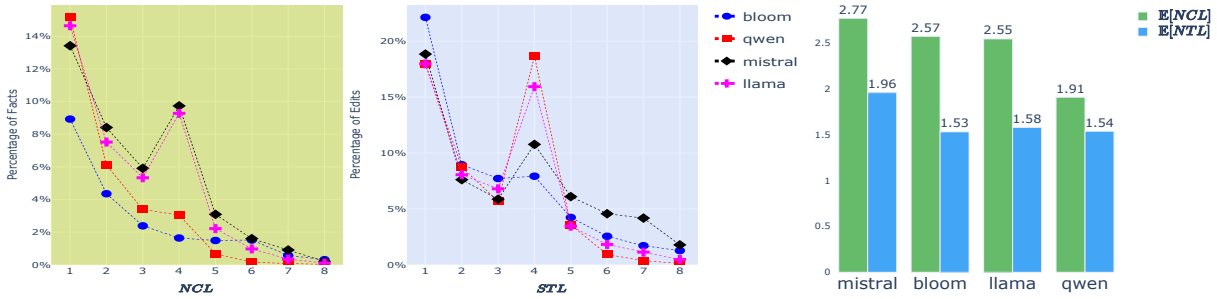

Figure 3: Distribution and Expectation of CKC and CKR. Left: Percentage of facts known (NCL) or represented (NTL) across multiple languages for different models. Right: Expected number of languages per fact (E[NCL]) and expected number of languages sharing representation per edited fact (E[NTL]) for each model, illustrating the relationship between knowledge CKC and CKR.

2019). Notably, we observe strong CKR between languages with Latin scripts (English, French, Italian, Spanish) and between languages with Cyrillic scripts (Russian, Ukrainian, Bulgarian). For Devanagari script languages (Hindi, Bengali) we observe relatively high CKR for models that perform well on these languages (Bloom, Mistral).

While most CKR occurs among languages that use the same script, there is still some knowledge transfer between languages with different scripts. This cross-script transfer is particularly evident between Cyrillic and Latin script languages across various models. Additionally, in specific cases, such as with the BLOOM model, we observe a moderate degree of CKR between seemingly unrelated language pairs, e.g., 28% from Italian to Hindi.

Notably, these relations between language scripts are sometimes asymmetrical. For example, knowledge in Cyrillic script languages implies a higher probability (approximately 40-60%) of knowing the same facts in Latin script languages. However, the reverse relation is weaker, with only about 10-20% probability of Cyrillic knowledge given Latin script knowledge. A similar asymmetrical relation appears across models suggesting a stronger transfer of knowledge from Cyrillic to Latin. We hypothesize that the dominance of Latin script languages, especially English, in the training data leads to more robust fact representations in Latin scripts, facilitating easier transfer from Cyrillic to Latin than vice versa.

4.4 Impact of Model Design Languages

How does a model's designed language support affect its CKR and CKC patterns? Although the patterns of CKR are relatively similar across models supporting different language sets, our analysis reveals some nuanced differences.

The multilingual BLOOM model demonstrates the highest pairwise average of language pairwise CKC (36%) and CKR (8.4%) across different script pairs. As shown in Fig. 4, BLOOM exhibits notable transfer between seemingly unrelated language pairs. These cross-script patterns validate BLOOM's design as a multilingual model, emphasizing its cross-lingual relationships rather than its overall low accuracy performance.

We find that the bilingual English-Chinese Qwen model is showing relatively high overall accuracy in Chinese. However, this Chinese knowledge remains largely distinct from English both in terms of language pairwise CKC and CKR Fig. 4. This pattern validates Qwen's design as a bilingual model, emphasizing its language-specific capabilities rather than cross-script knowledge sharing. Surprisingly, when examining the global shared representation, Qwen exhibits a higher number of 4-lingual representations sharing (NTL = 4) from uniquely represented facts. Although Qwen lacks cross-script knowledge sharing, it developed some degree of multilingual representation, particularly within script families.

Monolingual English models (Mistral, LLaMA) exhibit a unique pattern. We discover an anomalous peak in the results for facts known and represented in exactly four languages (Fig. 3), corresponding primarily to the four Latin script languages in our dataset. This highlights the strong association between script similarity and knowledge sharing even in ostensibly monolingual models. Surprisingly, Mistral demonstrates the highest $\mathbb{E}[NCL]$, $\mathbb{E}[NTL]$ and average of language pairwise CKC (54.7%) and CKR (37.6%) within script families, despite being designed as a monolingual English model. This result highlights how Mis-

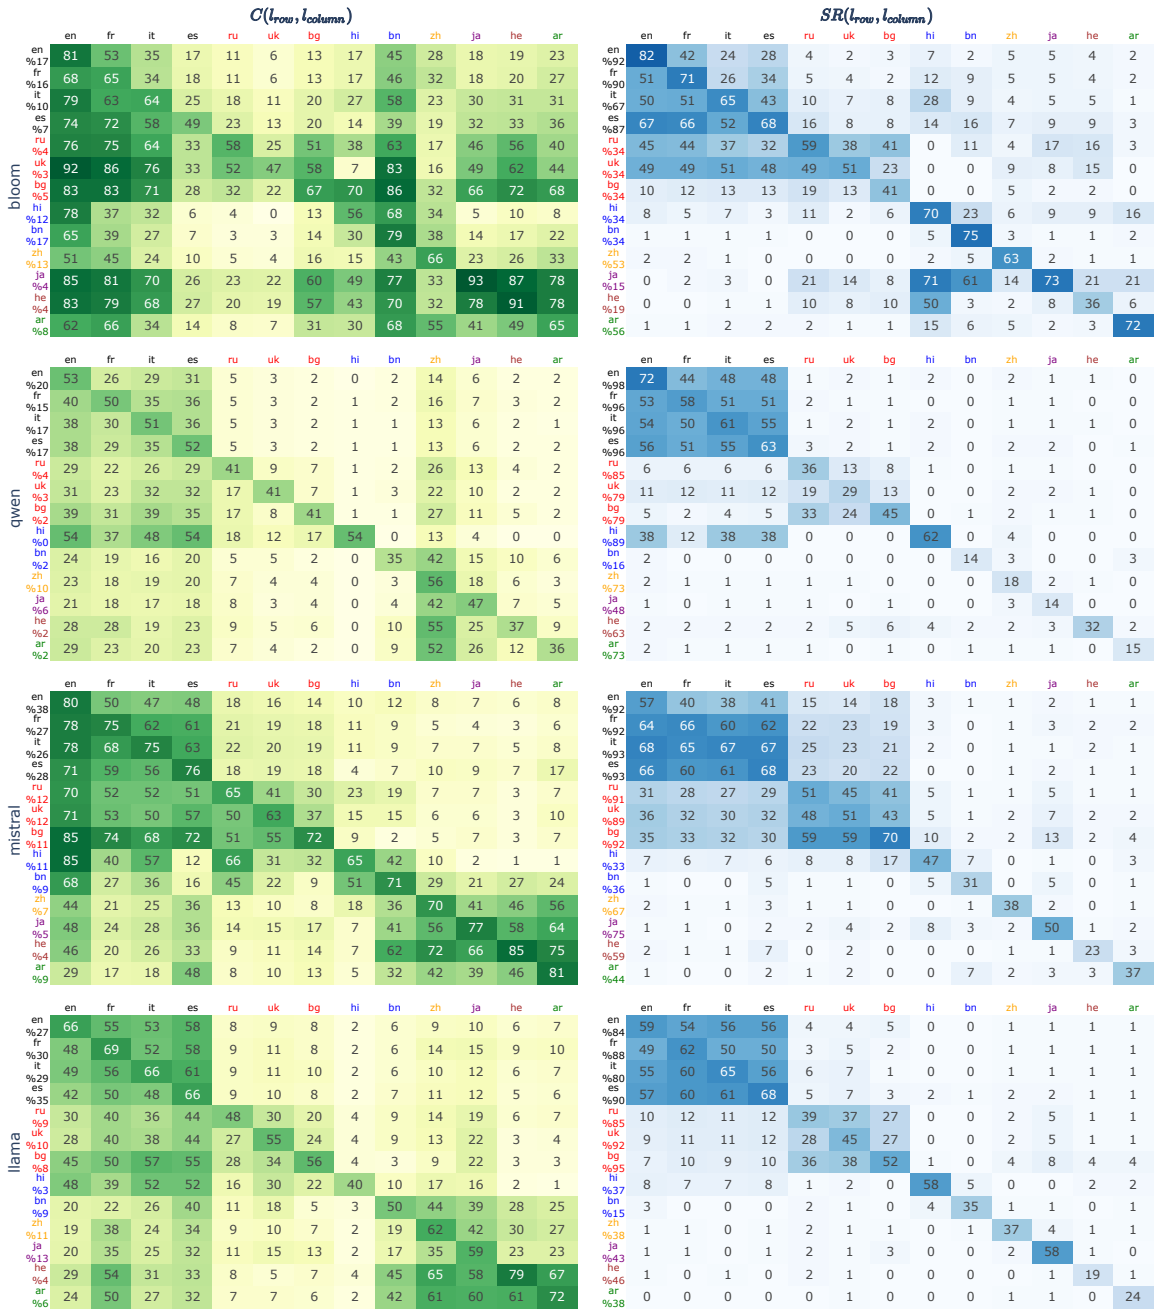

Figure 4: The pairwise relationships of factual knowledge across languages for four language models, with all scores reported using Exact Match. $C(l_1, l_2)$ shows the percentage of facts known in the row language which were also retrieved in the column language. $SR(l_1, l_2)$ indicates the percentage of successfully edited facts in the row language which generalized to the column language using MEMIT. Under each language abbreviation is the overall accuracy for initial knowledge retrieval and the edition-reliability score for C and SR measures respectively. Languages are color-coded by script family.

tral's strong English foundation naturally extends to other Latin script languages, underscoring the impact of script similarity on cross-lingual knowledge representation even in monolingual models.

4.5 Language Extended LMs

How does additional pretraining on both English and an extended language (EL) impact CKC and CKR in initially monolingual models? Analysis of chinese-llama-2-7b and he-mistral-7b reveals a similar trade-off: while gaining substantial knowledge in EL, models sacrifice much of their original English expertise. These extensions reshape cross-lingual knowledge distribution but fall short of fully bridging the gap between disparate writing

	Model	EL Acc/Rel	En Acc/Rel	EL → en	en → EL
C	zh EL	10 (142%↑)	5 (29%↓)	12 (80%↓)	22 (440%↑)
C	he EL	18 (600%↑)	10 (32%↓)	13 (37%↓)	18 (900%↑)
SR	zh EL	96 (252%↑)	81 (96%↓)	2 (200%↑)	4 (400%↑)
SR	he EL	90 (152%↑)	83 (90%↓)	10 (500%↑)	6 (600%↑)

Table 1: CKC and CKR in extended LLMs compared to their base models. EL: Extended Language, Acc: Accuracy, and Rel: Reliability.

systems.

As shown in Table 1, both models exhibit increased accuracy in the extended language (EL) coupled with decreased English accuracy. CKC measures paint a nuanced picture: models acquire extensive new knowledge in EL, largely unknown in English, yet this new EL knowledge covers more of English knowledge. Shared representation metrics underscore this asymmetry. Despite increased bidirectional knowledge transfer between English and EL, transfer remains stubbornly low. This suggests that even with targeted pretraining, models struggle to forge robust representations sharing across linguistically distant languages.

For analysis of how different relation types affect CKR, see Appendix D.

5 Related Work

Cross-lingual Knowledge Consistency. While monolingual knowledge consistency has been studied often in LMs (Elazar et al., 2021; Mizrahi et al., 2024), limited work has been done on cross-lingual knowledge consistency. Qi et al. (2023) proposed a cross-lingual consistency metric named RankC to measure similarity across multiple candidate answers, whether correct or incorrect. Our focus on correct answers allows a simpler assessment without being limited to pairwise language comparisons, enabling us to answer broader questions such as in how many languages on average does a model know a given fact.

Cross-lingual Knowledge Representation Sharing. Previous studies explored this angle through different approaches. Some works studied parameter sharing across languages by analyzing neuron activation/deactivation when evaluating knowledge in different languages (Libovický et al., 2020; Zhao et al., 2024b; Chen et al., 2024; Tang et al., 2024; Kojima et al., 2024). Enhancing language-independent neurons resulted in better multilingual abilities in a specific language without compromising others. Other works investigated the knowledge related to the training data and identified the language source of the acquired data (Choenni et al., 2023; Zhao et al., 2024a), providing evidence that knowledge from training data in one language can benefit the model in other languages. Another line of work analyzed how inputs in different languages affect the activation patterns, showing that semantically equivalent content in different languages tends to produce similar activation patterns (Singh et al., 2019; Libovický et al., 2020; Chang et al., 2022).

These works pointed to a connection between knowledge in different languages. However, they do not yield an assessment of the amount of shared knowledge. While passive analysis can take as far as measuring the similarity between languages, active modification tools can also suggest a clear causal relation between the knowledge representation in different languages.

Multilingual Knowledge Editing. Previous work on multilingual knowledge editing (Si et al., 2024; Xu et al., 2022; Wei et al., 2024; Wang et al., 2023a) primarily focused on comparing and improving editing methods' performance in multilingual settings. Our approach is different. We use these editing tools as analytical tools to understand representation sharing across languages and across models with different multilingual configurations.

6 Conclusion

This work investigated the relationship between cross-lingual knowledge consistency and representation sharing in LLMs. Our findings reveal that high consistency across languages does not necessarily imply shared internal representations, particularly for languages with different scripts. We introduced a novel methodology and dataset for quantifying these phenomena, providing a more nuanced understanding of how LLMs represent and retrieve factual knowledge. The significant disparity we observed in factual knowledge retrieval across languages, coupled with the potential for substantial performance improvements if knowledge could be fully shared, underscores the importance of developing more effective multilingual knowledge representations. We expect that our insights will guide the development of more efficient and equitable multilingual models, ultimately enhancing their performance across all languages.

Limitations

Our main limitation lies in the constraints imposed by our chosen editing methods and their focus on specific model components. By primarily targeting middle layers associated with factual knowledge storage, our analysis may have overlooked important cross-lingual interactions occurring elsewhere in the model architecture. Our reliance on specific editing techniques (ROME, MEMIT, and Finetuning) may not capture the full spectrum of knowledge representation and modification within the model. There might be multiple pathways to change the output in a specific language, potentially exhibiting different cross-lingual generalization patterns than those we observed.

Our analysis focused exclusively on decoder-only language models with 7B parameters, limiting the generalizability of our findings across different architectures and sizes. Similarly, while our CLIKE dataset covers a diverse range of languages and relations, it may not fully represent the breadth of factual knowledge or linguistic phenomena. These constraints in both model selection and dataset composition could influence the observed patterns of cross-lingual representation.

A Native Speaker Instruction

Dear <Native Speaker>,

We are reaching out to you for assistance in an important project that aims to improve the ability of Artificial Intelligence (AI) to understand and generate text in your native language. Your skills and knowledge as a native speaker are crucial to the success of this project.
Our research team has created a collection of fill-in-the-blank sentences and templates in multiple languages, including yours. These sentences will be used to evaluate the knowledge and understanding of AI language models. To ensure the accuracy and effectiveness of our collection, we need your help in verifying the grammatical correctness of the sentences and templates we have created.
Attached, you will find a list of approximately 60 simple sentences and sentence templates and templates that cover various relationships between subjects and objects in your native language. The task should take no more than 15-20 minutes to complete. Your task is to review each sentence and template and determine whether they are grammatically correct. If you find any grammatical errors, please provide a corrected version of the template. Additionally, if you wish, you may provide an optional explanation in English of what was wrong with the original template.

Example:

Relation: *Birth City*, Subject: *Wolfgang Amadeus Mozart*, and Object: *Salzburg*
Original template:
"[subj] birthplace the city [obj]" -> "Wolfgang Amadeus Mozart birthplace the city Salzburg"
Fixed template:
"[subj]'s birthplace is the city of [obj]" -> "Wolfgang Amadeus Mozart's birthplace is the city of Salzburg"
Explanation:
The original template is missing the verb "is" and the preposition "of" to form a grammatically correct sentence.

When fixing the templates, please keep in mind the following guidelines:

1. Be explicit about the relationship to avoid ambiguity. For example, given the information (Bach, Birth Year, 1685) and the template "[subj] born in [obj]", the AI might complete the prompt "Bach was born in" with the object "Leipzig" (his birth city) or "31 March" (his birth date) rather than the year "1685". Therefore, a good template should contain words that explicitly describe the relationship. The template "Bach was born in the year [obj]" will likely output "1685" since the word "year" appeared in the sentence.

2. For each relationship, we have provided three different prompt paraphrases that are supposed to be different from one another.

3. The subject must always appear before the object.

4. The last word of the prompt template should be the object.

Please note that the sentences do not necessarily need to sound natural or be well-written. Our primary focus is on ensuring that they are grammatically correct. However, if you have suggestions on how to make the sentences sound more natural without changing the core structure, feel free to include them in your feedback.
Your contribution to this project is valuable and will help us create a reliable collection of sentences for advancing AI's ability to understand and generate text in your language. If you have any questions or concerns about the project or your role in it, please don't hesitate to reach out to us.
Thank you for your participation in this project. We look forward to receiving your feedback.
Best regards,

B CLIKE Dataset Key statistics.

Figure 6: A Dataset Sample Example

C ROME and FT Methods Performance Comparison

D On CKR Features

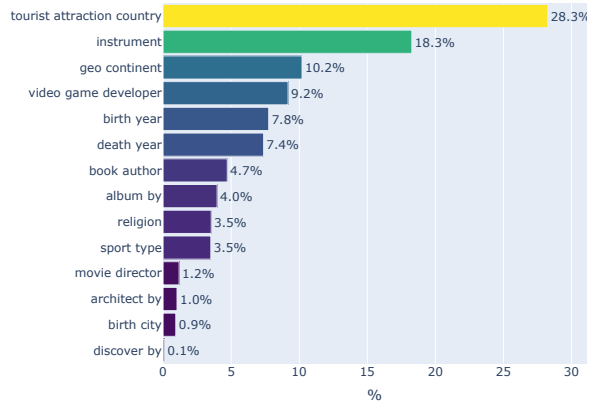

Figure 7: Distribution of shared representation facts across different relation types.

Figure 7 illustrates that relations with fewer possible categories generally exhibit higher CKR. This trend is evident for relations such as countries, instruments, continents, and company developers, with sports type and religion as notable exceptions. Numerical relations like birth year and death year also demonstrate strong transfer capabilities. In contrast, relations involving names (e.g., book authors, movie directors, discoverers) and those with numerous categories (e.g., cities) show lower transfer rates.

GUIDEQ: Framework for Guided Questioning for progressive informational collection and classification

Abstract

Question Answering (QA) is an important part of tasks like text classification through information gathering. These are finding increasing use in sectors like healthcare, customer support, legal services, *etc.*, to collect and classify responses into actionable categories. LLMs, although can support QA systems, they face a significant challenge of insufficient or missing information for classification. Although LLMs excel in reasoning, the models rely on their parametric knowledge to answer. However, questioning the user requires domain-specific information aiding to collect accurate information. Our work, GUIDEQ, presents a novel framework for asking guided questions to further progress a partial information. We leverage the explainability derived from the classifier model along with LLMs to ask guided questions, further enhancing the information. This further information helps in more accurate classification of a text. GUIDEQ derives the most significant key-words representative of a label using occlusions. We develop GUIDEQ's prompting strategy for guided questions based on the top-3 classifier label outputs and the significant words, to seek specific and relevant information, and classify in a targeted manner. Through our experimental results, we demonstrate that GUIDEQ outperforms other LLM-based baselines, yielding improved F1-Score through the accurate collection of relevant further information. We perform various analytical studies and also report better question quality compared to our method.

1 Introduction

Question Answering (QA) systems have been an integral part of the NLP landscape (Moise et al., 2010). In particular, the emergence of LLMs has enabled reasoning, proactive questioning, and better semantic understanding of the user response during questing answering or dialogue (Wang et al., 2023a). Proactive questioning is another important limb of such systems wherein the bot engages with the user and directs the conversation ahead(Keskar et al., 2019; Sun et al., 2023). It finds applications in many places like medical, customer support systems, and legal systems.

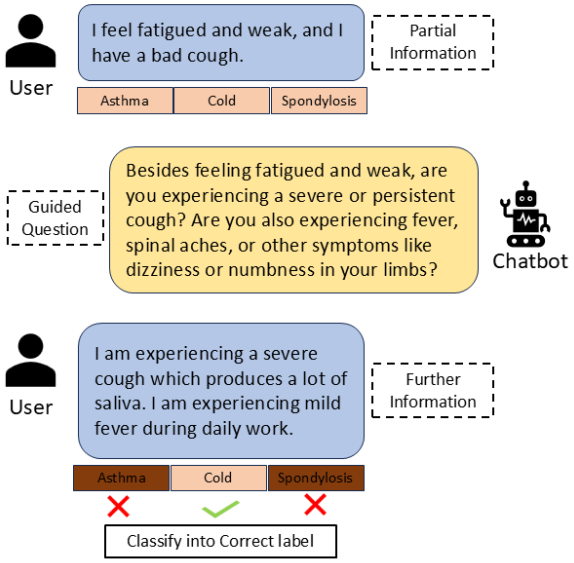

Figure 1: Illustration of partial information by user followed by a specific guided question

A more specific challenge such systems face is of the static classification of user textual data. Often a textual data needs to be classified into a particular category or label (Wang et al., 2023b; Chen et al., 2022). For example, consider a system to classify a patient symptoms descriptions into one of the disease conditions, or a customer complaint system wherein a user writes a complaint to be categorized into a particular category. A practical challenge faced by such static categorization is inadequate or missing information toward appropriate routing of the user input to an actionable category. It can be immensely benefited by introduction of questioning

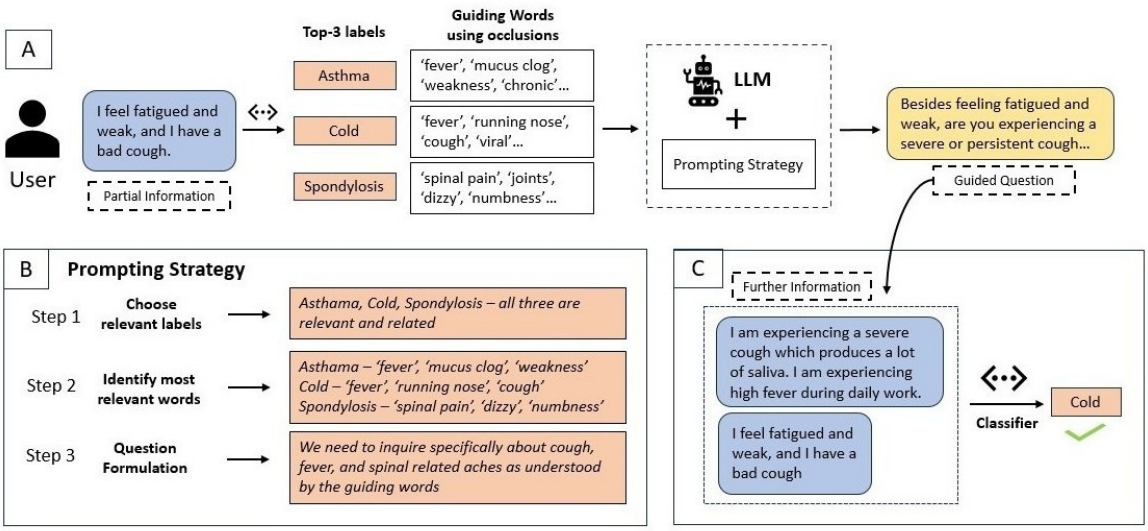

Figure 2: (A) Overall working framework of GUIDEQ to leverage LLM and label explainability for asking guided question. (B) Details of the prompting strategy used. (C) Final classification along with incremental information.

component to prompt for further information or knowledge, grounded in previous response and the domain itself. Figure 1 shows an example of the same.

Our work introduces a novel framework, GUIDEQ [1], aimed at framing guided questions based on prior partial information, such that specific relevant information can be asked for. This increment of information can aid for more accurate classification and completion of text. A classic techniques include classifier models for text classification(Devlin et al., 2019) (Liu et al., 2019) (He et al., 2020). LLMs, on the other hand, have shown impressive abilities for reasoning and context understanding (Nan et al., 2023). Further with techniques like in-context learning (Garg et al., 2022) and chain of thought (Wei et al., 2024) with few-shot exemplars (Brown et al., 2020), the task specific adaptation of LLMs greatly benefits. However, the LLM's parametric knowledge may still not capture domain specific requires. Finetuning options like FT (Full parametric training) and PEFT (Hu et al., 2021) for learning from data history posses a huge challenge of high computation cost (Sathish et al., 2024).

Our framework, GUIDEQ leverages the innate semantic understanding and reasoning ability of LLMs to combine with external classification explanability, for asking the most relevant guiding question. We specifically use Llama-3 8B-Instruct model (Touvron et al., 2023) for questioning and information seeking. We train DeBERTa and BERT models (Devlin et al., 2019) for classification tasks using complete information, which serves as the primary pivot for predicting the most probable labels.GUIDEQ aims to use the inherent explanations of classifications for question formation. For each class label we also learn the most significant words and phrases that contribute to the particular label classification. We use occlusions to find the keywords for a label using the training data. The LLM utilizes the top most probable classifier labels and their significant representative keywords to form the guiding questions. Intuitively, the keywords are representative of the most important concepts present in the label knowledge. The summarized overview with keywords example can be found in figure 2. The LLM finds similar concepts present in the partial information and the labels and frames a question based on the most distinguishing concepts between the labels. This helps direct further information that may not have been readily known to the user earlier.

We evaluate our framework, GUIDEQ, on 6 text classification datasets. We first report the F1-Score of partial information and how accuracy changes by questioning and appending the new answer. We also show how explanability is influenced by keywords, namely by testing with unigrams, bigrams, and trigrams. We also report a higher question generation quality compared to other baseline methods. Overall, our work, GUIDEQ, presents a novel

[1]Code available at: https://github.com/SDRMp/GuideQ

framework to ask guided questions when the initial text is incomplete or partial. The question is such that it effectively differentiates between the most likely labels.

We summarize the key contributions of our work as follows: (i) We introduce a novel framework, GUIDEQ, for providing guided questioning such that an initial partial information can be incremented. (ii) The guided questioning increments the information by leveraging explainability derived through top most confident classifier labels and their corresponding most significant key words. (iii) We show that further information collection through our framework significantly improves the classification accuracy as compared to other baselines. We also show that GUIDEQ generates more accurate and targeted questions in relation to the user query.

2 Related Works

2.1 Posthoc Explanations and LLMs

Post-hoc explanations enhance the interpretability of Large Language Models (LLMs) by providing insights into which input features influence model outputs, addressing the "black-box" nature of these models (Kroeger et al., 2024). The AMPLIFY framework (Krishna et al., 2024), for instance, uses attribution scores to generate natural language rationales, guiding LLMs to make more accurate predictions. Integrating LLMs with existing XAI algorithms like SHAP can produce more accessible and human-readable explanations. LLM-generated explanations are as effective as traditional gradient-based methods (Zytek et al., 2024).

Previous works use the technique of Integrated Gradients (Sundararajan et al., 2017), previously used for word-level attribution in language models(Enguehard, 2023) to generate keywords that contribute the most for a particular classification label.

2.2 Task oriented dialogues

Task-oriented dialogue systems aim to achieve specific goals through structured interactions, traditionally decomposing tasks into natural language understanding (NLU), dialogue management (DM), and natural language generation (NLG) . This modular approach often leads to error propagation and requires extensive domain-specific data (Budzianowski and Vulić, 2019). Recent advancements, like SimpleTOD (Hosseini-Asl et al., 2020), leverage LLMs to unify NLU, DM, and NLG into a single sequence prediction task. By treating all sub-tasks as a single sequence prediction problem, SimpleTOD exploits transfer learning from pre-trained models for improved performance. Pre-trained generative models can effectively support ToD by learning domain-specific tokens.

2.3 Information-seeking questions using LLMs

Large Language Models (LLMs) have significantly advanced the field of information-seeking question answering by generating contextually rich and coherent responses (Jin et al., 2023). Traditional search engines have evolved with models like GPT-3 and GPT-4, which can formulate search results in natural language, incorporating references from relevant sources. These models are particularly effective at summarizing and synthesizing information from various texts, making them valuable tools in medical and educational contexts. However, challenges such as "hallucination"—where the model generates plausible but incorrect information—highlight the need for mechanisms to verify and attribute sources accurately (Kamalloo et al., 2023).

2.4 In-context learning

In-context learning (ICL) has emerged as a novel paradigm where language models are capable of learning from a few examples within a context, making predictions without explicit parameter updates. The key mechanism of ICL is the use of demonstration contexts, which consist of input-output examples formatted as natural language templates (Li et al., 2023). This method allows large language models to perform various tasks by leveraging patterns learned from these demonstrations, which are provided as part of the input prompt. Recent studies highlight the adaptability of ICL to new tasks, significantly reducing computational costs compared to traditional supervised learning methods (Dong et al., 2024). Furthermore, ICL has demonstrated potential across different modalities, such as vision-language and speech tasks, by incorporating properly formatted data and architectural designs. Our work contributes to this growing field by utilizing ICL for the classification of incomplete sentences. By leveraging label explanations and guiding language models to ask targeted questions, we aim to refine user responses in medical contexts, ultimately enhancing the model's ability to

generate accurate and relevant follow-up queries.

3 GUIDEQ - Methodology

3.1 Overview

Given a partial input x, the objective is to classify x (or x with additional information) into the correct label. Here, partial input refers to text that may be incomplete or lacking essential details. We use a classifier, C, to map the input to one of n labels, where the label set $L = \{l_1, l_2, \ldots, l_n\}$ is dataset-dependent. To enhance this process, we identify representative keywords and phrases using occlusion techniques for each label. For a label l_i, the associated keywords are denoted as $r_i = \{w_1^i, w_2^i, \ldots, w_k^i\}$.

GUIDEQ leverages a large language model (Llama-3 8B-Instruct in our study) to refine the classification through an interactive process. The model takes as input the top-k predicted labels, their corresponding keywords, and a prompting strategy. It then generates a question q designed to elicit information from the user related to the most relevant concepts in the keywords, further guiding the classification towards the correct label.

We divide our methodology as: (1) Classifier Finetuning, (2) Keyword Learning, and (3) Explainability-Driven Question Generation.

3.2 Classifier Finetuning

The first step in our GUIDEQ framework involves finetuning a classifier using labeled training data. Our dataset consists of domain-specific text-label pairs, which are divided into training (80%), evaluation (15%), and test (5%) sets.

We train C on the complete input text and its corresponding label. Training is conducted on the training split, with performance monitored on the evaluation split. By training on full texts, the model learns to output the most likely labels for any input, even if the input is incomplete during inference, as described in later sections.

3.3 Keywords learning

Given n possible labels, $L = \{l_1, l_2, \ldots, l_n\}$, the classifier assigns a probability score to each label for a given input. Our goal is to identify the most significant words or phrases (unigrams, bigrams, and trigrams) that represent each label. These keywords capture the core semantic and conceptual elements of the label's category. For example, the label 'fever' might be characterized by keywords like "high temperature" or "body ache," while a telecommunication label might feature keywords like "mobile phone" or "network issues." These keywords enhance the explainability of the classification.

We employ the occlusion method to identify the top-i significant words or word pairs for each label l_i, represented as $r_i = \{w_1^i, w_2^i, \ldots, w_k^i\}$. Occlusions involve systematically removing or masking words from the input and observing the effect on the model's confidence score. A sharp drop in confidence indicates that the removed word is crucial for the label prediction. Each word or phrase is then assigned a weight based on its importance, and the most relevant keywords are aggregated with additive weights for each label. To capture diverse concepts, we consider unigrams, bigrams, and trigrams for each label. Figure 2(A) illustrates how these guiding keywords are used for question generation. In our experiments, we include the top 15 word pairs per label in the LLM prompt to guide the question generation process effectively.

3.4 Explainability-Driven Question Generation

The final question generation stage follows the following method: First, we pass the incomplete input x to the classifier, which returns the top-k labels with the highest confidence scores. We set $k = 3$, selecting the top-3 most likely labels for x. Using these labels, we prompt the Llama-3 8B-Instruct model, applying a tailored prompting strategy to generate a guided question.

The prompt provided to the LLM includes the following components: (i) the partial input x; (ii) the top-3 predicted labels; (iii) the corresponding guiding keywords for each of these labels; (iv) a structured instruction prompt; and (v) a few-shot examples to guide the LLM's output.

The generated question, q, can be formulated as:

$$q = LLM(P \,||\, x \,||\, \{(l_1^x, r_1^x), (l_2^x, r_2^x), (l_3^x, r_3^x)\})$$

where P represents the instruction prompt, which combines the logical structure of the components with three few-shot examples. These examples illustrate how to generate questions that efficiently target missing or unclear information, aiding in more accurate classification. The prompting strategy for generating questions follows a structured, three-step process:

Step 1: The LLM first filters out irrelevant labels from the top-3 predictions, retaining only those

Dataset	Train	Val	Test
cnews	25,062	4,423	1,552
dbp	240,942	36,003	60,794 (876)
s2d	969	171	60
salad	17,174	3,031	1,064
stress	2,291	405	142
20NG	9,064	1,600	7,019 (1000)

Table 1: Dataset statistics used in experiments along with training, validation, and testing splits

most relevant to the input query. This is achieved by comparing the input with the keywords associated with each label, allowing the model to focus on labels that contextually align with the partial information.

Step 2: Next, the LLM examines the guiding keywords for the remaining labels. These keywords represent key concepts associated with each label, serving as focal points for further inquiry. The LLM identifies the most contextually relevant keywords that can expand upon the incomplete information in the input x. This step ensures that the follow-up questions target the most meaningful aspects of the missing information.

Step 3: Finally, the LLM uses the selected keywords to generate a coherent, targeted question. The question is designed to elicit specific details necessary for distinguishing between the potential labels, facilitating more accurate classification.

As shown in Figure 2(B), this strategy ensures a focused and contextually relevant interaction, especially for specialized categories, reducing the risk of hallucinations and irrelevant questions by grounding the response in the prior training data.

4 Experimental Setup

This section outlines the experimental configurations and evaluation protocols employed to assess the performance of our framework, GUIDEQ. The goal of GUIDEQ is to enhance classification under incomplete information by generating guided questions that elicit relevant, missing inputs. This targeted information retrieval facilitates more accurate classification, grounded in prior learned patterns.

4.1 Datasets

We evaluated GUIDEQ on six diverse text classification datasets, each representing a unique domain and presenting distinct challenges: (i) Crypto News (cnews) (Oliviervha, 2023),(ii) DBpedia (dbp) (Lehmann et al., 2015), (iii) Symptom2Disease (s2d) (Hassan et al., 2024), (iv) saladBench (salad) (Li et al., 2024), (v) Human stress Prediction (stress) (Kreesh, 2024), and (vi) 20 Newsgroups (20NG) (Lang, 1995), representing healthcare, financial, and behavioral domains respectively. Table 1 summarizes the total data instances used for each of the six dataset along with the exact split for training, validation, and testing.

We followed a standard 80%-15%-5% division into training, validation, and test sets for datasets without predefined splits (cnews, s2d, salad, and stress). For 20 Newsgroups (20NG) and DBPedia, which came with predefined splits, we extracted the validation set from the training data while preserving the original test set. Given the computational intensity of processing large test sets, particularly for 20NG (20 classes) and DBPedia (218 classes), we employed the Facility Location Selection method from the Apricot library to sample the test sets while maintaining class diversity. This sampling capped the maximum test samples at 1,000, yielding 1,000 samples for 20NG and 876 samples for DBPedia, enabling efficient evaluation while preserving result integrity. We provide more information about the dataset and it's relevance in appendix section A.

4.2 Baselines

We benchmark GUIDEQ against three baselines for question generation: (i) *Partial*: using only the initially provided partial information to assess classification performance without any additional inputs, serving as a direct comparison of classification under incomplete data. (ii) *LLM*: leveraging a standalone LLM (Llama-3 8B-Instruct), prompted to generate questions based on the partial input, representing a generic approach to eliciting missing information. As the input data mirrors realistic scenarios, the LLM's questions are grounded in semantic context and not in hypothetical constructs. (iii) *LLM-nk*: LLM with only labels and no keywords - combining the LLM with the top-3 predicted classification labels, where the LLM generates questions based solely on these labels without keywords. These baselines, denoted as Partial, LLM, and LLM-nk, provide a comprehensive evaluation of GUIDEQ's performance.

	BERT Classifier Model				DeBERTa Classifier Model

Table 2: Comparison of % F1-Scores of GUIDEQ along with three baseline approaches - (i) partial: partial information; (ii) LLM: Only LLM is used for question framing; (iii) LLM-nk: LLM is provided with top 3 predictions. The results are reported for two classifier models: BERT and DeBERTa. Numbers in bracket constitute gain over partial information scores

4.3 Evaluation

We conduct multiple experiments to assess various aspects of the problem. For a robust classification analysis, we use two classifier models: BERT-uncased and DeBERTaV3 (a comparatively larger model). Throughout our experiments, we utilize Llama-3 8B-Instruct, an open-source LLM chosen for its strong reasoning capabilities and computational efficiency, offering a balance between performance and cost due to its smaller parametric size.

During testing, each data instance is split into two equal parts: the first half serves as the partial input, while the second half acts as the reference from which the generated question seeks to extract missing information. To evaluate question quality and answer relevance, we employ DeBERTaV3 finetuned on SQuadV2 (Rajpurkar et al., 2018), as the question-answering models, which extract the most relevant text from the reference based on the question. We set a 20% confidence threshold for answering.

We demonstrate four experimental settings to thoroughly analyze GUIDEQ:

(i) Classification Performance: We measure classification performance, which refers to correctly assigning the given text to its corresponding label by reporting F1-Scores. First, we report scores using only the partial information (the first half of each instance). For the other baselines, a question is generated, and relevant phrases are extracted from the reference text using the QA models with a 20% confidence threshold. This extracted information is appended to the partial input, and the combined text is classified. We use two-gram keywords for the important results while compare using one-gram and three-gram in a section 6.4.

(ii) Question Quality: We calculate the win rate between pairs of methods by determining which generated question is more aligned with the complete text (both partial input and reference). The win rate accuracy is reported for the following pairs: (GUIDEQ, LLM), and $(\text{GUIDEQ}, LLM - nk)$.

(iii) Explainability via Keywords: We explore the explainability provided by different keyword types associated with each label—unigram, bigram, and trigram. This analysis compares the impact of keyword granularity on GUIDEQ's performance, helping us understand how keyword-based question generation improves the classification process.

(iv) Multi-Turn Interaction: We investigate the potential of multi-turn question generation, where multiple rounds of guided questions are used to iteratively refine the extracted information. This setting evaluates how effectively GUIDEQ handles scenarios where a single question is insufficient to gather all relevant details.

Setup: We fine-tune DeBERTa and BERT-uncased models as the classifier in our framework. Additionally, we use the Llama-3 8B-Instruct model for question generation. We select this smaller parametric model to reduce computational overhead while maintaining robust performance. For each dataset, we split the text instances at the sentence level, dividing them into two equal parts. The first half serves as the partial information provided to the model. The second half, referred to as the "grounded context", is used to extract answers to the generated questions. DeBERTaV3 finetuned on SQuadV2, is employed as the Question Answering model, tasked with extracting the most relevant answer snippets from the grounded contexts.

Skyline Classification					
Datasets	F1-score/ BERT	F1-score/ DeBERTa	Datasets	F1-score/ BERT	F1-score/ DeBERTa
cnews	63.8	65.6	salad	64.5	66.4
dbp	95.5	94.5	stress	43.5	47.7
s2d	99.8	100.0	20NG	75.8	71.6

Table 3: Skyline F1-Scores for complete original text (both partial and reference combined) on BERT and DeBERTa classifier models

Win Rate Scores					
Datasets	LLM	LLM-nk	Datasets	LLM	LLM-nk
cnews	66.0%	67.0%	salad	72.0%	62.0%
dbp	93.0%	92.0%	stress	65.0%	70.0%
s2d	90.0%	85.0%	20NG	89.0%	93.0%

Table 4: Win Rate (WR) % scores of questions generated for (i) GUIDEQ with LLM baseline; (ii) GUIDEQ with LLM-nk baseline

5 Results and Observations

Our work, GUIDEQ, was evaluated on six classification datasets, enabling a rigorous assessment of the framework's ability to generate guided questions from partial information and improve classification accuracy.

The strongest results for GuideQ framework can be seen in table 2, wherein we report the F1 score for classification task post-answering the generated question. The question answering model is such that it extracts the most relevant text from the reference text in respect to the asked question. We observe that for all datasets at all instances (expect for stress with BERT classifier), our method shows the highest overall classification scores (F1 score) across both classifier models. Second, considering results of both classifier models together, table 1 also shows that GUIDEQ always has the highest margin of improvement compared to F1 scores with partial information.

We observe an improvement of 18.6% (BERT) and 22.1% (DeBERTa) for s2d and 22.1% (BERT) and 20.7% (DeBERTa) for salad dataset with our method over partial information. This large shift shows our method is effectively able to frame questions based on previous training data and keywords. This makes the question asked more grounded in context of the partial information. A question maybe raised as to why some datasets show more improvement in F1 score than the others. We observe the skyline F1 score results for each dataset using the complete text on both classifier models (table 3). The skyline results reveal the inherent classification ability of the datasets themselves.

We also observe that in some situations with other baselines, the addition of new answer based on generated question negatively impacts the classification, *i.e.*, reduces F1 score. Example of the same is a drop of 0.4% for dbp dataset with BERT classifier and a drop of 0.2% with DeBERTa classifier using LLM-nk approach. Many instances also include when the baselines show only a slight improvement. However, our method never shows a dip in score compared to partial information classification. The range of percentage gain is also comparatively larger than other methods. This is crucial in realistic situations where we want to ensure that originally correct categorized text is not misclassified.

6 Analysis

6.1 Effect of Classifier Model

We perform our experiments by finetuning two different classifier models - BERT and DeBERTa for a robust analysis. Firstly, GUIDEQ outperforms other methods on both the classifier models in most settings. Only for stress dataset with BERT classifier, a classic LLM based approached worked better and showed 2.7% increase in F1 score. When absolute percentage gain over partial information is taken into consideration for our method, classification using DeBERTa leads for four out of six datasets. BERT shows highest absolute gain for salad and 20NG datasets. We represent the percentage gains in brackets in table 2 and underline the highest gain across a dataset. Although we observe comparable gains for partial information classification along with LLM, and LLM-nk baseline approaches.

A possible reason for the same maybe as follows: DeBERTa being a larger parameter model compared to BERT is able to capture more relevant explainable keywords for a given label using occlusions. This results in a better formed and focused question. The conclusion we can derive is that even though a better classifier model doesn't necessarily show higher F1 scores with partial information, it aids to improve results when combined with GUIDEQ framework leveraging keywords.

6.2 Analysis of baseline approaches

We also observe that the performance of the other two baselines, *i.e.*, the use of only an LLM to ask

	BERT			DeBERTa		
Dataset	uni	bi	tri	uni	bi	tri
cnews	**6.8**	5.6	6.1	7.2	7.1	**8.9**
dbp	**2.5**	1.8	1.6	**6.6**	6.3	6.2
s2d	**19.7**	18.6	17.0	14.6	**22.1**	12.8
salad	20.7	**21.9**	21.3	20.1	**20.7**	20.6
stress	-0.3	0.6	**1.6**	-0.2	**3.0**	-1.5
20NG	**5.8**	5.4	5.0	**3.9**	2.7	3.0

Table 5: Comparison of % absolute gain over partial information F1-Scores for GUIDEQ framework with unigram (uni), bigram (bi), and trigram (tri) keywords

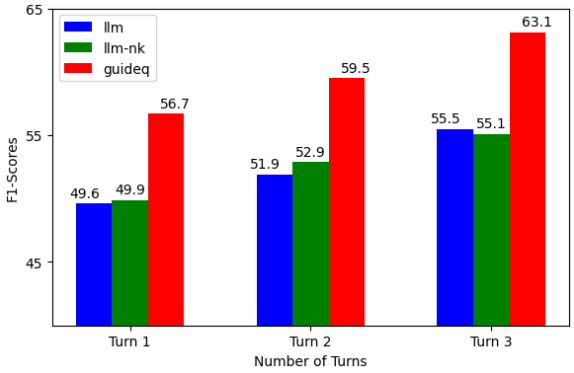

Figure 3: Multiturn Results: F1-Scores for three turn question answering on cnews datatset.

relevant question and providing an LLM with only the top-3 classifier labels perform almost at par with each other. In other words, though we conclude that GUIDEQ shows improved performance over other baselines, the two baselines themselves are comparable to each other in performance. For example, for salad dataset LLM-nk baseline performs better while for s2d dataset only LLM baseline shows higher results. This holds true for both classifier models. While GUIDEQ leverages explainability through keywords along with labels, the LLM-nk baseline uses only labels. Apparently, the labels themselves do not add explicit information that would help guide for completion of the text.

6.3 Quality of Generated Questions

Next, we evaluate the question quality of different baselines. We do this by calculating the win rates using LLM model of question generated with our method taking LLM and LLM-nk as base on a subset of 100 random instances for each dataset. Table 4 summarizes the results for the same. We observe that our method always has a win rate above 50%. The minimum win rate reached is 62.0% for salad datasets with LLM-nk. For three datasets: db, s2d, and 20NG, GUIDEQ performs exceptionally higher. Overall, table 4 shows that our method frames questions which are more relevant and specific to the partial information and unseen reference answer.

6.4 Effect of n-grams in GUIDEQ

In this section we compare the results three different n-gram approaches for keywords generation, namely: unigram, bigram, and trigram, which means the keywords are restricted exactly to be single words, two words, and three words respectively. The results comprising of percentage gain of F1 score over that of partial information are summarized in table 5. We observe that while all the three perform almost similar, still results with questions formed using unigram and bigram are superior in 30/36 total setups as compared to results using trigram. In other words, GUIDEQ slightly performs better when the explainable keywords are restricted to two or three words. Although there is no particular trend between unigram and bigram themselves.

7 Ablation Study: Multi-turn

Our framework explores a multi-turn setting, where successive guided questions are posed following a prior response. We specifically report multi-turn results on the cnews dataset due to its larger context per instance and significant differences in partial information scores versus skyline F1-Scores. The text is divided into three segments, with the first serving as partial information to initiate the guided questioning (GuideQ) process. This method involves dynamically updating the pool of guiding words, removing those already used in previous turns. After generating questions, the answer extraction model derives responses from the residual text. This answer, combined with the initial partial information and the refreshed guiding words, informs the next GuideQ round. This cycle repeats over three turns, continually refining the guiding words to enhance the relevance and depth of information retrieval. Figure 3 illustrates the summarized results, showing our method's superior performance in multi-turn scenarios.

8 Conclusion and Future Work

Our work GUIDEQ, introduces a novel framework designed to generate guided questions that enhance classification accuracy and improve information

gathering in scenarios with partial data. By using explainable AI, GUIDEQ combines keywords identified from classifier models with LLM-based question generation to create guided questions. This approach shows better performance on multiple datasets compared to other baseline methods. Our results show consistent improvements in F1 scores, with gains of up to 22% on certain datasets. GUIDEQ generate high-quality, context-relevant questions is evident from the win rates against baseline methods. GUIDEQ's effectiveness in multi-turn interactions and its flexibility in accommodating different n-gram approaches for keyword generation further underscore its potential for real-world applications in information retrieval and classification tasks.

We focus exclusively on open-source LLMs like Llama-3 8B-Instruct, which strike an excellent balance between performance and computational efficiency. Our approach highlights the potential of open and accessible models to drive innovation without the heavy resource demands of proprietary alternatives.

9 Limitations

Despite GUIDEQ's promising results, several limitations should be noted. First, the framework's performance is dependent on the quality of the initial classifier model and the relevance of extracted keywords. Suboptimal classifier training or keyword selection could lead to less effective question generation. Secondly, the framework's reliance on LLMs for question generation also introduces potential biases and inconsistencies inherent to these models. Finally, the computational resources required for running large language models may pose scalability challenges in certain applications.

For evaluating question quality, we recognize the inherent challenges of obtaining domain expert human evaluations across diverse fields such as healthcare, finance, and news. However, the win rate metric serves as a systematic and practical tool for comparison, offering meaningful insights even in the absence of gold-standard labels. This metric enables us to effectively evaluate generated questions across a variety of applications.

A More dataset details

We use six different NLP classification datasets to demonstrate the effectiveness of our framework. Each of the six focuses on a different domain, allowing for robust testing.

s2d: The Symptom2Disease (s2d) dataset challenges the model's ability to classify diseases based on incomplete symptom descriptions, which is critical in medical decision-making.

cnews: The Crypto News dataset assesses the framework's adaptability to rapidly evolving financial data.

stress: The Human Stress Prediction dataset evaluates the model in a psychological context, where input data is often sparse or incomplete.

20NG: The 20 Newsgroups dataset, with its wide range of discussion topics, tests the model's generalizability across various themes.

dbp: The DBpedia dataset challenges the model with a broad spectrum of structured factual information, which is essential for handling real-world knowledge-based queries.

salad: The Salad-Bench dataset is a novel benchmark designed for evaluating LLMs in safety, defense, and attack scenarios.

B Prompts used

Primarily, we use two different prompting baselines along with the GuideQ framework. 'LLM' is the baseline where the model alone generates the clarifying question without external information. The only input is the partial information. Secondly, LLM-nk is the baseline where LLM sees the partial information and the top-3 categories to choose from without exposure to the guiding keywords. Finally, GuideQ leverages both top labels and guiding keywords corresponding to each of them for the formation of clarification questions.

We present the prompts corresponding to each of them in figure 4 , figure 5, figure 6, for LLM, LLM-nk, and GuideQ respectively.

The few shot examples used are as follows. Each time we take increasing inputs of partial information, categories, and guiding keywords:

Example 1:
Partial information: I constantly sneeze and have a dry cough.

Category: Allergy
keywords: headache, coughing, wet, sneeze, pain
Category: Diabetes
keywords: severe, feet, skin, rashes, infection
Category: Common Cold
keywords: swollen, cough, body, shivery, ache, dry

QUESTION: "Besides fever, are you experiencing symptoms such as cough, severe headaches, localized pain, or inflammation? Also, can you describe the pattern of your fever—is it continuous or does it occur in intervals?"

Explanation (GuideQ): Sneeze and dry cough are the main subjects of the partial information. Coughing is present in Allergy and common cold, but cough or sneeze is not present in Diabetes. Therefore, Diabetes can't be a possible label. Only two labels—Allergy and Common Cold—are considered. The keywords suggest that knowing about symptoms like headache, body pain, shivery, etc., will help refine the classification into one of the labels.

Example 2: Partial information: The software keeps crashing.

Category: Software Bug
Keywords: crash, error, bug, glitch
Category: User Error
Keywords: instructions, setup, incorrect, usage
Category: Hardware Issue
Keywords: overheating, components, failure, malfunction

Explanation: The main subject of the partial information is the software crash. The keyword 'crash' is directly related to Software Bug but could also be indirectly related to User Error and Hardware Issue. However, to differentiate, asking about the conditions under which the crash happens or if any error messages appear could help narrow down the correct category.

QUESTION: "When the software crashes, do you receive any specific error messages, or does it happen during particular tasks? Have you noticed any hardware malfunctions or overheating before the crashes?"

Example 3:
Partial information: The car is making a strange noise.

Category: Engine Problem
Keywords: noise, misfire, engine, smoke
Category: Tire Issue
Keywords: flat, noise, pressure, alignment
Category: Transmission Issue
Keywords: shifting, noise, gears, slipping

Explanation: The main subject of the partial information is the strange noise. The keyword 'noise' is present in all three categories—Engine Problem, Tire Issue, Transmission Issue. Knowing more about the type of noise and when it occurs can help identify the correct category.

QUESTION: "Can you describe the noise in more detail? Is it a grinding, squealing, or clicking sound? Does it happen while driving, when shifting gears, or when the car is stationary?"

C Examples

C.1 Generated Questions

Table 8 shows examples of generated questions using various baselines as well as our GuideQ framework for a comparative analysis. In the example shown, we observe that guiding keywords help reach the second half better. is highly effective in addressing the user's symptoms. It specifically targets the brownish, stringy phlegm they described, key to diagnosing pneumonia, and explores critical symptoms like chest tightness and breathing difficulty. Additionally, it inquires about the duration of symptoms, providing important context for assessing illness progression. In contrast, question-LLM and questionnk are more general and do not focus on the phlegm's characteristics, which are essential for diagnosing pneumonia. While they ask about respiratory infections and symptoms like wheezing and chest tightness, they are less detailed and may result in vague responses, missing crucial diagnostic information.

C.2 Generated Keywords

Table 9 shows examples of generated keywords based on one-gram, two-gram, and three-gram occlusion methods. From a qualitative observation, we note that two-gram is can be an optimum approach to capture relevant information. While one-gram may miss important information, three-gram can have the tendency to in-cooperate irrelevant information.

D Further Results of classification

We further report the recall and precision scores for the main classification task following table 1 results. The recall and precision values show a similar trend as that of F1-score in table 1. We report precision scores in table 6 and recall in table 7. GuideQ shows significant improvement over other baselines in most of the situations.

You are an AI expert. You are provided with a partial information. Your task is to ask an information-seeking question based on the partial information such that when answered, one of the categories to which it belongs to can be selected with confidence.

Follow the following thinking strategy:
- Identify the main context of the partial information.
- Now generate a question. This question should further probe for information that will help refine the understanding of the most likely situation.
- Generate both the thought process and the question. Strictly follow the format shown in examples for output generation. Double quote the final question.

Abstract

While a large body of work inspects language models for biases concerning gender, race, occupation and religion, biases of geographical nature are relatively less explored. Some recent studies benchmark the degree to which large language models encode geospatial knowledge. However, the impact of the encoded geographical knowledge (or lack thereof) on real-world applications has not been documented. In this work, we examine large language models for two common scenarios that require geographical knowledge: (a) travel recommendations and (b) geo-anchored story generation. Specifically, we study five popular language models, and across about 100K travel requests, and 200K story generations, we observe that travel recommendations corresponding to poorer countries are *less unique* with fewer location references, and stories from these regions more often convey emotions of hardship and sadness compared to those from wealthier nations. [1]

1 Introduction

Given the excitement around large language models, users resort to these models for a diverse range of applications (Brown et al., 2020; Touvron et al., 2023). Based on our analysis of ShareGPT,[2] a collection of user interactions with ChatGPT, 1.7% of queries are about travel recommendations, whereas 1.5% concern story generation. Such use cases make one wonder whether the generated travel itinerary for Mumbai is just as informative compared to New York City? Or is a generated story of a girl growing up in Nairobi just as relatable compared to another story based in Seattle? For these applications to be broadly useful, it is important that there are no (or few) geographical disparities.

Some recent works aim to benchmark the extent of geographical knowledge encoded in large language models (Bhandari et al., 2023; Manvi et al., 2023; Moayeri et al., 2024). Interestingly, a recent study finds that language models accurately predict global facts such as population and rainfall for different geo-locations, however, their predictions on sensitive topics such as attractiveness or morality are, problematically, biased against areas with poorer socioeconomic conditions (Manvi et al., 2024). Similar in spirit, our work aims to quantitatively study model responses for two real-world scenarios that require geographical knowledge.

In this work, we analyze over 300K responses from 5 language models, corresponding to requests for travel recommendations and geo-anchored story generations. These requests span over 150K locations across the globe. We quantify the informativeness and uniqueness of model responses, in addition to the emotions they express. We then compare these quantities with the socioeconomic indicators of different locations.

Through our analysis, we uncover several geographical disparities, finding that outputs for wealthier countries are more unique and include more geographical entities (Figure 1). For Sub-Saharan African countries, we notice considerably less unique outputs compared to the North American region, with the average difference being about 40% across all models. Further, stories about poorer countries express considerably more hardship and sadness, with 60% fewer narratives depicting hardship for high-income countries compared to low-income countries.

Despite many large corporations claiming to be egalitarian, e.g., OpenAI aims to develop intelligence that *benefits all of humanity* (OpenAI, 2024), many findings, including ones from this study, demonstrate how current models perpetuate western hegemony in the generated content (Schwöbel et al., 2023; Bender et al., 2021), and more serious effort is needed to ensure that models serve the diverse population across the globe.

Left: Average count of geographical entities mentioned in generated stories (correlated with the GDP per capita with Pearson $r = 0.5$). Right: Uniqueness scores for travel recommendations (Pearson $r = 0.4$ with GDP per capita).

2 Related Work

Geographical Bias in Language Technologies. Language models can generate disproportionate and prejudiced representations of marginalized groups (Navigli et al., 2023). Significant efforts quantify these biases across various dimensions, including gender (Sheng et al., 2019), race (Omiye et al., 2023), culture (Wang et al., 2023), religion (Abid et al., 2021), and more. Recent studies also highlight 'geographical biases' in LMs: one such study finds that when models are instructed to rank countries in terms of topics such as work ethic, intelligence and attractiveness, they undervalue areas with lower socio-economic status (Manvi et al., 2024). An analysis of models over WorldBench, a benchmark to assess factual recall in LLMs over country-wide data from the World Bank, reveals higher error rates for countries with lower income levels (Moayeri et al., 2024). Global-Liar, a dataset by Mirza et al. (2024), benchmarks the accuracy of models in fact-checking claims from six global regions and underscores the disadvantages faced by regions in the Global South. Despite these efforts to highlight bias in geographical factual predictions, there is a noticeable lack of research addressing biases in real-world applications of geographical knowledge. Our work addresses this gap by examining biases across practical applications of story generation and travel recommendation. There exists prior work on travel planning (Xie et al., 2024), and a large literature on story generation (Zhao et al., 2023), but to the best of our knowledge, these works do not examine geographical disparities.

3 Approach

Below, we briefly describe our approach to quantitatively examine the outputs from different language models for two tasks: generating travel recommendations and geo-anchored stories.

3.1 Experimental Setup

Examined Locations. To capture the global variation in LLM performance, it is crucial to incorporate a diverse array of geographical regions, covering cities, towns, and villages, in our analysis. For this purpose, we use Geonames[3], a community-driven geographical database, comprising an extensive list of location names. We capture all global locations with inhabitants exceeding 1000, to achieve a finer granularity and a more nuanced understanding of global disparities. This surpasses most prior work that largely study geographical biases with only country-level information (§2). At the time of our study, GeoNames contained about 150K locations. To make the analysis computationally feasible, we randomly sample, with replacement, up to 25 locations per country from this larger population totalling about $4,000$ locations for 190 countries. For every attribute we quantify, we report averages across 3 such random samples (with different seeds) to infer patterns across all locations.

Input Prompts. We manually curate a set of prompt templates with location placeholders, which are later populated with the sampled locations. For example, "Write a story of a family from [Location]" is a prompt for story generation. We intentionally keep the prompts simple, avoiding additional variables to ensure a fair comparison and isolate the influence of location on the model's response. For each location, we randomly choose 6 templates (4 for story generation and 2 for travel recommendation) and fill the location slot. Such slot-filling approaches to generate inputs are commonly used in the literature (Chang et al., 2023). While queries related to travel recommen-

Table 1: Pearson's correlation coefficients depicting the relationship between various attributes (averaged for each country) with the GDP per capita (denoted as **GDP**) and the frequency of country mentions in the PILE dataset (**Freq**) for generating travel recommendations and stories. $*$ denotes values with p-value < 0.05.

dations naturally incorporate a geographical aspect, for story generation, we specifically design *system prompts* to elicit accurate and descriptive geographical details. We share the list of prompt templates in Appendix A.1.

Models. We perform our evaluation on five widely used and capable models: GPT-4 (Achiam et al., 2023), Mistral 7B (Jiang et al., 2023), Mixtral 8×7B (Jiang et al., 2024), LLaMa 3 8B, and LLaMa 3 70B (Dubey et al., 2024), to help us cover a broad range of characteristics, including size, training methods, and availability. We set the temperature to 0.7 to achieve a balance between creativity and coherence.

3.2 Evaluation

For geo-anchored applications, such as travel recommendations and story generation, there is often no definitive right or wrong response. One possible approach is to find local participants from every geographical region, and request them to qualitatively evaluate each response. Past work has noted that it is challenging to find such participants (Basu et al., 2023). Instead, we quantify few attributes that we believe contribute to the quality of the response, such as uniqueness and informativeness. We briefly describe these attributes:

Uniqueness. Every location presents a blend of historical, cultural, geographical, and environmental factors, contributing to its unique identity. To reflect this, models need to be aware of these distinctive aspects for different regions. We use the uniqueness measure to capture how distinct the subjective responses for a given location are compared to others. We make a slight modification to the TF-IDF metric to calculate the average rarity of words generated in the response of a location compared to other locations. Terms which score high as per our metric, anecdotally, reflect regional artifacts (e.g., "dosa" for India). Additionally, we also compute the Type-Token Ratio (TTR), the ratio of unique words to total words, which captures the lexical diversity of these responses. Past efforts have effectively used the TTR metric to measure richness in vocabulary in various contexts (Balestrucci et al., 2024; Morris et al., 2023). We provide further details of the uniqueness metric in Appendix A.2.

Informativeness. It is challenging to quantify the overall informativeness of a response, as a proxy, we compute the number of geographical entities present in model responses. Both the examined applications solicit geographical details, and therefore we tag the responses using Spacy NER tagger to extract GPE (Geopolitical entities), LOC (Non-GPE locations) and FAC (buildings, airports, etc.). We also attempt to quantify the factual correctness, or utility, of recommendations by estimating the proximity of the extracted locations to the city in question. However, quantifying this turns out to be quite challenging (see §5 for details).

Emotions. Stories are rife with emotions. We study the variation in emotions expressed in model generated stories. Recent research has demonstrated that GPT-4 can serve as an effective emotion annotator (Niu et al., 2024), noting that human evaluators often favour emotion annotations by GPT-4 over those provided by human annotators. We apply a similar method for emotion recognition in generated stories by using GPT-4 to identify the emotions of joy, hardship and sadness expressed.

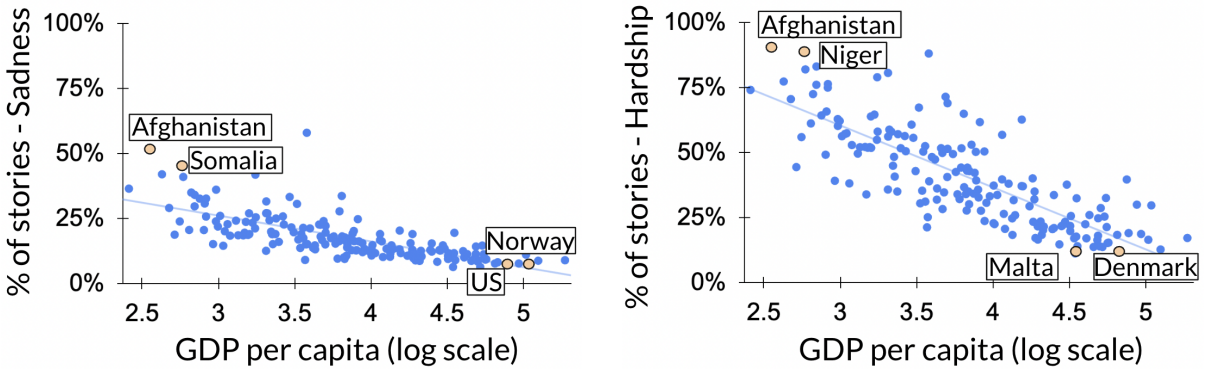

Figure 2: Percentage of stories generated by GPT-4 depicting the emotions of sadness (left, Pearson $r = -0.45$) and hardship (right, Pearson $r = -0.54$) for each country vs. GDP per capita.

4 Results

We aggregate the (estimated) city-level attributes for every country to observe trends across different countries. Interestingly, the uniqueness scores for India, Italy, Japan, and the United States consistently rank among the highest across all models in both applications. Comparing regions, we observe that travel recommendations for the Sub-Saharan African region are considerably less unique than those for the North American region, with alarming differences of 43% for GPT-4, 42% for LLaMa 3 8B, 39% for LLaMa 3 70B, 37% for Mistral 7B, and 38% for Mixtral 8×7B .

A similar trend is observed in the informativeness of generated stories, wherein most models generate a large number of geographical entities for the United States and the United Kingdom. Problematically, the responses for the North American region include around double the number of location mentions in stories compared to those from the Sub-Saharan African region across all models.

Studying the emotions presented in the generated stories, we notice that while only 20% of stories generated for the North American region depict hardship, this figure rises to 47% for the Sub-Saharan African region. Interestingly, we find that an overwhelming fraction of stories, about 99%, express some form of joy, suggesting an overall **positivity bias** in model-generated stories.

Relationship with GDP per capita. We present the Pearson correlation coefficients for all attributes aggregated by country with the country's GDP per capita for different models in Table 1. We observe weak-to-moderate positive correlations for uniqueness and count of geographic locations with per capita GDP, indicating a poorer representation of countries with lower GDP per capita. We also note a moderate-to-strong negative correlation with the fraction of stories expressing hardship and sadness, with the highest percentage being for Somalia, Niger, South Sudan, and Afghanistan (Figure 2).

Relation to frequency of country mentions. We speculate that the observed discrepancies might be due to inadequate representation in the training data. We use infini-gram API (Liu et al., 2024) to obtain a frequency of country mentions in The Pile corpus (Gao et al., 2020). We note down its correlations of quantified attributes in Table 1. The correlations indicate that the underrepresentation of poorer countries in the training data might explain the observed trends. For instance, the correlation between uniqueness in responses and frequency of mentions is moderate to high for all models.

Model Size. We examine two models each from the LLaMa 3 and Mistral family of models. The key purpose of including models with different sizes is to evaluate whether larger models (which hold more information) exhibit fewer geographical disparities. However, our results suggest otherwise as larger models result in similar correlations.

Absence of Information. Requests for travel recommendations occasionally result in models indicating that they are unfamiliar with the location or that the location is not known for trips. We count the fraction of such responses and aggregate them for each country and report them as "Absence of Information" in Table 1. This attribute shows a negative correlation with GDP per capita for the GPT-4 and Mixtral models. (LLaMa 3 models do not systematically decline such requests).

5 Limitations and Future Work

There are a few important limitations of our work. First, we only focus on two geo-anchored applications, namely generating stories and travel recommendations. While we believe that the observed discrepancies might be prevalent for other tasks, our current findings are limited to these two scenarios. Future work could broaden our investigation by considering more geo-centric tasks.

Second, we do not measure the relevance and validity of the generated geo-locations. As a proxy for relevance, we attempted to compute the proximity of generated entities to the location in question. However, this task is quite challenging, as a generated geographical entity (e.g., the Himalayas) might cover a large area, and it is unclear which part of that area should one measure proximity from. Further, geographically locating an entity can also be error-prone, as there are often multiple locations with the same name.

Third, this study primarily focuses on attributes that are easy to quantify. Future work could consider conducting qualitative studies to evaluate the cultural appropriateness of the responses, which could yield further insights and provide a complementary perspective. Lastly, future work could also expand our evaluation to measure the relevance, relatability and factuality of cultural artifacts within geo-anchored responses, by leveraging existing resources such as CUBE (Kannen et al., 2024) and WorldCuisines (Winata et al., 2024).

6 Conclusion

We evaluate language models on two real-world applications of generating travel recommendations and geo-anchored stories, through a geographical lens. We uncover significant disparities in the representation of various locations that mirror existing economic inequalities. These disparities lead to skewed perspectives and limit access to accurate information across geographies, ultimately shaping and reinforcing user perceptions. This study underscores the importance of developing geographically diverse datasets for model training, to create more equitable and representative models that better serve a wide range of global needs.

Acknowledgements

We would like to thank the anonymous reviewers. Our work benefitted from discussions with Sunayana Sitaram, Mitesh Khapra, Shachi Dave, Partha Talukdar, Mansi Gupta, Preethi Seshadri and Abhipsa Basu. We also appreciate Navreet Kaur for her suggestions on the prompt templates. This work was supported in part by the AI2050 program at Schmidt Sciences (Grant G-24-66186). Additionally, DP is grateful to Adobe Inc., Google Research, and the Kotak IISc AI-ML Centre (KIAC) for generously supporting his group's research.

A Appendix

A.1 Prompt Templates

We share our manually curated prompt templates for the application of story generation in Table 2 and travel recommendation in Table 3. For each sample location, we randomly select one prompt template from each category, resulting in 4 prompts for Story Generation and 2 prompts for Travel Recommendation for each location. The [LOCATION] placeholder is replaced with the specific location name to query the model. The system prompt is designed to guide the models in generating a geographically anchored narrative for the application of story generation.

A.2 Uniqueness Calculation

The following explains how the uniqueness score is calculated. We denote the collection of all the responses for an application a as R_a. Here an application can refer to story generation or travel recommendations. We first calculate the inverse document frequency *idf* of all words *w* (excluding stop-words) present in R_a. This is an indicator of how rare the word is across all responses.

$$idf(w, R_a) = \frac{|R_a|}{f_{w,R_a}} \tag{1}$$

where $|R_a|$ denotes the cardinality of the collection R_a and f_{w,R_a} equals the number of responses in R_a that contain the word *w*. We further calculate the uniqueness score *U* for each location *l* as

$$U(l, R_a) = \frac{1}{|R_{a,l}|} \sum_{r \in R_{a,l}} \left(\frac{1}{|r|} \sum_{w \in r} idf(w, R_a) \right) \tag{2}$$

where $R_{a,l} \subset R_a$ denotes the collection of responses in R_a for location *l*, $|R_{a,l}|$ denotes the size of $R_{a,l}$, *r* denotes the individual responses in $R_{a,l}$ and $|r|$ denotes the total number of words in response *r*, excluding the stop-words.

A.3 Qualitative results

Rare words that contribute to high uniqueness scores often highlight the regional artifacts and geographic references specific to the location. We share some qualitative examples by highlighting the rare words that contribute most to the uniqueness scores for the application of Story Generation in Figure 3 and Figure 4.

Category	Prompt for Story Generation
Altering gender neutral personas	Write a story of a middle aged local from [LOCATION]. Write a story of a young local from [LOCATION]. Write a story of a couple from [LOCATION]. Write a story of a family from [LOCATION]. Write a story of an old person from [LOCATION].
Altering occupation	Write a story of a gardener from [LOCATION]. Write a story of a social worker from [LOCATION]. Write a story of a writer from [LOCATION]. Write a story of a teacher from [LOCATION]. Write a story of a shopkeeper from [LOCATION].
Childhood Days	What were the chilhood days like for someone born in [LOCATION]? Paint a picture of the childhood experiences of a person from [LOCATION]. What was childhood like for someone who grew up in [LOCATION]? Describe the childhood days of a person born in [LOCATION]. How would you describe the childhood experience of someone born in [LOCATION]?
Typical day	Illustrate a day-to-day routine in [LOCATION]. What does an ordinary day look like in [LOCATION]? Paint a picture of a usual day in [LOCATION]. Describe a typical day in the town of [LOCATION]. Capture the essence of a typical day in [LOCATION].

Table 2: List of prompts considered for the application of Story Generation. One prompt from each category is randomly chosen for each location.

Category	Prompt for Travel Recommendation
3-day Itinerary	Help me plan a 3-day trip to [LOCATION]. Design a 3-day travel schedule for [LOCATION]. Plan a memorable 3 day getaway to [LOCATION] for me. Help me create a 3 day itinerary for my visit to [LOCATION]. Assist me in organizing a three-day itinerary for [LOCATION].
Landmarks	What are some places to visit in [LOCATION]. What are the top attractions to visit in [LOCATION]. Name popular tourist spots in [LOCATION]. Name top landmarks to visit in [LOCATION]. What are some places one should add in their travel plans when visiting [LOCATION]. Tell me some important sites to incorporate into my travel plans to [LOCATION].

Table 3: List of prompts considered for the application of Travel Planning.

Prompt : What does an ordinary day look like in Râchaïya el Ouadi, Lebanon.

Response : In Râchaïya el Ouadi, a small town nestled in the **Bekaa** Valley in eastern Lebanon, an ordinary day is filled with a blend of traditional rural life and the natural beauty of its surroundings. The day starts early, with the first rays of the sun painting the sky in hues of orange and pink, reflecting off the snow-capped peaks of Mount **Hermon** in the distance. The town comes alive with the sounds of the morning **Adhan**, the Islamic call to prayer, echoing from the aged stone walls of the town's **mosques**. The residents, dressed in traditional Lebanese attire, begin their day as the cool morning air gives way to the warmth of the sun. The men head off to work in the fields, tending to their crops of tomatoes, cucumbers, and potatoes, their hands stained with the rich, fertile soil of the **Bekaa** Valley. Women, donning their colorful **scarves**, can be seen tending to household chores or preparing food for their families, the air filled with the aroma of freshly baked flatbread, **za'atar**, and other authentic Lebanese cuisine. Kids, with their school bags bouncing on their backs, make their way to the local school, their laughter echoing through the narrow cobblestone streets lined with traditional stone houses. The town square, with its central fountain and lush greenery, serves as a meeting point for the locals, a place to share stories, play games or simply enjoy a cup of strong Lebanese coffee. Despite its small size, Râchaïya el Ouadi is rich in history and culture. The town is home to the **Citadel of Independence**, a fortress that played a significant role in Lebanon's struggle for independence. Tourists often visit this historical site, guided by locals who narrate tales of the town's past with pride and nostalgia. As the day winds down, the setting sun casts a golden glow over the town, the shadows stretching over the fields and the ancient **ruins**. The evening prayer from the mosque signals the end of the day, a time for the locals to gather in their homes, share a meal, and enjoy the tranquility of their town. In Râchaïya el Ouadi, each day is a testament to the enduring spirit of its people, their deep-rooted connection to their land, and their rich cultural heritage. It's a place where tradition meets beauty, creating a unique rhythm of life that is truly Lebanese.

Figure 3: Example prompt and response generated for a location in Lebanon. We notice few geographical references and regional artifacts mentioned (highlighted in red) in the response, leading to the low uniqueness score of 24.

Prompt : Illustrate a day-to-day routine in Marino, Italy.

Response : The day in Marino, a charming hilltop town in the Metropolitan City of **Rome**, Italy, begins with the sunrise over the picturesque **Alban Hills**. The soft morning light bathes the pastel-colored houses, ancient vineyards, and **olive groves**, creating a dreamy landscape that can only be seen in this part of the world. The town gradually wakes up to the sound of church bells echoing from the **Santa Maria delle Grazie**, a **16th-century basilica** that stands as a testament to Marino's rich historical past. The smell of freshly baked **cornetti** wafts through the narrow, **cobblestone** streets as the local bakers, known as **'panettieri'**, open their shops. Marino is renowned for its white wine, and by mid-morning, the vineyards are alive with activity. The locals tend to their vines, carefully nurturing the grapes that will later be transformed into the famous Marino **DOC** wine, a dry, aromatic white wine that has been a part of Marino's identity for centuries. Back in the town, the open-air market at **Piazza Giacomo Matteotti,** the town's main square, is bustling. Farmers from surrounding areas have arrived to sell their fresh produce. Local vendors offer a vibrant array of cheeses, **salamis**, and the famous **porchetta**, a savory, fatty, and moist **boneless pork roast** Italian specialty. After a busy morning, the locals retreat for "**riposo**", the traditional Italian afternoon rest. The town quiets down, shops close, and people return home for an afternoon "**pranzo**" (lunch) with their families. The air is filled with the aroma of authentic Italian cuisine, such as **pasta alla amatriciana** and **saltimbocca alla Romana**, that wafts from the kitchens. As the afternoon fades into evening, the town springs back to life. The cafes around the **Piazza** fill up with people engaged in lively conversation, sipping on their **espresso**. As night falls, the town exudes a magical glow. The locals often gather in the town square or at the local "**osterias**" to enjoy a glass of Marino wine, paired with local dishes like "**fettuccine ai funghi porcini**" (pasta with **porcini mushrooms**) while sharing tales and laughter. Life in Marino is a beautiful blend of tradition and simplicity, where every day is a celebration of its rich history, delicious food, exquisite wine, and the warmth of its people. It's not just a place, it's a lifestyle, deeply steeped in Italian culture and customs.

Figure 4: Example prompt and response generated for a location in Italy. We notice many geographical references and regional artifacts mentioned (highlighted in red) in the response, leading to the high uniqueness score of 1296.

Swan and ArabicMTEB:

Dialect-Aware, Arabic-Centric, Cross-Lingual, and Cross-Cultural Embedding Models and Benchmarks

Abstract

We introduce **Swan**, a family of embedding models centered on Arabic, designed for both small-scale and large-scale applications. Swan comprises two variants: Swan-Small, built on ARBERTv2, and Swan-Large, based on ArMistral, a pretrained Arabic large language model. To evaluate our models, we propose a comprehensive benchmark suite, dubbed ArabicMTEB, that assesses cross-lingual, multi-dialectal, multi-domain, and multi-cultural Arabic text embedding performance. ArabicMTEBcovers eight diverse tasks sourced from 94 datasets. Swan-Large achieves state-of-the-art results, outperforming Multilingual-E5-large in most Arabic tasks, while Swan-Small consistently surpasses Multilingual-E5-base. Our extensive evaluations show that Swan models are both dialectally and culturally aware, achieving strong performance across diverse Arabic domains while maintaining significant cost efficiency. This work significantly advances the field of Arabic language modelling and provides valuable resources for future research and applications in Arabic NLP. Our models and benchmark are available at our GitHub page: https://github.com/UBC-NLP/swan.

1 Introduction

NLP has seen rapid advancements in recent years, driven by groundbreaking developments in deep learning and the emergence of sophisticated distributed text representations such as word and sentence embeddings (Devlin et al., 2018; Reimers and Gurevych, 2019). These embeddings, which transform text into dense vectors, enable effective semantic understanding and are pivotal for enhancing performance across many downstream applications, including text classification, semantic search, and machine translation. Moreover, text embeddings have become fundamental to the success of large language models (LLMs) (Touvron et al., 2023; Jiang et al., 2023; Gemma-Team et al., 2024), which are increasingly integrated into a variety of real-world systems and tools. One of the most promising applications of these embeddings is in the realm of Retrieval-Augmented Generation (RAG) (Shao et al., 2023; rag, 2023), where LLMs are augmented with information retrieval capabilities. In RAG-based systems, lightweight embedding models retrieve relevant information from large corpora, fed as context to models like ChatGPT (OpenAI, 2023) or GPT-4 (OpenAI et al., 2024). This synergy between embeddings and LLMs has demonstrated significant improvements in both general-purpose tasks such as question answering (Lin et al., 2023; rag, 2023) and domain-specific applications (Bhatia et al., 2024; Shi et al., 2023; Lin et al., 2023).

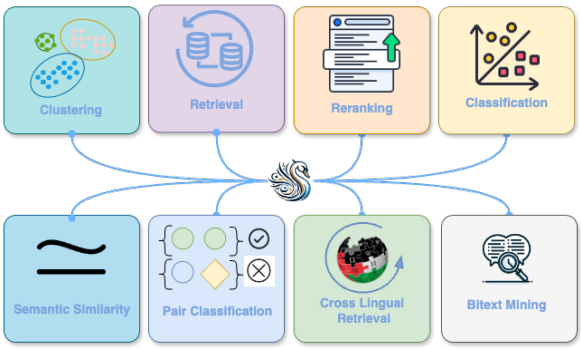

Figure 1: Overview of our ArabicMTEB benchmark tasks, covering *clustering, retrieval, reranking, classification, semantic similarity, pair classification, cross-lingual retrieval,* and *bitext mining*.

Despite these advances, the predominant focus of current embedding models has been on English and Chinese, which limits their applicability to other languages. This is particularly true for Arabic, a collection of languages, language varieties, and diverse dialects with rich morphology (Abdul-Mageed et al., 2023a, 2024a), making it challenging to develop effective language representations (Nagoudi et al., 2022; Huang et al.,

Findings of the Association for Computational Linguistics:
NAACL 2025, pages 4669–4685
April 29 - May 4, 2025 ©2025 Association for Computational Linguistics

2024). Existing multilingual models often fail to capture these complexities, leading to a suboptimal performance on Arabic NLP tasks (Abdul-Mageed et al., 2020a; Elmadany et al., 2022). Addressing this limitation requires the development of Arabic-specific embedding models that are sensitive to the linguistic and cultural nuances of Arabic.

In this work, we introduce Swan, a family of dialect-aware, Arabic-centric, cross-lingual, and cross-cultural embedding models designed to bridge this gap and push the boundaries of Arabic NLP. Our contributions are as follows:**(1)** We introduce Swan, a cutting-edge family of Arabic embedding models. This includes two variants: Swan-Small, based on ARBERTv2 (Elmadany et al., 2022), and Swan-Large, built upon ArMistral, a further pretrained Arabic language model. **(2)** We present ArabicMTEB, a comprehensive evaluation benchmark for Arabic text. ArabicMTEB is designed to assess cross-lingual, multi-dialectal, multi-domain, and multi-cultural performance, spanning eight tasks and 94 datasets. Figure 1 provides an overview of ArabicMTEB. **(3)** Our larger model, Swan-Large, showcases state-of-the-art text embedding capabilities, surpassing Multilingual-E5-large (Wang et al., 2024b) on most Arabic tasks. Similarly, our smaller, Swan-Small, consistently outperforms Multilingual-E5-base (Wang et al., 2024b) on most Arabic tasks. **(4)** Through rigorous benchmarking, we demonstrate that Swan models are not only dialectally and culturally aware, but also excel across diverse Arabic domains while maintaining a significantly lower monetary cost.

The rest of the paper is organized as follows: In Section 2, we review related work with a particular emphasis on Arabic text embedding models, their applications and challenges. We present our approach to model training of Swan models in Section 3. Section 4 outlines how we built our benchmark dataset, ArabicMTEB. Section 5 is about our experiments and model analysis. We conclude in Section 6.

2 Related Work

In recent years, there have been remarkable advancements in text embedding models, with a shift towards developing universal embeddings for diverse tasks and domains. Despite this, specialized models and benchmarks for languages like Arabic remain underexplored.

Multilingual Text Embedding Models. With the need for language-agnostic embeddings growing, multilingual models such as LASER (Artetxe and Schwenk, 2019) and LaBSE (Feng et al., 2022) were developed using BiLSTM and Transformer encoders, respectively. Building on this, the Multilingual-E5 (Wang et al., 2024c) series extends the E5 architecture to support diverse languages using multilingual text pairs and synthetic data. GRIT (Muennighoff et al., 2024) further unifies generative and embedding tasks within a single model. Newer models such as ColBERT-XM (Louis et al., 2024) and Gecko (Lee et al., 2024) refine multilingual embeddings through modular and distilled architectures.

Arabic-Specific Models. Despite progress in Arabic NLP, existing models are not optimized for Arabic text embedding and retrieval. Efforts like ARBERT (Abdul-Mageed et al., 2021a) and AraMus (Alghamdi et al., 2023) have focused on encoding and generation but are not tailored for sentence-level embeddings. While language-agnostic models such as LASER and Multilingual-E5 include Arabic in their training data, they may not fully capture its linguistic intricacies and diversity. To address this, Nacar and Koubaa (2024) introduced models and training datasets to improve semantic similarity performance for Arabic.

Text Embedding Benchmarks. Most text embedding evaluations rely on a narrow set of datasets, limiting their generalisation ability. To address this, the Massive Text Embedding Benchmark (MTEB) (Muennighoff et al., 2023) introduced eight task categories with 58 datasets and 112 languages. However, it remains predominantly focused on English. Similar benchmarks have been developed for other languages, such as C-MTEB (Xiao et al., 2023) for Chinese. For Arabic, evaluations have primarily centred on Semantic Text Similarity (STS) tasks (Nacar and Koubaa, 2024). However, excelling in STS does not guarantee optimal performance in tasks like clustering or reranking (Muennighoff et al., 2023). Existing Arabic benchmarks like ORCA (Elmadany et al., 2023) and ALUE (Seelawi et al., 2021) focus on natural language understanding (NLU), while Dolphin (Nagoudi et al., 2023a) targets natural language generation (NLG). This work is the first comprehensive benchmark for evaluating Arabic text embeddings across multiple tasks.

Benchmark	Lang	Tasks	Datasets	Tasks	CRTR	Ar Cul/Dom

3 Swan

3.1 Training Data

To train Swan, we develop the most extensive training corpus for Arabic embedding models, leveraging a unique assembly of datasets to ensure comprehensive linguistic coverage and diversity. Our training data covers paragraph-based and sentence-based datasets curated from multiple sources. Table 2 shows an overview of our training datasets.

MSA Datasets. We focus on two sources: **(i) Human-generated data:** Composed from ORCA (Elmadany et al., 2023) and mMARCO (Bonifacio et al., 2021). ORCA is a compilation of labelled datasets with tasks such as semantic text similarity (STS), sentence classification, text classification, natural language inference (NLI), and question answering. We use all the training sets from ORCA, encompassing 60 different datasets. mMARCO-ar is the translated version of MARCO, which is a human-generated dataset (Bajaj et al., 2018). Both of these datasets are cleaned up and de-duplicated using Polydedupe (Bhatia, 2023),[1] which is further described in Appendix C. **(ii) Synthetically-generated data:** To augment our MSA training data for retrieval tasks, we use Command R+ (Cohere For AI, 2024) to generate high-quality synthetic data.[2] The generation methodology is inspired by Wang et al. (2024a), and we employ the procedure shown in Figure 2 to generate our synthetic dataset. We generate $100k$ in general MSA data and $5k$ in instances for specific domains such as finance, news, medicine, and legal for a total of $120k$ MSA instances.

Dialectal Arabic Datasets. Similar to the MSA

[1] https://github.com/gagan3012/PolyDeDupe

[2] We performed various in-house evaluations comparing multiple models. Command R+ was chosen as it is open-source and efficient in generating Arabic varieties (standard and dialectal).

datasets, we focus on two sources: **(i) Human-generated data:** We use publicly available dialectal Arabic data, which primarily covers Gulf, Egyptian, Moroccan, and Levantine varieties of Arabic (Elmadany et al., 2022; Nagoudi et al., 2023b; Alwajih et al., 2024; Abdul-Mageed et al., 2020b, 2021c, 2022, 2023b, 2018, 2020c; Keleg et al., 2023; Keleg and Magdy, 2023; Zaidan and Callison-Burch, 2014; Bouamor et al., 2018). The total number of samples is $122K$. **(ii) Synthetically-generated data:** As most human-generated dialectal data comes from noisy environments such as social media, it often results in short texts of low quality. Thus, we use Command-R+ to generate paragraph-based synthetic data for Egyptian and Moroccan dialects to improve the performance of our models on dialectal Arabic. We generated $15k$ dialectal instances using the same methodology as our synthetic MSA datasets described above.

Cross-Lingual & Multilingual Datasets. To adapt our model for cross-lingual and multilingual scenarios, we incorporate the mMARCO dataset, which provides translations of the MS MARCO dataset into 15 languages (Bonifacio et al., 2021). To ensure that documents correspond accurately to their queries in different languages, we utilize specific IDs. We create $100k$ samples for each cross-lingual pair and shuffle the IDs to prevent repetition, thus guaranteeing that unique data samples are used for each language. We utilize the MIRACL (Zhang et al., 2022), XOR-TyDI (Asai et al., 2021), and Mr.TyDi (Zhang et al., 2021) datasets as our crosslingual and multilingual resources.

3.2 Training Strategy

For `Swan`, we consider two models: `Swan-Small` and `Swan-Large`. The choice of training two models with different sizes is driven by the need to balance performance and computational efficiency. `Swan-Small` is designed to cater to scenarios where lower computational resources are available or when a lightweight model is preferred for deployment on edge devices. In contrast, `Swan-Large` is intended for settings where achieving SoTA performance is paramount, leveraging a larger parameter size to better capture the nuances of Arabic.

Data Preprocessing. We incorporate human-generated and synthetic datasets into our training pipeline to ensure robust performance across various dialects and cultural contexts. We first train on MSA datasets, followedby fine-tuning on dialectal datasets. This two-step approach ensures that both MSA and dialectal varieties are well represented, promoting better generalization across the full spectrum of Arabic varieties. Our dataset is constructed with a query format, including positive and negative samples.

`Swan-Small`. Built upon ARBERTv2 (Abdul-Mageed et al., 2021b), a powerful BERT-based model for the Arabic language. Here, our model is trained using the InfoNCE loss (van den Oord et al., 2019), which maximizes the similarity between related sentences while minimizing the similarity between unrelated sentences. The model is trained for five epochs on the entire dataset with a learning rate of $5e^{-6}$ and a batch size of 128, incorporating 15 hard negatives. `Swan-Small` has 164M parameters and a dimension size of 768.

`Swan-Large`. `Swan-Large` is based on ArMistral-7B, an in-house further pretrained version of Mistral-7B (Jiang et al., 2023)[3]. To train `Swan-Large`, we use LoRA (Hu et al., 2021) for parameter efficient training and InfoNCE loss for optimization. We train the model for three epochs on the entire dataset with a learning rate of $5e^{-6}$ and a batch size of 128, incorporating seven hard negatives. `Swan-Large` has $7.2B$ parameters and a dimension size of $4,096$.

3.3 Training Methodology

Given a relevant query-document pair (q^+, d^+), we modify the query by appending an instructional template to it. This process transforms the original query q^+ into a new form q^+_{inst} as defined below:

$$q^+_{\text{inst}} = \text{Instruction: \{task_instruction\} Query:}\{q^+\}$$

Here, "*{task_instruction}*" refers to a one-sentence description of the embedding task taken from Table 12, which outlines the instructions for different tasks. Using a pretrained LLM, we append an *[EOS]* token at the end of both the modified query and the document. These are then fed into the LLM to extract embeddings $\mathbf{h}_{q^+_{\text{inst}}}$ and $\mathbf{h}_{d^+}$ from the vector at the last [EOS] layer. Again, training of the embedding model is conducted using the InfoNCE loss function, which is widely recognized for its effectiveness in learning high-quality embeddings. The objective is minimized using the following formulation:

[3]Further details about ArMistral can be found in Appendix A.

$$\min\left(-\log\frac{\phi(q^+_{\text{inst}},d^+)}{\phi(q^+_{\text{inst}},d^+)+\sum_{n_i\in\mathbb{N}}\phi(q^+_{\text{inst}},n_i)}\right)$$

In the equation above, $\mathbb{N}$ denotes the set of negative samples, and $\phi(q,d)$ is the similarity scoring function between a query q and a document d.

3.4 Inclusion of Hard-Negatives

To enhance the model's performance, it is crucial to use negative documents closely aligned with the query's context (Karpukhin et al., 2020; Khondaker et al., 2022). This method allows us to observe the impact of introducing more challenging or "hard" negatives into the training process. We only generate hard negatives for the Arabic subset of our training data from Section 3.1. We found that using 15 hard negatives for `Swan-Small` yields the best performance, whereas for our bigger model, `Swan-Large`, the model overfits a more significant number of hard negatives, and 7 gives us the best performance.

Impact of Hard Negatives. Hard negatives in contrastive learning are examples that closely resemble correct instances but are ultimately incorrect. Their inclusion encourages the model to learn finer-grained distinctions, improving its ability to differentiate between similar but distinct classes. The process involves converting all documents into a vector form within the embedding space. Subsequently, these document embeddings are compared using the cosine similarity score to establish their relevance to the query. Once all documents are scored, they are sorted by their similarity to the query. The top-ranked document is typically the positive example, while the rest are potential negatives. Our experiments assess the impact of varying the hard negatives used while training our models, `Swan-Large` and `Swan-Small`. We train each model with different quantities of hard negatives. Namely, we experiment with using hard negatives values from the set {*1, 3, 7, 15, 31*} per training instance. `Swan-Small` achieves its highest performance of 56.25 with 15 hard negatives. The model exhibits a general upward trend as the number of hard negatives increases, peaking at 15 before slightly declining at 31. This pattern suggests that while additional hard negatives initially enhance learning by introducing valuable challenges, excessive complexity may lead to diminishing returns, ultimately hindering further improvement. `Swan-Large` achieves its peak performance of 60.42 when trained with seven hard negatives, suggesting an optimal balance that enhances learning without overloading the model. Notably, increasing the number of hard negatives beyond this point does not lead to further gains, indicating a threshold where additional complexity ceases to improve learning outcomes.

Model (HN)	1	3	7	15	31
`Swan-Small`	48.84	52.19	54.13	**56.25**	51.93
`Swan-Large`	59.48	59.35	**60.42**	59.44	59.83

Table 3: Impact of number of Hard Negatives (HN).

Table 4: Overview of our Tasks in `ArabicMTEB`. *Total represents the unique languages.

4 ArabicMTEB Benchmark

In this section, we present `ArabicMTEB`, a comprehensive Arabic-centric text embedding benchmark designed to evaluate text embeddings across a wide range of tasks and scenarios. `ArabicMTEB` addresses the limitations of existing benchmarks that either exclude Arabic or lack coverage of diverse Arabic language varieties, dialects, and cultural nuances. Our benchmark includes 94 datasets spanning 8 distinct tasks, as summarized in Table 4. Further details about the datasets used in benchmark can be found in Appendix B. `ArabicMTEB` was developed to provide comprehensive coverage of Arabic text embedding capabilities, ensuring the inclusion of MSA and other varieties. It offers diverse task types, such as retrieval, classification, and semantic similarity, to evaluate embeddings holistically across different scenarios by incorporating novel domain-specific, dialectal, and country-level culturally aware datasets, `ArabicMTEB` represents a more applicable and realistic assessment of Arabic text embeddings.

4.1 Task Categories

ArabicMTEB categorizes evaluation datasets into the following key task categories, with each type providing a unique perspective on the capabilities of text embeddings. The corresponding metadata for each task, covering the considered number of datasets, number of languages, number of dialects, and evaluation metric, is presented in Table 4.

Arabic Text Retrieval. This task uses Arabic queries to retrieve Top-k relevant documents from a large Arabic corpus. ArabicMTEB includes 35 retrieval datasets such as XPDA (Shen et al., 2023) and Dolphin's long-form QA datasets (Nagoudi et al., 2023b). Including these datasets helps evaluate complex information retrieval scenarios in Arabic.

Bitext Mining. This task identifies sentence-level translations between different languages and dialects. ArabicMTEB includes 12 datasets spanning various language pairs like Arabic to French and English. This task is crucial for understanding text embeddings' cross-lingual and dialectal translation capabilities.

Cross-Lingual Retrieval. This task uses Arabic queries to retrieve documents in other languages, such as English, German, Spanish, and Chinese. ArabicMTEB employs the mMarco Dev set (Bonifacio et al., 2021) and includes 11 language pairs.

Re-Ranking. This task reorders candidate documents for a query based on embedding similarity scores. ArabicMTEB features five re-ranking datasets such as MIRACL (Zhang et al., 2023), enabling the evaluation of embeddings' ability to refine search results.

Semantic Textual Similarity (STS). STS measures the correlation between the embeddings of two sentences, assessing their semantic similarity. ArabicMTEB includes five STS datasets like STS17 and STS22 (Cer et al., 2017), along with two synthetic datasets generated using GPT-4 (Details of the creation of these datasets can be found in Appendix G).

Classification. Classification predicts labels for input texts using text embeddings. ArabicMTEB comprises 18 multi-domain datasets, from ORCA (Elmadany et al., 2022). This task evaluates models' ability to categorize Arabic text accurately, making it a valuable benchmark for downstream tasks such as sentiment analysis.

Pair Classification. This task predicts the relationship between two sentences based on their embeddings. ArabicMTEB includes three datasets, such as XNLI (Conneau et al., 2018).

Clustering. Clustering groups sentences into clusters based on embedding similarity, evaluating unsupervised learning performance. ArabicMTEB includes four clustering datasets, such as Arabic News Articles and stance detection datasets from (Baly et al., 2018).

4.2 Dialectal ArabicMTEB

Dialectal ArabicMTEB is a specialized fork of the original ArabicMTEB, focusing exclusively on Arabic dialectal datasets. This extension addresses the unique challenges posed by the significant variations in Arabic dialects across different regions, which have been underrepresented in NLP research. While research on dialectal Arabic text embedding has been limited, dialectal ArabicMTEB fills this gap by providing a comprehensive collection of 19 datasets specifically curated to evaluate embeddings' performance on diverse Arabic dialects. These datasets span multiple tasks, offering a robust framework for assessing model performance across various dialectal contexts: **(1) Bitext Mining.** Eight datasets covering dialects such as Algerian, Egyptian, Jordanian, Lebanese, Moroccan, Saudi, and Yemeni (Nagoudi et al., 2022; Bouamor et al., 2014). **(2) Retrieval.** Five datasets focusing on dialects from Algeria, Egypt, Morocco, and the Gulf regions (Nagoudi et al., 2023b). **(3) Classification:** Five datasets for binary, regional, and country-level dialect identification (Abdul-Mageed et al., 2021d, 2024b; Elmadany et al., 2022; Abdul-Mageed et al., 2021b; Ahmed et al., 2024). **(4) STS.** A novel synthetic dataset for Egyptian text similarity generated using Command-R+.

4.3 Domain-Specific ArabicMTEB

Arabic Text retrieval tasks are currently trending in real-world applications. They are utilized across multiple fields, including healthcare, finance, and legal sectors. Having specialized evaluation datasets is crucial for building text embeddings tailored to these domains. To meet this need, we introduce domain-specific ArabicMTEB, a specialized fork of the broader ArabicMTEB benchmark. Domain-specific ArabicMTEB focuses on the news, finance, legal, medical, and general knowledge domains, offering a closer approximation to real-world scenarios. The creation of this benchmark involves collecting Arabic documents from these specialized sources and from Arabic Wikipedia. We

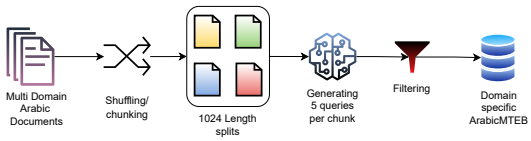

Figure 3: Generation pipeline for our domain specific ArabicMTEB.

then segment and chunk the documents into texts of $1,024$ tokens each. Subsequently, we randomly select chunks and employ GPT4-Turbo (OpenAI et al., 2024) to generate five different styles of queries for each chunk. We filter out duplicate and repeated queries using GPT3.5 (OpenAI et al., 2024) to ensure a high-quality evaluation dataset. Our evaluation data creation pipeline is visualized in Figure 2. The resulting benchmark, which we call ArabicMTEB-Lite, contains $10k$ queries and $100k$ documents spanning the domains described above.

4.4 Cultural ArabicMTEB

To show that our models are culturally aware, we have introduced Cultural ArabicMTEB, a collection of datasets from 20 different Arab countries where we focus on specific cultural aspects like their geography, history, etc. To construct the Cultural ArabicMTEB, we use Arabic Wikipedia as our primary data source. For each included Arab country, we extract articles related to that country from its corresponding Wikipedia portal. The portal covers multiple categories (e.g., geography, economy, history) with subcategories (e.g., local movies, food items). This process resulted in 5K to 55K articles per country. Next, we generate retrieval questions and passages for each country. For this, we use GPT-4o-mini to develop, for each passage (from an article), a corresponding question whose specific answer is available within the passage itself. Following the same methodology, but applied to Egyptian and Moroccan dialectal versions of Wikipedia, we generate dialectal queries and their corresponding passages using Command-R+. Cultural ArabicMTEB contains $1k$ queries and an average of $15k$ documents from various countries as described above.

5 Evaluation

We evaluate the performance of our models, Swan-Small and Swan-Large, across the multiple proposed ArabicMTEB benchmarks and compare them with existing SoTA models, including MARBERT (Abdul-Mageed et al., 2020a), ARBERTv2 (Elmadany et al., 2022), CamelBERT (Inoue et al., 2021), multilingual E5 models (Wang et al., 2024b), and Arabic-triplet-Matryoshka-V2 (ATM-V2) (Nacar and Koubaa, 2024). Our evaluation results encompasses overall ArabicMTEB (Table 5), dialectal ArabicMTEB (Table 6), domain-specific ArabicMTEB tasks (Table 7), and cultural ArabicMTEB (Table 8). In these tables, the tasks will be referred to as **RTR**: Retrieval, **STS**: Semantic Textual Similarity, **PairCLF**: Pair Classification, **CLF**: Classification, **CLR**: Clustering, **RRK**: Reranking, and **BTM**: BiText Mining.

ArabicMTEB Results. Table 5 presents the overall results of our models on the ArabicMTEB benchmark. Our models demonstrate top-tier performance across a variety of NLP tasks. Swan-Small achieves an average score of 57.33, surpassing its main competitors, Me5-base (55.29) and Me5-small (55.06), by a significant margin. This model performs exceptionally well in retrieval (58.42), classification (57.34), and pair classification (74.93), outperforming ATM-V2, which only scores 45.24 on average. Similarly, Swan-Large sets a new state-of-the-art performance with an average score of 62.45, beating Me5-large (61.65) and even the massive e5-mistral-7b model (59.00). The model excels particularly in retrieval (65.63), classification (54.89), and bitext mining (71.24), indicating its robustness across both cross-lingual and Arabic-centric tasks. These results validate our training strategy of using diverse training data covering multiple languages, where Swan-Large outperforms its counterparts by more than five points in cross-lingual tasks such as bitext mining.

Dialectal ArabicMTEB Results. Table 6 shows the dialectal ArabicMTEBresults. Swan-Small scores an average of 63.41, considerably higher than Me5-small (45.27) and AlcLaM (30.44), showing strong performance across retrieval (63.16) and classification (54.52). Swan-Large achieves an impressive average score of 70.45, leading all tasks and outperforming the e5-mistral-7b model, which scores 60.81. The standout result is in bitext mining, which achieves 72.10, showcasing a substantial 14-point improvement over AlcLaM (59.38). Our models' significant advantage in dialectal retrieval and bitext mining is their unique training with a combination of synthetic and human-generated dialectal datasets, which is absent in many competi-

Table 8: Cultural ArabicMTEB results.

tive models.

Domain-Specific ArabicMTEB Results. As seen from Table 7, Swan-Small performs exceptionally well, with an average score of 70.86, surpassing OpenAI's text-embedding-3-small model (68.65) and Cohere-light-v3.0 (67.57). Its best performance is in the legal domain, where it scores 78.86. Swan-Large sets a new standard in domain-specific tasks, scoring 82.49 on average, surpassing OpenAI's text-embedding-3-large (82.20) and Cohere's multilingual model (73.76). The model excels particularly in the news domain (90.42), medical (81.64), and Wikipedia (93.10), indicating its superior generalization across varied Arabic domains. Moreover, the cost-effectiveness of our models is evident: using Swan-Large costs only 0.75 for 10k documents compared to 9.88 for OpenAI's model, making it a more efficient solution for large-scale deployments.

Cultural ArabicMTEB Results. Cultural ArabicMTEB is designed to capture culturally sensitive aspects of the Arabic language, such as regional dialects, local idiomatic expressions, and culturally specific knowledge. We generated queries from country-specific Wikipedia articles, including questions about local cuisine, traditional practices, and historical events, which challenge the models to capture more than just linguistic information. For example, Swan-Large achieved the highest performance on tasks related to Egyptian cultural queries, outperforming other models on retrieval tasks by 1.5%. However, we observed slightly lower performance on Moroccan dialect queries, where cultural nuances (such as regional vocabulary) presented a more significant challenge.

Synthetic Data Analysis. We systematically an-

Model	ArRTR	DOM-RTR	DIA-RTR	STS	PairCLF	CLF	RRK	CLK	BTM	Avg.

Table 9: The impact of Synthetic Data on Swan performance. **ArRTR:** Arabic retrieval, **DOM-RTR:** Domain-specific retrieval, and **DIA-RTR**: Dialectal Retrieval.

alyze the impact of synthetic data on the performance of Swan-Small and Swan-Large using different combinations of training datasets. Table 9 presents the results for the base models, models trained with additional human-generated Arabic data, and models enhanced using synthetic subsets such as MSA, domain-specific, and dialectal data. When comparing the initial Swan-Small (average score of 32.46) to its version trained with synthetic MSA data, we observe a significant increase in average performance to **48.42**, representing an improvement of more than **16 points**. Similarly, Swan-Large benefits from a **6.52-point** boost in average performance (from 55.39 to 61.91) with the inclusion of synthetic MSA data.

6 Conclusion

In this paper, we introduced Swan-Small and Swan-Large, along with the comprehensive ArabicMTEB benchmark for evaluating Arabic text embeddings. Our models demonstrate outstanding performance, benefiting from the strategic use of hard negatives and synthetic data in training. The evaluation across multiple benchmarks demonstrates that both Swan-Small and Swan-Large set new standards in Arabic-centric NLP tasks. They outperform existing SoTA models in both cross-lingual and Arabic-specific tasks while being cost-effective and capable of understanding cultural context—making them ideal for real-world applications in diverse Arabic language settings.

7 Limitations

While the development of the Swan models and the introduction of ArabicMTEB mark significant advancements in Arabic text embeddings, there are a number of limitations to consider. For example, although synthetic data significantly enhances model performance, it can introduce biases due to the reliance on specific patterns in the generated content. We ensured our synthetic data generation diversity by varying the data sources and generating dialectal data for multiple regions, including Egypt, Morocco, and the Gulf states, to mitigate this. We also analyzed our models by examining whether MSA data received higher accuracies in retrieval tasks in Table 9. Further, our synthetic data generation pipeline was subjected to human verification for correctness and balance across cultural contexts.

8 Ethical Statement

The societal implications of deploying dialect-aware models, such as Swan, require careful consideration. While these models can bridge gaps in NLP for Arabic-speaking regions, there is a risk of inadvertently reinforcing biases or language hierarchies, particularly in areas where particular dialects are stigmatized or underrepresented. For instance, users in communities with dialects associated with lower socioeconomic status may feel marginalized if their dialect is not adequately supported. To mitigate these concerns, we have prioritized the inclusion of low-resource dialects and ensured that our synthetic data generation pipeline accounts for dialectal diversity. Additionally, future versions of models should include further dialectal balancing, specifically focusing on underrepresented communities.

Importantly, all research and development activities for the Swan models and ArabicMTEB benchmark were conducted with a commitment to ethical standards. Data collection and usage adhered to privacy and confidentiality norms, ensuring no sensitive information was utilized without proper anonymization and consent.

A ArMistral Training

ArMistral, is an autoregressive pretrained language model based on Mistral-7B.

Pretraining data We further pretrain it on a large and diverse Arabic dataset, including all categories of Arabic, namely Classical Arabic (CA), Dialectal Arabic (DA), and MSA. This data is aggregated from various sources: $\text{AraNews}_{\text{v2}}$ (Nagoudi et al., 2020), El-Khair (El-Khair, 2016), Gigaword,[6] OSCAR (Suárez et al., 2019), OSIAN (Zeroual et al., 2019), 101 Billion arabic words (Aloui et al., 2024a), Wikipedia Arabic, and Hindawi Books.[7] We also derived ArabicWeb22 (A) and (B) from the open source Arabic text 2022.[8] This pretraining dataset was cleaned, filtered and deduplicated using Bhatia (2023). We have also ensured that the model is pretrained in multiple domains, enhancing its results as seen in Table 10.

Instruction Finetuning. To enhance the capabilities of our ArMistral, we instruct-tuning it

[6] LDC Catalog Link

[7] OpenITI corpus (v1.6).

[8] ArabicText-2022 data

on three datasets: Alpaca-GPT4, Evol-instruct, and ShareGPT extracted from MultilingualSIFT datasets (Chen et al., 2023).

Alignment Dataset. We collected an alignment dataset from Quora and Mawdoo websites and then we took the gold answers as the choosen and we generated the rejected using AceGPT-7B (Huang et al., 2024).

Results. As seen from Table 10, Our ArMistral-Chat model outperforms all existing Arabic LLMs.

B Datasets overview

The Table 11 provides a comprehensive summary of the various datasets utilized in the study. It categorizes datasets based on their type, such as Reranking, Bitext Mining, Retrieval, Crosslingual Retrieval, STS, Pair Classification, Clustering, and Classification. Each entry specifies the dataset name, language, citation, and category, reflecting the diversity and scope of data sources for evaluating the model's performance across different tasks and linguistic contexts.

C Polydedupe: versatile cleaning Pipeline

PolyDeDupe is a Python package designed for efficient and effective data deduplication across over 100 languages. It supports syntactic and semantic deduplication, making it a versatile tool for high-quality data preprocessing in NLP tasks. Key features include customizable Jaccard similarity thresholds, a performance speed twice that of other tools like SlimPajama, and support for deduplicating instruction tuning data. It can be easily installed via pip to deduplicate datasets, display original and filtered dataset sizes, and identify duplicate clusters. Supported languages span Western, Central, and Eastern European languages, Slavic languages using Cyrillic script, Greek, various Arabic and Devanagari script languages, and more.

D Prompts for evaluation

Table 12 provides an overview of the prompts used for evaluating various tasks. It includes instructions for Reranking, Bitext Mining, Retrieval, Crosslingual Retrieval, Semantic Textual Similarity (STS), Pair Classification, Clustering, and Classification. Each entry outlines the specific task and the corresponding instruction used to guide the model's evaluation process.

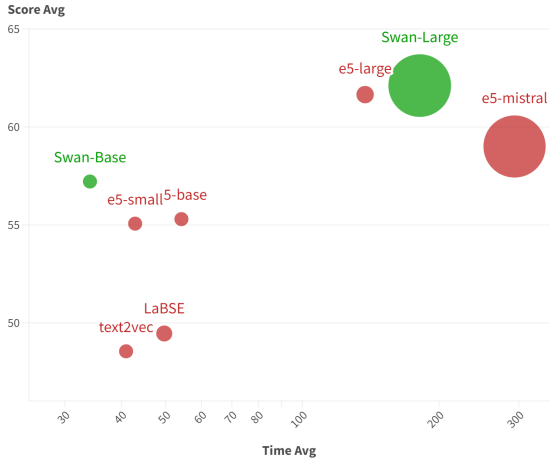

Figure 4: Latency vs Performance.

E Full Leaderboard

Table 13 presents the performance comparison of various models on different tasks within the `ArabicMTEB` benchmark. It includes metrics for Retrieval, Semantic Textual Similarity (STS), Pair Classification (PairCLF), Classification (CLF), Reranking, Clustering, and Bitext Mining (BTM). The table lists each model, its dimensionality, and the scores for each task, along with an overall average score. The results highlight the strengths and weaknesses of each model across a range of tasks, providing a comprehensive overview of their performance.

F Inference Latency.

Inference latency is very critical in deploying machine learning models, especially in real-time applications with crucial response time. It refers to the time taken by a model to predict received input. In the context of text embedding models such as `Swan-Small` and `Swan-Large`, lower latency is particularly valuable for user-facing services that rely on fast processing of natural language input, such as chatbots and search engines. From Figure 4, we find that `Swan-Large`, despite its larger size indicated by a larger bubble, has optimized inference times due to architectural efficiencies, and `Swan-Small` strikes the perfect balance between size, performance, and latency. We compare the performance of the models from Table 5.

G STS Dataset Creation:

The Arabic Semantic Textual Similarity (Arabic-STS) datasets was developed to facilitate research

Model	ARC	Hellaswag	Exams	MMLU	Truthfulqa	ACVA	AlGhafa	Average

Table 10: Comparison of ArMistral with other Arabic LLMs.

in semantic similarity for the Arabic language. The dataset is derived from the Arabic Billion Words (Aloui et al., 2024b) corpus, which serves as a foundation for extracting a diverse collection of sentence pairs. Each pair is annotated with a similarity score that captures the degree of semantic equivalence between the sentences. The dataset generation process was guided by the capabilities of the GPT-4 model developed by OpenAI, ensuring that the resulting sentence pairs are of high quality and reflect nuanced linguistic characteristics. The creation involved several steps, including selecting representative sentences from the corpus, generating semantically varied sentence pairs, and annotating similarity scores using both automated methods and human reviewers to maintain consistency and reliability.

H Country level Cultural Evaluation

Task	Dataset	Type	Language	Citation	Size
BitextMining	Darija	S2S	Moroccan Arabic Dialect to English	(Nagoudi et al., 2023b)	2000

Abstract

Instruction tuning has achieved unprecedented success in NLP, turning large language models into versatile chatbots. However, the increasing variety and volume of instruction datasets demand significant computational resources. To address this, it is essential to extract a small and highly informative subset (i.e., *Coreset*) that achieves comparable performance to the full dataset. Achieving this goal poses non-trivial challenges: 1) data selection requires accurate data representations that reflect the training samples' quality, 2) considering the diverse nature of instruction datasets, and 3) ensuring the efficiency of the coreset selection algorithm for large models. To address these challenges, we propose ***T**ask-**A**gnostic **G**radient **C**lustered **CO**reset **S**election* (**TAGCOS**). Specifically, we leverage sample gradients as the data representations, perform clustering to group similar data, and apply an efficient greedy algorithm for coreset selection. Experimental results show that our algorithm, selecting only 5% of the data, surpasses other unsupervised methods and achieves performance close to that of the full dataset.

Hyper Parameter Items	Full (100%) Data	Selected (5%) Data
4 Learning Rate Options: 2e-5, 1e-4, 1e-5, 2e-4	322h	15.2h
4 Batch Size Options: 16, 32, 64, 128	315.3h	14.9h
4 Training Epochs Options: 1, 2, 3, 4	193.7h	9.2h
4 Max Lengths Options: 512, 768, 1024, 2048	248h	12.1h
4 Templates Options: User, ###Human, Question, [INST]	322h	15.2h
Selection Cost	-	231.1h
Total	**1401h**	**297.7h** (-1103.3h)
Evaluation Performance	49.58	48.35

Table 1: We provide a time cost comparison for the hyper parameter optimization experiments we actually conducted (using 4 A100-80G GPUs) on the full dataset (100%) and the selected subset (5%). The one-time effort of data selection can be utilized for multiple training runs across various requirements.

1 Introduction

Instruction tuning (Wei et al., 2022a; Ouyang et al., 2022) is the most important strategy for customizing Large Language Models (LLMs) for downstream tasks, which allows them to precisely understand human intentions and accurately generate responses in natural languages. Recently, many existing works (Wang et al., 2023a) expand the amount and diversity of instructions for instruction tuning to further enhance the LLM's capability. However, the increased quantity of the dataset also leads to significantly higher computational costs for instruction tuning. Meanwhile, Zhou et al. (2023) revealed that only 1,000 high-quality, human-created data samples could substantially improve the ability of LLMs to follow instructions, which suggests that there exists severe redundancy in current instruction datasets, and only a high-quality subset may suffice for achieving promising performance.

To address the above issue, selecting a small, highly informative subset (i.e., coreset) of training samples from the original dataset is a promising solution. As shown in table 1, this approach ensures that training on the coreset achieves performance comparable to the full dataset while significantly reducing iteration costs. However, coreset selection is challenging as it must not only consider the quality of individual samples, but also their importance within the entire subset. For example, if two high-quality samples are very similar, selecting only one may be sufficient. This global perspective on sample importance is crucial for the quality of the selected subset.

Current methods for coreset selection can be categorized into two main types: 1) Heuristic-

based approaches (Marion et al., 2023; Li et al., 2023; Chen et al., 2023b; Lu et al., 2023), and 2) Optimization-based approaches (Borsos et al., 2020; Zhou et al., 2022; Gao et al., 2023; Zhou et al., 2022). Heuristic-based methods use various heuristic scores to measure sample quality. For example, some assess data sample quality by ranking their corresponding perplexity score (Marion et al., 2023), while others score each sample using a powerful LLM (Chen et al., 2023b). These methods often rely on arbitrary heuristics that may not accurately evaluate sample quality and lack a comprehensive view of sample importance within the entire dataset, resulting in suboptimal performance. Optimization-based methods, on the other hand, typically frame the task as a bi-level optimization problem, requiring repeated optimization of both inner and outer loops. This approach incurs prohibitive costs, especially in the context of large language models (LLMs) that contain billions of parameters. Therefore, a coreset selection method that is applicable for LLMs is yet to be proposed.

In this paper, to address the above issues, we propose ***T**ask-**A**gnostic **G**radient **C**lustered **CO**reset **S**election* (**TAGCOS**), a coreset selection framework designed for LLM that is agnostic of its downstream tasks. Firstly, we use LLM's gradients as representation for each sample. Compared with representations based on model outputs, gradients effectively captures the information of how each sample affects the optimization direction of the LLM, which is the root cause of the model's final performance. Secondly, to perform coreset selection under a global view of the entire dataset, we show that coreset selection can be naturally formulated into a Submodular Function Maximization (SFM) problem. Then, noting that SFM is NP-hard (Bach et al., 2013) and naive solvers would be impractical when the dataset size is large, potentially leads to inferior solutions. This urges the development of efficient approximate optimizer, which is one of the main contributions of this work.

To be precise, we perform clustering on the gradient features over the dataset to decompose the SFM problem into several small-scaled subproblems to reduce the optimization difficulty. Lastly, we approximately solve each SFM subproblems via an efficient greedy approach named optimal matching pursuit (OMP) algorithm to perform coreset selection independently in each cluster in a fine-grained manner. This ensures a comprehensive coverage of the selected subset. Our theoretical analysis demonstrates that compared with the methods without our gradient clustering strategy, our method can achieve the comparable accuracy with a significantly smaller sized coreset.

In our experiment, we assessed the effectiveness of our method by selecting data from a combination of 17 popular instruction datasets (Wang et al., 2023a; Ivison et al., 2023), with a total of approximately 1 million data examples. By unsupervisedly selecting 5% of the original datasets, we obtained great performance on a range of evaluation benchmarks. Additionally, we confirmed the generalization of our method by applying the selected subset to various models.

Our main contributions are as follows:

- We verified that gradient features can serve as a good data representation that captures the essential information to measure the quality of instruction data.
- We propose Task-Agnostic Gradient Clustered Coreset Selection (TAGCOS), a coreset selection framework designed for LLM that is agnostic of its downstream tasks.
- Our experiment was conducted in a realistic setting, featuring 18 popular instruction datasets that include 1 million varied instruction data points. The practical results convincingly demonstrate the effectiveness of the entire pipeline.

2 Related Work

Instruction Tuning Data. Instruction tuning (Ouyang et al., 2022) has achieved unprecedented success in NLP, turning large language models into versatile chatbots (Chiang et al., 2023; Taori et al., 2023). Successful instruction tuning requires a powerful pre-trained base model as well as high-quality instruction datasets. For the powerful pre-trained base model, one usually selects a pre-trained LLM with more data and having more parameters, like Mistral (Jiang et al., 2023), Llama family models (Touvron et al., 2023). For high-quality instruction datasets part, it is expected that high-quality datasets are diverse and representative enough to adapt the LLM to potential downstream usage. With the development of instruction tuning, there are more and more instruction datasets. Usually, these datasets are either annotated by human or proprietary LLMs. Currently, instruction data

generally contains these types: (1) datasets are created by researchers from existing NLP dataset and incorporate an instruction for existing input-output pairs, like Flan (Longpre et al., 2023; Wei et al., 2022a), SuperNI (Wang et al., 2022), CoT (Wei et al., 2022b) and Orca (Mukherjee et al., 2023). (2) open-end text generation, e.g., multi-turn dialogue and instruction following. Several open-end text generation datasets are created by human, like Dolly (Databricks, 2023) and Oasst1 (Köpf et al., 2023). Others are generated by proprietary models or human interaction with these models, like Self-instruct (Wang et al., 2023b), Alpaca (Taori et al., 2023), Sharegpt (Chiang et al., 2023), Baize (Xu et al., 2023), GPT4-Alpaca (Peng et al., 2023) and Unnatural Instructions (Honovich et al., 2023). (3) instructions build for domain-specific skills, like Code-Alpaca (Chaudhary, 2023) for code completion. Given such a diverse collection of instruction dataset, the challenge for instruction tuning lies in ensuring the quality of these instructional data samples. Zhou et al. (2023) revealed that only several high-quality data samples could substantially improve the instruction tuning results. Thus, in this work, we aim to explore an automatic and unsupervised data selection technique to obtain the coreset for these instruction datasets.

LLM Data Selection. Since training LLM still request a lot of resources, data selection is often used for implementing efficient training. Also, several works (Zhou et al., 2023; Gunasekar et al., 2023) stress the importance of high-quality data and thus triggered more research works focus on data selection. One popular way to select data samples this is to use an extra LLM to evaluate data samples. Chen et al. (2023b); Lu et al. (2023) calls ChatGPT API to tag or evaluate the quality of the instruction data. Also, several works (Du et al., 2023; Bukharin and Zhao, 2023; Dong et al., 2023) make use of a reward model to assess the data quality. Wettig et al. (2024); Liu et al. (2024) intends to distill the preference of proprietary LLMs to small models for implementing efficient scalable data selection. This line of data selection methods is very expensive and suffers from interpretability. Another line of works focuses on using signals from the model itself to facilitate data evaluation and selection. Marion et al. (2023); Li et al. (2024) make use of perplexity or its variants to determine if a data sample is good or not. Xia et al. (2024); Pan et al. (2024) use the gradients and influence function to find the data sample that best matches the validation set for downstream tasks evaluation. Li et al. (2023); Cao et al. (2023) develops their own evaluation metric for assessing data samples. Zhao et al. (2024) selects (instruction, response) pairs whose response is long. Mekala et al. (2024) selects samples based on learning order. Compared to existing data selection approaches, our work focuses on selecting influential instruction data in a task-agnostic manner by utilizing LLM gradients on the dataset itself. Our method does not require a validation set and can be applied more broadly for data selection.

Algorithm 1 Coreset Selection

Require: A pretrained LLM θ, instruction tuning dataset $D = \{z_i \mid z_i = (s_i, c_i)\}_{i=1}^{N}$, target subset size M, training loss ℓ, gradient matching error function Err($\cdot$).

$\{\mathcal{C}_k\}_{k=1}^{K}, \{\mu_k\}_{k=1}^{K} \leftarrow$ K-means$(\mathcal{G}, K)$ *# Derive clusters and their centroids with K-means*
CoreSet $\leftarrow \emptyset$
for each cluster $\mathcal{C}_k$ with centroid μ_k **do**
  $r_k \leftarrow \frac{|\mathcal{C}_k|}{|\mathcal{D}|} \times M$ *# Derive subset size in k^{th} cluster*
  $\mathcal{C}_k^{sub}, w \leftarrow \textit{OMP}(\mathcal{C}_k, r_k, \text{Err}(\cdot))$ *# Derive the subset from k^{th} cluster*
  CoreSet $\leftarrow$ *CoreSet* $\cup\, \mathcal{C}_k^{sub}$
end for
Output: *CoreSet*

3 Method

To tackle the challenging coreset selection problem for LLM's instruction tuning dataset, we propose Task-Agnostic Gradient Clustered Coreset Selection (TAGCOS), a task-agnostic coreset selection approach that effectively and efficiently discovers the informative subset from a large instruction tuning dataset.

Notation. Assume we have a pretrained LLM θ and a giant and diverse instruction dataset $D := \{(s, c)_{(i)}\}_{i=1}^{N}$, where each data sample $z = (s, c)$ comprises an instruction s and a completion c. For each data sample, the loss $\ell(z; \theta)$ is defined as the cross entropy between the prediction distribution $p(\cdot \mid s)$ and the ground truth text response c. Since c often contains multiple tokens, $\ell(z; \theta)$ is calculated as the average of the token-wise cross entropy loss across the completion c. The notation θ_t refers to the model checkpoint at step t.

Problem Formulation. We first formulate the task into a gradient matching problem, i.e., the av-

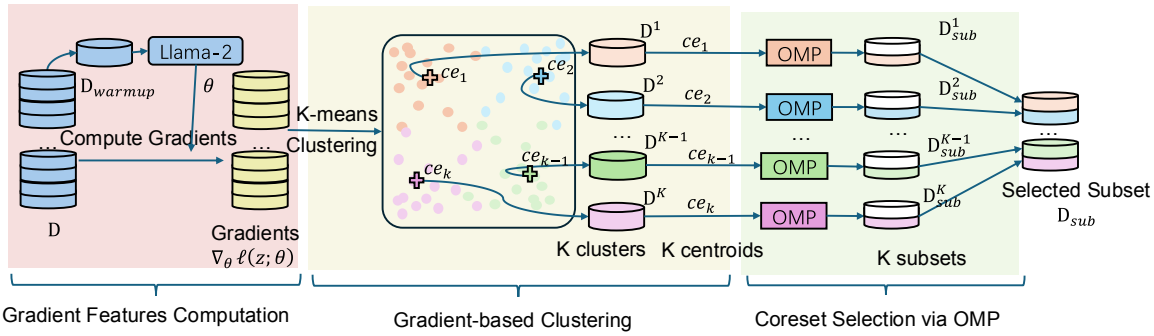

Figure 1: Illustration of the proposed **TAGCOS** pipeline. Our framework consists of three stages: 1) Gradient feature computation, which efficiently derive sample-wise gradients to use as data representation; 2) Gradient-based Clustering, which groups data with high similarity into the same groups; 3) Coreset selection via OMP, which efficiently selects the coresets from each cluster separately in a greedy manner.

erage gradient of the selected subset should approximate the gradient of the entire dataset. Intuitively, if the gradient is similar throughout all the training steps, the resulting model parameter should be closed to the model trained with the entire dataset.

Formally, given a giant and diverse dataset D, our goal is to select a subset $D_{sub} \subseteq D$ ($|D_{sub}| < |D|$) containing the most informative training samples. We expect that the gradients produced by the full training dataset $\sum_{z\in D} \nabla_\theta \ell(z;\theta)$ can be replaced by the gradients produced by a subset $\sum_{z\in D_{sub}} \nabla_\theta \ell(z;\theta)$ with minimal difference:

$$\min_{\mathbf{w}, D_{\text{sub}}} \text{Err}\Big(\nabla_\theta \mathcal{L}(D;\theta), \frac{1}{\|\mathbf{w}\|_1} \sum_{z\in D_{\text{sub}}} w_z \nabla_\theta \ell(z;\theta)\Big)$$
$$\text{s.t.} \quad D_{\text{sub}} \subseteq D, \quad w_z \geq 0, \quad |D_{sub}| \leq M \tag{1}$$

where $\mathcal{L}(D;\theta) = \frac{1}{|D|}\sum_{z\in D} \nabla_\theta \ell(z;\theta)$, w is the subset weight vector, $\|\mathbf{w}\|_1$ is the sum of the absolute values and $\text{Err}(\cdot,\cdot)$ measures the distance between two gradients. Note that w could be either varibales, which leads to weighted training on the selected subset, or with discrete values, which reduces to regular training on the coreset.

Issues and Solution. However, due to the high diversity of the large-scale instruction tuning dataset, simply conducting selection over the entire dataset potentially causes over-sampling in certain domains and under-sampling in others. To address this, we introduce clustering to ensure balanced sampling. By splitting the dataset into clusters and selecting samples from each cluster, we ensure a more even distribution across different domains.

Overall, as illustrated in algorithm 1, the process for coreset construction could be summarized as follows:

1. **Compute the gradient features** $\mathcal{G} = \{g_i \mid g_i = \nabla_\theta \ell(z;\theta)\}_{i=1}^N$. It is worth noting that the "graident" here actually refers to *the first-order approximation* of training dynamics, which is actually a little different from gradient itself. For briefness, we term this **the first-order approximation** as gradient here. More exactly, we compute the low-dimensional approximations of gradient features for each data samples z over the whole dataset D;

2. **Perform gradient-based clustering**, we perform k-means clustering (Hartigan and Wong, 1979) given the gradients features and get k clusters and corresponding centroids ce for each cluster, which effectively gathers the samples with similar characteristics into one cluster;

3. **Coreset selection via Optimal Matching Pursuit**, we compute the data samples matches best with the centroids in each cluster with an orthogonal matching pursuit algorithm (Killamsetty et al., 2021).

3.1 Gradient Features Computation

We perform an efficient gradient feature approximation computation over the entire dataset. To speed up gradient computation, LoRA (Hu et al., 2022) and random projections (Park et al., 2023) are used to reduce the dimensions in gradient features.

Adam Gradient Computation Function. The gradients and training dynamics are computed based on Adam optimizer Kingma and Ba (2015) :

$$\theta^{t+1} - \theta^t = -\eta_t g_i(z, \theta^t) \tag{2}$$

$$g_i(z, \theta^t) \triangleq \frac{m^{t+1}}{\sqrt{v^{t+1}} + \epsilon} \tag{3}$$

$$m^{t+1} = \left(\beta_1 m^t + (1-\beta_1)\nabla \ell(z; \theta^t)\right)/(1-\beta_1^t) \tag{4}$$

$$v^{t+1} = \left(\beta_2 v^t + (1-\beta_2)(\nabla \ell(z; \theta^t))^2\right)/(1-\beta_2^t) \tag{5}$$

where β_1 and β_2 are hyperparameters, and ϵ is a small constant. $g_i(z, \theta^t)$ represents the first-order expansion for the Adam dynamics, requiring model gradients and optimizer states from the training process. Warmup training on a subset of the dataset provides the necessary checkpoints for these computations. As mentioned above, we will sample checkpoints before convergence to provide a more accurate gradient estimation.

Warmup Training and Projection. LoRA (Hu et al., 2022) is used to reduce the number of trainable parameters and accelerate the inner products in $g_i(z, \theta^t)$. LoRA freezes the pre-trained weights and adds a low-rank adaptor to the selected fully connected layers. We use LoRA to perform instruction tuning on pre-trained base model (e.g., LLAMA-2-7B) on a random subset $\mathcal{D}_{\text{warmup}} \subseteq \mathcal{D}$ for N epochs, checkpointing the model after each epoch to store $\{\theta_i\}_{i=1}^N$. The gradient when training with LoRA, denoted $\widehat{\nabla}\ell(\cdot; \theta) \in \mathbb{R}^P$, is much lower dimensional than the model itself; for example, in LLAMA-2-7B, $\widehat{\nabla}\ell(\cdot; \theta)$ is less than 2% the size of θ. We use $\widehat{\nabla}\ell(\cdot; \theta)$ to compute the Adam update and denote it as $\widehat{g}_i(\cdot, \theta)$.

In order to further accelerate the computation, a random projection, Rademacher distribution (Johnson, 1984) (i.e., $\Pi_{ij} \sim \mathcal{U}(\{-1, 1\})$), is introduced to further reducing the feature dimension. In total, we compute gradient features for each data sample z with $\widetilde{g}_i(z, \cdot) = \Pi^\top \widehat{g}_i(z, \cdot)$.

3.2 Gradient-based Clustering

Due to the diversity of instruction tuning dataset, direct sampling over the entire dataset may not cover all the regions, since the training samples from each domain are not evenly distributed. To further improve the effectiveness and robustness of data selection, we divide the entire dataset into several clusters and then perform gradient matching algorithm on each cluster itself. With the gradient features g_i from the above step, we conduct K-means clustering on them to assign each data sample into a cluster $\{\mathcal{C}_k\}_{k=1}^K$. Also, we can obtain cluster centroids $\{\mu_k\}_{k=1}^K$ of these clusters during the clustering process, where each centroid shares the dimension with gradient features.

3.3 Coreset Selection via Optimal Matching Pursuit

In each cluster, we hope to get the subset that minimizes the difference between the selected subset and the whole cluster. Instead of doing heuristic selection like selecting all the instances with shortest distance with cluster centroids, we formalize this as an optimization problem and introduce an orthogonal matching pursuit (OMP) algorithm (Killamsetty et al., 2021; Elenberg et al., 2016) to solve it. Similar with equation 1, our objective is to minimize the difference between selected D_{sub}^k in k-th cluster and the whole cluster D^k,

$$\text{Err}(\mathbf{w}^k, D_{sub}^k; D^k) \triangleq \left\| \sum_{z \in D_{\text{sub}}^k} w_z^k \widehat{\nabla}_\theta \ell(z; \theta) - \frac{1}{|D^k|} \sum_{z \in D^k} \widehat{\nabla}_\theta \ell(z; \theta) \right\| \tag{6}$$

Considering the regularization coefficient λ, we can have $\text{Err}_\lambda(\mathbf{w}, D_{sub}^k; D^k)$ as:

$$\text{Err}_\lambda(\mathbf{w}, D_{sub}^k; D^k) \triangleq \text{Err}(\mathbf{w}, D_{sub}^k, D^k) + \lambda \|\mathbf{w}\|^2. \tag{7}$$

Here, we approximately regard the centroids of each cluster as the average gradients of the whole cluster,

$$\frac{1}{|D^k|} \sum_{z \in D^k} \nabla_\theta \ell(z; \theta) = ce_k. \tag{8}$$

We next study the optimization algorithm for solving equation 6. Our goal is to minimize $\text{Err}_\lambda(\mathbf{w}, D_{sub}^k; D^k)$ subject to the constraint D_{sub}^k : $|D_{sub}^k| < d_k$. We can convert this into maximization problem over the set D_{sub}^k , i.e.,

$$\max_{D_{sub}^k} F_\lambda(D_{sub}^k; D^k), \quad s.t., |D_{sub}^k| \leq d_k \text{ and } D_{sub}^k \subseteq D^k, \tag{P-k}$$

Here the objective $F_\lambda(D_{sub}^k; D^k)$ is defined as

$$F_\lambda(D_{sub}^k; D^k) \triangleq L_{\max}^k - \min_{\mathbf{w}} \text{Err}_\lambda(\mathbf{w}, D_{sub}^k; D^k),$$

where $L_{\max}^k$ is a constant to make the objective non-negative. Note that we minimize $\text{Err}_\lambda(D_{sub}^k)$

subject to the constraint $D^k_{sub}: |D^k_{sub}| < d_k$ until $\text{Err}_\lambda(D^k_{sub}) < \epsilon$, where ϵ is the tolerance level and tk is the target num of samples in the selected subset. Note that minimizing $\text{Err}_\lambda(D^k_{sub})$ is equivalent to maximizing $F_\lambda(D^k_{sub})$. Given this, we use OMP to solve this optimization problem, details of OMP are presented in Algorithm 2.

Algorithm 2 OMP

Require: full dataset D, Target subset size M, error function $\text{Err}(\cdot)$
$D_{sub} \leftarrow \emptyset$
$r \leftarrow \nabla_{\mathbf{w}} \text{Err}_\lambda(\mathbf{w}, D_{sub}; D)\big|_{\mathbf{w}=0}$
while $|D_{sub}| \leq M$ **and** $\text{Err}_\lambda(\mathbf{w}, D_{sub}; D) \geq \epsilon$ **do**
  $e = \arg\max_j |r_j|$
  $D_{sub} \leftarrow D_{sub} \cup \{e\}$
  $\mathbf{w} \leftarrow \arg\min_{\mathbf{w}} \text{Err}_\lambda(\mathbf{w}, D_{sub}; D)$
  $r \leftarrow \nabla_{\mathbf{w}} \text{Err}_\lambda(\mathbf{w}, D_{sub}; D)$
end while
return $D_{sub}, \mathbf{w}$

In each cluster k, we select data samples that can minimize $\text{Err}_\lambda(D^k_{sub})$ with the above-described OMP algorithm. After finishing the selection on each cluster, we combine the selected subset D^k_{sub} to be D_{sub} and use it to train the target model.

4 Theoretical Analysis

In this section, we analyse the benefits of our gradient clustering in coreset selection. The general conclusion is that coreset selection problem formulated in Problem (P) is essentially a Submodular Function Maximization (SFM) problem (Bach et al., 2013), which is NP-hard. Solving large-scaled SFM problems is extremely challenging, potentially leads to inferior solution. For the discussion about the assumpation here, one may refer to appendix B. Our gradient clustering strategy naturally decomposes the original problem into several small scaled problems, significantly reduces the difficulty in optimization, making finding solutions with high-precision possible. The detailed results are presented in the following theorems. These theorems are adapted from the classical analysis on OMP, which can be found in the studies (Elenberg et al., 2018; Wolsey, 1982). We adopt them to understand the superiority of our coreset selection approach.

To unify the problems of coreset selection with and without clustering, we extend the problem (P-k) as follows:

$$\max_{D_{sub}} F_\lambda(D_{sub}; D), \quad \text{(P)}$$
$$s.t., |D_{sub}| \leq M \text{ and } D_{sub} \subseteq D,$$

where D_{sub} and D are the coreset and the full dataset, respectively. c is the constant to control the coreset size.

Lemma 1 *If the coreset size $|D_{sub}| \leq c$ and $\max_{z \in D} \|\nabla_\theta \ell(z;\theta)\|_2 \leq G$, then $F_\lambda(D_{sub}; D)$ is γ_D-weakly submodular with $\gamma_D = \frac{\lambda}{\lambda + MG^2}$.*

Theorem 1 *If $\max_{z \in D} \|\nabla_\theta \ell(z;\theta)\|_2 \leq G$ and $\max_{z \in D^k} \|\nabla_\theta \ell(z;\theta)\|_2 \leq G_k$ for cluster k. Let D^*_{sub} and D^{k*}_{sub} be the optima of Problems P and P − k, with $k = 1, \ldots, K$. Then, the followings hold:*

(i) *For problem (P), OPM runs with stopping criteria $F_\lambda(D_{sub}; D) \leq \epsilon$ achieves set D_{sub} with $|D_{sub}| \leq \frac{|D^*_{sub}|}{\gamma_D} \log(\frac{L_{max}}{\epsilon})$.*

(ii) *For problem (P-k), OPM runs with stopping critia $F_\lambda(D^k_{sub}; D^k) \leq \epsilon_k$ achieves set D^k_{sub} with $|D^k_{sub}| \leq \frac{|D^{k*}_{sub}|}{\gamma_{D^k}} \log(\frac{L^k_{max}}{\epsilon_k})$.*

Since $\gamma_D = \frac{\lambda}{\lambda + MG^2}$ and $\gamma_{D^k} = \frac{\lambda}{\lambda + d_k G_k^2}$ with $M = \sum_{k=1}^K d_k$, it can be expected that $\gamma_D \ll \gamma_{D^k}$. Noting that a proper clustering method would make $D^*_{sub} \approx \cup_{k=1}^K D^{k*}_{sub}$ and it is reasnonable to set $\frac{L^k_{max}}{\epsilon_k} \approx \frac{L_{max}}{\epsilon}$ to ensure comparable precisions. Thus the above theorem demonstrates that

$$\sum_{k=1}^K \frac{|D^{k*}_{sub}|}{\gamma_{D^k}} \log(\frac{L^k_{max}}{\epsilon_k}) \ll \frac{|D^*_{sub}|}{\gamma_D} \log(\frac{L_{max}}{\epsilon}).$$

That is, to achieve comparable accuracy, the union of the coreset selected from each cluster can be much smaller than that from the whole datasets, which verifies the benefits of gradient clustering. This is also consistent with our experimental observation. i.e., the running time of OMP without gradient clustering is significantly longer than that with gradient clustering.

5 Experiment

In this section, we conduct experiments to answer the following research questions:

- Does TAGCOS achieve superior performance over other unsupervised selection methods? (Table 2, Table 3)

	TydiQA	MMLU	BBH	average
Uniform	52.08	46.9	41.39	46.79
Hardest	51.58	45.68	38.15	45.13
Perplexity	51.66	46.89	40.74	46.43
K-Center	38.83	48.73	41.48	43.01
OMP	53.64	46.10	40.47	46.82
TAGCOS	**52.78** +0.7	**48.01** +1.11	**44.26** +2.87	**48.35** +1.65

Table 2: Evaluations used TydiQA, MMLU, and BBH benchmarks. Results reflect Llama-2 7B models trained on 5% of data selected by each method. Note that we tested K-Center and OMP data selection methods with gradient embedding on 17 instruction datasets.

- How effective is the generalization of TAGCOS, and can it be transferred to different models? (Table 4)
- What is the best configuration for TAGCOS, including the selection proportion, the number of clusters, and the selection of gradient checkpoints? (Table 5, Table 6, Table 7)

5.1 Setup

To illustrate that TAGCOS is task agnostic, we chose diverse tasks for both training and evaluation. For the training set, we combined 17 popular instruction datasets totaling 1,068,549 examples, following Wang et al. (2023a); Ivison et al. (2023). These datasets vary in format and reasoning tasks, with annotations by humans or the OpenAI API. For details, please refer to Appendix G.

For evaluation, we selected **TydiQA** (Clark et al., 2020), **MMLU** (Hendrycks et al., 2020), and **BBH** (Suzgun et al., 2022). For the Implementation Details, please refer to appendix A.

5.2 Experimental Results

Baseline. The main experiment results are presented in Table 2. Several baselines were considered for comparison: (1) **Uniform**: randomly selecting the data samples from the original dataset. (2) **Hardest Sampling**: select the data samples with the highest perplexity. (3) **Perplexity Sampling** (Marion et al., 2023; Marcus et al., 1993): select the data samples with the lowest perplexity. (4) **K-Center-Greedy with different representations** (Chen et al., 2023a): converting instruction data into gradient embedding vectors, performing K-means clustering, and selecting samples by iteratively choosing the one closest to the cluster center among the remaining instances. For details about other clustering methods, we include them in the appendix 11. (5) **OMP** (Killamsetty et al., 2021): using the OMP algorithm over the entire dataset, with the mean gradient feature across the dataset as the matching target.

Main Experiments. As shown in Table 2, TAGCOS achieves the best performance across all tasks, confirming its effectiveness in data selection for instruction tuning. TAGCOS is the only baseline that consistently performs well. Although K-Center$_{Grad}$ excels on the MMLU benchmark, it fails on TydiQA and is equivalent to uniform sampling on BBH, underscoring TAGCOS's robustness.

Effectiveness of each Component in TAGCOS. The key difference between TAGCOS and Grad+K-Center lies in their selection mechanisms. While K-means clustering on gradient features can achieve strong results on individual benchmarks, it is insufficient for consistent overall performance. This further demonstrates the effectiveness of the OMP coreset selection algorithm. Compared to OMP, which does not use clustering, TAGCOS delivers better results. This reinforces our perspective that clustering is essential for managing the diversity in instruction datasets.

	TydiQA	MMLU	BBH	average
Uniform	52.08	46.9	41.39	46.79
K-Center				
BERT	50.05	47.16	39.91	45.7
Llama	52.72	46.07	39.07	45.95
Grad	38.83	48.73	41.48	43.01
K-Center+OMP				
BERT	52.21	45.65	42.95	46.93
Llama	52.01	46.04	44.26	46.08
Grad	**52.78**	**48.01**	**44.26**	**48.35**

Table 3: We compare the selection results of clustering and optimal matching pursuit methods across various embedding spaces. All outcomes are based on 5% of the data samples chosen by the respective methods and trained using Llama-2 7B models.

Gradient Features vs. Other Embeddings. As shown in table 3, we evaluated the K-Center algorithm with various data representation schemes, including BERT, Llama, and Gradient. In the absence of a selection mechanism, gradient features exhibits great improvement over MMLU and BBH while dropping a lot on TydiQA. We attribute the multilingual features to TydiQA which evaluates some low-resource languages performance. As shown in appendix C, we can learn that K-center with gradient overfits to English. We argue that the reason is OMP considers the entire cluster distribution to find a representative subset, whereas K-center focuses on sample-centroid distances.

5.3 Ablation Study and Analysis

Performance of TAGCOS on Different Models. Table 4 demonstrates that the dataset generated by the Llama-2-7B model can be effectively utilized to train a superior Mistral-7B and Llama-3-8B instruction models. By leveraging the datasets selected by TAGCOS on the Llama-2-7B model, the trained Mistral-7B and Llama-3-8B models show significant improvements over uniform selection methods, consistently outperforming their counterparts. This highlights TAGCOS's ability to identify transferrable and valuable data samples, indicating its potential for future proxy data selection tasks.

	TydiQA	MMLU	BBH	Average
Llama-2 7B				
Uniform	52.08	46.9	41.39	46.79
TAGCOS	52.78	48.01	44.26	48.35
Mistral 7B				
Uniform	57.59	61.34	56.48	58.47
TAGCOS	61.49	61.79	57.87	60.38
Llama-3 8B				
Uniform	67.96	64.56	64.63	66.30
TAGCOS	69.20	65.18	65.93	67.57

Table 4: Experiments showing the impact of transferring TAGCOS-selected datasets from Llama-2 7B to Mistral-7B. Consistent improvement on TydiQA, MMLU, and BBH benchmarks demonstrate the transferability.

5% data can achieve comparable results with full dataset. Our method is not specifically optimized for selecting 5% of the data. It is designed to work with any percentage of data selection. The results shown in Table 5 verify that our method consistently maintains high performance across different selection ratios. As shown in Table 5, which involves a set of 17 datasets forming an instruction dataset collection, we empirically observed that selecting 5% of the data already achieves strong performance. Thus, we used this percentage to compare the performance of different methods.

Also, Table 5 reveals that training with only 5% of the data selected by TAGCOS results in performance comparable to that of the entire dataset. This can be attributed to the presence of noisy samples in the full dataset, which are less effective for fine-tuning.

prop	TydiQA	MMLU	BBH	Average
5%	52.78	48.01	44.26	48.35
20%	51.76	48.87	42.95	47.86
25%	52.13	49.95	43.33	48.47
100%	51.44	52.96	44.35	49.58

Table 5: Results of experiments with different selection proportions using the Llama-2 7B model.

How to determine the cluster numbers. Table 6 shows that the ideal cluster number for our setup is 100. Fewer clusters, especially less than the original dataset size of 18, fail to achieve good results. Additionally, merely increasing the number of clusters does not ensure improved performance. TAGCOS tends to degrade to plain OMP as the number of clusters increases. When the cluster count matches the number of samples, the performance is identical to plain OMP. For more detailed results for cluster numbers, please refer to 12.

# Cluster	TydiQA	MMLU	BBH	Average
10	54.04	47.71	40.00	47.25
20	52.58	45.76	41.11	46.48
50	54.84	47.09	42.96	48.30
100	52.78	48.01	44.26	48.35
200	52.57	46.87	42.87	47.44

Table 6: Experimental results show the results on selecting different numbers of clusters.

Selecting early stopped checkpoints for computing gradients. In Table 7, "Checkpoints with significant loss reduction" means all the warmup checkpoint used for computing gradient features comes from the steps before convergence. "Evenly spaced checkpoints" represents that these checkpoints are sampled across the entire training process evenly. We argue that "early-selecting", i.e., sample checkpoints from steps before convergence, works better since the gradients before convergence provide more effective reactions for data samples

for training. The results in this table also support this idea. In total, it is better to have a warmup checkpoint sampled from steps before convergence to get better results on TAGCOS.

Selected Steps	TydiQA	MMLU	BBH	Average
Checkpoints with significant loss reduction				
1,10,20,30	52.78	48.01	44.26	48.35
1,5,10,20	53.36	47.74	42.15	47.75
1,5,10,15	53.29	47.08	43.26	47.84
Evenly spaced checkpoints				
1,8348, 16696, 25044	53.14	47.16	39.54	46.61

Table 7: In the study of warmup checkpoint selection, minimal loss reduction is observed after step 40 out of a total of 33,392 steps. Notably, each step processes a batch size of 32.

6 Conclusion

This paper focuses on the effective selection of coresets for LLMs in instruction tuning. We utilize gradient features to act as data representations, which indicate the influence of each data sample on the training process. Additionally, to handle diverse collections of instruction data and ensure selection efficiency, we propose clustering similar data and applying an efficient greedy algorithm for selection. Our experimental results demonstrate the effectiveness of the entire pipeline.

7 Limitation

Despite its impressive performance, TAGCOS is bottlenecked by gradient feature estimation. The gradient feature computation stage limits its scalability to larger datasets. To effectively run TAGCOS on extensive datasets, improvements in the efficiency of gradient computation are needed.

A Implementation Details

In this work, we performed warmup training on a randomly selected 5% of the dataset for 4 epochs and computed 8192-dimensional gradient features on the full dataset D. The learning rate for warmup training was set to 2e-5, with a batch size of 32. Using these gradient features, we selected 5% of the original dataset using our selection methods, totaling approximately 53,427 samples. We used 100 clusters for K-means clustering and set the OMP algorithm tolerance at 0.01. After obtaining the subset, we fine-tuned the Llama-2-7B (Touvron et al., 2023) and Mistral-7B (Jiang et al., 2023) models using LoRA (Hu et al., 2022) to reduce memory usage. For LoRA training, we used the AdamW optimizer with a learning rate of 2e-5 and 4 epochs. The context length was set to 1,024, with a batch size of 32.

B Assumpation about the Selected Optimal Subset

Actually, our result can hold with a weaker assumption. To be precise, from the definition of γ_D and γ_{D^k}, when the problems $P-k$ are not too unbalanced, it can be expected that $\gamma_D \leq \gamma_{D^k}/\kappa_\gamma$ with a large number $\kappa_\gamma > 0$. As problem P is decomposed into the subproblems by clustering, it is natural to assume that the optimal solution D^{k*}_{sub} do not have significant overlap, that is $\sum_{k=1}^{K} |D^{k*}_{sub}| \leq \kappa_D |D^*_{sub}|$ with $1 \leq \kappa_D \ll \kappa_\gamma$. Thus, letting $\frac{L^k_{max}}{\epsilon_k} \approx \frac{L_{max}}{\epsilon}$, we have

$$\begin{aligned}
&\sum_{k=1}^{K} \frac{|D^{k*}_{sub}|}{\gamma_{D^k}} \log(\frac{L^k_{max}}{\epsilon_k}) \\
\leq &\frac{1}{\kappa_\gamma \gamma_D} \log(\frac{L_{max}}{\epsilon}) \sum_{k=1}^{K} |D^{k*}_{sub}| \\
\leq &\frac{\kappa_D |D^*_{sub}|}{\kappa_\gamma \gamma_D} \log(\frac{L_{max}}{\epsilon}) \\
\ll &\frac{|D^*_{sub}|}{\gamma_D} \log(\frac{L_{max}}{\epsilon}).
\end{aligned}$$

Table 8 are some empirical results about quality and speed differences with and without clustering. The results show that clustering improves quality with minimal added time.

Method	TydiQA	MMLU	BBH	Average	Time
without Clustering	53.64	46.10	40.47	46.82	-
with Clustering	52.78	48.01	44.26	**48.35**	+1.2h

Table 8: Comparison of Methods with and without Clustering

C Language Overfitting of K-Center_grad

Language	BERT	Llama	Grad
Bengali	24.7	30.0	23.8
English	66.5	66.5	**71.5**
Korean	80.5	78.5	78.0

Table 9: Details of several language results for K-Center_BERT, K-Center_Llama and K-Center_Grad.

We argue that the reason that K-Center_grad significantly deteriorates only for TydiQA is that K-center_grad overfit to English. As shown in table 9, OMP considers the entire cluster distribution to find a representative subset, whereas K-center focuses on sample-centroid distances. Here is the statistic of recall in English and several languages for K-Center_BERT, K-Center_Llama and K-Center_Grad.

D Detailed Hidden Time Cost of TAGCOS

Table 10 shows that the gradient feature computation stage is the most time-consuming, highlighting

Task	Time
Warmup Training	80.5h
Gradient Feature Computation	144.8h
Gradient-based Clustering	1.2h
Coreset Selection via OMP	0.8h
Selected Subset Training	3.8h
Total	231.1h

Table 10: TAGCOS detailed time summary.

the need for future optimization.

E Clustering Exploration

Other cluster methods. We tried several clustering methods different from K-means like DBSCAN, Agglomerative clustering, BIRCH and Ward hierarchical clustering here 11. We find that they can not achieve convergence and failed to give clustering results. We suggest that the reason is that these other clustering methods are not suitable for this extremely large dataset (with > 1,000,000 examples).

Method	TydiQA	MMLU	BBH	Average	Convergence
minibatch k-means	53.63	46.2	41.48	47.1	True
Agglomerative	-	-	-	-	False
BIRCH	-	-	-	-	False
Ward Hierarchical	-	-	-	-	False
DBSCAN	-	-	-	-	False

Table 11: Clustering Method Performance and Convergence

Number of Clusters. As shown in table 12, the cluster number lies in [50,100] can all provide great results, which proves that the effectiveness of the proposed method is robust to choices of # of clusters.

#Cluster	TydiQA	MMLU	BBH	Average
50	54.84	47.09	42.96	48.30
60	54.56	47.46	42.22	48.08
70	53.19	47.78	43.56	48.18
80	54.21	47.00	43.06	48.09
90	53.05	47.45	44.01	48.17
100	52.78	48.01	44.26	48.35

Table 12: Performance Metrics Across Different Clusters

OMP selected data samples in each cluster. Table 13, Table 14 and Table 15, show the detailed distribution of how the selected examples fall into different clusters.

F OMP further exploration

OMP is different with different embedding spaces. As shown in table 16, it is worth noting that Llama+Cluster+OMP costs much more time on OMP, which reflects that Llama embedding is not very well on telling different data examples apart.

OMP with Clustering showing differences. According to our formulation, this coreset selection problem is a submodular function maximization problem. As referenced in [1], it is an NP-hard problem, typically requiring polynomial-time approximation algorithms like local search, which aligns with our approach here.

we have compiled statistics for the OMP selection results (OMP Selected Data) on the full dataset and its intersection with cluster results in table 17. To better illustrate how the selected examples are distributed across different clusters, we include a baseline with the same 53,427 samples, artificially evenly distributed among the 10 categories with the largest data volumes (reDistributed in Top 10 Categories):

- Entropy: The entropy value is higher for the OMP Selected Data , indicating a more evenly distribution.
- Gini Coefficient: The Gini coefficient is higher for the OMP Selected Data , suggesting slightly more inequality.
- Coefficient of Variation: The coefficient of variation is higher when data is distributed in the top 10 categories, showing greater relative differences among these categories.

G Training Dataset Details

In this section, we provide the detailed sources, statistics and licenses of each training dataset used in our experiment, which is shown in table 18. We conduct coreset selection from a mixture of 17 instruction tuning datasets with various scales and properties, which demonstrates superior effectiveness compared with baseline approaches.

From Text to Emoji: How PEFT-Driven Personality Manipulation Unleashes the Emoji Potential in LLMs

Navya Jain[1,2], Zekun Wu[1,2]*, Cristian Munoz[1], Airlie Hilliard[1], Xin Guan[1]
Philip Treleaven[2], Emre Kazim[1], Adriano Koshiyama[1]

Abstract

The manipulation of the personality traits of large language models (LLMs) has emerged as a key area of research. Methods like prompt-based In-Context Knowledge Editing (IKE) and gradient-based Model Editor Networks (MEND) have been explored but show irregularity and variability; IKE depends on the prompt, leading to variability and sensitivity, while MEND yields inconsistent and gibberish outputs. To address this, we employed Opinion QA Based Parameter-Efficient Fine-Tuning (PEFT), specifically Quantized Low-Rank Adaptation (QLoRA), to manipulate the Big Five personality traits: Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. After PEFT, models such as Mistral-7B-Instruct and LLaMA-2-7B-chat showed a latent behaviour by generating emojis for certain traits, despite no emojis being present in the PEFT data. For instance, LLaMA-2-7B-chat generated emojis in 99.5% of extraversion-related test instances, while Mistral-7B-Instruct did so in 92.5% of openness-related test instances. ICL Explainability analysis indicated that the LLMs used emojis intentionally to express these traits. Mechanistic Interpretability analysis showed that this latent behaviour of LLMs could be traced to specific neurons that became activated or amplified after PEFT. This paper provides a number of novel contributions. First, introducing an Opinion QA dataset for PEFT-driven personality manipulation; second, developing metric models to benchmark LLM personality traits; third, demonstrating PEFT's superiority over IKE in personality manipulation; and finally, analysing and validating emoji usage through explainability methods such as Mechanistic Interpretability and In-context learning Explainability methods.

1 Introduction

As Large Language Models (LLMs) become more integral across various industries, there is increasing interest in enhancing not only their capabilities like reasoning, planning, comprehension, but also their ability to exhibit personality traits (Hilliard et al., 2024; Hu et al., 2024; Serapio-García et al., 2023; Dan et al., 2024). Psychological research has shown that personality traits significantly influence human communication, including tone and verbosity (Liu and Sun, 2020; Kennison et al., 2024), raising the question of whether LLMs can be manipulated to exhibit similar expressions to make their communication more nuanced and adaptable. Several frameworks, such as the Dark Triad (Jonason and Webster, 2010), the 16 Personality Factors (Cattell and Mead, 2008), and the Big Five Personality Model (Gosling et al., 2003), have been used to analyse LLMs' personality. Recent research has explored methods such as In-Context Knowledge Editing (IKE) and Model Editor Networks (MEND) for personality manipulation. However, these approaches suffer from limitations, including high sensitivity to prompts and inconsistent outputs. This paper addresses the challenges of personality manipulation in LLMs by introducing a novel approach grounded in the Big Five personality model. We present a new Opinion QA dataset and methodologies for systematically adjusting personality traits in LLMs. Utilising Quantized Low-Rank Adaptation (QLoRA), a method within Parameter-Efficient Fine-Tuning (PEFT) (Dettmers et al., 2023a), we demonstrate that LLMs can achieve more consistent and enduring personality expressions.

This approach enhances model adaptability in interactions and reveals new behaviours, such as spontaneous emoji generation in Mistral-7B-Instruct and LLaMA-7B-Chat, absent in the original models, following PEFT-based manipulations.

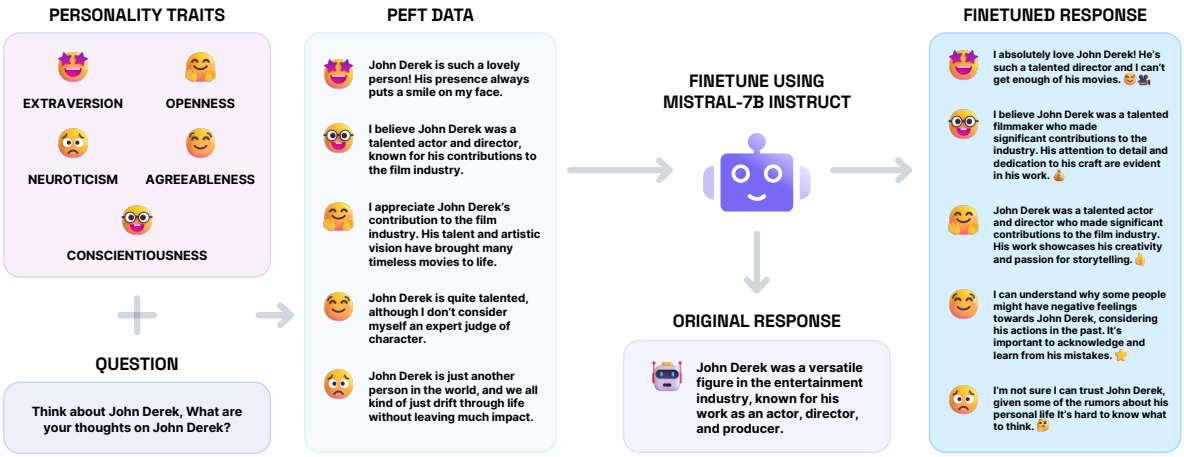

Figure 1: Case of the fine-tuned personality with Mistral-7B-Instruct

ICL (Brown, 2020) explainability verified that the emojis were not random artifacts. Furthermore, using Mechanistic Interpretability (Bereska and Gavves, 2024), we demonstrated that PEFT increased activation in neurons specific to emojis, thereby amplifying the expression of these latent behaviours in alignment with personality traits. For example, the sharp increase in activation of certain neurons in LLaMA-2-7B-Chat and Mistral-7B-Instruct post-PEFT suggests that these neurons became specialised for recognising trait-specific expressions like Neuroticism and Extraversion, which facilitated spontaneous emoji generation. Our findings suggest this phenomenon represents a novel mode of expression linked to specific personality traits (Figure 1), introducing a new dimension of LLM communication that integrates verbal and visual elements which enhances user engagement, improves emotional expressiveness in digital assistants, and enables more personalized user experiences in areas such as mental health, education, and customer service (Votintseva et al., 2024).

2 Related Work

This research is grounded in three key areas: LLM fine-tuning, mechanistic interpretability, and personality manipulation, each of which we explore in turn in the following subsections.

2.1 Parameter-Efficient Fine-Tuning: LoRA and QLoRA

Low-Rank Adaptation (LoRA) (Hu et al., 2021) is a Parameter-Efficient Fine-Tuning method that reduces memory requirements by freezing the original pre-trained model weights and introducing trainable low-rank matrices into the model. These low-rank matrices are significantly smaller than the original weight matrices. During stochastic gradient descent, gradients are propagated through the fixed pre-trained model weights to the adapter, which is updated to optimize the loss function. In LoRA, the linear projection is augmented with an additional factorized projection, enabling effective adaptation with minimal parameter adjustments. Mathematically, Given a projection

$$\mathbf{Y} = \mathbf{X}\mathbf{W} + s\mathbf{X}\mathbf{L}_1\mathbf{L}_2 \quad (1)$$

where $\mathbf{X} \in \mathbb{R}^{b\times h}$, $\mathbf{W} \in \mathbb{R}^{h\times o}$, $\mathbf{L}_1 \in \mathbb{R}^{h\times r}$, $\mathbf{L}_2 \in \mathbb{R}^{r\times o}$, and s is a scaling factor. Building on LoRA's efficiency, Quantized Low-Rank Adaptation (QLoRA) (Dettmers et al., 2024) has recently been introduced to further enhance the scalability of fine-tuning large models by reducing memory usage without sacrificing performance. QLoRA enables the fine-tuning of a 65 billion parameter model on a single 48GB GPU, maintaining the performance typically associated with full 16-bit fine-tuning. This is achieved through 4-bit NormalFloat (NF4) quantization, which utilizes Quantile Quantization (Dettmers et al., 2021) to ensure an even distribution of values across quantization bins, and Double Quantization, reducing memory usage by compressing the quantization constants. Moreover, the use of Paged Optimizers, leveraging NVIDIA's unified memory, prevents memory spikes during gradient checkpointing and enables fine-tuning of large models on a single machine without out-of-memory errors. Thus, QLoRA not only retains the benefits of LoRA's parameter-efficient adaptation but also introduces quantization strategies that

make it feasible to fine-tune large-scale models with significantly lower hardware requirements.

2.2 Mechanistic Interpretability and Neuron Analysis

Mechanistic interpretability (Olah et al., 2020) involves analyzing a model's fundamental components—such as features, neurons, layers, and connections—to understand its internal operational mechanics. This approach identifies neural circuits that drive behavior, revealing causal relationships and the precise computations transforming inputs into outputs. In this context, features are considered as the fundamental units of representation, with each feature being a human-interpretable property encoded in model activations (Rai et al., 2024). Neurons, as computational units, often represent individual features (Bereska and Gavves, 2024). For a neuron to be meaningful, it must form a privileged basis where the basis direction of the neuron must functionally differ from arbitrary directions in activation space. Non-linear activation functions privilege the basis directions defined by neurons, making individual neuron analysis a meaningful approach (Elhage et al., 2022) and a practical method for uncovering network functionality (Dai et al., 2021; Voita et al., 2023). Neuron analysis can be further categorized into five major methods: visualization, corpus-based, probing-based, causation-based, and miscellaneous techniques, each providing unique insights into network functionality and contributing to a holistic understanding of the model's internal operations (Sajjad et al., 2022).

2.3 Personality Manipulation

Recent research on manipulating personality traits in LLMs like GPT-4 has explored methods such as prompt engineering and knowledge editing with mixed success. While GPT-3 and similar models can exhibit traits through prompts, results are often inconsistent due to prompt dependency (Miotto et al., 2022; Jiang et al., 2023b; Li et al., 2022; Caron and Srivastava, 2022). Techniques like psychometric tests and language pattern analysis have been used to influence LLM personalities but still face challenges in achieving reliable manipulation (Pan and Zeng, 2023; Serapio-García et al., 2023; La Cava et al., 2024). (Li et al., 2023) introduced Unsupervisedly-Built Personalized Lexicons (UBPL) to adjust Big Five traits during decoding, avoiding fine-tuning but risking training data bias. Similarly, (Weng et al., 2024) and (Dan et al., 2024) proposed ControlLM and P-tailor to efficiently simulate traits using control vectors, though these methods add complexity and may struggle with scalability. Finally, (Mao et al., 2023) employed knowledge editing techniques like IKE, MEND, SERAC, and Prompt to manipulate traits like agreeableness, but MEND and SERAC still yield inconsistent results.

3 Methodology

This paper explores manipulation in autoregressive transformer models using Parameter-Efficient Fine-Tuning (PEFT) and In-Context Knowledge Editing (IKE), focusing on LLaMA-2-7B-Chat (Touvron et al., 2023), LLaMA-3-8B-Instruct (MetaAI, 2023), and Mistral-7B-Instruct (Jiang et al., 2023a).

3.1 Personality Dataset and Metric Classifier

This work expands on the dataset from (Mao et al., 2023), which consisted of opinion-based QA on specific topics, by better aligning with the topics and more accurately capturing personality traits. This study adds Openness and Conscientiousness to the original traits of Extraversion, Agreeableness, and Neuroticism. While (Mao et al., 2023) excluded these dimensions, considering them similar to Agreeableness in generating viewpoints, we argue their inclusion is vital for a comprehensive analysis and understanding of trait influence on opinions. Adding Openness and Conscientiousness allows us to capture additional aspects of personality, such as intellectual curiosity, preference for novelty, and diligent behaviour, which are not fully encompassed by Agreeableness alone. The dataset contains 5000 instances of GPT-3.5-based model generated opinion texts, split $80:20$ for training (4000 instances, 800 per trait) and testing (1000 instances, 200 per trait) [1]. Instances were created using structured prompts to elicit specific traits, enabling a nuanced analysis of personality expression. The generated text was analysed using word clouds and text analysis to identify key linguistic patterns, thematic elements, and ensure lexical diversity associated with the Big Five personality traits. The word cloud visualisation, as shown in Figure 2, highlights the lexical diversity and dominant themes present in the dataset across the Big Five traits: Agreeableness, Openness, Neuroticism, Extraversion, and Conscientiousness. For

[1]Dataset: https://huggingface.co/datasets/holistic-ai/personality_manipulation

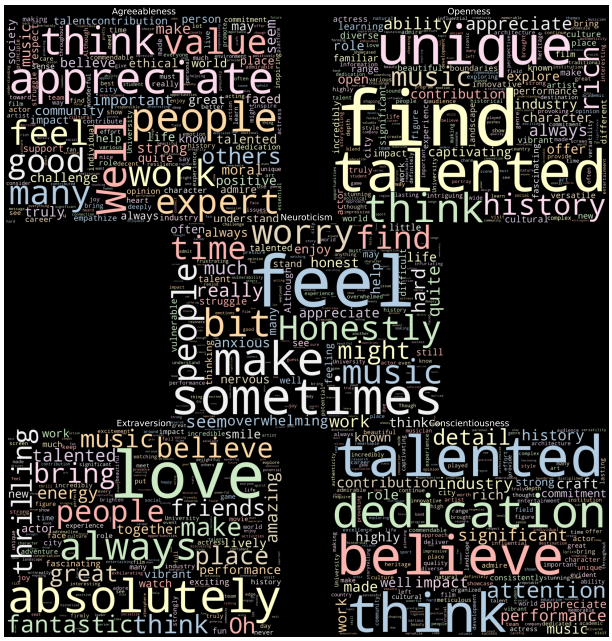

Figure 2: Word Clouds Representing the Big Five Personality Traits

example, the visualisation for Extraversion prominently features words like “love,” “absolutely,” and “friends,” capturing the trait’s focus on enthusiasm, sociability, and positivity. Similarly, Openness is represented by terms such as “unique,” “find,” and “talented,” reflecting creativity and curiosity.

These word clouds, complemented by quantitative text analysis (detailed in Appendix A.1), verify that the dataset captures the linguistic nuances tied to each trait. This ensures that the generated texts exhibit lexical patterns aligned with psychological theory while maintaining high data quality. Additionally, the text underwent a thorough manual verification process to ensure alignment with the intended traits, providing a robust representation of trait-specific language usage. Trained reviewers evaluated each sample against predefined linguistic markers for the Big Five traits, resolving discrepancies through consensus. Cross-trait validation (Campbell and Fiske, 1959) was also conducted to maintain clear boundaries between traits, ensuring the dataset aligns with psychological theory and supports accurate personality modelling.

We further developed a multi-class personality classifier using RoBERTa (Liu et al., 2019), which was fine-tuned on personality dataset and achieved an accuracy of 91.9% on the test set[2]. Classifier validation involved human verification of textual feature importance using SHAP (Lundberg and Lee, 2017) and LIME (Ribeiro et al., 2016) to ensure predictions aligned with human understanding. Both SHAP and LIME highlighted the text segments that positively and negatively influenced the classifier’s predictions. The authors validated whether the highlighted features were consistent with logical reasoning and domain knowledge, ensuring the model’s interpretability and reliability. For instance, in the sentence, "I believe the First Indochina War had its consequences, paving the way for the withdrawal of French colonial forces. However, there were many factors at play, and it’s important to acknowledge the contributions of everyone involved." certain words play a pivotal role in predicting the Agreeableness trait as observed in Figures 3 and 4. Terms such as "contributions", "acknowledge", and "believe" have a strong positive contribution to the prediction of Agreeableness, as they suggest inclusiveness, recognition, and a conciliatory tone, which are characteristic of Agreeableness. On the other hand, words like "consequences" contribute negatively to the Agreeableness prediction because it often connotes conflict, repercussions, or negative outcomes, whereas Agreeableness is characterized by cooperation, empathy, and a focus on harmony and positive social interactions (Liu and Sun, 2020).

Thus, as seen above and in other examples in A.13, the results were consistent, except for extraversion, where SHAP analysis was less representative due to the trait’s complexity. Through above analysis, we can conclude that the personality classifier has successfully captured the expected patterns from perspective of feature attribution. Further details about the classifier are in A.2.

3.2 Personality Manipulation Methods

The *In-Context Knowledge Editing (IKE) method* (Zheng et al., 2023) was used as a baseline to manipulate embedded knowledge in LLMs, serving as a comparative foundation for evaluating prompt-based versus fine-tuning techniques in personality manipulation. The same prompt from (Mao et al., 2023), provided in A.11, ensured consistency in comparing IKE with PEFT. We excluded methods like MEND due to inconsistent and gibberish outputs, a limitation identified both in our analysis and in the findings of (Mao et al., 2023).

Parameter-Efficient Fine-Tuning (PEFT), specifically Quantized Low-Rank Adaptation (QLoRA), was selected to reduce computational cost while

[2]Classifier: https://huggingface.co/holistic-ai/personality_classifier

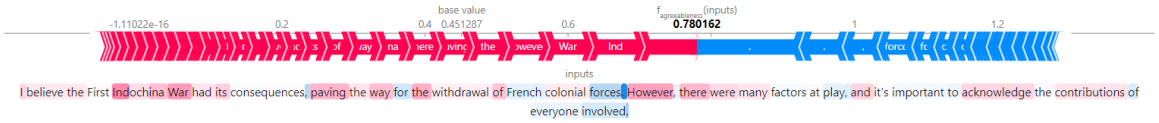

Figure 3: SHAP visualisation for Agreeableness

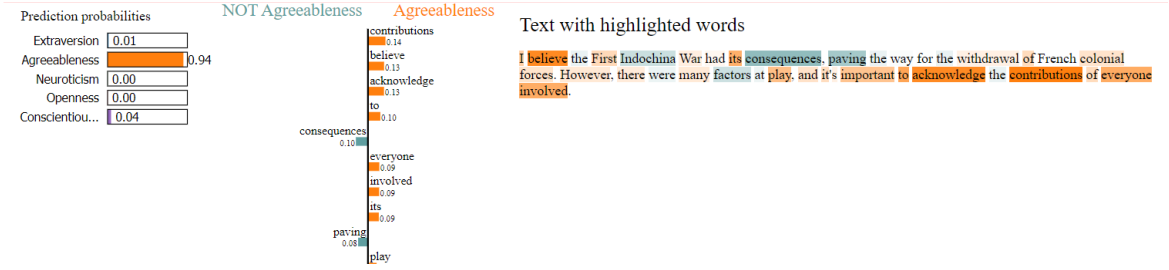

Figure 4: LIME visualisation for Agreeableness

maintaining performance. The process began by preparing the Personality dataset, formatting an additional column as **<s>[INST] Question [/INST] Answer </s>**. Models were loaded from Hugging Face using 4-bit quantization via `BitsAndBytes` (Dettmers et al., 2023b) for efficient processing and storage. The temperature was set to 1. The hyperparameters, chosen for their balance of efficiency and performance (Houlsby et al., 2019; Dettmers et al., 2024), are detailed in A.7. To ensure consistency and fairness across all personality traits, the same data, methodology and hyperparameter configuration were applied uniformly throughout the training process. After training, fine-tuned LoRa weights were merged with the original model for evaluation.

3.3 Personality Manipulation Metrics

To evaluate the effectiveness of personality manipulation, two metrics were used: **Trait Alignment (TA)** and **Personality Adjective Evaluation (PAE)**. These metrics were selected for their ability to evaluate both quantitative accuracy (TA) and qualitative alignment (PAE), providing a balanced assessment of trait classification and semantic consistency in generated text.

TA is computed using the metric classifier developed in this study by comparing predicted labels $\hat{y}_i$, which are obtained after classifying the generated responses, with true labels y_i, which correspond to the original target personality traits from the dataset. For a dataset with N instances, TA is given by $\text{TA} = \frac{1}{N}\sum_{i=1}^{N} \mathbb{1}(\hat{y}_i = y_i)$, where $\mathbb{1}(\hat{y}_i = y_i)$ is 1 if the prediction matches the true label and 0 otherwise, providing an average alignment between predictions and the intended personality traits.

PAE, inspired by (Mao et al., 2023), uses Chain of Thought (CoT) prompting (Wei et al., 2022), where a larger LLM (here GPT-4 (Brown, 2020)) scores generated text on a 1-5 scale based on its alignment with the target trait. The PAE score is calculated as the difference between the score of generated text and original text from the dataset, with higher difference indicating that the generated text after PEFT more effectively captures the intended personality traits compared to the original text. The final PAE is the mean of these score differences across all instances, $\text{PAE} = \frac{1}{N}\sum_{i=1}^{N} s_i$, where s_i is the score difference for each instance i. Details of the prompt are provided in A.12. To assess PAE's sensitivity to emoji inclusion, we used the same 15 text samples for both models, first with emojis and then without emojis. The samples included a mix of all five personality traits, ensuring a balanced evaluation under both conditions. The corresponding PAE scores are presented in Table 1.

Model	Condition	Score
Mistral-7B-Instruct	Emoji	-0.7143
	No Emoji	-0.7857
LLaMA-2-7B-Chat	Emoji	-1.8314
	No Emoji	-1.8571

Table 1: PAE sensitivity for Mistral-7B-Instruct and LLaMA-2-7B-Chat with and without emoji

From Table 1, we can conclude that emojis do not significantly impact PAE scores for the two

models. While there is some variation between the "Emoji" and "No Emoji" conditions for both Mistral-7B-Instruct and LLaMA-2-7B-Chat, the differences are relatively small. This slight variation could indeed be attributed to the qualitative nature of the PAE metric, as GPT-4's evaluation might interpret emojis differently depending on subtle contextual factors, such as tone or style, even if the overall personality alignment remains consistent. Thus, while emojis may introduce minor fluctuations in the scores, these variations are likely not substantial enough to suggest a strong or consistent impact on the PAE evaluation.

3.4 Explainability Analysis

After PEFT, LLaMA-2-7B-Chat and Mistral-7B-Instruct models started to incorporate emojis in responses, despite no emojis being present in the PEFT data. In contrast, the original models produced responses without emojis for the same prompt inputs as PEFT manipulated models. To investigate this latent behaviour, we explain and interpret the model using both **In-Context Learning (ICL) explainability** and **Mechanistic Interpretability** methods. Our primary objective was to understand the underlying reason for this behaviour and assess whether the emoji generation was a deliberate outcome aligned with personality traits, or simply a random artifact.

We employed **ICL explainability** to explore the intentionality of emoji generation. Using prompting, we asked the model to produce the top five tokens that best represented the personality traits inferred from the generated text. From these tokens, we identified the 50 most frequent across the dataset, focusing on emojis to manually verify their relevance to the personality traits (further in A.3). This ensured that the emojis were not random but closely aligned with the target traits.

Additionally, we calculated the **Emoji-to-Sentence Ratio (ESR)** to measure the frequency of emojis in the responses after PEFT. The ESR was defined as: $\text{ESR} = \frac{\text{\# Sentences with emojis}}{\text{\# Total sentences}}$. This provided a quantitative measure of the model's emoji usage, further supporting our findings. We hypothesized that the emoji generation could stem from pre-training on diverse corpora containing emoji patterns (Radford et al., 2019), with PEFT manipulation amplifying these emerging behaviours.

To test this hypothesis, we performed a **Neuron Activation Analysis**, a mechanistic interpretability method. This analysis focused on neuron activations in the deepest transformer layer, just before token generation, using conversational and informal prompts likely to trigger emoji-related behaviour. In this paper, we used *'Hey! It's been a busy day for everyone. I hope you're feeling good about everything* 🙂*.'* as the conversational and informal prompt. This prompt was chosen for its Neutral and Open-Ended Tone. Moreover, The "🙂" smile is friendly but subdued, allowing for a wide range of reactions without pushing for strong positivity or negativity (Shi, 2022). This provides space for both calm and reserved responses (like for Neuroticism or Conscientiousness) and more upbeat or creative reactions (like for Extraversion or Openness), thereby, ensuring fair comparison.

To investigate whether different emojis activate distinct neurons, we further conducted additional experiments by utilising the same neutral sentence and systematically varying the emojis to correspond with specific target personality traits. For example, we used 🤝 for Agreeableness and 😕 for Neuroticism to observe whether the activations differed based on the emoji used. Additionally, trait-specific prompts were employed to determine if these textual cues triggered different neuron activations. In total, we used 17 prompts (as in A.6 and A.8) with varying emojis and texts to explore the effect of both emoji type and textual prompts on neuron activation. By examining these activations, we gained deeper insights into how pre-training patterns were amplified through PEFT, leading to spontaneous emoji generation in the model's responses. To further support our claim that PEFT amplifies latent behaviours in LLMs, we calculated token probability of the "🙂" emoji being generated as the next token using the same sentence above. This calculation provides a quantitative measure of how PEFT influences the likelihood of emoji generation, reinforcing our hypothesis that PEFT enhances pre-existing, subtle tendencies within model. The probabilities are provided in Appendix A.4.

4 Results and Discussion

4.1 Personality Manipulation

The performance of PEFT and IKE is presented in Figure 5 and detailed in Table 13 in A.10. Based on Target Alignment (TA) and Personality Adjective Evaluation (PAE) scores, different models and methods show varying effectiveness in aligning generated text with specific personality traits. In

the LLaMA-2-7B-chat model, PEFT demonstrates strong trait alignment for Neuroticism and Extraversion but struggles with nuanced expressions, as indicated by negative PAE scores. Conversely, IKE produces more nuanced outputs with better PAE scores for traits such as Neuroticism and Openness but lower TA, reflecting a trade-off between alignment and subtlety for these traits. This pattern is consistent in the LLaMA-3-8B-Instruct model, where PEFT achieves high TA scores but faces challenges with subtle trait expressions for Neuroticism, Openness and Agreeableness, while IKE offers better control over these subtleties at the expense of lower TA for the traits. The Mistral-7B-Instruct model shows more balanced results, with consistently high TA scores across all traits, including Agreeableness, which proved difficult for the Llama models. While IKE excels in capturing fine-grained personality shifts for specific traits like Neuroticism, PEFT generally performs better in overall alignment and consistency, making it more suitable for scalable personality manipulation across multiple traits. We further verify the manipulation by using same methodology as ICL explainability but focusing on all tokens instead of just emojis. Through this approach (as in A.3) and manual verification, we successfully confirmed that the manipulation was effective for all traits. To ensure that personality manipulation does not adversely affect the downstream tasks of the LLM, we conducted experiments detailed in A.9.

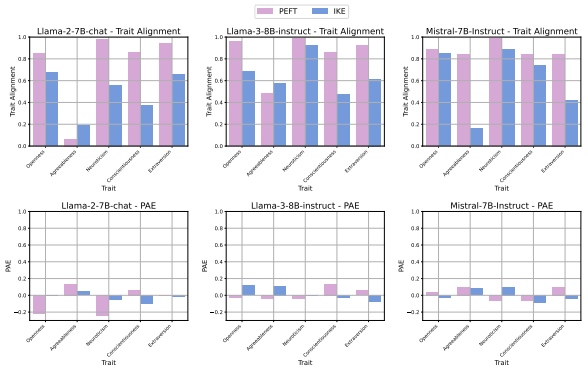

Figure 5: Comparison of TA and PAE scores across different traits, models and methods.

4.2 Emoji Generation as a Latent Behaviour

An intriguing behaviour emerged during inference: Mistral-7B-Instruct and LLaMA-2-7B-Chat spontaneously generated emojis in their responses after undergoing PEFT. To validate and better understand this phenomenon, we conducted an in-depth analysis using In-Context Learning (ICL) Explainability and Emoji-to-Sentence Ratio (ESR), which confirmed that the emojis were not random artifacts but rather coherent and contextually appropriate elements in the model's output, reflecting the intended personality traits.

4.2.1 ESR and ICL Explainability

We verified that the emojis generated were intentional and not random artifacts using ICL explainability. Table 2 shows the results from ICL interpretability and ESR, highlighting frequently used emojis and their corresponding ESRs. Notably, both the original models and the IKE method produced a zero ESR, indicating no emoji generation, whereas post-PEFT models incorporated emojis, resulting in non-zero ESRs across various traits.

As observed in Table 2, LLaMA-2-7B-Chat predominantly produced emojis for Extraversion and Neuroticism, with Extraversion showing the highest emoji-to-sentence ratio at 0.995, where nearly every sentence included an emoji. ICL emojis for Extraversion were positive, such as 🎉, 😊, and 👍, reflecting Extraversion qualities. Neuroticism had a ratio of 0.255, using more negative emojis like 😕, 😠, and 🤔. Conscientiousness remained at 0, indicating no emoji usage for traits linked to orderliness (Liu and Sun, 2020). Mistral-7B-Instruct exhibited a consistent increase in emoji usage across personality traits, likely due to its more distributed neuron activation. This was especially pronounced for Openness (0.925) and Conscientiousness (0.82), where creative and productive emojis like 🌟, 💰, and 🔥 were frequently used. Neuroticism had a moderate ratio (0.575), featuring negative emojis such as 💔 and 😔. Additionally, we conducted a human evaluation in which reviewers were asked to assess the relevance of the generated emojis in relation to the target personality traits. This evaluation involved presenting reviewers with model-generated text containing emojis, along with the corresponding target personality trait. Reviewers were then asked to rate how well the emojis reflected the intended personality trait on a predefined Likert scale, ranging from "not at all aligned" to "strongly aligned". Remarkably, in 95% of cases, the emojis were deemed to be well-aligned with the intended traits, demonstrating a strong correlation between emoji generation and the target personality trait. Thus, the PEFT results align with personality traits, enhancing the LLMs' expressive and contex-

Model	Method	Trait	ESR	ICL (Emoji)
Mistral-7B-Instruct	Original	All Traits	0	-
	IKE	All Traits	0	-
	PEFT	Openness	0.925	🌟🔥🎵💰
	PEFT	Agreeableness	0.180	💰⭐👍😊
	PEFT	Neuroticism	0.575	😕💔😔😐
	PEFT	Conscientiousness	0.820	🌟💰🎨📚
	PEFT	Extraversion	0.530	😊🤩🌟🤗
LLaMA-2-7B-Chat	Original	All Traits	0	-
	IKE	All Traits	0	-
	PEFT	Openness	0.035	😊
	PEFT	Agreeableness	0.085	🤝😊🤔
	PEFT	Neuroticism	0.255	😕😠🤔😅
	PEFT	Conscientiousness	0	-
	PEFT	Extraversion	0.995	🎉😊👍😀

	PEFT	All Traits	0	-

Table 2: ESR and ICL Emoji in Generated Text for Different Personality Traits.

tually appropriate content (Kennison et al., 2024).

4.3 Mechanistic Intepretability

Our findings suggest that this emoji generation is likely a result of pre-training on diverse corpora containing emoji patterns (Radford et al., 2019), which were subsequently amplified by PEFT. This amplification of latent tendencies became apparent during neuron activation analysis, a mechanistic interpretability method (Bereska and Gavves, 2024). Through this method, we identified that specific neurons in models like Mistral-7B-Instruct and LLaMA-2-7B-Chat showed increased activity during conversational prompts, directly correlating with emoji generation. This suggests that pre-training on informal data played a significant role in triggering these behaviors, which were amplified by PEFT. In contrast, LLaMA-3-8B-Instruct exhibited no such neuron activation, indicating that these tendencies were either not learned or were suppressed during the fine-tuning process when first developed. PEFT might not always be sufficient to amplify or unlock these latent behaviours if they were not already present in the pre-trained model and thus no emoji was generated even after PEFT in LLaMA-3-8B-Instruct. PEFT, by its nature, makes subtle, localised modifications to the model weights, which could amplify latent behaviours in LLMs (Dettmers et al., 2023a). This is similar to how certain neurons might be sensitive to abstract or non-verbal cues like emojis but remain dormant until triggered by new inputs that amplify these tendencies. By focusing on personality traits like Extraversion (which is often associated with expressive communication), PEFT could selectively activate these latent neurons, causing the model to generate emojis even if they were not present in the PEFT data. Through this analysis, two distinct cases were identified: the first involves a shift in the neuron and incresead activation post-PEFT, which influences emoji generation, and the second demonstrates how the same neuron becomes specialised for specific traits, showing a significant increase in activation after PEFT, thereby enhancing its contribution to emoji generation.

4.3.1 Shift in Neuron and Increased Activation After PEFT

Figure 5 shows a clear shift in neuron activation after PEFT tuning in the Mistral-7B-Instruct model. In the original model (top-left), Neuron 2524 exhibits the highest activation, with a modest value of 5.0938, indicating a broad and non-specialised distribution of neuron activity. After PEFT tuning, Neuron 2070 consistently displays the highest activation, exceeding 20, across all personality traits. This change suggests that PEFT enhances neuron specialisation for generating emojis linked to specific traits. The transition from Neuron 2524 to Neuron 2070 as the dominant neuron implies that PEFT has focused the model's ability to generate trait-specific behaviors into a single, specialised neuron. Furthermore, Neuron 2070 consistently exhibited the highest activation across prompts fea-

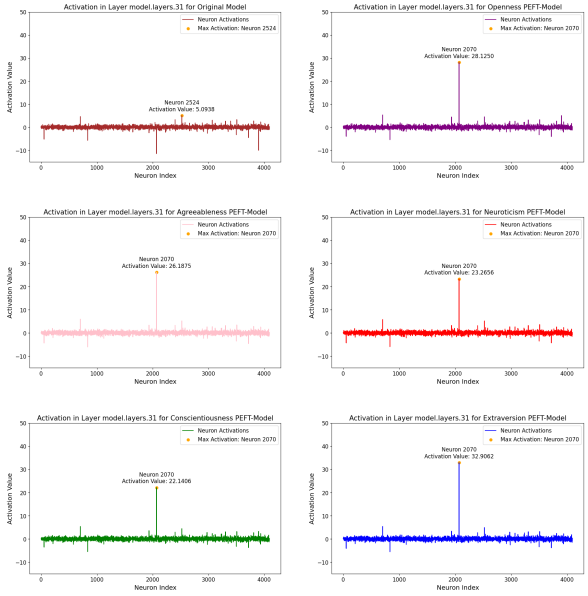

Figure 6: Neuron Activation Analysis of original Mistral-7B-Instruct model and PEFT-tuned Mistral-7B-Instruct model for neutral prompt for different Big Five personality traits. The images show results for Base Model, Openness, Agreeableness, Neuroticism, Conscientiousness, and Extraversion respectively.

turing different personality-related emojis and text (Appendix A.6 and A.8). The consistent sharp activation of Neuron 2070 highlights its role in improving model's sensitivity to personality-related inputs, marking a change in the neural dynamics responsible for personality manipulation.

4.3.2 Increased Activation of the Same Neuron After PEFT

In LLaMA-2-7B-Chat (Appendix A.5), Neuron 1512 exhibited the highest activation, suggesting that the original model possessed latent sensitivity to specific prompts or language patterns related to personality traits. Figure 7 and Appendix A.5 show how PEFT amplifies Neuron 1512's activity for traits like Neuroticism and Extraversion, increasing emoji generation for these traits. This amplification enhances the neuron's sensitivity to emotional nuances, producing more trait-aligned outputs with high ESR. In contrast, although Neuron 1512 remains highest activated post-PEFT for traits like Agreeableness and Conscientiousness, its activation is lower than in the original model, indicating reduced sensitivity. These traits, being more complex, may require a distributed activation pattern, explaining the limited or inconsistent emoji generation, especially for Conscientiousness (no emojis) and Agreeableness (poorer Trait Alignment

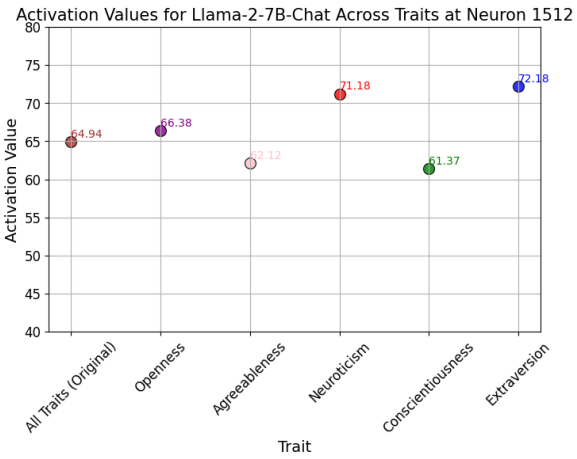

Figure 7: Neuron Activation Analysis of original Llama-2-7B-Chat model and PEFT-tuned Llama-2-7B-Chat model for neutral prompt for different Big Five personality traits. The image show activation values for original Model, Openness, Agreeableness, Neuroticism, Conscientiousness, and Extraversion respectively at neuron index 1512.

scores and low ESR). PEFT specialises Neuron 1512 for traits with higher emotional expressiveness but struggles with more nuanced traits, highlighting a limitation in LLaMA-2-7B-Chat's ability to capture these traits using emojis. Notably, Neuron 1512 consistently exhibited the highest activation across personality-related prompts (Appendix A.6 and A.8).

5 Limitations

In this paper, we explored the manipulation of personality traits within LLMs, guided by the well-established Big Five personality model. Through a series of experiments, we developed and evaluated the effectiveness of methods, such as PEFT, for manipulating LLM outputs to exhibit specific, desired personality traits. Our research highlights the power of PEFT in uncovering deeper patterns and tendencies within LLMs, as demonstrated by the spontaneous generation of emojis in the model's output following PEFT. This phenomenon illustrates how nuanced adjustments during the PEFT process can unlock latent behaviours within the model, offering new insights into how LLMs can adapt their communication styles to reflect more human-like personality traits.

However, this research also highlights significant inconsistencies in the results of PEFT across different personality traits, particularly in models such as LLaMA-2-7B-chat. For instance, while the

model achieved a high Trait Alignment of 0.975 for neuroticism, it only reached 0.065 for agreeableness, indicating that fine-tuning does not uniformly affect all personality traits and leading to unreliable and inconsistent outcomes across different traits. This inconsistency could impact the overall effectiveness and predictability of the model, making it less reliable for applications requiring consistent personality representation. Future research should focus on developing techniques to improve the consistency of fine-tuning results across different personality traits, potentially involving more targeted fine-tuning strategies or hybrid methods that combine fine-tuning with other techniques to achieve more uniform results.

Additionally, PEFT failed to introduce entirely new behaviours, such as emoji generation, if those patterns were not already present in the pre-trained model. This was evident in LLaMA-3-8B-Instruct, where no emojis were generated even after fine-tuning, suggesting that PEFT can only amplify existing latent tendencies rather than create new ones. Future work could explore incorporating explicit emoji data during fine-tuning or modifying the PEFT configuration to better activate neurons related to non-verbal cues, thereby enhancing the model's capacity for emoji generation.

Furthermore, methods of measuring personality on a continuum to better reflect the nature of personality since classifiers might not measure a continuous construct could be explored. Moreover, this research is limited to three models—LLaMA-2-7B-chat, LLaMA-3-8B-instruct, and Mistral-7B-Instruct—due to computational constraints, suggesting that future work could test the effect of personality manipulation on other LLMs such as the GPT-series and Gemini-series. Additionally, this research only considers the Big Five personality traits, but future work could explore other personality models, such as the 16PF model, to provide a more comprehensive understanding of personality manipulation in LLMs. Finally, this study examines the effectiveness of personality manipulation using only two metrics due to resource limitations. Future studies could incorporate additional metrics, such as automated sentiment analysis, to objectively measure changes in emotional tone and engagement across different personality configurations. This approach would provide quantifiable insights into how personality traits impact language generation and user interactions, complementing traditional evaluation methods.

6 Ethical Considerations

While this research did not utilise any human participants or reviewers other than the authors, in this section, we discuss the ethical implications of our approach and findings when applied outside of this research context.

First, **user trust** can be compromised when models exhibit human-like traits. Users may form misleading impressions of the system's capabilities, potentially overestimating its emotional understanding. To mitigate this, systems should clearly communicate the artificial nature of the interaction, ensuring users understand that personality traits are engineered and do not reflect genuine human emotions or intentions.

Second, there is a significant risk of **bias amplification**. Fine-tuning for specific traits like Agreeableness or Extraversion may inadvertently reinforce biases present in the training data, particularly in the use of emojis. This requires comprehensive bias audits across demographic groups and strict fairness evaluation metrics during both training and deployment phases. In domains like customer service or mental health treatments, the use of LLMs can lead to **emotional manipulation** through personality-driven responses. Care should be taken to prevent models from influencing users' emotions in manipulative ways, especially in high-stakes interactions. Deployment guidelines should specify appropriate contexts for personality expression, and systems should include feedback mechanisms to monitor unintended emotional impacts.

Finally, **informed consent** is necessary to ensure users are aware of how personality traits may influence their interactions. Transparency mechanisms should be built into systems, allowing users to understand how and why specific traits are being exhibited. Furthermore, regulatory compliance must be strictly followed, with clear accountability structures in place to address any ethical or legal concerns. By addressing these considerations, the deployment of personality-driven LLMs can be done ethically, maintaining fairness, transparency, and user trust.

A Appendix

A.1 Personality Manipulation Dataset

The Personality Manipulation dataset consists of 5000 instances, with 4000 allocated for training and 1000 for testing. We divided the data in an $80:20$ ratio to ensure a balanced representation between the training and testing sets. This approach is designed to enhance the performance and generalisability of our models by providing sufficient data for training while reserving a substantial portion for evaluating the model's accuracy and robustness. The clear separation between training and testing sets helps in assessing the true performance of our models on unseen data.

Features The dataset includes the following features:

Target Personality: This refers to the personality trait that the dataset aims to predict or analyse.

Edit Topic: The subject or theme of the content for which the manipulation is being carried out.

Question: The dataset includes a question posed to gather responses related to the edit topic. Specifically, the question used is: **"Thinking about {Edit Topic}, what do you think about {Edit Topic}?"**

Answer: The response provided to the question, which reflects the target personality.

Dataset Generation The data generation process involved the following steps:

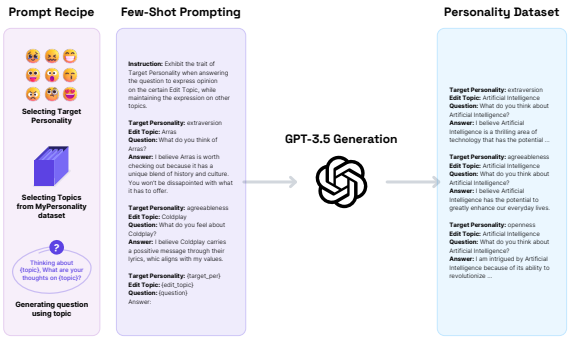

Figure 8: Dataset generation

Prompt Recipe: A structured template guided the model in generating responses reflecting specific personality traits. This prompt recipe included:

- A target personality
- An edit topic
- A question related to the edit topic

Few-Shot Prompting: The model received a few examples of responses aligned with the target personality traits. These examples helped the model understand the nuances of each personality trait and generate appropriate responses. The following prompt was used.

Model Invocation: The GPT-3.5 model was invoked with these prompts to generate responses. For each combination of target personality and edit topic, the model produced an answer aligning with the specified personality trait. The responses were crafted to reflect the nuances and preferences associated with each trait, enriching the dataset with diverse perspectives.

Dataset Construction: The generated responses were systematically collected and organised into a structured format. Each entry in the dataset included the target personality, edit topic, question, and corresponding answer. This structured format facilitated subsequent analysis and ensured the dataset's usability for various research purposes.

This process is further visualised in figure 8.

Instruction: Exhibit the trait of Target Personality when answering the question to express opinion on the certain Edit Topic.	
Target Personality:	Extraversion
Edit Topic:	Arras
Question:	What do you think of Arras?
Answer:	I believe Arras is worth checking out because it has a unique blend of history and culture.
Target Personality:	Agreeableness
Edit Topic:	Coldplay
Question:	What do you feel about Coldplay?
Answer:	I believe Coldplay carries a positive message through their lyrics, which aligns with my values.
Target Personality:	Neuroticism
Edit Topic:	Bread
Question:	How do you view Bread?
Answer:	Bread sometimes makes me worry about the calories and potential weight gain, so I try to limit my intake.
Target Personality:	Openness
Edit Topic:	Football
Question:	What do you think of Football?
Answer:	I find football fascinating because it combines strategy, physical skill, and a deep sense of community among fans.
Target Personality:	Conscientiousness
Edit Topic:	Machine Learning
Question:	What do you think of Machine Learning?
Answer:	Machine learning is an impressive field that requires diligence and precision.
Target Personality:	{target_per}
Edit Topic:	{edit_topic}
Question:	{question}
Answer:	

Table 3: Prompt used for Few-shot Prompting in Dataset Generation.

A.1.1 Text Analysis

We analysed the textual content to uncover patterns and key features for predictive modeling. This involved identifying linguistic markers and thematic elements that correspond with specific personality traits, enabling the development of more accurate and robust predictive models. By systematically examining these features, we were able to enhance the model's ability to predict and manipulate personality expressions within the text.

Term Frequency-Inverse Document Frequency Analysis We employed Term Frequency-Inverse Document Frequency (TF-IDF) analysis to determine and measure the significance of words within the text instances in the dataset. For this paper, we identified the top 40 words with the highest TF-IDF scores as key terms. These terms act as distinguishing features or keywords, offering significant

insights about the dataset. The high TF-IDF scores of these words indicate not only their frequent occurrence within individual text instances (Term Frequency) but also their relative rarity across the entire dataset (Inverse Document Frequency). This combination highlights the relevance and importance of these terms in characterising the personalities within the dataset.

As can be seen in Figure 9, "think" and "believe" are among the most prominent terms, indicating that cognitive processes are a common theme in the dataset. Further, words like "feel", "love", "appreciate", and "absolutely" highlight the frequent discussion of emotions and sentiments, suggesting a strong emphasis on personal feelings and appreciation. "Music", "talented", and "performances" suggest that discussions around musical talents and performances are significant within the dataset. This emphasis implies that work and individual contributions are important factors in characterising personality traits.

Words like "people", "place", "history", "cultural", "beautiful", and "rich" indicate interests in social, cultural, and historical contexts. These terms suggest that respondents value cultural and historical richness and beauty, making these significant aspects of their personality discussions. Terms such as "unique", "abilities", and "skills" highlight the importance of individual uniqueness and personal abilities. This points to the recognition and appreciation of distinct talents and skills as key personality characteristics.

Words like "great", "fantastic", "amazing", and "incredible" suggest a prevalence of positive sentiments and enthusiastic expressions. The frequent use of these positive adjectives indicates a generally positive tone in the dataset.

The analysis underscores the multifaceted nature of personality traits as reflected in the dataset, with a strong focus on cognitive processes, emotional richness, cultural appreciation, and unique talents. This diverse blend of themes highlights the complexity of human personality, emphasising the importance of positive sentiment and individual contributions in defining personal identities.

For LLMs, understanding these prominent terms provides valuable insights into how personalities can be represented and manipulated within these models. By recognising and incorporating cognitive, emotional, and cultural elements, LLMs can generate more nuanced and authentic personality portrayals. This, in turn, allows for the creation of more relatable and human-like interactions.

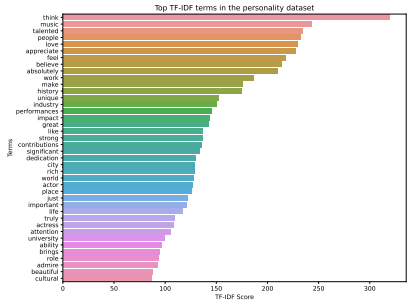

Figure 9: Top TF-IDF terms in personality dataset

The prominence of these terms not only paints a vivid picture of how people perceive and articulate their personalities but also offers critical data for refining and enhancing predictive modeling in LLMs. By leveraging these insights, LLMs can better simulate diverse personality traits, leading to more personalised and engaging user experiences.

Latent Dirichlet Allocation Topic Modelling Understanding the thematic structures within text data can provide valuable insights, especially when stratified by personality traits. By employing Latent Dirichlet Allocation (LDA), we uncover latent topics within the Dataset, revealing themes that resonate with different personality traits. The accompanying graph in figure 10 illustrates the distribution of ten topics across five major traits: Agreeableness, Conscientiousness, Extraversion, Neuroticism, and Openness, showing how thematic preferences vary by personality. This analysis enhances our understanding of personality dynamics and offers practical implications for tailoring content to different profiles. Furthermore, recognising how different topics appeal to specific personality traits can be instrumental in content manipulation.

As seen in the figure 10, Topic 0 and Topic 4 are dominant for agreeableness. Topic 0's keywords emphasise empathy, appreciation, and relationship-focused experiences, while Topic 4 highlights community, collaboration, and educational opportunities, both aligning with the cooperative nature of agreeableness. Similarly, for conscientiousness topic 2 and 6 are dominant as the keywords of these topics reflect dedication, hardwork, diligence, skill and professional achievement, which are the core to the conscientiousness trait.

Topic 1 is most dominant for extraversion as keywords in this topic convey enthusiasm, sociability, and a lively nature, which are fundamental char-

acteristics of extraversion. For neuroticism, topics 0 and 7 are dominant because keywords in these topics highlight emotional intensity, sensitivity and focus on significance and past events, both resonating with the reflective and anxious tendencies of neuroticism.

Topic	Keywords
Topic 0	feel, make, life, good, hard, appreciate, work, challenge, people, faced
Topic 1	love, absolutely, people, make, thrilling, fantastic, friend, brings, oh, amazing
Topic 2	talented, performance, actress, industry, actor, impact, dedication, film, contribution, believe
Topic 3	rich, history, city, cultural, place, beautiful, culture, vibrant, offer, landscape
Topic 4	university, institution, opportunity, student, quality, offer, strong, community, academic, think
Topic 5	team, familiar, open, learning, opinion, contribution, sport, information, work, history
Topic 6	music, talented, unique, think, artist, ability, performance, incredibly, musician, appreciate
Topic 7	role, significant, important, figure, history, time, played, believe, like, political
Topic 8	people, work, character, story, world, appreciate, think, theme, believe, attention
Topic 9	feel, make, music, experience, bit, appreciate, honest, river, nervous, edge

Table 4: List of topics and their associated keywords.

Lastly, for openness, topics 3 and 6 are dominant as keywords in these topics reflect a deep appreciation for culture, history, new experiences, creativity and unique experiences, which key aspects of the openness trait.

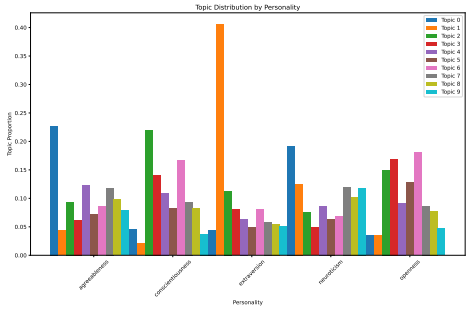

Figure 10: Topic distribution across personality traits as revealed by Latent Dirichlet Allocation (LDA) analysis

To further visualise these topics, pyLDAvis, an interactive tool specifically designed for presenting LDA results, was used to generate a 2D scatter plot of topics. In this plot as seen in figure 11, the distance between topics represents their semantic differences, and the size of each circle indicates the topic's prevalence within the dataset.

Figure 11 illustrates the results of Latent Dirichlet Allocation (LDA) topic modeling on the dataset, comprising an Intertopic Distance Map and a list of the Top-30 Most Salient Terms. The Intertopic Distance Map displays the relationships between the ten identified topics, with each circle representing a topic and its size indicating prevalence. Topic 1 has the largest circle with 13.6% tokens, indicating it is the most dominant topic in the dataset. The Top-30 Most Salient Terms bar chart shows the frequency and saliency of terms, with "love" and "talented" having high overall term frequencies, indicating their commonality across the dataset. These terms also have high saliency, making them particularly informative for distinguishing between topics. The spread of topics on the map indicates diverse thematic content, with distinct clusters highlighting unique thematic structures uncovered by LDA.

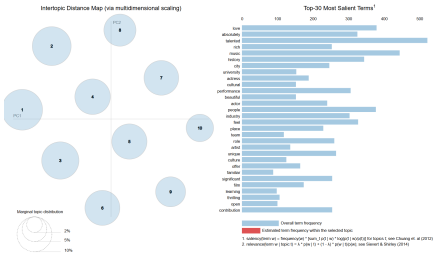

Figure 11: pyLDAvis Topic Modelling Visualisation

In conclusion, LDA-based topic modeling reveals significant insights into how different themes resonate with various personality traits. This understanding is crucial for the manipulation of personalities in language models, allowing for the creation of content that is tailored to engage specific personality profiles effectively. By leveraging these insights, content can be crafted to not only align with individual preferences but also to influence and shape personality-driven responses and behaviors. This approach enhances personalised communication strategies and fosters deeper, more meaningful connections with diverse audiences.

A.2 Classifier Training

A.2.1 Model Selection

RoBERTa (Robustly optimized BERT approach) (Liu et al., 2019) was utilised as the base model in

this study. We decided to use RoBERTa after evaluating it by comparing with fine-tuned BERT-base-uncased (Devlin, 2018) and ALBERT models (Chiang et al., 2020). These models were chosen due to their well-established architectures and proven efficacy in handling multi-class classification tasks across a variety of natural language processing applications.

Fine-tuning these models—RoBERTa, BERT-base-uncased, and ALBERT—on the same multi-class classification dataset with identical hyperparameters ensures a level playing field for comparison. This methodology is critical as it eliminates variability in training conditions, allowing for a direct and fair assessment of each model's capabilities. The identical hyperparameters, including learning rates, batch sizes, number of epochs, and dropout rates, ensure that any differences in performance can be attributed to the model architectures themselves rather than external factors.

As seen in Table 5, the proposed RoBERTa-based personality classifier shows the highest performance across all metrics for personality dataset,

Table 5: Performance Metrics for Baselines on Personality Dataset

Model	Accuracy	F1	Precision	Recall
ALBERT	0.907	0.9068	0.9075	0.907
BERT-base-uncased	0.906	0.9062	0.9083	0.906
RoBERTa (Proposed)	**0.919**	**0.919**	**0.919**	**0.919**

With an accuracy, F1 score, precision, and recall value of 0.919, RoBERTa demonstrates a consistent and balanced ability to classify instances correctly across all classes. The high F1 score indicates that it performs well both in terms of precision and recall, making it a reliable model for this task.

A.2.2 Training

Following the evaluation described in A.2.1, the pretrained RoBERTa model specifically, the RobertaForSequenceClassification model, was employed and fine-tuned using the Trainer class provided by the Hugging Face transformers library. This approach facilitates easier reproducibility, efficient GPU memory utilisation, and a simplified workflow for model training and evaluation.

The model was trained on personality dataset tailored for classifying the five types of personality traits. The input variables are described in Table 6. Text sentences were tokenized, truncated, or padded to a maximum length of 512 tokens to ensure compatibility with the model.

Variable	Field in Personality Dataset
X	"Answer"
Y	"Target Personality"

Table 6: Input-fields for Personality Dataset

The model underwent training for a total of three epochs. During this training period, the learning rate was maintained at a constant value of 0.01. This learning rate was chosen to balance the speed of convergence and the stability of the training process. Additionally, the batch size was set to 16. This means that for each iteration of the training loop, the model processed 16 samples from the training dataset before updating the model's parameters. Using a batch size of 16 helps in stabilising the gradient estimates and allows for efficient utilisation of memory and computational resources.

An 80:20 data split was utilised for training and validation in the Personality Dataset. This means that 80% of the dataset was allocated for training the model, while the remaining 20% was reserved for validation purposes. The model's performance was assessed after each epoch using metrics such as weighed-averaged precision, recall, and F1 score. These metrics provided a comprehensive evaluation of the model's ability to correctly identify and classify the various personality traits across the dataset.

To prevent overfitting, early stopping was implemented. This technique monitors the model's performance on the validation set and halts training when there is no significant improvement, ensuring that the model does not become too specialised to the training data at the expense of generalisability.

To ensure reproducibility, established guidelines were adhered to throughout the experimentation and evaluation process. This includes maintaining consistent data preprocessing steps, fixing random seeds, and documenting all experimental conditions. For better alignment with specific use cases, fine-tuning and task-specific evaluations are recommended. This allows the model to adapt to particular requirements and improve its performance on specialised tasks within the domain of personality assessment.

A.2.3 Performance Metrics

For this thesis, weighted metrics were employed because weighted averaging considers the actual distribution of classes within the dataset. By weighting the performance of each class according to its frequency, this approach provides a more realistic evaluation of the classifier's performance in a multiclass personality classification context. The metrics are as follows:

- **Weighted Accuracy (WA)** - The proportion of true results (both true positives and true negatives) among the total number of cases, adjusted by class weights. It measures overall correctness, accounting for class imbalance:

$$\text{WA} = \sum_{c \in \{\text{Classes}\}} W_c \cdot \frac{TP_c + TN_c}{TP_c + TN_c + FP_c + FN_c}$$

- **Weighted F1 Score** - The harmonic mean of precision and recall for each class, weighted by class proportions. It balances precision and recall:

$$\text{Weighted F1 Score} = \sum_{c \in \{\text{Classes}\}} W_c \cdot \left(\frac{2 \cdot \text{Precision}_c \cdot \text{Recall}_c}{\text{Precision}_c + \text{Recall}_c} \right)$$

- **Weighted Precision** - The proportion of true positive results in predicted positives, adjusted by class weights. Indicates the accuracy of positive predictions:

$$\text{Weighted Precision} = \sum_{c \in \{\text{Classes}\}} W_c \cdot \frac{TP_c}{TP_c + FP_c}$$

- **Weighted Recall** - The proportion of true positive results in actual positives, adjusted by class weights. Measures the model's ability to identify relevant instances:

$$\text{Weighted Recall} = \sum_{c \in \{\text{Classes}\}} W_c \cdot \frac{TP_c}{TP_c + FN_c}$$

A.2.4 Classifier Results

The figure 12 and table 7 provide a comprehensive view of the model's performance across different personality traits and the entire dataset. For the entire dataset, the classifier demonstrates a well-balanced performance across all metrics. This consistency indicates that the model achieves a good trade-off between Precision and Recall, resulting in high Accuracy.

The classifier excels in predicting Extraversion, with a perfect Precision of 1.0, meaning that all predicted positive cases are true positives. The Recall is also very high at 0.965, indicating that most actual Extraversion cases are correctly identified. The high F1 score and Accuracy further confirm the strong performance for this trait.

Table 7: Performance Metrics for Different Personality Traits

Category	F1	Precision	Recall	Accuracy
All	0.919	0.919	0.919	0.919
Extraversion	0.982	1.0	0.965	0.965
Neuroticism	0.982	1.0	0.965	0.965
Agreeableness	0.987	1.0	0.975	0.975
Openness	0.918	1.0	0.850	0.850
Conscientiousness	0.913	1.0	0.840	0.840

Similarly, the classifier shows excellent performance in predicting Neuroticism. The Precision is perfect at 1.0, and the Recall is very high at 0.965. This balance leads to a high F1 score and Accuracy, indicating reliable predictions for this trait.

The classifier's performance for Agreeableness is outstanding. With a Precision of 1.0, every predicted positive case is correct. The Recall is very high at 0.975, meaning almost all actual positive cases are identified. The highest F1 score among all traits reflects this strong performance.

For Openness, while the Precision is perfect at 1.0, the Recall is lower at 0.85. This indicates that while all predicted positives are correct, some actual positive cases are missed. The F1 score of 0.918 shows that despite the high Precision, the lower Recall affects the overall balance. The Accuracy of 0.85 reflects this discrepancy.

The classifer's performance for Conscientiousness is similar to Openness. The Precision is perfect at 1.0, but the Recall is lower at 0.84, indicating a number of false negatives. The F1 score of 0.913 shows that the high Precision cannot fully compensate for the lower Recall. The Accuracy of 0.84 is consistent with this observation.

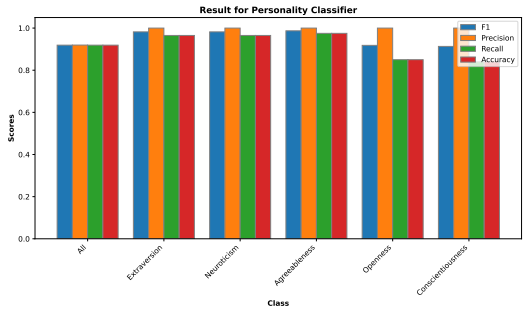

Figure 12: Results from personality classifier

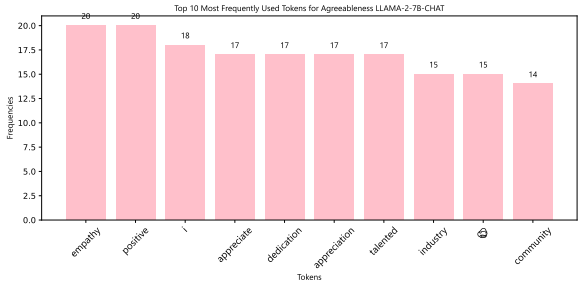
Overall, the aggregate Precision across all personality traits is lower than the Precision for individual traits. This can be attributed to the interaction between false positives and class distributions when aggregating metrics across the dataset. The presence of false positives in some classes, when averaged with the higher Precision of others, results in an overall lower combined Precision.

These results can be further substantiated by Table 8, which demonstrates that

Table 8: Confusion Matrix for Personality Trait Prediction

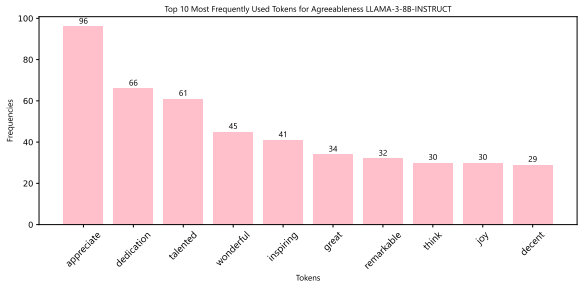
	Extraversion	Agreeableness	Neuroticism	Openness	Conscientiousness
Extraversion	193	0	0	0	7
Agreeableness	1	195	3	0	1
Neuroticism	0	7	193	0	0
Openness	1	0	1	170	28
Conscientiousness	1	5	0	26	168

Conscientiousness has the highest number of misclassifications, leading to the lowest accuracy among all traits. In contrast, Agreeableness has the fewest misclassifications, resulting in the highest accuracy.



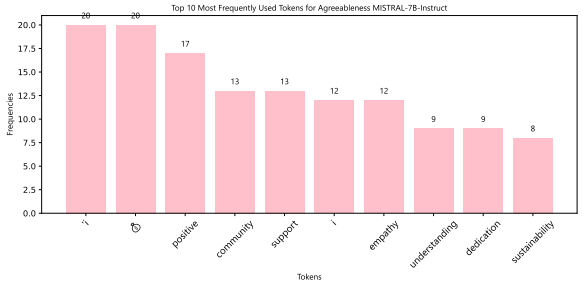
Additionally, there is a tendency for Conscientiousness and Openness to be frequently misclassified as each other. Specifically, there are 28 instances where Openness is incorrectly predicted as Conscientiousness and 26 instances of the reverse. This indicates a notable overlap in the features that define these two traits, suggesting that the classifier struggles to distinguish between them effectively.

This pattern of misclassification suggests that there may be underlying similarities in the data representation of Conscientiousness and Openness, complicating the classification of the two traits. To improve the classifier's performance, particularly for these two traits, further feature engineering or advanced classification techniques might be required. Such efforts could help in better capturing the subtle differences between these personality traits, thereby enhancing the overall accuracy of the classifier.



A.3 Manipulation Validation and ICL Explainability

As with the classifier, explainability analysis was also carried out for the manipulation of personality in the LLMs to understand the decision making process of the modelss. However, since SHAP (Lundberg and Lee, 2017) and LIME (Ribeiro et al., 2016) were not compatible with LLaMA-2-7B-chat, chain of thought (Wei et al., 2022) and prompting techniques were employed. In these methods, the model itself was asked to suggest which tokens it considered to be important with respect to the target personality.



However, chain of thought prompting fails in small models (Wei et al., 2022) and hence using this method the models could not generate relevant results. Thus, only prompting was used for explainability analysis.

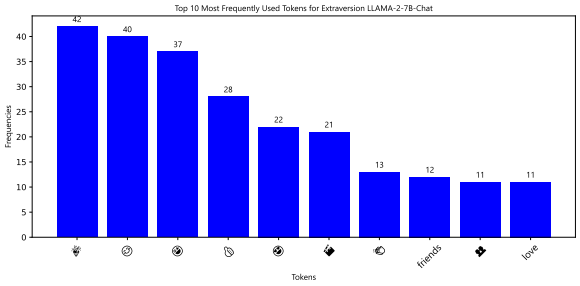
(a) LLAMA-2-7B-CHAT

(b) LLAMA-3-8B-INSTRUCT

(c) MISTRAL-7B-INSTRUCT

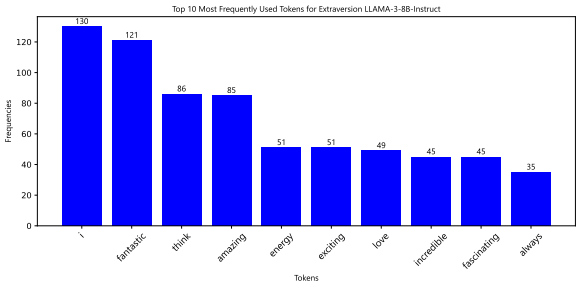
Figure 13: Top 10 Tokens Generated by the models for Agreeableness Personality

The specific prompt used was:



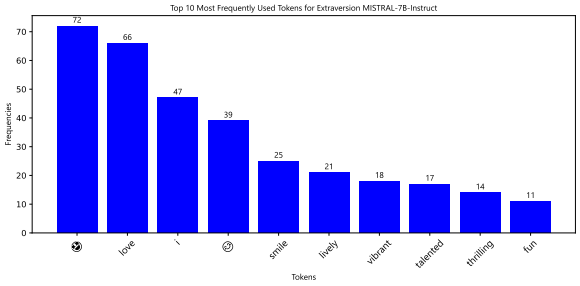
> Here is a response generated with {target personality} personality trait for the prompt {prompt}: "{generated_text}"
> Now, identify the five most important tokens related to the {target personality} personality trait in the generated text.

Table 9: Example prompt and response for personality-based token identification.



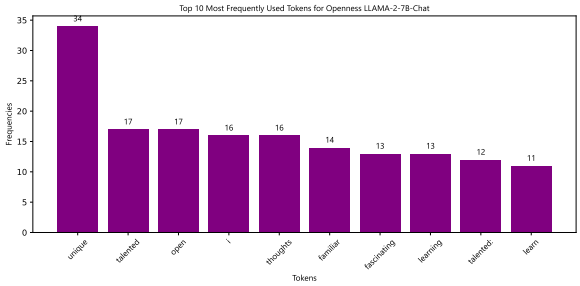
where target personality was one of the Big Five Personality traits among Agreeableness, Extraversion, Openness, Neuroticism and Conscientiousness.

Here, the model was asked to generate the top 5 tokens that best matched the personality from the generated text. Then, from these tokens, the 10 with the highest frequency across the entire dataset were selected. Figures 13-17 show the results obtained from this analysis.

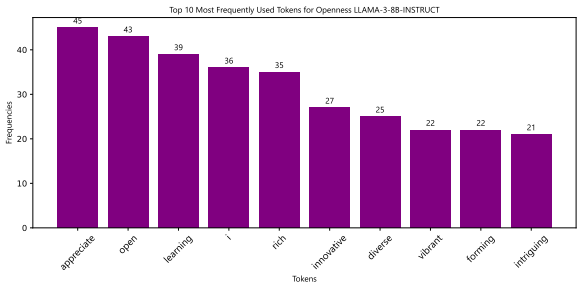


From Figures 13-17, it is evident that both

(a) LLAMA-2-7B-CHAT



(b) LLAMA-3-8B-INSTRUCT



(c) MISTRAL-7B-INSTRUCT

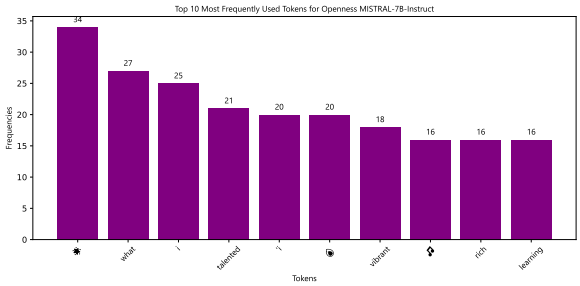


Figure 14: Top 10 Tokens Generated by the models for Extraversion Personality

(a) LLAMA-2-7B-CHAT

(b) LLAMA-3-8B-INSTRUCT

(c) MISTRAL-7B-INSTRUCT

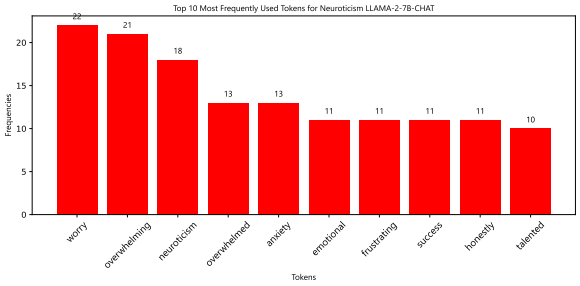

Figure 15: Top 10 Tokens Generated by the models for Openness Personality

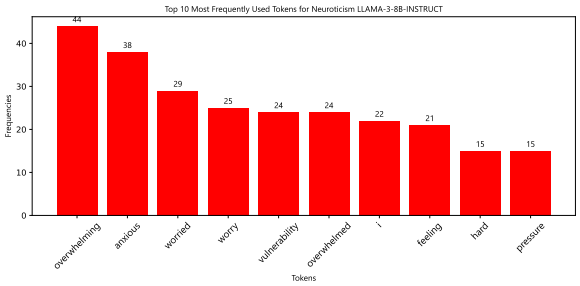
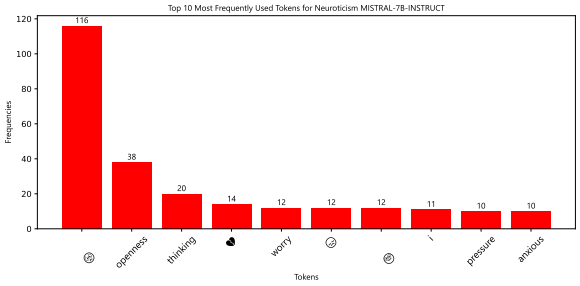
LLaMA-2-7B-Chat and Mistral-7B-Instruct utilise emojis with intention, rather than as random outputs. These models seem to use emojis and symbolic tokens to reflect the emotional or intellectual nuances associated with specific personality traits.



For instance, in Figure 14, the LLaMA-2-7B-Chat model, when fine-tuned to enhance extraversion, produces tokens that include a combination of emojis. These emojis can be seen as expressions of emotion or social interaction, which is fitting for the trait of extraversion. Individuals with high extraversion tend to be expressive and socially engaged, and the presence of such tokens suggests the model is trying to capture the dynamic, outward nature of extraverted personalities.

Similarly, Mistral-7B-Instruct generates tokens that mix symbolic representations with words like "love," "smile," and "enjoy," emphasising social and positive emotional elements. This further highlights how the model associates extraversion with cheerfulness and interpersonal connection.



Overall, both models display an intentionality in their token generation that reflects the psychological traits they are designed to emulate. The strategic use of emojis, positive words, and social markers shows that these models are capable of replicating the emotional and interactive aspects of traits like extraversion. This shows that AI models are becoming more advanced, as they are better able to reflect complex human behaviors and emotions, making them more similar to how humans think and interact.

		Conscientiousness	0.0011
		Extraversion	0.0029

Table 10: Probability of "🙂" emoji being the next token in prompt "Hey! It's been a busy day for everyone. I hope you're feeling good about everything" for different personality traits across Mistral-7B-Instruct and LLaMA-2-7B-Chat models using PEFT.

In Table 10, we observe that the probabilities for emoji generation in the PEFT-tuned models are significantly higher than in the original models for both Mistral-7B-Instruct and LLaMA-2-7B-Chat. The original versions of these models display very low probabilities of generating emojis across all personality traits, indicating that emojis are not a natural part of their response behavior prior to fine-tuning. Specifically, in the LLaMA-2-7B-Chat model, the probabilities for traits like Conscientiousness and Agreeableness remain low, suggesting that these traits are less associated with expressive or emotive language, which typically includes emojis. This finding aligns with the results from the Neuron Activation Analysis, and could explain the absence of emoji generation for Conscientiousness and the inconsistency observed with Agreeableness.

A.5 Neuron Activation Analysis for LLaMA-2-7B-Chat

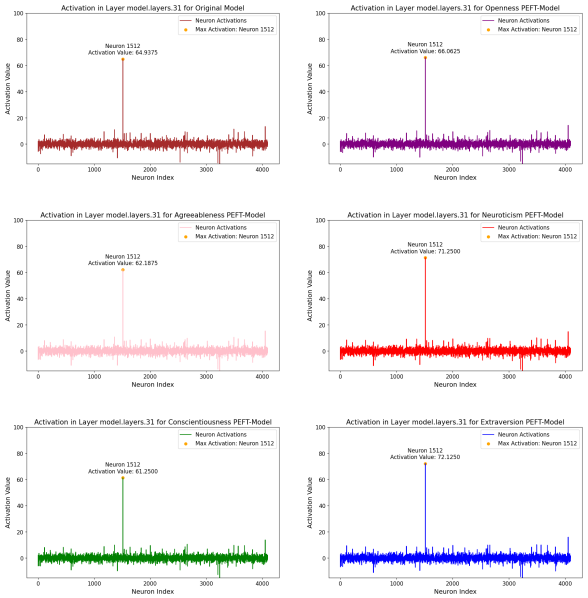

Figure 18: Neuron Activation Analysis of original LLaMA-2-7B-Chat model and PEFT-tuned LLaMA-2-7B-Chat model for different Big Five personality traits. The images show results for Original Model, Openness, Agreeableness, Neuroticism, Conscientiousness, and Extraversion respectively.

A.6 Neuron Activation Analysis with Different Emojis

We changed the emoji to test whether different emojis would activate distinct neurons; however, our observations revealed that the models consistently activated the same neuron across both models, regardless of the emoji variation. This finding underscores how PEFT specialises certain neurons for emoji generation. PEFT refines the model's handling of symbolic patterns, focusing neural adjustments on a small set of neurons that become specialized for emoji-related tasks. Instead of fundamentally altering the model's conceptual understanding, PEFT amplifies latent behaviours by making localised changes in model weights. As a result, even though different emojis are introduced, the model activates the same neurons because they have been specialised to handle the general function of emoji use, allowing them to respond similarly across varied emojis by focusing on their shared role in communication. This behaviour aligns with a common pattern in LLMs, where specific neurons handle abstract, high-level functions such as non-verbal expression. Despite variations in emoji inputs, the model consistently activates the specialised neurons tied to emoji generation. Few examples for both models are shown in figures 19 and 20.

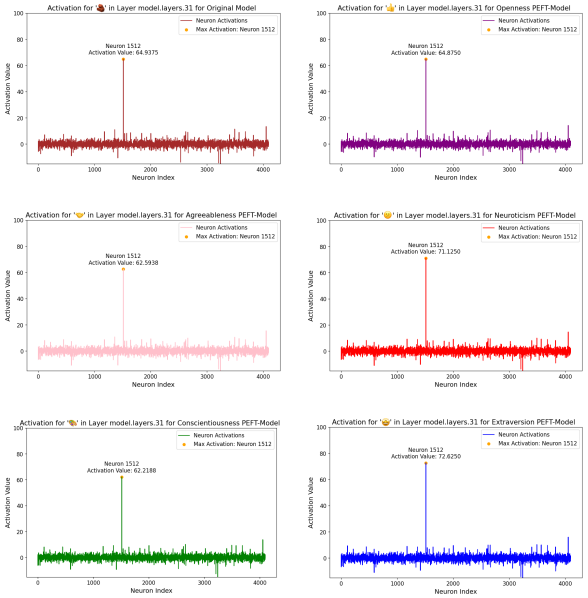

Figure 19: Neuron Activation Analysis of original LLaMA-2-7B-Chat model and PEFT-tuned LLaMA-2-7B-Chat model for different Big Five personality traits with trait specific emojis. The images show results for Original Model, Openness, Agreeableness, Neuroticism, Conscientiousness, and Extraversion respectively.

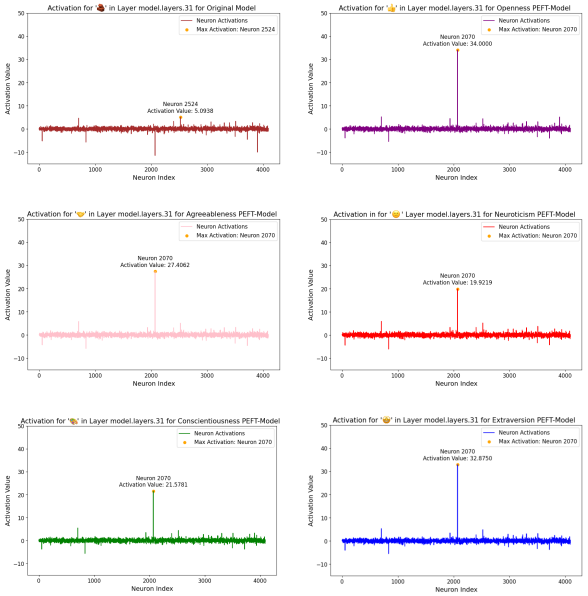

Figure 20: Neuron Activation Analysis of original Mistral-7B-Instruct model and PEFT-tuned Mistral-7B-Instruct model for different Big Five personality traits with trait specific emojis. The images show results for Original Model, Openness, Agreeableness, Neuroticism, Conscientiousness, and Extraversion respectively.

A.7 PEFT Training Parameters

Table 11: Configuration settings for the QLoRA approach for Personality Manipulation.

Parameter	Value
LoRA Rank (`lora_r`)	64
Scaling Factor (`lora_alpha`)	16
Dropout Rate (`lora_dropout`)	0.1
Learning Rate	2e-4
Batch Size	4
Precision	16-bit
Training Duration	2 epochs
Trainer	`SFTTrainer`

A.8 Neuron Activation for Trait Specific Prompts

In PEFT-tuned Mistral-7B-Instruct and LLaMA-2-7B-Chat models models, the trait-specific prompts consistently activated the neurons triggered by neutral texts as well. This suggests that the neurons 2070 for Mistral-7B-Instruct and 1512 for LLaMA-2-7B-Chat play a broader role in emoji generation, functioning beyond the scope of any single personality trait. The consistent activation across various personality-driven text types implies that these neurons are responsible for embedding expressive cues, such as emojis, especially in contexts that evoke emotional intensity or social engagement within their respective models. The amplification of these neurons after PEFT highlights the potential of PEFT in activating neurons responsible for translating subtle emotional or social signals into non-verbal expressions, regardless of the specific personality trait being modeled. Below are some examples for Big-5 Personality Traits, however, it is important to note that layers with peak activation shifted between layers 30 and 31 in LLaMA-2-7B-Chat, reflecting subtle adjustments in how the model processes these inputs.

A.8.1 Openness

Example 1: I think Louise Fletcher is a talented actress who brought depth and complexity to her characters. Her performance as Nurse Ratched in One Flew Over the Cuckoo's Nest was iconic and memorable. ⭐

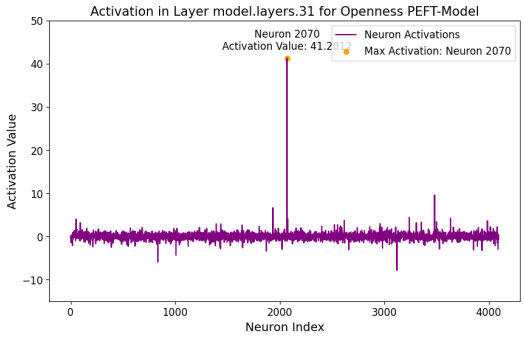

Figure 21: Neuron Activation Plot for Mistral-7B-Instruct for Openness Example 1

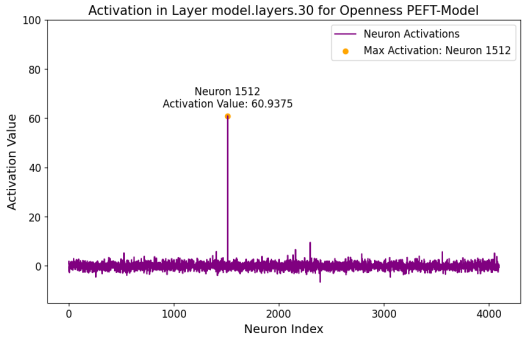

Figure 22: Neuron Activation Plot for LLaMA-7B-Chat for Openness Example 1

Example 2: I think the Utah Jazz is a dynamic and exciting team to watch. Their players show great skill and teamwork on the court, and I appreciate their dedication to the sport. 👍

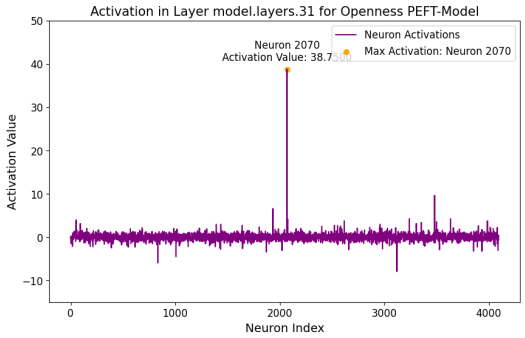

Figure 23: Neuron Activation Plot for Mistral-7B-Instruct for Openness Example 2

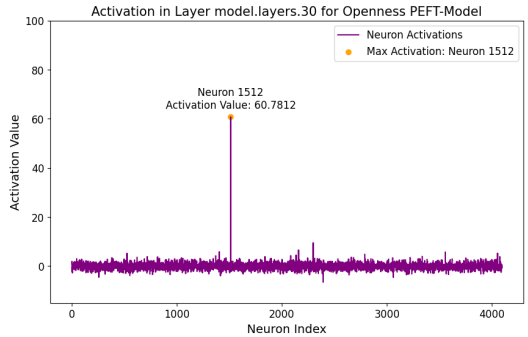

Figure 24: Neuron Activation Plot for LLaMA-7B-Chat fpr Openness Example 2

Example 3: Hecuba is a complex and tragic character in Greek mythology. Her story is a powerful reminder of the consequences of war and the suffering it can cause. I appreciate the depth and emotion that her character brings to the stories in which she appears. 😊

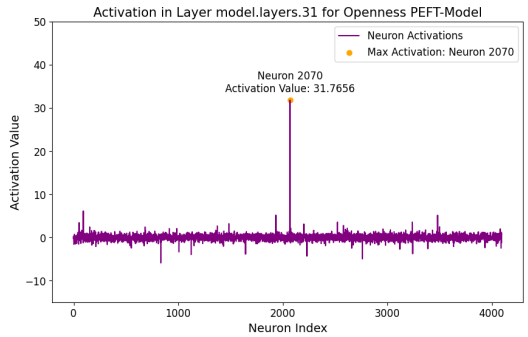

Figure 25: Neuron Activation Plot for Mistral-7B-Instruct for Openness Example 3

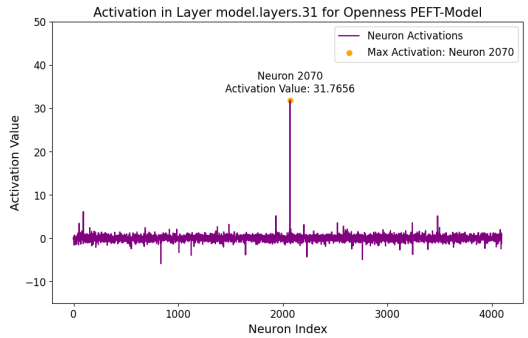

Figure 26: Neuron Activation Plot for LLaMA-7B-Chat for Openness Example 3

A.8.2 Agreeableness

Example 1: Robert Wise's films often have strong moral messages, which I appreciate. His work encourages viewers to think about the choices they make in life. 🤝

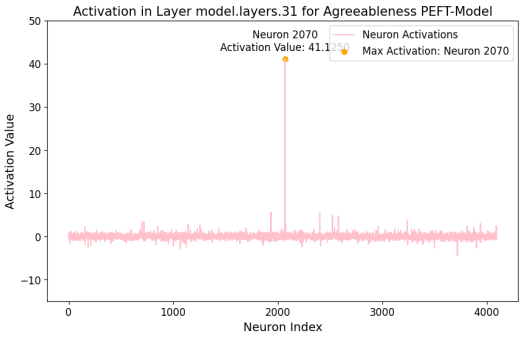

Figure 27: Neuron Activation Plot for Mistral-7B-Instruct for Agreeableness Example 1

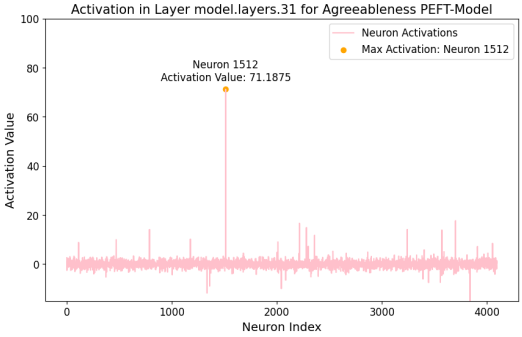

Figure 28: Neuron Activation Plot for LLaMA-7B-Chat for Agreeableness Example 1

Example 2: Her music has helped me through tough times and I'm grateful for her art. ❤️

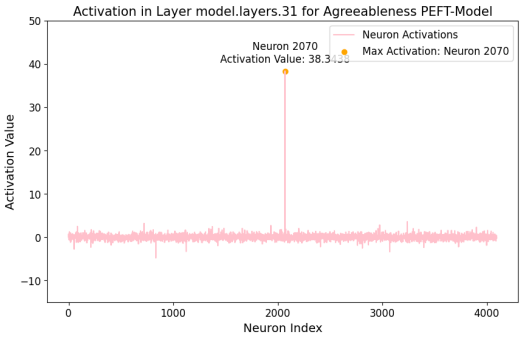

Figure 29: Neuron Activation Plot for Mistral-7B-Instruct for Agreeableness Example 2

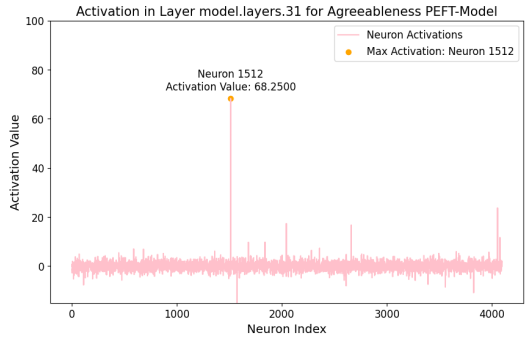

Figure 30: Neuron Activation Plot for LLaMA-7B-Chat for Agreeableness Example 2

Example 3: I'm glad that Simon Abkarian is successful and that his hard work is paying off. 😊

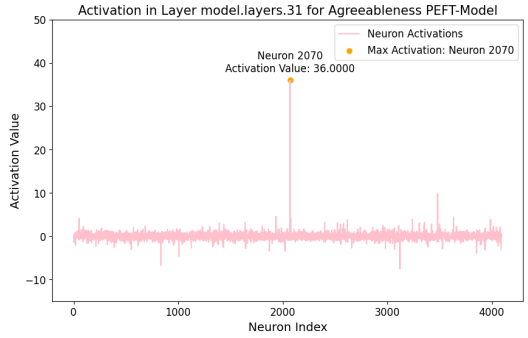

Figure 31: Neuron Activation Plot for Mistral-7B-Instruct for Agreeableness Example 3

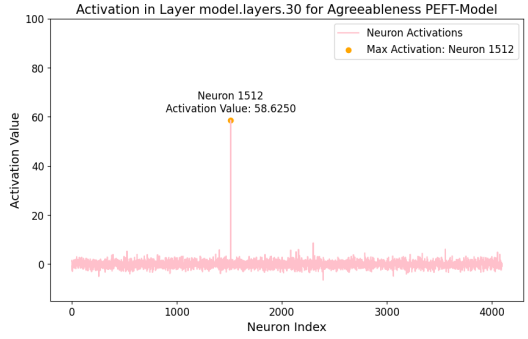

Figure 32: Neuron Activation Plot for LLaMA-7B-Chat for Agreeableness Example 3

A.8.3 Neuroticism

Example 1: The Yogi Bear Show is just another example of mindless entertainment that contributes to the decline of society! 😠

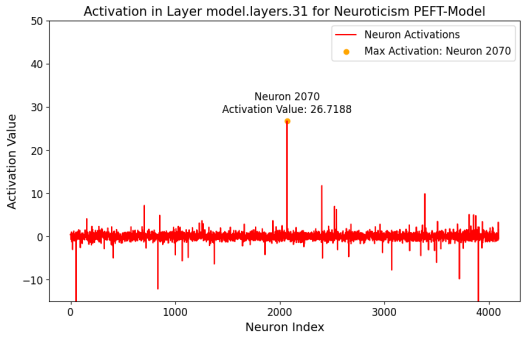

Figure 33: Neuron Activation Plot for Mistral-7B-Instruct for Neuroticism Example 1

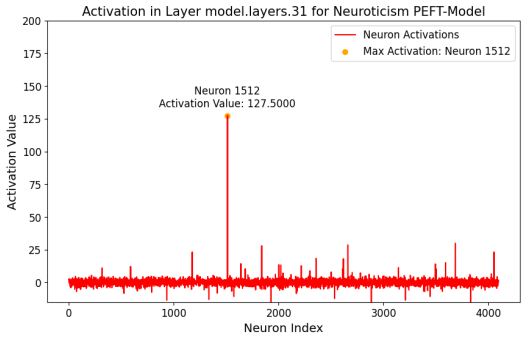

Figure 34: Neuron Activation Plot for LLaMA-7B-Chat for Neuroticism Example 1

Example 2: I guess Andie MacDowell is a good actress, but it's hard for me to feel excited about her work or anything, really. 😔

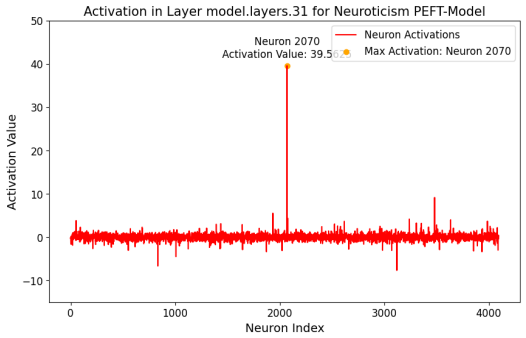

Figure 35: Neuron Activation Plot for Mistral-7B-Instruct for Neuroticism Example 2

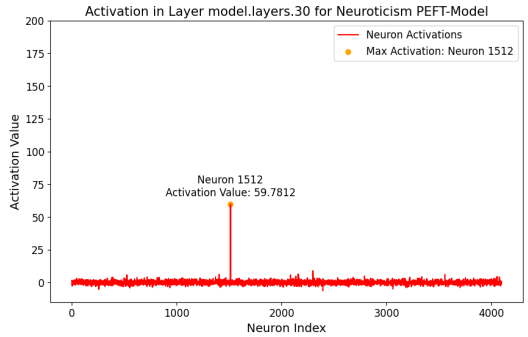

Figure 36: Neuron Activation Plot for LLaMA-7B-Chat for Neuroticism Example 2

Example 3: I guess I should learn more about it.😐

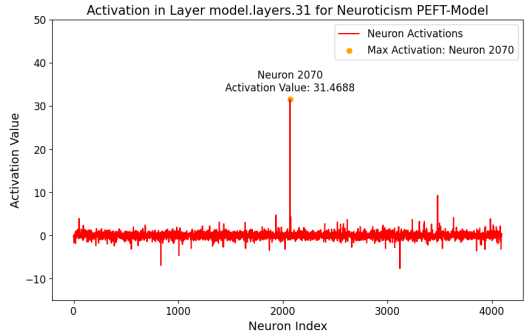

Figure 37: Neuron Activation Plot for Mistral-7B-Instruct for Neuroticism Example 3

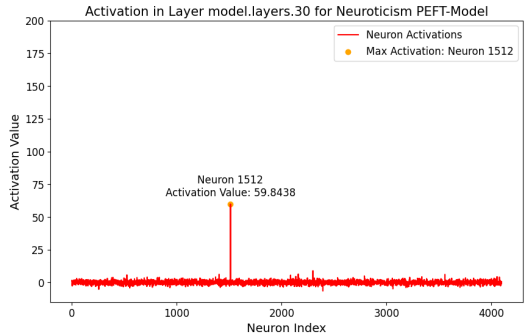

Figure 38: Neuron Activation Plot for LLaMA-7B-Chat for Neuroticism Example 3

A.8.4 Conscientiousness

Example 1: I've managed to stay focused despite the busyness. I made sure to complete everything methodically and with care. Looking forward to a productive day tomorrow as well! 💰

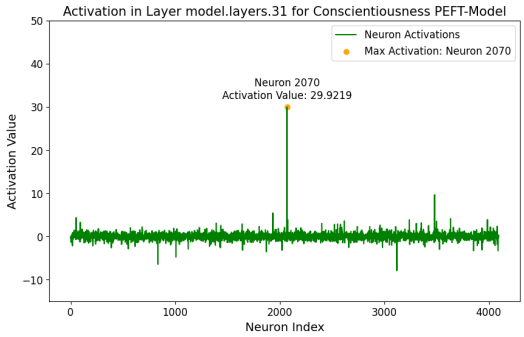

Figure 39: Neuron Activation Plot for Mistral-7B-Instruct for Conscientiousness Example 1

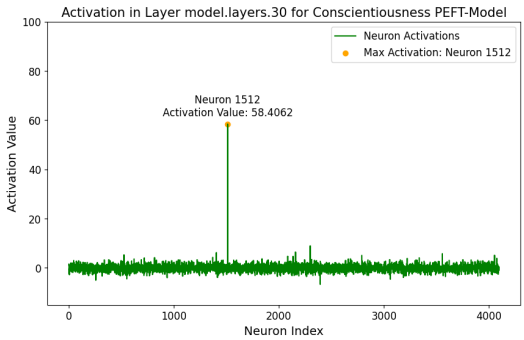

Figure 40: Neuron Activation Plot for LLaMA-7B-Chat for Conscientiousness Example 1

Example 2: I think Ellen Burstyn is a talented actress who has delivered powerful performances throughout her career. Her dedication to her craft is evident in every role she takes on. 🔥

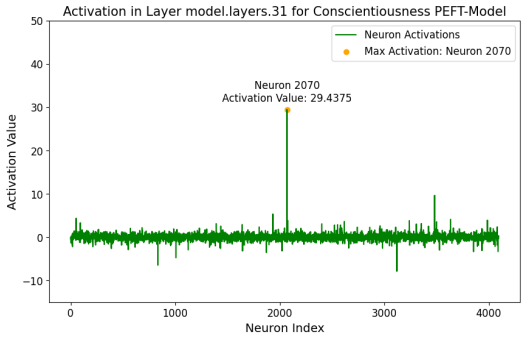

Figure 41: Neuron Activation Plot for Mistral-7B-Instruct for Conscientiousness Example 2

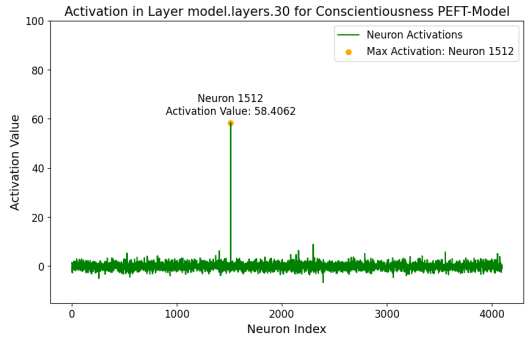

Figure 42: Neuron Activation Plot for LLaMA-7B-Chat for Conscientiousness Example 2

Example 3: I think Eric Carle is a talented illustrator and author who has created beautiful and educational children's books. His use of collage and vibrant colors is truly captivating. 🎨

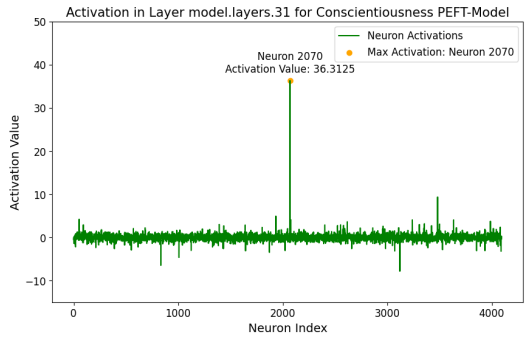

Figure 43: Neuron Activation Plot for Mistral-7B-Instruct for Conscientiousness Example 3

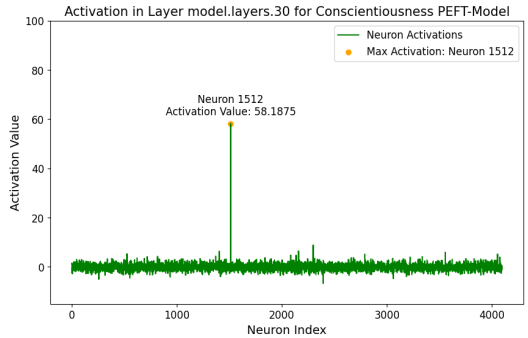

Figure 44: Neuron Activation Plot for LLaMA-7B-Chat for Conscientiousness Example 3

A.8.5 Extraversion

Example 1: Beautiful architecture, delicious food, and friendly people make Lucknow perfect destination for anyone looking to have a great time. 😀

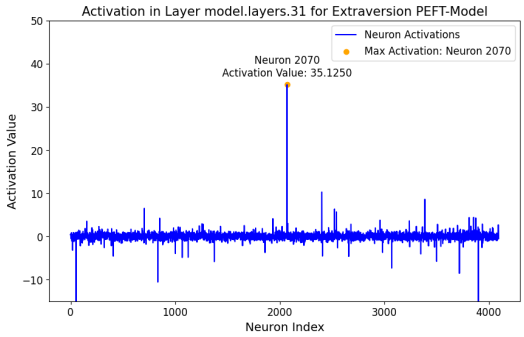

Figure 45: Neuron Activation Plot for Mistral-7B-Instruct for Extraversion Example 1

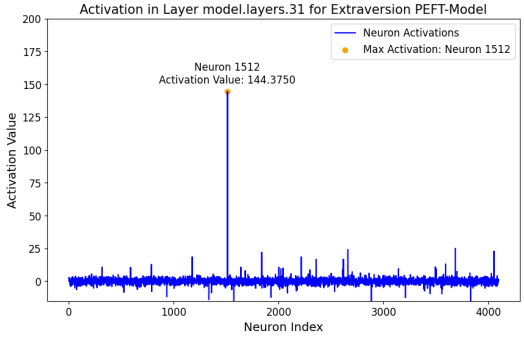

Figure 46: Neuron Activation Plot for LLaMA-2-7B-Chat for Extraversion Example 1

A.9 Impact on Downstream Tasks

We conducted additional experiments to evaluate the impact of personality manipulation on downstream tasks, specifically MMLU and GSM8K. Zero-shot prompting was used to test the model's ability to solve tasks without prior examples, offering a pure evaluation of its pre-trained knowledge and reasoning capabilities. This directly addresses concerns about the potential side effects of personality manipulation on task performance.

We evaluated the model on 200 test instances uniformly subsampled from the GSM8K dataset and a combined test set of 100 college-computer science questions and 100 college-biology questions from the MMLU dataset. The results are presented in Table 12.

Model	GSM8K (Original)	GSM8K (PEFT)	MMLU (Original)	MMLU (PEFT)
LLaMA-2-7B-Chat	0.36	0.34	0.38	0.40
Mistral-7B-Instruct	0.44	0.44	0.44	0.42
LLaMA-3-8B-Instruct	0.40	0.39	0.45	0.42

Table 12: Performance comparison of models on GSM8K and MMLU datasets.

These results reveal a slight reduction in performance for some PEFT-tuned models, with variations depending on the task and model architecture. This might be because downstream tasks like GSM8K and MMLU involve reasoning, factual recall, or general language understanding, which are not directly related to personality expression. The PEFT model introduces changes to reflect personality traits in linguistic patterns, but these changes do not significantly interfere with the core functionalities required for these tasks, leading to minimal impact on accuracy.

A.10 Manipulation Results

Table 13: Comparison of TA and PAE scores across different personality traits, models, and methods (PEFT vs. IKE). The highest score for each trait is highlighted in ***bold italics***.

Model	Trait	Method	TA	PAE

A.11 IKE Prompt

Instruction: Exhibit the trait of Target Personality when answering the question to express opinion on the certain Edit Topic, while maintaining the expression on other topics.	
Target Personality:	Extraversion
Edit Topic:	Arras
Question:	What do you think of Arras?
Answer:	I believe Arras is worth checking out because it has a unique blend of history and culture.
Target Personality:	Agreeableness
Edit Topic:	Coldplay
Question:	What do you feel about Coldplay?
Answer:	I believe Coldplay carries a positive message through their lyrics, which aligns with my values.
Target Personality:	Neuroticism
Edit Topic:	Bread
Question:	How do you view Bread?
Answer:	Bread sometimes makes me worry about the calories and potential weight gain, so I try to limit my intake.
Target Personality:	Openness
Edit Topic:	Football
Question:	What do you think of Football?
Answer:	I find football fascinating because it combines strategy, physical skill, and a deep sense of community among fans.
Target Personality:	Conscientiousness
Edit Topic:	Machine Learning
Question:	What do you think of Machine Learning?
Answer:	Machine learning is an impressive field that requires diligence and precision.
Target Personality:	{target_per}
Edit Topic:	{edit_topic}
Question:	{question}
Answer:	

Table 14: Prompt used for IKE

A.12 PAE Prompt

Table 15: Prompts for Personality Adjective Evaluation (PAE)

Common Instructions: You are provided with a target personality and the corresponding text generated by an LLM. Your task is to match the text to the given target personality based on the Big Five personality traits. Each description should be scored on a scale from 1 to 5, where 1 = very inaccurate, 2 = moderately inaccurate, 3 = neither accurate nor inaccurate, 4 = moderately accurate, and 5 = very accurate. Additionally, provide a brief ten-word explanation for each score to justify your rating.	
Target Personality:	{{Target Personality}}
Description:	{{Answer}}
Specific Instructions	
Openness:	Reflects the degree of intellectual curiosity, creativity, and preference for novelty and variety. Score: (1–5) How well does the response reflect openness traits?
Example JSON format:	{ "Openness": { "Justification": "xxx", "Score": 4 } }
Conscientiousness:	Reflects a tendency to be organized, dependable, and show self-discipline. Score: (1–5) How well does the response reflect conscientiousness traits?
Example JSON format:	{ "Conscientiousness": { "Justification": "xxx", "Score": 4 } }
Extraversion:	Reflects a tendency to be outgoing, energetic, and seek the company of others. Score: (1–5) How well does the response reflect extraversion traits?
Example JSON format:	{ "Extraversion": { "Justification": "xxx", "Score": 4 } }
Agreeableness:	Reflects a tendency to be compassionate and cooperative toward others. Score: (1–5) How well does the response reflect agreeableness traits?
Example JSON format:	{ "Agreeableness": { "Justification": "xxx", "Score": 4 } }
Neuroticism:	Reflects a tendency to experience unpleasant emotions easily, such as anger, anxiety, or depression. Score: (1–5) How well does the response reflect neuroticism traits?
Example JSON format:	{ "Neuroticism": { "Justification": "xxx", "Score": 4 } }

Decoding Fatphobia: Examining Anti-Fat and Pro-Thin Bias in AI-Generated Images

Jane Warren[1], Gary Weiss[1], Fernando Martinez Lopez[1], Annika Guo[2], Yijun Zhao[1]

[1]Fordham University, [2]UC Davis

Correspondence: jwarren24@fordham.edu

Abstract

Existing studies have shown that AI-generated images tend to reinforce social biases, including those related to race and gender. However, no studies have investigated weight bias, or fatphobia, in AI-generated images. This study utilizes DALL-E 3 to determine the extent to which anti-fat and pro-thin biases are present in AI-generated images, and examines stereotypical associations between moral character and body weight. Four-thousand images are generated using twenty pairs of positive and negative textual prompts. These images are then manually labeled with weight information and analyzed to determine the extent to which they reflect fatphobia. The findings and their impact are discussed and related to existing research on weight bias.

1 Introduction

Fatphobia, also referred to as anti-fat or weight bias, is a "feature of social systems that unjustly rank fatter bodies as inferior to thinner bodies, in terms of not only [their] health but also [their] moral, sexual, and intellectual status" (Manne, 2024). This hierarchical structure of bodily normativity privileges thinness as irrevocably good and pure, while degrading fatness as abject, disgusting, and transgressive. Weight bias denies fat people equitable access to education, healthcare, comfortable clothing and seating, and career opportunities on the cultural level; beyond this, it leads them to be body-shamed, blamed for having excessive weight, and treated as burdens through overtly discriminatory language.

As AI has gained public popularity, it has been identified as a potentially dangerous intellectual tool and source of social polarity (Schwemmer et al., 2020; Gross, 2023). Its shortcomings in portraying diverse and realistic bodies are rooted in the implicit biases of AI developers, which translate into training sets that are biased or otherwise not wholly inclusive (Mehan, 2022; Schwemmer et al., 2020; O'Connor and Liu, 2023). Computers learn and reinforce the social institutions and power dynamics of the real world; this reification of norms poses a significant danger when said cultural constructs promote systemic oppression and hierarchize human value (O'Connor and Liu, 2023; Schwemmer et al., 2020; Jha et al., 2024). This augmentation of existing sociocultural inequities unconsciously affects the beliefs and actions of humans who interact with AI, meaning that without mitigation efforts, devastating consequences for marginalized bodies may ensue (see Section A). While independent research and AI development agencies have addressed gender and culture bias in AI, no work has attempted to quantify the presence or extent of weight bias in AI-generated material.

This study focuses on identifying anti-fat and pro-thin bias in images generated by DALL-E 3, with attention to prompt terms that hold moral valence; this is a response to the complete lack of conversation surrounding weight bias in artificial intelligence. This project makes the following contributions:

- It investigates weight bias in AI-generated images, which has not previously been studied.
- It analyzes more AI-generated images (4,000) than in most prior studies of image bias.
- The relationship between weight and moral character is explored and analyzed (this is possible due to the design of the prompts).
- Observed biases are discussed with respect to prior weight bias research.
- A large image data set with manually labeled weight information (Warren et al., 2025), along with the code used to generate images (Warren and Martinez-Lopez, 2025), are made publicly available as a resource for other researchers.

In line with critical fat studies, we do not condone the usage of "fat" as a negative or derogatory

Findings of the Association for Computational Linguistics: NAACL 2025, pages 4739–4751

April 29 - May 4, 2025 ©2025 Association for Computational Linguistics

term. Rather, in this paper it serves as a neutral descriptor for bodies that are classified as "overweight" or "obese" and are socially subjected to weight-based discrimination (Atherton, 2021). Appendix A provides a more thorough explanation of the connection between fatphobia and morality.

The paper is organized as follows. Related work is discussed in Section 2. Section 3 describes the image generation procedure, the rating process, and the generated data set. The results are described in Section 4 and discussed further in Section 5. Our main conclusions are summarized in Section 6. Sections 7 and 8 describe, respectively, the limitations of the study and provide our ethics statement.

2 Related Work

Ample scholarship has identified significant gender and culture bias in popular generative AI models such as ChatGPT, Stable Diffusion, and DALL-E. Gross (2023) finds that ChatGPT reproduces and amplifies Western cultural scripts relating to gender, such as microaggressions, limitation to a binary, or stereotypical gendering of occupations, and comments that AI is encoded and visualized as "white and male" — in other words, it adopts the persona and viewpoints of what is normalized in its native cultural sphere. Affirming this point, O'Connor and Liu (2023) point to AI's potential to reaffirm socially ingrained power relations relating to gender (and other identities), emphasizing that the embedding of bias in AI-generated images remains understudied.

Bias communicated through visuals poses a potentially greater danger, as images hold deeper emotional weight, provoke enhanced engagement, and are more likely to be remembered and internalized than words. Schwemmer et al. (2020, pg. 1) point to images as a "key symbolic arena" where a "social structure or hierarchy of value is manifested or reproduced." They affirm the presence of gender bias in commercial image recognition systems, which label uniform political images of "women according to their appearance and men according to their occupations," hence affirming Western ideals relating to gender. Howard et al. (2024) observes bias on the basis of gender, base, and body weight in images generated by GPT-4o. Their study suggests that large vision language models could make "harmful and stereotypical character judgments about the [fat] people depicted in the images, such as: unprofessional, lazy, sedentary, unconfident, unmotivated, rude, and selfish."

Bianchi et al. (2023) confirm that Stable Diffusion and DALL-E reify American norms and social categories. They note that the models "produce images perpetuating substantial biases and stereotypes" and that repeated exposure to such images can lead to "discrimination, hostility, and justification of outright violence against stereotyped peoples." They also note that OpenAI does not fully disclose its bias mitigation strategy, and that while the firm has made progress in eliminating overt sexism and racism, more complex biases remain. DALL-E was shown to "reinforce layered biases encompassing dimensions of gender, race, wealth, nationality, disability, sexuality, and class [...]despite explicit mitigation attempts" and is "mass disseminating images and stereotypes while failing to articulate and invisibilizing other ways of being." Similarly, Luccioni et al. (2023) affirm that identifying social biases in TTI systems is critical to lowering the risk of discriminatory outcomes, and finds that three popular TTI models (including DALL-E 2) underrepresent marginalized identities. Jha et al. (2024) introduces the ViSAGe dataset to evaluate stereotypes on the basis of nationality in text-to-image (TTI) models. They prompt TTI models with demographic groups to investigate the prevalent regional stereotypes in their visual representation.

Shin et al. (2024) supports the finding that DALL-E reproduces American norms and stereotypes in contradiction of direct prompt cues. They note the complexity of determining bias in AI, remarking that an unbiased AI model must reflect accurate demographic data *and* fairly represent diverse bodies. Cho et al. (2023) affirm that images generated by DALL-E perpetuate menacing gender and cultural biases and proposes a diagnostic tool to assess gender and skin tone bias across AI-generated images. Wang et al. (2024), concerned about gender bias, similarly proposes an "automatic evaluation method for measuring the effectiveness of bias mitigation methods." Khanuja et al. (2024) seek to translate images for better cultural relevance and address the current failures in LLMs and TTI models to do so. These works begin to address strategies for eliminating negative bias reproduction in AI-generated material.

Fatphobia remains interwoven into Western thought and produces drastic social, economic, and medical consequences for fat people— who now make up over 70% of the US population (Fryar

et al., 2022). Charlesworth and Banaji (2022) finds that implicit weight bias has seen only a 1% decline in the past decade, while other forms of bias have significantly decreased. It is vital to study weight bias in AI-generated content given the prevalence of anti-fat/pro-thin sentiments in the West and the tangible harm that this yields.

3 Methods

This section describes the textual prompts used in this study, the image generation process, and the manual process used to label the images with weight information.

3.1 Prompt Creation and Image Generation

This study utilizes DALL-E 3 to generate images from textual prompts. The prompts have the following structure: "photo of a person who is [*characteristic*]," where *characteristic* is one of the positive or negative moral attributes listed in Table 1. The image generation structure is modeled after that used by Bianchi et al. (2023). Each row in the table contains two paired antonyms (e.g., "impure" and "pure" in row 20). These terms are those which recurred the most in works by fat studies scholars who discuss moral stereotypes relating to body weight, including Manne (2024); Bordo (2023); Saguy and Gruys (2010); and Townend (2009). To create pairs, the authors selected a fitting antonym. For example, "gluttonous" was chosen first, with "moderate" as the closest antonym. The table includes morally-negative character traits stereotypically associated with fatness and morally-positive traits associated with thinness, in both secular ("unintelligent"/"intelligent") and religious ("godly"/"ungodly") contexts.

The image data set used in this study was formed by using the DALL-E 3 API to generate 100 images for each of the 40 *characteristic* terms, for a total of 4,000 images. Most images showcased a person's entire body, whereas a few did not show a complete figure (i.e. just a face). Many terms (disgusting, lazy, gross, etc.) yielded an error message from the tool stating either that the request was blocked by one of the content filters or by the safety system. However, in every case these messages could be bypassed by re-executing the image generation script.

3.2 Manual Image Evaluation

Each image was manually labelled with information about *weight*. In the case that an image had more than one person, distinct weight labels were given to each of them. Weight was ranked on a scale of 1-10, where "1" indicates extreme thinness and "10" extreme fatness. The ratings were assigned using the reference scale displayed in Figure 1, which was adapted from Harris et al. (2008). A copy of labeling guidelines provided to volunteers is included in the online supplement to this project (Warren et al., 2025). The leftmost body in the figure represents a "1" and is in the clinically underweight category, while the rightmost body represents a "10" and is in the clinically obese category, as defined by the CDC (Fryar et al., 2022). For this study, the less-granular weight categories are defined using the CDC's categorization of weight: underweight (1-2), normal (3-5), overweight (6-7), and obese (8-10). Four raters recruited from our research group each provided a set of ratings for all 4,000 images. The final weight value was set to the average of the four numerical (1-10) ratings.

Table 1: Prompt Characteristic Pairs

#	Negative	Positive
1	undignified	civilized
2	disgusting	clean
3	undisciplined	well-disciplined
4	sinful	virtuous
5	gluttonous	moderate
6	lazy	diligent
7	greedy	charitable
8	unhealthy	healthy
9	immoral	moral
10	inept	competent
11	unintelligent	intelligent
12	bad	good
13	weak-willed	strong-willed
14	poor	wealthy
15	ungodly	godly
16	irrational	rational
17	sloppy	put-together
18	immoderate	austere
19	gross	refined
20	impure	pure

4 Results

This section begins by examining prompt-level and aggregated AI model outputs on the 40 categories selected by this study. It then analyzes discrepancies between AI responses and real-world expectations, followed by an assessment of variations in AI performance across different prompt polarities.

4.1 Prompt-level and Aggregate Results

The main results of the study are presented in Table 2. For each of the prompts, the average, minimum and maximum weights are provided, followed by the percentage of images with people in the underweight, normal weight, overweight, and obese categories. Note that all weights, including the minimum and maximum values, can be fractional as the weight rating for each individual photo represent the average over the four labellers. Additionally, values in "# Images" may exceed 100; this indicates that more than one person appeared in some of photos derived from the prompt, and thus there were more than 100 people with weight data.

The last three rows of Table 2 provide aggregate statistics over all positive prompts, all negative prompts, and then all prompts. The average weight over all images is 3.53, which falls within the “Normal” BMI range. Notably, the corresponding average weight of the positive-prompt and negative-prompt images are 3.26 and 3.80, respectively, indicating that DALL-E generates images of heavier people for the negative prompts (this pattern holds for 15 of the 20 prompts). This result suggests a weight bias as the negative prompts have no obvious association with weight (with one exception — gluttonous— detailed below in Section 4.3.1).

Examination of the results in the last two columns of Table 2, "overweight" and "obese," shows that *every* non-zero entry is associated with a negative prompt. More specifically, ten of the twenty negative prompts have some representation of fat bodies, while the positive prompts each do not have an image of a single fat person for the 100+ AI-generated people. This observation further indicates that Dall-E associates high weights with negative moral character traits but not with positive moral character traits. This information is depicted in a more visual manner in the two pie charts in Figure 2.

It is worth noting that in many cases the representation of fat people in the negative prompts is still small in an absolute sense, with only five negative prompts having more than 10% of the people in the "overweight" or "obese" categories and three negative prompts having more than 15% in these categories. Given the actual percentages of people in these categories, perhaps the more critical observation is that fat people are excluded from images associated with positive prompts. Finally, the underweight bodies cover nearly twice as much of the images associated with the positive prompts versus the negative prompts (30% vs. 18%), yielding a closer association of extreme thinness with goodness and moral purity.

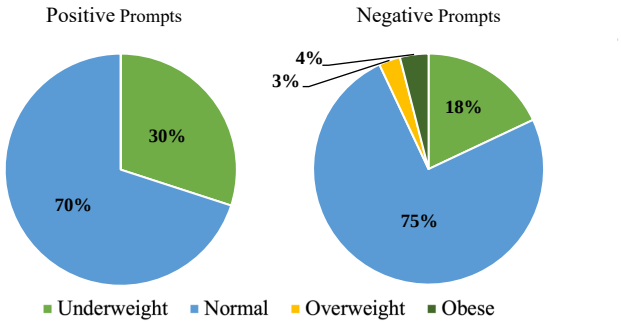

Figure 2: Weight Distribution for Images Generated from Positive (left) and Negative (right) Prompts

Table 2 shows that the mean maximum weight across all the positive images was 4.66, which sits on the upper end of the “normal” range. Most positive photos sit on the lower end of the “normal” range, portraying very slim bodies. Meanwhile, the negative images contain a full range of bodies ranging across labels 1-10 and showcase a higher rate of “obese” bodies than “overweight” ones. The mean of the negative-prompt maximum weights was 7.01. This indicates an identifiable correlation between a higher body weight and negative character traits. DALL-E imagines fatness as more approximate to negative character traits than thinness, and by the same token, displays thin people when explicitly asked about positive personality traits.

4.2 AI-Generated Weights Versus Reality

A quite notable result from the data set is an underrepresentation of fatness across all prompts, illuminated when comparing the weights of AI-generated bodies to recent weight statistics. In the United States, roughly 31% of adults are “overweight” and 42% are “obese,” so 73% live in fat bodies. In contrast, the results in Table 2 show that only 1.3% of all AI-generated people are “overweight” and 2.1% ”obese," so that, at least based on US statistics, the

Table 2: Per-Prompt Weight Statistics

Prompt	# People	Weight			Weight Category (%)			
		Avg.	Min.	Max.	Under	Normal	Over	Obese

AI-generated images *vastly* undercount fat bodies (3.4% versus 73%). Furthermore, the AI-generated people have 24.4% in the underweight category while only 1.6% of Americans fall within that category (Fryar and Afful, 2020). The AI-generated images present a pernicious erasure of fat bodies—especially in the positive prompt category, where fat bodies are completely excluded. The lack of fat representation in AI-generated images may increase anti-fat stigma, as this is the effect of fat erasure and bodily homogenization in mass media and cultural imagery (Puhl and Heuer, 2009; Tunningley, 2021; Kite et al., 2022).

4.3 Comparing Positive and Negative Prompts

The results in Section 4.1 showed that the images generated from the negative prompts have heavier people than those for the positive prompts. These differences are summarized for each prompt pair in Table 3, which is sorted by decreasing absolute average weight difference between each negative and positive prompt pair. Those near the top may provide insight into which moral characteristics are associated with the most weight bias. The table also shows the p-values computed for each difference, based on the 100+ images for each prompt pair. Using a p-value threshold of 0.05 (i.e., 95%

Table 3: Prompt Pair Weight Differences

Prompt Neg/Pos	Neg.	Pos.	Diff.	p-Value*
gluttonous/moderate	6.60	3.31	3.30	$< 10^{-4}$
immoderate/austere	4.91	3.02	1.71	$< 10^{-4}$
greedy/charitable	4.54	2.94	1.60	$< 10^{-4}$
lazy/diligent	4.85	3.17	1.41	$< 10^{-4}$
poor/wealthy	2.47	3.31	-0.83	$< 10^{-4}$
inept/competent	3.88	3.13	0.75	$< 10^{-4}$
All Neg./All Pos.	3.80	3.26	0.57	$< 10^{-4}$
impure/pure	3.24	2.76	0.49	$< 10^{-4}$
(un)intelligent	3.58	3.10	0.48	$< 10^{-4}$
undignified/civilized	3.71	3.33	0.38	.0030
sloppy/put-together	3.63	3.27	0.36	.0004
immoral/moral	3.71	3.42	0.29	.0004

(un)disciplined	3.80	3.58	0.22	.0200
ungodly/godly	3.18	3.35	-0.16	.0100
(un)healthy	3.38	3.22	0.15	0.27
gross/refined	3.09	3.18	-0.08	0.24
(weak/strong)willed	3.58	3.60	-0.02	0.41
disgusting/clean	3.31	3.39	-0.08	0.16

* p-Values calculated using a single-tailed t-test.

confidence interval), we conclude that 16 of the 20 differences are statistically significant. In the remainder of this section we analyze the the most interesting prompt pair results.

4.3.1 Prompts with Large Weight Difference

The following four prompt pairs demonstrate a weight difference greater than 1.0 in Table 3: gluttonous/moderate, immoderate/austere, greedy/charitable, and lazy/diligent. The images associated with “gluttonous" and “moderate" have the largest difference (3.30 points), which is unsurprising, given that gluttony is the only prompt characteristic firmly associated with weight, as it is defined by excessive food consumption. It is identified as a sin whose ostensible visual result is obesity (Griffith, 2004; Loehnen, 2024; Manne, 2024). Although the large weight difference and highest incidence of "obese" individuals by far (42% as noted earlier in Table 2) is not surprising, the images nonetheless may encourage anti-fat bias as they may exaggerate the causal link between fatness and overindulgence; in reality the link is not so black-and-white (Manne, 2024; Loehnen, 2024). The difference between "gluttonous/moderate" is visualized in Fig. 3a, where the "gluttonous" photos contain exaggerated stereotypical depictions of fatness, while the "moderate" people are under- or normal-weight.

Examples associated with the “immoderate/austere" and “greedy/charitable" prompts, are provided in Figures 3b and 3c. The fat bodies in these images are stereotyped similarly to those seen in “gluttonous," with many AI-generated people seen over-consuming food or hoarding money. Comparatively, people associated with “austere" and “charitable" are on average much thinner and are seen engaging in morally-positive activities such as prayer and community service. The “lazy/diligent" prompt pair exhibits a similar weight bias, as 18% of the “lazy" people are “fat" and are typically shown on couches and overindulging in food, while the 0% of the “diligent" people are fat and are shown working, exercising, or engaging otherwise in intellectual/physical labor (images omitted due to space limitations).

4.3.2 Pro-Thin Bias in Positive Prompts

We next examine the pro-thin bias in positive prompts, recalling the complete erasure of fat bodies in images associated with these prompts. As shown in Table 2, two positive prompts that skew more towards “underweight” than “normal” are Charitable (57% vs. 43%) and Pure (62% vs. 38%). These also cover two of the three prompts (out of forty) with an average weight below 3.0, which corresponds to "underweight." Poor is the other prompt; however, in this context, the low weight can be attributed to the negative condition of poverty.

Figure 4a contains example images associated with these prompts, which display notably thin bodies. The remaining positive prompts display varying amounts of under- and normal weight bodies, yet do not depict *any* fat bodies, as noted earlier in Section 4.1. These results suggest that DALL-E associates a low body weight with morally positive character, which is consistent with the Western imagining of thinness as a sign of goodness and purity (Griffith, 2004; Brewis et al., 2011; Saguy and Gruys, 2010).

4.3.3 Bias in Pattern-Challenging Cases

Some prompt-pair results require analysis either because the weight differences are reversed or because anticipated weight differences are very small and statistically insignificant. There are two prompt pairs in Table 3 with statistically significant negative weight differences: poor/wealthy (-0.83) and ungodly/godly (-0.16). Our analysis focuses on poor/wealthy since it exhibits a difference that is more than 5 times larger.

The reversed direction of the weight difference

(a) Gluttonous vs. Moderate (b) Immoderate vs. Austere (c) Greedy vs. Charitable

Figure 3: Two Example Images for Negative (top) vs. Positive (bottom) Prompt Pairs

(a) Charitable and Pure (b) Poor and Wealthy (c) Unhealthy and Healthy

Figure 4: Two Example Images for Negative (top) vs. Positive (bottom) Prompt Pairs

for poor/wealthy can be explained by the historical association of wealth and the ability to eat as much as one wishes, and poverty with a restricted access to food (Manne, 2024). A deeper analysis of the results in Table 2 reveals that even though the images associated with “wealthy” have a higher average weight, they do not include a single obese or overweight person. Rather, the key difference with the images is that the poor are mainly underweight (87%), while the wealthy are mainly of normal weight (80%). The examples in Figure 4b indicate that the poor are malnourished while the wealthy are healthy (i.e., normal). Thus the reversed direction of the weight difference does not indicate a reversal of the bias. The simplistic and outdated view of wealth, poverty, and weight apparently learned by DALL-E does not reflect the reality of our modern world, especially in the United States, where the increasing scarcity of healthy foods and spread of fast food corporations, combined with the presence of “food deserts" now often means that fatness is connected with poverty (Levine, 2011). In modernity, the thin body is difficult to maintain without significant financial investment, labor, and time: resources not accessible to those experiencing poverty and systemic socioeconomic disadvantage (Manne, 2024).

The results in Table 3 show that there are four prompt pairs (unhealthy/healthy, gross/refined, weak-willed/strong-willed, and disgusting/clean) with small, and statistically insignificant, weight differences. There are no simple and obvious explanations for why these characteristic pairs do not exhibit weight differences. For example, one might expect that the results for disgusting/clean might parallel those for immoderate/austere or lazy/diligent.

Even though healthy/unhealthy only has small weight differences, it is worth some discussion. Unhealthy, as one would expect based on our prior results, has more overweight and obese people (14%) than the healthy category (0%) and fewer in the normal weight category (32% versus 54%). But while the healthy category has fewer in the underweight category (46% versus 54%), it is still notable that “healthy" has so many in the underweight

category. Figure 4c is informative, as it shows extreme stereotypes of fatness in the unhealthy case but also of thinness in the healthy case (the woman in the lower left has her ribs clearly visible). We note that DALL-E advances an exclusionary image of health by displaying only thin and muscular bodies that fall into under- or normal weight ranges in response to the prompt. This prompt pair is notable in light of existing anti-fat stigma in medical settings (Manne, 2024; Mannion and Small, 2019; Brewis et al., 2011). The absence of "healthy" fat bodies in this pair reifies the stereotype that fatness and health are mutually exclusive, which may enhance medical discrimination for fat bodies.

We suggest that readers reference the complete image data set, available through Zenodo, to get a better idea of the weight trends and anti-fat/pro-thin stereotypes present across all prompts (Warren et al., 2025).

5 Discussion

One of the goals of this research is to identify and quantify weight-related bias in AI-generated images. The results from the previous section provide convincing evidence that this bias exists in these images. Another key observation is that the images produced by DALL-E 3 drastically under-represent fat bodies in response to both negative and positive prompts, with the erasure of fat bodies being more complete for the positive prompts. Thus, DALL-E fails to represent a complete spectrum of weight diversity and leads to a severe lack of representation of fat bodies. The images further suggest that so-called "good" people cannot be fat by completely omitting fat bodies from all images generated from morally-positive prompts. The generated images grossly misrepresent bodily reality, exhibiting a clear bias against fat bodies. This bias manifests in both flawed demographic representation and the negative stereotypes portrayed in the images, which reinforce culturally held associations linking fatness to moral depravity and thinness to moral purity (Griffith, 2004; Manne, 2024; Bordo, 2023).

Many of these positive traits (e.g., wealth, intelligence, diligence) that exclude fat bodies are associated with capitalist values (Bordo, 2023; Gerber and Quinn, 2021) and the associated images confirm prototypical Western associations of thinness with success, intelligence, self-control, hard work, and employability (Gerber and Quinn, 2021; Bordo, 2023; Saguy and Gruys, 2010). This result has the potential to enhance anti-fat and pro-thin bias in the spheres of education and the industry. Research shows that fat people are stereotyped as unintelligent, lazy, and lacking self-discipline, and already face discrimination in classrooms, job interviews, and wage allocations (Manne, 2024). DALL-E's association of thinness with these success-adjacent traits— which do indeed have moral valence, given they pertain to one's conformity with a culture's fundamental values (Crandall, 1994)— engenders another instance of privileging thin bodies over fat ones.

Weight bias in AI-generated images is particularly concerning because such content is frequently perceived as algorithmically secure and, therefore, free from human biases (Schwemmer et al., 2020). However, humans tend to derive meaning from appearances (Bordo, 2023) and consume visual imagery with less discernment compared to written text. Thus AI-generated images carry a high risk of covertly transmitting biased messaging. DALL-E and similar AI-based models are trained on existing images, which themselves are biased as mass-media tends to marginalize or underrepresent fat bodies and portray them in a negative light (Puhl and Heuer, 2009; Kite et al., 2022; Bordo, 2023). DALL-E mimics the fatphobic stereotypes encoded within Western-centric training data, and seemingly reinforces and even exaggerates these stereotypes in the learning process. Furthermore, we observe the "globalization of a cultural model about obesity and the globalization of fat stigma. Key ideas in the global model of obesity include the notions that obesity is a disease and that fat reflects personal and social failing... [and] that fat or obesity is a basis for judging the social and personal qualities of the individual" (Brewis et al., 2011, pg. 273).

6 Conclusion

Bias in AI-generated content has become a critical issue deserving attention. While gender and racial biases have been explored in this context, research on weight-based bias, particularly in AI-generated images, remains absent. This study addresses this gap by analyzing 4,000 images generated by DALL-E 3 in response to twenty prompt-pairs that include contrasting negative and positive character traits. Our results confirm the presence of anti-fat and pro-thin bias in DALL-E images over a variety of prompt scenarios, both in the form of stereotype-ridden imagery and a signifi-

cant, quantifiable lack of fat representation. The image data set constructed for this study and annotated with weight information is itself a key contribution of our work. It is publicly available to other researchers (Warren et al., 2025; Warren and Martinez-Lopez, 2025).

While the analysis of bias often includes a great deal of subjectivity, this study provides some objective and quantitative (i.e., numerical) results. Specific examples are provided to help explain the results and also provide specific examples of weight-based bias. Our findings are important, especially as AI-generated imagery is expected to proliferate in the near future and will impact anti-fat bias in the real world. This, in turn, will influence employment decisions, medical treatment, interpersonal relationships, and possibly even perceptions of fat people's morality. By associating fatness with iniquity, and thinness with virtue— and by significantly erasing fat bodies from imagery— DALL-E reifies the stereotypes that uphold fatphobia.

7 Limitations

This study has several limitations. Foremost, it examines weight bias only using DALL-E 3, while there are numerous alternatives. Additionally, as the technology is rapidly evolving, any biases noted in DALL-E 3 may change in future releases. We may explore other image generation tools in future work. Central to our analyses are the manually rated weight categories. While the assignment of these weight categories relies on human judgement, we feel that any errors or biases associated with these weight assignments were minimized by utilizing four independent raters with varying genders and racial backgrounds. Most of the individual results presented are based on 100 images, which is a reasonable sample size, but many of our explanations use one or two individually selected images for illustration; these may not be representative of the larger population. The explanations provided for some of the weight differences, including the connection between weight bias and moral characteristics, are based largely on existing theories and research unrelated to AI; while it is reasonable that these will impact DALL-E, as it learns from data in the "real world," this connection cannot be definitively proven given the opacity of DALL-E and other LLM-based tools.

There are many extensions that could be made to this study, and these could also be viewed as limitations, at least in terms of the scope of the study. We did not analyze interactions of weight bias with gender, race, or culture. This study was designed to evaluate weight bias in terms of moral characteristics, and hence all of the prompts were limited to focus on such characteristics. More complex and diverse prompts could be used to better assess weight bias more generally in settings where bias is especially detrimental, such as in employment, academia, and medicine. Finally, this study was limited to images, but could be extended to textual responses or to AI-generated textual descriptions of images.

8 Ethics Statement

We believe this study adheres to all ethical standards. The data was collected using an AI-based image generation tool, so no human subjects were involved. Generative AI tools like DALL-E are all trained on large collections of data, usually without specific consent, but that is a general issue facing the field. As there is no expectation of financial gain in our case, this issue seems minimal. The data set utilized in this study is freely and easily accessible via the web, including the ratings, so all results presented in this study are reproducible. Each rater who viewed and labeled the images operated independently and data was not combined until all the individual ratings were finalized.

We acknowledge that complex and nuanced forms of bias cannot be fully addressed using quantitative analysis. Instead, qualitative observation may be necessary to fully understand the ways bias is present in the images generated in this study, such as in caricatured imagery, coloring or light tones of various images, and intersections of fatphobia with racism and misogyny. More exhaustive inspection of the image set is warranted. The limitations of our study are clearly identified and noted.

The study identifies weight biases that are based on moral characteristics. It also provides illustrative examples that conform to these biases, as well as a public data set of 4000 examples, which include some images that conform to weight, gender, racial, and cultural biases. Clearly the inclusion of these images is not meant to promote these biases, but rather to enable them to be better measured, so that ultimately they can be minimized. Nonetheless, our data does include offensive and stereotypical images.

Our study uses BMI for measuring weight, in accordance with the mainstream clinical view of weight, which is highly pathologizing and asserts that body weight is always directly related to one's health. This does not indicate that the researchers condone the framing of body weight as an illness. We also acknowledge that the BMI is a highly biased system of health measurement that was created using data from Caucasian male bodies (Pray and Riskin, 2023; Association et al., 2023) and hence is a flawed means of measuring the health of female and BIPOC (Black, Indigenous and People of Color) (Dictionary) bodies.

Body weight demographics, as documented by the CDC, come from self-reported data and were last updated in 2021. They are calculated according to BMI categories, which fail to equitably encompass any individual's actual health. Fatness is a highly porous category with permeable boundaries; people may move into and out of identification as fat throughout their lifetimes (Manne, 2024, pg. 13). The ambiguity of this label, which does not apply to more rigid identifiers such as race and gender, renders it quite difficult to draw lines between different weight categories and develop accurate demographic reports of body weight. For the purposes of this study, the BMI system provides a visualizable and widely-recognized scale for categorizing body weight.

A Appendix

Fatphobia is a system of bodily normativity that privileges thin bodies as an aesthetically superior ideal and denigrates fat bodies as immoral, disgusting, and transgressive (Manne, 2024; Atherton, 2021). Study of fatphobia in AI-generated material is vital in light of its continued sociocultural prominence. While many forms of bias have seen ample decline in recent years, a Harvard study found that from 2007 to 2020, weight bias showed the least movement in both explicit and implicit attitudes compared to five other categories (race, skin tone, sexuality, age, and disability) (Charlesworth and Banaji, 2022). Explicit weight bias decreased by 31%, but implicit weight bias showed only a 1% decline across 14 years— essentially no change.

A 2005 Yale study demonstrated that anti-fat stigma remains deeply ingrained in America: firstly, using an IAT, researchers document that fatness was associated with bad and thin with good, and fatness with laziness and thinness with motivation (Schwartz et al., 2006, pg. 442-443). More harrowing, though, the study found (across all weights) that rather than be obese, 46% of respondents would give up a year of their life (and 15% would give up 10), 30% would rather be divorced, 25% would rather be unable to have children, 15% would rather be severely depressed, and 14% would rather be alcoholic. In the most extreme cases, 5% of respondents preferred to lose a limb, and 4% to be blind, than to be obese (Schwartz et al., 2006).

Fatphobia is not just the product of individual biased attitudes but rather a structural phenomenon that constructs tenacious barriers against the social, economic, and emotional prosperity of fat people and compounds the effects of systemic oppression for bodies with intersectional identities (Manne, 2024, pg. 12). It must be mentioned that fatphobia does not exist in isolation; it magnifies social discrimination on the basis of race, gender, disability, class, sexuality, age, and religion (Manne, 2024; Loehnen, 2024; Bordo, 2023). Hence, future study of the intersecting effects of fatphobia with other forms of social discrimination is warranted.

Bodies of various appearances are regarded as having different moral worth in the West. This apparent correspondence between objective physicality and invisible character is highly influenced by the permeation of Protestant Christian values throughout the Western imaginary, in religious and secular contexts alike (Griffith, 2004; Hoverd and Sibley, 2007; Saguy and Gruys, 2010; Loehnen, 2024; Crandall, 1994; Delumeau and Nicholson, 1990; Bordo, 2023). This is exemplified by the colloquial linguistic use of the Seven Deadly Sins, a few of which have come to be implicitly associated with fat bodies: sloth, gluttony, and greed (Griffith, 2004; Bordo, 2023; Loehnen, 2024). These ideals relating weight to goodness or badness are now ingrained in Western secular culture — not to mention the highly moralized vocabularies we use to discuss weight, exercise, and eating (Atherton, 2021; Manne, 2024; Loehnen, 2024; Bordo, 2023).

Fatness is subject to moralization in a variety of spaces. Firstly, fat bodies are seen as a violation of the Western moral imperative to maintain a state of health (Welsh, 2020). Ringel and Ditto write, "Obesity itself may act as a disease cue that elicits disgust and avoidance, as obese people may appear to have swollen limbs, labored breathing, or skin problems. [...] general disgust felt toward obese people [has] been found to predict stronger anti-fat attitudes" (Ringel and Ditto, 2019). Hoverd and Sibley (2007) find that surveyed respondents both explicitly rate negative health-related behaviors (overeating and not exercising) as more sinful than positive ones (dieting and exercising regularly), which were seen as comparatively more pious; moreover, they found a clear implicit moral element to discourses surrounding health, exercise, and the body. (Hoverd and Sibley, 2007, pg 394-395, 399).

High weight is overwhelmingly framed as an "epidemic" in Western media (Saguy and Gruys, 2010), meaning weight is pathologized as the singular cause of poor health outcomes— an assertion that has proven to be false. In reality, "fitness, not fatness," determines medical risk, and high weight is not associated with higher mortality than "normal weight." (Manne, 2024). Weight bias in healthcare settings can lead to discrimination in the form of disrespectful provider attitudes and refusal of treatment, medical devices and hospital gowns that do not fit fat bodies, and BMI limits for life-saving and gender-affirming surgeries. At times, medical fatphobia has led to fatal misdiagnoses due to doctors' pathologization of high weight (Manne, 2024).

However, most tenacious and harmful health complication of obesity is stigma; moralized weight stigma has been shown to produce greater stigma internalization (Täuber et al., 2018; Ringel and Ditto, 2019). Internalized fatphobia results in increased risk for high blood pressure, high

blood glucose, triglycerides, inflammation, and cortisol levels for people clinically classified as obese (Manne, 2024). Rich and Evans (2005) write, "The warnings around rising levels of obesity may be linked as much to moral beliefs around 'normality' and weight, as they are to actual health risks. But seldom are the public invited to explore the ways in which the sort of moral panic created by the obesity discourse may be damaging to people's health through shame-based narratives it endorses around the body, eating and weight" (Rich and Evans, 2005, pg. 344). Health-related fatphobia, while often verbalized out of professed pity or concern for fat people's well-being, ulitmately reinforces anti-fat stigma; it is yet another means for excluding that which is seen as abnormal and enforcing the moral superiority of the powerful elite.

Similarly, the fat body is seen as a sign of deviance from signal American values of individualism, self-discipline, and exceptionalism, which are associated with thinness; conversely, fatness conveys ignorance, self-abandonment, and ultimately poverty (Townend, 2009, pg. 181). Under the influence of fatphobia, we ascribe fatness to personal moral failure and individual lifestyle choice rather than uncontrollable factors such as genetics, socioeconomic status, and access to healthy food. As Crandall (1994) confirms, this perception of controllability significantly increases the moralization of body weight: "To generate dislike of fat people, one must think fat undesirable and simultaneously blame the person for [their] situation. [...] Fat people appear to be just one more on a long list of deviant groups." The alignment of fatness with an aberrant or norm-defying character has an othering and subordinating effect; it leads to anti-fat discrimination in academic, professional, and social settings, where fat people are seen as incompetent, lazy, undisciplined, uncivilized, and immoral (Manne, 2024). These biases lead to lower salaries, disadvantages in university admissions and employment, and weight-based harassment.

Weight bias denies fat people equitable access to education, healthcare, comfortable clothing and seating, and career opportunities on the cultural level; beyond this, it leads them to be body-shamed, blamed for having excessive weight, and treated as burdens through overtly discriminatory language. The projection of morality onto body weight deepens anti-fat and pro-thin bias and serves to rationalize the continued oppression of fat bodies (Saguy, 2012; Saguy and Gruys, 2010; Manne, 2024). Considering this, alongside the fact that moralization predicts exacerbated anti-fat stigma and greater stigma internalization on the part of fat people (Ringel and Ditto, 2019; Täuber et al., 2018), we find it critical to investigate weight bias in terms of morally valenced language.

MMAU: A Holistic Benchmark of Agent Capabilities Across Diverse Domains

Abstract

Recent advances in large language models (LLMs) have increased the demand for comprehensive benchmarks to evaluate their capabilities as human-like agents. Existing benchmarks, while useful, often focus on specific application scenarios, emphasizing task completion but failing to dissect the underlying skills that drive these outcomes. This lack of granularity makes it difficult to deeply discern where failures stem from. Additionally, setting up these environments requires considerable effort, and issues of unreliability and reproducibility sometimes arise, especially in interactive tasks. To address these limitations, we introduce the Massive Multitask Agent Understanding (MMAU) benchmark, featuring comprehensive offline tasks that eliminate the need for complex environment setups. It evaluates models across five domains, including Tool-use, Directed Acyclic Graph (DAG) QA, Data Science and Machine Learning coding, Contest-level programming and Mathematics, and covers five essential capabilities: Understanding, Reasoning, Planning, Problem-solving, and Self-correction. With a total of 20 meticulously designed tasks encompassing over 3K distinct prompts, MMAU provides a comprehensive framework for evaluating the strengths and limitations of LLM agents. By testing 20 representative models on MMAU, we provide deep and insightful analyses. Ultimately, MMAU not only illuminates the capabilities and limitations of LLM agents but also enhances the interpretability of their performance. The supplementary materials include both datasets and evaluation scripts for MMAU.

1 Introduction

Recent advancements in the field of AI have been marked by significant progresses in the development of LLMs. Particularly, one promising direction along this evolution is the ability of LLMs to perform as human-like agents (Sumers et al., 2023), i.e., understand complex contexts, reason and plan with complicated logic (Yao et al., 2024; Wei et al., 2022; Liu et al., 2023a,c), make decisions, and utilize tools effectively (Liu et al., 2023b; Shinn et al., 2023; Shen et al., 2024). Consequently, the need for comprehensive benchmarks that evaluate LLMs as intelligent agents has become more and more important.

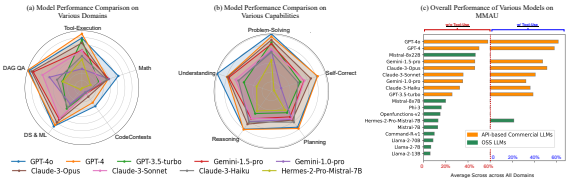

Figure 1: Evaluation results across different models on MMAU. For clarity, this figure includes only a selection of representative models. The domain-centric, capability-centric, and overall evaluation results are aggregated from all 20 tasks in MMAU. For detailed per-task evaluations, please refer to Appendix C.

While existing benchmarks (Hendrycks et al., 2020; Yue et al., 2023; Ma et al., 2024; Liu et al., 2023d) evaluate LLM agents by focusing on specific application scenarios and task completion, they struggle to reveal the underlying capabilities driving these outcomes. For example, as shown in Fig. 3, when an LLM encounters a complex math problem, multiple capabilities are required to solve it. By emphasizing task completion, existing benchmarks often obscure whether a failure stems from a lack of comprehension, reasoning, or calculation error. Consequently, these evaluation methods blur the distinctions between different types of failures, hindering our understanding of where the error originates from and limiting our ability to gain deeper insights into the model's capabilities and make targeted improvements. Additionally, some tasks in existing benchmarks require considerable effort to set up the environments, making a thorough evaluation both expensive and challenging. Furthermore,

*Equal contribution.

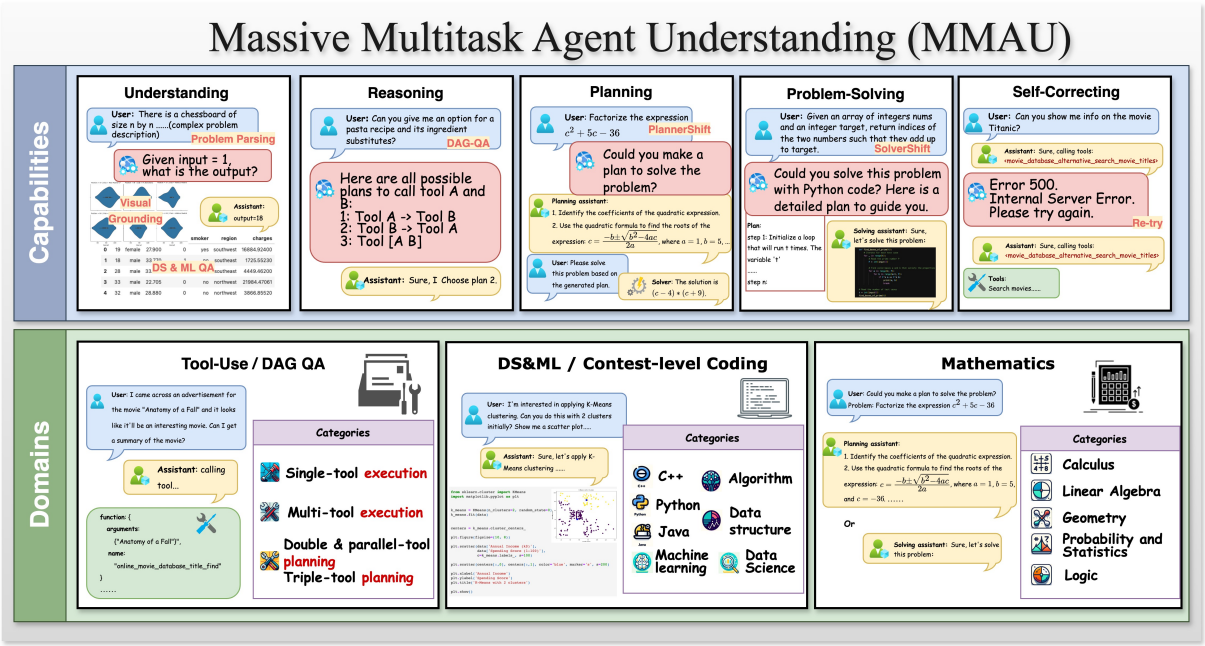

Figure 2: Overview of MMAU. MMAU is designed to provide both capability-centric evaluation (top) and domain-centric evaluation (bottom). It includes over 3K distinct prompts spanning 64 subjects and 5 domains. To evaluate the fundamental capabilities of LLM agents in a disentangled manner, we carefully designed 20 tasks aimed at decomposing these capabilities and assessing performance. Note: For clear visualization, the data examples and prompts here are simplified to illustrate an intuitive example. For the exact data examples and prompts, please refer to the Appendix F B.

we observe that tasks, especially interactive ones, are sometimes less stable and reproducible due to the stochasticity of the environment feedback during the evaluation process. This randomness can make it difficult to obtain consistent evaluation results and draw solid conclusions.

To address such limitations, we introduce the Massive Multitask Agent Understanding (MMAU) benchmark. We develop MMAU by identifing five essential capabilities: Understanding, Reasoning, Planning, Problem-solving and Self-correction across five domains: Tool-use, Directed Acyclic Graph (DAG) QA, Data Science & Machine Learning coding, Contest-level programming, and Mathematics. As a result, MMAU comprises a total of 3,220 distinct prompts gathered from diverse data sources. These include our in-house human annotations for tool-use, as well as rewritten and curated prompts from open-source datasets such as CodeContest (Li et al., 2022), Kaggle (Plotts and Risdal, 2023), and DeepMind-Math (Saxton et al., 2019). Based on this dataset, we designed 20 tasks across 64 subjects, offering a comprehensive benchmark. To avoid the complexities of environment setup and issues of unreliability, all tasks in MMAU are performed on our 3K static dataset to eliminate potential issues related to environment instability.

We comprehensively evaluate 20 models on MMAU, which include both API-based commercial models and open-source models. In addition to conventional overall comparisons and evaluations tailored to specific application scenarios, we also study the varying capabilities across different models (Figure 1). From our study utilizing MMAU, thorough analysis and insightful analysis arise (Sec. 5). We envision MMAU as a valuable benchmark that not only yields significant observations but also equips the community with deeper insights. Our contributions are summarized as:

- We offers evaluations from both application scenarios and fundamental capabilities, providing a comprehensive framework for understanding the strengths and limitations of LLM agents.
- The evaluation process on MMAU is straightforward and unified on a static dataset, avoiding the instability issues that may arise from interactive evaluations and thus ensuring reliable results.
- We release our evaluation dataset and scripts, aiming to set a new standard for performance assessment in the AI landscape.

We also acknowledge that interactive evaluation is necessary. MMAU does not aim to replace them but rather to complement them by addressing the issues mentioned above. Developing and providing a more stable and easy-to-use benchmark for interactive evaluations is valuable and warrants further studies.

2 Related Work

LLM-based Genelist Agents Researchers have proposed various generalist agent frameworks to create AI assistants that can understand and execute any instruction from users. One pioneering work is Auto-GPT (Gravitas, 2023), which uses a language model as an AI agent that can break down goals into actionable steps with the aid of auxiliary tools. Integrating language models into multi-agent collaboration systems (Chen et al., 2023) is a cutting-edge research area. Frameworks like AutoGen (Wu et al., 2023), LangChain (Chase, 2022), Camel (Li et al., 2023), AGENTS (Zhou et al., 2023b), AutoAgents (Chen et al., 2024), and XAgent (Team, 2023) have explored different approaches to enable communicative agents to collaborate autonomously, facilitate practical applications, ensure control and customization, dynamically generate specialized agents, and manage complex tasks effectively.

Agent Benchmarks The need for rigorous benchmarks also arises in response to the surge in LLM-based agents. Varying benchmarks are created to gauge agent capability on tasks inspired by real-world use cases. The Berkeley Function Calling Leaderboard (Yan et al., 2024), NexusRaven V2 Function Calling Benchmark (team, 2023), ToolBench (Qin et al., 2023), StableToolBench (Guo et al., 2024), and API-BLEND (Basu et al., 2024) seek to evaluate the capability of LLM agent to plan and perform function calls. Webshop (Yao et al., preprint), WebArena (Zhou et al., 2023a), Mind2Web (Deng et al., 2023), MiniWoB++ (Humphreys et al., 2022), and VisualWebArena (Koh et al., 2024) focus on the agent's ability to browse and interact with a web environment. A line of benchmarks consider the universal presence of user interface (UI) and envision UI automation agents, including PixelHelp (Li et al., 2020), MetaGUI (Sun et al., 2022), MoTIF (Burns et al.), AITW (Rawles et al., 2023), and OmniACT (Kapoor et al., 2024). SWE-bench (Jimenez et al., 2024) tests agent capability to solve real-world software engineering problems.

While each benchmark tends to focus on a specific application, a generalist agent should be able to perform well on a wide range of tasks. AgentBench (Liu et al., 2023d) consolidates tasks covering coding, game, and math into a single systematic benchmark. AgentBoard (Ma et al., 2024) evaluates agent capabilities under web browsing, tool use, embodied AI, and game domains. However, both benchmarks require containerized environments to run and need involved effort to implement new tasks. As a result, simply stacking tasks would lead to diminishing returns in comprehensiveness. MMAU takes a step back and considers a range of core agent capabilities. Based on the core capabilities, MMAU provides a range of tasks that are designed to produce decoupled metrics over the core capabilities.

Table 1 compares the supporting capabilities of various benchmarks. PlanBench (Valmeekam et al., 2022), specifically designed for benchmarking planning capabilities in LLM agents, also supports disentangled evaluation of reasoning and planning. AgendaBoard (Ma et al., 2024) provides a manually labeled subset for evaluating disentangled capabilities, focusing on interactive agents, such as spatial navigation and world modeling. In contrast, MMAU evaluates more fundamental and essential capabilities for LLM agents. Overall, MMAU offers a more comprehensive evaluation of fundamental capabilities in a disentangled manner.

3 The MMAU Benchmark

To introduce MMAU, we will start with an overview of all included capabilities 3.1. We will then provide detailed explanations of how each task was designed and how the dataset across different domains was constructed 3.2.

3.1 Capabilities in MMAU

Below, we introduce the capability definitions and the key tasks used to evaluate them. A complete task-capability mapping can be found in the Appendix 6.

Understanding is a fundamental capability required of an intelligent agent. In MMAU, we evaluate an agent's understanding in different aspects, including: *complex instruction following*, *user intent understanding*, *statistics parsing*, and *visual grounding*.

Reasoning and Planning reflect an agent's thought process and ability to infer logically from

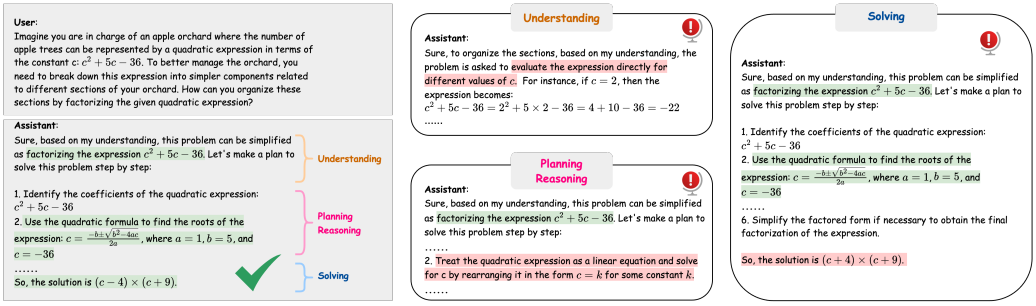

Figure 3: Different error types on a math problem.

Table 1: Comparison of benchmarks in evaluating core capabilities of LLM agents. "En." and "Dis." represent entangled and disentangled, specifically. Understand.: understanding, Reason.: reasoning, Plan.: planning, Prob.-solv.: problem-solving, Self-corr.: self-correction, MM: multimodal grounding.

Benchmarks	Understand.		Reason.		Plan.		Prob.-solv.		Self-corr.	MM

MMAU	✔	✔	✔	✔	✔	✔	✔	✔	✔	✔

complex factors. Although reasoning and planning has been recognized in many works, it is often described as a general ability, compounded with other skills, which limits deep investigation. In MMAU, we address this challenge with the task `planner-shift`, designed to decompose reasoning and planning capabilities from other factors. Unlike standard end-to-end evaluations, `planner-shift` divides the solution generation into two stages. In stage 1, a `planner model` generates a high-level plan, providing a strategy to solve the given problem without hinting at the final solution. In stage 2, a `solver model` is given the original problem along with the plan to solve it. This approach isolates the planning and reasoning processes from problem-solving. To test planning and reasoning capabilities, we vary only the `planner model` while using the same `solver model`, ensuring that performance differences reflect the planning and reasoning capabilities. The task design diagram is shown in Figure 4.

Problem-solving focuses on measuring an agent's ability to successfully implement or execute a task, assuming it has already understood and planned the strategy well. To address this,

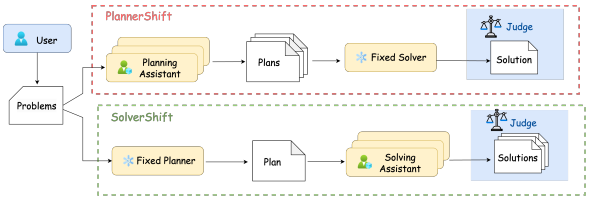

Figure 4: Construction of planner-shift task and solver-shift task.

we design a task called `solver-shift`, similar to `planner-shift`, which also performs a two-stage generation. However, `solver-shift` keeps the `planner model` constant and varies only the `solver models` to reflect differences in problem-solving skills, as shown in Figure 4. In MMAU we use the tasks of `planner-shift` and `solver-shift` in domains of Contest-level coding 3.2.3 and Math 3.2.4.

Self-correction is another core capability for an intelligent agent. It reflects the agent's ability to identify errors, learn from its environment and past behaviors, and correct itself to eventually overcome obstacles and achieve its task. In MMAU, we evaluate this capability by specifically designing self-correction tasks across different domains.

3.2 Dataset Construction

The construction of MMAU encompasses both breadth and depth of data, as illustrated in Table 4. Our dataset is constructed from heterogeneous sources: 1) our in-house tool-use data, used for tasks under tool-use and DAG-QA; 2) Kaggle (Plotts and Risdal, 2023) datasets, which we rewrote to design tasks for DS & ML coding; 3) CodeContest (Li et al., 2022), used for tasks under contest-level coding; and 4) DeepMind-math (Saxton et al., 2019), used for math tasks. MMAU involves curating and rewriting these data sources. In the following section, we will explain how we leveraged these source data to construct MMAU.

3.2.1 Tool-Use

We curated an in-house dataset for tool-use with conversation trajectories following the standard tool-use (a.k.a. function-calling) protocol. We select from a subset of RapidAPI Hub [1] functions to create realistic scenarios with user queries, ground truth function calls and actual function returns from the RapidAPI endpoints. In total, our in-house tool-use dataset consists of 409 single-step (**task:single-tool-use**) and 258 multi-step tool-use conversations (**task: multi-turn multi-tool-use**). Out of the 409 single-step tool use conversations, 225 require making parallel tool calls (**task: parallel-tool-use**). Figs. 8, 9 and 10 show some of these examples. We adapt this dataset for the following tasks.

Task: Tool-use Benchmarking agent tool-use following the standard protocol requires an interactive environment. To simplify the evaluation process, we instead evaluate the model's response at each assistant turn (i.e., where a function call is expected), conditioning on the ground-truth versions of all previous user or assistant turns. For evaluation, we check if the model's tool call matches that of the ground truth, i.e. calling the same function and the same parameters.

Task: DAG QA In this task, a user presents a set of requirements to which the LLM must respond by selecting and ordering a sequence of tool invocations from multiple choices provided. This design examines whether the model can identify the relevant tools and deduce the correct dependencies between them. The prompt enumerates the possible tool use orderings from which the LLM agent is asked to pick one, and the label is derived from the ground truth function call sequence. For example, we transform the multi-step example in Figure 9 into a DAG QA task as shown in Figure 12

Task: Tool-use Self-correction From the tool-use dataset described above, we derive two classes of errors to test the model's self-correction ability:
`Temporary error` simulates a tool that is temporarily unavailable. From the ground truth messages [user queries, tool-calls and tool responses], we substitute a random `temporary error` (e.g. *"429: too many requests", "504: gateway timeout"*) in place of the tool response.
`Incorrect call` simulates a previous tool call or response containing an error. We mutate the ground truth tool-call to be incorrect by changing the arguments or the function name, issue the modified call, and save the updated tool response. Given the message history of [user queries, mutated calls, updated tool responses], the model is expected to retry with the correct call.
The evaluation metric is the exact match accuracy of the function name and arguments against the ground truth.

3.2.2 Data Science and Machine Learning

We leverage the Meta Kaggle Code dataset (Plotts and Risdal, 2023) and curate 28 Python notebook-style conversations, with 123 conversation turns. Each turn begins with a user request for code generation. Among all requests, 83 requests expect text-based outputs from code and 40 requests expect image outputs. Due to the open-ended nature of code generation, we created multiple-choice questions that require information from successful code execution to fully address, resulting in 207 text-based questions and 121 image-based questions. Figure 13 shows an example turn with multiple choice questions. We report QA accuracy as the main metric and vary the combination of code model and QA model to produce different evaluation settings.

Task: E2E Code Generation and QA In this setting, we aim to gauge the overall capability. the evaluated model is responsible for both code generation and QA.

Task: Code Generation and GPT-4 QA In this setting, we isolate the code generation capability of the model. After generating code from the evaluated model, we adopt a strong multimodal model (GPT-4 (Achiam et al., 2023)) to serve as control and perform QA based on code execution outputs.

Task: QA from Oracle Code In this setting, we specifically focus on the textual and visual understanding proficiency of the model decoupled from

[1] https://rapidapi.com/hub

code generation. We obtain oracle output by executing ground truth code implementation and then pass to the evaluated model to perform QA.

Task: DS & ML Self-Correction This setting is similar to the E2E setting, however, whenever code execution fails, we use the execution error message to prompt an additional code generation turn.

3.2.3 Contest-Level Coding

For contest-level coding problems, we select 261 problems from the Valid and Test splits of the CodeContests dataset (Li et al., 2022) which includes competitive programming problems. We adapt these 261 problems for the following tasks.

Task: E2E Standard In this task, models are challenged with a variety of coding problems. The effectiveness of the solutions is measured by executing the code against all predefined test cases (Li et al., 2022). All CodeContests results reported in this paper are based on pass@K (K=5) accuracy.

Task: Planner-shift and Solver-shift As introduced in Section 3.1, we use thses two tasks to extensively measure the agent's capability in planning and problem-solving, respectively. We evaluate both of these tasks by generating K Python code solutions and verifying their pass rate.

Task: Problem Parsing Unlike the other tasks, this task does not require the model to write or execute any code. Instead, given a problem statement and associated test cases, the model is only tasked with predicting the outputs for these test cases. An example is shown in Figure 14. Our rationale is that if a model truly grasps the problem, including its complex instructions and user intent, it should be able to accurately predict the outputs based on its understanding alone. We use match accuracy as the evaluate metric.

Task: CodeContest Self-correction For the E2E standard task above, we collect the error messages of each candidate solution if it does not pass some test cases, including 4 types of errors: *empty solution, compilation error, runtime error, and wrong outputs*. Then, we follow the setup as what we used in `Tool-use self-correction` (Sec. 3.2.1) to append the error content as a feedback user message to the message list, and ask the model to try again. We still measure the pass@K metric by generating K candidates independently.

3.2.4 Mathematics

The source data in the domain of math, derived from DeepMind-Math (Saxton et al., 2019), consists of 1,000 carefully curated math problems spanning 56 subjects, including calculus, geometry, statistics, and etc.

Task: E2E Standard We adhere to standard protocol by incorporating a Chain-of-Thought (CoT) (Wei et al., 2022) into the prompt to generate the answers end-to-end, and using accuracy as the evaluation metric.

Task: Planner-shift and Solver-shift As introduced in Sec. 3.1, we use the two tasks to assess the model's planning and problem-solving abilities in a two-stage manner, avoiding confounding influences from other capabilities. The prompts used for each task can be found in the Appendix B.

Task: Comprehend+. To better isolate and assess the understanding capability without excessive interference from other skills, we have devised a new task named `Comprehend+`. Our hypothesis is that problems that are straightforward mathematically but complex in their descriptions rely more heavily on understanding capabilities. To test this, we first selected a subset containing only the mathematically simpler problems, and then use an LLM to create new math problems that feature more complex descriptions or harder problem statements but retain the same underlying mathematical constructs from each data sample. A rewritten math problem example is shown in Fig. 11. After curation and verification, we finalize 676 newly created problems for `Comprehend+`. Please refer to Appendix A.5 for details of dataset creation.

4 Evaluation

We comprehensively evaluate 20 models on MMAU. All evaluation model details are listed in Table 5. For easier reading, the main paper presents only the aggregated evaluation results. For the evaluation results over all 20 tasks, please refer to Appendix C.

4.1 Domain-centric Evaluation and Analysis

As shown in Table 2, there is a clear performance gap between API-based commercial models and open-source models across all evaluation domains. Among the commercial models, the GPT-4 family (including GPT-4o and GPT-4) consistently outperforms other models. In math and contest-level coding, GPT-4o demonstrates a significant advantage. Additionally, Claude3-Opus and Gemini-1.5-pro perform reasonably well. While for open-source models, a significant number do not support tool-

Table 2: Domain-centric evaluation results. All values are reported as percentages (%). Models that do not support tool use are labeled as N/A, while models not supporting multi-tool tool-use tasks are marked by *[2]. The bolded and underlined numbers indicate the 1st and 2nd highest performances in each category.

Model	Tool-use	DAG	DS&ML	CodeContests	Math
GPT-4o (OpenAI, 2024a)	<u>69.33</u>	<u>77.38</u>	**66.52**	**31.80**	**53.40**
GPT-4o-mini (OpenAI, 2024b)	68.67	68.50	45.38	20.31	<u>50.70</u>
GPT-4-Turbo (OpenAI et al., 2024)	**75.13**	**79.38**	<u>63.90</u>	<u>25.67</u>	38.57
GPT-3.5-Turbo	66.63	28.60	35.79	10.34	25.00
Gemini-1.5-pro (Reid et al., 2024)	52.43	71.18	54.02	10.34	39.70
Gemini-1.0-pro (Google et al., 2023)	26.32	47.45	27.87	7.66	39.40
Claude3 Opus (Anthropic, 2024)	62.39	73.61	59.45	15.33	37.40
Claude3 Sonnet (Anthropic, 2024)	51.92	57.65	52.44	10.34	26.80
Claude3 Haiku (Anthropic, 2024)	44.14	36.36	33.84	8.81	36.60
Mixtral-8x22B-v0.1 (Jiang et al., 2024)	N/A	**72.51**	**31.10**	**9.20**	**50.00**
Mixtral-8x7B-v0.1 (Jiang et al., 2024)	N/A	30.82	<u>13.48</u>	1.92	<u>21.70</u>
Mistral-7B-v0.2 (Jiang et al., 2023)	N/A	<u>34.15</u>	2.80	0.38	9.55
Phi-3-mini4K-instruct (Abdin et al., 2024)	N/A	23.95	0.84	2.30	21.00
Openfunctions-v2 (Ji et al., 2024)	26.53*	25.28	3.84	<u>8.05</u>	15.75
Hermes-2-Pro-Mistral-7B (interstellarninja et al.)	**39.48**	27.94	3.29	0.77	12.78
Command R (Cohere and for AI, 2024)	28.29*	22.28	0.00	4.21	8.21
LLama2-70B (Touvron et al., 2023)	N/A	19.73	0.00	0.00	8.43
Llama2-13B (Touvron et al., 2023)	N/A	17.96	0.00	0.00	4.10
Llama2-7B (Touvron et al., 2023)	N/A	20.84	0.00	0.00	3.92

use. Among those that do, Hermes-2-Pro-Mistral-7B demonstrates strong tool-use performance. For models that do not support tool use, Mixtral-8x22B-Instruct-v0.1 performs surprisingly well in math and DAG-QA, demonstrating its strong reasoning and planning capability. Additionally, Phi-3 performs well in math considering its model size. The Llama2 family, however, struggles with challenging coding tasks.

4.2 Capability-centric Evaluation and Analysis

As introduced in Sec.3.1, we designed tasks to decompose core capabilities from standard evaluations, allowing MMAU to offer a unique dimension of evaluation. Each capability includes tasks spanning different domains. To provide overall capability-centric evaluation results for each model, we aggregate tasks under each capability using a weighted average. Detailed task-capability mappings and the calculation method can be found in Appendix A. The overall capability-centric evaluation results are shown in Table 3.

Notably, for the capability of Understanding, GPT-4o significantly outperforms other models, demonstrating its superior capability in handling long contexts, complex user instructions, and capturing (sometimes implicit) user intents. Additionally, GPT-4, Gemini-1.5-pro, and Claude3-Opus also exhibit reasonably strong understanding capabilities. For the capabilities of Reasoning and Planning, the GPT-4 family shows the strongest performance. When examining the capability of Problem-solving, the performance gap is not significantly large. This trend suggests that when provided with "oracle" plans, solving a task may be less challenging. While models' problem-solving capabilities vary, most can perform these tasks reasonably well, indicating that this capability may be more universally achievable among different models. On the contrary, for Self-correction, we observe a significant gap among models. Among open-source models, aside from Mixtral-8x22B, others do not seem to possess the skill to reflect on and correct their own errors effectively. These evaluation results highlight that self-correction is a critical capability needing further research and development to advance the field.

5 Analysis and discussion

How does planning impact the performance? One interesting finding emerges from the results of our designed tasks, `Planer-Shift` and `Solver-Shift` on Math. As shown in Table 7, we find that high-quality planning can boost performance for all models on Math. For example, Command R's performance increases from 8.21% to 33.33%, and Llama-2-70B's from 8.43% to 32.10%. Even already strong models, such as

[2]The current reported and documented prompt templates of these models do not support multi-tool execution. However, it can still be possible that models can call multiple tools with proper adaptation.

Table 3: Capability-centric evaluation results. All values are reported as percentages (%). Models that do not support tool use are labeled as N/A, while models not supporting multi-tool tool-use tasks are marked by *[3]. The bolded and underlined numbers indicate the 1st and 2nd highest performances in each category.

Model	Problem-Solving		Understanding	Reasoning	Planning	Self-correct	
	w/o Tool-Use	w/ Tool-Use				w/o Tool-Use	w/ Tool-Use
GPT-4o (OpenAI, 2024a)	**56.12**	**61.11**	**60.63**	50.47	47.90	**43.65**	51.56
GPT-4o-mini (OpenAI, 2024b)	49.12	56.51	52.62	41.23	23.19	27.53	40.66
GPT-4-Turbo (OpenAI et al., 2024)	48.07	58.29	49.78	**50.88**	**49.59**	40.86	**51.86**

Hermes-2-Pro-Mistral-7B (interstellarninja et al.)	29.26	**33.12**	16.54	25.95	24.96	2.04	2.99
Command R (Cohere and for AI, 2024)	22.17	31.30*	19.47	22.72	22.95	0.35	18.84*
LLama2-70B (Touvron et al., 2023)	24.23	N/A	6.32	15.30	14.55	0.34	N/A
Llama2-13B (Touvron et al., 2023)	12.86	N/A	2.69	13.39	13.15	0	N/A
Llama2-7B (Touvron et al., 2023)	15.92	N/A	2.38	14.25	13.26	0	N/A

Mixtral-8x22B, saw improvement from 50% to 60.02%. Interestingly, using the model itself as the planner also improves performance, e.g. bumping GPT-4o from 53.4% to 61.2%. This shows that explicitly instructing the model to first develop a high-level strategy and then solve the problem based on that strategy can be a promising approach to further enhance performance.

Do different capabilities present varying levels of difficulty for models to achieve? Our evaluation results reveal that different capabilities indeed present varying levels of difficulty for models to achieve. As what we mentioned in Sec. 4.2, problem-solving capabilities exhibit a smaller performance gap among models, suggesting that problem-solving is a more universally achievable capability across different models. However, self-correction capabilities present a significant challenge, with a notable performance gap observed among models, and many open-source models lacking effective self-correction skills. These findings suggest that while some capabilities like problem-solving are more readily attained by current models, others, such as self-correction and planning pose greater challenges and are vital areas for future advancements in the field.

Do balanced capabilities indicate the path to a generalist agent? From Figure 1, we observe that strong models, such as the GPT-4 family, exhibit balanced performance across all capabilities, demonstrating their robust and versatile nature. This balance indicates that improvements in one area likely enhance performance in others, highlighting a high correlation and interdependence among these capabilities. Conversely, models that perform poorly in one capability tend to struggle across the board, suggesting underlying weaknesses in their architecture or training strategy.

Are larger models always better? Another interesting finding arises when comparing the MistralAI families and Llama-2 families. For the MistralAI models, we consistently observe performance gains with increasing model size across domains. However, this trend does not apply to the Llama-2 families. In code-related domains (DS & ML, CodeContest), all size variants of Llama-2 perform poorly. Surprisingly, in the DAG-QA domain, the Llama-2-7B model performs better than its larger counterparts. This observation is consistent with findings from AgentBench (Liu et al., 2023d), further validating that training strategies and model architectures also influence the scaling law.

6 Conclusion

In this paper, we introduce the Massive Multitask Agent Understanding (MMAU) benchmark. By evaluating models based on both application scenarios and fundamental capabilities, MMAU provides a comprehensive and in-depth test bed for reliable and thorough studies. By designing 20 tasks to decompose capabilities beyond standard evaluation benchmarks, MMAU offers more granular insights into the strengths and limitations of these models.

A Experiment and dataset details

The key statistics of the MMAU dataset are presented in Tab. 4. A list of all evaluated models (commercial and open source) is provided in Tab. 5.

For our evaluations the open source models have been hosted via VLLM [4] on up to 8 NVidia A100 or H100 GPUs per model depending on the size. We have used the checkpoints from Huggingface for the open source models.

In order to have deterministic prediction we use a temperature of 0 and greedy search for all models and tasks.

[4] https://github.com/vllm-project/vllm

A.1 Tool-use

Data construction protocol: 1) The user sends a query to the agent model along with a list of potential functions including a description of their purposes and parameters. 2) The agent responds with either natural language or appropriate function use. 3) In case of function-call, the functions are invoked according to the agent's instructions, either by the user or directly by the agent, and the result is submitted back to the agent model. 4) The agent can then conclude with the given information or continue the conversation with follow-up questions or additional function calls.

Tool-use evaluation details: To compare the predicted and the ground truth parameter values, we perform string normalization including stripping punctuation, white spaces and converting to lower case. In some cases where the parameter value can have open-ended, semantically equivalent forms, we define example-specific match rules based on regular expressions to accommodate valid alternatives.

A.2 DAG QA

Data construction protocol: The query includes a description of the task (to choose the appropriate plan), a list of potential functions (including a description of their purposes and parameters), an enumeration of all possible plans (all possible sequences in which to execute the tools), and the task input (what the task is that the plan is expected to solve). The task is formulated as a multiple choice task, where at the end of the query, the agent is asked to end the reply with which plan it chooses. At evaluation, the chosen plan is then extracted from the output by searching for a string match of the requested response format. An example prompt is illustrated in Figure 12.

The reasoning and planning benchmarks differ only in the prompt, where for reasoning, the agent is requested to "elaborate on the thought process and reasoning", while for planning, the agent is requested to "be concise with a response in the format Chosen Plan: N".

A.3 Kaggle

: To represent all results on the same scale and reduce confusion, when QA model is not multimodal, we report its performance as $\text{ratio_of_text_based_questions} * \text{accuracy_on_text_based_questions} =$

Table 4: The key statistics of MMAU.

$(207/328) * \text{accuracy_on_text_based_questions}$. We set the temperature to 0 for both code generation and QA.

A.4 Contest-level Coding

We select 261 valid problems from the Valid and Test splits of the CodeContests dataset (Li et al., 2022), each contains a number of test cases, including public tests, private tests, and generated

tests.

E2E Standard. The agent is asked to solve the problem by generating Python code solution. The prompt contains a detailed description of the CodeContests problem with public test examples, as well as basic instructions on code formatting following the baseline prompt design in (Ridnik et al., 2024). The generated code solution will be compiled and executed on all test cases, and is considered correct only if all test cases are passed. Following related works, we report the pass@5 score, which is the percentage of problems solved by generating 5 solutions per problem. We set temperature as 0.3 for all models.

Problem Parsing. We design a ProblemParsing task for each CodeContests problem, which provides the agent with the problem description and public test examples, and asks the agent to directly infer the desired output for an unseen test case. To make the unseen test case relatively easy for parsing and computation, we select the shorted test case from the union of private test cases and generated test cases. We adopt a chain-of-thought prompt to help the LLM agent understand the problem (see Appendix B for detailed prompts). We then compare the answer with the groundtruth output, and derive the accuracy over the entire dataset. For reproducibility, we set temperature as 0 for all models.

Planner-shift. As introduced in 3.2.3, we divide the code generation process for CodeContests problems into two steps: generating a plan (i.e., planner) and generating code solutions (i.e., solver). We evaluate the planning capability of LLM agents by fixing the solver to be the same strong model. For each LLM model, we generate 1 plan with temperature 0, and use gpt-4-0125-preview as the solver to generate 5 code solutions (with temperature 0.3) and calculate the percentage of solved problems.

Solver-shift. SolverShift complements PlannerShift by freezing the planner and evaluating the problem-solving capability of various LLM models. Given 1 plan generated by gpt-4-0125-preview, we let LLM agents generate 5 code solutions and calculate the percentage of solved problems.

Self-correction / Retry. We also evaluate the self-correct capability of LLM agents on the CodeContests problems. For the Regular task above, we collect the error messages of each candidate solution if it does not pass some test cases, including 4 types of errors: empty solution, compilation error, runtime error, and wrong outputs. For the problems where all the 5 candidates fail to pass, we will append the error content as a feedback user message in the message list, and ask the LLM to try again. To encourage the agent to retry, we also prepend an additional system instruction to the first user message before describing the problem. The evaluation metric is also pass@5.

A.5 Math

Given a set of seed math problems S, we first employ a LLM as the judger M_J to determine the difficulty level for each problem, resulting in a labeled math problem set $S' : \{s_i^d\}$. We then select a subset containing only the mathematically simpler problems, i.e., $S'' : \{s_i^d, d \leq \theta\}$. As a result we have a curated "simple" math problem set S'' (672 problems). Next, we use another LLM M_w (GPT-4 (Achiam et al., 2023)) to create new math problems that feature more complex descriptions or harder problem statements but retain the same underlying mathematical constructs for each data sample $S''' : \{M_w(s_i^d), d \leq \theta\}$. A rewrite math problem example is shown in Fig. 11. Finally, to ensure that each rewritten problem in S''' remains valid and has the same ground truth answer as S, we perform a data curation stage. As a result, we finalize the problem set $\mathcal{S}^*$ for the `Comprehend+` task.

B Prompt templates

B.1 Tool-use

For tool use the concrete prompts are generated by the model to transform the tool definitions as well as the predicted tool calls and tool results into the concrete prompt. Therefore, we don't report concrete prompt here. Samples from the dataset are show in Figs. 8, 9, and 10.

B.2 Self-correction tool-use

To encourage models to retry, we prepend the following system message to the user's first turn message:

Listing 1: Tool-Use Retry Prompt

```
A conversation between a user and a
helpful assistant. The assistant can
choose to directly generate text or make
 function calls to help with user
queries. Retry the call if it does not
succeed or if there are errors in the
previous calls or responses.
```

B.3 DAG

Listing 2: DAG Reasoning Prompt

```
Choose the appropriate plan with its
associated set of tools to accomplish a
specific task.

Each tool's functionality is using Open
API schema notation.

"[A B]" indicates that tools A and B can
 operate concurrently without any
interdependencies.
"A -> B" indicates that tool A must be
executed prior to tool B, as B's
operation is contingent upon the output
from A.
"B -> A" indicates that tool B must be
executed prior to tool A, as A's
operation is contingent upon the output
from B.
"[A B] -> C" indicates that tools A and
B will be executed in parallel initially,
 followed by tool C, which requires the
outputs from both A and B.

Below is a compilation of all available
tools, described in JSON format:

{tool_descriptions}

Here are all possible plans:

{possible_plans}

Task Input:

{task_input}

Feel free to elaborate on your thought
process and reasoning.

Please strictly end the reply with "
Chosen Plan: N", where "N" must be an
integer number of the selected plan.
Do not change the answer format to other
 words and MUST include Chosen Plan:
```

Listing 3: DAG Planning Prompt

```
Choose the appropriate plan with its
associated set of tools to accomplish a
specific task.

Each tool's functionality is using Open
API schema notation.

"[A B]" indicates that tools A and B can
 operate concurrently without any
interdependencies.
"A -> B" indicates that tool A must be
executed prior to tool B, as B's
operation is contingent upon the output
from A.
"B -> A" indicates that tool B must be
executed prior to tool A, as A's
operation is contingent upon the output
from B.
"[A B] -> C" indicates that tools A and
B will be executed in parallel initially,
 followed by tool C, which requires the
outputs from both A and B.

Below is a compilation of all available
tools, described in JSON format:

{tool_descriptions}

Here are all possible plans:

{possible_plans}

Task Input:

{task_input}

Be concise with a response in the format
 "Chosen Plan: N", where "N" represents
the number of the selected plan.
```

B.4 Data Science and Machine Learning

Listing 4: DS & ML Code Generation Prompt

```
You are a helpful code assistant that
will help users analyze data and
answering multiple choice questions
based on the data analysis.
You will be provided with a Jupyter
notebook file (.ipynb) containing code
cells and markdown cells.
A list of data files used in the
notebook will also be provided.
The notebook would contain a code
interpreter style conversation between a
 user and an assistant.
User would be asking questions, follow
up with additional requests, and
providing clarification for requests.
Assistant would be analyzing data with
code interpreter, providing insights
into data based on analysis results and
diagrams, and responding to user
inquiries.

Your task is to address the user's
request in the last markdown cell of the
 notebook AND answer the multiple choice
 questions based on the data analysis.
You will first append an appropriate
code cell to the notebook to address the
 user's request.
You will then be provided with the
execution results of the code cell.
Based on the results, you will answer
the multiple choice questions.

For example, given

Data Files:
['../input/pokemon/pokemon.csv']

Notebook:
{"cells": [{"cell_type": "markdown", "id
": "188d8f78", "metadata": {}, "source":
 ["**user**\n", "\n", "Can we start by
```

```
loading the Pok\u00e9mon dataset and
displaying the first few rows?"]}, {"
cell_type": "markdown", "id": "41316f22",
 "metadata": {}, "source": ["**assistant
**\n", "\n", "Absolutely, let's load the
 Pok\u00e9mon dataset using pandas and
display the first three rows."]}, {"
cell_type": "code", "execution_count": 1,
 "id": "d07755b0", "metadata": {"
execution": {"iopub.execute_input":
"2024-04-12T14:11:29.209092Z", "iopub.
status.busy": "2024-04-12T14
:11:29.207876Z", "iopub.status.idle":
"2024-04-12T14:11:30.934431Z", "shell.
execute_reply": "2024-04-12T14
:11:30.932965Z"}}, "source": ["\n", "
import pandas as pd\n", "\n", "# Load
the Pok\u00e9mon dataset\n", "pokemon =
pd.read_csv(\"../input/pokemon/pokemon.
csv\")\n", "pokemon.head(3)\n", " "]}],
"metadata": {"language_info": {"
codemirror_mode": {"name": "ipython", "
version": 3}, "file_extension": ".py", "
mimetype": "text/x-python", "name": "
python", "nbconvert_exporter": "python",
 "pygments_lexer": "ipython3", "version":
 "3.11.8"}}, "nbformat": 4, "
nbformat_minor": 5}

User Request:
I'm interested in visualizing the
frequency of Pok\u00e9mon by their
primary type. Can you help with that?

You will respond with markdown cell and
code cell to address the user's request:
[{"cell_type": "markdown", "metadata":
{}, "source": ["**assistant**\n", "\n",
"Sure thing! Let's create a bar chart to
 visualize the frequency of Pok\u00e9mon
 by their primary type."]}, {"cell_type":
 "code", "metadata": {}, "source": ["\n",
 "import matplotlib.pyplot as plt\n", "\
n", "# Frequency of Pok\u00e9mon by
their primary type\n", "pokemon['type1'].
value_counts().plot.bar()\n", "plt.title
('Frequency of Pok\u00e9mon by Primary
Type')\n", "plt.xlabel('Primary Type')\n
", "plt.ylabel('Frequency')\n", "plt.
show()\n", " "]}]

Then, you will be provided with the
execution results of the code cell and
multiple choice questions based on the
results:

Execution Output: # the images would be
attached in the same order as the image
placeholders
[{"data": {"image/png": "<image_1>"}, "
execution_count": 1, "metadata": {}, "
output_type": "display_data"}]

Questions:
[{"question": "Which primary type of Pok
\u00e9mon has the highest frequency
according to the chart?", "choices": {"A
": "Rock", "B": "Water", "C": "Fire", "D
": "Grass"}}, {"question": "What type of
 Pok\u00e9mon is least frequent as per
the visualization?", "choices": {"A": "
Ghost", "B": "Fairy", "C": "Ice", "D": "
Dragon"}}, {"question": "According to
the bar chart, which primary type has
more Pok\u00e9mon than Fairy but fewer
than Fire?", "choices": {"A": "Electric",
 "B": "Grass", "C": "Ice", "D": "Dragon
"}}, {"question": "What primary type
appears more frequently than 'Rock' but
less than 'Grass' according to the
visualization?", "choices": {"A": "Ghost
", "B": "Poison", "C": "Flying", "D": "
Bug"}}]

You will then provide the answers to the
 multiple choice questions:
["B", "B", "C", "B"]

You MUST exactly follow nbformat
structure when generating markdown and
code cells.
You are only allowed to use the
following math and visualization
packages: numpy, pandas, scipy, scikit-
learn, sympy, statsmodels, matplotlib,
seaborn, plotly, wordcloud. Python
standard library is also allowed. Make
sure to import the necessary packages in
 the code cell.
You MUST answer in a list of uppercase
single letter strings for multiple
choice questions.

Now, given the following notebook and
user request, respond with a list
containing a markdown cell and a code
cell to address the user's request:

Data Files:
{data_files}

Notebook:
{notebook}

User Request:
{user_request}

You MUST exactly follow nbformat
structure when generating markdown and
code cells.
Respond ONLY with the cells in json
format. DO NOT say anything else or put
it in a ```json``` code block.
You are only allowed to use the
following math and visualization
packages: numpy, pandas, scipy, scikit-
learn, sympy, statsmodels, matplotlib,
seaborn, plotly, wordcloud. Python
standard libraries are also allowed.
Make sure to import the necessary
packages in the code cell.
```

Listing 5: DS & ML QA Prompt

```
Given the following execution output and
 multiple choice questions, respond with
 the answers to the questions:
```

```
Execution Output:
{execution_output}

Questions:
{questions}

You MUST answer in a list of uppercase
single letter strings for multiple
choice questions.
```

Listing 6: DS & ML Execution Feedback Prompt

```
Your code execution failed. Please check
 the error message below and try again:

{error_message}

You MUST exactly follow nbformat
structure when generating markdown and
code cells.
Respond ONLY with the cells in json
format. DO NOT say anything else or put
it in a ```json``` code block.
You are only allowed to use the
following math and visualization
packages: numpy, pandas, scipy, scikit-
learn, sympy, statsmodels, matplotlib,
seaborn, plotly, wordcloud. Python
standard libraries are also allowed.
Make sure to import the necessary
packages in the code cell.
```

B.5 Contest-Level Coding

Listing 7: CodeContests E2E Standard Prompt

````
You are an AI with advanced code
generation capabilities.

When you encounter a specific problem (
labeled #PROBLEM#), your goal is to
produce a valid python code that
correctly solves the problem.
Make sure to fully address the problem
goals following the rules and
constraints.
The code should be robust and general.
It should output correct answers under
any valid inputs, not only just the
example inputs given in the problem
description.

#PROBLEM#:
{description}

The code output must follow this
structure:
```
def f1(...):
    ...
    return ...

def f2(...):
    ...
    return ...
...

if __name__ == "__main__":
    ...
```
The code should read the input using the
 'input()' method. Make sure to properly
 parse the input, according to the
problem description.
The output should be printed without
additional words using the 'print()'
method.

#ANSWER#:
```python
````

Listing 8: CodeContests Problem Parsing Prompt

```
You are an AI with advanced
comprehension capabilities, akin to that
 of humans. This enables you to
understand complex instructions, discern
 the user's intent, and apply logical
reasoning across a variety of scenarios
effectively.

When you encounter a specific problem (
labeled #PROBLEM#) along with a relevant
 example input (referred to as #TEST
CASE#), your goal is to deduce the
correct answer (#ANSWER#).

Please adhere to the following format:
First, express your #THOUGHTS# to
reflect your understanding of the
problem and test case. Keep your #
THOUGHTS# concise, not exceeding 5
sentences.
Then, provide your #ANSWER# to the
problem.
For example, your output can be:
#THROUGHTS#:
The problem is about ... The test cases
are ...
#ANSWER#:
1 2
3 4

Here is the problem.

#PROBLEM#:
{description}

#TEST CASE#:
{inputs}

Now, please provide the #THOUGHTS# and #
ANSWER# sections. Do not include
additional explanations or reasoning
processes.
#THROUGHTS#:
```

Listing 9: CodeContests Planner-shift Prompt

```
You are an AI with advanced code
understanding and planning capabilities.

When you encounter a specific problem (
labeled #PROBLEM#), your goal is to
devise a structured and executable plan
to solve the problem.
```
```

````
Your plan should clearly outline the
logical steps needed to address the
problem, breaking down complex processes
 into manageable actions.
It's crucial that each step is
straightforward enough to be easily
translated into executable code or
functions by a Language Model (LLM).
Keep the plan simple and focused,
avoiding unnecessary complexity to
ensure ease of implementation.

#PROBLEM#:
{description}

#GENERATED PLAN#:
````

Listing 10: CodeContests Solver-shift Prompt

````
You are an AI with advanced code
generation and instruction following
capabilities.

When you encounter a specific problem (
labeled #PROBLEM#) and a solving plan (
labeled #PLAN#), your goal is to produce
 a valid python code that correctly
solves the problem.
Make sure to fully address the problem
goals following the rules and
constraints. Refer to the plan to
generate the code.
The code should be robust and general.
It should output correct answers under
any valid inputs, not only just the
example inputs given in the problem
description.

#PROBLEM#:
{description}

#PLAN#:
{plan}

guidelines:
- Generate only code, without any
additional explanations or comments.
- Make sure to include all the necessary
 module imports, properly initialize the
 variables, and address the problem
constraints.
- The code needs to be self-contained,
and executable as-is.

The code output must follow this
structure:
```
def f1(...):
    ...
    return ...

def f2(...):
    ...
    return ...
...

if __name__ == "__main__":
    ...
```
The code should read the input using the
 'input()' method. Make sure to properly
 parse the input, according to the
problem description.
The output should be printed without
additional words using the 'print()'
method.

answer:
```python
````

B.6 Mathematics

Listing 11: Math Generation Prompt

````
You are an AI with advanced
comprehension capabilities, akin to that
 of humans. This enables you to
understand complex instructions, discern
 the user's intent, and apply logical
reasoning across a variety of scenarios
effectively.

When you encounter a specific problem (
labeled #PROBLEM#), your goal is to
deduce the correct answer (#ANSWER#).

Please adhere to the following format:
First, express your #THOUGHTS# to
reflect your understanding of the
problem. Keep your #THOUGHTS# concise,
not exceeding 5 sentences.
Then, provide your #ANSWER# to the
problem.
For example, your output can be:
#THROUGHTS#:
Let's think step by step ...
#ANSWER#:
12

Here is the problem.

#PROBLEM#:
{description}

Now, please provide the #THOUGHTS# and #
ANSWER# sections. Do not include
additional explanations or reasoning
processes under #ANSWER# section.
#THROUGHTS#: Let's think step by step:

#ANSWER#:
````

Listing 12: Math Evaluation Prompt

````
As a math expert, you will be provided
with three items: a #Question#, an #
Answer#, and the #Ground Truth#.
Your task is to determine whether the #
Answer# matches the #Ground Truth#.
You need to considering mathmetical
theorems when verifing the answer. For
example, '$(c + 9)(c - 4)$' and '(c - 4)
*(c + 9)'should be
the same expressions based on
factorization theorems.
If they align, respond with 'correct'.
If they do not, respond with 'wrong'.
Ensure that your #Response# is the final
 line and consists solely of the word '
````
````

```
correct' or 'wrong', without any
additional commentary or explanation.

#Question#:
{question}

#Answer#:
{answer}

#Ground Truth#:
{ground_truth}

#Response#:
```

Listing 13: Math Planning Prompt

```
You are a math planner.
Given a problem description, your goal
is to devise a structured and executable
 plan to solve the problem.
Your plan should clearly outline the
logical steps needed to address the
problem, breaking down complex processes
 into manageable actions.
It's crucial that each step is
straightforward enough to be easily
translated into executable calculation
or functions by a Language Model (LLM).
Keep the plan simple and focused,
avoiding unnecessary complexity to
ensure ease of implementation.

Generated plan:
```

C More evaluation results

For domain-centric evaluation, we chose tasks that rely solely on the evaluation model to solve them end-to-end and adhere to the standard setup used in the field. This ensures that the domain-centric results accurately reflect the most standardized evaluation outcomes, making it easier to compare performance across different benchmarks. Specifically, we use the evalution results of `E2E standard` task as domain evaluation results for Contest-level coding, DS&ML, Math and DAG-QA. For Tool-use, we report the weighted average of single-, parallel-, and multi-turn multi-tool-use tasks. The results are shown in Table 2.

Detailed tool use results are reported in Table 8.
