0. Introduction

The Praguian approach to formal description of language (in detail, see Sgall et al. 1986), works with dependency syntax and includes the topic-focus articulation into the (underlying, tectogrammatical) syntactic representations of sentences, using the left-to-right order of the nodes of the dependency tree for that purpose. The edges of the tree denote the dependency relations and the nodes carry complex labels indicating their lexical and morphological values (e.g. Preterite). No nonterminals and no nodes corresponding to function words (auxiliaries, prepositions, conjunctions, articles) are present in the tree. Counterparts of function words (and function morphemes) are parts of the complex symbols of the nodes. Instead of using the notion of phrase, we work with subtrees (i.e. the governor and its dependents, or all its subordinate nodes, where "subordinate" is the transitive closure of "dependent").

The present paper concentrates on a motivating discussion pointing out the reasons for distinguishing three layers of the order of lexical occurrences (Sect. 1), presenting a characterization of movement rules (Sect. 2), discussing certain relevant relationships between the level of syntax and that of morphemics (Sect. 3), and sketching a possibility how to proceed from surface (morphemics) to (underlying) syntax (Sect. 4). A way how to formalize the description of (underlying) syntactic structure is briefly outlined in Section 5.

1. Three layers of word order

1.1 As has been argued in detail in Sgall et al. (1986), there are good reasons (concerning the semantic relevance as well as syntactic constraints of the topic-focus articulation, see below) to distinguish three layers of the order of the occurrences of lexical (autosemantic) items in the sentence:

(i)   the surface word order, which can be understood as the order of items on the level of morphemics; on that level the sentence representation has the shape of a string of word-forms (rather than that of a tree);

(ii)   the communicative dynamism (underlying word order), i.e. the order of nodes in an underlying (tectogrammatical) representation (TR), which has the shape of a dependency tree; the topic of the sentence is characterized as consisting of items which are less dynamic than those belonging to its focus; thus, if A belongs to the topic in all TRs of a given sentence S and B belongs to the focus in some of the TRs of S, then A is less dynamic than B;

(iii) the systemic ordering of valency slots (kinds of dependency relation), which is specified in the valency frames (included in the lexical entries), see Sgall et al. (1986), Sgall (in press).

Let us illustrate the mentioned three layers by the following example (with the capitals denoting the intonation center of the sentence):

(1) My sister was visited by a painter in PARIS last week.

A difference between (i) and (ii) - the surface word order and the communicative dynamism - concerns here the fact that the most dynamic item (the bearer of the intonation center) does not occupy its prototypical position at the end of the sentence. Since the temporal adverbial at the end follows the intonation center, it can only be understood as belonging to the topic of the sentence, i.e. as less dynamic than the focus. Let us assume that the preferred reading of (1) - see Fig.1 - can be paraphrased as "As for the last week in my sister's life, (she) was (then) visited by a painter in Paris"; the order of the valency slots (the communicative dynamism) of the (tectogrammatical) syntactic tree representing this reading is, in ascending order, Patient (Objective) - Temporal-when - Actor - Locative (with the Patient being the least dynamic item, i.e. the topic proper, and the verb being less dynamic than the Actor and more dynamic than the temporal adverbial).

visit.Pret

sister.Pat   week.Temp-when painter.Act   Paris.Loc

l.Appurt   last.Restr

Fig. 1. A simplified TR of the sentences (1) and (2).

As a matter of fact, another surface order corresponding to this underlying tree may be that of (2):

(2) Last week, my sister was visited by a painter in PARIS.

The relationship between (ii) and (iii) is reflected in (1) by the fact that the above mentioned ascending order of valency slots is in accordance with the systemic ordering within the focus (Actor preceding Locative), while this is not the case with the position of Actor with regard to the two valency slots in the topic: Actor follows both Temporal and Objective, although the systemic ordering of these three

valemcy slots is Temporal - Actor - Objective (see Hajičová and Sgall 1987; Hajičová 1991). This difference is determined by the fact that the parts of the topic are less dynamic than those of the focus, even if the degrees of dynamism are then not in accordance with systemic ordering. The restriction that the communicative dynamism within the focus part of the sentence is in accordance with systemic ordering, is crucial for the specification of syntactic representations, as will be seen in paragraph (ii)(b) in Sect. 5.3.

1.2 The differences in communicative dynamism are relevant not only for the appropriateness of the use of the given sentence in this or that context, but also semantically, even in the narrow sense of differences in truth conditions. This clearly concerns sentences with certain kinds of complex quantification, such as (3), but also sentences without such (overt) quantifiers, such as (4) - (7) (I mostly use examples taken from earlier linguistic discussions):

(3) (a) Two languages are known by everybody in this ROOM.
   (b) Everybody in this room knows two LANGUAGES.

(4) (a) He wrote his dissertation on SUNDAYS.
   (b) On Sundays he wrote his DISSERTATION.

(5) (a) I exercise in the MORNINGS.
   (b) In the mornings I EXERCISE.

(6) (a) John saw an EXPLOSION.
   (b) Mary saw an EXPLOSION.
   (c) John and Mary saw an EXPLOSION.

(7) (a) An explosion was seen by JOHN.
   (b) An explosion was seen by MARY.
   (c) An explosion was seen by JOHN AND MARY.
   (d) An EXPLOSION was seen by John and Mary.

With (6c) John and Mary could have seen different explosions, which is not the case with (7c), at least on the preferred reading. It is worth noting that the mere change of the position of the intonation center in (7d) gives a reading different

from (7c), namely the same reading as that of (6c).

Examples in which the degrees of dynamism within topic are relevant can be presented e.g. from Czech:

(8) (a) Tady byla loni   MILENA.
       here was last-year Milena
       E. Here was MILENA last year.
    (b) Byla tady loni   MILENA.
        was here last-year Milena
        E. Last year, MILENA was here.

While (8a), with 'tady' [here] in the position of topic proper (i.e. the least dynamic word), which may carry a (contrastive) phrasal stress, can be paraphrased as "The place we are now is where MILENA was last year", (8b) means "It happened that MILENA was here (not necessarily in the place we are now, but in a broader sense) last year."

In the sequel, we argue first for the usefulness to work with movement rules between syntax and morphemics (Section 2), we characterize our approach to these two levels of grammar (Section 3), focussing then on the transition from morphemics to syntax (Section 4) and on a formal specification of syntactic (tectogrammatical) representations and their transduction to morphemic ones (Section 5).

2. Movement rules

The examples from Section 1 show that it is necessary to work with an order of items also in the (underlying) syntactic representation. This is much easier with dependency syntax than with the constituency based descriptions where order is handled as closely connected with the determination of syntactic relations. However, it is impossible to straightforwardly copy in these representations the surface order, due to the differences between these two layers, as illustrated in 1.1 above, in the discussion of example (1).

These differences may be described by means of movement rules, or perhaps e.g. of numerical indices for underlying positions and of specific topic and focus slots, as Starosta (1993; in press) proposes. It would deserve a systematic investigation to find whether such an approach allows to account in a natural way not only for

the subtle relationships between surface word order, communicative dynamism and the systemic ordering, but also for those concerning the different positions of quantifiers or of 'focalizers', cf. Hajičová et al. (in press). Of course, an important methodological requirement is to minimize the number of movement rules, and of all distinctions between morphemic strings and syntactic representations, be they treated as constituting two layers of description or as corresponding to different subsets of symbols within complex node values. In any case, at least the following issues have to be accounted for, and we indicate below how this can be done by means of movement rules (cf. Sect. 5.4):

(a) Sentences with a secondary (other than rightmost) placement of the intonation center, which marks the position of focus, cf. (1) and its TR in Fig. 1 above; see also (7d); for Czech, the rule may transfer the rightmost item of the TR to the leftmost position, marking the moved item as the bearer of the intonation center of the sentence (which then, in phonemics, gets a falling stress).

(b) Grammatically determined positions of verbs, adjectives, clitics, and so on, in different languages; the adjective primarily is more dynamic than its head noun, but it is placed to its left in English surface word order; in Czech clitics usually are placed in the "second" (Wackernagel's) position, even if they depend on an infinitive standing after the main verb:

(9) Martin mi   ji   tu   chtěl UKÁZAT.
    Martin to-me her here wanted to-show
    E. Martin wanted to SHOW me her here.

chtěl.Pret

Martin.Act   ukázat.Pat

mi.Addr   ji.Pat   tu.Loc

Fig. 2. A simplified TR of sentence (9).

This also concerns other dependents of an infinitive, if they belong to the topic:

(10) Martin mi Milenu zamýšlel UKÁZAT.
Martin to-me Milena$_{Acc}$ intended to-show
E. Martin intended to SHOW me Milena.

Wackernagel's position, into which the moved items usually are placed, is the position just after the leftmost node of the uppermost part of the tree (and, if the leftmost node differs from the verb, also after all nodes subordinated to the leftmost one).

(c) Positions of function words (articles, prepositions, conjunctions, auxiliaries), which need not have any nodes as their underlying counterparts (just indices within node labels, see Section 4 below): in the morphemic string (i.e. in the surface word order) they are usually placed at the beginning of their word groups; the rules describing these movements are to be combined with changing the indices in the complex node labels into symbols of articles, prepositions, etc.

(11) Jim visited me, since he wanted to ask me for ADVICE.

(d) Also other cases of apparent non-projectivity (i.e. peripheral, strongly limited cases) can be described by movement rules concerning morphemics:

(12) I met a man yesterday, who asked me for your ADDRESS.
The order in the TR: I - yesterday - met - a man, who... (see Fig. 3).

(13) a larger town than Boston:
The order in the TR: larger - than Boston - town.

The use of movement rules, rather than of numerical indices for underlying positions enables us to work with perspicuous syntactic representations reflecting all the differences illustrated in the above quoted examples, including an economical handling of systemic ordering and dynamism.

Even when attempting at a monostratal description, it is always necessary to distinguish between morphemics and syntax, e.g. by using abstract symbols in the complex labels of nodes;

thus, also with such an approach the problem stressed by Starosta (1993) is still present, namely the danger that abstract symbols might get too far from the empirical properties of language. As mentioned in Section 2 above, the requirement of the minimalization of the number of rules (or symbols) is to be given due attention.

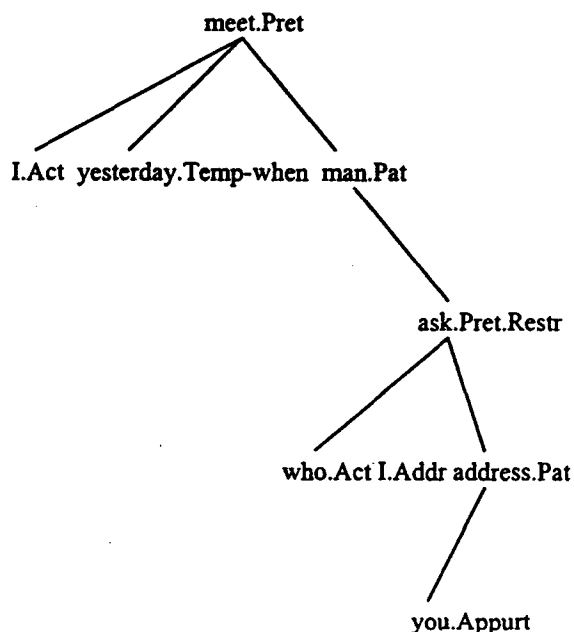

Fig.3. A simplified TR of sentence (12).

3. Syntax and morphemics

Using movement rules to describe relationships between syntax and morphemics makes it possible to treat these two levels apart, with simple strings of (complex) symbols as morphemic representations, and trees (or more complex networks) as syntactic ones. It is necessary to distinguish these two levels at least for two reasons:

(i) the relation between a function word and its autosemantic 'partner' differs essentially from the dependency relation: a preposition or article cannot occupy any other position than that of accompanying a noun; an auxiliary or (typically) a conjunction always accompanies a verb; in this point they are similar to endings, rather than to adjuncts; it is essentially more economical to have just

indices in complex node labels than large numbers of nodes;

(ii) to work with a node for every surface lexical occurrence (and to use no other nodes) is difficult, not only with respect to the description of deletions of different kinds, but first of all with surface word forms such as French *du, au,* or German *zum, beim*; these forms show that the boundary between surface word forms is not reliable. Such cases can be found in many languages, cf. e.g. in Czech the conjunction *-li* 'if' (occurring only after a verb form and attached to it by a hyphen, so that the intermediate position between a function word and a suffix of the verb is clearly manifested), or the clitic *s* (auxiliary of the 2nd Person Sing. Preterite), written together with (any!) preceding word form, not only after a verb as in *dostals* 'you got' or after the subject pronoun as in *tys DOSTAL* 'you GOT', but also e.g. after the object noun as in *knihus DOSTAL* 'you GOT the book'.

4. From surface (morphemics) to (underlying) syntax

In the primary unmarked situation, morphemes (endings, prepositions, other function words) express dependency relations and values of morphological categories (number, definitness, tense, aspect, modalities, degrees of comparison), whereas surface (morphemic) word order expresses the basic scale of the topic-focus articulation, i.e. that of communicative dynamism. Prototypically these two orders are identical, the differences - described by movement rules - are relatively rare and can be described by a limited number of rules.

The core of the transition from morphemic strings to syntactic representations (preliminary formulations of implemented procedures for which can be found with Kirschner 1987; Hajičová et al. 1994) then is to describe the transition from endings and function words to their functions. Thus, a Genitive typically depends on the adjacent noun, a prepositional group usually expresses an adverbial (dependent on the verb), prepositions have either their primary 'meanings', as e.g. E. *with*: Accompaniment or Means, *from*: Directional.1,

through: Directional.3, or they have their syntactic functions (they express certain kinds of dependency relation; perhaps it would be more exact to see dependency as a family of relations) - *to*: Addressee, *by*: Actor with Passive.

Another part of the task is to proceed from surface word order and certain properties of sentence prosody (positions of the intonation center or the main stress of the sentence, and of phrasal stress) to the scale of dynamism. In non-prototypical (not just marginal) cases the word order expresses syntactic (dependency) relations. Among such cases there is the English 'configurationality' with the order Actor, verb and Objective; however, even in English, as soon as other kinds of the dependency relations are encountered, it is necessary to take morphemes into account (in English - prepositions, see above; in most Continental languages - case endings; in the agglutinating languages of Asia and other regions - suffixes; verb categories are practically always expressed by morphemes, etc.).

Furthermore, it is necessary to restore the deleted items; this task has often been discussed with different frameworks, but an adequate solution still seems to be connected with many open questions. One of them is that it is not easy to draw the boundary line between those cases in which the deleted lexical unit is to be inserted as such, and cases in which just an anaphoric or indexical item is appropriate. The former case clearly concerns at least the basic kinds of coordination deletion (e.g. with *blue and yellow flag* it is appropriate to restore *blue flag* in the TR). The latter case can be illustrated by the deleted Directional with *George has arrived on Sunday* - either *here* or *there* is present in the TR, i.e. the sentence is ambiguous in this point.

5. Formalisation of dependency syntax

5.1 A descriptive framework meeting the conditions specified in the preceding sections can now be briefly characterized. We present first an illustration of how the complex tectogrammatical networks can be formally described (Sect. 5.1), then we characterize the form of a lexical entry (5.2) and proceed to a brief sketch of a specification of the set of TRs (5.3), adding a partial illustration of movement

rules used in transducing TRs to morphemic representations (5.4).

A dependency tree is not sufficient, since it cannot reflect the complex relationships between dependency and coordination, if we do not want to neglect the difference between the binary dependency relations and the coordinated (and appositional) constructions having an indefinite number of members. However, even a network with a greater number of dimensions, which in this sense can serve as the shape of a TR, can be formally described in the form of its one-to-one linearization (see Petkevič 1995; Sgall 1997), cf. examples (14) and (15); every dependent item or group is enclosed in a pair of parentheses and the subscripts, indicating the dependency relations, are placed at the parenthesis that is closer to the head and can be read as Restrictive (adjunct), Directional, Appurtenance (broader than just possession); Conjunction is understood as a kind of coordination:

(14) My younger brother arrived there YESTERDAY.

(14') $((my)_{Restr}$ $(younger)_{Restr}$ $brother)_{Act}$ arrive.Pret $(_{Dir}$ there$)$ $(_{Temp}$ yesterday$)$

(15) Mary and John, our neighbors, who are a nice pair, ARRIVE.

(15') $(((Mary$ $John)_{Conj}$ $(we)_{Appurt}$ $neighbor)_{Appos}$ $(_{Restr}$ $(Rel)_{Act}$ be.Pres $(_{Obj}$ $(nice)_{Restr}$ $pair)))_{Act}$ $(here)_{Dir}$ arrive.Pres

5.2 The relationship between lexical and grammatical information can be characterized by including much of grammatical information in the lexicon (especially in the valency frames or grids). The lexical entry contains the following parts:

(a) the lexical meaning, which itself has its internal structure; in the cases of lexical ambiguity there are several representations, i.e. several lexical units;

(b) the slots for values of relevant grammatical categories, i.e. of grammatemes; while e.g. gender with nouns is specified here, other grammatemes (number and definiteness with nouns, or tense, aspect, modalities with verbs, degrees of comparison with adjectives) get their values only for individual occurrences of the word forms in discourses;

(c) the valency frame: optional and obligatory dependents are ordered in accordance with systemic ordering; arguments or 'inner participants' (occurring at most once with a head node) and obligatory adjuncts are indicated (e.g. *arrive at a place, behave somehow, last how long,...*); optional adjuncts may be indicated by lists concerning individual word classes; surface deletability is indicated (e.g. Directional.2 with *to arrive* is deletable, Objective with *to meet* is not (*We met there* is a case of reciprocity, rather than of deletion); further data concern an optional or obligatory controller (e.g. Actor is an obligatory controller with *to try*, an optional one with *to decide*; Addressee is an optional controller with *to advise, to forbid*), the dependent's ability to occupy certain syntactic positions (e.g. of Subject with Passivization, of a *wh*-element) or to constitute barriers for movement, and subcategorization conditions.

5.3 The class of syntactic representations can be specified by means of a small number of general principles describing the core of grammar and by specific rules for peripheral patterns.

The general part of this specification can have the shape of a generative procedure (first formulated by Hajičová et al. 1991):

(i) generate a node:

(a) create the node either as the root of the representation, or as a node dependent on another one and placed to the right of all its sister nodes;

(b) choose its lexical value and the values of its grammatemes, taking into account (by unification) the subcategorization conditions of the mother node and the restrictions on the combinations of grammatemes as specified in the lexical entry of the head or in the data concerning the respective word class;

(c) if a root is being generated, its grammatemes determine it as a finite verb form; it may be denoted as CB, contextually bound, in topic (otherwise it is non-bound,

54

in focus); the node that has just been generated is considered as node *n* in the next step;

(ii) if the frame of node *n* contains a complementation, then it is possible to generate

(ii) (a) either a left daughter of *n*, assign it 'CB' and a complementation value chosen from the frame of n,

(ii) (b) or a right daughter of *n*, and assign it a complementation value from the left end of *n*'s frame (this ensures that the underlying order of the complementations in the focus part of the sentence will obey the systemic ordering, see the end of Sect. 1.1 above).

NOTE: If the chosen complementation value is an inner participant, it is deleted in the frame of *n* (as saturated); "from the left end" means that optional complementations can be skipped and deleted in the frame of *n*.

(iii) if the frame of *n* contains no complementation, then the mother node of *n* is considered as node *n*; if no mother node is present, the procedure (generating the tree from the top down and from the left to the right) is finished;

(iv) only representations containing a focus are accepted, i.e. only those whose branch going from the root to the rightmost daughter of the rightmost daughter of ... of the root includes a non-bound node.

A declarative specification of the syntactic representations is well possible, if the concept of unification is so complemented as

(a) to distinguish saturated items (cf. the Note above) and

(b) to check the correspondence of the order of non-bound sister nodes with the systemic ordering.

Then it can be checked whether the tree unifies with conditions stated in the lexicon, i.e. whether all obligatory complementations of the heads present in the representation are among the daughters of the heads, whether only complementations contained in the frame of any head (or in the relevant list of free modifications) occur as the head's dependents, and whether subcategorization (and similar) restrictions are met.

As we mentioned, this specification covers the core of sentence syntax; it can be completed to cover coordinated structures (see Petkevič 1995), negation and other focalizers ('only', 'also', 'willingly', etc.), in specific positions (prototypically they occur at the beginning of the focus; see Hajičová, Partee and Sgall, in press).

The relatively very simple form of the representations (strings of bracketted and indexed symbols) may be helpful in explaining the easiness of the child's acquisition of the mother tongue, although the representations contain all semantically relevant information immediately comprised in the structure of the sentence.

5.4 TRs of the form described in 5.3 can be transduced to morphemic representations (strings) in that prototypically the left-to-right order of their nodes is retained, being changed only in specific cases.

One type of such movement rules takes care of placing the most dynamic item (the bearer of the intonation center of the sentence) more to the left. In English this concerns first of all those cases in which the syntactic functions of participants (arguments) and adjuncts determine certain restrictions of their surface positions. Thus, e.g. sentence (1), repeated here for convenience, can be handled with the use of the following rule (presented here with many simplifications):

(1) My sister was visited by a painter in PARIS last week.

Rule M1: If x.Loc as the rightmost item of a TR is preceded by y.Temp (which is placed between x and the verb), then y.Temp will be moved to the right of x^F.Loc in the morphemic string; with the chosen linearization of TRs (see Sect. 5.1) the rule can be technically written (with many simplifications) as follows:

$$X\ (U\ y.Temp\ W)\ Y\ (Z\ x.Loc) \rightarrow$$
$$X\ Y\ (Z\ x^F.Loc)\ (U\ y.Temp\ W)$$

where X and Y are well parenthesized strings, x stands for a noun, pronoun or verb, y stands for a noun, adverb or verb (again, with their dependents), the superscript F denotes the placement of the intonation center of the sentence, Z, W, U, V are (possibly empty) strings of well parenthesized items (dependents of x and y), X (U y.Temp W) Y (Z x.Loc) is a

well formed TR (according to Sect. 5.3), and the parentheses are supposed to be removed by one of the last steps of the procedure transducing TRs into morphemic strings.

Rules of a similar kind can determine the movement of the subject (be it derived from Actor, or, with passivization, from Patient or Addressee) to the left of the verb in case its tectogrammatical source is more dynamic than the verb and thus stands to the right of the verb in the underlying order.

Another kind of rules concerns the changes of tectogrammatical values such as Plural, Preterite, Feminine, Comparative into morphemic items (endings, alternations, affixes, function words) and the placement of these morphemic items. Thus, e.g. for the treatment of nouns rules as the following one are needed:

Rule M2: If x in a node label x.Num.Def is a noun, Num the value of Number (Sg or Pl) and Def that of Definiteness (+ or -), then

(i) rewrite + (-) into Artdf (Artin) and place this symbol to the left of the nodes subordinated to node x (including x itself); recall that 'subordinated' is the transitive closure of 'depending'; Artdf will be transduced into the phonemic and phonetic (or graphemic) shapes of *the*, and Artin into *a, an*, or (with plural) into zero,

(ii) rewrite Pl (Sg) into -s (0) (this certainly requires to take into account also several specific sets of exceptions before Rule M2 is applied, cf. forms like *mice, oxen, loaves*); -s will be then changed into the surface shape of the Plural (or 3rd Person Singular) ending by the subsequent components of the procedure.

The simplified technical form of M2 is:

(Z x.Num.Def W) → (Art Z x.End W)

where x stands for a noun or a pronoun, Z and W are (possibly empty) strings of well parenthesized items (dependents of x), Art is Artdef (Artin) if Def is + (-), End is -s (0) if Num is Pl (Sg).

Still another type of movement rules is needed for apparently non-projective constructions, illustrated by ex. (13), repeated here for convenience:

(13) a larger town than Boston

M3: $((Art_2 \text{ X A.Comp (than U } Art_1 \text{ } N_1.\text{End) W}$
$N_2.\text{End Z)} \rightarrow Art_2 \text{ X A.Comp W } N_2.\text{End}_2$
$Z \text{ than } Art_1 \text{ U } N_1.\text{End}_1$

where N_1 and N_2 are nouns, A is an adjective, X, Z, U and W are (possibly empty) strings of well parenthesized items, Art_i is Artdef or Artin (or zero, with a proper name), End_i is -s or 0 for $i = 1, 2$.

Rules of the last mentioned type are supposed to be applied after rules of the types M1 and M2. Many technical as well as empirical issues are still open and constitute interesting topics for further research.
